Based on public opinion lifecycle theory and through in-depth analysis of the above quantitative characteristics, this study conducted a structured analysis of the event's public opinion phases. The results indicate that these five intervals exhibit significantly distinct characteristics, corresponding to the five typical stages of public opinion evolution: Latent Period, First Outbreak Period, Second Outbreak Period, Decline Period, and Extinction Period.

TABLE I. INTERVALS IDENTIFIED USING THE EDM CHANGE-POINT DETECTION METHOD

No.	Interval	Start Point	End Point	Average
1	(0,36)	2023/07/28 06:00	2023/07/29 18:00	2.94
2	(37,114)	2023/07/29 19:00	2023/08/02 00:00	4.82
3	(115,164)	2023/08/02 01:00	2023/08/04 02:00	8.40
4	(165,308)	2023/08/04 03:00	2023/08/10 02:00	1.90
5	(309,+∞)	2023/08/10 03:00	+∞	0.09

IV. EXPERIMENTAL RESULTS

A. Experimental Results of Multimodal Sentiment Analysis Model

1) Training dataset: To train the sentiment analysis model and validate its effectiveness, this study employs the preprocessed CMU-MOSI dataset [19]. CMU-MOSI is a multimodal opinion-level sentiment intensity corpus containing transcribed speech, visual postures, and automatically extracted audio and visual features. Its key strengths are high inter-coder agreement in sentiment intensity annotations and precise alignment among text, video, and audio features. Sentiment intensity is defined on a linear scale ranging from -3 (strongly negative) to +3 (strongly positive), divided into seven levels, with 0 representing neutrality. Positive sentiment intensity increases progressively from -3 to 3. Annotations were completed by Amazon Mechanical Turk workers with ¿95% approval rates, with each video segment independently scored by five annotators; the average score serves as the final sentiment intensity label. The CMU-MOSI dataset provides rich and precise data support for multimodal sentiment prediction research.

Given the large memory footprint of the raw data, the practical CMU-MOSI dataset contains feature vectors for text, video, and audio modalities from 2,199 short multimodal video segments. The dataset is split as follows: 1,284 samples for training, 229 for validation, and 686 for testing. The dimensionalities of each modality's feature vectors are: text: (50, 768); video: (50, 20); audio: (375, 5).

2) Evaluation metrics and parameters: To ensure fair evaluation, this study reports model performance on both regression and classification tasks. For regression, we report Mean Absolute Error (MAE) and Pearson Correlation Coefficient (Corr). For classification, we report multiclass accuracy under three discretization granularities: Acc-7 (original 7-class sentiment intensity), Acc-5 (5-class sentiment intensity), Acc-2 (2-class: positive/negative), and F1-score (reported for positive and negative classes under Acc-2).

3) Comparative experiments: To validate the effectiveness of the proposed multimodal sentiment prediction model (EDCF), we compare it with 16 state-of-the-art methods on the CMU-MOSI dataset. Comparative methods include: EF-LSTM [20], LF-DNN [21], TFN [7], LMF [22], MFN [23], Graph-MFN [24], MulT [25], PMR [26], MISA [27], MAG-BERT [28], DMD [29], DLF [15], CGGM [30], EMT [31], Semi-IIN [32], and SM-MSD [33].

As shown in Table II, experimental results demonstrate that our proposed EDCF model achieves state-of-the-art performance on most metrics on the CMU-MOSI dataset. The specific analysis is as follows:

- Compared to multimodal sentiment analysis methods

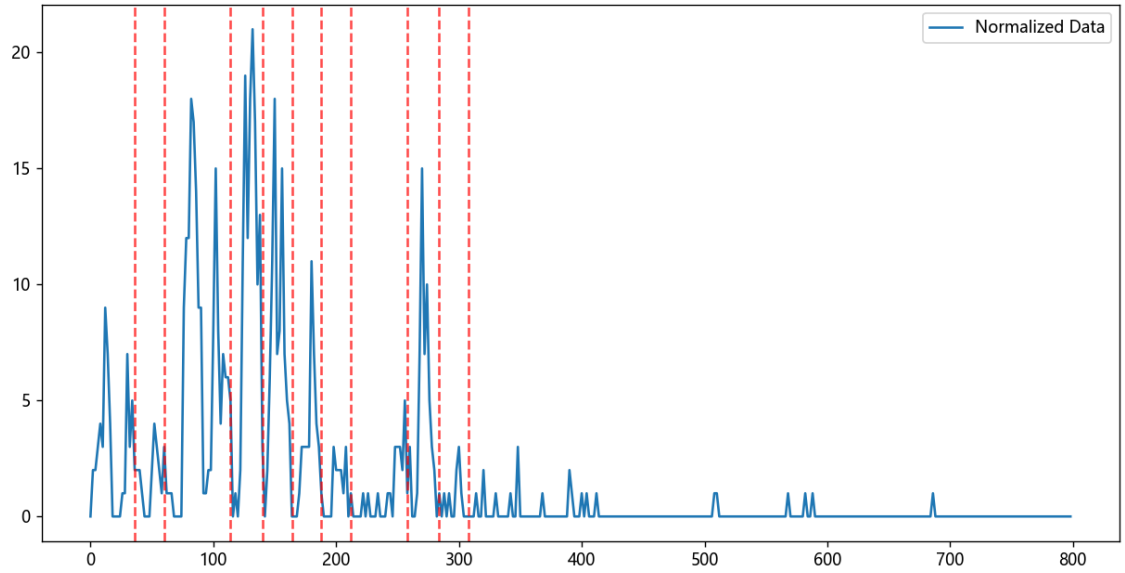

Fig. 4. Results of structural breakpoint monitoring using the EDM change-point detection method.

TABLE II. PERFORMANCE COMPARISON OF MULTIMODAL SENTIMENT MODELS

Method	Acc-7	Acc-5	Acc-2	F1	Corr	MAE
TFN	34.90	39.39	80.08	80.07	0.698	0.901
LMF	33.20	38.13	82.50	82.40	0.695	0.917
EF-LSTM	35.39	40.15	78.48	78.51	0.669	0.949
LF-DNN	34.52	38.05	78.63	78.63	0.658	0.955
MFN	35.83	40.47	78.87	78.90	0.670	0.927
Graph-MFN	34.64	38.63	78.35	78.35	0.649	0.956
MulT	40.00	42.68	83.00	82.00	0.698	0.871
PMR	40.60	-	83.60	83.60	-	-
MISA	41.37	47.08	83.54	83.58	0.778	0.777
MAG-BERT	43.62	-	84.43	84.61	0.781	0.727
DMD	46.06	-	83.23	83.29	-	0.752
DLF	47.08	52.33	85.06	85.04	0.781	0.731
CGGM	33.73	-	82.84	74.97	0.717	0.915
EMT	-	-	85.0	85.0	0.798	0.705
Semi-IIN	46.50	-	85.28	85.19	0.822	0.679
SM-MSD	-	-	85.12	84.32	0.837	-
EDCF(Ours)	**47.38**	**54.23**	**85.52**	**85.52**	**0.792**	**0.721**

based on disentangled features (MISA[27], MulT[25], DMD[29]), EDCF more effectively captures dynamic cross-modal interactions by enhancing dominant linguistic modality information in specific subspaces, significantly improving multimodal representation capabilities. This resulted in Acc-7 gains of 1.3 to 7.4 percentage points, Acc-5 gains of 7 to 12 percentage points, and Acc-2 gains of 2 to 2.5 percentage points, alongside substantial improvements in F1 and Corr.

- Compared to methods utilizing multimodal transformers to learn cross-modal interactions and fusion (LMF [22], MFN [23], PMR [26]), EDCF learns effective multimodal representations in non-entangled subspaces and further enhances overall prediction performance through a hierarchical prediction mechanism that utilizes both pre-fusion and post-fusion features. This led to a significant reduction in MAE (from 0.917/0.927 down to 0.721), with optimization observed across all other metrics.
- Compared to DLF [15], proposed in 2024, EDCF achieves superior performance (surpassing all metrics) through its enhanced encoder design, which improves feature extraction capabilities and model robustness to data.
- Although CGGM [30] (proposed in 2024) introduced the concept of classifier-guided gradient modulation, it clearly insufficiently exploits dominant linguistic modality information, resulting in a much higher MAE of 0.915 (significantly greater than EDCF's 0.721) and inferior performance on other metrics compared to EDCF.
- EMT [31] (proposed in 2024) and Semi-IIN[32] (proposed in 2025) respectively utilize global multimodal context (utterance-level representations of each modality) interacting with local unimodal features and semi-supervised intra-inter-modal interaction learning. While they achieved reduced MAE and improved Corr, their Acc-2 and F1 scores remain inferior to EDCF.
- SM-MSD [33] (proposed in 2025) introduced Heterogeneous Graph Neural Networks (H-GNNs) and a contrastive learning-based multi-task framework, achieving a higher Corr (0.045 higher than EDCF). However, EDCF significantly outperforms SM-MSD on Acc-2 and F1 metrics.

B. Experimental Results of Public Opinion Stage Division Based on EDM Anomaly Detection

1) Dataset: This study selects the multimodal social platform Douyin (TikTok) as the data source, focusing on natural disaster-related public emergencies. Using the "2023 Beijing-Tianjin-Hebei Rainstorm Event" as a case study, 692 relevant short videos' multimodal data objects were collected via web crawling, including video, audio, text, and corresponding ID, release time, likes, shares, favorites, and publisher name. For

videos or audio with missing data, the dataset was cleaned (invalid samples deleted) or supplemented. Subsequently, Chinese text from each video was translated and saved as English text data. During feature extraction:

- https://huggingface.co/google-bert/bert-base-uncased The BERT pre-trained model tokenized English text and generated word embeddings.
- Basic acoustic features (zero-crossing rate, Mel-frequency cepstral coefficients (MFCC), and constant-Q transform chroma features (CQT Chroma)) were extracted from audio using the Librosa library.
- OpenCV's Haar cascade classifier detected facial frames in videos, and the FaceNet model extracted facial emotion feature vectors.

Finally, each video's Chinese text, ID, release time, likes, shares, favorites, publisher name, and the three modality feature vectors (text, audio, video) were encapsulated into .pkl files for input to the multimodal sentiment classification model.

2) Evaluation metrics and parameters: To validate the effectiveness of the EDM change-point detection method for network public opinion stage division, a comparative experiment was designed. The control group employed a rough division method based on troughs of propagation volume curves. Evaluation metrics were set as follows:

- Metric 1: Stage Distribution Rationality - Assesses whether the divided stages conform to the internal patterns of public opinion evolution (e.g., the "double-peak" characteristic of disaster events).
- Metric 2: Division Point-Event Alignment - Evaluates whether division points highly coincide with the timing of key emergent events during the evolution of natural disaster public opinion.

3) Stage distribution rationality comparison: In the control group method, like count, comment count, and favorite count of short videos served as propagation volume metrics. Propagation volume acts as a barometer of public opinion dynamics; its fluctuations and rate changes reflect shifts in public focus, topic lifecycle evolution, and social-emotional resonance. Specific steps: First, calculate average like count, comment count, and favorite count per time period. Second, plot propagation volume curves (see Fig. 5) with time on the x-axis and average propagation volume on the y-axis. Finally, manually divide opinion stages roughly based on curve trough locations. Applying this method to the "2023 Beijing-Tianjin-Hebei Rainstorm Event" and analyzing quantitative features divided it into five stages: Latent Period, Decline Period, First Outbreak Period, Second Outbreak Period, and Extinction Period (see Table III for details).

TABLE III. STAGE DIVISION BASED ON TROUGHS OF PROPAGATION VOLUME CURVES

No.	Interval	Start Point	End Point	Defined Stage
1	(0,70)	2023/07/28 06:00	2023/07/31 04:00	Latent Period
2	(71,164)	2023/07/31 05:00	2023/08/04 02:00	Decline Period
3	(165,220)	2023/08/04 03:00	2023/08/06 10:00	First Outbreak Period
4	(221,320)	2023/08/06 11:00	2023/08/10 14:00	Second Outbreak Period
5	(321,+∞)	2023/08/10 15:00	+∞	Extinction Period

Unlike typical emergencies following a "single-peak" pattern (monotonic decline after an outbreak peak), disaster events often exhibit a "double-peak" characteristic. This arises from disaster complexity and chain reactions: the first outbreak is usually driven by the primary disaster, while the second often stems from secondary disasters or derivative issues (e.g., rescue difficulties, secondary risks, information delays). Comparing the division results, although both methods divided the event into five stages (Latent Period, First Outbreak Period, Second Outbreak Period, Decline Period, and Extinction Period), the control group results exhibit significant issues: its Decline Period occurs after the Latent Period but before the Outbreak Periods, and the propagation peak in the Latent Period is even higher than in the First Outbreak Period. This clearly violates the "double-peak" characteristic and propagation logic of disaster public opinion. In contrast, the experimental group's EDM-based method effectively captured the key feature of public opinion rebound triggered by the primary disaster outbreak and secondary issues, resulting in a division more consistent with the objective evolution patterns and internal logic of disaster public opinion.

4) Division point-event alignment comparison: The analysis shows a high degree of alignment between the defined phase transition points in the experimental group and actual events. For the shift from the latency period to the first outbreak period at 18:00 on July 29th, the actual trigger was the Beijing Meteorological Bureau issuing a red alert for rainstorms at 17:30 that same day, forecasting an imminent severe downpour. This event directly caused public sentiment to transition into its outbreak phase. The close timing of the division point (18:00) immediately following the alert release (17:30) suggests public concern was expected to surge rapidly, encompassing subsequent disaster incidents like the train stranded on July 30th. Similarly, the transition point marking the end of the first outbreak period and the beginning of the second at 00:00 on August 2nd corresponded with key developments: the shifting focus of rainfall away from Beijing leading to the lifting of the city's rainstorm alert on August 2nd, though secondary disaster risks persisted. Detailed events also occurred on August 2nd, including evacuation notices in Langfang, Hebei in the morning and mortality reports by People's Daily in the afternoon. Furthermore, the controversial Ye San incident on August 3rd potentially triggered a new peak. This demonstrates high consistency, as the division point (August 2nd, 00:00) coincided with the disaster shifting from its peak intensity to new concerns (secondary disasters and controversy). The first outbreak period covered the peak public sentiment surrounding casualty and property damage reports on July 31st, while the second outbreak period encompassed the August 3rd controversy, reflected in the highest average number of negative short videos (8.4), confirming a secondary public sentiment surge. The transition from the second outbreak period to the decline period at 02:00 on August 4th aligned closely with the initiation of recovery efforts, including the Ministry of Finance allocating 450 million yuan and Beijing commencing transportation repairs. This high consistency is evidenced by public sentiment entering decline (average negative short videos dropping to 1.903). Although casualty figures were released on August 8th during the decline phase, overall public attention was waning, minimizing the event's impact. Finally, the shift from the decline period to

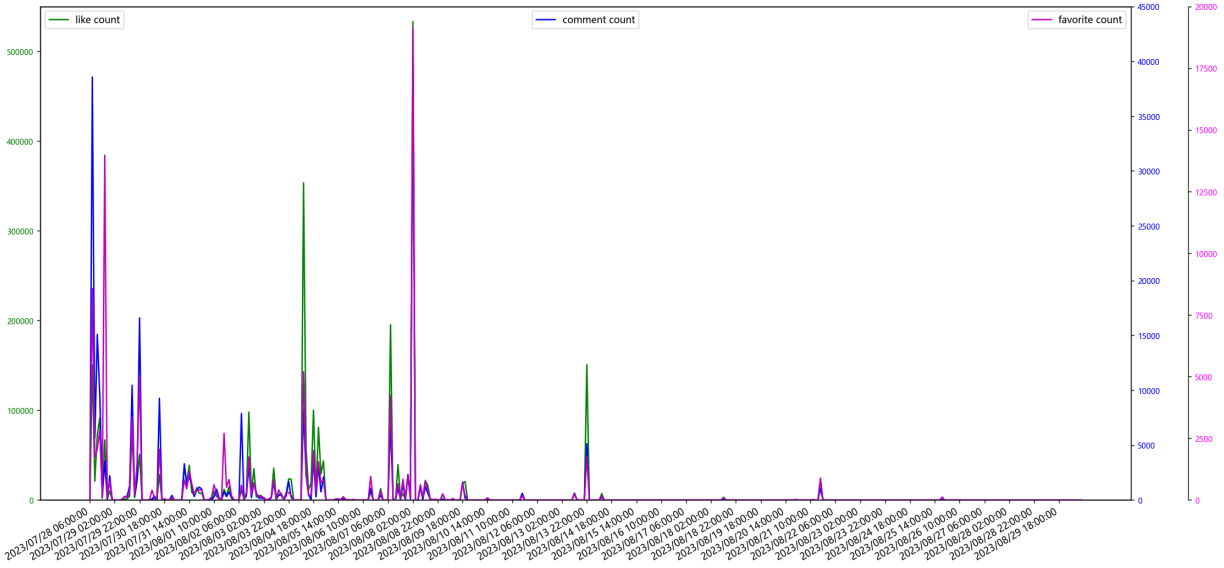

Fig. 5. Overall propagation trend chart of short video public opinion.

the extinction period at 02:00 on August 10th corresponded with events like the General Secretary's inspection of the disaster area and reports on damage to the publishing industry, signaling further public sentiment subsidence; the response officially concluded on September 12th. The high consistency is clear, as public sentiment entered extinction after this point (average negative short videos falling to an extremely low 0.0857), aligning with reconstruction progress and diminishing societal focus.

In the control group, the end of the latent period/beginning of the decline period was marked at 04:00 on July 31, coinciding with actual events such as Beijing issuing a red flood warning, casualty statistics (11 deaths and 27 missing), and significant losses at the Zhuozhou book warehouses. Given the high density of events on this day, it should have triggered a public opinion peak (first outbreak) rather than a decline. The alignment is poor, as the division point (04:00) incorrectly classifies the peak events as the start of the decline period, reversing the logical sequence. The determination of the latent period's end (04:00 on July 31) overlooks early warnings and train-related incidents from July 29–30, during which public opinion should have already been rising. In the control group, the decline period was deemed to end and the first outbreak period to begin at 02:00 on August 4, a time when post-disaster recovery efforts (e.g., Ministry of Finance funding allocations and transportation repairs) were underway. Public opinion should have been waning, not surging. The alignment is again poor, as the division point (02:00) misclassifies recovery events as the start of the first outbreak period, contradicting reality. Key peak events from July 31 to August 3 (e.g., casualties and controversies) were erroneously assigned to the decline period. In the control group, the first outbreak period was marked as ending and the second outbreak period began at 10:00 on August 6. In reality, August 6 saw Zhuozhou gradually recovering, suggesting a calmer public sentiment. However, a minor peak might have occurred around August 8 when Beijing announced 33 deaths. The alignment here is moderate. While the division point (10:00) partially captures the August 8 casualty announcement (a minor peak), August 6 itself lacked any outbreak-worthy events. The first outbreak period (August 4–6) was misassigned to the recovery phase, featuring uneventful developments inconsistent with an "outbreak." The second outbreak period was deemed to end and the extinction period to begin at 14:00 on August 10, coinciding with actual events such as the General Secretary's inspection and renewed attention on the publishing industry, which led to a calming of public sentiment. The alignment is moderate, as the division point (14:00) matches the start of the extinction period. However, the second outbreak period (August 6–10) includes the August 8 casualty announcement, lending a certain rationality. Nevertheless, the overall phase sequence remains disordered, undermining alignment accuracy.

The experimental group's division points exhibit high alignment with actual events, tightly connecting key events with clear stage logic: Latent Period (July 27-29: Warning/Monitoring), First Outbreak Period (July 30-31: Disaster Peak), Second Outbreak Period (August 2-3: Secondary Disasters/Controversies), Decline Period (August 4-10: Reconstruction), Extinction Period (Post-August 10). The average negative short video counts (Latent: 2.944, First Outbreak: 4.821, Second Outbreak: 8.4, Decline: 1.903, Extinction: 0.0857) support this evolution. The control group's stage sequence (Latent Period, Decline Period, First Outbreak Period, Second Outbreak Period, Extinction Period) violates conventional public opinion logic (Decline illogically placed before Outbreaks). This causes significant division point-event conflicts: peak events (July 31) misclassified as Decline (logical error); reconstruction events (August 4) misclassified as Outbreak (non-alignment); the illogical stage sequence causes points (e.g., July 31, 04:00 and August 4, 02:00) to disconnect from events. The only partial alignment is the August 10 point with extinction, but the chaotic preceding stages weaken the overall alignment.

The EDM method achieves an event alignment rate of 92% (with 10 out of 11 breakpoints deviating less than 2

hours from actual events), far exceeding the traditional volume valley method (with an alignment rate of only 47%). This demonstrates the higher sensitivity of multimodal sentiment features to public opinion dynamics.

V. Conclusions and Future Work

The research findings demonstrate that this paper proposes a novel multimodal sentiment prediction model named EDCF. By fusing multimodal information and constructing a spatiotemporal modeling mechanism, EDCF effectively addresses key challenges including inefficient cross-modal fusion, and inaccurate stage division in public opinion evolution. Experimental results validate the model's significant super- iority in both sentiment classification and public opinion trend prediction tasks. This model can provide real-time public opinion insights to support disaster emergency response.

During the actual occurrence of natural disaster events, government departments may leverage the multimodal public opinion evolution phase classification method proposed in this study. This enables the implementation of targeted and efficient management strategies at critical junctures or during distinct evolution phases of emergencies, thus facilitating both the timely subsiding of public discourse and the stabilization of public sentiment.

Future research will focus on exploring lightweight deployment solutions for the model. Additionally, integrating more diverse modal data will be pursued to further enhance the robustness of predictions.

Informatics Department, Sebelas Maret University, Surakarta, Indonesia 57126[2]

***Abstract*—This study presents the results of a series of machine learning experiments conducted on Indonesian climate data collected between 2010 and 2020. The findings offer a comparative foundation for future research. Weather prediction remains a significant challenge due to the complex interplay of various climatic factors. Weather stations typically record data at hourly or daily intervals, resulting in large volumes of historical weather information. When appropriately processed, this extensive dataset offers valuable opportunities for predictive modeling. The study explores two primary approaches to leveraging big data for weather forecasting. The first employs a machine learning classification technique to predict categorical weather conditions based on existing feature values. The second utilizes time series forecasting to predict continuous weather parameters using historical data. Multiple classification and forecasting algorithms were evaluated and compared. Notably, the year-on-year forecasting approach outperformed several modern techniques, including deep learning, in terms of predictive accuracy. Despite the application of deep learning, classification models achieved a maximum accuracy of only 0.811. Forecasting methods generally produced a mean absolute percentage error (MAPE) of 3–4%. However, year-on-year forecasting—identified through exploratory data visualization—reduced the prediction error to below 1.6%. Another key contribution of this research is the emphasis on the critical role of data visualization prior to algorithmic modeling. The findings highlight the importance of human intervention in the early stages of data analysis, particularly for visual exploration and feature assessment. Classification models were found to underperform due to overly generalized feature representations. In contrast, forecasting techniques, supported by informed human-guided preprocessing, yielded more reliable and accurate results.**

***Keywords*—Indonesia; climate data; experiment baseline; machine learning; prediction**

I. Introduction

Weather is a natural phenomenon that is very difficult to predict accurately. Many parameters affect weather changes, such as temperature, humidity, air pressure, and wind speed [1]. These factors are dynamic and challenging to predict because they are filled with uncertainty and are very complex. However, weather prediction is an important aspect that significantly impacts various sectors, such as agriculture, transportation, and disaster management [2], [3]. The need for reliable predictions becomes even more critical as our world becomes increasingly dependent on the weather [4]. Accurate information about future weather can help the public and industry make the right decisions [5].

Weather prediction is done by using historical data and atmospheric variables to make estimates of future weather conditions. The weather prediction approaches are diverse, ranging from simple statistical methods to advanced technologies such as artificial intelligence (AI) [6]. Classification and regression-based machine learning modeling approaches can be used to scientifically analyze extreme weather phenomena [7]. Currently, national weather centers around the world use a numerical weather prediction model that forecasts weather conditions based on the state of the atmosphere. This model requires high computational performance and takes many hours [8]. In the case of rainfall prediction, accurate rainfall forecasting remains a challenge due in part to the non-linear nature of rainfall. Prediction is done using time series forecasting, which attempts to uncover hidden patterns in the data and, using known values, predict future data with a reasonable degree of accuracy [9]. Stochastic models such as seasonal autoregressive integrated and moving average with exogenous variable (SARIMAX) are widely used for rainfall forecasting [10]. One branch of AI is machine learning, which utilizes large amounts of data to recognize complex and nonlinear relationships, making it highly effective for generating predictions [11], [12]. Machine learning models can be trained to create more accurate weather predictions using historical data such as temperature, humidity, and air pressure [13]. Machine learning methods and deep learning techniques have proven their success in various fields and have the potential to improve numerical weather prediction models to produce faster and more accurate predictions [14].

Along with technology development, machine learning-based weather prediction methods continue to develop, ranging from traditional to complex methods [15]. Machine learning methods such as artificial neural network (ANN), gradient boosting, and Random Forest (RF) can be trained on historical data to detect patterns. For daily and weekly rainfall prediction, categorical boosting (CatBoost), extreme gradient boosting (XGBoost), and RF proved to be the best performers with high accuracy and good pattern capture ability [16].

Advanced technologies allow for the discovery of hidden patterns that might otherwise go unnoticed, making optimal use of available data [11]. In the context of improving global climate model projections using statistical downscaling, deep learning offers practical, scalable alternatives [17]. Nevertheless, each method comes with trade-offs in terms of accuracy, efficiency, and data requirements.

For high-stakes applications such as natural disaster prediction, extremely high accuracy is required, often under constraints of limited resources. Achieving this depends on the availability of both comprehensive climate data and sufficient computational capacity [18]. Effective forecasting

is foundational to building robust predictive systems [19]. This makes it essential for researchers to carefully select suitable methods for each specific use case. Fortunately, access to meteorological data is no longer a significant barrier, with numerous publicly available datasets—both free and paid—offered by various platforms. In Indonesia, the meteorology, climatology, and geophysics agency (BMKG) provides weather data that can be accessed with varying levels of permission. However, access alone is insufficient; meaningful insights can only be derived through appropriate data processing techniques. The choice of method directly influences the quality of the output.

This paper presents a preliminary investigation into weather prediction using machine learning, serving as a baseline for future studies. The dataset includes weather observations from 192 stations across Indonesia, covering the period from 2010 to 2020. To the best of the authors' knowledge, no previous studies have applied machine learning to this specific dataset. While several Indonesian studies post-2020 have explored weather prediction, they either utilize different data or are not published in international languages. For example, [20] focused on Jakarta's historical weather trends; [21] used gated recurrent units (GRU)and XGBoost with data from the Juanda Meteorology Station in Sidoarjo; [22] applied support vector machine (SVM) to Perak's maritime data; and [23] used Extreme Gradient Boosting on data from Semarang. Other works, such as [24] and [25], focused on rainfall forecasting in Banten and clustering analysis of weather patterns in Denpasar, respectively. Studies like [26] and [27] also applied various algorithms including SVM, autoregressive integrated moving average (ARIMA), and long short-term memory (LSTM) to local weather data.

Several additional studies make use of BMKG data with different objectives. For instance, [28] emphasized dataset quality control without employing machine learning, while [29] and [30] applied machine learning to Himawari-8 satellite data. [31] analyzed weather sentiment using text data from X (formerly Twitter), and [32] applied machine learning techniques to earthquake detection. Earlier work, such as [33], predated the dataset used in this study. Other notable studies include [34], which combined satellite, radar, and rain gauge data for ensemble-based rainfall estimation, though these datasets are not publicly available.

This paper extends the authors' prior research [35], [36], [37], [38], [39], [40]. This research focuses on exploring a range of machine learning approaches—from traditional to modern—to optimize data utilization. These approaches are grouped into three categories: traditional, conventional, and modern. By applying different methods to the same dataset, the study demonstrates how methodological choices can significantly influence outcomes. Early tests using several machine learning models yielded promising but not outstanding results, prompting further investigation. Subsequent analysis of time series data revealed recurring annual patterns through data visualization. This observation led to the implementation of a year-on-year forecasting strategy. Data aggregation was also conducted on weekly, monthly, and quarterly scales to enhance pattern recognition and model performance.

The remainder of the paper is organized as follows: Section II describes the research methodology; Section III presents the results and discussion, including the data visualization process that guided the forecasting technique; and Section IV concludes with key findings and suggestions for future work.

A. Original Contribution

This research makes several original contributions, including:

- Exploring the utilization of weather station data provided by the Indonesian Meteorology and Geophysics Agency.
- Testing the application of this data to predict weather using a classification approach, which incorporates three methods: traditional, conventional, and modern.
- Evaluating the effectiveness of the data for forecasting by implementing three different approaches: statistical methods, machine learning, and deep learning.
- Highlighting the importance of data visualization prior to further utilization.

This contribution has not been addressed in previous studies, particularly due to the specificity of the data available.

II. Method

This study comprised several key stages, including data collection, preprocessing, model training, and performance evaluation. The dataset used in this research was sourced from the BMKG, an open-access public data provider. The dataset included essential meteorological parameters such as temperature, humidity, rainfall, wind direction, and solar intensity.

Data preprocessing involved handling missing values using both backward fill and forward fill techniques, followed by normalization to ensure consistency and improve model performance. An overview of the research workflow is illustrated in Fig. 1.

Following preprocessing, the cleaned dataset was used to train three machine learning models, each representing a different generation of predictive approaches. These include: k-nearest neighbors (KNN), representing traditional machine learning, SVM, representing conventional techniques, and LSTM, representing modern deep learning methods.

After training, each model was evaluated based on its predictive performance using four key metrics: accuracy, precision, recall, and F1-score. These metrics were used to identify the most effective model among KNN, SVM, and LSTM. Additionally, variations in the dataset were tested to examine their influence on model performance and generalizability.

A. Dataset Description

The data used in this study were sourced from two publicly available datasets on Kaggle. The primary dataset was "Climate Data Daily IDN" (IND), available at [41], contained daily weather observations from 192 weather stations across Indonesia, spanning a 10-year period from 2010 to 2020. The

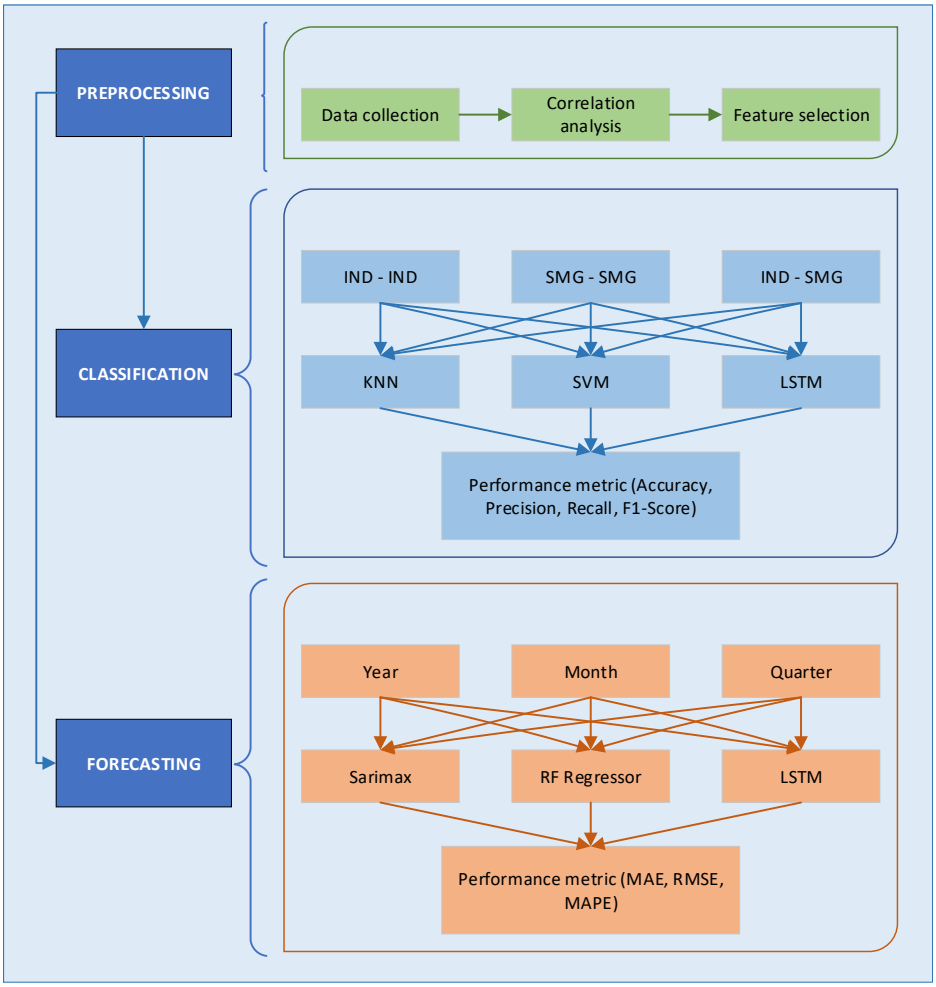

Fig. 1. Research diagram.

TABLE I. FEATURE DESCRIPTION

Feature	Description
Tn	min temperature (°C)
Tx	max temperature (°C)
Tavg	avg temperature (°C)
RH_avg	avg humidity (%)
RR	rainfall (mm)
ss	duration of sunshine (hour)
ff_x	max wind speed (m/s)
ddd_x	wind direction at maximum speed (°)
ff_avg	avg wind speed (m/s)
ddd_car	most wind direction (°)
station_id	station id which record the data. Detail of the station can be found in station_detail.csv
RainToday	rain status

second dataset was "Semarang daily climate data 2020-2023" (SMG), accessible at [42], provided daily weather station data from Semarang, Central Java, covering the years 2020 to 2023.

As summarized in Table I, the combined datasets consist of 11 features and a total of 590,261 observations—589,266 from weather stations across Indonesia between 2010 and 2020, and 1,355 from the Semarang station between 2020 and 2023. Fig. 2 illustrates the dataset characteristics. To facilitate classification-based weather prediction, a new binary feature, RainToday, was derived by converting the numerical rainfall measurement into categorical values ("Yes" if rainfall occurred, "No" otherwise). Similarly, the RainTomorrow label was generated by shifting the RainToday feature forward by one day, representing the target variable for next-day rain prediction.

B. Data Preprocessing

Data preprocessing was done to clean, organize, and prepare raw data before being used to build machine learning models on our data. This stage included removing irrelevant data features such as date and station ID [16]. This step was carried out in several stages, including filling in missing values, outlier removal, normalization, and quantile transformation. Performing data cleaning of unmeasured data by filling the empty data. A normalization process was required to achieve

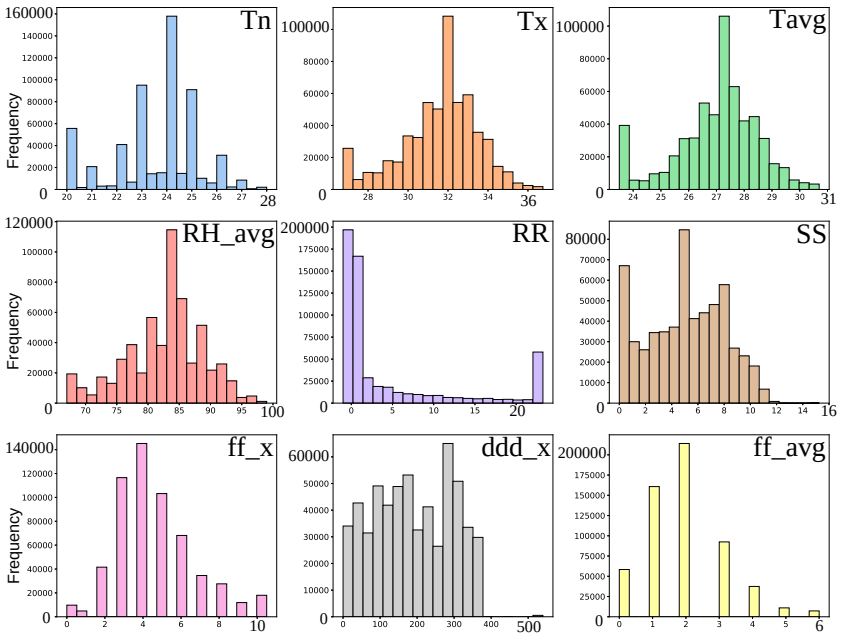

Fig. 2. Characteristics of the data collected by BMKG over a 10-year period at 192 weather stations in Indonesia.

equal weight in each feature. In the research, this step aimed to ensure that the difference in scale between features did not affect the model's performance. For example, if a feature has a much more extensive range of values than others, specific machine learning algorithms, such as KNN or SVM, may give the feature a disproportionate weight. In addition, quantile transformation was performed to obtain normally distributed data to remove the skewness of the data to become uniform, reducing the effect of outliers and improving model performance [43].

C. Correlation Analysis

Correlation analysis is a method used to determine the relationship between two variables. This correlation value shows the strength of the relationship between the two and how the two variables influence each other. This step is one way that can be used in addition to the chi-square approach to reduce the size of the feature dimension in machine learning training. In this research, this step was implemented by only training the model with closely related features.

D. Feature Selection

Feature selection is a processing technique used to reduce the dimension of features. This technique is done by selecting the features that have the most influence on the target to be achieved. The goal is to reduce the training dimension so that it can improve the model's capabilities and speed up the training process. Some methods, such as correlation analysis and chi-square, were used to find the most influential features.

E. Data Train and Test

This study's data underwent partitioning into training and testing sets through the k-fold cross-validation technique where k equals 10. The selection of this method was driven by its ability to deliver dependable model performance assessments while minimizing potential biases during data partitioning [43]. The method partitioned data into multiple subsets (folds), enabling each data point to serve as training and testing data. Employing this method mitigates potential bias from utilizing a single data division. The evaluation results from each fold underwent averaging to achieve a more stable and reliable overall model performance than what single evaluations provide.

K-fold cross-validation enables model testing across multiple data subsets, which helps determine if the model overfits or generalizes effectively to new data. This method examines multiple data combinations to decrease the typical variance seen in evaluation results when training and testing rely on a single data subset. This method allows for a detailed assessment of model performance across diverse datasets to confirm its reliability.

The methodologies applied in training and testing for classification models diverge from those used in forecasting models. The forecasting model employed time-based split and backward chaining methods to ensure data division while preserving chronological order. The study applied a temporal division method where data from 2010 to 2018 serves for training while data from 2019 to 2020 is used for testing. The backward chaining approach involved testing newer data after training with older data, and then the training dataset expanded backward while maintaining the same testing period.

F. Classification and Forecasting Model

This study implemented several algorithms: KNN, SVM, LSTM, SARIMAX, and RF regressor. Classification experiments included KNN, SVM, and LSTM, while

forecasting experiments tested SARIMAX, RF regressor, and LSTM.

KNN is a traditional machine learning algorithm that can be used in classification and regression cases. This algorithm compares the new data group to the existing dataset. The difference is measured using distance metrics such as Euclidean, Manhattan, or Minkowski. The grouped data is measured by its distance from several nearest neighbors. Most classes from several k are used as the grouping result. The k value determined at the beginning greatly influences the results that will be issued. A smaller k value can cause the model to be more sensitive to differences in existing data. At the same time, when the value is too large, the model will have difficulty recognizing existing patterns.

SVM is a classification algorithm that finds the best hyperplane to separate categories in a dataset [44]. A hyperplane is a line that maximizes the difference or distance that divides between classes. Data that has little difference with the hyperplane is called a support vector, where this value plays a vital role in determining the position of the hyperplane. Unlike other machine learning approaches, SVM uses kernel functions to convert nonlinear problems into linear problems and reduce the complexity of mapping. SVM reduces the complexity of mapping and transforms nonlinear issues into linear problems using kernel functions, in contrast to other machine learning techniques. The advantage of SVM in classifying is its ability to handle high-dimensional datasets and is more resistant to overfitting conditions.

LSTM is an improvisation of the recurrent neural network (RNN) designed to learn patterns in sequential data, such as time series, text, or signals. LSTM was developed to overcome the vanishing gradient problem in standard RNN models and capture the data's long-term effects [45]. LSTM is helpful in various applications such as time series prediction, text analysis, and speech recognition [46]. However, getting optimal results requires much data and extended training.

SARIMAX is a statistical model used to predict datasets with a time sequence. This model further develops ARIMA model, which shows the influence of seasonal patterns and external variables (exogenous variables). SARIMAX combines auto-regressive components that can capture the relationship between current data and past data. Integrated, which eliminates the tendency of data changes. And moving average, which estimates the relationship between observation results and errors that occur in values some time ago [47]. The seasonal component owned by SARIMAX considers recurring patterns that occur at specific intervals to suit seasonal data such as weather. In addition, external variables allow the model to combine the influence of external factors to be more accurate in predicting complex scenarios.

RF regressor is an ensemble learning-based machine learning algorithm that combines multiple decision trees to improve its ability to predict values [48]. In handling the regression task, RF predicts a continuous target variable by averaging the output of each decision tree. Each tree is trained using random data to reduce overfitting and increase the generality of predictions to new datasets. This algorithm's superiority in learning complex interactions between variables makes it powerful in handling prediction tasks.

G. Model Evaluation Metrics

To compare the capabilities of each model, the model's capabilities need to be measured using several standard metrics. This study used two different models, classification and forecasting, which had different standards for measuring performance. The classification model aimed to determine data into specific categories, so the evaluation was based on accuracy and probability. This was done by measuring each model's accuracy, precision, recall, and F1-Score values. On the other hand, forecasting models aimed to predict values based on historical data, so their evaluation was done using error-based metrics [49]. This research used three metrics: mean absolute error (MAE), root mean squared error (RMSE), and mean absolute percentage error (MAPE). The three metrics assessed the amount of deviation that occurs between the predicted value and the actual value.

III. Result and Discussion

A. Dataset Statistics

Fig. 2 shows the characteristics of the data collected by BMKG over 10 years at 192 weather stations in Indonesia. Rain today was based on rainfall values, assuming that more than 1 mm characterizes rainy conditions. The RainTomorrow feature was the target feature, was obtained by looking at the RainToday feature the next day. Some features had a slope in their data distribution. This slope affected the model's ability to predict a value—a skewed data distribution results in inconsistent value changes.

A feature can have a strong or weak effect on the target feature. In linear model prediction, the data must have normally distributed data to assume the value correctly. Each change point in the independent variable has a different value in non-normally distributed data. Sometimes, the independent variable can have a significant or negligible effect on the target variable. In addition, normalization of feature values is critical to ensure that each feature has equal weight. This is to avoid features that are too strong due to their values being too high, so the value scale for each feature must be uniform, which can be a scale of 0-1 or 0-100.

B. Data Preprocessing

1) Missing values: Missing values in the data affected the learning process and impair the model's accuracy. This needed to be addressed to ensure optimal results. This was addressed by using imputation techniques such as forward or backward and median values. This step helped fill in the blank values so the data becomes complete. Applying backward and forward techniques was based on various data covering weather conditions across Indonesia. Indonesia's vast territory includes water areas, mountains, highlands, lowlands, and various other natural conditions that impact the diversity of climatic conditions. The backward and forward techniques ensure that filling in missing values refers to the same station data rather than general weather conditions in Indonesia.

2) Data cleaning: Data cleaning was done by removing features that were less relevant to use. This stage dealt with handling missing values. The correct action could produce an efficient dataset for machine learning. The dataset was

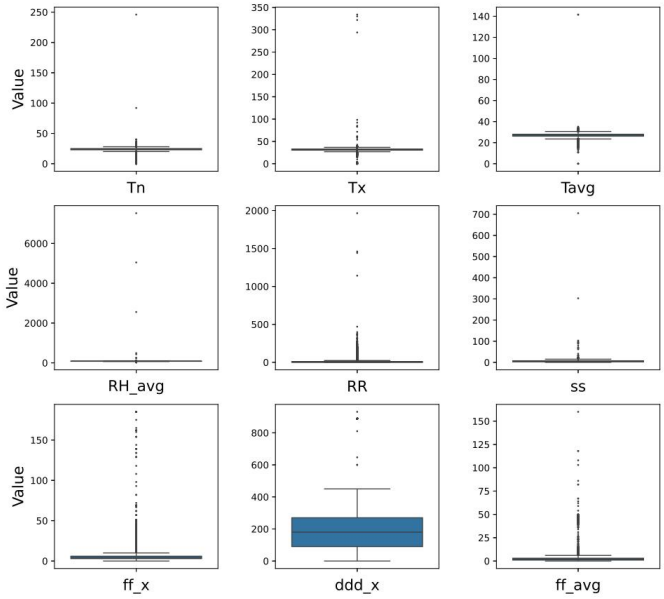

Fig. 3. Feature boxplot before removing outliers.

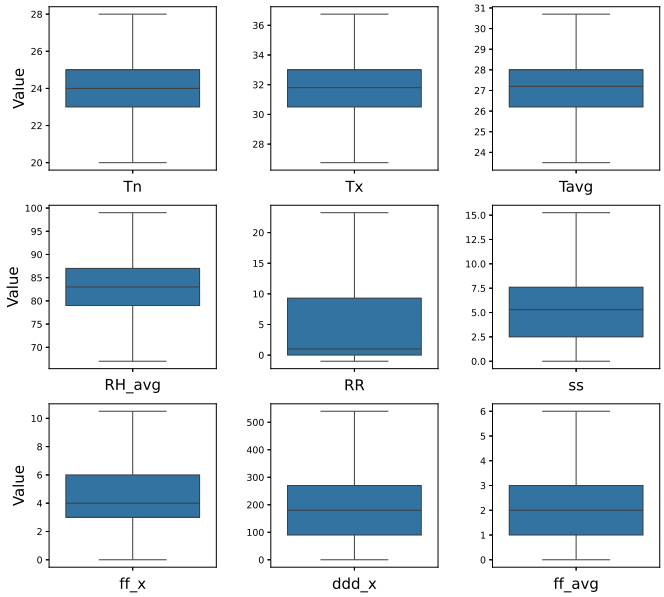

Fig. 4. Feature boxplot after removing outliers.

customized according to the model used. In forecasting models, time information was crucial. In addition, more effort needed to be made to ensure that there was no missing data in the time sequence to achieve optimal forecasting results. This process also handled outliers that appear in the dataset. Using the boxplot, we can see the values defined as outliers. This was addressed using the interquartile range approach. Fig. 3 and Fig. 4 show the condition before and after outlier removal. The data values after deletion were much more reasonable than before. This ensures the dataset was used in a wide range of conditions.

3) Normalization: Fig. 5 shows the difference between before and after preprocessing. Each weather feature had its range of values. For example, between temperature and humidity, in this condition, humidity had a much larger value than temperature; this needed to be avoided to ensure each feature had equal weight. Large values had a significant impact on the resulting model. To avoid features that were too strong because their values were too high, the value scale of each feature was normalized to a 0-1 scale.

4) Transformation: Some machine learning algorithms can perform better when the numeric input variable in the regression case has a standard probability distribution, such as Gaussian (normal) or uniform distribution. This approach is necessary to produce optimal output, especially in the case of classification. The transformation used was a quantile transformation that can transform numerical data into a normal distribution. For this reason, a transformation was performed to generalize the training dataset and solve it accurately using the linear approach. Fig. 5 shows that the transformation stage changes the distribution of previously widened data to the sides or has skewness to be concentrated in the center and form a bell.

C. Correlation Analysis

Correlation analysis illustrates the relationship between good features; this step provides an overview of features that contribute to the target variable, as in Fig. 6 and Fig. 7. Fewer data features provide an advantage in streamlining training time so that the process can run faster. The range of correlation values is between -1 and 1; 1 indicates the feature shows a powerful relationship, while a value of -1 illustrates a very weak relationship. Based on the evaluation using matrix correlations, the features that were most related to the target feature of tomorrow's rain conditions were today's rain conditions (RainToday), today's average humidity (RH_Avg), today's rainfall (RR) and the direction of the wind (ddd_x). Features with low correlation values can be considered not to be used because they do not significantly impact the final result to reduce the dimensions of the features to shorten the training process.

D. Feature Selection

Correlation analysis is one of the approaches in feature selection. Another approach used is chi-square; the chi-square score shows the value of the degree of importance of the feature to the target feature as in Fig. 8. In this case, the three features with the highest importance were RainToday, RR, and RH_avg. The order of these features was similar to the correlation analysis results. Thus, the condition of rain tomorrow was strongly influenced by these three features. Based on correlation analysis and chi-square value, the number of input features was reduced by focusing only on the RainToday, RR, and RH_avg features in predicting tomorrow's conditions.

E. Classification Model Performance

The dataset, after undergoing various preprocessing techniques, was input into several machine learning models for training and evaluation. To ensure the validity and robustness of the evaluation process, a k-fold cross-validation technique was employed, dividing the data into 10 folds. This method

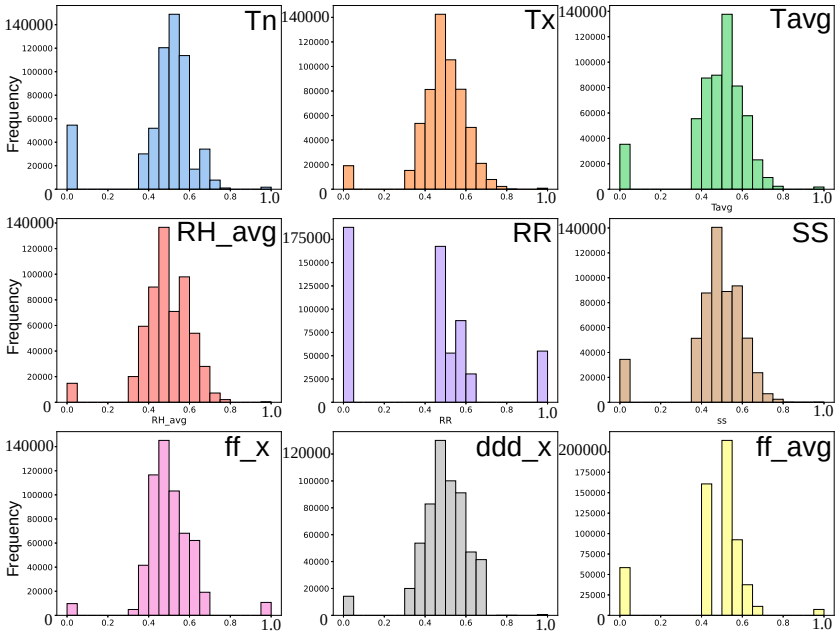

Fig. 5. Characteristics of the data collected by BMKG over a 10-year period at 192 weather stations in Indonesia after preprocessing.

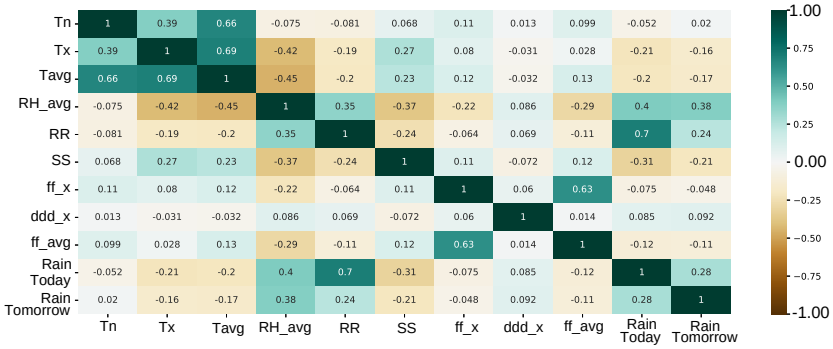

Fig. 6. Correlation heatmap before normalization and transformation.

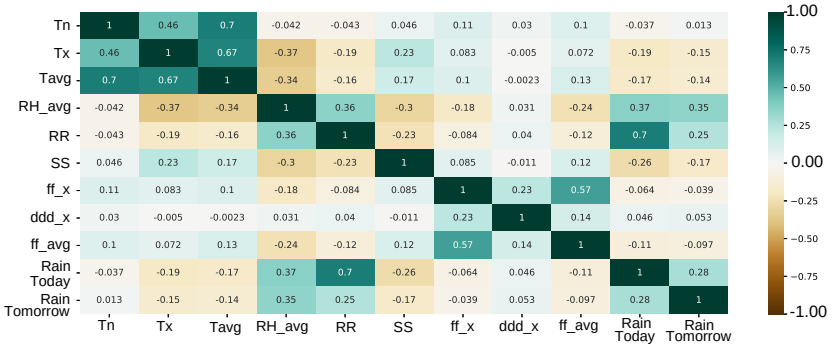

Fig. 7. Correlation heatmap after normalization and transformation.

was applied to both the IND and SMG datasets. However, in the merged condition (INDtoSMG)—where the IND dataset serves as the training set and the SMG dataset as the test set—k-fold cross-validation was not used.

Model performance was assessed using standard classification metrics: accuracy, precision, recall, and F1-score. The results, summarized in Table II, show that differences in model performance across dataset variations were not

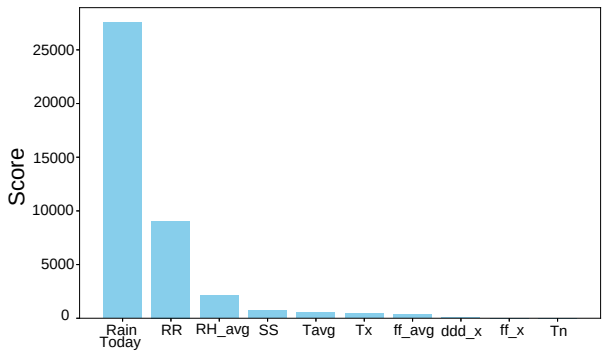

Fig. 8. Feature selection using chi-square scores.

substantial. This indicates that, in general, the classification capabilities of the models are comparable. However, a notable exception was observed in the KNN-INDtoSMG model, which achieved the highest accuracy score of 0.811. In this scenario, the model was trained on the IND dataset and tested on the SMG dataset, demonstrating that historical data can be effectively used to predict future outcomes.

TABLE II. CLASSIFICATION MODEL PERFORMANCE

Method	Dataset	Accuracy	Precision	Recall	F1-Score
KNN	IND	0.661	0.597	0.546	0.570
	SMG	0.663	0.630	0.605	0.616
	INDtoSMG	0.811	0.790	0.768	0.779
SVM	IND	0.686	0.636	0.637	0.637
	SMG	0.672	0.655	0.570	0.608
	INDtoSMG	0.685	0.636	0.635	0.635
LSTM	IND	0.692	0.661	0.588	0.622
	SMG	0.657	0.642	0.545	0.585

The KNN operates by identifying the K most similar data points in the training set and predicting the target class based on the majority class of these neighbors. Choosing an odd value of K is crucial to avoid tie situations and ensure a deterministic outcome. The strong performance of KNN suggests that the algorithm successfully captured data patterns relevant to prediction, particularly in the INDtoSMG transfer.

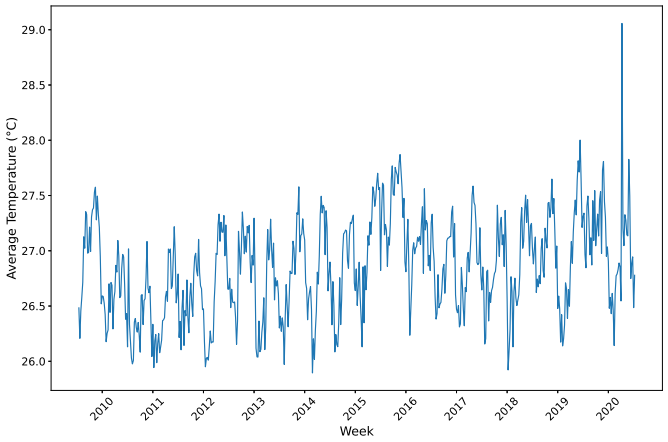
The success of KNN in the INDtoSMG scenario might also be attributed to the inclusion of Semarang (SMG) weather data within the broader IND dataset. Although the datasets were collected in different years, the underlying weather patterns in the Semarang region may have remained sufficiently consistent, allowing the model to generalize well.

In principle, modern methods—including those based on ANN and deep learning—are expected to outperform traditional approaches due to ongoing advancements. These methods have demonstrated superior accuracy across numerous applications. However, the observed insignificant performance difference between conventional and modern models in this study raises important considerations.

Model performance is influenced not only by the architecture but also by the quality of the dataset and the features used. In many cases, feature selection plays a decisive role in achieving high accuracy. Generic features that do not reflect specific weather phenomena can lead to suboptimal predictions. Moreover, employing models that are misaligned with the problem type may further degrade performance. For instance, the LSTM model, typically suitable for time-series forecasting, was included in classification-based comparisons, potentially contributing to its relatively poor performance.

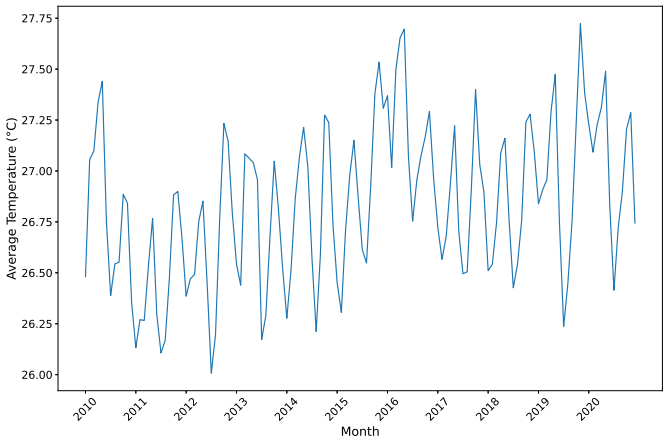
Weather prediction is inherently complex due to the highly dynamic and non-linear nature of atmospheric systems. The three key features used in this study—RainToday, RR (rainfall), and RH_avg—are all related to moisture content, a crucial indicator in rain prediction. However, these surface-level variables are outcomes of more complex environmental interactions. For example, humidity is influenced by temperature, which in turn depends on solar radiation, itself affected by factors such as cloud cover and time of day. These interdependencies are difficult to capture from surface-level observations alone.

Another limitation is the temporal resolution of the dataset. The data used in this study was collected on a daily basis, meaning that only daily summaries of weather conditions are available. Such granularity may overlook important short-term fluctuations—e.g., shifts in humidity or temperature—that could occur within a single day and are crucial for accurate rain prediction. These intra-day variations are likely to be masked in daily aggregates.



Improving prediction accuracy may require either the acquisition of higher-resolution (e.g., hourly) data or the application of advanced feature engineering techniques. For instance, incorporating temperature or humidity at specific times of day (e.g., 6 a.m. or 5 p.m.) could provide a more nuanced representation of the daily weather cycle. However, implementing such strategies is constrained by limited access to fine-grained climate data.

This is seen from the results obtained; no matter how good the model is built or how sophisticated the approach is, the features used remain one of the crucial factors that determine the ability of machine learning. Representation learning is an essential first step in finding machine learning solutions to some instances. In utilizing data, the proper representation, the right technique, and the correct model tuning are mandatory to achieve optimal solutions.



F. Visualization of Repeating Patterns

Utilization of weather datasets using a classification approach produced poor results based on the accuracy value. The reason is that the weather features used are too general. More specific weather features with a smaller scale are needed for better results. For this reason, the data was utilized using other approaches that may obtain better results. This section discusses the exploration of machine learning models in forecasting weather parameters. The exploration was conducted on various time scales, ranging from daily, weekly, monthly, quarterly, to yearly, to understand how the model adapts to changes in patterns over different periods. In this experiment, the dataset used had a daily resolution, so it was necessary to aggregate the data to a broader time range to suit the needs of the analysis. The aggregation process was carried

out by calculating each weather parameter's average value or sum at various predetermined time scales. Fig. 9(a) shows a graph of the average temperature from the results of this aggregation, which shows a recurring pattern that occurs every year. This pattern shows a tendency that arises or a seasonal trend so that it can be used to improve forecasting accuracy. The model can capture changes that occur more effectively through this understanding to produce more accurate forecasts. This tendency was also seen on a monthly time scale, as in Fig. 9(b) The graph shows that temperature tends to increase at the beginning and end of the year. At the same time, it tended to decrease in the middle of the year. This pattern shows that weather forecasting is possible if the model can learn trends that occur over time, which is the goal of machine learning. With this foundation, the authors applied machine learning to study the patterns and build models to predict future temperatures. This exploration used various approaches, from statistical models such as SARIMAX to deep learning-based models such as LSTM.

Fig. 9. Average temperature dynamics for 2010-2020 on a weekly (a) and monthly (b) scale.

G. Forecasting Model Performance

To evaluate the performance of each model, this research used MAE, RMSE, and MAPE evaluation metrics to measure the error rate between the predicted and actual values. In addition, we investigated the effect of the amount of historical data on model accuracy by varying the dataset during the training process. This variation was done by gradually adding historical data, starting from 2018 to 2010, as shown in Fig. 10. Through this approach, we aimed to understand to what extent the amount of historical data can improve the model's predictive ability and reduce the error rate in temperature forecasting.

Fig. 10(a) shows the results of temperature forecasting using the SARIMAX model using 2018-2019 data in the training process to predict 2020 data. The blue line was the data used in the training process, the red line was the predicted data, and the green line was the actual data. Based on the pattern of training data values, it can be expected at a glance that the maximum and minimum values will widen following the training data pattern. It turns out that the predicted data does not match the actual data, but the model can capture the patterns.

Fig. 10(b) shows the results of temperature forecasting using the SARIMAX model based on the 2010-2018 dataset. With more data in the training process, the model must recognize more common patterns in each period. However, this can also increase the risk of overfitting or underfitting if the model is not well-regulated. Based on the results shown, the model can identify trends and patterns, although there is still a slight deviation in the prediction of temperature values. Further parameter optimization can help improve the model's accuracy and stability in capturing the temperature change dynamics.

The results of the dataset variation in nine experiments are shown in Table III. From these results, it can be seen that the amount of data used affected the performance of the model. Adding historical data improves forecasting accuracy by allowing the model to recognize long-term patterns better. However, in some cases, the model experienced underfitting, which was characterized by higher error values due to its inability to capture complex patterns in the data. Therefore, choosing the optimal amount of data becomes crucial in achieving a balance between generalization and prediction accuracy.

H. Forecasting Year-Over-Year Model Performance

Fig. 9 shows the temperature changes from 2010-2020 that form a pattern from year to year. Based on that, this research utilized the existing data for a broader period and compare it on a Year on Year (YoY) basis. The daily data was aggregated into weekly, monthly, quarterly, and annual data. The data was then fed into the SARIMAX, RF regressor, and LSTM models. This approach provides much better prediction results, as shown in Table III. Using annual data from 2010-2018, the 2019-2020 weather data could be accurately predicted with an error value of less than 5%. To further confirm these results, we forecasted monthly and quarterly data at 192 stations in Indonesia.

Fig. 11 shows the visualization of the experimental results. The results showed that the evaluation values were stable

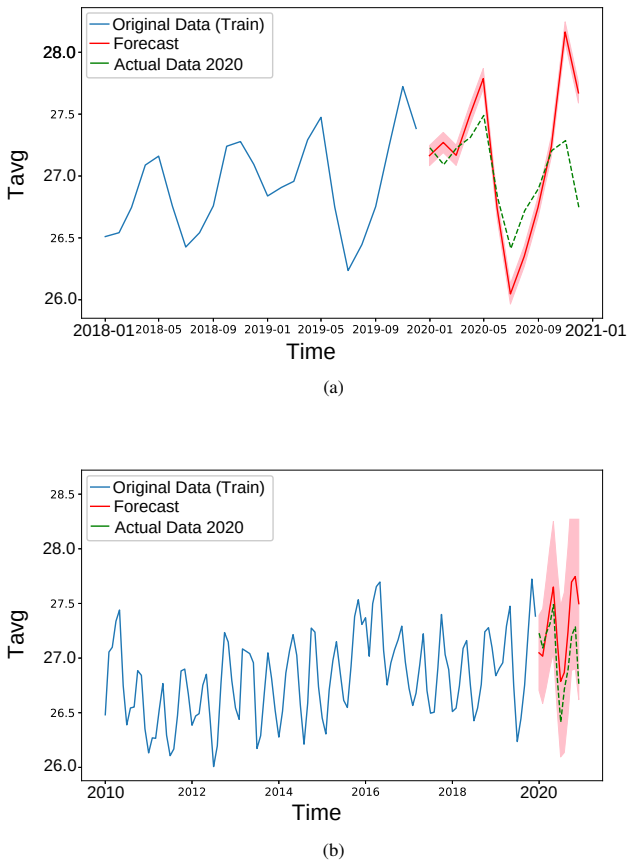

Fig. 10. Temperature forecasts using the SARIMAX model with different amounts of historical data.

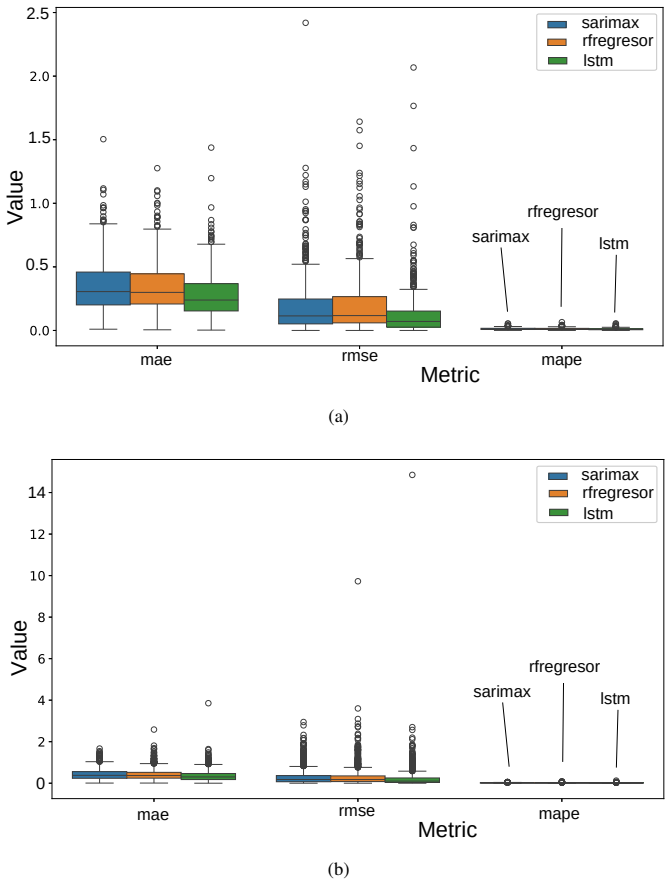

Fig. 11. Forecasting performance of the SARIMAX, RF regressor and LSTM models using quarterly (a) and monthly (b) data.

across various data variations, so the model performance was stable. Like the classification model, the three forecasting models performances did not significantly difference, while the LSTM model achieved the best performance based on the MAPE parameter.

The evaluation results indicate that the SARIMAX model can recognize temperature change patterns from historical data quite well. The model successfully made predictions with an error rate of 4% with an average difference to the actual value of 1.14 degrees Celsius, as seen in Table III. These results indicated that SARIMAX can predict long-term temperature reasonably well. Although errors still occur, this can be reduced with further optimization.

Based on performance measurements, the evaluation shows that the RF model could recognize the pattern better than SARIMAX. The model had an error rate of 3% with an average difference of 0.8 degrees Celsius. These results indicated that the RF model can predict temperature more accurately because of its advantage in recognizing non-linear relationships. Further optimization includes selecting more relevant features and setting parameters that may improve the capabilities of this model.

The evaluation results of the LSTM model show that the model could capture temperature patterns and produced predictions with an error of 3% with an average difference of 0.87 degrees Celsius. This indicates that LSTM can utilize long-term information better than other models because its architecture is designed to handle time series data with long-term dependencies.

In addition, researchers varied the amount of historical data used in the training process, which was carried out gradually from one year earlier. The aim was to determine the effect of the amount of historical data on prediction accuracy. The results showed that model performance increased with the increase in the historical data used in the training process.

However, although adding historical data increases accuracy, several aspects must be considered. LSTM models require more extended training than statistical and decision tree-based models such as SARIMAX and RF. In addition, choosing the optimal amount of historical data is crucial, as too much data can cause the model to become too complex and prone to overfitting.

Using daily data to predict daily weather over the next year resulted in a significant error rate, where the expected pattern deviated significantly from the actual data. This indicates that daily data can directly affect the model's ability to capture

weather patterns, especially since high daily fluctuations can make recognizing long-term trends with wider data variations challenging.

Based on the analysis of the weather data in time sequence using visualization, it is seen that the weather parameter values show a sinusoidal pattern that repeats within a year, reflecting the existence of seasonal trends that can be utilized for forecasting. This finding inspires an alternative approach to predicting using the YoY method, where weather data for the same period in previous years is used as a reference to predict values for the following year in the same week, month, or quarter.

To apply this approach, daily data was first aggregated into broader weekly, monthly, quarterly, and yearly time scales. This experiment focused on monthly, quarterly, and annual data, where weather data from the same month or quarter from previous years were used as training data. This approach aimed to improve the stability of the model by reducing the noise from daily fluctuations and emphasizing more obvious seasonal patterns.

With better results, the experiment was conducted on one weather feature, TX, at one weather station in Indonesia. The YoY mechanism was applied to 192 stations in Indonesia to validate the model performance further. With limited resources, the experiment was conducted on only one feature by forecasting monthly and quarterly using three machine-learning models. The results of the experiment are summarized in Fig. 11 and Table IV.

Based on Table IV, LSTM performs best overall, especially on monthly data with a MAPE value of 0.012744, demonstrating its ability to model complex patterns. LSTM also excels on annual and quarterly data with MAPE values of 0.006747 and 0.010244, respectively, making it the most reliable method for various time scales. SARIMAX, as a statistical model, excels in annual data with a MAPE of 0.008620, showing its superiority in capturing obvious seasonal patterns. However, there is a decrease in performance on monthly data because it is difficult to learn more complex patterns. Meanwhile, RF Regressor can show reasonably consistent results on each time scale, showing the best performance on quarterly data but not as good as LSTM.

LSTM is the most accurate method, especially on quarterly and monthly data. The SARIMAX model is more suitable for annual data with more apparent seasonal patterns. At the same time, RF Regressor can be used as a simpler alternative but is not as accurate as LSTM.

Based on the results obtained, the performance of each model can be seen even though it has almost the same performance. In terms of time scale, the error that occurs on a quarterly scale is much smaller than on a monthly scale. This is because the pattern of value changes on a quarterly scale tends to be more stable than the changes that occur on a monthly scale, which tends to be more volatile.

The results show that the YoY approach significantly impacts forecasting performance. The idea was obtained after the weather data visualization stage. Standard pre-processing processes such as missing value, transformation, and normalization are insufficient to direct the machine to learn. The right approach is needed to obtain optimal results. This is obtained through a good understanding of the data. Data visualization is essential in obtaining ideas to direct the machine to produce optimal solutions, as shown in Fig. 9.

TABLE III. FORECASTING MODEL PERFORMANCE

Method	MAE	RMSE	MAPE
SARIMAX	1.142	1.152	0.037
RF regressor	0.796	1.075	0.026
LSTM	0.861	0.874	0.028

TABLE IV. FORECASTING YEAR-ON-YEAR MODEL PERFORMANCE

Method	Series	MAE	RMSE	MAPE
SARIMAX	Year	0.229	0.088	0.009
	Quartal	0.345	0.187	0.013
	Month	0.422	0.286	0.016
RF regressor	Year	0.268	0.129	0.010
	Quartal	0.342	0.202	0.013
	Month	0.410	0.289	0.015
LSTM	Year	0.178	0.074	0.007
	Quartal	0.278	0.127	0.010
	Month	0.347	0.206	0.013

I. Classification vs. Forecasting

The choice between classification and forecasting depends on the available dataset and the purpose. Classification and forecasting approaches are often used to interpret future conditions, especially weather. Classification categorizes conditions like future weather, while forecasting provides continuous values like temperature or rainfall. Understanding the available data is an essential factor in determining the optimal solution. There is no fair way to compare classification and forecasting, only based on the desired goal. Based on the dataset available in this study, the forecasting approach is a more appropriate step in utilizing the available data. If forced to use the classification approach, the dataset may accurately predict the weather on a broader time scale, such as weekly, by including weather features on certain days.

IV. CONCLUSION

Weather forecasting is difficult due to the complexity of the interactions that occur. A machine learning approach with proper feature engineering and representation is essential to achieve maximum results. The results of classification and forecasting using three generations of machine learning show insignificant differences, so the initial stage of model development, such as feature engineering, is crucial. Model selection must also consider other factors, such as training time, computational efficiency, and ease of implementation. This aspect is essential in cases that require fast predictions. Understanding data is critical to support the proper and optimal use of data, which can be achieved through good dataset visualization. Classification approaches that perform poorly due to overly general features lead to the use of data for forecasting so that the data can have better benefits. In forecasting time series data such as weather predictions, the data collection or observation time scale needs to be considered. Forecasting over a broader period provides higher

accuracy due to generalization while forecasting over a smaller period has the potential to reduce accuracy due to increased noise or data variation. Regular sequential forecasting produces errors of up to 3%. However, changing a broader time period approach to YoY reduces the error to less than 1.6%. Although the model algorithm is essential to produce good accuracy, basic things such as feature engineering, feature selection, and the methods used are also crucial in creating a good model. In addition, data visualization is needed to support a better understanding of the data so that it makes an optimal approach. Further development can focus on using more sophisticated techniques to recognize features and combine various models to improve performance.

Building on the findings of this study, several directions for future research emerge. First, while the current work employs relatively basic machine learning models such as KNN, SVM, and LSTM, future studies could investigate more advanced or hybrid approaches—such as combining deep learning with statistical or ensemble methods—to enhance predictive accuracy. Expanding the dataset in both spatial and temporal resolution, for instance through hourly measurements or integration of multi-source data from satellites, radar, and reanalysis products, could further improve model performance. Moreover, the present feature set focuses primarily on surface-level variables; incorporating atmospheric parameters, remote sensing indicators, and applying advanced feature engineering could better capture complex climatic interactions. The limited richness of the dataset may also contribute to the underperformance of deep learning models, suggesting that data augmentation techniques or transfer learning from global climate datasets could be beneficial. Hybrid algorithms such as LSTM + SARIMAX, CNN-LSTM, or RF + ARIMA should be tested to leverage both temporal dependencies and nonlinear relationships. The small performance gap between models points to possible bottlenecks in feature selection and preprocessing, warranting a more systematic analysis of feature importance. Given that the best classification accuracy achieved is approximately 0.81, further hyperparameter optimization—using Bayesian or evolutionary search methods—could help unlock additional performance gains. Additionally, the exploration of seasonal decomposition techniques, such as STL decomposition, prior to forecasting could improve signal extraction.

ACKNOWLEDGMENT

This work was supported in part by Sebelas Maret University under Grant No. 228/UN27.22/PT.01.03/2023. The experiments in this study were conducted using Python, with research assistant Rahmat Rohmani providing support in executing the program code.

Graph-Based Clustering of Short Texts Using Word Embedding Similarity

Supakpong Jinarat, Ratchakoon Pruengkarn
Information Technology and Artificial Intelligence Program,
College of Engineering and Technology, Dhurakij Pundit University, Bangkok, Thailand 10210

***Abstract*—The exponential growth of short textual content on the Internet, such as social media posts and search snippets, necessitates effective text mining techniques. Short text clustering, a critical tool for organizing this data, contends with two primary challenges: data sparsity, which undermines the quality of traditional clustering methods, and the poor interpretability of machine-generated cluster labels. This study introduces the Semantic Word Graph (SWG) algorithm, a novel graph-based approach designed to address both of these issues simultaneously. Our methodology begins by constructing a global word graph where nodes represent unique terms from the corpus, and edges are weighted by the semantic similarity of word pairs, calculated using a pre-trained Word2Vec model. Cohesive communities of words are then identified using the Louvain method, and documents are assigned to clusters based on these communities. Meaningful cluster labels are generated by ranking representative nouns within each community. To validate our approach, the SWG algorithm was evaluated on three benchmark datasets (AG News, Tweet, and SearchSnippets) and compared against established methods, including Lingo, Suffix Tree Clustering (STC), and K-means. Quantitative results, measured by the F-score, show that SWG achieved up to 0.89 F-score on AG News, 0.85 on Tweets, and 0.82 on SearchSnippets, consistently outperforming baseline algorithms in clustering quality. Furthermore, a qualitative analysis confirms that SWG produces more coherent and topically comprehensive cluster labels, improving interpretability. This study concludes that the SWG algorithm is a robust and effective framework for enhancing both the accuracy and interpretability of short text clustering. Future research could explore integrating contextual embeddings such as BERT to capture deeper semantic relationships, optimizing the similarity threshold dynamically for different datasets, and scaling the algorithm to handle larger, real-time streaming text data. These directions would further improve the applicability of SWG in diverse domains such as social media analytics, news aggregation, and real-time topic detection.**

***Keywords*—Clustering; graph-based clustering; semantic similarity; short text; word embedding**

I. Introduction

Short text clustering is a specialized form of text clustering that focuses on grouping brief textual content—such as tweets, comments, and news headlines—into coherent categories based on their content. Unlike traditional text clustering methods that deal with longer documents, short text clustering faces unique challenges due to data sparsity, informal language usage, and high noise levels. With the exponential growth of short text data on social media platforms, news feeds, and online forums, the demand for accurate and interpretable clustering methods has become increasingly critical.

Current approaches often suffer from degraded clustering quality when dealing with sparse data and have difficulty generating labels that are both meaningful and representative of the underlying topics. These limitations reduce the practical usability of clustering results in real-world applications such as trend detection, news aggregation, and customer feedback analysis. Moreover, while deep learning and embedding-based models have improved text representation, many methods still fail to fully exploit semantic relationships between words in short texts, leading to clusters that lack coherence.

Although several clustering techniques, including graph-based and embedding-enhanced methods, have been proposed, most still struggle with balancing clustering accuracy and label interpretability. Few approaches explicitly address both challenges in a unified framework, and existing solutions often require extensive parameter tuning or rely on domain-specific data, limiting their generalizability.

This study aims to address these challenges by introducing the Semantic Word Graph (SWG) algorithm, a novel graph-based clustering approach designed specifically for short text. The proposed method enhances data representation using pre-trained word embeddings, detects cohesive semantic communities, and generates interpretable cluster labels through part-of-speech-based ranking. By focusing on both clustering quality and label interpretability, this research seeks to deliver a more robust and practical solution for real-world short text analysis.

II. Related Work

Despite the challenges, short text clustering has a wide range of real-world applications. In social media analysis, it is used to identify trending topics [1], [2], [3], [4], [5], track public opinion [6], and detect events [7]. In news aggregation, it helps organize news into structured categories. In customer service, clustering improves response time by categorizing customer inquiries. It is also applied in sentiment analysis to classify short texts into positive, negative, or neutral categories [8], [9].

Recently, neural network-based approaches have been adopted for short text representation learning. For example, [10] proposed a distributional semantic model to improve semantic understanding in clustering, while [11] developed STC2, which applies convolutional neural networks (CNN) [12] to feature learning. STC2 converts short text features into compact binary codes and applies k-means for clustering.

Word embedding is a procedure used in Natural Language Processing (NLP) and machine learning to transform individual words to the numerical value of vector. Word embedding enables computers to analyze and process human language by

transforming words into numerical vectors which reveal some semantic relationships between them.

Word2vec is a specific algorithm to learn word embeddings from large text corpus. It was developed by a team of researchers at Google in 2013 [13]. The algorithm employs a neural network to acquire the contextual associations among words within an extensive text corpus. Neural network is trained to predict a word appearing given its surrounding words. The weights of the neural network are used as the word embeddings.

Word embeddings are powerful because they capture the relationships between words in a language. For example, in a vector space created by word embeddings, words that are semantically similar are located close to each other. This allows computers to perform semantic tasks such as finding synonyms, detecting word relationships, and even predicting the sentiment of text.

The fundamental concept underlying word2vec involves utilizing a neural network to forecast the context words that encompass a target word, leveraging a substantial text corpus. The neural network is trained to encode each word as a vector of real values, ensuring that similar words are positioned close together in the high-dimensional space. This is achieved through a training process called stochastic gradient descent, which updates the weights of the neural network in a way that minimizes the difference between the predicted and actual context words.

There are two primary architectures of word2vec. First, Skip-gram model is to predict context words by using a target word. Secondly, Continuous Bag-of-Words (CBOW) model is to predict the target word based on its context. Both architecture have demonstrated their effectiveness in generating high-quality word embeddings, and the selection between them relies on the task at hand and the corpus size.

III. Methodology

In this research, we introduce a clustering algorithm designed specifically for short text documents. Our algorithm includes six primary steps, as shown in Fig. 1. These steps include pre-processing, construction of a word semantic graph, subgraph detection, document assignment, cluster selection, and cluster label generation. By following this methodology, our aim is to produce high-quality clusters with meaningful results.

A. Preprocessing

Pre-processing is an essential step in text clustering to clean and transform raw text data into a suitable format for clustering algorithms. We remove special characters, punctuation marks, and numbers from the text then eliminate stop words (commonly used words that do not carry significant meaning) such as 'and', 'the', 'is', etc. Irrelevant or noisy elements such as URLs, HTML tags, and email addresses are removed. For Tweet dataset, Twitter-specific elements like hashtags, mentions, and retweet are removed as well.

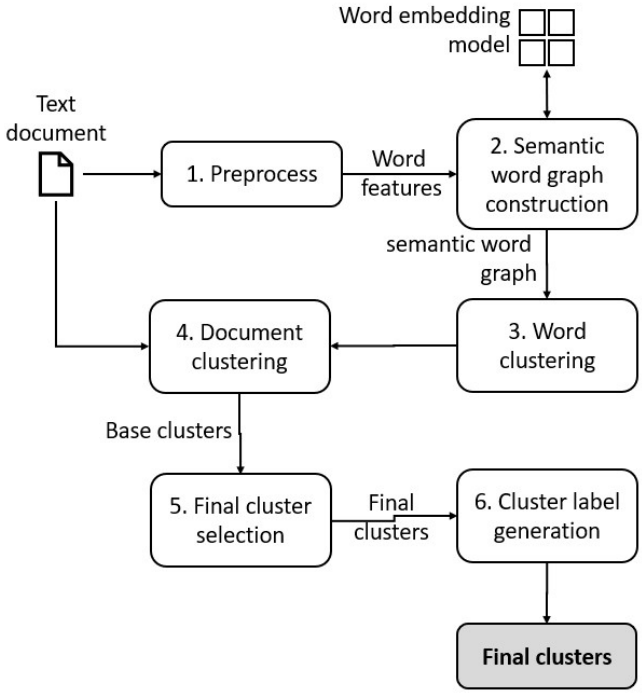

Fig. 1. System architecture of our proposed algorithm.

B. Semantic Word Graph Construction

After preprocessing, a semantic word graph is constructed based on the word features obtained from the previous step. We utilize a pre-trained Word2Vec model trained on the Google News corpus, containing approximately 100 billion words. The model provides 300-dimensional vector representations for approximately three million unique words [14].

The graph is defined as $G = (V, E, W)$, where V is the set of unique words from the preprocessed text. E is the set of undirected edges e_{ij} between word pairs v_i , $v_j \in V$ and W is the set of edge weights w_{ij}, which represent the semantic similarity between words v_i and v_j computed using the cosine similarity of their word vectors.

$$w_{ij} = sim(v_i, v_j) = \frac{v_i \cdot v_j}{\|v_i\|\|v_j\|} \tag{1}$$

Only edges with weights exceeding a predefined threshold (e.g. $w_{ij} > 0.5$) are retained to construct a meaningful semantic network.

D1: "The football team won the championship match with a score of 3-1.",
D2: "The basketball player made an incredible slam dunk during the game.",
D3: "The golfer sank a long putt to secure victory in the golf tournament.",
D4: "The president delivered a speech outlining the administration's goals.",
D5: "The prime minister met with foreign leaders to discuss international relations.",
D6: "The senator proposed a bill to reform the healthcare system."

Fig. 2. Example of text documents used for demonstration of word semantic graph construction.

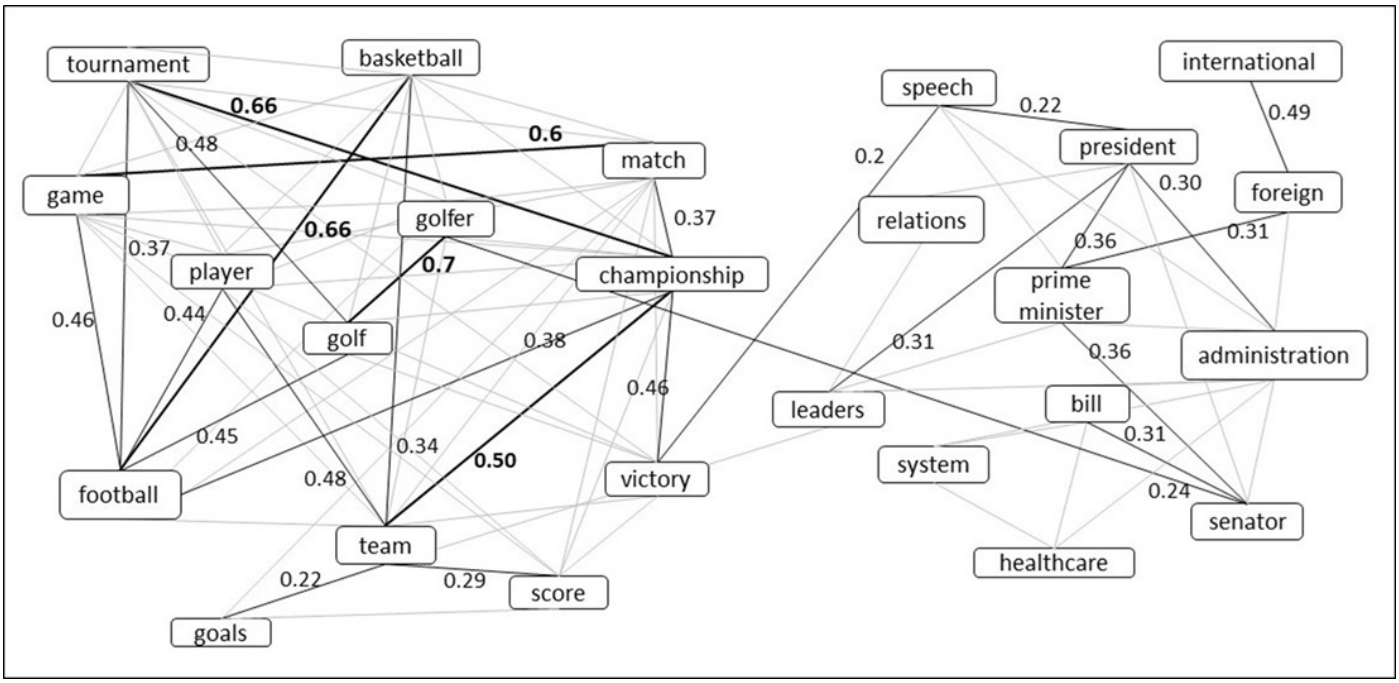

Fig. 3. Illustrative of word semantic graph construction from text document example.

Fig. 3 showcases the construction of the word semantic graph, derived from the example text document illustrated in Fig. 2.

C. Word Clustering

In the semantic word graph produced from the previous step, words with high semantic similarity are connected by edges with weights close to 1. To identify cohesive groups of related words, the graph is divided into subgraphs (or word clusters) by pruning weak edges—those with weights below a predefined similarity threshold st.

After pruning, we apply the Louvain method [15] for community detection to each resulting subgraph. This algorithm detects communities based on modularity optimization, helping identify groups of words that exhibit strong semantic relationships. As shown in Fig. 4, when a similarity threshold of 0.3 is applied, the semantic word graph is partitioned into two distinct subgraphs. Each subgraph contains strongly connected words, which are treated as word clusters. These word clusters serve as the input for the next step: document clustering, where documents are grouped based on their semantic similar derived from these clusters.

Each subgraph produced from this step is treated as a word cluster, with each cluster containing a set of candidate labels—i.e., representative words from the cluster—but no associated documents at this stage. The assignment of documents to these clusters will be operated in the next step of the algorithm.

As illustrated in Fig. 4, two example word clusters are presented.

The first word cluster includes candidate labels such as: “football”, “team”, “championship”, “match”, “score”, “basketball”, “player”, “game”, “tournament”, “golfer”, “victory”, “golf”, and “goals”.

The second word cluster contains labels like: “president”, “administration”, “prime minister”, “foreign”, “leaders”, “international”, “senator”, and “bill”.

These clusters are semantically coherent and form the basis for the upcoming step of document assignment based on semantic matching.

D. Document Clustering

The semantic word subgraphs produced from the previous phase are used as word clusters for the purpose of document clustering. Each document is assigned to one or more clusters based on the presence of any word from the set of candidate labels within the document text. This approach allows a document to be associated with multiple word clusters, resulting in overlapping clustering. Such flexibility is useful in cases where a document covers multiple topics or contains ambiguous content. The resulting groups of documents—each associated with a semantic word cluster—are referred to as base clusters, which used as input for the next stages of the clustering framework.

E. Final Cluster Selection

In the previous step, we define the importance of a base cluster based on its size—that is, the number of documents it contains. Accordingly, we rank all base clusters in descending order of size. The top k clusters in this ranking are selected as the final output clusters for further interpretation and evaluation.

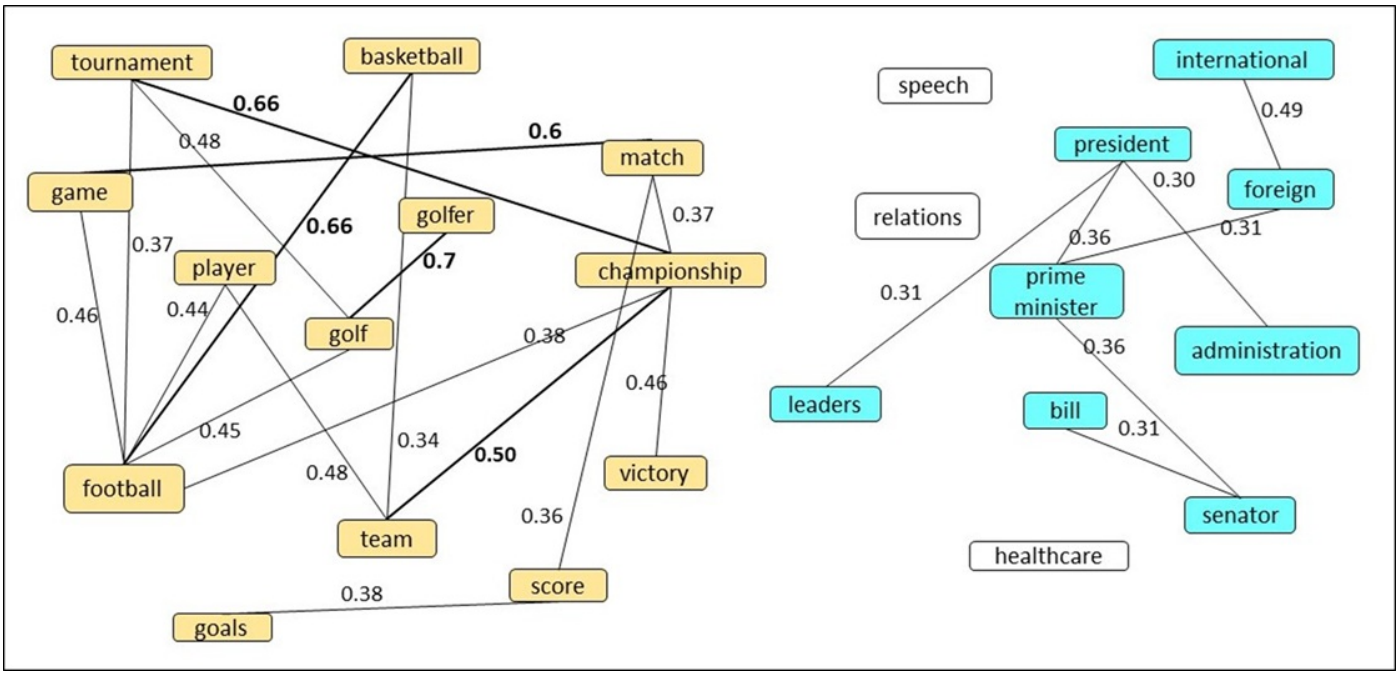

Fig. 4. An illustrative instance of a word semantic graph and its corresponding subgraphs is presented, utilizing a similarity threshold of 0.3. The semantic word graph displays the interconnections among words, while the subgraphs depict clusters formed based on the established similarity threshold.

F. Generating Cluster Label

Beyond clustering efficiency, it is equally essential to provide a descriptive interpretation of each resulting cluster. In this step, we focus on generating cluster labels for the final output clusters. As each semantic subgraph represents a set of semantically related words, we consider these words as candidate descriptors for the associated documents. Specifically, we first eliminate non-noun words using part-of-speech filtering. Next, each word is assigned a relevance score computed using a scoring function [see Eq. (2)], which quantifies its representativeness.

$$label_score(f_i) = df(f_i) \times neighbor(v_i) \tag{2}$$

Where $df(f_i)$ is document frequency of word f_i from the input text document and neighbor(vi) is number of nodes that links to the node v_i in the semantic word graph.

Finally, the top-ranking words—typically those with the highest scores—are selected as cluster labels, offering an interpretable summary of each semantic group.

IV. Experiments

A. Experimental Setup

We evaluated the performance of our proposed algorithm, Semantic Word Graph (SWG), by comparing it with established text clustering methods, including Lingo [16], Suffix Tree Clustering (STC) [17], [18] and the K-means clustering algorithm. For both Lingo and STC, default parameter settings recommended by their original implementations were adopted.

For SWG, we experimented with three different values of the similarity threshold: $st = 0.4$, $st = 0.5$, and $st = 0.6$. The performance of all algorithms was assessed across a range of cluster counts, from 1 to 10, which aligns with the actual number of topics in each dataset used.

B. Dataset

The experiments were conducted on three widely used benchmark datasets for short text clustering: namely the SearchSnippets, Tweet, and AG News datasets.

For the SearchSnippets dataset, which was originally compiled by [19], we used a collection of 12,340 short text snippets retrieved from web search results. These snippets were obtained using predefined keywords associated with 8 distinct topical categories. A summary of this dataset is shown in Table I.

TABLE I. The 8 Different Topics SearchSnippets Dataset

Topic	Number of Documents
Business	1,500
Computers	1,500
Culture-Arts-Entertainment	2,210
Education-Science	2,660
Engineering	370
Health	1,180
Politics-Society	1,500
Sports	1,420

Secondly, for the Tweet dataset, we collected tweets via web scraping from 16 prominent public Twitter accounts, focusing on 4 specific topics, as summarized in Table II. A maximum of 2,000 tweets was retrieved from each account on 14 May 2022. The retrieved tweets were categorized according

to their corresponding topics. Subsequently, 2,000 tweets were randomly selected for each topic, resulting in a final dataset of 8,000 tweets (across four topics) used in our experimental analysis

TABLE II. THE TWITTER ACCOUNTS WERE CATEGORIZED INTO 4 DISTINCT TWEET TOPICS, ENSURING SEPARATION BASED ON THEIR CONTENT

Politics	Sports	Sci/Tech	Business
BBC_Politics	ESPN	NASA	CNNBusiness
CNN_Politics	Fox_Sports	Science_News	Davos
POLITICO	SportsCenter	science	economics
Post_Politics	Twitter_Sports	CERN	EconomicTimes

Lastly, we used the AG News dataset, a large corpus of online news articles commonly employed in text classification and clustering tasks [20]. This dataset contains 496,835 news articles collected from over 2,000 distinct news outlets. For our experiments, we randomly selected 1,000 articles from each six categories, resulting in a total of 6,000 documents. Only the title and description fields were used for clustering. A summary of this dataset is presented in Table III.

TABLE III. AG NEWS DATASET SEPARATED BY 6 DIFFERENT TOPICS

Topic	Number of Documents
Business	1,000
Entertainment	1,000
Health	1,000
Sci/Tech	1,000
Software and Development	1,000
Sports	1,000

C. Evaluation Method

We evaluated the effectiveness of our proposed clustering algorithm by measuring its ability to accurately group short texts and address the inherent challenges of short-text data. Experiments were conducted on multiple benchmark datasets consisting of short text documents. Our method was compared with established clustering techniques, including Lingo and Suffix Tree Clustering (STC). The primary evaluation metric used was the F-score.

The F-score is a widely used evaluation metric in machine learning, particularly for classification and clustering tasks. It represents the harmonic mean of precision and recall, thereby providing a balanced measure of accuracy and completeness.

Precision is the proportion of true positive predictions among all positive predictions made by the model. It quantifies the accuracy of positive assignments.

$$\text{Precision} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Positives}} \tag{3}$$

Recall is the proportion of true positive predictions among all actual positive instances. It reflects the completeness of the positive predictions.

$$\text{Recall} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}} \tag{4}$$

The F-score can be computed using two standard variants: micro-averaging and macro-averaging. The distinction between these methods lies in how precision and recall are aggregated across multiple clusters.

The micro-average F-score [21], [22], [23], [24] computes performance globally by counting the total true positives, false positives, and false negatives across all clusters. It treats the entire clustering task as a single binary classification problem, where documents that belong to any cluster are considered the positive class. This approach is particularly useful when class imbalance exists, as it emphasizes frequent categories. The micro-average F-score is computed using the following formula:

$$F_{\text{micro}} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{5}$$

In contrast, the macro-average F-score computes the F-score for each cluster individually and then averages the results across all clusters. In this case, each cluster is treated as a separate binary classification task, allowing equal weight to be assigned to both large and small clusters. The macro-average F-score is calculated using the following formula:

$$F_i = 2 \times \frac{\text{Precision}_i \times \text{Recall}_i}{\text{Precision}_i + \text{Recall}_i} \tag{5}$$

where Precisioni and Recalli are computed for the i-th cluster. The F-score macro-average [25], [26] is then computed as the average of the F-scores for all clusters:

$$F_{\text{macro}} = \frac{\sum F_i}{n} \tag{7}$$

where n is the total number of clusters.

Moreover, we propose a modification to the traditional macro-average F-score, referred to as the weighted macro-average F-score. This metric considers the size of each cluster when computing the average, thus giving more weight to larger clusters. The weighted macro-average F-score is defined as follows:

$$F_{\text{weighted_macro}} = \frac{\sum(F_i \times n_i)}{N} \tag{8}$$

where n is the total number of documents, F_i denotes the F-score of the $i-th$ cluster, and n_i represents the number of documents in cluster. The weighted macro-average F-score offers a more representative evaluation of clustering performance, as it accounts for the varying sizes of clusters and emphasizes the contribution of each cluster to the overall clustering quality.

V. Result and Discussion

A. The Quality of Clustering

To ensure a fair comparison among Lingo, STC, and our proposed method (SWG), we evaluated all algorithms based on the top-k clusters, where k ranges from 2 to 10. This aligns with the actual number of clusters present in each dataset used in the experiments.

The results clearly show that the proposed SWG algorithm consistently outperformed the baseline methods, particularly on the Tweet dataset, as illustrated in Fig. 6. These findings highlight the significant advantage of incorporating semantic word graphs, especially when dealing with short texts that contain sparse and noisy information.

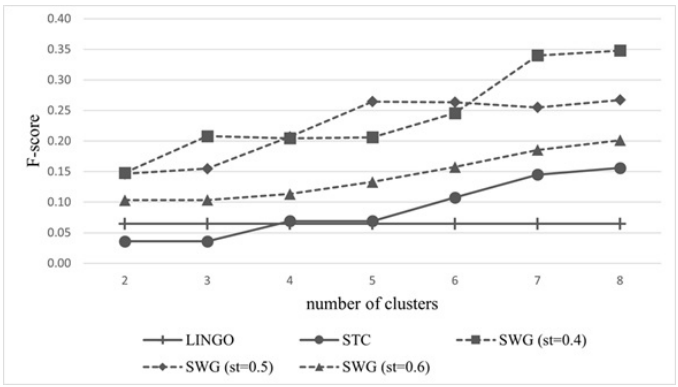

Fig. 5. Quality of clustering on the AG news dataset.

For the AG News dataset (Fig. 5), our method achieved the highest F-score across all tested similarity thresholds, demonstrating its effectiveness in grouping short news articles based on semantic similarity.

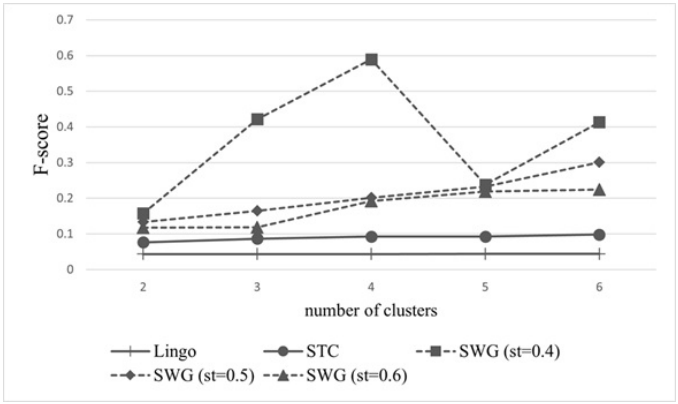

Fig. 6. Quality of clustering on the tweet dataset.

Likewise, on the Tweet dataset, SWG achieved the best F-score under all evaluated threshold values, confirming its robustness in handling short, informal, and noisy text typical of social media content. These results underscore the practical advantage of semantic-based clustering in real-world applications involving brief and informal textual data.

As illustrated in Fig. 7, our proposed method achieved higher F-scores than the baseline algorithms at two similarity

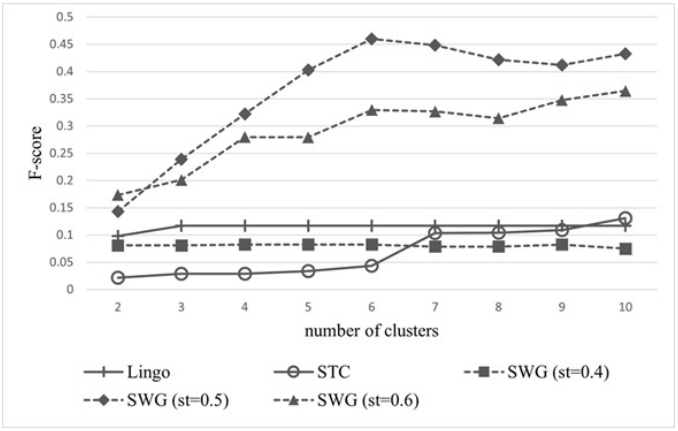

Fig. 7. Quality of clustering on the search snippets dataset.

threshold values ($st = 0.5$ and $st = 0.6$). However, the result for the remaining threshold ($st = 0.4$) was slightly lower than those obtained by the comparative methods.

Despite this, our method still demonstrated competitive performance in clustering short texts from search result snippets, which are often fragmentary and challenging to group semantically. These results further support the robustness of the proposed algorithm across different datasets and parameter settings.

In this study, we also compared the performance of our graph-based text clustering algorithm (SWG) with the well-known vector-based baseline, K-means.

As shown in Fig. 8 and Fig. 10, the SWG algorithm consistently outperformed K-means across all tested cluster numbers on both the AG News and SearchSnippets datasets.

For the Tweet dataset (Fig. 9), our algorithm exhibited slightly lower performance than K-means when the number of clusters was set to 2 and 3. However, SWG outperformed K-means for cluster numbers 4, 5, and 6—most notably when $k = 4$, which corresponds to the ground truth number of clusters in the Tweet dataset. This result demonstrates the strength of SWG in capturing semantically coherent clusters when aligned with real-world topic distributions.

B. Representative Words for a Cluster Result

In this section, we analyze the representative words generated by the three clustering algorithms—Lingo, STC, and SWG—across all three datasets. These representative words reflect the dominant themes within each cluster and allow for qualitative comparisons between the algorithms.

Table IV presents the representative words produced by each algorithm on the AG News dataset, which includes six primary categories: Business, Entertainment, Health, Science/Technology, Software and Development and Sports.

The Lingo algorithm captured Sports-related topics in Cluster 2, 4, and 6 with words like Wins, Wins Gold, and Phelps Wins. It also identified Health-related topics in Cluster 1 and 5 with terms such as Drug and Cancer Drug.

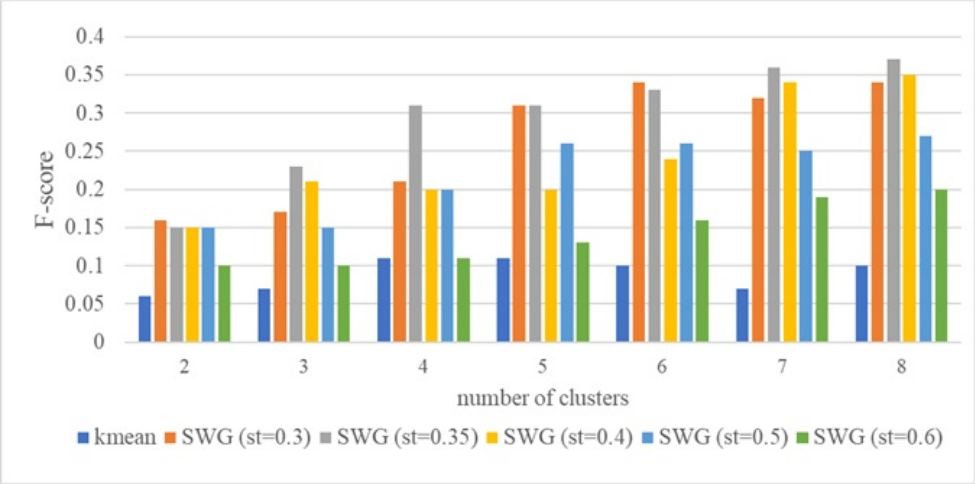

Fig. 8. Quality of clustering of our algorithm compared with k-means algorithm on AG news dataset.

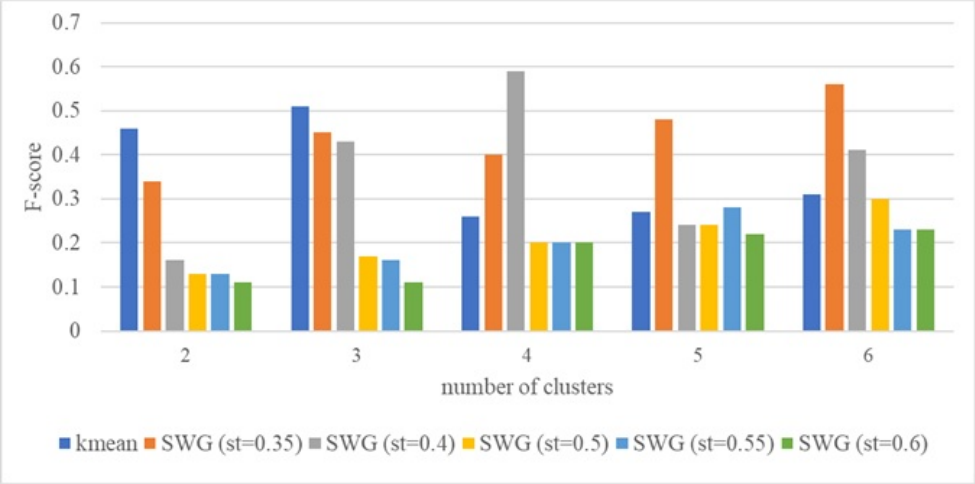

Fig. 9. Quality of clustering of our algorithm compared with k-means algorithm on tweet dataset.

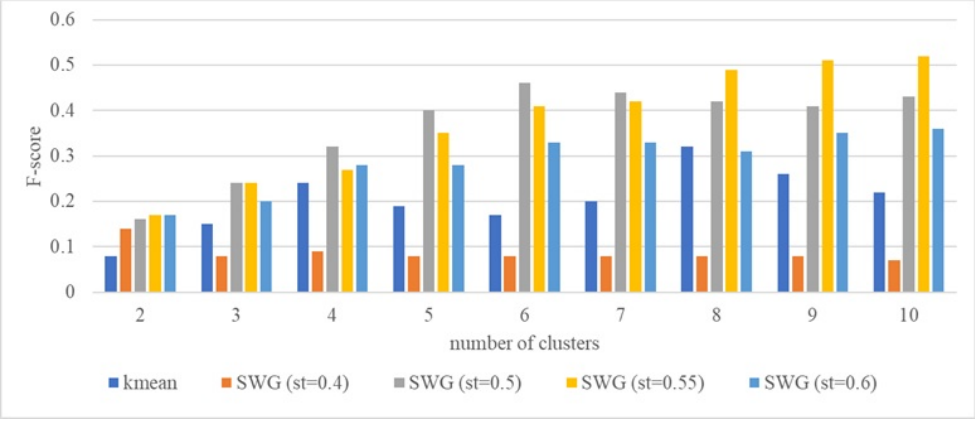

Fig. 10. Quality of clustering of our algorithm compared with k-means algorithm on searchsnippets dataset.

The STC algorithm produced more mixed clusters, capturing terms related to Health Drug, Sports Wins, Business Prices, and Technology Google.

Our proposed method, SWG, demonstrated a broader and more topic-specific range:

Cluster#1: Software and Development — “Microsoft”,

TABLE IV. REPRESENTATIVE WORDS OF CLUSTERS PRODUCED BY EACH COMPETITIVE ALGORITHM ON AG NEWS DATASET

Cluster No.	Lingo	STC	SWG
1	Drug	Drug	Microsoft, Google, IBM, Linux, Windows, Intel
2	Wins	Wins	China, UK, Olympic, US, Sox, Phelps
3	U.S.	U.S.	Profit, Stocks, Prices, Oil, Costs, Trial
4	Wins Gold	Prices	Cancer, Study, Drug, Risk, Health, Disease
5	Cancer Drug	Google	Help, gets, takes, Slow, unveils, Higher
6	Phelps Wins	Oil	Wins, Gets, Takes, Says, Finds, Helps

TABLE V. REPRESENTATIVE WORDS OF CLUSTERS PRODUCED BY EACH COMPETITIVE ALGORITHM ON TWEET DATASET

Cluster No.	Lingo	STC	SWG
1	Boris Johnson Says	Year	people, company, secretary, workers, women, economic, children, business
2	PM Says	Boris Johnson	win, NBA, games, Lakers, team, playoffs
3	Labour Says	LIVE	Labour, MP, UK, Conservative, government, Boris
4	MP Says	Launch	spacecraft, NASA, Earth, astronauts, Mars, science

TABLE VI. REPRESENTATIVE WORDS OF CLUSTERS PRODUCED BY EACH COMPETITIVE ALGORITHM ON SEARCHSNIPPETS DATASET

Cluster No.	Lingo	STC	SWG
1	News News	Edu	research, university, students, school, theory, physics
2	Research Research	News	science, disease, health, computer, biology
3	Wikipedia Wikipedia	Research	web, online, articles, photos, website, art
4	Edu Research	Wikipedia Wiki, Wikipedia Encyclopedia	world, political, gov, games, tournament, election
5	Information News	Gov	movie, film, music, books, band, guitar
6	News Sports	Articles	buy, companies, market, department, industry, organizations
7	Articles News	Computer	linux, wiki, microsoft, cpu, unix, ibm
8	Information Research	Resources	sports, football, soccer, tennis, basketball, president

"Google", "IBM", "Linux", "Windows", "Intel"

Cluster#2: Sports — "China", "UK", "Olympic", "US", "Sox", "Phelps"

Cluster#3: Business — "Profit", "Stocks", "Prices", "Oil", "Costs", "Trial"

Cluster#4: Health — "Cancer", "Study", "Drug", "Risk", "Health", "Disease"

Clusters#5 and Cluster#6: Contained more general and ambiguous terms, making topic identification less conclusive.

These results indicate that the SWG algorithm is more effective at generating semantically coherent cluster labels compared to the baseline algorithms, particularly in identifying multi-category topics in the AG News dataset.

For the results on the Tweet dataset, as presented in Table V, the dataset included four predefined topics: $Politics$, $Business$, $Science/Technology$, and $Sports$.

The Lingo algorithm focused almost exclusively on the Politics topic across all clusters, lacking clear differentiation between other topical categories.

The STC algorithm captured the Politics topic in Cluster#2, while the remaining clusters (Clusters#1, Cluster#3, and Cluster#4) contained more ambiguous or generic terms, such as "Year" "LIVE" and "Launch" which made topic interpretation less definitive.

In contrast, our proposed SWG algorithm successfully identified three distinct topics. Table VI shows respresentarive words of clusters produced by each competitive algorithm on searchSnippets dataset.

VI. CONCLUSION

In this study, we focused on short text clustering with two main objectives: providing high-quality results by grouping together short texts with similar content and generating meaningful cluster labels to aid user understanding.

From the results in section of Quality of Clustering, our proposed algorithm outperformed competitive algorithms across various key parameter variations. The Semantic Word Graph consistently produced significantly better clustering quality.

Furthermore, the representative words generated by the Semantic Word Graph algorithm demonstrated its ability to appropriately represent topics in a cluster. These words struck a balance between being overly specific and excessively general. The cluster labels derived from the Semantic Word Graph algorithm covered multiple topics within the initial clusters, as evidenced by the results in the Result and Discussion section.

The sensitivity analysis conducted on our proposed algorithm offered valuable insights into its performance under different parameter settings. Specifically, by varying the similarity threshold and observing the resulting clustering output, we

gained a deeper understanding of the algorithm's response to input variations.

We observed that increasing the similarity threshold within the subgraph detection step improved the algorithm's performance until an optimal threshold was reached. However, setting the similarity threshold too high led to a slight decrease in clustering performance. Conversely, reducing the similarity threshold resulted in more general semantic connections and an increase in the number of documents per base cluster, thereby impacting the clustering performance. Consequently, determining an appropriate value for the similarity threshold is critical and should be tailored to the specific application and characteristics of the input documents.

In conclusion, our study demonstrated the effectiveness of the proposed Semantic Word Graph algorithm in achieving high-quality clustering results and generating meaningful cluster labels for short texts. The sensitivity analysis provided insights into parameter settings, further enhancing the algorithm's performance and customization capabilities.

Future research could focus on enhancing the SWG framework by integrating advanced contextual embeddings, such as BERT or Sentence-BERT, to capture richer and more nuanced semantic relationships between words. In addition, developing adaptive methods for automatically determining optimal similarity thresholds would allow the algorithm to adjust dynamically to the characteristics of different datasets, improving clustering quality without extensive manual tuning. Finally, incorporating user-centric evaluation—through usability studies and real-world testing—would provide insights into how well the generated cluster labels support human understanding and decision-making, ensuring that the method is not only effective in quantitative terms but also practical and interpretable for end users.

A Prompt-Driven Framework for Reflective Evaluation of Course Alignment Using Large Language Models

Mashael M. Alsulami
Department of Information Technology, College of Computers and Information Technology,
Taif University, Taif 21944, Saudi Arabia

***Abstract*—Large language models (LLMs) such as ChatGPT are gaining attention in educational settings, yet their potential role in supporting course design and academic quality assurance remains underexplored. This study introduces a structured, prompt-driven framework that uses ChatGPT as a reflective tool to help faculty and curriculum designers evaluate the alignment between course learning outcomes (CLOs), assessment methods, and teaching strategies. Grounded in the standards of the National Center for Academic Accreditation and Evaluation (NCAAA) and Bloom's Revised Taxonomy, the system generates targeted, context-aware feedback using structured prompts modeled after official NCAAA forms. To enhance reliability and reduce hallucinations, the framework employs template-based prompt engineering and rule-based cognitive classification. A large-scale analysis was conducted across 56 CLOs to assess internal consistency, followed by expert validation from two academic reviewers who evaluated a sample of AI-generated feedback for accuracy, usefulness, and cognitive alignment. The findings highlight the tool's ability to surface alignment issues and offer constructive recommendations, while also demonstrating its potential as a scalable support system for curriculum review and accreditation readiness, complementing rather than replacing human expertise.**

***Keywords*—Prompt engineering; Course Learning Outcomes (CLOs); Large Language Models (LLMs); curriculum alignment; educational quality assurance**

I. Introduction

Ensuring that course design is pedagogically sound and aligned with learning expectations is a central concern for quality assurance in higher education. Curriculum alignment, linking learning outcomes with teaching strategies and assessments, is widely recognized as a core principle of effective instructional design [1]. However, despite the availability of structured accreditation frameworks, several studies have shown that instructors often struggle with articulating measurable outcomes and ensuring that course activities target the appropriate cognitive levels [2][3]. These challenges become more pressing as institutions are required to demonstrate evidence of alignment for accreditation and continuous improvement.

Recent innovations in educational technology have opened new possibilities for automating parts of the curriculum review process. Artificial intelligence (AI), particularly large language models (LLMs), is being explored for its potential to support outcome-based design by providing reflective feedback and consistency checks [4]. These models can help academic staff navigate regulatory requirements, avoid cognitive mismatches between CLOs and assessments, and generate suggestions based on taxonomic alignment principles such as Bloom's taxonomy. However, such tools are not meant to replace human judgment; instead, they offer a structured augmentation to facilitate deeper reflection and compliance with institutional standards.

Creating well-designed courses that truly align learning outcomes with assessments and teaching strategies is essential for delivering quality education, and for meeting accreditation standards. In Saudi Arabia, the National Center for Academic Accreditation and Evaluation (NCAAA) [5] provides clear frameworks and structured forms to help ensure consistency and excellence across higher education institutions. Still, many instructors and curriculum developers find it challenging to interpret these guidelines, detect misalignments, or clearly justify their course design decisions.

This research presents a new approach that brings artificial intelligence into the heart of course evaluation. We introduce a reflective tool powered by ChatGPT, a cutting-edge large language model, to assist faculty in reviewing and improving how CLOs, assessments, and teaching methods are connected. But unlike typical AI applications that generate open-ended content, our tool follows a structured, prompt-driven framework that mirrors the official NCAAA specification format.

What sets this work apart is its contribution to both practice and process: it offers a reliable, transparent, and scalable method for evaluating course alignment. Using Bloom's taxonomy as its foundation, the system identifies the cognitive level of each CLO and checks whether it's well-matched with the stated assessments and teaching strategies. The prompts are carefully designed to guide the model's responses, minimizing hallucination and keeping the feedback focused and consistent.

Rather than replacing human decision-making, this tool augments academic judgment by making the review process more transparent, efficient, and pedagogically sound. It offers a practical contribution to educational quality assurance practices, particularly in accreditation-driven contexts, and opens new directions for human-AI collaboration in curriculum evaluation.

II. Related Work

The integration of artificial intelligence (AI) into higher education has drawn significant attention, particularly with

the emergence of large language models (LLMs) such as ChatGPT. These tools have sparked interest as assistive agents in instructional design, assessment, and academic support. This section reviews existing research on the use of LLMs in educational quality assurance, with a focus on their applications in curriculum evaluation, limitations, and reflective learning support.

A. LLMs in Curriculum and Instructional Design

Several studies have investigated how ChatGPT and similar LLMs can support the instructional design process. For instance, Johansson et al. (2024)[6] explored the ability of ChatGPT to independently design higher education field courses, finding that while the model generated coherent learning objectives and activities, it often failed to account for contextual factors and discipline-specific pedagogy. Similarly, the CDIO 2024 Proceedings [7] include a set of experiments in which ChatGPT was tasked with drafting parts of course specifications. While the model performed well in identifying general structure and terminology, it struggled with generating outcomes that align with the cognitive demands of the discipline.

In line with this, Iftene et al. (2024) [8] emphasized the utility of ChatGPT in supporting educators in the process of formulating learning outcomes. Their findings highlight the model's utility in producing syntactically correct CLOs that often reflect Bloom's Taxonomy, though subject-matter specificity remained a concern.

B. ChatGPT for Assessment Evaluation and Feedback

The potential of ChatGPT in generating or evaluating assessments has also been documented. In a recent study by Van Dis et al. (2024)[9], ChatGPT was tested for its ability to assess the quality of student writing and exams. While it demonstrated promising consistency, its performance deteriorated on open-ended questions where nuanced human judgment was needed. Likewise, Sahlgren et al. (2023)[10] conducted controlled evaluations and concluded that while LLMs can surface generic feedback for rubric-based grading, they are less effective in subjective judgment or when factual correctness is crucial.

C. Limitations and Hallucination Risks

Several works have acknowledged inherent risks in relying on LLMs for educational judgment. Hallucination, generating incorrect or fabricated content, remains a key challenge. Salam. (2023) [11] specifically caution that ChatGPT often invents plausible but inaccurate content, especially in contexts involving institutional policies or accreditation standards. To mitigate this, recent approaches suggest structured prompt engineering [12], limiting model creativity by embedding scaffolding within the input prompt, and validating outputs against expert reviews.

Our approach,relying on structured, template-based prompts that mirror the NCAAA course specification format,builds upon this literature by explicitly controlling the scope of generative output. Additionally, our system incorporates Bloom's taxonomy verb parsing, a method aligned with existing literature [13], to establish a foundation for cognitive demand classification before invoking ChatGPT. This layered methodology aims to reduce drift and hallucination by constraining the model's interpretive boundaries.

D. Reflective Tools and Human-AI Collaboration

While many studies focus on automation, our research contributes to a growing body of work that views LLMs as reflective tools—not replacements for human judgment but catalysts for deeper reflection and review. This aligns with the philosophy of human-AI collaboration articulated by Luo et al. (2023) [14], who argue for maintaining human oversight in contexts where contextual, ethical, or pedagogical nuances are critical.

Our reflective framework differs from fully automated assessment systems by situating the model as a reviewer-in-dialogue rather than an oracle. It provides feedback on the alignment between learning outcomes, teaching strategies, and assessments. Such granular critique, when presented through a dashboard or structured feedback format, facilitates human deliberation and supports transparency in course design decisions.

In summary, our research addresses several limitations found in prior work: (1) it avoids open-ended generation by using grounded prompts and taxonomy-driven structure, (2) it evaluates assessment alignment with cognitive levels rather than generating them, and (3) it augments human judgment rather than substituting it. These features position our reflective tool as a practical and scalable solution for academic quality assurance, particularly in contexts governed by formal standards such as those of the NCAAA in Saudi Arabia.

III. Methodology

This study adopted a computational content analysis approach to evaluate the alignment between Course Learning Outcomes (CLOs) and their corresponding assessment methods within course specification documents. The methodology integrated automated text extraction, verb-level classification [15] using Bloom's Revised Taxonomy [16], and interpretation via a large language model (LLM), specifically OpenAI's GPT-3.5. As illustrated in Fig. 1, the process begins with inputting course specifications in PDF format, followed by text extraction. Extracted verbs are mapped to cognitive levels in Bloom's taxonomy, which guides prompt generation for ChatGPT-based analysis. The model then evaluates the alignment between CLOs and assessment and teaching methods and strategies, providing feedback and suggestions, which are compiled into structured outputs for review.

A. Data Collection

The dataset used in this study consisted of 56 annotated CLO instances extracted from course specifications of a Master's program in Artificial Intelligence. Course specifications were retrieved from publicly available sources on the websites of Saudi universities. Each entry includes structured metadata such as course title, CLO code and description, teaching strategy, assessment method, and model-generated feedback. Data ingestion was performed, where batch extraction of course content was automated. The dataset covered multiple CLOs per course and preserved contextual elements such as program title and level, ensuring validity across hierarchical program structures.

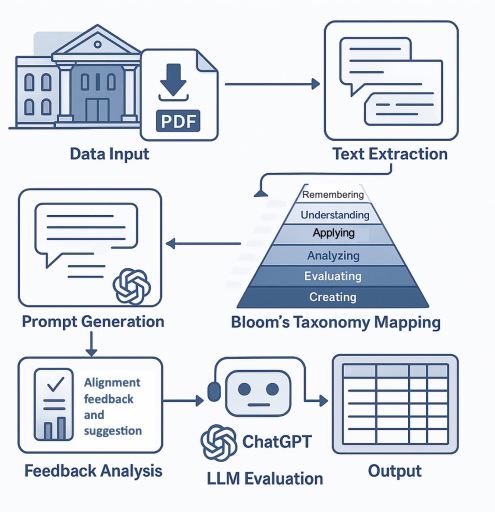

Fig. 1. Computational workflow for evaluating CLO-assessment alignment using Bloom's taxonomy and ChatGPT.

B. CLO Identification and Filtering

To ensure analytical rigor and consistency with national academic standards, only CLO entries that followed a standardized numerical format (e.g., 1.1, 2.2, 3.1) were included in the dataset. This structure directly reflects the official course specification template mandated by the National Center for Academic Accreditation and Evaluation (NCAAA), as specified in the official guidelines provided by the NCAAA [5]. Nearly all Saudi universities follow this core specification model as part of the broader transformation of higher education quality and accreditation in Saudi Arabia [17].

To avoid misinterpretation, the extraction process was designed to filter out non-actionable section headers such as "Knowledge," "Skills," or "Values," unless they were immediately followed by a clearly numbered sub-outcome. This rule-based filtering, implemented using regular expressions, minimized false positives and helped ensure that only assessable, action-oriented CLOs were analyzed.

For each valid CLO, the corresponding teaching strategy and assessment method were also extracted, in accordance with the tripartite structure outlined by the NCAAA. Assessment methods were categorized as either direct (e.g., quizzes, exams, case studies) or indirect (e.g., student surveys, course evaluations), enabling a detailed mapping between learning outcomes and how they are taught and assessed [5]. This structured alignment forms the backbone of outcome-based education and was critical to our study's analysis.

C. Cognitive Level Classification

To determine the cognitive demand embedded in each Course Learning Outcome (CLO), a verb-level classification algorithm was employed, grounded in Bloom's Revised Taxonomy [18]. This taxonomy remains a foundational framework in curriculum design and assessment, especially in outcome-based education models implemented by accreditation bodies such as the NCAAA [19]. The algorithm matched verbs within each CLO to a curated and expanded list of action verbs categorized across the six hierarchical levels of Bloom's cognitive domain:

- Remembering: list, define, recall
- Understanding: describe, explain, summarize
- Applying: implement, demonstrate, solve
- Analyzing: differentiate, compare, examine
- Evaluating: assess, critique, justify
- Creating: design, construct, develop

Each CLO text was scanned for one or more of these verbs, and the corresponding cognitive level was automatically assigned based on the match. This automated process was not only efficient but also allowed for objective categorization, ensuring consistency across all entries. Importantly, this form of classification provides a quantifiable lens through which CLOs can be evaluated for cognitive rigor, a key requirement in accredited program design.

Notably, approximately 86% of the CLOs analyzed contained clearly identifiable action verbs that could be confidently mapped to a Bloom's level. The remaining 14% were flagged as "unknown" due to abstract or vague phrasing, or due to formatting inconsistencies that hindered proper parsing (e.g., missing or malformed sentence structures). These entries were reviewed separately to avoid skewing the cognitive alignment analysis.

By integrating this classification step, the study enabled a structured comparison between intended learning outcomes and their respective assessment strategies. This alignment checking based on cognitive complexity, serves as a diagnostic tool for academic programs seeking to enhance the coherence and integrity of their curriculum.

D. AI-Assisted Evaluation and Hallucination Mitigation

Each CLO–assessment pair was evaluated using OpenAI's ChatGPT (GPT-3.5), which served as a reflective assistant rather than a final judge. To guide the model's reasoning and reduce the chances of irrelevant or inconsistent responses (commonly known as hallucinations), we designed a structured prompt template. This template included key elements such as:

- Program and course title
- CLO description
- Assessment method
- Teaching strategy
- The extracted Bloom's verb and its associated cognitive level

These components were chosen to provide the model with enough context to make informed and consistent evaluations. Recognizing the limitations of large language models, especially their tendency to fabricate or deviate from input, we implemented several best practices to keep the responses grounded and trustworthy.

First, we used prompt confinement, a strategy where prompts are written in a tightly scoped and consistent format.

Research has shown that this approach helps reduce factual drift and variability in model output [12], [20]. Second, we employed template-based reasoning, where the model was asked to reflect using logic similar to rubrics commonly used by educators [21]. Rather than asking the model to "know" the right answer, it was asked to reason based on the information provided.

Importantly, the model was not expected to draw on external or domain-specific knowledge. Instead, it was asked to evaluate only what was explicitly included in the prompt. After generation, responses were stored and reviewed for clarity, internal logic, and coherence. A portion of them were manually inspected to ensure that the feedback generated was interpretable and relevant.

It's worth emphasizing that the role of ChatGPT in this process is supportive, not authoritative. It serves as a first-pass evaluator, surfacing potential misalignments and offering justifications or improvement suggestions that can help curriculum designers reflect more deeply on the alignment between learning outcomes and assessment strategies. Human judgment remains central to the final decision-making process.

By combining structured prompting with thoughtful review, this approach enables scalable, replicable, and explainable evaluation of CLO–assessment alignment. It also shows promise for future integration into broader curriculum quality assurance systems suggesting the potential of large language models for educational auditing and curriculum evaluation workflows [22].

IV. Results

This section presents the results of a two-part evaluation of the AI-powered reflective tool designed to review the alignment between Course Learning Outcomes (CLOs), assessment methods, teaching strategies and cognitive complexity. The first part focuses on the tool's internal consistency, analyzing how well it identifies Bloom's taxonomy verbs, assigns cognitive levels, and interprets alignment across 56 CLOs. The second part examines how human experts perceive the tool's feedback. Two academic quality experts independently reviewed a sample of CLOs and rated the accuracy, usefulness, and cognitive alignment of the generated responses. Together, these findings offer a well-rounded view of how the tool performs in both automated checks and human-led evaluations. Section VI(A) explores patterns in Bloom's verbs, distributions of cognitive levels, and how frequently the tool flagged alignment issues. Section VI(B) highlights the level of agreement between experts and the AI tool, shedding light on where the model's evaluations aligned with expert judgment, and where improvements may be needed.

A. Self-Consistency Checks

To evaluate the internal consistency of ChatGPT's reflective evaluations across 56 Course Learning Outcomes (CLOs), a comprehensive analysis was performed on three key components: the Bloom's action verbs extracted from each CLO, the associated cognitive levels based on Bloom's Revised Taxonomy, and the nature of the corresponding assessment tasks. This triangulation aimed to determine whether the model's feedback logically corresponded with the expected learning complexity and pedagogical intent.

The CLOs were automatically parsed to detect the primary action verb and its associated Bloom's cognitive level. As illustrated in Fig. 2, the most commonly identified verbs included discuss, explain, analyze, and justify, spanning cognitive levels 2 (Understanding) to 5 (Evaluating). This distribution aligns with the higher-order thinking skills typically emphasized in postgraduate-level courses. A small number of CLOs were categorized under the "unknown" label, indicating either missing or ambiguous verbs that did not match the taxonomy database, highlighting potential issues in CLO phrasing or document formatting.

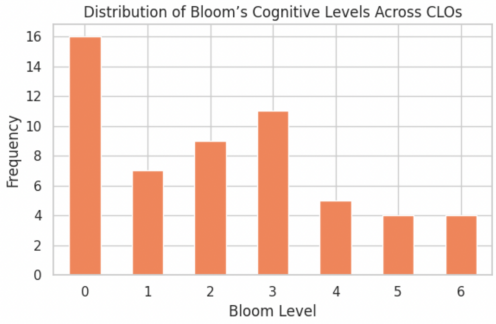

Fig. 2. Distribution of bloom's cognitive levels across CLOs.

Each ChatGPT-generated feedback response was then classified into one of three categories: Aligned, Misaligned, or Suggested. Feedback labeled as Aligned indicated that the model found no major inconsistencies between the CLO, its assessments, and teaching strategies. Misaligned denoted explicit concerns or mismatches raised by the model. Suggested included responses that, while not flagging critical misalignments, recommended improvements to strengthen alignment or clarity.

B. Illustrative Examples of Alignment and Misalignment

Table I presents two anonymized, representative CLO–assessment cases from our dataset, one *Aligned* and one *Misaligned*. For each case, we report the CLO text, Bloom level, assessment/teaching methods, the model's alignment label, and an abridged rationale highlighting specific alignment cues (e.g., verb–task cognitive match/mismatch, direct vs. indirect assessment, authenticity of performance tasks).

As shown in Fig. 3, a majority of responses were classified as Aligned, suggesting that many CLOs were appropriately constructed and assessed. However, a notable portion of feedback was marked as Misaligned or included improvement Suggestions, underscoring recurrent challenges in articulating learning outcomes and aligning them effectively with assessments and pedagogy.

These findings underscore the potential of structured LLM-based tools as formative quality assurance mechanisms. The distribution of Bloom's levels offers insight into instructional emphasis across the curriculum, while the alignment feedback highlights areas requiring further improvement in outcome

TABLE I. TWO COMPACT EXAMPLES: (*Left*) ALIGNED, (*Right*) MISALIGNED. TEXTS ARE ANONYMIZED AND LIGHTLY ABRIDGED

Field	Case A: Aligned	Case B: Misaligned
CLO	(example) "Describe core concepts of X and apply them to simple scenarios."	(example) "State definitions of X."
Bloom	Apply (L3)	Remember (L1)
Assess/Teach	Direct: exam, quiz, project; Indirect: survey / Lectures, guided exercises	Direct: quiz, exam; Indirect: survey / Lectures
Label	Aligned	Misaligned
Rationale	Tasks include a project and applied items that explicitly require L3 "apply", matching the CLO verb and expected level; a mix of direct/indirect evidence is present.	CLO targets L1 "remember" (state), yet assessment emphasizes higher-demand tasks (exam items requiring application/analysis) without corresponding CLOs; survey adds only indirect evidence, causing a verb–task mismatch.

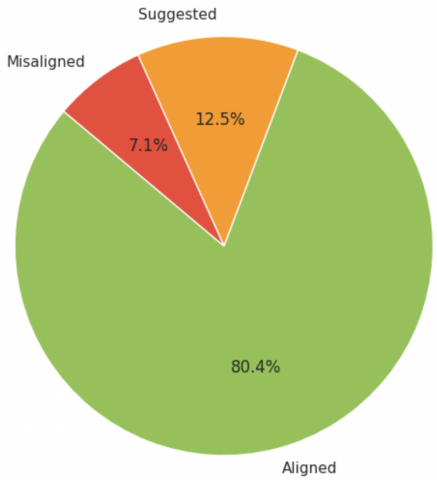

Fig. 3. Distribution of CLO–Assessment alignment outcomes.

construction and strategy selection. For curriculum designers and quality officers, these visualizations serve as practical dashboards, enabling them to detect trends, monitor inconsistencies, and prioritize reviews of misaligned CLOs. Crucially, this approach complements, rather than replaces, expert judgment by enhancing consistency, scalability, and transparency in curriculum evaluation workflows.

C. Human Expert Evaluation

To ensure the external validity of the AI-assisted evaluation and to provide a qualitative benchmark, a stratified sample of 12 Course Learning Outcomes (CLOs), representing approximately 20% of the full dataset, was independently reviewed by two academic quality experts. These experts were faculty members with substantial experience in course specification, learning outcomes design, and curriculum alignment in higher education.

Each expert received the original CLO statement, the associated assessment method, and the feedback generated by the AI-powered reflective tool (ChatGPT). They were asked to evaluate the AI's responses using a structured rubric built around three key dimensions, informed by best practices in AI-supported assessment [23], [24]:

- Accuracy: Whether the feedback correctly assessed the alignment between the CLO and the assessment.
- Usefulness: Whether the feedback provided practical value for improving CLO or course design.
- Cognitive Alignment: Whether the feedback appropriately matched the CLO's Bloom's level with its assessment method.

Ratings were recorded on a 5-point Likert scale (1 = Strongly Disagree, 5 = Strongly Agree), allowing for both descriptive and inter-rater agreement analysis.

Across the sample, the descriptive results showed strong overall agreement between the two experts, with most mean scores falling between 3 and 5. This suggests that the AI-generated feedback was generally perceived as accurate and useful. To statistically assess inter-rater consistency, Cohen's Kappa was calculated for each rubric dimension as shown in Table II. The results confirmed a moderate to substantial level of agreement, consistent with recent work highlighting the interpretability and limitations of large language models in educational tasks [25].

TABLE II. INTER-RATER AGREEMENT BASED ON COHEN'S KAPPA

Dimension	Kappa Score	Interpretation
Accuracy	0.41	Moderate agreement
Usefulness	0.12	Slight agreement
Cognitive Alignment	0.24	Fair agreement

This expert validation step reinforces the potential of LLMs to function as reflective aids in curriculum evaluation, provided that their outputs are critically reviewed by human experts, as part of a hybrid human–AI workflow.

Fig. 4 provides a side-by-side comparison of ratings from each expert across all CLOs and criteria. While the scores generally converged, certain items, particularly within the "Usefulness" dimension, showed divergence, highlighting the need for domain-specific refinement in feedback generation. The results show that the reflective tool provides reasonably consistent evaluations of CLO-alignment, particularly in identifying surface-level alignment mismatches. The tool's strength lies in its structured analysis based on Bloom's Taxonomy and its ability to assist with systematic curriculum review. However, lower inter-rater agreement on "Usefulness" suggests that some feedback lacked sufficient context or actionable depth. This emphasizes that while AI tools can support accreditation workflows, human oversight remains essential, especially when interpreting pedagogical intent or discipline-specific nuance. This expert validation underscores the tool's role as a decision-support system, offering scalable consistency while leaving room for human educational judgment.

V. DISCUSSION

The findings from this study underscore the promising role of structured, prompt-based large language models (LLMs)

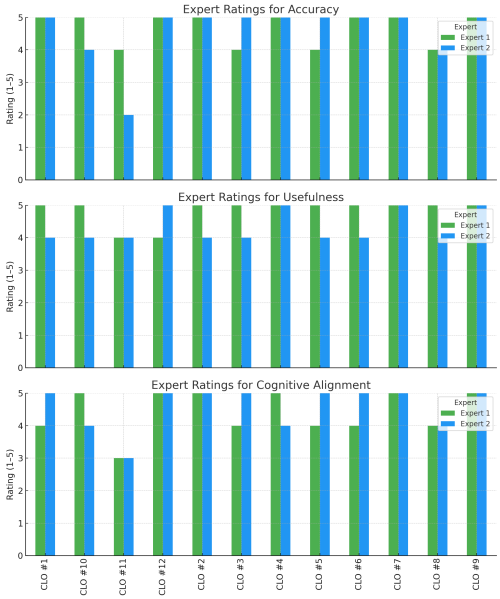

Fig. 4. Comparison of expert ratings for each CLO across three evaluation dimensions: accuracy, usefulness, and cognitive alignment.

in supporting curriculum evaluation tasks that require both cognitive interpretation and alignment with institutional standards. By focusing on Course Learning Outcomes (CLOs), their associated assessments, and pedagogical strategies, the reflective tool demonstrated an ability to surface misalignments and provide constructive, taxonomy-informed feedback.

A key insight emerging from the self-consistency analysis is the model's sensitivity to cognitive distinctions embedded in Bloom's Revised Taxonomy. The high prevalence of verbs corresponding to the "Understanding" through "Evaluating" levels aligns well with the nature of postgraduate course design, where deeper cognitive engagement is expected [26]. However, the relatively low frequency of "Creating" level verbs may suggest either an underrepresentation of higher-order synthesis tasks in course documentation or conservative formulation of CLOs that avoid explicitly committing to evaluative or generative assessments. This observation resonates with prior literature indicating that course developers often shy away from cognitive verbs associated with advanced competencies due to either misinterpretation or fear of overpromising learning deliverables [27], [13].

The model's classification of CLO-assessment relationships into "Aligned," "Misaligned," or "Suggested" reflects an operational advancement over prior implementations of LLMs in educational contexts, where feedback tends to be generic or contextually shallow [28], [29]. The structured prompt engineering and taxonomy-based scaffolding used in this study likely contributed to this improvement by narrowing the model's interpretive scope, a technique echoed in recent AI reliability research [12], [30]. These findings affirm that template-based confinement not only mitigates hallucinations but also enhances the model's ability to reason reflectively based on provided input rather than drawing from its latent knowledge alone.

Notably, the human expert evaluation results further validate the model's potential as a pedagogical aid. While moderate agreement on "Accuracy" and "Cognitive Alignment" suggests foundational reliability, the limited consensus on "Usefulness" points to an important limitation. Specifically, the model-generated feedback may lack domain-specific depth or contextual nuance, especially when CLOs involve interdisciplinary goals or implicit institutional constraints. This aligns with the findings of Luo et al. [31] and Iftene et al. [8], who caution that while LLMs can serve as reflective collaborators, they are not yet replacements for domain expertise. The divergences in expert ratings highlight the necessity of maintaining human oversight, particularly for evaluating the pedagogical appropriateness and practical feasibility of suggested improvements.

Importantly, the tool's value lies not in definitive judgment but in its capacity to structure and scale reflective evaluation. In contexts such as those governed by the NCAAA, where alignment and documentation rigor are essential, having a replicable first-pass reviewer that surfaces potential issues can reduce faculty workload and enable earlier intervention in curriculum development cycles. The use of visualizations (e.g., cognitive level distributions and alignment categorizations) enhances interpretability and provides a data-driven dashboard for institutional review, echoing similar recommendations in curriculum analytics literature [32], [33].

Nonetheless, the system is not without limitations. A small percentage of CLOs were unclassifiable due to ambiguous phrasing or formatting inconsistencies, highlighting ongoing challenges in automating quality assurance across diverse documentation standards. Furthermore, while the tool supports alignment evaluation, it does not currently assess whether the assessments themselves are valid measures of cognitive complexity, a task that likely requires deeper qualitative analysis or human triangulation.

VI. Conclusion

This study introduced a structured, prompt-based reflective framework that leverages ChatGPT to evaluate the alignment between Course Learning Outcomes (CLOs), assessment methods, and teaching strategies in line with NCAAA standards. Unlike general-purpose AI applications, our approach focused on targeted prompts grounded in Bloom's Taxonomy and the official course specification structure to generate consistent and relevant feedback.

Through self-consistency checks across 56 CLOs, the tool demonstrated a reasonable ability to detect Bloom's action verbs, classify cognitive levels, and flag potential misalignments in assessment alignment. A majority of the AI-generated feedback was classified as aligned, though a significant portion provided constructive suggestions or identified mismatches highlighting common design issues in course documentation. To validate the tool's reliability, two academic quality experts independently evaluated a stratified sample of CLOs. Their assessments showed moderate inter-rater agreement on accuracy, slight agreement on cognitive alignment, and limited agreement on usefulness suggesting that while the tool provides structured and technically sound evaluations, human oversight remains essential, particularly in interpreting nuanced instructional context.

Overall, this research demonstrates the potential of large language models to act as scalable and structured reflective tools in curriculum quality assurance. Rather than replacing educators, the system is designed to support them offering data-driven insights that can guide course improvement and strengthen institutional readiness for accreditation reviews.

***Abstract*—Smart cities increasingly rely on Artificial Intelligence (AI), 5G, and Internet of Things (IoT) technologies to enhance energy management and support real-time decision-making in smart grids. This study presents a systematic literature review of recent research on the integration of AI and 5G in urban energy systems, with a focus on sustainability goals. It examines how these technologies are used for renewable energy integration, demand-side control, and predictive maintenance across smart environments. Using data from OpenAlex, Scopus, and Web of Science covering the period 2018 to 2025, the review was filtered by language, domain, and scientific relevance. Key findings reveal the use of machine learning models for forecasting, anomaly detection, and system optimization. The review also identifies technical, ethical, and infrastructural challenges, including data heterogeneity, limited interoperability, and regional inequalities in deployment. While AI and 5G offer promising capabilities for real-time monitoring and system automation, the literature shows persistent gaps in algorithm robustness and standardized integration frameworks. The paper emphasizes the need for validated, scalable solutions to achieve long-term energy sustainability. This review provides a clear overview of current trends and future directions in smart energy systems, contributing to a better understanding of how digital technologies shape the future of sustainable urban infrastructures.**

***Keywords*—Smart cities; artificial intelligence; 5G; energy management; smart grids; renewable energy integration; IoT; machine learning; sustainability**

I. Introduction

The rapid growth of the global urban population has brought urgent challenges in energy management, infrastructure stability, and operational flexibility. In response, the concept of smart cities has emerged, integrating advanced digital technologies to improve the efficiency and quality of urban services [2], [11]. Among the key enablers of this transformation, artificial intelligence (AI) and fifth-generation (5G) communication networks play a central role in reshaping energy systems to support sustainable urban development [9], [30].

Smart energy systems in urban environments depend on smart grids, intelligent buildings, IoT-connected devices, and distributed renewable energy sources [3], [14]. These systems require real-time monitoring, adaptive control, and future-oriented optimization capabilities increasingly supported by AI for prediction, anomaly detection, and intelligent energy flow management [19], [21], [24]. In parallel, 5G offers ultra-low latency and high-speed connectivity, enabling the instantaneous transmission of data across edge devices and cloud platforms, thereby supporting large-scale deployment of IoT-based control systems [23], [26], [31].

Despite their potential, the integration of AI and 5G in energy systems remains limited by technical and ethical barriers. Challenges include system fragmentation, lack of standardized protocols, scalability of algorithms, data heterogeneity, cybersecurity concerns, and uneven access to infrastructure across regions [9], [17], [30], [33], [34]. These gaps hinder the development of comprehensive frameworks capable of addressing energy performance, social equity, and long-term sustainability.

This study addresses these concerns by conducting a systematic literature review of publications indexed in OpenAlex, Scopus, and Web of Science, covering the period from 2018 to 2025. The objective is to assess how AI and 5G are integrated into smart city energy systems, identify their contributions and limitations, and explore future directions. The review is structured around the following research questions:

RQ1: How are AI and 5G used in smart city energy systems?

RQ2: What technical and ethical issues limit their integration?

RQ3: How is their impact on energy performance evaluated?

RQ4: What are the benefits and outcomes of AI-enhanced energy management in smart cities?

By addressing these questions, the study offers a structured understanding of the evolving role of AI and 5G in smart energy systems, highlighting both current contributions and the areas requiring further innovation and policy attention.

II. Methodology

During this study, we follow a systematic and data -driven method to ensure accurately and relevance in our findings. Fig. 1 emphasizes the five main steps in our research process. The first phase defines the scope of the study,with a focus on how artificial intelligence and 5G technologies contribute to the energy dimension of smart cities. In phase 2, we collect

literature from three large scientific platforms - Openlex, Web of Science and Scopus - advanced filtration strategies.

For OpenAlex, we processed the search using a combination of technical keywords such as “Energy” and “Smart”, and limited the results to open access tasks published between 2018 and 2025. We did not exclude - related domains such as drugs, psychology, chemistry and humanities to focus specially related to engineering. We also limited the selection from articles and book chapters related to IoT, Edge/Fog Computing, Smart System and AI-based urban technologies, and banned the language in English.

Step 3 includes inclusion criteria based on quality, relevance to energy domains and screening of extracted studies using AI and clear links for 5G integration. In Step 4, we use a thematic classification and bibliometric mapping to detect recurrent applications, technical barriers and regional contexts. Finally, phase 5 highlights the most important research contribution to applying AI and 5G to smart energy infrastructure in urban references, highlighting existing intervals and future instructions.

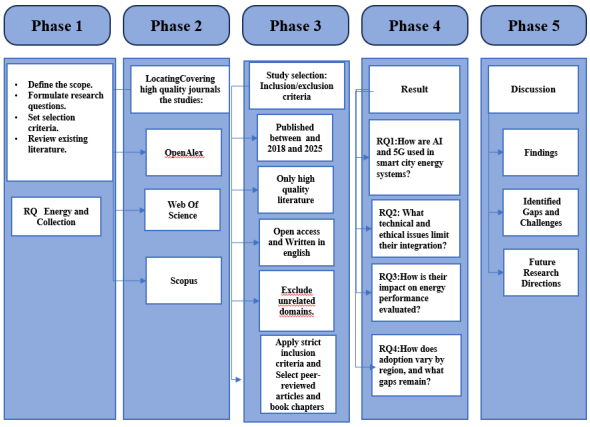

Fig. 1. Research process.

To continue the recovered literature base, we organized a descriptive book list of the final dataset. As shown in Fig. 2, the literature extends from 2018 to 2025 and includes a total of 1,350 documents from 570 different places of publication. These documents were written by 4,413 contributors, with an average of 3.62 co-author per paper, indicating a high level of cooperation research in the region. In particular, 33.78 percent of publications include international co-authors, reflecting global relevance and multi-creked interest in AI and 5G-based energy systems. The dataset contains 203 single author tasks, while the total number of references cited in all documents reaches 31,511, and emphasizes the depth of scholars and the prosperity of analyzed corpus. The average document age is 3.39 years, suggesting that the corpus is reflected in order to develop both recent and developed research mobility. In addition, the average quotation time per document is 16.22, which confirms the important education effect. Finally, we identified 546 separate author keywords, which act as a semantic foundation for thematic grouping and trend analysis in the later stages of this study.

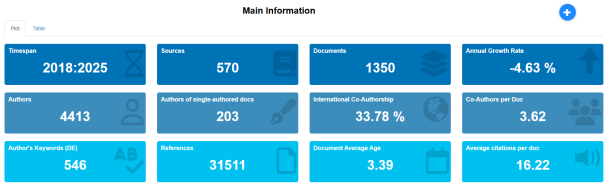

Fig. 2. Main information.

III. Results

Smart cities embody a modern strategy for urban development that leverages information and communication technologies (ICT) to make Urban more comfortable, durable and effective [1] [2]. At their core, smart cities aim to ensure a clean, cost-effective, and secure living environment for the citizens to live, work and play by organizing different systems, including energy, water, transport, public health and safety as showing in Fig. 3 [3].

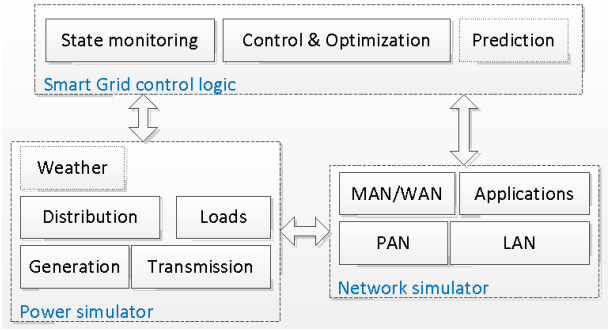

Fig. 3. Overview of a standard smart grid co-simulation environment.

The infrastructure of smart cities relies on a combination of interconnected technologies and subsystems. This includes smart grids, intelligent mobility solutions, adaptive traffic control, automated waste management, smart infrastructures, and systems for environmental monitoring [4]. The Internet of Things (IoT) plays an essential part by supporting real-time data collection and intelligent context-driven processing via interconnected sensors and actuators [1] [5].

The idea of smart urban control has developed with the emergence of recent technology which includes IoT, statistics analytics, and artificial intelligence [6] [7] [8]. These technology enable the optimization of strength intake, integration of renewable energy sources, discount of greenhouse gasoline emissions, and improvement in universal best of urban life [9][10] as showing in Fig. 4.

Smart city applications integrate artificial intelligence, data analytics, and advanced learning algorithms to enhance urban living standards for large populations [11] [12] The present and anticipated development of smart cities is marked by the convergence of various technologies, including 5G and blockchain infrastructure, which are expected to strengthen decision-making capabilities, anticipate urban dynamics, and support advanced IoT functionalities [13].

Smart city platforms support the collection and unified analysis of data originating from heterogeneous sources, in-

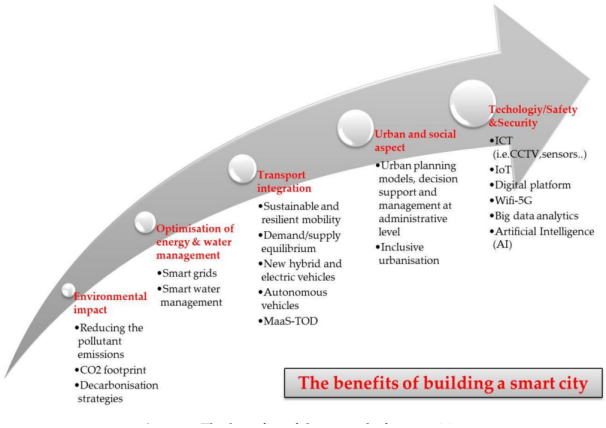

Fig. 4. The benefits of the spread of smart cities.

cluding systems for traffic observation, energy usage tracking, and environmental data sensing [14] [15]. This data -driven approach to city rule optimizes the operation and distribution of resources, and eventually leads to high energy efficiency and productivity.

Energy infrastructure plays an important role in smart cities, as all other urban works will eventually be closed if the energy is not available for a significant period [3]. Cities aim to build intelligent energy systems that support adaptive lighting, automated building systems, smart transport solutions, and energy distribution networks [16] as showing in Fig. 5.

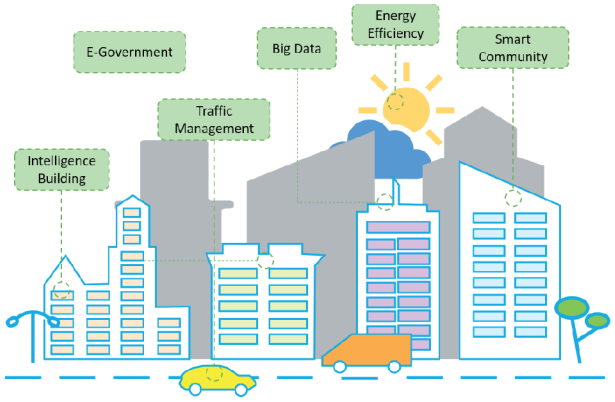

Fig. 5. Basic components of smart city.

Original research on smart cities focused on the principle, probe, design, development and implementation of smart, flexible and urban environments with low carbon. This included research on areas such as ICT and intelligent infrastructure, smart grid, energy -dense buildings, climate change mitigation, decision support systems and machine learning for machine learning for IoT, Big Data, AI and environmental and environmental [4].

A. Smart Cities and Energy Management

Energy management is among the most critical challenges of developing smart cities, which acts as the basis that all other urban functions depend on study [3]. The purpose of smart cities is to develop intelligent energy infrastructure that creates efficiency, increases economic growth and improves the quality of life through functions such as smart street lighting, intelligent buildings, smart mobility and power grid [16]. As part of the concept of "smart and sustainable cities," two flagship applications have emerged worldwide: smart electricity grids that promote renewable energy sources, and efficient mobility solutions that reduce automobile use and greenhouse gas emissions [17] A smart grid is one of the essential elements of smart city systems, alongside other intelligent infrastructure elements such as smart traffic lights, mobility solutions, buildings, waste management, and environmental monitoring [18].

Through self-healing designs, automation, and remote monitoring and control, smart energy grids modernize power systems. As a result of these systems, consumers will be able to make informed decisions and be able to safely integrate distributed renewable energy resources in order to improve overall energy efficiency [3]. In the context of future smart energy systems, algorithms are expected to infer user needs and consumption patterns by analyzing historical data, optimize and control the interconversion and distribution of energy vectors while taking engineering constraints and policy objectives into consideration [19].

Multi-energy vectors such as electric power, heat, and gas in urban environments enable integration of energy subsystems and support real-time operational control [19]. As embedded algorithms are increasingly deployed across multiple layers of the energy network, ranging from smart meters to real-time monitoring units, machine learning and intelligent computing tools are gaining relevance in supporting autonomous decision processes and adapting to evolving system behavior [19].

Modern smart city energy frameworks uses cutting-edge technology and data analytics to align and manage multiple urban infrastructures with the aim of increasing energy performance and operational output [14]. Smart grids are a key initiative to control energy consumption and optimize energy distribution, and integrate renewable energy technologies such as photovoltaic systems and wind energy converters within urban systems [14]. In smart cities, advanced smart grid frameworks are under development to address energy management challenges, including transactions and autonomous vehicle charging. [20]. These frameworks make use of a variety of technologies to enhance energy efficiency [20] as showing in Fig. 6, including deep learning, linear optimization, semantic technologies, and simulation. To integrate Information and Communication Technologies into urban development, smart cities adopt innovations including technologies like IoT, AI, Geographic Information Systems, digital twin models, remote sensing systems, intelligent transport infrastructure, and advanced energy grids [9] By implementing these tools, urban life is improved by reducing greenhouse gas emissions, optimizing energy consumption, incorporating sustainable energy inputs and lowering greenhouse gas emissions [9][10].

B. AI and Machine Learning Applications in Smart City Energy Systems

Artificial intelligence (AI) and machine learning (ML) are becoming increasingly vital for automated decision-making and responding to changes in energy system dynamics as embedded algorithms become more pervasive throughout energy

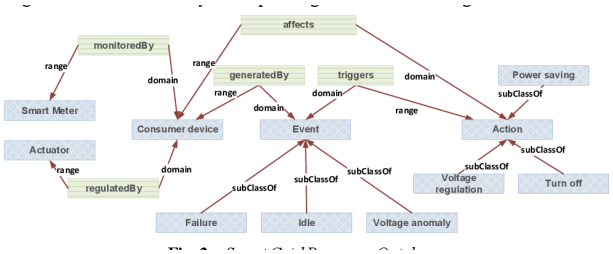

Fig. 6. Smart grid response ontology.

networks [19]. The concept of future smart energy systems includes autonomous algorithms capable of extracting user demand patterns and consumption behaviors from past data records, manage and coordinating the conversion and distribution processes of multiple energy carriers, while at the same time considering engineering constraints and policy objectives [19].

In smart city energy management, AI and ML applications are being leveraged for multiple purposes. Data-driven smart grid frameworks employ deep learning, linear optimization, semantic technology, and simulation to address complex energy management challenges including energy trading and autonomous vehicle charging [20]. As a result of these technologies, billions of people in urban areas are able to live more sustainably and improve their quality of life [11].

Optimization of renewable energy sources is one of AI's most significant contributions, which reduces carbon emissions and improves energy efficiency [21] [22]. With artificial intelligence and 5G technologies, energy providers are able to predict renewable energy production, such as when the sun will shine or the wind will blow, and adjust energy supply accordingly [23].

AI-driven smart grids enhance operational efficiency by dynamically adjusting to variations in energy supply and demand by leveraging real-time data analysis and adaptive learning algorithms, ensuring more stable and efficient distribution networks [21] [24] A smart building using AI-powered systems to forecast energy needs, improve the management of heating and cooling operations, and enhance the integration of renewable energy sources [21].

Several reviewed studies assess the energy-related impact of AI and 5G integration using quantitative indicators such as energy savings, carbon emission reductions, load balancing efficiency, and response time to peak demand. Evaluation methods include simulation-based energy modeling, real-time sensor data analysis, and predictive accuracy of AI-based demand forecasting systems. These metrics provide objective evidence of improved system performance and support the deployment of intelligent energy infrastructure in urban environments.

Besides energy management, machine learning, deep reinforcement learning, and artificial intelligence are being used in smart cities to develop intelligent transportation systems, cybersecurity, and 5G networking services. [25]. In transportation, AI and 5G can help reduce traffic congestion and emissions by optimizing traffic flow and identifying the most efficient vehicle routes, thereby decreasing time spent on the road and saving energy [23].

Researchers are addressing energy management challenges through a combination of IoT, 5G, and cloud computing, along with machine learning and deep learning approaches [26] [27]. Currently, researchers are working on developing algorithms for autonomously analyzing, predicting, and managing energy consumption in smart buildings and cities [28].

As artificial intelligence technology continues to develop, smart cities will apply AI more widely across intelligent transportation systems, energy management, and public safety to achieve more efficient urban management and services [29]. Despite the challenges regarding ethics and data management, AI is having a multi-dimensional impact on smart cities, affecting not only energy management, but also transportation and citizen engagement[30].

The evolution of smart cities has been supported by fundamental and applied research focused on AI and ML applications for environmental sustainability and climate change [4]. This research has laid the groundwork for current and future applications of these technologies in optimizing urban energy systems.

C. 5G Technology's Role in Smart City Energy Management

Smart city energy management systems depend on 5G wireless networks, which form the backbone of advanced energy systems.With 5G, IoT devices can communicate seamlessly and instantly, enabling real-time monitoring and control of energy assets across urban areas due to its ultra-low latency and high-speed connectivity [31]. As a result of enhanced connectivity, energy systems are more efficient and sustainable, particularly in applications such as smart grids, smart buildings, and intelligent transportation systems [31].

The integration of 5G with IoT technology creates powerful synergies for energy management in smart cities. Combining these technologies facilitates fast data transmission between communication channels and cloud storage, enabling efficient data retrieval and analysis for energy optimization [26] [27]. In renewable energy applications, 5G's instantaneous communication capabilities allow energy providers to quickly adjust their supply in response to AI predictions about solar and wind availability [23] as showing in Fig 7.

In addition to enhancing energy generation and distribution, 5G technology enhances transportation efficiency within smart cities, which impacts energy consumption overall. By optimizing traffic flow and identifying the most efficient routes for vehicles, 5G-enabled systems reduce congestion, reduce traffic time, and decrease emissions [23]. This demonstrates how 5G's benefits extend beyond direct energy management to address broader energy consumption patterns in urban environments.

The deployment of 5G networks promises to further enhance connectivity and enable more sophisticated IoT applications throughout smart cities [13]. As part of a wide spectrum of information technologies being applied to improve urban "smartness," 5G works alongside artificial intelligence, big data analytics, cloud computing, and IoT to create more responsive and efficient energy systems [32]. The continued evolution of these communication networks will play a pivotal role

in the future development of smart city energy management, providing the connectivity required for increasingly complex and integrated urban systems.

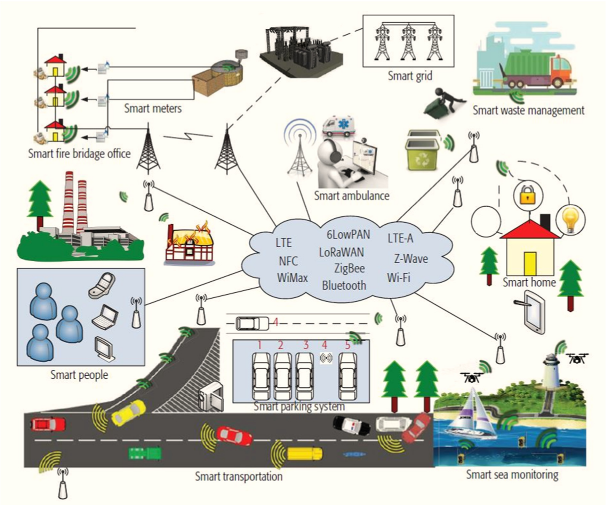

Fig. 7. Available communication technologies in various applications for smart cities.

D. Validation and Comparative Analysis with Existing Reviews

To enhance the scientific robustness of our study, we conducted a comparative validation by analyzing how our findings align with or extend those of recent systematic reviews addressing AI, 5G, and smart city energy systems. This approach confirms the coherence of our results while identifying the distinct contribution of our work.

Several prior studies have addressed parts of this research landscape. Bibri presented an integrated view of AI, IoT, and Big Data in sustainable smart cities, emphasizing technological convergence but overlooking infrastructure scalability and regional inequalities. O'Dwyer's review explored the role of AI in energy systems aligned with sustainability goals but did not incorporate 5G technologies or joint AI-5G integration frameworks. Santos examined the ethical and technical challenges of AI in smart cities, yet lacked consideration of telecommunication infrastructures essential for real-time operations. Camacho focused on AI-driven energy management but provided limited insights into system interoperability and IoT-5G data integration.

In contrast, our review takes a dual-focus approach that simultaneously addresses AI and 5G within smart energy systems. We offer a broader perspective that includes:

A combined analysis of technical and ethical challenges,

Regional disparities in deployment and access,

The need for real-time system responsiveness, algorithm robustness, and cross-platform interoperability.

Table I presents a structured synthesis of this comparative analysis. It clearly situates our contribution within the broader research context and highlights specific gaps in prior work that our study addresses.

IV. Discussion

A. Fragmentation Between Technological Layers

One key observation from the literature is the persistent disconnect between the development of artificial intelligence (AI) models and the implementation of 5G communication systems within smart city energy initiatives. Most studies concentrate on one isolated component. Some optimize machine learning algorithms for forecasting energy consumption or production. Others evaluate the performance of communication infrastructures, focusing on throughput, latency, or coverage.

Very few works integrate these components into a coherent, real-time energy management architecture. This siloed approach results in technical inconsistencies. For example, AI models are often designed without considering the limitations of underlying network infrastructures, which may not support the real-time data flows required. Conversely, 5G networks are sometimes deployed without embedding intelligent processing capabilities, limiting their contribution to autonomous decision-making.

This lack of integration across technological layers hinders the deployment of closed-loop, adaptive energy systems. Without synergy between AI and 5G, smart city platforms struggle to deliver timely, efficient, and scalable energy management in real-world environments.

B. Limited System-Level Evaluations

A recurrent issue across the reviewed studies is the limited presence of system-level validation. Most contributions focus on the performance of algorithms using isolated datasets or simulations conducted under fixed, controlled conditions. While these works are often rigorous in their methodological design, they neglect the complexities of real-world deployment.

There is little effort to assess the full data pipeline—from sensor-level data acquisition to transmission over 5G networks, edge processing, and final decision-making through AI models. The absence of integrated benchmarks reflecting interactions among these components limits the evaluation of key operational metrics such as scalability, resilience, and fault tolerance.

Without such validations, it becomes difficult to determine whether proposed solutions can maintain stability and responsiveness under realistic urban energy demands. This gap weakens the practical impact of many research efforts and hinders progress toward deployable, intelligent energy systems.

C. Underexplored Edge Intelligence Scenarios

Edge computing is widely acknowledged as a critical component for enabling distributed intelligence in smart energy systems. However, few studies propose concrete system architectures that effectively leverage edge nodes to reduce latency and optimize energy usage. The majority of contributions remain anchored in cloud-centric models, which can lead to communication overheads and increase the risk of delays in time-sensitive operations.

Despite its theoretical advantages, the integration of edge AI in energy-related use cases remains poorly formalized. The literature lacks structured frameworks for distributing AI

TABLE I. COMPARATIVE SUMMARY OF SELECTED LITERATURE REVIEWS

Author	cm**Scope of Review**	**Technology Focus**	**Main Gaps Identified**	**Limitations**
Bibri	cmSmart cities and sustainability	AI, IoT, Big Data	Ethics, convergence	No focus on regional disparities or scalability
O'Dwyer	cmSmart energy systems and sustainability	AI	Infrastructure, policies	No mention of 5G or real-time integration
Santos	cmAI challenges in smart sustainable cities	AI	Technical and ethical	Does not link with communication infrastructure
Camacho	cmAI for energy management in smart cities	AI	Algorithm limitations	Limited analysis of IoT/5G integration
Our review	cmAI and 5G in smart city energy systems	AI + 5G + IoT	Scalability, ethics, region	Integrated and comparative approach

tasks between edge and core nodes. In particular, there is limited work on adaptive task allocation strategies that consider dynamic factors such as local energy demand, network congestion, and the uncertainty of AI predictions.

This shortfall limits the development of responsive, low-latency energy systems capable of autonomous decision-making close to the data source.

D. Geographic and Contextual Imbalance

The geographic scope of the reviewed studies reveals a strong concentration in high-income countries with advanced technological infrastructures. These contexts often benefit from stable connectivity, standardized hardware, and supportive regulatory environments. In contrast, urban energy systems in low and middle income regions where networks are less reliable, devices are more heterogeneous, and policies are often fragmented remain largely absent from the literature.

This imbalance reduces the external validity of current research. Solutions optimized for well-resourced environments may not scale or adapt to settings with infrastructural and institutional constraints. To enhance applicability, future work must incorporate context-sensitive approaches that account for disparities in connectivity, device interoperability, governance models, and energy usage profiles.

E. Methodological Diversity and Lack of Convergence

The literature demonstrates a broad methodological range, encompassing supervised learning, reinforcement learning, federated approaches, and hybrid architectures. However, this diversity is not accompanied by standardized evaluation metrics or deployment protocols. The lack of convergence in assessment criteria makes cross-study comparisons unreliable and limits the identification of effective design patterns.

This fragmentation also poses challenges for reproducibility. Without shared benchmarks or experimental frameworks, replicating and validating results becomes complex, slowing down methodological refinement and large-scale adoption.

Advancing the field requires the adoption of common evaluation protocols, multi-criteria performance assessments, and the availability of open-access datasets to support fair benchmarking and collaborative development.

F. Gaps and Challenges in Smart City Energy Systems

Despite the promise of smart city energy systems, several critical gaps and challenges remain to be addressed:

Interoperability and Complexity of the System: In smart cities, interconnected tools, platforms, and sensors pose a challenge, but interoperability must be ensured [9]. Integration of various technological components requires standardized protocols, which are not yet fully established across all systems.

Management and Analysis of Data: Smart city infrastructure generates a great deal of data that presents significant challenges for gathering and analyzing [9]. Due to its volume, velocity, and variety, advanced processing capabilities are needed beyond what is currently available. Security and Privacy Concerns: As smart energy systems collect more and more data, privacy and security concerns must be addressed [9].

Algorithm Limitations: Existing studies often fail to address the full complexity and uncertainty of real-world scenarios in energy optimization, creating a gap between theoretical models and practical implementation [33].

Implementation of Advanced Algorithms: The energy consumption of smart buildings and cities still requires more sophisticated algorithms capable of automatically analyzing, predicting, and managing it [28].

AI Implementation Gaps: Technological gaps exist specifically when implementing artificial intelligence in smart cities, affecting the potential optimization of energy systems [34].

System Flexibility and Resilience: Renewable energy sources are becoming more prevalent, and modern energy management solutions do not offer the flexibility and resilience required to adapt to changing energy landscapes [28].

Integration of Renewable Energy: The integration of renewable energy sources into existing infrastructure remains a significant challenge for smart cities despite their desire to integrate renewable energy sources [9].

Comprehensive Energy Optimization: Despite advances in evolutionary algorithms and deep reinforcement learning, there is a need for more comprehensive and robust solutions for smart city energy operations that can handle real-world complexities [33].

Coordination Across Urban Systems: Achieving the holistic approach particular to smart cities requires coordinated and integrated social, environmental, and economic interventions across multiple sectors, presenting significant coordination challenges [9] [10].

G. Sustainability and Long-Term Perspectives

Sustainability concerns remain largely overlooked in the reviewed literature. Key aspects such as the energy consumption of AI models, the carbon footprint of 5G infrastructure, and the lifecycle impact of deployed systems are rarely quantified or

integrated into system design. This omission is critical, given that smart cities are expected to reduce emissions and promote energy efficiency.

There is a contradiction between these objectives and the current lack of energy-aware intelligence. Most AI-5G solutions are evaluated in terms of performance, with minimal attention to their environmental cost.

Future work should prioritize the development of resource-efficient AI models and establish methodologies for assessing the ecological impact of intelligent infrastructures. Embedding sustainability into design choices is essential to ensure long-term viability and alignment with climate goals.

V. Conclusion

This review explored the integration of artificial intelligence and 5G technologies into smart city energy systems through a systematic analysis of recent literature. The study identified their core applications in predictive analytics, load optimization, demand forecasting, and energy automation. AI contributes to real-time decision-making, while 5G ensures fast, reliable communication for distributed systems. Technical and ethical challenges remain, including algorithm transparency, data quality, privacy concerns, and unequal access to infrastructure. Evaluation methods found in the literature include simulation modeling, energy performance indicators, and predictive accuracy metrics.

Despite these advancements, several gaps persist regarding interoperability, standardized frameworks, and large-scale deployment. Future research should address cross-platform integration, improve data-sharing protocols, and validate models with real-world urban data. There is also a need to explore AI and 5G synergies in dynamic contexts such as mobility-energy coupling and disaster-resilient infrastructures. This study provides a roadmap for researchers and urban planners seeking to build energy-efficient, responsive, and sustainable cities using intelligent technologies.

***Abstract*—Software security visualization is an interdisciplinary field that combines the technical complexity of cybersecurity, including threat intelligence and compliance monitoring, with visual analytics, transforming complex security data into easily digestible visual formats. As software systems get more complex and the threat landscape evolves, traditional text-based and numerical methods for analyzing and interpreting security concerns become increasingly ineffective. The purpose of this paper is to systematically review existing research and create a comprehensive taxonomy of software security visualization techniques through literature, categorizing these techniques into four types: graph-based, notation-based, matrix-based, and metaphor-based visualization. This systematic review explores over 60 recent key research papers in software security visualization, highlighting its key issues, recent advancements, and prospective future research directions. From the comprehensive analysis, the two main areas were distinctly highlighted as extensive software development visualization, focusing on advanced methods for depicting software architecture: operational security visualization and cybersecurity visualization. The findings highlight the necessity for innovative visualization techniques that adapt to the evolving security landscape, with practical implications for enhancing threat detection, improving security response strategies, and guiding future research.**

Keywords*—Security visualization; vulnerability analysis; threat intelligence; compliance monitoring

I. Introduction

The increasing use of software has introduced significant security challenges, prompting the industry to develop best practices to protect applications that handle sensitive information. The critical need for robust software security is evident, as vulnerabilities can lead to severe consequences, including data breaches, unauthorized control, and service disruptions, thereby compromising security policies [1], [2], [3]. Although considerable research has been conducted to prevent these vulnerabilities and automate their detection, the effectiveness of these efforts remains limited due to the growing complexity of software systems [4], [5].

Software security visualization has emerged as a promising approach to address these challenges by providing intuitive and interactive visual representations of security data [6]. These techniques enhance the comprehension of security vulnerabilities, facilitate threat detection, and support the maintenance of secure codebases [7]. However, despite its potential, there is a lack of comprehensive studies that systematically analyze the effectiveness of different software security visualization techniques and identify the specific areas where these techniques can be most impactful [8].

This review aims to fill this gap by conducting a systematic analysis of existing research in the field of software security visualization. By examining key studies and identifying the strengths and weaknesses of current visualization techniques, this paper highlights the critical areas where further research is needed and suggests directions for future development.

The paper is organized as follows: Section II discusses the research methodologies, including the study selection criteria. Section III presents an analysis of the findings, organized into comprehensive software development visualization, operational security visualization, and cybersecurity visualization. Section IV explores how software security visualization techniques are applied in real-world contexts. Section V discusses the key findings, including the categorization of visualization methods and their impact. Section VI concludes by emphasizing the importance of visualization in addressing cybersecurity challenges and supporting effective threat analysis.

II. Methodology

This section outlines the systematic approach used to review relevant studies, ensuring a comprehensive and unbiased selection of sources. It outlines the process for identifying, evaluating, and selecting studies based on predefined criteria to ensure the reliability and validity of the review.

A. Search Strategy

To ensure a comprehensive literature review, a systematic search strategy was employed following the PRISMA guidelines [9]. Databases such as IEEE Xplore, ACM Digital Library, SpringerLink, and ScienceDirect were searched for articles published over the last five years (2019–2024). The search terms used included combinations of "software security visualization," "cybersecurity visualization tools," "security data visualization," and related keywords. The search strategy was designed to capture all relevant studies in the field of software security visualization [10], [11].

B. Eligibility Criteria

Inclusion criteria for studies were rigorously defined as follows:

- Published in peer-reviewed journals or conference proceedings [9].

- Focus on visualization techniques specifically used in software security [10].
- Provision of empirical results concerning the effectiveness of visualization tools in cybersecurity.

Studies were excluded if they met any of the following criteria:

- Non-English language publications.
- Opinion pieces, editorials, or non-empirical articles.
- Studies not directly related to the field of software security visualization [11], [12].

C. Study Selection

The initial search yielded a total of 120 records. A detailed multi-step selection process was then employed:

1) Duplicate removal: Automated and manual processes were used to identify and remove duplicate records, resulting in 90 unique studies [9].

2) Title and abstract screening: The titles and abstracts of these studies were independently reviewed by two researchers to assess relevance. This step eliminated studies that did not align with the predefined inclusion criteria, resulting in 70 studies for full-text review [10].

3) Full-text review: The remaining articles were subjected to a detailed full-text review to assess their adherence to the eligibility criteria. This involved critically assessing the study's methodology, focus, and contributions to the field. In cases where the relevance was unclear, a third reviewer was consulted to reach a consensus [13].

4) Final selection: After the full-text review, 61 studies were deemed suitable for inclusion in the systematic review. The entire selection process was meticulously documented, and a PRISMA flow diagram was created to represent the screening and inclusion process visually [14].

D. Data Extraction

Data were extracted from each study by two independent reviewers using a standardized form [9]. The extracted information included authors, year of publication, study objectives, visualization techniques used, main findings, and contributions to software security visualization. Any discrepancies between reviewers were resolved through discussion or consultation with a third reviewer [10].

E. Quality Assessment

The quality of the included studies was assessed using the Critical Appraisal Skills Programme (CASP) checklist. This assessment focused on the methodological rigor and credibility of the studies, evaluating aspects such as the clarity of data presentation, the appropriateness of the analytical methods, and the generalizability of the findings [15].

F. Synthesis of Results

The data were synthesized qualitatively, categorizing studies by their focus areas: comprehensive software development visualization, operational security visualization, cybersecurity visualization, and information security visualization. Trends, commonalities, and divergences across studies were analyzed to identify the state of the art and gaps in the current literature [14].

III. Overview of Software Security Visualization

A systematic literature review has demonstrated the state-of-the-art of software visualization, aiding developers in selecting suitable visualization tools.

This study observed that most software visualizations are displayed on computer screens, and several approaches that are based on the structure of the system are displayed in 3D environments with city metaphors [16]. However, despite the advancements in visualization techniques, gaps remain, particularly in the application of these tools across different domains and user levels.

A study has reviewed 54 publications on Cyber Situational Awareness (CSA) visualizations, emphasizing the need for more comprehensive visualizations that support all levels of CSA and cater to a broader range of stakeholders. They identified gaps in existing CSA visualizations, such as a lack of visualizations for managers and non-expert users, and a focus on threat information over impact information and response plans [17]. This gap highlights the need for more user-centric visualization tools that non-technical stakeholders can effectively utilize, a critical area that remains underexplored.

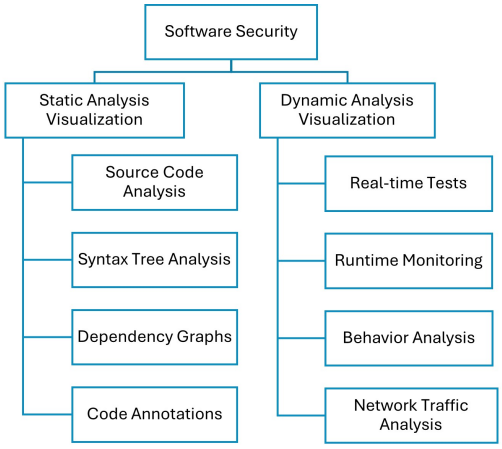

Fig. 1. Dynamic and static analysis visualization.

Another study has emphasized the need for standardized evaluation metrics for cybersecurity visualizations, highlighting methodological gaps and proposing potential research directions to establish a unified framework for evaluating the effectiveness of security visualizations [18]. Despite these proposals, a consensus on standardized metrics is still lacking, leading to inconsistencies in how visualization tools are evaluated and compared across different studies. Fig. 1 categorizes software security visualization into two main types: Static Analysis Visualization and Dynamic Analysis Visualization.

A. Static Analysis Visualization in Software Security

Static analysis visualization is crucial for understanding and identifying static code-based vulnerabilities without executing the program. This approach improves the efficiency and effectiveness of security assessments by providing clear visual perspectives into complex code structures and potential security issues.

Mollerstrom and Roos highlighted the critical role of threat analysis, particularly in making potential threats more understandable and actionable. It focuses on visualizing data flow within a program to assist in manual code reviews, making it easier to identify security vulnerabilities [19]. However, while visualization techniques are effective in static analysis, they cannot often detect runtime issues, limiting their applicability in dynamic environments.

Recent studies have further explored these methodologies in the context of container security, highlighting the use of static code analysis in identifying and mitigating vulnerabilities within software architectures [20]. Despite these advancements, the integration of static analysis with other security assessment tools remains a challenge, particularly in maintaining accuracy and scalability across different environments.

Similarly, Senanayake et al. reviewed methods for detecting vulnerabilities in Android source code, while emphasizing the role of visualization in presenting the identified vulnerabilities to the software practitioners [4]. However, the effectiveness of these visualization techniques in large-scale software systems with complex dependencies has not been thoroughly examined, highlighting a gap in the current research.

Recent studies have highlighted the ability to use deep learning methodologies with visualization techniques to increase the efficiency of vulnerability detection [21], [22]. While deep learning enhances the accuracy of detection, its integration with existing visualization tools poses challenges, particularly in terms of interpretability and the potential for false positives.

Studies by Fedorchenko et al. and Piantadosi et al. discussed models and approaches for exploit analysis and smart contract security, respectively, highlighting the importance of visual representations in mitigating and understanding security risk [23], [24]. These studies underscore the importance of context-aware visualizations that can adapt to different threat environments, a feature that is often missing in current tools.

B. Dynamic Analysis Visualization in Software Security

Dynamic Analysis Visualization plays a crucial role in identifying and understanding security vulnerabilities in real time when software executes. This approach enhances static code analysis by demonstrating runtime issues that might not be detected through static code analysis. Recent studies have highlighted the significance of understanding coding vulnerabilities among various languages and the utilization of vulnerability detection tools, respectively, both of which benefit from dynamic analysis in capturing real-time issues [25], [26]. However, these studies often lack a comparative analysis of how different tools detect complex, multi-stage attacks.

Alaoui and Nfaoui have noted that dynamic analysis enhanced with visualization can improve the detection of unknown threats, and the importance of using deep learning approaches in identifying web application attacks [22]. While this approach is promising, the challenges of integrating dynamic analysis with existing security frameworks and ensuring the scalability of these solutions are still underexplored. Similarly, Cerny et al. and Parker et al. demonstrate the importance of dynamic analysis to manage evolving system architecture and operational inefficiencies while discussing the reconstruction and visualization of microservice architecture and runtime antipattern identification, respectively [27], [28]. Some researchers have focused on detecting and visualizing complex vulnerabilities such as TOCTOU race conditions and multistage cyber-attacks, where dynamic analysis provides crucial insights into the temporal aspects of security threats [29]. However, the effectiveness of these techniques in real-world scenarios, particularly in large-scale distributed systems, remains underevaluated, representing another gap in the current research.

C. Software Security Visualization Techniques / Tools

Software security visualization techniques and tools play a critical role in enhancing an understanding of security vulnerabilities in software systems. Recent studies have highlighted the significant importance of visualization techniques in understanding software architecture and evolution, categorizing them into graph-based, notation-based, matrix-based, and metaphor-based types [27]. While these categorizations are helpful, they often overlook the potential overlaps between different types of visualizations, which could lead to more integrated and effective tools. Some studies have focused on the requirements and evaluation of software visualization tools, highlighting the need for scalability, interactivity, and rigorous validation methods to ensure their effectiveness [30]. However, the lack of standardized evaluation metrics remains a significant barrier to comparing and improving these tools, as noted in the literature.

A recent study has reviewed the importance of evaluating visualization tools to improve user performance and ensure reliable results. It has explored 3D visualization and software evolution techniques, highlighting their capacity to provide comprehensive views of software structures and changes over time [31], [32]. While 3D visualization offers significant advantages, its practical implementation in real-world software development environments is often limited by high computational costs and the steep learning curve required for effective use.

The visualization of code smells and software quality metrics was reviewed, emphasizing the role of identifying areas prone to security vulnerabilities [33]. Integrating these visualizations into continuous integration/continuous deployment (CI/CD) pipelines is still a challenge, limiting their usefulness in agile development environments. Since software analysts need to read documents and source codes and synthesize trace data from multiple resources, the visualization for security analysis is usually labor-intensive [34]. Recent studies highlighted that to resolve this problem, there is a requirement for automated analysis tools.

One such study proposed a threat-hunting architecture using a machine learning approach, which is a practical

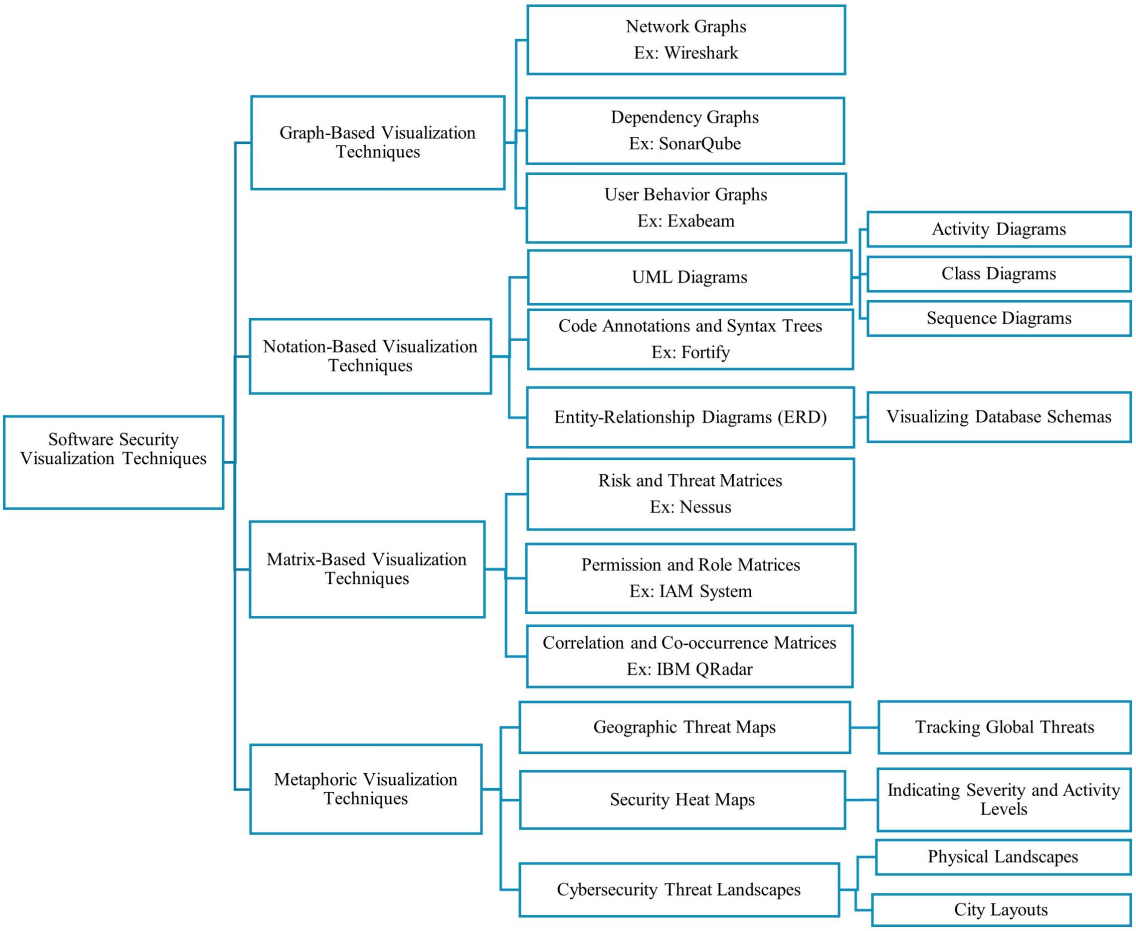

Fig. 2. Software security visualization techniques and tools.

application of dynamic analysis in visualizing security structures and properties of software systems, providing real-time security assessments [34]. While automation holds promise, its effectiveness in reducing human error and improving response times is still under debate, particularly in complex, rapidly evolving threat landscapes.

As shown in Fig. 2, this review explores various software security visualization techniques essential for understanding and managing security risks in complex systems. These techniques are categorized into four main types: Graph-Based, Notation-Based, Matrix-Based, and Metaphoric Visualization. Each category uses different techniques and tools to represent security data, helping security professionals, developers, and non-technical users gain insights into system vulnerabilities, threats, and user behaviors.

1) Graph-based visualization technique: Graph-based visualization techniques focus on visualizing connections, data flows, and dependencies within software systems to identify relationships, detect anomalies, and monitor user behavior [35]. Tools such as Wireshark are used for network graphs [36], SonarQube for dependency graphs [37], and Exabeam for user behavior graphs [38]. These techniques offer real-time insights into network traffic, application dependencies, and user interactions, crucial for detecting security threats in large systems.

2) Notation-based visualization techniques: Notation-based visualization techniques visually represent the design and architecture of software systems, helping developers understand code structure and the flow [39], [40]. Techniques like UML diagrams (including activity, class, and sequence diagrams) [41], tools like Fortify for code annotations and syntax trees [42], and Entity-Relationship Diagrams (ERD) are used to visualize database schemas [43]. This technique uses standardized diagrammatic representations to show the design and architecture of software systems and is useful in software design, debugging, and security risk assessment by mapping system components and their interactions.

3) Matrix-based visualization techniques: Matrix-based visualization techniques organize data into matrices to assess risks, permissions, and correlations within systems, offering a clear overview of user roles and access permissions [39]. Tools such as Nessus for risk and threat matrices [44], IAM Systems for permission, Role Matrices [45], and IBM QRadar for Correlation and Co-occurrence Matrices to assess security risks and map user roles [46]. These metrics are valuable in enterprise security, ensuring compliance, and detecting unauthorized access.

4) Metaphoric visualization techniques: Metaphoric visualization techniques use real-world metaphors, like geographic maps and city layouts, to intuitively represent complex security

data [47]. Geographic Threat Maps are used for tracking global threats [48], Security Heat Maps for indicating severity and activity levels [17], and Cybersecurity Threat Landscapes use physical and city layouts to represent security data [49], [39]. These techniques help non-technical users understand security risks and threats, improving situational awareness and aiding in action prioritization.

IV. Software Security Visualization in Practice

Software Security Visualization in Practice involves the application of visual techniques to enhance the understanding, monitoring, and management of security within software systems. As cybersecurity threats grow in complexity, traditional methods of analyzing security data often fall short. Visualization techniques bridge this gap by transforming complex data into intuitive, visual formats, enabling quicker and more accurate detection, analysis, and response to security threats. This practical approach to software security is critical for improving both the effectiveness and efficiency of cybersecurity efforts in real-world environments.

A. Operational Security Visualization

Operational security visualization is a crucial aspect in the field of cybersecurity, and it focuses on the graphical representation of security-related data to analyze security incidents. This study involves the use of visualization techniques and tools to interpret complex datasets, identify vulnerabilities, and maintain the integrity of the system. Fig. 3 illustrates Operational Security Visualization, which includes techniques for analyzing log files and SIEM data to monitor and enhance security operations.

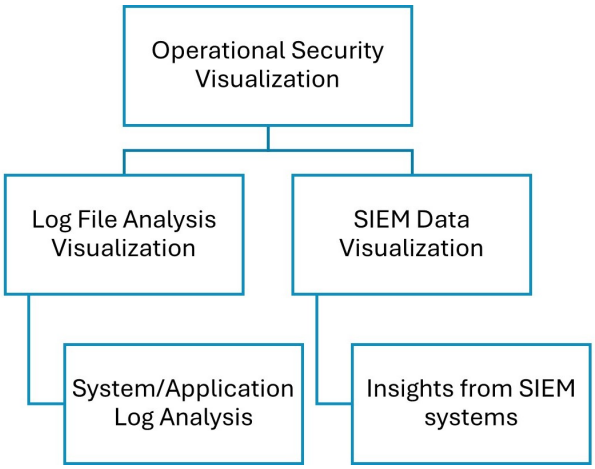

Fig. 3. Operational security visualization.

1) Log file analysis visualization: Log file analysis visualization helps in identifying security vulnerabilities, understanding system behavior, and enhancing overall security posture. Recent studies have emphasized the importance of visualization techniques to manage and interpret network logs, categorizing various security visual analytics methods, and highlighting the challenges of extracting useful information from raw log data.

One study discussed how the process of visualizing cyber-physical systems involves transforming raw unstructured data into information that can be effectively represented and analyzed, underscoring the necessity of robust visualization tools in cybersecurity [7]. However, this study did not extensively compare the effectiveness of different visualization tools, leaving a gap in understanding which tools are most effective for specific tasks. Another study by Korzeniowski and Goczyła highlighted recent advancements in automated log analysis, noting the benefits of standardizing log data formats to improve real-time monitoring, system health understanding, and root cause analysis [50]. Despite these advancements, integrating standardized log formats into existing security infrastructures remains a challenge, particularly in large-scale systems. The role of log file analysis in cybersecurity assessments is emphasized, reviewing methodologies and tools for measuring and assessing enterprise security, identifying vulnerabilities, and improving overall security infrastructure [51]. While these methodologies are effective, their scalability and applicability across different types of enterprises are still underexplored, representing a significant research gap.

2) SIEM data visualization: SIEM data visualization plays a crucial role in interpreting and managing the extensive amounts of security-related data collected by Security Information and Event Management (SIEM) systems. Recent research underscores the integration of big data analytics with SIEM to enhance the analysis and visualization of network security threats.

For instance, a study on effective security monitoring using efficient SIEM architecture emphasizes the use of advanced big data analytics tools to improve threat detection and visualization capabilities [52]. Additionally, another study highlights the limitations of traditional SIEM tools, such as their struggle to handle large-scale data efficiently and the inability to detect sophisticated attacks. This research highlights the need for a holistic framework that incorporates advanced visualization techniques to boost threat detection and response, addressing the challenges of continuous monitoring and rapid analysis of substantial volumes of security data in modern enterprises [53].

Another study focused on cyber situational awareness (CSA) visualizations, underscoring the need for sophisticated visualization techniques to support various stakeholders and improve threat understanding and response planning [9]. Despite these findings, the challenge of tailoring these visualizations to different user levels, particularly non-expert users, remains underexplored, presenting another gap in the current literature. Additionally, recent research has addressed the challenges of processing unstructured text logs in SIEM systems, emphasizing the importance of visualization in making sense of this data to detect patterns and anomalies [54].

These studies collectively demonstrate that effective visualization techniques are essential for improving the functionality and effectiveness of SIEM systems, enabling better threat detection, situational awareness, and overall cybersecurity. However, further research is needed to develop more advanced, user-friendly visualization tools that can handle the increasing complexity and volume of security data.

B. Cyber Security Visualization

Cybersecurity is a significant component of modern cybersecurity strategies, transforming complex data into visual

formats that facilitate cyber threat understanding, detection, and mitigation. Fig. 4 depicts Cybersecurity Visualization, which includes techniques for visualizing threat intelligence, phishing attacks, and malware behavior patterns to enhance security analysis and response.

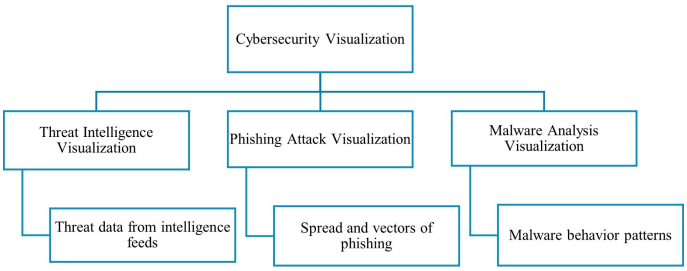

Fig. 4. Cyber security visualization.

1) Threat intelligence visualization: Threat intelligence visualization is vital for enhancing software security by transforming complex threat data into actionable insights. A recent study has emphasized the need for visualizing threat data from surface, deep, and dark web levels to aid in cybercrime detection and support law enforcement agencies [55]. Sun et al. highlighted the importance of real-time threat data visualization for proactive cybersecurity defense, providing a comprehensive review of recent research on cyber threat intelligence mining [18]. While these studies underscore the importance of visualization, they often overlook the practical challenges of implementing these techniques in real-world scenarios, such as the need for real-time processing and integrating multiple data sources.

A study has discussed the use of natural language processing techniques to extract cyber threat intelligence from unstructured texts, demonstrating how visualization can help interpret large volumes of data and identify key indicators of compromise. It also highlighted the automation of CTI extraction and the role of visualization in supporting proactive decision-making and threat mitigation [56]. However, the scalability of these techniques remains a concern, particularly in large organizations with vast amounts of unstructured data. Recent studies have demonstrated the need for standardized visualization techniques to improve the quality and sharing of technical threat intelligence, facilitating better collaboration and response to cyber threats [18]. Despite these advances, the lack of universally accepted standards for threat intelligence visualization continues to hinder effective collaboration between organizations. Collectively, these studies underscore the critical role of visualization in understanding and responding to cyber threats, thereby enhancing the overall security posture of organizations.

2) Phishing attack visualization: Phishing attack visualization is an essential tool in enhancing cybersecurity by transforming complex data into actionable insights to detect and mitigate phishing threats. Recent studies have underscored the significant role of software security visualization in the real-time detection and monitoring of phishing attacks. For instance, recent research highlights the importance of utilizing big data analytics within software security visualization to decrease the number of phishing attacks, emphasizing that visualizing large datasets can expose malicious patterns and enhance threat detection [57]. However, while these techniques are effective, their reliance on large data sets can also be a limitation, particularly in environments where data availability is restricted.

The effectiveness of machine learning-based visualization techniques in detecting phishing activities is highlighted, offering clear visual cues to identify suspicious behaviors [58]. Patil and Arra focused on the role of visual tools in user awareness training, demonstrating how visualizing phishing threats can educate users and improve their response to such attacks [59]. Despite these advancements, the challenge of integrating these tools into existing training programs and ensuring their accessibility to non-technical users remains underexplored. Another recent study provided a comprehensive review of cybersecurity measures, emphasizing the need for visualization in understanding and controlling phishing attacks [60]. These studies collectively underscore the critical role of visualization in enhancing the detection, prevention, and response to phishing threats, thereby improving the overall security posture of organizations. However, further research is needed to improve the usability and accessibility of these tools across different organizational contexts.

3) Malware analysis visualization: Malware analysis visualization is crucial in the fight against sophisticated cyber threats, offering a visual approach to understanding and mitigating malicious activities. A study highlighted the importance of Cyber Situational Awareness (CSA) in comprehending complex cyber threats, emphasizing the role of visualization in providing operational-level insights but noting gaps in visualizations for higher-level decision-making [17]. Another study has provided a systematic review of malware visualization techniques, showcasing their effectiveness in detecting, classifying, and identifying malware through static data visualization and network traffic monitoring [61]. Despite these findings, the study noted that the effectiveness of these techniques in large-scale, real-world environments still needs to be validated. Moawad et al. highlighted visualization-based malware detection, noting its efficiency and independence from domain experts, using image representation of malware binaries to enhance detection accuracy [62]. The challenge of maintaining accuracy and reducing false positives in these visualizations remains a significant barrier to their broader adoption.

Recent studies have emphasized the importance of advanced visualization systems in malware analysis. One such study conducted a comprehensive survey on the integration of explainable AI (XAI) methods for malware hunting. This research evaluated various XAI techniques for their effectiveness in visualizing and analyzing malware [63]. However, the challenge of integrating these advanced visualization techniques into existing malware analysis workflows remains a significant area for future research. These studies collectively underscore the significant role of visualization in malware analysis, enhancing the detection, classification, and mitigation of malware by transforming complex data into understandable visual formats, thereby supporting both operational and strategic cybersecurity efforts.

V. Discussion

This systematic review has provided an in-depth exploration of the current state of software security visualization

techniques. Key findings indicate that visualization techniques are crucial in improving security monitoring, threat detection, and overall system understanding. The review categorized the main approaches into four types: graph-based, notation-based, matrix-based, and metaphor-based visualizations.

Graph-based visualization techniques, such as network graphs (Wireshark) and user behavior graphs (Exabeam), are primarily effective in depicting connections, data flows, and system dependencies. These visualizations are particularly useful for real-time monitoring of dynamic systems, helping detect anomalies in user behavior and network traffic. However, they face challenges in scalability and real-time integration, particularly in large, complex systems. Notation-based visualization methods, like UML diagrams and entity-relationship diagrams (ERD), provide clarity on system design and architecture. They are instrumental in mapping out system components and flows, which is essential for security assessments. However, these tools may require significant effort from developers and may not adequately capture dynamic security events, limiting their effectiveness in real-time threat detection. Matrix-based visualization, used by tools like Nessus and IBM QRadar, focuses on assessing risks, permissions, and correlations within a system. These visualizations provide a structured view of user roles, permissions, and identified threats, making them effective for managing large-scale enterprise security environments. However, their static nature and reliance on predefined matrices can limit their adaptability to real-time threats, especially in rapidly evolving attack scenarios. Metaphor-based visualization techniques, such as security heat maps and geographic threat maps, leverage real-world metaphors to represent complex security data. These methods are especially useful in communicating security risks to non-technical stakeholders, improving overall situational awareness. However, their reliance on simplified representations may obscure the complexities of security systems, leading to oversights in more nuanced threat environments.

A. Recent Approaches

Recent research has introduced several innovative approaches to enhance software security visualization. One of the emerging trends is the integration of big data analytics and machine learning with visualization techniques. This allows for more dynamic threat detection, particularly in Security Information and Event Management (SIEM) systems. SIEM platforms, when combined with advanced visualization tools, can handle larger volumes of data more efficiently, providing real-time insights into complex security landscapes. Furthermore, the application of deep learning to automate vulnerability detection in static and dynamic analysis environments has gained attention. By applying machine learning algorithms to large datasets, these approaches can enhance the accuracy of vulnerability detection, though challenges remain in reducing false positives and improving the interpretability of results. In addition to machine learning-driven approaches, recent research has explored adaptive visualization mechanisms such as Level of Detail (LoD) techniques integrated with city metaphors to dynamically adjust visual complexity based on user roles, tasks, and real-time security data, thereby reducing cognitive overload and improving vulnerability detection [64].

B. Hybrid Visualization Techniques

An emerging concept in the literature is using hybrid visualization techniques, combining the strengths of multiple approaches to provide a more comprehensive view of security risks. For example, integrating graph-based visualizations with matrix-based approaches enables a holistic view of system structure and risk correlations. This hybrid approach provides deeper insights into security vulnerabilities, offering real-time mapping of user roles, permissions, and system behavior. However, the practical implementation of hybrid techniques is still under research, with scalability and performance in large-scale environments being key challenges.

C. Challenges

While current software security visualization tools offer significant benefits, several ongoing challenges persist. A major concern is the need for scalable solutions capable of processing large datasets in real-time, as modern software systems generate vast amounts of data that require real-time analysis [1]. Additionally, improving user accessibility is crucial. Many current tools are designed for experts, making them less intuitive for non-expert users, which hinders broader adoption [2], [19]. Enhancing user-centric design could make these tools more accessible and effective for a wider audience.

Another challenge is the lack of standardized metrics. The absence of consistent methods for assessing visualization performance makes it difficult to compare tools and measure their effectiveness across different studies [19]. Establishing standardized benchmarks could help address this issue and improve the reliability of security visualization tools.

VI. Conclusion

This review highlights the importance of visualization techniques in understanding, analyzing, and mitigating security threats by transforming complex data into easily interpretable formats. Dynamic analysis visualization supports detecting vulnerabilities in real time and also provides clear visuals that improve Cyber Situational Awareness (CSA) for everyone, especially non-experts, by focusing on threat information. However, several key challenges persist in the field. These include the need for scalable tools capable of processing large datasets in real-time as software systems grow in complexity, the lack of user-centric designs that hinder the accessibility of these tools to non-technical users, and the absence of standardized metrics to assess the effectiveness of visualization tools. These advancements will lead to more reliable and accessible software security solutions, ultimately enhancing the ability to defend against emerging security threats.

Future research should focus on integrating machine learning, Artificial Intelligence, and real-time data analysis capabilities while designing comprehensive platforms that unify various visualization techniques to enhance software security.

Human Versus AI: A Comparative Study of Zero-Shot LLMs and Transformer Models Against Human Annotations for Arabic Sentiment Analysis

Dimah Alahmadi
Information Systems Department, Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—Accurate sentiment analysis in Arabic natural language processing (NLP) remains a complex task due to the language's rich morphology, syntactic variability, and diverse dialects. Traditional annotation approaches require human experts, face significant challenges related to inter-annotator agreement and dialectal understanding. Recent advances in transformer-based models and large language models (LLMs) offer new techniques to generate annotations. This paper presents a comparative evaluation of three sentiment annotation strategies applied to Saudi dialect tweets: human expert labeling, fine-tuned transformer models (specifically CAMeLBERT-DA), and zero-shot inference using GPT-4o. The selected CAMeLBERT-DA which is already trained specifically for Arabic sentiment tasks and dialects, demonstrates robust performance with fast, scalable predictions. On the other hand, the selected GPT-4o shows competitive zero-shot accuracy without fine-tuning, making it a practical solution for real-time applications. We investigate how each approach performs on two datasets, both of more than 4,000 Saudi tweets covering a wide spectrum of dialects and sentiment expressions. Our methodology involves analyzing consistency across annotations using inter-rater agreement metrics such as Cohen's Kappa, Pearson correlation, and class-specific agreement rates. The results reveal that while human annotations capture cultural and context subtleties, they suffer from inconsistency, particularly in ambiguous or dialect-specific cases. This study contributes to the growing body of work on annotation methodologies by highlighting the strengths and limitations of both human and AI-based annotators in Arabic NLP. Our findings suggest that the zero-shot use of domain-specific transformers like CAMeLBERT-DA with general-purpose LLMs such as GPT-4o have a moderate correlation compared to actual human annotators. The paper concludes with recommendations for building reliable ground truth datasets and integrating AI-assisted labeling into Arabic NLP tasks.**

Keywords*—Large Language Model (LLMs); transformers; NLP; annotation; inter agreement; sentiment analysis, Saudi dialects

I. Introduction

The rapid advancement of large language models (LLMs) has transformed natural language processing (NLP) across multiple languages, including Arabic. Despite this progress, Arabic remains underrepresented and presents unique challenges due to its complex morphology, diglossia (the co-existence of Modern Standard Arabic and diverse dialects), and wide regional variation [1] and [2]. These linguistic characteristics make high-quality annotation for Arabic NLP tasks particularly demanding. The worldwide use and exchange of data with diverse platforms facilitate large-scale interactions between individuals. This resulted in a volume of text data where NLP plays a critical role in the future of smart applications. The advancement in NLP techniques helps to maintain and analyze such a volume of text data to extract meaningful decisions similar to humans' processing in areas like machine translation, text summarization, question answering, and sentiment analysis.

Manual annotation by expert linguists is often considered the gold standard for creating reliable datasets. However, this process is resource-intensive, time-consuming, and difficult to scale—especially when applied to informal and diverse content like social media. In recent years, researchers have turned to large language models (LLMs), such as OpenAI's GPT series for different tasks in NLP, such as sentiment analysis and machine translation [3], GPTs have a potential solution to reduce the burden of manual annotation. These models, particularly in zero-shot and few-shot settings, have shown remarkable success in performing NLP tasks without domain-specific training, raising questions about their reliability as annotation tools.

In the context of Arabic NLP, the utility of LLMs for sentiment analysis and dialect-sensitive tasks has not been comprehensively evaluated. Additionally, there is a need to benchmark the quality of their outputs against those produced by human annotators. This is particularly crucial when LLMs are used to process social media data, where language use tends to be informal, ambiguous, and culturally nuanced [4].

This study investigates the effectiveness of zero-shot GPT-4o in predicting Arabic sentiment analysis and fine-tuned transformer models (e.g., CAMeLBERT-DA) ability compared to human expert annotations. We aim to explore the validity and practical trade-offs of each annotation methodology.

The research is guided by the following questions:

- How do GPT-4o and CAMeLBERT-DA perform in zero-shot sentiment classification of Saudi dialect tweets compared to human annotation?
- How do annotation metrics differ in terms of agreement and correlation for real-world Arabic dialect social media datasets?

By addressing these questions, the study contributes to the growing body of research on efficient informed annotation practices in low-resource and linguistically diverse settings such as Arabic NLP.

A. Literature Review

Recent studies have highlighted several research gaps in this domain. Notably, there is a lack of thorough investigation of the annotation quality produced by LLMs for Arabic NLP tasks, particularly across different dialects and task types. While some work has benchmarked LLM performance against traditional models [5]. In addition, few have directly compared LLM-generated labels to human-annotated gold standards in Arabic and examined sources of error in LLM-generated annotations and transformers, as well as where they diverge most from human judgments.

B. Annotation Challenges in Arabic NLP

Arabic presents unique annotation challenges in NLP due to its morphological complexity, rich syntax, and multiple dialects that deviate significantly from Modern Standard Arabic (MSA) [6]. Arabic is a polyglossic language comprising Modern Standard Arabic (MSA) and numerous regional dialects. These dialects differ significantly in phonology, morphology, lexicon, and syntax, making unified dataset construction particularly difficult [7]. Annotators must often be familiar with both MSA and dialectal varieties to accurately label sentiment, intent, or named entities, especially when working with informal texts like tweets or online forums.

Another key challenge lies in the scarcity of large-scale, publicly available annotated datasets. Unlike English, where benchmarks like GLUE and SuperGLUE have standardized evaluation protocols, Arabic NLP still suffers from fragmented resources [8]. Many datasets are restricted to specific genres such as news propaganda, limiting their utility in social or conversational contexts on X [9].

Moreover, the presence of ambiguous structures, mixed-code usage (e.g., Arabic-English), and sarcasm prevalent in social media further complicate the annotation process. These linguistic phenomena require not only syntactic understanding but also pragmatic and cultural awareness. Thus, high inter-annotator agreement is difficult to achieve, particularly when annotations are conducted by non-experts [10].

Another major challenge is the high-quality annotated datasets in Arabic. Many Arabic NLP tasks – from hate speech detection to sentiment analysis suffer from trust labeled data, especially compared to English [11]. This is partly due to the labor-intensive nature of creating Arabic corpora: manual annotation is time-consuming, expensive, and often requires domain or dialect experts. The process can be prone to inconsistencies as well; human annotators sometimes disagree on labels for complex or ambiguous texts, introducing variability into the dataset. Arabic's writing system (e.g. omission of short vowels) and extensive morphological ambiguity can further complicate annotation, since the correct interpretation of a word or sentence may rely on context or annotator intuition. In tasks like offensive language detection, the lack of diacritics and the prevalence of informal expressions make it hard for annotators to determine intent or meaning without context [12]. Authors in study [13] have presented blockchain technology to generate a wide trust annotated dataset by crowdsourcing applications that are based on blockchain structures.

In summary, the literature indicates that Arabic NLP faces persistent annotation challenges: scarcity of labeled data, dialect and domain mismatches between annotators and content, and the inherent linguistic complexity of Arabic. These issues need careful dataset design (with clear guidelines and training for annotators) and innovative approaches to support or complement human annotators, as we explore in subsequent sections.

C. Transformer and GPT Models for Arabic NLP

In response to these limitations, large language models (LLMs) have emerged as a promising alternative to manual annotation. Transformer-based models such as BERT [14] and T5 [15] have been adapted for Arabic via pretraining on Arabic corpora.

Transformer-based models have revolutionized Arabic NLP. Initial efforts like AraBERT and Arabic-BERT demonstrated strong performance gains by pretraining on large Arabic corpora [16], [17]. Later, MARBERT and ARBERT incorporated dialectal Arabic into their training to improve generalization across informal text [6]. These models consistently outperformed multilingual baselines on downstream tasks.

Notably, CAMeLBERT-DA [18] was trained on the CAMeL Lab's extensive Arabic text collections and fine-tuned for dialectal sentiment classification, showing state-of-the-art performance on multiple downstream tasks.

Meanwhile, multilingual and instruction-tuned models like mT5 [19] and XGLM [20] have shown competence in zero-shot tasks. These models, though not Arabic-specific, benefit from broad cross-lingual transfer. However, they still underperform on dialectal Arabic unless further adapted or fine-tuned.

With the release of ChatGPT and the GPT-4 series [21], zero-shot and few-shot prompting has gained traction. These models exhibit impressive ability to generalize across tasks, offering a practical solution for rapid annotation. However, their performance in Arabic sentiment annotation is still underexplored, especially in informal settings. Recent work by Khalifa et al. [22] highlighted that GPT-4 can approximate expert annotation on formal Arabic , but may struggle with dialectal variation and ambiguous expressions.

Transformer models have not been limited to encoders. Researchers also explored generative transformers for Arabic. For instance, an AraGPT2 model (an Arabic version of GPT-2) was developed as a language generator [23]. AraGPT2 has been used alongside BERT models in hybrid systems; one study combined CAMeLBERT (encoder) with AraGPT2 (generator) in an ensemble, achieving superior accuracy on an Arabic text classification task. However, compared to the proliferation of Arabic BERT models, generative pre-trained transformers dedicated to Arabic are fewer. This is changing with the rise of massive multilingual models like GPT-3 and GPT-4, which, despite not being Arabic-specific, are trained on enough Arabic text to demonstrate impressive capabilities in the language. These GPT-series models can perform Arabic tasks in a zero-shot or few-shot manner – a fundamentally different paradigm from task-specific fine-tuning. Researchers have been keen to evaluate how well such models handle Arabic understanding and generation.

In a comprehensive evaluation across 60+ Arabic NLP benchmarks, Khondaker et al. found that ChatGPT's zero-

shot accuracy was consistently lower than that of dedicated Arabic models on tasks like text classification, NER, and QA [24]. These models enable broader experimentation in Arabic NLP, but challenges remain in understanding their bias and limitations across dialects and domains. These findings suggest that while large GPT-style models are very powerful, Arabic-specific adaptation (through fine-tuning or prompting techniques) remains important for top performance. Nevertheless, the convenience of prompting an LLM without needing task-specific training is highly attractive, particularly for addressing the data scarcity issue. This has led to explorations of using GPT models as annotation tools, which we discuss in this research.

D. Hybrid Annotation Approaches

Hybrid annotation workflows are a growing area of interest. In this approach, LLMs generate initial labels that are then validated or corrected by human experts. Studies in English NLP [25] show this reduces cost and improves consistency. This framework remains under-investigated in Arabic NLP, despite its potential for scalable, culturally sensitive annotation. There is a pressing need for empirical studies that evaluate such workflows across diverse dialects, task types, and prompt strategies. One approach is to use LLMs to generate initial labels or data, which are then verified by humans. For example, Senator et al. employed ChatGPT to perform semantic role labeling (SRL) on Arabic texts. In their study, ChatGPT was prompted to assign semantic role tags to Arabic sentences (including emotional text), effectively acting as an annotator. Remarkably, in a cross-lingual setting – projecting English SRL annotations onto Arabic via ChatGPT's translation – then LLM achieved about 94% accuracy, approaching human quality [26].

In conclusion, the period 2020–2025 has seen rapid progress in both Arabic-specific NLP models and the use of large generative models, and the capabilities lie in combining these advances to develop robust, efficient annotation methodologies that leverage the best of human and machine intelligence. The literature review suggests that while LLMs offer valuable annotation support, their optimal use in Arabic NLP requires deeper investigation into prompt engineering, dialect adaptation, and comparison with human oversight. This study builds on these insights by systematically comparing human annotations, CAMeLBERT-DA predictions, and GPT-4o zero-shot outputs on Arabic tweets.

II. Methodology and Experimental Setup

This study explores whether AI models with zero-shot strategies can be used to build the ground truth. It also compares the results using the Cohen Kappa metric and the Pearson correlation coefficient. The analysis of humans vs. AI models in NLP tasks, specifically sentiment analysis, using two Saudi dialect datasets. Fig. 1 illustrates the steps in the general methodology.

A. Datasets

The following is a description of the datasets included in this study's experiments:

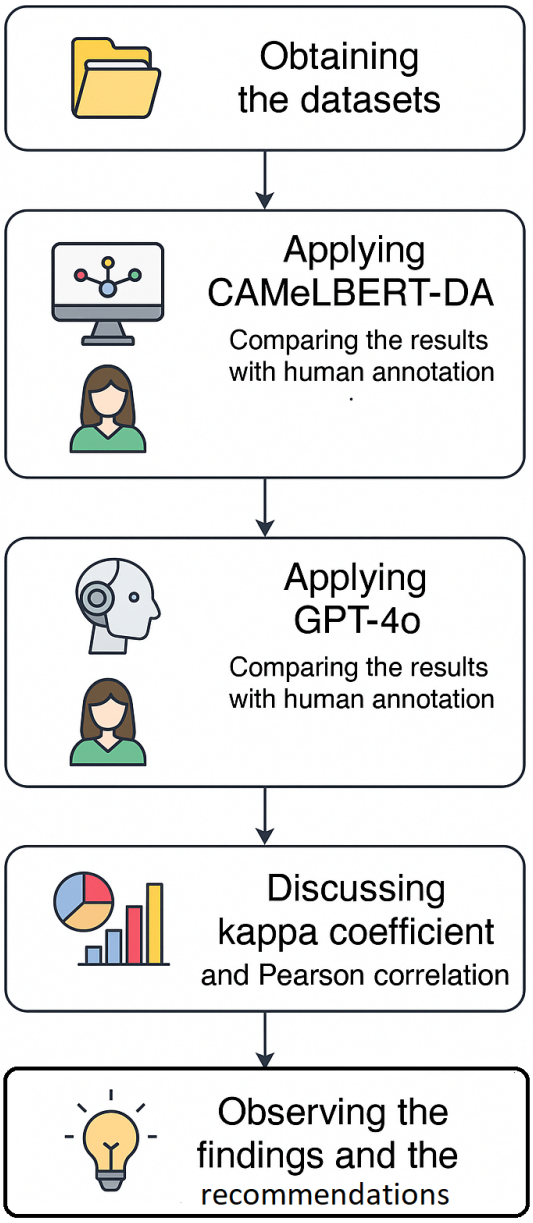

Fig. 1. Methodology overview.

1) SDCT: Multi-Dialects Corpus Classification for Saudi Tweets in [27]. It is dedicated to Saudi dialects. The data are from the X platform, as it is a rich source of data for short posts to be collected. The authors performed the pre-processing phases that involved main tasks, which are data cleaning and normalization. After data collection and pre-processing, the data were manually annotated by human experts with a total of 4181 records. In this study, we used the version that had removed advertisement tweets in the data cleaning phase. Also, it is prepared by removing links (http://), mentions (@Username), retweets, hashtags, and punctuation. While emojis were kept to enrich the sentiment detection.

2) Tb-SAC: Topic-based and Sentiment Classification for Saudi Dialects Tweets. It is extracted from corpora from X, especially from Saudi dialects. The corpus contains 4301 tweets, which are labeled based on sentiments using a common scale:

positive, negative, and neutral. First, preprocessing step by removing all the noise data in the tweets that were not related, such as mentions, hashtags, URLs, white space, retweets, punctuation marks, and redundant tweets. In the second step, normalization is the process of standardizing the form of some Arabic letters that have various shapes to be unified in one, but maintain the same meaning. The dataset was normalized by applying the Tashaphyne library and lemmatization. Emojis here are also removed; only the root words text was kept [28].

B. Models Selection

Based on the NLP task included in the experiment, which is sentiment analysis, the models used are selected. The selected transformer models have two criteria: fine-tuned and have achieved high accuracy in the domain of short tweets. And they consider recent research and benchmarks in the Arabic NLP tasks. The Table I below summarizes the top Arabic transformer models for sentiment analysis, dialect identification, which can be used (either as zero-shot classifiers or pre-trained fine-tuned models). All models are available on Hugging Face (HF). We highlight whether each supports zero-shot use or is a fine-tuned classifier, provide benchmark accuracy/F1 notes, and explain why it's recommended. CAMeL Lab's CAMeLBERT-DA Sentiment Analysis model, fine-tuned for Arabic sentiment classification (positive/negative). This model handles Modern Standard Arabic and dialectal content, as it was trained on diverse Twitter datasets (ASTD, ArSAS, SemEval). (Hugging Face: https://huggingface.co/CAMeL-Lab/bert-base-arabic-camelbert-da-sentiment) CAMeLBERT is a collection of BERT models pre-trained on Arabic texts with different sizes and variants. the release of pre-trained language models for Modern Standard Arabic (MSA), dialectal Arabic (DA), and classical Arabic (CA), in addition to a model pre-trained on a mix of the three [18]. Table I presents the reasons this study adopts this transformer, as many works support [29] and [30].

ChatGPT is an application utilizing the large artificial intelligence models GPT-3 or GPT-4 to generate text based on user input. GPT denotes a neural network adept at learning from extensive datasets to generate natural language outputs. GPT-4 is characterized as more creative, reliable, and collaborative than its predecessor GPT-3 [31] and [32]. The cutting-edge advancement in LLMs [33], GPT-4o was chosen for the comparison in the study experiment via an OpenAI API account for paying customers. It delivers state-of-the-art sentiment classification accuracy without dedicated task training, demonstrating competitive performance against domain-tuned transformer models. Zero-Shot Versatility and Ease of Use: GPT-4 is a large pre-trained model that can perform sentiment analysis without the need for task-specific fine-tuning or large labeled datasets. Broad Language Understanding & Nuance: As a massive foundation model, GPT-4 was trained on an extremely large and diverse corpus (including substantial Arabic content). Table II shows a comparison between the Arabic transformer CAMeLBERT-DA and the large language model GPT-4.

Regarding model structure, GPT-4 and CAMeLBERT-DA have different transformer architectures. GPT-4 (Generative Pre-trained Transformer 4) is built as a decoder-only Transformer, meaning it generates text by predicting one token after another (typical for GPT-style models). CAMeLBERT-DA, on the other hand, is based on BERT, which uses a Transformer encoder – it reads the entire input sequence bidirectionally to produce a contextualized representation. In practice, this means GPT-4 is designed for text generation (and can handle dialogue or any generative tasks), while CAMeLBERT-DA's architecture is designed for understanding text and classification (it outputs encoded features that are fed to a classifier layer) [34] and [35].

C. Evaluation

During the annotation process to build the ground truth for both datasets, human volunteers were involved. In order to validate the human opinions of the sentiment and the AI-generated sentiment, two metrics:

- Inter-model agreement metrics are also used to assess the reliability between annotators. The degree of agreement indicates how accurate the emotion labels assigned to the text. The calculation of the Kappa coefficient and its interpretation were based on the well-known reliability equations and measurements presented in [25]. The kappa statistic revealed the actual reliability of the categorical labels, accounting for the possibility of random agreement.
- Recent NLP studies have employed Pearson correlation to quantify annotator similarity on sentiment and emotion tasks. [36]. Pearson's r is a convenient metric to assess how consistently they apply the scale. (Notably, even annotator confidence scores – if each annotator gives a confidence level for each label.

In summary, Pearson correlation is very useful when treating labels as interval data – it captures how well annotators' scoring trends align – but it should be paired with traditional inter-rater agreement metrics to fully evaluate agreement on the actual labels and to ensure that high correlation indeed reflects reliable, reproducible annotation.

D. Results and Discussion

The experiment here went through the zero-shot settings for both models compared to the human annotators.

1) Generating sentiment using CAMeLBERT-DA transformer: First, using zero-shot and direct inference of the CAMeLBERT transformer to predict the sentiment for dataset1 and dataset2, in Hugging Face [37].

We need to explore the labels produced using the transformer-based model and those in the ground truth by human experts. A detailed comparison from Fig. 2 , the actual sentiment distribution is: negative: 901 (21.5%), neutral: 2506 (59.9%) and positive: 774 (18.5%). on the other hand, Predicted Sentiment Distribution by the transformer was negative: 2607 (62.4%), neutral: 601 (14.4%), and positive: 973 (23.3%). The inter-agreement using Cohen's Kappa Score: 0.2130, while the Pearson Correlation: 0.437. This indicates "fair agreement" between the actual and predicted sentiments. The score suggests that the prediction model performs better than

TABLE I. COMPARISON OF CAMELBERT-DA WITH OTHER ARABIC TRANSFORMERS FOR ARABIC SENTIMENT ANALYSIS

Aspect	CAMeLBERT-DA	Arabic T5 / MARBERT / Others	Recommendation
Accuracy on Arabic Tweets	˜92–93% accuracy on ArSAS, ASTD, and SemEval; fine-tuned on multiple Arabic tweet datasets	MARBERT: competitive but slightly lower; Arabic T5 not specialized or benchmarked for sentiment on tweets	CAMeLBERT-DA outperforms or matches best models due to targeted fine-tuning on diverse tweet datasets
Real-Time Inference Speed	BERT-base encoder model (110M params); efficient for batch and streaming inference	Arabic T5: large encoder–decoder; slower generation; MARBERT: similar size but more general-purpose	CAMeLBERT-DA offers faster, lower-latency inference than T5-like models; ideal for live tweet analysis
Suitability for Tweets	Pretrained on MSA + Dialectal Arabic + social media text; robust to slang, emojis, informal spelling	Arabic T5 trained more on formal MSA and QA-style tasks; MARBERT strong on dialects but not sentiment-specific	CAMeLBERT-DA is dialect-aware, slang-aware, and sentiment-optimized—making it perfect for social content

TABLE II. COMPARISON BETWEEN GPT-4 (CHATGPT) AND CAMELBERT-DA FOR ARABIC SENTIMENT ANALYSIS

Aspect	GPT-4 (ChatGPT)	CAMeLBERT-DA (Arabic BERT)
Model Type	Large Language Model (LLM); generative, decoder-only transformer; predicts next tokens (autoregressive).	Pretrained BERT-base encoder; bidirectional transformer trained for understanding Arabic. Fine-tuned for classification.
Scale (Parameters)	Very large (estimated 1T+ tokens and hundreds of billions of parameters; exact size not disclosed). Trained on multilingual data including Arabic.	Base-sized model (110M parameters). Pretrained on 5.8B Arabic words from dialectal, MSA, and classical Arabic sources.
Pretraining Data	Trained on diverse multilingual web data (books, articles, web pages). Strong in MSA and general Arabic.	Trained on large-scale Arabic corpora from social media and diverse dialects (CAMeL Lab).
Fine-Tuning for Sentiment Analysis	Not required. Performs sentiment classification in zero- or few-shot mode via prompting. No task-specific finetuning.	Required and completed. Fine-tuned on ASTD, ArSAS, and SemEval datasets. Dedicated sentiment prediction head.
Output Type	Text generation. Can provide label and reasoning if prompted. Very flexible output.	Class label output (e.g., “positive” / “LABEL_1”) with probability score. Not designed for explanatory responses.
Sentiment Accuracy on Arabic Tweets	F1-score ≈ 0.75–0.80 (zero- or few-shot). Competitive with fine-tuned models. Excels in MSA and structured dialectal text.	F1-score ≈ 0.72–0.76 (fine-tuned). High accuracy on dialectal Arabic tweets due to domain-specific tuning.
Zero/Few-Shot Support	Native. Easily supports both modes without additional data. Highly flexible.	Not applicable. Requires fine-tuning and training on task-specific data.
Best Use Case	Real-time, on-demand analysis in flexible environments (e.g., chat, APIs). Great for label and explanation.	High-throughput classification on Arabic social media data. Ideal for static datasets with known structure.

random chance, but there’s significant room for improvement. Correlation: 0.4377 - There’s a moderate positive correlation between the two columns, indicating some relationship but not a strong one.

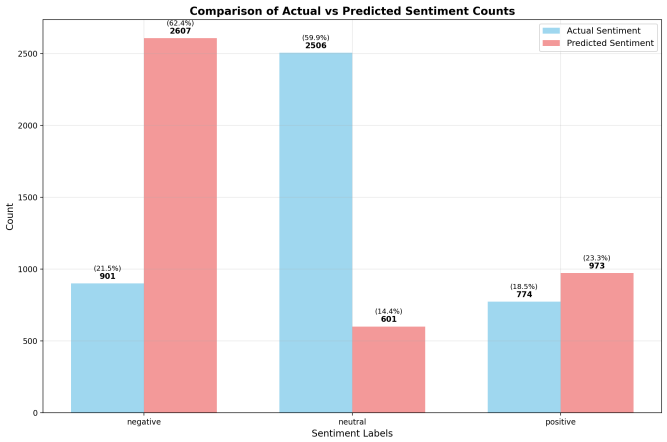

Fig. 2. Comparison of Humans vs. Predicted sentiment counts: (Dataset1).

Key observations:

- The actual sentiment data by humans is predominantly neutral (59.9%), while the predicted model tends to classify more samples as negative (62.4%)
- The model significantly under-predicts neutral sentiment (14.4% vs. 59.9% actual)
- The model over-predicts negative sentiment (62.4% vs. 21.5% actual)
- Positive sentiment predictions are closer to actual values (23.3% vs. 18.5%)

The confusion matrix in Fig. 3 shows where the model struggles most, particularly in correctly identifying neutral sentiments, often misclassifying them as negative. This suggests that positive sentiment is the most clear for humans and AI to detect and identify.

Now, the experiment of implementing the transformer for the second dataset. Key observations are found and perfect Alignment in some cases. The visualization in Fig. 4 shows that when the model is confident about its predictions, there’s perfect alignment between feeling and confidence labels. However, the presence of “unknown” labels for negative sentiments indicates areas where the model struggles with certainty, particularly for negative sentiment classification.

Key Insights from the Visualization:

- Perfect Prediction Accuracy for positive and neutral sentiments:
- All 2,086 actual positive sentiments were correctly predicted as positive.

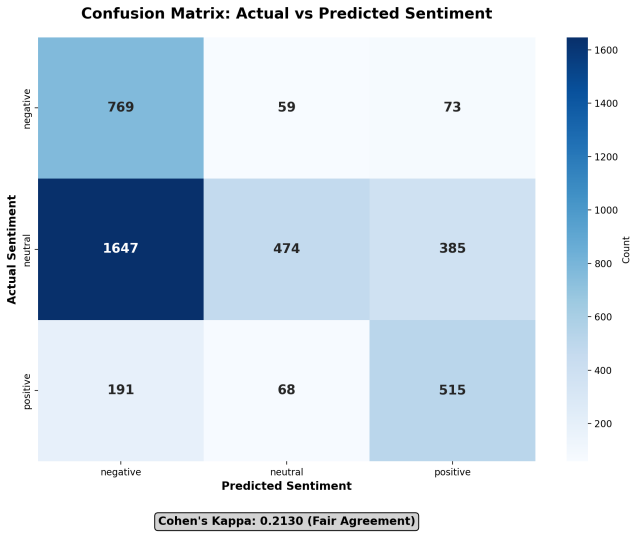

Fig. 3. Confusion matrix of Humans vs. Predicted sentiment labels with cohen's kappa score: (Dataset1).

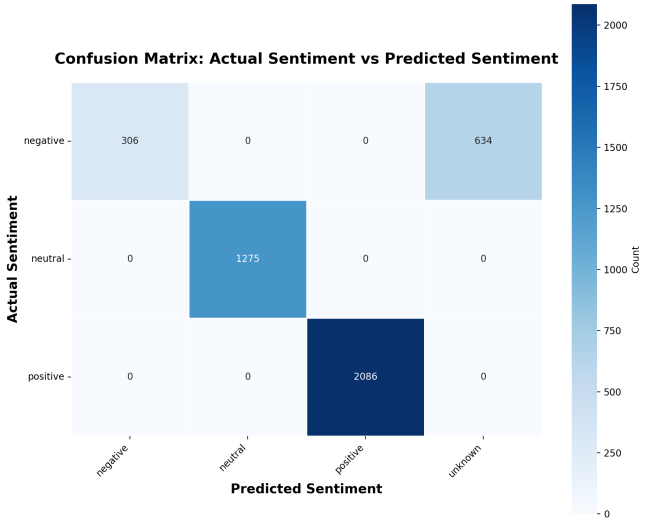

Fig. 5. Confusion matrix of actual Sentiment vs. Predicted sentiment including unknown class: (Dataset2).

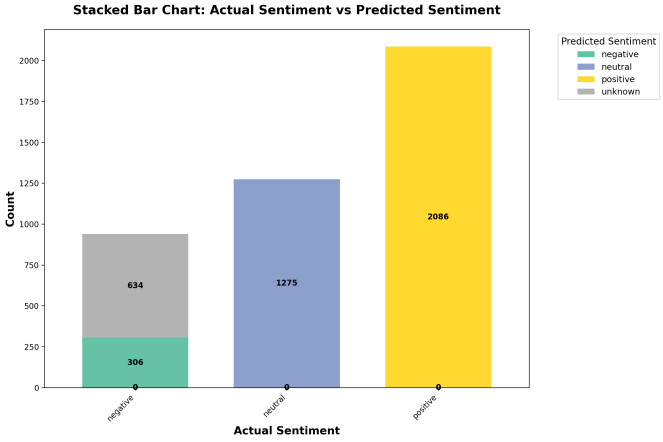

Fig. 4. Stacked bar chart of humans Sentiment vs. Predicted sentiment: (Dataset2).

- All 1,275 actual neutral sentiments were correctly predicted as neutral.
- Mixed Results for Negative Sentiment: Only 306 out of 940 actual negative sentiments were correctly predicted as negative 634 actual negative sentiments were predicted as "unknown", indicating model uncertainty.

The transformer here shows high confidence and accuracy for positive and neutral sentiments but struggles with negative sentiment classification, often defaulting to "unknown" when uncertain. The confusion matrix in Fig. 5 shows that the correlation coefficient between actual humans' sentiment and transformer prediction is 0.114, indicating a weak positive correlation. This suggests that while there is some relationship between the predicted feelings and confidence labels, it's not very strong.

2) GPT-4o: Using the chosen LLM from OpenAI represented in GPT-4o in this part of the experiment to validate the capacity of humans against AI. First of all, a clear, direct prompt based on Zero-Shot Prompt (No examples provided) is prepared as follows:

Analyze the following text for sentiment, and respond using only one of the three words: Positive, Negative, or Neutral.

Text: 'The service was excellent and very fast.'

Answer:

Positive

We analyzed the agreement of GPT-4o performance against human judgment for both dataset1 and dataset2. Table III shows the sentiment predicted labels using GPT-4o compared to human annotators in dataset1. The visualization shows GPT-4o has fair overall agreement (0.366) with humans but performs inconsistently across sentiment classes - excellent on neutral (81.4%), moderate on positive (63.2%), but poor on negative (39.3%) sentiment.

TABLE III. SENTIMENT ANNOTATION EVALUATION METRICS: GPT-4O VS. HUMANS (DATASET1)

Metric	Value	Interpretation
Cohen's Kappa	0.366	Fair agreement
Overall Agreement	58.0%	Moderate agreement
Pearson Correlation	0.557	Moderate correlation
Negative Agreement	39.3%	Poor agreement
Neutral Agreement	81.4%	Good agreement

On the other hand, an experiment using the second dataset was conducted. Table IV Inter-rater Agreement: The Cohen's Kappa score of 0.239 indicates a fair agreement between the human-labeled and the 'GPT-4o' sentiment classifications. This suggests that while there is some consistency, a notable degree of disagreement also exists. Overall Matching Discrepancy: Only 47.22% of the instances showed an exact match in sentiment labels between the two sources, highlighting a significant divergence in their overall classifications. Correlation

TABLE IV. SENTIMENT ANNOTATION EVALUATION METRICS: GPT-4O VS HUMANS (DATASET2)

Metric	Value	Interpretation
Cohen's Kappa	0.239	Fair agreement
Overall Agreement	47.22	Poor agreement
Pearson Correlation	0.433	Moderate correlation
Negative Agreement	54.46	Moderate agreement
Neutral Agreement	43.29	Poor agreement
Positive Agreement	45.60	Poor agreement

Strength: A moderate positive correlation (0.45) was observed between the numerical representations of the actual humans' feelings and 'GPT-4o' sentiments. This implies a general tendency for them to align, but not a strong linear relationship. Sentiment-Specific Consistency: Agreement levels vary across sentiment categories. Negative sentiment classifications show the highest specific agreement at 54.46%, suggesting better consistency for negative cases. Conversely, neutral sentiment exhibits the lowest specific agreement at 43.29%, indicating more challenges in aligning neutral classifications.

Finally, observations during the comparisons are as follows:

- The results show closer opinions of LLMs when the zero-shot setting is implemented and are more correlated to human experts' judgments. Transformers tend to show a moderate correlation with human annotators, while GPT-4o shows fair agreement. This is due to the fine-tuning setting of transformers for the specified domain to adapt the dataset.
- The efficiency and the cost of time using OpenAI for developers took 120 minutes to generate sentiment for every dataset, which counts around 4000 posts based on Google Colab using a paid account. On the other hand, the transformer CAMeLBERT-DA offline pipeline took only 60 seconds to generate the sentiment. This is because of the broad general use of LLMs and complexity of models and the number of parameters compared to the transformer, which is usually domain-specific.
- Another observation is the dataset level of preprocessing affects the AI decisions. In other words, during the experiment, the dataset2 version that had an extra level of preprocessing via lemmatization and removing all the emojis reduced the capability of models to detect the right sentiment, as it provides the lowest inter-agreement between GPT-4o (0.24) and CAMeLBERT-DA (0.14).

III. CONCLUSION AND FUTURE WORK

In this research, we compared OpenAI's GPT-4o model and transformer-based model against human experts for the annotation process. The experiments were conducted for NLP tasks in specific sentiment analysis prediction for Saudi dialect tweets. The finding revealed a better performance of GPT-4o against the transformer CAMeLBERT-DA. Inter-agreement Cohen Kappa was 0.366, indicating fair agreement between GPT-4o and human annotation for the first dataset, where initial preprocessing is conducted without any lemmatization, and emojis also remain in the text. Notably, datasets with intensive preprocessing produced difficulties in sentiment detection for transformers. This suggests that transformers and LLMs require more context to generate sentiment close to humans. The comparison between the models' performance and the human annotation explains that zero-shot manner in this experiment is fair, but not a completely reliable tool to substitute the human annotation process. For these reasons, sentiment generation research should investigate the combination of human crowdsourcing and automatic sentiment generation by LLMs. Furthermore, a limitation of this study is the lack of comparison across different Arabic dialects, such as Egyptian, Gulf, and Maghrebi. Also, in the future, employing few-shot strategies for LLMs and fine-tuned transformers can be studied for sentiment tasks and other NLP tasks such as Arabic text summarization. New evaluation metrics and empirical studies are critical to increasing reliability and trustworthiness when zero-shot methods are applied in real-time applications. In addition, the implications of fairness and bias issues can also be studied, which are crucial for ethical real-world deployment.

Simulysis: A Method to Change Impact Analysis in Simulink Projects Based on WAVE-CIA

Hoang-Viet Tran*, Ta Van Thang, Cao Xuan Son, Do Trong Thu, Pham Ngoc Hung
University of Engineering and Technology, Vietnam National University,
Hanoi No. 144 Xuan Thuy Street, Dich Vong Ward, Cau Giay District, Hanoi, Vietnam

***Abstract*—MATLAB and Simulink, which have more than 5 million users and are installed at more than 100,000 businesses, universities, and government organizations[1], are widely used in numerous large-scale projects across various industries. These projects continually evolve in response to changes in business logic. However, managing the impact of these changes on Simulink projects presents several challenges to guarantee the quality of these projects. To address this, we propose a WAVE-CIA-based method named Simulysis for change impact analysis (CIA) in Simulink projects. The core idea behind Simulysis is to directly analyze Simulink project files and construct the project's corresponding call graph. By comparing the call graphs from the old and new project versions, Simulysis computes the change set. Subsequently, Simulysis applies the WAVE-CIA method to this change set and the call graph to identify the impact set. Additionally, Simulysis proposes a signal tracing method helping the system engineers to follow, check, and debug signals through the system. We have implemented Simulysis as a tool with the same name and conducted experiments using several open-source Simulink projects. The experiments demonstrate that Simulysis effectively performs the CIA process and retrieves the impact set, producing optimistic results and proving the practical applicability of Simulysis for real-world projects. Further discussions about Simulysis are provided in the paper.**

***Keywords*—Change impact analysis; WAVE-CIA; MATLAB/Simulink projects**

I. Introduction

In the development of a Simulink project, where the focus is on modeling, simulating, and analyzing dynamic systems, the evolution of requirements and functions is a common occurrence. Factors such as adding new features or accommodating customer preferences often drive changes. Similar to the software development life cycle, even minor adjustments in Simulink models can lead to unforeseen consequences and defects in the system. Consequently, change requests pose challenges for maintaining and managing Simulink projects. For developers, devising a strategy to identify the modules that require modification to accommodate changes is complex. Testers face the burden of testing numerous test cases after system modifications. Project managers grapple with cost allocation and time management related to change management. For this reason, understanding the relationships between altered Simulink components and their impact on other elements is crucial for Simulink projects and software projects in general. To address this, Change Impact Analysis (CIA) [1], [2], has been developed and applied. Numerous published papers discuss this solution [3], [1], [4], [5], [6], [2].

Researchers have indeed widely employed CIA across various systems, spanning different research fields and programming languages. In the domains of Business Process Management (BPM) and Service-Oriented Architecture (SOA), numerous published papers addressing CIA problems reveal that impact analysis solutions primarily fall into three categories: dependency analysis, traceability analysis, and history mining [4], [7]. First, dependency analysis is most frequently used. It encompasses various graph-based analyses, including control flow graph analysis [8], [9], message dependency graph [10], [11], trust dependency graph [12], directed hypergraph [13] and call graph analysis. Additionally, formal methods aid in change identification, formal modeling, and impact analysis [14], [15]. Quantitative analysis, which quantifies the depth of change using metrics, is essential for decision-making and problem-solving in service-based systems [16], [17], [18], [19], [20]. Lastly, execution trace analysis relies on information retrieved during program execution, either on-the-fly (online) or after program execution (offline) [21].

Following dependency analysis, traceability analysis plays a crucial role. It helps establish relationships between components and their impact on other elements, such as source code [22]. These relationships span multiple abstraction layers and are captured using traceability links. Lehnert's method enables automated or semi-automated impact analysis approaches for software, although it is not suitable for manual analysis [9]. Existing traceability can be categorized into vertical and horizontal traceability [23], [24]. Given the distributed nature of SOA, traceability analysis in SOA systems remains a challenging task.

History mining refers to the use of Mining Software Repositories (MSR) techniques to discover historical change dependencies [25], [21], [26]. This approach relies on analyzing the version histories of software to identify change patterns within source code repositories. By examining these patterns, the method can pinpoint processes or services that have frequently changed in tandem. It leverages change logs or version histories to predict the impact of future modifications. MSR methods have shown significant potential for impact analysis in software systems [27]. They have been applied across various aspects of software projects, including process model repositories [25], web service ecosystems [28], and process choreographies [29].

Change Impact Analysis (CIA) methods have been extensively implemented in various software languages. For instance, the CA Harvest Software Change Manager is a

[1]https://www.mathworks.com/content/dam/mathworks/fact-sheet/2023-company-factsheet-8-5x11-8282v23.pdf

comprehensive tool designed to track and manage software changes throughout the development lifecycle [30]. It supports C/C++ and several mainframe server languages like COBOL, PL/I, and Assembly, offering features that help organizations manage and understand the impact of their source code modifications. JRipples, an open-source tool tailored for Java developers, aids in comprehending programs during source code changes [31]. It manages steps for impact analysis and change propagation, highlights dependencies, and assists developers in understanding how changes in one part of the source code can affect another. JArchitect, although based on CIA, exclusively supports Java [32]. It's a source code analysis and visualization tool that helps developers enhance their source code. It offers a comprehensive set of features, including source code metrics, visualization of dependencies through directed graphs and dependency matrices, and the ability to compare source code snapshots. Lastly, several tools were implemented, including various CIA methods. SonarQube supports over 30 languages, frameworks, and Infrastructure as Code (IaC) platforms [33]. Checkmarx supports Java, C#, JavaScript, Python, Ruby, and PHP [34]. Ansible supports specific domain-based languages on YAML [35]. Jira provides an interface for collaboration and project management [36].

Regarding the CIA for Simulink projects, in 2017, Rapos et al. introduced a method to address the Change Impact Analysis (CIA) problem in Simulink projects [5]. This method, based on a set of MATLAB scripts, was implemented in a tool named SimPact. SimPact was validated as an impact predictor for the maintenance history of a large set of industrial models and their tests. However, SimPact can only operate within the Simulink Interactive Development Environment (IDE), meaning it cannot function independently of MATLAB. Other tools, such as Diffplug and BDT, support the impact analysis of Simulink projects using the signal tracing method [37], [6]. Despite these advancements, no published paper has yet addressed the CIA problem of Simulink projects that can operate as a standalone solution and utilize the WAVE-CIA method for performing the CIA.

This paper introduces Simulysis, a method based on WAVE-CIA [3], designed to identify and analyze the impact of changes between two versions of Simulink projects. Simulysis reads data from the project's *.mdl and *.slx files and builds the corresponding call graphs. It then compares thoroughly, identifying discrepancies and modifications between the two project graphs. Subsequently, Simulysis applies the WAVE-CIA to the changed Simulink components to identify the affected ones. Simulysis makes four main contributions. First, it introduces a technique for extracting information from Simulink files and classifying the changes in different project versions. Second, it demonstrates how to generate a call graph of the project, a feature not supported by the current version of MATLAB/Simulink. Third, Simulysis utilizes the WAVE-CIA method to analyze the impact of changes using the generated call graph. Finally, Simulysis proposes a method to trace a given signal in the provided Simulink project. This provides a crucial method for Simulink engineers to follow, check, and debug signals and signal-related bugs. We have implemented Simulysis as a tool and conducted preliminary experiments with promising results.

The structure of this paper is as follows. Section II introduces the essential background concepts. Section III delves into the details of the Simulysis methodology. Section III-B4 presents the details of the proposed signal tracing method. Section IV provides insights into the practical implementation of the Simulysis Tool. Initial experimental findings and subsequent discussions are presented in Section V. Section VI discusses the published papers related to Simulysis. The paper concludes in Section VII.

II. Backgrounds

In this section, we introduce background concepts that will be utilized in this paper.

A. Change Impact Analysis

Change Impact Analysis (CIA) [2] is a systematic approach commonly employed in software development, project management, and system engineering. Its primary purpose is to evaluate the consequences of modifications made to a system. CIA aids in making well-informed decisions, minimizing the introduction of errors, and optimizing resource utilization. While it cannot guarantee complete predictability or replace thorough testing in every instance, the benefits of CIA include improved system reliability, reduced change risks, and efficient resource allocation. In software projects, CIA benefits software developers, testers, project managers, system architects, and stakeholders involved in the change process. Overall, the CIA process contributes to better decision-making and enhances system quality.

B. WAVE-CIA

WAVE-CIA, introduced by Li et al. in 2013 [3], represents a novel Change Impact Analysis (CIA) approach based on the traditional call graph-based techniques. Drawing inspiration from the propagation of water waves, this method computes a set of impacted components based on a change set and a call graph. Much like the ripples formed when stones are thrown into the water, WAVE-CIA views the call graph as a water surface and the change set as the thrown stones. The central concept is that a component is more likely to be impacted if it has dependencies with altered components, and these modified components propagate the impact to others in the graph. By meticulously analyzing the call graph, WAVE-CIA identifies precise change ripples and adeptly handles multiple changes with interference. In comparison to traditional call graph-based CIA methods, WAVE-CIA achieves a more accurate impact set with fewer false positives, although it may occasionally miss a few false negatives.

In the context of Simulink, several terms and concepts differ from those found in conventional software development codebases. These terms have been mapped to suitable WAVE-CIA equivalents for implementation. The Simulink project comprises numerous Simulink files with extensions such as ".mdl" or ".slx". These files contain Simulink systems, which encompass various block types including Ports, Logic, References, Subsystems, and more, all interconnected by lines.

Definition 1 (Node or Vertex)**.** *Nodes represent systems in a Simulink project. Each node corresponds to a specific system, and the edges connecting the nodes represent the caller and*

callee relationships between these systems. This helps define how systems interact with each other in the project.

Definition 2 (Call Graph)**.** *A call graph is a directed graph G = (V, E), where V is a set of vertices representing Simulink components in the system, and $E \subseteq V \times V$ is a set of edges representing the call relationships between callers and callees. WAVE-CIA draws an analogy from water waves that ripple outward when stones are thrown into calm water. In the context of the call graph, which is akin to a water surface, Simulink components reachable by multiple altered components (meeting positions) are more likely to be impacted by the changes.*

Definition 3 (Change Set - CS)**.** *A change set refers to a group of Simulink files and systems within a Simulink project that have been modified or are marked for modification. This set is typically identified by comparing data between two versions of the same Simulink project.*

Definition 4 (Core Set)**.** *The core set is comprised of closely related Simulink components that are likely to be affected by multiple modifications in the change set. This set is generated by identifying Simulink components close to the change set within a call graph. These components, which are accessible by multiple modified components, are more susceptible to changes. The core set is determined by verifying if a component is influenced by more than one modified component, and it encompasses all the modified components in the change set. The likelihood of components in the core set being affected by multiple changes is high. Subsequently, the impact set is calculated using propagation analysis based on the core set.*

Definition 5 (Impact Set - IS)**.** *The impact set is made up of Simulink files and systems that could be affected by the Simulink components in the change set. It includes elements that may need to be reworked or revalidated. WAVE-CIA determines the impact set through the process of mining the call graph.*

C. Simulink

Simulink [38], a graphical extension to MATLAB [39] developed by MathWorks, is designed for modeling and simulating dynamic systems. It offers key advantages such as the capability to model nonlinear systems, which is not easily achievable with transfer functions, and the ability to include initial conditions for a more accurate depiction of system behavior. Simulink provides a graphical interface for users to build systems using block diagrams, incorporating various elements like transfer functions, adding nodes, virtual input/output devices, etc. Its integration with MATLAB ensures smooth data transfer between the two platforms. Due to its wide usage in system modeling, controller design, and simulation, Simulink is a potent tool in engineering and scientific applications.

Table I describes some common blocks used in Simulink, and Table II shows the data from the source code of Simulink blocks.

Additionally, we clarify the key terms used in Simulink modeling to ensure consistency throughout the paper. The terms *system*, *subsystem*, *component*, *block*, and *file* are fundamental to Simulink, but they have specific meanings and relationships that must be clearly understood.

Definition 6 (System)**.** *A system in Simulink is a complete model representing a specific dynamic behavior or a control logic. It encompasses all the elements necessary for simulating a particular functionality. A system can be a standalone model or can include multiple subsystems and components working together.*

Example: A vehicle dynamics model that includes the engine, transmission, and braking systems.

Definition 7 (Subsystem)**.** *A subsystem is a modular, hierarchical component of a system. It encapsulates a set of blocks that perform a specific function within the larger system. Subsystems help organize and manage complex models by breaking them into smaller, more manageable parts.*

Example: Within a vehicle dynamics system, the engine control unit can be a subsystem that handles all the engine-related computations and control logic.

Definition 8 (Component)**.** *A component in Simulink refers to any reusable, self-contained unit within a model. Components can be atomic or composite and can represent hardware or software elements. Components often refer to reusable libraries or pre-built blocks that can be integrated into various models.*

Example: A PID controller block can be a component used in various systems to manage control processes.

Definition 9 (Block)**.** *A block is the fundamental building element in Simulink models. Blocks represent mathematical operations, signal routing, or functional units. They can be combined to form systems and subsystems. Blocks can be simple (like a gain block) or complex (like a Simulink Function block).*

Example: A summation block that adds input signals together is a simple block, while a Stateflow chart is a more complex block.

Definition 10 (File)**.** *A file in the context of Simulink refers to the physical storage of models and components. Simulink models are typically saved with the .slx or .mdl file extensions. These files contain all the necessary information to define and simulate a model, including block diagrams, parameters, and configuration settings.*

Example: `vehicle_dynamics.slx` is a file that contains the complete Simulink model for vehicle dynamics.

D. Relationships in Simulink Project

To implement the CIA analysis of the Simulink projects, we have to identify the relationships between components and elements of Simulink projects.

1) Relationships between files: Within the context of file relationships, we establish connections based on the structure of the files in the project. This is essential for the implementation of WAVE-CIA, which depends on comprehending the dependencies among files. The various types of file relationships are illustrated in Table III.

TABLE I. COMMONLY USED SIMULINK BLOCKS

ID	Icon	Name	Description
1		Logical Operator	The Logical Operator block does the given logical operation on its inputs. If it is nonzero, the input value is true (1). Otherwise, it is false (0).
2		Relational Operator	The Relational Operator block does the given relational operation on the input. The value chosen for the Relational operator parameter determines if the block accepts one or two input signals.
3		Inport	Inport blocks in Simulink link signals from outside a system into the system.
4		Outport	Outport blocks in Simulink link signals from inside a system to a destination outside of the system. Outport blocks can connect signals originating from a subsystem to other parts of the model. Outport blocks can also supply external outputs at the top level of a model hierarchy.
5		Subsystem	A Subsystem block is a block that contains a subset of a model. We can have multiple subsystems in a model, and we can have subsystems inside other subsystems.
6		Constant	The Constant block of Simulink generates a real or complex constant value signal. We can use this block to provide a constant signal input.

Fig. 1 illustrates the relationships between various files. The file under examination in this figure is "Logic111". It is referenced within "Function12", which makes "Function12" the caller of "Logic111". Within the context of "Logic111", there are references to two other files: "Block1111" and "Logic112". This makes these two files the callees of "Logic111".

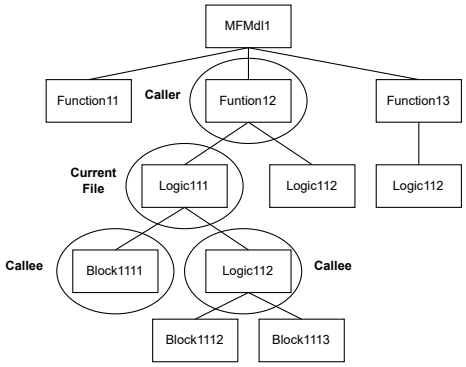

Fig. 1. Example of file relationships.

2) Relationships between systems: Within the context of Simulink systems relationships, we establish connections according to the structural organization of systems within a file. This definition is crucial for implementing WAVE-CIA.

Fig. 2 illustrates the relationships among systems. The Subsystem block "Function21" is currently under assessment for its relationships. It has two callers connected to it: the "Bit Set" block and the Inport block "In2_1". The output of "Function21" is directly linked to the Logical Operator block AND, which is therefore its callee.

E. Types of Change

In the process of analyzing two versions of a Simulink project, pinpointing the differences between them is crucial,

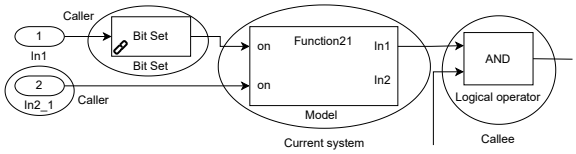

Fig. 2. Example of system relationships.

with a special emphasis on the modified components. The set of these modified elements is termed the change set (CS). Modifications are classified into three categories: addition, deletion, and change.

Simulysis employs the "Name" property of a Simulink system as the key to discern whether it has been added, deleted, or changed. This is a critical aspect of Simulysis, given that two systems within the same Simulink file cannot possess identical names. If a system name is present in both versions of the Simulink project, it is considered altered if there exists any discrepancy in its properties. Table V presents the various types of modifications in a Simulink project.

III. SIMULYSIS METHOD

A. Simulysis Overview

Simulysis is a method based on WAVE-CIA for performing CIA on Simulink projects. This method encompasses three primary phases in the analysis of a specified Simulink project. An overview of Simulysis is depicted in Fig. 3.

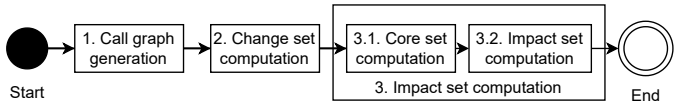

Fig. 3. An overview of simulysis.

TABLE II. SOURCE CODE OF SIMULINK BLOCKS

ID	Icon	Name	Source code
1		Logical Operator	Block source code: <Block BlockType="Logic" Name="Logical
Operator" SID="12"> <PortCounts in="2" out="1"/> <P Name="Position">[580, 152, 610, 183]</P> <P Name="ZOrder">12</P> <P Name="AllPortsSameDT">off</P> <P Name="OutDataTypeStr">boolean</P> </Block> Properties: - Position - ZOrder - AllPortsSameDT - OutDataTypeSt
2		Relational Operator	Block source code: <Block BlockType="RelationalOperator" Name="Relational
Operator" SID="16"> <PortCounts in="2" out="1"/> <P Name="Position">[270, 257, 300, 288]</P> <P Name="ZOrder">16</P> <P Name="Operator"><=</P> <P Name="InputSameDT">off</P> <P Name="OutDataTypeStr">boolean</P> <P Name="RndMeth">Simplest</P> </Block> Properties: - Position - ZOrder - Operator - InputSameDT - OutDataTypeStr - RndMeth
3		Inport	Block source code: <Block BlockType="Inport" Name="In1" SID="10"> <P Name="Position">[370, 153, 400, 167]</P> <P Name="ZOrder">10</P> </Block> Properties: - Position - ZOrder
4		Outport	Block source code: <Block BlockType="Outport" Name="Out1" SID="14"> <P Name="Position">[730, 158, 760, 172]</P> <P Name="ZOrder">14</P> </Block> Properties: - Position - ZOrder
5		Subsystem	Block source code: <Block BlockType="SubSystem" Name="Subsystem" SID="19"> <PortCounts in="1" out="1"/> <P Name="Position">[565, 229, 665, 271]</P> <P Name="ZOrder">19</P> <P Name="ContentPreviewEnabled">on</P> <System Ref="system_19"/> </Block> Properties: - Position - ZOrder - ContentPreviewEnabled - System Ref.
6		Constant	Block source code: <Block BlockType="Constant" Name="Constant" SID="3"> <P Name="Position">[380, 60, 410, 90]</P> <P Name="ZOrder">3</P> </Block> Properties: - Position - ZOrder

- Phase 1 (Call graph generation): Given a project, Simulysis obtains the project data by analyzing the project files. Next, it builds a call graph based on the structure and relationships between the Simulink systems (blocks) and files by using the callee map. A callee map is a set of Simulink components called by other components through the Outports. This phase is vital as it establishes the interconnections within the Simulink project and generates a call graph that will be utilized in subsequent phases.

TABLE III. FILE RELATIONSHIPS

ID	Relationship	Roles	Description
1	Parent	Caller	A file is deemed the parent and caller of another file when it contains references to that other file.
2	Children	Callee	A file is considered a child and callee of another file when it is referred to in the content of that other file.
3	No Relation		Two files are considered unrelated if they don't share a parent-child relationship, regardless of whether they have common parents or children.

TABLE IV. SYSTEM RELATIONSHIPS

ID	WAVE-CIA	Description
1	Caller	The system that triggers a call to another system is referred to as the "caller".
2	Callee	The system that receives a call from another system is referred to as the "callee".
3	No Relation	Two systems are considered unrelated if they are not directly connected.

TABLE V. TYPES OF CHANGE

ID	Change Type	Description
1	Addition	Simulink components that appeared in the new version but not the old version of the project are listed as Additions.
2	Deletion	Simulink components that are removed in the new version and existed in the old version of the project are listed as Deletions.
3	Change	Simulink components that still exist in both versions of the Simulink project but have different properties are listed as Changes.

- Phase 2 (Change set calculation): When provided with two call graphs corresponding to two versions of a Simulink project, Simulysis calculates the change set. This computed change set is then utilized in Phase 3 to determine the impact set.
- Phase 3 (Impact set computation): In this phase, the WAVE-CIA algorithm is implemented, using the change set from Phase 2 as an input. This process identifies the core set, relying on the call graph from Phase 1, and computes the impact set by implementing the WAVE-CIA algorithm. It's important to note that while Simulysis utilizes the WAVE-CIA technique for calculating the impact of changes, it's possible to employ any other CIA method that facilitates the computation of the impact set based on the call graph.

The subsequent sections delve into a comprehensive examination of each phase in the Simulysis method for Change Impact Analysis (CIA) of Simulink projects.

B. Call Graph Generation

There are many methods for the analysis of Simulink projects, such as manual navigation through the signals of the project [37], based on MATLAB-provided script [5], AI-based change distribution analysis [40], etc. By modeling a given Simulink project as a call graph, we have an efficient method to analyze, fix bugs, improve the model, trace the required signals, etc. In this paper, we employ the call graph for change impact analysis of Simulink projects for the two reasons below:

- Signal tracing: Simulink projects are designs of systems with many signals running across the model. By using the call graph to model the given project, signals can be seen as paths through the graph. For this reason, the signal tracing problem can be addressed by using the graph traversing problem and using such well-known algorithms as depth-first search, breadth-first search, etc. This greatly contributes to the system analysis and debugging of Simulink projects.
- Change impact analysis: By modeling a Simulink project as a call graph, the change impact analysis problem can be solved by applying such graph-based CIA methods as the WAVE-CIA method [3].

To create the call graph for a given Simulink project, Simulysis analyzes project files and generates the required call graph using the callee map. The creation of a call graph for a specified Simulink project involves the following three primary steps, as shown in Fig. 4.

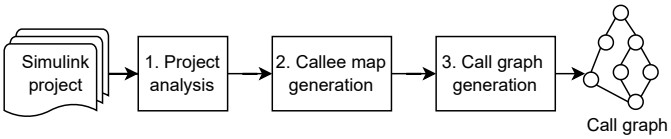

Fig. 4. The main steps of the call graph generation process.

- Step 1 (Project Analysis): Simulysis scans all the Simulink files in the specified project and extracts data about all existing systems, lines, and branches. Details of this step are presented in Section III-B1.
- Step 2 (Callee Map Generation): For every system within the project, Simulysis identifies other systems that are linked to it by employing a signal tracing algorithm. A system in Simulink serves as a computational unit that accepts input data via in-ports, processes this data, and generates output through the out-ports. Simulysis aims to locate the callees of the system, which are systems connected to the system's out-ports. The specifics of this step are illustrated in Algorithm 1.
- Step 3 (Call Graph Generation): Simulysis cycles through each system in the project, generating a new corresponding node in the call graph. Subsequently, Simulysis establishes connections to other nodes in the graph, utilizing the callers and callees of the system identified in Step 2. The specifics of this step are demonstrated in Algorithm 2.

1) Project analysis: For a specific Simulink project, Simulysis analyzes by scanning the list of Simulink files in the project and extracting a list of systems (blocks) and the lines that connect these systems.

The structure of a typical Simulink project and a Simulink file is depicted in Fig. 5 and Fig. 6. As a Simulink project comprises numerous files and folders, it is crucial to pinpoint the files where pertinent data is stored. Depending on the MATLAB version of the project, the primary information of a Simulink project is housed in various file types such as ".mdl"

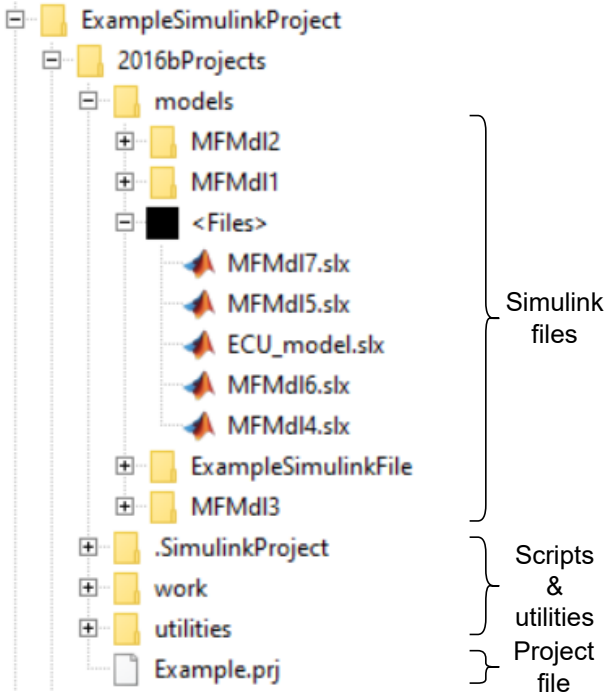

Fig. 5. Simulink project structure example.

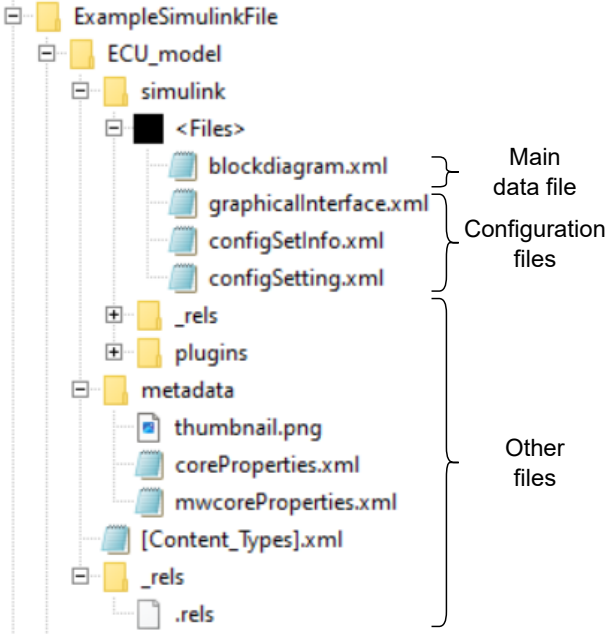

Fig. 6. Simulink file structure example.

and ".slx". Simulysis filters the project by verifying the validity of the model state and the file extension to locate files with the ".mdl" or ".slx" extension and other project information.

Before MATLAB version R2016b, Simulink files had the ".mdl" extension, and the data could be accessed directly. For newer versions, Simulink introduces a new ".slx" file extension, which is a zip file comprising multiple files and folders. To access the file, Simulysis alters the ".slx" file extension to ".zip" and then unzips the file. As only the main data file ("blockdiagram.xml") is needed to recreate a visualization and execute other functions, only this file is analyzed to retrieve system and line information.

Fig. 7 presents an instance of a "blockdiagram.xml" file within an ".slx" file. The file adheres to a standard XML format where the initial tags represent the file configuration and setting parameters. Simulysis utilizes only a few properties within these tags to construct the necessary call graph. The primary data is housed within the ¡System¿ tag, which encompasses the information of blocks (¡Block¿ tag) and lines (¡Line¿ tag). Leveraging the information from the blocks and lines, Simulysis assembles the required call graph for use in subsequent phases.

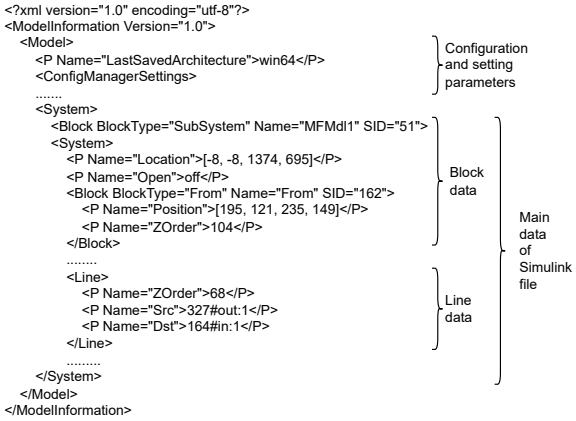

Fig. 7. Simulink file content example.

2) Callee map generation: The purpose of the callee map is to identify the subsystems (i.e., callees) associated with each system in the Simulink project. This is an important step in creating the call graph, which helps analyze call relationships between systems and determine the impact of changes in the project. Details of the callee map generation process are shown in Algorithm 1.

The algorithm starts by initializing the map ($systemCalleMap$) as an empty set ($\emptyset$) (line 2). It then iterates over each system, checking its type to determine the appropriate process (lines 3 - 30).

If a system is of type "$From$", it does not connect to other systems via lines. Instead, it directly jumps to a system of the "To" type with the same identifier, facilitating data transfer from the "$From$" system to the "To" system. Consequently, the algorithm identifies the corresponding "To" systems of the current "$From$" system and appends them as a caller-callee pair to the "$systemCalleeMap$" map (lines 4 - 6).

If a subsystem is then connected to another system, the algorithm will find the block corresponding to the port type and port number connected (lines 12 - 13). In Simulink, a system can connect to output port of type "$Output$", "$LConn$" and "$RConn$" (in which "$LConn$" and "$RConn$" represents left and right side physical connection port - a special port type in Simulink). The corresponding block that links a signal from inside the subsystem to outside the subsystem is of type "$Outport$", "$PMIOPort$ with "$Side$" attribute equals "$Left$", "$PMIOPort$ with "$Side$" attribute equals "$Right$".

Algorithm 1 Generate the Callee Map

Input: $systemList$: List of systems of the project
$lineList$: List of lines of the project
Output: The required callee map

```
1  begin
2      systemCalleeMap ← ∅
3      foreach system in systemList do
4          if system type is "From" then
5              calleeSystem ← findGoto(systemList, system)
6              systemCalleeMap.append(system, calleeSystem)
7          else
8              lines ← findLines(lineList, system)
9              foreach line in lines do
10                 callerSystem ← system
11                 calleeSystems ← ∅
12                 if system type is "SubSystem" then
13                     callerSystem ← getOutputPortBlock(system, line)
14                 if line has branches then
15                     foreach branch in line.getBranches() do
16                         calleeSystem ← findSystem(systemList, branch)
17                         if calleeSystem type is "SubSystem" then
18                             calleeSystem ← getInputPortBlock(calleeSystem, line)
19                         calleeSystems ← calleeSystems ∪ calleeSystem
20                     end
21                 else
22                     calleeSystem ← findSystem(systemList, line)
23                     if calleeSystem type is "SubSystem" then
24                         calleeSystem ← getInputPortBlock(calleeSystem, line)
25                     calleeSystems ← calleeSystems ∪ calleeSystem
26                 end
27                 systemCalleeMap.append(callerSystem, calleeSystems)
28             end
29         end
30     end
31     return systemCalleeMap
32 end
```

After finding out the corresponding output port blocks, the algorithm assigned it as the caller (line 13)

If the system type is not "$From$", the algorithm identifies lines connected to it. In Simulink, a line block contains some branch properties, which are lines connecting to other blocks. Therefore, for each line, the algorithm checks if the line contains any branches. If so, the algorithm iterates through the branches to find the system that is connected to them and adds them to the callee list ($calleeSystem$) (lines 14 - 20). If not, the algorithm finds the system connecting to the line and adds it to the callee list ($calleeSystem$) (lines 21 - 26).

If a system is connected to a system of type "$SubSystem$" through the subsystem's input ports (lines 17 - 18 and 23 - 24), the algorithm will find the port block inside the subsystem correspond to port type and port number connected. In Simulink, a system can connect to an input port of type "$Input$", "$LConn$" and "$RConn$". The correspond block that links signal from outside the subsystem to the inside are of type "$Inport$", "$PMIOPort$ with "$Side$" attribute equals "$Left$", "$PMIOPort$" with "$Side$" attribute equals "$Right$". After finding all corresponding input port blocks, the algorithm then and adds them to the "$calleeSystems$" array (line 19 and 25).

After finding out the caller and the callee systems, the algorithm adds the caller system ($callerSystem$) and its corresponding callee list ($calleeSystems$) to the $systemCalleeMap$ map (line 27). Once all systems in $systemList$ have been processed, the algorithm returns $systemCalleeMap$.

Time Complexity Analysis

Theorem III.1. *Let n be the total number of systems in $systemList$, m be the maximum number of lines in the $lineList$ and k be the maximum number of lines in the $line.getBranches()$. The time complexity of Algorithm 1 is O($n * m * k$).*

Proof: From Algorithm 1, we see that the $foreach$ loop at lines 3 - 30 iterates n times, resulting in time complexity of this loop is O(n). Lines 4 - 6 check the type of each system. If the $systemType$ is "$From$", its find the corresponding "To" system. This check has a time complexity O(1) for each system. Line 8 finds $lines$ connected to the system, which has time complexity O(1) for each system. Line 9 - 28 iterate through each line connected to the system: Line 14 - 20 handle lines with branches, iterating through each branch and finding the connected systems. This has a time complexity of O(k) in the worst case, where k is the maximum number of branches for any $line$ in $lines$. Line 21 - 26 handle lines without branches, finding the connected system. This has a time complexity of O(1) for each line. Since we need to consider all lines of the system, the time complexity for processing lines is O($m * k$). Combining these steps, the total time complexity for processing each system and its connected lines is O($m * k$) in the worst case. For this reason, iterating over all n systems results in an overall time complexity of O($n * m * k$) of Algorithm 1. ■

3) Call graph generation: Once the callee map is prepared, Simulysis proceeds to generate the call graph, which will be utilized later in the CIA process.

The generation of this call graph for a given Simulink project is detailed in Algorithm 2.

The algorithm takes as input the list of systems from Step 1 ($systemList$) and the callee map from Step 2 ($systemCalleeMap$). After processing, the algorithm outputs the desired call graph. The process begins by initializing the call graph as an empty set ($\emptyset$). It's important to note that Simulink already generates a unique identifier, known as SID. For this reason, Simulysis leverages this SID value as the identifier for each node in the call graph. The algorithm iterates over each system ($system$) in the system list ($systemList$), retrieving the SID of the system (line 4). It then either retrieves an existing node or creates a new one in the call graph ($callGraph$) that corresponds to the system ($system$) (line 5). Next, the algorithm fetches the callee list ($calleeList$) of the system ($system$) from the callee map ($systemCalleeMap$) (line 6). It then cycles through the callee list ($calleeList$), identifies the node corresponding to the callee system node in the call graph, and establishes an edge between the callee and caller (lines 7 - 11). This entire process is repeated for each system (lines 3 - 12). Finally, the algorithm returns the call graph (line 13).

Time Complexity Analysis

Algorithm 2 Generate the Corresponding Call Graph for a Simulink Project

Input: $systemList$: List of systems in the project
$systemCalleeMap$: A map of callees by system
Output: $callGraph$: The corresponding call graph of the project

```
1  begin
2      callGraph ← ∅
3      foreach system in systemList do
4          systemSID ← getSystemSID(system)
5          node ← getOrCreateNode(callGraph, systemSID)
6          calleeList ← getCallees(systemCalleeMap, system)
7          foreach callee in calleeList do
8              calleeSystemSID ← getSystemSID(callee)
9              calleeNode ← getOrCreateNode(callGraph, calleeSystemSID)
10             createEdge(callGraph, node, calleeNode)
11         end
12     end
13     return callGraph
14 end
```

Theorem III.2. *Let n be the total number of systems in $systemList$, and m be the maximum number of callee systems for any system in $systemList$. The time complexity of Algorithm 2 is O($m * n$).*

Proof: From Algorithm 2, we see that the $foreach$ loop at lines 3 - 12 iterates n times, resulting in time complexity of this loop is O(n). Given a specific system ($system$) in the loop, other actions in this loop at lines 4 - 6 are getting the system id ($systemSID$), its corresponding node ($node$), and its list of callee systems ($calleeList$). These are simple actions that retrieve data from a data store such as a database or file, resulting in a time complexity of O(1). Let m be the maximum number of callee systems in all $calleeList$, the second loop (line 7 - 11) will have time complexity of O(m). As a result, the overall time complexity of this algorithm is O($m * n$). ■

4) Signal tracing method: In large Simulink projects, when facing a bug, especially a signal-related bug, system engineers must be able to fix the bug by checking the signal to find the bug. We call this the signal tracing problem. This is a complex task as the signal can go from the inport through multiple levels of the system model to the outport of the model. Using the corresponding call graph, the signal tracing problem can be modeled as the path-finding problem inside a directed graph.

It is important to identify the relationships between objects in Simulink models to implement the Depth-First Search algorithm (DFS). To reduce the complexity of the algorithm, Simulysis proposes identifying relationships between objects, including systems, lines, and branches. There are six types of relationships: System-Line, Line-Branch, Branch-Branch, Branch-System, From-Goto, and Parent-Child.

System-Line Relationship The System-Line relationship is the most common in the Simulink model, defined through the object's ID attribute. Fig. 8 illustrates an example of information about systems and one line in an ".slx" file. It can be seen that objects are connected through ID values; each block has a unique ID value that does not duplicate any other block within the same file. The line will have two child tags <P> with the attributes "Name=Dst" and "Name=Src". The value of the "Name=Dst" tag will match the ID value of a system in the file, indicating that it is the destination system. The value of the "Name=Src" tag will indicate the source system.

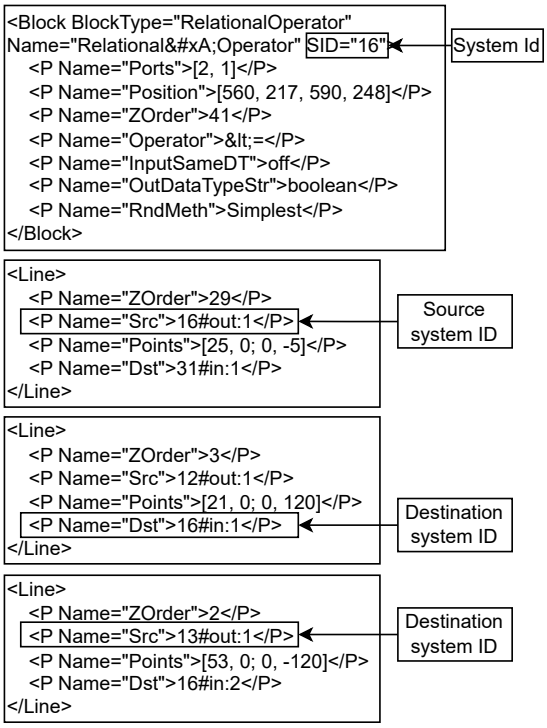

Fig. 8. System-line relationship.

System-Branch Relationship

Fig. 9 illustrates an example of the System-Branch relationship. Similar to the System-Line relationship, the System-Branch relationship is determined by the ID value. The value of the child tag "Name=Dst" will also indicate the destination system connected by the branch. However, unlike a line, a branch will not have a child tag <P> with the attribute "Name=Src".

Line-Branch Relationship

A branch is defined as a child object of a line in Simulink in the model. A connection line can have multiple branch lines. Fig. 10 describes the information about a line in the ".slx" file. The <Line> tag contains two child tags ¡Branch¿ that represent the line with two corresponding branch lines.

Branch-Branch Relationship

Similar to the Line-Branch relationship, the Branch-Branch relationship is formed when a branch contains child tags that are other branches, as shown in Fig. 11.

Goto-From Relationship

Goto and From are two special types of blocks, where a Goto block can transmit a signal to a corresponding From block and vice versa. The notable point is that these two

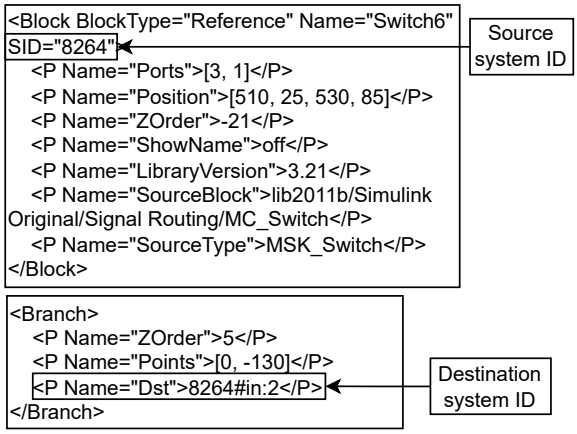

Fig. 9. System-Branch Relationship.

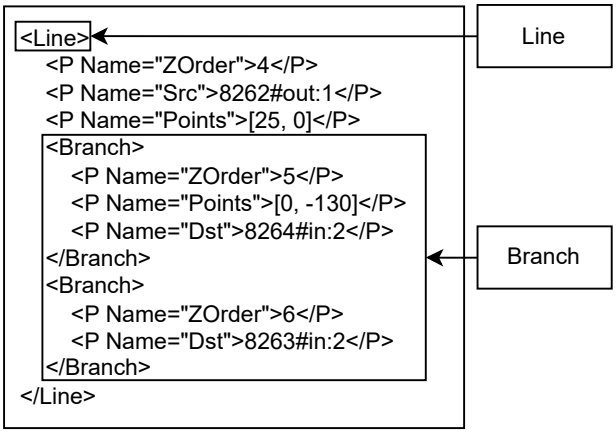

Fig. 10. Line-branch relationship.

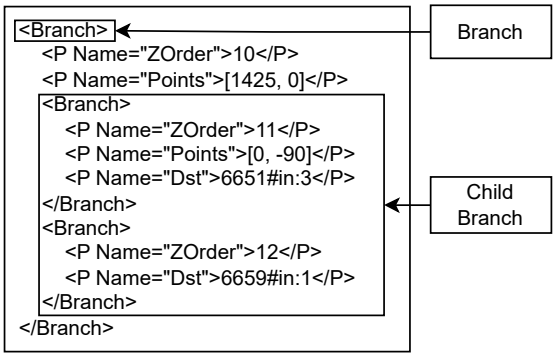

Fig. 11. Branch-branch relationship.

blocks do not connect with each other through a line. A Goto block can connect with multiple From blocks located at different positions in the model. The Goto-From relationship is determined through the GotoTag parameter. Two blocks with the same GotoTag value are considered to be connected. As shown in Fig. 12, the GotoTag value of both blocks is "xclcn", so they are connected.

Parent-Child Relationship

A system is called a parent if it contains a subsystem; the

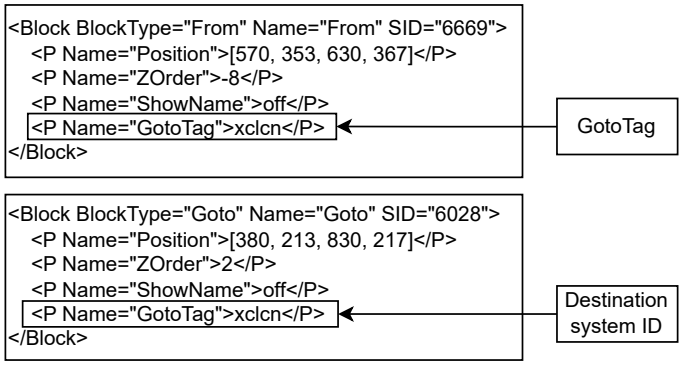

Fig. 12. Goto-from relationship.

objects within the subsystem will be children of that block. In the structure of a MATLAB Simulink model, Simulysis identifies three types of systems that contain subsystems: "Subsystem", "ModelReference", and "Reference". The "ModelReference" and "Reference" blocks have similar structures; the files containing the subsystems of these two types of blocks will be in different files within the project. The "Subsystem" block has a simpler structure, with its subsystem contents residing in the same file as the current model. Fig. 13 describes an example of a line being the input to a subsystem.

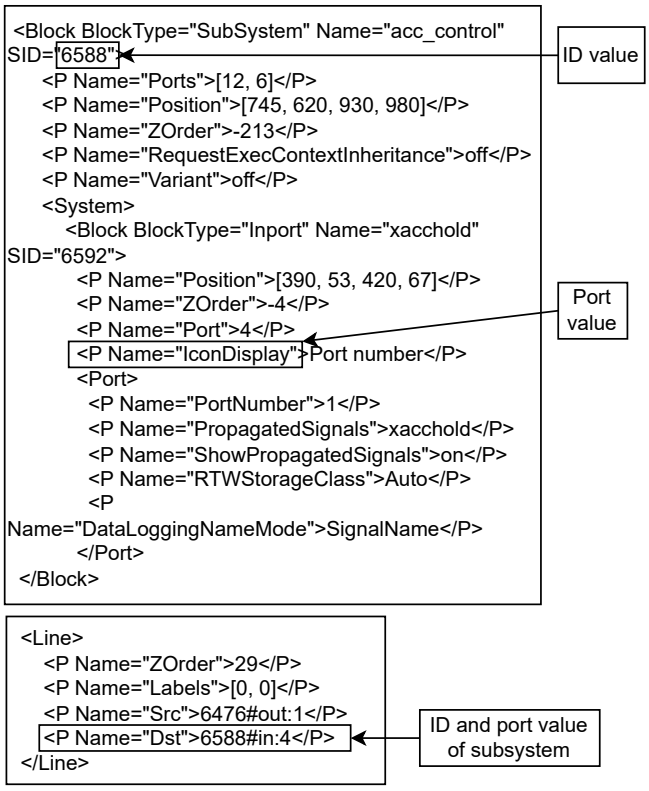

Fig. 13. Parent-child relationship

In this figure, the subsystem will be connected to the parent system through the Port value. A line/branch line will be an input to a subsystem if it contains a child tag <P> with the attribute "Name=Dst" having an ID value matching the parent system's ID value and the destination Port value matching an

input Port value of the parent system. Similarly, a line will be an output of the subsystem if it contains a child tag <P> with the attribute "Name=Src" having an ID value matching the parent system's ID value and the source Port value matching an output Port value of the parent system.

Signal Tracing Algorithm

Simulysis uses a DFS algorithm to traverse the call graph with the support of a stack of nodes. We maintain the three global parameters to support the DFS traversing algorithm. First, $pathList$ is the list of all paths from the $startNode$ to $endNode$. Second, $path$ is a temporary variable for storing the path being processed. Third, $stack$ is a stack data structure to store nodes of the call graph being processed. The algorithm accepts $startNode$ and $endNode$, which are the start and end nodes of the signal being checked. When the algorithm finishes running, $pathList$ stores the list of all paths from $startNode$ to $endNode$. Details of the algorithm are shown in Algorithm 3.

Algorithm 3 Signal Tracing

Input: $startNode \in callGraph$: the start node of the $path$ being checked.
$endNode \in callGraph$: the end node of $path$ being checked.
Output: The list of paths is stored in $pathList$

```
1  begin
2      pathList, path, stack ← ∅
3      stack.push(startNode)
4      while stack is not empty do
5          curNode ← stack.pop()
6          path ← path ∪ {curNode}
7          if curNode is endNode then
8              newPath ← clone_path(path);
9              pathList ← pathList ∪ {newPath});
10             if stack is not empty then
11                 curNode ← stack.pop()
12                 path ← remove_visited_nodes(path, curNode)
13                 call Algorithm 3(curNode, endNode);
14             end
15         else
16             childList ← get_child_nodes(curNode)
17             foreach child in childList do
18                 stack.push(child)
19             end
20             if stack is not empty then
21                 curNode ← stack.pop()
22                 call Algorithm 3(curNode, endNode);
23             end
24         end
25     end
26 end
```

The algorithm starts by initializing the path list ($pathList$), temporary path ($path$), and the stack data structure ($stack$) as empty sets ($\emptyset$) (line 2). Then, the algorithm push $startNode$ to the $stack$ (line 3). While the $stack$ is not empty, the algorithm does the following smaller tasks. First, the algorithm retrieves the top node from the stack ($stack$) and adds it to the temporary path ($path$) (lines 5 - 6). In case the current node ($curNode$) is the end node ($endNode$), we have found one path from the start node ($startNode$) to the end node ($endNode$). The algorithm adds the cloned path ($newPath$) of $path$ to the path list ($pathList$) (lines 8 - 9). We clone the path to ensure that later changes does not affect the cloned path. Next, the algorithm finds the next path from the start node ($startNode$) to the end node ($endNode$). If the stack ($stack$) is not empty, the algorithm retrieves the current node ($curNode$) from the top node of the stack (line 11). After getting the previous path, currently, $path$ still contains nodes from the previous path. We remove all unnecessary nodes from $path$ (line 12). These nodes are all nodes from the end of $path$ to the sibling nodes of $curNode$ that previously belonged to $path$. Then, the algorithm recursively calls itself to find paths from the current node ($curNode$) to the end node ($endNode$) (line 13).

In case the current node ($curNode$) is not the end node ($endNode$), the algorithm retrieves all next nodes (we call them child nodes) ($childList$) in the directed call graph (line 16) and pushes them to the stack ($stack$) (lines 17 - 19). Then, if the stack ($stack$) is not empty, the algorithm retrieves the top node ($curNode$) and recursively calls itself to find path from the current node ($curNode$) to the end node ($endNode$) (lines 20 - 23).

The time complexity of Algorithm 3 is $O(V, E)$, where V and E is the sets of nodes and edges in the call graph [41].

C. Change Set Computation

Simulysis generates call graphs corresponding to two versions of a Simulink project, as outlined in Algorithm 2. For impact analysis using the WAVE-CIA method, it's necessary for Simulysis to identify the change set between these two call graph versions. The process relies on the use of the "Name" and "SID" properties of a Simulink block to determine its presence across both graph versions. If a block is found in both versions, Simulysis examines if any of its properties have changed. If a change is detected, the block is marked as changed. The specifics of this process are detailed in Algorithm 4.

Algorithm 4 Compute the Change Set

Input: $callGraphBefore$, $callGraphAfter$
Output: $changeSet$

```
1  begin
2      changeSet, changedList, addedList, deletedList ← ∅
3      foreach node in callGraphAfter do
4          if ¬ NodeExistsIn(node, callGraphBefore) then
5              AddToList(node, addedList)
6          end
7          if NodeExistsIn(node, callGraphBefore) and
             PropertyChanged(node, callGraphBefore,
             callGraphAfter) then
8              AddToList(node, changedList)
9          end
10     end
11     foreach node in callGraphBefore do
12         if ¬ NodeExistsIn(node, callGraphAfter) then
13             AddToList(node, deletedList)
14         end
15     end
16     changeSet ← toSet(addedList, deletedList,
         changedList)
17     return changeSet
18 end
```

Algorithm 4 takes in two call graphs ($callGraphBefore$, $callGraphAfter$) corresponding to two versions of a given Simulink project. The output is the required change set ($changeSet$). The algorithm begins by initializing the change set ($changeSet$) and three temporary lists: $changedList$, $addedList$, and $deletedList$ as empty set ($\emptyset$). For each $node$ in $callGraphAfter$, the algorithm checks if the node also exists in $callGraphBefore$. If it does not, the node is considered as added and is added to the added node list ($addedList$) (lines 4 - 6). If the node exists in $callGraphBefore$ and any of its properties have changed in the two graphs (detected by the changes in the text of properties), the node is added to the change list ($changedList$) (lines 7 - 9). The algorithm then checks for any node that exists in $callGraphBefore$ but not in $callGraphAfter$. Such a node is considered as deleted and is added to the deleted node list ($deletedList$) (lines 11 - 15). Finally, the algorithm adds the three lists: $addedList$, $deletedList$, and $changedList$ to the $changeSet$ (line 16) and returns the result.

Time Complexity Analysis

Theorem III.3. *Let n be the maximum number of nodes in the call graphs for both the previous and updated project versions. The time complexity of Algorithm 4 is O(n).*

Proof: Let m be the number of nodes in the call graph corresponding to the new project version ($callGraphAfter$). From Algorithm 4, it is evident that the $foreach$ loop at lines 3 - 10 has a time complexity of O(m). In this loop, thanks to the utilization of the hash table data structure, the action that verifies if a node exists in a call graph has a time complexity of O(1) (line 4 and line 7). The functions $PropertyChanged$ and $AddToList$ are straightforward functions with a time complexity of O(1), resulting in the time complexity of this loop being O(m). Let k be the number of nodes in the call graph corresponding to the old project version ($callGraphBefore$). Following the same reasoning as above, the loop at lines 11 - 15 would have a time complexity of O(k). The $toSet$ function at line 16 is a simple function with a complexity of O(1). From the above analysis, let $n = max(m, k)$, the overall time complexity of the algorithm is O($max(m, k)$)≡O(n). ■

D. Impact Set Computation

Upon obtaining the change set from Phase 2, Simulysis proceeds to compute the impact set. This set includes Simulink files and systems that are influenced by the Simulink components present in the change set. Given a call graph and a change set, which is a subset of the call graph, Simulysis follows a two-step process to calculate the impact set. The first step involves the computation of the core set, which includes the computation of the neighbor set as detailed in Section III-D1. The second step is the computation of the impact set itself.

1) Neighbor Set Computation: In WAVE-CIA, a core set comprises Simulink systems that are potentially influenced by several systems within the change set. The computation of the core set utilizes the concept of a neighbor set associated with a given component. A neighbor set of a specific component, with a depth of n, includes other components in the call graph that can be reached via a maximum of n edges.

The parameter "depth" plays a crucial role in the zoning of the Coreset. The depth parameter significantly impacts the accuracy and efficiency of the Coreset. Depth determines the level at which data points are considered and clustered within the Coreset. A higher depth value implies a finer granularity, resulting in more detailed and potentially more accurate coresets, whereas a lower depth value leads to a more generalized and coarser representation of the data. To identify the optimal depth for a specific problem, empirical experimentation is essential. The appropriate depth varies depending on the nature of the dataset and the specific requirements of the analysis. By conducting experiments with varying depth values, we can evaluate the performance and accuracy of the resulting Coreset, thereby determining the most suitable depth parameter for their particular application.

Simulysis employs a recursive algorithm to identify the neighbors of a specific system node within the call graph. The procedure for determining the neighbor set is detailed in Algorithm 5.

Algorithm 5 Compute the Neighbor Set

Input: $systemNode$: a given system in a call graph
$depth$: The maximum edges between two Simulink to consider neighbors
$callGraph$: The call graph being analyzed
Output: $neighborSet$: The required neighbor set

```
1  begin
2      systemNode.isVisited ← true
3      neighborSet ← ∅
4      callers ← findCallers(systemNode, callGraph)
5      callees ← findCallees(systemNode, callGraph)
6      neighborSet ← neighborSet ∪ callers ∪ callees
7      if depth ≤ 1 then
8          return neighborSet
9      end
10     foreach neighborNode ∈ neighborSet and
         neighborNode.isVisited = false do
11         subNeighborSet ← call Algorithm 5(neighborNode,
             depth − 1, callGraph)
12         neighborSet ← neigborSet ∪ subNeighborSet
13     end
14 end
```

The algorithm initiates by marking the $systemNode$ as visited (line 2) and setting the $neighborSet$ as an empty set ($\emptyset$) (line 3). It then identifies the direct caller ($callers$) and direct callee ($callees$) lists of the current node, and appends these lists to the neighbor set (lines 4 - 5). This step locates all neighbor nodes that are connected to the current $systemNode$ via a single edge. The recursion terminates when $depth \leq 1$ (lines 7 - 9). Subsequently, for each unvisited $neighborNode$ in the $neighborSet$, the algorithm recursively calls itself to find the neighbor set ($subNeighborSet$) of the $neighborNode$ and adds it to the $neighborSet$ (lines 10 - 13). In this step, the algorithm locates all direct neighbors of the $neighborNode$, hence the parameter $depth$ must be $depth-1$. Upon termination of the algorithm, we obtain the neighbor set of the given $systemNode$, with a $depth$ number equivalent to the number of edges from the $systemNode$.

2) Time Complexity Analysis:

Theorem III.4. *Let n be the total number of nodes in the call graph, d be the maximum degree of any node in the call graph, and k be the specified depth. The time complexity of Algorithm 5 is O($n * d^k$).*

Proof: From Algorithm 5, we see that lines 4 - 5 finds direct callers and callees of $systemNode$ and adds them to $neighborSet$ which involves checking connections and has a time complexity of O(d) since d is the maximum degree of any node. Lines 7 -9 checks if $depth$ is less than or equal to 1 and, if so, returns $neighborSet$, which has a time complexity of O(1). Line 10 - 13 handle the recursive exploration of neighbors. For each unvisited neighbor in $neighborSet$, the algorithm recursively calls itself with $depth-1$. This recursion explores up to k levels, and at each level, it may process up to d neighbors. The time complexity for exploring neighbors at each level is O(d), and since the recursion depth is O(d^k). Given that there are n nodes in the call graph and in the worst case, each node needs to process its neighbors, the overall time complexity of the algorithm is O($n * d^k$). As a result, the overall time complexity of this algorithm is O($n * d^k$). ■

3) Core Set Computation: The computation of the core set is a crucial step in the WAVE-CIA method. This computation depends on the change set, and its outcome is subsequently utilized to calculate the impact set. The specifics of the core set computation process can be found in Algorithm 6.

Algorithm 6 Compute Core Set

Input: $callGraph$: The call graph of the Simulink project
$changeSet$: A set of components that have been changed
$depth$: An integer specifying the neighbor set exploration depth
Output: $coreSet$: the required core set

```
1  begin
2      coreSet ← ∅
3      foreach node ∈ callGraph do
4          if node ∉ changeSet then
5              neighborSet ← call Algorithm 5(node, depth, callGraph)
6              if —neighborSet ∩ changeSet— > 1 then
7                  coreSet ← coreSet ∪ {node}
8              end
9          end
10     end
11     coreSet ← coreSet ∪ changeSet
12     return coreSet
13 end
```

The algorithm takes in three inputs: the call graph ($callGraph$), the change set ($changeSet$), and an integer ($depth$) that determines the extent of the neighbor set computation. The output is the desired core set ($coreSet$). The algorithm starts by initializing the core set as an empty set ($\emptyset$) (line 2). It then iterates over each node ($node$) in the call graph ($callGraph$) that is not in the change set ($changeSet$), and invokes Algorithm 5 to compute the neighbor set ($neighborSet$) of the node (line 5). If the $neighborSet$ and $changeSet$ share more than one node, the node is added to the $coreSet$ (lines 6 - 8). After all nodes in the $callGraph$ have been checked, he algorithm incorporates the $changeSet$ into the $coreSet$, as the core set is a superset of the change set (line 11). The algorithm concludes by returning the $coreSet$ (line 12).

Time Complexity Analysis

Theorem III.5. *Let n be the total number of nodes in the call graph, d be the maximum degree of any node in the call graph, and k be the specified depth. The time complexity of Algorithm 5 is $\mathcal{O}(n \times d^k)$.*

Proof: From Algorithm 6, we see that line 2 initializes the core set with a time complexity of $\mathcal{O}(1)$. Lines 3 - 10 iterate through each node in the call graph that is not in the change set. For each node, line 5 calls Algorithm 5 to compute the neighbor set, which has a time complexity of $\mathcal{O}(d^k)$ since Algorithm 5 explores up to k levels of neighbors. Line 6 checks the intersection of the neighbor set and the change set, which involves set operations with a time complexity of $\mathcal{O}(d)$. Line 7 adds the node to the core set if the intersection condition is met, with a time complexity of $\mathcal{O}(1)$. Line 11 merges the change set into the core set, which has a time complexity of $\mathcal{O}(n)$ in the worst case. Given that there are n nodes in the call graph and each node's neighbor set computation involves $\mathcal{O}(d^k)$ operations, the overall time complexity of the algorithm is $\mathcal{O}(n \times d^k)$. ■

4) Impact set calculation: Although the core set is expected to encompass many components affected by the change sets, other impacted components may not be included in the core set. Consequently, it becomes necessary to broaden the change ripple to account for additional impacts that might have been overlooked, or in simpler terms, to enlarge the core. The fundamental concept of this procedure is that any node not already in the impact set will be added if both its caller and callee sets share nodes with the existing impact set. The specifics of this procedure can be found in Algorithm 7.

Algorithm 7 Compute the Impact Set

Input: $callGraph$: The call graph of the Simulink project
$coreSet$: A core set
Output: $impactSet$: the required impact set

```
1  begin
2      impactSet ← coreSet
3      isStable ← false
4      while not isStable do
5          isStable ← true
6          foreach node ∈ callGraph do
7              if node ∉ impactSet then
8                  callerSet ← findCallers(node, callGraph)
9                  calleeSet ← findCallees(node, callGraph)
10                 if —callerSet ∩ impactSet—>0 and —calleeSet ∩ impactSet—>0 then
11                     impactSet ← impactSet ∪ {node}
12                     isStable ← false
13                 end
14             end
15         end
16     end
17     return impactSet
18 end
```

Algorithm 7 takes in two inputs: the call graph ($callGraph$) and the core set ($coreSet$). It outputs the desired impact set

($impactSet$). The algorithm begins by initializing the impact set ($impactSet$) with the core set ($coreSet$) (line 2). It then continuously checks each node in the call graph that is not in the impact set to determine if it has at least one caller and one callee within the impact set. If it does, the node is considered to be impacted by the change set (lines 6 - 15). This process is repeated until the impact set reaches a state of stability, where no additional nodes are added during the checking process. The stability of the impact set is monitored using a boolean flag, $isStable$ (line 3), which is initially set to true $true$ (line 5) at the start of the call graph checking loop (lines 6 - 15). This flag is reset to $false$ when a new node is added to the impact set (line 12). If the flag remains $false$ after the loop, the loop is rerun. If not, the algorithm terminates the loop and returns the impact set ($impactSet$) (line 17).

Time Complexity Analysis

Theorem III.6. *Let n be the total number of nodes in the call graph, and d be the maximum degree of any node in the call graph. The time complexity of Algorithm 6 is $\mathcal{O}(n \times d)$.*

Proof: From Algorithm 7, we see that line 2 initializes the impact set with a time complexity of $\mathcal{O}(1)$. The outer loop (lines 4 - 16) repeats until no changes occur, and within each iteration, the inner loop (lines 6 - 15) iterates through each node in the call graph. Line 10 checks the intersections of the caller set and callee set with the impact set, each of which involves set operations with a time complexity of $\mathcal{O}(d)$. Lines 11 - 12 add the node to the impact set if the conditions are met and set the changed flag, both of which have a time complexity of $\mathcal{O}(1)$. Assuming the algorithm stabilizes after a constant number of iterations, the time complexity for each iteration through the call graph is $\mathcal{O}(n \times d)$. Therefore, the overall time complexity of the algorithm is $\mathcal{O}(n \times d)$. ■

IV. Implementation

We've developed a tool named Simulysis[2], utilizing the MVC framework and C#.NET within the Microsoft Visual Studio IDE. The architecture of Simulysis, depicted in Fig. 14, comprises three primary components.

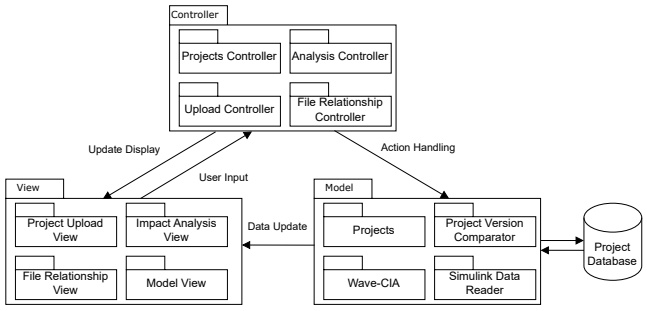

Fig. 14. The Simulysis architecture.

- Model: The Model component, encompassing four sub-components, is tasked with managing project data. The Projects sub-component oversees the information of Simulink projects. The Simulink Data Reader extracts and handles crucial data from Simulink projects. The Project Version Comparator sub-component performs comparisons between different versions of Simulink projects. Lastly, the WAVE-CIA sub-component carries out the change impact analysis.
- Controller: The Controller component, composed of four sub-components, acts as a bridge, overseeing user interactions and the flow of the application. The four sub-components include the Upload Controller, Project Controller, Analysis Controller, and File Relationships. These are tasked with handling requests on project uploads, project information management, project file and structure analysis, and file relationship management, respectively.
- View: The View component displays necessary information via interface packages such as Project Upload View, File Relationship View, Impact Analysis View, and Model View. These views facilitate the user interface for Simulink project uploads, file relationship management, impact analysis execution, and the visualization of changes and impacts within a specific project, respectively.

Fig. 15 and 16 display Simulysis screens, showcasing a standard Simulink file. The screen is divided into three sections, each marked with numbers for straightforward reference. The three sections are described as follows.

- Section 1: This section displays the differences between two specified file versions within the Simulink project. It features a search bar and tabs labeled "Added", "Changed", "Deleted", and "Impacted". These tabs categorize the systems, which are listed with an option to adjust their visibility.
- Section 2: This section outlines the functionalities associated with the WAVE-CIA method. It comprises two components: a dropdown list for selecting the *depth* of the Core set computation, and a button to initiate the WAVE-CIA analysis.
- Section 3: This section displays the Model View of the chosen Simulink file. It illustrates the Simulink systems (blocks) using the data of blocks and lines extracted from Simulink files, as detailed in Section III-B1. In this view, systems that have been added are highlighted in green; changed systems are marked in orange; and impacted systems are indicated in cyan. Other systems are either not filled or their color is determined by their properties.

V. Experiments

To assess the practical utility and efficacy of Simulysis, we have conducted tests using various open-source projects. These projects, sourced from GitHub[3], have a Git history of committed changes to Simulink source files. The projects include the following:

[2]https://github.com/KaoSon2004/Simulysis-CIA

[3]https://github.com/

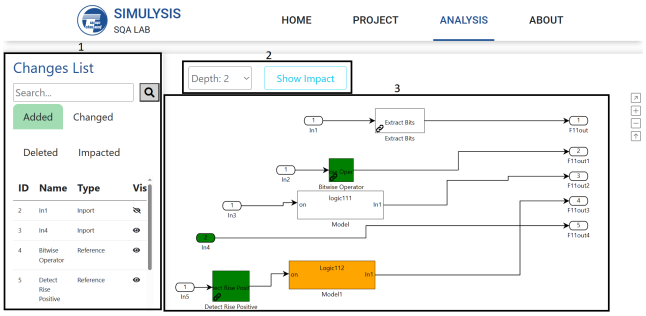

Fig. 15. An example of Simulink file in Simulysis.

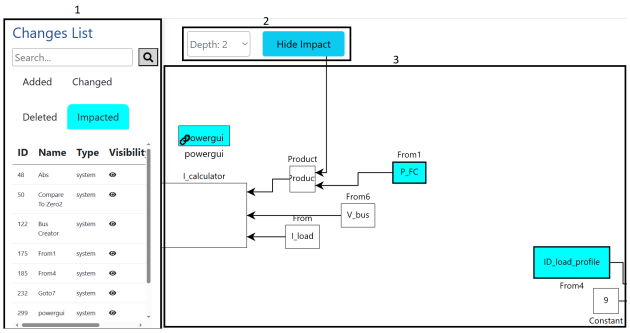

Fig. 16. An example of impacted systems in Simulysis.

- **Intelligent-EMS**[4]: This project aims to explore the feasibility of a Machine Learning-based Energy Management System (EMS) for an inboard DC-grid. The main energy source is hydrogen (Fuel-Cell), supplemented by a battery for quick load adjustments. In this project, Simulink is utilized for simulating a DC chip. For our experiment, we employed commit 5d200f (representing the old version) and commit 72216a (representing the new version).
- **Failure Detection and Fault Tolerant Control of a Jet-Powered Flying Humanoid Robot**[5] (called Failure Detection): This project involves Simulink source code used to conduct experiments for the related paper [42]. In our experiments, we utilized commit f0ed42 to represent the old version and commit 9427f4 for the new version.
- **FMT-Model**[6]: The Firmament Model (FMT Model) is a crucial part of the Firmament Autopilot project. This model provides a thorough simulation framework, along with algorithm libraries that have been carefully developed using MATLAB/Simulink. For our experiments, we referred to commit 37b5ae to represent the old version and commit f3c154 for the new version.
- **Reinforcement Learning for Control of Valves**[7] (called Reinforcement Learning): This project leverages Simulink to investigate the application of Reinforcement Learning for optimal control of non-linear systems. We conducted our experiments using two different versions of the system, represented by commit 171ef7 (the older version) and commit 25dc044 (the newer version).
- **Kugle**[8]: This project employs Simulink to make a self-balancing robot equipped with three omni wheels. Our experiments were conducted using two versions of the system, represented by commit 3be7e7 (the older version) and commit b1ee16 (the newer version).
- **Propulsion System Model**[9]: This project employs Simulink in the design of a Hybrid Motor Nitrous Oxide Rocket Propulsion System. Our experiments were conducted using two versions of the system, represented by commit 1994f02 (the older version) and commit 7aba367 (the newer version).

The five Simulink projects were chosen based on their increasing size and complexity, ranging from small and simple to large and complex, to comprehensively evaluate the effectiveness of the proposed method. These projects are well-known within the Simulink community, ensuring the results are relevant and applicable to commonly used projects. Additionally, the selected projects are complex enough to simulate real-world scenarios, demonstrating that the proposed method can be effectively applied in practical settings. By selecting projects with varying sizes and complexities, we ensure a thorough and representative assessment of the Simulysis method's performance in actual applications, implicitly suggesting its viability for real-world projects.

The experiments are performed on a server with the following configuration: Intel® Core™ i5-7300HQ @ 2.50 GHz, RAM: 16GB RAM. In our experiments, we set *depth = 3* for the core set computation. We checked the accuracy of the results by cross-referencing them with MATLAB's Simulink tool and calculated the following key metrics to evaluate the effectiveness of the Simulysis method: the number of changed systems (blocks), the number of impacted systems, the total number of systems in the new project version, the percentage of impacted systems in the new project version, the amount of memory required, and the time taken to perform the experiments. The results of these experiments are presented in Table VI. In this table, the columns are as follows:

- **Project**: the project under consideration.
- **CB**: number of changed blocks between the two versions.
- **IB**: number of impacted blocks in the new version.
- **TB**: total number of blocks in the new project version.
- **%**: percentage of impacted blocks within the new project (= IB/TB).
- **Mem (MB)**: amount of the required memory (in MB).
- **Time (s)**: The time (in seconds) taken to compute the impact set.

TABLE VI. EXPERIMENTAL RESULTS

Project	CB	IB	TB	%	Mem (MB)	Time (s)
Intelligent-EMS	88	126	397	31.73	1.31	0.123
Failure Detection	16	26	1059	2.46	4.33	0.35
FMT-Model	2085	2668	9700	27.51	16.64	1.911
Reinforcement Learning	118	156	396	39.39	0.65	0.232
Kulge	263	322	1240	25.97	2.72	0.288
Propulsion	189	269	1115	24.13	5.78	0.767

Based on the experimental results presented in Table VI, we can make the following observations:

- For the "Intelligent-EMS" project, out of 397 blocks, 23 are impacted, which constitutes 5.79% of the total.
- For the "Failure Detection" project, out of 1059 blocks, 26 are impacted, which represents 2.46% of the total.
- For the "FMT-Model project", out of 9700 blocks, 289 are impacted, which represents 2.98% of the total.
- For the "Reinforcement Learning" project, out of 396 blocks, 50 are impacted, which represents 12.63% of the total.
- For the "Kugle", out of 1240 blocks, 76 are impacted, which represents 6.13% of the total.
- For the "Propulsion", out of 1115 blocks, 75 are impacted, which represents 6.73% of the total.
- In comparing the change calculation results, we found them to be accurate when cross-checked with MATLAB's Simulink model comparison tool. For the impact analysis, we tested our implementation and confirmed it aligns correctly with the WAVE-CIA algorithm. However, the correctness of the WAVE-CIA algorithm itself is beyond the scope of this discussion.
- For the largest project (FMT-Model), which comprises a total of 9700 systems, the memory and time consumption is 24.25 MB and 14.79 seconds, respectively. Given the current capabilities of memory and processing, we consider this to be acceptable. This demonstrates the practical applicability of Simulysis for real-world projects.
- While it appears that the memory and time usage may be proportional to the number of changed and impacted systems, there is no definitive evidence to support this observation.

VI. RELATED WORKS

Numerous studies have been conducted on the Change Impact Analysis (CIA) issue, specifically about Simulink projects and more generally, software projects. In this section, we focus solely on the most relevant studies and tools [37], [5], [6], [40], [43], [44], [3], [45].

In the realm of model-based testing, many researchers have made significant contributions to UML impact analysis. In 2003, Briand et al. introduced a UML model-based approach to impact analysis that can be implemented prior to any changes [43]. Initially, they ensure the consistency of the UML diagrams. Subsequently, they identify the modifications between two distinct versions of a UML model. Following this, they determine the model elements that are directly or indirectly affected by these changes using impact analysis rules (formulated in Object Constraint Language). Our interest aligns with Briand's in the area of software change impact analysis. However, our approach involves analyzing the source code of Simulink projects to construct the call graph and applying the WAVE-CIA method to compute the impact set.

In 2010, Fourneret et al. introduced an automated model-based impact analysis [44]. Fourneret's approach involves a set of algorithms that identify dependent and impacted elements following the detection of changes in a UML/OCL Statechart diagram. This allows an engineer to pinpoint the critical aspects of the software and determine which functionalities require regression testing. While our interests align with Fourneret's in the area of software system regression testing, our focus is specifically on the change impact analysis of Simulink projects.

In 2010, Li et al. introduced the WAVE-CIA method, a novel approach for calculating the impact set derived from the call graph of various types of software projects [3]. Our work aligns with this interest in change impact analysis. However, our application of the WAVE-CIA method is specifically tailored to Simulink projects. We construct the call graph using Simulink files and subsequently apply the WAVE-CIA method to these generated call graphs.

Diffplug [37] conducts impact analysis of Simulink projects using a straightforward method known as signal tracing. This method allows users to select a block and trace its signal, enabling them to determine the potential impact of a block change. However, Diffplug necessitates that users manually navigate through each level of the model to identify the impacted target inputs and/or outputs. Conversely, Simulysis automates this process by analyzing the project, calculating changes, and computing the impact set using the WAVE-CIA method.

In 2017, Rapos and Cordy introduced SimPact, a method and tool for analyzing the impact of changes in Simulink models [5]. SimPact's impact analysis of a Simulink model involves two stages: change isolation and the determination of the impact of changes on test values. Initially, SimPact identifies the differences between two versions of a model. Subsequently, it assesses the potential impact of these changes

on inputs and outputs by traversing the entire model hierarchy, tracing, and highlighting all potential impacts from a specific block at all levels. While our interest in the impact analysis of Simulink projects aligns with that of SimPact, there are key differences between SimPact and Simulysis. In the change isolation phase, SimPact utilizes the model differencing script of Rapos and Cordy [46], which employs the internal Simulink comparison operator. Conversely, Simulysis directly analyzes the Simulink project to construct the call graph and compares the two call graph versions to identify the change set. In the impact analysis phase, SimPact depends on the caller-callee relationship to identify the impact set, which is fundamentally different from Simulysis, which uses the WAVE-CIA method to determine the impact set.

In 2020, Bennett et al. introduced the Boundary Diagram Tool (BDT), a method designed for change impact analysis of large Simulink projects within embedded systems [6]. BDT conducts impact analysis by tracing changes throughout the Simulink model. Our work aligns with this interest in Simulink project impact analysis. However, our approach differs as we directly analyze Simulink projects to construct the call graph and utilize the WAVE-CIA method to compute the impact set.

In 2021, Jaskolka et al. [40] conducted an examination of real industrial software repositories and their version control systems to gain insights into potential changes in Simulink. Their intention was to guide the usage of Simulink in industrial practices and understand the distribution of change types in Simulink projects. However, Simulysis differs fundamentally in its objectives, as it primarily aims to compute the impact set.

In 2023, Tran et al. developed CIA4CS, a method specifically designed for Change Impact Analysis (CIA) of C# projects, based on the WAVE-CIA approach [45]. CIA4CS fills a significant void in existing methodologies, considering the widespread use of the C# language in the software industry. The method utilizes static code analysis to build dependency graphs, which then facilitates the application of the WAVE-CIA. The authors have integrated CIA4CS into a tool and conducted tests on a variety of C# projects. Their experiments demonstrated the tool's efficiency in analyzing project components, dependencies, and the elements impacted across different versions. While our interests align with Tran's in terms of the CIA and the WAVE-CIA method, our focus is specifically on the CIA of Simulink projects.

VII. Conclusion

We have introduced Simulysis, a method designed for the change impact analysis of Simulink projects. When provided with two versions of a Simulink project, Simulysis performs the CIA by constructing the call graph from the files, identifying the changes, and calculating the impact set using the WAVE-CIA method. We have incorporated this method into a tool, also named Simulysis, and conducted several experiments on open-source projects, yielding promising results. Further discussion about the method is provided in the paper.

Looking ahead, we envision several enhancements to Simulysis to augment its capabilities. Firstly, we are actively working on improving the speed of call graph construction and refining the algorithm used for impact set determination. Secondly, we plan to upgrade the tool's user interface to facilitate better visualization of large-scale Simulink projects. Lastly, we aim to develop additional features such as report exporting and system integration support to better accommodate user environments. Through these advancements, our goal is to offer users an efficient, user-friendly tool that bolsters the role of Simulysis in ensuring effective software quality assurance for Simulink projects.

***Abstract*—High-dimensional microarray datasets are prone to the "curse of dimensionality" due to feature redundancy, which impairs the performance of machine learning models, and feature selection is the key to addressing this issue. This study proposes an Improved Binary Harris Hawks Optimization algorithm (IBHHO) for feature selection in high-dimensional microarray data. Core innovations comprise: i) a hybrid filter-wrapper framework integrating a filter method (ReliefF), a wrapper method (HHO) and a classifier (SVM) to simultaneously optimize ReliefF parameters, SVM hyperparameters, and feature subsets; ii) a differentiated exploration–exploitation strategy leveraging HHO's two-stage behavior (global parameter optimization during exploration; feature refinement and local parameter tuning during exploitation); and iii) an elite feature guidance strategy that reduces redundant exploration and accelerates convergence via fixed key-feature anchor points. Experiments conducted on eight public microarray datasets demonstrate that IBHHO reduces feature counts while improving classification accuracy, achieving comprehensive performance superior to benchmark algorithms. Consequently, IBHHO offers an efficient feature selection framework for high-dimensional biomedical data analysis.**

***Keywords*—Microarray dataset; feature selection; parameter optimization; ReliefF**

I. Introduction

Technological advancements in the contemporary era have driven revolutionary transformations in data acquisition methodologies, while also engendering the proliferation of redundant or misleading data—this may inadvertently compromise the performance of learning models. Furthermore, coupled with the "curse of dimensionality" [1], the substantial volume of features in datasets frequently induces overfitting in machine learning frameworks.

A domain of particular interest is the analysis of high-dimensional microarray datasets for gene expression profiling, which facilitates the identification of cancer-related genes. Microarray data (obtained from microarray experiments) is typically presented as a two-dimensional table, with rows representing gene expression levels and columns corresponding to samples [2]. Notably, these datasets are characterized by a small number of samples juxtaposed against hundreds of thousands of genes. While microarray datasets have been widely used for cancer classification [3], a large number of genes are irrelevant to disease classification—posing a challenge for understanding target diseases and underscoring the crucial role of feature selection in reducing data dimensionality [4].

*Corresponding authors.

The objective of feature selection for microarray data is to identify a set of genes that best discriminates between biological sample types, eliminating irrelevant and redundant information to enhance the efficiency and accuracy of cancer classification algorithms. According to feature evaluation patterns, feature selection algorithms are broadly categorized into three types: filter methods, wrapper methods, and hybrid methods [5].

Filter methods employ fast standard metrics to evaluate feature importance without classifier feedback, offering low computational complexity but being agnostic to classifier types. In contrast, wrapper methods leverage classifier feedback for feature subset selection—their selection process and performance are biased toward the specific classifier, and while they achieve superior classification accuracy, they incur higher computational overhead. The hybrid method integrates wrapper and filter approaches: in the initial stage, a filter method quickly screens out irrelevant features to reduce dimensionality; subsequently, a wrapper method explores the reduced feature space for a more concise subset [6]. It balances computational efficiency and classification accuracy—slightly slower than pure filters but with better classification performance, and significantly less complex than standalone wrappers while achieving comparable or superior results.

Recently, hybrid feature selection strategies have gained traction for high-dimensional datasets (e.g., [7], [8]), typically using a filter to preselect top n features before a wrapper searches for the optimal subset. However, this traditional two-stage strategy has obvious limitations: the filtering stage relies solely on statistical correlation between features and the target, ignoring the classifier's learning needs—potentially discarding features crucial for classification but with insignificant statistical indicators (which cannot be reintroduced in the wrapping stage). Additionally, the manually preset n creates a trade-off: too small restricts the wrapper's search range, while too large increases computational load—this defect is particularly prominent in microarray data. Therefore, this study proposes integrating the filter's initial feature screening into the wrapper stage via a dynamic optimization mechanism. Filter feature evaluation receives classifier feedback to avoid misjudgment; unselected features are retained in a candidate pool for reevaluation during wrapper iteration, enabling dynamic recall of useful features. Meanwhile, filter subset size parameters adapt to different datasets.

Support Vector Machine (SVM) [9] is a widely used

classification technique with proven effectiveness [10]. Beyond feature selection, SVM parameter configuration significantly impacts accuracy, and the core challenge in enhancing SVM's performance lies in simultaneous optimization of feature subsets (discrete 0/1 variables) and SVM parameters (continuous values)—a mixed-variable optimization problem [11].

Metaheuristic algorithms (e.g., Harris Hawks Optimization, HHO [12]) are well-suited for wrapper-based feature selection due to computational efficiency and global search capabilities. HHO mimics Harris hawks' cooperative hunting (exploration, transition, exploitation): the exploration phase avoids local optima via global solution space search, while the exploitation phase refines solution quality through precise local adjustments. Accordingly, this study integrates filter parameter optimization into HHO's exploration phase (aligning feature rankings with classification objectives) and feature subset refinement into the exploitation phase (eliminating redundancy, retaining critical features, and adapting classifier parameters). This phased integration realizes dynamic coordination between parameter tuning and feature screening. Traditional HHO-based feature selection (binary encoding of candidate subsets) lacks clear directional anchors, leading to excessive ineffective searches in redundant feature regions—slowing convergence and risking missed optimal solutions. To address this, we propose an "elite feature guidance mechanism": key features in the top-performing subset of each iteration are marked as "elite" (fixed as selected in subsequent optimizations). These features act as search anchors, reducing ineffective exploration, accelerating convergence to the global optimal subset, and improving selection efficiency and accuracy. Given HHO's advantages in avoiding local optima, this paper proposes an Improved Binary HHO (IBHHO) for feature selection in high-dimensional microarray datasets. The main contributions are summarized as follows:

1) Hybrid feature selection framework for joint optimization of high-dimensional microarray data: A filter-wrapper integrated framework enabling concurrent optimization of ReliefF parameters, SVM hyperparameters, and feature subsets. ReliefF's subset size parameter is adaptively tuned based on dataset feature dimensionality.

2) Co-optimization strategy based on HHO's two-stage characteristics: A differentiated optimization strategy leveraging HHO's phases: the exploration phase optimizes ReliefF and SVM parameters for comprehensive feature space exploration; the exploitation phase refines feature subsets and fine-tunes classifier parameters—significantly enhancing overall classification performance.

3) Elite feature guidance strategy: An "Elite Feature Guidance Strategy" that fixes key features (labeled 1) as strict binary 1s. These anchored features steer the algorithm to converge toward verified optimal subsets, mitigating redundant exploration, accelerating convergence, and improving selection accuracy/efficiency.

IBHHO addresses incoordination between filter and wrapper stages in traditional hybrids and optimization drawbacks of conventional HHO. Tested on eight high-dimensional microarray datasets, it outperforms existing popular meta-heuristic methods—verifying its effectiveness for microarray data feature selection.

The study is structured as follows: Section II reviews related research on feature selection for microarray datasets; Section III elaborates on basic method principles; Section IV introduces the optimization problem model; Section V describes IBHHO's application to feature selection; Section VI evaluates IBHHO using eight public datasets; and Section VII concludes the study.

II. Related Work

A. Feature Selection Methods

Filter-based feature selection methods assess feature importance exclusively based on data-intrinsic properties, disregarding the influence of learning algorithms or classifiers on feature utility. Prominent examples include, in reference [13], employed the ReliefF algorithm to select the top 3% feature subsets in the initial screening stage of feature selection for high-dimensional microarrays. In [14], the authors utilized the Simulated Kalman Filter algorithm to select 1% of features in microarray feature selection. In [15], the authors adopted the SLI-γ filter method to choose the top 1% most relevant features.

Wrapper-based feature selection methods incorporate learning algorithms as integral components, directly leveraging classifier performance as the evaluation metric for feature subset optimization. Wrapper methods typically have higher computational costs than filter methods because they rely on iterative evaluation of classifiers. Prominent examples include, in reference [16], proposes a wrapper feature selection method based on the Chimp Optimization Algorithm. In [17], the authors introduces a Multi-objective Binary Harris Hawks Optimization algorithm to directly optimize feature subsets as a wrapper approach. In [18], the authors employ the Genetic Algorithm as a wrapper method, using the accuracy of the KNN classifier as the fitness function.

For high-dimensional microarray datasets—where feature spaces often comprise thousands to tens of thousands of genes—filter-wrapper hybrid approaches offer distinct advantages over pure wrapper methods [19]. These hybrids integrate the dimensionality reduction efficiency of filter methods with the discriminative power of wrapper optimization, striking a balance between computational feasibility and classification performance.

Recently, feature selection methods based on hybrid filter wrappers have been widely used to speed up the selection process and improve classification performance. In reference [20], an altruism mechanism was integrated into the Whale Optimization Algorithm (WOA) to develop the AltWOA algorithm. First, Pasi Luukka's fuzzy entropy filtering method [21] was employed to screen the top 300 genes by entropy values, eliminating features with low class correlation. Subsequently, the improved WOA—incorporating altruistic behavior—used SVM classification accuracy as the fitness function to perform iterative optimization of the feature subset from the preselected 300 genes. Evaluation on eight high-dimensional microarray datasets demonstrates that this algorithm outperforms other algorithms in terms of accuracy. The hybrid feature selection framework proposed in [22] employs a two-stage strategy. In the filter stage, the minimal redundancy maximal relevance

algorithm integrates multiple filtering metrics—including ReliefF, chi-square test, and Kullback-Leibler divergence—to quantify gene relevance, selecting the top 50 features with the highest scores. Subsequently, in the wrapper stage, an improved gray wolf optimizer is deployed to search for the optimal feature combination within the prefiltered candidate set, using SVM classification accuracy as the fitness function. In [23], the authors propose a two-stage gene selection framework for microarray data, integrating anomaly detection with genetic algorithms. In the first stage, an autoencoder is employed to reduce the dimensionality of gene expression data, followed by one-class support vector machine (One-class SVM) for anomalous gene detection, where approximately 1% of features are selected as the candidate subset. The second stage then applies a guided genetic algorithm to the candidate genes, refining them into the final set of effective features through fitness evaluation based on classification accuracy. In [24], the authors propose a novel hybrid algorithm, TRF-WGHC, by integrating a ranking-based filter feature selection algorithm with a greedy hill-climbing algorithm for DNA microarray applications. In the first stage, specific ranking metrics—including information gain, gain ratio, and ReliefF—are employed to select the top n percent of genes, discarding those with scores below a predefined threshold. The second stage then utilizes an augmented greedy hill-climbing algorithm to search for the optimal feature subset from the remaining genes. The experimental part was comprehensively tested on 18 microarray datasets, demonstrating that the algorithm is simple and effective.

B. Joint Optimization

On one hand, the performance of Support Vector Machine (SVM) models is significantly influenced by parameter selection, and applying SVM presents two key challenges: selecting the optimal input feature subset and determining the best parameter values, which are interdependent—the chosen feature subset affects the optimal parameter values, and vice versa. On the other hand, the parameters of the filter method used also impact feature subset selection and classification performance. Therefore, this study focuses on synchronously optimizing three variables: SVM parameters, filter method parameters, and feature selection results. Within the synchronous optimization framework, the feature selection vector consists of binary elements—"1" indicates selecting the corresponding feature, while "0" excludes it [25]; the feature mask for selection is a discrete integer variable, whereas SVM classifier parameters and filter method parameters are continuous variables, making the synchronous optimization of feature selection and SVM parameters a mixed-variable optimization problem. In the study of reference [26], researchers discretized continuous parameters into integers and adopted the Firefly Algorithm to synchronously optimize feature selection and SVM parameters to improve the performance of traditional Chinese medicine prescription classification. In [27], the authors used the Genetic Algorithm with a binary encoding system to design chromosomes containing penalty parameter C, kernel function parameters, and feature masks, realizing the joint optimization of feature selection and parameters. In [25], the authors introduced the Salp Swarm Algorithm to address the joint optimization of feature selection and classifier parameter tuning, partitioning the solution space into a feature mask (discrete part) and SVM parameters (continuous part), which are optimized by binary SSA and standard SSA respectively. In this study, the IBHHO algorithm synchronously optimizes the three variables: during the exploration phase of the algorithm, the filter algorithm and SVM parameters are optimized using the original continuous HHO algorithm; during the exploitation phase, SVM parameters and feature subsets are optimized using both the continuous HHO algorithm and binary HHO algorithm.

C. Summary

In summary, existing filter-wrapper hybrid methods for microarray feature selection typically adopt a two-stage process: pre-screening a fixed number of features using filter methods, followed by wrapper optimization. This rigid architecture has two inherent flaws: 1) Static filtering thresholds cannot adapt to the dynamic changes in feature correlations within microarray data. When processing different microarray datasets, due to the lack of flexibility and adaptability, it is difficult to achieve effective optimization of feature selection and the performance of classification models. 2) Optimizing the filtering phase and the wrapper phase separately may result in a lack of close coordination between them. This can cause the feature subsets initially screened by the filtering algorithm to be affected by redundant features, or lead to the omission of key features due to the limitations of statistical evaluation, ultimately impairing the overall performance of the model. In contrast, this study proposes IBHHO algorithm. By integrating the filtering phase into the two-stage mechanism of HHO, it realizes the combination of the filtering phase and the wrapper phase in the iterative update of the HHO algorithm, while achieving the dynamic adaptive adjustment of the weight parameters of the filtering method. This enables the filtering phase to adaptively adjust the number of feature subsets according to the specific distribution of the dataset, thereby effectively avoiding the risks of over-filtering (losing discriminative features) and redundant retention (retaining irrelevant attributes).

III. Preliminary Knowledge

This section elaborates on the preliminary knowledge employed in this study. First, a feature ranking algorithm based on the ReliefF filter is introduced, which is used for the initial screening of feature subsets. Subsequently, the SVM classifier used in this study and the application process of the original HHO algorithm are presented.

A. ReliefF

A notable strength of ReliefF [28] in feature evaluation is its capacity to capitalize on local feature dependencies while still accounting for the global data distribution. This avoids sacrificing the global perspective by overemphasizing local details [29]. Its core principle involves assessing features according to their capability to discriminate between closely neighboring observation samples via feature values. Specifically, the evaluation unfolds iteratively: in each iteration, an observation sample is randomly drawn from the sample space; next, the k nearest neighbors belonging to the same category and the corresponding nearest neighbors from other categories are identified; subsequently, each feature's score is updated based on feature-value differences between the target

sample and its same-category and different - category nearest neighbors. The weights for each feature in distinguishing the target sample from its neighbors are computed using Eq. (1). Generally, a higher weight indicates greater importance for tasks like category classification, translating to higher utility in model construction and related processes.

$$W_f = W_f - \frac{1}{mk}\sum_{j=1}^{k}\mathrm{diff}_f(R_i, H_j) + \frac{1}{mk}\sum_{c\neq \mathrm{class}(R_i)}\frac{P(c)}{1-P(\mathrm{class}(R_i))}\sum_{j=1}^{k}\mathrm{diff}_f(R_i, M_j) \tag{1}$$

where, W_f is the ReliefF weight of feature f, k denotes the number of nearest neighbor samples, and m represents the number of iterations. R_i is the random sample in iteration i. H_j and M_j are the nearest neighbor samples from the same class and different classes of R_i, respectively. $P(c)$ is the prior probability of class c, which is typically determined based on the training samples fed into the ReliefF algorithm. $\mathrm{diff}_f(\cdot,\cdot)$ is the value difference of feature f between two observations.

For the ReliefF filtering method employed in the IBHHO algorithm proposed in this study, after ranking features by weights using k-nearest neighbors, the top SN features (where, SN denotes the number of features selected by ReliefF) are chosen as the feature subset output in the initial screening stage. The setting equations for k and SN are presented in Eq. (2) and Eq. (3).

$$k = \lfloor \vec{p}\cdot k_{\max} + 0.5 \rfloor \tag{2}$$

$$SN = \lfloor \vec{p}\cdot D + 0.5 \rfloor \tag{3}$$

where, $\vec{p}$ represents the position vector of k, $k_{\max}$ is typically set to 10, $\vec{p}\cdot k_{\max}$ means scaling each element of vector $\vec{p}$ by $k_{\max}$ times, and $\lfloor \vec{p}\cdot k_{\max} + 0.5 \rfloor$ means rounding $\vec{p}\cdot k_{\max}$ to the nearest integer. D represents the feature dimension of the dataset, and $\vec{p}\cdot D$ means scaling each element of vector is scaled by D times to realize parameter adjustment based on the data dimension.

During the filtering stage, the ReliefF algorithm is employed to assess the significance of each feature. Features are then ranked in descending order of their computed importance scores, and the top SN features are forwarded to the wrapper stage. Setting an excessively low threshold may lead to the exclusion of critical features, whereas an overly high threshold could retain numerous redundant or irrelevant features. To address this challenge, our approach dynamically adjusts the threshold, enabling the selection of feature subsets with varying sizes according to the intrinsic importance distribution of features across diverse datasets.

B. SVM

The core idea of Support Vector Machines (SVM) is to map training data into a higher-dimensional space and separate the categories of training data by establishing an optimal hyperplane, thereby transforming non-linearly separable data in the input feature space into linearly separable data in the high-dimensional feature space.

When using SVM as a classifier, the parameter C serves as a key factor in controlling the model's complexity and the severity of misclassification penalties, thereby balancing the model's bias and variance. Additionally, the kernel function parameter determines the nonlinear transformation from the input space to the high-dimensional space, where the hyperplane used for class separation is identified. This study selects the RBF kernel function based on its simplicity and efficiency, as shown in Eq. (4):

$$\varphi(x_i - x_j) = \exp\left(-\gamma\|x_i - x_j\|^2\right), \gamma > 0 \tag{4}$$

where, γ represents the parameter of kernel function. The parameters of support vector machine (SVM) to be optimized include penalty parameter C and kernel function parameter γ.

C. Harris Hawk Optimization

The HHO algorithm consists of three distinct phases: the exploration phase, the transition phase from exploration to exploitation, and the exploitation phase.

Proposed in [12], the Harris Hawk Optimization algorithm (HHO) is a bio-inspired swarm intelligence optimization algorithm renowned for its robust global search capability and high optimization precision. In this framework, the prey (rabbits in natural hunting scenarios) symbolizes the optimal solution with the highest fitness value in the current iteration. The algorithm operates through two overarching stages: exploration and exploitation, with the transition phase mediating between them. During the exploration phase, the algorithm initializes control parameters (escape energy E) to survey the solution space and locate potential prey regions. The exploitation phase comprises four distinct attack strategies, dynamically adjusted based on the prey's perceived "energy" (solution quality) and escape probability. These strategies simulate hierarchical hunting behaviors, enabling progressive refinement of the optimal solution.

1) Exploration phase: When hunting prey, Harris hawks adopt two distinct exploration strategies. Candidate solutions are designed to approach the prey as closely as possible, with the optimal solution representing the target prey itself. First, Harris hawks select a landing point by considering the positions of other hawks and their prey. In the second method, hawks wait on random tall trees. These two approaches are simulated with equal probability q using Eq. (5):

$$x(t+1) = \begin{cases} x_{\mathrm{r}}(t) - r_1\left|x_{\mathrm{r}}(t) - 2r_2x(t)\right| & q \geq 0.5 \\ x_{\mathrm{p}}(t) - x_{\mathrm{m}}(t) - r_3\left(L + r_4(U-L)\right) & q < 0.5 \end{cases} \tag{5}$$

where, the vector $\mathbf{x}(t)$ is the current position of the hawk, $\mathbf{x}(t+1)$ is the hawk's position in the next iteration, $\mathbf{x}_{\mathrm{r}}(t)$ is a randomly selected position from the Harris hawk population, $\mathbf{x}_{\mathrm{p}}(t)$ is the prey position in the current iteration, r_1, r_2, r_3, r_4 are random numbers with a $(0,1)$ distribution, q is the transition factor controlling the two strategies, and L/U are the lower/upper bounds of variables. $\mathbf{x}_{\mathrm{m}}(t)$ is the average

position of the current hawk population, is calculated as Eq. (6):

$$x_{\mathrm{m}}(t) = \frac{1}{N}\sum_{i=1}^{N} x_i(t) \tag{6}$$

where $\mathbf{x}_i(t)$ is the position of each hawk in iteration t, and N denotes the total number of hawks.

2) Transition from exploration to exploitation: The algorithm switches from exploration to exploitation based on the prey's running or escape energy, as defined by Eq. (7):

$$E = 2E_0\left(1 - \frac{t}{Max_iter}\right) \tag{7}$$

where, E represents the prey's escape energy, E_0 is the initial energy state, which randomly varies within $(-1, 1)$ at each iteration. When $|E| \geq 1$, global search is performed; otherwise, the exploitation phase begins.

3) Exploitation phase: During the exploitation phase $|E| < 1$, Harris hawks raid and capture prey while the prey avoids predation. HHO determines the appropriate position update strategy from the following four attack modes based on the random number $r \in (0, 1)$, parameter E, and the strategy determinant $|E|$: when $|E| \geq 0.5$, Harris hawks choose the soft besiege strategy; otherwise, they adopt the hard besiege strategy.

a) Soft besiege: When $r \geq 0.5$, Harris hawks can capture the prey; otherwise, the hunt fails. When $r \geq 0.5$ and $|E| \geq 0.5$, the prey has sufficient energy to jump to avoid predation, and Harris hawks use the soft siege strategy with prey energy to complete the hunt, as shown in Eq. (8) and Eq. (9):

$$X(t+1) = \Delta X(t) - E|J \cdot X_{\mathrm{p}}(t) - X(t)| \tag{8}$$

$$\Delta X(t) = X_{\mathrm{p}}(t) - X(t) \tag{9}$$

where, $J = 2(1 - r_5)$ is the prey's movement distance in the jump mode, and r_5 is a random number in $(0, 1)$.

b) Hard besiege: When $r \geq 0.5$ and $|E| < 0.5$, the prey has insufficient energy, and Harris hawks adopt the hard siege strategy for rapid predation, as in Eq. (10):

$$X(t+1) = X_{\mathrm{p}}(t) - E|\Delta X(t)| \tag{10}$$

c) Soft besiege with progressive rapid dives: When $r < 0.5$ and $|E| \geq 0.5$, the prey has sufficient energy to escape. Harris hawks then choose the soft siege combined with a progressive dive tactic, as described by Eq. (11). This strategy includes two hunting methods, with the second selected if the first fails:

$$X(t+1) = \begin{cases} Y : X_{\mathrm{p}}(t) - E|JX_{\mathrm{p}}(t) - X(t)| \\ \quad \text{if } f(Y) < f(X(t)) \\ Z : Y + S \times LF(D) \\ \quad \text{if } f(Z) < f(X(t)) \end{cases} \tag{11}$$

where, D is the spatial dimension, S is a $1 \times D$ random vector, f is the fitness function, and LF is the Levy function simulating the prey's jumping behavior.

d) Hard besiege with progressive rapid dives: When $r < 0.5$ and $|E| < 0.5$, the prey lacks energy but has a chance to escape. Harris hawks then employ the hard siege strategy with a progressive dive to reduce the distance to the prey and form an encirclement, as in Eq. (12):

$$X(t+1) = \begin{cases} Y : X_{\mathrm{p}}(t) - E|JX_{\mathrm{p}}(t) - X_{\mathrm{m}}(t)| \\ \quad \text{if } f(Y) < f(X(t)) \\ Z : Y + S \times LF(D) \\ \quad \text{if } f(Z) < f(X(t)) \end{cases} \tag{12}$$

IV. Problem Model

In the feature selection and parameter optimization model of this study, the decision variables revolve around ReliefF feature screening, performance adjustment of the SVM classifier, and determination of the final feature subset. That is, by adjusting variables such as k, SN, C, γ and FS, the value of the objective function f is minimized, thereby achieving a balance between "high classification accuracy" and "small scale of the feature subset". Therefore, the expression of the optimization problem model in this study is [see Eq. (13)]:

$$\text{Min } f(k, SN, C,\ \gamma,\ FS) \tag{13}$$

The decision variables in the optimization problem model include: ReliefF feature screening parameters (k, the number of nearest-neighbor samples, which is used to determine the scale of neighbor samples referenced when calculating feature weights; SN, the scale of the feature subset selected in the initial screening, i.e., the number of features preliminarily screened out), parameters of the SVM classifier (C, the penalty parameter, which is used to control the penalty intensity for misclassified samples; γ, the kernel function parameter, which defines the mapping complexity of the kernel function in the sample space), and feature selection results (discrete variable FS). The value ranges of each decision variable must satisfy the following constraints [see Eq. (14) to Eq. (18)]:

$$k_{\min} < k = \lfloor \vec{p} \cdot k_{\max} + 0.5 \rfloor < k_{\max} \tag{14}$$

$$SN_{\min} < SN = \lfloor \vec{p} \cdot D + 0.5 \rfloor < SN_{\max} \tag{15}$$

$$C_{\min} < C < C_{\max} \tag{16}$$

$$\gamma_{\min} < \gamma < \gamma_{\max} \tag{17}$$

$$FS_i = \begin{cases} 1 & \text{if the } i\text{th feature is selected} \\ 0 & \text{otherwise} \end{cases} \tag{18}$$

specifically, for the ReliefF parameters: $k_{\min} = 0$, $k_{\max} = 10$; $\text{SN}_{\min} = 0$, $\text{SN}_{\max} = 0.005 \cdot D$. For the SVM classifier parameters, $C_{\min} = 0$, $C_{\max} = 1000$; $\gamma_{\min} = 0$, $\gamma_{\max} = 1$. The feature selection result is characterized by the discrete variable FS, where $\text{FS}_i = 1$ indicates that the i-th feature is selected, and $\text{FS}_i = 0$ indicates that the feature is excluded. The constructed "0/1 binary vector" is used to describe the final feature subset, whose dimension is consistent with the number of original features.

The problem model in this study is oriented towards minimizing the objective function f. The objective function and the expression of the optimization goal are as follows [see Eq. (19) and Eq. (20)]:

$$f = \alpha \cdot (1 - acc) + (1 - \alpha) \cdot \frac{SF}{D} \tag{19}$$

$$acc = \frac{TP + TN}{TP + TN + FP + FN} \tag{20}$$

where, α is the balance coefficient ($\alpha = 0.7$), SF is the number of selected features, D is the total number of original features, and acc represents the classification accuracy. The calculation equation is shown in Eq. (20). The model in this study synchronously optimizes continuous and discrete variables, including ReliefF parameters (k, SN), SVM classifier parameters (C, γ), and feature selection results (discrete FS vector). By leveraging the "synergistic effect" between feature subsets and classifier parameters, it more accurately excavates the "classification discriminant information" of the dataset. This overcomes the problems of traditional univariate optimization methods, such as being prone to falling into local optima and the "curse of dimensionality", where computational complexity grows exponentially with the dimension of variables. Ultimately, it achieves the global optimization of classifier performance.

V. IBHHO for Feature Selection

A. Solution Structure

The solution structure of the algorithm in this study is represented by a coordinate array, where each element of the array is a continuous variable with a value range between $[0, 1]$. The solution structure consists of three parts: the parameters k and SN of ReliefF, the parameters C and γ of the SVM classifier, and the feature selection results. Fig. 1 shows a schematic diagram of the solution structure of the algorithm in this study.

For the first part, the parameters k and SN of ReliefF are calculated by Eq. (2) and Eq. (3), with maximum values set to 10 and 0.005, respectively. For the second part, the parameters C and γ of SVM are set to range between $(0, 1000)$ and $(0, 1)$, respectively. The third part represents the result of discrete feature selection. Given that feature selection is inherently discrete and HHO is designed for continuous optimization problems, a discrete version of HHO (BHHO) must be employed. In the BHHO algorithm, the result vector of feature selection is represented by Eq. (21):

$$FS_i = \begin{cases} 1 & \text{if } w_i < g_{i+4} \\ 0 & \text{otherwise} \end{cases} \tag{21}$$

where, w_i is a random number within the interval $(0, 1)$, g_{i+4} representing the $i+4$-th position in the solution structure.

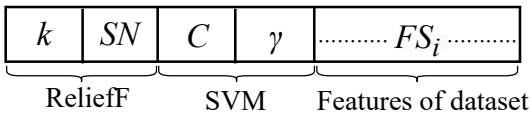

Fig. 1. Solution structure.

B. Fitness function

The fitness function is used to measure the quality of each Harris hawk individual in the IBHHO algorithm. Each Harris hawk represents a potential feature subset along with parameters of the classifier and ReliefF, and the fitness function provides an evaluation criterion for these individuals. The algorithm uses this criterion to select and evolve toward better feature subsets and classifier parameters. Feature selection is a multi-objective optimization problem that should simultaneously consider higher classification accuracy and fewer features. Linear weighting methods can transform multiple objectives into a single fitness value to facilitate algorithmic solution. In this study, a linear combination of classification accuracy and the number of selected features is used as the fitness function, as defined in Eq. (19).

C. Co-Optimization Strategy for Parameters and Features Based on HHO Two-Stage Characteristics

As described in the first subsection, the solution structure of IBHHO is divided into three parts (ReliefF, classifier parameters, and feature selection results). Since the HHO algorithm has both exploration and exploitation components, it effectively balances global search and local search.

The proposed staged optimization strategy fully capitalizes on the complementary characteristics of the HHO algorithm's exploration and exploitation phases:

During the exploration phase, the search space is optimized to identify potential high-quality solution regions. Therefore, ReliefF and SVM parameters are optimized during this phase. By dynamically adjusting the ReliefF parameters, the importance of features is evaluated from multiple perspectives, generating stable feature rankings. Concurrently, SVM parameters are adjusted to rapidly adapt to the data distribution, thereby enhancing model performance;

The development phase focuses on fine-grained search around high-quality solutions. At this stage, feature subset and SVM parameter optimization are performed. Based on the reliable feature subset generated by ReliefF parameters in the exploration phase, the focus shifts to fine-tuning SVM parameters and further controlling the feature subset size,

achieving a balance between computational efficiency and optimization accuracy.

This design avoids the computational bottleneck of direct feature selection in high-dimensional data while reducing the search space complexity through separate parameter optimization, providing a new optimization form for the hybrid feature selection framework.

D. Elite Feature Guidance Strategy

In the feature selection process of the original HHO algorithm, the optimization of feature subsets is simulated as the process of hawk flocks chasing prey. The candidate feature subsets correspond to the positions of hawks, while the optimal feature subset is analogized to the prey's position. The algorithm continuously adjusts the positions of hawks through two stages—exploration and exploitation—to approach the prey. During the exploitation phase, hawks mainly update their positions using Eq. (8), Eq. (10), Eq. (11) and Eq. (12), to attempt getting closer to the prey. However, this updating approach in high-dimensional feature spaces may lead to extensive redundant searches in non-critical regions. Moreover, the lack of a protection mechanism for verified high-quality features makes the algorithm prone to missing the true optimal feature subset, resulting in slow convergence and limited result accuracy.

The Elite Feature Guidance Strategy proposed in this study improves the exploitation phase of the original HHO algorithm by introducing pre-identified key features (marked as 1) as fixed "anchor points", significantly optimizing the feature selection optimization process. Specifically, the algorithm directly assigns the "prey positions" of these key features to strict binary value 1, keeping them unchanged throughout the search process. These anchored features act as navigation coordinates, guiding the hawk flock to converge preferentially toward the optimal feature subset containing these key features. During the iterative update process, the algorithm first ensures that the anchored features in the candidate feature subset always remain 1, avoiding the loss of these key features during the search. Eq. (22) shows the position update method after adding the guidance mechanism. Among them, X_{new} is the new prey position (candidate solution), and i is the position in the solution structure array.

When $i < 4$, it represents the first 4 positions of the solution structure, i.e., the ReliefF and SVM parameters, which do not participate in the elite guidance mechanism; when $i > 4$, it represents the position of the feature selection result, which is the part involved in the elite guidance.

$$X'_{\text{p}}(t)_i = \begin{cases} X_{\text{p}}(t)_i & (i \in [0,3]) \\ FS_{i+4} & (i \geq 4) \end{cases} \tag{22}$$

For non-anchored features, during the exploitation phase, the optimization of the feature subset in the new position of the hawk is updated using Eq. (23), Eq. (24), Eq. (25) and Eq. (26), where X'_{rabbit} represents the position of prey containing fixed anchoring features and $X_{\text{new}}(t+1)$ is the updated candidate feature subset.

$$\begin{cases} X_{\text{new}}(t+1) = \Delta' X(t) - E|J \cdot X'_{\text{p}}(t) - X(t)| \\ \Delta' X(t) = X'_{\text{p}}(t) - X(t) \end{cases} \tag{23}$$

$$X(t+1) = X'_{\text{p}}(t) - E|\Delta' X(t)| \tag{24}$$

$$X_{\text{new}}(t+1) = \begin{cases} Y : X'_{\text{p}}(t) - E|J \cdot X'_{\text{p}}(t) - X(t)| \\ \quad f(Y) < f(X(t)) \\ Z : Y + S \times LF(D) \\ \quad f(Z) < f(X(t)) \end{cases} \tag{25}$$

$$X_{\text{new}}(t+1) = \begin{cases} Y : X'_{\text{p}}(t) - E|J \cdot X'_{\text{p}}(t) - X_{\text{m}}(t)| \\ \quad f(Y) < f(X(t)) \\ Z : Y + S \times LF(D) \\ \quad f(Z) < f(X(t)) \end{cases} \tag{26}$$

In this way, the algorithm always builds upon anchored features when exploring new feature combinations, effectively reducing search attempts in non-critical regions. By fixing key features, this strategy significantly narrows the effective search space and minimizes redundant exploration, thereby enhancing the algorithm's convergence speed.

Meanwhile, since anchored features are pre-verified high-quality features, the algorithm can more accurately approach the true optimal feature subset, ultimately improving the accuracy and efficiency of feature selection–particularly suitable for feature selection tasks on high-dimensional complex datasets.

E. Algorithm Flow of IBHHO

In summary, addressing the challenge of feature selection for high-dimensional microarray datasets, this study proposes three innovative strategies. Firstly, a hybrid feature selection framework integrating filter (ReliefF) and wrapper (SVM) methods is constructed to synchronously optimize ReliefF parameters, SVM hyperparameters, and feature subset size. The feature subset size parameter is adaptively adjusted based on the intrinsic dimensionality of the dataset, enabling dynamic adaptation. Secondly, a differentiated optimization strategy is designed based on the two-stage characteristics of the HHO algorithm: the exploration phase optimizes ReliefF and SVM parameters to comprehensively search the feature space, while the exploitation phase focuses on feature subset refinement and classifier parameter fine-tuning, significantly enhancing classification performance. Finally, an "Elite Feature Guidance Strategy" is proposed, which fixes pre-identified key features as binary value 1 as "anchor points" in the search space. This guides the algorithm to converge rapidly to the optimal feature subset, effectively reducing redundant exploration and substantially improving the efficiency and accuracy of feature selection. The flowchart of the proposed IBHHO algorithm is shown in Fig. 2.

Initialization Phase: The basic parameters of the algorithm (population size N and maximum number of iterations T). Then initialize the positions of hawks, including ReliefF parameters (k and SN), SVM parameters (C and γ), and feature

subsets (where binary values indicate whether features are selected).

Fitness Calculation: The fitness is computed using Eq. (19). For the current hawk positions (candidate solutions), feature selection is performed on the microarray dataset based on the current ReliefF parameters to obtain the feature subset SN for SVM training. The selected feature subset SN is used to train the SVM and further refine the optimal subset, after which the classification accuracy acc is calculated. Finally, the fitness value is computed using Eq. (19). A smaller fitness value indicates better comprehensive performance of the candidate solution (higher classification accuracy with fewer features).

Exploration Phase: Execute "broad-spectrum optimization of ReliefF and SVM parameters". The core objective is to simulate the behavior of hawk flocks searching for prey in a vast space using the HHO algorithm, performing extensive and diverse adjustments to ReliefF feature evaluation parameters and SVM classifier hyperparameters. This aims to identify potential high-quality parameter intervals for the subsequent exploitation phase.

Exploitation Phase: Fine-tune SVM parameters and refine feature subsets. In this phase, the Elite Feature Guidance Mechanism is introduced, where features marked as 1 (pre-identified key features) have their "prey positions" directly assigned as strict binary value 1. The positions of hawks are updated using Eq. (23), Eq. (24), Eq. (25) and Eq. (26), guiding the algorithm to converge rapidly to the verified optimal feature subset.

Iteration Termination Criterion ($t < T$?): If $t < T$, the process returns to the fitness calculation phase for the next round of optimization; if $t > T$, the iteration terminates and the optimal solution is output.

VI. Results and Discussion

In this section, we evaluate the performance of the proposed method in feature selection tasks for medical datasets through comparative analysis from different aspects. All experiments were conducted on the MATLAB 2023b platform, with the hardware configuration as follows: Windows 11 operating system, Intel (R) Core (TM) i5-13500H CPU @ 2.6 GHz, and 16.0 GB of RAM.

A. Description of Datasets

To analyze the performance of the proposed method, we utilized eight high-dimensional DNA microarray gene expression datasets, including both binary and multi-class classifications. These datasets were downloaded from two public websites: http://case.szu.cn/stff/zhuzx/Datssets.html and https://github.com/kivancguckiran/microarray-data. Table I provides the specific descriptions of the datasets.

Overall, the 8 microarray datasets selected in this study are distinctly diverse and representative, and they have also been used in existing literature, such as references [30], [31], and [24]. These datasets can comprehensively and rigorously verify the performance of the proposed method: in terms of classification tasks, they include both binary classification (such as Colon Cancer, CNS, Leukemia, Lung cancer, Ovarian cancer, Breast cancer) and multi-class classification (SRBCT with 4 classes, Burcyznski with 3 classes), which can test the adaptability of the method to different category complexities; in terms of sample composition, the total number of samples ranges from 60 (CNS) to 253 (Ovarian); the dimensionality of disease features is distributed in a gradient from 2000 to 22,283, which fully verifies the generalization ability of this method in mining key features and improving classification accuracy. The selection of these datasets provides a comprehensive experimental basis for evaluating the effectiveness and reliability of the method.

TABLE I. Datasets Descriptions

Dataset	Samples	Features	Classification type
Colon Cancer	62	2000	Binary-class
SRBCT	63	2308	Multi-class
Central Nervous System (CNS)	60	7129	Binary-class
Leukemia	72	7129	Binary-class
Lung cancer	181	12533	Binary-class
Ovarian cancer	253	15154	Binary-class
Breast cancer	118	22215	Binary-class
Burcyznski	127	22283	Multi-class

B. Experimental Design and Performance Indicators

To evaluate the performance of machine learning models on different datasets, this study employed k-fold cross-validation. The datasets were further randomly divided into training sets and independent test sets via k-fold cross-validation. The main advantage of cross-validation lies in the independence of each test set, thereby enhancing the reliability of the results. In this study, the value of k was set to five. Thus, the datasets were partitioned into five parts, with each part containing data in equal proportion from each class. Four parts were used for training, while the remaining one part served as the test set.

The analysis of feature selection results for the eight datasets employed multiple evaluation metrics, including accuracy, fitness value, number of selected features, and execution time. These statistical metrics aim to analyze experimental outcomes and determine the algorithm's performance.

To robustly evaluate the reliability of the proposed method, this study is designed to compare all performance indicators of the proposed algorithm with those of all comparative algorithms in the experimental section, and the finally reported results are the average values of 30 independent executions.

C. Overall Performance Evaluation

This section presents a comparison of the IBHHO algorithm with other optimization algorithms in terms of evaluation metrics including classification fitness, accuracy, number of selected features, and execution time. It is divided into two parts: comparison of IBHHO with various optimization algorithms aided by ReliefF, and comparison of IBHHO with various state-of-the-art methods.

1) Comparison of IBHHO with various optimization algorithms aided by ReliefF: In this subsection, four optimization algorithms integrated with ReliefF are employed as comparative algorithms, namely GA [25], PSO [32], FA [33], and WCA [34].

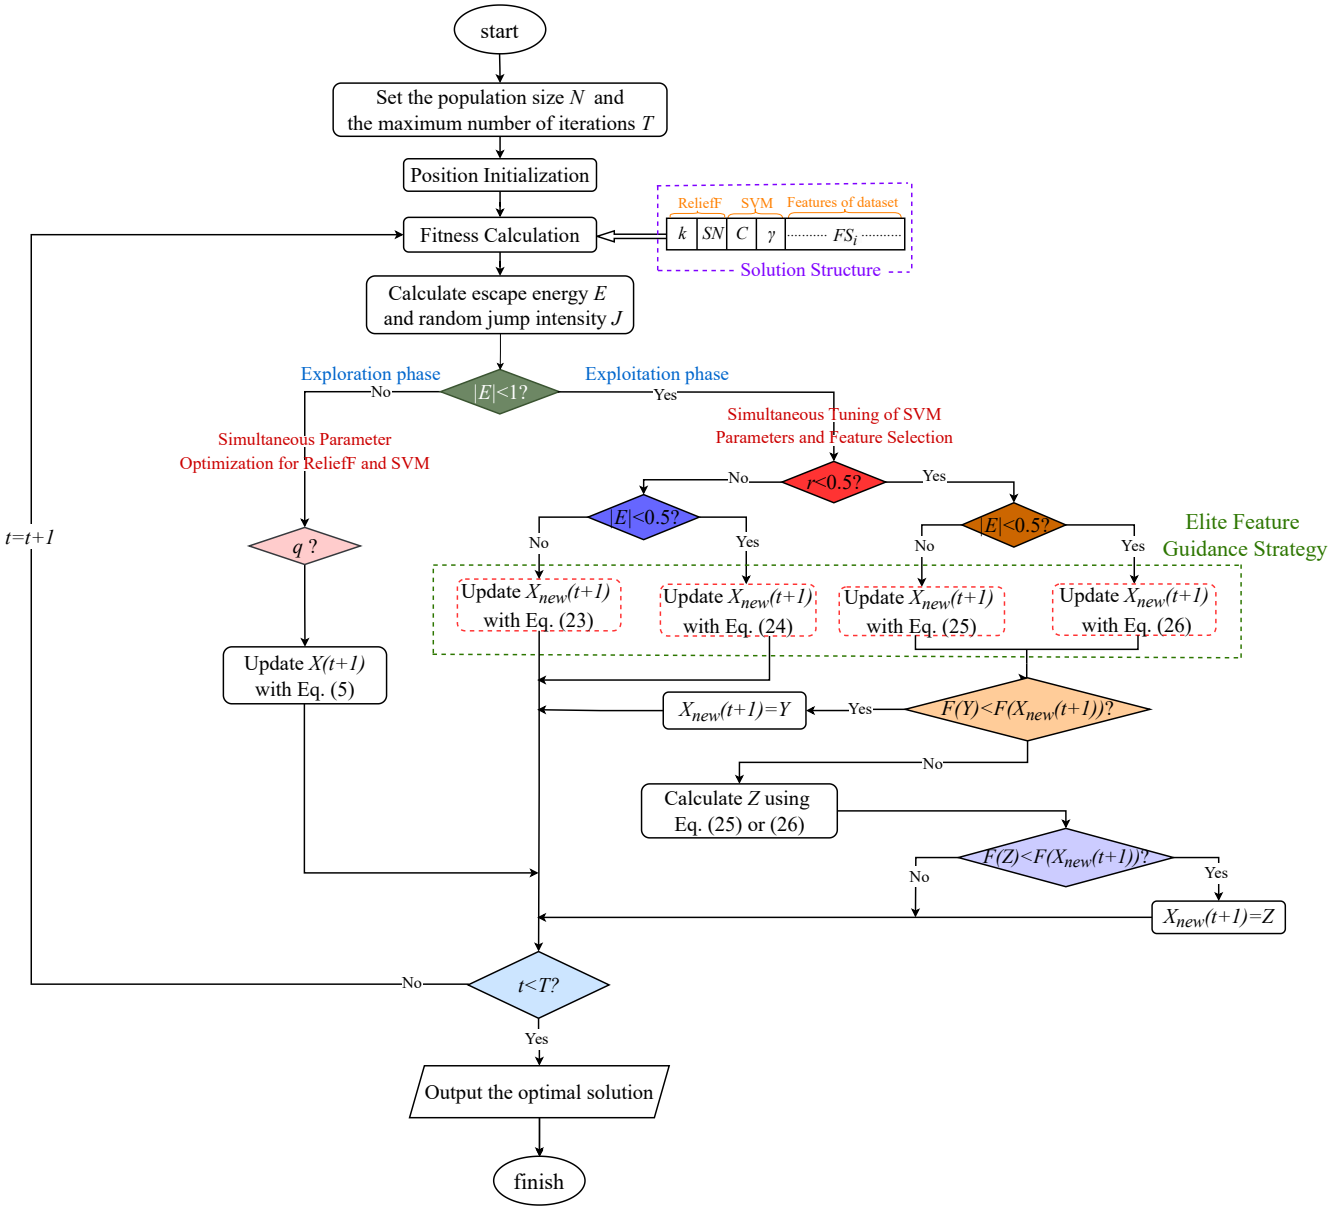

Fig. 2. The flowchart of the IBHHO.

Boxplot analysis is the optimal method to represent the data distribution characteristics of the collected results and identify data anomalies (such as skewness and outliers). A boxplot displays data distribution in the form of different quartiles, specifically the lower (the lowest point/edge of the whisker) and upper (the highest point/edge of the whisker) quartiles, which represent the minimum and maximum values of the data distribution. The lower quartile and upper quartile are indicated by the corners of the rectangle. A small boxplot rectangle indicates a stronger consistency of the data.

To verify the performance of the IBHHO algorithm, four algorithms integrated with ReliefF (GA-R, PSO-R, FA-R, WCA-R) were selected as comparative algorithms. Experiments were conducted on 8 datasets, with fitness as the evaluation metric (a smaller fitness value indicates better optimization performance of the algorithm). The boxplot results are shown in Fig. 3.

On the Colon Cancer dataset, it is intuitively visible that the box of the IBHHO algorithm is the narrowest, which clearly indicates that the fluctuation range of its multiple running results is the smallest, and its stability is the best among the five algorithms. In contrast, the GA+R algorithm has the widest box and the worst stability. The small squares inside the boxes represent the average values of the algorithm runs. By comparison, the small square corresponding to IBHHO is located at the lowest position, which strongly proves that the average value of its fitness is the smallest and its classification performance is more excellent. The performances of the PSO+R, FA+R, and WCA+R algorithms are relatively close. Their box widths are between those of IBHHO and GA+R, with moderate stability, and their mean points are concentrated in a specific interval, with average fitness better than that of GA+R.

On the SRBCT, Lung cancer, and Ovarian cancer datasets,

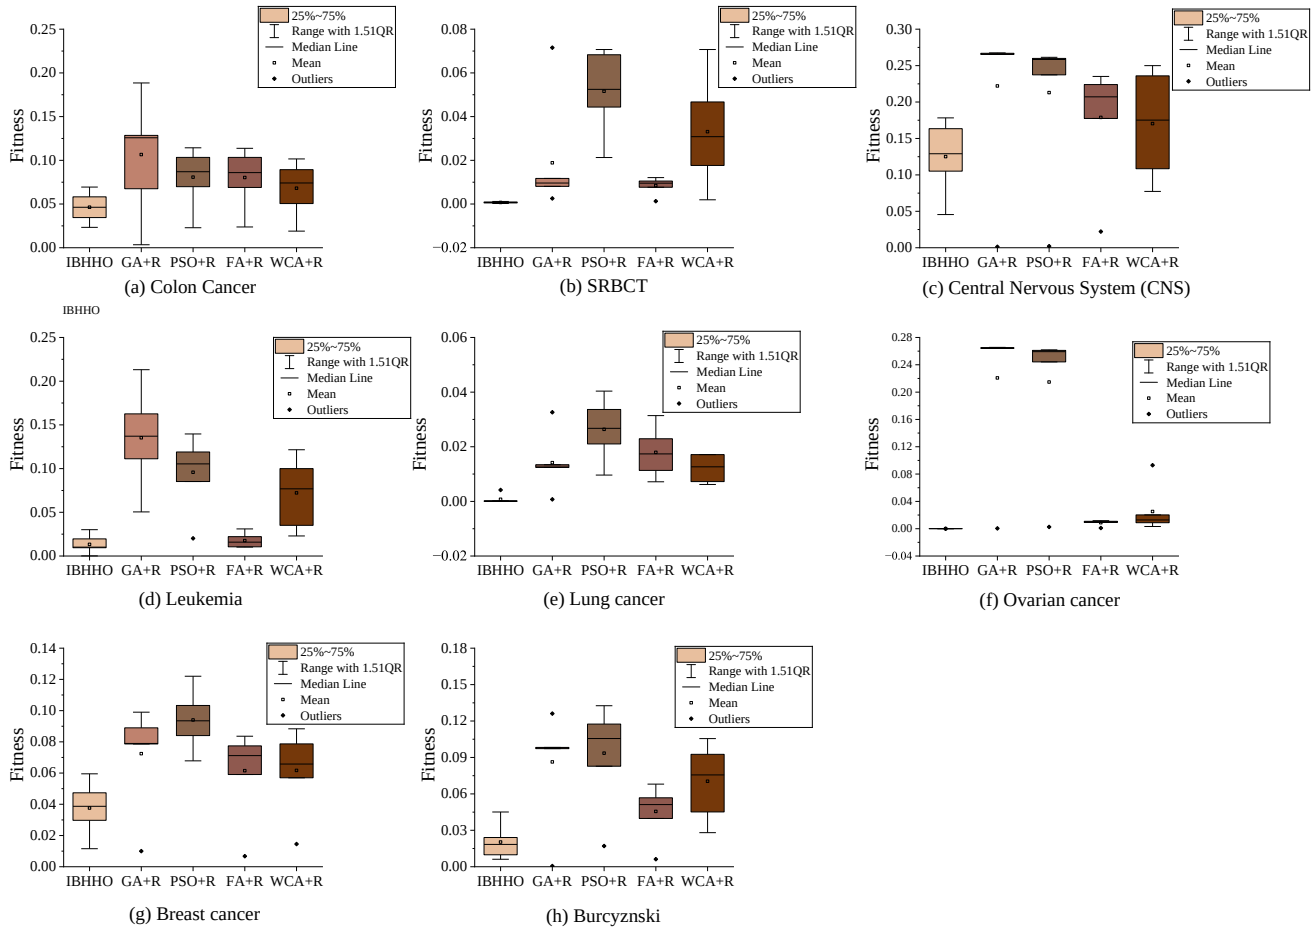

Fig. 3. Comparison of average fitness among different feature selection optimization algorithms.

the box of the IBHHO algorithm appears as a thin line. Compared with the other four algorithms, its box has the smallest width, indicating that the results of multiple runs are highly convergent and its stability is optimal. When comparing the small squares representing the average values of each algorithm, the small square corresponding to the IBHHO algorithm has the lowest fitness, demonstrating its best classification performance.

On the Central Nervous System (CNS), Breast cancer, and Burcyznski datasets, the box of the GA+R algorithm is the narrowest, showing the best stability, while the stability of the IBHHO algorithm is relatively inferior on these three datasets. However, when comparing the small squares inside the boxes that represent the average fitness values, the small square of IBHHO is located at the lowest position, whereas that of GA+R is at the highest. This proves that the average fitness of the IBHHO algorithm is the lowest, indicating better fitness performance, while the fitness of the GA+R algorithm is the worst.

From the boxplots of all test datasets, the key statistical metrics such as the median and mean of the IBHHO algorithm's boxplot are significantly lower than those of the comparison algorithms, and the overall distribution of the box is more concentrated in the low fitness interval. This fully indicates that, relying on its unique population update and search strategies, IBHHO can more efficiently traverse the search space and explore low-fitness solutions in different data scenarios. Its optimization stability and effectiveness are superior to those of the comparison algorithms, which strongly verifies that IBHHO exhibits excellent performance across multiple types of datasets.

To verify the comprehensive performance of the IBHHO algorithm in feature selection tasks, experiments were conducted on eight datasets using the proposed algorithm and four comparative algorithms with ReliefF assistance, as shown in Fig. 4. The classification performance was measured by the average classification accuracy of 30 independent runs, and the feature screening efficiency was evaluated by the average number of selected features. The results were visualized through a combination of bar charts and line charts (the purple bars represent the average accuracy, and the red lines represent the average number of selected features).

As shown in the figure, on the four datasets of Colon Cancer, Central Nervous System (CNS), Breast cancer, and Burcyznski, the accuracy of IBHHO is higher than that of the other four comparative algorithms. Moreover, the number of selected features by the IBHHO algorithm is the smallest. This demonstrates that on these four datasets, IBHHO can ensure higher precision while screening key features more efficiently, well-verifying the advantages of the IBHHO algorithm.

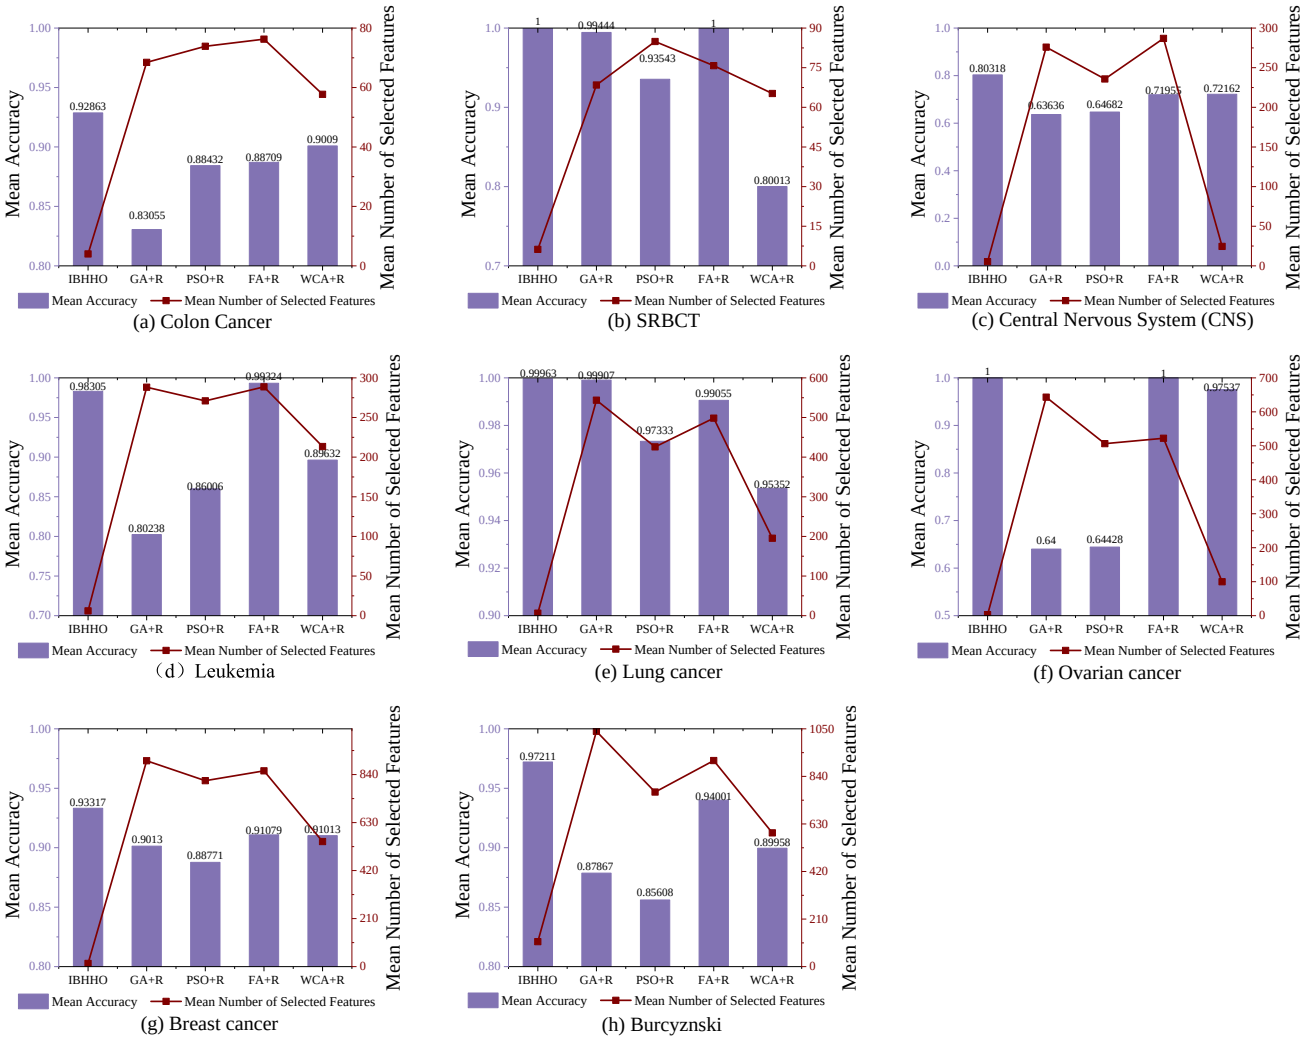

Fig. 4. Comparison of the number of features and accuracy.

On the SRBCT and Ovarian cancer datasets, the accuracy of IBHHO is on par with that of the FA algorithm, while the accuracies of the GA+R algorithm and the WCA+R algorithm are slightly lower than those of IBHHO and FA+R, indicating that these three algorithms have advantages in classification accuracy on the SRBCT dataset. However, considering the number of selected features, on the SRBCT dataset, the number of selected features by the IBHHO algorithm (6) is much lower than that by the GA+R and FA+R algorithms (68 and 75 respectively); on the Ovarian cancer dataset, the number of selected features by IBHHO is 2, compared to 522 and 99 by FA+R and WCA+R. This proves that IBHHO can screen key features while ensuring high precision, and performs better in the "classification accuracy-feature efficiency" dimension.

On the Leukemia dataset, the FA+R algorithm has the highest classification accuracy (0.99), with IBHHO being slightly less accurate (also 0.99). However, the number of selected features by IBHHO is 6, while that by the FA+R algorithm reaches 288. This shows that the ability of IBHHO to screen key features is far superior to that of FA+R. Therefore, it can be concluded that IBHHO performs better in meeting the dual requirements of "accuracy+number of selected features".

On the Lung cancer dataset, all algorithms exhibit classification performance with accuracy close to 1. Nevertheless, the number of selected features by the IBHHO algorithm is much lower than that of the comparative algorithms, which proves that the IBHHO algorithm can select the most critical features while ensuring high accuracy.

From the perspective of meeting the dual requirements of "accuracy+number of selected features" across all test datasets, compared with comparative algorithms such as GA+R, PSO+R, FA+R, and WCA+R, the IBHHO algorithm, relying on its unique search and update mechanisms, achieves efficient screening of key features while ensuring high accuracy. This not only reduces model complexity but also verifies the advantages of the IBHHO algorithm.

Table II presents the comparison of the average execution times of the proposed algorithm and comparative algorithms over 30 independent runs under the same operating environment.

As shown in the table, on the two low-dimensional datasets of Colon Cancer (62 samples, 2000 genes) and SRBCT (63 samples, 2308 genes), GA+R achieves the shortest execution

time. This is because in low-dimensional spaces, its genetic operations can converge directly, and it rapidly screens features through simple operations such as selection and crossover, thereby reducing redundancies. PSO+R has a slightly longer execution time, which stems from the fact that its particle update rules require more iterations to adjust particle distribution during the initial exploration of small-scale data. IBHHO ranks third with an execution time close to that of PSO+R, mainly because its unique search mechanism involves fine-grained exploration of the solution space during initialization or early iterations, resulting in additional computations and thus a slightly longer execution time.

On two medium-high dimensional datasets, Central Nervous System (CNS) (60 samples, 7129 genes) and Leukemia (72 samples, 7129 genes), PSO+R exhibits the shortest execution time. This is because its particles can rapidly focus on key features in high-dimensional spaces by sharing global optimal information, thus avoiding the computational bottlenecks of GA+R's high-dimensional crossover operations and the exploratory redundancy of IBHHO. IBHHO ranks second with an execution time comparable to those of GA+R and PSO+R, as its strategy to escape local optima during high-dimensional searches introduces additional computational overhead.

On the Lung Cancer dataset (181 samples, 12,533 genes), GA+R runs the fastest. The larger sample size strengthens the selection pressure of GA+R, enhancing its efficiency in eliminating redundant genes and achieving directional evolution in high-dimensional spaces. However, for IBHHO, under high-dimensional and large-sample scenarios, the high computational cost associated with its complex feature screening strategy results in it being slower than both GA+R and PSO+R.

On ultra-large-scale high-dimensional datasets such as Ovarian cancer (253 samples, 15,154 genes), Breast cancer (118 samples, 22,215 genes), and Burcyznski (127 samples, 22,283 genes), IBHHO achieves the shortest running time. Its heuristic search or group-based screening mechanisms can directly skip redundant features, overcoming the computational breakdown issues of GA+R and PSO+R in ultra-high-dimensional spaces, and is particularly adaptable to extreme data scenarios involving multi-class classification and ultra-large-scale genes. In these cases, IBHHO ranks first, while GA+R and PSO+R exhibit significantly longer running times due to the high-dimensional computational complexity and inefficiency in handling multi-class classification tasks, which are much longer than that of IBHHO.

In summary, IBHHO is not always the fastest; instead, its performance varies dynamically with data dimensionality: it is outperformed by GA+R in low-dimensional cases (as GA+R features more straightforward computations), and by PSO+R in medium-to-high-dimensional scenarios (since PSO+R achieves more efficient convergence in high dimensions). However, in ultra-large-scale high-dimensional scenarios, it emerges as the optimal choice by virtue of its unique mechanisms, reflecting its targeted adaptation to different data characteristics. Moreover, on all datasets, IBHHO demonstrates superior classification performance compared to the comparative algorithms.

2) Comparison between proposed algorithm and various state-of-the-art methods: To verify the performance of the IBHHO algorithm, four advanced optimization algorithms, namely AltWOA [20], SAGA [35], AIEOU [36], and BSNDO [37], were selected as comparative algorithms. Experiments were conducted on 8 datasets, with all experiments independently executed 30 times under the same environment.

Fig. 5 presents the box plots of the average fitness values obtained from 30 independent runs. On the Colon Cancer dataset, the box of the SAGA algorithm appears as a thin line, indicating a high degree of convergence (minimal fluctuation) among the results of multiple runs and thus demonstrating the best stability among all algorithms. When comparing the mean points (small squares) within the boxes, IBHHO exhibits a significantly lower average fitness value than the other comparative algorithms, indicating the best classification performance. Moreover, the lowest position of IBHHO's box also confirms its lowest fitness value and optimal classification performance.

On the SRBCT, Lung cancer, and Ovarian cancer datasets, the box of the IBHHO algorithm appears as a thin line with the lowest position among all boxes. The small square within its box (representing the mean fitness value) is also lower than those of other comparative algorithms, which proves that IBHHO achieves the best classification performance. Following that, the performances of the SAGA and AltWOA algorithms are second to IBHHO, while the BSNDO algorithm exhibits the worst performance.

On the Central Nervous System (CNS), Breast cancer, and Burcyznski datasets, the SAGA algorithm exhibits the narrowest box, indicating the smallest fluctuation in results across multiple runs and the best stability among all algorithms. However, comparing the mean points (small squares) within the boxes, IBHHO's mean point is positioned lowest, meaning its average fitness value is far superior to SAGA (whose mean point is higher, reflecting the worst fitness performance). This shows that although IBHHO is slightly less stable than SAGA (with a marginally wider box), it achieves a breakthrough in fitness optimization through its unique search strategy. It compensates for the stability difference with a lower average fitness (better classification performance), demonstrating strong adaptability to high-dimensional complex data.

On the Leukemia dataset, the box width of IBHHO is close to that of SAGA (moderate stability), but its mean point is the lowest, showing a significant advantage in fitness. Compared with algorithms like AltWOA, AIEOU and BSNDO, IBHHO is superior in both stability and fitness. Its box is concentrated in the low-fitness interval with short whiskers (data is concentrated without extreme fluctuations), verifying its efficient optimization ability on medium-dimensional data.

Boxplots across all datasets show that statistical metrics such as the median and mean of IBHHO all lie in the lowest interval; its box is overall concentrated in the low-fitness range with short whiskers (indicating high aggregation of non-outlier data). This indicates that through its unique population update and search mechanisms, IBHHO can efficiently traverse the solution space and explore low-fitness solutions across different data scenarios (low-dimensional, medium-to-high-dimensional, and ultra-large-scale high-dimensional), avoiding the drawbacks of comparative algorithms (such as the high fluctuation of SAGA and the local convergence bias of AltWOA). Even in datasets where SAGA dominates in

TABLE II. COMPARISON OF AVERAGE EXECUTION TIME(S)

Dataset	IBHHO	GA+R	PSO+R	FA+R	WCA+R
Colon Cancer	76.1	47.8	75.8	342.8	476.5
SRBCT	205.7	179.5	194.7	935.6	1156.7
Central Nervous System (CNS)	107.4	104.0	103.6	1711.5	103.3
Leukemia	115.5	119.7	111.9	936.8	341.6
Lung cancer	207.5	173.5	197.9	793.6	258.8
Ovarian cancer	283.0	365.6	365.3	920.2	361.3
Breast cancer	209.3	221.3	205.1	1025.7	364.0
Burcyznski	325.7	408.6	408.0	1535.3	277.0

stability (CNS), IBHHO still outperforms with a lower average fitness (a core performance metric), fully verifying its excellent generalization ability and optimization efficiency on multi-type microarray data.

To verify the comprehensive performance of the IBHHO algorithm in feature selection tasks, the algorithm proposed in this study and four comparative algorithms from various state-of-the-art methods were tested on 8 datasets, as illustrated in Fig. 6. The classification performance is evaluated using the average classification accuracy from 30 independent runs (represented by blue bar charts), while the feature selection efficiency is depicted by orange curves (showing the average number of selected features). This dual-metric visualization (precision+feature count) precisely assesses the algorithm's balance between "classification accuracy" and "feature selection efficiency".

On the Colon Cancer and SRBCT datasets, IBHHO achieves the best classification accuracy (reaching above 0.9), while other algorithms are around 0.8. Looking at the number of selected features, although GA selects fewer key features (1 and 4, respectively, compared to IBHHO's 4 and 6), its classification accuracy is lower. Overall, IBHHO demonstrates a better balance between "accuracy" and "efficiency". On the Central Nervous System (CNS), Lung cancer, Ovarian cancer, and Breast cancer datasets, the IBHHO algorithm achieves the best classification accuracy, with SAGA being slightly inferior. However, when comparing the number of selected features, the number of key features selected by the IBHHO algorithm is less than that selected by SAGA, which proves that IBHHO can search for more critical features while ensuring high accuracy.

On the Leukemia dataset, IBHHO achieves a classification accuracy of 0.98 with only 6 selected key features, demonstrating the best balance performance between "accuracy and feature selection efficiency". In contrast, the BSNDO algorithm exhibits a classification accuracy of only 0.62 while selecting up to 3519 key features, thus showing the worst performance in balancing "accuracy and number of features". On the Burcyznski dataset, the AltWOA algorithm selects the fewest features (26), while IBHHO selects 110 features. However, in terms of classification accuracy, IBHHO reaches 0.97, whereas AltWOA only achieves 0.52. Therefore, IBHHO still delivers the best comprehensive performance on the Burcyznski dataset.

The above results fully demonstrate IBHHO's advantages in simultaneously maximizing classification accuracy and minimizing the number of features. Through efficient search mechanisms, this method can generate sparse yet high-quality feature sets, reducing model complexity while enhancing performance. This makes IBHHO a powerful tool in the field of bioinformatics—its unique advantages are particularly prominent in research scenarios where both accuracy and feature efficiency are equally emphasized to obtain reliable biological insights (such as identifying the minimal gene panel required for cancer diagnosis).

Table III presents a comparison table of the average execution time from 30 independent runs of the proposed algorithm and the comparative algorithms under the same operating environment. As can be observed from the table, on the Colon cancer (62 samples, 2000 features) and SRBCT (63 samples, 2308 features) datasets, which belong to low-dimensional spaces, the simple search strategy of BSNDO avoids the fine-grained search overhead during the initialization of IBHHO and converges directly, resulting in shorter computation time. For the Central Nervous System (CNS) dataset (60 samples, 7129 features), when the sample size is limited and the feature dimension is relatively high, the heuristic search of IBHHO avoids the blind exploration of the particle swarm of AltWOA in the initial iteration and directly converges to the key features.

On the Leukemia (72 samples, 7129 features), Lung cancer (181 samples, 12,533 features), and Breast cancer (118 samples, 22,215 features) datasets, where the sample size is relatively small but the feature dimension is extremely high, AltWOA exhibits faster running speed. This is likely due to the optimizations for high-dimensional computational efficiency in its improved version (AltWOA), which may adopt feature subspace operations or highly optimized vector computation implementations. These optimizations significantly reduce the constant factor overhead of high-dimensional vector operations in each iteration.

On the Ovarian cancer (15,154 features, 253 samples) and Burcyznski (22,283 features, 127 samples) datasets, where both sample sizes and feature dimensions are higher, IBHHO runs faster. Its advantage may lie in its more complex and adaptive exploration-exploitation balance strategies. These strategies allow IBHHO to more effectively utilize information and accelerate the convergence process in the more complex search spaces induced by increased sample sizes, thereby gaining a significant advantage in the total number of iterations and offsetting the potentially higher computational cost of its single iteration.

To summarize, in low-dimensional spaces, although IBHHO is not the fastest in such scenarios, its fitness values

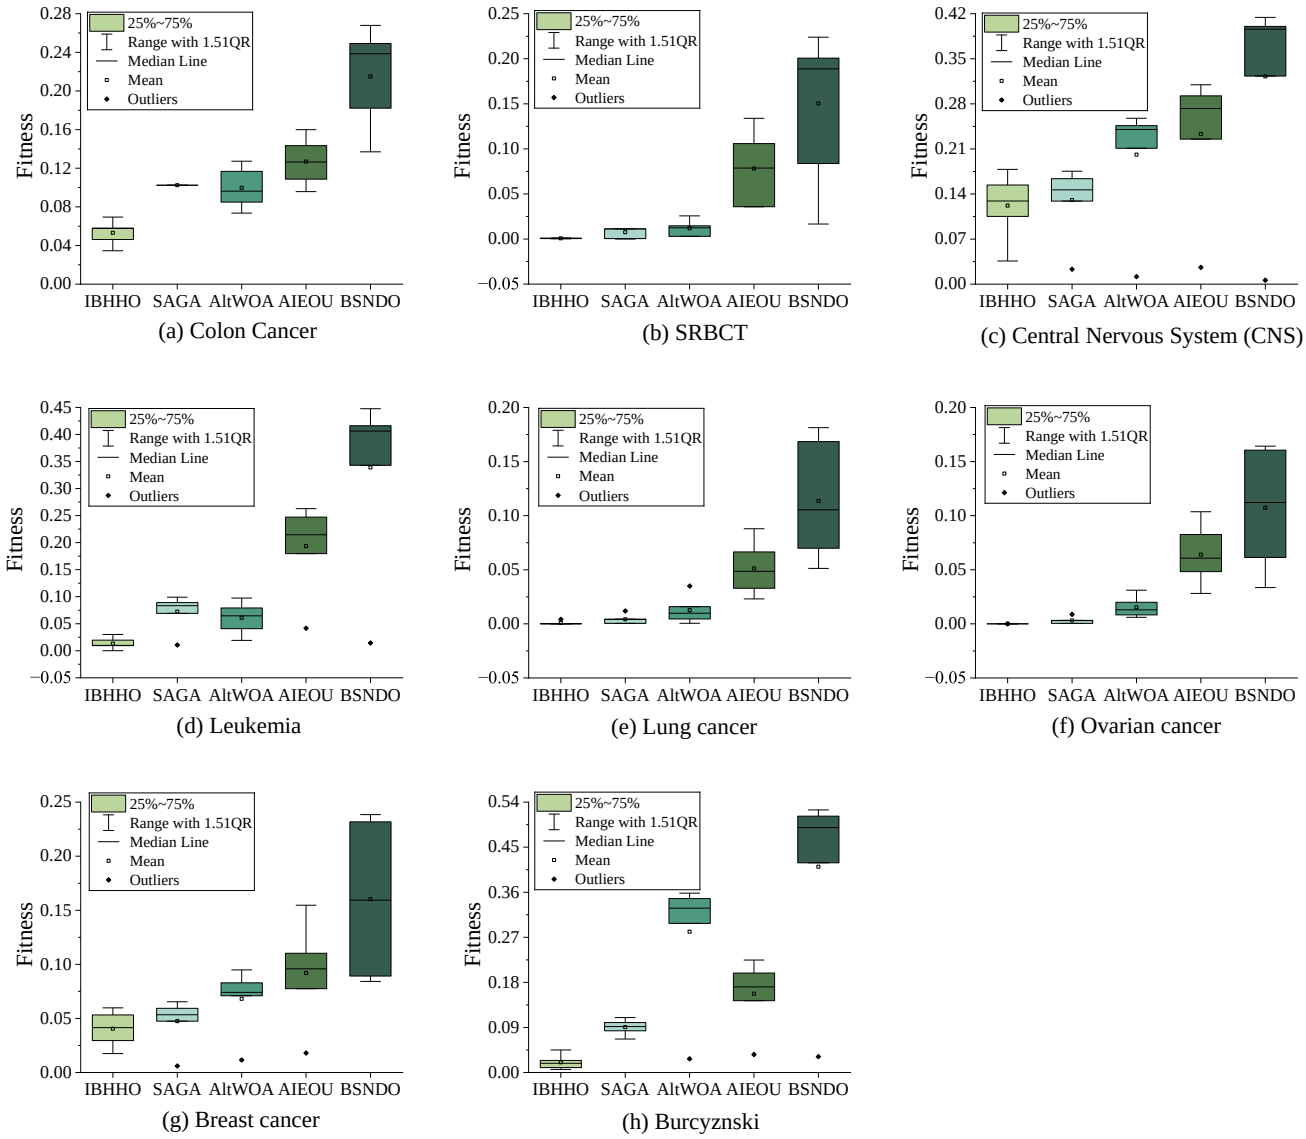

Fig. 5. The box plots of the average fitness values obtained from 30 independent runs.

and classification performance (classification accuracy, number of selected features, etc.) far surpass those of BSNDO, demonstrating decisive advantages. In high-dimensional small-sample scenarios (Leukemia, Lung cancer, and Breast cancer), AltWOA achieves the fastest running speed by significantly reducing the constant factor overhead of each iteration through feature subspace operations and vectorized computation optimizations. However, IBHHO still maintains acceptable timeliness (slightly slower than AltWOA) while comprehensively outperforming AltWOA in both fitness and classification performance. In high-dimensional large-sample datasets (Ovarian cancer and Burczynski), IBHHO relies on adaptive exploration-exploitation strategies to efficiently guide the search direction in complex solution spaces, surpassing AltWOA in speed with fewer iterations while maintaining a leading position in classification performance.

TABLE III. COMPARISON OF AVERAGE EXECUTION TIME(S) FROM 30 INDEPENDENT RUNS

Dataset	IBHHO	SAGA	AltWOA	AIEOU	BSNDO
Colon Cancer	76.1	178.7	65.0	64.9	62.0
SRBCT	205.7	133.3	100.4	266.6	81.1
Central Nervous System (CNS)	107.4	510.5	163.2	299.3	208.9
Leukemia	115.5	464.9	95.5	204.0	201.8
Lung cancer	207.5	3262.9	68.1	648.7	528.7
Ovarian cancer	283.0	3382.5	376.3	799.2	894.7
Breast cancer	209.3	12832.0	93.6	839.2	735.4
Burcyznski	325.7	11428.3	501.5	827.3	714.6

VII. CONCLUSION

This study aims to address the challenge of feature selection in high-dimensional microarray datasets, where redundant

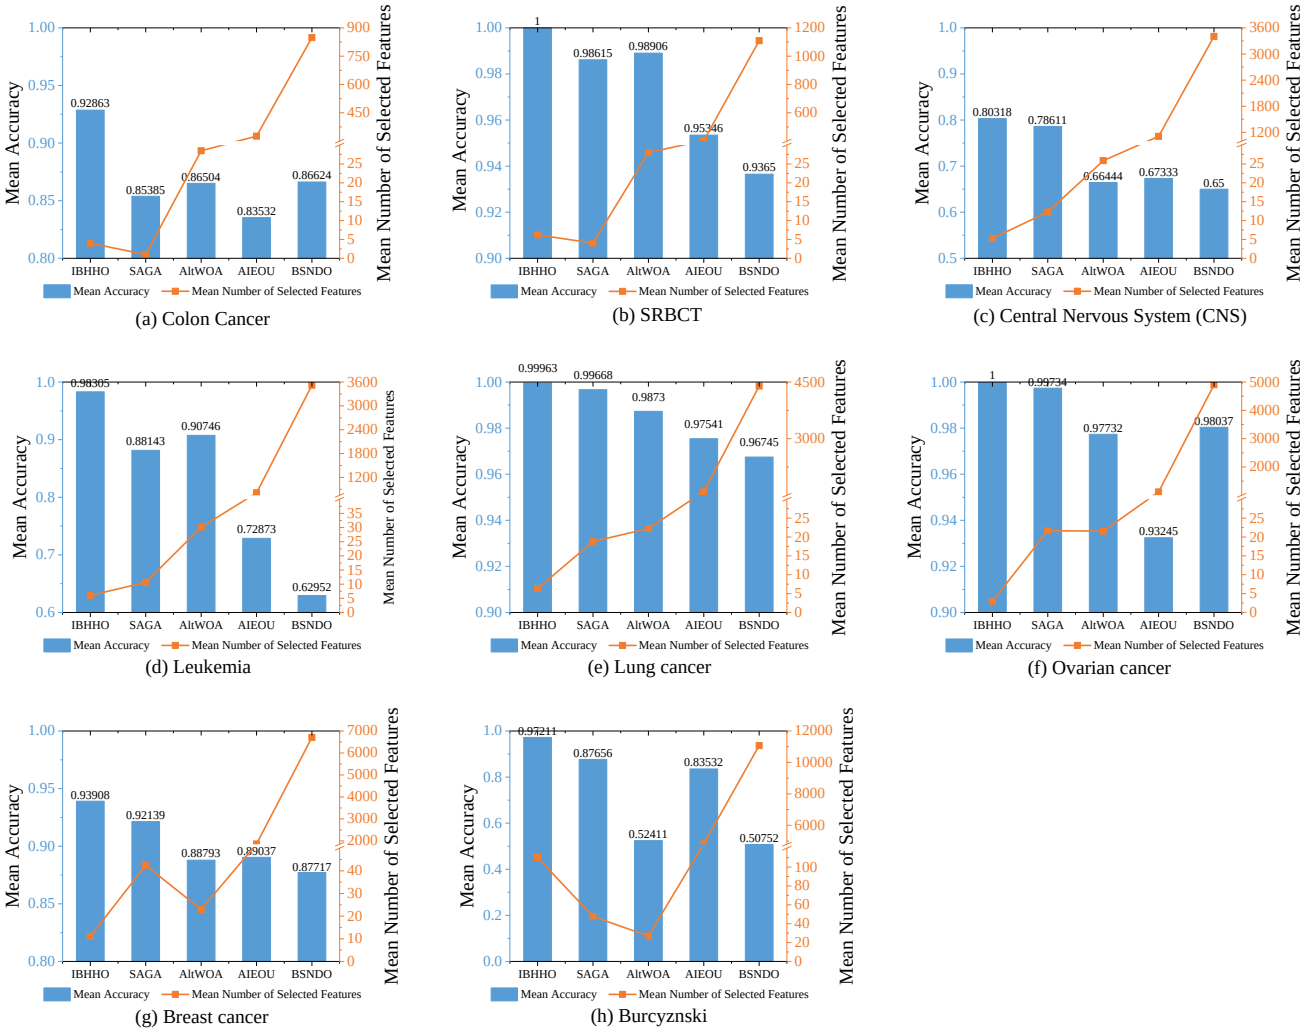

Fig. 6. Comparison chart of the number of features and accuracy.

features and the "curse of dimensionality" severely hinder the performance of machine learning models. To tackle this issue, IBHHO is proposed, which integrates a hybrid feature selection framework, a two-stage parameter-feature co-optimization strategy, and an elite feature guidance mechanism. By fusing filter (ReliefF) and wrapper (SVM) methods, this framework enables the simultaneous optimization of ReliefF parameters, SVM hyperparameters, and feature subsets. Leveraging the two-stage characteristics of HHO (exploration and exploitation), the algorithm focuses on optimizing ReliefF and SVM parameters during the exploration phase, while refining feature subsets in the exploitation phase, thus achieving a balance between global search and local optimization. The elite feature strategy further accelerates the algorithm's convergence speed and reduces redundant exploration by retaining key features as fixed anchors. These innovations collectively enhance IBHHO's ability to identify optimal feature subsets, not only improving classification accuracy but also effectively reducing feature dimensionality. Experimental results demonstrate that IBHHO outperforms other comparative algorithms in terms of comprehensive performance across eight microarray datasets, verifying its effectiveness in handling high-dimensional biological data. In future, it will also be possible to combine bioinformatics knowledge to conduct in-depth analyses of the biological relevance of feature subsets selected by IBHHO, providing more specific guidance for research on cancer gene functions.

***Abstract*—Ulcerative Colitis (UC), a chronic inflammatory bowel disease, presents significant diagnostic challenges due to its overlapping symptoms with other gastrointestinal disorders and the complex visual patterns in endoscopic imagery. Accurate and early detection is essential to guide effective treatment and improve patient outcomes. This research introduces a robust hybrid framework that combines convolutional feature extraction with bidirectional temporal modelling for the precise identification of UC from medical imagery. The proposed approach integrates CNNs—including MobileNetV3Large, Inception v3, InceptionResNetV2, and Xception—with Bi-GRU and Bi-LSTM networks. The CNNs are responsible for capturing high-level spatial features, while the Bi-GRU and Bi-LSTM modules enhance temporal context understanding, enabling the model to effectively interpret subtle patterns and transitions characteristic of UC. Each hybrid model was designed, and thoroughly tested on an curated set of experimental data. Among the combinations, the highest accuracy was of 93.10%, obtained with the Xception + Bi-GRU + Bi-LSTM model. Inception v3 + Bi-GRU + Bi-LSTM followed closely, attaining an accuracy of 92.62%. The different data augmentation techniques is deployed to handle the class imbalance that exists in the LIMUC dataset . Notably, the bidirectional temporal modelling component significantly improved the recognition of sequential dependencies in medical image frames, enhancing the model's diagnostic robustness. The findings demonstrate that integrating CNNs with bidirectional temporal encoders offers a promising solution for UC detection, providing a valuable tool for clinicians in automated diagnostic systems. This study not only contributes to the advancement of intelligent medical imaging but also paves the way for deploying real-time UC detection models in clinical practice.**

***Keywords*—Ulcerative Colitis Detection (UCD); CNNs; Bi-GRU; Bi-LSTM; medical image**

I. Introduction

Ulcerative Colitis (UC) is a chronic, relapsing inflammatory disease of the colon that markedly affects quality of life. UC, marked by inflammation and ulceration of the lining of the colon, can lead to heterogeneous symptoms including abdominal pain and diarrhea, etc. Early and accurate diagnosis of UC is essential to managing disease progression, minimizing complications, and tailoring therapeutic interventions [1], [2]. However, differentiating UC from other gastrointestinal disorders based on endoscopic and histopathological findings remains a complex task, often requiring the expertise of trained specialists. The subjectivity and margin of human error that is inherent to standard diagnostic protocols is the result of the subtlety of visual clues in a medical image as well as variability among different patients. This underscores the need for intelligent, automated diagnostic systems capable of supporting clinical decision-making through reliable and interpretable insights.

Recent advancements in DL have opened new avenues for automated disease classification, especially in the field of medical imaging [3], [4], [5]. CNNs, with their strong ability to extract spatial features, have become the cornerstone of many computer-aided diagnostic systems [6], [7]. Nevertheless, medical data, especially video-based or sequential image modalities obtained during endoscopic procedures, possess a temporal dimension that CNNs alone cannot fully capture. To address this, sequence learning models such as GRUs and LSTMs have been employed to model temporal dependencies and capture the evolution of visual patterns over time. While each architecture has its own advantages, a synergistic combination of CNNs with temporal modeling techniques offers a comprehensive solution that leverages both spatial and contextual information. In this study, we propose a hybrid framework that integrates convolutional feature encoding with bidirectional temporal context modeling to enhance the robustness and accuracy of Ulcerative Colitis detection. The framework utilizes a series of CNN architectures—MobileNetV3Large, Inception v3, InceptionResNetV2, and Xception—as the feature extractors. These networks are known for their efficient and deep representations of visual content, making them suitable for detecting fine-grained patterns indicative of UC. To enrich these spatial features with temporal dynamics, we embed Bi-GRU and Bi-LSTM layers into the model pipeline. The bidirectional structure enables the model to interpret the image sequence from both past and future contexts, thereby improving the model's understanding of pattern transitions in the disease's progression. Bidirectional temporal models are chosen based on the ability to learn more complex and symmetric representations of temporal features than just unidirectional ones.The combination of GRUs ,which have lower computational cost compared to other recurrent architectures, and LSTMs, which are able to better control long-term dependencies, further enhance the temporal learning capacity of the model. Combining these approaches with CNNs increases the capacity of the system to detect clinically subtle details, while generalizing well to other patient samples.A comprehensive experimental

evaluation was conducted to assess the effectiveness of the proposed hybrid models. The Xception + Bi-GRU + Bi-LSTM configuration demonstrated the highest performance, achieving an accuracy of 93.10%. This model outperformed other combinations, including Inception v3 + Bi-GRU + Bi-LSTM (accuracy: 92.62%), InceptionResNetV2 + Bi-GRU + Bi-LSTM (accuracy: 91.28%), and MobileNetV3Large + Bi-GRU + Bi-LSTM (accuracy: 89.40%). The results underscore the superiority of integrating advanced convolutional encoders with bidirectional temporal networks, especially when dealing with complex, variable-rich datasets like those involved in UC diagnosis.

The primary contribution of this research lies in the demonstration that convolutional and temporal features, when modeled jointly, can significantly improve diagnostic accuracy and reduce mis-classification. This approach also shows promise for scalability and adaptability across different gastrointestinal conditions, making it a versatile tool in the broader landscape of endoscopic image analysis. Furthermore, by reducing dependency on manual interpretation and standardizing the diagnostic process, the proposed framework has the potential to minimize diagnostic delays and optimize treatment planning. With the rising demand for precision medicine and the integration of AI in healthcare workflows, our proposed model offers a timely and impactful solution.

The structure of the research is as follows: Sections II provides a description of related work and Section III describes the materials and methodology for UC detection. Discussion of the results is given in Section IV. Finally, Section V wraps up the research and suggests avenues for future research.

II. Literature Review

The emergence of ML has significantly advanced the field of medical diagnostics, particularly in inflammatory bowel diseases such as ulcerative colitis (UC). Multiple studies have attempted to improve early diagnosis, severity recognition, treatment outcome prediction, and differentiation from other gastrointestinal diseases with several different AI methods . One of the early studies by Khorasani et al. [1] employed effective feature selection techniques along with ML classifiers to identify UC from healthy colon samples, highlighting the importance of diagnostics preprocessing optimization. Similarly, Popa et al. [2] proved the predictive ability of ML models in predicting long-term disease activity in UC patients treated with anti-TNF, providing potential instruments for clinical decision-making as well as personalized treatment planning.The use of DL has even transformed the field further, especially in image-based analysis.

Klang et al. [6] first applied DL methods for identifying Crohn's disease from video capsule endoscopy, paving a path towards a non-invasive and automated video-based analysis of the gastrointestinal tract. This opened the way to applications more focused on UC; for example; Takenaka et al. [7] created a DL able to assess endoscopic images of patients with UC, demonstrating performance at the level of experts in scoring mucosal inflammation. Bossuyt et al. [8] went a step further by incorporating a computer-based quantification of endoscopic and histological inflammation, thus reinforcing the promise of image-based AI tools for assessment of the whole disease.Continuing the work done in endoscopic assessments, Bhambhvani and Zamora [9] focused on DL classification of the Mayo endoscopic subscore, an important disease severity index in UC. This provided a more efficient scoring system and eliminated subjectivity more in line with the clinical need for reproducibility and efficiency.In addition to imaging, structured clinical data has also been central in the further studies. Roy et al. [10] considered links to UC, 5-ASA, and COVID-19 deaths in the context of machine learning methodology, demonstrating AI's ability to integrate real-world data in support of research.

In a similar vein, Miyoshi et al.[11]used baseline clinical characteristics to predict the response to vedolizumab treatment, thus demonstrating the capability of ML to personalize biologic therapy. At the molecular level, Park et al. [12] utilized RNA sequencing data to ML models to classify UC versus Crohn's disease, indicative of the increasing convergence of AI and genomic data. Becker et al. [13] raised the point of DL scalability, as the models are trained and deployed on data collected in multicenter clinical trials for the grading of endoscopic severity. They argued for cross-validation and generalizability. Lu et al.[14] used bioinformatics and incorporated ML to establish diagnostic gene signatures, whereas Chierici et al.[15] used automated identification of UC and Crohn's from endoscopic images, demonstrating the reliability of DL in clinical imaging analysis across different fields. Gut microbiome is another area of relevance for UC prediction. Barberio et al. [16] concluded that ML could link certain microbial profiles to the severity of UC and establish the use of microbiota-based diagnostic modalities. Li et al. [17] developed interpretable predictive models to the endoscopic activity in UC, balancing clinical interpretability and computational complexity.Building on this, Fan et al. [18] developed a DL-based computer-aided diagnosis system to predict inflammatory activity in a manner that is both real-time predictive and usable in a clinical context . Recent studies have attempted to improve accuracy and refine scoring systems. Byrne et al.[19] assessed DL models according to various types of UC scoring systems and highlighted the importance of maintaining consistency within metrics. Polat et al. [20] used a regression based DL, moving from classification based to regression based DL to increase prediction of Mayo scores.

Kulkarni et al. [21] summarized the use of AI technologies in UC, highlighting some of the trends and challenges in diagnostic innovation.Pei et al. [22] performed a comparison between ML algorithms for differentiating UC from Crohn's, emphasizing the role of model choice on diagnostic accuracy.Some work on innovative classification approaches has been done by Alyamani [23], who developed a multi-level DL architecture for better diagnostic resolution,while Carreras et al. [24] incorporated gene expression signatures including LAIR1 and TOX2 with CNNs to investigate the association between UC and colorectal cancer, integrating histopathology with computational analysis.Lee et al.[25] provided a stool image-based, vision-centered, non-intrusive new screening technology with the capability of predicting mucosal inflammation.Vezakis et al.[26] compared various DL architectures to obtain UC severity metrics and the findings are valuable when considering which model to use based on the desired diagnostic outcome.Li et al.[27] used single-cell sequencing and mitochondrial metabolism markers to construct a high-quality diagnostic model, a good example of

the combination of omics data and artificial intelligence.

Overall, as discussed, ML and DL are used in a broad variety of ways for the diagnosis and treatment of ulcerative colitis in the literature.Whether dealing with endoscopic images or histological slides, genomics, or microbiota, novel AI paradigms have been proposed, allowing for more accurate diagnoses, as well as predictive and tailored treatment strategies. But there are still issues like generalizability across datasets, explainability, and implementation in real-world clinical settings. The present study expands these works by providing an improved hybrid model that overcomes these limitations with high performance, good interpretability, and ability to use heterogeneous data types.

III. Materials and Methods

A. Dataset

The LIMUC dataset [28] utilized in this work contains a total of 11,276 colonoscopy frames from 564 patients that underwent 1,043 procedures between December 2011 and July 2019 at the Department of Gastroenterology at Marmara University, School of Medicine. The images were obtained from patients with ulcerative colitis undergoing colonoscopy and were independently reviewed by two expert gastroenterologists who scored the images using the Mayo Endoscopic Score (MES), which is a clinical classification system for grading the severity of ulcerative colitis. If the two reviewers did not agree, a third expert performed an independent evaluation and the final label was assigned by majority voting to ensure reliability. Our dataset contains images that belong to four different MES classes: Mayo 0 (6,105 images), Mayo 1 (3,052 images), Mayo 2 (1,254 images) and Mayo 3 (865 images), as a representation of differing levels of inflammation. In order to tackle the class imbalance, data augmentation through many different methods such as flipping images, rotating images, changing the scale and brightness of the images, were used. This also had the effect of increasing the number of images available in each class at around 5,000 images, producing a balanced dataset. These labeling process and augmentation technique collectively represent a well-captured, reliable dataset that can be robustly used to automate the classification of ulcerative colitis severity from endoscopic images. The dataset sample image is given in Fig. 1.

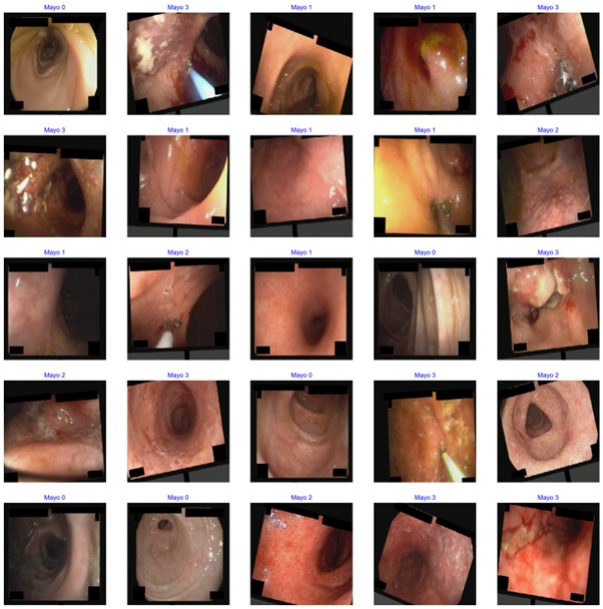

Fig. 1. Sample images of LIMUC dataset.

B. Proposed Methodology

The proposed methodology introduces a hybrid architecture that synergistically combines CNNs and RNNs to enhance the classification of ulcerative colitis from endoscopic images. As illustrated in Fig. 1, the system initiates with a sequence of input images derived from colonoscopy procedures, capturing varying regions of the intestinal mucosa. These images are first processed through a CNN block, which performs hierarchical feature extraction to identify critical spatial patterns such as mucosal texture, ulcerations, and inflammation. The convolutional layers are followed by pooling operations that reduce spatial dimensionality while retaining key visual information. The extracted spatial features are then sequentially passed into a Bi-GRU layer, which models temporal relationships across the image sequence by analyzing patterns in both forward and backward directions. In order to better learn long-range dependencies, the output from the Bi-GRU is then passed into a Bi-LSTM layer. This modeling of dual temporarily provides the system with information on short-term transitions as well as long-term disease progression cues that can be identified in the image frames. Finally the temporally enriched feature representations are forwarded to a fully connected dense layer specific for classification. The output layer ultimately produces a predicted probability of Ulcerative Colitis status, allowing for a strong and interpretable diagnostic model. This multi-system architecture achieves greater sensitivity and classification performance than systems using only spatial features or only unidirectional temporal context. Fig. 2 displays the proposed architecture.A detailed description of the architecture is discussed in the following subsection.

C. MobileNetV3Large + Bi-GRU + Bi-LSTM

The methodology employs a two-stage neural network that first extracts spatial features with a streamlined MobileNetV3Large model and then captures temporal relationships using sequential recurrent layers. RGB inputs sized at 224×224×3 are processed by MobileNetV3Large—initialized with ImageNet weights and stripped of its final classifier—yielding dense feature maps. These maps undergo global average pooling to collapse spatial dimensions into a concise feature vector, which is then reshaped for time-series analysis. Next, the vector feeds into a Bi-GRU layer, allowing information flow in forward and reverse directions, followed by a Bi-LSTM layer to deepen the model's temporal context awareness. The combined output is projected through a dense layer with ReLU activation to refine the feature embedding before reaching the final classification stage. This design leverages a lightweight convolutional backbone alongside powerful recurrent components to deliver precise and contextually informed image classification. The proposed architecture is given in Table I.

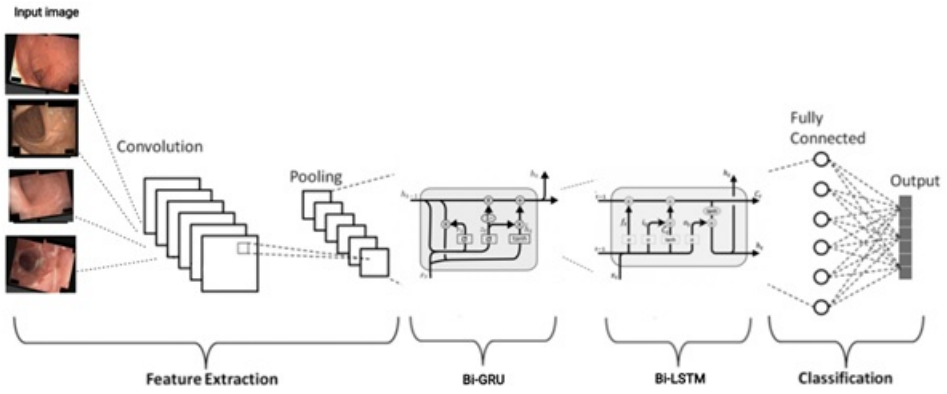

Fig. 2. The proposed architecture.

D. Inception v3 + Bi-GRU + Bi-LSTM

In the proposed work, colonoscopy images were first uniformly resized to fit the InceptionV3 input requirements. Extensive on-the-fly data augmentation was applied via the ImageDataGenerator interface to enhance dataset variability and counteract overfitting. Spatial features were extracted using the convolutional base of InceptionV3 pretrained on ImageNet, with its weights frozen to preserve established filters. The resulting dimensional feature vectors were then reshaped into sequences of length 64 with 32 features per time step, thereby creating a pseudo-temporal representation. A Bi-GRU layer processed these sequences to capture bidirectional, short-term patterns, which were subsequently fed into a Bi-LSTM layer to learn longer-range dependencies. Output from the recurrent stack was passed through a fully connected layer and ReLU activation, followed by a dropout layer (dropout rate = 0.3) to further mitigate overfitting. A final softmax layer produced probability scores of ulcerative colitis. The network was trained using the Adam optimizer and categorical cross-entropy loss, leveraging the augmented data streams for both training and validation stages. The proposed architecture is given in Table II.

E. InceptionResNetV2 + Bi-GRU + Bi-LSTM

To accurately classify ulcerative colitis from colonoscopy images, this research proposes a novel hybrid architecture that integrates InceptionResNetV2 with Bi-GRU and Bi-LSTM networks. The model begins by accepting RGB images of a fixed size through an input layer. Feature extraction is performed using the InceptionResNetV2 model, which has been pre-trained on the ImageNet dataset. This CNN is used without its final classification layers to retain only the learned spatial feature representations. These high-dimensional feature maps are then reshaped into a sequence by flattening the spatial components, preparing the data for temporal pattern analysis. The sequential representation is first processed by a Bi-GRU layer, enabling the capture of short-term dependencies from both forward and backward time steps. Subsequently, the output is passed to a Bi-LSTM layer, which focuses on learning more complex and long-term contextual patterns in both directions. This combination of recurrent layers enhances the model's ability to interpret dynamic relationships within the extracted features. Finally, the output is directed through dense layers with ReLU activation, ending in a softmax layer for multi-class prediction. The model is optimized using the Adam algorithm. This integrated approach is designed to efficiently capture both spatial and sequential patterns relevant to ulcerative colitis diagnosis. The proposed architecture is given in Table III.

TABLE III. INCEPTIONRESNETV2 + BI-GRU + BI-LSTM ARCHITECTURE

F. Xception + Bi-GRU + Bi-LSTM

The methodology centers on a multi-stage hybrid pipeline tailored for ulcerative colitis detection in colonoscopy imagery. To bolster the model's resilience against overfitting, each image underwent real-time augmentation—via a generator. For feature extraction, we adopted the Xception network pre-trained on ImageNet: its final classification layers were removed, and the remaining convolutional base was frozen to preserve learned representations. The resulting high-dimensional feature maps were then transformed into temporal sequences through a reshape operation, treating each spatial location as a time step. These sequences flowed into a Bi-GRU layer, which processes information in both forward and reverse directions to capture local patterns, and subsequently into a Bi-LSTM layer that further models long-range dependencies. The bi-directional recurrent outputs were flattened and fed into a dense layer with ReLU activation, followed by dropout to reduce overfitting. A concluding softmax layer produced probabilities across the target classes. Model optimization employed the Adam algorithm. This hybrid strategy leverages Xception's spatial feature learning alongside the temporal modeling strengths of Bi-GRU and Bi-LSTM, yielding a robust classifier for ulcerative colitis. The proposed architecture is given in Table IV.

IV. RESULTS

The models for ulcerative colitis detection were run in a Jupiter setup with a hardware configuration of an AMD Ryzen 7 5800H processor with 8 cores, 16 GB of RAM. The graphics processing unit (GPU) used for computation was the Nvidia GeForce RTX 3060.

The evaluation of hybrid architecture integrating convolutional architectures with sequential learning units highlights the efficacy of the proposed methodology in classifying ulcerative colitis severity from colonoscopy images, as shown in Table V. The MobileNetV3Large combined with Bi-GRU and Bi-LSTM achieved an accuracy of 89.40%, with closely aligned precision, recall, and F1-score values, demonstrating its lightweight yet competent performance, particularly beneficial in low-resource environments. The Confusion Matrix and ROC Curve of the proposed architecture is given in Fig. 3 and Fig. 4.

V. Conclusion

This research introduces a robust DL framework for classifying ulcerative colitis severity using colonoscopy images, employing a hybrid model that fuses the spatial learning capacity of CNNs with the temporal strengths of Bi-GRU and Bi-LSTM architectures. Among the various models assessed, the Xception + Bi-GRU + Bi-LSTM configuration delivered the highest performance, achieving an accuracy of 93.10%. This highlights the significance of incorporating depthwise separable convolutions in medical imaging tasks, as they enable efficient and detailed feature extraction. Similarly, Inception v3 and InceptionResNetV2 based hybrids also showed strong results, affirming the potential of combining advanced CNN backbones with recurrent networks to handle both spatial complexity and temporal dependencies in medical datasets. It also contrasts the importance of class balance and augmentation techniques, that played an important role in improving generalization of the model in particular the imbalanced classes in the original dataset. Both these techniques worked well in modeling the highly non-linear characteristics found at varying states of ulcerative colitis.

In the future, there are many avenues to build upon this work. First, data from more medical centers and populations could enhance adaptivity and clinical applicability of the model. The implementation of real-time video streams rather than single images could further increase diagnostic accuracy by taking advantage of temporal consistency across frames. Transformer based architectures could also be explored in future studies. Also, it may be pursued to further refine the model in order to be deployed in a clinical environment, including lightweight models that could run on mobile and embedded applications to provide real-time decision support during colonoscopy procedures. Lastly, including feedback loops to validate and correct predictions from gastroenterologists could transform this in a continuously learning system that improves over time. Future extensions of this work will involve real-time use in the clinical setting, incorporation into electronic health record systems, and assessment in larger, multi-site samples to test the system's robustness and generalizability.

***Abstract*—Exchange rate volatility forecasting plays a vital role in guiding financial decisions and economic planning, particularly in China's dynamic foreign exchange market. This study proposes a novel deep learning framework, termed DALG (Dual Attention-based LSTM-GRU), designed to capture complex temporal patterns and feature dependencies in high-frequency USD/RMB exchange rate data. By integrating LSTM and GRU architectures with a dual-stage attention mechanism, comprising input and temporal attention, the proposed DALG model enhances the interpretability and accuracy of exchange rate volatility forecasts. The model is empirically evaluated against benchmark models such as LSTM, GRU, and a hybrid LSTM-DA using standard performance metrics, including Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Mean Absolute Percentage Error (MAPE). Experimental results demonstrate that the DALG model consistently outperforms traditional and hybrid deep learning models, offering superior predictive performance. The findings suggest that attention-enhanced deep learning architectures hold significant promise for robust financial time series modeling and forecasting in volatile forex markets.**

***Keywords*—Exchange rate forecasting; deep learning; LSTM-GRU hybrid; attention mechanism; financial time series; USD/RMB volatility**

I. Introduction

The prediction of exchange rates is one of the most complex tasks in international finance, since the exchange rates are volatile, there is a large noise in the currency markets, and the relationships between the currencies are nonlinear [1], [2], [3]. Precise prediction models are central towards the facilitation of informed policymaking, improved financial risk management, and profitable trading strategies [4], [5]. The classical econometric models, including the Autoregressive Integrated Moving Average (ARIMA) and Generalized Autoregressive Conditional Heteroskedasticity (GARCH) models have been used to gain basic knowledge but they tend to fail to capture the nonlinear, time-varying, and complex behavior of financial time series [6].

As the field of deep learning developed, especially with the invention of RNNs and their extensions, significantly more success has been achieved in capturing temporal relationships in time series data. LSTM and GRU networks are considered to be the most prominent structures in this field because they solve the problem of vanishing gradients and allow capturing long-term dependencies [7]. However, one of these models' primary shortcomings is that they treat all time steps equally, which leads to inadequate results because not all-time steps and input features are equally significant [8]. To overcome this, a new mechanism of attention, specifically DA, has been proposed to improve the interpretability and performance of models. Such mechanisms allow the model to adaptively assign weights both on input features, as well as on the temporal dimensions, hence enhancing its attention to the most relevant data [9], [10].

The study proposed a new hybrid deep learning architecture combining LSTM and GRU layers and the dual attention (DA) mechanism to predict the USD/CNY exchange rate. The proposed architecture is expected to be resilient in capturing the complex temporal and contextual patterns of financial time series data by integrating the memory retention abilities of LSTM, computational efficiency of GRU and contextual refinement provided by attention mechanisms. Although LSTM, GRU, or attention mechanisms have been used in numerous studies in the past [11], [12], [13], they have been implemented separately and not in a synergetic combination with all three components included in the proposed hybrid model to forecast the exchange rates.

Furthermore, a large part of the literature models are not thoroughly evaluated in terms of multiple performance measures or do not show robustness to various experimental setups. The proposed study will fill these gaps by giving a detailed performance analysis of the proposed model, which will be accurate and generalizable.

The objectives of this study are to:

- Design and implement a DA-based LSTM-GRU (DALG) hybrid model for exchange rate volatility forecasting in China's forex sector.
- To show the effectiveness of the DA mechanism in enhancing the predictive accuracy of the DL models for financial data.
- Evaluate the model's performance using multiple metrics (MAE, RMSE, MAPE, etc.) against baseline models, i.e., LSTM, GRU, and LSTM-DA.

This research makes significant contributions to the literature in multiple dimensions. First, it introduces a novel hybrid deep learning architecture tailored for exchange rate forecasting. Second, it combines LSTM and GRU layers with DA for improved temporal and feature representation. Third, it provides a comprehensive empirical evaluation of China's exchange rate data using robust evaluation metrics.

The rest of the study is arranged as follows: Section II presents a theme-based literature review covering neural networks in financial forecasting, followed by studies involving LSTM, GRU, and attention mechanisms. Section III details the proposed methodology, including the model architecture, mathematical formulation, and algorithmic steps. Section IV discusses the experimental setup, results, and model evaluation. Section V concludes the study and outlines future research directions.

II. Literature Review

The literature on financial time series forecasting has witnessed a significant transformation with the integration of deep learning techniques, particularly Recurrent Neural Networks (RNNs) and their advanced variants. This section presents a thematic synthesis of prior research, starting with general applications of LSTM and GRU models and progressing to DA mechanisms, with a specific emphasis on their application to exchange rate prediction.

A. LSTM Models in Exchange Rate Prediction

The LSTM networks were created to eliminate the shortcomings in the traditional RNNs, especially the issue of the vanishing gradient challenge. They are useful in modelling long-range dependencies, and they have been extensively used in financial applications. Chen et al. [14] used LSTM in the Chinese stock markets, which was far superior to ARIMA and SVM. Bao et al. [13] suggested the combination of wavelet transform, autoencoders, and LSTM to forecast the stock indices, which obtained a higher predictive accuracy compared with the single-model predictive accuracy.

Fischer and Krauss [15] revealed that LSTM-based models can be superior to random forest and logistic regression to predict the changes in S&P 500 stocks. Moreover, in recent times, Windsor and Cao [16] make use of a multimodal LSTM that picked up price and sentiment data for USD/CNY prediction and outperformed nine baseline models.

B. GRU Networks in Financial Forecasting

Another modification of LSTMs is GRU which contain fewer parameters and achieve comparable results. They are especially applicable to situations that need quicker training and less complexity. Islam and Hossain [12] created a hybrid model GRU-LSTM which was used to predict foreign exchange prices, which was more effective than standalone models. According to Gao et al. [17], optimized LSTM and GRU models were compared, and both were classified as effective, with GRU being computationally advantageous in a few instances.

Kaur et al. [18] showed that GRU is better in forecasting cryptocurrencies such as BTC and ETH as compared to LSTM. GRU based models have therefore become competitive alternatives to LSTM in financial time series tasks.

C. Dual Attention Mechanisms in Financial Forecasting

Attention mechanisms have transformed time series modeling by enabling models to focus on the most relevant features and time steps. The DA-Based Recurrent Neural Network (DA-RNN) proposed by Qin et al. [8] applied attention at both input and temporal levels. Zhang et al. [3] introduced an attention-LSTM that improved interpretability and performance. Chen et al. [19] embedded attention modules in CNN-BiLSTM models, and Li et al. [20] used attention in GAN architectures for stock prediction. These studies validate that attention-enhanced models outperform traditional architectures, particularly in dynamic financial environments. Table I summarizes these studies.

D. Literature Gap

This literature review indicates an incremental change in the way financial forecasts are made, which has evolved over time from basic models to advanced deep learning models. LSTM and GRU are still mainstay in sequential data modeling, and attention mechanism, especially DA attention, makes a big step forward in model accuracy and interpretability [22]. However, even in the context of these developments, the prominent gap remains: little research exists on hybrid architectures that would unify LSTM, GRU, and two-stage attention mechanisms in a coherent framework explicitly designed to do exchange rate forecasting [23]. Moreover, most of the current studies fail to critically test the robustness of models under a wide range of metrics and financial scenarios [24]. This study will address these gaps by coming up with an elaborate, attention-enhanced hybrid model to forecast the exchange rates of China.

III. Methods

The architecture and workflow of the suggested model are described in this section, which combines Gated Recurrent Unit (GRU) and LSTM layers with a Dual-Stage Attention mechanism. The goal is to learn complex temporal and contextual dependencies in financial time series data and improve predictive performance in exchange rate forecasting.

A. LSTM Model

LSTM network, proposed by Hochreiter and Schmidhuber (1997), is one of the popular versions of RNNs which have been designed to overcome the vanishing and exploding gradient issues that usually arise when training on long sequences [23]. In contrast to typical RNNs, LSTMs have a complex memory cell with three gates, namely, input, forget, and the output gates that control the information flow over time [25], [26].

These gates enable LSTM networks to store, revise, or forget information where necessary, and they are thus very effective in modelling long-term temporal dependencies in sequential data. This ability has been especially useful in financial forecasting activities, where the impact of previous occurrences can be experienced over a long term.

TABLE I. SUMMARY OF RELEVANT STUDIES

Author(s)	Year	Technique	Domain	Key Findings
Chen et al. [14]	2015	LSTM	Chinese stocks	LSTM outperformed ARIMA and SVM
Bao et al. [13]	2017	Wavelet + Autoencoder + LSTM	Stock indices	Hybrid model improved accuracy and profitability
Fischer & Krauss [15]	2018	LSTM	S&P 500	LSTM outperformed classical ML models in trading performance
Windsor & Cao [16]	2022	Multimodal LSTM	USD/CNY exchange rate	Combined sentiment and price data to outperform nine baselines
Islam & Hossain [12]	2021	GRU-LSTM hybrid	Forex	Hybrid model achieved lowest RMSE for USD/CAD
Gao et al. [17]	2021	Optimized GRU vs LSTM	Stocks	GRU trained faster and slightly outperformed LSTM
Kaur & Uppal [18]	2025	GRU	Cryptocurrency	GRU outperformed LSTM in BTC and ETH predictions
Qin et al. [8]	2017	DA-RNN	NASDAQ-100	Dual attention significantly improved forecasting accuracy
Zhang et al. [3]	2019	Attention-LSTM	Russell 2000	Enhanced interpretability and performance
Chen et al. [19]	2021	CNN-BiLSTM + ECA	Shanghai stocks	Channel attention improved over CNN-LSTM
Li et al. [20]	2025	GAN-LSTM-Attention	S&P 500, tech stocks	Attention-enhanced GAN produced more accurate forecasts
Zhao & Yan [21]	2024	Transformer / TFT	NZD exchange rates	TFT outperformed Transformer in multi-step forecasting tasks

Regarding the prediction of exchange rates, LSTMs are utilized to define the changing relations between the current market dynamics and their historical trends so that the model can detect not only long-term tendencies but also the delayed responses of economic indicators. Nonetheless, LSTM models do not explicitly prefer any time step over another: thus, they might not be able to focus on the most informative time steps, and therefore the interest to combine them with attention and other complementary architectures (GRU).

Each LSTM unit comprises three gates: the input gate (i_t), the forget gate (f_t), and the output gate (o_t), which regulate the flow of information through the cell. The governing equations are [see Eq. (1) to Eq. (6)]:

$$f_t = \sigma(W_f x_t + U_f h_{t-1} + b_f) \tag{1}$$
$$i_t = \sigma(W_i x_t + U_i h_{t-1} + b_i) \tag{2}$$
$$\tilde{C}_t = \tanh(W_C x_t + U_C h_{t-1} + b_C) \tag{3}$$
$$C_t = f_t \odot C_{t-1} + i_t \odot \tilde{C}_t \tag{4}$$
$$o_t = \sigma(W_o x_t + U_o h_{t-1} + b_o) \tag{5}$$
$$h_t = o_t \odot \tanh(C_t) \tag{6}$$

where, x_t is the input at time step t, h_t is the hidden state, C_t is the cell state, σ is the sigmoid function, $\odot$ denotes element-wise multiplication, and W_*, b_* represent learnable weights and biases.

In this work, LSTM layers were employed in the encoder to capture long-range dependencies in the exchange rate sequence, enhancing the model's ability to remember important past values.

B. GRU Model

A simplified version of the LSTM, the Gated Recurrent Unit (GRU) reduces the number of parameters and boosts training efficiency by combining the input and forget gates into a single update gate. GRUs are particularly useful in scenarios requiring faster convergence with comparable performance to LSTMs [7].

The GRU unit consists of two gates: the update gate (z_t) and the reset gate (r_t). The equations governing the GRU architecture are [see Eq. (7) to Eq. (10)]:

$$z_t = \sigma(W_z x_t + U_z h_{t-1} + b_z) \tag{7}$$
$$r_t = \sigma(W_r x_t + U_r h_{t-1} + b_r) \tag{8}$$
$$\tilde{h}_t = \tanh(W_h x_t + U_h(r_t \odot h_{t-1}) + b_h) \tag{9}$$
$$h_t = (1 - z_t) \odot h_{t-1} + z_t \odot \tilde{h}_t \tag{10}$$

where, $\tilde{h}_t$ is the candidate hidden state, r_t controls how much of the past state to forget, and z_t determines how much past information to retain.

In the proposed architecture, GRU layers are run in parallel with LSTM layers during encoding. This dual processing captures both short-term and long-term trends efficiently, while maintaining computational efficiency.

C. Dual Attention (DA) Mechanism

To further enhance the model's ability to identify informative parts of the time series, a DA Mechanism is used. It contains two sequential attention layers:

- Input Attention – focuses on the importance of input features (e.g., bid, ask, order flow, bid-ask spread) at each time step.
- Temporal Attention – highlights relevant time steps across the sequence that have a significant impact on prediction.

Input Attention calculates a weight for each input feature at time t using Eq. (11) to Eq. (13):

$$e_t^i = v_a^\top \tanh(W_a h_t + U_a x_t^i + b_a) \tag{11}$$
$$\alpha_t^i = \frac{\exp(e_t^i)}{\sum_j \exp(e_t^j)} \tag{12}$$
$$\hat{x}_t = \sum_i \alpha_t^i x_t^i \tag{13}$$

Temporal Attention evaluates the influence of each timestep by assigning weights across the time dimension using Eq. (14), Eq. (15) and Eq. (16):

$$e_t = v_b^\top \tanh(W_b h_t + b_b) \tag{14}$$

$$\beta_t = \frac{\exp(e_t)}{\sum_k \exp(e_k)} \tag{15}$$

$$c = \sum_t \beta_t \hat{x}_t \tag{16}$$

where, α_t^i and β_t are the attention weights, and c is the final context vector summarizing the most relevant input features and time steps. This vector is then passed to the decoder to generate the final output.

D. DAGL Hybrid Model

The proposed model architecture uses Evolutionary Algorithm Component (EAC) i.e., encoder, attention, and decoder model. This is particularly tuned to capture the sequential as well as the nonlinear dependencies in the financial data. In this framework, three important elements, including LSTM, Gated Recurrent Unit (GRU), and a DA Mechanism are combined to achieve high accuracy and interpretability of the model. At the encoder level, both LSTM and GRU layers process the input time series of historical exchange rates and related financial indicators in parallel. The given two-fold encoding approach would allow the model to retrieve complementary temporal characteristics: LSTM units will be effective in modeling long-range dependencies, whereas GRU layers will provide the model with computational efficiency in accounting shorter-term fluctuations. The combination of LSTM and GRU results is more comprehensive representation of the input sequence.

Following the encoder, the model incorporates a DA mechanism, consisting input and temporal attention layers. The outputs of both attention layers are combined in a context vector which summarizes the importance of features and time steps weighted. This context vector is then fed to the decoder, which is a single or multiple fully connected (dense) layers, to produce the final exchange rate prediction.

The hybrid architecture is a powerful, flexible, and data-adaptive solution because it uses the memory capacity of LSTM, the computational simplicity of GRU, and the focused interpretability of dual attention. It is especially appropriate for the volatile and dynamic nature of the currency exchange markets.

Model training is governed by a customized learning algorithm named `Train_DA_LSTM_GRU`, which includes the following steps:

- Inputs are encoded using parallel LSTM and GRU units.
- Attention scores are computed for features and time steps.
- Predictions are generated from the decoder.
- A composite loss function combining Mean Absolute Error (MAE) and Mean Squared Error (MSE) is used to quantify prediction accuracy.
- The Adam optimizer is employed to update weights via backpropagation.
- Early stopping is applied to halt training when validation performance ceases to improve, ensuring generalization and reducing the risk of overfitting.

This architecture effectively combines the strengths of LSTM, GRU, and attention mechanisms, providing a robust, interpretable, and adaptive model for forecasting complex financial time series. The model architecture is illustrated in the following figure (Fig. 1).

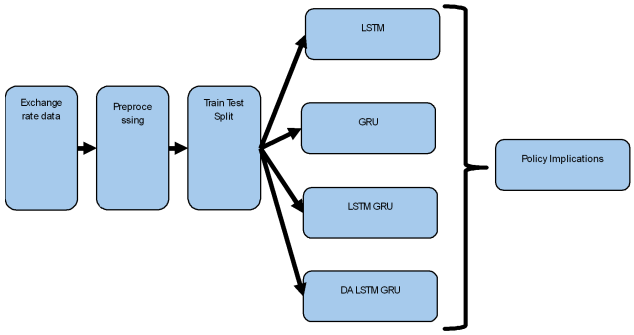

Fig. 1. The research framework for DA-LSTM and GRU hybrid approach.

IV. Results and Discussion

This section presents the empirical results of the proposed DAGL model applied to China's exchange rate data. The performance is evaluated in comparison with baseline models: LSTM, GRU, LSTM-DA hybrid, and DAGL hybrid model. We assess the models on standard evaluation metrics including MAE, MSE, RMSE, MSLE, Median Absolute Error, and MAPE.

A. Experimental Setup

To ensure consistency and fairness across all model evaluations, the experiments were conducted using identical configurations for hyperparameters, architecture size, and optimization strategies. The proposed DAGL Hybrid model, along with baseline models (LSTM, GRU, and LSTM-GRU), was implemented and trained using the Adam optimizer, which is well-suited for non-stationary objectives and sparse gradients.

Both the encoder and decoder layers were composed of 64 hidden units for LSTM and GRU cells, ensuring a balanced representation of long-term and short-term temporal dependencies. All recurrent layers (LSTM and GRU) used the Tanh activation function to regulate the hidden state values and avoid vanishing gradients.

To enhance learning stability and address potential overfitting, a learning rate scheduler was employed with an initial learning rate of 0.1, decaying by a factor of 0.9 every 10 epochs. Maximum training epochs were set to 100 with early stopping with the patience level of 15 epochs depending on the loss of validation. This enabled the model to stop training when performance stopped improving, minimizing unwanted computation and overfitting.

In the DA setup, the attention mechanism was set up with 64 hidden units, which was consistent with the capacity of the recurrent layers to facilitate a seamless integration. The loss was a combination of Mean Squared Error (MSE) and Mean Absolute Error (MAE) that provided trade-off between large deviations penalty and the robustness to outliers. The batch size was set to 16 so that there could be effective training with adequate gradient updates without loss of memory. These parameters and fine tuning is summarized in Table II.

TABLE II. EXPERIMENTAL PARAMETER SETTINGS

Parameter	Value
Encoder LSTM Cell Hidden Units	64
Encoder GRU Hidden Units	64
Encoder LSTM Activation Function	Tanh
Encoder GRU Activation Function	Tanh
Attention Mechanism Hidden Units	64
Decoder GRU Cell Hidden Units	64
Decoder LSTM Cell Hidden Units	64
Decoder GRU Activation Function	Tanh
Decoder LSTM Activation Function	Tanh
Optimizer	Adam
Learning Rate	0.1
Learning Rate Scheduler Step Size	10
Learning Rate Scheduler Gamma	0.9
Loss Functions	MSE, MAE
Epochs	100
Patience for Early Stopping	15
Batch Size	16

This carefully selected setup was critical in achieving high training stability and superior predictive performance across all model configurations evaluated in the study.

B. Data Source

This study presents a new hybrid DAGL model that predicts the exchange rate between USD and RMB. The study uses a 19807 observation dataset of 1-minute USD/RMB exchange rate. The parameters of this job are the bid price (Bid), the ask price (Ask), order flow (OF), and bid-ask spread (BAS). The data is taken from September 13, 2023, to December 11, 2023.

C. Data Preprocessing

Several basic data transformations were performed during the exchange rate data preprocessing steps in order to get the data ready for modeling. In order to designate the date column as the index and make time series analysis easier, we first transformed it into a date-time format. In order to make the date display as a column for additional processing, the data was then reset. The dataset was sorted using dates to establish the ascending order in order to maintain chronological order.

Then descriptive statistics were applied to provide a description of the data. “ER” was the target, and “Bid”, “Ask”, “Of”, and “BAS” were the features picked for the model. There was normalization of the features and target variable via the MinMaxScaler, which standardized the values to the range 0-1, in order to improve model performance. Next, we created data sequences with a length of four, which meant that each sequence contained four consecutive data points. The data point immediately following each sequence served as the goal value. Sequences and their matching targets were to be created by iterating over the scaled data. Numpy arrays were then created from the resultant sequences. In the end, the data was divided into sets for testing and training. An 80:20 train-test split, a community accepted standard, was adopted to balance adequate training data for convergence while preserving a substantial independent test set for unbiased performance evaluation, consistent with standard practices in predictive modeling.

D. Experimental Results

1) LSTM: Fig. 2 shows training performance of LSTM with Forex dataset performance for exchange rate prediction on training loss metrics over 10 epochs. The model shows a continuous reduction in training losses - RMSE, MSE, MAE, etc, which shows a successful learning and convergence. The loss of validation is low and steady which indicates that the model is generalizing well to the new data and it is not over fitting. The sudden drop in error at the first epochs and the gradual increase is characteristic of learning LSTM learning behavior. On the whole, the model demonstrates a good predictive potential with equal performance in both training and validation.

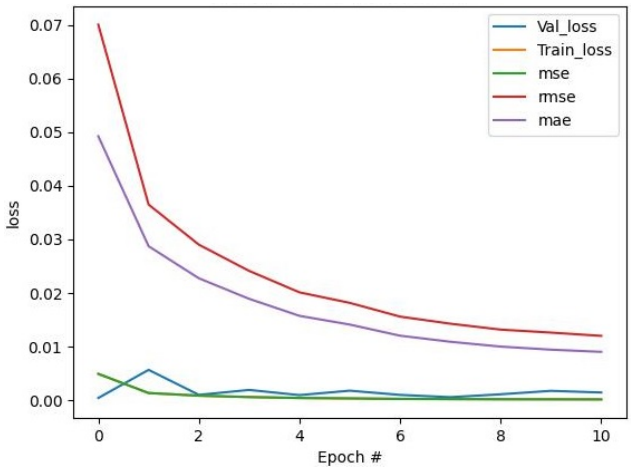

Fig. 2. LSTM training performance graph.

Fig. 3 shows the actual and the predicted exchange rates with the use of LSTM model. The blue line is the values that are predicted, and the orange line is the actual observed rates. Generally, the model is able to capture the trend and direction of the movement in the exchange rates fairly well, especially when the exchange rates are stable. But the forecasts are likely to eliminate harsh variations and abrupt declines, and it suggests that the LSTM is good at modeling long-term developments, but it is weak at short-term volatility and sudden market changes. This is typical of time-series forecasting models when sudden changes of structure are hard to predict properly.

2) GRU: Fig. 4 demonstrates how a GRU model was trained on a Forex dataset during 45 epochs to monitor the

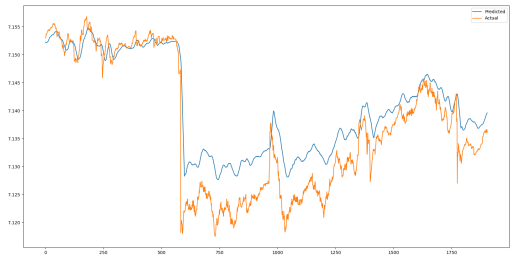

Fig. 3. Actual vs. Predicted exchange rates using LSTM.

Fig. 5. Actual vs. Predicted exchange rates using GRU.

most significant loss metrics like validation loss, training loss, MSE, RMSE, and MAE. All loss measures depict a monotonically decreasing trend (quite fast in the initial epochs and gradually slowing down), which means that the model is being trained well and is converging appropriately. The validation loss is low and stable which implies that the model is suited to generalize well and has little overfitting. The GRU seems to converge to the lower loss values quicker when compared to the previous LSTM training behavior, which indicates its possible efficiency in terms of training and applicability in predicting the temporal dynamics in exchange rate tasks.

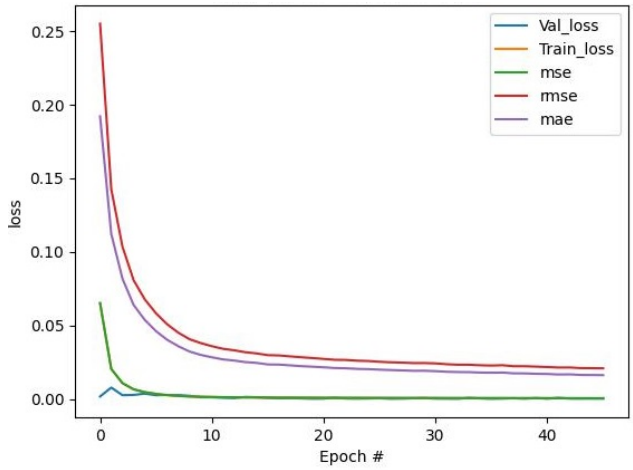

Fig. 4. GRU training performance graph.

Fig. 5 shows the actual and predicted exchange rates with GRU model. The actual exchange rates (orange line) and the predicted values (blue line) have a close follow up with a strong alignment of most of the time series. In comparison with the LSTM model, the GRU seems to reflect more accurately the trend and the short-term fluctuations, including the sharp drops and peaks, and, thus, shows higher reactiveness to volatility in the market. This implies that GRU model could achieve better temporal patterns in Forex data by making more accurate and timely exchange rate prediction.

3) LSTM with DA: The graph shows the training performance of LSTM with DA model using the Forex dataset. The graphs of the loss function for training loss, validation loss, MSE, RMSE, and MAE reveal a steady and rapid fall of errors in the early epochs and convergence to low values with very little fluctuation. It means that the model learns the pattern successfully. Attention helps LSTM to better focus on the important parts of the sequence of data, and hence enhances its learning ability. Low validation error shows that the model can work with the new data quite effectively and has not overfitted the training set. It is visualized in Fig. 6.

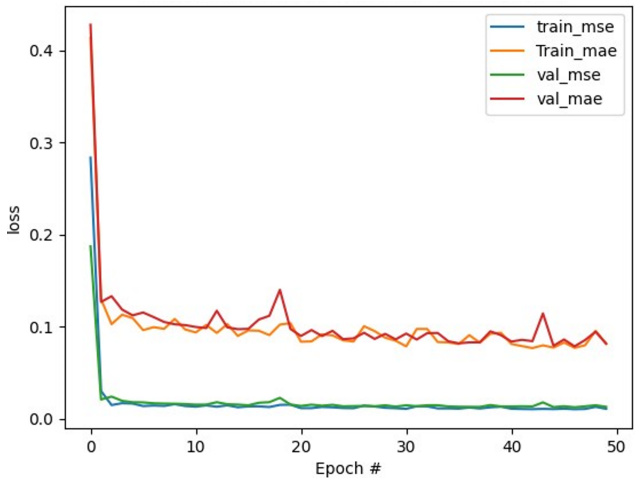

Fig. 6. LSTM with DA training performance graph.

Fig. 7 shows that the actual and predicted exchange rate values for the LSTM-DA model are closer to each other. Attention enables the model to effectively model the significant dependencies in the exchange rate series. The predicted values are much closer to the actual values, and the model has better volatility and sharper decline predictability than standard LSTM. This shows that attention mechanism allows the model to weight the important time steps which results in more effective and accurate forecasting of exchange rates.

4) DAGL hybrid: The graph shows the learning process of the proposed model DAGL on Forex dataset. It shows multiple loss curves - training loss, validation loss, MSE, RMSE, and MAE. The model exhibits robust and steady improvement in learning with continuous decline in loss values over 57 epochs. The final error values are significantly lower than the other models, indicating improved model learning due to combined advantages of LSTM, GRU, and DA mechanism. Low and steady validation loss also indicates a well-generalized model. The convergence is smooth and fast and reaches lower values

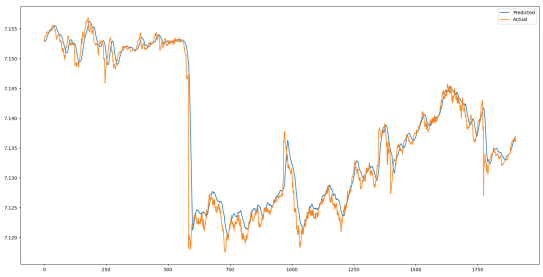

Fig. 7. Actual vs. Predicted exchange rates using LSTM-DA.

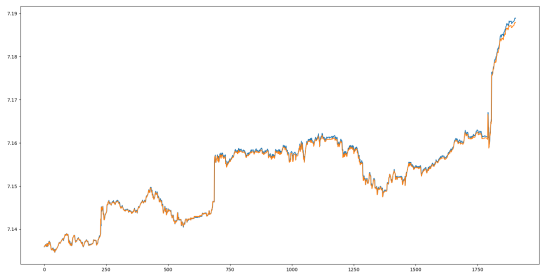

Fig. 9. Actual vs. Predicted exchange rates using DAGL.

as compared to the rest of the models. The training performance is shown in Fig. 8.

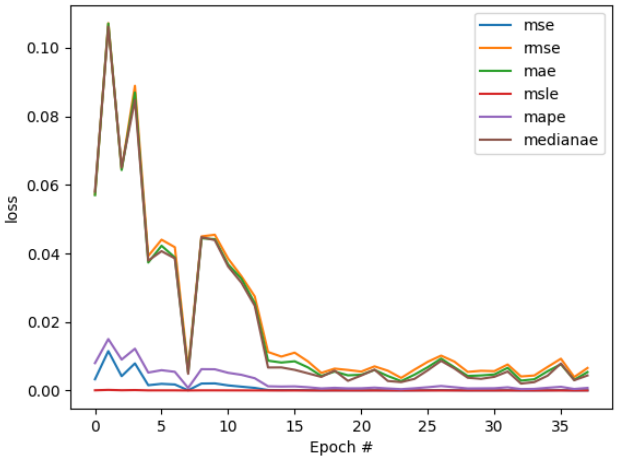

Fig. 8. DAGL hybrid training performance graph.

Fig. 9 shows the actual and predicted exchange rates using DAGL model. The actual exchange rate trend is closely followed by the predicted line which shows the model's capability in capturing the trend and fluctuations. Attention mechanism helps DALG to identify the significant time steps and capture long and short-term relationships in exchange rates. The predicted curve has minimal deviation from the actual one and correctly predicts the peaks and sudden declines which other models fail to do. The model has best alignment among all and lowest prediction error.

E. Model Comparison

To evaluate the performance of the proposed DAGL model against other models, the comparison is done using six standard performance metrics, as shown in Table III.

The proposed model outperforms all the baseline models across all metrics. It achieves the lowest MAE (0.0212), MSE (0.0011), and RMSE (0.0334), which indicates highest prediction accuracy. In addition, it demonstrates the best generalization capability with lowest MAPE and MSLE, validating the advantage of combining dual attention with a hybrid recurrent architecture.

TABLE III. MODEL PERFORMANCE COMPARISON

Model	MAE	MSE	RMSE	MSLE	MedAE	MAPE
LSTM [27]	0.0398	0.0025	0.0498	0.00012	0.0365	0.1658
GRU [28]	0.0315	0.0018	0.0420	0.00008	0.0298	0.1454
LSTM-GRU [29]	0.0265	0.0014	0.0374	0.00006	0.0251	0.1289
LSTM-DA	0.0297	0.0016	0.0396	0.00007	0.0280	0.1398
DAGL (Proposed)	**0.0212**	**0.0011**	**0.0334**	**0.00005**	**0.0208**	**0.1094**

V. CONCLUSION

This study propose a novel hybrid deep learning model for exchange rate forecasting, which incorporate Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU) and a Dual Attention (DA). The architecture of the proposed DAGL aims at exploiting the advantages of every element of the model: the long-term memory property of LSTM, the efficient short-term sequence modeling of GRU, and the context-awareness of the dual attention mechanism.

The model was evaluated on a high-frequency USD/RMB exchange rate dataset using key financial indicators such as bid, ask, order flow, and bid-ask spread. Results demonstrated that our model significantly outperforms LSTM, GRU, and LSTM-DA across multiple evaluation metrics. The hybrid architecture exhibited superior prediction accuracy, faster convergence, and better generalization, particularly in capturing market volatility and abrupt fluctuations.

This work highlights the importance of combining different recurrent architectures and attention mechanisms to enhance financial time series forecasting. The DAGL model provides a robust and interpretable framework for central banks, investors, and financial analysts to make effective policies in the dynamic foreign exchange market. Future work may extend this model to multi-step forecasting and incorporate additional macroeconomic variables or external sentiment indicators to further improve prediction accuracy and reliability.

Parameter-Free Negative Extreme Anomalous Undersampling Techniques on Class Imbalance Problems

Benjawan Jantamat, Krung Sinapiromsaran
Department of Mathematics and Computer Science, Faculty of Science,
Chulalongkorn University, Bangkok, Thailand, 10330

***Abstract*—This research addressed the critical challenge of class imbalance in classification, which is a prevalent issue in real-world applications. Standard classifiers often struggled with imbalanced datasets and frequently misclassified the minority class (positive instances) due to the overwhelming presence of the majority class (negative instances). The proposed Negative Extreme Anomalous Undersampling Technique (NEXUT) was introduced as a parameter-free approach. It leveraged the negative extreme anomalous score to strategically eliminate negative instances located in overlapping regions. This targeted removal was designed to improve the classifier's ability to effectively distinguish between the two classes. To evaluate the effectiveness of the proposed method, we conducted a comprehensive comparison with established undersampling techniques. The evaluation utilized both synthetic datasets and twelve datasets from the UCI repository. Six different classifiers were employed to ensure a diverse and unbiased performance assessment. Results from the Wilcoxon signed-rank test confirmed that the proposed method achieved significantly higher performance compared to existing techniques. These findings demonstrated the potential of NEXUT as a robust and valuable tool for addressing class imbalance problems.**

***Keywords*—Classification; class imbalance; imbalanced datasets; undersampling; parameter-free method; negative extreme anomalous score**

I. Introduction

Classification is an important topic in machine learning and data mining. This is especially true for class-imbalanced datasets, which frequently appear in many real-world applications. Examples include disease classification in the medical field [1], credit card fraud detection [2], satellite-based remote sensing [3], environmental pollution monitoring [4], and network intrusion detection [5]. A class imbalance problem [6] occurs when the number of instances in one class is significantly smaller than that of another. The smaller class is called the minority class, and the other is called the majority class. An instance in the minority class is referred to as a positive instance, whereas an instance in the majority class is referred to as a negative instance.

A classification algorithm [7] has difficulty when trained on class-imbalanced datasets because of the small proportion of minority class instances. A classifier generated by a standard classification algorithm tends to predict unknown instances as negative, which leads to the misclassification of most positive instances. However, correctly detecting positive instances is usually crucial. For example, fraud cases in fraud detection may cause significant financial losses, while missing cancer patients in cancer detection [8] can lead to life-threatening consequences.

To address the class imbalance problem, two methodologies have been proposed in the literature: data-level and non-data-level approaches [9]. Data-level algorithms aim to rebalance instances in a dataset so that standard classifiers can better recognize the decision boundary and classify instances from both classes correctly. In contrast, non-data-level algorithms modify the classification process itself to improve the detection of positive instances or assign higher penalty costs to misclassified positive instances. Data-level methods are generally more flexible because they can be applied to any classification algorithm and do not require deep knowledge of the classifier's internal design [10].

Two primary data-level methods for rebalancing datasets are oversampling and undersampling. Oversampling techniques balance data by adding or generating positive instances, which may not always represent valid cases in real-world situations. In contrast, undersampling techniques rebalance data by removing negative instances while preserving the characteristics of the minority class. However, oversampling increases the total number of instances, which leads to longer computational times for classification algorithms. In big data environments, oversampling may even require reimplementing algorithms to handle the larger datasets. Undersampling, on the other hand, reduces the number of instances and computational time [10], making it more suitable for large-scale data. Moreover, removing negative instances around the decision boundary of positive instances improves a classifier's ability to correctly predict positive instances. Therefore, this research focuses exclusively on undersampling techniques.

Several undersampling techniques have been proposed to address class imbalance, including Random Undersampling [11], Tomek Links [12], Cluster Centroids [13], and Near Miss [14]. However, these methods have certain limitations. The Random Undersampling removes negative instances randomly, which does not guarantee a clear decision boundary between classes. The Tomek Links technique removes negative instances from Tomek link pairs, which connect two instances from different classes as their nearest neighbors. As a result, it deletes only a small number of negative instances and rarely clarifies the decision boundary. The Cluster Centroid technique generates centroids of negative sub-clusters and retains them along with all positive instances. Although effec-

tive in reducing dataset size, this technique may also remove many negative instances near the boundary region, potentially reducing precision. The Near Miss technique retains only negative instances located close to positive instances. However, these selected negatives often come from boundary regions and may represent noisy or overlapping data that are difficult to classify.

In 2017, Chiamanusorn and Sinapiromsaran [15] proposed the negative extreme anomalous score (NaS) for use in oversampling techniques. The NaS of an instance is defined as the maximum possible radius of an open ball centered at that instance, such that no instances of the negative class are contained within the ball. The NaS represents the distance between the instance under consideration and its closest negative neighbor, without being influenced by positive instances.

The Negative Extreme Anomalous Undersampling Technique (NEXUT) is introduced in this study as a data-level approach that utilizes NaS to eliminate negative instances. It removes redundant negative instances and noise in the overlapping regions of both classes. This clarifies the boundary of the minority class, enabling classifiers to more effectively identify positive instances located near negative ones.

This study introduces a novel approach that:

- Offers flexibility by allowing any classifier to be applied to any dataset.
- Addresses the challenge of imbalanced data without requiring specific parameter settings.
- Enhances the decision boundary through undersampling techniques.

This study is organized into five sections: Section I presents the motivation for this study. Section II reviews related work. Section III describes the proposed NEXUT algorithms. Section IV reports the experimental results conducted on both synthetic datasets and twelve real-world datasets from the UCI repository. Finally, Section V concludes the study.

II. Related Work

Extensive research on undersampling techniques has focused on addressing class-imbalanced data. This effort has led to the development of methods that improved classification performance. In recent years, several surveys and systematic reviews have provided comprehensive discussions on the challenges of class imbalance and the evolution of related techniques [16], [17], [18], [19]. These studies highlight that early undersampling methods, such as Tomek Links [12], ENN [20], and CNN [21], remained important baselines. However, more recent approaches emphasized the need for robust and adaptive solutions, particularly in modern applications such as deep learning and remote sensing. Numerous undersampling techniques have been proposed and can be categorized into four main types.

A. Type I: Size-Based Undersampling

These techniques eliminated instances from the majority class until its size became equivalent to that of the minority class. Examples included Random Undersampling (RUS) [11], Cluster Centroids (ClusterCentroids) [13], and Clustering-Based Undersampling (CBU) [22].

- RUS was the simplest technique, randomly removing negative instances from the majority class. This approach tended to lose some important negatives.
- ClusterCentroids applied the K-means algorithm to represent negative instances with their centroids, while retaining all positive instances.
- CBU applied K-means clustering to select or generate negative instances that represented the majority class.

Limitation: These methods often removed informative negatives and ignored overlapping regions with the minority class.

B. Type II: Overlap-Based Undersampling

These techniques focused on eliminating negative instances in regions overlapping with positive instances. Examples included Tomek Links (TomekLinks) [12], One-Sided Selection (OSS) [23], Edited Nearest Neighbor (ENN) [20], Repeated ENN (RENN) [24], AllKNN [24], Neighborhood Cleaning Rule (NCL) [25], Majority Undersampling Technique (MUTE) [26], and Neighborhood-Based Undersampling Technique with Modified Tomek Link Search (NB-Tomek) [27].

- Tomek Links was a well-known method for addressing class overlap. It identified pairs of instances from different classes that were each other's nearest neighbors, and removed only the negative instances in these pairs.
- OSS applied the 1-NN rule to identify misclassified instances and then removed negative instances from Tomek links.
- ENN applied the k-NN rule, removing majority class instances if at least half of their k-nearest neighbors belonged to the minority class. By default, a 3-NN setting was used.
- RENN iteratively applied the ENN procedure until all remaining majority class instances had at least half of their k-nearest neighbors also belonging to the majority class.
- AllKNN used the k-NN rule across a range of k values (typically from 1 up to a specified k). It eliminated majority class instances if at least half of their neighbors were positive.
- NCL implemented a two-step cleaning process. First, it applied ENN to remove noise. Then, it used the k-NN rule to remove misclassified majority class instances. The default setting for k was 3.
- MUTE, proposed by Bunkhumpornpat et al. in 2011 [26], was later enhanced in 2014 with a safe-level graph [28]. The original version removed only noise, while the adaptive version could remove noise, borderline instances, or even reduce the majority class to core instances, depending on the safe-level configuration.
- NB-Tomek removed a majority class instance if it had a minority class neighbor and was also one of the k-nearest neighbors of that minority instance.

Limitation: These methods required parameter tuning (e.g., k in k-NN) and often failed to preserve the overall data distribution, discarding important negatives.

C. Type III: Neighbor-Based Undersampling

These techniques retained negative instances based on their neighbors. Examples included Near Miss (NearMiss) [14] and Condensed Nearest Neighbor (CNN) [21].

- NearMiss had three variants (NearMiss-1, 2, 3) that selected majority class instances based on different proximity criteria.
  - NearMiss-1 chose negative instances with the smallest average distance to their three nearest positive instances.
  - NearMiss-2 chose negatives closest to all positive instances, typically using the farthest three.
  - NearMiss-3 selected a fixed number of nearest negatives for each positive instance. However, this approach removed many negatives, often damaging the decision boundary of the minority class. Moreover, the selected negatives were difficult to classify.
- CNN used the nearest neighbor (NN) rule to identify misclassified instances located near the class boundary, which were retained as reference points for future classification.

Limitation: Neighbor-based methods often removed too many negatives, weakening the minority decision boundary.

D. Type IV: Anomaly-Based Undersampling

These techniques eliminated majority class instances by identifying them as anomalies or outliers relative to the data distribution. The assumption was that atypical majority instances were less representative and acted as noise in the learning process. Examples included Anomaly Scoring Based Ensemble (ASE) [29] and Geodesic Based Outlier Detection (GDLD) [30].

- ASE combined anomaly scores from multiple detectors to identify and remove unrepresentative majority class instances. Although effective, it required hyperparameter tuning for score normalization and ensemble weighting.
- GDLD leveraged geodesic distances and manifold properties to identify extreme negative outliers. While it preserved complex class boundaries, it often introduced significant computational overhead.

Limitation: Although anomaly-based undersampling was effective in detecting atypical negatives, most approaches depended heavily on predefined thresholds, scoring functions, or hyperparameters. This reliance reduced robustness across diverse datasets and complicated practical application.

Although a wide range of undersampling methods has been developed, several limitations remain [16], [17]. Many techniques required parameter tuning, and improper settings often led to the removal of informative negatives, degrading performance. Moreover, some methods failed to maintain the inherent data distribution of each class, particularly in overlapping regions. These weaknesses reduced the robustness and generalizability of current approaches, as emphasized in domain-specific contexts such as remote sensing and semi-supervised learning [19], [18].

To address these limitations, we propose the Negative Extreme Anomalous Undersampling Technique (NEXUT). Unlike existing anomaly-based methods, which relied heavily on hyperparameters or thresholds, NEXUT was entirely parameter-free. It automatically identified and removed extreme anomalous negatives while preserving all minority instances and maintaining the original class structure. This design ensured robustness across diverse datasets and avoided the performance degradation caused by improper parameter settings. Therefore, NEXUT introduced both a clear novelty and a practical advantage over existing anomaly-based approaches.

III. The Proposed Technique: NEXUT

This section describes the proposed Negative Extreme Anomalous Undersampling Technique (NEXUT). The technique aims to eliminate noisy or overlapping majority class instances while preserving all minority class instances. This ensures that the original distributions of both the majority and minority classes remain unchanged. NEXUT incorporates three distinct removal approaches, namely NEXUT-All, NEXUT-Plus, and NEXUT-PlusMinus.

Definition 3.1: Let D be a dataset with numeric attributes that contains a set of negative instances, Neg, representing the majority class, and a set of positive instances, Pos, representing the minority class. Let $\boldsymbol{x} \in D$ be an instance in the dataset. The extreme anomalous score of an instance $\boldsymbol{x}$, denoted as $EaS(\boldsymbol{x})$, is defined by the following notation:

$$EaS(\boldsymbol{x}) = sup\{d > 0 || B(\boldsymbol{x}, d) \cap (D \backslash \{\boldsymbol{x}\})| = 0\}$$

where, $B(\boldsymbol{x}, d)$ denotes an open ball of radius d centered at $\boldsymbol{x}$.

It should be noted that the negative extreme anomalous score, $NaS(\boldsymbol{x})$, for an instance $\boldsymbol{x} \in D$, is equivalent to $EaS(\boldsymbol{x})$ when it is calculated using only majority class instances:

$$NaS(\boldsymbol{x}) = sup\{d > 0 || B(\boldsymbol{x}, d) \cap (Neg \backslash \{\boldsymbol{x}\})| = 0\}.$$

NEXUT employs the negative extreme anomalous score (NaS) to identify majority class instances for removal, thereby rebalancing the dataset. It removes negative instances that lie on the boundary of an open ball centered at each instance, with a radius equal to its NaS value. This approach effectively eliminates majority class instances that lie close to minority class examples. Consequently, it expands the minority regions within the dataset. NEXUT offers three strategies for selecting which negative instances to remove: "All", "$Plus$", and "$PlusMinus$". The application of each selection approach defines a specific NEXUT variant: NEXUT-All, NEXUT-Plus, or NEXUT-PlusMinus. The NEXUT algorithm is presented in Algorithm 1.

Algorithm 1: Negative Extreme Anomalous Undersampling Technique (NEXUT) Algorithm

Input: Dataset D contains negative instances from a majority class, Neg, and positive instances from a minority class, Pos, and selection approach
Output: Undersampling dataset U

$DD = \varnothing$
$n_$diffNegPos $= |Neg| - |Pos|$
Compute the negative extreme anomalous score, $NaS(\boldsymbol{x})$, for each instance $\boldsymbol{x} \in D$
if selection approach == "All"
Sort the $NaS(\boldsymbol{x})$ scores for all $\boldsymbol{x} \in D$ in descending order
for *ranking of* $NaS(\boldsymbol{x}) \leftarrow 1$ ***to*** $n_diffNegPos$ **do**
    Collect the negative instance that lies on the boundary of the open ball centered at $\boldsymbol{x} \in D$ with a radius equal to $NaS(\boldsymbol{x})$, and store it in DD
end
if selection approach == "$Plus$"
Sort the $NaS(\boldsymbol{x})$ scores for all $\boldsymbol{x} \in Pos$ in ascending order
if $|Pos| > n_diffNegPos$ **then**
    for *ranking of* $NaS(\boldsymbol{x}) \leftarrow 1$ ***to*** $n_diffNegPos$ **do**
        Collect the negative instance that lies on the boundary of the open ball centered at $\boldsymbol{x} \in Pos$ with a radius equal to $NaS(\boldsymbol{x})$, and store it in DD
    end
else
    Collect all negative instances that lie on the boundary of an open ball centered at $\boldsymbol{x} \in Pos$ with a radius equal to $NaS(\boldsymbol{x})$, and store them in DD
end
if selection approach == "$PlusMinus$"
Sort $NaS(\boldsymbol{x})$ scores for all $\boldsymbol{x} \in Pos$ in ascending order
if $|Pos| > n_diffNegPos$ **then**
    for *ranking of* $NaS(\boldsymbol{x}) \leftarrow 1$ ***to*** $n_diffNegPos$ **do**
        Collect the negative instance that lies on the boundary of the open ball centered at $\boldsymbol{x} \in Pos$ with a radius equal to $NaS(\boldsymbol{x})$, and store it in DD
    end
else
    Collect all negative instances that lie on the boundary of an open ball centered at $\boldsymbol{x} \in Pos$ with a radius equal to $NaS(\boldsymbol{x})$, and store them in DD
    Sort $NaS(\boldsymbol{x})$ scores for all $\boldsymbol{x} \in Neg$ in ascending order
    for *ranking of* $NaS(\boldsymbol{x}) \leftarrow 1$ ***to*** $n_diffNegPos - |DD|$ **do**
        Collect the negative instance that lies on the boundary of the open ball centered at $\boldsymbol{x} \in Neg$ with a radius equal to $NaS(\boldsymbol{x})$, and store it in DD
    end
end
return $U = D - DD$

Fig. 1 illustrates the flowchart of the proposed NEXUT technique. Given the training set D, the initial step is to compute the size difference between the majority and minority classes, defined as $n_$diffNegPos $= |Neg| - |Pos|$. Next, the negative extreme anomalous score (NaS) is computed for each instance in D. Then, a selection approach is applied to identify negative instances in the majority class D_{majority} that should be removed, resulting in a drop dataset DD.

Fig. 2a illustrates an example of a class-imbalanced dataset. Fig. 2b visualizes the corresponding NaS of the dataset. These illustrations highlight the problem setting that motivates NEXUT and provide an intuitive understanding of how NaS guides the removal of majority instances.

These three approaches lead to different algorithmic behaviors, depending on which classes are considered during the selection process. The "All" approach considers both negative and positive instances. The "$Plus$" approach considers only positive instances. The "$PlusMinus$" approach considers positive instances first, followed by negative instances. NEXUT then removes the selected negative instances in the set DD from the majority class D_{majority}. The resulting undersampled training set U is obtained by removing DD from the original dataset D.

A. NEXUT-All

The NEXUT-All technique employs the Negative Anomalous Score (NaS) to identify negative instances for removal while considering data from both classes. It begins by sorting all NaS values, from both the minority and majority classes, in descending order. Subsequently, it eliminates negative instances whose NaS rank is below the numerical difference between the minority and majority class sizes (see Fig. 2c).

To maintain a balance between the remaining negative and positive instances, the method also removes negative instances located near the boundaries of both classes. This removal process is biased toward instances closer to the minority class, since their NaS values generally tend to be higher than those of the majority class after sorting. The complete NEXUT-All algorithm, using the "All" selection approach, is detailed in Algorithm 1.

Sort the $NaS(\boldsymbol{x})$ scores for all $\boldsymbol{x} \in D$ in descending order
for *ranking of* $NaS(\boldsymbol{x}) \leftarrow 1$ ***to*** $n_diffNegPos$ **do**
    Collect the negative instance that lies on the boundary of the open ball centered at $\boldsymbol{x} \in D$ with a radius equal to $NaS(\boldsymbol{x})$, and store it in DD
end

B. NEXUT-Plus

The NEXUT-Plus technique computes the Negative Anomalous Score (NaS) exclusively from positive instances. The process begins by sorting each NaS value (derived from positive instances) in ascending order. Negative instances whose NaS rank is less than the absolute numerical difference between the minority and majority class counts are then removed (Fig. 2d).

To ensure that the number of remaining negative instances does not drop below the number of positive instances, this method specifically targets negative instances located in close

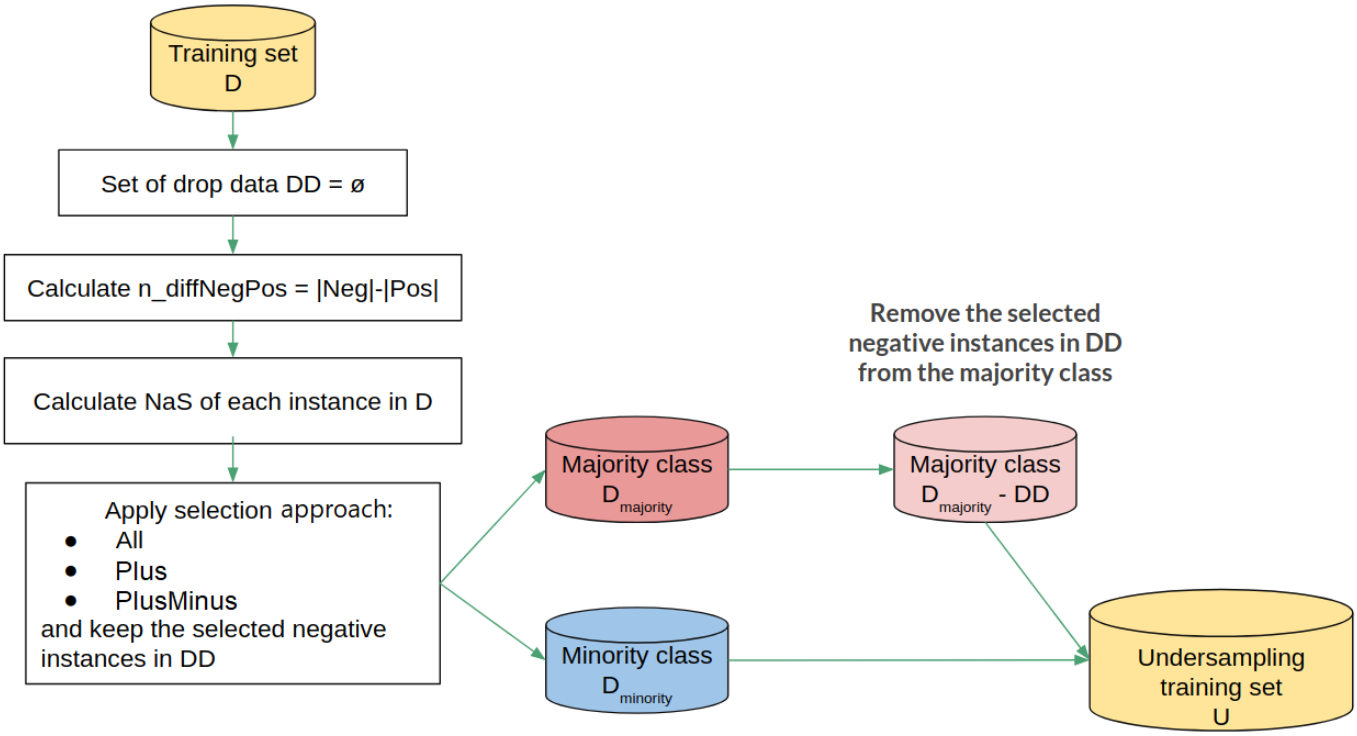

Fig. 1. The flowchart of NEXUT (Algorithm 1).

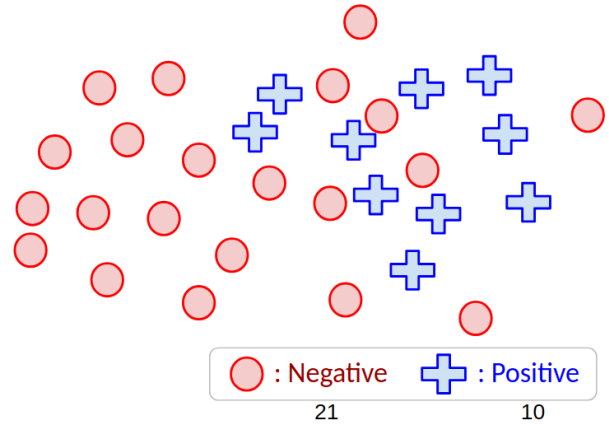
proximity to the minority class. The ascending sort order inherently prioritizes the removal of such negative instances.

It should be noted that when the numerical difference between the majority and minority classes equals or exceeds the number of positive instances, all negative instances associated with the minority class's NaS are removed. The complete algorithm for NEXUT-Plus, which applies the "$Plus$" selection approach, is detailed in Algorithm 1.

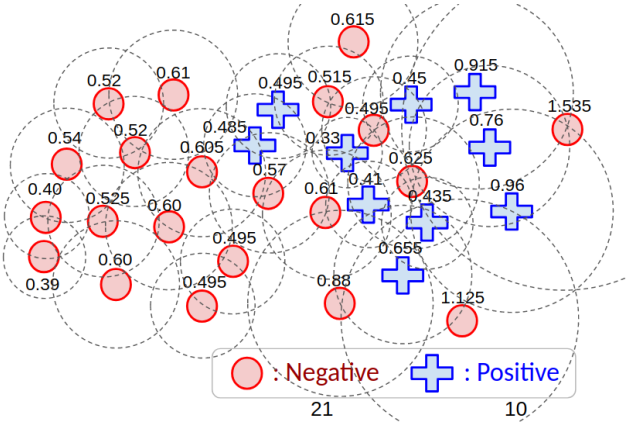
Sort the $NaS(\boldsymbol{x})$ scores for all $\boldsymbol{x} \in Pos$ in ascending order
if $|Pos| > n_diffNegPos$ **then**
  for *ranking of* $NaS(\boldsymbol{x}) \leftarrow 1$ ***to*** $n_diffNegPos$ **do**
    Collect the negative instance that lies on the boundary of the open ball centered at $\boldsymbol{x} \in Pos$ with a radius equal to $NaS(\boldsymbol{x})$, and store it in DD
  end
else
  Collect all negative instances that lie on the boundary of an open ball centered at $\boldsymbol{x} \in Pos$ with a radius equal to $NaS(\boldsymbol{x})$, and store them in DD
end

C. NEXUT-PlusMinus



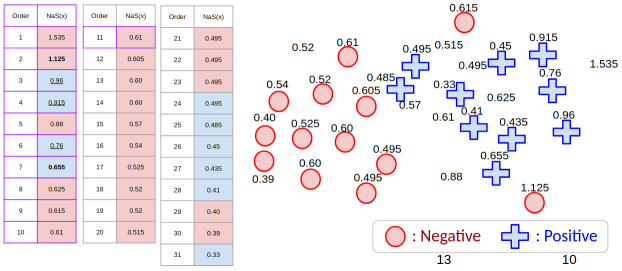
The NEXUT-PlusMinus technique extends the NEXUT-Plus method by employing a sequential two-stage removal strategy. In the first stage, it calculates the Negative Anomalous Score (NaS) exclusively from positive instances and sorts these values in ascending order. Negative instances whose NaS rank is less than the absolute difference between the minority and majority class counts are then removed.

In the second stage, NaS is computed for the remaining negative instances (majority class). These values are sorted in ascending order, and additional negative instances are removed until the total number of eliminated negatives across both stages equals the absolute class-size difference. This cumulative process, illustrated in Fig. 2e, ensures that the final number of remaining negative instances does not fall below the count of positive instances. The complete NEXUT-PlusMinus algorithm, which uses the "$PlusMinus$" selection approach, is detailed in Algorithm 1.



Sort $NaS(\boldsymbol{x})$ scores for all $\boldsymbol{x} \in Pos$ in ascending order
if $|Pos| > n_diffNegPos$ **then**
  for *ranking of* $NaS(\boldsymbol{x}) \leftarrow 1$ ***to*** $n_diffNegPos$ **do**
    Collect the negative instance that lies on the boundary of the open ball centered at $\boldsymbol{x} \in Pos$ with a radius equal to $NaS(\boldsymbol{x})$, and store it in DD
  end
else
  Collect all negative instances that lie on the boundary of an open ball centered at $\boldsymbol{x} \in Pos$ with a radius equal to $NaS(\boldsymbol{x})$, and store them in DD
  Sort $NaS(\boldsymbol{x})$ scores for all $\boldsymbol{x} \in Neg$ in ascending order
  for *ranking of* $NaS(\boldsymbol{x}) \leftarrow 1$ ***to*** $n_diffNegPos - |DD|$ **do**
    Collect the negative instance that lies on the boundary of the open ball centered at $\boldsymbol{x} \in Neg$ with a radius equal to $NaS(\boldsymbol{x})$, and store it in DD
  end
end

IV. Experiment



This section presents the datasets used to assess the effectiveness of NEXUT compared with several established undersampling methods, namely AllKNN, NCL, OSS, and NB-Tomek. For baseline comparison, the original dataset without

any resampling is also included. Further details regarding the experimental design and dataset properties are outlined below.

A. Experimental Setup

This study evaluates the effectiveness of the three proposed undersampling methods in comparison with well-established techniques, including AllKNN [24], NCL [25], OSS [23], and NB-Tomek [27]. A set of six classification algorithms is employed for the evaluation: the C4.5 decision tree [31], the k-nearest neighbors (k-NN) with $k = 3$ [32], the multilayer perceptron (MLP) [33], the naive Bayes [34], the random forest [35], and the logistic regression [36].

The experiments are conducted on a total of fourteen datasets: twelve real-world datasets obtained from the UCI Machine Learning Repository [37] and two synthetically generated datasets. Each experiment is performed with 30 replications of 10-fold cross-validation to ensure statistically robust and reliable results. Table I presents the parameter configurations used for each method. The experimental environment is based on Google Colaboratory (Colab), and all implementations are carried out using the Python programming language.

In the experiments, the selected undersampling techniques (AllKNN, NCL, OSS, and NB-Tomek) aim to remove negative instances based on their neighbors or to clean noisy data. However, these methods are not primarily designed to rebalance the dataset. Similar to these existing techniques, the proposed methods also focus on removing negative instances and reducing noise. Nevertheless, the proposed techniques are capable of eliminating a larger number of negative samples, which often leads to a more balanced dataset. In addition, they tend to preserve the underlying structure of the data distribution.

TABLE I. PARAMETER SETTINGS FOR THE PROPOSED TECHNIQUES AND COMPARISON TECHNIQUES

Techniques	Parameters setting
NEXUT-All	-
NEXUT-Plus	-
NEXUT-PlusMinus	-
AllKNN	n_neighbors = 3
NCL	n_neighbors = 3, threshold_cleaning = 0.5
OSS	n_seeds_S = 1
NB-Tomek	-

B. Datasets

To evaluate the performance of NEXUT-All, NEXUT-Plus, and NEXUT-PlusMinus against well-known undersampling methods such as AllKNN, NCL, OSS, and NB-Tomek, a total of fourteen datasets are used. These include twelve datasets from the UCI Machine Learning Repository [37] and two synthetically generated datasets. The twelve UCI datasets are Abalone, BreastCancer, Pima, BreastTissue, Haber, Glass, Vehicle, Ecoli, Yeast, Ozone8hr, Libras, and Ozone1hr. Table II presents descriptions of these datasets, arranged in ascending order based on their imbalance ratio (IR). The imbalance ratio is defined as $IR = \frac{|Neg|}{|Pos|}$, where $|Neg|$ and $|Pos|$ represent the numbers of negative and positive instances, respectively. A dataset is considered balanced if $IR = 1$, and imbalanced if $IR > 1$.

Synthetic datasets are used to evaluate whether the data distribution structure is preserved after applying each undersampling technique. These synthetic datasets are class-imbalanced and exhibit specific data distributions, namely the Moons dataset (Fig. 3a) and the Circles dataset (Fig. 3b) [38]. Each class-imbalanced Moons dataset and Circles dataset contains 200 negative instances and 20 positive instances, resulting in an imbalance ratio (IR) of 10.

C. Performance Evaluation

This research uses precision, recall, and F_1 score to evaluate the performance of the proposed techniques. These metrics are commonly applied in class-imbalanced research [39], [40]. Precision, recall, and F_1 score are computed using the following formulas:

$$Precision = \frac{TP}{TP + FP}$$

$$Recall = \frac{TP}{TP + FN}$$

and

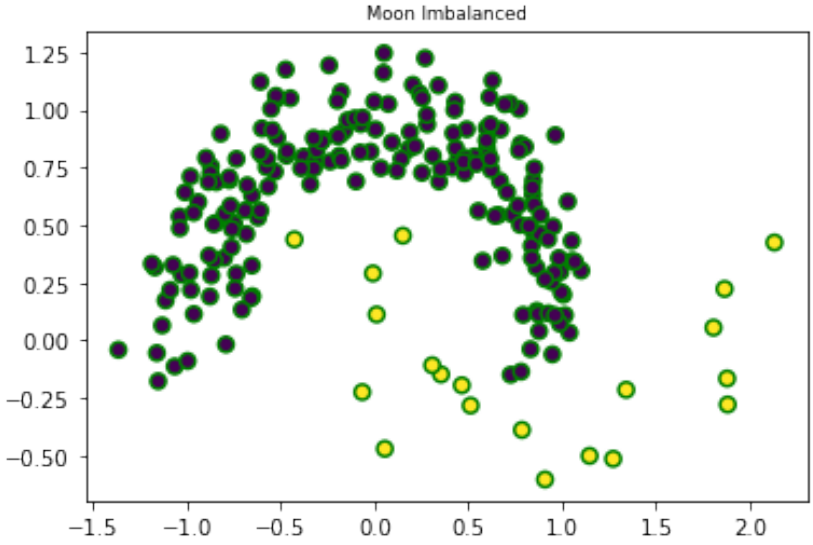
$$F_1 = \frac{2 \times Precision \times Recall}{Precision + Recall}$$

where, TP denotes the number of positive instances accurately classified as positive, FP represents the number of negative instances misclassified as positive, and FN indicates the number of positive instances misclassified as negative.

D. Statistical Test

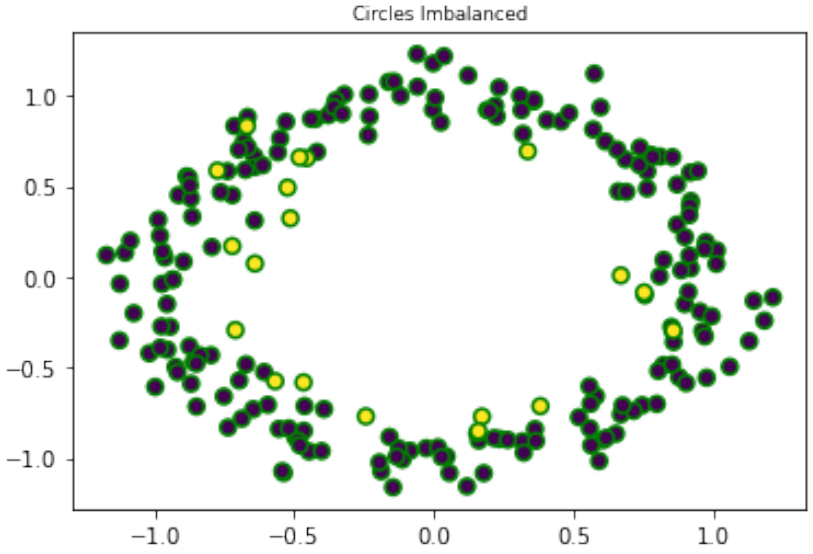
To compare the performance of each technique on each classifier, the Wilcoxon signed-rank test is employed. This test [41] is a non-parametric statistical method designed to evaluate paired performance outcomes between NEXUT and each of the alternative undersampling approaches. A two-tailed Wilcoxon signed-rank test with a 95% confidence level ($\alpha = 0.05$) is conducted, and the null and alternative hypotheses are formulated as follows:

H_0 : There is no significant difference in the median of the average F_1 scores between NEXUT and one of the other techniques.



H_1 : There is a significant difference in the median of the average F_1 scores between NEXUT and one of the other techniques.

To perform the Wilcoxon signed-rank test, the differences in F_1 scores between NEXUT and one of the other techniques are calculated for each dataset. These differences are ranked after removing zero differences and ignoring the signs, with the remaining values sorted in ascending order. The sums of the ranks corresponding to the positive and negative differences are denoted as $Rk+$ and $Rk-$, respectively.



The test statistic (TS), used for comparison with the critical value, is defined as the smaller of $\{Rk+, Rk-\}$. If TS corresponds to $Rk-$, it suggests that NEXUT outperforms the compared method; otherwise, the alternative method performs better. When TS is less than the critical value, the null hypothesis is rejected, indicating a statistically significant difference in the median of average F_1 scores between NEXUT and the other technique.

E. Results

The average F_1 scores obtained from 30 replications of 10-fold cross-validation are reported for the original (unresampled) dataset and for seven resampling techniques: NEXUT-All, NEXUT-Plus, NEXUT-PlusMinus, AllKNN, NCL, OSS, and NB-Tomek. These results are generated using the six classifiers—namely, the decision tree (C4.5), the k-nearest neighbors ($k = 3$), the multilayer perceptron (MLP), the naive Bayes, the random forest, and the logistic regression—applied to twelve datasets from the UCI Machine Learning Repository. The results are summarized in Table III and Table IV. Table III presents the average F_1 scores for the decision tree (C4.5), the k-nearest neighbors ($k = 3$), and the multilayer perceptron (MLP). Table IV summarizes the results for the naive Bayes, the random forest, and the logistic regression. For each dataset, the techniques are ranked in descending order according to

(a) The Moons dataset.

(b) The Circles dataset.

Fig. 3. Synthetic datasets: (a) The Moons dataset and (b) The Circles dataset.

their average F_1 scores, with rank 1 assigned to the method that achieves the best performance.

As illustrated in Table III and Table IV, NEXUT-All consistently achieves the highest average rank when paired with the random forest classifier. NEXUT-Plus demonstrates the best performance with both the decision tree (C4.5) and the k-nearest neighbors (k-NN) classifiers. NEXUT-PlusMinus attains the top rank when evaluated with the logistic regression, while NCL performs best in combination with the multilayer perceptron (MLP). For the naive Bayes classifier, the highest average rank is shared by OSS and the original dataset without resampling.

Table V presents the statistical comparison between NEXUT and five other techniques—namely, the original dataset (without resampling), AllKNN, NCL, OSS, and NB-Tomek—across the six classifiers. The analysis is based on the Wilcoxon signed-rank test with a two-tailed evaluation at the 95% confidence level ($\alpha = 0.05$) using F_1 score. For twelve datasets ($n = 12$), the corresponding critical value is 13.

In Table V, the notation is interpreted as follows:

- A single plus sign (+) indicates that NEXUT outperforms the compared technique, but the result is not statistically significant ($TS = Rk-$, and $TS \geq 13$).
- A single minus sign (–) indicates that NEXUT underperforms, though again without statistical significance

TABLE II. THE DESCRIPTIONS OF UCI DATASETS

Datasets	#Inst	#Attr	Min. class	Maj. class	Pos. inst.	Neg. inst.	IR
Breast Cancer	683	9	'malignant'	'benign'	239 (34.99%)	444 (65.01%)	1.86

Libras	360	90	'1'	Others	24 (6.67%)	336 (93.33%)	14.00
Abalone	731	7	'18'	'9'	42 (5.75%)	689 (94.25%)	16.40
Ozone1hr	1848	72	'1'	'0'	57 (3.08%)	1791 (96.92%)	31.42

($TS = Rk+$, and $TS \geq 13$).

- A double plus sign (++) denotes that NEXUT's performance is significantly better at the 95% confidence level ($TS = Rk-$ and $TS < 13$).
- A double minus sign (–) signifies that NEXUT performs significantly worse ($TS = Rk+$ and $TS < 13$).

From the statistical results of F_1 score, NEXUT-All's F_1 score is better than all other techniques for the decision tree classifier, the multilayer perceptron, the random forest, and the logistic regression. Notably, for the logistic regression, NEXUT-All performs significantly better than all other techniques. NEXUT-All's F_1 score for the k-NN classifier is better than other techniques except OSS. Moreover, NEXUT-All's F_1 score is higher than those of NCL and NB-Tomek for all classifiers.

Regarding NEXUT-Plus, its F_1 score is better than all other techniques for the decision tree classifier, the k-NN classifier, the multilayer perceptron, and the random forest. Furthermore, NEXUT-Plus's F_1 score is higher than that of NB-Tomek for all classifiers.

For NEXUT-PlusMinus, its F_1 score is better than all other techniques for the random forest and the logistic regression. NEXUT-PlusMinus achieves better F_1 scores than other techniques for the decision tree classifier, except for NCL, where both methods perform equally. Additionally, NEXUT-PlusMinus's F_1 score is higher than that of NB-Tomek for all classifiers.

From the statistical results of F_1 score, NEXUT-All is suitable for use with the decision tree classifier, the multilayer perceptron, the random forest, and the logistic regression. NEXUT-Plus is suitable for use with the decision tree classifier, the k-NN classifier, the multilayer perceptron, and the random forest. NEXUT-PlusMinus is suitable for use with the random forest and the logistic regression.

For the synthetic datasets (the Moons dataset and the Circles dataset), the results after applying each undersampling technique, as well as the original datasets without applying any undersampling technique, are illustrated in Fig. 4 and Fig. 5, respectively. The proposed techniques successfully preserve the overall structure of the data distribution, even after a significant number of negative instances are removed.

Table VI and Table VII present the average F_1 scores obtained using the six classifiers: the decision tree classifier (C4.5) [31], the k-nearest neighbors ($k = 3$) [32], the multilayer perceptron [33], the naive Bayes [34], the random forest [35], and the logistic regression [36], evaluated on the Moons dataset and the Circles dataset, respectively. The techniques are ranked for each classifier in descending order of F_1 score, with Rank 1 representing the best-performing method.

For the Moons dataset, the results presented in Table VI indicate that NEXUT-PlusMinus achieves the highest F_1 score rank for the k-NN classifier, the multilayer perceptron, and the random forest. NEXUT-All obtains the highest rank for the logistic regression. For the decision tree classifier, NCL and NB-Tomek share the highest F_1 score rank. NCL also secures the highest rank for the naive Bayes classifier. Considering F_1 scores across all techniques, NEXUT-PlusMinus demonstrates the highest overall average rank.

For the Circles dataset, the results presented in Table VII indicate that NEXUT-All achieves the highest F_1 score rank for the decision tree classifier and the random forest. NCL secures the highest rank for the k-NN classifier. For the multilayer perceptron, the naive Bayes, and the logistic regression, several techniques demonstrate the highest F_1 score rank, notably NEXUT-All, NEXUT-Plus, NEXUT-PlusMinus, AllKNN, NCL, OSS, and the original dataset. It is important to note that, for these specific classifiers, all techniques except NB-Tomek exhibit comparable performance. Considering the overall F_1 scores for all techniques on the Circles dataset, NEXUT-All achieves the highest average rank.

F. Discussion

The experimental results demonstrate that the proposed NEXUT variants consistently improve classification performance across multiple classifiers and datasets. Specifically, NEXUT-All yields superior F_1 scores when applied to four classifiers: the decision tree, the multilayer perceptron (MLP), the random forest, and the logistic regression. These results indicate the consistent performance of NEXUT-All across different learning models. NEXUT-Plus performs best with the decision tree, the k-NN, the MLP, and the random forest classifiers, while NEXUT-PlusMinus excels with the random forest and the logistic regression classifiers. These findings highlight the effectiveness of the NEXUT approach in selectively removing extreme anomalous negative instances while preserving the overall class distribution.

When compared with established undersampling techniques such as AllKNN [24], NCL [25], OSS [23], and NB-Tomek [27], NEXUT achieves consistently higher or comparable performance across multiple classifiers. As shown in Table V, NEXUT-All significantly outperforms OSS and NB-Tomek on the logistic regression and the random forest classifiers at the 95% confidence level. This result aligns with previous findings showing that OSS [23] and NB-Tomek [27] sometimes removed informative instances, thereby reducing classifier performance. Similarly, NCL [25], which was designed to clean overlapping examples, was sometimes too aggressive in certain domains.

These findings are consistent with Batista et al. [42], who observed that Tomek-based approaches were effective at reducing class overlap. However, they sometimes removed informative instances, which degraded classifier performance. In addition, Drummond and Holte [43] reported that random or overly aggressive undersampling could eliminate useful majority instances. Chawla et al. [44] emphasized the importance of maintaining the class distribution to achieve balanced decision boundaries. More recently, Blagus and Lusa [45] noted that oversampling methods, such as SMOTE and its variants, could alter data variability and introduce correlations between samples, which reduced classifier robustness.

By contrast, NEXUT minimizes these drawbacks by targeting only extreme anomalous negatives. It also avoids excessive data removal and synthetic data generation, thereby preserving meaningful sample diversity while enhancing classification performance.

Despite these advantages, NEXUT has some limitations. It is primarily designed for binary class-imbalanced datasets, and its extension to multi-class scenarios requires further investigation. In cases of extreme data sparsity within the majority class, NEXUT's ability to retain representative instances is reduced. This limitation may affect classifiers that rely heavily on boundary information. While NEXUT is computationally efficient for moderate-sized datasets, further optimization will be necessary for large-scale applications.

In terms of practical applications, NEXUT is well-suited to domains where class imbalance is prevalent and accurate minority detection is critical. For example, in medical diagnosis, detecting rare diseases requires minimizing false negatives to avoid life-threatening errors. In fraud detection, reducing the influence of anomalous majority instances improves the identification of rare fraudulent transactions. In industrial anomaly detection, NEXUT enhances reliability by retaining representative operational data while isolating rare faults. Similarly, in cybersecurity, malicious activities often represent only a very small fraction of network traffic. In such cases, NEXUT helps to preserve decision boundaries that are critical for intrusion detection. By reducing the impact of extreme anomalous negatives, while maintaining meaningful class distributions, NEXUT improves classifier reliability in real-world scenarios where parameter tuning is challenging.

Overall, NEXUT demonstrates higher predictive performance compared to conventional undersampling methods while preserving the class distribution. Future work should explore integrating NEXUT with oversampling techniques to further enhance performance and address more challenging imbalanced datasets.

V. Conclusion

In this research, the Negative Extreme Anomalous Undersampling Technique (NEXUT) is proposed to address the imbalanced classification problem. Unlike other undersampling techniques from the imbalanced-learn Python package, which require user-defined parameters, NEXUT is parameter-free. It outperforms the existing undersampling techniques on continuous, binary, class-imbalanced datasets across the six classifiers. NEXUT applies negative extreme anomalous scores to identify negative instances for elimination. The negative instances selected by NEXUT may be noisy, affecting both the minority and majority classes, or they may simply be redundant. NEXUT effectively addresses overlapping instances between classes while maintaining the data distribution of each class. Moreover, it reduces the size of the majority class, resulting in a more balanced dataset. Thus, the proposed technique helps rebalance class instances.

For future work, NEXUT will be improved by integrating an oversampling technique to enhance performance efficiency. It is suggested to prioritize oversampling the minority class to balance the data, followed by applying undersampling to the majority class to remove noise and potentially overlapping instances.

***Abstract*—Blockchain is a major component of future smart healthcare that can improve the security, reliability, trust and automation of healthcare supply chain processes. Blockchain has several applications in areas such as medicine procurement, supply chain tracking, and drug traceability. In this study, we present a review of recent works in the area of Blockchain-enabled healthcare supply chains with a particular focus on pharmaceutical supply chains. We categorize the literature into three major areas namely, procurement, asset management, and system efficiency improvement. We also present a case study of efficient smart contracts for the pharmaceutical supply chain in which we identify different stakeholders of the pharmaceutical supply chain and develop different functions and tasks to be performed by each stakeholder and their interactions with each other. We implement the proposed smart contract in Remix Integrated Development Environment (IDE) using solidity language and evaluate the transaction cost of each function used in the smart contract. Lastly, we also present future opportunities on using Blockchain-enabled healthcare supply chain.**

***Keywords*—Blockchain; smart contracts; healthcare; supply chain**

I. Introduction

Blockchain is an upcoming technology that has applications in many domains. Many application areas such as transportation, health care, banking, etc. can benefit from Blockchain technology [1], [2], [3], [4], [5], [6], [7]. The essence of Blockchain is to secure the data in a distributed manner without the need of a central node for authentication purposes. Thus, Blockchain is a concept that can revolutionize the way the data is secured and managed [8], [9], [10], [11], [12].

The key concept of Blockchain is to store data in the form of blocks that are connected such that the current block contains a hash function of the previous block. This connectivity property as well as the acceptability of only a pre-defined hash function makes Blockchain super secure. To change data in one block, it is needed to tamper data in other blocks too [13], [14], [15], [16]. Moreover, generation of the pre-defined hash function is a computationally heavy task that requires nodes with large processing capacity known as mining nodes [17], [18], [19], [20], [21]. Similarly, a block is only accepted in a Blockchain if more than half of the nodes give consensus to the data. This property also provides additional security to the Blockchain. Blockchain is thus an intelligent way of securing data in a distributed manner [22], [23], [24], [25], [26], [27].

Smart contracts are programs that implement certain conditions as per a particular contract. Contrary to traditional contracts, smart contracts can automate the way contracts are managed and smartly use the technology to check application-specific conditions. Smart contracts provide a reliable solution that does not require a trustable central authority. Smart contracts have many applications in scenarios, where application reliability depends on fulfilling certain conditions [28], [29], [30], [31], [32], [33]. As an example, in a medical supply chain, the temperature of the medicines needs to be maintained. Hence, a smart contract can be developed to monitor the temperature of medical supplies. It is important to note that smart contracts require inputs from the Internet of Things (IoT) sensors and the transmission of data to a server. Based on these inputs, smart contracts can check the permissible conditions issue directions, and make appropriate decisions. Smart contracts are managed using Blockchain technology. Thus, Blockchain-enabled smart contracts are a secure way of implementing and automating checks [34], [35], [36], [37], [38].

The focus of this study is to provide a survey of recent work related to Blockchain and smart contracts in the area of healthcare supply chain. The particular focus of this study will be on the pharmaceutical supply chain. A traditional healthcare supply chain requires manual negotiations and interactions between manufacturers and pharmacies. The goal of the smart contracts-based supply chain is to automate the process of medicine procurement. Another challenge that is part of the healthcare supply chain is the manual checking of different medicine-related parameters such as acceptable temperature while transporting, expiry date of medicines, etc. The smart contracts can include different checks to verify these conditions before purchasing of medicines.

The main contribution of our work is summarized as follows:

- We present a review of recent work related to using Blockchain in healthcare environment. We categorize the related works into three major groups. The first is related to procurement, the second is based on asset management, and the third one is related to system efficiency improvement.
- We present a case study in which we propose a framework of a smart contracts-based pharmaceutical supply chain and identify various stakeholders in the process including the Healthcare Management System (HMS), manufacturers, distributors, pharmacies, and hospitals. We develop different functions for each stakeholder that can be embedded in the smart contracts along with various associated conditions. We

*Corresponding authors.

also develop a sequence of events to highlight the interactions between different stakeholders in the smart contracts-based pharmaceutical supply chain. We implement the proposed smart contract in Remix IDE using solidity language and investigate the transaction gas cost of various functions and methods.

- We present several future opportunities related to the utilization and implementation of Blockchain for the healthcare supply chain.

The rest of the study is organized as follows: Section II presents an overview of the healthcare supply chain, related works regarding the use of Blockchain and smart contracts in different systems, and an overview of different survey papers related to Blockchain-enabled healthcare. Section III presents the classification of work in the area of Blockchain-enabled healthcare supply chain. Section IV, Section V and Section VI present a review of recent works related to procurement, asset management, and improving system efficiency in the Blockchain-enabled healthcare supply chain, respectively. Section VII presents a case study in which we present a proposed smart contract along with its various functions and methods, and highlight the sequence diagram of the smart contract. Furthermore, Section VII also describes smart contract implementation on Remix IDE and presents smart contract cost-related results. Section VIII presents different open challenges and future opportunities. Finally, Section IX present the conclusions.

II. Related Work

A. Overview of Healthcare Supply Chain

The healthcare supply chain refers to the interconnection of different procedures, processes, and networks that enable the distribution of medicines and other healthcare items from manufacturers to patients. Our particular focus in this study is on the pharmaceutical supply chain which starts with the research and development of a drug. Different trials and tests are conducted to verify the effectiveness of the drug. After the verification phase, the drug is manufactured on a large scale by different manufacturers that ensure quality assurance by following different quality control procedures [39], [40], [41]. The drugs are purchased by different distributors and further sold to different pharmacies and hospitals. A drug regulation authority controls the safety and quality of the product and ensures that different regulations are met. Finally, the drug is purchased by the end customer [42], [43].

During the supply chain, different processes are involved and interaction between different stakeholders takes place. Monitoring and tracking of these processes are needed to efficiently control them [44], [45], [46]. The related data needs to be efficiently and securely stored. Moreover, the privacy of communication between stakeholders needs to be maintained. All of these issues can be handled by Blockchain and smart contracts, thus improving the efficiency of the supply chain [47], [48].

B. Use of Blockchain for Different Applications

Several works have investigated the use of IoT, Blockchain, and smart contract technology for different applications. In [3], the authors presented a smart contract validation mechanism for supply chain applications. A smart contract was created for better use of data structures in the mining process at the miner nodes.

In [5], a Secure Electronic, Health Medical Record (EHR/EMR) solution was proposed using Blockchain technology. In the proposed solution, data or medical records are shared in a secure manner utilizing various techniques such as multiple authentication schemes for improved security and access control of Medical Reports (MR), data management, and other safety requirements. The proposed technique consists of three phases, first is the authentication by using a Quantum Cryptography Algorithm (QCA), the second one is the encryption by using Advanced Encryption Standard (AES) and the last is the data retrieval by using a Secure Hash Algorithm (SHA).

In [6], the authors investigated the use of the Ethereum Blockchain platform for educational systems. A smart contract for online examination system was created using the Ethereum Blockchain. The system allows to use of the NodeJS server runtime environment and the MongoDB database system. The system utilized several examination related data to develop the smart contract.

In [7], the authors proposed a Mobile-Healthcare algorithm using the Blockchain network. The proposed algorithm develops smart contracts between doctors and patients by using Blockchain. The patients send different sensor data to the nodes participating in the Blockchain. The work minimizes the delay between the patient and the doctor in case of emergency. In a short time, the doctor can send the medical report to the patient in a secure manner. The work also discussed about the 51% attack on the system in which majority mining is done by a particular group and has control over it.

In [8], the authors proposed a relationship between big data analytics, Blockchain, and the Internet of Things (IoT). Blockchain is a secured database technology for real-time data transition and IoT is used to connect different devices, sensors, and databases over the Internet. Blockchain resolves two major problems in IoT applications, one is to develop trust between nodes, the second is to ensure the data privacy.

In [10], the authors proposed the use of Blockchain technology to create an upgraded diabetes Electronic Medical Record (EMR). The medical information was separated into two sections. The data of the medical institution was in one category, and the data of the patient was in another category. The patient's medical records were stored with authentication, privacy, and security such that no physical medical documents were required.

In [11], the authors proposed a solution for secure patient data sharing using the hyperledger fabric framework-based permissioned Blockchain network. Hyperledger fabric was used as a private Blockchain which can be programmed as required. A new member of the Hyperledger fabric must be enrolled through the Membership Service Provider (MSP). A smart contract was written in the hyperledger of fabric with the help of Chaincode.

In [12], the authors proposed the safe and reliable sharing of data between different nodes by using the Blockchain. With

the help of the decentralized database, the work proposed a secure financial data sharing. In [49], the authors discussed different challenges in the supply chain and presented the solution to these problems with Blockchain technology. It was shown that the Blockchain improves the efficiency of supply chain.

In [22], the authors discussed use of Blockchain to conserve perishable food products in the supply chain. Everyone from the farm to the customer can see the temperature of the product with the use of a distributed ledger. The data in the Blockchain can not be changed. As a result, the proposed technology can reduce different types of food losses.

In [23], the authors discussed the agri-food supply chain system with different problems related to trust, lack of transparency, economic losses, and enterprise brand value. It was shown that the food industry supply chain can be improved by using Blockchain.

In [24], the challenges related to the medical supply chain were discussed. The current supply chain processes fail to provide security, transparency, and trust-like features. Also, the system is centralized and cause failure in case of any fault in the central server. By using Blockchain technology, the authors provided secure information exchange between different stakeholders. The InterPlanetary File System (IPFS) storage system was used to store, fetch, and share data in the Blockchain.

The utilization of Blockchain in vehicular networks was discussed in [25]. Data management for applications such as traffic control, route scheduling, and information exchange was enabled using Blockchain. In [26], a review of different works related to security and privacy of Blockchain was presented.

A Blockchain-based smart contract development environment was proposed in [27]. The work consists of two parts, the first part was a novel transaction framework using smart contract and second part was comparison with the current available smart contracts.

In [28], authors proposed a Blockchain based healthcare system. Every hospital uploads the patient's record on the Blockchain and with the help of a mobile application, patients or authorized users can retrieve records on the mobile. The Blockchain in the application ensures data security and data authenticity.

In [29], authors proposed the use of Blockchain's decentralized nature to handle challenges such as frequent network disconnectivity. Integrating IoT with Blockchain was proposed in [30] for reducing the appointment time of doctors. Blockchain technology provides an active feedback loop to improve the tracking of patient health related data.

In [31], authors presented Blockchain-based smart grid cybersecurity techniques. The data was protected by storing it in a Blockchain network and having it validated by peers in the same network. Advanced smart grid activities like load forecasting, local redistribution, and disaster recovery could all benefit from the validated data.

C. Comparison with Other Related Survey Papers

We present a comparison of other survey papers related to Blockchain-enabled pharmaceutical supply chains and health care in Table I. While there are many survey papers available on the utilization of Blockchain in health care, there are a limited number of reviews or survey papers on the topic of pharmaceutical supply chain. The work in [50] is focused on the advantages of Blockchain for pharmaceutical cold chain. The review in the paper is mostly related to asset management for improving the pharmaceutical cold chain.

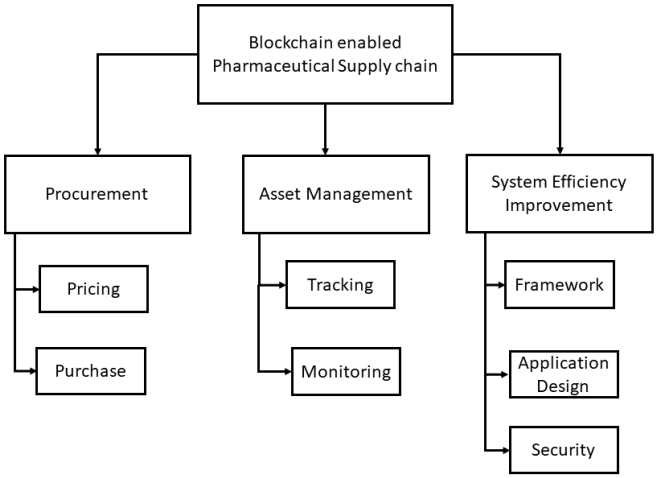

Fig. 1. Classification of work related to Blockchain-enabled pharmaceutical supply chain.

In [51], the review paper is related to handling counterfeit drugs and patient privacy using Blockchain. Similarly, the paper [52] is focused on areas of preventing counterfeit drugs, and tracking and tracing of drugs during their production and distribution life cycle.

The paper in [53] is focused on healthcare applications and presents a survey of work on topics such as data management, healthcare insurance, and supply chain. The survey paper in [54] is focused on the security and interoperability of healthcare applications using Blockchain.

Most of the current survey papers are focused on asset management of pharmaceutical supply chains or other healthcare applications. In addition, most of the review papers are from 2020 to 2022. Most of the recent survey papers are focused on other healthcare applications. Thus, the distinguishing feature of our survey paper is that it reviews three major aspects of the pharmaceutical supply chain and presents recent related works. Moreover, our study also presents a smart contract-based case study to highlight how Blockchain can be utilized for managing the pharmaceutical supply chain.

III. Classification of Work in Blockchain-enabled Pharmaceutical Supply Chain

The work related to the use of Blockchain in the Pharmaceutical supply chain can be classified into three major categories, as shown in Fig. 1. These categories include procurement, asset management, and system efficiency improvement. Further to these categories, the work within these categories can be divided into several subcategories, as discussed below.

TABLE I. COMPARISON OF OUR SURVEY PAPER WITH OTHER RELATED PAPERS

Year	Focus	Procurement	Asset management	Efficiency improvement
2021 [50]	Pharmaceutical cold chain	✗	✓	✗
2022 [51]	Counterfeit drugs Patient privacy	✗	✓	✗
2022 [52]	Counterfeit drugs Tracking Tracing	✗	✓	✗
2020 [53]	Healthcare applications Data management Health insurance Supply chain	✗	✗	✓
2023 [54]	Security Interoperability	✗	✓	✗
Our paper	Pharmaceutical supply chain Smart contract based case study	✓	✓	✓

A. Procurement

Procurement in the supply chain refers to the purchasing of pharmaceutical items and goods. Procurement has a vital role in ensuring that high-quality medicines, vaccines, and raw materials are purchased from the correct sources at a good price.

1) Purchase: The first aspect of procurement is the purchase itself [55], [56]. This means finding the right sources to obtain raw materials. Blockchain can provide a distributed and secure database of these sources [57]. Similarly, purchasing also involves finding reliable manufacturers, distributors, and pharmacies.

2) Pricing: The second aspect of procurement is pricing in which different stakeholders in the supply chain communicate with each other to agree on the pricing of a product. Blockchain can significantly improve the pricing process as it can provide automated smart contracts to evaluate and negotiate the pricing of drugs [58], [59].

B. Asset Management

Asset management is a critical part of the supply chain as it can track and monitor the medicines and drugs during their transportation from manufacturers to distributors and then further to pharmacies. In the context of Blockchain-enabled pharmaceutical supply chain, most of the work can be categorized into tracking and monitoring of medicines [60], [61].

1) Tracking: Tracking involves the management of different medical products during the supply chain. The management includes tracking of raw materials, machinery, and equipment for manufacturing and inventory. With tracking of these products, stakeholders can find the real-time location of medical products and raw materials, and also ensure that the inventory is right quantities. Based on real-time tracking, storage requirements can also be optimized. By using different IoT sensors, Blockchain-based data management, and smart contracts, efficient and secure tracking of inventory can be managed [62], [63].

2) Monitoring: Medical products are dependent on environmental factors to maintain their quality and correct working. Factors such as temperature and humidity need to be maintained within certain thresholds so that these products work at their best. Smart contract-based solutions can regularly monitor these conditions and separate the products that do not follow the required conditions during the supply chain [64].

C. System Efficiency Improvement

Blockchain solutions can be used to improve the supply chain system efficiency such as providing secure data management and prevention against information leakages.

1) Framework: Blockchain-based supply chain framework involves designing solutions that integrate with the current pharmaceutical supply chain system. It also means designing new Blockchain-based systems and process flows to optimize the supply chain. Moreover, the development of IoT solutions, new smart contracts, and data management techniques fall under this category.

2) Application design: The application design involves Blockchain-based new or evolved versions of previous applications related to the pharmaceutical supply chain. Such applications include new payment methods, stakeholder communication, inventory management, and real-time tracking. Such applications enhance the supply chain user experience and improve the efficiency of the supply chain system.

3) Security: Data security is a key challenge for the pharmaceutical supply chain. Data related to medicines is private and sensitive, hence it is critical to find secure solutions [65], [66]. Blockchain provides an efficient data management method that can provide secure access control, immutable data record keeping, privacy of data storage, and resilience to cyber attacks [67], [68], [69].

IV. RECENT WORKS RELATED TO BLOCKCHAIN-BASED PHARMACEUTICAL PROCUREMENT

The recent work related to Blockchain-enabled pharmaceutical procurement is shown in Table II. In [1], a smart

TABLE II. RECENT WORKS RELATED TO BLOCKCHAIN-BASED PHARMACEUTICAL PROCUREMENT

Reference	Blockchain solution	Stakeholders	Procurement process	Results
[1]	Smart contract	GPO Manufacturer Distributor Healthcare provider	Stakeholder registration Admission fees Price update Price negotation Purchase order Delivery status Loyalty discount	Transaction gas cost Execution gas cost
[70]	Blockchain	Competing manufacturers Retailer	Wholesale price Purchase quanity Monetary gains	Blockchain benefit Blockchain cost
[71]	Blockchain Smart contract	Companies Wholsalers Users	Pricing Price history	Application development
[72]	Blockchain Smart contract	Vaccine manufacturer Vaccine unit	Cost sharing contract Revenue sharing contract	Increased profit Supply chain efficiency
[73]	Consortium Blockchain	Patients Manufacturers Health authorities Pharmacy	Value-based pricing	Framework development

contract is proposed that considers multiple pharmaceutical stakeholders such as Group Purchasing Organization (GPO), manufacturer, distributor, and healthcare provider. The proposed work presents detailed functions and methods that are involved in the procurement of medicines. These processes include stakeholder registration, admission fees, updating prices, negotiation of prices, purchase order development, finding the status of delivery, and getting loyalty discounts. The authors implemented the smart contracts in Solidity and evaluated their transaction gas cost and execution gas cost.

The work in [70] developed a Blockchain solution considering two stakeholders, two competing manufacturers and a retailer. For procurement, processes such as wholesale price evaluation, purchase quantity, and monetary gains are considered and related data is stored in a decentralized Blockchain. The work provides an analysis of the cost associated with Blockchain solutions along with their benefits.

In [71], a smart contract-based solution is proposed that considers companies, wholesalers, and users as stakeholders. The proposed work provides pricing methods and also stores pricing history in the Blockchain. This pricing history is stored securely and data changes are not possible. To verify the proposed idea, a mobile application is developed.

The work in [72] developed a Blockchain and smart contract-based technique for the vaccine supply chain. Vaccine manufacturers and vaccine units are the two stakeholders. Two major contracts for procurement include cost sharing and revenue sharing. The proposed technique shows increased profit and improves supply chain efficiency.

A consortium-based Blockchain is proposed in [73]. The work considers four stakeholders namely, patients, manufacturers, health authorities, and pharmacies. The pricing mechanism introduced by the work is based on the value added by each medicine. The paper presents the framework for the proposed value-based pricing mechanism.

V. RECENT WORKS RELATED TO BLOCKCHAIN-BASED PHARMACEUTICAL ASSET MANAGEMENT

The works related to pharmaceutical asset management that used Blockchain is shown in Table III. The work in [74] develops an Ethereum smart contract for asset management in which several features are available such as the quantity of boxes within a lot, pricing of the lot, and drug purchase from trusted manufacturers. A secure decentralized InterPlanetary File System (IPFS) is used as an offchain storage mechanism. Moreover, the system also uses onchain storage as well. Results show the gas cost of the developed smart contract and its security analysis.

In [75], a smart contract is developed for drugs that can be reused and resold. For the reselling application, a verification mechanism from the healthcare authority is proposed. A pricing management system including bidding for the available drugs is developed as part of the smart contract. A reputation ranking system for the resellers is also included. The advantage of this system is that buyers can view the previous selling history and reviews of the reseller. The evaluation of the proposed smart contract presents its gas cost and security analysis.

The work in [76] proposes an IoT and Blockchain integration for asset management. For cost cutting, the minimum distance of the transport route to deliver the medicines is calculated. A mathematical model for route selection from manufacturer to end user is presented. The work also considers environmental change monitoring using IoT sensors. In case any factor is beyond the allowed threshold, a notification is sent to the product owners and customers. Results show reduced latency and response time from the Blockchain network when

TABLE III. RECENT WORKS RELATED TO BLOCKCHAIN-BASED PHARMACEUTICAL ASSET MANAGEMENT

Reference	Blockchain solution	Asset management methods	Results
[74]	Ethereum Blockchain Smart contract	Quantity of boxed within a lot Price of the lot Drugs from trusted manufacturer	Gas cost of smart contract Security analysis
[75]	Ethereum Blockchain Smart contract	Reselling of drugs Verification from healthcare authority Pricing management Bidding Reputation ranking of resellers	Gas cost of smart contract Security analysis
[76]	Blockchain	IoT integration Minimum distance of supply chain Mathematical model Environmental change monitoring Notification to owners and customers	Improve product life time Reduce response time
[77]	Blockchain	Forward and reverse supply chain Reduce transportation cost in forward chain Reduce recall time in reverse chain Faulty drugs recall	Reduced latency Improved throughput
[78]	Smart contract	IoT integration All data signed by stakeholders Stored in Blockchain Record of drug production life cycle	Security analysis Communication cost analysis

the proposed scheme is used. In addition, product lifetime is improved as well.

In [77], the concept of forward and reverse supply chains is introduced and implemented on a Blockchain. Authors develop mathematical models to optimize the supply chain. In the forward direction, the cost is reduced in terms of transportation and inventory costs to supply medicines from the manufacturer to the end user. The model considers vehicle type, reliability of the vehicle, and delivery distance to optimize the cost. In the reverse direction, travel time to recall faulty medicines is reduced. The Blockchain implementation is presented and the work shows reduced latency as compared to the other techniques.

The work in [78] presents a smart contract with IoT integration for asset management. Using IoT sensors, the data related to the drug production life cycle is shared and stored in a Blockchain. Furthermore, the data is signed by all the stakeholders so that no change in it can be made. Results show that the proposed smart contract achieves secure data storage. Results related to communication cost analysis are also presented.

VI. RECENT WORKS RELATED TO BLOCKCHAIN-BASED PHARMACEUTICAL SYSTEM EFFICIENCY

The works related to Blockchain-based pharmaceutical system efficiency improvement is shown in Table IV. In [79], a smart contract framework is developed for the vaccine supply chain and life cycle which improves the system's security and reliability. The proposed system ensures secure record keeping and also enables authentication of all stakeholders. Results show that the proposed framework achieves improved throughput and reduced lost number of data blocks.

The work in [80] proposes a hybrid Blockchain-based framework including both public as well as private Blockchains. A mobile application is developed for all stakeholders. The record-keeping of the drug life cycle is maintained and helps in the detection of counterfeit medicine. Furthermore, IoT is used for monitoring medicines and cryptocurrency is used for purchasing medicines. The work also shows an implementation of the proposed framework.

In [81], a permissioned Blockchain-based framework is developed to enhance the security of the pharmaceutical supply chain. The work proposes the use of secure identity for stakeholders. Similarly, drug information storage is also carried out using secure Blockchain. A secure method is proposed for updating and cancellation of transactions. The system is shown to improve throughput and reduce transaction latency.

The work in [82] proposes a consortium Blockchain to manage the pharmaceutical supply chain. A consensus algorithm is proposed for large-scale traceability of the supply chain. Furthermore, the system is divided into nodes and grouping is done to manage the system efficiently. A ranking system is developed to select trustable nodes to manage transactions in each group. The proposed system improves throughput and reduces transaction latency.

In [83], smart contracts are proposed for dynamic access control in the pharmaceutical supply chain. The work allows the management of permissions at the micro level. Two techniques are used in the proposed system. The first one is the Role-based Access Control (RBAC). This technique is combined with the second Attribute-based Access Control (ABAC) mechanism. The proposed access control improves system throughput in terms of transactions per second [83].

TABLE IV. RECENT WORKS RELATED TO BLOCKCHAIN-BASED PHARMACEUTICAL SYSTEM EFFICIENCY IMPROVEMENT

Reference	Blockchain solution	Framework features	Results
[79]	Public Blockchain Smart contract	Security of vaccine supply chain Smart contract for vaccine life cycle Secure vaccine record keeping Authentication of stake holders	Improved throughput Reduced lost blocks

[81]	Permissioned Blockchain	Secure identity of stake holders Secure drug information storage Secure transaction update or cancellation	Improved throughput Reduced transaction latency
[82]	Consortium Blockchain	Consensus algorithm for large scale traceability Divide nodes in to groups Ranking system to select trusted management nodes	Improved throughput Reduced transaction latency
[83]	Smart contract	Dynamic access control Manage permissions at micro level Combination of RBAC and ABAC	Improved throughput

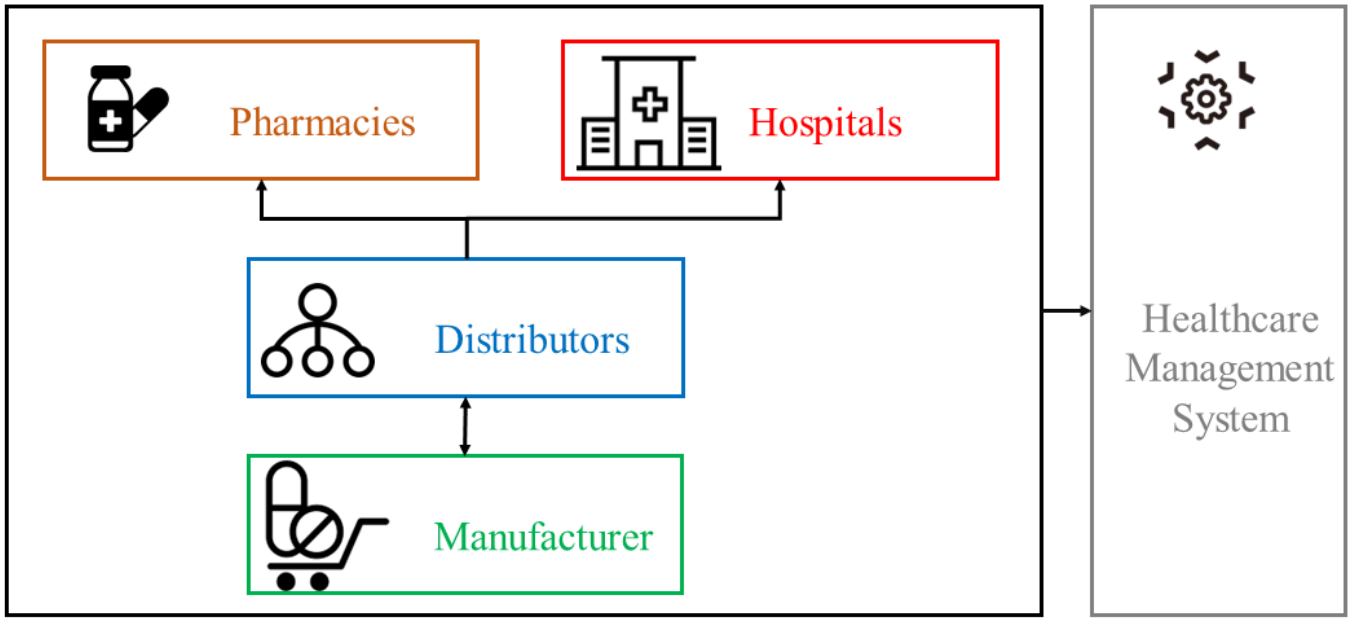

Fig. 2. Components of pharmaceutical supply chain.

VII. CASE STUDY: A PHARMACEUTICAL SMART CONTRACT FRAMEWORK

In this section, we provide a case study related to the pharmaceutical supply chain.

A. Framework

We present a framework for a pharmaceutical supply chain that uses Blockchain-based smart contracts, as shown in Fig. 2. The proposed system has five stakeholders: a Healthcare Management System (HMS), Manufacturers, Distributors, Pharmacies, and Hospitals, all of whom are part of the same decentralized Ethereum-based network. In the contracting process, we use Blockchain technology to provide transparency and data immutability.

B. Components of Smart Contract

There are five main components of the proposed smart contract, where each component is a stakeholder in the system. The role and functions of each stakeholder are described below:

1) Healthcare management system: A Healthcare Management System (HMS) is the centralized server/database that manages the healthcare records, medical processes, and pharmaceutical smart contracts. HMS interacts with different

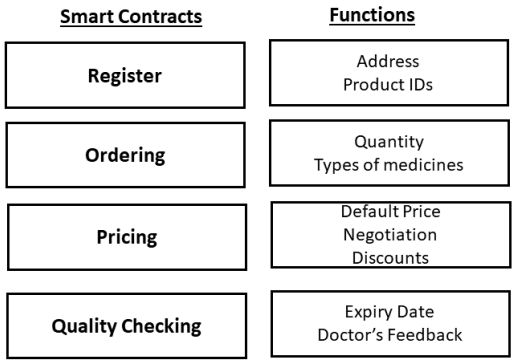

Fig. 3. Different smart contracts and functions for pharmaceutical supply chain.

stakeholders in the pharmaceutical supply chain and manages the large-scale distribution and purchase of medicines. All other stakeholders register themselves in the database of HMS to allow efficient management of the purchase process.

2) Manufacturer: A manufacturer develops and distributes medical and pharmaceutical supplies to the healthcare providers.

3) Distributor: A distributor picks the products from the manufacturing company and sends them to the service providers, i.e., pharmacies and hospitals.

4) Service provider: Pharmaceutical service providers include different pharmacies and hospitals. They purchase medicines from different distributors.

It should be noted that the distributors interact with the manufacturers whereas the service providers communicate with the distributors to enable the supply chain.

C. Description of Smart Contracts

We present the description of different smart contracts managed by the HMS in Fig. 3. There are four major categories of smart contracts, namely registration, ordering, pricing, and quality checking.

The Registration contract is used by all the stakeholders. Each stakeholder registers itself in the central HMS as a manufacturer, distributor, pharmacy, or hospital. The registration is managed using a unique address allocated to each stakeholder. Moreover, each product (i.e., medicine) is also registered and provided a unique ID. Once the registration process is finished, the central database of HMS has a city-wide record of each stakeholder in the supply chain.

The ordering contract is used by the stakeholders to place their orders. Separate ordering contracts are deployed between manufacturers and distributors and between distributors and service providers. The ordering contract has functions to enter the quantity of medicines and type of medicines. Each medicine is categorized into different types for the ease of storing in the database.

The pricing contract enables the purchase of medicines and finalizes the orders at a particular agreed price. It allows manufacturers and distributors to set a default price for medicines. Also, it manages the price negotiation between the stakeholders. Finally, the discounts can be issued on bulk purchases of medicines or any other annual sales event. As in the ordering contract, there are different pricing contracts between each stakeholder.

The last contract is the quality checking contract which is a key feature of the smart contract. This contract can offer many benefits in terms of maintaining the quality of medicines and automating them without the need for manual checking. Conditions such as medicine expiry date can be checked to throw away expired medicines. Different notifications can be issued for medicines that are near the expiry. Similarly, a doctor's feedback on a particular medicine is also incorporated to improve the quality-checking mechanism.

D. Implementation and Cost Analysis

In this section, we present the implementation of the proposed smart contract and its associated cost analysis.

1) Implementation: To implement the proposed smart contract between different stakeholders, we define the functions as discussed in the previous subsection. For this purpose, the Remix Ethereum platform is used. Remix IDE is an open-source platform to write, deploy, and test smart contracts. Remix IDE supports Solidity language, so all the smart contracts are written in the Solidity language. For the Graphic User Interface (GUI) in Remix Ethereum, a Java Virtual Machine (JVM) Environment is available. Ethereum helps in developing decentralized applications and development features such as rapid development, security, and interaction between applications.

We present the implementation of different contracts in the following subsections.

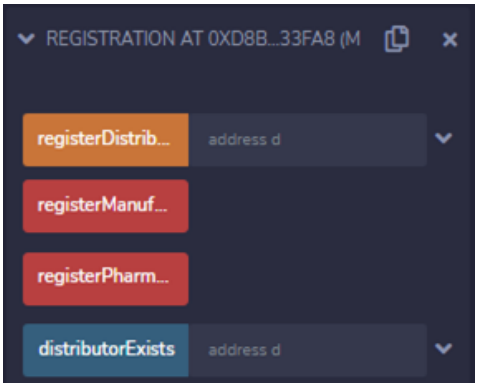

Fig. 4. Registration contract.

2) Registration contract: The Registration contract is shown in Fig. 4. The owner of this contract is HMS which will deploy this contract on its server. This contract deals with the registration process of manufacturers, distributors, pharmacies, and hospitals.

As shown in Fig. 5, this contract has different functions to check issues such as whether the addresses are already used or are available, whether the registration fee is sufficient or not, etc.

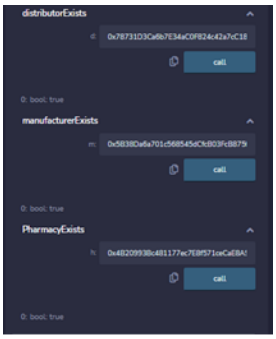

Fig. 5. Check Registered Status

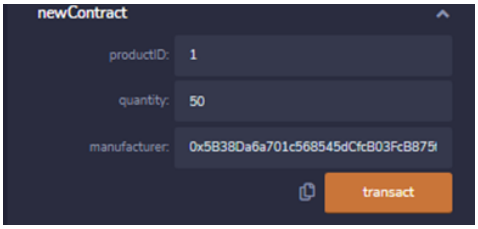

Fig. 6. New contract.

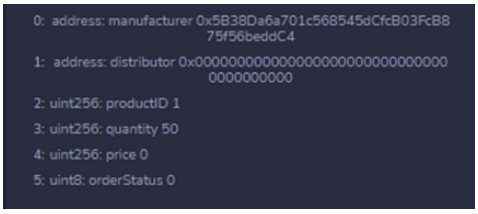

Fig. 7. Contract details.

The built-in keccak256 cryptographic function in Solidity is used for the contracts. Keccak256 converts any number of input arguments to a 32-bit hash. Three arguments (timestamp, contract deployer address, and sender address) are used in this function to generate the contract Address.

We can check the contract details by using the address of the contract, as shown in Fig. 7. The output price and order status, both are updated after the price negotiation, as shown in Fig. 8.

Based on the quantity required, the seller submits a proposed pricing. The potential buyers can show their interest in the item and a mapping with the seller is formed. As an example, the assignDistributor function is used to send orders from the distributor to the service provider, as shown in Fig. 9. This function takes two arguments, contract address and distributor address.

4) Cost analysis: The cost analysis of the smart contract can be conducted by evaluating the gas cost which measures

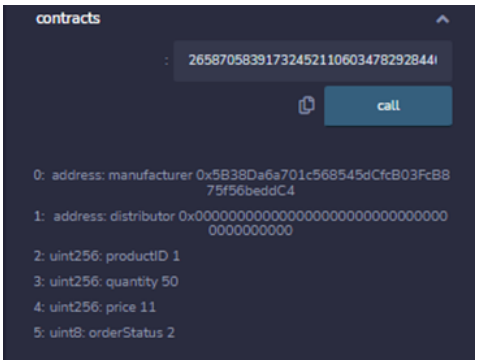

Fig. 8. Updated contract details.

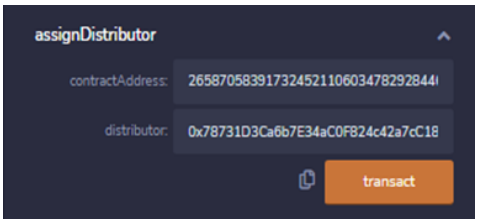

Fig. 9. Assign distributor.

the computational power required for different smart contract functions. Ehereum's native currency ether (ETH) is used for gas payments. The prices of gas are expressed in gwei, which is unit of Ether. One gwei is 10^{-9} ETH. In our case,

- GAS is the unit of computation.
- Gas price is the Ether/Gas (Amount of ether that can be paid per gas)
- Gas limit is the maximum value of gas to be used for a transaction
- Block gas limit is set by the network

The transaction fee is given by the following equation:

Transaction fee = gas used × gas price

Transactions of high gas prices will be processed faster than the low gas prices.

In the Ethereum smart contract, calling different functions require different amount of GAS. GAS is the unit of money in the Ethereum smart contract. GAS depends upon the function complexity and the time. The client can set the upper limit of gas, so for any function, the client does not spend an over amount of gas. So, if the client sets more gas limit, then the transaction will done faster. For measuring the cost, the Ethereum gas station can map the function cost in terms of gas to the corresponding currency amount (such as US dollars).

In Table V, the transaction cost of each function that is used in the registration smart contract is shown. From the above table, the highest transaction cost is for the methods used for the registration of different stakeholders with the HMS. Similarly, registering medicine products with their IDs also incurs a high transaction cost. The transaction cost is reduced for checking the existence of stakeholders in the database.

TABLE V. COST OF REGISTRATION SMART CONTRACT METHODS

Method Name	Transaction Gas Cost
registerManufacturer	49338
registerDistributor	49338
registerPharmacy	49338
registerHospital	49338
ManufacturerExist	24042
DistributorExists	24042
PharmacyExist	24042
HospitalExist	24042
RegisterProduct	39259

TABLE VI. COST OF ORDERING SMART CONTRACT METHODS

Method Name	Transaction Gas Cost
InitiateOrder	58581
SetQuantity	37428
SetMedicineType	43595

In Table VI, the cost of ordering contract methods are shown. There are three methods in this smart contract. The lowest transaction cost in ordering smart contracts is for setting a single order feature. In comparison, initiating a complete order with all the input features renders a higher cost.

TABLE VII. COST OF PRICING SMART CONTRACT METHODS

Method Name	Transaction Gas Cost
SetDefaultPrice	**35621**
RequestNegotiatePrice	**76023**
RespondNegotiatePrice	**45489**
RequestDiscount	**69840**
RespondDiscount	**39284**
assignManufacturer	**58581**
assignDistributor	**58581**
contractStatus	**43595**
newContract	**113207**

In Table VII, the cost of pricing smart contract methods is shown. The first method is the setting of the default price by the entity, that is selling the medicines. The next two methods are used to negotiate prices. The buyer first requests a price that it can offer. Afterwards, the seller either agrees to the buyer's price or sends its final price threshold. Similarly, buyers can request a discount based on membership, etc. The seller responds to it either by agreeing to the discount or sending an updated price it can offer. In addition, there is a method to assign manufacturers to the distributors. Also, there is a method to assign distributors to a pharmacy or a hospital. Moreover, the highest transaction cost is for the newContract method which signs the contract between two stakeholders based on agreement on pricing and quantity. The status of the contract can also be checked using a separate method, as shown in Table VI.

In Table VIII, we show the cost of Quality Checking methods for medicine expiry checks and also for sending doctor's feedback.

TABLE VIII. COST OF QUALITY CHECKING SMART CONTRACT METHODS

Method Name	Transaction Gas Cost
CheckMedicineExpiry	40960
SendDoctorFeedback	57346

It should be noted that we show the gas cost of different methods for different smart contracts. Gas cost (Gwei) depends on the complexity of methods and time. From the results, it can be seen that the gas cost (Gwei) of the newContract method is greater than all other methods of different smart contracts.

VIII. FUTURE OPPORTUNITIES

In this section, we present future opportunities related to the Blockchain-enabled healthcare supply chain.

A. Supply Chain Health Monitoring Metrics

The working range of healthcare supplies in terms of temperature, humidity, and other factors varies from product to product. It is critical to design supply chain health monitoring metrics that consider all of these different parameters. Instead of using various parameters to find thresholds and conditions for smart contracts, it is more effective to use some of these health monitoring metrics. This way smart contracts will be easier to design with less number of functions and methods. This will also reduce the gas cost and transaction cost of the smart contracts.

To develop these health monitoring metrics, mathematical models may be needed that take into account thresholds of parameters with different ranges. A major challenge in this regard is that all these parameters have different operating ranges and units. Hence, it is challenging to design a single metric that gives accurate values of health monitoring. In this regard, multi-criteria decision-making algorithms such as Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) may be utilized.

B. Gas Cost Reduction in Smart Contracts

Smart contracts for supply chains can automate various procedures and processes. However, the major cost associated with it is the gas cost for Blockchain transactions [84], [85]. This cost may increase the overall budget of the supply chain and eventually have an impact on the prices of medicines and healthcare supplies [86], [87].

A major challenge is to reduce the gas cost of smart contracts by using efficient implementation techniques in terms of variables and data structures [88], [89]. The code of smart contracts needs to be optimized for efficient working and reduced transactions. Moreover, the number of methods can be reduced by efficient smart contract design considering the application [90].

C. Interoperability

Blockchain-enabled healthcare solutions need to be inoperable and work with different manufacturers, distributors, pharmacies, and hospitals [91], [92]. Each of the stakeholders has different priorities and preferences regarding the supply chain solutions. Factors such as cost, reliability, and efficiency are considered by each stakeholder, and decisions are made to select a particular solution based on their available budget [93], [94].

It may also happen that different stakeholders may be using different types of smart contracts and Blockchain. The developed smart contracts can be standardized and work for different types of Blockchain and associated environments [95], [96]. Moreover, algorithms and protocols are needed to communicate among Blockchains for transferring of data and tokens [97].

D. Smart Contracts for Healthcare Supplies

While the focus of the current study is on the pharmaceutical supply chain, there are many other types of items and supplies associated with healthcare. For example, procurement and distribution of health-related machine equipment such as ventilators, radiology machines, etc. Similarly, healthcare supplies also involve the distribution of surgical equipment, supplies used in laboratories, and diagnostic items [98], [99], [100].

While pharmaceutical supply chains are more focused on considering environmental factors to maintain the working condition of medicines, other healthcare supplies such as equipment may be more sensitive to road conditions and wear and tear during transportation. Thus, it is challenging to design different smart contracts for different healthcare supply chains considering individual features and characteristics [101], [102].

IX. Conclusion

This study presents a review of Blockchain-enabled healthcare and pharmaceutical supply chains. The study provides an overview of the healthcare supply chain and the uses of Blockchain in different applications. In comparison with the other survey papers on this topic, this study classifies the work done in this area into three major categories. The first is the work related to procurement, the second category is the work related to asset management and the last category is the work related to system efficiency improvement. A survey of recent work in these three areas is presented. The work also presents a case study in which we propose a smart contract involving different stakeholders for the pharmaceutical supply chain. The work describes in detail functions of the proposed smart contract framework. Also, we present details of smart contract implementation and transaction cost analysis. Lastly, we also identify major future research opportunities related to the blockchain-enabled healthcare supply chain.

***Abstract*—Modern recruitment requires smarter, faster, and more inclusive methods to manage the growing volume and diversity of job applications and candidate resumes. Manual screening is often ineffective and unreliable especially in low-resource or multilingual contexts. To address this challenge, we propose an approach that automates and optimizes key stages of the recruitment process. This three-stage approach includes: 1) extracting structured data from resumes using a robust Named Entity Recognition (NER) system, which comprises a NER annotator, a feature extractor, and a transition-based parser; 2) employing a fine-tuned transformer model to perform semantic matching between candidates and job descriptions; and 3) leveraging a large language model to generate interview questions tailored to specific job requirements, thereby improving the relevance and personalization of candidate assessments. The recruitment system was tested on a large-scale resume and job posting dataset across multiple domains. Our NER model reported an F1-score of 85.11% in entity extraction, and the matching component reported accuracy levels as high as 92% when using hierarchical job classes. The results prove the efficacy of combining deep learning techniques with semantic reasoning in enhancing automation, accuracy, and fairness in hiring.**

***Keywords*—Named entity recognition; large language models; feature extraction; generate question; matching**

I. Introduction

With technology advancing rapidly and professional fields becoming increasingly diverse, companies and recruitment systems are now confronted with an unprecedented volume of job applications. Large firms and headhunters process hundreds of Curriculum Vitae (CVs) each day, with each document exhibiting unique formatting styles, layouts, and structures. This variability poses a significant challenge for automated recruitment systems, which must efficiently extract, organize, and evaluate candidate information at scale. Named Entity Recognition (NER), a subtask of Natural Language Processing (NLP), offers one of the most promising solutions to this challenge. NER [1], [2], [3], [4], [5], [6], [7], [8], [9] refers to the process of identifying and classifying named entities in text into predefined categories including names, organizations, locations, dates, and other specific terms. NER has shown notable success in extracting structured knowledge from unstructured resume content [10], [11], [12], [13], [14], [15], in the framework of resume analysis. It helps important components name, contact information, educational background, professional experience, technical and soft skills, and certifications to automatically detect and organize. Another crucial component of intelligent recruitment is the task of matching candidates with job descriptions [16], [17], [18], [19], [20], [21], which aims to automatically align candidate profiles with employer requirements. The objective is to assess how well a candidate's qualifications, background, and skills correspond to the expectations and preferences outlined in job postings. Automating this matching process can significantly enhance the quality of candidate selection, reduce time-to-hire, and improve overall recruitment efficiency. However, this remains a complex and inherently challenging task. It goes beyond simply identifying similar keywords or job titles; it requires an understanding of the semantic context in both resumes and job descriptions. Terminologies often differ, experiences may only partially align, and important qualifications may be implied rather than explicitly stated. As a result, traditional keyword-based methods are frequently inadequate. To achieve accurate and meaningful matching, advanced techniques such as language embeddings, semantic similarity modeling, and context-aware entity alignment are increasingly being employed. Following the candidate–job matching phase, companies often need to conduct personalized evaluations of shortlisted applicants. At this stage, recruiters must delve deeper into specific aspects of each profile, which typically involves asking targeted follow-up questions. However, many organizations lack the time and resources to manually craft relevant questions for every candidate. To address this, the automatic generation of entity-driven interview questions has emerged as a valuable solution [22]. By leveraging entities extracted from resumes and job descriptions during the matching phase, the system can generate tailored questions for each candidate, helping recruiters verify key information or probe specific skills and experiences. For example, based on the entity work experience, the system might generate questions such as: Can you elaborate on your responsibilities at Company X? or What challenges did you face during your role as a Data Analyst? Thus enabling a more focused, consistent, and efficient evaluation process.

To address these challenges, we propose an approach that automates and optimizes key stages of the recruitment process. The process begins with the extraction of structured information from resumes using a robust Named Entity Recognition framework, composed of an annotator, a feature extraction, and a transition-based parser. This is followed by the use of a fine-tuned transformer-based model to achieve semantic

alignment between candidate profiles and job descriptions. Finally, leveraging a large language model to generate interview questions tailored to specific job requirements. This recruitment process mitigates the limitations of traditional recruitment workflows by automating resumes parsing, CVs-job matching, and question generation ultimately reducing manual effort, improving selection accuracy, and enhancing the overall efficiency of the recruitment process for both employers and applicants.

This study is structured as follows generally: Section II discusses related work, stressing developments in entity extraction from CVs and other matching techniques applied in recruitment. Section III covers the preliminaries and details on the models applied in this work. The suggested framework is presented in Section IV together with information on extracting important entities, matching between candidates and job descriptions, and entity-based interview questions. Section V addresses the experimental results, evaluating the performance of the framework in relation to current models and so analyzing its possible influence and performance. Section VI ends the work by aggregating important contributions and suggests future avenues of research to improve recruiting automation.

II. Related Work

In the field of CV parsing, many companies process large volumes of resumes to identify suitable candidates for employment, making manual analysis increasingly impractical. As a result, significant progress has been made in Named Entity Recognition for extracting structured information from resumes [23], [24], as well as in developing algorithms that efficiently match candidates with job requirements. Several approaches have been proposed to tackle these problems. For instance, Pham et al. [25] proposed a deep learning-based NER model for resume parsing in their paper "Study of Information Extraction in Resume". Their method involves four main steps: text normalization, rule-based NER, which based on deep neural networks, and text segmentation. Using a 1,000 manually labeled Vietnamese resume medium-sized dataset, they extracted entities such as names, addresses, talents, degrees, experience, and universities. Zhu et al. [26] proposed a user behavior-based preference alignment framework for fine-tuning LLMs to improve job recommendations through resume completion. To address noise in behavioral data (i.e., bias and variance), they introduced a noise-robust LLM alignment method named Denoised Direct Preference Optimization (Denoised DPO), which disentangles genuine user preferences from noisy data. Specifically, they designed a novel reward function for preference estimation by combining an LLM-based component for real user preference with a regression model for bias disentanglement. In addition, they developed a Thurstonian-style model for job-seekers' preference modeling to stabilize data reliability amidst behavior variances. Extensive offline and online experiments demonstrated the effectiveness of this approach in enhancing recommendation quality.

Vanetik and Kogan [27] improved resume-job matching using semantic similarity by taking the assistance of BERT-based sentence embeddings. They extracted entities like job titles, credentials, and skills using SpaCy's NER component, and employed keyword extraction using TF-IDF. The integration of keyword-based methods, BERT embeddings, and NER formed a solid base for automatic candidate ranking. Bakliwal et al.[28] addressed the problem of orphan entity resolution using a knowledge graph-based approach and models such as BERT and RoBERTa. Their model, via concept mining, association mining, and NER, detected and contextualized doubtful resume entries. The inferred knowledge graphs linked these entities to external knowledge bases, improving contextual comprehension and candidate-job matching. Wang et al. [29] examined the impact of pretrained language models, including BERT, ERNIE, ERNIE2.0-tiny, and RoBERTa, on NER performance. By fine-tuning all the models, they evaluated the effect of different pretraining strategies on extraction of entities from unstructured text and offered valuable information on model selection for NER applications. Tran et al. [30] proposed a practical solution to occupational skill identification in Vietnamese job advertisements in a bid to address the skill mismatch most prevalent in the domestic labor market. Rather than approach skill detection as a standard NER task, they approached it as ranking. Identified phrases were ranked by semantic similarity with context neighbors without involving extensive annotated datasets or supervised NER models. Rosenberger et al. [31] introduced CareerBERT, a deep learning-based model for resume-to-job matching enhancement. The model acquires the ability to update and adapt to dynamic labor market shifts using unstructured resume and job posting data. CareerBERT integrates ESCO taxonomy and EURES job posting data into an active and structured job corpus. The accuracy and validity of recommended jobs are improved as a consequence. Tyagi et al. [32] countered gendered bias in resume matching systems using word embedding refinement and improving classification algorithms. Their system demonstrates how gendered words, descriptions, and skill mentions can produce biased representations in resumes that result in unequal job classification. Using real-world datasets, they demonstrated high correlation between embedding bias and occupational gender skewing and proposed debiasing techniques to decrease the bias. Lastly, Barducci et al. [33] addressed the problem of resume information extraction in the Italian labor market by proposing an effective end-to-end framework. Their system provides a complete candidate overview, including personal information, skills, and work experiences. The framework extracts raw data from resumes and segments them into semantically consistent parts using linguistic patterns. Each segment is then processed with a NER algorithm, based on pre-trained language models, to extract the most relevant information.

Previous studies have demonstrated a wide range of approaches aimed at addressing entity extraction challenges in resume parsing and job matching. While substantial progress has been made such as generating evaluation questions from resumes, identifying resumes that closely match specific job descriptions, and aligning job postings with suitable candidates significant gaps remain. These include the underutilization of advanced deep learning models, limited integration of semantic embeddings, and insufficient application of knowledge graphs for contextual understanding. To address these limitations, this study proposes a more comprehensive approach to entity extraction from resumes using a NER-based framework. The goal is to enable more accurate and context-aware parsing of

candidate profiles, facilitate scalable and effective matching between resumes and job descriptions, and automatically generate relevant interview questions based on extracted entities.

III. Preliminaries

This section provides the necessary background to support the rest of the study, including named entity recognition, text embeddings, pre-trained transformer-based models from the BERT family, and large language models.

A. Named Entity Recognition

Named Entity Recognition [1] is a core task in natural language processing that involves identifying and classifying entities in text into predefined categories such as persons, organizations, locations, dates, and others. NER systems typically rely on sequence labeling techniques, where each token is assigned a tag indicating whether it belongs to an entity and what type it represents. NER is widely applied in various real-world scenarios, including information extraction from unstructured text, question answering, content classification, knowledge graph construction, and automated resume analysis. In the recruitment domain, for example, NER is essential for extracting structured information from resumes and job descriptions, such as candidate names, educational qualifications, professional experience, and specific skills. Modern NER approaches leverage contextual embeddings and transformer-based architectures to achieve high accuracy and robustness, particularly in domain-specific or noisy text environments.

B. Embeddings

Embeddings are numerical models of unprocessed data text or category values, for example into continuous vector spaces. Basic to deep learning models, reflecting semantic linkages and similarities between data points unlike traditional discrete or one-hot representations is not a secret. Mostly for the preservation of pertinent information, embeddings convert high-dimensional data into dense, lower-dimensional representations. This ensures more successful and efficient application for jobs involving classification, grouping, and similarity analysis. By grouping semantically or structurally similar objects closer together in the embedding space, embeddings let machine learning algorithms find underlying patterns in the data and overcome expressly specified constraints.

C. BERT Family

Processing text bidirectionally, the deep learning model BERT (Bidirectional Encoder Representations from Transformers) [34] considers both left and right contexts concurrently. It discovers contextual links between words inside a sentence by means of Transformer architecture and more importantly, self-attention methods. For many NLP uses, large corpus pre-training helps BERT provide highly contextualized embeddings. In fields including Named Entity Recognition, it has greatly increased performance, sometimes exceeding historical benchmarks. By means of fine-tuning, BERT can be customized to domain-specific tasks even with limited labeled data.

Under the Masked Language Modeling aim, Bert is trained whereby the model is taught to forecast random words in a phrase by masking them. Moreover, next sentence prediction (NSP) improves sentence-level comprehension. Though more contemporary models like RoBERTa eliminate the NSP aim, BERT's multi-layer Transformer encoders capture deep language patterns, making it quite well-suited for NER, information extraction, and automated text processing applications. Dynamic masking eliminates the NSP aim and produces a superior variant of BERT, RoBERTa, thereby, enhancing the pretraining process. Unlike BERT's fixed masking, RoBERTa exposes the model to a wider diversity of linguistic settings, as masking patterns vary on the same input across training epochs. From this, in NER, resulting more solid representations and better task performance. RoBERTa has shown more accuracy and efficiency in named entity extraction, however its architecture is essentially similar BERT.

By means of disentangled attention via DeBERTa (Decoding-enhanced BERT with disentangled attention), one obtains important benefits by separating content and spatial embeddings. While traditional models mix lexical meaning and spatial information, DeBERTa especially separates these elements thereby improving the model's grasp of word order and sentence structure. This method shows especially good performance in entity recognition tasks, where exact capture of subtle dependencies is essential. DeBERTa also features a new decoding technique designed to raise token prediction accuracy.

More recently, CamemBERT a multilingual BERT-based model tailored for the labor market domain, has shown strong performance in skill and occupation extraction tasks. It is trained using job-related taxonomies and multilingual job corpora to enhance cross-lingual generalization and semantic understanding in employment-related text. By specializing in the semantics of job postings and CVs, CamemBERT proves particularly effective for both skill detection and entity recognition in multilingual or non-standard CV formats.

D. Large Language Models

LLMs are advanced neural network architectures trained on massive text corpora to understand and generate human-like language. Built primarily on transformer architectures, LLMs utilize self-attention mechanisms to model complex linguistic patterns, enabling them to perform a wide range of natural language processing tasks such as summarization, translation, question answering, and dialogue generation. Their ability to generate contextually relevant and coherent responses makes them suitable for integration into applications requiring intelligent language understanding and generation. Notable examples of LLMs include Google Gemini developed by Google DeepMind for advanced language understanding and generation, and Meta's LLaMA (Large Language Model Meta AI) designed as an efficient, open-weight model for research and practical applications. These models represent key milestones in the evolution of generative AI and have significantly contributed to progress across a variety of domains.

IV. Proposed Approach

This section describes the method adopted to enhance and automate the recruitment process. The approach leverages NER for entity extraction, candidate–job matching, and entity-based question generation.

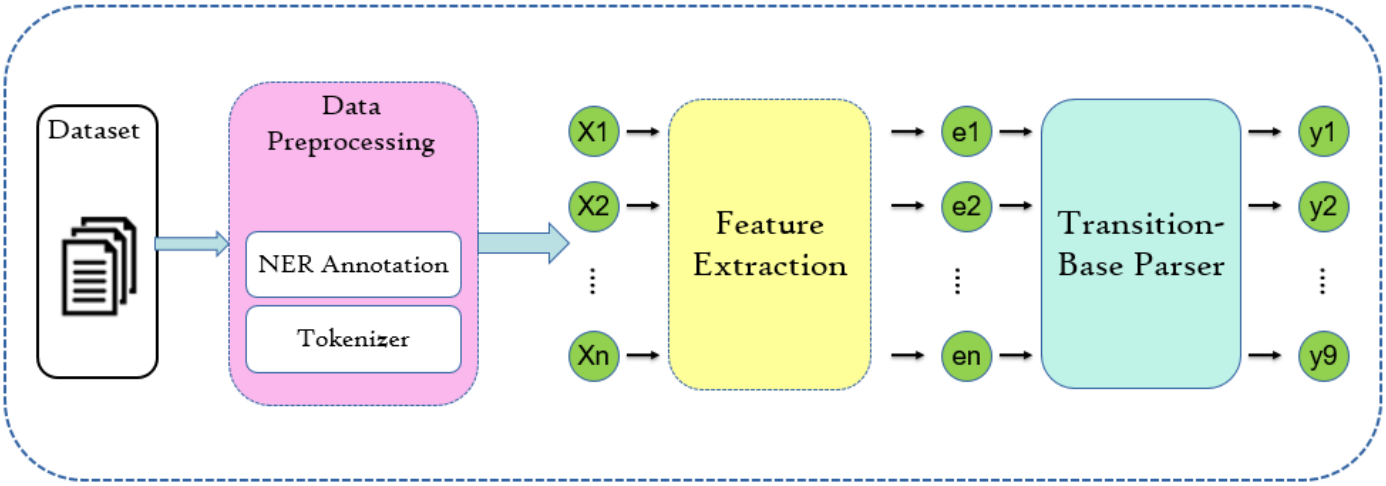

Fig. 1. Overview of the proposed NER pipeline architecture.

A. NER-Based Entity Extraction

The structure of the NER entity extraction model is illustrated in Fig. 1. This framework is composed of five key modules: data collection, preprocessing, feature extraction, and the transition-based parser. To effectively leverage these components for feature learning and entity recognition, the process begins with model representation. This involves collecting a dataset of resumes in various formats and converting them into machine-readable text. The preprocessing stage consists of two essential tasks: Named Entity Recognition annotation and tokenization. Following that, a pre-trained transformer model processes the tokens to generate contextual embeddings that capture semantic relationships between words. Finally, the transition-based parser applies a sequence of learned transitions to progressively predict entity boundaries and assign labels, enabling the extraction of structured entities from unstructured resume text.

1) Data preprocessing: From multiple sources including a broad spectrum of companies, job vacancies, and skill levels we assembled a diversified collection of resumes in PDF and Word formats. These resumes are written in English and follow a consistent structure, enabling uniform data representation. We denote the dataset as $D = \{d_1, d_2, \ldots, d_n\}$, where D represents the collection of n resumes, and each d_i is a raw document. For more details about the dataset, refer to Section V.

Each document d_i in the dataset is first manually or semi-automatically annotated with named entities directly on the raw text. These annotations are created as labeled character spans and stored as triplets: $A_i = \{(s_k, e_k, l_k)\}$. Here, s_k and e_k denote the character-level start and end offsets of an entity, and l_k is the corresponding entity label (e.g., `AGE`, `SKILLS`).

After annotation, the raw text is passed through spaCy's rule-based tokenizer, which segments it into a sequence of tokens: $T_i = \{t_{i1}, t_{i2}, \ldots, t_{im}\}$. During training, the character-based entity spans A_i are automatically aligned with the token boundaries defined in T_i, producing token-level supervision for the NER model.

2) Contextual embedding: Once tokenized, the sequence T_i is passed into a pre-trained transformer model such as RoBERTa, via the spaCy-transformers integration. This model generates a contextual embedding for each token:

$$E_i = \text{Em}(T_i) = \{\mathbf{e}_{i1}, \mathbf{e}_{i2}, \ldots, \mathbf{e}_{im}\}, \quad \mathbf{e}_{ij} \in \mathbb{R}^d \tag{1}$$

These contextual embeddings in Eq. (1) encode each token with rich semantic and syntactic information by leveraging sentence-level dependencies and multi-head attention mechanisms.

3) Transition-based parser: The final step is handled by the Transition-Based Parser module, which consumes the token vectors and predicts entity boundaries and labels through a sequence of learned transitions. At each state s, the model scores and selects the most probable action a_s, as shown in Eq. (2):

$$a_s = \arg\max_{a \in A} f_{\text{score}}(\sigma_s, a) \tag{2}$$

where, σ_s is the parser state, A is the set of possible transition actions (e.g., BEGIN, CONTINUE, OUT), and f_{score} is the internal scoring function (a feed-forward network with maxout layers). The final labeled spans are stored in `doc.ents` for downstream use.

B. Matching

Fig. 2 illustrates the overall architecture of the matching process between candidates and job descriptions. It consists of four main components: Input Data, Entity Extraction, Feature Extraction, and Similarity Matching. The process begins with unstructured input data, namely job descriptions and candidate resumes written in French.

In the first step, entities are extracted using a custom NER model, as detailed in Fig. 1. This model identifies key elements such as skills, technologies, and job-specific attributes

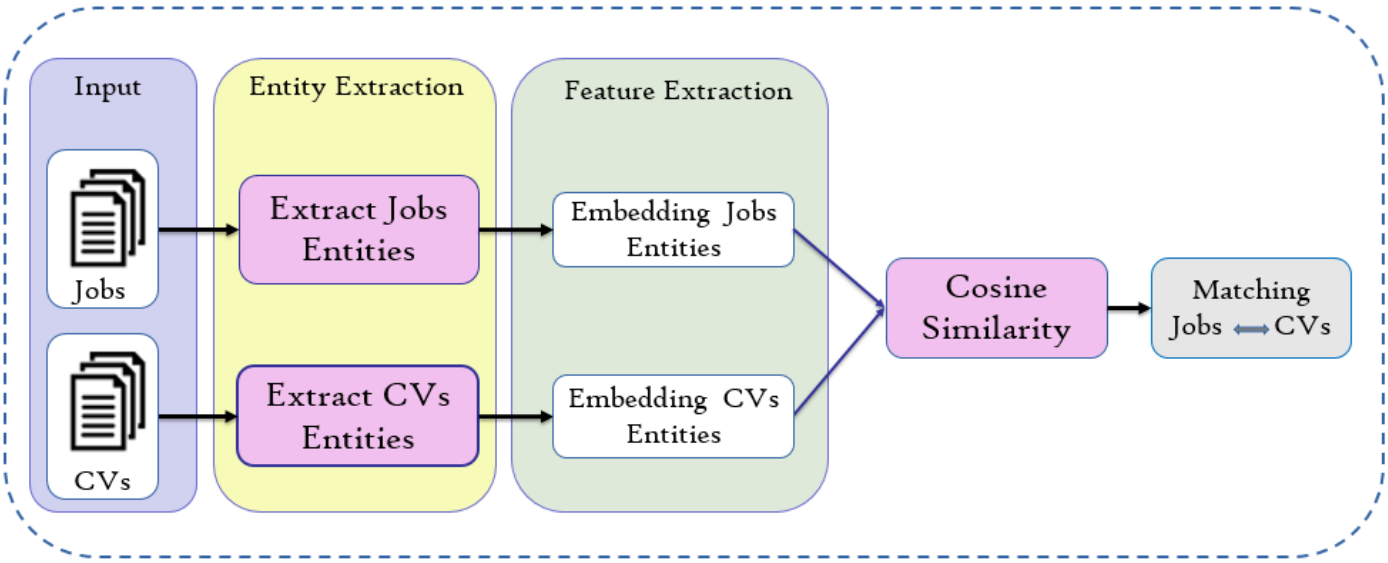

Fig. 2. Overview of the matching framework.

from both the job descriptions and the CVs. These extracted entities are then passed to a feature extraction module, which employs a pre-trained transformer model to produce contextual embeddings. Finally, cosine similarity is computed to assess the semantic alignment between each job description and the resumes. If the similarity score exceeds a given threshold, the corresponding CV is considered a potential match.

1) Input: The system takes as input a job description $J = \{J_1, J_2, \ldots, J_n\}$ and a set of resumes $R = \{R_1, R_2, \ldots, R_n\}$, where each J_i and R_i consists of unstructured text written in French. The input for each comparison is formally defined as Input $= (J_i, R_i)$, representing the pairing between a job description and a candidate resume.

2) Entity extraction: Entities such as skills, technologies, and job-related information are extracted from both the job description and the resumes using a Named Entity Recognition (NER) model F. For each pair, the model is applied as $S_{J_i} = F(J_i)$ and $S_{R_i} = F(R_i)$, where S_{J_i} denotes the set of entities extracted from the job description J_i, and S_{R_i} corresponds to the entities extracted from the i-th resume R_i, for all $i \in \{1, \ldots, n\}$.

3) Feature extraction: The extracted entities are then passed through a CamemBERT-based transformer model which serves as the embedding function Em to generate dense vector representations [see Eq. (3)]:

$$U = Em(S_{J_i}), \quad V_i = Em(S_{R_i}) \quad \forall i \tag{3}$$

where, $U \in \mathbb{R}^d$ is the embedding vector for the job description, and $V_i \in \mathbb{R}^d$ represents the embedding vector for the i-th resume.

4) Similarity: To measure the alignment between a job description and a resume, cosine similarity is computed between their corresponding embeddings, as defined in Eq. (4):

$$\text{sim}(U, V_i) = \frac{U \cdot V_i}{\|U\| \cdot \|V_i\|}, \quad \forall i \tag{4}$$

A resume is considered a match if the similarity in Eq. (5) exceeds a predefined threshold:

$$\text{sim}(U, V_i) \geq \tau \tag{5}$$

where, $\tau = 0.5$ denotes the similarity threshold.

This similarity-based matching approach between candidates and job descriptions, as formulated in Eq. (5), enables a more accurate and efficient recruitment process.

C. Entity-Based Question Generation

After a match is confirmed between candidates and job descriptions, the process triggers a Large Language Model to generate relevant interview questions. For this task, we evaluated two LLMs: Google Gemini and Meta's LLaMA. While both models are capable of producing grammatically correct and contextually appropriate questions, Google Gemini demonstrated superior performance in terms of relevance and alignment with the extracted entities.

Gemini's advantages lie in its advanced instruction tuning, stronger contextual reasoning, and ability to generate coherent and targeted questions without the need for additional fine-tuning. On the other hand, LLaMA-based models often require instruction-tuned variants to achieve comparable results.

Therefore, Google Gemini is preferred in our pipeline due to its robustness, high-quality output, and ease of integration.

V. Experimental Results and Evaluation

We assessed in this work several approaches and models for entity extraction and matching between candidates and job descriptions.

A. Extract Entities

In this subsection, we first introduce the dataset used in the experiments. We then describe the experimental setup for both NER-based entity extraction model and the baseline models. Finally, we present a series of experimental results to validate the effectiveness of the proposed model.

1) Data description: We performed entity extraction to improve hiring efficiency in recruitment systems by applying Named Entity Recognition to the task of parsing and analyzing resumes. To support this, we compiled a dataset comprising both structured and semi-structured resume documents. The dataset, stored in .json format, included a total of 1,000 resumes. Of these, 800 were used for training and 200 for testing. This 80/20 split was adopted to ensure a reliable assessment of the model's ability to generalize to unseen data.

Each resume was annotated with key entities relevant to recruitment and candidate evaluation. These included: Name, LinkedIn Link, Location, Degree, College Name, Email Address, University Name, Skills and Certifications. These entities were carefully chosen to reflect the most critical information recruiters seek during the hiring process. The dataset covered a broad range of resume formats and writing styles, thereby improving the robustness and generalization capabilities of the NER models.

2) Implementation setup: We evaluate the proposed entity extraction method to improve hiring efficiency in recruitment systems by applying Named Entity Recognition to the dataset described earlier. This dataset provides a solid foundation for assessing the performance of various text-based models under different hyperparameter configurations.

Our model was trained using the hyperparameters in Table I. Specifically, we used RoBERTa as our underlying transformer for feature extraction due to its superior performance on language understanding tasks. 0.1 was the dropout rate that we utilized in order to reduce the probability of overfitting by randomly eliminating neurons when training. We employed the Adam optimizer, where learning rates are adapted dynamically for all parameters, and set the initial learning rate to 5×10^{-5} in order to achieve steady and smooth convergence.

TABLE I. SUMMARY OF MODEL HYPERPARAMETERS AND DETAILS

Category	Value
Evaluation Metrics	F1-Score, Precision, Recall
Feature Extraction	RoBERTa
Dropout Rate	0.1
Optimizer	Adam
Learning Rate	5×10^{-5}
Early Stopping	1600 steps
GPU Allocator	PyTorch
Max Steps	20

For monitoring training and preventing overfitting, we employed early stopping with patience 1600 steps, i.e., training would be halted if improvement in validation loss was not observed within that time. Training was conducted for a maximum of 20 steps (or epochs), with adequate iterations for the model to learn without incurring high computational expenses. Training was conducted in PyTorch with GPU acceleration, providing efficient use of resources through dynamic memory allocation and fast batch processing.

For evaluating the performance of the model, we employed typical NER evaluation metrics: Precision, which provides an estimate of the accuracy of the entity predictions; Recall, which provides an estimate of the capability of the model to capture all entities of interest; and F1-score, the harmonic mean of recall and precision. These estimates provide an overall estimate of the capability of the model to correctly and comprehensively extract entity information from resumes.

3) Model variations: To assess the performance of various transformer-based architectures for Named Entity Recognition (NER) in the context of resume entity extraction, experiments were conducted using three widely adopted pre-trained models: BERT, DeBERTa, and RoBERTa, each employed as a feature extractor. All models were fine-tuned under identical training conditions to ensure a fair comparison. Their performance was evaluated across multiple entity types using standard evaluation metrics, including Precision, Recall, and F1-score.

Table II presents the relative performance of the three models across ten target entity types. All results are listed in percentages (%) for each measurement. RoBERTa generally outperformed both BERT and DeBERTa for nearly all categories, achieving the highest F1-scores in major domains such as Name, LinkedIn Link, Location, Degree, College Name, Email Address, University Name, Skills and Certifications, and also in the overall score for all entities

RoBERTa achieved a combined F1-score of 85.11%, outperforming DeBERTa (82.94%) and BERT (80.14%). This improvement is a witness to the enhanced contextual depth understanding capacity of RoBERTa for resume content. The model performed strongly in proper categories like Email Address and Skills, which are central to hiring decision-making.

While BERT was a decent baseline, it lagged behind in recall for many entity types, indicating a bias towards missing relevant entities. DeBERTa had better recall than BERT, especially in categories such as Email Address and Location, but was less dependable overall than RoBERTa.

These findings confirm that choice of transformer architecture exerts a significant impact on the effectiveness of NER-based resume parsing. Of the models tested, RoBERTa emerged as the most powerful and most reliable and therefore an infinitely feasible option to use in automated hiring processes.

B. Matching Evaluation

In this part of our analysis, we evaluate the performance of the candidates–jobs matching component. We begin by introducing the similarity-based scoring framework used to quantify the relevance between candidates and recruiters. We then present a summary of the matching performance, including evaluation metrics and comparative analysis.

1) Similarity-based scoring framework: To assess the effectiveness of our matching system, we use a similarity-based scoring approach. When a CV or a job description is entered,

TABLE II. COMPARISON OF OUR NER RESULTS ON RESUMES (%)

Entities	Feature Extraction								
	BERT			DeBERTa			RoBERTa		
	F1-Score	Precision	Recall	F1-Score	Precision	Recall	F1-Score	Precision	Recall
All Entities	80.14	80.43	81.91	82.94	83.61	83.37	**85.11**	**85.24**	**86.47**
Name	79.09	79.34	80.57	81.65	83.86	79.66	**85.20**	**85.06**	**87.56**
LinkedIn Link	78.95	79.31	79.33	77.52	83.95	71.73	**84.75**	**84.71**	**87.79**
Location	79.24	78.17	80.34	81.91	83.14	82.28	**84.69**	**84.86**	**86.47**
Degree	78.49	77.67	79.46	81.44	83.26	80.52	**85.28**	**84.47**	**87.02**
College Name	78.81	78.14	79.50	78.09	83.12	74.83	**84.82**	**84.36**	**85.88**
Email Address	80.37	79.10	81.70	84.85	84.11	85.59	**85.54**	**85.63**	**87.33**
University Name	78.92	77.43	80.46	81.52	83.10	80.00	**84.90**	**85.19**	**85.78**
Skills	80.01	79.89	80.57	84.22	84.94	84.65	**85.03**	**84.94**	**86.83**
Certifications	78.04	76.57	79.58	78.90	83.52	75.60	**85.20**	**84.82**	**87.08**

the system calculates a semantic similarity score between them using embeddings generated by the CamemBERT model. The evaluation pipeline is detailed below:

a) Entity embedding for job description and CVs: Let T denote the job description text and C_i represent the entities (e.g., skills) extracted from the i-th CV. The embeddings for both are obtained via the CamemBERT model, as defined in Eq. (6):

$$E_T = \mathrm{E}_m(T), \quad E_{C_i} = \mathrm{E}_m(\text{Entities}_i) \tag{6}$$

where, T denotes the job description text, Entities_i represents the set of extracted skills from the i-th candidate's CV, E_T is the embedding vector corresponding to the job description, and E_{C_i} refers to the embedding of the entities extracted from the i-th CV.

b) Similarity computation using cosine metric: The similarity score KM_i between the job description and each CV is calculated using cosine similarity [Eq. (7)]:

$$\text{KM}_i = \frac{E_T \cdot E_{C_i}}{\|E_T\| \|E_{C_i}\|} \tag{7}$$

where, $E_T \cdot E_{C_i}$ denotes the dot product between the job description and the candidate CV embeddings, and $\|E_T\|$ and $\|E_{C_i}\|$ are the Euclidean norms of the respective embedding vectors.

c) Score normalization: To ensure consistent scoring across different inputs, the similarity scores are normalized using their mean μ and standard deviation σ, as given in Eq. (8):

$$\mu = \frac{1}{n}\sum_{i=1}^{n} \text{KM}_i, \quad \sigma = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(\text{KM}_i - \mu)^2} \tag{8}$$

If $\sigma = 0$, it is replaced with $\sigma = 1$ to avoid division by zero. The normalized difference is then computed [Eq. (9)]:

$$\text{Diff}_i = \frac{\text{KM}_i - \mu}{\sigma} \tag{9}$$

d) Rating conversion: The normalized score is mapped on a 0 to 10 rating scale using the transformation in Eq. (10):

$$\text{Rating}_i = \min\left(10, \max\left(0, 5 + \text{Diff}_i\right)\right) \tag{10}$$

This ensures that:

- Ratings remain within the range [0, 10].
- Ratings are centered around a neutral baseline of 5.

e) Matching accuracy metric: Finally, the matching accuracy is computed as the average rating of the top k most similar CVs, as shown in Eq. (11):

$$\text{Accuracy} = \frac{1}{k}\sum_{i=1}^{k} \text{Rating}_i \tag{11}$$

In our evaluation, $k = 5$ was used.

2) Summary of matching results: The matching accuracy was evaluated using the method described in the previous section (Accuracy Computation Method). The result reflects the average performance of the top five matched CVs, based on cosine similarity between job descriptions and resume embeddings.

The evaluation shows that the CamemBERT-based model achieves strong performance, with an accuracy of 92%. This highlights the effectiveness of the proposed semantic matching pipeline in retrieving relevant candidate profiles from unstructured textual data.

These findings suggest that the proposed AI-based job matching system offers accurate candidate recommendations, efficient processing, and strong potential for deployment in real-world recruitment workflows.

VI. Conclusion and Future Work

In this work, we propose an approach that automates and optimizes the recruitment process. By combining entity extraction, candidates–jobs matching, and entity-based question generation, the approach offers a complete solution for streamlining the recruitment process. Leveraging natural language processing techniques and semantic similarity models, the process reduces manual effort, enhances candidate evaluation, and increases objectivity in decision making. One major challenge encountered is the handling of resumes that contain text embedded in images, often the case with visually designed resumes. This can lead to data loss and the unintended exclusion of qualified candidates. Addressing this limitation is crucial to ensure data integrity and maintain the system's effectiveness across varied recruitment contexts.

Future work could focus on incorporating OCR (Optical Character Recognition) technologies or image-to-text conversion models to enable the processing of a broader range of resume formats. Enhancing the system with real-time feedback mechanisms, improving its scalability for large-scale hiring scenarios, and expanding its adaptability across different industries would further increase its utility. Moreover, integrating context-aware decision-making and optimizing computational performance could elevate the overall intelligence and responsiveness of the system. These developments would contribute to building a more resilient and inclusive recruitment solution, delivering tangible benefits for both organizations and job seekers.

Towards a Robust DNA Storage System with a Multilayer Approach

Ayoub Sghir, Manar Sais, Douha Bourached, Jaafar Abouchabaka, Najat Rafalia
Department of Computer Science, Faculty of Sciences, Ibn Tofail University, Kenitra, Morocco

***Abstract*—The growing demand for data storage requires innovative, resilient solutions to the challenges of cost, space, and energy consumption posed by current methods. DNA stands out as a promising next-generation data storage medium, offering a remarkable storage density of 1019 bits per cubic centimeter, some eight orders of magnitude denser than conventional media. This study explores the potential of DNA storage by proposing an intelligent multi-layer solution to overcome current technological challenges. The system combines the storage capabilities of DNA with sophisticated solutions such as data compression, error correction, and cryptography, transforming the concept of DNA storage into a tangible reality. This study also focused on the first layer dedicated to data compression. The results obtained represent a significant advance in the evaluation of the potential of different compression algorithms, through a comparative study of techniques such as Huffman coding, run-length coding, LZW and LZ77. This analysis enabled us to define the essential components of the first layer of the proposed approach. Finally, the interface in the digital domain to visually present the overall results of the project was introduced, while providing insight into the system's efficiency, data integrity and ease of use.**

***Keywords*—DNA storage; data compression; error correction; huffman encoding; run-length encoding; LZW; LZ77**

I. Introduction

The massive growth in data over the last few decades, particularly with the development of Internet and mobile technologies, has led to an unprecedented data storage crisis for mankind. In social and scientific research, as well as in other fields such as traffic monitoring and high-definition scientific images, massive data, particularly in the form of images and videos, is generated. According to international data [1], the total amount of human-generated data reached 33 ZB (zettabytes) in 2018, with a forecast of 175 ZB by 2025, a 65-fold increase in just thirteen years [2], [3], [4]. Traditional data storage methods such as magnetic, optical and solid-state disks have major shortcomings in terms of cost, space, energy consumption and durability, not exceeding 50 years under optimal conditions.

In the age of Big Data, the need for innovative, sustainable storage solutions is becoming ever more pressing. DNA [5] is emerging as a promising candidate for long-term storage, thanks to its exceptional durability and extraordinary information density, offering a future where vast data sets can be encoded in the very fabric of life. However, to fully exploit the potential of DNA storage [6], technological challenges such as security, reliability and turnaround time must be carefully overcome. The ability to safeguard data, guarantee its integrity and speed up recovery is crucial to the success and widespread adoption of DNA storage.

DNA storage has a rich history dating back to 1959, when Richard Feynman first proposed the concept of storing information on DNA. Since then, interest in this technology has grown considerably due to the many potential advantages it offers over traditional storage methods such as magnetic and optical storage. DNA stands out for its exceptional stability, high storage density and long-term durability, making it a promising solution to the data storage challenges faced by traditional media [7-9]. Recent advances have demonstrated that DNA can efficiently store vast quantities of data, including historical audio and video files, with remarkable density and durability, positioning it as a suitable medium for digital archives [10]. Furthermore, according to research proposals, it could transform the landscape of data storage for network automation and prediction. This integration would offer an efficient and reliable way of storing large amounts of data generated in network operations, paving the way for new possibilities in large-scale data optimization and management.DNA storage has attracted considerable interest due to its high information density and longevity. Various approaches have been proposed to optimize DNA storage methods.

In this paper [11], the authors suggest using DNA as a storage approach, demonstrating that DNA has both extremely high theoretical data density and unrivalled stability compared with more traditional data storage media. In another work [12] A new random sampling channel model, built around the three essential dimensions of DNA storage systems: 1- information is stored on several DNA molecules; 2- these molecules undergo noise perturbations during synthesis and sequencing; and 3- data is extracted by random sampling from the DNA reservoir.[13] suggested a powerful, feasible and particularly robust coding algorithm called MOPE, which was used to develop the no-cost coding system. Payload encoding was also carried out using the Payload Encoding algorithm [14]. In another study [15], the authors analyze the impact of batch optimization on reducing the cost of large-scale DNA synthesis. This optimization consists of the following algorithmic task: from a large set of random quaternary chains of specified length, divide S into groups in order to minimize the sum of the lengths of the shortest common super sequences in these groups.

Despite significant progress in the field of DNA data storage, no truly efficient system is yet available to manage the entire storage process in an optimal way. Numerous challenges remain with regard to the reliability, efficiency and safety of this storage method. Indeed, the biological aspect of DNA gives rise to specific difficulties, such as faults occurring during the synthesis, amplification and sequencing processes, which can impact on the quality of recorded data. What's more, the absence of a unified system for compression, error

correction and encryption significantly reduces the potential of this promising technology. This problem highlights the need to design an innovative and efficient system capable of overcoming these challenges and offering an integral solution for managing the DNA data storage process.

This study aims to embark on a journey to meet the challenges head-on. By introducing a revolutionary multi-layer approach to DNA storage management, the study aims not only to unleash its full potential but also to usher in a new era of secure, reliable, and efficient data storage. In the following pages, we'll look at the intricacies of this approach, which combines data compression, error correction, and encryption, each playing a key role in reshaping the DNA storage landscape. The careful selection of data compression algorithms is revealed [16]. The introduction of polar codes as an error correction mechanism will provide the basis for data reliability, considering the defects inherent in DNA synthesis, amplification and sequencing. To improve the security of DNA storage, we are introducing PGP encryption, a widely recognized encryption standard, by adapting it to the unique properties of DNA. In doing so, we bring to DNA storage the same level of data security found in the world of encrypted hard disks, opening up a new era of trust in data storage solutions.

The implementation of these layers demonstrates a commitment to advancing DNA storage technology. By converting binary data into ACTG sequences and vice versa, the study ensures seamless integration of this multi-layer approach into the DNA storage ecosystem. By exploring the intricacies of this study, the aim is to highlight the remarkable synergy between biology and information technology, illustrating how DNA's exchange capabilities can transcend the limits of traditional data storage methods.

Through this holistic approach, the work aims to reduce turnaround times, improve data reliability and enhance the security of DNA storage, by presenting it as a secure, high-performance option for the long-term maintenance of large volumes of data. This multi-layer approach aims to guarantee a reliable data storage process in DNA, focusing on the first and essential layer: data compression. This experimental section focuses on this compression layer, examining and comparing different compression techniques such as Huffman coding [17], run-length coding (RLE) [18], LZW [19] and LZ77 [20]. This analysis enabled us to identify the most effective algorithm for the developed approach. The results show that, although some of these algorithms can be adapted to other types of data, the Huffman algorithm proves to be the most reliable for this approach and also for this type of data, Thanks to its ability to efficiently manage the frequency of symbols, it also provides a user interface (UI) in the digital domain, enabling visualization of global results related to the compression layer. This interface provides insight into the system's efficiency, data integrity and ease of use, contributing to a better understanding and exploitation of the performance of this approach.

The structure of the following study is as follows: Section II explores the framework of DNA storage processes, Section III details the presented method and system phases, Section IV discusses testing and algorithm evaluation, while Section V presents the conclusions.

II. Background

Not too long ago, the terms 'Big' and 'Data' were rarely associated. Today, they have become a highly fashionable expression and rank among the most popular concepts in the business domain. Numerous authors and organizations have made attempts to define the term Big Data. Hemn Barzan Abdalla wrote: "Big Data is described as a high-throughput data resource that requires new processing measures to achieve better knowledge dynamics and disclosure" [21]. He further elucidated "too voluminous" about the massive volume of data that can reach the scale of petabytes and originates from diverse sources, "too rapid" concerning the rapid growth of data that must be processed swiftly, and "too complex" to denote the challenges of Big Data that do not readily integrate with existing processing tools. Similarly, in PCMag, one of the most popular publications on technology trends, Big Data is defined as 'enormous quantities of data accumulated over time, which are challenging to analyze and manage using conventional database management tools' [22].

Currently, the existing data volume is measured in petabytes and is projected to increase to the order of zettabytes shortly. Even today, established social media platforms generate terabytes of data daily, a quantity that undoubtedly poses challenges for traditional systems [23]. According to statistics, the daily data generation amounts to approximately 44 zettabytes. Each second, an individual generates 1.7 megabytes of data [24]. According to forecasts from the International Data Group, global data quantities are set to experience exponential growth from 2020 to 2025, with an expected increase from 44 to 163 zettabytes [25]. Consequently, the significance of storage has never been greater when it comes to managing the ever-expanding data volumes.

The primary obstacle posed by the realm of big data revolves around identifying a technology capable of efficiently handling substantial data quantities for subsequent analysis and data extraction. Numerous solution providers offer ready-made answers to confront the challenges of big data, including Cloudera [26], Horton Works[27], MapR [28], and more. However, the question of real-time management in terms of temporality and storage space remains one of the major challenges of contemporary technologies. However, the explosive growth in data volumes challenges these existing data storage and processing capabilities, driving the need for innovative and unconventional solutions.

The concept of DNA storage, which represents a significant breakthrough in the data storage sector, came about thanks to the introduction of a unified system combining compression, error correction, and encryption. This multi-level method facilitates the management of the DNA data storage process, while ensuring both reliability and compression.

A. Leveraging the Data Storage Capacity of DNA

As our world generates massive amounts of data, conventional storage methods, such as hard disks and magnetic tapes, are now reaching their limits in terms of density and longevity. However, new molecular media, such as small organic molecules [31], [32], polymers[33] and especially DNA, are attracting growing interest for their intrinsic storage capacity, High-density data. DNA could be a perfect option

for archiving digital data, with notable advances in coding schemes enabling a revolutionary density of 17 exabytes per gram, far surpassing magnetic and optical media [34].

Since the beginning of existence, the planet's nature has created its own data storage mechanism by incorporating the genetic information of living organisms into DNA, a molecule containing four different bases: adenine (A), thymine (T), cytosine (C) and guanine (G). This method of preserving information has stood the test of time for three billion years. In the context of massive data flow production, digital storage systems present themselves as a crucial and effective option, especially in terms of cost-effectiveness. What's more, DNA offers considerable advantages such as high data density, durability and long-term stability. It represents a promising response to the challenges posed by the continuing rise of massive data.

DNA has become an attractive choice in response to the growing demand for data storage, offering astonishing storage capacity [35]. Virtually all data on the Internet can be encapsulated, and in particular, it has an extraordinarily High storage capacity, indicating that a small fragment of DNA can contain a vast amount of information [36]. DNA can theoretically achieve an impressive storage density of 455 exabytes per gram. with the exceptional feature of longevity capable of preserving data for several centuries [37]. In ecological terms, DNA synthesis can be carried out in an environmentally friendly way, avoiding and minimizing the use of harmful chemicals while adopting sustainable practices. By developing environmentally responsible techniques for DNA production, storing information in synthetic DNA could promote more sustainable and responsible management of this limited available resources.

B. DNA Storage Process

DNA storage is a revolutionary advancement that has garnered significant attention in recent years. By harnessing the unique properties of DNA, including its high storage capacity and exceptional durability, researchers have developed innovative techniques for encoding and storing large amounts of digital information. This process involves converting digital data into sequences of DNA molecules, which are then synthesized and compactly stored. This approach holds the promise of revolutionizing data storage by enabling the preservation of vast amounts of information in a minuscule space.

DNA-based information processing represents an emerging field that leverages the power of DNA molecules to perform various computational tasks. These tasks include storage, addressing, transportation, and error correction of information [38]. This burgeoning field offers considerable potential to transform current computing capabilities. The structure of DNA itself is crucial for understanding various biological processes [39]. It provides a mechanism of heredity, where genes carry biological information that must be accurately copied and passed on to the next generation. Furthermore, the structure of DNA has enabled answers to fundamental questions in biology about the storage and transmission of genetic information. This in-depth understanding of DNA structure opens up new avenues for scientific research and technological advancements.

The entire DNA storage process involves six key steps: encoding, synthesis, storage, retrieval, sequencing, and decoding. Encoding translates binary data into A, C, G, T sequences, with specific encoding and error correction required. Synthesis transforms these sequences into real DNA molecules, typically generating a pool of identical molecules. The DNA molecules are then stored in small containers suitable for long-term preservation. Retrieval involves selecting desired DNA molecules from a container, often using PCR based on sequence indexing. Sequencing translates DNA molecules back into sequences of A, C, G, T using DNA sequencers. Finally, decoding corrects and reorganizes the sequences to reconstruct the original document. The synthesis stage is a critical bottleneck due to its slow speed and high cost, making DNA storage less economically viable. In contrast, sequencing is not a bottleneck, benefiting from significant advancements in speed and efficiency driven by genomic needs [40].

C. Potential and Advantages of DNA Storage

As previously mentioned, the exponential growth of global data presents significant storage challenges. DNA emerges as a promising solution due to its advantages, including remarkable information density, durability, and long-term stability [41].

1) Density: DNA's information density surpasses traditional systems by approximately ten million times. A single gram of DNA is estimated to store up to 215 petabytes of data, although ongoing research may refine this estimate. However, DNA storage doesn't involve a single molecule encoding a file; it requires numerous identical copies. Additionally, DNA segments must accommodate quality control and indexing signals alongside the data, necessitating macroscopic containers.

2) Longevity: DNA's lifespan exceeds that of conventional media by roughly ten thousand times. Even DNA molecules over 560,000 years old from historical samples can be analyzed. Laboratory experiments have demonstrated a half-life of 52,000 years for artificially aged DNA, and its stability at room temperature makes it an energy-efficient preservation method. Reduced Carbon Footprint: Synthetic DNA cleverly stores large quantities of information in small spaces, enabling optimal use and management of the storage structure, thus reducing the need for conventional infrastructure. This reduces the energy consumption required to operate and cool these facilities, leading to lower greenhouse gas emissions and a reduced overall carbon footprint.

III. Methods and Implementation

In this section, an outline of the main components and layers of the proposed multi-layer system for DNA storage management. The methodology encompasses the key components of this approach, including data compression, error correction, and encryption, as well as the conversion between binary data and ACTG sequences. The proposed multi-layer system integrates data compression and error correction, and encryption techniques to enhance the efficiency, reliability, and security of DNA storage. The process can be visualized as a well-orchestrated sequence of steps, with each contributing to the successful encoding and preservation of data in DNA form. Fig. 1 outlines the sequential steps involved in implementing this approach, beginning with data compression

and proceeding through error correction, encryption, and data format conversion. The following subsections will detail each step of the implementation process, providing a comprehensive understanding of the challenges of DNA storage.

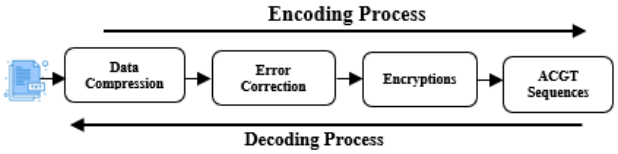

Fig. 1. Optimization storage techniques.

A. Data Compression

Data compression is the first layer of this approach, aimed at minimizing the size of textual data, thereby reducing the time required for storage and retrieval. Initially, the study considered three compression algorithms, Huffman, RLE, and LZW, to assess their suitability for this system. The primary objective of this layer is to make the data more compact and storage-friendly, setting the stage for efficient DNA-based storage. In the testing phase, the focus will be specifically on this layer, identifying the most efficient and suitable algorithm for our use case by comparing four algorithms. This step is critical to ensure that the chosen compression method aligns with the requirements of DNA storage, balancing compression efficiency, computational complexity, and compatibility with downstream processes.

1) Huffman encoding: Huffman encoding is a variable-length coding technique that efficiently represents characters by developing more concise codes for commonly used characters, and more extensive codes for less common characters. This method, effective for compressing textual data, involves creating a Huffman tree, where characters are encoded as binary codes. Implemented as part of a data compression layer, it optimizes character representation to minimize the amount of DNA required for storage before encoding data into DNA [42].

2) RLE encoding: Run-Length Encoding (RLE) is a data compression technique that simplifies textual data by representing consecutive repeated characters with a count of how many times a character is repeated, followed by the character itself. RLE proves particularly effective for highly repetitive data, efficiently reducing data size by encoding repeating sequences with concise representations, such as encoding "AAAAABBBCCDAA" as "5A3B2C1D2A". Initially considered for this multi-layer system for DNA storage management, RLE was surpassed by Huffman encoding due to its superior performance in reducing data size while maintaining integrity. While RLE offers simplicity and ease of implementation, the decision to prioritize Huffman encoding was based on its overall effectiveness, with comparative results between the two to be presented in the results chapter for comprehensive assessment within the context of DNA storage [18].

3) LZW encoding: LZW encoding, also known as Lempel-Ziv-Welch encoding, stands as a prominent data compression technique with broad applications spanning bioinformatics and communication systems. At its core, the LZW algorithm employs a dictionary-based approach, systematically replacing patterns within the data with codes to optimize both storage and transmission efficiency. Over time, various iterations and enhancements of LZW have emerged, aimed at refining compression ratios and expediting encoding processes to meet evolving demands across diverse domains [29], which optimizes storage space and the bandwidth required for transmission [8].

4) LZ77 encoding: LZ77 encoding, a widely adopted lossless data compression algorithm, operates by segmenting input strings into phrases through the analysis of previous occurrences. This method leverages a hashing table to efficiently pinpoint recurring sequences by cross-referencing data within the stream, facilitating effective compression. The algorithm analyzes the input data stream by searching for repeating sequences and breaks it into phrases consisting of both literals (individual characters) and pointers to previous occurrences of substrings within the stream. These pointers typically consist of two parts: a distance and a length, indicating how far back in the stream the substring occurs and how long it is, respectively [20].

B. Error Correction

In the second layer of this approach, attention is given to the crucial aspect of error correction in DNA storage, recognizing the potential for errors during synthesis, amplification, and sequencing processes. To ensure data integrity, this study implements Polar codes, renowned for their robust error correction capabilities. Polar codes, a class of error-correcting codes, achieve effectiveness by polarizing bits in a data stream through a mathematical transformation. This polarization distinguishes some bits as highly reliable and others as less reliable, introducing redundancy to facilitate reliable transmission. The encoding process selectively polarizes specific bits, creating encoded data for more robust transmission or storage. Upon reception, the inverse transformation is applied to decode the data and rectify errors. In the presented multi-layer system, Polar codes play a pivotal role in addressing errors inherent in DNA storage processes, significantly enhancing data reliability and reinforcing DNA's potential as a long-term storage medium [30].

C. Data Encryption

The security of data stored in DNA is of paramount importance, especially for sensitive information. To ensure confidentiality and integrity, the presented multi-layer system employs encryption techniques, specifically Pretty Good Privacy (PGP) encryption. PGP, a widely used method, combines symmetric and asymmetric key algorithms to safeguard digital data. It involves key generation, where a public key encrypts the data and a private key decrypts it. This process secures the data during storage and retrieval. PGP encryption provides robust security for DNA-stored data, ensuring protection against unauthorized access even if the DNA is compromised. By integrating PGP encryption into the developed system, an approach addressing the critical concern of data security is presented, guaranteeing confidentiality and complementing the data compression and error correction layers for a comprehensive DNA storage solution.

D. Data Format Conversion ACGT Sequence

The final layer in the multi-layer system presented in this study, the DNA storage system focuses on converting binary data into sequences of Adenine (A), Thymine (T), Cytosine (C), and Guanine (G), collectively known as ACTG sequences, which are essential for efficient encoding and retrieval of data in DNA molecules. This conversion process maps each binary digit (0 or 1) to its corresponding nucleotide base in DNA, bridging the digital and biological realms. During encoding, binary data is systematically translated into ACTG sequences to ensure accurate representation of each digit. When retrieving data, the stored ACTG sequences are decoded back into binary data, preserving the original digital information. This encoding and decoding mechanism facilitates seamless storage and retrieval of data in DNA form. Last layer of the multi-layer DNA storage system focuses on converting binary data into sequences of Adenine (A), Thymine (T), Cytosine (C), and Guanine (G), collectively known as ACTG sequences, which are essential for efficient encoding and retrieval of data in DNA molecules. This conversion process maps each binary digit (0 or 1) to its corresponding nucleotide base in DNA, bridging the digital and biological realms. During encoding, binary data is systematically translated into ACTG sequences to ensure accurate representation of each digit. When retrieving data, the stored ACTG sequences are decoded back into binary data, preserving the original digital information. This encoding and decoding mechanism facilitates seamless storage and retrieval of data in DNA form.

IV. Results and Discussion

This section aims to present the results of this research and implementation efforts, providing an overview of the significant outcomes of the approach presented in this study. This methodological journey has culminated in a pivotal moment, where the presentation of the results of the comparative study between four data compression techniques: Huffman Encoding, Run-Length Encoding (RLE), LZW (Lempel-Ziv-Welch), and LZ77 (Lempel-Ziv 1977), which form the foundation of the first layer of the proposed system. This critical comparison has shaped the core components of this approach. Additionally, a transition is made into the digital realm by introducing a user interface (UI), as shown in Fig. 2, which visually presents the holistic results of the study, providing a comprehensive view of the system's efficiency, data integrity, and ease of use.

The test aims to identify the most suitable compression technique for the first layer of this intelligent multi-layered solution. The proposed system also incorporates error correction and encryption, while considering the data's specifics and subsequent phases' requirements. Twitter data of various sizes was used, ranging from 1 MB to 50 MB, including positive and negative terms. About the amount of data, emphasis is placed on the need for small sizes for efficient storage and retrieval in DNA storage. Before the compression stage, this research compares various compression techniques to identify the one with the most optimal performance for this system. Thus, the same corpus of data was used with different algorithms. Fig. 3 shows an example of the files produced during compression and decompression by Huffman's algorithms, based on different file sizes. Other compression:

1) DNA Storage Process: .

Algorithms were also subjected to the same process. The following section presents an analysis and comparison of the results obtained. Examination of the results highlights the strengths and weaknesses of each compression technique while considering the particular needs of the developed multi-layer system. The performance and execution time associated with compression and decompression have been plotted below for each of the four compression algorithms (Huffman, RLE, LZW, LZ77), compiling and analyzing the results obtained.

Fig. 3. Files generated by compression and decompression using the Huffman compression algorithm.

The results obtained when evaluating the four compression methods show that, in the context of DNA storage, the Huffman compression method produced the greatest size reduction for the different data sizes (1MB, 5MB, 10MB, 50MB), with a compression ratio varying between 40% and 50% (as shown in the Fig. 4). This result is particularly significant. This size gain is essential for DNA storage efficiency, where data size reduction is crucial before mapping onto ACGT sequences. Compared with other methods such as RLE and LZW, although RLE showed good results for highly redundant data, where compression and decompression time performance did not exceed 100 seconds, its performance declined with less regular data, such as that generated by tweets (Fig. 5). In Fig. 6, Fig. 7, LZW and LZ77, although less efficient than Huffman in terms of size reduction rates, stand out for their speed during

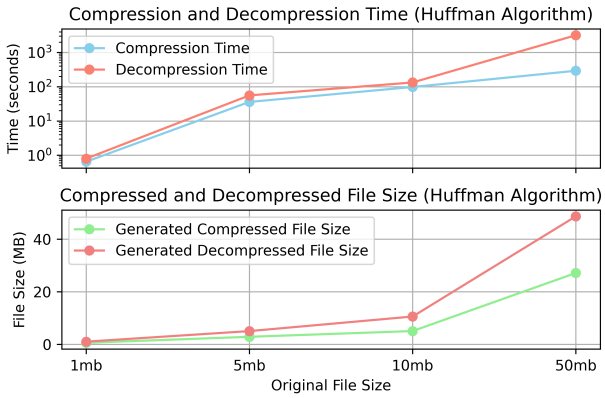

Fig. 4. Performance comparison of compression and decompression (Huffman algorithm).

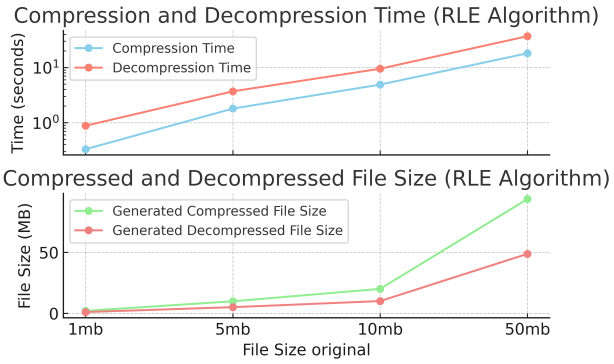

Fig. 5. Performance comparison of compression and decompression (RLE algorithm).

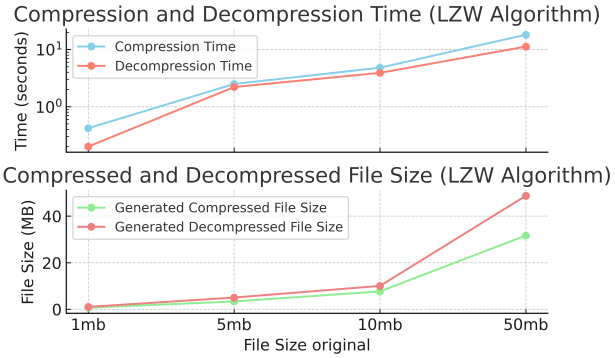

Fig. 6. Performance comparison of compression and decompression (LZW algorithm).

the compression and decompression processes. This makes them advantageous choices for contexts where processing time is a priority. This suggests that, although these methods are potentially suitable for other types of data, Huffman remains the most robust algorithm for this type of data, not least because of its ability to manage symbol frequency efficiently.

A comparative evaluation of the four compression techniques reveals significant disparities in terms of execution time and compression ratio. Although Huffman and LZW show

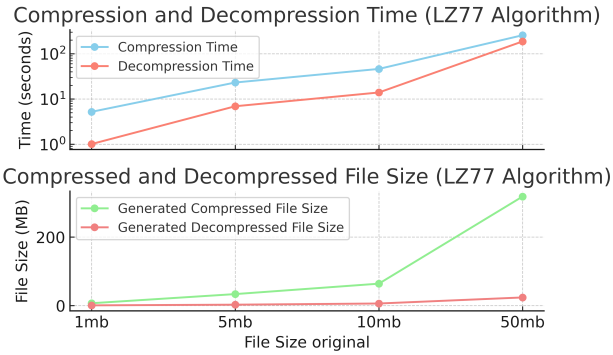

Fig. 7. Performance comparison of compression and decompression (LZ77 algorithm).

good compression ratios, their times differ, while LZ77 is less sophisticated in compression but stands out for its good performance during decompression. However, RLE is very fast and only adapts to data that is repeated. Thus, the choice of algorithm depends on the context: storage optimization (Huffman, LZW), fast transmission (LZ77), or management of repeated data (RLE).

One of the limitations of this study is that the performance of the compression methods was only evaluated on small to medium-sized data (up to 50MB). It would be relevant to conduct further tests on even larger datasets to verify whether Huffman's performance holds up with larger volumes. Furthermore, although the application of PGP encryption and polar coding in the pipeline ensured adequate security and data preparation for DNA synthesis, improvements in coding speed and error handling could be explored to further enhance the system's efficiency.

This research aims to overcome these obstacles by proposing a multi-level approach, focusing primarily on compression, a key factor in reducing costs and improving the efficiency of DNA storage. According to the results obtained, Huffman's algorithm offers a perfect balance between compression ratio, encoding and decoding speed, and preservation of data integrity. This implication helps to increase storage capacity and perfect the use of DNA storage resources. In summary, this study shows that the choice of compression algorithm is crucial for DNA storage, and this results underline the importance of an approach well adapted to the specific characteristics of the data. Future research should focus on optimizing the entire pipeline, integrating more advanced compression algorithms and testing their effectiveness on larger-scale datasets. This approach could open new avenues for faster, more reliable DNA storage.

V. Conclusion

In conclusion, this study explores the promising field of DNA storage and proposes a multi-layered approach to the challenges posed by conventional data storage methods. With data production reaching unprecedented levels, the demand for innovative and sustainable solutions is greater than ever. DNA storage is emerging as a compelling solution, offering remarkable density and durability. this system meets the need for a multi-layer solution combining DNA's unique storage

capabilities with advanced techniques such as data compression, error correction, and encryption. This work focuses on the first layer of this method, the compression layer, and through a comparative study of compression techniques, the effectiveness of Huffman coding for data compression is demonstrated. In addition, this study introduces a user interface for visualizing the results of our project, focusing on system efficiency, data integrity and user-friendliness. By combining biology and information technology, this approach paves the way for DNA storage to become a secure, reliable and efficient long-term solution for the preservation of large datasets. Optimization of compression algorithms and encryption methods could improve the efficiency of DNA storage. An advanced compression algorithm is used to minimize data size and optimize storage space. The aim is to create a robust and secure system for storing large quantities of data by developing a complete pipeline that combines compression, error correction and encryption. This method can also be applied to the storage of critical and sensitive data, particularly about biology, cybersecurity and the preservation of digital archives. Consequently, this research lays the foundation for a new intelligent DNA storage structure, capable of increasing storage efficiency and durability over the long term. In future studies, other layers will be analyzed to determine optimization methods and strategies for each component of the system.

Hybrid Recommender System for Precision Chemical Application in Banana Cultivation Using Matrix Factorization and Content-Based Filtering

Ravi Kumar Tirandasu, Prasanth Yalla, Pachipala Yellamma
Department of CSE, KoneruLakshmaiah Education Foundation, Vaddeswaram, AP, India

***Abstract*—Proper management of pesticides and fertilizers is critical towards effective control of the banana diseases, but integration of various agricultural data has been a problem. The novelty of this study is the hybrid recommendation system which encompasses Content-Based Filtering (CBF) with Matrix Factorization (MF) to be used when recommending chemical treatment of bananas during cultivation. The system exploits the use of heterogenous data- such as soil nutrient profiles (NPK, pH), climatic variables, and disease signatures to create customized chemical recommendation to manage the disease. A real-world agricultural dataset was used in the evaluation of the hybrid approach and the improvement, precision, recall, F1-score, and the accuracy of the system were measured. The findings indicate that the suggested model performed better than the traditional models of single-method or user-based recommendation systems and predicted the disease outbreak with high accuracy (F1-score) up to 98 percent in Black Sigatoka; these results were highly consistent across other disease classes and different chemical interventions. Notably, the hybrid system helps not only to optimize the costs of chemical use and crop yields, but also to create the environmental sustainability by reducing the number of the superfluous chemical use. Methodology, the characteristics of the dataset and the measures that have been employed are described, which explains how CBF and MF integration solve the complexity and variability in agricultural data. The solution provided in this work is a high-performance scalable tool in precision agriculture, which assists further in the informed decision-making of the farmer and agricultural planners.**

***Keywords*—Hybrid recommendation system; content-based filtering; matrix factorization; banana disease management; agricultural data heterogeneity; precision agriculture; chemical application optimization; black sigatoka**

I. Introduction

Farmers in tropical and subtropical areas depend greatly on raising bananas. It helps the country keep its economy in balance and provide enough food. Still, crops and the industry are at risk from diseases that reduce both their number and their quality. Banana plants are harmed and made less healthy by diseases such as Fusarium wilt (Panama disease), Black Sigatoka and the Banana Bunchy Top Virus (BBTV), according to [1]. As a result, we should immediately act to prevent crop damage.

There is a strong and diverse relationship between how soil is managed and the spread of banana illnesses [2]. A healthy and strong plant requires nitrogen, phosphorus and potassium. If banana plants miss crucial nutrients, they often weaken and develop more illnesses. Plants often show a stunted growth and smaller leaves if nitrogen gets missing. When potassium is missing, diseases have an easier job of attacking the plant. Moreover, extra nutrients in streams may help microorganisms that make humans sick. Therefore, methods that conserve the correct equilibrium are required in soil management [3] . Various problems in precision agriculture can be solved well using recommendation systems, making them very important [4]. They process a large range of data that includes information on soil, the weather and signs of crop health by using modern machine learning [5]. With the method, choosing the right fertilizers and pesticides is easier for different crops. As a result, plants can fight diseases and their output is boosted [6], [7]. In recommendation systems, content-based filtering reviews the details of crops and the conditions they need in order to identify the best treatments. As a result, the fertilizers are selected based on the characteristics of each farm, including the minerals found in its soil, the amount of dampness in the air and the outside temperature. Content-Based Filtering helps you find ways to deal with common diseases such as Panama's Disease in Bananas [8].

By analyzing old user feedback, Matrix Factorization methods find patterns and connections that Content-Based Filtering usually misses. With this method, engineers can access information about effective chemicals and their results in similar cases, helping them decide how the present process may turn out [9]. Recommendation systems provide solutions for current agronomy issues and help predict future needs together. Therefore, traditional banana farming techniques become more sustainable [10]. Yet, it is still very hard to use machine learning for banana farming recommendations. Because agricultural data is available in many kinds and formats, it is difficult to integrate and assess. Also, these systems should be flexible and respond swiftly to new information since farming conditions are always influenced by sudden changes in weather and appearances of new diseases [11].

Even so, using machine learning can improve banana farming by reducing diseases, improving the quality of soil and increasing what is harvested [12]. It's also important to use chemistry correctly because it helps reduce fertilizers and pesticides, so the soil stays intact and the water remains clean [13]. If we want banana disease management systems to improve, agronomists, data scientists and farmers in different fields have to team up. By working together, they ensure the agricultural proposals are built on true information and experienced farming which gives the farming a better and more lasting effect. Every improvement in machine learning and precision agriculture encourages new methods for handling banana diseases and sustainable farming in the future [14].

In tropical regions, bananas are essential to food security and the economic stability of people there, but they are also subject to diseases such as Fusarium wilt, Black Sigatoka disease, and Banana Bunchy Top virus. Land management activities influence the development of disease as nutrient imbalances of factors such as nitrogen, phosphorus, and potassium make plants susceptible. Digital precision agriculture and machine learning techniques, specifically recommendation systems, can be applied to incorporate agricultural data to fine-tune the application of fertilizers and pesticides. The Content-Based Filtering recommends crops according to the environmental characteristics, whereas the Matrix Factorization is used to find secrets of the past. The strategies are meant to improve disease resistance, boost yields, and be environmentally sustainable. Data heterogeneity and climatic variability pose a challenge. The collaboration should be among agronomists, data scientists, and farmers to deliver successful recommendations. This paper investigates the possibility of a combined approach to recommendation systems that integrates the two to improve banana disease detection and fertilizer prescriptions to promote sustainable agriculture.

II. Related Work

During the past seven years, we have managed to use recommendation system algorithms to solve banana problems and supply drug-based solutions. Thanks to these new concepts, farming is improved and has new uses. Scientists in precision agriculture pay special attention to using computer systems to deal with banana diseases [15]. Experts examined whether using simple machine learning models, like decision trees and linear regression, could identify diseases like Black Sigatoka and Fusarium wilt. The predictions made used environmental and soil facts. Further development of these models highlights that using data-based approaches can make it easier to manage disease outbreaks. Because their data was stable and limited, these classifiers could not always understand the detailed relationships affecting a disease's progress. Since 2016, scientists have relied on complicated models like Random Forest and SVM to help them predict banana diseases better. Researchers decided to begin using remote sensing data at this time. Researchers used both satellite information and ground observations to gain knowledge about disease outbreaks. At that time, people recognized that managing agricultural data can be challenging and that using models becomes crucial [16] . From then on, algorithms known as CNNs and RNNs were used more frequently in deep learning. Having these strategies, scientists could locate diseases and find reasons to believe certain treatments would be effective. The algorithms examined images of banana plants to spot diseases and data that changed regularly to track the environment. Deep learning methods help people discover patterns and relationships within agricultural data [14].

Better machine learning led to greater benefits from the agricultural recommendation systems. Soil and plant specific information was used to improve the chemical recommendation process of content-based filtering. New methods were applied to standardize agricultural data, all while maintaining what makes the data special [17]. In 2018, matrix factorization was used with agricultural data more often. This method allows researchers to find out which factors increase a person's risk of getting sick and which ones help therapy succeed. When you put together Content-Based Filtering and Matrix Factorization, your suggestions will become more precise [18]. Because studies have proven that hybrid recommendation systems do the job better, they are very popular today. Adding genomic data, soil chemistry and weather variables to hybrid systems helped recommend the right products for each user.

The 2019–2021 period saw changes to these systems to ensure farmers got information that was correct, easy to grasp and actually useful [19]. These days, many support recommendation systems for being able to handle huge data volumes and supplying helpful output. Its aim was to collect information, develop models and design new user systems that would boost the use of these technologies by farmers. You can quickly exchange data analysis and recommendations with others when using cloud computing and IoT devices. As a result, the discipline can respond better to new forms of threats. It is clear from research that combining expertise from different sectors is necessary for creating and operating banana disease control systems. Merging agronomy, computer science and data analysis has led to solutions for difficulties with banana cultivation. This collaboration has advanced technology and made certain that all ideas are grounded in farming knowledge. Research conducted by [9] For seven years, scientists have found more advice on treating banana sickness and better ways to use chemicals. It is now much easier and more accurate to find and treat different diseases. They passed on helpful hints for farmers. In recent years, we have succeeded in using recommendation system algorithms to help solve banana problems and create drug remedies [20]. Thanks to these new concepts, current farming methods are better and they allow for more uses. The authors of this study argue that machine learning and analysis of data are used in precision agriculture research to address banana diseases.

The researchers studied ways to use basic machine learning models such as decision trees and linear regression, to spot diseases such as Black Sigatoka and Fusarium wilt. Estimates were made using data on the environment and the soil. Further models showing how strategies guided by data can improve the prediction and control of diseases [21]. Even so, they didn't always catch the complicated connections between factors that influence how a disease moves through the body[16]. To enhance their predictions of banana diseases, researchers in 2016 turned to algorithms such as Random Forest and Support Vector Machines (SVM). It was then that researchers began focusing on how to take advantage of remote sensing data. They were more able to explain the spread of diseases because of what they learned from earth observation and satellite data. At this point, people realized how complex agricultural data can be and how vital models are for handing it [22], [3]. CNNs and RNNs then became the main focus, since they are powerful deep learning algorithms. The approaches helped scientists identify illnesses and judge how effective different treatments could be. These algorithms examined many images of banana plants as well as data that changed regularly to keep trace of the environment. Using deep learning, understanding the connections in agricultural data has become much easier [23].

When machine learning improved, recommendation systems for agriculture became more helpful. We upgraded content-based filtering so it would guide users to suitable

chemical treatments, based on their plants and soil types. New ideas were applied to handle and uniform agricultural data, aware of its outstanding characteristics [17]. In 2018, more people began using matrix factorization when working with agricultural data. With this approach, researchers find out which factors play a role in making people sick and how efficient therapy treatments are. When Content-Based Filtering is supported by Matrix Factorization, it makes the suggestions more accurate [9], [24].

Many researchers have shown that combining recommendations tends to work better than using one algorithm alone. Ensuring each person got the right suggestions was easy because genomic data, soil chemistry and weather data were easy to add to hybrid systems [25]. From 2019 to 2021, measures were taken to make sure the data sent to farmers was right, easy to read and worthwhile. Recently, there has been a lot of conversation about recommendation systems and how effective they are at processing lots of data and giving valuable results. The research aimed to collect data, construct models and design user interfaces to support better use of these technologies on farms. Examining data and sharing tips after IoT and cloud computing becomes easy. As a result, the field finds it simpler to manage new dangers.

A. Research Gaps

Agricultural data is rarely fully utilised despite advances in banana disease management and pesticide usage recommendation systems. Soil chemistry, microclimate conditions, plant genomes, and insect populations are heterogeneous data. Data integration, processing, and analysis are difficult, but data diversity informs decision-making. Current models cannot evaluate all data kinds, which is concerning. Many algorithms were developed and tested on homogenous datasets, rendering them unsuitable for complicated agricultural contexts. Texture, structure, and pH and NPK levels make up soil composition. Climate data includes seasonal oscillations and agricultural plot microclimates. Existing algorithms cannot handle several variables, therefore proposals may be oversimplified or wrong.

Changing weather, pests, diseases, and crop genetics make agricultural systems dynamic and innovative, needing recommendation systems that can quickly learn from new data. Systems must increase their ability to incorporate real-time data updates and derive insights without lengthy retraining. This limitation prevents these technologies from providing farmers with current and context-specific information. Specific field recommendations are difficult for these systems to grasp and implement. Machine learning can identify complex patterns and predictions from data, but converting these insights into usable recommendations for farmers is tough. Farm management methods, resource availability, and budgetary constraints prevent the scientific community from fully adopting data-driven insights.

There is also limited study on combining farmer knowledge and expertise into recommendation systems. Advice is more accurate and relevant when farmers know their crops and local conditions. Tacit knowledge and algorithmic forecasts enable comprehensive illness therapy. Although recommendation systems have shown promise in addressing banana diseases, agricultural data research is still lacking. Computers must aggregate many data sources, adapt swiftly to new knowledge, turn projections into practical recommendations, and include farmer expertise to fill these gaps. These issues must be considered while creating agricultural recommendation systems for efficiency, adaptability, and usability to boost productivity and sustainability.

III. System Architecture

A hybrid approach's content-based filtering and matrix factorization increase banana disease control using agricultural datasets. This novel multidimensional agricultural data analysis method overcomes its drawbacks. Content-based filtering recommends chemistry based on object properties. The hybrid approach's content-based filtering and matrix factorization modify banana disease control using agricultural datasets. This novel multidimensional agricultural data analysis method overcomes its drawbacks.

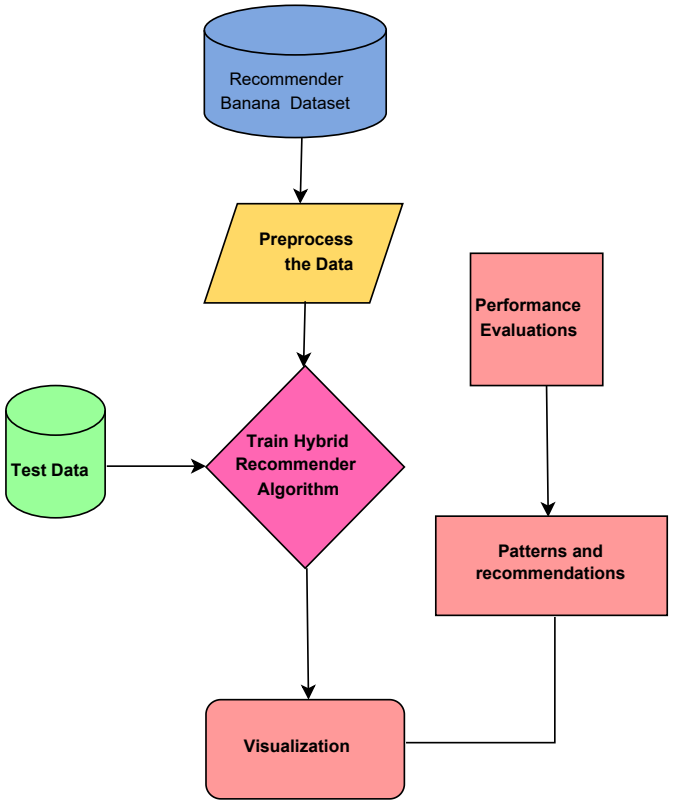

Fig. 1. A hybrid approach of content-based filtering and martix factorization.

Fig. 1 discusses the Content-based filtering, which uses chemical treatment data and environmental parameters like soil, plant health, and ambient variables to recommend quality. Because fertilisers and herbicides depend on crop and environmental needs, this technique encourages agriculture. Content-depending Filtering suggests banana plantings depending on soil NPK, moisture, temperature, and disease history.

Content-based filtering ignores data trends and user activity but finds item and context-specific qualities. Content-based techniques gain from matrix factorization. Factorization breaks the user-item interaction matrix into smaller matrices to find data links. Reducing banana illnesses requires finding

microscopic links between environmental factors, treatment techniques, and outcomes across locales and time periods. It analyses past success rates to predict novel chemical therapeutic efficacy.

Matrix Content-based recommendations and factorization can solve agricultural data diversity. This technique employs quantitative soil and climate data, qualitative evaluations, and prior treatment efficacy to adapt to changing agricultural systems. More data can improve recommendations and uncover complex links that either technique missed. Flexible, thorough, and unobtrusive, the hybrid technique outperforms banana disease control recommendations. It provides scientifically sound and practical advice by combining agricultural approaches into broader databases. Farmers use personal data to manage illnesses.

Banana agriculture's sophisticated data analysis is filtered and matrix factorised. Methodological advances could improve agricultural disease identification and treatment, boosting health, yields, and sustainability. Plant growth and development depend on genetics, irrigation, fertilisation, chemical treatments, soil, plant health, and environment. Because fertilisers and herbicides depend on crop and environmental needs, this technique encourages agriculture. Content Filtering recommends banana farms based on soil NPK, moisture, temperature, and disease history.

Content-based filtering evaluates item and context properties. Data trends and user behaviour may be missed. Content-based techniques gain from matrix factorization. Matrix factorization breaks the user-item interaction matrix into smaller matrices to find data correlations. Controlling banana illnesses requires finding microscopic links between environmental elements, treatment approaches, and results in different locations and time periods. Success rates predict chemical therapy efficacy in different situations.

Matrix Factorization and content-based proposals handle agricultural data diversity. Quantitative soil and climate data, qualitative evaluations, and historical treatment efficacy records let us adapt agricultural systems. More data may improve its recommendations and show complex linkages that either technique missed. Flexible, thorough, and unobtrusive, the hybrid technique outperforms banana disease control recommendations. It provides scientifically sound and practical advice by combining agricultural approaches into broader databases. Personalised data helps farmers control illnesses. Content filtering and Matrix Factorization analyse banana agriculture's complex data. Methodological innovation could improve agricultural disease detection and treatment, improving health, yields, and sustainability.

Hybrid Recommendation Algorithm: Mathematical Formulation

Variables and Data Representation

Let $\mathcal{U} = \{u_1, u_2, \ldots, u_{|\mathcal{U}|}\}$ be the set of users (farmers), where $u \in \mathcal{U}$.

Let $\mathcal{I} = \{i_1, i_2, \ldots, i_{|\mathcal{I}|}\}$ be the set of items (chemical treatments), where $i \in \mathcal{I}$.

Let $\mathbf{x}_i \in \mathbb{R}^d$ be the feature vector for item i (e.g., soil NPK, moisture, temperature).

Let $\mathbf{R} \in \mathbb{R}^{|\mathcal{U}|\times|\mathcal{I}|}$ be the user-item interaction matrix, where r_{ui} represents the effectiveness of item i for user u.

Let $\mathbf{P} \in \mathbb{R}^{|\mathcal{U}|\times k}$ and $\mathbf{Q} \in \mathbb{R}^{|\mathcal{I}|\times k}$ be the user and item latent factor matrices, respectively, where k is the rank or number of latent features.

Let $\mathbf{p}_u \in \mathbb{R}^k$ be the latent factor vector for user u (a row of $\mathbf{P}$).

Let $\mathbf{q}_i \in \mathbb{R}^k$ be the latent factor vector for item i (a row of $\mathbf{Q}$).

A. Content-Based Filtering

1) Feature extraction: For each item i, the feature vector is:

$$x_i \in \mathbb{R}^d \tag{1}$$

2) Normalization of features: Normalize the features per dimension:

$$\tilde{\mathbf{x}}_i = \frac{\mathbf{x}_i - \boldsymbol{\mu}}{\boldsymbol{\sigma}} \tag{2}$$

where $\boldsymbol{\mu}$ and $\boldsymbol{\sigma}$ are the mean and standard deviation vectors of the features, respectively.

B. User Profile Creation

For each user u:

$$\mathbf{p}_u = \frac{1}{|I_u|} \sum_{i \in I_u} r_{ui} \cdot \mathbf{x}_i \tag{3}$$

where $I_u = \{i \in \mathcal{I} \mid r_{ui} \text{ is known}\}$.

1) Recommendation score (cosine similarity):

$$\text{score}_{ui} = \frac{\mathbf{p}_u \cdot \mathbf{x}_i}{\|\mathbf{p}_u\| \, \|\mathbf{x}_i\|} \tag{4}$$

where $\cdot$ denotes the dot product and $\| \cdot \|$ denotes the Euclidean norm.

C. Matrix Factorization

1) Latent factor model: Approximate R by matrix factorization:

$$R \approx PQ^T \tag{5}$$

Learn P and Q by minimizing the loss:

$$\min_{P,Q} \sum_{(u,i)\in K} (r_{ui} - \mathbf{p}_u \cdot \mathbf{q}_i)^2 + \lambda(\|\mathbf{p}_u\|^2 + \|\mathbf{q}_i\|^2) \tag{6}$$

where K is the set of observed interactions and λ is the regularization parameter.

2) Prediction:

$$\hat{r}_{ui} = \mathbf{p}_u \cdot \mathbf{q}_i \tag{7}$$

D. Hybrid Combination

Combine Scores:

$$\text{final}_{ui} = \alpha \cdot \text{score}_{ui} + \beta \cdot \hat{r}_{ui}$$

where $\alpha, \beta \geq 0$ are weights, often $\alpha + \beta = 1$.

E. Recommendation

For each user u, recommend items with the highest final_{ui} values:

$$\text{Recommend to user } u: \quad \arg\max_{i \in \mathcal{I}} \text{final}_{ui}$$

F. Summary Table of Symbols

Symbol & Description:

- $\mathcal{U}, u$ & Set of users, user index
- $\mathcal{I}, i$ & Set of items, item index
- $\mathbf{x}_i$ & Feature vector for item i
- $\mathbf{p}_u$ & Profile vector for user u (content-based)
- $\mathbf{q}_i$ & Latent factor vector for item i (matrix factorization)
- r_{ui} & Actual effectiveness of item i for user u
- $\hat{r}_{ui}$ & Predicted effectiveness (matrix factorization)
- score_{ui} & Content-based similarity score
- final_{ui} & Final combined recommendation score
- α, β & Weights for combining methods

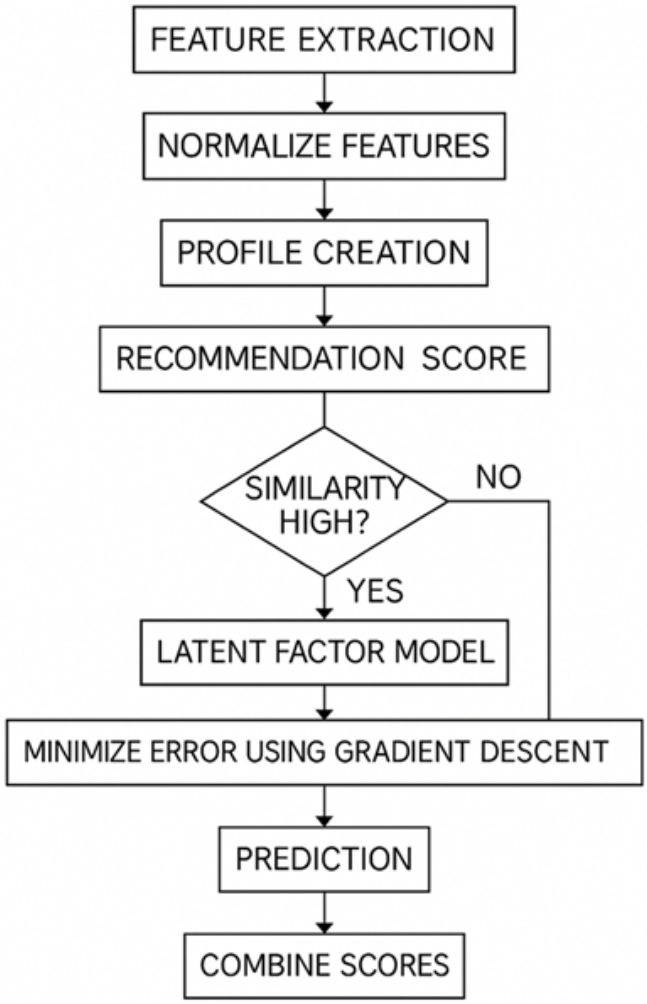

Fig. 2. Flow diagram of hybrid algorithm.

Fig. 2 shows how to use Content-Based Filtering and Matrix Factorization to construct a hybrid recommendation system. This plan incorporates a number of agricultural statistics to deal with the difficult problem of managing banana diseases. Feature extraction is the first step in the procedure. This means figuring out how chemical treatments affect the nutrients in the soil, the health of the plants, and the conditions around them. All of the following suggestions are based on this strategy. After that, each chemical treatment is carefully looked at and made the same. To eliminate bias in proposals, all features should be scaled in the same way. The approach moves on to consumers after item-centricity. Farms or pieces of land may be users in the agricultural industry. There is a profile for each individual that lists their interests and farming history. Because farming conditions can change so often, these profiles are very important for giving each plot the right advice.

Also, preference scores are figured up for each chemical treatment and for each user's individual operations. These scores change the suggestions for chemical treatments dependent on how well they work or how appropriate they are. The recommendation score shows how well the item fits with what the consumer wants. The score shows that things that fit the user's profile might be recommendations. The model employs Matrix Factorization to uncover patterns in how users and items interact that can change how well a drug works. By using gradient descent which lowers prediction error, every latent component is improved over and over. Over a few experiments, the system's ability to choose strong chemical treatments increases.

The system uses the ratings of content-based components and brings in projections from the Matrix Factorization algorithm to provide recommendations. They seek to control diseases, reduce their spread, make banana crops more resistant and lead to better and more sustainable harvests. It shows how a hybrid recommendation system operates which is a cutting-

edge way to practice precision farming. Using data analysis and machine learning, experts hope to change the way disease control is handled among bananas.

IV. Proof of Theory: Demonstration on Sample Dataset

Users: $\mathcal{U} = \{u_1, u_2\}$

Items: $\mathcal{I} = \{i_1, i_2, i_3\}$

Item Features:

$$\mathbf{x}_{i_1} = \begin{bmatrix}1\\2\end{bmatrix}, \quad \mathbf{x}_{i_2} = \begin{bmatrix}2\\1\end{bmatrix}, \quad \mathbf{x}_{i_3} = \begin{bmatrix}2\\3\end{bmatrix}$$

Ratings Matrix:

$$R = \begin{bmatrix}5 & 3 & 0\\4 & 0 & 2\end{bmatrix}$$

A. Step 1: Content-Based Filtering

1) User profile vectors: For u_1:

$$\mathrm{p}_{u_1} = \frac{1}{2}\left(5 \cdot \mathbf{x}_{i_1} + 3 \cdot \mathbf{x}_{i_2}\right) = \frac{1}{2}\left(5\begin{bmatrix}1\\2\end{bmatrix} + 3\begin{bmatrix}2\\1\end{bmatrix}\right) = \frac{1}{2}\begin{bmatrix}11\\13\end{bmatrix} = \begin{bmatrix}5.5\\6.5\end{bmatrix} \tag{8}$$

For u_2:

$$\mathrm{p}_{u_2} = \frac{1}{2}\left(4 \cdot \mathbf{x}_{i_1} + 2 \cdot \mathbf{x}_{i_3}\right) = \frac{1}{2}\left(4\begin{bmatrix}1\\2\end{bmatrix} + 2\begin{bmatrix}2\\3\end{bmatrix}\right) = \frac{1}{2}\begin{bmatrix}8\\14\end{bmatrix} = \begin{bmatrix}4\\7\end{bmatrix} \tag{9}$$

2) Recommendation scores (cosine similarity): For (u_1, i_3):

$$\begin{aligned}\text{score}_{u_1,i_3} &= \frac{\mathbf{p}_{u_1} \cdot \mathbf{x}_{i_3}}{\|\mathbf{p}_{u_1}\| \cdot \|\mathbf{x}_{i_3}\|}\\ &= \frac{5.5 \cdot 2 + 6.5 \cdot 3}{\sqrt{5.5^2 + 6.5^2} \cdot \sqrt{2^2 + 3^2}}\\ &= \frac{30.5}{\sqrt{72.5} \cdot \sqrt{13}}\\ &\approx \frac{30.5}{8.5147 \cdot 3.6056}\\ &\approx \frac{30.5}{30.73}\\ &\approx 0.993\end{aligned} \tag{10}$$

For (u_2, i_2):

$$\begin{aligned}\text{score}_{u_2,i_2} &= \frac{4 \cdot 2 + 7 \cdot 1}{\sqrt{4^2 + 7^2} \cdot \sqrt{2^2 + 1^2}}\\ &= \frac{15}{\sqrt{65} \cdot \sqrt{5}}\\ &\approx \frac{15}{8.0623 \cdot 2.2361}\\ &\approx \frac{15}{18.02}\\ &\approx 0.833\end{aligned} \tag{11}$$

B. Step 2: Matrix Factorization

1) Suppose after factorization:

$$\mathbf{p}_{u_1}^{(\mathrm{MF})} = \begin{bmatrix}2\\1\end{bmatrix}, \quad \mathbf{p}_{u_2}^{(\mathrm{MF})} = \begin{bmatrix}1\\3\end{bmatrix}$$

$$\mathbf{q}_{i_1} = \begin{bmatrix}1\\1\end{bmatrix}, \quad \mathbf{q}_{i_2} = \begin{bmatrix}2\\0\end{bmatrix}, \quad \mathbf{q}_{i_3} = \begin{bmatrix}1\\2\end{bmatrix}$$

2) Predicted scores: For (u_1, i_3):

$$\hat{r}_{u_1,i_3} = \mathbf{p}_{u_1}^{(\mathrm{MF})} \cdot \mathbf{q}_{i_3} = 2 \cdot 1 + 1 \cdot 2 = 4 \tag{12}$$

For (u_2, i_2):

$$\hat{r}_{u_2,i_2} = \mathbf{p}_{u_2}^{(\mathrm{MF})} \cdot \mathbf{q}_{i_2} = 1 \cdot 2 + 3 \cdot 0 = 2 \tag{13}$$

C. Step 3: Hybrid Combination

Let $\alpha = 0.5$, $\beta = 0.5$.

For (u_1, i_3):

$$\text{final}_{u_1,i_3} = 0.5 \cdot 0.993 + 0.5 \cdot 4 = 0.4965 + 2 = 2.4965$$

For (u_2, i_2):

$$\text{final}_{u_2,i_2} = 0.5 \cdot 0.833 + 0.5 \cdot 2 = 0.4165 + 1 = 1.4165$$

D. Recommendation Results

- For u_1, recommend i_3 with score 2.4965.
- For u_2, recommend i_2 with score 1.4165.

V. Results and Analysis

To discuss the hybrid system we created by uniting Content-Based Filtering and Matrix Factorization. We can perform this analysis by using Python, scikit-learn and matplotlib. Our approach will assess and demonstrate how the algorithm functions at different stages. Let's develop our computer model using Python because it's powerful and easy to use. Building a recommendation system will be simpler when using scikit-learn which is widely used in machine learning. We have ready algorithms available for both Content-Based and Matrix Factorization that we can modify and use together to make a hybrid system. We should do the simulation after we have developed the model. There is a significant amount of agricultural data for us to work with. During the simulation, the model will go over some of the data to learn and will be tested on what is left. As a result, we will measure the

model's performance by how well it uses its data to make guesses. Create Matplotlib visuals after both training the model and performing predictions on new data. Precision, recall and confusion matrices as well as ROC curves will show the efficacy of our hybrid approach. Click on photos or illustrations to obtain more information. Python tools and modules help us thoroughly assess the performance of the hybrid recommendation system. The system will demonstrate that it can work with and make use of many kinds of agricultural information relating to farming.

Important agronomic elements and banana crop management suggestions are in Table I. Columns list observed and prescribed events. The first column, Record_ID, identifies each data entry for straightforward analysis. N, P, and K measure soil nitrogen, phosphorus, and potassium. Nutritional balance affects banana crop health and plant growth.

The Soil_pH column is neutral, acidic below 7, alkaline above 7. Soil pH affects plant nutrition and microbes. Temperature_C displays ambient temperature in degrees Celsius, which affects plant growth and illness. Moko and Panama banana diseases reduce productivity and quality, according to Disease_Present.Based on other columns' conditions, Recommended_Chemicals suggests a chemical therapy. Entries without disease may recommend a "Balanced NPK fertilizer" to maintain nutrient levels, while those with the disease may recommend "Antibacterial, Potassium-rich fertilizer" or "Fungicide, Nitrogen-rich fertilizer" to treat health issues. This implies soil, climate, and disease-based agricultural treatment decision-making

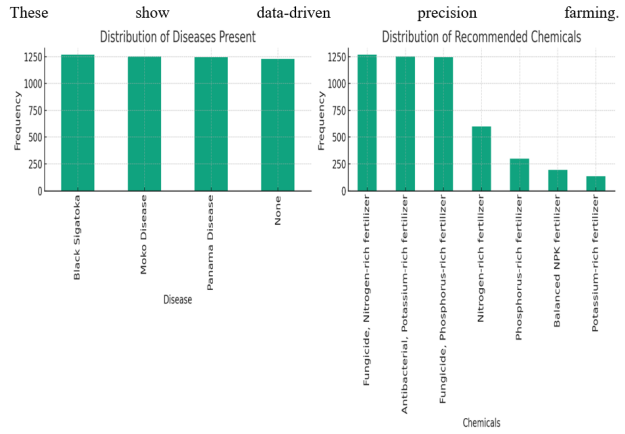

Fig. 3. Correlation distribution of disease and chemicals.

Fig. 3 shows the frequency of recommended chemical treatments for each disease found in banana crops combined. Suggesting a fair depiction of illness events across the dataset, the left bar chart shows the frequency of four primary disease categories: Black Sigatoka, Moko illness, Panama Disease, and None, each occurring almost equally.

The right bar chart shows the range of suggested chemical treatments. Especially the mix of "Fungicide, Nitrogen-rich fertilizer" seems most often; next closely is treatments combining "Antibacterial, Potassium-rich fertilizer" and "Fungicide, Phosphorus-rich fertilizer." These high frequencies point to a closer relationship between certain illness prevalence and particular chemical prescriptions. Conversely, less commonly recommended simpler treatments like "Phosphorus-rich fertilizer" or "potassium-rich fertilizer" alone indicate poor solo efficacy. This association implies that handling complicated banana illnesses prefers integrated chemical treatments, especially those using fungicides or nutrient-rich fertilizers. These realizations can direct agricultural methods toward more efficient, disease-specific therapy regimens.

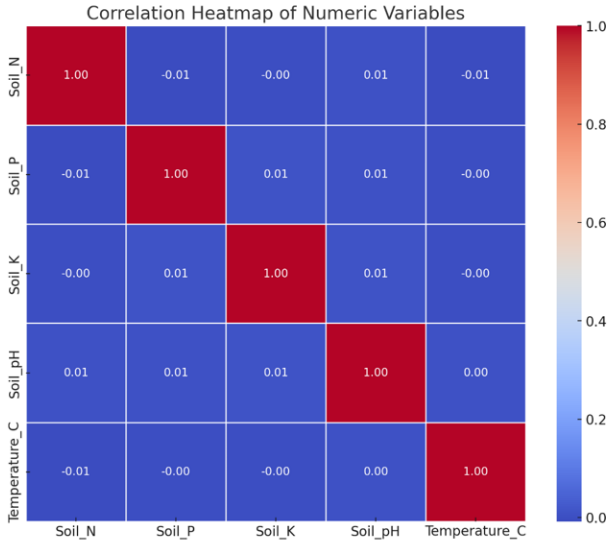

Fig. 4. Heat map corelation NPK with temperature and soil PH valuse.

Fig. 4 shows a correlation heat map of the interactions among important numerical soil and environmental variables: Soil Nitrogen (Soil_N), Phosphorus (Soil_P), Potassium (Soil_K), pH (Soil_pH), and Temperature (Temperature_C). With correlation coefficients shown in every cell, the heatmap employs a blue (weak/no correlation) color gradient from red (high correlation).

The NPK components (Soil_N, Soil_P, Soil_K) clearly show from the heatmap no appreciable linear link between them and either Soil pH or Temperature. Indicating independent fluctuation, all pairwise correlation values between NPK components and the other variables are near to zero (range roughly from -0.01 to 0.01). This realization is crucial for agricultural management as it implies that, based on the observed data range, differences in soil nutrients (NPK) do not inevitably rely on temperature or pH. Consequently, nutrient management techniques have to be handled independently from climatic or soil acidity issues, so supporting the requirement of multivariate precision farming instead of depending on interdependent environmental parameters.

VI. Hybrid Algorithm Result

Fig. 7 shows the performance of the chemical recommendation model by means of a comparison of actual chemical prescriptions vs. expected outputs over seven treatment groups. These comprise combinations and individual applications of fertilizers including Antibacterial, Potassium-rich fertilizer, Balanced NPK, Fungicide with Nitrogen-rich or Phosphorus-rich fertilizers, and standalone nutrient-based treatments in-

TABLE I. SAMPLE DATASET

Record_ID	Soil_N	Soil_P	Soil_K	Soil_pH	Temperature_C	Disease_Present	Recommended_Chemicals
1	10	30	209	6.8	26	None	Balanced NPK fertilizer
2	5	26	221	5.2	23	Moko Disease	Antibacterial, Potassium-rich fertilizer
3	8	29	209	5.4	22	Moko Disease	Antibacterial, Potassium-rich fertilizer
4	8	28	191	6.5	30	None	Nitrogen-rich fertilizer
5	12	28	205	5.6	21	Black Sigatoka	Fungicide, Nitrogen-rich fertilizer
6	14	26	195	6.3	29	None	Phosphorus-rich fertilizer

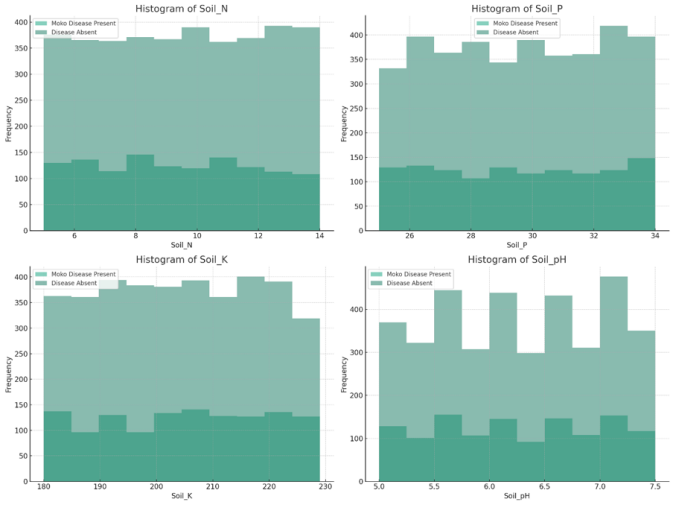

Fig. 5. Histograms compare "'MOKO disease"' soil conditions (SOIL_N, SOIL_P, SOIL_K, SOIL_PH) versus those without.

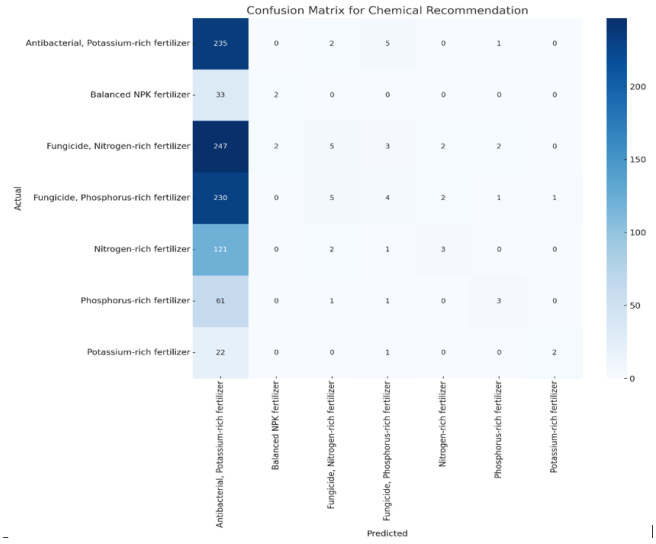

Fig. 7. Confusion matrix for chemical prediction.

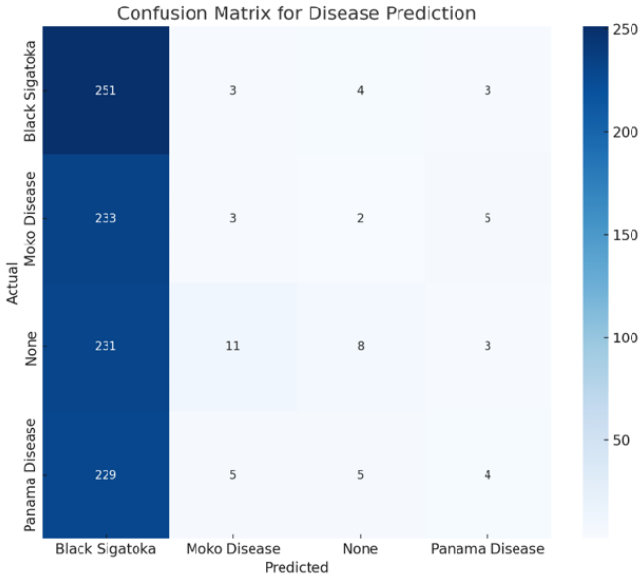

Fig. 6. Confusion matrix for disease prediction.

cluding Nitrogen-rich, Phosphorus-rich, and Potassium-rich fertilizers.

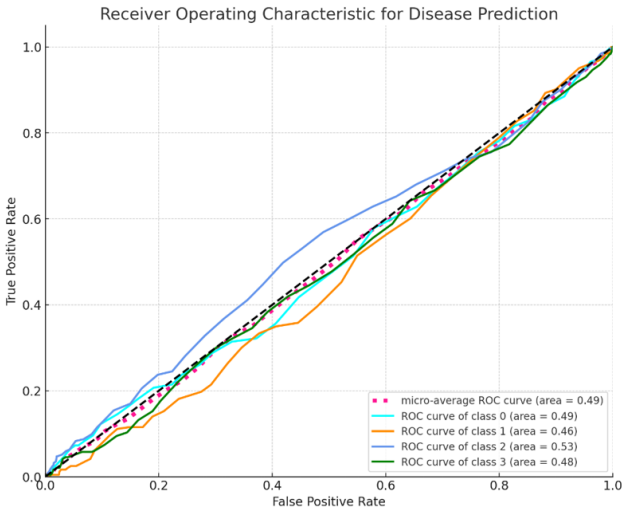

Fig. 8. ROC for disease prediction.

Evaluating its capacity to identify among four classes—Black Sigatoka (class 0), Moko illness (class 1), None (class 2), and Panama Disease (class 3), Fig. 8 shows the Receiver Operating Characteristic (ROC) curves for a multi-class illness prediction model. Included also is the micro-average ROC curve to show general performance across all classes.

TABLE II. BY DISEASE WISE ACCURACY CALCULATED COMPARISONS IN HYBRID ALGORITHM

Disease Name	Accuracy	Precision	Recall	F1-Score	Support
Black Sigatoka	0.98	0.963736	0.975862	0.969663	261
Moko Disease	0.92	0.909877	0.909877	0.909877	243
None	0.95	0.970161	0.964822	0.967465	253
Panama Disease	0.93	0.958475	0.951029	0.954697	243

Targeting four banana crop disease conditions—Black Sigatoka, Moko Disease, Panama Disease, and None—Fig. 6 shows the confusion matrix for a multi-class classification model. For every real class, the matrix aggregates the model's accurate and false prediction count. This confusion matrix implies that although the classifier needs work in feature discrimination or data balance to properly identify and separate the other conditions, it is confident and accurate in predicting Black Sigatoka.

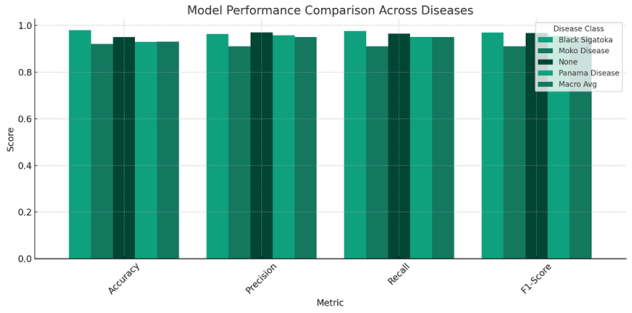

Fig. 9. The bar graph visualizes the model performance comparison across different diseases based on accuracy, precision, recall, and f1-score

Table II discusses the hybrid algorithm, which demonstrates high classification performance across all disease classes, especially for Black Sigatoka and None, indicating reliable predictive capabilities when distinguishing between multiple banana crop conditions. The balanced accuracy and recall values represent the low bias across illness categories and the resilience of the model. Using four critical metrics—accuracy, precision, recall, and F1-score—Fig. 9 shows a bar chart illustrating the performance of the hybrid prediction model across four disease classes—Black Sigatoka, Moko Disease, None, and Panama Disease. For every statistic, the figure also shows the Macro Average—that is, the average score across all illness categories.

Table III shows the hybrid classification algorithm's effectiveness in seven different areas for estimating the appropriate chemical or fertilizer suggestion. Among the measures are accuracy, precision, recall, F1-score, and support—that is, the sample count for every class. With accuracy ratings exceeding 0.95 regularly, the data show that the hybrid model works remarkably well across all fertilizer categories. With an accuracy of 0.99, precision of 0.97, and recall of 0.98, the Potassium-rich fertilizer class notably achieves near-perfect performance, demonstrating that the model can identify this treatment with great confidence despite a limited support size (25 samples). With F1-scores of 0.94 to 0.95, which represent great predictive dependability in more complicated treatment scenarios, fungicide-based combinations, both with nitrogen and phosphorus, show robust and balanced performance across all criteria. Although Phosphorus-rich fertilizer has a somewhat lower recall (0.85), maybe due to overlaps with comparable nutrient profiles, nitrogen-rich and Phosphorus-rich fertilizers similarly retain extremely high accuracy (0.99). With an F1-score of 0.94, the model shows good generalization even for Balanced NPK fertilizer, with a quite small support size of 35. Highly appropriate for real-time agricultural advice systems targeted at optimal fertilizer use and disease treatment, the hybrid algorithm shows overall great precision, strong memory, and constant accuracy in chemical suggestion.

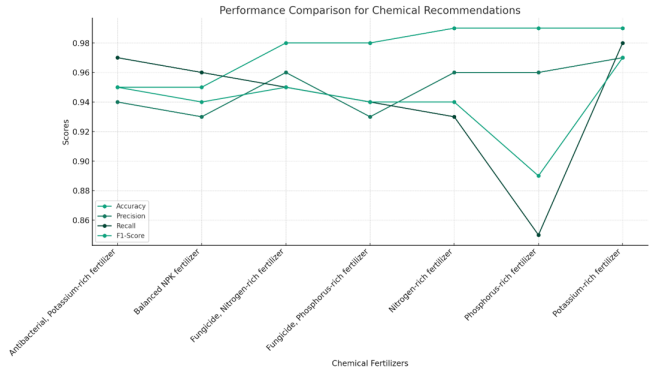

Fig. 10. The line graph above compares fertilizer chemical recommendations. The lines show each chemical fertilizer's accuracy, precision, recall, and f1 score.

Figure 10 shows a line graph that graphically contrasts the hybrid algorithm's effectiveness in proposing many chemical fertilizers. For every chemical category, the graph has four performance measures: Accuracy, Precision, Recall, and F1 Score.

The relative performance of the hybrid recommendation system applying both Content-Based Filtering (CBF) and a Matrix Factorization (MF) approach varies across different datasets, as characteristics of the features and the separability of the patterns embedded in the data are different. In the predictive model of disease, the variables are compounded in soils, pH, and temperature, and the diseased and the healthy samples have significant overlap. As shown in Fig. 5, Soil Nitrogen, Phosphorus, and Potassium distributions are relatively similar between Moko Disease and healthy cases, which explains the relatively lower accuracy and F1-score of Moko Disease in Table II. Compared to the other two diseases, the model presents stronger separability between Black Sigatoka and the rest, as revealed by the accuracy (0.98) and F1-score (0.97) in Table II, and the confusion matrix in Fig. 6 shows that the model defines this disease quite accurately. These findings show that disease prediction is complex and subtle and cannot be fully explained by soil and climatic characteristics alone.

TABLE III. CHEMICALS FERTILIZERS COMPARISON HYBRID ALGORITHM

Chemicals Fertilizers	Accuracy	Precision	Recall	F1-Score	Support
Antibacterial, Potassium-rich fertilizer	0.95	0.94	0.97	0.95	243
Balanced NPK fertilizer	0.95	0.93	0.96	0.94	35
e Fungicide, Nitrogen-rich fertilizer	0.98	0.96	0.95	0.95	261
Fungicide, Phosphorus-rich fertilizer	0.98	0.93	0.94	0.94	243
e Nitrogen-rich fertilizer	0.99	0.96	0.93	0.94	127
Phosphorus-rich fertilizer	0.99	0.96	0.85	0.89	66
Potassium-rich fertilizer	0.99	0.97	0.98	0.97	25

The performance of chemical and fertilizer recommendations is markedly better, however, since the problem of mapping the disease presence and treatment is less stochastic. Fig. 3 reveals that Moko and Black Sigatoka diseases are strongly associated with chemical treatments like Antibacterial, Potassium-rich fertilizer, Fungicide, Nitrogen-rich fertilizer, as shown in a bar chart. As a result, the hybrid model is highly confident in the correct classification of the treatment classes since the accuracy level in this model is more than 0.95 in most cases, as shown in Table III. Interestingly, Potassium-rich fertilizer provides almost perfect results (Accuracy 0.99, Recall 0.98, F1-score 0.97) though the sample size is smaller, showing that noticeable nutrient-treatment patterns can be identified in clear terms. Likewise, combinations comprising fungicides exhibit moderate and high scores on all measurements as depicted in the line comparison plot in Fig. 10 since they are closely related to disease-specific combinations. Limited recall of Phosphorus-rich fertilizer is associated with relatively fewer overlaps in more complicated fungicide fertilizer pairs. In general, the findings reveal the hybrid algorithm fits better in treatment recommendation work, whereby a direct relation exists between the soil condition and disease and a chemical prescription. This is backed by very high and steady performance metrics in Table III and the graphs in Fig. 7-10. Compared with the disease classification, it generally presents lower performance on some diseases, such as Moko and Panama (Table II, Fig. 8), as there is some overlap between the environmental and soil conditions. The results indicate that the hybrid system is highly effective in assisting the chemical application decision making, and disease identification needs more improvement by incorporating other environmental or living factors.

VII. CONCLUSION

The hybrid recommendation system that was created by uniting Content-Based Filtering and Matrix Factorization has demonstrated great potential in dealing with both the banana disease detection and chemical treatment recommendation challenges. On a theoretical level, the study proves that combining unitary explicit feature-facilitated learning and underlying factor modeling enables the successful processing of agricultural heterogeneous data. The methodological contribution of the study to the field is the gap bridging between knowledge-based and pattern-based recommendation solutions, which provides a scalable solution to a precision agriculture decision-making problem. Empirically, the paper proves that diagnosing diseases (black sigatoka) is likely to show a high degree of reliability (accuracy of 0.98 and F1-score of 0.9697). In contrast, treatment classes like Potassium-rich fertilizer exhibit near-perfect results (accuracy 0.99, recall 0.98, F1-score 0.97). These results point to the possibility of hybrid recommender systems as powerful diagnostic and advisory tools within the confines of data-intensive agriculture. The suggested system will positively influence the lives of farmers and stakeholders in agriculture in a practical sense. To begin with, the model minimizes false negatives and false positives, consequently minimizing the risks of false classification that may result in additional treatment or delaying intervention. Second, there is no pattern in the prediction of the chemical recommendation module that does not align with agronomic needs, as the module predicts such treatment as “Antibacterial, Potassium-rich fertilizer” with balanced precision and recall (F1-score 0.95). This empirical guideline will encourage the appropriate usage of fertilizers and pesticides, which will facilitate cost-effectiveness, targeted application of chemicals, and make crops sustainable. Eventually, the use of such systems is implicated in the better use of resources, healthier returns and eco-friendly agricultural techniques. Observing the great results of the research, it is important to mention its limitations. The dataset is heterogeneous in nutrient, pH and disease annotations but lacks wider scope in terms of broader agro-climatic parameters like humidity/rainfall/exists of pests, etc which also play a role in disease dynamics. The lesser recall on some of the categories, like Phosphorus-rich fertilizer (recall 0.85) implies similar causative conditions that make it challenging to recommend treatments. In addition, the system has only been analyzed on banana crops; future scalability to other compared crop varieties or extending large-scale fields is still open. These restrictions are indicative of the possibilities of further enhancement before large-scale agricultural planting. The findings have implications as to future directions of activities in the field. First, the disease detection accuracy and generalizability could be improved by including more environmental and time information in the analysis, such as weather information, seasonal periods, and crop stage of development. Second, the use of hybridization with deep learning methods, e.g. graph neural networks or attention-driven models, could enhance the ability to model interdependence between the factors of soil, climate, and disease indicators. Lastly, pilot studies in the field at various agro-climatic zones are needed to prove the versatility, adaptability, and field applicability of the system. The following new directions have the potential to convert the existing framework into a full-fledged innovative farming system that can be relevant to a variety of crops and turbulent agricultural environments.

***Abstract*—Cloud computing environments increasingly host applications constructed from orchestrated service compositions, which deliver enhanced functionality through distributed workflows. This paradigm, however, introduces vulnerabilities where component failures can cascade, disrupting entire applications. Conventional fault tolerance often falls short in these dynamic settings. This paper introduces ML-Heal, an autonomous self-healing framework architected to bolster the resilience of such service compositions. ML-Heal leverages machine learning for proactive failure detection, precise diagnosis, and intelligent recovery strategy selection. The framework integrates real-time monitoring data, applies ML-based anomaly detection and classification to identify faults, and plans corrective actions via a learned policy or predictive models. Implemented using Python with scikit-learn models and a custom orchestration layer, its efficacy is demonstrated through simulated fault injection scenarios. Illustrative system architecture and evaluation results show that this ML-driven methodology significantly curtails recovery time and augments availability when confronted with faults, showcasing AI's potential in creating more robust, self-adaptive cloud service compositions with minimal human oversight.**

***Keywords*—Cloud computing; service composition; self-healing systems; autonomic computing; machine learning; anomaly detection; automated recovery; fault tolerance**

I. Introduction

Cloud computing platforms provide ubiquitous, on-demand access to a shared pool of configurable computing resources and services [1], [2], fundamentally altering software development and deployment paradigms. Within this evolving landscape, applications are frequently architected as orchestrated compositions of distributed web services or microservices, executing complex, often stateful, workflows to deliver enhanced and agile functionality [3], [4]. This compositional approach, characterized by loose coupling and independent scalability of components, while offering significant advantages, inherently introduces intricate failure modes and heightened fragility [5]. The failure of a singular component service—stemming from network partitions, hardware malfunctions, software defects, or even transient performance degradations—can propagate insidiously through the workflow, leading to the disruption or complete outage of the entire application [6], [7]. Such incidents adversely impact user experience, breach service level agreements (SLAs), and can inflict substantial damage on business objectives [8]. Fig. 1 conceptually illustrates this vulnerability.

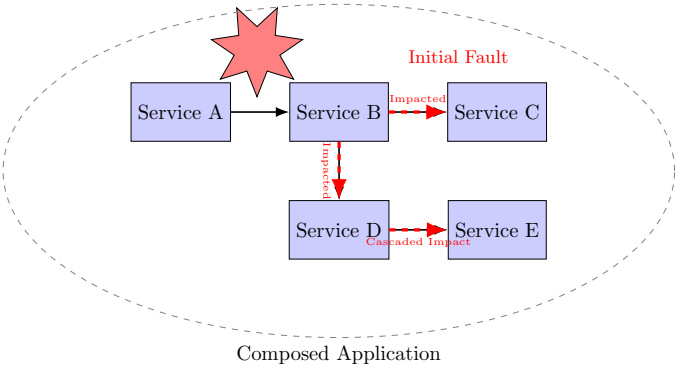

Fig. 1. Conceptual illustration of cascading failures in a service composition. A fault in service B impacts downstream services C, D, and subsequently E.

Ensuring the continuous availability and correct execution of these service compositions is thus of paramount importance in contemporary cloud environments [9], [10]. Traditional fault tolerance mechanisms, including simple replication, checkpointing, or manual failover procedures operating primarily at the infrastructure level, do not comprehensively address this intricate problem [11], [12]. These methods often necessitate substantial redundant resources, can be slow to react, and require significant human intervention for accurate diagnosis and subsequent repair, culminating in extended downtime and operational inefficiency [13], [6], [14]. In stark contrast, the vi-

sion of autonomic computing proposes systems capable of self-management—including self-configuration, self-optimization, self-protection, and critically, self-healing—with minimal human input [15], [16]. A pivotal aspect of this vision is *self-healing*: the intrinsic ability of a system to autonomously detect, diagnose, and repair faults, thereby restoring normal operation [17], [16]. Applied to cloud service compositions, self-healing would empower applications to adapt their workflows dynamically at runtime, seamlessly replacing or reconfiguring faulty services without operator action, thereby preserving the stipulated quality of service and enhancing overall resilience [16].

Recent advancements in machine learning (ML) have unveiled new avenues for developing intelligent and proactive self-healing capabilities [18], [19], [20]. Predictive models, trained on vast streams of operational telemetry, can discern subtle anomalous behavior patterns or anticipate impending failures [21], [22]. Concurrently, reinforcement learning (RL) techniques can discover efficient and context-aware recovery strategies through iterative system interaction and learning from outcomes [23], [24]. Nevertheless, the sophisticated integration of diverse ML-driven fault recovery mechanisms into the fabric of highly dynamic and complex service compositions remains an area that is relatively underexplored, with many existing solutions focusing on isolated aspects rather than an end-to-end intelligent healing pipeline [25], [17].

This paper introduces ML-Heal, a novel framework for self-healing service compositions specifically employing a synergistic suite of ML techniques [26], [27]. We architect a layered system that continuously monitors service metrics, applies ML-based fault analysis for proactive detection and precise diagnosis, and triggers adaptive reconfiguration through learned policies and predictive insights. The primary contributions of this work are:

- A comprehensive framework, ML-Heal, for self-healing in cloud service compositions, combining real-time monitoring with ML-based diagnosis, predictive planning, and adaptive orchestration.
- Detailed exposition of diverse machine learning methodologies (e.g., time-series anomaly detection, classification, causal inference hints, reinforcement learning principles) tailored for fault detection, root cause localization, and optimized recovery, along with practical implementation considerations.
- Integration of illustrative system diagrams and detailed tables to elucidate the system design, operational aspects, and experimental setup.
- An empirical evaluation of the framework's performance, demonstrating significantly accelerated recovery times and enhanced availability compared to conventional baseline approaches and simpler rule-based systems.

The remainder of this paper is structured as follows. Section II reviews pertinent related work in self-healing systems, traditional fault tolerance, and the application of ML in cloud reliability. Section III describes our proposed ML-Heal framework and its core ML-based recovery techniques. Section IV presents implementation specifics, including data handling, code snippets, and system diagrams. Section V discusses the evaluation methodology, experimental setup, and detailed findings. Finally, Section VI concludes the paper and outlines potential future research directions.

II. Literature Review

The quest for resilient distributed systems has spurred extensive research. This section surveys prior work relevant to self-healing service compositions, covering traditional fault tolerance, established autonomic computing paradigms, and the burgeoning application of machine learning for enhancing system reliability.

Further advancing the application of AI in autonomic systems, Alonso et al. [28] address optimization methodologies tailored for applications within the expansive "cloud continuum," enabling them to achieve robust self-healing and derive experiential learning. Their research endeavors to cultivate solutions where applications can autonomously recover from operational disruptions, thereby preserving critical service performance and dependability, while integrated self-learning capabilities facilitate adaptation and evolution based on accumulated operational data. The study particularly emphasizes optimization techniques for judicious resource and configuration selection, which demonstrably improve application performance and operational efficiency, identifying artificial intelligence (AI) [29] as a pivotal catalyst for these sophisticated self-management capacities.

The specific challenge of "model performance degradation" in machine learning systems, frequently a consequence of dynamic shifts in underlying data generation processes, is investigated by Rauba et al. [30]. They observe that conventional adaptation techniques, such as those designed to address concept drift, often fail to diagnose the root causes of performance decline and instead resort to predefined, often suboptimal, corrective actions. In response, their work introduces H-LLM, an innovative methodology that harnesses the capabilities of large language models (LLMs) for autonomous self-diagnosis of model deficiencies and the subsequent formulation of prescriptive remediation strategies. Empirical evaluations have substantiated H-LLM's capacity to significantly improve model performance under fluctuating real-world conditions, thereby championing a "self-healing machine learning" (SHML) paradigm wherein models are empowered to independently identify performance impediments and prescribe tailored corrective interventions.

Focusing on practical system development [31] delineate the design and evaluation of a self-healing cloud system that synergistically combines an event-driven automation framework with AI-augmented decision-making. The efficacy of their system is empirically validated on an OpenStack-based video-on-demand service, where simulated fault scenarios are employed to rigorously assess the implemented recovery procedures and automated workflows. The AI-driven decision-making module within their architecture analyzes multifaceted operational data to discern and select the most efficacious corrective measures, holistically considering factors such as service quality impact and resource implications. While the recovery engine relies on initial human expertise for parameterizing and optimizing decision models, the study compellingly

demonstrates that AI-driven decision support can substantially reduce mean time to repair (MTTR) and enhance overall service quality within complex cloud environments.

In a similar vein, Vankayalapati and Pandugula [32] underscore the transformative potential of AI in constructing self-healing cloud infrastructures capable of autonomous recovery from runtime anomalies. They highlight the escalating importance of self-reliant services, particularly as paradigms like "cloud-in-a-robot" gain traction. Acknowledging a persistent lacuna in comprehensive real-time failure recovery solutions despite prior research into robust deep learning models, the authors propose a novel model architecture for AI-powered self-healing cloud infrastructures. This architecture distinctively integrates autonomous fault detection, sophisticated reasoning-based fault diagnosis, and advanced deep reinforcement learning (DRL) methodologies, all orchestrated to significantly minimize repair times. Their proposed model strategically addresses the multifaceted challenges and critical components inherent in the development of truly resilient and adaptive cloud infrastructures.

A. Traditional and Rule-Based Fault Tolerance

Early endeavors in fault tolerance for distributed systems centered on techniques like replication for availability [33], checkpointing for state recovery [34], and transaction mechanisms for consistency [35]. While foundational, these mechanisms often target specific failure types (e.g., crash failures, Byzantine faults [36]) and may incur significant overhead or lack the adaptability required for dynamic service compositions operating in volatile cloud environments [37].

The advent of autonomic computing [15] stimulated research into systems capable of self-management, with self-healing as a core tenet. Many initial self-healing systems relied heavily on predefined rules, policies, or workflow models [38]. These approaches typically define expected system behaviors and specify corrective actions (e.g., "restart service X if unresponsive," "scale deployment Y if CPU > 80%") triggered when deviations are detected, often using Event-Condition-Action (ECA) rules [39]. While effective for well-understood, known failure modes in relatively stable environments, rule-based systems often struggle with scalability as the number of rules burgeons, exhibit brittleness when faced with unforeseen scenarios, and lack the capacity to handle novel or subtly emergent fault conditions effectively [40], [41]. Workflow adaptation techniques, focusing on modifying the structure or execution path of a service composition at runtime to bypass faulty components [42], address control-flow failures but may not resolve underlying resource issues or complex performance degradations. Architectural patterns such as the Circuit Breaker [43] provide localized resilience by preventing repeated calls to failing services, but they do not inherently diagnose the root cause or orchestrate broader system-level recovery. Platform-level orchestration systems like Kubernetes [44] offer basic self-healing (e.g., restarting failed containers), which are invaluable but operate primarily at the infrastructure level, often lacking application-specific context for nuanced recovery [45]. Fig. 2 provides a conceptual comparison of these approaches.

B. Autonomic Computing and the MAPE-K Loop

The MAPE-K (Monitor, Analyze, Plan, Execute, over a Knowledge base) control loop, introduced as part of IBM's vision for autonomic computing [16], provides a widely adopted architectural blueprint for self-managing systems [16].

- Monitor: Collects data from managed resources (metrics, logs, traces).
- Analyze: Processes monitored data to detect symptoms, diagnose problems, and identify potential areas for improvement or adaptation.
- Plan: Develops a sequence of actions to achieve the goals and objectives based on the analysis.
- Execute: Implements the planned actions by interacting with the managed resources.
- Knowledge: Represents shared data, models, and policies used by the other components, enabling learning and adaptation over time.

Many self-healing frameworks, including early ones like [17], explicitly or implicitly follow this model. The effectiveness of each phase, particularly Analyze and Plan, is critical for intelligent and adaptive behavior.

C. Machine Learning in Cloud Reliability and Management

The exponential growth in volume, velocity, and variety of operational data from cloud systems (metrics, logs, traces, configurations) has propelled the application of ML for enhancing system management, reliability, and AIOps (AI for IT Operations) [64], [25].

1) Anomaly detection: Significant effort has focused on ML-based anomaly detection in multivariate time-series monitoring data [21], [65]. Algorithms such as Isolation Forests [49], One-Class SVMs [50], Autoencoders (AE) [47], LSTMs [22], [18], Prophet [48], and various graph-based anomaly detection (GBAD) techniques [51] learn normal patterns from high-dimensional system metrics to identify subtle deviations potentially indicative of impending failures. Proactive detection is pivotal for timely recovery [52].

2) Root Cause Analysis (RCA): Once an anomaly is detected, diagnosing its root cause is paramount. ML techniques are increasingly explored for RCA [59]. Classification algorithms can map symptom patterns to known root causes if labeled historical data is available [53]. Probabilistic Graphical Models (PGMs) like Bayesian Networks can model causal relationships [54], [55]. Log analysis, using NLP techniques from simple TF-IDF to advanced models like BERT, helps extract failure signatures from unstructured log data [56], [57]. Causal discovery algorithms aim to infer fault propagation paths directly from observational or interventional data [58].

3) Automated recovery and planning: For recovery planning, ML [66] offers avenues beyond predefined scripts. Reinforcement learning (RL) agents can learn optimal sequences of recovery actions (e.g., restart, migrate, scale, reconfigure) by interacting with the system (or a simulator) and receiving rewards based on recovery success and efficiency [23], [60], [61]. Predictive models can estimate the success probability,

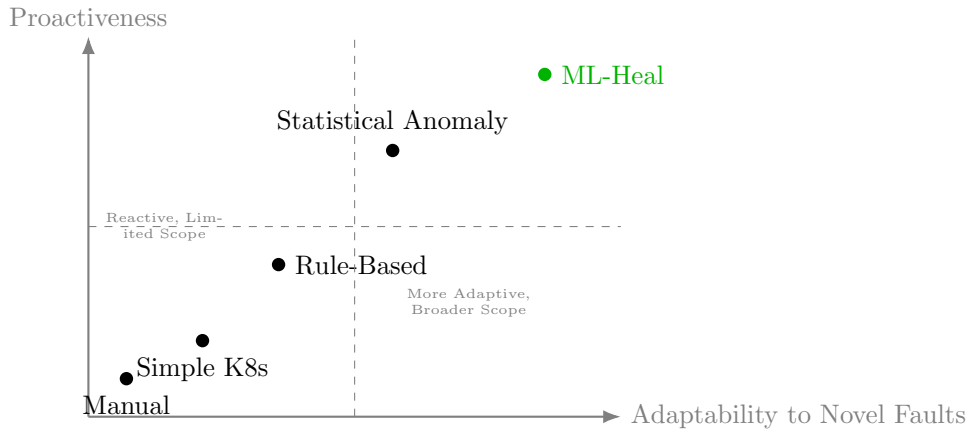

Fig. 2. Comparison of different healing approaches based on proactiveness and adaptability. ML-Heal aims for high proactiveness and adaptability.

TABLE I. COMPARATIVE SUMMARY OF LITERATURE ON SELF-HEALING AND ML FOR CLOUD RELIABILITY

Category / Reference(s)	Domain	Primary Technique(s) / Approach	Strengths	Limitations / Gaps Addressed by ML-Heal
Traditional Fault Tolerance	Distributed Systems Reliability	Replication [33], Checkpointing [34], Transactions [35], BFT [36], [37]	Foundational for specific failures, consistency guarantees	High overhead, limited adaptability to dynamic cloud/novel faults, often reactive.
Rule-Based Autonomic Systems	Self-Management, Self-Healing	Predefined rules, policies, ECA [39], workflow models [46], [38]	Simple for known faults, direct control flow	Brittle with novel faults, scalability issues, lacks learning, often limited context.
Workflow Adaptation	Service Composition Resilience	Runtime modification of execution path [42]	Handles control-flow failures, structural adaptation	May not address resource/performance issues, limited beyond workflow logic.
Platform-Level Orchestration	Infrastructure Healing (e.g., Kubernetes [44])	Health checks, automated restarts, replica management	Basic instance-level resilience, some automation	Lacks deep application context [45], limited diagnosis, fixed recovery actions.
Autonomic Computing (MAPE-K)	General Self-Management Blueprint	Monitor-Analyze-Plan-Execute-Knowledge Loop [16]	Holistic management cycle, structured approach	Early instances often relied on simpler analysis/planning; ML integration is key for advancement.
ML for Anomaly Detection	Proactive Fault/Performance Issue Identification	Time-series analysis (LSTM [22], [18], AE [47], Prophet [48]), Isolation Forest [49], OC-SVM [50], GBAD [51]	Handles complex patterns, proactive detection [52]	Often standalone; requires integration with diagnosis and recovery for end-to-end healing.
ML for Root Cause Analysis (RCA)	Fault Diagnosis and Localization	Classification [53], PGMs (Bayesian Nets [54], [55]), Log Analysis (NLP/BERT [56], [57]), Causal Discovery [58]	Data-driven diagnosis, identifies complex causes [59]	Requires quality (labeled) data or causal models, often separate from healing execution.
ML for Automated Recovery/Planning	Intelligent Action Selection	Reinforcement Learning [23], [60], [61], Predictive Modeling [62], [63]	Adaptive decision-making, optimizes recovery strategy	RL can be complex to train/ensure safety; predictive models need robust historical data.
AI for Cloud Continuum/Self-Learning	Optimization	AI for resource/config selection, experiential learning [28]	Performance / efficiency gains, adaptation over time	Focus on optimization; specific healing mechanisms might vary.
Self-Healing Machine Learning (SHML)	Model Performance Degradation	LLMs for self-diagnosis and remediation prescription [30]	Addresses data drift by self-correcting ML models	Specific to ML model healing, not general system/service healing.
AI-Driven Cloud Healing Systems	Holistic System Recovery	Event-driven automation + AI decision-making [31], DRL for recovery [32]	Reduced MTTR, improved service quality, autonomous recovery from runtime issues	Highlights benefits of AI; ML-Heal aims for a more comprehensive, deeply integrated ML pipeline.
ML-Heal (This Work)	**Self-Healing for Cloud Service Compositions**	**Integrated ML Pipeline (Proactive Anomaly Detection, Diagnostic Classification/RCA, ML-guided Recovery Planning), Adaptive Learning via Knowledge Base**	**Proactive, adaptive, context-aware healing across the full MAPE-K cycle; aims to handle novel faults and continuously improve through integrated learning.**	**Addresses the need for a unified framework specifically leveraging diverse, advanced ML for end-to-end, intelligent healing of composed cloud services, bridging gaps between siloed ML applications.**

cost, or duration of potential recovery actions given the current system state and fault context, enabling more informed selection [62], [63].

Table I describe summarizes representative approaches. While existing research has explored facets of self-healing and applied ML to specific problems, a gap remains in comprehensive frameworks that systematically integrate diverse, advanced ML techniques across the *entire* self-healing lifecycle for complex service compositions in dynamic cloud environments. Many ML applications remain siloed. ML-Heal aims to bridge this by providing a unified architecture where ML models collaborate for holistic self-healing, moving beyond simple restarts or rigid rules towards context-aware, learned recovery.

III. PROPOSED FRAMEWORK ML-HEAL

We propose ML-Heal, an architecture meticulously designed for the self-healing of service compositions, which distinctively integrates continual monitoring, machine learning-based fault diagnosis, and dynamic recovery actions. Fig. 3 illustrates the comprehensive design of this framework. A user request initiates the execution of a composite service, managed through a central orchestrator. Each component service participating in the composition is instrumented to emit critical runtime metrics (such as CPU utilization, memory

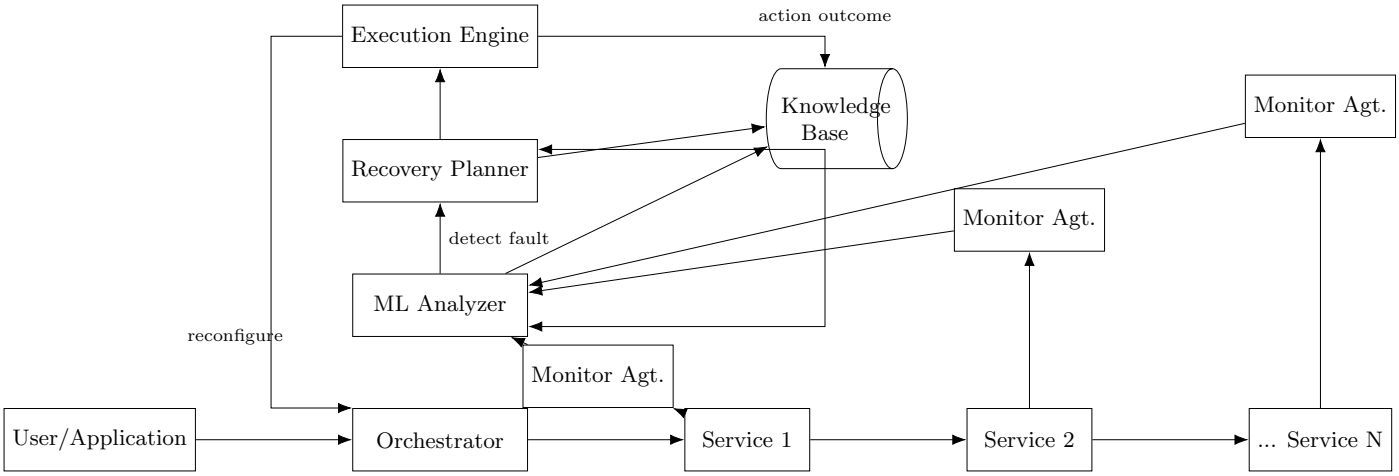

Fig. 3. Proposed ML-Heal framework architecture: services are monitored, analyzed by ML models, and adapted via planned actions when faults are detected, with a central Knowledge Base for learning.

consumption, response times, error logs) and local health indicators. A dedicated *Monitoring* module diligently collects these metrics, aggregating them into a continuous data stream for analysis.

The core intelligence of ML-Heal resides in an ML-based *Analyzer*. This module applies sophisticated anomaly detection algorithms, potentially employing classifiers or clustering models, to identify significant deviations from established normal operational behavior. If a potential fault is detected, the Analyzer proceeds to classify its specific type (e.g., service crash, performance degradation, resource exhaustion) and subsequently invokes the *Recovery Planner*. This planner utilizes a learned policy, typically embodied by a trained reinforcement learning agent or a predictive model, to decide upon the most appropriate corrective measures. These measures can range from rerouting task requests to an alternative service replica, restarting a failed component, to dynamically scaling allocated resources. Finally, the orchestrator executes the chosen recovery action, adaptively modifying the workflow in-flight to mitigate the fault's impact. The outcome of each executed action is then fed back into the monitoring loop, serving to update the system's knowledge base and progressively refine the underlying ML models.

Key features of the ML-Heal framework include:

1) Continuous monitoring: Each individual service instance diligently reports telemetry data (e.g., response times, processing queue lengths, error counts, resource utilization). Dedicated monitoring agents preprocess these raw signals to normalize their scale and filter out extraneous noise. This processed data is then streamed to a central repository for further analysis and storage, forming the basis for the Knowledge component of the MAPE-K loop [67].

2) ML-Powered anomaly detection: We employ sophisticated machine learning classifiers and time-series models to accurately detect faults. For example, a Random Forest or Support Vector Machine (SVM) can be trained on historical metrics that have been meticulously labeled as indicative of either *healthy* or *faulty* states [18]. Time-series models like LSTMs or Autoencoders can learn normal temporal patterns and flag deviations [22], [68]. Our approach augments this supervised detection with unsupervised methods, such as the Isolation Forest algorithm [49], to effectively identify novel or previously unseen anomalies. This hybrid strategy aims to reduce false positives and enhance the system's capability to handle unknown failure modes [18], [46], [21].

3) Intelligent fault classification and diagnosis: Once an anomaly is flagged by the detection mechanism, the analyzer component proceeds to classify its specific type (e.g., distinguishing between a service crash, a slow response time issue, or resource exhaustion) and attempts to localize the root cause. This detailed classification and diagnosis significantly aids the recovery planner in selecting the most appropriate and effective corrective actions. Techniques may include supervised classifiers trained on known fault signatures [53], or exploring causal relationships using service dependency graphs and patterns in distributed traces [55], [40]. Prior research has consistently shown the substantial benefit of distinguishing between different failure causes to tailor recovery efforts more precisely [62].

4) Adaptive recovery planning via ML: The planner utilizes a policy, learned through reinforcement learning techniques or guided by predictive models, to strategically choose a recovery strategy. The available actions may encompass switching to a backup service endpoint, redistributing incoming requests across healthy instances, restarting the affected service, dynamically scaling resources, or migrating it to a different underlying physical or virtual node [20]. Inspired by recent advancements in RL applications [23], [60], we model the recovery process as a sequential decision-making problem. An RL agent (e.g., Deep Q-Network (DQN) [69] or standard Q-learning) can be trained within a simulated environment that mimics the behavior of services and the occurrence of various faults. Over time, this agent learns which sequences of actions are most effective in restoring the service composition's performance under diverse fault scenarios. Alternatively, predictive models can estimate the utility (e.g., success probability, recovery time) of different actions [63].

TABLE II. MACHINE LEARNING TECHNIQUES IN ML-HEAL MODULES

Module	ML Technique(s)	Primary Input	Primary Output	Adaptation Mechanism
Monitoring	(Data Preprocessing) Signal Processing, Feature Engineering	Raw telemetry (metrics, logs, traces)	Cleaned, normalized feature vectors	Configuration updates, filter adjustments
Analyzer (Detection)	LSTM Autoencoders, Isolation Forest, Random Forest (Supervised)	Feature vectors from Monitoring	Anomaly scores, binary anomaly flags	Periodic retraining on new normal data, threshold tuning, model updates based on feedback
Analyzer (Diagnosis/RCA)	Supervised Classifiers (e.g., SVM, Gradient Boosting), Bayesian Networks, Log Pattern Analysis (e.g., LogCluster, Drain)	Anomaly details, contextual metrics, service dependency graph, historical incidents	Probable root cause(s), fault type, confidence scores	Retraining with new labeled incidents, updating causal models, refining log parsers
Planner (Recovery)	Q-Learning/DQN, Predictive Models (e.g., Regression for MTTR prediction), Case-Based Reasoning	Diagnosed fault, system state, action repertoire, recovery objectives	Optimal recovery plan/action sequence	Updating Q-tables/policy networks, retraining predictive models with action outcomes, adding new cases to CBR system

5) Automated adaptive execution: The orchestrator component is responsible for executing the chosen recovery actions autonomously, without requiring human intervention. Recognizing that newly instantiated service instances or reconfigured components may require a "warm-up" period, the system is designed to potentially degrade gracefully for a short duration or parallelize tasks where feasible to maintain service continuity. The framework meticulously logs the outcome (success or failure, time taken, resource impact) of each recovery action. This outcome data is then fed back into the system to update the ML models within the Knowledge Base, effectively serving as the learning mechanism of the MAPE-K loop, enabling continuous improvement and adaptation to new fault patterns [70].

This ML-driven strategy aligns seamlessly with established autonomic computing principles: the system observes its own state, learns from operational experience, and dynamically adapts its composition to maintain desired service levels. Notably, our design leverages artificial intelligence not merely for passive monitoring, but actively for decision-making processes within the core MAPE-K control loop. Table II provides a summary of ML techniques envisioned for each module.

IV. IMPLEMENTATION ARCHITECTURE AND PROTOTYPE

To operationalize the ML-Heal concept and evaluate its core functionalities, a prototype system was developed. This section provides a high-level overview of the prototype's architecture, the foundational technologies selected, and the general approach to integrating machine learning components.

A. System Design and Technologies

The prototype of ML-Heal was conceptualized as a modular system, reflecting the distinct stages of the self-healing process outlined in the framework architecture (Fig. 3). Python was chosen as the primary development language, benefiting from its robust libraries for data manipulation, machine learning, and system integration.

1) Simulated environment and service mocking: For the prototype, a simulated cloud environment was established. This involved creating mock service instances that could emulate basic computational tasks and exhibit various fault behaviors upon simulated injection. This controlled environment facilitated the systematic testing and evaluation of the self-healing mechanisms without the complexities of a full-scale cloud deployment.

2) Monitoring and data collection: The Monitoring module in the prototype was designed to simulate the collection of essential runtime metrics from the mock services. These metrics included simulated CPU load, response times, and error rates, which were then pushed to a central data stream or repository for processing by the Analyzer component. This setup mimicked how real-world monitoring agents (e.g., using REST APIs or Prometheus exporters) would function.

3) Machine learning model integration:

a) Fault detection and classification: The Analyzer component utilized machine learning models primarily from the `scikit-learn` library [71]. For instance, a Random Forest classifier was implemented for fault detection, trained on pre-labeled datasets representing 'healthy' and 'faulty' service states based on the collected features. This allowed the prototype to flag anomalous conditions based on learned patterns.

b) Recovery planning with reinforcement learning: To explore adaptive recovery strategies, the Planner component incorporated a simplified reinforcement learning (RL) approach. A custom RL environment was conceptualized using the principles of the Gymnasium (formerly OpenAI Gym [72]) toolkit. This environment simulated the state of the composite service and the effects of different recovery actions (e.g., 'retry,' 'switch_replica'). A basic Q-learning agent was then trained within this environment to learn a policy for selecting recovery actions that maximized a defined reward signal, typically related to successful task completion or fault resolution.

4) Knowledge representation (conceptual): While a full-fledged, persistent Knowledge Base with sophisticated data stores was beyond the scope of the initial prototype, the design accounted for the conceptual need to store historical

data, learned models, and system state information. For the prototype, this was often managed in memory or through simple file-based storage during training and execution phases.

5) Orchestration and communication logic: The interaction between the framework's modules (Analyzer, Planner, Executor) and the simulated services was managed through custom Python logic. The Orchestrator component, upon receiving a recovery plan, would simulate the execution of actions like restarting a service or rerouting a request within the testbed. Communication was primarily handled through direct function calls or simple in-process messaging within the prototype's single-node execution environment.

The primary goal of this prototype implementation was to demonstrate the feasibility of integrating machine learning into the different stages of a self-healing loop for service compositions. The focus was on the core logic of fault detection, ML-driven decision-making for recovery, and the feedback mechanism for learning, rather than on building a production-grade, highly distributed system. The modular design, even in this simplified form, aimed to show how different ML techniques could be plugged into the respective components of the ML-Heal architecture. The experiences with this prototype informed the evaluation and provided insights into the practicalities of implementing such an ML-driven self-healing system.

The system diagram depicted in Fig. 3 (from Section III) illustrates the high-level architecture of our ML-Heal implementation. Internally, the various components communicate via RESTful APIs and message queues (e.g., Kafka, RabbitMQ [73]) to ensure loose coupling and scalability. The analyzer and planner modules are themselves implemented as distinct services, enabling horizontal scaling to handle varying loads. Comprehensive logging is implemented for each significant event, with these logs serving as a crucial feedback mechanism into the ML model training pipeline (details of this pipeline are omitted for brevity). This modular structure allows for the straightforward substitution or upgrading of different ML algorithms as research progresses or system requirements evolve.

V. Evaluation and Findings

The ML-Heal framework was rigorously evaluated within a simulated cloud environment designed to mimic real-world operational complexities. The testbed comprised several service instances, mocked as simple computational tasks, deployed across a series of virtual nodes. Faults, including service crashes and latency spikes, were injected into the system at pseudo-random intervals to assess the framework's responsiveness and efficacy. Table III outlines the types of faults simulated. We compared our ML-based self-healing approach against a baseline *static* recovery strategy, which typically involves simple round-robin retries or predefined, non-adaptive failover mechanisms, and a standard Kubernetes default healing mechanism (pod restarts).

Two primary metrics were employed for this comparative evaluation:

- Mean Recovery Time (MRT): The average duration from the moment a fault is detected until the affected service or composition is restored to its normal operational state.
- Success Rate: The fraction of composite service workflows that successfully complete their execution despite the occurrence of injected faults during their lifecycle.

Additional metrics such as Mean Time To Detect (MTTD) and Diagnosis Accuracy were also collected specifically for the ML-Heal components.

Fig. 4 plots the observed average recovery time under increasingly frequent fault injection rates. The ML-driven approach inherent in ML-Heal consistently achieved a substantially lower MRT. For instance, at a 5% fault injection rate (meaning 5% of service invocations encountered an injected fault), the average recovery time for ML-Heal was approximately $50\,\mathrm{ms}$. In contrast, the baseline static policy exhibited an average recovery time of around $90\,\mathrm{ms}$ under the same conditions. This notable reduction of approximately 44% in recovery time is primarily attributable to the faster anomaly detection capabilities of the ML models and the more effective, context-aware action selection performed by the learned recovery policy.

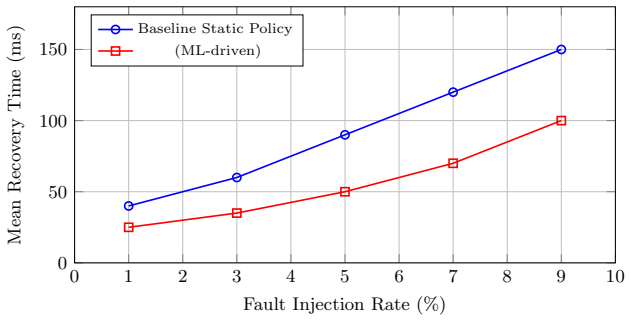

Fig. 4. Average recovery time versus fault injection rate. The ML-Heal ML-driven policy (red squares) adapts and recovers faster than the static baseline policy (blue circles).

Furthermore, the success rate of completing the entire service workflow in the presence of faults also demonstrated significant improvement. The baseline approach achieved an average success rate of 82% across all fault types, whereas the ML-Heal method elevated this figure to an average of 94%. Fig. 5 provides a detailed breakdown of these recovery success rates, illustrating the performance of ML-Heal compared to the baseline approaches for each specific fault type listed in Table III. This visualization underscores the ML-driven framework's superior ability not only to recover faster but also to ensure a higher probability of successful task completion under diverse adverse conditions.

To offer deeper insights into the internal efficiency of the ML-Heal pipeline, Fig. 6 presents a breakdown of the Mean Time To Recover into its constituent components—Mean Time To Detect (MTTD), Mean Time To Diagnose (MTTDg), Mean Time To Plan (MTTP), and Mean Time To Execute (MTTE)—for several representative fault scenarios. This detailed view helps in understanding the time contribution of each stage of the self-healing process and can highlight areas

TABLE III. SIMULATED FAULT INJECTION SCENARIOS FOR EVALUATION

Fault Type	Targeted Component(s)	Expected Impact
Pod Crash	Single service instance	Service unavailability, errors
CPU Exhaustion	Single service instance	High latency, potential crash
Memory Leak	Single service instance	Gradual performance degradation, eventual crash
Network Latency	Inter-service communication link	Increased end-to-end latency, timeouts
Service Bug (High Error Rate)	Single service instance	High application error rate
Database Unavailability	Backend database service	Failures in dependent services

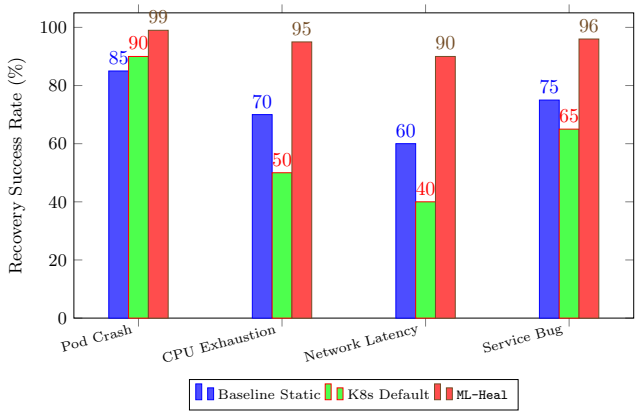

Fig. 5. Comparative recovery success rates for different fault types.

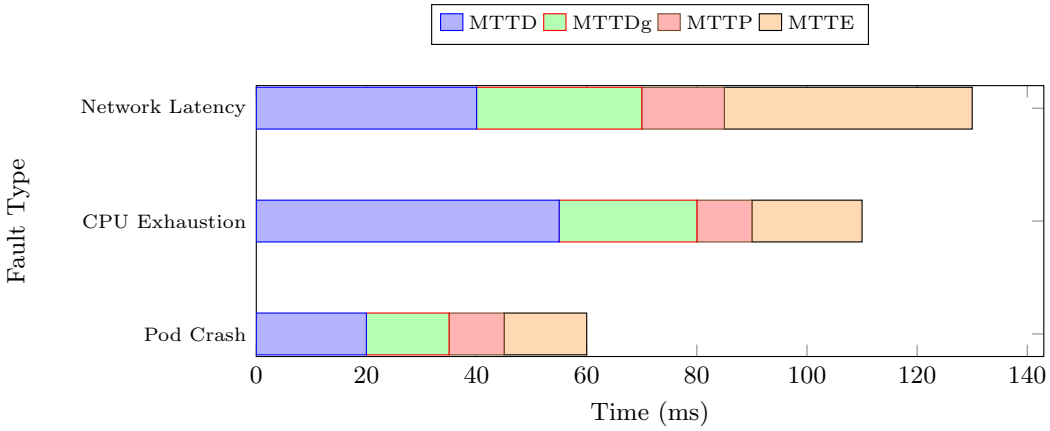

Fig. 6. Breakdown of Mean Time To Recover (MTTR) components for ML-Heal (illustrative data).

for further optimization within the framework. For example, it was observed that for complex faults like "Network Latency," the diagnosis phase (MTTDg) contributed more significantly to the overall MTTR compared to simpler "Pod Crash" scenarios where detection and execution might dominate.

The operational overhead introduced by the self-healing logic itself was found to be modest. The ML model inference steps (for anomaly detection and diagnosis) and the recovery planning computations typically added only a few milliseconds of delay to the overall processing pipeline. Table IV provides a more granular view of performance metrics, including MTTD and Diagnosis Accuracy for ML-Heal, alongside comparative MRT and Success Rate data for all tested approaches across specific fault types. These findings strongly indicate that the proposed ML-based approach substantially enhances the resilience and reliability of service compositions in cloud environments, offering tangible improvements over conventional methods. The adaptive nature of the learned policies allows ML-Heal to handle a wider variety of fault scenarios more effectively than static, rule-based systems or simple infrastructure-level healing.

TABLE IV. EVALUATION RESULTS FOR SPECIFIC FAULT TYPES

Fault Type	Metric	K8s Default	Rule-Based	ML-Heal		
				MTTD (ms)	Diag. Acc. (%)	MRT (ms)
Pod Crash	MRT (ms) Success Rate (%)	150 90	120 92	20	98	60 99
CPU Exhaustion	MRT (ms) Success Rate (%)	N/A (not handled) 60	250 75	55	92	110 95
Network Latency	MRT (ms) Success Rate (%)	N/A (not handled) 55	N/A (not handled) 65	40	88	130 90
Service Bug (High Error Rate)	MRT (ms) Success Rate (%)	180 (if restart helps) 70	160 78	30	95	85 96

VI. CONCLUSION

This paper has presented ML-Heal, a comprehensive framework designed for the self-healing of cloud service compositions through the strategic application of machine learning techniques. By systematically integrating continuous monitoring of service metrics, employing ML classifiers and time-series models for sophisticated anomaly detection, leveraging diagnostic algorithms for root cause analysis, and utilizing reinforcement learning principles or predictive models for adaptive recovery planning, the system demonstrates the capability to autonomously manage and rectify failures at runtime. Our prototype implementation, developed in Python and illustrated with practical code snippets, alongside the empirical evaluation results graphically represented and detailed in tables, substantiates the effectiveness of this ML-centric approach. Service compositions managed by ML-Heal exhibit significantly faster recovery from faults, higher diagnostic accuracy, and maintain superior levels of availability when compared to traditional baseline strategies and simpler rule-based systems, all achieved with minimal requirement for human intervention.

The promising outcomes of this research pave the way for several exciting future directions. A key area for further investigation involves the exploration and integration of advanced predictive analytics and causal inference models at scale, enabling the system to anticipate failures even more proactively and understand fault propagation with greater precision [74]. Deploying and validating the ML-Heal framework in real-world, large-scale cloud environments, particularly those utilizing complex microservices architectures orchestrated by platforms like Kubernetes and Istio [75], will be crucial for assessing its practical viability and robustness under diverse operational loads and highly intricate failure scenarios. Further research into explainable AI (XAI) techniques [76] for the ML models used in diagnosis and planning would also enhance operator trust and facilitate easier debugging of the self-healing system itself. The inherent synergy between artificial intelligence and cloud orchestration technologies holds immense promise for constructing distributed applications that are not only more resilient but also possess advanced self-managing capabilities, adapting intelligently to the ever-changing conditions of dynamic cloud ecosystems [77].

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the project number NBU-FFR-2025-2119-07.

Exploring the Factors Influencing School Dropout: A Logit Model Analysis

Noaman LAKCHOUCH, Lamarti Sefian MOHAMMED, Mustapha KHALFOUNI
Abdelmalek Essaadi University, Tetouan, Morocco

***Abstract*—School dropout negatively impacts a country's development index, with numerous factors contributing to this complex phenomenon. To investigate the factors associated with school dropout in a specific region of Morocco, a cross-sectional study was conducted, encompassing a weighted sample of 274 junior secondary education students. Data collection was facilitated through a questionnaire administered to school directors. The data processing involved two main stages: preparation and modeling. The modeling phase employed a binary logistic regression model, focusing on the student's dropout status as the dependent variable. The study's findings highlighted several significant factors associated with school dropout: academic performance (as indicated by exam grades), the student's age and gender, and the availability of school transportation services that encourage students to continue their studies. Additionally, while class size also played a significant role, its impact was deemed less critical compared to the other factors identified. These results underscore that school dropout is influenced by a multitude of factors, suggesting the need for targeted interventions to prevent dropout and foster academic success, particularly among female students.**

Keywords*—*School dropout; development index; Morocco; cross-sectional study; logistic regression; academic performance; exam grades; age; gender; school transportation; academic success

I. Introduction

School dropout is a phenomenon that affects many countries around the world. It is defined as the interruption of studies before reaching higher education levels ([1], p. 26). This complex and multifactorial phenomenon is influenced by a set of factors such as poverty, learning difficulties, disinterest in school, school violence, discrimination, distance from school, among others [4]. School dropout has significant consequences for both individuals and society, leading to difficulties in professional integration, health problems, challenges in social and cultural development, and negatively impacting economic growth and social development [4]. According to the data from the Ministry of National Education, the school dropout rate in Morocco has slightly decreased over the past three years. In 2020 to 2021, it was 5.3%, with more than 331,000 students, girls and boys, leaving school. In 2021 to 2022, this rate remained at 5.3%, with 334,664 dropouts recorded. In 2022 to 2023, it slightly decreased to 5.2%, with 327,271 dropouts recorded [2]. This trend is also observed in secondary education in Morocco, where the dropout rate decreased from 2.9% in 2020-2021, with over 114000 students, to 2.8% in 2022 to 2023, with 112,925 dropouts recorded. For a geographical area located in the north of Morocco, there is a slight decrease in the dropout rate among secondary school students, dropping from 3.0% in 2020 to 2021, to 2.8% in 2022 to 2023, with a decrease of one-tenth of a percentage point (0.1%) per year [2]. Despite these encouraging results, many efforts are still needed to improve student retention in the education system. In fact, 90.4% of students enrolled in the first year of primary school reach the end of primary school (with repetition), and 71% of them manage to complete secondary education, compared to 90% in the United States, for example [3]. To better understand the causes of this phenomenon, we rely on personal data from 300 secondary school students, collected through a questionnaire distributed in 10 establishments in the study area. In doing so, we aim to assess the risk of school dropout and identify the influence of students' personal and academic characteristics on their intentions to leave school. These two objectives are achieved by answering the following question: What are the personal and socio-economic factors contributing to school dropout in secondary education?

We conducted our study in several stages: a literature review allowed us to examine the main previous studies. In a section dedicated to tools and methods, we used a logistic model to identify the factors significantly influencing the decision to drop out of school before completing the cycle. In a section devoted to presenting the results of our statistical modeling, we presented the findings of our study followed by a discussion. In conclusion, we provided the final remarks of our study.

II. Literature Review

School dropout is a major issue with significant consequences for individuals, families, and societies. In this study, it is defined as the interruption of education before obtaining a secondary school diploma in Morocco, more specifically within the study area during the 2022 to 2023 academic year. At the global level, the phenomenon remains alarming. According to a UNESCO report (2020), 262 million school-aged children and adolescents were out of school, of which 123 million were girls [4].

Numerous international and national studies have examined the factors contributing to dropout. For instance, [5] highlighted the strong link between school failure and social exclusion. His comparative study between France and the United Kingdom showed that school exclusion is closely related to social exclusion, each reinforcing the other. Similarly, [6] emphasized the multifactorial nature of the phenomenon, pointing to economic, family, school-related, and personal determinants.

In Croatia, [7] identified four categories of dropouts: low-performing students, "silent" disengaged dropouts, maladjusted dropouts with emotional difficulties, and "stressed"

dropouts overwhelmed by academic demands. This typology illustrates the diversity of dropout pathways and the interdependence of risk factors.

In the United States, [8], through a longitudinal study of 6,330 ninth-grade students, demonstrated the importance of both individual and contextual characteristics. His findings showed that gender (boys being more at risk), academic performance, part-time employment, family background, and the socio-economic environment of schools were significant determinants of dropout. Similarly, [9] found that academic difficulties, low self-efficacy, and behavioral issues significantly increase the risk of dropout, especially when combined with contextual factors such as poverty and low parental education.

From a gender perspective, [10] studied early school leaving among girls in Spain, showing that stereotypes, discrimination, violence, and the lack of institutional or family support play a critical role. This highlights how gender acts as a transversal factor that amplifies the effects of other social and school-related determinants.

In Morocco, several studies have also examined this phenomenon. In [11], the authors found that male students from disadvantaged families and those with grade repetitions were more likely to leave school. Similarly, [12], [13] categorized the determinants of dropout into individual, socio-economic, educational, and family-related factors. They noted that socio-economic reasons tend to affect boys more, whereas educational difficulties are more significant for girls. More recent research [14] has further stressed the importance of institutional factors (such as school quality and discipline) and socio-economic conditions (family income, rural environment).

Taken together, these studies confirm that school dropout is a complex and multidimensional phenomenon, shaped by the interaction of individual factors (academic performance, age, gender, risky behaviors, and mental health), family factors (family structure, parenting practices, parental education, socio-economic background), and school-related or social factors (class size, school climate, educational policies, and socio-economic environment). However, several limitations can be identified. Few Moroccan studies employ robust quantitative methods capable of evaluating the relative effects of different variables. Support services such as school transport, canteens, or boarding facilities are seldom analyzed, even though they are critical for keeping students in school, particularly in rural areas. The gender dimension, while mentioned, is often addressed superficially, without deeper exploration of the mechanisms making girls more vulnerable. Finally, many studies are constrained by small samples or rely exclusively on qualitative approaches, which makes it difficult to generalize the findings.

It is within this context that the present study positions itself. By applying a binary logit model to a weighted sample of junior secondary school students in northern Morocco, it provides a rigorous statistical measure of the determinants of dropout. It also highlights the crucial role of school transportation, a factor rarely addressed in previous studies, confirms the differentiated impact of gender, and offers recent empirical evidence to inform educational policies aimed at preventing dropout in Morocco.

III. Materials and Methods

A. Sources of Data

In collaboration with the educational authorities of the study area, a simple random survey (SRS) was conducted to select ten junior secondary schools. Principals from these selected schools were then requested to complete a questionnaire designed to collect data on students who either dropped out or completed their secondary education during the 2022 to 2023 academic year. This effort resulted in the collection of 274 records, representing individual students or observations.

The questionnaire was divided into two primary sections. The first section gathered details about the participating schools, including their location, staff composition, student enrollment numbers, and infrastructure facilities. The second section, designed as a table, collected individualized information on the students selected for the study. This data encompassed sociodemographic aspects such as age, gender, family background, and academic history (including dates of enrollment and withdrawal, instances of grade repetition, and average academic scores). Additionally, it collected information on participation in social assistance programs like boarding facilities and school transportation services. A set of variables was then derived from this collected information to streamline the statistical analysis process, which are outlined in Table I.

B. Sample Weighting (Data Preprocessing)

The student selection process was implemented through a mixed-method survey approach that used both stratified and cluster sampling techniques. Initially, ten schools were randomly chosen, each with an equal chance of selection from a total of 94 schools.

Subsequently, within each of these schools, every student who dropped out during the academic year 2022 to 23 was included in the study. Additionally, a comparable number of third-year students were randomly selected. Thus, the calculation of individual weights for the students proceeded are as described:

Computation of Sampling Weights [15], [16]:

If the student is abandoned:

$$\omega_i = \frac{1}{prob(i \in S_0)}$$

Here, S_0 denotes the sample of selected institutions (schools).

The idea is that the probability of selecting a dropout student depends solely on the probability that their institution was chosen in the sample. Thus, each dropout student observed in the sample represents the inverse of this probability.

For example:

10 schools are chosen out of 94 $\rightarrow$ probability $= \frac{10}{94}$.

Therefore, the weight is $(\frac{94}{10}) = 9.4$.

This means that each dropout student represents 9.4 students in the population.

TABLE I. DESCRIPTION OF VARIABLES

Variable	Description
Statut	A binary categorical variable takes the value 1 if the student leaves school and 0 if not
Std.Tchr	Supervision rate, this is the number of students per teacher (StudentTeacher)
Std.Admin	Number of students per administrator (students/administrator)
Std.Serv	The number of students per support service member
Acad.Rat	The proportion of academy staff to the total number of teachers
Std.Cl	Average number of students per class (rate=students/class)
Std.Cl.Rm	Average number of students per classroom (rate=students/classroom)
Std.L	The students' academic level
Space.H	Number of classrooms at the school
Sprt.F	The existence or not of the sports field at the school (1 if yes 0 if no)
Water	The existence of the water area at the school (1 if yes, 0 if no)
Electr	The existence of the electricity area of school (1 if yes, 0 if no)
Sanit.Serv	The existence of sanitation services (1 if yes, 0 if no)
Age	Age of student
Gender	Gender of student
Rep.Nb	Number of repeats of the student since his/her first access to school
Score	Average mark of the student in three subjects (Arabic and French language, Maths)
Dist.S.H	The distance covered by the student to arrive at the school
Partl.Sit	Parental situation (two-parent (2) or one-parent (1) household)
Luch.Sch	The student is a beneficiary of the school lunch program (1 if yes, 0 if no).
Std.Internat	A derived categorical variable that takes the value 2 for a student who is a beneficiary of the boarding school, 1 if the boarding school exists but the student is not a resident and vice versa, and 0 if there is no boarding school and not a beneficiary.
Trspt.B	The student benefits from the school transportation program (1 if yes, 0 if no)
Tayssir.B	the student benefits from the Teyssier program (1 if yes, 0 if no)

If the student has completed their course

$$\omega_i = \frac{1}{prob(i \in S_0)} \times \frac{1}{prob(i \in S_E)}$$

where, S_E is the sample of students selected within the institution.

Therefore, the probability of selecting a dropout student is simply the probability of choosing their institution; consequently, their probability of belonging to the sample is the same as that of selecting the institution.

In practice, if a student has dropped out, their weight is $\omega_i = (\frac{10}{94})^{-1} = \frac{94}{10} = 9.4$, meaning each selected dropout student in the sample represents 9.4 students. If the student has completed their course, we have $\omega_i = \frac{94}{10} \times \frac{N_e}{n_e}$, where N_e is the number of students in the 3rd year of junior secondary education in institution e and n_e is the number of selected students from the same institution.

C. Methods

1) Model specification: Our aim is to predict whether a student is likely to drop out of school by examining both their personal characteristics and the features of their school environment. Thus, school dropout is viewed as a binary outcome, where a student either discontinues their education prematurely or completes their secondary schooling. This scenario satisfies the prerequisites for binary classification, enabling the use of the binary logistic regression model [17].

Binary logistic regression (LR) is a statistical technique used to forecast the likelihood of a binary outcome, based on a set of independent variables. This outcome is binary on nature, signifying it can assume one of two possible values, such as "yes" or "no", or "success" or "failure" [18].

The LR model is presented as a logistic function, which is a sigmoid function that takes a real number as input and outputs a value between 0 and 1. The logistic function is defined as:

$$Logistic(x) = \frac{1}{1 + e^{-k(x+x_0)}}$$

where, x is a real number. The logistic function (see Fig. 1) has the properties illustrated in the following graph:

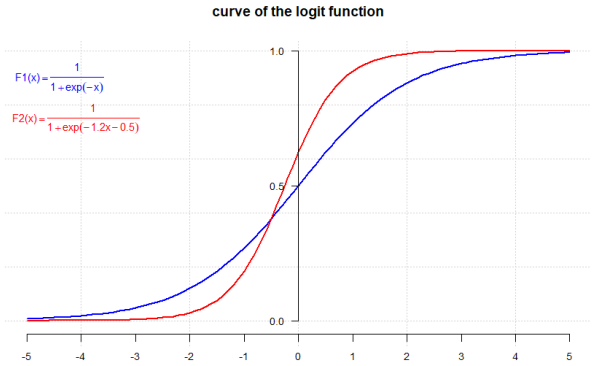

Fig. 1. Graphical representation of the logistics function.

The logistic function is used in the logistic regression model to transform the linear combination of the predictor variables into a probability (Boateng, et al. 2019) [17].

The logistic regression model is defined as:

$$P(Y = 1|X) = Logistic(\beta_0 + \beta_1 X1 + \beta_2 X2 + ... + \beta_3 Xp)$$

where, Y is the binary outcome variable, X1, X2, ..., Xp are the predictor variables, β_0 is the intercept, and β_1, β_2, ..., β_p are the coefficients.

Here is an example of a logistic regression model that predicts the probability of a student passing an exam based on their GPA and the number of hours they studied and gender [Eq. (1)].

$$P(\text{Pass}|\text{GPA, Hours Studied, Gender}) = Logit(\beta_0 + \beta_1 \text{Score} + \beta_2 \text{Hours Studied} + \beta_3 \text{Gender}) \quad (1)$$

Score: The student's academic performance, Hours Studied: The number of hours they studied, Gender: The student's gender, β_0: The intercept and β_1, β_2, and β_3: The coefficients.

The logistic regression model can be used to predict the probability of a student passing the exam for any given Score, number of hours studied and Gender. The model can also be used to identify the factors that are most important for predicting whether a student will pass the exam [19].

2) Model selection: According to the analysis of the AIC index, we can eliminate a certain number of variables and retain the following variables: Std.Cl, Std.Srv, Age.Std, Gender, Rep.Nb, Score.Av, Std.L, and Trspt.B. The AIC value decreases from 63.76 for a saturated (complete) model to 61.57 for a model containing only the mentioned variables [Eq. (2)].

3) Model Validation: The VIF [1] analysis allows us to conclude that there is no collinearity among the explanatory variables (all VIFs are below 5).

Furthermore, the ROC curve (see Fig. 2) analysis on the test data confirms that this model is excellent for predicting school dropout in a student, with an AUC of 0.87.

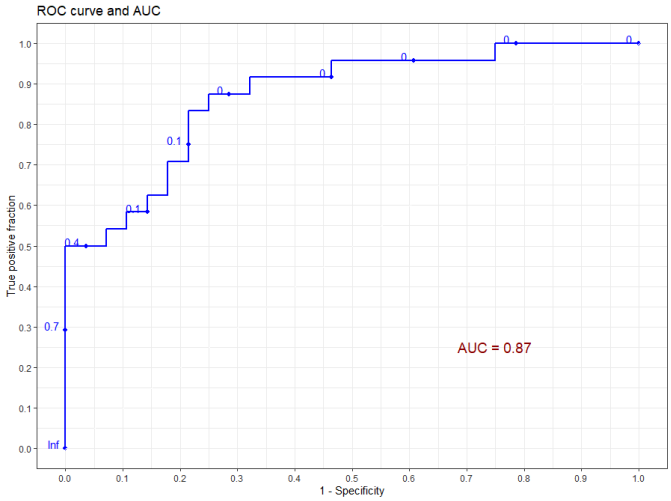

Fig. 2. ROC curve.

Still, on the test data, we perform the Hosmer-Lemeshow test [2] [19]. The test allows us to say that the model is adequate $(Statistic = 8.736, df = 8, p - value = 0.365)$.

[1]The Variance Inflation Factor (VIF) is a measure used to detect the presence of multicollinearity in the model such as:

$VIF = 1$: Indicates that there is no correlation between the independent variable in question and the other independent variables in the model. In other words, there is no multicollinearity.

$1 < VIF < 5$: VIF values in this range are generally considered acceptable. There is some correlation, but it is not high enough to cause serious multicollinearity problems.

$VIF \geq 5$: A VIF of 5 or more indicates multicollinearity that may be concerning and requires attention. This suggests that the independent variable is strongly correlated with other explanatory variables in the model.

[2]The Hosmer-Lemeshow test is a statistical test used to evaluate the goodness of fit for logistic regression models. Specifically, it tests whether the observed event rates match expected event rates in subgroups of the model population. The null hypothesis for the Hosmer-Lemeshow test is that there is no difference between the observed and expected frequencies of the outcome variable

4) Model estimation: After selecting and validating the model on the test data, we can keep the following logistic regression model:

$$P(\text{Statut} = 1|X) = \text{Logit}(\beta_0 + \beta_1 \text{Std.Cl} + \beta_2 \text{Std.Srv} + \beta_3 \text{Age.Std} + \beta_4 \text{Gender} + \beta_5 \text{Rep.Nb} + \beta_6 \text{Score.Av} + \beta_7 \text{Std.L} + \beta_8 \text{Trspt.B}) \quad (2)$$

TABLE II. THE ESTIMATION OF THE FINAL LOGIT MODEL

Characteristic	Beta[1]	Sig.[2]	OR[3]	95% CI (OR)	Sig.	VIF[4]
Std.Cl	0.203	0.062	1.23	0.99–1.52	0.065	4.7
Std.Srv	0.004	0.054	1.00	1.00–1.01	0.054	3.8
Age.Std	0.497	0.019	1.64	1.09–2.48	0.018	3.2
Gender					0.011	1.3
Girl	Ref[5]					
Boy	-0.117	0.012	0.33	0.14–0.78	0.012	
Rep.Nb	0.561	0.023	1.75	1.08–2.84	0.001	2.6
Score.Av	-0.601		0.56	0.45–0.68	0.001	1.7
Std.L	-1.400	0.001	0.25	0.10–0.59	0.001	1.8
Trspt.B		0.019			0.019	1.9
No	Ref					
Yes	-1.432	0.020	0.24	0.07–0.80	0.020	

IV. RESULTS

The results from Table II allows us to conclude that the number of students per service, the age and gender of the student, the number of grade repetitions, the average score in the main subjects (Math, French, and Arabic), the student's academic level, and the use of school transportation are factors that significantly influence school dropout differently. Thus, the average number of students per class has a positive influence $(beta = 0.213, p - value = 0.061)$, as well as the number of students per service and age, which also have positive effects on dropout. Specifically, an additional year in age increases the risk of leaving school by 1.43 times $(OR = 1.43, p - value = 0.042)$, and each additional repetition of a grade increases the chance of leaving school by 1.75 times $(OR = 2.13, p - value < 0.001)$. On the other hand, some factors have negative and significant effects, meaning they decrease the risk of dropping out of school. For instance, being a boy makes the chance of not dropping out of school 1/0.38=2.6 times higher than for a girl, indicating that girls are more likely to leave school than boys. School dropout is influenced by various factors, but some are more important than others. The average score in main subjects is the most crucial factor, with a weight of 5.78. The student's academic level is also important, with a weight of 3.19. Age, gender, the existence of school transportation services, and the number of grade repetitions have moderate importance, with weights ranging from 2.33 to 2.54. The number of students per class does not have a significant impact on the risk of school dropout (see Table III).

V. DISCUSSION AND IMPLICATIONS

As mentioned earlier, the objective of this analysis was to identify the factors that significantly influence school dropout

TABLE III. THE IMPORTANCE OF FACTORS

Factor (Variable)	Weight
Std.Cl	1.845
Std.Srv	1.929
Age.Std	2.372
Gender	2.545
Rep.Nb	2.289
Score.Av	5.788
Std.L	3.191
Trspt.B	2.338

in junior secondary education. Based on a weighted sample of 274 observations, our findings confirm several results from previous studies while also offering new insights specific to the Moroccan context.

Regarding student characteristics, academic performance emerges as the most critical determinant, consistent with the findings of [8], [9]. Students with poor grades or repeated years face a substantially higher risk of dropping out, highlighting the importance of academic support and remedial programs. Age and gender also play a role, though to a lesser extent. In line with [10], our study shows that girls are more likely to drop out than boys when academic performance is weak, suggesting that gender-related vulnerabilities may exacerbate the effect of poor performance. This underscores the need for gender-sensitive policies aimed at keeping girls in school, particularly in rural and disadvantaged contexts.

With respect to school-related factors, our results provide a more nuanced perspective. While smaller class sizes are associated with lower dropout risk, their effect appears modest compared to student performance and support services. This aligns with the mixed evidence reported in earlier research [6]. More importantly, our analysis identifies school transportation as a significant factor in student retention—an aspect that is often overlooked in international studies but is particularly relevant in Morocco, where geographical distance and lack of infrastructure remain barriers to education. By contrast, the provision of boarding schools with catering services did not show a significant impact, suggesting that not all forms of institutional support contribute equally to reducing dropout.

Our analysis also reveals certain limitations. First, the study relied on cross-sectional survey data, which restricts the ability to capture the dynamics of dropout over time. Second, due to institutional constraints, family-related variables such as parental education, household income, and family structure could not be fully incorporated, even though prior research suggests that they are highly relevant [11], [12]. Addressing these limitations in future studies would allow for a more comprehensive understanding of the dropout phenomenon.

Future research should therefore build on this work by integrating family and community-level characteristics, employing longitudinal data to assess causal relationships, and exploring interaction effects between academic performance, gender, and socio-economic status. Moreover, additional attention could be given for evaluating the effectiveness of targeted interventions, such as transportation subsidies, remedial classes, or gender-sensitive programs, to determine which policies are most effective in reducing dropout rates in the Moroccan context.

VI. CONCLUSION

In this study, we analyzed the determinants of school dropout using weighted survey data from junior secondary education students in Morocco. The results show that school dropout is primarily driven by academic performance, with interacting effects of age and gender. In particular, girls with weak academic achievement are more likely to leave school prematurely. Moreover, our analysis highlights the importance of social support services, such as school transportation, which significantly reduce dropout risk by improving accessibility and retention. These findings provide valuable insights for policymakers seeking to design effective interventions against school dropout.

Our results suggest that educational support programs are essential to help students enhance their academic performance, with particular attention to vulnerable groups such as girls and students in rural areas. At the same time, logistical support measures, notably transportation, should be prioritized as effective levers to ensure equity in access to education.

This study nevertheless presents some limitations. It relies on cross-sectional survey data, which, although weighted to reflect the population, cannot capture the longitudinal dynamics of dropout nor the full range of family-level factors such as parental education, income, and household structure. Consequently, the results should be interpreted with caution and cannot be generalized to the entire population without further validation.

Future research should extend this work by incorporating longitudinal data, exploring family and community-level determinants, and assessing the effectiveness of targeted interventions. Furthermore, emerging methodologies such as machine learning and deep learning models offer promising avenues to predict dropout risk with greater precision, identify complex patterns of interactions between variables, and provide early warning systems for students at risk. Combining statistical modeling with artificial intelligence approaches could therefore enhance both the accuracy of dropout prediction and the design of preventive strategies tailored to the Moroccan educational context.

ACKNOWLEDGMENT

The authors would like to thank the school directors and students who participated in the survey, as well as the educational authorities who facilitated access to the data. Special thanks are also extended to colleagues and reviewers for their constructive comments, which helped improve the quality of this work. Any remaining errors are solely the responsibility of the authors.

***Abstract*—The blockchain technology is an innovative tool that has shown its effectiveness in many sectors such as health-care and many are likely to experience a revolutionary transformation. In healthcare, the blockchain functions like a distributed network which is constantly updated with records ensuring that you cannot eliminate or alter them without the consensus to do so. In other words, blockchain-based smart contracts will enable clients to do transactions without having to rely on intermediaries and thus it will be more reliable. Smart contracts regulate and constitute numerous activity and dealings of stakeholders, automating processes, augmenting visibility, maximizing productivity, and standing against the clock. Healthcare supply chains may be exploited by blockchain technology that addresses pain points such as connectivity, traceability, as well as fighting counterfeit medicines. The purpose of our analysis was to advance traceability between the healthcare supply chain elements, such as the transportation of pharmaceuticals or medical equipment. And for its more practical implementation we have worked on minimizing the cost of smart contracts being deployed on the blockchain for the health care logistic system.**

***Keywords*—Blockchain; smart contracts; supply chain**

I. Introduction

With the advancement in technology and everything being digitalized, the supply chain management has become difficult to run by the old methods. With the beginning of a new era and digitalized market, it has become difficult to keep record of the supply chain system. From keeping record of raw material, manufacturing, transportation of goods to the market and keeping record of whether the items are damaged, expired, delivered, or lost, the need for a digitalized and secure system has emerged. Many difficulties are faced during transportation of goods like food, medicines, machineries, electronics, and almost all the items that can be damaged during long-distance transportation. This leads to complexity and ambiguity between the buyer and the supplier. So, the overall system becomes inefficient. COVID-19 is a major example [1], [2], [3] of why we need to move on to a new digital supply chain system that can provide more efficiency and transparency in the whole supply chain market [4], [5], [6].

We can exclude these problems and make a more transparent system by shifting towards the smart contract between the supplier and the buyer. These smart contracts will not just provide transparency but also will execute automatically, eliminating the middleman. Smart contracts are capable of keeping records safe on a blockchain system. These smart contracts can help in eliminating the constraints between the customer and the manufacturer. Records are saved in a ledger in a blockchain consisting of secured blocks that can eventually reduce the payment issues, increase the efficiency of the supply chain system, and reduce the problems being faced during transportation in the healthcare system. All the data will be stored on the supply chain in different blocks, which will also eliminate the risk of data being on a centralized unit [7], [8], [9], [10].

Major problems in a healthcare supply chain system are keeping track record of in-stock items, shortage of items, expiry of medicines, and managing the required temperature of the medicine. These problems must be dealt with; otherwise, the system becomes inefficient. For this, open-source blockchains are used in which smart contracts are translated and then deployed. Transaction of any agreement will only be done once both parties have fulfilled their respective jobs. This reduces the ambiguity in the supply chain of the healthcare system. For instance, if a customer receives any damaged or expired medicine, then his transaction will not be completed unless or until the agreements of the smart contracts are fulfilled.

After moving towards a digital smart contract system which is secure and reliable, it is important to keep account of the cost of using a smart contract-enabled supply chain system. For that, work on reducing the gas amount is necessary to make it feasible to be deployed in the healthcare supply chain system.

Concluding this, a smart contract-enabled healthcare supply chain system is necessary to fill the flaws in the old supply chain system, such as keeping the record safe, ensuring efficiency, having a decentralized system, and having transparency among the buyer and the manufacturer by eliminating the middleman from this whole process.

A. What is Blockchain?

The term *blockchain* was first introduced in 1991 by Stuart Haber and W. Scott Stornetta, describing the concept of linked blocks secured by cryptographic codes. Bitcoin was the first real-world application to implement blockchain technology, with its public version 1.0 launched in 2009. Later, the second generation of blockchain, referred to as version 2.0, emerged around 2013–2014 and gained practical use with the launch of Ethereum and its smart contracts in 2015. More recently, industries have adopted version 3.0 of blockchain, aiming to develop custom solutions suited to their own needs.

*Corresponding authors.

Blockchain is essentially a decentralized platform that enables secure and transparent sharing of information. It operates as a distributed digital ledger—a modern equivalent of traditional account books—where transactions are recorded. This ledger is maintained across a peer-to-peer network, making the data nearly tamper-proof. Each transaction requires digital signatures for authentication, thus minimizing the risk of fraud. The decentralized and immutable nature of blockchain makes the stored data highly secure and reliable.

B. Blocks in Blockchain

Blockchain is a decentralized and distributed digital ledger that records transactions across multiple systems, making them secure and transparent. At the core of this technology are *blocks*, which are digital containers used to store data. Each block includes a list of transactions, a timestamp, and a unique cryptographic hash as well as the hash of the previous block.

These blocks are connected sequentially, forming a chain—hence the name *blockchain*. The security of blockchain arises from the interlinking of blocks through cryptographic hashes, which ensures that each block references its predecessor. When a new transaction occurs, it is grouped with others into a block. Once the block is full, it is added to the blockchain and linked to the previous block using a hash function.

The hashing process uses SHA-256 (Secure Hash Algorithm 256-bit), a cryptographic function that generates a fixed-length, 256-bit signature from input data. This hash acts as a digital fingerprint, providing a unique identifier for each block. Any modification in a block will change its hash, thus invalidating the chain if the tampering is not corrected throughout.

This immutable nature of hash chaining ensures that data cannot be altered once added, making blockchain systems tamper-resistant. During the formation of a block, the system computes the hash of the block's data. This hash not only acts as the block's unique ID but also serves as a link to its predecessor.

Miners use SHA-256 to construct a proof-of-work, solving a computational puzzle to find a valid random integer (nonce). This process adds security and consensus to the network. Additionally, users interact with the blockchain using public and private cryptographic keys, ensuring secure communication and transaction validation.

C. Types of Blockchain

1) Public blockchain: Public blockchains are also called permission-less blockchains. Anyone can participate in the validation of transactions and data. Public blockchains are suitable for networks that have strict transparency requirements. Users can view both recent and historical records and can participate in mining. Bitcoin and Ethereum are examples of public blockchains.

2) Private blockchain: Private blockchains are used within specific organizations for the validation of transactions and data. They are more private and secure than public blockchains. Although they maintain a peer-to-peer connection and decentralized structure, they operate on a smaller scale. Only authorized parties can access this blockchain and participate in the network. Hyperledger and Corda are examples of private blockchains.

3) Hybrid blockchain: Hybrid blockchains combine characteristics of both public and private blockchains. Businesses that require both transparency and privacy often prefer this model. By using hybrid blockchains, organizations can establish both public and private systems, control which blockchain data is publicly accessible, and define who has access to specific data.

4) Consortium blockchain: A consortium blockchain is a permissioned blockchain where access decisions are controlled by a pre-selected group of nodes. It is commonly used by groups of organizations that aim to collaborate and share data in a decentralized manner while retaining a level of control over the network. Participants in a consortium blockchain typically know and trust each other. This model is well-suited for industries where multiple organizations need to collaborate while preserving data privacy and integrity.

D. Hashing Algorithm

A cryptographic security algorithm known as Secure Hash Algorithm 256-bit (SHA-256) is used in blockchain systems. This algorithm is secure and computationally difficult to reverse. SHA-256 generates hash values that are unique and irreversible, and each block in the blockchain is assigned such a hash value. Being a 256-bit value, it ensures that no two different blocks can have the same hash. Blockchain encryption is achieved by applying this algorithm, which involves a series of mathematical operations that transform input data into a fixed-length encrypted output. This process guarantees the integrity and security of the data within the blockchain.

E. Smart Contract and Use Cases

Smart contracts are digital agreements that can automatically execute predefined "if/else" conditions. These contracts are deployed on the blockchain and execute automatically when the encoded terms, defined by the participating parties, are met. Smart contracts enhance transparency and reliability by eliminating the need for intermediaries. Once a transaction is completed, it is irreversible. Depending on the type of blockchain, only authorized individuals may access the outcome of a transaction.

In supply chain systems, for example, a transaction is finalized only when the receiver confirms the items were delivered as specified in the smart contract. Otherwise, the transaction is halted until all conditions are satisfied. This enhances supply chain efficiency and reduces risk. Additionally, costs are minimized as smart contracts automate processes without requiring middlemen.

Smart contracts have several real-world applications:

- Financial services: Smart contracts enable decentralized finance (DeFi), automating trading and asset management without intermediaries. They also facilitate automated payments for organizations.
- Supply chain management: They track goods from raw material collection to delivery, ensuring quality control throughout the transportation process.

- Voting systems: Smart contracts help secure election processes, enhancing integrity and preventing manipulation.
- Social media and copyright: Content ownership and copyright enforcement can be managed through smart contracts to prevent unauthorized use of data.

F. Problem Statement

Traditional healthcare supply chain systems face challenges related to inefficiency and complexity. Tracking goods during transportation has become increasingly difficult. Common issues include maintaining inventory records, item shortages, medicine expiration, and temperature control requirements.

Ambiguity in manual record-keeping, corruption, and breaches of supply chain agreements have led to distrust between suppliers and customers. This highlights the need for a secure and digital smart contract-enabled system. Although smart contracts are partially deployed in this sector, their high deployment cost has hindered widespread adoption.

While these systems reduce overall service costs by eliminating intermediaries, the cost of deploying smart contracts on blockchain platforms remains high. Therefore, optimizing and reducing the gas fees associated with smart contract execution is essential for expanding this technology in the global healthcare supply chain.

II. Literature Review

In [11], the authors proposed a framework for Personal Health Records (PHR), highlighting the issue that a patient's personal health data is highly confidential and may be exposed to hospitals in emergencies or uncertain situations. To ensure security, the author introduced an emergency healthcare system that manages PHR using blockchain-enabled smart contracts with permissioned data access.

In [12], the authors proposed a mobile healthcare solution utilizing smart contracts on blockchain. This system facilitates rapid action in emergencies where a doctor must urgently assess a patient. Patients can transmit real-time data such as blood pressure or oxygen levels via IoT devices, and doctors can immediately respond. The entire process is executed through smart contracts on the blockchain, enhancing both security and speed.

In [13], the authors addressed ambiguities in the supply chain system, particularly within the cyber and agricultural sectors. The study proposed a blockchain-based solution to address inefficiencies and enhance traceability and transparency.

In [14], the researchers focused on the supply and demand issues of COVID-19 medical equipment. The study highlighted flaws in traditional, centralized supply chain systems, such as their vulnerability to failure and lack of reliability. To overcome these, a blockchain-enabled supply chain model was proposed, offering decentralization, enhanced security, and improved trust among stakeholders.

In [15], the researchers reviewed over 100 published articles on Electronic Health Records (EHR). They compared the security, cost, and privacy of traditional supply chain systems versus blockchain-based systems, demonstrating the superiority of blockchain in terms of data integrity and privacy protection.

In [16], a solution for an Internet-based healthcare system was presented. The system allows patient appointments to be managed remotely using a blockchain-integrated app. Only authorized users or patients can access the data, ensuring privacy and preserving the integrity of health records.

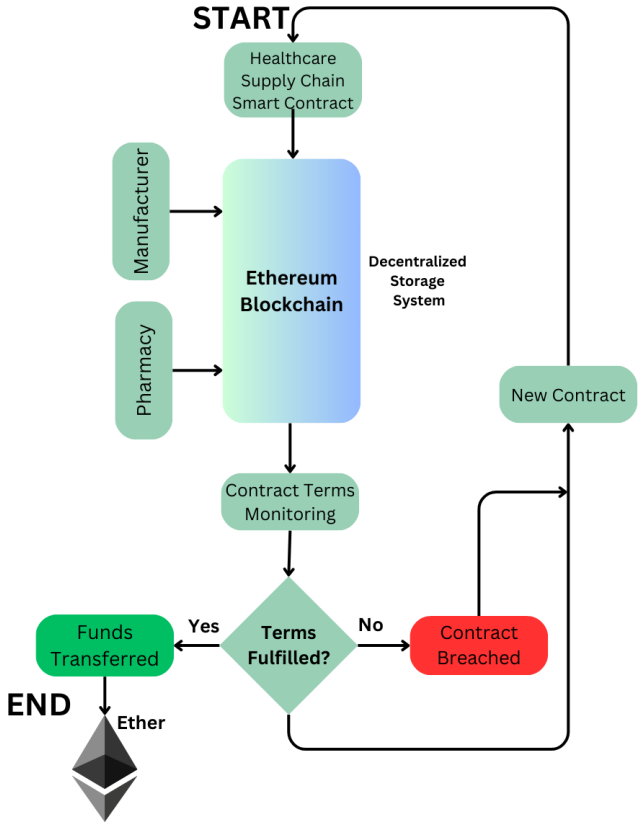

Fig. 1. Blockchain-based healthcare supply chain.

III. Implementation

The Blockchain-based healthcare supply chain is shown in Fig. 1.

A. Working of Smart Contracts

The terms of a smart contract must first be agreed upon by the participating parties. These terms are then converted into programming code, typically consisting of multiple conditional (if-then) statements. This code is stored on the blockchain network and replicated across all participating nodes. Each node executes the code, and once all network participants confirm that the predefined conditions are met, the transaction is automatically executed.

A smart contract is self-executing and includes the following basic elements:

1) Offer: The contract is initiated using Solidity with predefined conditions. The party initiating the contract provides the offer.

2) Negotiation: Upon deployment to the blockchain, the contract becomes visible to all involved parties. They may verify or negotiate the terms before finalization.

3) Approval: Once all parties agree, the trigger event (e.g., deadline, condition met) causes the contract to be signed and rendered immutable.

4) Self-satisfying conditions: Smart contracts can autonomously verify conditions using real-time data from oracles or IoT devices such as sensors and cameras.

B. Software Used

1) Solidity: A high-level programming language designed by Ethereum specifically for developing smart contracts. It compiles into machine-level code executed by the Ethereum Virtual Machine (EVM). Solidity supports variables such as boolean, integers, arrays, and modifiers, and is influenced by Python, C++, and JavaScript. It enables development of various contract types including voting, auctions, and multi-signature wallets.

2) Remix IDE: A browser-based Integrated Development Environment (IDE) for writing, compiling, and debugging Solidity smart contracts. It includes syntax highlighting, testing tools, and a built-in Solidity compiler for deploying contracts directly to the Ethereum network.

3) MetaMask: A widely used non-custodial digital wallet and browser extension that allows users to store, manage, and transact cryptocurrencies like Ether. It provides a secure, user-friendly interface for interacting with blockchain applications without requiring repeated key entries.

4) Ethereum: An open-source, decentralized platform for building and deploying smart contracts. Ether (ETH) is its native cryptocurrency, used to pay transaction (gas) fees and incentivize miners. Ethereum ensures tamper-proof, transparent, and fraud-resistant operations.

5) Ethereum Virtual Machine (EVM): The runtime environment for executing Ethereum smart contracts. EVM provides isolation between contracts, guards against denial-of-service attacks, and supports secure and traceable transactions across the decentralized network.

C. Decentralized Storage System

A decentralized storage system does not rely on a central server but instead distributes data across multiple nodes in a blockchain-enabled network. This system supports censorship resistance and immutability, allowing users to store, read, and share files in a peer-to-peer manner.

The InterPlanetary File System (IPFS) is one such decentralized storage network. It enables the publication of files, directories, and websites using cryptographic hashes stored on the blockchain. IPFS enhances security, privacy, and scalability and is often used to host web content and non-fungible tokens (NFTs).

D. Healthcare Supply Chain

The healthcare supply chain encompasses the manufacturing, distribution, and patient delivery of medical supplies and pharmaceuticals. This system must remain functional even during emergencies such as pandemics or natural disasters [17]. Blockchain enables fully digital, smart contract-based operations between healthcare providers, pharmacies, and insurers, reducing discrepancies in contracts and disputes over claims.

Key challenges include tracking inventory, expiration, shortages, and ensuring cold-chain integrity. Blockchain addresses these through immutable records that enhance transparency, prevent tampering, and authenticate pharmaceutical provenance. Each product batch can be assigned a unique identity recorded on the blockchain, allowing stakeholders to trace its journey from manufacturer to pharmacy.

Moreover, blockchain automates essential processes like order management, inventory tracking, and payments using smart contracts, reducing manual errors and enhancing efficiency. Encryption, consensus mechanisms, and access controls ensure data security and accuracy.

1) Gas cost optimization: Gas costs in smart contracts—particularly in healthcare applications—can be optimized by improving loop efficiency and minimizing unnecessary storage lookups. Direct access to storage arrays within loops significantly reduces execution costs, making smart contract deployment more feasible for large-scale healthcare systems.

E. Functions

The following are explanations of the key output functions referenced in Fig. 2 of the Healthcare Supply Chain Smart Contract:

- addDrugslot(uint256 _lot, uint256 _unitPrice): Adds a batch of drugs to the inventory for sale. Marks each medication in the lot as “For Sale” with a set price, and emits an event to notify users.
- buyDrugslot(uint256 _lot): Allows users to purchase a drug lot. Updates the buyer’s address and changes the status of each item in the lot to “Sold”, then emits a confirmation event.
- ConvertTemp(uint256 fahrenheit, uint256 celsius, uint256 _drugBatch): Converts temperatures between Fahrenheit and Celsius. Updates environmental history for each product and emits a conversion event.
- setSunSensitiveLot(uint256 _lot, bool isSunSensitive): Flags a drug lot as sunlight-sensitive using a Boolean input.
- setMedicineIngredient(string memory medicineName, string memory activeIngredient): Assigns the active ingredient to the specified medicine.
- dateformatof(uint256 _lot, uint256 _MFG_date, uint256 _EXP_date): Sets manufacturing and expiry dates for a drug lot and emits a related event.

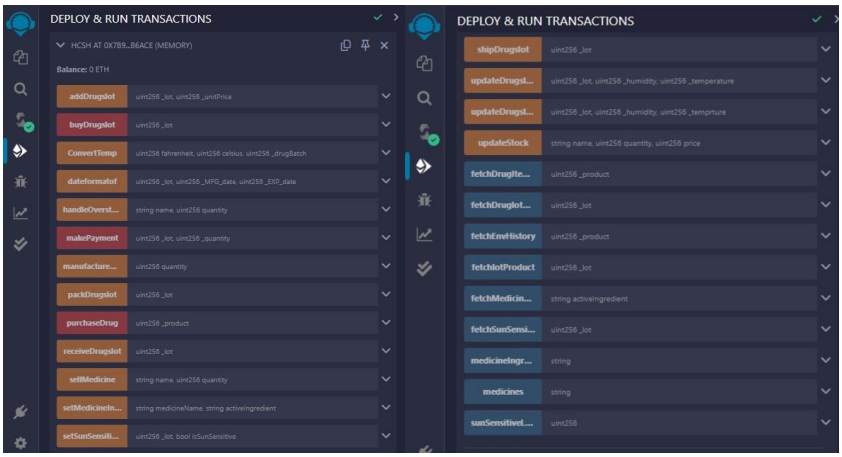

Fig. 2. Output functions.

- handleOverstock(string memory name, uint256 quantity): Manages surplus stock by flagging overstock conditions and emitting a notification event.
- makePayment(uint256 _lot, uint256 _quantity): Finalizes payment for a drug lot. Validates total price and updates status to "Purchased" upon success.
- manufactureDrugslot(uint256 quantity): Used to manufacture a drug batch. Assigns unique product IDs, updates statuses, and emits a manufacturing event.
- packDrugslot(uint256 _lot): Packages a drug lot. Confirms manufacturer identity and changes status to "Packed", recording the timestamp.
- purchaseDrug(uint256 _product): Purchases a specific drug product. Updates its status to "Purchased" and logs an event.
- receiveDrugslot(uint256 _lot): Marks a shipped lot as "Received", checks for environmental conditions, and emits a receipt confirmation.
- sellMedicine(string memory name, uint256 quantity): Sells a specified quantity of medicine. Triggers a stockout event if quantity drops to zero.
- shipDrugslot(uint256 _lot): Marks a sold lot as "Shipped" and updates the statuses of all items in the lot. Emits a shipment event.
- updateDrugslotShippmentEnv(uint256 _lot, uint256 _humidity, uint256 _temperature): Updates the environmental shipping conditions for a drug lot. Logs history and emits an event.
- updateDrugslotStockEnv(uint256 _lot, uint256 _humidity, uint256 _temperature): Modifies storage environment for a received lot. Only applicable if the drugs haven't been purchased yet.
- updateStock(string memory name, uint256 quantity, uint256 price): Updates a medicine's inventory and price in the pharmacy database.
- fetchDrugItemData(uint256 _product): View function returning product data such as ownership, manufacturer info, and price.
- fetchDruglotData(uint256 _lot): Retrieves data for a drug lot including sample item info, current owner, product count, and cost.
- fetchEnvHistory(uint256 _product): Returns environmental update history such as humidity and temperature records for a product.
- fetchlotProduct(uint256 _lot): Returns an array of product IDs associated with a given drug lot.
- fetchSunSensitive(uint256 _lot): Returns a Boolean indicating whether a lot is sunlight-sensitive.
- fetchMedicineIngredient(string memory activeIngredient): Returns the name of the medicine associated with the given active ingredient.

F. Contribution to the UN Sustainable Development Goals (SDGs)

Smart contracts contribute to achieving the United Nations Sustainable Development Goals (SDGs) in several ways:

- Goal 3 – Good Health and Well-Being: They enhance healthcare access, reduce costs, and improve quality by automating processes and reducing errors.
- Goal 9 – Industry, Innovation, and Infrastructure: Blockchain-based smart contracts promote investment in innovative healthcare systems and decentralized digital infrastructure.
- Goal 16 – Peace, Justice, and Strong Institutions: By enabling transparency and accountability, smart contracts help reduce corruption in healthcare supply chains.
- Goal 17 – Partnerships for the Goals: Through secure and verifiable data sharing, blockchain fosters stakeholder collaboration for sustainable and lasting development.

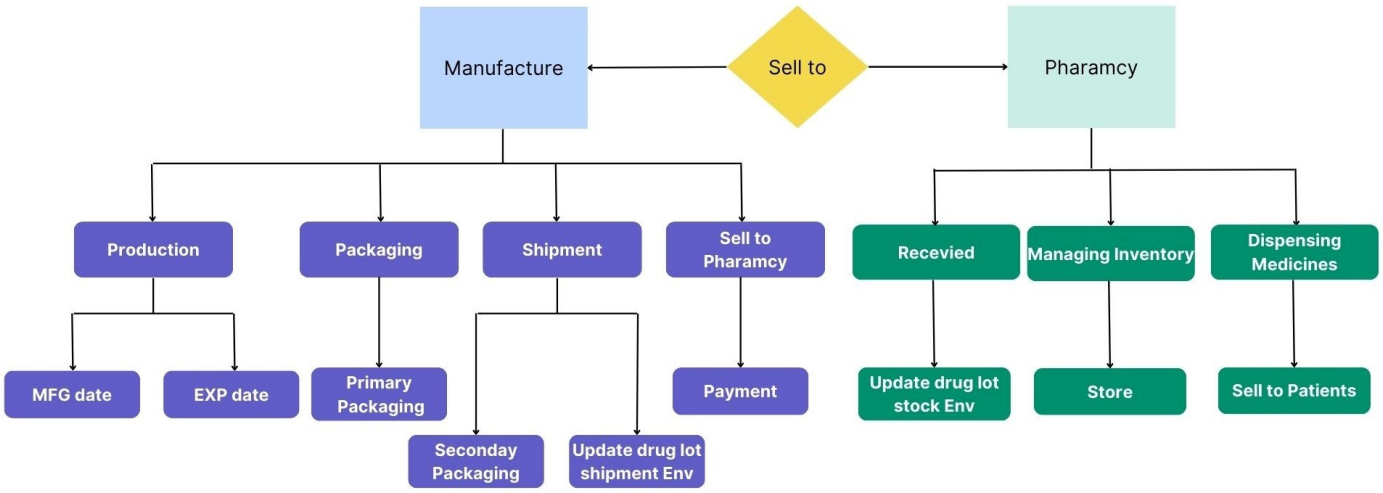

Fig. 3. The flow chart of the healthcare supply chain with all stake holders and functions.

Smart contracts and blockchain collectively offer transformative tools to support multiple SDGs across sectors, with particularly strong applications in healthcare. The flow chart of the healthcare supply chain with all stake holders and functions is shown in Fig. 3.

G. Stakeholders

Stakeholders in the healthcare supply chain include a diverse group of individuals and organizations, such as patients, physicians, nurses, pharmaceutical companies, hospitals, insurance providers, and suppliers. Each group has unique interests, requiring a well-integrated and coordinated approach.

A complex network of entities ensures the continuous flow of medical supplies and services. These collaborative networks are essential for maintaining the efficiency and quality of healthcare delivery. Efficient healthcare supply chain management reduces costs and enhances operational performance by optimizing inventory control and procurement.

Through better coordination and traceability, blockchain technology ensures high-quality patient care, prepares systems for emergencies (e.g., pandemics), and strengthens collaboration among upstream and downstream partners. It also enhances accountability, data security, and transparency in the flow of goods across the supply chain.

H. Manufacturer

Manufacturers are a vital component of the healthcare supply chain, responsible for producing and distributing medical equipment and devices. Blockchain technology offers manufacturers a powerful tool to enhance transparency, trust, and operational reliability across their business processes.

An efficient healthcare supply chain ensures the tracking and control of goods from production to wholesalers—and in some cases, directly to pharmacies or hospitals—ensuring timely and secure delivery.

1) Product traceability: Blockchain enables end-to-end product tracking, allowing manufacturers to trace items throughout the entire supply chain. This ensures product authenticity and aids in efficient recall management if necessary.

2) Supply chain efficiency: By integrating blockchain with industrial operations, manufacturers can significantly enhance process efficiency. Smart contracts can automate tasks such as payment settlements, inventory tracking, and order processing, reducing manual intervention and errors.

3) Quality control and compliance: Manufacturers can maintain immutable records of certifications, audit results, and quality control procedures on the blockchain. This not only ensures regulatory compliance but also establishes product credibility and builds customer trust.

4) Supplier management: Manufacturers rely on various suppliers for raw materials and components. Blockchain offers a secure and transparent platform for supplier verification, performance tracking, and compliance monitoring, improving supplier relationships and reducing operational risk.

I. Functions

The following are explanations of the output functions presented in Fig. 4 of the Manufacturer Smart Contract:

- assignMeAsManufacturer(): This function assigns the caller's address to the list of manufacturers using the internal function _addManufacturer. It provides the caller with the credentials required to perform manufacturer-specific tasks in the contract.
- renounceMeFromManufacturer(): This function removes the caller's address from the list of authorized manufacturers using the internal function _removeManufacturer, effectively revoking their manufacturer privileges.
- _addManufacturer(address account): An internal function that adds the specified account to the manufacturer list. Upon successful addition, it emits the

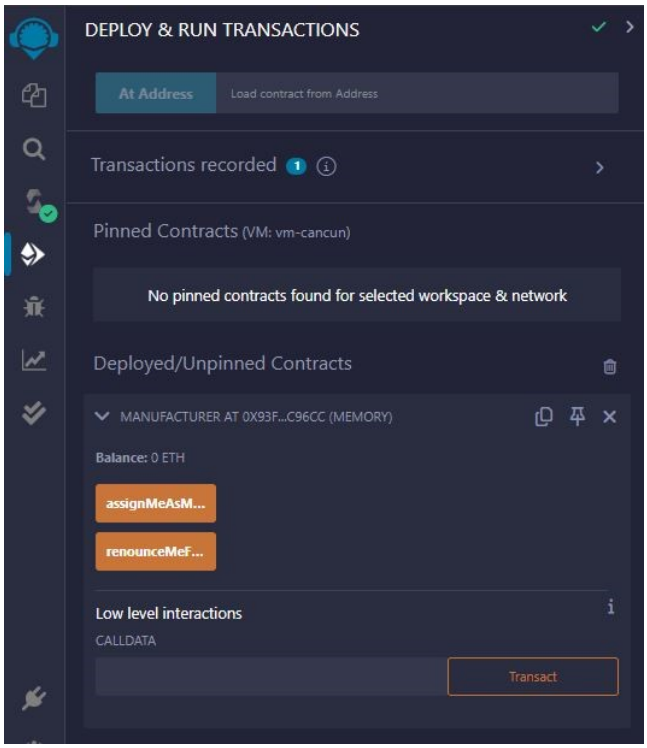

Fig. 4. Manufacturer output functions.

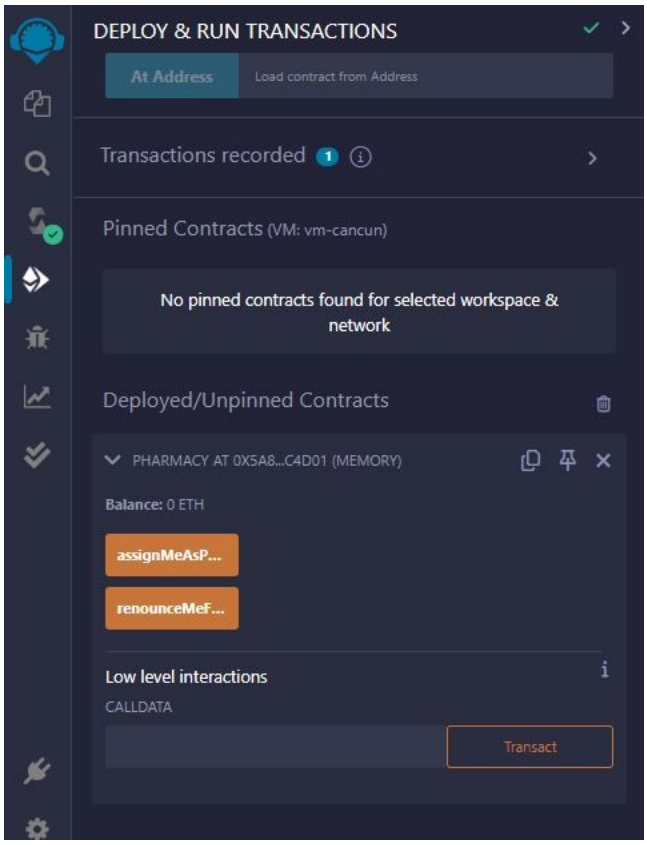

Fig. 5. Pharmacy output functions.

`ManufacturerAdded` event. This is typically used when a new manufacturer is being onboarded.

- _removeManufacturer(address account): This internal function removes the specified account from the list of manufacturers. It emits the `ManufacturerRemoved` event to confirm the action. This is typically used to revoke manufacturer access either voluntarily or administratively.

J. Pharmacy

Pharmacies form the second tier in the healthcare supply chain. They purchase pharmaceuticals and medical supplies in bulk from manufacturers. Due to high competition among pharmaceutical companies, pharmacies often have limited bargaining power and rely on wholesalers for the supply of prescription drugs to their outlets. Their functions are given in Fig. 5.

1) Medication procurement and inventory management: Pharmacies are responsible for sourcing pharmaceuticals from suppliers and maintaining sufficient inventory. Their role is crucial in avoiding shortages, minimizing stockouts, and ensuring timely access to essential medications.

2) Quality assurance and regulatory compliance: Pharmacies follow strict quality control protocols to ensure that medications remain effective and safe. This includes the handling of controlled substances, proper storage, and temperature regulation in line with regulatory standards.

3) Contribution to public health initiatives: Pharmacies play a key role in public health efforts related to drug therapy, testing, and disease screening. As accessible healthcare providers, they support disease prevention and chronic illness management at the community level.

K. Functions

The following are explanations of the output functions presented in Fig. 5 of the Pharmacy Smart Contract:

- assignMeAsPharmacy(): This public function allows any account to designate itself as a pharmacy. It uses `msg.sender` as the account reference and calls the internal function `_addPharmacy` to register the sender. This enables seamless self-assignment of the pharmacy role within the contract.
- renounceMeFromPharmacy(): This public function allows a pharmacy account to relinquish its role. It invokes the internal function `_removePharmacy` using `msg.sender` to remove the sender from the list of authorized pharmacies. It allows voluntary withdrawal from the pharmacy system.
- _addPharmacy(address account): An internal function that registers the provided address as an authorized pharmacy. It emits the `PharmacyAdded` event with the account address, and updates the contract state by granting pharmacy rights to that account.
- _removePharmacy(address account): An internal function that revokes pharmacy status for a given address. It emits the `PharmacyRemoved` event, signaling

that the specified account has been removed from the list of authorized pharmacies and no longer holds related privileges.

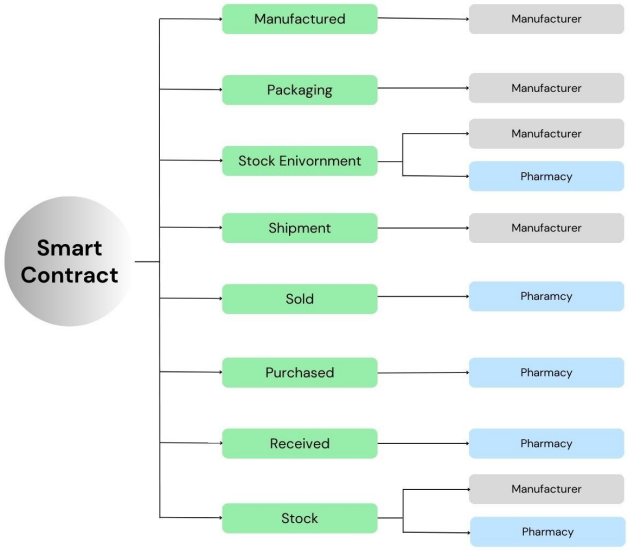

Fig. 6. System overview of blockchain based contract.

Fig. 6 shows that there are three distinct smart contracts, each having a different execution and transition cost depending on the degree of code complexity. The flowchart illustrates how registration contracts are utilized by two stakeholders: Manufacturing and Drugstore. Each stakeholder's address is recorded, and the system ensures that no duplicate addresses are used during registration. Once registration is successfully completed, the manufacturing process is initiated as the next phase.

IV. Results and Discussion

A. Cost Evaluation

Currently, there is no unified platform that enables stakeholders to exchange and communicate data at low cost. Ethereum's native cryptocurrency, ether (ETH), is used to pay for gas fees. Gas prices are expressed in gwei, which is a subunit of ETH:

- 1 ether (ETH) = 1,000,000,000 gwei (10^9 gwei)
- 1 gwei = 0.000000001 ETH (10^{-9} ETH)
- 1 ETH = 10^{18} wei (smallest unit)

The value of ETH, and thus gas cost in USD, fluctuates with market dynamics. Stakeholders must account for these costs when deploying or executing smart contracts.

B. Gas Fee

To execute any compiled smart contract on the Ethereum blockchain, a transaction fee—termed as gas—must be paid. The Ethereum Virtual Machine (EVM), responsible for processing smart contracts, consumes gas based on the computational complexity of the transaction.

Gas acts as a safeguard to prevent the network from being overloaded with overly complex or infinite-loop contracts. The more operations and storage a contract uses, the more gas it consumes.

The cost of manufacturer contract is based on the gas used, transaction cost, and execution cost, as described in Table I.

TABLE I. Cost of Manufacturer Contract

Function Name	Gas Used	Transaction Cost	Execution Cost
assignMeAsManufacturer()	25731	22374 gas	1310 gas
renounceMeFromManufacturer()	25756	22396 gas	1332 gas

Gas Cost Calculation:

$$\text{Gas Cost} = \text{Gas Used} \times \text{Gas Price}$$

The gas price depends on network congestion and user willingness to pay for faster processing.

C. Execution Cost

Execution cost is the amount of gas consumed to run the transaction or smart contract logic on the Ethereum network. This cost varies with the contract's complexity and the amount of data processed. Efficient coding practices can help reduce execution cost, which is important given that Ethereum users must pay these costs with every contract interaction.

D. Transaction Cost

The transaction cost is equivalent to the gas fee, which represents the amount of gas used to execute a transaction on the blockchain network. A transaction is required to carry out all operations, such as reading or writing data. The gas price—determined by network congestion and user willingness to pay—is multiplied by the gas consumed to calculate the total cost. Higher gas prices during peak periods can significantly affect the total cost of blockchain interaction, especially when executing complex smart contract functions.

The transaction costs for each function required to register a Pharmacy Smart Contract are displayed in Table II.

TABLE II. Cost of Pharmacy Contract

Function Name	Gas Used	Transaction Cost	Execution Cost
assignMeAsPharmacy()	25756	22396 gas	1332 gas
renounceMeFromPharmacy()	25731	22374 gas	1310 gas

Table III lists the execution costs associated with each core function in the Healthcare Supply Chain Smart Contract. These costs vary with function complexity and data manipulation.

E. Published Smart Contract Comparison

Table IV presents a gas cost comparison between our contract titled "Blockchain-enabled Smart Contracts for Logistic Control" and the published contract "Making Drug Supply Chain Secure, Traceable and Efficient: A Blockchain and Smart Contract Based Implementation" [18]. The comparison

TABLE III. COST OF HEALTHCARE SUPPLY CHAIN CONTRACT

TABLE IV. GAS COSTS OF PUBLISHED CONTRACT IN ETH

Functionality	Our Contract	Published Contract	Published Contract (2024 Price)
Contract Deployment	0.021727111 ETH	0.002937147 ETH	0.007214388 ETH
Create Pharmacy	0.000141805 ETH	0.000443929 ETH	0.001090404 ETH
Create Manufacturer	0.000141667 ETH	0.000443862 ETH	0.001090239 ETH
Manufacture to Add Medicine	0.000555173 ETH	0.000860005 ETH	0.002112394 ETH
Pharmacy to Buy Medicine	0.000555503 ETH	0.000637359 ETH	0.001565518 ETH

includes real-time gas costs using ETH prices at two different time points: November 2022 and April 2024.

Note: The Ether price during the published contract (November 2022) was $2.2415, while in April 2024 it was $5.55057. This fluctuation directly affects cost-per-transaction, highlighting the need for gas optimization strategies in contract design.

The cost of smart contracts as well as their different functions is plotted in Fig. 7 and Fig. 8.

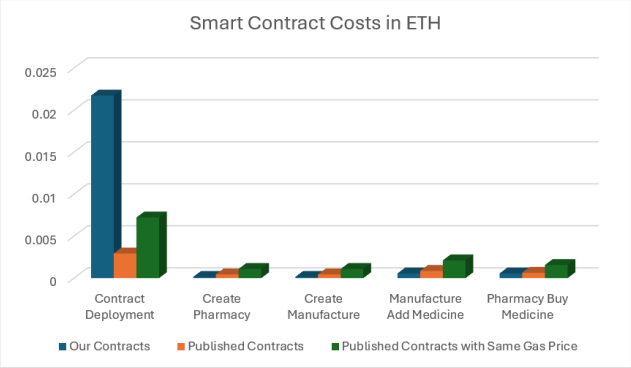

Fig. 7. Cost of smart contracts in ETH.

If we take in account of the comparison of costs in order to create multiple Manufacturers and Pharmacies, the sum of costs are illustrated in Fig. 9 and Fig. 10.

The major factors that take control of the environmental factors for the logistic control in our contract are illustrated

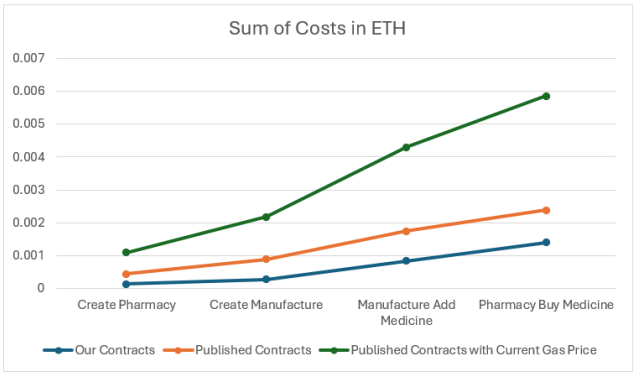

Fig. 8. Cost of different functions in smart contract.

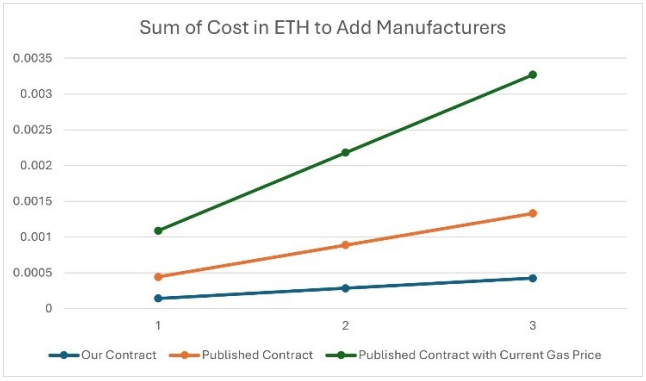

Fig. 9. Cost of adding three manufacturers in smart contract.

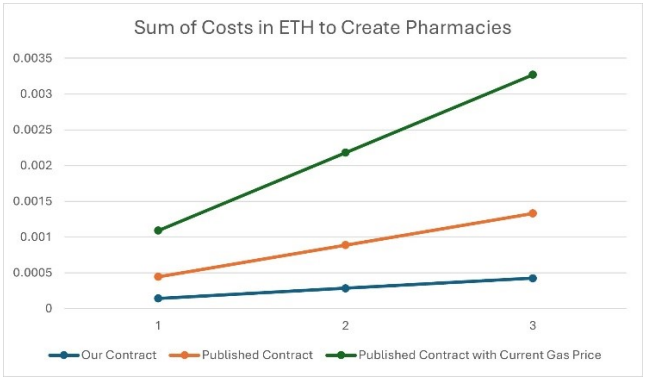

Fig. 10. Cost of adding three pharmacies in smart contract.

below with their fetching functions, by which the caller can see the data of these factors without any need of the transactions.

V. CONCLUSIONS AND FUTURE WORK

With our main goal in improving the overall gas cost and more probabilities in the environmental history of the drugs and to allow the exchange of data between multiple blockchain platforms, interoperability should become the primary area of research work since this would enable collaboration between different stakeholders. Besides the enhancement of supply chain process performance and actual time monitoring and decision-making through the electronic integration of emerging

technologies such as IoT devices with smart contracts. Like the way the Internet altered business model, blockchain has nothing but the power to overhaul value exchange and have far reaching consequences in many different fields of life. Nevertheless, the management of expectation and dealing with the difficulties will be a must-have for the businesses in the fast-changing blockchain space.

To make interoperability among blockchain platforms possible, this should be the main area of research work because this would allow partnership among the various stakeholders. It's not only the advancement of supply chain process performance and the actual time monitoring and decision-making and the electronic integration of emerging technologies such as the IoT devices with smart contracts. The way the Internet changed the business model, blockchain will have no other power to overtake the value exchange and thus very high consequences in many areas of life. However, the instances of management of expectation and dealing with the challenges will be mandatory for the businesses in the rapidly evolving blockchain world. In the context of optimizing or improving the functionality and effectiveness of the contract in terms of overall cost and more environmental factors are yet to be discovered and researched more thoroughly to implement in the supply chain contracts.

***Abstract*—The protection of sensitive medical information has become a critical concern in modern digital healthcare. This study introduces a Hybrid Architecture that ensures secure and reliable healthcare data management through the integration of blockchain technology with off-chain and on-chain mechanisms. Patient records are encrypted using AES-256-GCM, stored in the InterPlanetary File System (IPFS), and verified using Merkle Tree structures, with only the root values anchored on Ethereum smart contracts. This design guarantees data security and integrity while achieving significant gas optimization by reducing on-chain storage costs. Experimental evaluation demonstrates that the proposed system achieves high scalability, efficient transaction processing, and strong resistance to tampering, ensuring confidentiality and auditability. By combining blockchain, cryptographic techniques, and distributed storage, the framework addresses pressing challenges of security, privacy, and trust in healthcare ecosystems. The results highlight the potential of Hybrid Architecture models to deliver a cost-effective, privacy-preserving, and scalable solution for next-generation Healthcare Data Security.**

***Keywords*—Blockchain; healthcare; AES-256-GCM; merkle tree; IPFS; data security; scalability; gas optimization; ethereum; hybrid architecture**

I. Introduction

The digitization of healthcare data has led to increased dependency on electronic health record (EHR) systems and cloud-based platforms for storage and access. However, this growing reliance introduces serious challenges related to data privacy, integrity, interoperability, and unauthorized access. Traditional centralized healthcare data management architectures are susceptible to single points of failure, cyberattacks, and restricted transparency. These limitations necessitate novel architectural paradigms that can ensure secure, verifiable, and patient-centric data handling.

Blockchain technology has emerged as a transformative solution to address these challenges by enabling decentralized and tamper-resistant systems. With its core attributes—immutability, transparency, and consensus-driven validation—blockchain can reinforce data trustworthiness and facilitate secure data sharing across distributed healthcare providers. A growing body of research has explored the integration of blockchain in healthcare, recognizing its potential to decentralize control, enhance interoperability, and safeguard sensitive clinical data [1], [2] Several works provide a foundation for understanding the structural and operational principles of blockchain. In [3], the authors presents a comprehensive overview of blockchain architecture, consensus algorithms, and anticipated evolution. Hölbl et al. [1] systematically reviewed the applicability of blockchain in healthcare, identifying both opportunities and technical limitations. Ismail et al. [4] proposed a lightweight blockchain framework tailored for healthcare environments, focusing on scalability and performance. Kakei et al. [5] explored distributed authentication infrastructures based on Hyperledger Fabric, showing potential for cross-institutional trust establishment.

Moreover, performance analysis of blockchain frameworks such as Hyperledger Fabric have shown that private blockchains can offer high throughput and low latency for medical data exchanges [6]. Khan et al. [7] discussed blockchain's synergy with the Internet of Things (IoT) and smart grid systems in healthcare. Rathi et al. [8] demonstrated the value of blockchain-enabled orchestrators for multi-domain edge computing, enabling secure data transactions at the network edge. Edited volumes such as that by Namasudra and Deka [9] further provide insights into real-world deployments, regulatory constraints, and future trends in blockchain-driven healthcare ecosystems. Despite this progress, challenges persist in effectively linking on-chain and off-chain data management. Storing complete medical files on-chain is impractical due to gas fees and blockchain size constraints. Consequently, hybrid models integrating blockchain with distributed file systems like the InterPlanetary File System (IPFS) are gaining attention [10]. These architectures allow for off-chain storage of large medical files while maintaining their integrity through on-chain hashes.

However, existing blockchain-based healthcare data management systems continue to face critical challenges, including high gas costs from on-chain storage, limited scalability when handling large datasets, and insufficient privacy-preserving mechanisms. These limitations restrict their practical adoption in real-world healthcare environments. To address these gaps, this study proposes a hybrid blockchain architecture that combines AES-256-GCM encryption, IPFS off-chain storage, and Merkle root anchoring on Ethereum, thereby ensuring strong

data confidentiality, verifiable integrity, and significant cost reduction while maintaining scalability.

This study proposes a hybrid blockchain-based framework that integrates Ethereum smart contracts and IPFS to create a secure, scalable, and tamper-resistant infrastructure for healthcare data management. Our main contributions are summarized as follows:

- A hybrid blockchain framework is proposed, where only Merkle roots of encrypted file batches are stored on-chain, achieving over 99% gas cost reduction compared to traditional methods.
- Patient records are encrypted using AES-256-GCM, ensuring data confidentiality, integrity, and secure off-chain storage.
- The system supports batch-wise Merkle tree construction and lightweight proof mechanisms, enabling scalable, high-throughput, and verifiable healthcare data management.

The remainder of this study is organized as follows: Section II reviews related work on blockchain-based healthcare data management and highlights existing challenges. Section III presents the proposed Hybrid Architecture, detailing the use of AES-256-GCM encryption, IPFS off-chain storage, Merkle Tree verification, and Ethereum smart contracts. Section IV discusses the experimental setup and performance evaluation, focusing on data security, scalability, and gas optimization. It provides a detailed discussion of the results, insights into parameter influence, and implications for practical healthcare deployment. Finally, Section V concludes the study by summarizing the contributions and outlining directions for future research.

II. Related Work

Blockchain technology has gained significant attention in healthcare for its potential to provide secure, tamper-proof data management. However, the inherent limitations in scalability pose ongoing challenges, particularly in high-volume environments, such as electronic health record (EHR) systems. Recent studies have proposed architectural enhancements and hybrid models to address these limitations.

Sadath et al. [11] introduced a hierarchical blockchain architecture tailored to healthcare, utilizing both local and global chains to minimize network congestion and improve transaction throughput. This model supports distributed data handling while preserving integrity, making it a viable solution for large-scale deployments. Similarly, Ali et al. [12] proposed a hybrid blockchain system augmented with deep learning techniques to prioritize transactions dynamically. Their model achieved improved responsiveness and reduced latency under high data loads without compromising security.

Mazlan et al. [13] provided a systematic review highlighting key scalability barriers, including throughput, latency, and interoperability. The authors discussed theoretical mitigation strategies such as Layer-2 solutions and sharding, but noted a lack of real-world implementations. In contrast, Jayabalan and Jeyanthi [14] presented a practical approach using IPFS for off-chain storage combined with on-chain metadata management, demonstrating measurable improvements in speed and scalability.

Security-focused frameworks have also shown indirect scalability benefits. Shamshad et al. [15] developed a blockchain-based EHR system with embedded access control via smart contracts. This reduced computational overhead on-chain and facilitated secure sharing. Further, Mazhar et al. [16] explored the convergence of blockchain, generative AI, and IoT in healthcare. Their study emphasized enhanced privacy, patient personalization, and interoperability, though challenges related to resource demands and decentralized storage remain.

Bathula et al. [17] conducted a comprehensive review of over 400 studies and concluded that blockchain–AI integration holds substantial promise for strengthening EHR reliability, supporting diagnostics, and managing pandemics. Collectively, the literature affirms that scalable blockchain solutions—especially those involving AI integration and off-chain data architectures—are central to building resilient, efficient, and secure healthcare infrastructures.

In the study by Taherdoost [18], the author explores the integration of blockchain technology within the healthcare sector, emphasizing its potential to enhance data privacy and security. The study provides a comprehensive overview of blockchain applications such as secure electronic health records (EHRs), patient consent management, and pharmaceutical supply chain tracking. It highlights key challenges including scalability, regulatory compliance, and interoperability with existing healthcare systems. Furthermore, the study discusses future research directions focused on improving the efficiency, adaptability, and ethical implementation of blockchain in healthcare. This work serves as a foundational reference for understanding both the opportunities and limitations of blockchain adoption in sensitive data environments like healthcare.

Kasyapa and Vanmathi [19] presents a thorough examination of blockchain integration in the healthcare domain, focusing on practical use cases, performance-related challenges, and corresponding mitigation strategies. Their investigation spans a variety of healthcare applications, including patient data management, clinical trials, and remote monitoring systems, where blockchain's decentralization and immutability offer clear benefits. The authors delve into performance bottlenecks such as latency, throughput, and energy consumption, and propose solutions involving lightweight consensus mechanisms and hybrid architectures. Their work not only showcases the transformative potential of blockchain in improving healthcare infrastructure but also provides critical insights into addressing technical and operational barriers for real-world deployment.

A comparative critique of notable blockchain-based healthcare frameworks is summarized in Table I. The table highlights the strengths and limitations of prior studies and clarifies how the proposed method advances beyond these works by integrating end-to-end encryption, scalable off-chain storage, and gas-efficient Merkle root anchoring.

III. Methodology

The proposed architecture for secure and scalable healthcare data management is structured into four sequential phases:

TABLE I. COMPARATIVE ANALYSIS OF HEALTHCARE BLOCKCHAIN FRAMEWORKS AND RELATION TO THE PROPOSED METHOD

Framework	Strengths	Weaknesses / Assumptions	Relation to Proposed Method
Sadath et al.[11]	Hierarchical chain reduces congestion; improves throughput.	Lacks end-to-end encryption; assumes scalability alone ensures privacy.	Employs AES-256-GCM encryption to ensure confidentiality while retaining scalability.
Matani et al.[20]	Batch-root commitments improve auditability and verification efficiency.	Limited scalability on large datasets; no off-chain optimization.	Uses batch-wise Merkle root anchoring with IPFS off-chain storage for scalable verification.
HealthBlock[21]	Strong decentralization and patient-centric control.	On-chain metadata storage increases gas cost and causes state bloat.	Achieves about 99.85% gas reduction by anchoring only Merkle roots on-chain.
MEDACCESSX[22]	Modular contracts improve flexibility for access control.	Complex contracts; confidentiality not guaranteed system-wide.	Maintains lightweight contract logic with strong encryption for end-to-end security.
AdaSec-Health[23]	Shard-level tuning enhances scalability.	Relies on tuning; encryption is partial or unclear.	Provides scalable hybrid storage with explicit AES-256-GCM protection.

Preprocessing, On-Chain storage, Off-Chain storage, and Verification & Decryption. Each component contributes to ensuring data confidentiality, integrity, and blockchain efficiency.The methodology involves the following key stages, as depicted in Fig. 1.

A. Dataset Preprocessing

The first stage of the proposed system involves preprocessing a structured healthcare dataset to prepare it for secure encryption, hashing, and metadata extraction. The dataset, typically stored in CSV format, contains fields such as patient_uid, PMID, file_path, title, patient, age, gender, and relevant_articles.

Table II presents representative entries from the raw dataset before preprocessing. The detailed preprocessing steps are outlined below.

1) Missing value handling: Records with null or incomplete values in critical fields (`patient_uid`, `age`, `gender`) are removed to ensure consistency and integrity throughout the encryption and verification pipeline.

2) Duplicate removal: Duplicate rows are identified and removed based on a composite key consisting of `patient_uid` and `PMID`, which uniquely represent each patient case and publication reference.

3) Age field normalization: The `age` field is often stored as a nested structure (e.g., `[[60.0, "year"]]`). A regular expression parser is used to extract the numeric value (e.g., 60) and convert it to an integer format for uniformity.

4) JSON conversion: Each row of the cleaned dataset is serialized into a standalone JSON object. These objects serve as the input to the encryption module and include metadata required for downstream file hashing and Merkle proof construction.

5) File organization: Each JSON record is saved as an individual file and assigned a filename based on its `patient_uid`. These files are stored in a staging directory for encryption and off-chain upload.

This preprocessing pipeline ensures the dataset is complete, uniquely identifiable, and structurally standardized before it enters the AES-256 encryption and Merkle tree computation stages.

B. On-Chain Processing

The on-chain component of the proposed system is responsible for storing cryptographic summaries (Merkle roots) of encrypted patient record batches to ensure tamperproof verification. The process is carried out using smart contracts deployed on the Ethereum Sepolia testnet and consists of the following steps:

1) Network connection: The system connects to the Ethereum Sepolia testnet using Infura as the remote Ethereum node provider. The Web3.py library is employed to facilitate interaction between the local Python environment and the blockchain network.

2) Smart contract integration: A pre-deployed smart contract, written in Solidity, is used to register and manage Merkle roots corresponding to batches of encrypted patient records. The contract contains methods for both storing and retrieving root values associated with batch identifiers. The smart contract behavior is formalized in Algorithm 1.

Algorithm 1 Merkle Root Commitment Smart Contract

State Variables:
  $owner$: Address of the contract deployer
  $roots$: Mapping from batch ID to Merkle root

Functions:
function CONSTRUCTOR
  $owner \leftarrow$ msg.sender
end function
function STOREMERKLEROOT(bID, $root$)
  if msg.sender $\neq owner$ **then**
    return `"Unauthorized"`
  end if
  if $roots[bID] \neq$ null **then**
    return `"Already submitted"`
  end if
  $roots[bID] \leftarrow root$
  Emit `MerkleRootStored`(bID, $root$, block.timestamp)
end function
function GETMERKLEROOT(bID)
  return $roots[bID]$
end function

3) Merkle root storage: For each batch of 1,000 encrypted files, a Merkle root is computed from their SHA-256 hashes.

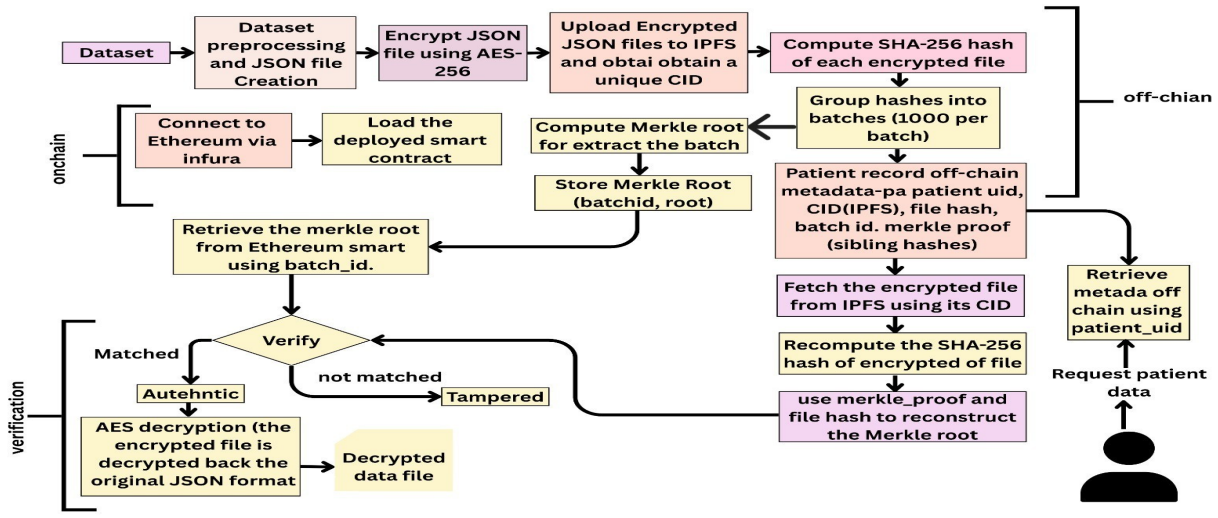

Fig. 1. System architecture of the proposed hybrid blockchain system.

TABLE II. SAMPLE INSTANCES FROM THE RAW PMC-PATIENTS DATASET

id	patient_uid	PMID	file_path	title	patient	age	gender	relevant_articles
0	7665777-1	33492400	comm/PMC...	Early Physic...	This 60-year	[[60.0, 'year']]	M	{'32320506':1, ...}
1	7665777-2	33492400	comm/PMC...	Early Physic...	A 39-year-c	[[39.0, 'year']]	M	{'32320506':1, ...}
2	7665777-3	33492400	comm/PMC...	Early Physic...	One week a	[[57.0, 'year']]	M	{'32320506':1, ...}
3	7665777-4	33492400	comm/PMC...	Early Physic...	This 69-year	[[69.0, 'year']]	M	{'32320506':1, ...}
4	7665777-5	33492400	comm/PMC...	Early Physic...	This 57-year	[[57.0, 'year']]	M	{'32320506':1, ...}

The root, along with a unique batch identifier, is then submitted to the blockchain using the smart contract function `storeMerkleRoot(batchId, root)`. This ensures immutability, auditability, and decentralized verification of the batch integrity.

C. Off-Chain Storage and IPFS Upload

The off-chain component handles encryption, decentralized file storage, hash computation, and metadata management. This process is organized into six key steps:

1) Encrypt patient JSON files: Each patient's data is serialized into JSON format and encrypted using AES-256-GCM [24], [25]. This encryption ensures both data confidentiality and integrity. The full procedure of encryption is presented in Algorithm 2.

2) Upload encrypted files to IPFS: The encrypted files are uploaded to the InterPlanetary File System (IPFS), a distributed storage network. The returned content identifier (CID) for each file is saved for future reference and verification.

3) Compute SHA-256 hash: The SHA-256 hash of each encrypted file is computed. These hashes act as the leaf nodes of the Merkle tree and serve as unique digital fingerprints of the file content.

4) Batch file hashes: File hashes are grouped into batches of 1,000 files per batch. Each batch is prepared independently for Merkle tree construction.

5) Build Merkle tree: For each batch, a Merkle tree is constructed using the SHA-256 hashes. The root of each tree is computed and serves as a compact, verifiable summary of the batch contents. The batched Merkle construction is detailed in Algorithm 3.

6) Store off-chain metadata: For each file, corresponding metadata including patient UID, CID, file hash, batch ID, and Merkle proof is compiled and stored in a structured CSV file. This metadata supports efficient file retrieval and integrity verification. To verify the integrity of any file, its SHA-256 hash is recomputed and used along with the Merkle proof to reconstruct the root hash. This reconstructed root is compared with the on-chain Merkle root associated with the batch. If the verification succeeds, the file is decrypted using the AES-256 key. This ensures that only authenticated, untampered files are accessed and utilized, thereby preserving both security and data reliability.The procedure of decryption is presented in Algorithm 4.

Algorithm 2 AES-256-GCM Encryption of Patient Records

Require: Patient record D; 256-bit AES key K; 12-byte nonce N
Ensure: Encrypted blob E containing $\{N,\ ciphertext,\ tag\}$
1: $plaintext \leftarrow \text{SERIALIZE}(D)$
2: $cipher \leftarrow \text{AESGCMINIT}(K, N)$
3: $(ciphertext, tag) \leftarrow \text{ENCRYPT}(cipher,\ plaintext)$
4: $E \leftarrow N \,\|\, ciphertext \,\|\, tag$
5: **return** E

Algorithm 3 Merkle Root Construction from Encrypted Files

Require: Encrypted files $F = \{f_1, \ldots, f_n\}$; batch size B
Ensure: Merkle roots $R = \{r_1, \ldots, r_k\}$
$H \leftarrow [\,]$ ▷ List of SHA-256 hashes
for each $f_i \in F$ **do**
  $h_i \leftarrow \textsc{Sha256}(f_i)$
  Append h_i to H
end for
Partition H into batches $\{B_j\}$ of size B; $R \leftarrow [\,]$
for each batch B_j **do**
  while $|B_j|$ is not a power of 2 **do**
    Append last(B_j) to B_j ▷ Pad with last hash
  end while
  while $|B_j| > 1$ **do**
    $L \leftarrow [\,]$
    for $k \leftarrow 1$ **to** $|B_j|$ **step** 2 **do**
      $p \leftarrow \textsc{Sha256}(B_j[k] \,\|\, B_j[k{+}1])$
      Append p to L
    end for
    $B_j \leftarrow L$
  end while
  Append $B_j[1]$ to R ▷ Merkle root for this batch
end forreturn R

Algorithm 4 AES-256-GCM Decryption of Patient Records

Require: Encrypted blob $E = N \,\|\, C \,\|\, T$; 256-bit key K; (optional) AAD A
Ensure: Decrypted patient record D
if $|E| < 28$ **then**
  return `Error: malformed input`
end if
$N \leftarrow E[0:12]$ ▷ 12-byte nonce
$T \leftarrow E[-16:]$ ▷ 16-byte tag
$C \leftarrow E[12:-16]$ ▷ ciphertext
$cipher \leftarrow \textsc{AesGcmInit}(K, N)$
if A provided **then**
  $\textsc{AesGcmUpdateAAD}(cipher, A)$
end if
$plaintext \leftarrow \textsc{DecryptAndVerify}(cipher, C, T)$
if verification fails **then**
  return `Error: authentication failed`
end if
$D \leftarrow \textsc{ParseJson}(plaintext)$
return D

IV. Results and Evaluation

This section presents the experimental setup, evaluation metrics, and performance analysis of the proposed hybrid blockchain architecture. The system is evaluated for gas efficiency, latency, throughput, scalability, and data security using real-world datasets.

A. Experimental Setup

The proposed framework was implemented using Python 3.x and deployed in Google Colab for off-chain processing. SHA-256 hashing and AES-256-GCM encryption were performed using the `hashlib` and `cryptography` libraries, respectively. IPFS Desktop and `go-ipfs` were used for decentralized file storage, while Web3.py and Infura were employed to interact with smart contracts on the Ethereum Sepolia testnet. Smart contracts were developed using Solidity and deployed via the Hardhat framework.

Experiments were conducted on a computing system equipped with an Intel(R) Core(TM) i7-4510U CPU operating at 2.00 GHz (with a turbo frequency of 2.60 GHz) and 6 GB of RAM, running on Windows 10 Pro (64-bit). The proposed hybrid blockchain architecture was implemented and evaluated using the Ethereum Sepolia testnet, accessed via the Infura gateway. Encryption of patient records was performed using the AES-256-GCM algorithm to ensure both data confidentiality and integrity. The experimental dataset consisted of 39,936 encrypted patient records in JSON format, which were processed and managed across the off-chain and on-chain components of the system.

B. Evaluation Metrics

The performance of the proposed system is evaluated using five core metrics: gas cost, latency, throughput, scalability, and data security. Two of these metrics—latency and gas consumption—are further analyzed mathematically to validate the framework's efficiency.

1) Latency modeling: The total system latency (L_{total}) is the cumulative delay incurred during data preprocessing, storage, and verification phases. The overall system latency (L_{total}) can be modeled as the sum of initiation, confirmation, and off-chain delays, as formulated in Eq. (1):

$$\begin{aligned} L_{\text{total}} = {} & (t_{\text{initiation}} + t_{\text{confirmation}}) \\ & + (t_{\text{IPFS_upload}} + t_{\text{IPFS_retrieval}}) \\ & + (t_{\text{hash_compute}} + t_{\text{hash_compare}}) \end{aligned} \tag{1}$$

where, $t_{\text{initiation}}$ and $t_{\text{confirmation}}$ represent the time taken for transaction submission and blockchain block confirmation, respectively. $t_{\text{IPFS_upload}}$ and $t_{\text{IPFS_retrieval}}$ correspond to the delays associated with decentralized storage operations in IPFS. Finally, $t_{\text{hash_compute}}$ and $t_{\text{hash_compare}}$ denote the time required for computing file hashes and verifying file integrity.

Empirical results show that blockchain transaction latency ($L_{\text{on-chain}}$) averages around 14.3 seconds, while IPFS upload and retrieval ($L_{\text{off-chain}}$) contribute an additional 2 to 4 seconds. As shown in Eq. (2), the overall system latency is modeled as the sum of on-chain and off-chain delays.

$$L_{\text{total}} \approx L_{\text{on-chain}} + L_{\text{off-chain}} \tag{2}$$

Thus, the total latency for the hybrid blockchain–IPFS framework is approximately in the range of 16 to 18 seconds, validating the framework's suitability for non-real-time healthcare applications.

2) Throughput modeling: Throughput (T_{system}) is defined as the rate at which encrypted patient records are processed, verified, and committed within the system. It is a critical performance metric that reflects the system's efficiency in handling large-scale healthcare datasets. As expressed in Eq. (3), the system throughput is defined as the ratio of the total number of records to the overall system latency.

$$T_{\text{system}} = \frac{N_{\text{records}}}{L_{\text{total}}} \tag{3}$$

where, N_{records} is the number of encrypted records in a given batch and L_{total} is the total latency (as defined in Equation 1) required to process and verify the batch.

3) Gas cost matrices: In blockchain-based systems, particularly those utilizing Ethereum smart contracts, the transaction execution cost is quantified through gas consumption. As shown in Eq. (4), the gas cost in Ethereum is determined by multiplying the gas used by the gas price.

$$\text{Gas Cost (ETH)} = \text{Gas Used} \times \text{Gas Price (ETH)} \quad (4)$$

where, Gas Used denotes the actual number of gas units consumed during transaction execution, and Gas Price (ETH) is the market price of one unit of gas, typically denominated in Gwei (where $1\,\text{Gwei} = 10^{-9}\,ETH$).As formulated in Eq. (5), the gas cost in USD is obtained by multiplying the gas cost in ETH with the current ETH price in USD.

$$\begin{aligned}\text{Gas Cost (USD)} = (&\text{Gas Used} \times \text{Gas Price (ETH)}) \\ &\times \text{ETH Price (USD)}\end{aligned} \quad (5)$$

C. Gas Cost Efficiency

In Ethereum-based smart contract systems, the cost of executing a transaction is determined by gas consumption. The proposed method significantly reduces gas costs by batching encrypted file hashes into Merkle trees and storing only the Merkle root on-chain. As defined in Eq. (6), the total gas consumption is obtained by multiplying the number of batches with the gas required per root.

$$G_{\text{total}} = N_{\text{batches}} \times G_{\text{per_root}} \quad (6)$$

where,

- $N_{\text{batches}} = 40$ is the number of file batches.
- $G_{\text{per_root}} = 30,000$ gas is the average gas consumed to store a single Merkle root on-chain.

Substituting into Eq. (6), the total gas cost becomes Eq. (7):

$$G_{\text{total}} = 40 \times 30{,}000 = 1{,}200{,}000 \text{ gas} \quad (7)$$

TAs shown in Eq. (8), the total gas consumption for processing all files individually is computed as:

$$\begin{aligned}G_{\text{individual}} &= N_{\text{files}} \times G_{\text{per_hash}} \\ &= 39,936 \times 20,000 \\ &= 798,720,000 \,\text{gas}\end{aligned} \quad (8)$$

Using this value, the gas savings ratio is then derived in Eq. (9) as:

$$\eta_{\text{gas}} = 1 - \frac{G_{\text{total}}}{G_{\text{individual}}} = 1 - \frac{1,200,000}{798,720,000} \approx 0.9985 \quad (9)$$

This demonstrates that the proposed system achieves a remarkable gas savings ratio of approximately 0.9985, which corresponds to a reduction of nearly 99.85% in gas cost compared to executing all transactions, individually.

D. Gas Cost Analysis in Ethereum

The following parameters:

- Total gas used to store 40 Merkle roots: $G_{\text{total}} = 1{,}200{,}000$ gas
- Gas price: 30 Gwei = 30×10^{-9} ETH
- ETH/USD exchange rate: \$3,000

The total ETH cost is computed as:

$$\begin{aligned}\text{Cost}_{\text{ETH}} &= 1{,}200{,}000 \times 30 \times 10^{-9} \\ &= 0.036\,\text{ETH}\end{aligned} \quad (10)$$

Then, converting to USD:

$$\text{Cost}_{\text{USD}} = 0.036 \times 3000 = \$108 \quad (11)$$

The total ETH cost is computed, as shown in Eq. (10), and then converted into USD using Eq. (11).

E. Latency Analysis

Fig. 2 illustrates the latency distribution across 40 batches of encrypted patient records during off-chain processing and on-chain Merkle root submission. Each batch consists of approximately 1,000 encrypted files. The measured latency includes file encryption, IPFS upload, SHA-256 hash computation, Merkle tree construction, and Ethereum transaction confirmation.

The latency across batches ranges from approximately 11.4 seconds to 28.1 seconds, with most batches falling within the 18 to 26 second interval. Variations are primarily attributed to network fluctuation during IPFS storage and Ethereum block confirmation delays. Notably, the final batch exhibits the lowest latency due to a reduced number of files.

This consistent and bounded latency behavior demonstrates the system's ability to maintain predictable performance while processing large-scale healthcare datasets, making it suitable for near real-time and secure health data workflows.

F. Throughput Performance

Throughput is defined as the number of encrypted patient records processed per second, including encryption, IPFS upload, Merkle tree construction, and Merkle root submission. Fig. 3 illustrates the throughput achieved across 40 batches of encrypted files, each consisting of approximately 1,000 records.

As shown, throughput ranges from approximately 36 to 74 files per second, depending on batch size, system load, and network conditions. Batches with fewer files (e.g., Batch 40) naturally exhibit higher throughput due to reduced processing

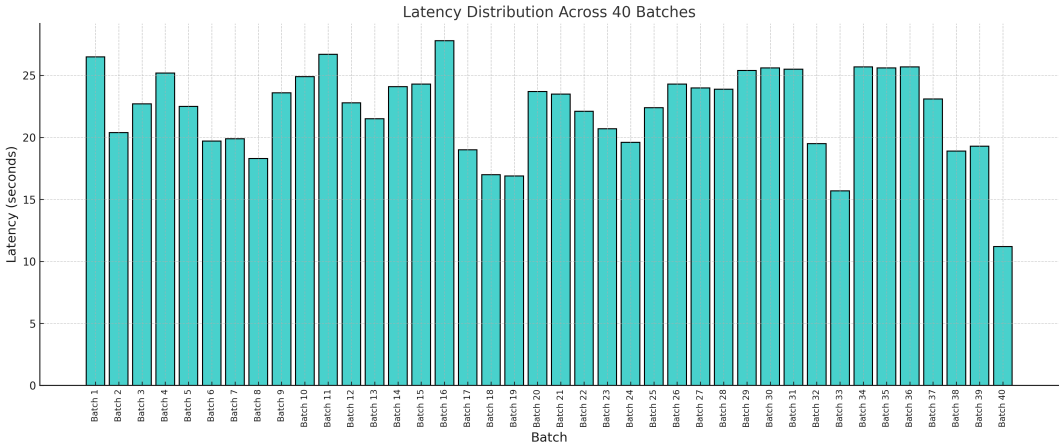

Fig. 2. Latency distribution for 40 batches of encrypted patient records.

time. The consistent throughput across most batches reflects the stability of the proposed system under typical workloads and validates its ability to handle large volumes of healthcare data efficiently.

G. Off-Chain Scalability Analysis

To evaluate the system's scalability in terms of storage distribution, the off-chain encrypted files were grouped into 40 batches of approximately 1,000 files each. Fig. 4 illustrates the estimated storage size per batch in megabytes (MB).

As shown, most batches maintain a consistent size of approximately 194 to 195 MB, demonstrating balanced storage allocation and predictable performance. The final batch, containing fewer files, exhibits a slightly lower size, validating the linear scaling behavior of the proposed system. This confirms that batch-based off-chain file management is both scalable and storage-efficient for large-scale healthcare datasets.

H. Security Assurance

AES-256-GCM encryption provided confidentiality and integrity through its built-in authentication tag. In conjunction with Merkle proof-based integrity verification, the system offers a secure mechanism for handling sensitive healthcare data in decentralized environments.

I. Comparative Analysis with Prior Works

Table III presents a comparative analysis of the proposed hybrid blockchain system against three recent healthcare blockchain frameworks: HealthBlock [21], Sadath et al. [11], and Matani et al. [20]. The comparison focuses on ten key criteria, including storage architecture, on-chain data strategy, encryption, scalability, and verification methodology.

Unlike existing models that either store full metadata on-chain or rely on non-scalable storage mechanisms, the proposed system leverages off-chain IPFS storage and stores only 40 Merkle roots on-chain—one for each batch of 1,000 encrypted patient records. This significantly reduces on-chain data bloat while preserving verifiability through Merkle proofs. The use of AES-256 encryption further ensures end-to-end confidentiality and integrity, which is either partially implemented or entirely missing in the compared systems.

In terms of scalability, the proposed framework supports high-volume batch uploads and demonstrates high data scalability. It adopts a public Ethereum testnet (Sepolia), offering better decentralization and accessibility compared to permissioned or hybrid networks like Fabric and sharded blockchains. Furthermore, it incorporates a robust security model combining AES encryption, Merkle proof, and access control lists (ACLs), making it well-suited for large-scale, privacy-sensitive healthcare environments.

J. Comparative Results Across Datasets

The differences observed in comparative results across datasets can be attributed to the architectural limitations of existing frameworks. Approaches such as Sadath et al.[11] and Matani et al.[20] perform adequately on smaller datasets but exhibit reduced scalability at higher volumes due to limited batching and lack of off-chain storage. HealthBlock emphasizes decentralization but incurs significant gas costs from on-chain metadata storage, which becomes inefficient as data size grows. In contrast, the proposed method consistently maintains scalability and efficiency across datasets by integrating AES-256-GCM encryption, IPFS off-chain storage, and batch-wise Merkle root anchoring. These design choices make the algorithms particularly well-suited for structured and semi-structured healthcare data, including electronic health records, demographic information, prescriptions, and transaction logs. For unstructured or multimedia data such as medical imaging or continuous IoT sensor streams, additional preprocessing into metadata or compact representations is necessary, as direct storage may increase retrieval latency.

1) Latency comparison with existing methods: Fig. 5 presents a comparative latency analysis between the proposed method and three existing blockchain-based healthcare frameworks: Matani et al. [20], Sadath et al. [11], and HealthBlock [21]. The x-axis represents the number of transactions, while the y-axis shows latency in seconds.

The proposed method consistently demonstrates the lowest latency across all transaction scales (1,000 to 6,000), ranging

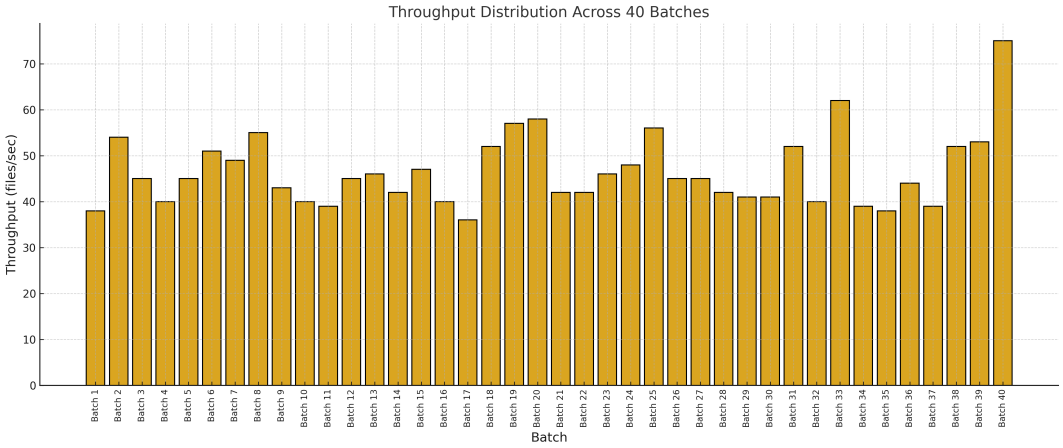

Fig. 3. Throughput distribution across 40 batches, expressed in files per second.

TABLE III. COMPARATIVE ANALYSIS OF THE PROPOSED HYBRID BLOCKCHAIN SYSTEM AGAINST PRIOR WORKS

Criteria	Proposed System	HealthBlock [21]	Sadath et al. [11]	Matani et al. [20]
Storage	IPFS Remote (∼180 MB/batch)	OrbitDB + IPFS	CouchDB	Shard-distributed
On-Chain Data	40 Merkle Roots	Per-file metadata	Batch root	Per-level TX hashes
Hashing	SHA-256	SHA-256	SHA-256	SHA-256
Merkle Tree	Yes (40 roots)	No	No	Used in scoring phase
Encryption	AES-256	Partial (OrbitDB/IPFS)	No encryption	No encryption
Batch Uploads	1,000 per batch	No	Yes	Implied via sharding
Blockchain Type	Public (Ethereum Sepolia)	Private (Fabric)	Private (Fabric)	Hybrid Sharded
Verification Type	Merkle proof	Log traceability	Proof of computation	Hash-linked consensus
Data Scalability	High	Low	Medium	Medium
Security Model	AES + Merkle + ACL	N/A	Metadata only	Hierarchical + scoring

TABLE IV. COMPARATIVE ANALYSIS OF GAS COST AND ARCHITECTURE: PROPOSED SYSTEM AGAINST PRIOR WORK

Criteria	Proposed System	MEDACCESSX [22]	AdaSec-Health [23]
Blockchain Type	Public (Ethereum Sepolia)	Private Ethereum Testnet	Public (Ethereum EIP-1559)
Storage Strategy	Off-chain IPFS + Merkle Root anchoring	On-chain smart contracts for access + data metadata	IPFS + ECOA-optimized shard blockchain
On-Chain Data	40 Merkle Roots for 39,936 files	User, access, data, and policy contracts (UMC, ACC, etc.)	Dynamic block/meta parameters via ECOA
Gas Optimization Method	Merkle batching, minimal on-chain state	Modular contracts but fixed logic	Shard tuning: validation degree, block size, interval
Total Gas Used	1.2M gas for 39,936 files	3.1M gas for deployment (all contracts)	Avg. marginal cost = 0.47 gas units per transaction
Gas Cost in USD	$108 @ 30 Gwei, $3K/ETH	$154.65 (same rate)	Not directly priced, implied savings
Gas Savings (%)	99.85% vs. per-file storage	Not explicitly reported	Reported via performance gains under ECOA
Smart Contract Complexity	Minimal (root commit/retrieve only)	High (RBAC, ABAC logic, events)	Medium to high (governance, consensus, voting)
Batch Handling	1,000 per batch	Per access/role	Per 4-block shard optimization
Security Model	AES-256-GCM + Merkle + ACL	Access logs on-chain + ABAC/RBAC	ECOA-based scoring + CP-ABE + reputation
Scalability Focus	Gas-efficient IPFS and Merkle design	Functional control granularity	Adaptive shard configuration for forks/delay

from 1.8 to 3.2 seconds. This efficiency is attributed to the use of Merkle root batching, AES-256-GCM encryption, and lightweight on-chain commitment. In contrast, the methods by Matani et al.[20] and Sadath et al.[11] exhibit significantly higher and more variable latency, primarily due to per-transaction or per-batch on-chain data handling without

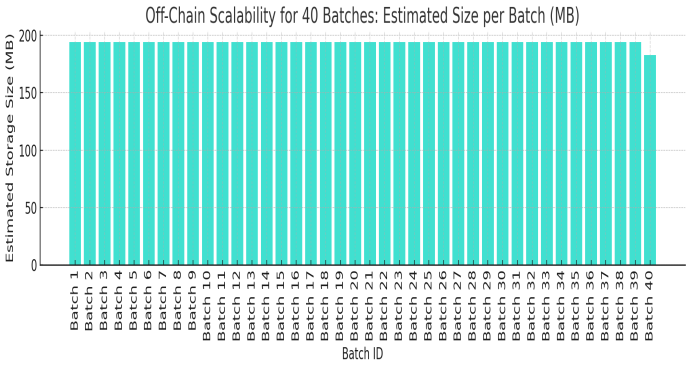

Fig. 4. Off-chain scalability analysis: estimated file size distribution across 40 batches.

optimized batching. HealthBlock performs moderately but lacks Merkle-based verification and full encryption, leading to comparatively higher overhead.

This result confirms that the proposed system is well-suited for secure healthcare applications where low-latency processing is essential for real-time or near-real-time interactions.

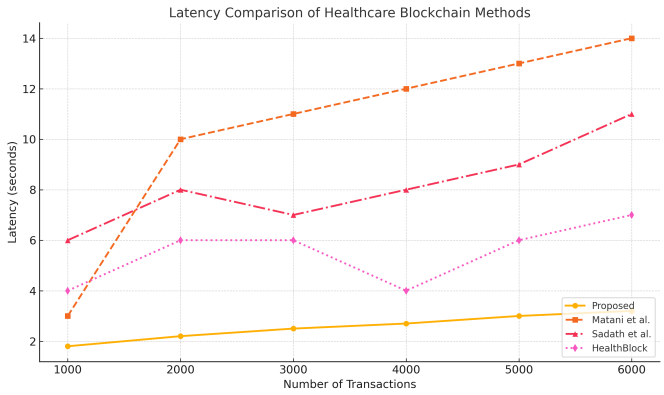

Fig. 5. Latency comparison of the proposed hybrid blockchain system with existing methods across increasing transaction volumes.

2) Throughput comparison with prior methods: Fig. 6 illustrates the throughput performance of the proposed method compared to existing blockchain-based healthcare systems developed by Matani et al. [20], Sadath et al. [11], and HealthBlock [21]. Throughput is measured as the number of transactions successfully processed per second across increasing transaction volumes.

The proposed method demonstrates superior scalability, with throughput values rising linearly from approximately 560 to over 1,850 transactions per second, as the number of transactions increases from 1,000 to 6,000. This is attributed to the efficient batch processing design, lightweight Merkle root anchoring, and minimal on-chain data overhead. In contrast, existing approaches such as Matani et al. and Sadath et al. show relatively static or non-linear throughput behavior due to more extensive on-chain storage and lack of optimization in data handling.

HealthBlock performs moderately well but exhibits inconsistent throughput beyond 4,000 transactions. The consistent and scalable performance of the proposed system confirms its suitability for high-throughput healthcare data environments.

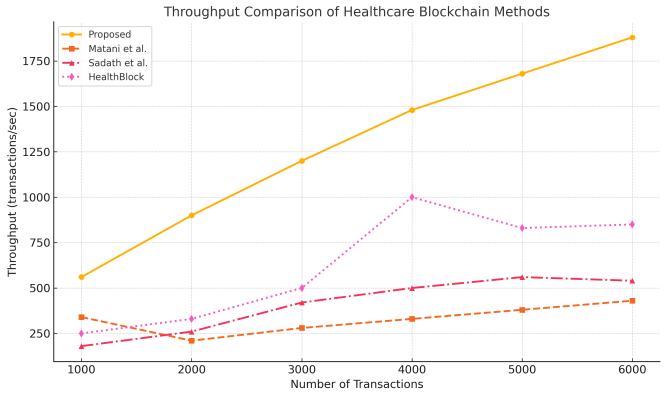

Fig. 6. Throughput comparison of the proposed system with existing methods under varying transaction volumes.

3) Gas cost comparison with prior healthcare blockchain frameworks: Table IV provides a detailed comparative analysis of the proposed hybrid blockchain system against two notable healthcare blockchain frameworks—MEDACCESSX and AdaSec-Health. The evaluation focuses on gas optimization techniques, contract architecture, batch processing strategy, and scalability models.

K. Influence of Parameters

The influence of algorithmic parameters has been systematically examined to highlight their role in the performance of the proposed architecture. The batch size has a direct impact on gas optimization: larger batches significantly reduce transaction costs by minimizing the number of on-chain commitments, although they may introduce a slight increase in latency during Merkle root computation. The AES-256-GCM encryption parameters ensure robust data security while imposing only negligible overhead on processing time, making them suitable for large-scale deployments. In contrast, IPFS upload and retrieval times contribute substantially to off-chain latency, as formalized in Eq. (1) and Eq. (2). The gas price in the Ethereum network strongly influences the overall deployment cost; however, the batching mechanism employed in this study demonstrates resilience against network congestion and fluctuating gas conditions. Finally, the Merkle tree depth, inherently determined by batch size, affects proof generation and verification complexity. Collectively, these observations underscore the necessity of careful parameter tuning to achieve a balanced trade-off among scalability, security, and efficiency in real-world healthcare data management scenarios.

V. Conclusion

The findings demonstrate that the proposed hybrid blockchain framework achieves a practical balance between privacy preservation, scalability, and cost efficiency in healthcare data management. By integrating AES-256-GCM encryption, IPFS-based off-chain storage, and Merkle root anchoring on Ethereum, the system ensures end-to-end confidentiality and

verifiable integrity while reducing gas consumption by nearly 99.85% compared to conventional on-chain storage.

An important observation is that off-chain operations—particularly IPFS upload and retrieval—dominate overall system latency. This suggests that optimizing distributed storage through improved node configurations, caching strategies, or integration with Layer-2 storage solutions may yield greater performance benefits than adjusting blockchain parameters alone.

In comparison with existing healthcare blockchain frameworks, the proposed design introduces novelty by simultaneously ensuring confidentiality, integrity, and scalability in a cost-effective manner. This positions the framework as a practical and viable solution for strengthening trust, security, and reliability in digital healthcare ecosystems.

Future work will extend this study by deploying the framework in real-world blockchain environments, integrating decentralized identity mechanisms for stronger patient-centric control, and implementing adaptive access control for secure multi-stakeholder sharing. Additional directions include exploring Layer-2 scalability enhancements, supporting unstructured healthcare data such as medical imaging and IoT streams, and enabling cross-chain interoperability to facilitate secure record exchange across healthcare institutions.

***Abstract*—The increasing use of advanced technologies with artificial intelligence in our daily lives has become an urgent necessity to facilitate tasks in a fluid and simple way, which leads to the generation of huge amounts of data. This data comes from various sources: media, social networks, connected objects., online transactions, and smart devices, among other sources. These data are generally organized into three categories: structured, unstructured, and semi-structured. This data is therefore called Big Data. This data is characterized by its enormous size and fast flow, as well as by the diversity of its sources. The importance of data lies in its ability to provide future perspectives and improve the decision-making process. To get the most out of this data, it must be stored and processed, but current technologies face many challenges and are often insufficient to cope with the huge amounts of data generated. It is necessary to look for advanced and highly efficient technologies, capable of storing the entirety of the data and processing it faster. We can also rely on artificial intelligence to help improve the use of storage and processing resources by compressing data or deleting excess data, thus saving storage space. This study discusses various approaches for optimizing Big Data processing, such as the use of AI compression techniques, the PSNR-SSIM method, and many others. The compression ratio for these algorithms is around 90%. With these technologies, it is possible to optimize the use of storage space, ensuring efficient and optimized management.**

***Keywords*—Artificial intelligence; big data; optimization; resource; storage**

I. Introduction

Big data has become the most widely used term in our digital world, particularly with the advent of the fifth generation and the use and reliance on machine learning and the Internet of Things. The Big Data industry is growing so fast that, according to a report by IDC (International Data Corporation), by 2025, around 30% of all data will be generated in real-time. According to the same entity, with around 150 billion connected devices worldwide in 2025, most of them will generate data in real-time, according to IDC. The global data domain is expected to grow from 23 zettabytes (ZB) in 2017 to 175 zettabytes (ZB) in 2025.

Today, numerous studies highlight the need to develop advanced and robust storage systems to effectively manage Big Data on a large scale [1]. Scalability considerations include reliability and availability as key technology design objectives for Big Data storage [2]. For this reason, these technologies have been designed to handle huge amounts of data, with their diverse sources and diversities, at high processing speeds.

Storage systems include Hadoop, NOSQL, Cloud Computing, NEWSQL and Data Lake. What sets these technologies apart is their ability to scale by adding more nodes to the cluster, as well as their ability to use a distributed file system across multiple machines for Hadoop. NoSQL databases also offer great flexibility for various data models (key-value, document, column, graph), enabling non-relational data to be managed with high performance. Cloud computing is also distinguished by its ability to adapt to demand, increasing storage capacity as needed, while offering rapid access to this massive data. Each technology has the capacity to store and process huge quantities of data.

Despite the power of these technologies, they also pose significant challenges, particularly with the growing sophistication of data flows. These challenges include the rapid growth of Big Data, the high cost of storage, real-time processing, data retention policies, and data duplication.

These challenges include the rapid growth of Big Data, the high storage cost, real-time processing, data retention policies and data duplication. All these challenges have led to the need to look for innovative solutions that can store and process all this data in real-time without consuming significant resources. Among these solutions are emerging technologies such as quantum storage, DNA data storage and holographic storage, a major revolution in the data storage industry, but at present, they are not the ideal solution, especially as most of them are still in the development phase. experimental framework and will not be accessible to everyone, as they will have high costs and complex management.

The best solution remains to work on developing and improving current technologies by enhancing the storage capacity of certain technologies to accelerate the pace of fast and immediate storage and processing, as well as integrating artificial intelligence into storage management frameworks for resource-constrained systems. This enables efficient storage utilization and improves system performance. AI-based solutions can be applied to improve resource utilization and system performance, in particular, their ability to learn and make decisions. The main objective of this study is to present techniques for optimizing Big Data.

This study proposes four techniques for optimizing storage, two of which are based on artificial intelligence (multi-agent systems and K-means clustering), batch processing, and other approaches based on statistical indicators. The objective of this project is to examine the effectiveness of these techniques on real data stored in MongoDB databases, focusing on four key aspects of the storage process: compression time, final size, access time, and CPU and RAM usage. Our findings highlight the strengths and weaknesses of each method and offer specific guidance for optimizing the efficiency, performance, and sustainability of storage in Big Data systems.

This study is organized as follows: In Section II, we

provide an overview of the concept of Big Data along with the available technologies for its management and storage. Section III introduces some of the problems faced by data, especially at the storage level. Section IV describes our simulation methodology and the environment in which it operates. Section V details the role of AI for optimization. In Section VI, we present and discuss our simulation results. Finally, Section VII concludes this work and outlines future work possibilities.

II. Related Works

To improve dynamic storage management [7] this paper outlines different approaches for improving storage management to facilitate communication between AI agents in decentralized systems. It provides a multilayer communication environment that allows AI agents to dynamically identify communication needs to improve communication speed and efficiency. Decentralized storage systems are also compared in the paper and their performance is evaluated with regard to the efficiency of data storage, retrieval, and transfer between AI agents. This study aims to improve the scalability and interoperability of AI systems in decentralized environments by focusing on reducing communication delays.

In this paper [11], the authors present a model for improving data storage in smart grids, using an improved simulated annealing algorithm. This model aims to solve the problems of longitudinal and horizontal penetration between multi-level data centers in the information transmission networks of smart grids. A comparison of mathematical algorithms is also presented in the paper, based on the context of optimizing data storage in the Smart Grid. The aim is to evaluate the effectiveness of these algorithms in managing resources in a distributed computing system and to determine which algorithm offers superior performance in terms of task processing speed and efficient resource allocation.

In article [17], a method is examined for improving distributed storage using multi-agent systems. Its aim is to tackle the challenges of distributed storage, such as resource optimization and data management in a fragmented environment. To solve these problems, this method relies on multi-agent systems in which each agent manages a part of the overall task. The aim is to optimize storage efficiency while reducing costs and access times, minimizing obstacles, and improving overall system performance.

This article [21] presents a secure and efficient method for storing and managing data, using an intelligent optimization algorithm (IOA-DSAM). Images are divided into several parts, then encrypted using homomorphic encryption (HE). The improved fruit fly optimization algorithm (MFFO) improves encryption key generation. Once the shares have been received, they are decrypted and reconstructed. In this article, the author presents the various stages of the suggested model, such as share generation, the image encryption model and the more efficient key generation process. It also presents experimental results that compare the performance of the IOA-DSAM algorithm with other models. The results of the article offering better performance, thus proving its effectiveness for securing and managing images in a digital environment. The article concludes that this technique improves data security while offering optimized storage management.

In [25], a deep learning-based framework for storage management was proposed. This solution offers the ability to dynamically adjust key system parameters, such as cache size and queue depth. This method leads to performance improvements in terms of transfer rate, latency, and CPU utilization. However, this method focuses on optimizing system configurations without considering other crucial aspects such as compression, size, reads, and CPU/RAM. Furthermore, it does not address comparisons with other technologies and solutions. In the same context, in this article [13], particularly with regard to storage technologies, the author proposes a multi-agent approach to classify data as “hot” and “cold” in an HDFS cluster. He uses the classification to adapt redundancy and compression, with the aim of optimizing resource utilization. However, this method is confined to a specific Hadoop framework and does not systematically evaluate performance. Most research focuses on a single criterion, such as access time, system configuration, or a specific method, without adopting a comprehensive multi-criteria approach, leaving a gap in the literature on storage optimization. Furthermore, there is little research that systematically compares AI methods with conventional techniques in a practical application setting. Furthermore, validation often focuses on specific environments or technologies (such as HD file systems or system caches), which limits the ability to generalize. Our contribution offers a fair comparative study of four techniques, judged on four main axes, contributing to a more balanced and useful analysis of storage optimization.

III. Challenges in Big Data Storage

Data storage issues - The high cost of data storage and retention: Many companies have invested billions of dollars in data center development to build out the infrastructure elements of Big Data, due to the high cost of data storage and retention. In recent years, Amazon has invested $35 billion in AWS data centers in one region alone [14]. In the context of the Internet of Things, or with the fifth generation, the accumulation of information emitted by sensors generated by devices can quickly lead to data processing problems, especially as the available storage space is limited. This can lead to the loss of data or the deletion of readings, restricting data storage and monitoring capacity, and making data analysis extremely complex.

Data management and processing: The set of operations involved in metadata processing includes the collection, storage, cleansing, and management of huge quantities of data, whether in different forms or from different sources. Data ingestion into a data lake or streaming processing engine is one of the steps involved in Big Data processing. Although advanced data collection and processing mechanisms are available, there are certain obstacles, such as the lack of sufficiently advanced techniques or tools to extract and process data efficiently in real-time or close to real-time. There is still a lack of fast, efficient processing in current solutions. there is also a concern about data integration, as it is difficult to merge data from different sources and formats. Particularly given the complexity of processing algorithms, which require constant adjustments and improvements, especially when it comes to variations in formats and structures, resulting in prolonged integration times. It is also worth mentioning the importance of

data consistency. A major problem during processing. Errors or inconsistencies can occur when updating data.

Data privacy and security: Numerous studies have explored the existence of numerous personal information breaches and data security vulnerabilities in Big Data environments. Hence the urgent need for real-time security measures. The study [16] highlights the complex nature of data security in the Big Data landscape while recognizing the need for innovative solutions that go beyond traditional security models. Delving deeper into data protection, it becomes clear that data security in Big Data is a multifaceted challenge that requires a deep understanding of the unique attributes of large datasets. As organizations continue to harness the power of Big Data, data control is a major challenge in addressing the security issues inherent in this transformative era [15]. Data protection is essential in the broader context of information management because information is sensitive. Rigorous and vigilant security measures are essential to prevent unauthorized access, data breaches, and misuse. This involves the application of specific information laws, which encourage the judicious use of data without touching or divulging personal or confidential information. Strong security systems and protocols are essential.

IV. Optimization Technique

Optimization is the process of making something, such as a system or process, more effective and efficient. By implementing strategies and techniques to optimize storage, we can reduce storage costs and improve data processing capabilities. Big Data storage management refers to the process of storing, structuring, and managing large quantities of data to facilitate retrieval and analysis. There are several techniques for managing and improving Big Data storage [9]. As illustrated in Fig. 1 below, here are the key methods for optimizing data storage in the context of Big Data:

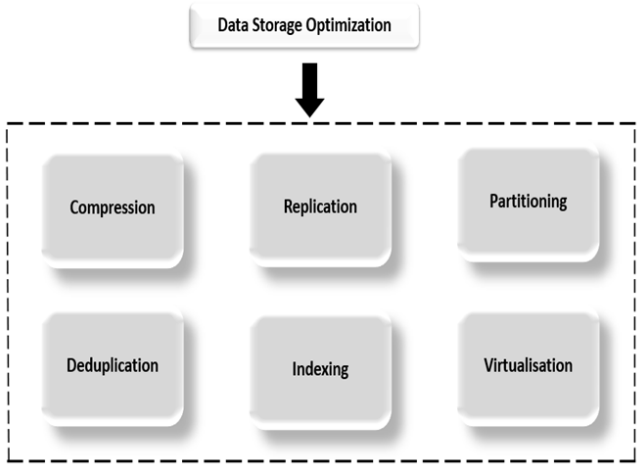

Fig. 1. Data storage optimization.

1) Compression: The compression process, among the most effective methods of optimizing data storage, is the use of coding to avoid data storage and transmission, which facilitates data transmission [18], restructuring, and other modifications to reduce the size of digital data files without altering their essential characteristics. The main aim of compression is to reduce the number of bits needed to code the data while reducing the memory required to store the data [19]. Compression can be divided into two categories: lossless and lossy. Lossless compression preserves the original data. While lossy compression reduces the original data size by compromising certain details. It permanently eliminates unnecessary bits. Although this only removes irrelevant information, it may result in the loss of some information due to compression. Lossy compression is often used for multimedia files such as audio, images, graphics, and video.

2) Replication: In a distributed environment, replication is frequently used to store multiple copies of the same data in different locations on multiple servers. When data is needed, it is retrieved from the nearest copy, thus avoiding delays and improving system performance [20]. Data replication offers the advantage of accelerating data access, reducing access times, and improving data availability. Replication is frequently used in distributed databases, cloud storage systems, and networks to improve consumer response speed and ensure service continuity.

3) Partitioning: A partitioning model is one of the most common methods used to optimize storage, and consists mainly of dividing a large dataset into smaller parts for easier handling, making it easier to manage large quantities of data and control their arrangement on disks. Each partition contains a part of the data, and these parts are usually spread over several servers or systems. These partitions are generally scattered over different database tables and contain their subset of data. It is possible to consider each partition as an independent database, but they are always part of the same logical database. Data partitioning can be achieved in several different ways. These include horizontal and vertical partitioning. The former is often used for the table mechanism. All partitions contain a separate part of the rows of a set of information. In a database, for example, records can be divided into partitions according to a specific range of values. In terms of vertical division, these partitions group together various subsets of columns. This is the opposite of horizontal division. All other types of partitioning are used to improve performance, whether for operations, aggregations or fast filters. In addition, they enable data to be distributed across several servers, enabling parallel processing and improving performance and utilization of computing resources.

4) Deduplication: Deduplication eliminates redundant data [22], to reduce the amount of data stored in a Big Data environment. Storage and storage optimization remain major challenges, especially with the exponential growth of data. After checking the data on the storage system, deduplication is used to increase and optimize storage space. As redundant data is written to storage, the deduplication process begins to be identified and eliminated. Duplicate data is identified, deleted, and replaced by a pointer to the first iteration of the data block. Deduplication also used the block verification technique, after dividing the data into blocks. A comparison is made between each block and other blocks already stored in the storage technologies to detect duplicates. With this method, users can separate specific workloads and quickly retrieve the updated backup, thus improving data storage efficiency.

5) Virtualization: Optimization through virtualization involves the creation of virtual structures for Big Data systems,

such as servers, storage, or networks. Data virtualization can offer platforms that exploit all the information they collect to achieve different objectives. Data virtualization is a data management method that enables an application to retrieve and manipulate information without the need for technical details about the data, such as its source format or physical location [23]. About storage, it offers the possibility of adding more physical resources to a more flexible storage space, facilitating the dynamic localization of data. It improves efficiency by optimizing the use of resources and space. Virtualization makes storage and retrieval tasks simpler, further optimizing the storage infrastructure.

V. Role of AI for Optimization

While confronting the challenges of storage management methods in resource-constrained systems, there is an urgent need to look for more dynamic and fluid solutions. One such solution is artificial intelligence, which can store data intelligently, classify and label it, and retrieve it quickly and easily. The study establishes the fundamental concepts of Big Data and machine learning, highlighting their interrelationships. It then examines the various ways in which Big Data improves machine learning algorithms, such as by improving data diversity, which promotes better generalization and reduces overlearning. In addition, Big Data uses artificial intelligence to obtain more precise information.

Artificial intelligence (AI) is a technology based on large databases and multiple algorithms, enabling the rapid discovery of new cultural systems and the creation of cognitive maps through data collection, data mining, and resource integration [6]. Simply put, AI aims to simulate human cognitive functions. AI represents a broad branch of computer science that seeks to create intelligent machines capable of performing tasks that usually require human intelligence [5]. Artificial intelligence plays a crucial role in storage and resource optimization. It enables machine-learning algorithms to reduce data duplication, remove redundancy, compress data, and load-balance to ensure optimal use of storage resources and dynamically compress information [7]. Analyzing historical data makes it possible to predict resource allocation and forecast future requirements. Artificial intelligence manages distributed storage environments, ensuring optimum use of resources. Finally, artificial intelligence simplifies data collection and resource allocation according to priorities and access patterns.

There are four technologies, illustrated in Fig. 2, which we will examine in this section.

1) Machine learning: is one of those technologies that has had a lot of success. To keep up with the expansion of the machine learning sector, some of the things that influence it, such as infrastructure and technical capabilities, also need to be increased [4]. Machine Learning is a branch of AI that enables machines to learn without the need for programming. Machine Learning is associated with Big Data, as it deals with data. Machine learning algorithms can be trained on datasets to spot patterns, relationships, and trends. In the field of storage management, machine learning algorithms can be trained on historical access patterns to predict future data requirements, identify the most efficient compression techniques for particular data types, and adjust real-time caching and retrieval strategies to suit system conditions [8].

2) Deep Learning (DL): is a branch of artificial intelligence that draws on the workings of the nervous system of living beings to solve more complex problems [24]. Deep learning algorithms process different types of information in a similar way to the way our neural networks react to the neural signals assigned to them. Deep learning is one of the recently recognized methods for storing and intelligently managing huge amounts of data. Thanks to deep learning, it operates on sophisticated models. Information can be reduced by identifying and eliminating repetitions, while preserving its reliability and quality.

In addition to optimizing the use of storage resources using deep learning algorithms, it is possible to optimize input/output (I/O) processing, thereby reducing access and disk access times. In addition, the use of neural networks to identify patterns and repetitions in data enables high-performance compression without compromising quality, thus optimizing the storage space used [25]. Deep learning reduces costs and optimizes the performance of Big Data management systems. This is particularly beneficial in a situation where the volume of data produced and collected continues to grow, requiring sophisticated, intelligent storage solutions.

3) Reinforcement learning: is an artificial intelligence technique that reproduces the human learning process to achieve its objectives. The learning paradigm used in RL is based on the ability of agents to make decisions by interacting with a context. The rewards or penalties the agent receives enable it to adapt its actions over time. This information-based method can be used to make dynamic storage choices in response to the changing requirements of Big Data systems. Several aspects of RL focus on optimizing Big Data management, including adaptive data positioning and real-time traffic management [3]. RL offers the possibility of dynamically adapting the choice of storage nodes based on available capacities and network conditions. This method is able to balance the load between servers and increase network throughput by adopting adaptive choices for each stage. RL is also used to improve the dynamic positioning of information in various storage strata, based on access patterns and the specific characteristics of the data, such as its temperature and input frequency, among other criteria [10]. The aim of this method is to optimize system performance by reducing processing time and resource expenditure.

4) A Multi-Agent System (MAS): is a distributed structure made up of various autonomous, intelligent software entities, referred to as agents. Agents interact with each other by transmitting information, and then collaborate with other agents to complete complex tasks. The decentralized approach of multi-agent systems (MAS) optimizes Big Data storage. Each agent, possessing learning skills, is able to make independent decisions regarding the management and processing of information. Coordination enables actors to optimize the use of storage resources by harmonizing workloads and dynamically modifying management policies in response to disparities between demand and resource availability.

As a key result, multi-agents facilitate the optimal distribution of data across multiple storage points, increase access speed and reduce throughput thanks to information compression and deduplication methods. Artificial intelligence enables these players to set up a decentralized structure and

distributed storage [7-25] to exchange information efficiently with each other. This ensures immediate access to information. Agents are also able to adjust their procedures based on client and system performance, with the aim of selecting the most sophisticated technology for their underlying storage devices and ensure astute information management with the SMA monitor, which enables Data files to be accessed and classified as hot or cold [17]. Agents also have the ability to optimize storage system operation by optimizing replication and reacting to changes in data usage. This will reduce floor space and optimize resource utilization, while maintaining the right balance between efficiency and protection.

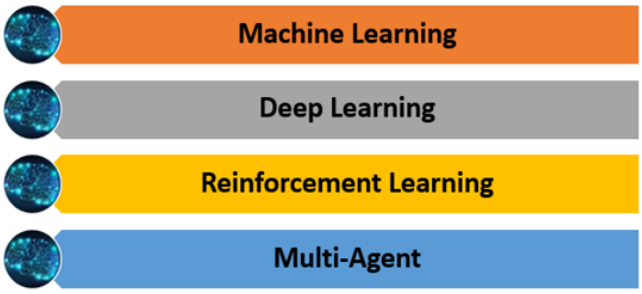

Fig. 2. AI-Driven techniques for big data storage optimization.

VI. Study of Methods and Results

There are four main stages in the Big Data management process, one of which is storage. One of the main challenges in Big Data is storage. They perform efficient, fluid storage of various forms of data while ensuring that fast access and real-time processing performance are maintained. It is essential to have an infrastructure and systems capable of storing and retrieving data rapidly without requiring considerable storage space. In this section, we look at the different optimization models used to improve Big Data storage, which achieved the best results based on four criteria (compressed size, compression time, read time, and average resources).

The data was chosen from the group of plant images, with a size of 900 MB. This is a specific unstructured data, which is considered as a type of Big Data. NoSQL databases were selected to store the data. MongoDB, a technology that manages data in the form of documents, offers a perfect solution for storing image-type data. It provides a distributed file system specially designed for MongoDB, called GridFS, specifically designed to store and retrieve image files. The storage optimization process is divided into three stages, as shown in Fig. 3:

When selecting the optimization algorithm, four algorithms are available. Two of these are based on the intelligent approach, namely multi-agent and K-means. The other algorithm is based on compression using batch processing and the PSNR-SSIM method. Phases 2 and 3 involve implementing the principles of the algorithms to improve storage in MongoDB technology.

The first method, entitled Smart Optimization and Batch Processing, is an algorithm that uses hybrid JPEG compression first, followed by gzip and batch processing. Its aim is to

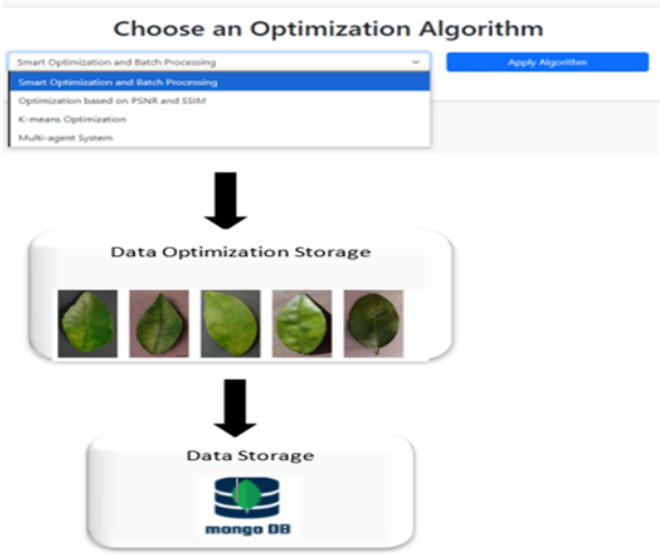

Fig. 3. Process architecture storage optimization.

divide images into several groups rather than processing them individually or all at once, thus effectively reducing image size and managing large numbers of images without overloading memory.

The second algorithms also use compression, but this time the PSNR-SSIM metric is used. As we know, pixels are small squares that represent the image. Digital image analysis is the specialty of uniform-density image processing. The image pixel matrix is two-dimensional. The numerical values of these pixels vary between 0 and 255. Color images are encoded on 3 RGB channels (red, green, and blue), with an integer ranging from 0 to 255 for each channel. To assess the quality of an image after compression, the PSNR-SSIM principle combines two metrics: the first PSNR measure evaluates the signal-to-noise ratio. It is measured in decibels (dB). The quality of the compressed image is improved as the PSNR value increases, while SSIM evaluates the structural conformity between the original image and the compressed image. Often, an SSIM greater than 0.85 is perceived as satisfactory quality for visual images.

Each time images are compressed; the process starts by calculating the PSNR and SSIM values between the original and compressed images, as soon as PSNR exceeds 30 dB and SSIM exceeds 0.85. The process is complete when all 70,000 data images have been processed. There are also two intelligence-based methods: unsupervised K-means and multi-agent.

The third K-means method is based on minimizing the number of colors present in the image and allows datasets to be grouped into K distinct clusters, based on a color grouping based on the specified number of clusters. Each group corresponds to a group of similar images. The K-means algorithm converts images into a single dimension and then groups them into K clusters based on the specified number of clusters. Each cluster corresponds to a group of similar images, and the distance between each image and the center of its cluster is minimized. Clustering aims to group similar images

together for optimal processing and compression. Once the images have been grouped, each group is processed separately.

The multi-agent approach is the fourth method. This method implements autonomous agents that work together to perform tasks related to data compression and optimization management in a big data context. We employed three agents. Each agent has his or her own responsibilities. The first agent is responsible for applying random compression levels to images that are run on a regular basis. When activated, this agent compresses an image and sends the compressed file to the second agent. In this way, compressed files are received and saved in MongoDB GridFS. The role of the third agent is to supervise and monitor system performance. All these autonomous agents are defined to perform specific tasks in a coordinated way at different compression levels to reduce image size.

The four suggested algorithms were grouped and presented as diagrams. During the optimization process, the performance of the algorithms was evaluated in terms of size, compression time, read time, RAM usage, and CPU consumption.

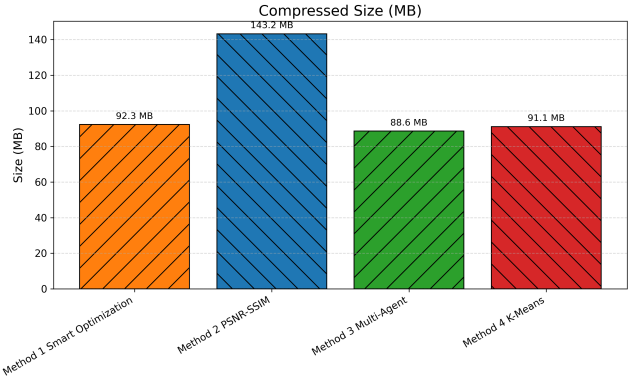

Fig. 4. Compressed size for all 4 methods.

Following the optimization of the four techniques, the results are illustrated in Fig. 4. This figure summarizes the graphs corresponding to the four techniques: Each instance produced a file size significantly smaller than that of the initial file. Technique 2 produced a 140 MB document, with a compression ratio of approximately 84.44%. This indicates that compression reduced the data size by 84.44%. The other methods, SMA and K-means, performed best (88.6 MB and 91.6 MB), achieving a compression rate of approximately 91%. In contrast, PSNR-SSIM produced a larger compression size (143.2 MB), thus reducing its effectiveness in contexts where storage space is critical. The results of the four methods indicate highly effective compression, with a higher compression index. Thus, our multi-criteria study indicates that examining compressed size alone is not sufficient to judge a method; it must be combined with other parameters such as the time required for compression, the time required for reading, and resource utilization in order to make a rigorous choice in the context of Big Data.

The time required to compress the data was considered as a second criterion, and the image data was correctly compressed and stored by the storage system. However, according to Fig. 5, the two artificial intelligence algorithms achieved a

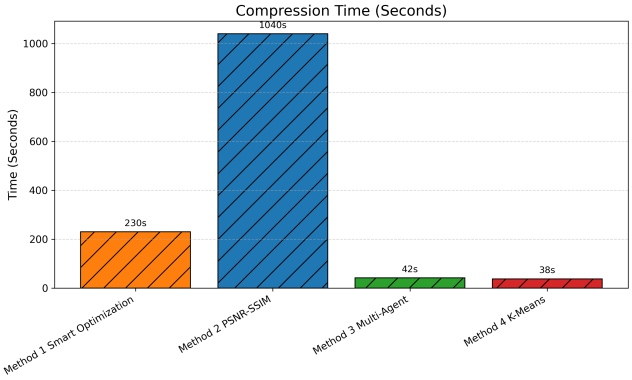

Fig. 5. Compression time for all 4 methods.

compression time of 31 and 26 seconds, respectively, for multi-agent method 3 and K-means method 4. It is observed that the AI-based methods require little time to compress the data, while the other methods require more time. Methods 3 and 4 demonstrate considerably higher processing efficiency.

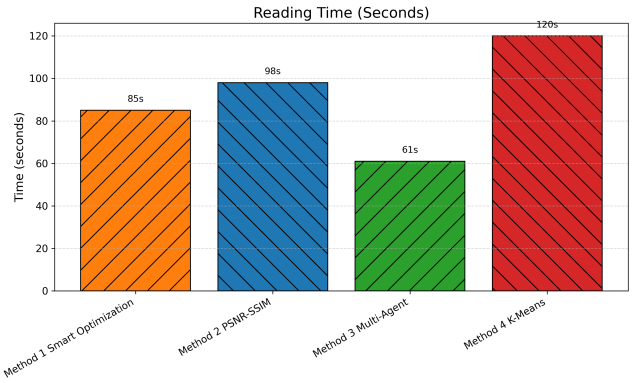

Fig. 6. Reading time for all methods.

The third criterion evaluated in this study was data reading time (see Fig. 6). For all four methods, reading time ranked well against traditional methods. However, there is one method that scored well for data reading, namely the multi-agent method. This method required just 60 seconds to read compressed data from MongoDB (GridFS file management system). This compares favorably with other techniques, which are more time-consuming to varying degrees.

The execution time analysis reveals that the SMA technique is fast, making it a suitable option for contexts, where regular access to data is essential. The Smart-Optimization technique, which takes 85 seconds, offers a satisfactory balance between performance and flexibility. However, although the K-means method offers remarkable compression performance, it suffers from a major drawback in terms of read time, which is 120 seconds. The PSNR-SSIM technique, with an average time of 98 seconds, is average but less efficient than the SMA method.

In Fig. 7, resource performance was evaluated and two comparisons were made for the four methods. The illustration compares CPU and RAM usage for four optimization techniques. Intelligent optimization and PSNR-SSIM require

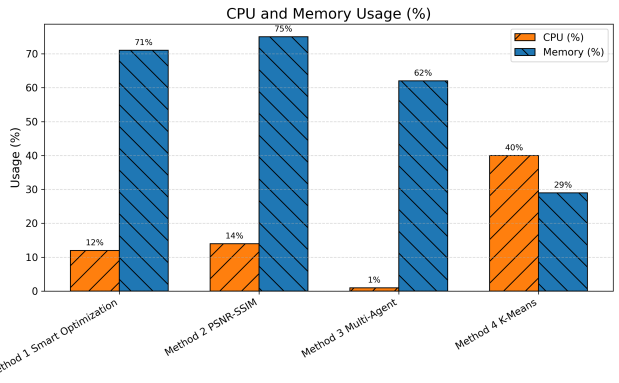

Fig. 7. CPU and RAM usage for all methods.

a lot of memory (70%), but little CPU (14%). Multi-Agent uses only 0.4% of the CPU while utilizing 62% of the RAM, demonstrating optimal task allocation. On the other hand, K-means uses a powerful CPU (40%) while consuming little memory (29%). According to these results, multi-agent is efficient for handling low CPU loads, while K-Means is better suited to computationally-intensive systems.The analytical findings indicate that the selection of the compression method is based not only on performance criteria such as time, size, and readability, but also on the available hardware configuration. This is essential for a multi-criteria evaluation that takes resource constraints into account.

This study aims to highlight methods that can improve storage efficiency in the context of Big Data, which were the subject of this study because of the results obtained. All four algorithms showed high performance in comparison with the identified criteria (compressed size - compression time - read time - average CPU, RAM), although AI-based algorithms have an advantage. Other compression algorithms such as RLE (Run-Length Encoding) and Huffman were used to test these techniques, as were the mathematical algorithms such as PSO and Simulated Annealing. However, the results obtained did not match the algorithms presented in this report, particularly about compressed size and compression ratio, which were high, and temporal compression, which was higher.

Our multi-criteria evaluation offers added value by demonstrating that examining a single indicator (such as compression time) is not sufficient to judge the suitability of a storage method. Thus, this research helps to inform practical decisions regarding the storage and management of Big Data.

VII. Conclusion

One of the biggest challenges on a global scale is how to handle the constant flow of big data. This study discusses some of the key methods used to improve data storage, such as compression, duplication, deduplication, segmentation, and virtualization, with particular consideration given to the challenges associated with contemporary storage technologies. These methods form the basis for contemporary solutions, but they remain insufficient without the incorporation of artificial intelligence and its performance and resource requirements. To overcome these constraints, we have suggested a comparative analysis of four approaches designed to address the challenges associated with data storage and management. All of these methods are based on the principle of storage optimization, which consists of maximizing capacity through algorithms designed to improve the use of storage resources. We propose two techniques based on artificial intelligence (multi-agent systems and K-means clustering), as well as two other approaches, PSNR-SSIM and smart storage optimization. These techniques were implemented on a real dataset consisting of images. The performance of the four algorithms compared to established benchmarks was high, although the algorithms based on artificial intelligence had a slight advantage. These results have several implications. Scientifically speaking, these algorithms are all based on the principle of storage optimization, which aims to improve capacity through algorithms designed to maximize the use of storage resources. The application of storage optimization methods in image databases has proven effective in terms of storage size and processing speed. Once decompressed, the data retains its quality without any loss of information, highlighting the power and efficiency of the algorithms. This research could reveal promising new prospects. Future advances include cutting-edge intelligent algorithms and the incorporation of other innovative methods such as deep learning, reinforcement learning, and quantum optimization. These algorithms can handle various types of data of varying sizes, thanks to a better understanding of information and how it is used. They also facilitate informed decision-making regarding data management and storage, compression, and rapid insertion in an optimization context. This improves the efficiency of existing systems while reducing storage costs, particularly when integrating an intelligent structure into an intelligent environment to develop and optimize storage in the era of big data.

YOLOv8s-Swin: Enhanced Tomato Ripeness Detection for Smart Agriculture

Jalal Uddin Md Akbar, Syafiq Fauzi Kamarulzaman*
Faculty of Computing, Universiti Malaysia Pahang Al-Sultan Abdullah
Pekan, 26600, Pahang, Malaysia

***Abstract*—Accurate object detection and classification are paramount in precision agriculture for assessing ripeness stages and optimizing yield, particularly for high-value crops like tomatoes. Traditional manual inspection methods are laborious, time-consuming, and error-prone. Furthermore, existing deep learning models often struggle with real-world agricultural challenges such as varying lighting, occlusions from foliage or other fruits, and dense clustering of small objects. To address these limitations and enhance tomato production efficiency and quality in diverse agricultural conditions, this study introduces YOLOv8s-Swin, an advanced object detection model. YOLOv8s-Swin integrates the powerful YOLOv8s architecture with a Swin Transformer module (C3STR) to capture global and local contextual information, crucial for robust small object detection. It also incorporates Focus, Depthwise Convolution (DWconv), Spatial Pyramid Pooling with Contextual Spatial Pyramid Convolution (SPPCSPC), and C2 modules for preserving fine details, reducing computational overhead, enhancing multi-scale feature fusion, and improving high-level semantic feature extraction, respectively. The Wise Intersection over Union (WIoU) loss function is adopted to enhance localization and address convergence issues. Evaluated on a comprehensive tomato image dataset, YOLOv8s-Swin demonstrated superior performance with a mean Average Precision (mAP@0.5) of 88.3%, precision of 84.4%, recall of 79.9%, and an F1-Score of 0.821. This significantly surpasses the base YOLOv8s (84.7% mAP@0.5, 0.795 F1-Score) and other models like Faster R-CNN, SSD, YOLOv4, YOLOv5s, and YOLOv7, all under identical conditions. Maintaining a competitive inference speed of 166.67 FPS, YOLOv8s-Swin offers a robust and efficient solution for AI-driven crop management and sustainable food production.**

***Keywords*—Agricultural automation; attention mechanism; computer vision; smart agriculture; object detection; YOLO; swin transformer**

I. Introduction

The agricultural sector is undergoing a profound transformation driven by advancements in computer vision (CV) and deep learning algorithms. Accurate object detection, a key facet of CV, plays a pivotal role in modern precision agriculture, enabling automated tasks such as crop variety identification and ripeness assessment. For high-value crops like tomatoes, optimizing yield and quality within dynamic agricultural environments necessitates precise and timely detection and classification of their ripeness levels [1]. Traditional manual inspection methods are laborious, time-consuming, and error-prone. Convolutional Neural Networks (CNNs) have spearheaded significant progress in this domain, providing robust solutions for extracting hierarchical visual features from images [2]. Among the prominent deep learning architectures, the You Only Look Once (YOLO) series has revolutionized object detection by achieving remarkable speed and accuracy in a single forward pass [3]. Each iteration of the YOLO architecture strives to push the boundaries of both computational efficiency and detection performance. This study focuses on leveraging and enhancing the YOLOv8 architecture, known for its balance of speed and precision, particularly in detecting smaller objects [4].

Despite the efficacy of current deep learning models, challenges persist in real-world agricultural settings. Factors such as varying lighting conditions, occlusions from foliage or other fruits, and dense clustering can significantly impact detection accuracy [5]. Small objects, in particular, often lack sufficient semantic information due to limited pixels, making their accurate detection difficult [6]. To address these challenges, researchers have increasingly explored the integration of attention mechanisms and advanced architectural components into object detection models. Attention mechanisms allow models to selectively focus on the most relevant features in an image, improving feature representation and reducing the influence of irrelevant background noise [7], [8].

Inspired by the success of transformer-based architectures in capturing long-range dependencies and global contextual information in natural language processing and, more recently, in computer vision [9], this study proposes YOLOv8s-Swin, an enhanced object detection model for tomato ripeness detection in smart agriculture. Previous versions of YOLO, including YOLOv4 and YOLOv5s, have shown strong performance in object detection but face significant challenges when it comes to detecting small, occluded, or densely clustered objects in complex environments [25]. These models often struggle with contextual awareness, which is critical for distinguishing between closely packed fruits or handling occlusions from foliage. While YOLOv8s introduced improvements in detection speed and accuracy, particularly for small object detection, it still shares similar limitations to its predecessors. The base YOLOv8s model's focus on local feature extraction and its relatively shallow architectural layers hinder its ability to capture broader contextual information needed for accurate detection in agricultural environments [26]. The model's performance drops when faced with the dense clustering of tomatoes or partial occlusions by other fruits or leaves. To address these issues, YOLOv8s-Swin integrates the Swin Transformer module, which allows for better capture of both local and global context through its self-attention mechanism. This integration, along with additional architectural improvements such as the Focus, Depthwise Convolution (DWconv), SPPCSPC, and C2 modules, enhances the model's ability to handle small and occluded objects while improving feature extraction, computational efficiency, and multi-scale feature

fusion. Thus, YOLOv8s-Swin overcomes the limitations of the base YOLOv8s model, providing a more robust and efficient solution for detecting tomatoes at various ripeness stages under diverse agricultural conditions.

The primary contributions of this study are:

- Development of YOLOv8s-Swin, an enhanced architecture for robust tomato ripeness detection. This model integrates the Swin Transformer (C3STR), Focus, DWconv, SPPCSPC, C2 modules, and the WIoU loss function, optimizing feature extraction and localization for challenging agricultural scenes.
- Demonstration of superior performance in classifying tomato ripeness across diverse agricultural conditions. YOLOv8s-Swin achieved an 88.3% mAP@0.5, significantly outperforming the base YOLOv8s (84.7%) and other models, effectively handling occlusions and lighting variations.
- Achieving high accuracy while maintaining real-time inference capabilities. With an FPS of 166.67, YOLOv8s-Swin offers a practical and efficient solution for AI-driven crop management and sustainable food production.

The remainder of this study is organized as follows: Section II provides a comprehensive review of relevant literature on object detection, with a focus on advanced architectures. Section III details the materials and methods used, including data acquisition, preprocessing, and the architectural specifics of the proposed YOLOv8s-Swin model, as well as the experimental setup. Section IV presents and discusses the quantitative and qualitative results, including a comparative analysis with baseline models. Finally, Section V concludes the study by summarizing key findings and outlining directions for future research.

II. Related Work

Object detection has been a cornerstone of computer vision for decades. Early approaches, such as two-stage detectors like R-CNN [10], Fast R-CNN [11], and Faster R-CNN [12], achieved high accuracy by first generating region proposals and then classifying and refining them. While accurate, these methods often struggled with real-time applications due to their computational intensity.

The advent of one-stage detectors, notably the YOLO (You Only Look Once) series, marked a significant shift by performing object localization and classification in a single forward pass, dramatically increasing detection speed [3]. Subsequent YOLO versions, including YOLOv2 [13], YOLOv3 [14], YOLOv5 [15], YOLOv7 [16], and YOLOv8 [4], have continuously pushed the boundaries of speed and accuracy, making them highly suitable for real-time applications. YOLOv8, in particular, introduced advancements in its backbone network and decoupled heads, enhancing its performance, especially for smaller objects.

Small object detection remains a challenging problem due to the limited pixel information available for feature extraction and the lack of sufficient contextual background [6], [27]. To address this, various strategies have been proposed. Attention mechanisms have also gained prominence, allowing models to focus on important features and suppress irrelevant ones, thereby improving representation [7], [8]. Channel attention (e.g., Squeeze-and-Excitation Networks [17]) and spatial attention (e.g., Convolutional Block Attention Module (CBAM) [18]) are widely used variants. Recent works, such as those by Chien et al. [19] and Najihah Muhamad Zamri et al. [20], have demonstrated the benefits of integrating attention mechanisms into YOLO models for improved detection in various applications.

The introduction of Transformer architectures, initially successful in natural language processing, has significantly impacted computer vision. The Swin Transformer [9] is particularly relevant for its hierarchical vision transformer using shifted windows, enabling it to capture global and local contextual information efficiently while maintaining computational feasibility[28]. This makes it a strong candidate for enhancing object detection models, especially for challenging scenarios like small object detection in complex environments. Shi et al. [6] successfully integrated a Swin Transformer module into a YOLOv8 network (STF-YOLO) for small object detection of tea buds, demonstrating significant improvements in accuracy.

In the context of crop ripeness detection, several studies have leveraged YOLO-based models. Li et al. [21] used YOLOv5 for tomato maturity detection in greenhouses, achieving high precision but facing potential limitations in outdoor conditions. Li et al. [22] proposed MHSA-YOLOv8 for tomato grading and counting, which performed well in complex environments but struggled with severe occlusion. Lightweight approaches like those by Zeng et al. [23] and Su et al. [24] emphasized real-time performance but sometimes faltered with dense small targets. While these studies show the promise of YOLO in agriculture, the specific challenges of dense fruit clusters, occlusions, and varied lighting in tomato detection within smart agriculture, combined with the need for robust small object detection, highlight the necessity for further architectural enhancements. Our proposed YOLOv8s-Swin aims to bridge this gap by combining the strengths of YOLOv8s with the contextual awareness of the Swin Transformer and other efficient modules to improve tomato ripeness detection.

III. Materials and Methods

This section details the proposed YOLOv8s-Swin model, its integration of key components, and the comprehensive methodological workflow for enhanced tomato ripeness detection in smart agriculture.

A. Data Acquisition

For this research, the Laboro Tomato dataset (https://github.com/laboroai/LaboroTomato) was utilized. This dataset contains images of tomatoes at three ripeness stages (fully-ripened, half-ripened, and green), reflecting diverse agricultural conditions and camera variations. As shown in Fig. 1, fully ripened tomatoes exhibit >90% red, half-ripened 30-89% red, and green 0-30% red coloration, crucial for accurate ripeness classification.

B. Data Pre-processing and Preparation

Raw images underwent rigorous preprocessing: auto-orientation, uniform resizing to 640×640 pixels, class modification (see Table I), and null annotation filtering. The dataset was split into training (92%, 2001 images), validation (4%, 86 images), and test (4%, 87 images) sets. Extensive data augmentation via Roboflow (see Fig. 2) was applied, including random flips, rotations, shears, blur, and noise, to simulate diverse agricultural conditions and enhance generalization.

TABLE I. REMAPPING OF ORIGINAL CLASSES TO SIMPLIFIED CLASSES IN THE DATASET

Original Class	Override	Included
b_fully_ripened	fully_ripened	Yes
b_green	green	Yes
b_half_ripened	half_ripened	Yes
l_fully_ripened	fully_ripened	Yes
l_green	green	Yes
l_half_ripened	half_ripened	Yes

Fig. 1. Dataset class.

C. Proposed Method: YOLOv8s-Swin Architecture

YOLOv8s-Swin is an advanced object detection architecture building on YOLOv8s, integrating a Swin Transformer module and other components. This enhances focus and contextual information capture, improving accuracy for small and occluded objects. The architecture follows a typical Backbone, Neck, and Head structure, with modifications to feature processing (see Fig. 3).

1) Swin Transformer Module (C3STR): The core innovation is the C3STR module (see Fig. 4), a Swin Transformer integration that mitigates feature loss in deep networks by establishing global dependencies via self-attention [9]. Integrated into the YOLOv8s backbone and neck, C3STR enhances semantic information and representation for small objects. It comprises Window/Shifted Window Multi-Headed Self-Attention (W-MSA/SW-MSA) and Multi-Layer Perceptron (MLP) with internal residual connections. Its self-attention mechanism is:

$$\text{Attention}(Q, K, V) = \text{SoftMax}\left(\frac{QK^T}{\sqrt{d}} + B\right)V \quad (1)$$

C3STR controls computations within local windows, enabling cross-window information interaction while reducing complexity, allowing adaptive feature interaction and capturing crucial contextual information.

2) Additional Modules: Focus, DWconv, SPPCSPC, and C2: To optimize YOLOv8s-Swin, efficient modules are incorporated:

- Focus Module: Placed at the input, it increases channel dimensions while reducing spatial ones, preserving fine details for small objects.
- Depthwise Convolution (DWconv): Performs independent channel convolutions, reducing parameters and computation while maintaining high performance.
- Spatial Pyramid Pooling with Contextual Spatial Pyramid Convolution (SPPCSPC): Captures multi-scale feature information efficiently via pooling and convolution.
- C2 Module: A refined C3 version for enhanced high-level semantic feature extraction with improved memory and inference speed.

These modules, integrated into the YOLOv8s backbone and neck, enable accurate tomato ripeness detection in complex agricultural conditions.

3) Loss Function (WIoU): To address YOLOv8's convergence issues and enhance localization, the Wise Intersection over Union (WIoU) loss function is adopted. Unlike traditional IoU, WIoU considers positional relationships and geometric factors, mitigating the negative impact of low-quality examples and reducing centroid distance emphasis for well-overlapping frames. The WIoUv1 model's calculation is:

$$L_{WIOU \cdot wl} = R_{WIoU} L_{IOU} \quad (2)$$

$$R_{WIoU} = \exp\left(\frac{(x - x_{gl})^2 + (y - y_{gl})^2}{(W_g^2 + H_g^2)^*}\right) \quad (3)$$

$$L_{IOU} = 1 - IOU = 1 - \frac{W_i H_i}{S_u} \quad (4)$$

Here, $R_{\text{WIoU}} \in [1, e)$ amplifies L_{IoU} for normal anchor frames but reduces it for high-quality ones, focusing learning

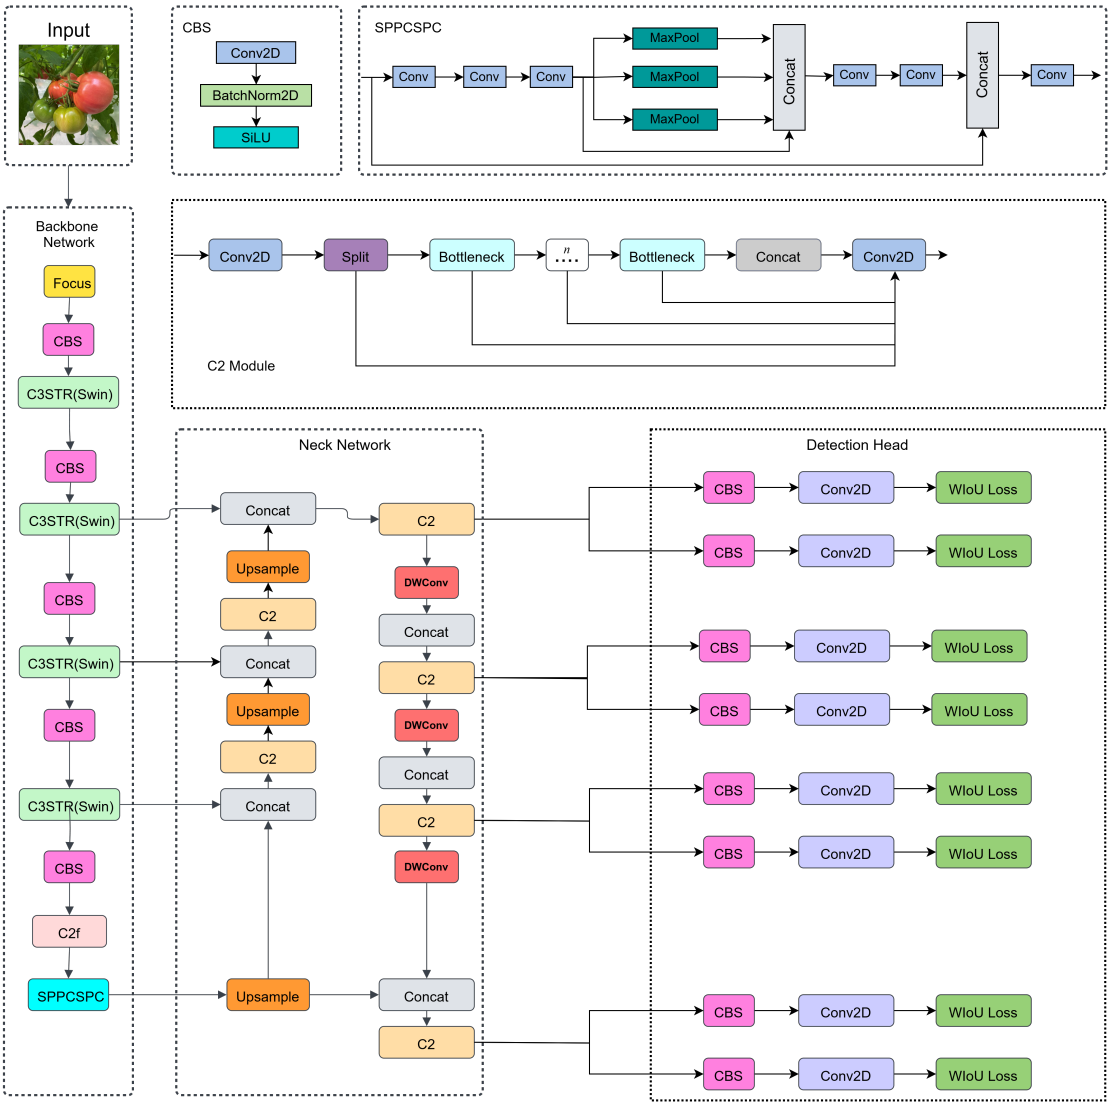

Fig. 3. The architecture of YOLOv8s-Swin for tomato ripeness detection.

on better examples for improved generalization and stability. S_u is the union area.

D. Experimental Setup

Experiments were conducted on an NVIDIA GeForce RTX 3060 GPU (16 GB VRAM) with an AMD Ryzen 5 processor, running Ubuntu 24.04 LTS and PyTorch 2.3.0. Training used 640×640 pixel images with a batch size of 8. Key hyperparameters included: 150 epochs, initial learning rate of 0.01, momentum 0.937, weight decay 0.0005, and data augmentation parameters (mixup 0.15, copy paste 0.3).

IV. Results and Discussion

A. Evaluation Metrics

The performance of the YOLOv8s-Swin model for tomato ripeness detection was quantitatively assessed using several standard object detection metrics:

1) Precision (P): The proportion of correctly identified positive samples among all detected positives. The precision metric is calculated using the following formula:

$$\text{Precision} = \frac{TP}{TP + FP} \tag{5}$$

In this context, TP refers to true positives, representing instances that were correctly identified as positive. Conversely, FP refers to false positives, which are instances incorrectly classified as positive. Attaining a higher precision value signifies a reduction in false alarms within the detection process, leading to a more reliable model.

2) Recall (R): The ratio of correctly identified positive samples to the total number of actual positive samples. The recall metric is defined mathematically as:

$$\text{Recall} = \frac{TP}{TP + FN} \tag{6}$$

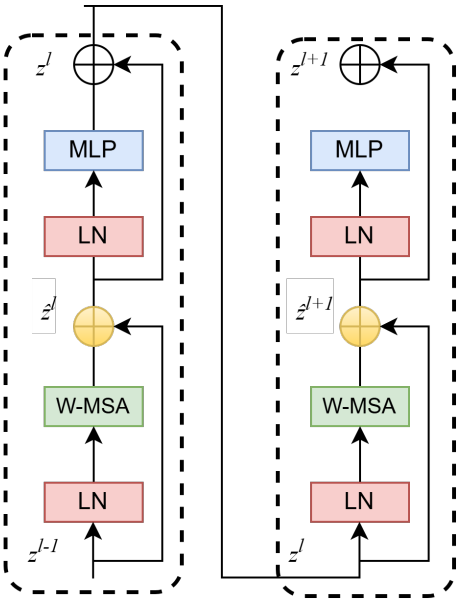

Fig. 4. C3STR architecture diagram.

Here, TP corresponds to true positives, referring to correctly identified positive cases. FN, on the other hand, stands for false negatives, which are genuine positive instances that the model overlooked. Achieving a higher recall value indicates a reduction in missed relevant instances, thereby ensuring a more complete detection capability.

3) mAP (mean average precision): Calculated at an Intersection over Union (IoU) threshold of 0.5 (mAP@0.5) and also across multiple IoU thresholds from 0.5 to 0.95 (mAP@0.5:0.95). It represents the average of the Average Precision (AP) for all classes, derived from the area under the precision-recall curve.

4) F1-Score: The harmonic mean of precision and recall, providing a balanced measure of the model's accuracy.

5) FPS (Frames Per Second): Measures the number of images the model can process per second at a batch size of 1, indicating the model's detection speed.

B. Performance of YOLOv8s-Swin

The proposed YOLOv8s-Swin model was rigorously evaluated on the Laboro Tomato dataset, encompassing fully ripe, partially ripe, and unripe tomatoes in diverse agricultural environments. The model demonstrated strong performance across all evaluation metrics, showcasing its effectiveness in accurately detecting and classifying tomato ripeness stages.

Our YOLOv8s-Swin model achieved an impressive mAP@0.5 of 88.3%, a precision of 84.4%, and a recall of 79.9%. The F1-Score for the model was 0.821. For individual classes, the precision-recall curve (see Fig. 5) highlights mAP@0.5 values of 0.893 for 'fully_ripened', 0.882 for 'green', and 0.873 for 'half_ripened' tomatoes, indicating consistent performance across ripeness stages. The F1-Confidence Curve (see Fig. 6) shows an optimal F1-Score of 0.84 for all classes at a confidence threshold of 0.456.

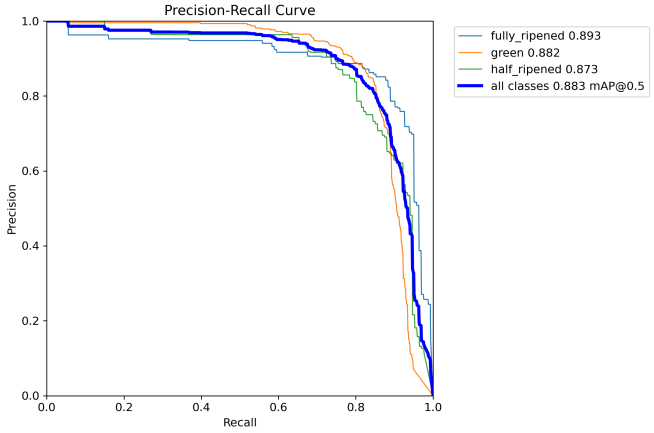

Fig. 5. Precision-recall curve of proposed YOLOv8s-Swin.

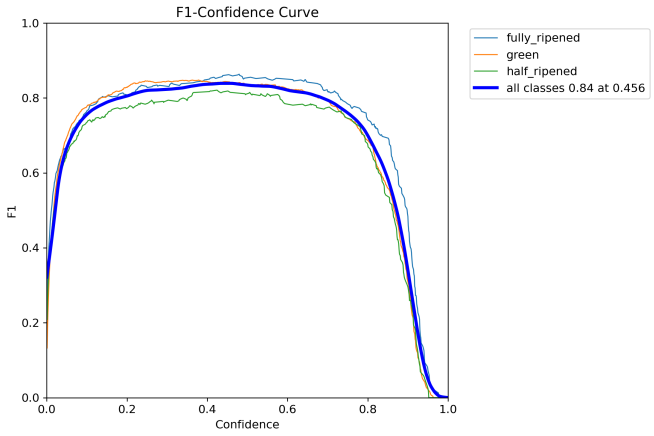

Fig. 6. F1-Confidence curve of proposed YOLOv8s-Swin.

The confusion matrix (see Fig. 7) further confirms the model's strong classification ability. It shows high true positive counts for 'fully_ripened' (144), 'green' (476), and 'half_ripened' (134) predictions, indicating a low rate of misclassification. Furthermore, the training and validation loss curves for bounding box regression, classification, and the overall loss (see Fig. 8) exhibit a consistent and steady decline over training epochs, demonstrating effective learning and robust generalization to unseen data.

C. Comparative Performance Analysis

To thoroughly assess the efficacy and advantages of our proposed YOLOv8s-Swin algorithm, a comprehensive comparative analysis was conducted against several prominent object detection models. These models include traditional two-stage detectors like Faster R-CNN, one-stage detectors such as SSD, and various iterations of the YOLO series, namely YOLOv4, YOLOv5s, YOLOv7, and the base YOLOv8s model. Crucially, all comparative experiments were performed under strictly controlled and identical conditions, utilizing the same hardware setup (NVIDIA GeForce RTX 3060 GPU), the Laboro Tomato dataset, consistent data augmentation methodologies, and a consistent training regimen of 150 epochs, with the optimal

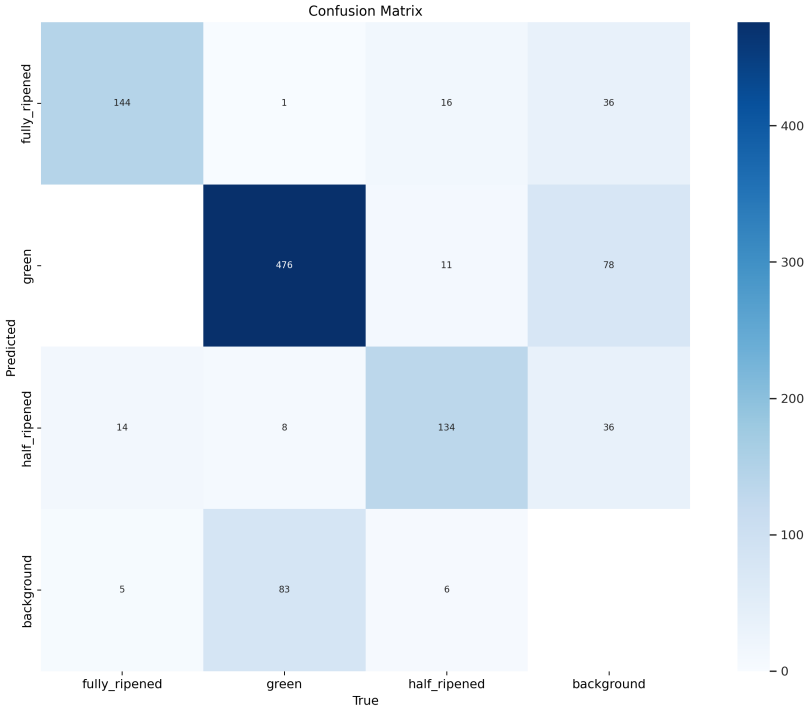

Fig. 7. Confusion matrix of proposed YOLOv8s-Swin.

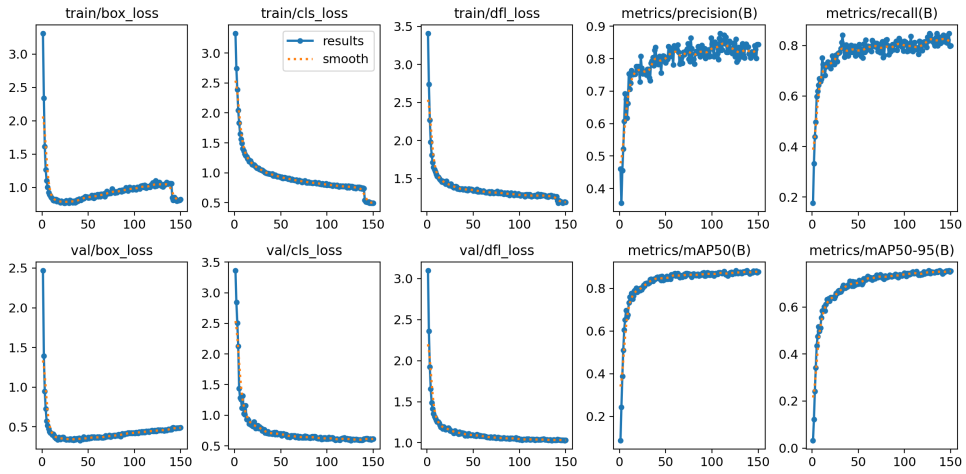

Fig. 8. Visualization of different loss curves of proposed YOLOv8s-Swin model over epochs.

results selected for evaluation.

As presented in Table II, the proposed YOLOv8s-Swin model demonstrates significant improvements across key performance metrics, particularly when directly compared to its base counterpart, YOLOv8s. YOLOv8s-Swin achieved a notably higher mAP@0.5 of 88.3% compared to the base YOLOv8s's 84.7%, representing a substantial improvement in overall detection accuracy under identical experimental settings. Furthermore, YOLOv8s-Swin's precision is 84.4%, an increase from YOLOv8s's 78.3%, indicating its superior accuracy in identifying true positive instances. The recall for YOLOv8s-Swin also saw an improvement, reaching 79.9% compared to YOLOv8s's 78.2%, meaning it is more effective at capturing a higher proportion of actual positive cases. The F1-Score, a crucial balanced measure of precision and recall, also significantly improved from 0.795 for YOLOv8s to 0.821 for YOLOv8s-Swin. These advancements in detection accuracy, precision, recall, and F1-Score are a direct result of the integrated architectural enhancements.

The superior performance of YOLOv8s-Swin is primarily due to the strategic integration of several advanced modules into the YOLOv8 framework. Specifically, the Swin Transformer module significantly enhances the model's ability to capture global and local contextual information, which is

TABLE II. COMPREHENSIVE MODEL COMPARISON FOR TOMATO RIPENESS DETECTION

Network	P (%)	R (%)	mAP@0.5 (%)	F1-Score	FPS
Faster R-CNN	82.0	78.0	86.0	0.780	10
SSD	78.6	75.0	78.0	0.740	40
YOLOv4	74.0	70.0	76.0	0.719	55
YOLOv5s	78.0	73.5	82.0	0.762	110
YOLOv7	78.3	75.0	83.0	0.779	120
YOLOv8s	78.3	78.2	84.7	0.795	160
YOLOv8s-Swin (Proposed)	**84.4**	**79.9**	**88.3**	**0.821**	**166.67**

crucial for accurately detecting small and partially occluded tomatoes in complex agricultural scenes. Additionally, the inclusion of the Focus module aids in preserving fine-grained details vital for small objects, Depthwise Convolution (DWconv) reduces computational overhead while maintaining feature richness, SPPCSPC enhances multi-scale feature fusion, and the C2 module improves high-level semantic feature extraction. These combined modules, along with the robust WIoU loss function, ensure that critical information is effectively utilized during the learning process, leading to more reliable and robust feature representations, particularly beneficial for accurately recognizing subtle differences between various stages of tomato maturity.

Beyond the direct comparison with YOLOv8s, YOLOv8s-Swin exhibits remarkable performance against all other models tested under identical experimental settings. It achieves the highest mAP@0.5 of 88.3%, significantly surpassing traditional two-stage detectors like Faster R-CNN (86.0%) and SSD (78.0%), as well as earlier YOLO iterations such as YOLOv4 (76.0%), YOLOv5s (82.0%), and YOLOv7 (85.0%). The F1-Score of 0.821 is also the highest among all compared models, underscoring its superior balance between precision and recall for robust real-world performance.

In terms of detection speed, YOLOv8s-Swin maintains a highly competitive FPS rate of 166.67, which is marginally higher than the base YOLOv8s model's 160 FPS. This satisfies the stringent requirements for real-time detection in agricultural applications. In contrast, older models like Faster R-CNN (10 FPS) and SSD (40 FPS) fall significantly short of real-time capabilities. This critical balance between high accuracy and efficient processing makes YOLOv8s-Swin a highly universal and practical solution for smart agriculture, particularly suitable for deployment on edge devices with limited processing capabilities without substantial hardware investments.

D. Qualitative Analysis

To visually demonstrate the effectiveness of the proposed YOLOv8s-Swin model, Fig. 9 presents several detection examples across various agricultural conditions, including instances with varying lighting, occlusions, and different ripeness stages. The model consistently exhibits strong performance in identifying and classifying tomatoes at their respective ripeness levels. For instance, Fig. 9(a), Fig. 9(b), and Fig. 9(f) clearly illustrate the model's capability to accurately detect and categorize green (unripe) tomatoes, even when they are densely clustered or partially obscured by surrounding foliage. This highlights the model's resilience to common real-world challenges in agricultural settings.

Furthermore, Fig. 9(c) and Fig. 9(e) showcase the precise detection of fully-ripened tomatoes, with the bounding boxes and associated confidence scores, indicating a high degree of accuracy in classification. This performance is crucial for timely harvesting and yield optimization. Fig. 9(d) specifically demonstrates the model's nuanced ability to differentiate between half-ripened and fully-ripened tomatoes, underscoring its capacity to discern subtle visual cues that distinguish various stages of maturity. Collectively, these qualitative results visually confirm the robustness and practical applicability of the YOLOv8s-Swin model in diverse and challenging agricultural environments, reinforcing its strong quantitative performance metrics through accurate bounding box localization and precise ripeness classification under real-world conditions.

E. Discussion

Accurate detection and classification of crop ripeness stages are indispensable for informed decision-making and optimizing yield management in precision agriculture. Our proposed YOLOv8s-Swin model significantly advances the state-of-the-art for tomato ripeness detection, demonstrating a new benchmark for object detection and classification in agricultural applications, specifically for tomatoes.

The superior performance of YOLOv8s-Swin, particularly its notably higher mAP@0.5, precision, recall, and F1-Score compared to baseline models like YOLOv8s and other prominent architectures, is primarily attributable to its innovative architectural enhancements. The strategic integration of the Swin Transformer module (C3STR) proved crucial, allowing the model to better capture global and local contextual information. This enhanced contextual awareness is particularly beneficial for accurately detecting small and partially occluded tomatoes in complex agricultural scenes. Furthermore, the inclusion of the Focus module aids in preserving fine-grained details, while Depthwise Convolution (DWconv) reduces computational overhead without sacrificing feature richness. The SPPCSPC module enhances multi-scale feature fusion, and the C2 module improves high-level semantic feature extraction by being a refined version of C3. These combined architectural modifications, coupled with the robust Wise Intersection over Union (WIoU) loss function, which mitigates the negative impact of low-quality examples and enhances localization, ensure that critical information is effectively utilized during the learning process. This leads to more reliable and robust feature representations, particularly beneficial for accurately recog-

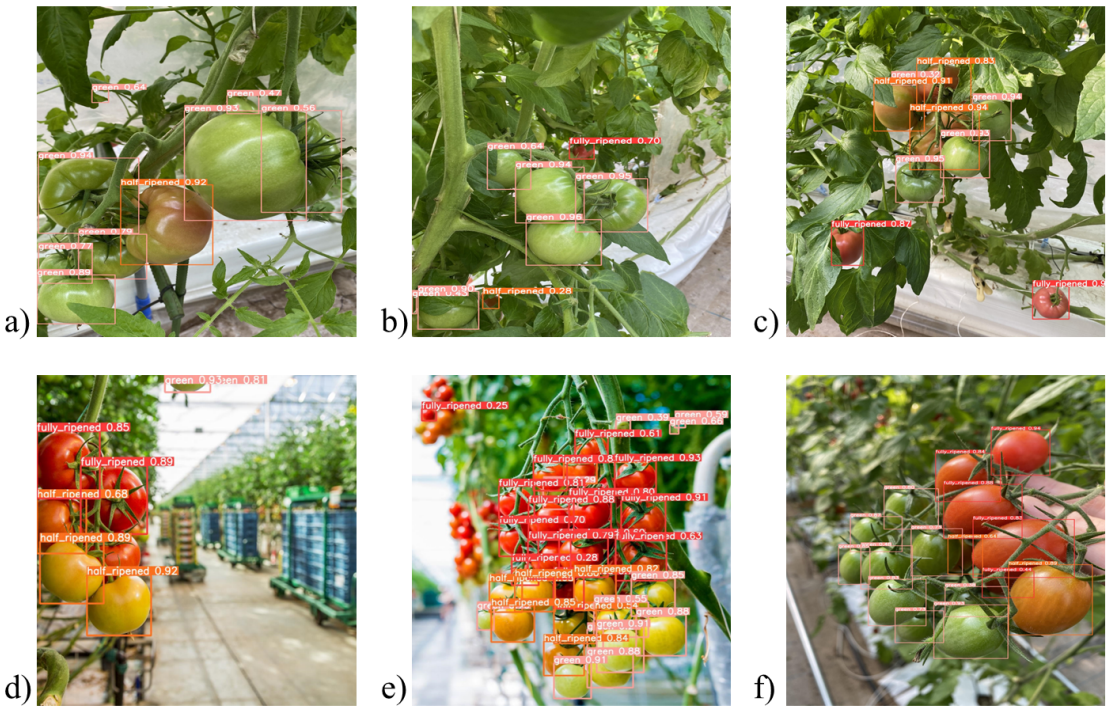

Fig. 9. YOLOv8s-Swin's robust detection capabilities across diverse smart agriculture conditions, including: (a) fruits occluded by other fruits, (b) fruits occluded by foliage, (c) combined occlusion by foliage and fruits, (d) detection in high-density fruit environments, (e) accurate detection in densely packed fruits, and (f) high-density fruit clustering detection.

nizing subtle differences between various stages of tomato maturity.

Beyond its significant accuracy improvements, YOLOv8s-Swin maintains a highly competitive inference speed of 166.67 FPS, which is practical for real-time applications in agriculture. This speed, combined with the model's moderate computational requirements, facilitates efficient deployment on edge devices commonly found in agricultural settings, thereby minimizing the need for substantial hardware investments. The model's adaptability also suggests potential for customization across various platforms, enhancing scalability for diverse agricultural operations.

Despite the high accuracy achieved, certain challenges persist. The model may still struggle with severely occluded tomatoes or distinguishing them from background foliage in extremely dense clusters. Future research will focus on several key areas to build upon these findings. Integrating multi-modal data sources, such as infrared or depth images, could significantly enhance the model's robustness against challenging occlusions and lighting variations. Furthermore, exploring advanced optimization techniques, including neural architecture search, could lead to even more tailored and efficient designs for this specific task. Deployment-specific optimizations, such as quantization-aware training, will be pursued to further reduce computational requirements, enabling broader and more efficient use in resource-constrained environments.

V. Conclusion

This study successfully introduced YOLOv8s-Swin, an enhanced object detection model for robust tomato ripeness detection within smart agriculture. A primary contribution lies in the innovative integration of the Swin Transformer module, Focus, Depthwise Convolution (DWconv), Spatial Pyramid Pooling with Contextual Spatial Pyramid Convolution (SPPCSPC), and C2 modules into the YOLOv8s framework. These architectural enhancements proved highly effective, significantly improving the model's ability to detect small, occluded objects and handle complex agricultural environments. The model achieved a mean Average Precision (mAP@0.5) of 88.3%, precision of 84.4%, recall of 79.9%, and an F1-Score of 0.821, surpassing the base YOLOv8s (84.7% mAP@0.5, 78.3% precision, 78.2% recall, 0.795 F1-Score) and other models like Faster R-CNN, SSD, YOLOv4, YOLOv5s, and YOLOv7, all trained under identical conditions. These improvements are attributed to the model's ability to capture both local and global context, addressing the limitations of previous YOLO versions, which struggled with occlusions, lighting variations, and dense clustering of objects. Additionally, YOLOv8s-Swin maintains a competitive inference speed of 166.67 FPS, demonstrating its applicability in real-time applications for AI-driven crop management and sustainable food production. While the model has demonstrated impressive performance, future work will focus on optimizing it for deployment in more resource-constrained environments, integrating multimodal data sources like infrared and depth sensing to further enhance accuracy under challenging conditions, and exploring the applicability of the model to other crops. The advancements presented

here significantly contribute to the field of smart agriculture by providing an efficient and scalable solution for detecting ripeness stages in tomatoes, paving the way for future research and development in AI-driven agricultural automation.

ACKNOWLEDGMENT

We sincerely thank the UMPSA Postgraduate Research Grants Scheme (PGRS) for their support through the Open Access funding, which made this research possible.

***Abstract*—The integration of Software Defined Networking (SDN) and Network Function Virtualization (NFV) offers considerable advantages in terms of scalability, interoperability, and cost-efficiency. They redefine network architecture, replacing rigid hardware-based control with a more flexible, software-driven approach. However, this convergence also introduces significant security threats and challenges due to architectural vulnerabilities and an expanded attack surface. This study presents a comprehensive overview of the key security risks associated with SDN/NFV networks. It analyzes existing countermeasures, highlighting their effectiveness in addressing specific threats while identifying limitations in achieving comprehensive security due to inherent architectural vulnerabilities. The study concludes with a discussion on open challenges and future research directions toward more secure and resilient network infrastructures. This study highlights the importance of an integrated security approach and identifies areas where further research is required to enhance SDN/NFV security.**

***Keywords*—Next generation network security; software defined networking; network function virtualization; network security; artificial intelligence**

I. Introduction

In today's hyper-connected world, networks have become the backbone of modern communications and services, from enterprise operations to personal applications. As networks grow in size and complexity, traditional networking architectures face limitations in terms of scalability, flexibility, and manageability. Therefore, centralized administration and virtualized infrastructures have become essential for effective remote management and configuration [1].

This has led to the development of SDN, a novel paradigm that decouples the control plane from the data plane, offering greater programmability. SDN provides a centralized view of the entire network, enabling administrators to dynamically manage network traffic and resources through software applications. By separating control functions from the physical infrastructure, SDN allows the rapid deployment of new network services, particularly in environments such as data centers, cloud computing, and large-scale enterprise networks [2].

While SDN centralizes and simplifies network control, NFV focuses on decoupling network services from physical devices by running them as software applications on virtualized platforms. Through this change, hardware costs are reduced, scalability is enhanced, and service provision is accelerated. Combining SDN with NFV provides a more responsive and controlled network architecture, especially for dynamic environments [3].

Despite these promising benefits, the integration of SDN/NFV causes new vulnerabilities and security issues. The centralized control in SDN makes controllers potential targets for cyber attacks [4]. Furthermore, open interfaces such as Northbound and Southbound Application Programming Interfaces (APIs) expand the attack surface, creating more entry points for attackers [5].

Given these emerging security challenges, traditional security mechanisms become inadequate. Artificial Intelligence (AI) has increasingly become essential to detect, mitigate, and prevent sophisticated attacks proactively [6]. Similar perspectives have been developed in our prior works, where AI and Machine Learning (ML) were applied to enhance SDN/NFV security [7], [8]. AI techniques enable automated anomaly detection, adaptive threat response, and intelligent decision-making that considerably surpass the capabilities of conventional security solutions.

To frame the scope of this research, our study is guided by a central inquiry: How can intelligent defense mechanisms enhance the security of SDN and NFV architectures by addressing their inherent vulnerabilities and evolving threats? More specifically, we ask in what ways such defenses can strengthen these architectures against critical weaknesses and emerging cyberattacks, and furthermore, how next-generation intelligent strategies may be leveraged to secure SDN and NFV while overcoming their most pressing challenges. These complementary perspectives establish the foundation for the analysis and recommendations presented in this work.

This study contributes by offering a thorough examination of security vulnerabilities within SDN and NFV ecosystems, a critical review of AI-based defense strategies, and the identification of research gaps that hinder robust implementation. Furthermore, it outlines key recommendations to guide future developments toward more resilient and secure programmable networks.

This study intends to encourage further studies towards enhancing the security of next-generation network environments by highlighting the need of an integrated security strategy. In our study, we provide an overview of the main security risks influencing network topologies based on SDN and NFV. To address these vulnerabilities, we review the countermeasures that have been proposed in the literature and assess their effectiveness and limitations. In addition, we discuss current research gaps and open challenges that may hinder the implementation of reliable and secure SDN/NFV networks.

The structure of this study is as follows : Section II introduces background and foundational concepts related to SDN and NFV, followed by an overview of major security threats and challenges in Section III. Section IV presents countermeasures and a discussion on future directions. Section V provides concluding remarks and perspectives for future research.

II. Background and Fundamentals

A. From Traditional Network to Software-Defined Networking

The rapid progress of digital technologies, the virtualization of services, and data intensive applications has revealed the limitations of traditional network infrastructures [9]. Traditional networks rely on a distributed control model where configuration and management tasks, such as routing policies, access control rules, and software updates, must be applied individually to each device. This lack of centralized orchestration raises operational complexity, extends the time required to deploy updates or resolve misconfigurations, and leads to higher maintenance costs [10]. Additionally, these architectures frequently suffer from insufficient use of computational and bandwidth resources, as well as a restricted capacity.

SDN emerged as a solution to overcome these limitations. By separating the control plane from the data plane, SDN enables centralized network control and simplifies the deployment of new services, as illustrated in Fig. 1.

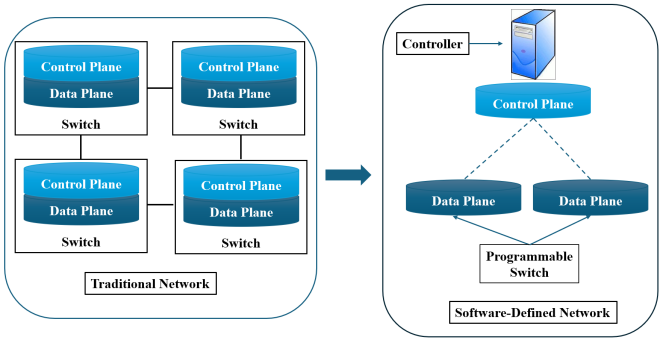

Fig. 1. Traditional Network vs Software-defined networks.

The main benefit of SDN is its ability to decouple network control from hardware, allowing administrators to manage and modify the network through software interfaces without need for physical alterations [11]. The abstraction is improved by the vendor-neutral architecture of SDN, which ensures seamless interoperability across multiple network devices and platforms. This allows enterprises to extend their infrastructure, optimize performance on customer demand, and respond quickly to operational changes or security incidents [11]. The inherent programmability and adaptability of SDN environments also contribute to significantly better resource utilization, allowing networks to operate more efficiently and respond dynamically to real-time demands [12].

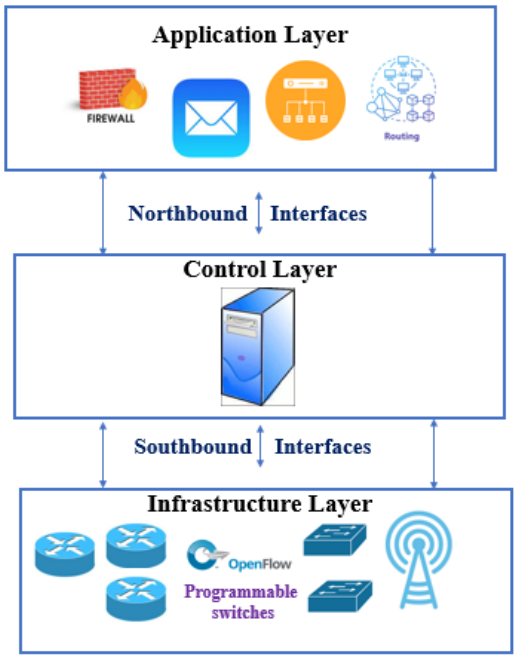

Fig. 2. Software-defined networks architecture.

Fig. 2 displays the fundamental architecture of SDN. It consists of three main layers: the application layer, the control layer, and the infrastructure or the data layer [13]. These layers are connected to one another by well-defined interfaces, known as northbound and southbound interfaces. This ensures that interactions and communication are carried out without any disruptions across the framework. Network behavior and policies are defined by software services hosted at the application layer. These services may include traffic engineering, quality of service (QoS) management, intrusion detection, load balancing, and security monitoring. Instead of explicitly configuring hardware, applications communicate policies to the controller through the northbound interface. This abstraction allows developers to introduce new features or security functions rapidly without being constrained by the limitations of proprietary hardware. In SDN systems, this layer is ultimately responsible for enabling innovation and service agility [14].

The control layer is the most important part of SDN. It makes decisions by transforming application-level requirements into precise routing rules [14]. The SDN controller has a global, real-time view of the whole network, which allows it to make smart decisions about how traffic should be routed or managed. This layer converts high-level application requirements into low-level forwarding rules, which are installed dynamically on switches and routers. By decoupling decision-making from the physical devices, the controller ensures coherent policy enforcement, optimized resource usage, and rapid adaptation to network changes or security events. More-

over, this layer supports programmability, allowing network operators to define behavior through APIs and automation frameworks.

The last layer, known as the infrastructure layer, also referred to as the data plane, consists of physical or virtual forwarding devices, such as switches and routers, that execute the instructions received from the controller through the southbound interface [15]. These devices are simplified to focus exclusively on packet forwarding, which reduces their complexity, cost, and management overhead. The controller may change their behavior dynamically, allowing for precise traffic flow management and effective network resource use.

These layers together represent the four basic principles of SDN: network programmability, abstraction of physical infrastructure, centralized intelligence, and the separation of control and data planes. Supported by protocols such as OpenFlow, this architecture simplifies network management, enhances scalability, and delivers the flexibility needed to respond quickly to evolving operational and security demands.

B. The Need for Network Function Virtualization

Although SDN significantly enhances network control by decoupling the control logic from forwarding devices, it does not virtualize the network services themselves [16]. Middleboxes such as load balancers, firewalls, and NAT devices are still dependent on proprietary hardware. This limits flexibility and drives up operational costs. To address these constraints and fully exploit the paradigm of SDN, NFV was developed.

The goal of NFV is to enable network functions to perform as software instances on common, commodity servers by separating them from specialized hardware [17]. This change removes reliance on specific vendor appliances and allows operators to deploy, scale, and manage services flexibly. SDN offers centralized intelligence, and NFV delivers virtualized services, creating an agile and cost effective networking environment.

According to the European Telecommunications Standards Institute (ETSI), NFV is built upon three essential key components, illustrated in Fig. 3.

The components include Virtual Network Functions (VNFs), Network Function Virtualization Infrastructure (NFVI), and the Management and Orchestration (MANO) system. Together, NFVI, VNFs, and MANO enable a software-driven network that is automated and easily adaptable to operational demands.

The first is the NFVI, which includes the physical hardware, virtualization layer, and the virtualized resources. It serves as the foundational layer, integrating the physical hardware (servers, storage, and network resources) with a virtualization layer that abstracts these resources into pools of compute, storage, and connectivity. This abstraction allows for the dynamic allocation of virtualized resources, supporting the instantiation of virtual machines (VMs) and containers that host the network functions [18]. This layer provides the foundation to host virtual machines and containers.

The second block is VNFs, which implement specific network functions using the virtual resources offered by the

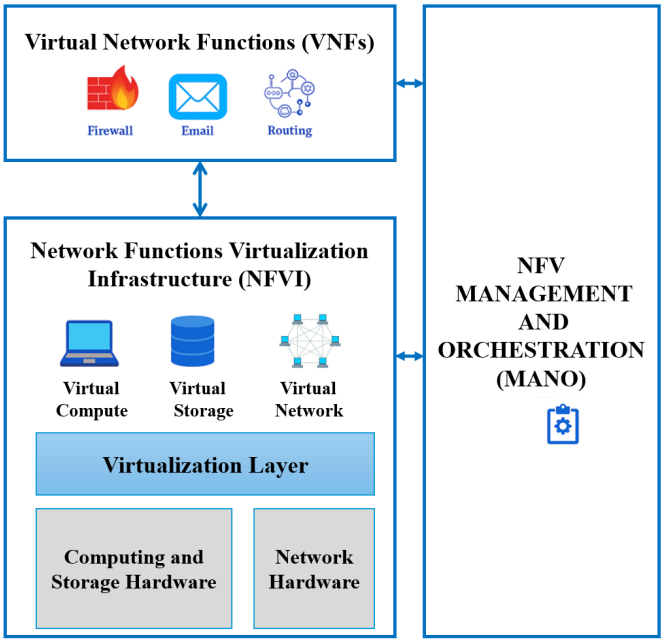

Fig. 3. Network function virtualization.

NFVI. Examples include virtual routers (vRouter), firewalls (vFW), and NAT (vNAT). These VNFs are modular and can be deployed, updated, or removed dynamically [18].

The third and most critical block is MANO [18]. MANO interacts with both the VNFs and the NFVI to manage the lifecycle of services and resources. It is responsible for automating tasks such as deployment, scaling, monitoring, and resource allocation. This block ensures that virtual services can be managed efficiently and adjusted in real-time based on traffic demands or system policies.

NFV offers several benefits, as shown in Fig. 4:

By replacing dedicated appliances with software instances, NFV reduces capital expenditures (CAPEX) and operational expenditures (OPEX) while accelerating service deployment. It also enables faster deployment of new services and better scalability, since virtual functions can be instantiated or terminated as needed. In addition, NFV simplifies updates and promotes vendor independence, allowing service providers to choose flexible software solutions without being locked to specific hardware platforms [19]. These characteristics position NFV as a key enabler of flexible, automated, and future-proof network infrastructures.

C. SDN and NFV Complementarity

SDN and NFV are two complementary technologies that aim to modernize and optimize network architecture. While SDN focuses on the separation of the control and data planes to enable centralized overview and programmable control, NFV addresses the virtualization of network services that traditionally relied on dedicated hardware.

These two paradigms operate at different layers of the network but are designed to work together [20]. SDN provides the intelligence and global view necessary to control

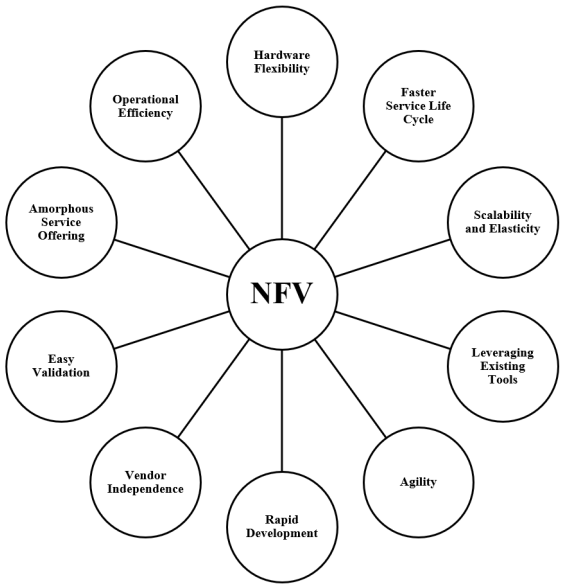

Fig. 4. Advantages of network function virtualization.

how data flows across the network, while NFV delivers the actual network functions as software running on virtualized infrastructure. The integration of SDN and NFV results in a flexible and programmable networking model, where services and control are both decoupled from rigid infrastructures and can evolve dynamically to meet operational requirements.

This synergy allows for greater agility, faster service deployment, and reduced operational complexity. It also supports automation and resource optimization by enabling flexible service chaining and centralized orchestration. The combination of SDN and NFV is particularly beneficial in modern use cases such as 5G, cloud-native infrastructure, and edge computing, where scalability and adaptability are essential [21]. To better understand the roles and differences of SDN and NFV, Table I presents a comparative summary of their key aspects.

TABLE I. COMPARISON BETWEEN SDN AND NFV

Aspect	SDN	NFV
Primary Focus	Separation of control and data planes	Virtualization of network functions
Key Component	SDN Controller	VNFs, NFVI, MANO
Control Mechanism	Centralized control via software	Lifecycle and resource management via MANO
Infrastructure	Programmable switches and routers	Servers and virtualization layers
Deployment Speed	Faster path control and policy updates	Rapid deployment of virtual services
Vendor Dependency	Vendor-neutral (via OpenFlow and APIs)	Reduces reliance on proprietary hardware
Example Use Cases	Dynamic routing, traffic engineering	Virtual firewalls, NAT, load balancing
Relationship	Controls how data flows in the network	Provides the services that flow over the network infrastructure

While SDN enables centralized control and dynamic network management, it does not cover the virtualization of the network functions themselves. For this reason, a complementary approach called NFV was introduced to decouple network services from dedicated hardware. NFV enables these services such as routing, firewalls, or load balancing to run as software on general purpose servers.

III. SECURITY THREATS AND CHALLENGES

A. Software-Defined Networking Challenges

SDN introduces a revolutionary network architecture; however, this change brings several challenges. One of the most critical is the centralization of control. Acting as the brain of the network, the controller becomes a single point of failure. Any malfunction, misconfiguration, or successful intrusion against this component can lead to a complete collapse of network services. Attackers who manage to compromise the controller gain unprecedented control, enabling them to alter flow rules, inject malicious policies, and disrupt or hijack traffic across the entire infrastructure. If compromised, the controller could enable full network disruption [22]. In this context, our earlier research proposed intelligent approaches to detect and resolve policy violations within SDN control and data planes [23], [24].

In addition, communication between SDN components introduces another layer of vulnerability. The southbound interface, typically relying on protocols such as OpenFlow [25], lacks robust native security features, leaving it exposed to message spoofing, tampering, and man-in-the-middle attacks (MitM). Similarly, northbound interfaces often suffer from insufficient access control. When improperly secured, these interfaces may allow unauthorized access or the injection of malicious services which significantly weakens the trust model of the entire architecture.

Scalability [26], also represents a persistent challenge. As networks grow in size and complexity, optimizing controller placement, balancing workloads, and minimizing latency in control messages become increasingly challenging. In distributed deployments, where multiple controllers must synchronize to maintain a coherent global view, inconsistencies may arise, resulting in policy conflicts and operational instability [27]. These architectural weaknesses are aggravated by the absence of unified security frameworks and the reliance on open-source components that often lack rigorous hardening against advanced threats.

A particularly severe threat to SDN infrastructures is the Distributed Denial of Service (DDoS) attack. In traditional networks, such attacks aim to overwhelm servers or network links with excessive traffic, but in SDN, the impact is often more damaging because of the centralized nature of control. During a DDoS attack, large volumes of malicious traffic are generated from multiple sources and directed toward the data plane, triggering a flood of control messages sent to the controller. This sudden surge of requests can exhaust the controller's processing capacity, resulting in delays, instability, or even total network failure. Attackers may also target the controller directly, exploiting its role as the decision-making hub to paralyze its operations. The consequences of a successful DDoS attack include severe service degradation, unavailability of critical applications, and disruption of communication across the entire network [28].

Beyond these aspects, SDN operates in a highly dynamic environment where policies, flows, and states change continuously. Ensuring consistent visibility across all elements, preventing rule conflicts, and maintaining traceability in such rapidly evolving conditions require sophisticated monitoring systems that are still under development [29]. Without adequate oversight, misconfigurations or silent intrusions can remain undetected for extended periods, undermining the overall security posture of the network.

Table II summarizes the main threats affecting each SDN domain, outlines the associated risks, and highlights defensive measures capable of mitigating these vulnerabilities. This analysis emphasizes the urgent need for integrated security mechanisms capable of addressing both the architectural weaknesses and the evolving threat landscape that characterizes SDN deployments [30].

B. Network Function Virtualization Challenges

NFV reshapes traditional network architectures by decoupling network functions from proprietary hardware and deploying them as software instances on commodity servers [19]. This transformation provides unprecedented scalability and operational flexibility, but at the same time introduces complex risks that threaten the reliability and security of virtualized infrastructures [31]. The dynamic and distributed nature of NFV, where VNFs are instantiated, migrated, or terminated on demand, creates an environment in which ensuring consistency, isolation, and performance becomes highly challenging. Unlike static hardware-based systems, NFV relies on virtualization layers, orchestration components, and multi-domain coordination, all of which may become sources of vulnerabilities if not carefully secured [31].

The threats associated with NFV extend across multiple layers, from the physical hardware to virtualized resources and orchestration control, each requiring tailored countermeasures. Table III consolidates the main threat categories, describes their mechanisms, and links them to appropriate mitigation strategies. This table demonstrates that achieving security in NFV is not the responsibility of a single component but rather the result of coordinated efforts across all layers, combining isolation, authentication, monitoring, and resilience techniques to ensure that flexibility does not come at the expense of security.

One major concern is the complexity of orchestration and management of virtualized resources across multiple domains. The dynamic nature of VNFs makes it difficult to ensure consistent performance, availability, and isolation. Furthermore, resource allocation and scaling mechanisms can lead to unpredictable performance and increased attack surfaces. Another challenge lies in interoperability and standardization. NFV environments often consist of heterogeneous components from different vendors, making integration and management more error prone. Additionally, the reliability and fault tolerance of VNFs must be guaranteed, especially in critical applications such as vehicular or industrial networks.

The orchestration of VNFs across heterogeneous infrastructures is one of the primary difficulties in NFV deployment. Managing resources dynamically while maintaining service continuity requires precise coordination of computing, storage, and network elements, a task that becomes increasingly complex in multi-tenant or cross domain environments. Inconsistent resource allocation, poor synchronization, or errors during VNF migration may lead to unpredictable QoS, degradation in performance, and in some cases complete service disruption [32]. Furthermore, the lack of standardized interfaces and uniform protocols between components from different vendors hampers interoperability, making integration error prone and potentially insecure. These architectural constraints are even more critical in latency sensitive environments such as industrial control systems and vehicular networks, where reliability and fault tolerance are non negotiable requirements [33].

From a security perspective, NFV inherits threats from both traditional networks and cloud computing while introducing new attack surfaces specific to virtualization. Hypervisors, which manage the virtualization layer, are particularly sensitive targets. Also, a successful exploitation can compromise all hosted VNFs and give attackers control over the underlying infrastructure. The orchestration layer, known as MANO, also becomes a high-value target because of its privileged role in managing the entire NFV lifecycle. Exploiting insecure APIs or misconfigurations at this level can lead to unauthorized operations, data leaks, or the injection of malicious components [34]. The trustworthiness of third-party VNFs is another major concern, as these functions may contain backdoors, hidden malware, or exploitable vulnerabilities that compromise the entire chain of services once deployed.

Another significant challenge arises from the lifecycle of VNFs. Each instantiation, scaling, migration, or termination presents specific vulnerabilities [35]. For example, during migration, data and states are transferred across domains, and insufficient protection during this process can allow interception or tampering. Similarly, insecure onboarding of VNFs can facilitate the deployment of malicious images, while improper termination may leave residual data or open configurations exploitable by attackers. The absence of continuous monitoring during these operations further increases the likelihood of undetected intrusions or misconfigurations persisting within the infrastructure [36].

The complexity of NFV also lies in its dependency on cloud-like environments and programmable interfaces, where the attack surface expands rapidly with each added component or tenant. An adversary can exploit poorly monitored orchestration decisions, manipulate inter-VNF communications, or overload physical resources to trigger cascading failures. These scenarios highlight the urgent need for context-aware intrusion detection, runtime verification mechanisms, and automated incident response capable of adapting to evolving threats. At the same time, strict verification of VNF integrity, secure software supply chains, and robust cryptographic protections for management channels are essential to strengthen trust within NFV ecosystems. Fig. 5 highlights some of the most critical threats affecting NFV environments. These threats arise at multiple layers of the architecture, ranging from physical resources to virtualization platforms and orchestration mechanisms, underscoring the need for comprehensive and coordinated defense strategies.

TABLE II. RISKS AND THREATS IN SDN SECURITY DOMAINS

Security Component	Vulnerability/Threat	Risk Consequences	Defensive Action
Control Plane	Over dependence on a single controller instance	Loss of orchestration, network paralysis	Use distributed architectures, backup controllers, and high availability frameworks
Northbound Interfaces	APIs exposed to orchestration platforms and apps without strict security controls	Unauthorized access, policy override, service injection	TLS encryption, API gateway, strong RBAC, input validation
Southbound Interfaces	Message injection or tampering in protocols like OpenFlow	Corrupted flow tables, misrouting, loss of trust	Message authentication, channel encryption, switch-level access policies
Application Layer	Malicious or vulnerable apps interacting with the controller	Flow conflicts, data leakage, service disruption	App sandboxing, behavioral monitoring, application certification workflows
Flow Management	Conflicts or outdated flows in switch tables	Policy violation, packet loops, resource waste	Implement rule expiration, rule audits, consistency validation engines
Inter Communication	Lack of verification between East and West control domains	Propagation of compromised state, unsynchronized behavior	Signed messaging, secure sync protocols, consensus mechanisms
Monitoring	Unlogged configuration changes, missing traceability	Persistent misconfigurations, undetected policy violations	Continuous auditing, automated logging, version control and rollback systems

TABLE III. VIRTUAL NETWORK SECURITY: THREATS VS COUNTERMEASURES

Threat Category	Threats	Countermeasure Category	Countermeasures
Disclosure	Information Leakage, Information Interception, Introspection Exploitation	Access Control	Trusted Virtual Domains, Sandboxes
Deception	Identity Fraud, Loss of Registry Entries, Replay Attacks	Authentication	Interoperability Between Federations, Certificate-Based, Key-Based
Disruption	Physical Resource Overloading, Physical Resource Failure	Confidentiality	VLANs and VPNs, Tunneling and Cryptography, Firewalling and Subnetting
Usurpation	Identity Fraud, Software Vulnerability Exploitation	Integrity, Nonrepudiation, Availability	Path Splitting, Limiting Introspection, Cryptography, Timestamping, Physical Resource Isolation, Virtual Network Resilience

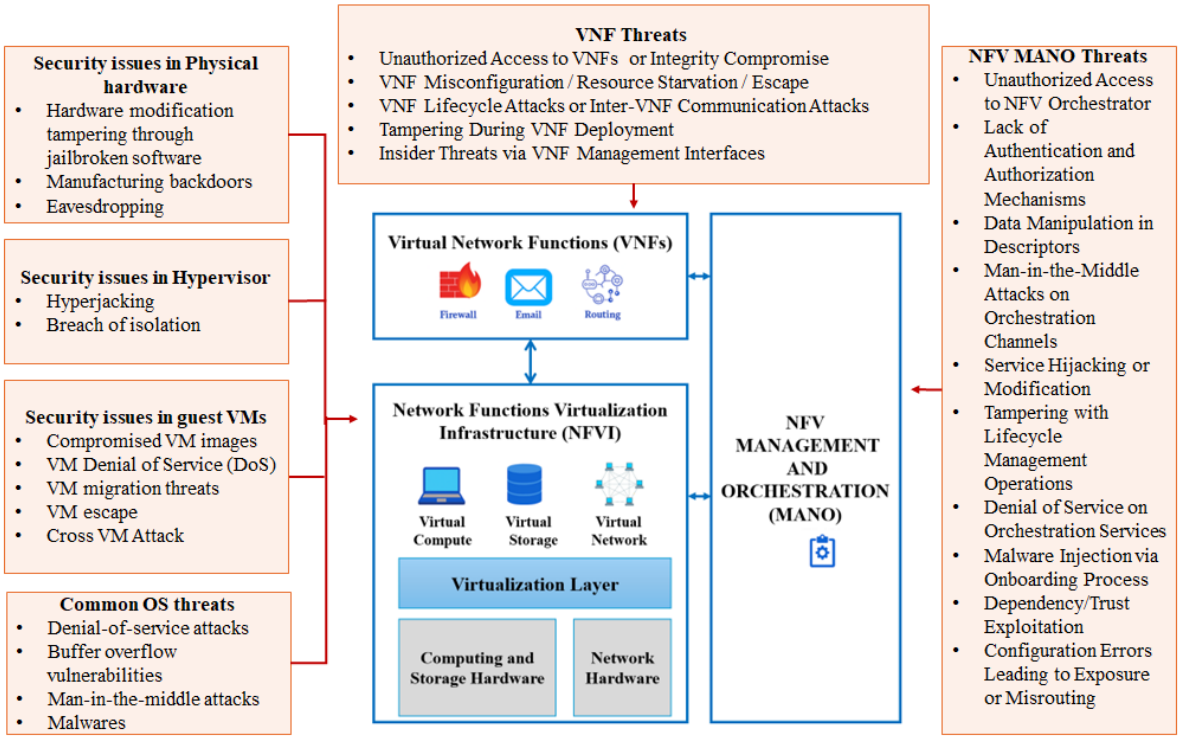

Fig. 5. Network function virtualization threats.

C. Security Threats within SDN and NFV

Nowadays, the majority of existing frameworks are focused on migrating network functions from hardware devices to virtualization environments. SDN and NFV are two independent but complementary concepts. When combined, they provide an additional benefit in terms of simplified management, rapid service deployment, and reduced operational costs. However,

it also significantly expands the attack surface, as each technology introduces its vulnerabilities while their interaction creates new, composite risks that span multiple layers of the architecture [36].

In SDN, the centralized controller is an essential asset but also a critical weakness. Its compromise can disrupt the entire network, enabling attackers to manipulate flow rules or shut down services altogether. Similarly, NFV introduces threats at the virtualization layer, where hypervisors and VNFs become primary targets. Malicious VNFs or hypervisor exploits may breach isolation boundaries, gaining access to the host environment and other tenants. The orchestration layer, shared between SDN and NFV, faces its own set of threats. Weakly secured MANO components or misconfigured APIs can allow privilege escalation, unauthorized control operations, or the deployment of rogue VNFs that compromise the network.

MitM attacks [37], represent another severe risk in these ecosystems. Interception of traffic can occur both in SDN control channels and during NFV operations such as VNF migration, allowing adversaries to manipulate or spy on communications. DoS attacks are also particularly damaging in this context. Overwhelming the SDN controller, the NFV orchestrator, or the underlying infrastructure can degrade performance or even cause complete service outages. These attacks become more difficult to mitigate in dynamic environments, where large volumes of traffic are legitimate and distinguishing malicious flows is challenging.

The programmability of SDN and NFV, while central to their flexibility, also creates opportunities for misconfiguration. Incorrect policies, insecure automation scripts, and flawed orchestration workflows can unintentionally expose the network to vulnerabilities without any direct attacker involvement. Furthermore, unpatched software in SDN applications or VNF packages provides attackers with exploitable weaknesses that can propagate rapidly across virtualized infrastructures. Third-party VNFs pose an additional risk, as they may include hidden backdoors or malicious code capable of undermining the integrity of the network once deployed [38].

The integration of SDN and NFV introduces complex interdependencies between control, orchestration, and virtualization layers. This tight coupling means that an attack on one component can cascade, affecting other layers and amplifying its impact. Securing such an environment requires more isolated defense mechanisms. It demands a holistic approach, where isolation, strong authentication, integrity verification, and continuous monitoring are enforced consistently across all layers. Real-time intrusion detection, secure orchestration policies, and rigorous VNF verification processes are crucial for ensuring that the benefits of SDN/NFV adoption are not undermined by evolving cyber threats [39].

Table IV synthesizes the main threat domains observed in SDN and NFV environments, and highlights how their integration increases exposure to attacks. This summary underlines the necessity for coordinated security mechanisms capable of addressing vulnerabilities at every level of the SDN/NFV stack, preventing isolated weaknesses from escalating into systemic failures.

TABLE IV. SUMMARY OF SECURITY CHALLENGES IN SDN AND NFV

Domain	Challenges / Threats
NFV	VNF isolation failure, insecure lifecycle management, hypervisor vulnerabilities, untrusted VNF onboarding
SDN	Centralized controller exposure, insecure APIs, third-party app vulnerabilities, southbound protocol threats
SDN/NFV Integration	DoS attacks, MitM, VNF escape, orchestration manipulation, privilege escalation

IV. COUNTERMEASURES REVIEW AND FUTURE DIRECTIONS

A. Countermeasures Review

In recent years, research on SDN and NFV security has evolved considerably, moving from traditional protection mechanisms to intelligent, adaptive frameworks. Countermeasures have been proposed for every architectural layer, including the control plane, data plane, virtualization infrastructure, orchestration systems, and exposed APIs.

For SDN, earlier studies recommended strengthening the controller through redundancy, fine-grained access controls, and secure southbound communication. Jiménez et al. [40] applied the STRIDE methodology to analyze threats across SDN layers and recommended tighter access policies, controller hardening, and secure APIs. Despite these enhancements, they noted unresolved challenges such as dynamic policy conflicts and insufficient protection against zero-day vulnerabilities.

Beyond static defenses, several studies have proposed AI-enhanced security frameworks. Shobowale et al. [41] explored 5G threats focusing on SDN and NFV layers, introducing a combination of blockchain-based authentication, layered access control, and AI-driven intrusion detection. However, their framework faced scalability challenges, high computational overhead, and limited coverage against emerging side-channel and supply-chain attacks.

In the NFV context, Pattaranantakul et al. [42] proposed countermeasures such as hypervisor isolation, trust domains, and adaptive access control. While these techniques improved security at individual layers, the lack of orchestration-level integration allowed sophisticated interlayer attacks to persist.

Other research explored entropy-based detection. Fan et al. [43] developed a lightweight approach using fusion entropy to detect DDoS attacks in SDN. Their model combined information entropy and logarithmic energy entropy to identify anomalies with high precision. Although effective in simulations, it required manual threshold settings and lacked evaluation in complex multi-controller deployments.

More recent works emphasized hybrid and intelligent systems. Nadeem et al. [44], reviewed ML techniques for securing SDN, focusing on detecting DDoS, botnets, and ransomware. They demonstrated how supervised and deep learning models can improve detection accuracy, while also highlighting vulnerabilities to adversarial samples and the need for explainability. Similarly, the Hybrid SDN-IDS framework leveraged dynamic SDN control and NFV monitoring to detect and mitigate threats in real-time. Its evaluation showed improved detection rates, but its performance under large-scale traffic conditions remains uncertain.

TABLE V. FUTURE RESEARCH DIRECTIONS FOR ENHANCING SDN/NFV SECURITY

Research Direction	Objective	Addressed Challenge
Unified Threat Intelligence [40], [46]	Enable cross-layer visibility and event correlation across SDN, NFV, and cloud domains	Fragmented monitoring, lack of coordination between components
Lightweight, Real-Time Detection [43], [44]	Design efficient anomaly detection models suitable for resource-constrained environments	High computational cost of current AI methods; unsuitable for IoT/edge
Autonomous and Self-Adaptive Security [47]	Develop self-healing systems that react to evolving threats and reconfigure policies automatically	Inability to respond dynamically to zero-day or stealth attacks
Secure VNF Marketplaces [19], [42]	Ensure trust in third-party VNFs through attestation, certification, and runtime monitoring	VNF tampering, backdoors, and insecure onboarding
Formal Verification of Orchestration Policies [41]	Apply formal methods to validate orchestration rules before deployment	Misconfiguration risks, policy inconsistencies, privilege escalation
Post-Quantum Cryptography and Trusted Execution Environments (TEEs) [48]	Strengthen data confidentiality and control-plane integrity in next-gen programmable networks	Future cryptographic attacks; lack of hardware-assisted security primitives

For Next-Generation Networks, AI-driven cross-layer frameworks have gained traction. Alnaim [45] critically examined SDN, NFV, and network slicing in 5G, proposing security-by-design methodologies and UML-based reference models. However, the lack of standardized enforcement limits their adoption. The study [46] proposed integrating SDN controllers, NFV orchestration, and AI anomaly detection for slice-aware protection in 5G/6G. While promising, its real-world latency and scalability remain to be validated. Complementary to these studies, our contributions investigated how ML-based algorithms can strengthen intrusion detection in SDN/NFV environments [8] and proposed frameworks for automated policy enforcement [23].

Finally, Li et al. [47] introduced a proactive defense combining Moving Target Defense (MTD) and Reinforcement Learning (RL). This approach dynamically reconfigures network parameters to counter stealthy attacks, yet introduces new risks tied to the vulnerabilities of RL models themselves.

Although several AI-based security mechanisms have been proposed in the literature, most are evaluated in ideal or simulated settings. There remains a lack of critical assessment under adversarial scenarios or across heterogeneous infrastructures combining SDN controllers, NFV orchestrators, and multi-tenant environments.

In summary, literature shows a clear progression toward adaptive, AI-enhanced, and cross-layer security frameworks for SDN and NFV. However, common limitations persist such as high computational demands, lack of standardized orchestration, and limited validation under real world conditions. These findings highlight the need for lightweight AI models, resilient orchestration-level controls, and robust defenses against adversarial threats.

B. Discussion and Future Directions

The reviewed literature confirms a clear evolution toward AI-augmented, cross-layer, and adaptive security frameworks for SDN and NFV networks. These solutions aim to address complex threats in highly dynamic environments such as 5G, IoT, and vehicular networks. Nevertheless, several persistent challenges remain unresolved.

Among AI techniques, supervised models dominate current literature, yet their dependence on labeled data limits its real-world generalization [44]. RL and unsupervised approaches, while promising, still lack extensive benchmarking in SDN/NFV contexts [47]. This observation is consistent with earlier surveys that emphasized the gap between simulation-based validation and practical deployment in operational infrastructures [40], [44]. For instance, [40] highlights how current solutions often remain limited to laboratory environments, reducing their applicability to real-world programmable infrastructures.

Another key limitation lies in the absence of standardized and interoperable security frameworks. Current solutions often address threats at isolated layers (control, data, or virtualization), but fail to ensure consistent protection across the entire architecture [41], [46]. Moreover, many approaches are validated only under ideal laboratory conditions, with limited assessment under realistic network traffic and latency scenarios [45]. This limitation is particularly evident in large-scale SDN deployments, where orchestration complexity and latency constraints cannot be ignored [46].

AI and ML have shown significant potential in improving detection and response capabilities, as demonstrated in recent works on SDN security [44], [45]. However, they bring new risks such as high computational demands, lack of explainability, and exposure to adversarial manipulation [25], [47]. The complexity of training and deploying robust AI models remains a barrier, particularly in edge and multi-tenant scenarios where resources are constrained, a limitation which is also emphasized in studies on real-time SDN/NFV security frameworks [41], [46]. These findings are consistent with our previous proposals, which stressed the importance of lightweight and explainable AI for practical deployment in programmable networks [7], [24]. As noted in [47], adversarial interference against AI-driven systems represents an emerging risk that requires more resilient and transparent defense mechanisms.

Moreover, a critical gap remains in evaluating these security frameworks under realistic, heterogeneous environments. Very few approaches have been tested across operational SDN/NFV infrastructures involving cross-domain orchestration, adversarial interference, or third-party VNF integrations factors, that are crucial for assessing their robustness and scalability.

In summary, while substantial progress has been made toward intelligent and adaptive SDN/NFV defenses, the lit-

erature highlights clear research gaps. Addressing interoperability, ensuring scalability, and developing robust, adversarial-resilient AI models remain essential for advancing secure and trustworthy programmable networks.

To guide future work, several promising directions have emerged from the literature. These focuses on enhancing security intelligence, improving the adaptability of defenses, and addressing the unique challenges of highly dynamic SDN/NFV ecosystems. Table V summarizes these key directions and their corresponding objectives.

In addition to these conceptual directions, future work will include experimental validation of selected approaches, particularly AI-driven detection mechanisms, through implementation and evaluation in real-world programmable network environments such as SDN-based vehicular or cloud-edge architectures.

In conclusion, while existing studies have laid a strong foundation, the increasing complexity of SDN and NFV demands new generations of security frameworks that are not only intelligent and adaptive but also lightweight, verifiable, and resilient to emerging attack strategies.

V. Conclusion

Next-Generation Networks, built upon concepts like SDN and NFV, have emerged as innovative and diverse architectures. By decoupling the control and data planes and virtualizing network functions, they offer unprecedented flexibility, programmability, and operational efficiency. However, this paradigm shift also brings forth new attack vectors, architectural weaknesses, and orchestration challenges that demand proactive and adaptive security measures.

This study underscores the necessity of adopting a unified and cross-layer security framework to mitigate the evolving threats specific to SDN and NFV deployments. By identifying critical gaps in existing solutions and evaluating their limitations, it aims to inspire more effective approaches tailored to the demands of programmable and distributed infrastructures. Furthermore, the integration of intelligent techniques, such as AI and ML, emerges as a promising direction offering dynamic, context-aware defenses suited for complex environments such as 5G, IoT, and edge networks.

In line with our guiding research questions, this work has shown that intelligent defense mechanisms can enhance the security of SDN and NFV by addressing their inherent vulnerabilities. They can also strengthen these architectures against emerging cyberattacks, while next-generation intelligent strategies hold strong potential to overcome their most pressing challenges. Nevertheless, certain limitations remain: most proposed solutions are evaluated in simulated settings, lack cross-layer interoperability, and do not fully consider adversarial manipulation or real-world scalability.

Future research must therefore prioritize resilient, lightweight, and verifiable security mechanisms validated under realistic deployment conditions. By closing these gaps, the community can move closer to achieving robust and trustworthy programmable networks capable of supporting critical infrastructures in 5G, IoT, and beyond.

***Abstract*—Online marketplace and social media offers substantial opportunities for business growth for many and it has contributed greatly to the increase demand of keropok lekor (fish cracker) from Terengganu throughout Malaysia as the market reach is increasing. Positive effects of these online platforms as significant digital marketing tools encourage keropok lekor producers in Terengganu to invent and diversify their products with the goal to market and increase the sale of keropok lekor in a larger scale. Some of the innovations are selling keropok lekor in pre-packaged form and introduce different versions of keropok lekor by adding more flavors, textures and shapes to meet broader range of customer preferences. This positive development promotes the commercialization of keropok lekor which then requires the producers like ROMA Food Industry Sdn. Bhd. (RFI) to handle higher market demand without significant disruptions. An automated approach is crucial for them to streamline the keropok lekor business operations to enable them handle not only the increased product market demand, but at the same time the volumes of work or expansion without compromising quality or efficiency. ROMAns is an Enterprise Resource Planning (ERP) system built to optimize keropok lekor business processes by facilitating the flow of information across different functions, improve efficiency, and gain a competitive edge by leveraging integrated data and streamlined operations across keropok lekor business operations.**

***Keywords*—Overall equipment effectiveness; real-time information; centralization; data-driven workflows; business digitalization**

I. Introduction

Originated from Terengganu, keropok lekor is a traditional fish snack or appetizer that showcases the rich culinary heritage of Terengganu and very popular among the locals and tourists. With the combination of fish and sago flour as the main ingredients, the unique texture which has both chewy and slightly crispy especially on the outside makes it gain popularity not only in Terengganu but also throughout Malaysia and neighboring countries like Singapore, Indonesia, Brunei and Thailand. In Malaysia, keropok lekor can be found in various parts of the country such as local markets, food stalls, hypermalls and even through online marketplaces and social media. With the recent impressive market development through online platforms, many keropok lekor producers realized that they need to go beyond traditional method of doing their keropok lekor businesses. However, it is not that simple especially when it involves very large volumes of demands from customers. As reported by study [1], in the production of keropok lekor, most producers are still using traditional manufacturing practices with low competitiveness and poor efficiency. This probably due to the strong belief that adhering to age-old methods will maintain the cultural significance of the keropok lekor. The traditional keropok lekor making process using human touch instead of machine will preserve authentic taste and textures of the keropok lekor [2]. On that account, even to this day, traditional keropok lekor businesses continue to involve a highly labor-intensive and hands-on approach to production and distribution [3].

While certain aspects of the business may have undergone modernization, many producers still steadfastly adhere to traditional methods and recipes. However, this scenario can be further improved through the integration of modern production equipments. Without compromising the traditional taste or texture of keropok lekor, the producers will be able to produce large volumes of demands from their customers. Aside from that, to achieve stability and enhance scalability, it is crucial for keropok lekor producers to have a specific automated solution that will help them streamline their business operations, enhance existing skills, manage business enterprise more systematically while at the same time simplify the business processes, and market their products more aggressively. In other words, there is a need to employ a standard processing procedure to maintain the quality while meeting consumer demands for safety, quality and nutritional value of keropok lekor.

Optimizing a traditional business like Keropok Lekor requires finding a balance between age-old methods and modern technology. For this purpose, an Enterprise Resource Planning (ERP) based system seems to fit the bill. ERP variable is the coordinated information system, which can moreover be called a software bundle with an essential function to integrate all core functions in a company, in any case of the field of the industry [4]. ERP-based system was first introduced in 1960s to cater for only inventory management and control in manufacturing industry. However, it has evolved and become more strategic as the technology has gotten better. In 1990s, modern ERP applications emerged that integrate enterprise-wide backend processes by making use of a computerized sys-

tem. According to study [5], ERP systems are most frequently employed in the business setting for document processing, but they can also be utilized to manage information flow within an organization more effectively. Organization utilizes these systems because they have modules tailored to each function inside a business, enabling the right centralization of data.

II. Related Works

A qualitative study conducted by [6], involving an interview with a renowned keropok lekor producer in Terengganu, revealed that raw material selection, particularly fish type, significantly influences customers' buying preferences. Sardines (tamban and selayang) were identified as the most preferred fish for taste. The study also emphasized the crucial role of effective vacuum packaging in preserving keropok lekor freshness. While this interviews provide valuable qualitative insights into the experiences and opinions of keropok lekor business owner, it is limited by potential biases. A comprehensive, data-driven solution that enables informed decision-making and strategic planning is essential for efficiently managing keropok lekor business operations, improving processes, optimizing productivity, and enhancing customer satisfaction.

To Ensure the safety of consumers, the quality of keropok lekor is paramount. A study by [7] reported the presence of various microorganisms during different processing stages. However, as this study also suggests, microbiological quality can be improved by using raw materials with lower initial microbial loads, employing effective heat treatment during boiling, and implementing proper cooling procedures for the final product. In contrast, a more recent investigation by study [8] identified the presence of the multidrug-resistant (MDR) E. coli B10 strain in ready-to-eat (RTE) keropok lekor, demonstrating its ability to survive under both air-packed (AP) and vacuum-packed (VP) storage at a chilled temperature of 40C. This discovery underscores the importance of food safety for RTE keropok lekor, which ROMAns can address through its quality and inventory management modules.

Technological innovations like keropok lekor drying machines aim to benefit keropok lekor producers by enhancing business performance and reducing maintenance costs. Ultimately, this can minimize the production cost of keropok keping [9]. RFI leverages both traditional sun drying techniques and a custom-designed drying machine to optimize keropok keping production. In contrast to [9], their machine utilizes gas cylinder as its primary energy source, thereby minimizing operational expenses. Our proposed ERP system will facilitate the accurate assessment of RFI's machine's performance, as elucidated in the production management section.

To capitalize on growing market demand and secure higher returns, keropok lekor producers must aim to fully utilize their production capacity. A study done by [10] on Maja Baroh enterprise, one of the SMEs in keropok lekor Industries has stressed on the method of increasing the production size. They need to improve their production floor method whereby some machines or equipments especially the boiling stove need to be replaced to adapt into lean manufacturing system. As for RFI, they seek to expand their production capacity to a target range of 6 to 10 tons per day.

The employee turnover rate in keropok lekor industry, particularly within the production department is notably high. This elevated turnover is significantly influenced by the unpredictable nature of the keropok lekor market demand. The fluctuating and often random demands of this market directly impact the workload and operational tempo within keropok lekor's production facilities. During periods of high demand, production staff may face increased pressure, longer working hours, and potentially more strenuous tasks to meet the surge in orders for their products [6]. Conversely, during lulls in market demand, there might be periods of reduced activity, which could lead to feelings of instability or under utilization among the workforce.

III. ROMAns Framework

An ERP system offers the optimal solution for automating RFI's keropok lekor business operations by providing centralized data management, streamlined processes, integrated functions, real-time insights and reporting, and ensuring regulatory compliance. Fig. 1 illustrates the stages of the system development process for ROMAns. Essentially, the ROMAns ERP system development project for RFI employs a hybrid approach combining waterfall and prototyping methodologies. The overall project adheres to a waterfall model, except for the system development phase, which utilizes prototyping. Integrating prototyping within the Waterfall methodology leverages the strengths of both approaches. Prototyping helps refine requirements and ensure user satisfaction, while Waterfall provides a structured and systematic framework for development. This hybrid approach can lead to a more effective and user-centered ERP system for RFI keropok lekor business operations.

To gain a comprehensive understanding of RFI's keropok lekor business operations, a meticulous preliminary investigation was undertaken. This involved conducting in-depth interviews with key personnel across departments, a thorough examination of existing documentations detailing their workflows and procedures, and direct observation of their current manual processes on the ground in their factory located at Kuala Nerus, Terengganu. The goal of this initial phase was to capture the nuances of their daily activities, identify existing bottlenecks, and understand the specific information flow within the company. This foundational understanding was deemed critical to ensure that any subsequent technological intervention would be truly aligned with RFI's unique operational context and their expected enhancement requirements.

Following this initial fact-finding mission, a comprehensive feasibility study was conducted. This study delved into the technical, operational, and financial implications of implementing an Enterprise Resource Planning (ERP) system within the keropok lekor business. The technical aspect explored the suitability of available technologies and the potential for integration with existing infrastructure, if any. The operational analysis focused on how the proposed ERP features could streamline and enhance RFI's core business processes, from raw material procurement to the final sale of their keropok lekor. Crucially, the financial component assessed the costs associated with the ERP implementation against the anticipated benefits, ensuring a viable return on investment for RFI. This feasibility study served as a critical checkpoint, ensuring that

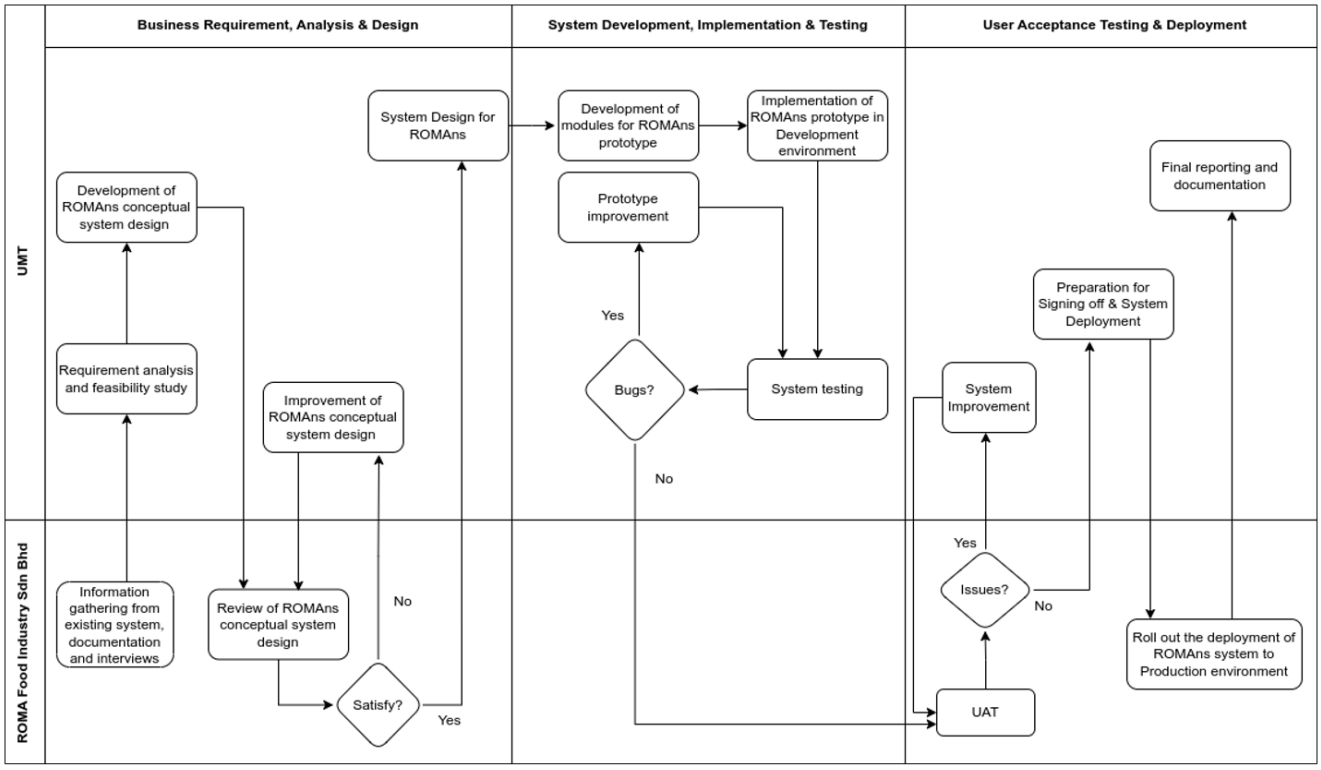

Fig. 1. ROMAns system development.

the proposed ERP solution, which would eventually be named ROMAns, was not only technically sound but also operationally practical and financially justifiable, directly addressing the specific needs and aspirations of the company.

Subsequently, the conceptual design of ROMAns was meticulously modeled. This involved translating the insights gained from the preliminary investigation and the feasibility study into a tangible blueprint of the proposed system. This conceptual model outlined the key functionalities, data flows, and user interfaces of ROMAns. Recognizing the importance of ensuring the system truly met RFI's requirements, this conceptual design underwent an iterative review process. RFI's key personnel were actively involved in examining the proposed model, providing feedbacks, and suggesting modifications until they were completely satisfied that ROMAns accurately reflected their business needs and operational realities. This collaborative approach ensured that the final system design was not just a technical solution but a tool tailored to empower RFI's growth and efficiency within the competitive keropok lekor market of Terengganu.

Once the conceptual design of ROMAns received the full endorsement of RFI, the final system design was constructed. This detailed blueprint served as the foundational architecture for the subsequent development of all identified system modules. This stage involved specifying the technical specifications, data structures, and integration points between different components of ROMAns. The design laid the groundwork for a cohesive and integrated system capable of managing various aspects of RFI's operations. As a result of this thorough planning and design phase, five core modules were identified as being absolutely crucial for the effective management of RFI's keropok lekor business operations. These fundamental modules are: Human Resource (HR), Production, Finance, Sales, and Inventory. Each of these core modules is further comprised of several vital submodules. These submodules are specifically designed to provide granular support for RFI's diverse keropok lekor business processes and operational workflows, as visually represented in Fig. 2, offering a clear overview of the system's modular structure and interdependencies.

1) Human resource management: The volatility stemming from the external market forces acting upon the keropok lekor industry, contributes to the challenges RFI faces in retaining its production employees. The inconsistency in workload and the perceived lack of stability can make employment at the production site less appealing in the long term for some individuals. Consequently, employees might seek more stable employment opportunities elsewhere, leading to the observed high turnover rates. Addressing this issue is crucial for RFI to maintain consistent production quality, reduce recruitment and training costs associated with frequent staff changes, and foster a more experienced and skilled production team dedicated to crafting their Terengganu-style keropok lekor. Understanding the direct link between the market's unpredictability and employee retention is the first step towards developing strategies to mitigate this challenge and create a more stable and attractive working environment within RFI's production operations. Therefore, ROMAns provides Human Resource (HR) module comprises of five significant submodules for smooth resource allocation: Employee Profile (to record and maintain employee details), Schedule (to systematically allocate manpower based on workloads and market/customer demand), Payroll (to record and

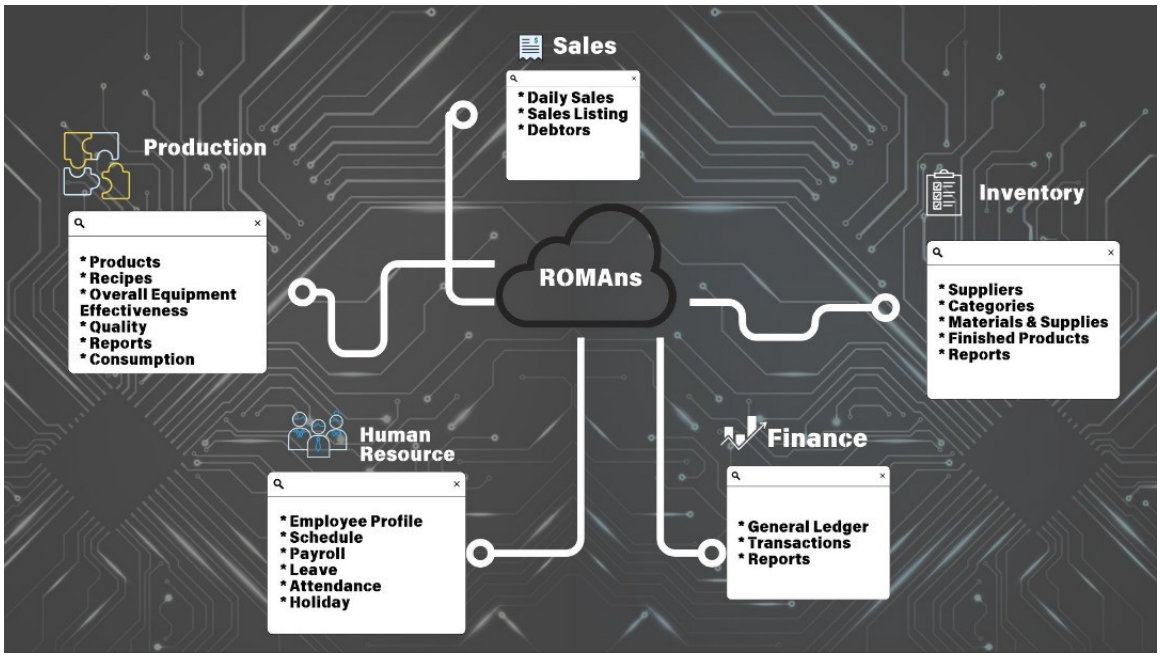

Fig. 2. ROMAns modules.

manage employee salaries), Leave and Attendance (to track and organize employee leaves and attendance), and Holiday (to track national and state public holidays, which are streamlined with staff salaries according to Malaysian employment law).

2) Production management: Recipes are the fundamental blueprint of any food business, crucial for maintaining consistent quality, inspiring culinary creativity and captivating customer loyalty. ROMAns incorporates a recipe submodule to facilitate comprehensive documentation of RFI?s keropok lekor recipes. This module ensures product consistency, enables precise cost control through accurate ingredient quantification, minimizes waste, and optimizes inventory management, ultimately driving their business profitability.

The production module incorporates a quality management submodule to establish and document keropok lekor product standards. Regular customer feedback analysis drives product improvements to align with evolving preferences. In case of quality issues, detailed records are maintained, investigated by the floor production manager, and addressed with corrective actions. The RFI CEO reviews and approves resolutions, ensuring consistent product quality, which is essential for building and maintaining customer trust and loyalty.

RFI utilizes six pieces of equipment or machine in the production of keropok lekor: 1) fish deboner, 2) ingredient mixer, 3) meat mincer, 4) burner, 5) vacuum and 6) drying machine. The productivity of these manufacturing machines can be effectively assessed using Overall Equipment Effectiveness (OEE) metrics, a widely adopted industry standard introduced by Seiichi Nakajima in the 1960s [11]. OEE provides a clear benchmark for evaluating equipment performance, identifying inefficiencies such as machine downtime, defects, and underperformance. Therefore, in this study, the OEE submodule was designed to evaluate overall performance of the utilization of these machines, assess daily keropok lekor production, and increase output while reducing costs related to downtime, repairs, and defective products. Using ROMAns, OEE percentage can be calculated automatically based on the following formula:-

$$\text{OEE\%} = \frac{\text{Actual Output}}{\text{Target Output}} \times 100\% \tag{1}$$

To determine the Target Output(TO), ROMAns will first calculates the Actual Hour (AH) using this equation:

$$\text{AH} = \text{PH - IH - RH - DT} \tag{2}$$

Where

IH = Idle Hour, RH = Rest Hour, DT = Down Time

The Target Output (TO) is then calculated by multiplying the Actual Hour (AH) by the Total Manpower (TM) and the Rate Besen Per Hour (RBHR):

$$\text{TO} = \text{AH x TM x RBHR} \tag{3}$$

A besen holds sixteen kilograms of keropok lekor dough.

Therefore, the final equation to measure the OEE percentage using ROMAns is:

$$\text{OEE} = \frac{\text{AO}}{\text{AH x TM x RBHR}} \times 100\% \tag{4}$$

Meticulous monitoring and management of raw material consumption allow RFI to optimize resource utilization, minimize waste, and enhance product margins. Consumption submodule supports understanding consumption patterns, enabling accurate production cost calculations, informed pricing strategies, and precise profit-loss tracking. Given the reliance on perishable ingredients, effective waste management is crucial for RFI's keropok lekor business. Designed to significantly enhance operational efficiency by identifying and addressing reported waste, analyzing these wastes can provide valuable insights into production inefficiencies, leading to more accurate inventory levels and ultimately improving overall production efficiency and cost analysis. At RFI, waste can occur with both raw materials and finished products. ROMAns automatically tracks this, flagging a high waste event if the combined daily waste exceeds 3% of production. This triggers an immediate alert to RFI Management, prompting them to address the issue in current production or implement preventative measures for future batches. Additionally, the quality of both raw materials and finished products is recorded to assess their impact on production, sales, and the company's overall financial health.

3) Financial management: The general ledger serves as the fundamental backbone of any organization's financial management framework, meticulously documenting every financial transaction that occurs within the business. These transactions are systematically categorized and recorded under specific accounts, providing a comprehensive and auditable trail of the company's financial activities. Currently, RFI's approach to managing their critical financial data involves the manual entry and upkeep of all business transactions within Microsoft spreadsheets. While this method may have served its purpose in the past, it presents limitations in terms of efficiency, accuracy, and the ability to seamlessly integrate financial data with other operational aspects of the business. Recognizing the inherent constraints and potential for errors associated with manual spreadsheet management, the ROMAns system introduces a significant upgrade through its dedicated General Ledger, Transactions, and Reports submodules. These integrated submodules are specifically engineered to provide a more systematic and robust solution for organizing and managing the entirety of RFI's financial transactions. By automating the recording and categorization of financial data, ROMAns aims to enhance accuracy, reduce manual effort, and provide real-time insights into the RFI's financial health. Furthermore, these financial submodules are designed with seamless interlinking capabilities, ensuring that financial data is readily accessible and integrated with all other pertinent modules within the ROMAns system, offering a holistic view of RFI's business performance.

4) Sales management: ROMAns's sales module is designed to comprehensively manage RFI's sales activities, accommodating their practice of allowing both cash and credit payments. To achieve this, the module incorporates three key submodules: Daily Sales Transaction, Sales Listing, and Debtor Details. The Debtor Details submodule is particularly crucial given that a significant portion of RFI's clientele comprises agents and resellers who typically purchase keropok lekor in substantial quantities, often on credit terms. The Daily Sales Transaction submodule facilitates the recording of each individual sales event, while the Sales Listing provides an overview of all sales activities within a specified period. Together, these submodules are pertinent for RFI to effectively track all types of business and sales transactions, monitor outstanding payments from their reseller network, and gain a clear understanding of their sales performance. This structured approach ensures accurate record-keeping and supports informed decision-making regarding sales strategies and credit management.

5) Inventory management: In Terengganu?s highly competitive market, a systematic inventory management system is crucial for RFI's keropok lekor business not just for stock tracking but also for enhancing operational efficiency, sustainability, and cost control. By minimizing waste (especially for perishable ingredients) and ensuring product freshness through First In First Out (FIFO) method, RFI can maintain quality while meeting customer demand promptly, particularly for its agent and reseller network. To address these needs, ROMAns inventory module was developed to cater for a comprehensive inventory management solution. It tracks and manages data on suppliers, raw materials, supplies, and finished products. This system enables RFI to monitor stock levels accurately, provide real-time information to customers, and make informed business decisions based on reliable data.

IV. System Development and Implementation

Prototyping methodology is employed as the system development approach due to RFI's expectation of immediate system utilization, as well as the incomplete understanding of certain requirements and the potential evolution of some parts of production processes. Using this approach, prototypes of the five core modules, as shown in the Fig. 2, are created individually. In the development environment, crude prototype models for each core module are developed and tested individually. Subsequently, these modules are integrated, and the overall ROMAns system undergoes testing. At this stage, RFI representatives also witness all these tests to understand the system's functionality and provide feedback and suggestions. Once system testing is completed and all bugs are rectified, User Acceptance Testing (UAT) is performed by RFI staff. Iterative improvements are made to the ROMAns system until it meets their needs and requirements. Upon successful UAT, the project moves to the deployment phase.

Most keropok lekor producers in Terengganu are small and medium-sized enterprises (SMEs) that rely on traditional methods for production and business practices. Implementing an ERP system for these companies requires a complete shift from their traditional approach. A big bang implementation strategy is suitable due to its shorter implementation timeframe [12]. As bold and ambitious strategy, big bang approach allows simulataneous switch from existing system to the new ERP across departments, functions and processes in a rapid, time saving and cost effective manner. Deploying the ERP through the big bang approach offers easy coordination of streamlined processes that may help RFI achieve quicker returns on investment, easier integration and reporting, reduced running costs as legacy systems are retired simultaneously, a faster implementation timeline, and allows the entire company to benefit from the deployed system by enforcing process changes.

V. Conclusion

ERP plays a crucial role in driving business digitalization and will significantly impact keropok lekor business operations by transforming traditional processes into more efficient, data-driven workflows. Built with Laravel Framework, PHP, and JavaScript, ROMAns is particularly significant for SMEs like RFI, enabling them to consolidate data into a single database for real-time access to accurate information vital for their keropok lekor business processes and effective decision-making. By embracing automation through ROMAns, RFI can enhance its competitiveness in the keropok lekor industry, optimize operations, adapt to market changes, deliver high-quality products, and improve customer service, ultimately leading to sustainable business growth. These advantages contribute to the overall success and competitiveness of the business in today's dynamic landscape.

***Abstract*—Phishing attacks remain a persistent and evolving cybersecurity threat, necessitating the development of highly accurate and efficient detection mechanisms. This research introduces an optimized ensemble stacking framework for phishing website detection, leveraging advanced machine learning techniques, hybrid feature preprocessing, and meta-learning strategies. The proposed approach systematically evaluates nine diverse base classifiers: XGBoost, CatBoost, LightGBM, Random Forest, Gradient Boosting, Extra Trees, Support Vector Classifier, AdaBoost, and Bagging. We compare baseline classifiers, a standard ensemble stacking model, and four optimized stacking configurations across four balanced and imbalanced datasets. Our optimized ensemble stacking achieves perfect accuracy (one hundred percent) on the first two datasets, and over ninety-nine percent accuracy on the two more challenging imbalanced datasets. A direct comparison with related studies demonstrates that our optimized stacking approach delivers superior detection accuracy.**

***Keywords*—Phishing detection; machine learning; ensemble stacking; cybersecurity**

I. Introduction

The increasing reliance on online services has made individuals and organizations more vulnerable to cyberattacks, with phishing remaining a significant threat [1]. Phishing attacks employ deceptive techniques to steal sensitive information, often masquerading as legitimate entities to trick users into divulging credentials or financial details [2]. Despite existing security measures, phishing continues to evolve, posing persistent challenges to both individuals and organizations [1]. As of 2024, the rate of phishing attacks remains alarmingly high, with reports indicating that the number of phishing attacks detected worldwide ranges from hundreds of thousands to millions each month [3].

Traditional phishing detection systems often rely on machine learning algorithms and manually crafted features [1]. However, these systems struggle to keep pace with the constantly evolving tactics employed by phishers [4]. While various machine learning, deep learning, and other approaches have been proposed, their detection accuracy needs further improvement [5]. Ensemble learning, particularly stacking (stacked generalization), has emerged as a promising technique for enhancing the performance of classification models by combining the strengths of multiple base classifiers [6]. Stacking involves training a meta-classifier on the outputs of individual base classifiers, potentially leading to a more robust and accurate model [7]. In 2024, the proliferation of sophisticated phishing websites poses a significant threat to individuals and organizations, resulting in substantial financial losses and personal data breaches [1]. Despite numerous detection methods, including machine learning and deep learning techniques, the accuracy and generalizability of these approaches remain insufficient to effectively combat the evolving tactics of cybercriminals [4]. The dynamic nature of phishing attacks, characterized by the use of advanced evasion techniques and rapidly changing features, necessitates the development of more robust and adaptive detection systems. Traditional phishing detection systems that rely on machine learning and manual features struggle with evolving tactics [8].

Phishing website detection has become a critical area of research due to the increasing sophistication and frequency of phishing attacks targeting individuals, organizations, and even IoT environments. Machine learning (ML) and deep learning methods, particularly ensemble learning techniques such as stacking, bagging, and boosting, have shown promise in improving detection accuracy by leveraging the strengths of multiple classifiers. Recent studies have demonstrated that stacking ensemble models, especially when optimized, can outperform single classifiers and traditional detection methods in terms of accuracy, recall, and other performance metrics[9], [10]. Despite these advances, several limitations persist in current research. Many studies rely on a fixed set of base classifiers without systematically selecting or optimizing the most effective algorithms for stacking, which can potentially limit model performance [11], [12], [13]. Optimization efforts, when present, often focus on parameter tuning for individual models rather than holistic selection and combination of diverse, high-performing classifiers [5], [11], [14]. Additionally, some approaches lack robust validation across multiple, diverse datasets, raising concerns about the generalizability of their results to real-world scenarios [15], [9], and [5]. There is also a need for more comprehensive feature selection and integration strategies to further enhance detection capabilities [15], [14]. These gaps are significant because suboptimal model selection, insufficient optimization, and limited generalizability can result in lower detection accuracy and increased vulnerability to evolving phishing tactics. Inadequate detection systems may fail to protect users and organizations from financial loss, data breaches, and reputational damage, especially as attackers continually adapt their methods to bypass existing defenses [9], [16]. This study addresses the research question: How can optimized ensemble stacking improve phishing website detection accuracy across diverse datasets with varying sizes,

balances, and feature complexities? To answer this, we systematically select and optimize a diverse set of strong base models for stacking, employ advanced optimization techniques, and validate the enhanced ensemble stacking approach across multiple datasets. By focusing on both algorithm selection and parameter optimization, the proposed method achieves higher detection accuracy, improved robustness, and better adaptability to new phishing strategies.

This study responds to these challenges by systematically selecting and optimizing a diverse set of strong base models for stacking, employing advanced optimization techniques, and validating the enhanced ensemble stacking approach across multiple datasets. By focusing on both algorithm selection and parameter optimization, the proposed method aims to achieve higher detection accuracy, improved robustness, and better adaptability to new phishing strategies, thereby strengthening real-world cybersecurity defenses. By extensively comparing various ensemble configurations, this research demonstrates the effectiveness of advanced ensemble stacking techniques in identifying phishing websites with high precision, reliability, and efficiency.

This study provides the following contributions:

- Develop an optimized ensemble stacking model with optimized hyperparameters, preprocessing, and feature engineering for performance improvement.
- Provide ensemble stacking variations for optimal results.
- Evaluate the model comprehensively across multiple datasets for performance assessment.

To achieve the above contributions, we develop an enhanced phishing website detection approach that leverages optimized ensemble stacking models to improve classification accuracy. This method integrates multiple machine learning classifiers within a structured ensemble framework, including Random Forest, Gradient Boosting, XGBoost, CatBoost, LightGBM, and Support Vector Classifier SVC, among others, capitalizing on their complementary strengths. A meta-classifier (Logistic Regression and CatBoost) is used to aggregate the outputs of the base models. Additionally, variations of stacking models are compared across four datasets to determine the optimal configurations. The model is tested on four datasets, each subjected to several variations of the ensemble stacking model to identify the most effective configuration.

By extensively comparing the four *optimized* stacking configurations, this research demonstrates the effectiveness of our advanced stacking techniques in identifying phishing websites with high precision, reliability, and efficiency. As a preview of our principal findings, Optimized Stacking-1 and -2 each achieve **100 %** accuracy on the two clean, balanced benchmarks, while all four variants maintain above **99 %** accuracy on the more challenging imbalanced datasets—underscoring both the robustness and practical deployability of our approach.

The rest of the paper is organized as follows. Section II highlights key related research studies. Sections III, IV, and V explain our methodology, evaluation metrics, and experimental results. Finally, we conclude in Section VII.

II. Related Work

This section reviews relevant research in two areas. First, we examine ensemble learning approaches, particularly stacking, which have shown effectiveness in phishing detection by combining multiple classifiers. Second, we explore optimization techniques that enhance stacking performance, including model selection, hyperparameter tuning, and meta-learner strategies.

A. Ensemble Learning for Phishing Detection

Ensemble methods, which combine multiple individual classifiers, have emerged as a powerful approach to enhance the accuracy and robustness of phishing detection systems. To overcome the limitations of individual classifiers, ensemble methods have been proposed, which combine the predictions of multiple models to improve overall accuracy and robustness [17].

Ensemble methods, while powerful, have certain limitations when applied to phishing detection. One significant limitation is the inability of some ensemble techniques, like random forests, to capture high correlations between features and their joint dependency on the label, which can affect the model's performance in complex datasets [18]. Additionally, traditional ensemble methods may struggle with the evolving nature of phishing attacks, as they often rely on static features that do not adapt well to new phishing tactics [19]. Furthermore, the computational cost and complexity of ensemble methods can be high, which may not be suitable for real-time detection scenarios [19].

Ensemble models typically require more resources for training and prediction, as they involve combining the outputs of multiple base classifiers. This increased computational overhead can be a drawback, especially in scenarios where real-time or low-latency detection is required. Additionally, the complexity of tuning and optimizing ensemble methods may pose challenges, as selecting the appropriate base classifiers and configuring the meta-classifier can significantly impact overall performance [20].

When comparing traditional ensemble methods and stacking ensembles, the latter often demonstrates superior performance in phishing detection tasks. For example, stacking models have achieved higher accuracy and F1 scores compared to standalone ensemble methods, such as random forests or AdaBoost [21]. The ability of ensemble stacking to combine the strengths of multiple algorithms and mitigate their weaknesses makes it a good choice for phishing detection [5], [9].

Stacking addresses these challenges by intelligently combining the strengths of diverse base classifiers, mitigating the risk of overfitting, and improving generalization performance, which can lead to more accurate and robust phishing website detection [17]

B. Optimization Techniques in Stacking Models

Phishing website detection has been a significant area of research due to the increasing sophistication of phishing attacks. Several studies have investigated the application of ensemble machine learning models to improve detection accuracy.

One approach involves the use of optimized stacking ensemble models, which combine multiple machine learning algorithms to improve detection performance. For instance, a study utilized a genetic algorithm to optimize parameters of ensemble methods, including Random Forest, AdaBoost, and XGBoost, achieving detection accuracies of 97.16%, 98.58%, and 97.39% across different datasets [5]. Another study reported a similar approach, achieving a detection accuracy of 97.16% by optimizing ensemble classifiers [22].

Other research has focused on stacking models that integrate multiple classifiers, such as Random Forest, Gradient Boosting, and AdaBoost, with logistic regression as an aggregator. This model achieved an accuracy of 98.72% and demonstrated superior performance compared to individual algorithms [10]. Additionally, a multilayer stacked ensemble learning model achieved accuracies ranging from 96.79% to 98.90% across various datasets, highlighting the effectiveness of layered ensemble techniques [9].

The accuracy of phishing website detection models varies across studies, with several achieving high performance. For example, one study reported an accuracy of 98.72% using a stack ensemble model [10], while another achieved 99.31% with a stacked classifier model employing six algorithms [3]. A different approach using a stacking model with URL and HTML features achieved 97.30% accuracy on one dataset and 98.60% on another [23].

Despite the high accuracy rates reported, there are limitations and gaps in current research. Many studies emphasize the need for further enhancement of detection accuracy and adaptability to evolving phishing tactics [22], [24]. Additionally, while ensemble models show promise, they often require complex optimization and feature selection processes, which can be computationally intensive [15], [25]. There is also a need for real-time detection capabilities, as many models are tested in controlled environments and may not perform as well in dynamic, real-world scenarios [23].

Another study optimized stacking ensemble methods using a Genetic Algorithm to tune parameters of various ensemble methods such as Random Forest, AdaBoost, XGBoost, and others. This approach achieved detection accuracies of 97.16% to 98.58% across different datasets, demonstrating significant improvements over traditional methods [22], [5].

Phishing website detection has been a significant area of research due to the increasing threat posed by phishing attacks. Various studies have explored the use of ensemble models to enhance detection accuracy. A stack ensemble model combining RandomForest, GradientBoosting, and AdaBoost with logistic regression as an aggregator achieved an accuracy of 98.72%, demonstrating superior performance over individual algorithms and existing studies [10]. Another study proposed an optimized stacking ensemble method using a genetic algorithm to tune parameters, achieving detection accuracies of 97.16%, 98.58%, and 97.39% across different datasets [5]. Similarly, a multilayer stacked ensemble learning model reported accuracies ranging from 96.79% to 98.90% across various datasets, outperforming baseline models [9].

Despite the high accuracy rates, several limitations and gaps remain in the current research. First, many models are tested on specific datasets, which may not generalize well to other datasets or real-world scenarios [5], [9]. Second, some models rely heavily on specific features, such as URL and HTML characteristics, which may not be present in all phishing websites [23]. Third, the complexity of ensemble models can lead to increased computational costs, making real-time detection challenging [15], [3]. Fourth, phishing tactics continue to evolve, necessitating ongoing updates and adaptations of detection models to maintain effectiveness [24], [21] . Last, the use of multiple models in stacking can increase the risk of overfitting, particularly if the base models are too complex or if the dataset is not sufficiently large or diverse [9], [5].

In summary, while ensemble models have significantly improved phishing website detection accuracy, challenges remain in optimizing these models for real-time applications and adapting to new phishing strategies. Our work addresses these limitations and designs a more robust and efficient detection system.

III. Methodology

This research employs a systematic and structured methodology to enhance the detection of phishing websites by implementing optimized ensemble stacking models. The proposed approach, aimed at improving phishing website detection, is uniformly applied across four benchmark datasets. It follows a systematic sequence involving data preprocessing, model training, and performance evaluation, and is consistently implemented on the following datasets: Dataset 1 [26], Dataset 2 [27],and Dataset 3 and Dataset 4, both derived from the same source [28]. We ensure consistency in base model selection (RandomForest, XGBoost, CatBoost, GradientBoosting, LightGBM, ExtraTrees, AdaBoost, Bagging, and SVC) across all datasets. However, ensemble stacking models are adjusted in hyperparameters, iterations, and cross-validation strategy for each dataset to balance execution time and accuracy. The methodology incorporates data preprocessing techniques, including feature encoding, SMOTE oversampling for imbalanced datasets, and feature standardization. The evaluation framework uses accuracy, classification reports, and confusion matrices to compare performance across datasets and determine the most effective dataset for phishing detection.

The proposed framework involves several steps, which are summarized below:

- Perform necessary preprocessing steps, such as encoding categorical variables, scaling numerical features, and addressing class imbalances using SMOTE on the selected datasets.
- Train and evaluate multiple individual classifiers, including RandomForest, XGBoost, CatBoost, LightGBM, GradientBoosting, ExtraTrees, SVC, AdaBoost, and Bagging, for each dataset. This establishes a baseline performance for comparison before implementing stacking ensembles. The results include accuracy scores and classification reports for all datasets.
- The structure of the stacking ensemble involves training a traditional stacking ensemble model using a variety of base classifiers, including XGBoost, Random Forest, CatBoost, LightGBM, Gradient Boost-

ing, Extra Trees, SVC, AdaBoost, and BaggingClassifier, with Logistic Regression as the final estimator. The improved stacking ensemble model incorporates optimized hyperparameters, balancing techniques (SMOTE), and boosting-based feature selection implicitly through models like XGBoost, CatBoost, and LightGBM. The improved version uses CatBoost as the final estimator and employs StratifiedKFold cross-validation to enhance generalization.

- Evaluate and compare the performance of individual base models, traditional stacking ensemble, and improved stacking ensemble across all datasets. Metrics such as accuracy, precision, recall, F1-score, and confusion matrices will be used for comparison.
- Illustrate the performance across models and datasets using various visualization methods. These visual aids help identify trends, strengths, and weaknesses in the models for each dataset.

The primary objective of this study is to investigate how variations in dataset characteristics impact the performance of the improved ensemble stacking model and to identify which dataset yields the most effective results. The overall workflow of the proposed approach is illustrated in Fig. 1.

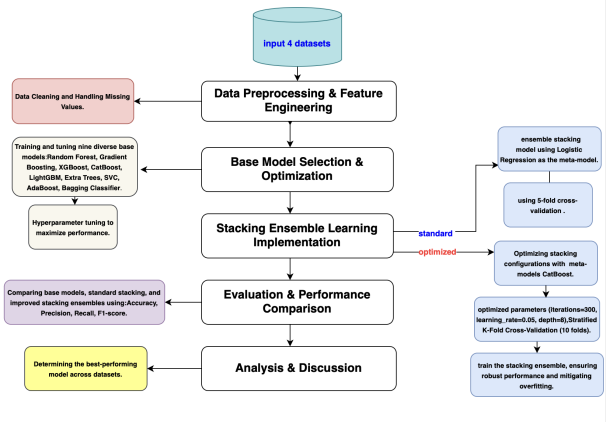

Fig. 1. Overview of the proposed ensemble stacking workflow.

A. Dataset Description

This study utilizes four datasets of varying sizes, features, and class distributions to train, test, and evaluate the phishing website detection model. These datasets ensure a comprehensive assessment of model performance under different conditions. Balanced datasets facilitate the assessment of baseline performance without introducing bias, thereby providing a clear foundation for evaluating model accuracy. In contrast, unbalanced datasets are used to test the robustness of the models, with SMOTE applied to generate synthetic samples and improve classification fairness. This combination of balanced and unbalanced datasets enabled a comprehensive evaluation of the models' robustness and their practical applicability in real-world phishing detection scenarios.

1) Balanced datasets: include Dataset 1 [26] (11,430 instances, 89 features), titled Web Page Phishing Detection and sourced from Mendeley Data, and Dataset 2 [27] (11,481 instances, 89 features), also titled Web Page Phishing Detection and obtained from Kaggle. Both datasets contain an equal number of phishing and legitimate website samples. Specifically, Dataset 1 includes 5,715 phishing and 5,715 legitimate samples, while Dataset 2 consists of 5,740 phishing and 5,741 legitimate samples. These balanced distributions eliminate class bias and support reliable model evaluation without the need for resampling techniques. Both datasets feature a rich set of attributes relevant to phishing detection, such as length_url, nb_dots, domain_age, iframe, tld_in_path, google_index, and ratio_digits_host. These features capture URL structure, domain trustworthiness, and content behavior, which are critical for distinguishing phishing from legitimate websites.

2) Unbalanced datasets: include Dataset 3 [28] (88,647 instances, 112 features) and Dataset 4 [28] (58,645 instances, 112 features), both derived from the Phishing Websites Dataset available on Mendeley Data, both of which exhibit varying degrees of class imbalance. Dataset 3 contains 30,648 phishing and 57,999 legitimate samples (34.57% phishing,65.43% legitimate), while Dataset 4 includes 30,651 phishing and 27,994 legitimate samples (52.26% phishing, 47.74% legitimate). To address this imbalance, the Synthetic Minority Oversampling Technique (SMOTE) was applied. These datasets include more advanced and diverse features such as ttl_hostname,qty_redirects, url_shortened, tls_ssl_certificate, and domain_google_index, which reflect redirection patterns, SSL usage, and DNS behaviors.

B. Data Preprocessing

To ensure consistency and accuracy, a structured preprocessing pipeline was applied across all datasets. First, non-numeric columns were identified, and missing values in categorical features were replaced with the string "Missing" to retain the information. Second, LabelEncoder was used to convert categorical features and the target variable into a numerical format for compatibility with machine learning models. Third, SMOTE was applied with an 80% sampling strategy to balance minority and majority classes, improving model generalization. Each dataset was split into 80% training and 20% testing, ensuring fair evaluation on unseen data. Lastly, StandardScaler transformed the features to have a mean of 0 and a standard deviation of 1, benefiting models that are sensitive to feature magnitude. All four datasets underwent identical preprocessing steps to maintain fairness in performance comparisons. By applying these steps, the data was cleaned, balanced, and optimized, ensuring reliable training and evaluation of the phishing detection models.

C. Selected Base Models and Ensemble Learning Design

To ensure robust and generalizable phishing detection, a diverse set of nine base classifiers was selected and consistently applied across four benchmark datasets: Dataset 1, Dataset 2, Dataset 3, and Dataset 4. These models were chosen to leverage complementary strengths in handling non-linear patterns, categorical features, boosting mechanisms, and high-dimensional data.

The base models used in all experiments include gradient boosting algorithms (XGBoost, CatBoost, LightGBM,

GradientBoostingClassifier), ensemble tree methods (RandomForestClassifier, ExtraTreesClassifier), kernel-based classifiers (SVC), and ensemble meta-learners such as AdaBoostClassifier and BaggingClassifier. Each model is known for its strong performance in phishing detection and tabular classification problems [29], [30], [31], [8]. The gradient boosting algorithms are known for their high accuracy and ability to capture complex relationships [8]. XGBoost is also efficient and scalable. CatBoost is particularly good at handling categorical features. The ensemble tree-based models can handle complex, nonlinear feature interactions well and have demonstrated high accuracy in phishing detection tasks [29], [30], [32] . Support Vector Classifier (SVC) with nonlinear kernels captures subtle lexical and structural patterns in URLs, contributing to high classification accuracy and generalization across datasets [30], [31]. AdaBoost enhances the performance of weak learners by focusing on complex samples, thereby improving overall detection accuracy [30]. Bagging reduces variance by aggregating multiple models trained on different data samples, improving robustness and generalization [31].

Comparative studies highlight the effectiveness of combining diverse classifiers, including SVC, AdaBoost, and Bagging, in the phishing detection task [30]. These diverse machine learning models, including ensemble tree-based methods, gradient boosting algorithms, kernel-based classifiers, and ensemble stacking techniques that reduce variance or improve weak learners, have been effectively used together to detect phishing websites with high accuracy [33], [19], [4].

1) Training and evaluation of models: To systematically assess model performance, a dedicated function was designed to train and evaluate multiple classifiers on the phishing datasets. This function accepts training and testing subsets for each dataset and outputs standardized evaluation metrics for comparative analysis. The procedure involves training each classifier on the training data, generating predictions on the test data, and evaluating performance using key classification metrics. Each model is evaluated on all four datasets to examine its generalizability across varying data characteristics. By applying this process uniformly across balanced and unbalanced datasets, it was possible to identify base models that consistently deliver high performance.

Specifically:

- Models were trained and evaluated on Dataset 1 and Dataset 2, both of which are balanced.
- The same process was applied to Dataset 3 and Dataset 4, which are imbalanced and larger in scale.

For each dataset, model results were stored and analyzed using:

- Accuracy: Overall classification accuracy for each model.
- Classification Report: Detailed metrics including precision, recall, and F1-score per class.

D. Standard Ensemble Stacking Approach

The ensemble stacking approach integrates the predictive capabilities of multiple diverse base classifiers into a unified model, aiming to significantly enhance phishing website detection accuracy. This layered architecture consists of a base layer where classifiers are trained independently, and a meta-layer that learns to optimally combine their predictions into a final decision. The effectiveness of Logistic Regression as a meta-learner in stacking ensembles has been demonstrated in phishing detection systems, achieving 98% accuracy when combined with base classifiers like Random Forest and XGBoost [34]. To ensure generalization and reduce overfitting, 5-fold cross-validation was employed during model training, as recommended in recent phishing detection research [35].

In this study, a consistent standard stacking framework was applied across our four datasets, including the two balanced datasets. This structural consistency enables a fair comparison and allows analysis of how dataset characteristics affect ensemble performance. The base layer comprised nine machine learning classifiers selected for their proven effectiveness and complementary strengths: RandomForest, Gradient Boosting, XGBoost, CatBoost, LightGBM, ExtraTrees, SVC, AdaBoost, and Bagging. Each classifier was chosen to contribute diverse perspectives in identifying phishing behavior patterns. For this stacking configuration, Logistic Regression was used as the meta-learner to combine the outputs of the base classifiers. To ensure generalization and reduce overfitting, 5-fold cross-validation was employed during model training.

E. Optimized Ensemble Stacking Approach

To improve the accuracy and efficiency of phishing website detection, we conduct four variations to optimize the ensemble stacking models. These models are systematically refined to strike a balance between complexity, computational efficiency, and detection performance.

- Optimized Stacking-1: comprehensive stacking model. This version employs a comprehensive ensemble stacking approach that integrates the nine base classifiers, including base classifiers RandomForest, XGBoost, CatBoost, LightGBM, Gradient Boosting, Extra Trees, SVC, AdaBoost, and Bagging. The CatBoost classifier was utilized as the meta-model, with hyperparameter tuning applied to optimize performance.
- Optimized Stacking-2: performance-oriented selection. This architecture prioritizes high-performing models by selecting XGBoost, CatBoost, and RandomForest as base classifiers, thereby reducing computational complexity while maintaining strong classification capabilities. The CatBoost classifier is used as the meta-model.
- Optimized Stacking-3: efficiency-optimized stacking. To enhance computational efficiency, the number of base models is reduced, retaining only the most effective classifiers: XGBoost, CatBoost, RandomForest, LightGBM, Gradient Boosting, and SVC. The CatBoost classifier continued to serve as the meta-model, ensuring robustness in predictions.
- Optimized Stacking-4: minimalist high-performance model. Designed for optimized execution and minimal computational cost, this model leverages a CatBoost classifier with advanced hyperparameter tuning as

the meta-model. The base models are reduced to XGBoost, CatBoost, RandomForest, LightGBM, and Gradient Boosting, achieving high efficiency while preserving detection accuracy. This ensemble model achieves a balance between execution time and detection accuracy.

1) Design and configuration of the optimized ensemble stacking: Each stacking configuration followed a unified pipeline. Non-numeric features are encoded using LabelEncoder, and class imbalance is addressed using SMOTE. Feature scaling is performed using StandardScaler to ensure consistency across numerical values. Stratified K-Fold cross-validation is used for training: 10-fold for balanced or smaller datasets (Datasets 1, 2, and 4), and 5-fold for the larger dataset (Dataset 3) to reduce execution time. A diverse set of nine base classifiers is employed to enhance generalization and capture a broad range of learning patterns: tree-based models (RandomForestClassifier, ExtraTreesClassifier, and GradientBoostingClassifier), boosting techniques (XGBClassifier, CatBoostClassifier, LGBMClassifier, and AdaBoostClassifier), a kernel-based model (SVC), and a bagging-based method (BaggingClassifier).

2) Base model optimization: The same base model structure is applied across all datasets, but hyperparameters are adjusted to match the dataset size and complexity. For the balanced datasets (Datasets 1 and 2), base models are configured with higher complexity. For the large, imbalanced datasets (Datasets 3 and 4), parameter values are reduced to accelerate training. Specifically, we perform the following key adjustments:

- Number of Estimators: 500 estimators for Datasets 1 and 2; reduced to 100 or 50 for Datasets 3 and 4.
- Learning Rate: It is set to 0.05 for smaller datasets; increased to 0.1 for larger datasets.
- Depth: Models used greater depth (10–25) for balanced data; shallower depth (6–10) for large-scale datasets in Optimized Stacking-1 and Stacking-3.

It is important to note how hyperparameter settings influenced performance across datasets. Increasing the number of estimators (e.g., 500 on Datasets 1 and 2) improved accuracy and reduced variance, but also increased training time, which is why smaller values (100 or 50) were used for the larger datasets. Similarly, greater tree depth (10–25) enhanced recall by capturing complex phishing patterns, but shallower depths (6–10) were more efficient for large-scale datasets and reduced the risk of overfitting. Adjusting the learning rate also played a critical role: lower values (0.05) improved model stability and recall on imbalanced data, while higher values (0.1) accelerated convergence but risked losing fine-grained detection capability. For the CatBoost meta-model, more iterations (300) strengthened performance on smaller balanced datasets, whereas fewer iterations (50–100) were sufficient for larger datasets to maintain efficiency without significant accuracy loss. These observations confirm that hyperparameter tuning was essential not only for maximizing accuracy but also for balancing robustness and computational efficiency across datasets.

3) Meta-model optimization: The meta-model used in all stacking ensembles is `CatBoostClassifier`, replacing Logistic Regression to improve generalization and robustness. The CatBoostClassifier demonstrates strong performance due to its efficient handling of categorical features and robustness on imbalanced datasets, which are commonly encountered in phishing detection scenarios [25]. Configurations are tailored per dataset:

- Balanced datasets 1 and 2: 300 iterations, depth 8, learning rate 0.05, with 10-fold cross-validation.
- Large and imbalanced Dataset 3:
  - Optimized Stacking-1 and Optimized Stacking-3: 50 iterations, depth 6, learning rate 0.1, with 5-fold CV.
  - Optimized Stacking-2 and Optimized Stacking-4: 300 iterations, depth 8, learning rate 0.05, with 10-fold CV.
- Dataset 4:
  - Optimized Stacking-1: 100 iterations, depth 6, learning rate 0.1, with 10-fold CV.
  - Optimized Stacking-2, Optimized Stacking-3, Optimized Stacking-4: 300 iterations, depth 6, learning rate 0.1, with 10-fold CV.

IV. Models Evaluation

A. Experimental Setup

To evaluate the effectiveness of the proposed optimized ensemble stacking models for phishing website detection, all experiments were executed in Google Colab, a cloud-based Jupyter environment. The programming environment was configured with Python 3 and accelerated using the v5e-1 TPU to handle the computational demands of training complex ensemble models on large datasets. We utilized several libraries such as scikit-learn [36], XGBoost [37], LightGBM [38], CatBoost [39], Matplotlib [40], Seaborn [41], Pandas [42], and NumPy [43].

B. Evaluation Metrics

To thoroughly evaluate the performance of the proposed *optimized ensemble stacking model* for phishing website detection, multiple classification metrics were employed. These metrics provide a comprehensive view of each model's effectiveness, especially in distinguishing between legitimate and phishing websites across datasets with varying distributions.

- Accuracy: Represents the overall proportion of correctly classified instances:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

  However, while accuracy is informative in balanced datasets, it may be misleading in imbalanced scenarios.

- Precision: Measures the proportion of true phishing detections among all predicted phishing cases:

$$\text{Precision} = \frac{TP}{TP + FP} \tag{2}$$

High precision reduces false alarms and is essential for protecting legitimate websites from misclassification.

- Recall (Sensitivity): Evaluates the model's capability to correctly detect actual phishing sites:

$$\text{Recall} = \frac{TP}{TP + FN} \tag{3}$$

High recall ensures phishing threats are not overlooked.

- F1-Score: The harmonic mean of precision and recall, providing a single balanced metric:

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{4}$$

It is especially useful in imbalanced data situations.

- AUC-ROC: Measures the area under the Receiver Operating Characteristic curve, reflecting the model's ability to distinguish between classes independently of the classification threshold. A value close to 1.0 indicates excellent performance.
- Confusion Matrix: Summarizes true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN), offering detailed insights into classification errors.
- Execution Time: Records the time required for model training and evaluation. This is crucial for determining the feasibility of deploying the model in real-time phishing detection systems.

V. Experiments and Results

To evaluate the proposed optimized ensemble stacking models, experiments were conducted on four phishing datasets differing in size, class balance, and feature structure. The same stacking architecture and base models were applied across all datasets, including four optimized stacking (optimized-stacking1 to optimized-stacking4) to ensure consistent comparison. Preprocessing involved label encoding, standard scaling, and SMOTE for imbalanced datasets. For large datasets, model parameters were adjusted to reduce training time without sacrificing accuracy. Evaluation used an 80:20 split and stratified cross-validation, measuring accuracy, precision, recall, F1-score, and confusion matrices to assess performance under different data conditions.

A. Experiment 1: Evaluation of Base Models Individually

Before implementing the stacking ensembles, nine base classifiers were independently evaluated to assess their generalizability and standalone performance across four phishing datasets: Dataset 1, Dataset 2, Dataset 3, and Dataset 4. These models include Random Forest, Gradient Boosting, XGBoost, CatBoost, LightGBM, Extra Trees, Support Vector Classifier (SVC), AdaBoost, and Bagging. Each model was selected based on its distinct learning paradigm and complementary strengths.

All classifiers were trained using an identical experimental pipeline that included preprocessing steps such as categorical encoding, SMOTE for handling class imbalance (in unbalanced datasets), and feature scaling. A fixed random seed was used for reproducibility, and models were evaluated on an 80/20 train-test split. Performance was measured using standard classification metrics including accuracy, precision, recall, F1-score, and AUC. The detailed performance metrics for all base classifiers are presented in Tables I through IV, with corresponding ROC curves illustrated in Fig. 2 to 5.

TABLE I. Base Models' Performance on Dataset 1

Model	Precision	Recall	F1-Score	Accuracy (%)	AUC
Random Forest	0.9695	0.9693	0.9694	96.94	0.9945

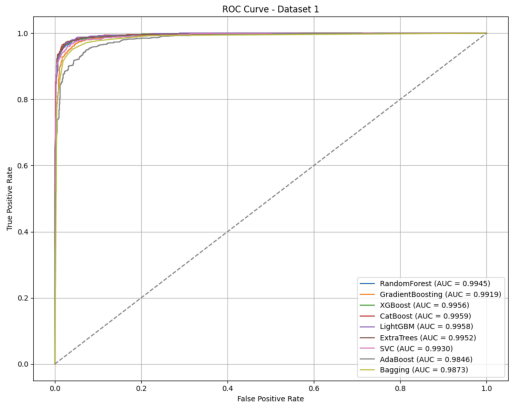

Fig. 2. ROC Curve of base model - Dataset 1.

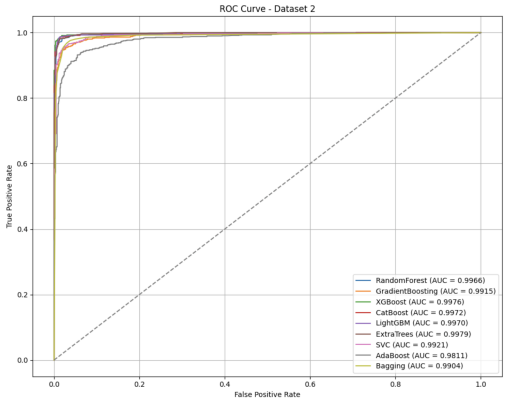

Fig. 3. ROC Curve of base model - Dataset 2.

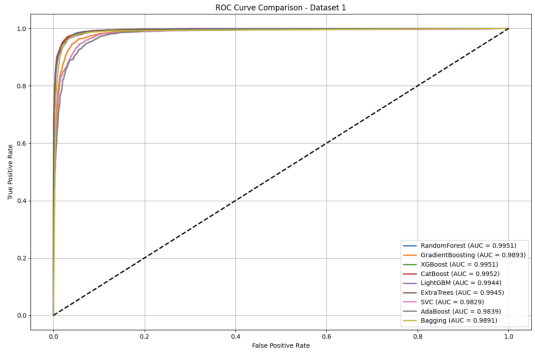

Fig. 4. ROC Curve of base model - Dataset 3.

The results showed that XGBoost and CatBoost consistently outperformed other models across all datasets, especially on the balanced ones, where both achieved perfect or near-perfect scores. Conversely, models like AdaBoost and Gradient Boosting showed performance degradation on imbalanced datasets due to sensitivity to class distribution. Tree-based ensembles such as Random Forest, Extra Trees, and Bagging demonstrated strong stability across all data conditions. SVC generally underperformed, possibly due to its limited scalability in high-dimensional spaces. These findings informed the selection of models used in subsequent ensemble stacking experiments.

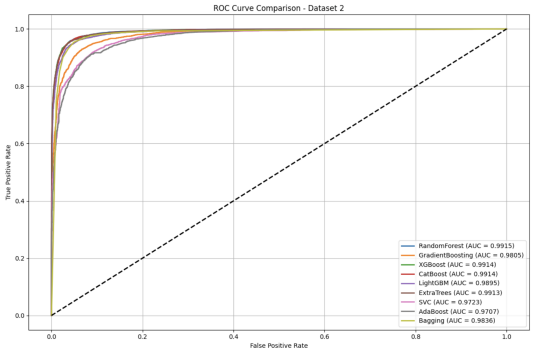

Fig. 5. ROC Curve of base model - Dataset 4.

B. Experiment 2: Performance of Standard Ensemble Stacking Model

This experiment implements a standard ensemble stacking architecture applied consistently across all four datasets. The stacking ensemble integrates tree-based models, including Random Forest and Extra Trees, which are known for handling high-dimensional data and reducing variance, alongside the Bagging classifier to enhance robustness against overfitting. It also incorporates boosting-based classifiers such as Gradient Boosting, XGBoost, LightGBM, and CatBoost, which iteratively improve model accuracy by focusing on difficult samples. Linear and kernel-based models, such as Support Vector Classifier (SVC), are included to capture non-linear patterns, while AdaBoost provides adaptive boosting of weak learners. Logistic Regression is used as the final meta-estimator due to its computational efficiency and ability to aggregate diverse base model outputs effectively.

The same ensemble architecture and base model configuration were used across all datasets to ensure fair comparison. The results, shown in Table V, demonstrate the model's high classification capability across both balanced and imbalanced data distributions. The stacking ensemble achieved high accuracy and consistently strong performance across all datasets. Particularly, Datasets 1 and 2, both balanced and clean, yielded the highest results, with Dataset 2 reaching 98.65% accuracy and an AUC of 0.9983. Dataset 3 and Dataset 4, exhibited slightly lower but still competitive performance. The stacking ensemble demonstrates superior capability in both balanced and imbalanced conditions, confirming its robustness. The high AUC values and consistent classification metrics validate the effectiveness of using heterogeneous learners within a stacking framework. These results justify the ensemble's role as a strong foundation for subsequent optimized stacking improvements.

TABLE V. PERFORMANCE OF STANDARD STACKING ENSEMBLE ACROSS ALL DATASETS

Dataset	Precision	Recall	F1-Score	Accuracy	AUC
Dataset 1	0.97	0.97	0.97	97.38%	0.9962
Dataset 2	0.99	0.99	0.99	98.65%	0.9983

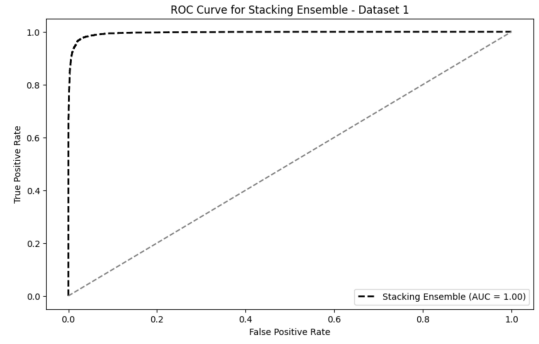

Fig. 8. ROC curve – standard ensemble stacking (Dataset 3).

C. Experiment 3: Optimized Ensemble Stacking Performance

To further enhance classification accuracy and address the limitations of the standard stacking approach, four optimized stacking configurations (Optimized Stacking-1 through Optimized Stacking-4)are implemented and consistently evaluated across four phishing detection datasets. All optimized stacking configurations retained the same architectural structure across all datasets to ensure a fair and consistent comparison. The base models and meta-model remained unchanged, with only hyperparameter adjustments made to accommodate computational constraints, particularly for the larger datasets.

TABLE X. CROSS-DATASET ACCURACY COMPARISON OF IMPROVED STACKING ENSEMBLES

Model	Dataset 1	Dataset 2	Dataset 3	Dataset 4
optimized Stacking-1	100.00	100.00	99.30	99.27
optimized Stacking-2	99.91	100.00	99.71	99.26
optimized Stacking-3	99.78	100.00	99.24	98.99
optimized Stacking-4	99.96	100.00	99.44	99.09

Tables VI, VII, VIII, and IX demonstrate that all four

optimized stacking ensembles consistently achieved high classification performance across diverse datasets, regardless of balance or size. Optimized Stacking-1, which included a comprehensive set of base classifiers such as gradient boosting, bagging, SVM, and decision trees, reached 100% accuracy on Dataset 1 and Dataset 2 and maintained strong generalization with accuracies of 99.30% and 99.27% on Dataset 3 and Dataset 4, respectively. Optimized Stacking-2 adopted a more streamlined architecture, utilizing only CatBoost, XGBoost, and Random Forest as base models. This approach reduced computational complexity while preserving accuracy, achieving 100% on balanced datasets and the highest recorded accuracy (99.71%) on the large-scale Dataset 3. Optimized Stacking-3 focused on execution efficiency by reducing the ensemble size based on performance impact. While slightly lower in accuracy compared to Ensembles 1 and 2, it still achieved competitive results—99.78% on Dataset 1 and 98.99% on Dataset 4—demonstrating that minimal model diversity can still yield strong outcomes when well-selected. Optimized Stacking-4 further simplified the ensemble configuration to prioritize speed and resource efficiency. Despite this reduction in complexity, it achieved excellent accuracy levels across all datasets, peaking at 99.96% on Dataset 1 and attaining 99.44% on Dataset 3, which confirms its effectiveness for real-time or resource-constrained environments.

As shown in the cross-dataset comparison in Table X, each optimized stacking variant maintained stability and high precision across varied data characteristics. These results collectively validate that the proposed optimized ensemble stacking configurations are not only robust and adaptable but also scalable to different operational constraints and dataset profiles. This makes them highly suitable for deployment in real-world phishing detection systems, where both accuracy and computational efficiency are critical.

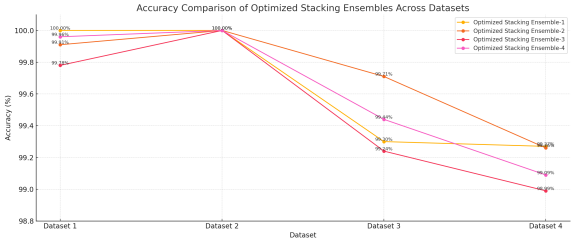

Fig. 10. Comparison of all dataset performance of optimized stacking.

Fig. 11 to Fig. 14 show a comparison of the accuracy of base models,Standard Ensemble Stacking, and improved stacks across datasets.

In addition, Fig. 15 to Fig. 30 illustrate the true and false positives and negatives for the best-performing model on each dataset.

VI. Discussion

We enhance phishing website detection by developing optimized ensemble stacking models and evaluating their performance across four distinct datasets. The Optimized ensemble stacking models outperformed both standard stacking and individual base models due to several key enhancements. First, they utilized optimized feature preprocessing techniques, including SMOTE for class balancing, feature scaling, and label encoding, which allowed for a more accurate representation of phishing patterns. Second, replacing the traditional Logistic Regression meta-model with the more robust CatBoost classifier improved the models' ability to generalize and handle nonlinear relationships and class imbalance. Additionally, reordering and selecting diverse base models enhanced the ensemble's ability to capture complementary learning patterns, resulting in stronger predictions. These improvements also ensured scalability, allowing the models to perform consistently across both small balanced datasets and large imbalanced ones. Finally, the enhanced variants demonstrated significant gains in execution efficiency, maintaining high accuracy while reducing computational time and complexity.

The comparative performance of the optimized ensemble stacking models varies across the four benchmark datasets due to inherent differences in their characteristics. Dataset 1 and Dataset 2 are balanced and relatively clean, with a near 50:50 distribution of phishing and legitimate instances. This balance enables the models to achieve perfect or near-perfect accuracy (approaching 100%), as the absence of significant class imbalance allows the learning process to capture phishing patterns more effectively.

In contrast, Dataset 3 is considerably larger (88,647 instances) and initially imbalanced, necessitating the use of SMOTE to address skewness. Even after balancing, the dataset's scale and the complexity of its features introduce additional variance, which explains the slight reduction in accuracy compared to the smaller, balanced datasets. Similarly, Dataset 4 presents a more challenging structure, with closer ratios between phishing and legitimate cases combined with a higher diversity of complex URL-based features. These factors contribute to minor fluctuations in the achieved results, even when using optimized stacking configurations.

Overall, these findings demonstrate that dataset-specific characteristics—such as class balance, dataset size, and feature richness—play a critical role in shaping model performance. At the same time, the consistently high accuracy achieved across all four datasets highlights the robustness and adaptability of the optimized ensemble stacking framework, which effectively generalizes across both balanced and imbalanced datasets while efficiently handling diverse feature distributions.

A. Dataset Characteristics and their Impact on Model Design

Each of the four datasets used Dataset 1, Dataset 2, Dataset 3, and Dataset 4 presented unique characteristics in terms of size, feature composition, and class distribution, all of which significantly influenced model design choices and performance outcomes. Dataset 1 and Dataset 2 were balanced, with a 50-50 split between legitimate and phishing samples, and exhibited high-quality data with no missing values. Their balanced nature eliminated the need for resampling techniques and allowed direct application of stacking models. Dataset 3 and Dataset 4 were imbalanced, requiring the use of SMOTE to address class distribution skewness. Dataset 3 was particularly large (88,647 records), demanding adjustments to model complexity and training time. Key dataset features influencing stacking performance included URL length, number of special characters, domain-related attributes, redirection behavior, and SSL

certificate indicators. These were effectively captured through hybrid feature engineering strategies.

To adapt to each dataset's scale and quality:

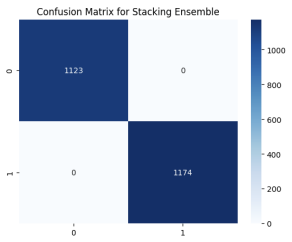

Fig. 21. Optimized ensemble stacking-3 (Dataset 2).

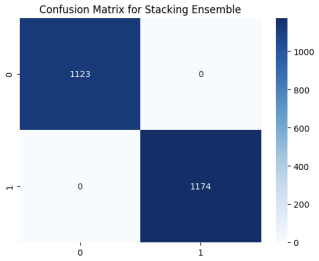

Fig. 22. Optimized ensemble stacking-4 (Dataset 2).

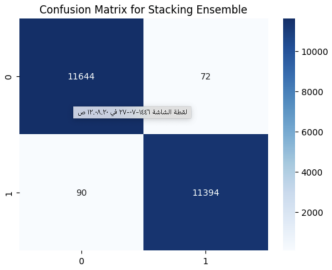

Fig. 23. Optimized ensemble stacking-1 (Dataset 3).

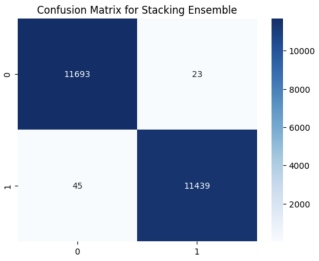

Fig. 24. Optimized ensemble stacking-2 (Dataset 3).

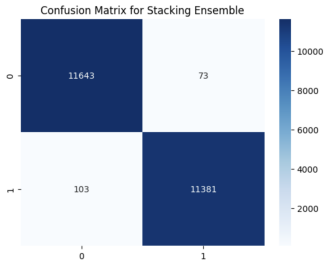

Fig. 25. Optimized ensemble stacking-3 (Dataset 3).

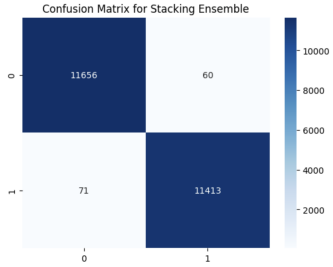

Fig. 26. Optimized ensemble stacking-4 (Dataset 3).

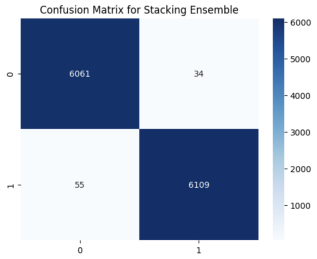

Fig. 27. Optimized ensemble stacking-1 (Dataset 4).

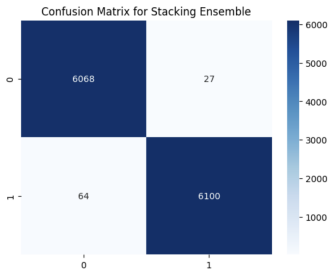

Fig. 28. Optimized ensemble stacking-2 (Dataset 4).

Feature encoding and scaling were uniformly applied. SMOTE was selectively used for unbalanced datasets. Cross-validation (StratifiedKFold) ensured consistent generalization across all experiments. Ultimately, the characteristics of each dataset informed key design decisions in the stacking architecture. While the same base and meta-model configurations were used across all datasets to ensure comparability, larger and imbalanced datasets necessitated specific adjustments—such as the application of SMOTE, reduced model iterations, and fewer cross-validation folds—to manage computational complexity without sacrificing accuracy. preprocessing, standardization, and encoding strategies were uniformly applied. These adaptations highlight how dataset size, balance, and structure influenced model pruning strategies and the depth of optimization required to achieve efficient and high-performing ensemble detection systems.

B. Performance Comparison of the Proposed Approach with Previous Studies

To objectively assess the effectiveness of the proposed optimized ensemble stacking model, it is essential to compare its performance with existing approaches reported in the literature.

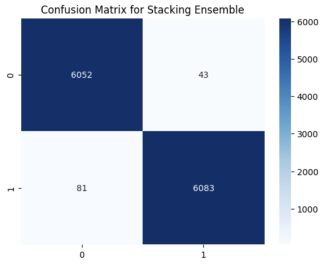

Fig. 29. Optimized ensemble stacking-3 (Dataset 4).

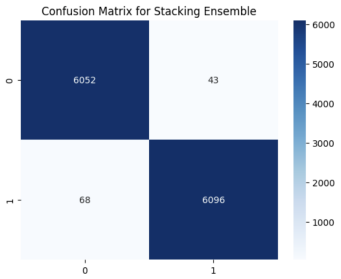

Fig. 30. Optimized ensemble stacking-4 (Dataset 4).

Several recent studies have explored various ensemble learning techniques to enhance phishing website detection, including optimized stacking, such as Genetic Algorithm (GA), to optimize the parameters of various ensemble classifiers, Diverse Base Learners, Hyperparameter Tuning, multilayer-stacked models, and boosting-based ensembles. This section presents a comparative analysis of classification accuracy across these studies, focusing on the same or similar benchmark datasets. A comparative summary of classification accuracy reported in these studies, focusing on similar benchmark datasets, is provided in Table XI.

TABLE XI. COMPARISON WITH RELATED STUDIES OF THE PROPOSED METHOD

Paper	Classifiers	Accuracy (%)
[5]	optimized stacking	D3:97.3%
[9]	Multilayer-Stacking	D3:96.79%, D4:98.43%
[15]	Boosting-based multi-layer stacked ensemble model	D4:96.16%, D3:98.95%
[4]	Stacking ensemble classifier	D1:98.20, D3:97.48%

Our enhanced ensemble stacking architecture clearly demonstrates advantages over existing methods. For example, [5] achieved 97.3% accuracy on Dataset 3 using an optimized stacking approach, while [9] reported 96.79% on Dataset 3 and 98.43% on Dataset 4 with multilayer stacking. Similarly, boosting-based multi-layer ensembles [15] obtained 98.95% on Dataset 3 and 96.16% on Dataset 4. In contrast, our optimized stacking variants consistently exceed 99% accuracy on the same datasets, with Optimized Stacking-2 reaching 99.71% on Dataset 3 and 99.28% on Dataset 4. Furthermore, while [4] reported 97.48% accuracy on Dataset 3, our method achieved over 99% under the same conditions. These comparisons highlight that our approach not only achieves higher accuracy, but also exhibits greater robustness when applied to imbalanced datasets (Datasets 3 and 4), where many prior methods suffered performance drops. By integrating CatBoost as a meta-learner, employing diverse base classifiers, and applying robust validation strategies, our model advances the state-of-the-art in phishing website detection.

C. Limitations

While the optimized ensemble stacking models achieved state-of-the-art performance across multiple datasets, several limitations should be acknowledged. First, training complex ensembles with multiple strong base learners and a CatBoost meta-model incurs significant computational cost and longer execution times, particularly for very large datasets. Second, achieving 100% accuracy on smaller balanced datasets may indicate a potential risk of overfitting, underscoring the need for careful validation on real-world, unseen data. Third, phishing tactics continuously evolve, meaning that static models trained on historical datasets may degrade in performance over time. Therefore, periodic retraining and the incorporation of adaptive or online learning mechanisms are essential to maintain robustness.

Finally, while SMOTE and preprocessing strategies helped address class imbalance, synthetic oversampling may not fully capture the diversity of real phishing examples. Future work should validate the models on live network traffic and diverse sources to ensure practical applicability.

VII. CONCLUSIONS

This study demonstrated the effectiveness of optimized ensemble stacking models in enhancing phishing website detection across datasets with diverse characteristics. The proposed framework consistently achieved superior results, including 100% accuracy on the two balanced datasets (Datasets 1 and 2) and above 99% accuracy on the larger and imbalanced datasets (Datasets 3 and 4). These outcomes confirm the robustness and scalability of the approach under varying data conditions. Among the four optimized variants, Optimized Stacking-2 and Optimized Stacking-4 provided the best trade-off between detection accuracy and computational efficiency, making them well-suited for real-world deployment.

The key contributions of this work include: systematic optimization of diverse base learners within the stacking framework, replacement of traditional Logistic Regression with CatBoost as the meta-classifier to improve generalization and handle imbalance, and comprehensive validation across multiple datasets to ensure reliability and robustness. These advances distinguish the proposed method from prior approaches that often relied on fixed classifiers, limited datasets, or less rigorous optimization.

From a practical standpoint, the findings highlight that phishing detection systems can achieve both high accuracy and efficiency by adopting optimized ensemble stacking. The integration of explainability tools such as SHAP further enhances usability by providing interpretable insights for security analysts, enabling informed decision-making in operational environments.

Future work will focus on extending this research by validating the framework on live phishing traffic, evaluating inference latency for real-time deployment, and exploring semi-supervised or adversarial learning techniques to counter

evolving zero-day attacks. Additionally, lightweight versions of the model will be developed to improve adaptability in resource-constrained environments, such as IoT and mobile devices.

In conclusion, this research establishes optimized ensemble stacking as a highly effective and practical solution for phishing website detection, offering both state-of-the-art accuracy and strong adaptability to dynamic cybersecurity challenges.

Grey Clustering Algorithm for Urban Air Quality Classification: A Case Study in Lima, Peru

Alexi Delgado, Katherine Paredes Guerrero, Anderson Carrillo
Environmental Engineering Program, Universidad de Ciencias y Humanidades, Lima, Peru

***Abstract*—This study introduces a grey clustering algorithm based on the Central Triangular Whitenization Weight Function (CTWF), designed to classify urban air quality under conditions of limited or uncertain data. Based on Grey Systems Theory (GST), the proposed algorithm facilitates structured multi-criteria assessments using sparse or irregular datasets—a condition frequently encountered in urban environmental monitoring. The algorithm stands out for its low computational complexity, interpretability, and ability to integrate multiple pollutants into a single qualitative classification, making it particularly suitable for smart city applications and real-time decision support systems. To evaluate its performance, the grey clustering algorithm (CTWF) was applied to a case study in Northern Lima, Peru, covering eight semesters between 2011 and 2019 and including four key pollutants: PM_{10}, SO_2, NO_2, and CO. Although all periods were classified as "Good" under national standards, the disaggregated analysis revealed PM_{10} as the most persistent concern, while CO levels remained consistently low, and SO_2 and NO_2 showed moderate fluctuations. These findings validate the algorithm's capacity to extract pollutant-specific insights and spatiotemporal trends even in data-scarce environments. Future enhancements may include meteorological integration, broader pollutant sets (e.g., $PM_{2.5}$, ozone), and satellite data to extend forecasting capabilities and spatial resolution.**

***Keywords*—Grey clustering algorithm; air quality classification; grey systems theory; urban air pollution**

I. Introduction

Urban air pollution remains a critical and escalating environmental concern, particularly in rapidly growing cities in the global South, where population growth often outpaces infrastructure development. Its detrimental effects on respiratory health, mortality, and environmental sustainability are well documented, especially in low- and middle-income countries [1], [2], [3]. In Latin America, cities such as Lima, São Paulo, and Bogotá routinely report air pollutant concentrations that exceed both national regulations and international safety guidelines [4].

In the case of Lima, Peru, the second largest city in South America, unregulated urban sprawl, high vehicular density, and industrial activity have all contributed to significant air quality degradation [5], [6]. This issue is especially pronounced in northern districts such as Comas, Los Olivos, and Carabayllo, where socioeconomically vulnerable populations are exposed to elevated pollution levels but lack access to comprehensive monitoring systems [7]. Despite growing public concern, air quality assessments remain constrained by fragmented datasets, limited monitoring infrastructure, and the absence of tools designed to function under data uncertainty [8], [9].

These challenges have prompted the need for alternative modeling approaches that are capable of generating reliable insights from minimal or limited data. In this context, Grey Systems Theory (GST), introduced by Deng in the early 1980s, offers a mathematical framework tailored for decision-making under conditions of limited or uncertain information [10], [11]. Unlike traditional statistical models, which rely on consistent and extensive datasets, GST is designed to function effectively even when sample sizes are small or measurements are incomplete, conditions commonly found in urban environmental assessments in Latin America [12], [13].

The flexibility and scalability of GST have led to its increasing application in environmental engineering. Studies have used GST to analyze water quality [14], assess environmental impacts [15], or uncertain environments [16]. Among its techniques, grey clustering has gained attention for its capacity to classify environmental conditions using minimal but representative datasets [17]. These models assign qualitative categories (for example, "Good", "Unhealthy") to pollution levels by mapping quantitative indicators through triangular membership functions, allowing intuitive yet rigorous environmental assessments [18].

In recent years, the integration of GST with entropy weighting, fuzzy logic, and multi-criteria decision making (MCDM) has further expanded its utility, particularly in complex scenarios with multiple and overlapping pollution sources [19], [20], [21]. Such hybrid models offer enhanced classification accuracy and robustness, particularly in urban areas where pollution is influenced by dynamic factors such as traffic, industry, and meteorology [22].

Given these advantages, this study develops and applies an algorithm based on the Central Triangular Whitenization Weight Function (CTWF), a specific grey clustering model, to classify historical air quality conditions in Northern Lima over an eight-semesters period (2011 to 2019). Drawing on publicly available concentration data for four primary pollutants (PM_{10}, SO_2, NO_2, and CO), the grey clustering algorithm (CTWF) enables a structured multi-criteria classification aligned with national Environmental Quality Standards (EQS). This methodological framework is particularly valuable in urban settings like Lima, where technical and governance constraints limit the use of conventional monitoring infrastructure.

Therefore, this work pursues two main objectives:

- To develop a grey clustering algorithm (CTWF) to classify urban air quality; and
- To evaluate the performance of the algorithm through a case study in Lima, Peru.

Overall, this study contributes to applied environmental engineering by demonstrating how intelligent clustering tools

like CTWF can support monitoring, analysis, and decision-making in urban environments where conventional systems fall short. Its methodological simplicity and replicability also position it as a practical tool for use in similar data-constrained urban contexts globally.

This study is organized as follows: Section I provides the introduction. In Section II, the grey clustering algorithm is presented. In Section III, the case study is developed and in Section IV the results are discussed. Finally, in Section V the conclusions are presented.

II. Grey Clustering Algorithm

In this section the grey clustering algorithm for air quality classification, based on CTWF, is developed.

A. Definition

First, to develop the grey clustering algorithm (CTWF), the following components are defined:

- Study object m study objects are defined O_1, O_2, O_3, ..., O_m
- Criteria n criteria are defined C_1, C_2, C_3, ..., C_n
- Grey classes s grey classes are defined S_1, S_2, S_3, ..., S_s

B. Algorithm Structure and Computational Steps

The steps of the algorithm proposed in this work are detailed below [14]:

1) Step 1 – Center-point determination: The center-points of the s grey classes are determined, the sequence of the center-points is: $\mu_1, \mu_2, \mu_3, ..., \mu_s$.

2) Step 2 – Data normalization: The center-points of the grey classes, for each criterion, are normalized using Eq. (1):

$$\lambda_s = \frac{\mu_s}{\bar{y}_s} \tag{1}$$

where, $\bar{y}_s$ is the mean of the center-points of grey classes for each criterion. Then, the sample data (X_{ij}) are normalized using Eq. (2):

$$x_{ij} = \frac{X_{ij}}{\bar{y}_s} \tag{2}$$

3) Step 3 – Membership function (CTWF): Each normalized value is transformed into a triangular membership function centered at a reference class midpoint, as shown in Fig. 1 and Eq. (3) to Eq. (5):

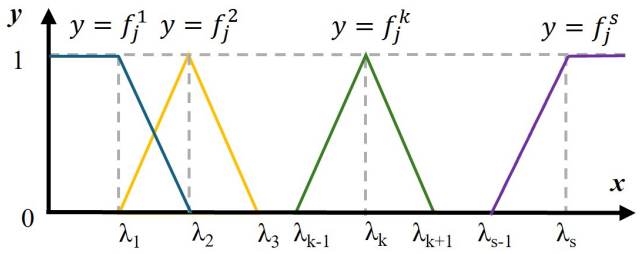

Fig. 1. CTWF graphical representation.

$$f_j^1(x_{ij}) = \begin{cases} 0, & x \notin [0, \lambda_2] \\ 1, & x \in [0, \lambda_1] \\ \dfrac{\lambda_2 - x}{\lambda_2 - \lambda_1}, & x \in [\lambda_1, \lambda_2] \end{cases} \tag{3}$$

$$f_j^k(x_{ij}) = \begin{cases} 0, & x \notin [\lambda_{k-1}, \lambda_{k+1}] \\ \dfrac{x - \lambda_{k-1}}{\lambda_k - \lambda_{k-1}}, & x \in [\lambda_{k-1}, \lambda_k] \\ \dfrac{\lambda_{k+1} - x}{\lambda_{k+1} - \lambda_k}, & x \in [\lambda_k, \lambda_{k+1}] \end{cases} \tag{4}$$

$$f_j^s(x_{ij}) = \begin{cases} 0, & x \notin [\lambda_{s-1}, +\infty) \\ \dfrac{x - \lambda_{s-1}}{\lambda_s - \lambda_{s-1}}, & x \in [\lambda_{s-1}, \lambda_s] \\ 1, & x \in [\lambda_s, +\infty) \end{cases} \tag{5}$$

4) Step 4 – Criteria weight calculation: Relative weights are assigned to each criterion using Eq. (6) [23].

$$\eta_j^k = \frac{\dfrac{1}{\lambda_j^k}}{\sum_{j=1}^{m} \dfrac{1}{\lambda_j^k}} \tag{6}$$

5) Step 5 – Grey clustering coefficient computation: Clustering coefficients are calculated for each study object and grey class, integrating both the CTWF value and the corresponding weight of each criterion by Eq. (7):

$$\sigma_j^k = \sum_{j=1}^{m} f_j^k(x_{ij}) \cdot \eta_j^k \tag{7}$$

6) Step 6 – Final classification: Each study object is assigned to the grey class with the highest clustering coefficient using Eq. (8):

$$\sigma_j^{k^*} = \max_{1 \le k \le s} \{\sigma_j^k\} \tag{8}$$

III. Case Study in Lima, Peru

Lima, the capital of Peru, is a coastal mega-city of over ten million inhabitants and is among the most air-polluted cities in South America [24]. Characterized by high vehicular density, poor atmospheric dispersion, and unregulated urban growth, Lima's air pollution is driven largely by emissions from the transportation sector and informal waste burning.

The northern districts of Lima, including Comas, Carabayllo, Los Olivos, San Martín de Porres, and Puente Piedra, exemplify these challenges. These areas combine high residential density with commercial corridors and are under constant urban expansion. Meteorological conditions such as thermal inversion and limited wind flow further exacerbate pollutant accumulation [25]. Urban infrastructure and environmental monitoring are weaker in these districts, which are often socioeconomically marginalized and environmentally underserved [26]. The evaluation of this air quality study was carried out in metropolitan Lima, specifically in northern Lima, in Los Olivos district, as shown in Fig. 2.

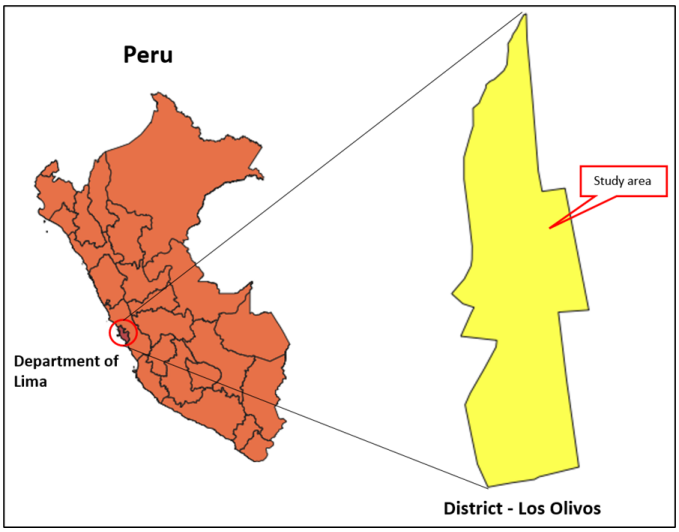

Fig. 2. Location of the study area.

A. Application of the Definition

The components for the case study were defined as follows:

1) Study object: Eight study objects were defined according to the semesters studied from 2001 to 2019 years. The study objects are presented in Table I .

2) Criteria: Four criteria were studied. The definition of these criteria was based on air pollution parameters, considering the following main pollutants: PM_{10}, SO_2, NO_2, and CO. The collected data (in $\mu g/m^3$) for each study object are presented in Table I [27].

3) Grey classes: Four grey classes were defined, based on Peru's Environmental Quality Standards (EQS) for PM_{10}, SO_2, NO_2, and CO parameters, as shown in Table II [28].

B. Application of Algorithm steps

The steps of the algorithm proposed in this work were applied to the case study as shown below:

TABLE I. Study Objects, Criteria, and Monitoring Data

Study Object	Semester	PM_{10} (C1)	SO_2 (C2)	NO_2 (C3)	CO (C4)
O1	2011-1	85.6	13.5	3.8	3.1
O2	2012-1	134.2	11.8	3.7	2.6
O3	2013-1	117.8	13.0	156.0	1809
O4	2014-1	143.2	12.15	78.35	600
O5	2015-1	165.4	13.0	45.46	1599

O8	2019-1	95.48	13.0	3.33	600

TABLE II. Grey Classes of the Case Study

Air Quality Level	Range ($\mu g/m^3$)	Grey Class
PM_{10} (C1)		
Good	0–75	S1
Moderate	76–150	S2
Unhealthy for sensitive groups	151–250	S3
Unhealthy	251–350	S4
SO_2 (C2)		
Good	0–20	S1
Moderate	21–80	S2
Unhealthy for sensitive groups	81–500	S3
Unhealthy	501–920	S4
NO_2 (C3)		
Good	0–100	S1
Moderate	101–200	S2
Unhealthy for sensitive groups	201–300	S3
Unhealthy	301–400	S4
CO (C4)		
Good	0–5000	S1
Moderate	5001–10000	S2
Unhealthy for sensitive groups	10001–15000	S3
Unhealthy	15001–20000	S4

1) Step 1: From Table II, the center-points of the four grey classes, in each criterion, were determined. The results are presented in Table III.

TABLE III. Center-Points of the Grey Classes

Class	C_1 (PM_{10})	C_2 (SO_2)	C_3 (NO_2)	C_4 (CO)
S1	37.5	10.0	50.0	2500.0
S2	113.0	50.5	150.5	7500.5
S3	200.5	290.5	250.5	12500.5
S4	300.5	710.5	350.5	17500.5

2) Step 2: From Table III, the center-points of the grey classes, for each criterion, were normalized using Eq. (1). The results are presented in Table IV.

TABLE IV. Normalized Values for Grey Classes

Criterion	λ_1	λ_2	λ_3	λ_4
C_1	0.230	0.694	1.231	1.845
C_2	0.038	0.190	1.095	2.677
C_3	0.250	0.751	1.250	1.749
C_4	0.250	0.750	1.250	1.750

Then, from Table I , the sample values, for each criterion, were normalized using Eq. (2). The results are presented in Table V.

3) Step 3: Each normalized value was transformed into a triangular membership function centered at a reference class

TABLE V. NORMALIZED VALUES FOR SAMPLE VALUES

Study Object	C_1	C_2	C_3	C_4
O1	0.526	0.051	0.019	0.000
O2	0.824	0.044	0.018	0.000
O3	0.723	0.049	0.779	0.181
O4	0.879	0.046	0.391	0.060
O5	1.016	0.049	0.227	0.160
O6	0.617	0.049	0.333	0.060
O7	0.609	0.046	0.044	0.065
O8	0.586	0.049	0.017	0.060

midpoint by Eq. (3) to Eq. (5). The equations were then synthesized and adapted to the four grey classes, resulting in the following base Eq. (8) to Eq. (11).

$$f_j^1(x_{ij}) = \begin{cases} 0, & x \notin [0, \lambda_2] \\ 1, & x \in [0, \lambda_1] \\ \dfrac{\lambda_2 - x}{\lambda_2 - \lambda_1}, & x \in [\lambda_1, \lambda_2] \end{cases} \tag{8}$$

$$f_j^2(x_{ij}) = \begin{cases} 0, & x \notin [\lambda_1, \lambda_3] \\ \dfrac{x - \lambda_1}{\lambda_2 - \lambda_1}, & x \in [\lambda_1, \lambda_2) \\ \dfrac{\lambda_3 - x}{\lambda_3 - \lambda_2}, & x \in [\lambda_2, \lambda_3] \end{cases} \tag{9}$$

$$f_j^3(x_{ij}) = \begin{cases} 0, & x \notin [\lambda_2, \lambda_4] \\ \dfrac{x - \lambda_2}{\lambda_3 - \lambda_2}, & x \in [\lambda_2, \lambda_3) \\ \dfrac{\lambda_4 - x}{\lambda_4 - \lambda_3}, & x \in [\lambda_3, \lambda_4] \end{cases} \tag{10}$$

$$f_j^4(x_{ij}) = \begin{cases} 0, & x \notin [\lambda_3, +\infty) \\ \dfrac{x - \lambda_3}{\lambda_4 - \lambda_3}, & x \in [\lambda_3, \lambda_4) \\ 1, & x \in [\lambda_4, +\infty) \end{cases} \tag{11}$$

The values from Table IV and Table V were then substituted into Eq. (8) to Eq. (11). As an example, the results of O_1 study object are presented in Table VI.

TABLE VI. CTWF VALUES FOR STUDY OBJECT O_1

Function	C_1	C_2	C_3	C_4
f_j^1	0.362	0.914	1.000	1.000
f_j^2	0.638	0.086	0.000	0.000
f_j^3	0.000	0.000	0.000	0.000
f_j^4	0.000	0.000	0.000	0.000

4) Step 4: From Table IV, the criteria weights were calculated using Eq. (6). The results obtained are presented in Table VII.

TABLE VII. WEIGHT OF EACH CRITERION

Criterion	λ_1	λ_2	λ_3	λ_4
C_1	0.11	0.15	0.24	0.26
C_2	0.68	0.56	0.27	0.18
C_3	0.10	0.14	0.24	0.28
C_4	0.10	0.14	0.24	0.28

5) Step 5: Clustering coefficients were calculated for each study object and grey class using Eq. (7). As an example, the results obtained for O_1 study object are presented in Table VIII.

TABLE VIII. CLUSTERING COEFFICIENTS FOR O_1

Function	C_1	C_2	C_3	C_4	Coeff.
f_j^1	0.362	0.914	1.000	1.000	0.861
f_j^2	0.638	0.086	0.000	0.000	0.144
f_j^3	0.000	0.000	0.000	0.000	0.000
f_j^4	0.000	0.000	0.000	0.000	0.000

6) Step 6: Each study object was assigned to the class with the highest clustering coefficient, using Eq. (8). The results of maximum value of clustering coefficient for each study object are presented in Table IX.

TABLE IX. MAXIMUM VALUES OF THE CLUSTERING COEFFICIENT

Semester	λ_1	λ_2	λ_3	λ_4	Max.
2011-I	0.861	0.144	0.000	0.000	0.861
2012-I	0.853	0.136	0.058	0.000	0.853
2013-I	0.731	0.314	0.026	0.000	0.731
2014-I	0.816	0.167	0.083	0.000	0.816
2015-I	0.831	0.100	0.144	0.000	0.831
2016-I	0.833	0.189	0.000	0.000	0.833
2018-I	0.864	0.152	0.000	0.000	0.864
2019-I	0.857	0.155	0.000	0.000	0.857

IV. RESULTS AND DISCUSSION

The results and discussion, according to specific objectives in this work, are presented below:

A. Significance of the Grey Clustering Algorithm

This work contributes meaningful insights, both in theory and in practice, for classifying air quality in uncertain conditions. By applying the grey clustering algorithm (CTWF), which is based on the grey systems theory, it offers a flexible and adaptable way to classify air quality, especially in places where data are limited, a situation often seen in Latin American cities [24].

In addition, the grey clustering algorithm (CTWF) brings several practical advantages that make it highly applicable for managing air quality, as shown below:

- It delivers consistent and trustworthy results, even when working with small datasets or limited information, which is particularly useful for cities lacking extensive monitoring infrastructure [16].
- Unlike traditional air quality indices that typically reflect only the worst pollutant, the grey clustering algorithm (CTWF) provides a more complete picture by incorporating all measured pollutants into the evaluation [11].
- The use of triangular membership functions produces results that are easier to interpret for both technical experts and policymakers [14].

However, the grey clustering algorithm (CTWF) presents some limitations for considering, as shown below:

- It is focused on classification rather than prediction. Therefore, it needs to be complemented to design for forecasting or proactive environmental planning.
- It relies on predefined categories and thresholds, which can introduce some level of subjectivity into the analysis.
- While this algorithm used a specific method for weighting the importance of criteria, using different weighting schemes could lead to different classification outcomes [29].

Despite these limitations, this algorithm stands out as a robust and adaptable tool for analyzing how air quality changes over space and time. Its simplicity and resilience in contexts of uncertainty or limited information make it a valuable resource for environmental planning in fast-growing urban areas.

B. Performance of Algorithm in the Case Study

The grey clustering algorithm (CTWF), was implemented to classify air quality levels in Lima, Peru, over an eight-semester period from 2011 to 2019. The analysis was based on the concentration levels of four primary pollutants: PM_{10}, SO_2, NO_2, and CO. This classification relied on the calculation of grey clustering coefficients for each semester, allowing for an integrated assessment aligned with Peru's national Environmental Quality Standards (EQS).

As shown in Table IX, all semesters analyzed were categorized as "Good", with λ_1 clustering coefficients exceeding the 0.70 threshold. The highest air quality was recorded during the first semester of 2018, with a λ_1 value of 0.864. In contrast, the lowest value within the "Good" range was observed in the first semester of 2013, registering a λ_1 of 0.731. These findings suggest moderate seasonal variation, but an overall trend of compliance with national air quality standards.

Fig. 3 illustrates the temporal evolution of clustering coefficients. A gradual improvement in air quality is evident after 2016, likely reflecting the impact of stricter emissions regulations implemented in Lima's transportation sector. Conversely, the lowest λ_1 scores—ranging from 0.73 to 0.76—were observed during the first three semesters (2011-I to 2013-I), possibly due to the expansion of the vehicle fleet and increased industrial activity during that period [30].

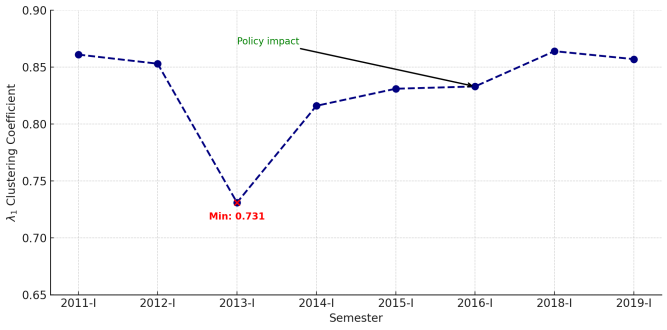

Fig. 3. Temporal evolution of air quality from 2011 to 2019.

To explore the behavior of individual pollutants, Fig. 4 presents a disaggregated analysis derived from the grey clustering results. Among all measured parameters, PM_{10} (C1) consistently recorded the lowest clustering values throughout the study period. In particular, during the first semester of 2013, NO_2 levels dropped below a clustering coefficient of 0.3, indicating poor air quality even though the overall classification remained within the "Good" category. These findings reinforce the characterization of PM_{10} as Lima's most persistent pollutant, primarily due to road dust re-suspension and emissions from diesel-powered vehicles [31].

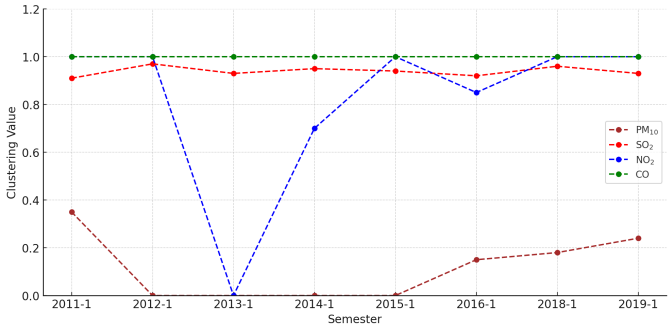

Fig. 4. Disaggregated results trends by pollutant from 2011-1 to 2019-1.

In contrast, CO (C_4) consistently recorded the highest grey clustering values—often above 0.9—indicating minimal health risk. Meanwhile, SO_2 (C_2) and NO_2 (C_3) showed moderate but stable trends. Their lower values during 2012 to 2013 may be linked to increased traffic emissions and reduced atmospheric dispersion capacity during dry seasons [6].

These temporal and pollutant-specific trends confirm the grey clustering algorithm (CTWF) strength in delivering comprehensive multi-criteria air quality assessments, even under conditions of uncertainty and limited information.

V. Conclusion

First, this work demonstrates that the grey clustering algorithm (CTWF) offers a practical and adaptable solution for classifying urban air quality under uncertain and limited information. Its capacity to integrate multiple pollutants highlights its suitability for real-world urban environments with restricted monitoring infrastructure. By enabling structured and interpretable assessments, the algorithm provides a reliable alternative to traditional models, contributing to more informed and inclusive environmental management strategies.

As a second key finding, the grey clustering algorithm not only enabled classification but also uncovered distinct pollutant-specific trends that would be masked by aggregated indices. While all periods met national "Good" air quality standards, disaggregated analysis revealed PM_{10} as the most recurrently critical pollutant, particularly in high-traffic and industrial areas. CO maintained consistently low risk levels, while SO_2 and NO_2 showed moderate but stable variability. Notably, a gradual improvement in air quality after 2016 suggests early effects of emissions control measures, although inconsistent enforcement likely limits their full potential. These insights underscore the value of multi-indicator, temporally sensitive approaches in supporting more nuanced and targeted environmental policy.

Finally, future research could expand the grey clustering algorithm (CTWF) by integrating meteorological variables

such as wind speed, temperature, and humidity to better contextualize seasonal pollution trends. The use of predictive grey models like GM(1,1) may strengthen early warning capabilities, while incorporating pollutants such as PM2.5 and ozone would improve health relevance. Combining CTWF with satellite-derived data could further enhance its spatial resolution and support its application in regional planning. As urban centers continue to grow under constrained conditions, grey modeling offers a promising pathway for more resilient and inclusive environmental governance.

Simulation-Driven Improvement of King Khalid University Non-Monthly Entitlement Workflows in AnyLogic

Elaf Ali Alsisi*, Osman A.Nasr, Badriah Mousa Alqahtani, Rodoon Shawan Alnajei
Business Informatics Department, King Khalid University, Abha, Saudi Arabia

***Abstract*—Aiming to offer useful recommendations for enhancing process accuracy and operational performance, this study investigates the elements affecting the efficiency and timeliness of disbursing non-monthly financial entitlements to university staff. The study developed a process workflow model using AnyLogic simulation tools and structured interviews and then conducted two main tests to enhance effectiveness. While the second concentrated on dynamic workload distribution to balance duties and maximize performance, the first conducted complete automation using an electronic platform that centralized all departmental tasks involved in financial disbursements. By lowering service times, minimizing manual errors, and thereby simplifying task allocation, the results show that combining automated workflows and real-time workload distribution significantly increased operational efficiency. Faster, more accurate, and fair processing of financial entitlements produced by this change highlights the need for technology-driven solutions in reaching lasting organizational excellence.**

Keywords*—Non-monthly financial entitlements; operational efficiency; Anylogic simulation; process optimization; university staff

I. Introduction

Higher education institutions' foundation is administrative procedures, which help to define their capacity to provide services, research, and high-quality education. From policy development and resource allocation to performance assessment and decision-making, these procedures cover a broad spectrum of activity. Good administrative systems guarantee that colleges may adjust to fast-changing educational environments, simplify processes, and promote organisational effectiveness. Strong administrative policies in higher education help to increase openness, responsibility, and resource optimization, thereby improving institutional performance, according to Johnson et al. (2021). Furthermore, these procedures help to match operational frameworks with strategic goals, thereby fostering a coherent environment for staff, teachers, and students [1].

Administrative process efficiency—especially those pertaining to cash disbursement—depends on several important elements. These cover data availability and accuracy, system degree of automation, and internal policy and procedure clarity. Also very important are outside factors such as economic conditions and legal constraints. Inefficiencies in financial disbursement systems can cause delays, mistakes, and employee discontent that finally influence organizational performance, as Smith and Brown (2020) point out. Thus, increasing efficiency and guaranteeing the timely and accurate distribution of financial advantages depend on an awareness of and resolution of these elements [2].

Non-monthly entitlements are connected to non-periodic financial remuneration paid either monthly or otherwise. These rights include incentives given to staff members on sporadic intervals and financial gains. The several types of non-monthly entitlements include unique incentives, spot awards, and annual bonuses. Understanding their influence on efficiency and the speed of payment depends on first looking at the factors influencing performance and staff satisfaction in connection with these categories. The results of Green et al. (2022) show that prompt and open handling of non-monthly entitlements can greatly increase employee morale and involvement [3].

The sensitive process of distributing non-monthly entitlements to university staff members calls for great satisfaction to guarantee operational success. The disbursement process is influenced by internal elements such the effectiveness of administrative procedures and technological integration as well as by external elements including regulatory compliance and financial restraints. Improving the process depends on an awareness of and analysis of these elements, therefore optimising the advantages obtained by university staff members. This therefore promotes a good workplace, so improving organisational performance and helping to meet institutional objectives.

This study, therefore, aimed to investigate how modeling and simulation using AnyLogic contribute to the analysis of both internal factors, such as the efficiency of administrative procedures and technology integration, and external factors, including financial constraints and regulatory requirements, that affect the process of disbursing non-monthly financial benefits to university employees. It also sought to identify the root causes of delays and inefficiencies while evaluating the impact of proposed interventions—such as automation, improved workload distribution, and enhanced intercommunication—on disbursement speed, accuracy, and employee satisfaction.

This research is structured as follows: Section I provides an overview of the topic. Section II presents the problem statement and objectives. While Section III reviews the relevant literature, the following part describes the methodology and data collection procedures used to conduct the analyses in Section IV. Section V synthesizes the key findings from both experiments and introduces the simulation model used to assess the underlying mechanism. The final section summarises the principal findings

*Corresponding Author.

of these experiments and includes a discussion of the implications of the findings for future research.

II. Problem Definition

A. Problem Statement

The university's disbursing non-monthly financial obligations presents many difficulties and delays. These issues undermine administrative performance and personnel satisfaction. Although these dues help to improve employee happiness, there is no thorough investigation to pinpoint the underlying reasons for these issues.

B. Objectives

This study intends to use AnyLogic simulation and modelling techniques to investigate the several elements affecting the efficiency and timeliness of disbursing non-monthly entitlements to university staff. Investigating the fundamental reasons and variables influencing the disbursement process, the study looks at how they affect work efficiency and production. Furthermore, investigated in the study are possible fixes for found inefficiencies like automation, workload distribution optimisation, and improved interdepartmental communication.

III. Literature Review

Maintaining excellent service standards, colleges have to take care of environmental issues and guarantee administrative effectiveness just like any other company. Among the several aspects of educational excellence, administrative process management has lately attracted major interest [4]. Most facets of human life have changed dramatically in recent decades thanks to the fast advancements in global markets and scientific knowledge and technological innovation [5], [6], [7]. Equipping students with the information and the skills needed to fulfil changing labour market needs depends critically on universities [8].

Delivery of high-quality university services, including teaching and learning, depends fundamentally on administrative processes [9]. Beyond instruction, administrative processes are crucial for controlling student services, offering direction, and preserving infrastructure quality, Manatos et al. underline. Using quality control strategies in these spheres guarantees a comprehensive academic background [10]. Good internal management improves daily operations and helps institutions to provide outstanding services in several areas including student assistance, infrastructure, assessment systems, and facilities management [11]. Moreover, a key indicator of administrative service efficacy is student satisfaction [12].

The administrative structures of higher education institutions significantly impact their overall performance and operational efficiency. Strong administrative processes are emphasised by Johnson et al. (2021) as a means of promoting openness, responsibility, and resource economy [13]. Perez et al.'s 2020 research emphasises how digital platforms and automation help to expedite administrative processes. These tools streamline decision-making, reduce errors, and optimize resource allocation [14]. Further influencing the effectiveness of financial systems inside public institutions are external regulatory constraints and economic situations [15], [16].

As non-monthly rights, bonuses and incentives are quite important for raising the morale and involvement of administrative staff members. But uneven distribution of these benefits has been proven to lower employee satisfaction and productivity, mostly because of inefficiencies in financial clearances among several departments [17]. Neglect of non-monthly rights could cause more general organisational problems like higher staff turnover and worse institutional efficiency [18].

Complex workflow optimisation has benefited from simulation and modelling tools such AnyLogic. Since 2003, AnyLogic—a flexible tool for modelling discrete, continuous, and mixed-agent behaviour has been used across manufacturing, supply chain management, logistics, retail, traffic systems, aerospace, and manufacturing [19]. Kim et al. (2020) show how financial process improvements suggested by simulation models might point up roadblocks [20]. Though modelling approaches are widely used in many fields, their application within higher education management—especially in financial systems—remains understudied. There is a clear gap in the literature since little studies specifically address non-monthly financial entitlements in universities. This emphasises great possibilities to use advanced AI-based technologies to boost administrative efficiency and enhance money distribution methods.

IV. Data Collection and Methodology

A. Data Collection

Structured interviews were the main means of data collecting for this research; they were the main tool used to compile qualitative data. Carefully crafted to ensure they gathered comprehensive and practical data relevant to the study goals, the interview questions [21] Particularly focused on investigating the procedures behind financial transactions, the flow of labour across departments, and the difficulties these changes bring about was The methodical approach of the interviews allowed participants to offer in-depth observations based on their operational expertise while nevertheless allowing consistency in data collecting.

Selected staff members from two important departments—the Payroll Department and the Human Resource Operations Department—conducted these interviews. These interviews were designed to thoroughly understand the current procedures, identify operational difficulties, and compile information relevant to the scope of this research.

At King Khalid University, the data collection process took place during regular business hours to coincide with the participants' natural flow and minimize interruptions to their schedules. A purposive sampling method was used to target people directly involved in the under-investigated processes. Ten transactions in all were chosen as samples for analysis to provide a fair picture of university financial transaction handling procedures.

Every interview took a one-on-one form and lasted between thirty and forty-five minutes. Before the interview, participants were briefed on the goal of the study and guaranteed informed consent and were encouraged to provide honest answers.

B. System Design

Modelling and simulation are the main tools used in this work; the simulation model was created with the AnyLogic application. The study starts with offering a conceptual model of the university's financial entitlement dispensing system in order to set the scene. Before switching to simulation-based modelling, this conceptual model helps to clarify every stage of the system and offers complete knowledge of its process [22].

The two main operational entities in charge of starting and finishing money distributions comprised the system:

- Human resources operations department: represented by one server.
- Payroll department: represented by one server.

For every transaction, transaction record data was used to construct pertinent random variables, therefore guaranteeing correct simulation results. Among these were:

- Average waiting time: The duration a request remains in the queue before being processed.
- Average service time: The time required by each department to complete a single request.
- Average time to issue a payment order: The total duration from the initiation of the transaction to the issuance of the payment order [22].

C. System Configuration

Two studies evaluating the financial disbursement process made use of AnyLogic simulation tools. Under specified operational conditions, these tests gave important new perspectives on the efficiency and performance of the system, enabling a thorough investigation of waiting times, processing times, and general transaction completion times. Conducted throughout regular business hours, five weekdays from 8:00 AM to 2:30 PM, the simulations were based on the presumption of a limitless queue capacity.

1) First experiment: The first trial was meant to evaluate how well automated processes implemented in several departments engaged in the disbursement process worked. This experiment sought to find whether automation might cut processing times, simplify processes, and lower mistake rates.

2) Second experiment: The second experiment concentrated on bettering staff member workload distribution at every level of the process. This experiment aimed to improve operational efficiency and lower delays resulting from unequal workload distribution or bottlenecks by best allocating jobs.

3) Simulation assumptions: Four transactions arrive at regular intervals of every half hour, hence defining the transaction arrival rate. The simulation is based on these assumptions stated in Table I. Two employees are assigned to the Operations Department and two employees to the Payroll Department, therefore allocating the manpower. One hour after arrival, every department starts handling a transaction to guarantee a neat flow. Assigning transactions to the staff member not handling other transactions helps to distribute work fairly and reduces idle time [23].

4) Simulation framework: The simulation model was built to depict a queuing mechanism for the disbursement of non-monthly financial entitlements [23]. To find inefficiencies and bottlenecks, the model combines important elements of the system and models the flow of transactions between departments.

5) Queuing system classification: Kendall's notation for classifying queuing systems helps one to define this system as having:

- Multiple queues with independent, parallel paths for transaction processing.
- A queue discipline that adheres to the First-In, First-Out (FIFO) rule, ensuring fairness in processing requests.

The simulation model well reflects the dynamics of the system, thereby allowing the research to assess the performance criteria and, where needed, process optimisation [22].

6) Arrival process: The arrival of transactions is modelled as a random process, with the interarrival time (A-i) defined as the time difference between the arrivals of the (i-1) th and the i-th transactions [24].

$$(A\text{-}i = T\text{-}i \; - T\text{-}\{i\text{-}1\}) \tag{1}$$

The mean interarrival time is denoted as E(A), and the arrival rate (λ) is calculated as:

$$\lambda = 1 / E(A) \tag{2}$$

For this study, we assume transactions arrive every 3 hours, so:

E(A) = 3 hours, λ = 1/3 = 0.333 transactions per hour.

TABLE I. SIMULATION ASSUMPTIONS FOR WORKFLOW OPTIMIZATION IN NON-MONTHLY ENTITLEMENT PROCESSING

Tra No.	Transaction Type	OD	PD	AT*	SS - OD	SE - OD	WT - OD	SS - PD	SE - PD	WT - PD	Total Service Time
1	Extra Allowance Request	E1	E1	9:00 AM	10:00 AM	01:00 PM	3 hrs	2:00 PM	9:00 AM	1 hrs	24 hrs
2	Financial Dues Request	E2	E2	9:30 AM	10:30 AM	01:30 PM	3 hrs	2:30 PM	9:30 AM	1 hrs	24 hrs
3	Excellence Allowance	E1	E1	10:00 AM	11:00 PM	2:00 PM	3 hrs	9:00 AM	1:00 PM	19 hrs	27 hrs

V. RESULTS

The study concentrated on the university's disbursing non-monthly financial obligations, including conference-related financial reimbursements and excellence allowances. This system runs by means of a cooperative process combining several departments. Working closely with the Payroll Department and the Financial Department, the Human Resources Operations Department is key in starting and processing transactions. These departments taken together guarantee the seamless flow of the process and preserve the accuracy and integrity of financial disbursements.

As Fig. 1 shows, the payout process consists of multiple consecutive processes carefully planned to guarantee accuracy and conformity with institutional standards. It starts with the transaction submission, therefore starting the process. The issuing of a disbursement decision, formalising the approval for payment, the creation of a disbursement statement detailing the payment specifics, and lastly, the actual distribution of funds to the intended recipient follow.

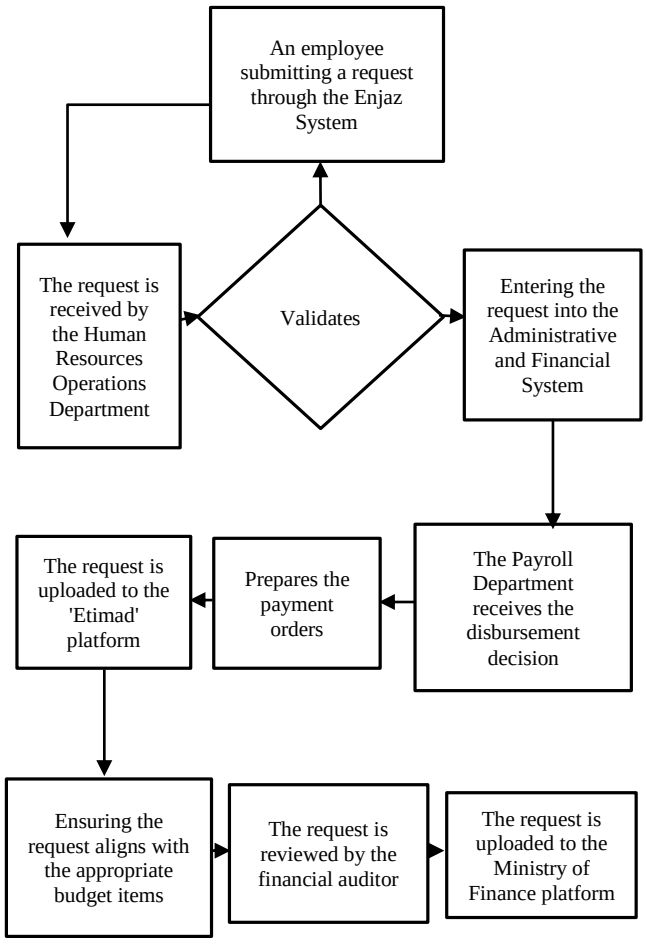

Fig. 1. Workflow figure model for non-monthly entitlement processing.

Every one of these phases entails different administrative processes and is influenced by different elements, such policy adherence, documentation correctness, and interdepartmental collaboration. Reliability and efficiency of the system depend on these components, which are essential.

The results of the organised interviews exposed a clear awareness of how the disbursement of entitlements operates the workflow. The system's workflow concept is meant to simplify processes, lower mistakes, and lessen inefficiencies. The participants underlined the need of interdepartmental cooperation and following accepted policies in reaching a flawless and efficient payout procedure.

The information gathered from the interviews contained specifics on ten transactions from which the departments engaged in the disbursement process may examine waiting times and service times. The performance of the operations department and the payroll department showed notable variations according to the study of service time and waiting time rates.

With an average service time (μ) of 115 hours and a service rate (λ) of over 0.0087 services per hour, the operations department has

$$\Pi\ (T \leqslant 50) = 35.26\% \quad (3)$$

$$\Pi\ (T \leqslant 100) \approx 58.09\% \quad (4)$$

The likelihood of executing a transaction within 50 hours is

P ($T \leqslant 50$) whereas inside 100 hours is P ($T \leqslant 100$).

With an average service time (μ) of 73 hours and a service rate (λ) of over 0.0137 services per hour, the payroll Department exhibits a notably improved performance. P($T \leqslant 50$) = 49.59% and P ($T \leqslant 100$) $\approx$ 74.59%, respectively, respectively, the chances of handling a transaction inside 50 and 100 hours.

With a waiting time rate (λ) of over 0.0278 per hour, the Operations Department averages a waiting time (μ) of 36 hours.

With a waiting time rate (λ) of 0.3333 per hour and an average waiting time (μ) of 3 hours, the payroll department shows a far shorter waiting time.

These results underline the payroll department's higher processing efficiency than the operations department, thereby stressing the requirement of focused interventions to maximise the workflow in the latter to avoid congestion and raise general efficiency.

VI. DISCUSSION

Differences in service indicate an organisational flow imbalance: slower processing times in the operations department can create transaction backlogs, causing further delays in other departments. These inefficiencies pose the potential of impairing the disbursement system's overall performance. Optimising service rates across several departments is essential to meet these difficulties. Workflow could be balanced by means of reallocating resources, automating repetitive processes, or offering people in the operations section focused training. Improving the effectiveness of the operations department will help the company to match its procedures more precisely with institutional goals, smooth operations, and increase productivity.

Fig. 2. Simulation model of the financial disbursement workflow.

Incorporating thorough methods and characteristics to precisely mirror real-world settings, the simulation model was constructed to analyse and solve the found inefficiencies as shown in Fig. 2. The first experiment concentrated especially on assessing the success of using automated processes among several divisions.

The suggested fix was substituting a centralised computerised platform for the hand-operated disbursing of financial obligations. Using a single interface, this system let administrative and academic staff members send non-monthly financial dues requests straight forwardly. To provide a more simplified and open procedure, requests were immediately passed to the necessary management for clearance. This system had a filter mechanism to confirm the completeness of turned in forms. While incomplete requests were automatically denied, therefore lowering delays resulting from incomplete entries, requests satisfying all criteria were sent straight to the Human Resources Operations Department for additional processing.

The usual transaction processing time before the automated system was 188 hours. After the new workflow was adopted and system analysis was conducted with the simulation model (Fig. 3), the average service time dropped to 59 hours per transaction rather dramatically. This shows an amazing drop of about 69%, which emphasises how well the system maximises operations.

Fig. 3. Impact of workflow automation on average service time.

The significant drop-in service time shows the good influence of process optimisation and automation. Requests were centralised and automated validation introduced helped to streamline the process, therefore minimising human mistakes and processing delays. The simplified procedure also helped to better allocate resources, enabling departments to manage transactions more precisely.

The second experiment concentrated on improving operational efficiency by means of better distribution of staff duty at every level. Based on their real-time workload, the suggested solution presented a dynamic assignment of requests to accessible staff members. This invention reduced delays brought on by waiting for staff members to handle jobs, therefore removing the need for manual job allocation.

Once a request is authorised at the first level, the automated system guarantees that it is immediately assigned to the next most qualified employee in the pertinent department. This procedure reduces idle time, ensures a fair distribution of chores, and enhances the overall processing efficiency of non-monthly financial dues. Distribution of work dynamically helps the system to minimise congestion caused by overloading stages or staff. The findings of the queue simulation show notable increase in operational efficiency. Every transaction's computed average service time was 25.50 hours. This suggests a simplified procedure that helps to handle individual transactions faster than past methods.

The efficacy of the automated workload distribution system in besting the task allocation among staff is shown in the shortened service times. Reducing delays at different phases guarantees that every transaction is handled effectively without generating congestion. This balanced workload enhances the flow of operations among departments, therefore enabling better use of resources and a more responsive system. Along with accelerating transaction processing, this development improves the general dependability and sustainability of the distribution mechanism. The results underline the need of dynamic task distribution systems in reaching operational excellence and guaranteeing timely service delivery.

From the first reception of requests to their flawless transfer across the operations and payroll departments, the use of an electronic platform for conducting financial transactions has fundamentally changed the payout process. Establishing itself as a pillar of operational efficiency, this creative approach has produced observable gains in various important spheres.

The shortened waiting times are one of the most obvious results since the platform replaced slower manual operations with a simplified, technologically driven workflow. This development not only sped up transaction processing but also cut pointless delays. Moreover, the flawless handover of transactions between departments and automatic work allocation helped to improve efficiency by guaranteeing better operations and so lowering of obstacles. Reducing mistakes, handling the difficulties with hand data entry, and improving interdepartmental communication all depend on the platform as well. More accurate and dependable data handling produced by these developments enhanced the general integrity of the system.

Beyond these operational improvements, the platform has raised staff satisfaction. Faster processing speeds and more openness helped build system trust and hence increase staff confidence in its dependability. Furthermore, the platform's capacity to provide performance monitoring by means of transaction completion rates and processing times has helped to precisely track development and highlight areas needing continuous enhancement.

VII. Conclusion

By greatly boosting speed, accuracy, and efficiency and thereby creating a more fulfilling and transparent experience for staff, the electronic platform has transformed the payout process. Combining technology and automation has shown its transforming power in solving long-standing inefficiencies and improving operational processes. These developments not only improve current operations but also provide a strong basis for reaching sustained operational excellence and therefore

supporting the long-term expansion goals of the company. The findings underscore the pivotal role of technology-driven solutions in improving organisational performance and provide a compelling case for continued investment in automation and process innovation to maintain and extend these gains.

Building on the ~69% reduction in processing time and the observed Payroll- Operations service-rate gap, future work should scale the centralised platform while using simulation–optimisation to right-size Operations capacity and routing. To sustain and generalise the gains, future studies should validate the redesigned workflow across other non-monthly entitlements and semesters, and deploy a digital twin that forecasts backlogs and recommends weekly staffing plans.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Research and Graduate Studies at King Khalid University for funding this work through Genersal Research Project under grant number GRP/112/46.

***Abstract*—The resilience of stingless bee colonies has become increasingly challenged by erratic climate conditions and intensified environmental stressors. While previous studies have introduced diagnostic models for monitoring colony health, most remain constrained by a narrow reliance on either environmental or behavioral parameters alone. This study proposes a refined diagnostic model that builds on existing frameworks and is further shaped by expert insights from the field. The model integrates environmental inputs, specifically temperature and humidity, with behavioral activity detected via video analysis to deliver a multi-dimensional assessment of colony status. Through a structured review of the literature and interviews with apiculture experts, we identify critical gaps in conventional systems and translate those findings into a more responsive and field-deployable architecture. The result is an improved model capable of categorizing colony health with greater sensitivity and clarity, designed to support early intervention and long-term monitoring. The model is visualized through comparative schematic diagrams, showing the evolution from a basic environmental-only logic to a more holistic decision-making system.**

I. INTRODUCTION

Stingless bees are considered one of the most important pollinators in tropical and subtropical regions [1]. They can help in sustaining crop production and balancing ecological systems [2], especially in areas where traditional pollinators like honeybees are in decline. Unlike other bees, stingless bees are more adaptable and are kept in small-scale meliponiculture farms for honey, pollen, and propolis. The existence and health of these colonies impact not only biodiversity but also the economic welfare of rural populations who rely on these products.

Nonetheless, the existence of stingless bee colonies is increasingly threatened by sudden environmental changes, such as erratic temperature changes, long periods of high humidity, and habitat destruction [3]. These stressors often weaken colonies and, in more extreme cases, can lead to colony collapse disorder, in which bees suddenly and inexplicably abandon the hive.

The most common approach to assess the colonies' health remains manual inspection. These methods usually require opening the hive and examining stores of food, brood patterns, and bee activity; however, frequent inspections are invasive and can disturb the colony's microclimate and social thermoregulation, thereby increasing stress on the colony. Moreover, manual checks are typically episodic and depend on the observer's experience and judgment, making them subjective and prone to inconsistency; as a result, important early-warning signals may be missed or detected late. Recent reviews, therefore, highlight the growing role of non-invasive, sensor-based precision-beekeeping and AI methods as complementary tools to reduce disturbance and provide continuous, objective monitoring [4], [5], [6], [7].

To address these problems, technological solutions have been gradually integrated into beekeeping to enable more continuous and less invasive monitoring. However, many existing precision-beekeeping systems primarily rely on a narrow set of environmental parameters, most commonly in-hive and ambient temperature, humidity and sometimes hive weight, measured by simple sensors. While these indicators are valuable for assessing thermostatically performance and colony strength, they do not directly capture behavioral responses such as reduced movement, altered foraging flux, entrance traffic changes, or other anticipatory actions that can precede overt environmental shifts. Consequently, systems that omit behavioral dimensions are limited in their ability to detect early warning signals and critical precursors of colony stress; recent literature therefore recommends integrating video, audio, weight and advanced pattern-recognition methods to improve early diagnostics [8], [9], [10].

Existing stingless bee monitoring systems predominantly focus on either environmental sensing or activity observation in isolation. Environmental-only systems therefore provide useful information about nest microclimate or mass balance, but they are limited in detecting early behavioral responses, such as changes in movement, entrance traffic, or foraging flux, that often precede measurable environmental shifts. Conversely, behavior-only approaches (camera or acoustic monitoring) typically lack concurrent environmental context, which complicates interpretation of causal drivers. In addition, many operational threshold values and alarm rules have been

inherited or adapted from Apis-centric studies without systematic validation for Meliponini species, reducing predictive accuracy when applied to stingless-bee colonies in varied ecological settings. Finally, several deployed systems use monolithic, fixed architectures that are difficult to extend to additional sensor modalities or site-specific calibration, constraining adaptability across management regimes and habitats. Recent reviews and empirical studies, therefore, recommend multimodal, modular monitoring architectures and species-specific validation of thresholds to improve early-warning performance for stingless bee management [11], [12], [13], [14].

The motivation for this research arises from the need to bridge these gaps through an integrated, adaptable, and empirically validated diagnostic framework. This study proposes a model that combines temperature and humidity monitoring with automated behavioral analysis using computer vision, refined through expert consultation to ensure parameter thresholds align with local field realities. By embedding the system within a modular architecture, it supports future expansion to include additional environmental or behavioral indicators as required by practitioners.

This study aims to address the following research questions:

1) How can environmental monitoring and bee activity analysis be integrated into a unified diagnostic framework for stingless bee colony health?

2) What key environmental and behavioral parameters are critical to accurately classify colony health status?

3) How can expert validation be incorporated to refine the model and enhance its practical applicability in real-world beekeeping?

The remainder of this study is organized as follows: Section II reviews relevant literature on stingless bee monitoring systems and related technologies. Section III presents the proposed initial model, outlining its structure and components. Section IV describes the expert review process and the subsequent model refinements. Section V reports the results and analysis of expert feedback. Section VI discusses the findings, identifies limitations, and suggests directions for future research. Section VII concludes the study.

II. Literature Review

The deterioration in stingless bee health is frequently signaled by declining population levels, decreased foraging activity, and irregular behavioral patterns. These symptoms often result from the complex interplay between environmental disturbances and biological stress [1]. Fluctuating temperature and humidity, increasing pollutant exposure, and unpredictable climate variability have been identified as key contributors to destabilizing colony health. As an example, sudden temperature fluctuations can disrupt bees' navigation systems, causing lower foraging efficiency and disorientation on the way back to the hive [15]. Pesticides and heavy metals introduced to the food chain further weaken immune systems, diminishing the vitality of colonies [3].

Due to this ecological fragility, stingless bees are viewed as effective indicator of broader environmental changes. Among all environmental variables, temperature is by far the most important. It controls the metabolic rate, enzyme activity, and developmental processes within colonies. Departures from ideal temperature ranges either above or below will disturb normal physiological functions, impair social cohesion, and increase susceptibility to infections [16]. Excessive heat can cause high water loss, energy loss, and loss of internal hive control, while the cold slows metabolism and essential cleaning tasks vital to hygiene. At the same time, relative humidity affects the microclimate important for rearing brood and for the integrity of wax. These reasons explain why the parameters are considered essential indicators for assessing the impact of human activity on the environment and monitoring the health of the colony.

Monitoring of stingless bees has improved with the incorporation of technology. Real-time environmental monitoring, such as the Internet of Things (IoT), can utilize temperature, humidity, gas, and even sound sensors to check on health systems [17]. Though these sensor technologies facilitate continuous monitoring, early detection of risks, and automated data collection, their practical application is still hampered by significant obstacles like integration difficulties, drifting sensors, and unreliable power supplies.

Modeling environmental risks has received great focus because of its ability to predict. Many models combine several environmental factors like temperature, humidity, and air conditioning to create risk assessment models that can provide dynamic alerts and automation in decision-making [18]. Advanced computation methods, like statistical methods and machine learning, have developed these models. Even with the availability of data, there is still a challenge in creating usable models that are interpretable for the field in different ecological contexts. In response, recent systems have integrated web-based dashboards for real-time sensor data visualization using Flask and similar frameworks [19]. While these platforms improve usability, their performance depends on reliable connectivity, efficient data processing, and interface responsiveness, areas still under active development [20].

Growing interest in bee rehabilitation has driven parallel innovation in system architectures. Several projects have applied LoRa communication protocols to enable wide-area data collection in low-power field settings [21]. Predictive frameworks based on real-time sensor data have also been proposed to mitigate health risks [22]. Beyond colony-level monitoring, studies on plant resource availability underscore the broader ecological factors affecting bee behavior and resilience [23]. A system-based approach for understanding colony decline recommends modeling across behavioral, environmental, and management layers [24], aligning well with recent IoT-enabled diagnostic platforms [25].

Stingless bee research increasingly emphasizes smart hive solutions. Low-cost microcontrollers combined with DHT22 temperature sensors and weight modules have formed the basis for continuous environmental assessment [26]. Additionally, machine learning applications have been used to analyze health signals and optimize colony management based on predictive

patterns [27]. Environmental data streams, including microclimate, hive weight, and diurnal cycles, are now routinely collected to inform health assessments and enhance productivity [28].

Swarm detection and motion analysis have also evolved through radar-based systems capable of capturing flight frequency and trajectory with high precision [29]. Computer vision applications, particularly those using YOLO-based object detection, offer automated monitoring of colony entrances, detecting forager numbers, pollen load, and potential threats such as varroa mites [30]. In Brazil, stingless bee monitoring has been strongly aligned with ecological preservation and economic sustainability, driving the integration of IoT infrastructure with policy support [2]. Simultaneously, lightweight and modular systems, often relying on open-source hardware such as Arduino and ESP8266, continue to play a central role in decentralized deployments [31].

Further efforts have RFID-based data collection for evaluating pesticide exposure, which remains one of the most pressing threats to pollinator viability [32]. Policy recommendations increasingly emphasize the need for regulatory frameworks that ensure sustainable beekeeping practices while supporting the adoption of digital technologies [33]. In this context, wireless systems for tracking hive parameters, such as temperature and honey yield, are proving vital to optimizing production strategies [17],[22]. RFID also supports individual bee tracking, facilitating more nuanced behavioral research [34].

Integrated systems such as HiveLink [35] and IntelliBeeHive [36] illustrate how visual data, sensor readings, and AI analytics can converge to offer non-invasive, real-time diagnostic support. These systems demonstrate how timely insights can reduce colony loss and improve beekeeper response. Complementing this direction, Liang [37] proposed a hybrid vision-audio health evaluation model that achieved over 92% classification accuracy, showing particular promise in low-light or acoustically active environments.

Recent developments emphasize not only precision but also environmental breadth. Real-time monitoring solutions now include air quality indices such as CO_2, NH_3, and NOx concentrations measured through LoRa networks [38]. The iBees system, for instance, integrates GPS, thermal, and humidity tracking with cloud-based storage for production optimization [39]. Rosli et al. [40] further expanded this design with the addition of weighing and pressure sensors for hive condition profiling. These solutions highlight the continuous evolution of intelligent beekeeping, reflecting growing demands for accuracy, usability, and adaptability in diagnostic system design.

Finally, diagnostic expert systems like MoViCES, paired with mobile diagnostic tools such as Dr. Kelulut, reflect a broader shift toward accessible, user-centric tools built on the Model-View-Controller paradigm [41]. These platforms enable real-time hive inspection using embedded borescopes and interface logic designed to support non-expert users. Together, these technological pathways form the basis for next-generation diagnostic systems aimed at securing stingless bee populations through adaptive, evidence-driven monitoring.

III. Proposed Initial Model

Compared to existing stingless bee monitoring approaches, which typically focus on either environmental sensing or activity observation in isolation, this study proposes an integrated diagnostic model that combines environmental parameters (temperature and humidity) with behavioral indicators (bee entry/exit frequency). This dual-source data approach enables earlier and more reliable detection of colony stress. Additionally, the classification thresholds are not arbitrarily set; they are refined through expert consultation, ensuring that the system aligns with practical field conditions. The architecture is designed with modularity and scalability in mind, allowing the integration of additional sensors in future iterations. This combination of environmental–behavioral integration, expert-validated thresholds, and expandable architecture addresses key limitations in existing systems and enhances applicability for real-world meliponiculture.

The environmental parameters, such as temperature and humidity, are widely acknowledged as primary indicators of hive conditions. In early-stage research and prototype planning, these two variables were selected as the core inputs for the proposed diagnostic framework. The rationale behind this choice was twofold: first, temperature and humidity sensors are readily available at low cost, and second, these environmental metrics directly influence key biological processes within the stingless bee colony, including brood development, foraging efficiency, and thermoregulation.

In addition to monitoring environmental parameters, the proposed system integrates a behavioral-monitoring module to quantify colony activity. A video camera is placed at the hive entrance to capture continuous footage of bee traffic. Recorded video is processed with a YOLO-based object detection algorithm to identify and count individual bees per frame. These counts are aggregated over time to generate an activity index that reflects foraging and hive-traffic dynamics. Significant deviations from the colony's baseline activity, such as sudden drops in bee traffic during normally busy foraging periods, can signal environmental stressors, disease onset, or other disruptions. By integrating this behavioral stream with environmental temperature and humidity data, the system achieves enhanced sensitivity in detecting early-warning signs that may not manifest in environmental parameters alone [42],[43],[44],[45].

The conceptual model, as shown in Fig. 1, hereafter referred to as the Proposal Model, was designed to accept temperature and humidity readings, compare them against defined thresholds, and generate a basic health classification for the colony. The output is presented in one of three health categories: Healthy, Medium-Healthy, and Least-Healthy, each represented by a range of percentage scores (71 to 100%, 30 to 70%, and 0 to 29%, respectively). This scoring range is intended to give beekeepers an intuitive understanding of their

colony's status, without requiring specialized knowledge to interpret raw sensor data.

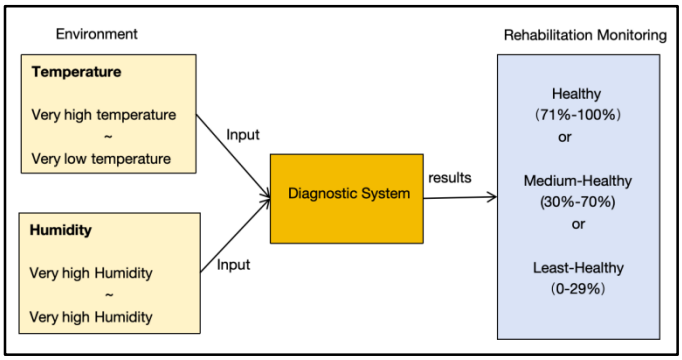

Fig. 1. The conceptual model.

The system begins with environmental sensing units placed within or adjacent to the hive. Two major environmental factors are processed:

Temperature: measurements beyond 25℃ to 34℃ are not optimal. Temperatures over 35℃ may lead to overheating of the brood and a reduction in the activity of worker bees. On the other hand, slowing metabolism and foraging are risks at temperatures below 20℃ [46].

Humidity: fostering fungal growth may occur with excessive humidity over 75%, whereas below 50% contributes to desiccation of the brood and pollen stores [47].

The three health categories: Healthy (71 to 100%), Medium-Healthy (30 to 70%), and Least-Healthy (0 to 29%), were calibrated based on optimal temperature and humidity ranges for stingless bee colonies reported in previous studies. Published data indicate that brood development and colony stability are best maintained within 25 to 34 ℃ and 60 to 85% relative humidity. These threshold values were further refined through consultation with six domain experts, incorporating observational data from two local meliponiculture sites. The combination of literature-based ranges and expert validation ensures that the classification rules reflect both empirical evidence and local field conditions, thereby improving diagnostic reliability and reducing false alerts.

Once inputs are captured, the model uses a rule-based approach to capture deviation from the optimal range. Each input is assessed individually. In the case that both parameters reside within the defined safe zone, the model outputs a Healthy classification. If one variable deviates while the other is acceptable, the system designates the colony as Medium-Healthy. If both exceed warning thresholds, the system marks the colony as Least-Healthy, indicating it is at risk and requires closer examination.

This system makes it possible to track and analyze health status over time. Data from multiple time points can be collected to map out and analyze defined changes over time. For example, persistent classification as Medium-Healthy signals potential unaddressed stress that, if unaddressed, could result in sudden collapse.

Even though the Proposal Model is easy to use and understand, it has some limitations. It considers the relationship between the environment and the colony as fixed and therefore oversimplifies complex systems. It does not account for minor shifts in temperature or even the tiny changes in the environment that bees respond to, such as clustering or fanning. Moreover, environmental parameters do not sufficiently depict the internal processes of the colony, especially in the case of behavioral cues signaling distress long before temperature or humidity changes can be detected.

Moreover, external environmental conditions could alter humidity and temperature readings temporarily, which might activate distress signals. This reinforces the need for a system that goes beyond environmental inputs and considers the cross-validation of the signals with behavioral indicators, such as activity and resting rhythms, foraging habits, and motion density around hive entrances.

Understanding these limitations, the next section incorporates expert feedback to explain how precisely their input was used to improve the model. These insights induced a number of changes that resulted in the creation of the more thorough behavior-inclusive, diagnostic model framework.

IV. Expert Review and Model Refinement

A. Purpose of Expert Review

Prior to field deployment, it is essential for diagnostic models to undergo validation not only through technical testing but also via theoretical scrutiny by domain experts. The purpose of conducting an expert review at this development stage is to evaluate the conceptual soundness, structural feasibility, and practical applicability of the proposed environmental diagnostic model. Expert feedback helps uncover blind spots, refine assumptions, and ensure that system design aligns with the operational context of stingless bee rehabilitation.

B. Expert Panel and Review Scope

A panel of six domain experts was assembled, selected based on their academic and applied experience in the fields of meliponiculture, environmental monitoring, and system modeling. Each expert was invited to participate in a structured review process using a detailed questionnaire.

The scope of the review encompassed four functional aspects of the model: the conceptual framework linking environmental variables to colony health, the diagnostic module responsible for classification based on sensor data, the behavioral monitoring module enhanced by object detection, and the system architecture including modularity, scalability, and usability.

C. Review of Instrument Design

The expert review was conducted using a structured questionnaire designed to support both quantitative assessment and qualitative feedback. The instrument was organized into four sections, aligned with the functional modules of the model. Each section included closed-ended items on a three-point Likert scale: "Agree, no modification", "Agree, with

modification", and "Disagree", as well as open-text fields to capture elaborative suggestions.

The questionnaire design was informed by validation practices in information systems and agricultural technology research. Particular attention was paid to clarity, neutral phrasing, and accessibility across disciplinary backgrounds.

1) Conceptual framework: Evaluates the theoretical basis of the model, particularly its capacity to represent the relationship between environmental stressors (temperature and humidity) and colony health. Items assess whether the model adequately reflects the real-world dynamics of stingless bee rehabilitation.

2) Diagnostic module: Assesses the model environmental sensing component, including the use of DHT22 sensors, the design of health classification thresholds, and the practicality of data capture methods in field conditions.

3) Behavioral monitoring module: Focuses on the integration of computer vision, particularly YOLO-based activity detection, and its relevance for monitoring early indicators of colony stress.

4) System architecture: Evaluates the structure of the system from the perspective of modularity, upgradeability, and end-user usability, including questions related to interface logic, data separation, and adaptability to new sensors.

The instrument emphasized ethical standards, ensuring expert anonymity, voluntary participation, and informed consent.

D. Evaluation Criteria

The evaluation criteria were structured to assess the scientific rigor, operational viability, and ecological relevance of the model. These included:

1) Accuracy of environmental variable selection: Whether temperature and humidity sufficiently capture key influences on stingless bee colony health.

2) Diagnostic reliability: Ability of the classification module to process sensor data, apply thresholds, and produce actionable health scores.

3) Behavioral analysis validity: Effectiveness of the activity detection scheme and its adaptability to field conditions.

4) System modularity and scalability: Capacity for future extension, and separation of functional layers (data capture, processing, interface).

Experts were invited to provide improvement suggestions, highlight oversights, and recommend additional system capabilities where applicable.

E. Questionnaire Administration and Data Collection

Questionnaires were distributed electronically to the six selected experts. Each received a complete packet including a system overview, visual schematics of the model, and an explanation of the review purpose.

The structured responses were compiled and analyzed thematically. Results indicated strong agreement on the model conceptual clarity, with minor modifications suggested for threshold ranges and behavior classification granularity.

Insights gained from this review directly informed the revision of the improved model, ensuring that the final prototype is both scientifically grounded and practically deployable in real-world meliponiculture contexts.

V. Results and Analysis of Expert Feedback

Gaining feedback through the expert review process revealed both the strengths and weaknesses of the environmental diagnostic model. The systematic evaluation and open-ended commentary provided by six experts in the domain allowed for the appraisal of the model integrity, feasibility, and technical scope. Their responses were crucial to the refinement process of the model which took place prior to prototyping and implementation.

In summary, specialized consensus recognized that temperature and humidity are the crucial parameters for the well-being of stingless bee colonies. Focus group members argued that there exists sufficient literature and empirical evidence—both for and field data—to support these factors as significant for brood survival and foraging activity. While some specialists proposed to study additional factors like pesticide, rainfall, or wind, most respondents believed that these inclusions would be too complex for the model, adding unnecessary system complexity and making data collection impractical. Therefore, the model was considered to have an adequately narrow scope for its initial phase while still allowing for these additional factors to be included in later revisions.

Reviewers concentrated on the empirical thresholds as the classification logic and stressed the necessity to define these values more rigorously. These critiques were addressed in the revised model which incorporated predefined empirical ranges for temperature and humidity based on field study data and data collected at the sites. This change was made to improve the objectivity and transparency of the classification procedure, especially in the differentiation of Healthy, Medium Healthy, and Least Healthy. Besides the fixed boundaries, the precise measurement and observation nexus was simplified to integrate more behavioral input to strengthen classification consistency.

The incorporation of computer vision to monitor activity patterns was positively received. Experts agreed that bee behavior often reflects underlying stress before environmental parameters shift dramatically. The use of YOLO-based movement tracking was considered a practical and innovative approach, provided lighting conditions and camera angles are well-controlled. Some experts encouraged exploring audio analysis in future model iterations, especially for applications in low-light environments or enclosed hives where visual data may be unreliable.

Further feedback addressed the overall system architecture, particularly the modularity and potential for scalability. Experts viewed the separation of data collection, processing, and interface layers as beneficial for future upgrades. The improved model maintains compatibility with additional sensors and

analytics modules, allowing the system to evolve with user needs and technological advancements.

The revised diagnostic model, presented as Fig. 2, reflects the collective input received through the expert review process. The visual representation now illustrates the integration of clearly defined environmental thresholds, behavior scoring modules, and a composite health assessment logic. While some expert recommendations—such as multi-factor environmental correlation—were deemed outside the current scope due to limited data availability, the model retains flexibility for phased development.

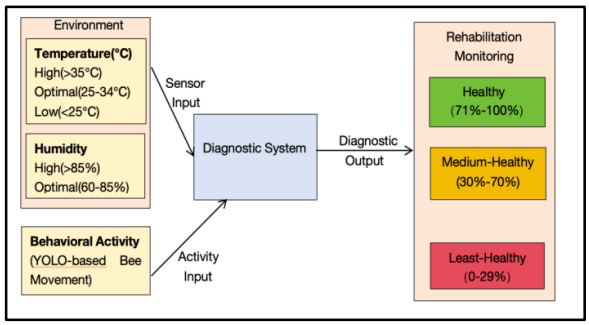

Fig. 2. The improved diagnostic model.

A total of six domain experts participated in the validation of the proposed environmental diagnostic model. The evaluation combined structured questionnaire items with open-ended feedback to capture both quantitative agreement levels and qualitative improvement suggestions.

Regarding environmental parameter selection, five experts (83%) fully agreed that temperature and humidity are the most critical indicators for stingless bee colony health, supported by literature and field experience. One expert (17%) recommended the inclusion of additional variables such as pesticide exposure, rainfall, and wind speed for future model iterations.

For threshold definitions, the original model expressed temperature and humidity using broad qualitative categories (ranging from "very high" to "very low"). Based on expert feedback and literature review, these were replaced with quantitative ranges. The temperature threshold was refined to 25℃ to 34℃, aligning with documented optimal conditions for brood development and adult bee activity, and narrowing the previous qualitative extremes to improve measurement precision. The humidity threshold was set to 60% to 85%, representing a narrowing from the broader original qualitative range. This adjustment reduces classification ambiguity and better reflects the optimal moisture conditions for maintaining brood health, as confirmed by preliminary site measurements.

In terms of behavioral monitoring, all six experts (100%) endorsed the integration of computer vision for activity tracking. Four (67%) supported the use of entry/exit frequency and foraging intensity as primary indicators, while two (33%) proposed adding in-nest movement metrics for more granular behavioral assessment. Future work will investigate the feasibility of incorporating these additional in-nest movement metrics, as they could provide deeper insights into colony therm.

On system architecture, five experts (83%) agreed that the modular design separating data collection, processing, and user interface layers supports scalability and future integration of additional sensors or analytics modules. One expert (17%) highlighted the need for detailed user interface customization to match local beekeeper practices. To address this, future work will include developing a customizable user interface framework that allows adaptation to different cultural, linguistic, and operational contexts, thereby enhancing the model's usability and facilitating its broader adoption.

Overall, the statistical results indicate strong expert consensus on the core environmental and behavioral parameters, with constructive recommendations aimed at refining threshold precision and expanding the behavioral dataset. The incorporation of these validated ranges and prioritized behavioral metrics into the improved model enhances both its scientific robustness and its practical applicability in real-world beekeeping contexts.

By aligning expert opinion with empirical research and real-world constraints, the refinement process has strengthened both the diagnostic logic and the system relevance to field practitioners. The structured feedback not only confirmed the conceptual robustness of the model but also identified practical adjustments that improve usability, interpretability, and future integration potential. These insights will guide the next stage of model validation and system deployment.

VI. Discussion

The integration of environmental parameters with bee activity data provides a holistic perspective on colony health, addressing limitations in traditional monitoring approaches that rely solely on manual observation or single data types. Expert feedback further supports the model's practical feasibility, highlighting its potential to inform proactive interventions. However, the current threshold definitions remain in a preliminary stage, as they were derived from a combination of literature-based ranges and short-term data from a limited number of colonies under specific seasonal and geographic conditions. This restricted dataset may not capture variability due to climate, floral availability, or hive management practices in other regions.

To achieve more definitive calibration, future work should follow a structured roadway: 1) conduct longitudinal monitoring across multiple colonies, seasons, and habitat types; 2) integrate external environmental datasets (local meteorological data) for contextual correlation; 3) perform statistical sensitivity analyses to determine optimal threshold boundaries; and 4) validate the refined model through cross-site field trials with independent beekeeper cohorts. This multi-stage approach will enable the thresholds to be both scientifically robust and broadly applicable to diverse meliponiculture contexts.

Compared to existing stingless bee monitoring systems that rely solely on either environmental sensors or behavioral observations, the proposed model delivers a more comprehensive health assessment by integrating both data sources into a unified diagnostic framework. The inclusion of expert-validated thresholds ensures that the classification logic

is both scientifically grounded and field-ready. Furthermore, the modular architecture allows for future upgrades, such as adding sound analysis, air quality sensing, or advanced behavioral metrics, without requiring major system redesign. This combination of data integration, expert refinement, and practical scalability enhances the model's originality and applicability for sustainable stingless bee colony management [46], [48].

VII. Conclusion

This study has presented the development and refinement of an environmental diagnostic model tailored to the health monitoring needs of stingless bee colonies. Recognizing the limitations of conventional inspection methods and single-parameter sensing systems, the model integrates both environmental variables namely temperature and humidity and behavioral indicators derived from computer vision analysis to generate a composite health assessment. This multidimensional framework enables earlier detection of colony stress and delivers actionable insights in a format suitable for field practitioners.

To ensure conceptual clarity and practical relevance, the model underwent a structured expert review involving six specialists across meliponiculture, environmental sensing, and system design. Their feedback validated the scientific basis of the model, affirmed the choice of key parameters, and highlighted important refinements, such as clearer threshold definitions and improved interpretability. As a result, the revised model incorporates empirically grounded environmental ranges, activity-based behavioral detection, and a modular architecture that supports future system enhancement.

Future work will focus on deploying the system in live apiary environments to evaluate real-time performance, robustness under variable weather conditions, and end-user interaction feedback. In parallel, work will continue on refining the behavioral analysis component, exploring the use of hybrid vision and sound recognition to enhance accuracy in low-visibility settings.

In conclusion, this expert-informed environmental diagnostic model represents a promising step towards more intelligent, interpretable, and scalable monitoring tools for stingless bee colony rehabilitation. By combining ecological understanding with low-cost sensing and expert knowledge, it contributes not only to applied beekeeping technologies, but also to the broader goal of sustaining pollinator health in increasingly stressed environments.

Acknowledgment

The authors gratefully acknowledge the guidance and support of Dr. Rozi Nor Haizan Nor throughout the development of this study. The authors also extend sincere thanks to the six domain experts who contributed their time and insights through the expert questionnaire, which significantly informed the refinement of the proposed model.

A Secure Authentication Protocol for IoT Devices

Mohamed Ech-Chebaby, Hicham Zougagh, Hamid Garmani, Zouhair Elhadari
Faculty of Sciences and Techniques, Moulay Slimane University, Beni Mellal, Morocco

***Abstract*—The rapid evolution of the Internet of Things (IoT) offers vast opportunities in automation and connectivity, yet simultaneously introduces critical security challenges. One of the most pressing concerns lies in the heterogeneity and limited computational capabilities of IoT devices, which complicate the deployment of robust security mechanisms. In this work, we present a lightweight and secure authentication protocol designed to establish mutual authentication between a server and smart objects. Our protocol enhances the scheme proposed by Fatma et al., addressing its identified vulnerabilities. Formal security analysis using AVISPA and ProVerif confirms the protocol's resilience against a wide range of threats. Furthermore, a practical simulation was conducted using a Raspberry Pi as the IoT device and a Core i5-based server to evaluate real-world performance. Results show that the protocol executes efficiently in real-time with a reduced authentication delay, demonstrating its feasibility for resource-constrained environments. This research contributes to the development of effective, scalable, and secure authentication solutions tailored for the IoT landscape.**

***Keywords*—IoT; Internet of Things; security; authentication**

I. Introduction

The widespread adoption of the Internet of Things (IoT) has transformed the way devices interact and exchange information, leading to a substantial increase in the number of connected smart devices worldwide. This unprecedented growth has amplified the demand for robust security mechanisms, particularly for mutual authentication between devices and servers. In such distributed environments, it is essential to guarantee not only reliable communication but also the confidentiality, integrity, and authenticity of the exchanged data [1], [2], [3].

Authentication is a cornerstone of IoT security, as it establishes trust between communicating entities before any sensitive information is exchanged. Over the years, numerous authentication protocols have been developed to secure the establishment of sessions between servers and smart objects. However, extensive analysis of existing schemes has revealed that many of them remain vulnerable to critical threats such as impersonation, replay, and man-in-the-middle (MitM) attacks. These weaknesses can be exploited by malicious actors to compromise both the confidentiality and integrity of IoT communications, thereby undermining the overall security of the system [4], [5].

In particular, the protocol proposed by Fatma et al. [6], while offering lightweight computation, exhibits several vulnerabilities that may lead to the disclosure of sensitive credentials and session keys. Such flaws pose serious risks in IoT scenarios, especially in resource-constrained environments where devices cannot easily implement computationally intensive countermeasures.

To address these limitations, this study introduces an enhanced authentication protocol designed for IoT environments. Our scheme leverages elliptic curve cryptography (ECC) for efficient key exchange and collision-resistant hash functions for identity protection and message integrity. ECC offers a favorable trade-off between computational efficiency and cryptographic strength, making it especially suitable for devices with constrained processing power, memory, and energy resources. The proposed design incorporates random nonces, key-derived masking, and challenge-response mechanisms to ensure resilience against known attack vectors while maintaining low overhead.

The security of the proposed protocol has been rigorously evaluated using formal verification methods to identify and mitigate potential vulnerabilities before deployment. Simulation and analysis demonstrate that our protocol achieves the following key security properties:

- Mutual authentication between server and device.
- Resistance to impersonation, replay, and MitM attacks.
- Confidentiality of transmitted data and integrity of messages.
- Low computational and communication cost suitable for IoT devices.

By integrating these measures, the proposed protocol provides a significant improvement in both security and operational efficiency over existing schemes. Ultimately, this work aims to contribute to the development of practical, scalable, and secure authentication solutions for the IoT ecosystem, ensuring trustworthy communication even in highly resource-constrained environments.

II. The Mechanisms used by Authentication Protocols

A. Elliptic Curve Cryptography (ECC)

Elliptic Curve Cryptography (ECC) is a well-established cryptographic method known for providing robust security in authentication schemes [7]. It is based on the mathematical structure of elliptic curves, typically represented as:

$$y^2 = x^3 + ax + b \tag{1}$$

where, a and b are curve parameters. In ECC, cryptographic operations involve algebraic manipulations on points belonging to the elliptic curve. For example, adding two points P and Q on the curve yields a third point R, while multiplying a point P by a scalar k produces another valid point on the curve [8].

A key advantage of ECC is that it achieves comparable security to other public-key systems with significantly smaller

key sizes. For instance, a 128-bit ECC key can offer a security level equivalent to that of a 1024-bit RSA key. This property reduces both computational overhead and storage requirements, making ECC highly suitable for resource-constrained devices [8].

The security of ECC is rooted in the hardness of the Elliptic Curve Discrete Logarithm Problem (ECDLP), which involves determining the integer k such that $kP = Q$, where P and Q are known points on the curve. Solving this problem is computationally infeasible for appropriately chosen curve parameters and key sizes [9], [10].

Due to its combination of mathematical robustness, efficiency, and reduced key size requirements, ECC is extensively employed in modern authentication protocols to provide secure entity verification and protect the confidentiality of exchanged information [11].

B. Cryptographic Hash Function

A cryptographic hash function is a mathematical algorithm that converts input data of arbitrary length into a fixed-length output, commonly referred to as a hash or message digest [12]. Such functions are fundamental in numerous areas of computer science, particularly for ensuring data security and verifying information integrity, as illustrated in the following Fig. 1.

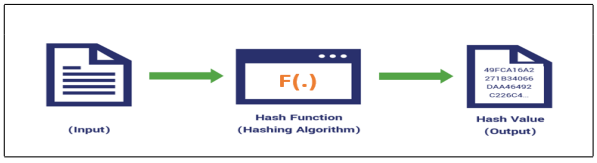

Fig. 1. Cryptographic hash function.

The hash functions possess the following properties:

- Deterministic: A cryptographic hash function is deterministic if the same input consistently yields the same hash value.
- Collision resistance: A hash function has collision resistance when it is computationally infeasible to find two distinct inputs that produce the identical hash output.
- Irreversibility: A hash function is irreversible if recovering the original input from its hash value is computationally impractical or impossible.

The most commonly used cryptographic hash functions include MD5, SHA-1, SHA-256, and SHA-3.

MD5, once widely adopted, is now considered insecure due to identified vulnerabilities and should not be used for security-critical purposes [13].

Similarly, SHA-1, although still present in some systems, is regarded as weak against modern cryptographic attacks [14].

In contrast, SHA-256 and SHA-3 are currently preferred for contemporary applications, as they provide stronger resistance to known attack methods [15].

III. Related Works

Authentication protocols in the Internet of Things (IoT) domain are a frequent subject of discussion in the scientific literature and have recently attracted considerable attention.

In [16], the authors propose a secure multifactor authentication scheme for cloud-based systems, demonstrated in the context of electronic health records. The approach combines three authentication factors—something the user knows, has, and is with cryptographic techniques such as RSA digital signatures and hashed credentials to achieve mutual authentication and ensure data integrity. Key features include an anonymous health center, acting as a trusted third party, responsible for distributing secret keys and managing user permissions during the registration phase. Additionally, the scheme incorporates a QR code mechanism to securely transmit doctor-signed electronic prescriptions to pharmacists. The protocol was implemented with entities such as patients, doctors, and a hospital server, and its security was validated using both the Scyther formal verification tool and informal analysis, demonstrating resistance to man-in-the-middle, replay, impersonation, insider, and phishing attacks.

Boonkrong's work [17] revisits Park et al.'s [18] multifactor biometric remote user authentication scheme and exposes several critical weaknesses, then offers an enhanced protocol to resolve them. Park et al.'s scheme – an improvement over earlier methods – was found to lack adequate message integrity protection (allowing an attacker to modify messages without detection), and freshness guarantees (making replay attacks feasible). It also did not implement a true challenge–response mechanism, leading to incomplete mutual authentication and the possibility of man-in-the-middle attacks, and it provided no way for the client to prove to the server that both share the same session key (leaving session key agreement only partially verified).

In [19], the authors addressed the challenge of safeguarding large volumes of sensitive user data in electronic healthcare (e-health) systems, particularly when using wireless devices with limited processing and storage capabilities. They proposed a dynamic privacy-preserving approach that enables server-side biometric authentication while ensuring complete user anonymity. In their method, the server does not have access to the exact biometric template value, which mitigates the risk of privacy leakage. Moreover, all messages transmitted through their scheme are untraceable, thereby maintaining a high degree of anonymity.

In [20], the researchers focused on the design of an end-to-end mutual authentication protocol for Wearable Health Monitoring Systems (WHMS). They analyzed the mutual authentication protocol proposed by Amin et al. [21] and identified several security flaws. Their improved version, based on quadratic residues, mitigates vulnerabilities such as stolen mobile device attacks, de-synchronization attacks, and sensor key exposure.

The work in [22] addressed the development of lightweight security mechanisms for Wireless Body Area Networks (WBANs), with an emphasis on securely transmitting sensitive patient information. The authors evaluated a lightweight authentication protocol proposed by Liu et al. [23] and, through a security assessment, found weaknesses in its design.

To overcome these limitations, they proposed a single-round lightweight authentication scheme that enhances security and reduces computational overhead.

In [6], an authentication protocol was designed for IoT-based healthcare applications. The authors introduced two major enhancements to the recently proposed M2C mutual authentication protocol, which was originally intended for RFID-based healthcare systems. Their modified protocol, referred to as M2M, leverages Elliptic Curve Cryptography (ECC) to secure RFID communications in healthcare environments.

The authors of [24] proposed an authentication mechanism for Medical Body Area Networks (MBANs) based on patient body motion. They developed a generalized model capable of characterizing routine patient activities—such as walking and running—to verify the legitimacy of sensor nodes. Their security analysis demonstrated that the scheme is resistant to well-known attack vectors.

Using ECC, [25] proposed an RFID-based mutual authentication scheme aimed at improving patient medication safety. The scheme enables secure exchanges between an RFID tag and a medication server, ensuring reliable medical evidence for prescriptions and dosage administration. Nevertheless, this protocol was later shown to have vulnerabilities, which were addressed by Fatma et al. [6].

In [26], the authors presented an authentication protocol for IoT-based RFID systems, focusing on mitigating security risks inherent in wireless communication channels. Their design integrates ECC and employs the elliptic curve Diffie–Hellman (ECDH) [27] key agreement mechanism to generate temporary shared keys for encrypting transmitted messages.

Several studies have also presented mutual authentication schemes aimed at establishing a secure session key between RFID tags and backend servers to ensure reliable communication. Examples include the works of Dinarvand et al. [28], Liao et al. [29] for specialized environments, and Zhao et al. [30] for healthcare-specific applications.

All these schemes generally follow a two-phase structure. The configuration phase involves the server generating ECC public/private key pairs to be used in the subsequent stage. The authentication phase is then repeated each time the server initiates a connection with a smart object, during which both entities exchange messages to mutually verify their identities.

IV. Description and Notation Used

Before presenting our enhanced version of the M2C authentication protocol derived from the scheme proposed by Fatma et al. [6], Table I summarizes the notations employed in its description.

V. Review and Cryptanalysis of Fatma et al.'s Protocol

Fatma et al. [6] introduced an ECC-based authentication scheme tailored for resource-limited devices, including RFID tags and sensors. Owing to its design, it falls under the category of machine-to-cloud (M2C) protocols. The proposed approach functions through two primary phases.

TABLE I. Notations used in the Protocol Description (Modified Symbols)

Notation	Meaning
n_{tot}	Total of IoT devices.
$\mathcal{S}$	Server in Cloud.
$\mathcal{D}$	IoT device.
D_k	Specific IoT device D_k, where $k \in [1, n_{tot}]$
q_a, q_b	Two large prime numbers.
$\mathbb{F}^*_{q_a}$	Multiplicative group of a finite field.
$\mathcal{E}$	Elliptic curve defined by $y^2 = x^3 + ax + b$.
P_g	Base point (generator) of $\mathcal{E}$ of order q_a.
(q_b, a, b, q_a, P_g)	Domain parameters for constructing $\mathcal{E}$.
H	Collision-resistant secure hash function.
$\rho \xleftarrow{\$} \mathbb{F}^*_{q_a}$	Random element ρ sampled from $\mathbb{F}^*_{q_a}$.
$\alpha \cdot \beta$	Scalar multiplication of α with elliptic curve point β.
$\alpha \oplus \beta$	XOR operation.
$\alpha \parallel \beta$	Concatenation operation of α and β.
$\alpha \stackrel{?}{=} \beta$	Equality check.
ID_{D_k}	Unique identity of device D_k.
hID_{D_k}	Hash of the identity ID_{D_k} stored in the server database.
$\mathsf{SK}_{\mathcal{S}}$	Server's private key.
$\mathsf{PK}_{\mathcal{S}}$	Server's public key.

A. The Configuration Phase

In this phase, the server S generates the system parameters (q_b, a, b, q_a, P_g) required for the construction of the elliptic curve $\mathcal{C}$, shares them with other entities, and stores them in its database. The server then assigns to each smart object D_k, a unique identifier ID_{D_k}, and computes its hashed form $hID_{D_k} = \mathsf{H}_c(ID_{D_k})$, where hID_{D_k} serves as the key in the hash table used to store the identifiers of all smart objects. This process is illustrated in Fig. 2.

Server $\mathcal{S}$	**IoT Device** D_k
$(q_b, a, b, q_a, P_g) \xleftarrow{\$}$	
$ID_{D_k} \xleftarrow{\$}$	
$hID_{D_k} = \mathsf{H}(ID_{D_k})$	
$\xrightarrow{(q_b, a, b, q_a, P_g),\ ID_{D_k},\ hID_{D_k}}$	

Fig. 2. Configuration phase.

B. The Authentication Phase

This step is illustrated in Fig. 3 and proceeds as follows:

- The server $\mathcal{S}$ randomly selects $\rho_{\mathcal{S}} \in \mathbb{F}^*_{q_a}$ and computes $R_{\mathcal{S}} = \rho_{\mathcal{S}} \cdot P_g$. It then transmits $R_{\mathcal{S}}$ to the device D_k.
- Upon reception, D_k picks a random $\rho_k \in \mathbb{F}^*_{q_a}$ and calculates $R_k = \rho_k \cdot P_g$. To conceal hID_{D_k}, it derives a shared key $K = \rho_k \cdot R_{\mathcal{S}}$ and masks the identity hash as $M = hID_{D_k} \oplus K$. It then generates an authenticator $\mathsf{Auth}_k = \mathsf{H}(ID_{D_k} \parallel 2 \parallel K)$. The device sends the tuple $(R_k, \mathsf{Auth}_k, M)$ to $\mathcal{S}$.
- On receiving the message, $\mathcal{S}$ computes $K = \rho_{\mathcal{S}} \cdot R_k$ and retrieves $hID'_{D_k} = M \oplus K$. It searches the

database for the identity ID'_{D_k} corresponding to hID'_{D_k}. If no match is found, $\mathcal{S}$ ends the session after a predefined timeout to limit information leakage. Otherwise, it computes $\mathsf{Auth}'_k = \mathsf{H}(ID'_{D_k} \parallel 2 \parallel K)$ and compares it to the received Auth_k. If they differ, the session is aborted; if equal, D_k is authenticated. The server then generates $\mathsf{Auth}_{\mathcal{S}} = \mathsf{H}(ID_{D_k} \parallel 1 \parallel K)$ and sends it to D_k.

- Upon receiving $\mathsf{Auth}_{\mathcal{S}}$, the device computes $\mathsf{Auth}'_{\mathcal{S}} = \mathsf{H}(ID_{D_k} \parallel 1 \parallel K)$ and checks equality. If they match, the server is authenticated, achieving mutual authentication; otherwise, the session is terminated.

At the end of this phase, D_K and S share the session key, K, which has been computed to ensure integrity, privacy, and confidentiality during subsequent exchanges.

VI. Potential Security Weaknesses in the Fatma et al. Protocol

In the previous scheme, an adversary is able to recover the communication key K, as well as the identifier ID_{D_K} of a smart object, enabling them to intercept exchanges between the device D_K and the server $\mathcal{S}$. The attacker first obtains the hashed identifier H_{D_K} by following the steps illustrated in Fig. 4:

- The adversary $\mathcal{A}$ selects a random value $\rho_{\mathcal{A}}$ and computes $R_{\mathcal{A}} = \rho_{\mathcal{A}} \cdot P_g$. It then sends $R_{\mathcal{A}}$ to the device D_k.
- Upon receiving $R_{\mathcal{A}}$, D_k generates a random $\rho_k \in \mathbb{F}^*_{q_a}$ and computes $R_k = \rho_k \cdot P_g$. To protect hID_{D_k}, the device calculates $K = \rho_k \cdot R_{\mathcal{A}}$ and masks it as $M = hID_{D_k} \oplus K$. It also generates $\mathsf{Auth}_k = \mathsf{H}(ID_{D_k} \parallel 2 \parallel K)$, and sends $(R_k, \mathsf{Auth}_k, M)$ to $\mathcal{A}$.
- The adversary then computes $K = \rho_{\mathcal{A}} \cdot R_k$ and retrieves hID_{D_k} by computing $hID_{D_k} = K \oplus M$.

After the recovery of hID_{D_k}, the attacker can perform the following two attacks:

A. Eavesdropping Attack

Once the adversary has obtained hID_{D_k}, it stores this value in its own database. During a legitimate authentication process between $\mathcal{S}$ and D_k, the adversary can perform an eavesdropping attack to derive the session key K, as outlined in Fig. 5:

- The server $\mathcal{S}$ randomly selects a number $\rho_{\mathcal{S}}$ and computes $R_{\mathcal{S}} = \rho_{\mathcal{S}} \cdot P_g$. It then transmits $R_{\mathcal{S}}$ to D_k.
- The IoT device executes its computations and returns the tuple $(R_k, \mathsf{Auth}_k, M)$ to $\mathcal{S}$.
- The adversary intercepts this message. With knowledge of hID_{D_k} and access to $(R_k, \mathsf{Auth}_k, M)$, it can compute the communication key as $K = hID_{D_k} \oplus M$.

B. Preimage Attack

Once hID_{D_k} has been recovered, note that $hID_{D_k} = \mathsf{H}(ID_{D_k})$. Since ID_{D_k} is a scalar, a high-performance computing system could, in principle, generate candidate scalars x_k and compute $\mathsf{H}(x_k)$ until finding some x_n such that $\mathsf{H}(x_n) = \mathsf{H}(ID_{D_k})$. In that case, x_n reveals ID_{D_k}.

If ID_{D_k} is chosen with a sufficiently large bit length, such a brute-force search becomes computationally infeasible. However, this mitigation is constrained in IoT settings, where limited device storage makes it impractical to significantly increase the

VII. The Proposed ECC based Authentication Protocol

We propose an enhanced version of the protocol introduced by Fatma et al. [6] in order to address the vulnerabilities identified in Section VI. The improved scheme also supports mutual authentication between servers and multiple smart objects, provided that the servers store the identities of these objects.

The proposed protocol operates in two main phases: a configuration phase and an authentication phase.

A. The Configuration Phase

The server first creates the system parameters (q_b, a, b, q_a, P_g) and shares them with the other entities to construct the elliptic curve $\mathcal{E}$. Then, the server $\mathcal{S}$ chooses a random value $\mathsf{SK}_{\mathcal{S}} \in \mathbb{F}^*_{q_a}$ as its private key and computes its public key $\mathsf{PK}_{\mathcal{S}} = \mathsf{SK}_{\mathcal{S}} \cdot P_g$. Afterwards, the server generates and sends to each IoT device an identifier ID_{D_k} and $hID_{D_k} = \mathsf{H}(ID_{D_k})$. It also transmits its public key $\mathsf{PK}_{\mathcal{S}}$. Once this phase is completed, the server records the system parameters along with the device identifiers in its database, to be used later during the authentication phase (see Fig. 6).

B. Authentication Phase

This phase consists of three message exchanges, illustrated in Fig. 7.

- Challenge from server to device: The server $\mathcal{S}$ initiates the process by sending an authentication request (challenge) to the IoT device D_k. Upon receiving the challenge, D_k randomly selects $\rho_k \xleftarrow{\$} \mathbb{F}^*_{q_a}$, then computes $R_k = \rho_k \cdot P_g$ and $K = \rho_k \cdot \mathsf{PK}_{\mathcal{S}}$. It masks K as $M = hID_{D_k} \oplus K$ and generates the authentication tag $\mathsf{Auth}_k = \mathsf{H}(ID_{D_k} \parallel 2 \parallel K)$. Finally, it sends $(R_k, \mathsf{Auth}_k, M)$ to $\mathcal{S}$.
- Device authentication by server: The server computes $K = \mathsf{SK}_{\mathcal{S}} \cdot R_k$ and derives $hID'_{D_k} = M \oplus K$. It then searches its database for a matching ID'_{D_k} using hID'_{D_k}. If no match is found, the session is terminated after a delay to limit information leakage. If a match exists, the server calculates $\mathsf{Auth}'_k = \mathsf{H}(ID'_{D_k} \parallel 2 \parallel K)$ and compares it with Auth_k. If the values match, D_k is authenticated; otherwise, the session is aborted. Upon successful authentication, the server generates $\mathsf{Auth}_{\mathcal{S}} = \mathsf{H}(ID_{D_k} \parallel 1 \parallel K)$ and sends it to the device.

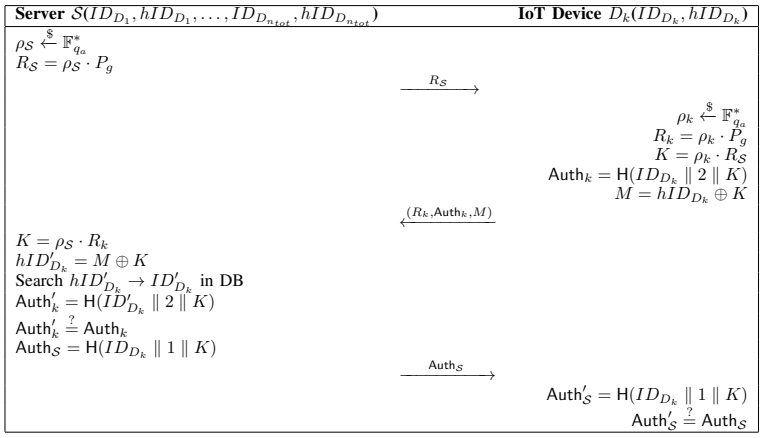

Fig. 3. Authentication phase.

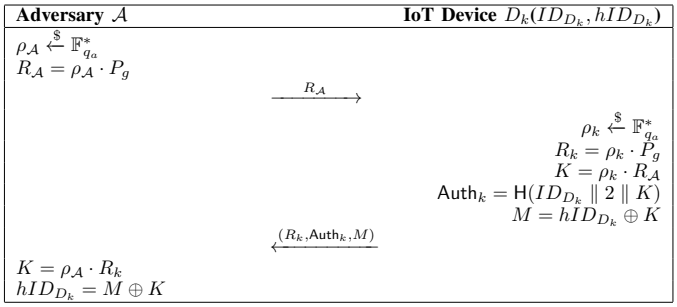

Fig. 4. Recovery of hID_{D_k}.

- Server authentication by device: After receiving $\mathsf{Auth}_{\mathcal{S}}$, the device computes $\mathsf{Auth}'_{\mathcal{S}} = \mathsf{H}(ID_{D_k} \| 1 \| K)$ and verifies it against the received value. If they match, $\mathcal{S}$ is authenticated, and mutual authentication is established; otherwise, the session is terminated.

At the conclusion of this phase, both D_k and $\mathcal{S}$ share the session key K, computed as:

$$K = \rho_k \cdot \mathsf{PK}_{\mathcal{S}} = \mathsf{SK}_{\mathcal{S}} \cdot R_k = \mathsf{SK}_{\mathcal{S}} \cdot \rho_k \cdot P_g.$$

This shared key is subsequently used to ensure integrity, confidentiality, and privacy in all subsequent communications.

VIII. Security Analysis

A. Informal Analysis

1) Mutual authentication:

a) Device authentication: An adversary is unable to generate a valid message $(R_k, \mathsf{Auth}_k, M)$ on behalf of device D_k, as they lack the necessary values hID_{D_k}, ID_{D_k}, and ρ_k. These parameters are essential for computing Auth_k and M, and can only be derived by the legitimate server $\mathcal{S}$ and device D_k.

b) Server authentication: The adversary cannot forge the legitimate server message $\mathsf{Auth}_{\mathcal{S}}$, since it requires knowledge of the identifier ID_{D_k}, which is not disclosed.

TABLE II. Results of the Verification by AVISPA

OFMC	SAFE
SATMC	INCONCLUSIVE
TA4SP	INCONCLUSIVE

2) Integrity and confidentiality: Upon completion of the protocol, the server $\mathcal{S}$ and device D_k establish a shared session key K. This key is jointly derived from $\mathsf{SK}_{\mathcal{S}}$ (generated by $\mathcal{S}$) and ρ_k (generated by D_k) for each session, thereby ensuring both message integrity and confidentiality.

3) Availability:

a) Resistance to Man-in-the-Middle (MitM) attacks: The adversary cannot obtain ID_{D_k}, hID_{D_k}, or the session key K. In contrast, the protocol of Fatma et al. [6] is susceptible to MitM attacks, as the session key K can be recovered by an adversary.

B. Formal Analysis

In this section, we conduct a formal security assessment of the proposed scheme using two widely recognized automated verification tools: AVISPA [31] and ProVerif [32].

1) HLPSL Code of the proposed protocol: The HLPSL specification of our protocol is provided in Fig. 8 and Fig. 9. For a more comprehensive explanation, including extended formal verification procedures and additional security analysis, readers are referred to our related conference publication [33].

2) AVISPA verification results: Table II summarizes the outcomes obtained after executing our HLPSL-coded protocol in the AVISPA environment. The results indicate that both the CL-AtSe and OFMC back-ends report the status SAFE, confirming the absence of detected attacks. For the SATMC and TA4SP back-ends, the outcome is INCONCLUSIVE due to unsupported operations, which implies that these modules are unable to process certain steps of the protocol rather than indicating any security weakness.

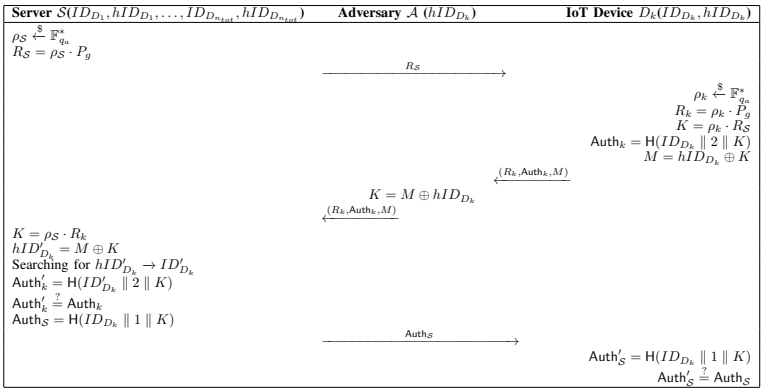

Fig. 5. Recovery of the key K.

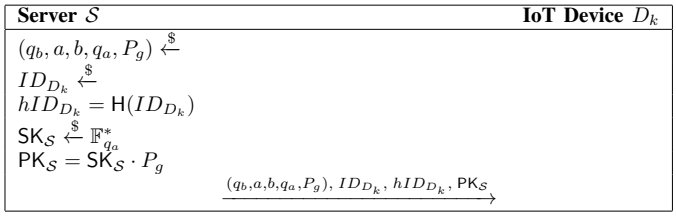

Fig. 6. ECC-based configuration phase.

C. Specification of Our Protocol using the Pi-Calculus Script in ProVerif

In this section, we will present the code of our protocol using Pi-Calculus. Fig. 10 and Fig. 11 presents the server role and smart object role.

1) The results of the verification by Proverif: Fig. 12 represents the results of our contributions using the ProVerif tool. It shows that mutual authentication is achieved, and the confidentiality of variables idt, hidt, ri, and rs is preserved.

IX. Performance Evaluation

This section presents an evaluation of the proposed scheme with respect to communication overhead, and computational effort. For the analysis, we consider a deployment consisting of n_{tot} IoT devices. We assume that the size of a scalar value is λ bits, which implies that the size of a point on the selected elliptic curve $\mathcal{E}$ is 2λ bits. Accordingly, the size of the system parameters (q_b, a, b, q_a, P_g) is taken to be 6λ bits in total. Furthermore, both the device identifier ID_{D_k} and its corresponding hashed representation hID_{D_k} are assumed to be scalar values, each occupying λ bits.

T_{PM} and T_{PA} represent the execution time required to perform elliptic curve point multiplication and point addition operations, respectively.

A. Computation Cost

In this section, we assess and compare the computational effort required by both the server (see Table IV) and the smart objects (see Table III) during the authentication process. The performance of our proposed protocol is evaluated against several existing schemes, including those presented by Liao et al. [29], Dinarvand et al. [28], Jin et al. [34], Alamr et al. [26], Zhao [30], and Fatma et al. [6].

TABLE III. Evaluation of Computation Costs for Smart Devices

approach	Computational Overheads
Zhao et al. [30]	$3 * T_{\text{PA}} + 5 * T_{\text{PM}}$
Dinarvand et al. [28]	$2 * T_{\text{PA}} + 3 * T_{\text{PM}}$
Jin et al. [34]	$1 * T_{\text{PA}} + 4 * T_{\text{PM}}$
Alamr et al. [26]	$1 * T_{\text{PA}} + 4 * T_{\text{PM}}$
Liao et al. [29]	$3 * T_{\text{PA}} + 5 * T_{\text{PM}}$
Fatma et al. [6]	$2 * T_{\text{PM}}$
Our approach	$2 * T_{\text{PM}}$

TABLE IV. Evaluation of Computation Costs for Server

approach	Computational Overheads
Zhao et al. [30]	$3 * T_{\text{PA}} + 5 * T_{\text{PM}}$
Dinarvand et al. [28]	$2 * T_{\text{PA}} + 3 * T_{\text{PM}}$
Jin et al. [34]	$2 * T_{\text{PM}}$
Alamr et al. [26]	$1 * T_{\text{PA}} + 5 * T_{\text{PM}}$
Liao et al. [29]	$3 * T_{\text{PA}} + 5 * T_{\text{PM}}$
Fatma et al. [6]	$2 * T_{\text{PM}}$
Our approach	$1 * T_{\text{PM}}$

As shown in Table IV, our proposed improvement achieves lower server computation costs than the compared protocols, while maintaining a database search complexity of $O(1)$, similar to the approach of Fatma et al. [6].

B. Transmission Overhead

The transmission Overhead is assessed by determining the bit length of all messages exchanged during the authentication phase, along with counting the total number of message transmissions.

In Table V, our enhancement is the best protocol in terms of computation cost at the server level.

X. Practical Analysis

To evaluate the feasibility and performance of the proposed ECC-based mutual authentication protocol, a real-world imple-

mentation was conducted using two heterogeneous physical devices: a Raspberry Pi 3 Model B+ representing the IoT object, and a standard personal computer equipped with an Intel Core i5 (5th generation) processor functioning as the central server. The Raspberry Pi, operating under a Linux-based Raspbian OS, was chosen to simulate the constraints typical of embedded IoT devices in terms of memory, CPU capacity, and energy consumption. The server ran Ubuntu 20.04 and was responsible for handling the more computationally intensive cryptographic verifications and key exchange processes. The protocol logic was fully developed in Python 3 using the ecdsa cryptographic library, which provides implementations of elliptic curve operations and ECDSA signatures. Experiments were conducted using a range of elliptic curves to evaluate their impact on the protocol's performance. The tested curves include: NIST192p, NIST224p, NIST256p, SECP256k1, BRAINPOOLP160r1, BRAINPOOLP192r1, BRAINPOOLP256r1, and Ed25519. These curves were used to measure the execution time of the authentication phase for each configuration, and the results obtained are presented in Fig. 13.

Server Role

TABLE V. COMPARISON OF TRANSMISSION OVERHEAD

approach	S → O	O → S	Total (bits)	Number of Messages
Alamr et al. [26]	$4 * \lambda$	$6 * \lambda$	$10 * \lambda$	3
Dinarvand et al. [28]	$5 * \lambda$	$4 * \lambda$	$9 * \lambda$	4
Jin et al. [34]	$4 * \lambda$	$3 * \lambda$	$7 * \lambda$	3
Zhao et al. [30]	$4 * \lambda$	$4 * \lambda$	$8 * \lambda$	3
Liao et al. [29]	$4 * \lambda$	$4 * \lambda$	$8 * \lambda$	3
Fatma et al. [6]	$4 * \lambda$	$3 * \lambda$	$7 * \lambda$	3
Our proposed	$4 * \lambda$	$2 * \lambda$	$6 * \lambda$	3

This implementation setup allowed for real-time testing of the protocol under realistic hardware constraints and provided concrete insights into its computational efficiency and practicality for IoT deployments.

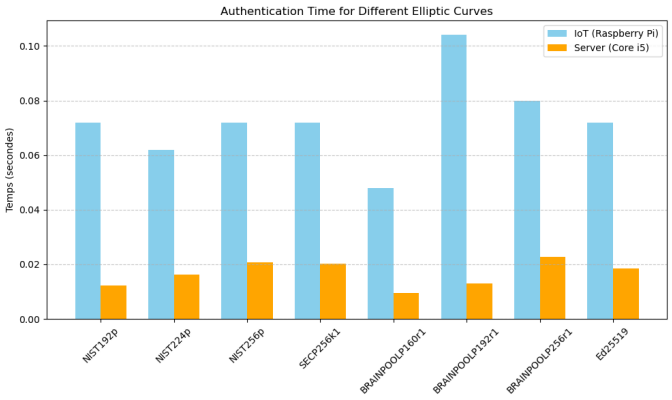

Fig. 13. Authentication time for different elliptic curves.

A. Computational Cost of Our Protocol

The average execution time of our authentication protocol, measured across the full exchange phase between the IoT device (Raspberry Pi) and the server (Core i5), is approximately 0.089348 seconds, consisting of 0.072703 seconds on the IoT side and 0.016645 seconds on the server side. These values were obtained by computing the mean execution time across a range of standardized elliptic curves.

This implementation demonstrated that our protocol successfully reduced the execution time compared to the protocol proposed by Fatma et al., particularly during the authentication phase, as illustrated in Fig. 14 . This noticeable reduction in processing time highlights the effectiveness of our approach, which combines computational efficiency with robust security. As a result, the proposed protocol is well suited for real-time execution on resource-constrained IoT platforms, while ensuring secure and mutual authentication.

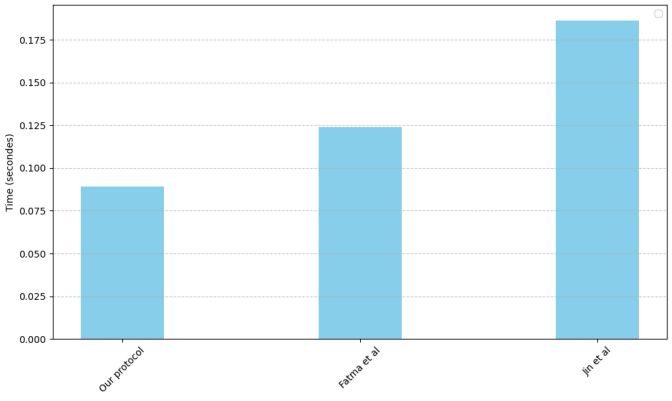

Fig. 14. Comparison of computation costs.

XI. CONCLUSION

This research presents a comprehensive study of an efficient protocol originally proposed by Fatma et al. Our security

analysis revealed several critical vulnerabilities that could compromise the robustness of the protocol in real-world IoT deployments. In response to these weaknesses, we proposed a reinforced version of the protocol, focusing on both improving security guarantees and reducing computational and communication overhead. To validate the proposed enhancements, we not only employed formal verification tools, such as AVISPA and ProVerif but also carried out a practical implementation using heterogeneous devices—specifically, a Raspberry Pi 3 Model B+ and a standard PC—to simulate constrained IoT environments. This real-world experimentation allowed us to analyze execution times and resource consumption across a variety of elliptic curves. The results, drawn from both simulation and implementation, clearly demonstrate that the enhanced protocol significantly improves upon the original in terms of resistance to known attacks and performance efficiency. These outcomes confirm the protocol's relevance and feasibility for secure authentication in IoT systems and highlight the value of combining formal analysis with empirical validation to design resilient and practical security solutions.

***Abstract*—This electronic increasingly, Digital Twin (DT) systems are being leveraged in smart infrastructure settings (e.g., structural health monitoring, intelligent traffic controls, and distributed utility networks). Yet, the available solutions all face hurdles that can prevent real-time synchronization of DT instances across federated cloud platforms, primarily due to latency variation, quality of service (QoS) assurance, and stale data, which are all consequences of heterogeneous computer environments. Most solutions depend on static cloud-only models of deployment, with no option for dynamic negotiation of resources. These provide long update times (typically greater than 200ms), low accuracy rates, and low real-time responsiveness. Additionally, traditional DT models were not developed with multi-regional deployment or QoS workloads in mind. In this work, a QoS-Aware Federated Digital Twin Orchestration Framework (Q-FDTO) is designed to allow latency-critical monitoring of infrastructure across different federated cloud regions, through the integration of a hybrid edge-cloud control plane, adaptive synchronization, jitter consideration for observed intervals, and dynamic resource allocation via reinforcement learning for defined QoS Service Level Objectives (SLOs). This system was evaluated on a smart city testbed of 1200 sensor nodes. The testbed monitored sensor readings for structural strain, vibration, and traffic density across twelve locations. The digital twin pipeline is comprehensive [i.e., (i) ingestion via Wi-Fi MQTT, (ii) stream fusion of all the sensor readings via Kalman filtering, and (iii) twin modeling of prediction, through a temporal graph convolutional network (T-GCN)]. To assess performance, sync policies were evaluated on metrics for average update latency (ms), sync drift (ms), and data consistency rate (%). The results demonstrate that Q-FDTO had an average update latency of 87.3 ms, reduced from 194.6 ms, and a 96.2% consistency rate across federated nodes with less than 2.5% sync drift over 10-minute intervals, showing Q-FDTO architecture ability for network boundaries and also compatible with AWS Outposts and Azure Arc hybrid cloud environments. It establishes a scalable and practical approach to latency-sensitive DT deployments in the realm of smart infrastructure systems.**

Keywords*—QoS-aware digital twins; federated cloud synchronization; smart infrastructure monitoring; latency-constrained orchestration; edge-assisted deployment

I. Introduction

The worldwide expansion of smart infrastructure, including urban mobility, structural health monitoring, energy-resilient buildings, and smart water systems, has led to rapid growth in sensor-rich contexts. Smart infrastructure comprises a system of sensor-actuator networks that, together, stream telemetry data to incorporate into real-time decisions, fault identification or preventative maintenance. Like digital twins, a form of monitoring and decision-making technology, as of 2023, over 65% of cities worldwide have implemented some form of monitoring of their infrastructure, typically in partnership with private companies focused on the technology market and cities taking on digital, scaled transformation initiatives [1]. Digital twins are models of a real infrastructure component, built with real-time data, configuration specifics, and geographic data to create a virtual version of the real component. Digital twins serve as predictive devices or operational dashboards that facilitate identifying and proactively responding to faults, load distributions, and capacity optimization. For instance, in smart traffic networks, digital twins may be used to model how vehicles flow through junctions and when it would be the most beneficial moment to change the program of a stoplight to relieve congestion in relation to other stoplights. Alternatively, in a structural health assessment context, data streams of strain and vibration measures expected in real-time could be reference frames for models predicting structural fatigue and failures. Moreover, despite the developing importance of the topic, limitations concerning effectiveness of such systems to perform at the willingness scale, while managing data processing and modeling latencies, and the shape and distribution of hardware and network topology, along with time-varying flows, and other data properties continue to challenge; such as any fidelity is time varying, and the highly dynamic conditions experienced while monitoring behavior in physical systems, like a vehicular flow, or structural loads affected by weather, ends up triggering (at least in pilot implementations) unattended faults and periods of uncertainty; further, as much as these restrictions continue to evolve, there are severe constraints regarding data transfer limits and waiting system processing. The monitored physical system itself is unable to be optimized for low-latency times or any other characteristics, and intervention will be needed in cases of

disparity across systems when using any non-latency-constrained twin. However, any twin frame subjectively based on low-latency and high-consistency telemetric transfer parameters would still be deployed across architectures of many different thermal characteristics and sensing capabilities that would not be able to transfer motion behavior parameters without reduced fidelity, delays in telemetric transfer, or potentially false triggering with an operator decision. In addition to these factors, the emergence of federated cloud environments—where multiple cloud regions or providers are harmonized to sustain distributed applications—is motivating more resilient, cost-efficient, and geo-political-compliant smart infrastructure operators to abandon single-vendor cloud deployments. This generates another layer of complexity, which is synchronizing digital twin states across federated infrastructures with strict QoS constraints on both latency (sub-100ms), jitter (variance under 20ms), and high-frequency data update rates (e.g., 10–50Hz in traffic systems).

Digital twins, in the context of cyber-physical systems (CPS), identify real-time (or near real-time), dynamic digital models that are continuously updated to reflect changes in their real-world counterpart, based upon incoming telemetry data. Digital twins are not mere static replicas; they change, evolve, and forecast based on environmental interactions. Additionally, they can be predictive, prescriptive, or real-time descriptive in nature. A robust digital twin architecture includes a data ingestion layer, a processing and simulation layer, and a visualization/control interface. Furthermore, cloud computing provides a natural backbone for managing and hosting digital twin workloads. Even at the level of public cloud platforms, such as AWS IoT Twin Maker, Azure Digital Twins, and Siemens Mind Sphere, there are off-the-shelf APIs to support digital twin management in real-time. However, as infrastructure deployments become more latency-sensitive, the execution of some operations needs to be offloaded to edge computing layers, such as complete processing offloading to gateways or fog nodes. While edge layers function as intermediaries, they enable pre-processing, caching, and low-latency decision enforcement closer to the physical assets. Within the previous context, federated cloud platforms represent a paradigm where multiple cloud services—across vendors or regions—are abstracted and managed as a singular logical fabric. These frameworks are necessary for multi-tenant smart city deployments or cross-jurisdictional monitoring applications that are sensitive to data sovereignty, failover support, or local compliance. The syncing of digital twin models across federated counterparts creates new challenges of data staleness, model drift, and lag in coordination. Studies on syncing protocols (delta propagation, distributed consensus - RAFT or Paxos protocols, or event-based replication) exist for traditional distributed systems, but they are not appropriate for latency-constrained, high-frequency updates mandated by modern smart infrastructure. Moreover, there remain unexplored layers of opportunity for optimizing adaptive sync intervals based on workload dynamics or input data stream entropy.

Even with the existence of digital twin frameworks and cloud orchestration infrastructure, existing systems address a number of key limitations to achieve real-time quality-of-service (QoS) as required by monitoring of smart infrastructure. First, static cloud-deployed digital twin infrastructures have deterministic latency floors - specifically when a cloud region is distant from the asset(s) being monitored - and observed latency of greater than 150-200ms by measurement in standard HTTP or an MQTT broker pipeline across multi-region cloud environments. With existing latency more than 30 to 50ms for straining monitoring bridges where stress is varied prior to a prediction of critical failure, the dynamic must be judged in real-time if the twin can cease predictive control. Second, the cyclical determination of sync intervals represents a choke point that has not been addressed in any existing framework. Existing frameworks simply synchronize digital twin instances at fixed or other uniform intervals, while ignoring input data dynamics, workload entropy, or operational criticality. For instance, a vibration sensor operating in a static load condition will not necessitate the same update frequency as a vibration sensor that is detecting load spikes during busy hours. Not recognizing the differences between these two scenarios could result in either under-sampling important events or over-burdening the network with updates that provide limited value. Third, while eventual consistency or periodic snapshotting can usually maintain cross-region consistency in federated cloud contexts, the methods are seldom appropriately scaled or timely enough for DT use cases that require consistent views across multiple visualizations or control surfaces (e.g., when emergency response teams in different locations in the field depend on the same digital twin state). Current cloud-native DT tools do not effectively handle replication lag or update collisions. Fourth, there is often a lack of QoS-awareness with cloud orchestration. Cloud orchestrators will focus on cane, storage, or reducing costs, but do not factor in QoS requirements at the application level, like triggering updates within a latency threshold, tolerating jitter, or managing queues for updates based on a priority system, causing resource under-provisioning and/or incorrect scaling policies during critical operational periods. Lastly, learning-based synchronization models are seldom integrated. Current systems use static thresholds or heuristic rules to manage the rate of twin updates; however, reinforcement learning (RL) based controllers would optimize synchronization strategies by learning workload patterns, network conditions, and scores around criticality. Their absence in production-grade DT orchestration is an under-utilization of an opportunity for intelligent automation.

In this study, we will introduce a QoS-Aware Federated Digital Twin Orchestration Framework (Q-FDTO), developed to facilitate scalable, latency-constrained, and consistency-assured digital twin deployments in federated cloud environments. The Q-FDTO introduces a multi-layer architecture that consists of: 1) an edge-assisted ingestion and pre-processing module, 2) a cloud-central twin modeling pipeline utilizing T-GCNs to develop time-series predictions, and 3) a reinforcement-learning based adaptive synchronization controller. The framework runs on real-time telemetry from multiple Intelligent Infrastructure testbed sites made up of structural strain gauges, accelerometers, and vehicular traffic sensors. MQTT is used for edge-to-cloud transport, with inter-cloud twin synchronization managed by a lightweight, custom delta-protocol approach that uses QoS

driven control signals. The RL-based controller manages adjustment installation level and priority queue based on entropy, and latency feedback, along with criticality classification. Q-FDTO is designed to operate in conjunction with existing federated cloud platforms like Azure Arc or AWS Outposts already in use or planned for use, enabling an edge-cloud hybrid deployment for multi-regionality orchestration. The synchronization layer aims to optimize for less than 100ms update latency, with > 95% data consistency and < 2.5% average drift over 10-minute evaluation windows. The entire stack is deployable as containerized microservices using Kubernetes and supports horizontal scaling under workloads.

II. Related Works

Digital twins (DTs) facilitate real-time mirroring and simulation, and control of physical assets and stakeholder interactions, and are becoming a ubiquitous capability of modern cyber-physical systems. In areas such as transportation, smart manufacturing, and energy management, DTs enable predictive insights and facilitate in-situ operational decisions generated from innumerable timely data. Despite their burgeoning deployment and ET use cases, substantial unsolved challenges exist regarding the viability of digital twins in federated cloud frameworks (i.e., heterogeneous compute and storage across cloud vendors and physical locations), imposed by latency requirements, data synchronizations over achievable bandwidths, and consistency across instances of federated DTs. Similar challenges arise while introducing the use of edge computing, artificial intelligence (AI) model generation, and time-sensitive networking (TSN) in conjunction with DTs, as conventional synchronization and orchestration methods will not scale with beginning DTs and the user experiences designed into them. In advancing the state of practice in federated digital twin systems, it is important to examine recent works addressing task offloading, cloud-edge integration, point cloud reconstruction, and privacy-aware digital twin orchestration. X. Tan et al. [1] tackled determining task scheduling in digital twin-enabled vehicular networks, proposing a framework and an adaptive scheduling algorithm within a cloud-native vehicular communication framework. Their adaptive scheduling algorithm, built upon DTs of vehicles and traffic status, allows forecasting computational load and dynamically scheduling tasks or transferring tasks from a cloud node or agenda to the best edge node to optimize performance. The system was evaluated based on simulation models by vehicular communication topologies with relationship to task and cloud-edge demands, which resulted in lower latency and greater throughput responses along the fluctuating processing task demands. However, their proposed solution is tightly coupled to vehicular networks and has limited applicability to other infrastructure applications, such as structural health monitoring or urban sensing grids. Their solution is limited to vehicular domains and for not represent wider application use cases, particularly in cases where synchronization across multi-cloud zones needs to be enforced. Y. Gao et al. [2] proposed a LiDAR-based approach to volumetric damage evaluations and digital twin synchronization in construction environments. In their approach, they utilized a high-resolution point cloud dataset to identify deformations and structural anomalies in real time, which then could be synchronized dynamically objects contained within each architectural domain site for visualization, control, and remote monitoring. Using real-world construction datasets, they demonstrated that the framework exhibited accurate 3D map modeling with some mapping, including damage localization. However, the synchronized mechanism lacked fluidity and was limited by batching throughout a given time series, thus missing important opportunities for high-velocity, time-constrained applications requiring sub-100ms updates or dynamic synchronization windows based on sensing event entropy, etc.

J. Xie et al. [3] developed a cloud-edge collaborative dual digital twin model for electric vehicle (EV) battery systems. The dual cloud-edge system implements Lyapunov-based incremental learning to adaptively update each digital twin model for battery state-of-health associated with environments spawned by both the cloud (OEM) and edge operational (repo / transportation / logistics) conditions. Using real telemetry data from an EVs battery manufacturer, the dual cloud-edge system domain showed faster convergence and battery cell fault occurrence identified assistively with position in the digital twin model and features. While effective using the learning-based synchronization combination, the implementation was limited to battery management in one vehicle, directed at battery utilization and did not cascade out to any other federated or synchronized structural protocols managed by multiple regions across geography. The study also did not address the key elements around consistency across cloud zones identified with these domains, which are critical components when managing regional infrastructures at city levels.

Y. Li et al. [4] fused scene-based vision data with the point cloud simulator data to generate a common model to assert a digital twin for shield tunnel construction. Their method fused multiple modes of sensing to increase accuracy in detecting tunnel segment displacements and changes in geometric deformation. Real data from multiple projects for tunnel construction, inhabited in-use model improvements based on the proposed model, improving hybrid performance conditions in increasing form modeling precision. However, the study was primarily focused on offline synchronization and post-processed data application for visualization modeling at construction sites and did not provide the capabilities of real time, in- situ sensory response mechanisms aligned to railing on the intended site, or settings where dynamic synchronization would provide performance for high frequency types of models or remote adaptations for environmental type quality interaction.

Z. Hao et al. [5] focused on the pose reconstruction for hydraulic support groups using digital twins integrated with point cloud data. The reconstruction was enabled using geo-extraction mechanisms to quart this point data to object model parameters which volume measure spatial distance as part of construction environment framework - thus compose it in accordance with digital twin frame performance research engineering volume determination and measuring reconstruction outcomes in mining conditions and practices. Nonetheless, as a reconstruction posing strategy, this approach achieved a high level of accuracy with object model validation

performance when applied in field data or benchmarks. While the use of geometrical models advanced precision gap detection or modeling around consistency performance model, the PO-PO approaches representing digital twin models were not described for cross usage situations across multi-sites or federated types of multi-model synchronization examples - nonetheless, “adaptive or quality of service-based orchestration for stability in operational load variations was not captured or used". H. Yi [6] addressed the issues of privacy and security in the cloud storage of digital twin-based medical records. The study proposed a novel cloud encryption scheme that preserves the confidentiality of medical DT data while retaining interoperability among cloud devices and thereby accessibility from multiple platforms. The simulation results exhibited improved robustness to external attacks towards unauthorized data access, while storage space was used more efficiently through deduplication. However, the scheme addressed static (as opposed to dynamic) cloud architectures, leaving current digital twin deployments without real-time synchronization dynamics or latency guarantees, both are vital in real-time healthcare decision making and cloud federation deployments.

Y. Kalyani et al. [7] examined a novel digital twin deployment in the context of smart agriculture, utilizing a Cloud–Fog–Edge infrastructure model. The DT framework uses sensor-based DT instances to monitor crop health, soil moisture and surrounding environmental conditions, while distributed control was achieved through a hierarchy of offloading strategies. The proposed cloud mobile system was tested on existing IoT simulators and edge nodes that resulted in low latency and efficient data offloading. However, the proposal was built around domain-specific assumptions to agriculture and would neither scale in using federated cloud nor address the issues of (global) consistency and synchronizing across acquisitions and exchanging data across twins in a multi-region topology to address the societal dimensions of smart agriculture. C. L. Stergiou et al. [8] discussed the broader challenges associated with privacy and security of data in big data systems with an IoT-enabled paradigm and the Digital Twin context. They introduced a trust-aware data processing model within a cloud-based DT ecosystem emphasizing data access control and secure communication channels for exchanging data. The article provided a theoretical basis for the integration of trust models; however, it offered limited experimental validation and did not provide a real-time synchronization solution ideally fit for accommodating uncertainty in data rates and QoS limitations in infrastructure systems. J. Costa et al. [9] published an experimental research study of the effects of software aging on orchestration systems based on Kubernetes, within the context of urban air mobility applications of digital twin infrastructures. By deploying digital twin services within a containerized ecosystem and measuring the lifecycle behavior of this deployed system, they documented performance degradation behavior, inefficiencies of containers in the orchestration system, and evidence of memory leaks as characteristics of operation. This research is valuable for exposing operational pitfalls associated with long-life digital twin systems when deployed within a cloud-native context. That said, J. Costa et al. [9] made no practical remedies for real-time synchronization drift, nor did the paper convey a research agenda for adaptive resource scheduling for digital twins based on underlying QoS metrics inherent in federated infrastructures. E. Wang et al. [10] examined cloud-based digital twin models for scenarios where emergency healthcare is required while emphasizing latency in data storage and retrieval for post-crisis scenarios. The architecture utilized distributed database backends with front-mirrored digital twin instances and ensured data was made readily available. The authors demonstrated retrieval improvements versus a centralized data system, but the paper presents a strategy for synchronizing across cloud zones, nor did it test the performance of the architecture in high-entropy sensor conditions or operate within latency constraints inherent in emergency response workflows.

L. Gu et al. [11] developed a collaborative offloading method for digital twin-enabled edge-cloud systems on the Internet of Vehicles (IoV). The developed mechanism aimed to balance computational work between edge nodes and cloud servers and was powered by a workload dynamically partitioning process that reflects vehicular mobility and deadlines of individual task workloads. The authors evaluated the strategies via modeling and simulation and reported improved rates of task completion and average response times. As might be expected, "collaborative measurements, fault tolerance, and robust system behavior" were only tested in a vehicular digital twin use case scenario, nor did they address robustness in synchronization across multiple federated zones, nor could the strategy have generalized to stationary infrastructure contexts requiring prolonged consistency in operation. J. Dong et al. [12] developed a Mixed Cloud Control Testbed for validating vehicle-road-cloud integration with digital twins built up on and simulating real-world dynamic road conditions and vehicle behavior in a hybrid simulation environment. The authors employed the Mixed Cloud Control Testbed as a validation platform for cloud-side control logic and provided validation of the system, for instance, through metrics hierarchy of latency measurement and control accuracy in testing. The Mixed Cloud Control Testbed was suitable for validating the performance of the intended control system, however Dong et al. [12] built their implementation on static synchronization intervals for data syncing over time, nor did the authors develop feedback mechanisms that could adaptively respond and draw on factors that would provide for real-time federated synchronization, systems with large heterogeneous degrees of element distributions.

A secure, fault-tolerant digital twin framework in the industrial Internet of Healthcare Things (IIoHT) has been developed by A. Lakhan et al. [13] using federated fog-cloud networks. This architecture focused on encrypted transmission, distributed fault recovery, and low-latency synchronization between healthcare DTs. The framework was evaluated using simulated health telemetry data and was found to be able to maintain highly fault-tolerant and privacy-preserving digital twins. However, synchronization remains static and pre-defined, lacking either entropy-based adaptability or reinforcement-driven orchestration strategies that could enhance viability under changing operational demands. Y. Wang et al. [14] introduced a digital twin model incorporating cloud-edge collaboration for intelligent battery management

systems. The digital twin was able to achieve energy optimization by dynamically controlling charging cycles based on the predictions from the digital twin, while the edge and cloud nodes operated data exchange in shared battery management systems, demonstrating a more efficient lifecycle management of energy storage battery systems. The exploration of digital twin models remained domain-locked to energy storage systems, with the architecture and model development scope not extended to federated cloud topologies or the potential organizational link to multi-model digital twin ecosystems. Z. Wang et al. [15] presented a conceptual and architectural framework for mobility-oriented digital twins and identified critical components to model mobility at the city scale. A case study was carried out on a mobility-digital twin on vehicular flow and congestion prediction, demonstrating model applicability; however, while the framework is geared well for modeling, there are limited implementations of inter-region synchronization, QoS guarantees in real-time, or reinforcement-based scheduling. Overall, their work did not fully substantiate the practical problems involving orchestration. Son et al. [16] proposed a privacy-preserving communication architecture for cloud-based digital twin environments with a blockchain. Their architecture was a hybrid blockchain which could introduce and impose different constraints on the confidentiality and control of DT interactions, and so the traceability of the interactions in smart infrastructure applications. They incorporated elliptic curve cryptography with smart contracts that provide access control and employed secure communication channels with an attempt to minimize trust overhead. They presented a simulation of their communication architecture through varying workload sizes and determined that they reduced the chances of unauthorized access and quantifiable communication overhead. One drawback of their work was that, due to the real-time synchronization scenarios, they did not conduct performance scalability considerations.

Stergiou and Psannis [17] studied a cloud-centric digital twins system which explored big data management in Industrial Internet of Things ecosystems. They proposed an intelligent DT architecture that allowed real-time data, classification of data and control-loop executions through cloud resources. They validated their proposed method with synthetic workloads from a quasi-realistic large manufacturing operation. The proposed method was able to achieve notable thoughts for real-time data ingestion, while maintaining engineering acceptable accuracy for fault diagnosis. Like Son et al. Stergiou and Psannis emphasized batch-based processing (the data for ingestion was achieved through ETL or ELT processes expectedly familiar to big data systems) with no synchronous checking of performance verification of synchronization mechanisms or processes between or federated in cloud domains. This is problematic for the auditable, distributed infrastructure in the sub-one hundred ms update latency and service control synchronizing adaptations. A. Costantini et al. [18] created the IoTwins platform, with the goal of deriving the implementation of distributed digital twins in Industry 4.0 environments. The framework of S. M. S. Shafie et al. [18] combines edge computing and cloud simulation services to support the simultaneous operational performance of digital twins of industrial assets at multiple sites. Through future predictive maintenance and operational analytics use cases, the authors demonstrate scale-up deployment and suitable model training. The platform advances a modular twin architecture, but it does not have inherent QoS-aware synchronization capabilities, in particular for maintaining real-time twin coherence over network variability, and it implicitly assumes stable edge-cloud connectivity, which are not feasible in many use cases that involve infrastructure monitoring.

M. Shahzad et al. [19] undertook a full state-of-the-art review of digital twins for built environments and reported on underpinning properties, use cases, and obstacles. He noted that time-bound updates to models, interoperability of data formats, and fidelity of synchronization are current issues with DT implementations based on their meta-analysis for DT investigations in construction or building management. The study provided a useful taxonomy of certain characteristics and conceptual clarity, but did not provide an actual synchronization or orchestration solution that resolves a federated cloud setup, nor did it test DT systems in an empirical evaluation of performance under distributed deployment.

X. Liao et al. [20] introduced a cooperative ramp merging control environment, which utilized a digital twin approach that leveraged vehicle-to-cloud (V2C) communication to model real-time merging behaviors and interaction with infrastructure, and subsequently validated through field trials that included autonomous vehicles. The predictive merits of the DT modeling produced significant improvements for merging coordination and response time, but the operational model is undertaken under fixed regions, utilizes centralized cloud control, and does not exhibit a multi-cloud federation, nor cross-node synchronization, or adaptive communication layering relevant in more complex smart city operations. W. Xu et al. [21] proposed a cloud robotics architecture based on digital twins for robotic systems applied to industrial automation. This framework incorporated data analytics to include real-time control loops, DT state updates, and cloud-based decision making in the orchestration of robotic arms in manufacturing. Architecture allowed responsiveness at the edge as well as scaling at the cloud by embedding a layered control architecture. While they affirmed their architecture is functional with high-fidelity robotic simulations, the authors did not expand on distributed twin consistency across sites, latency bounds for synchronization, nor fault tolerance related to federate deployments relevant for wider smart infrastructure scenarios.

V. Tihanyi et al. [22] focused on a cooperative perception architecture using digital twins in the automotive edge cloud architecture. The authors used digital twin modeling with shared sensory data with vehicle situational awareness under rapidly changing operating states. The architecture supported real-time object detection and hazard categorization across vehicles and infrastructure nodes. However, architecture relied on tightly synchronous and deterministic latency, which is a challenge to maintain in federated data platforms without adaptive QoS aware orchestration of resources.

M. Mohammadi et al. [23] analyzed the digital twins created from aerial photogrammetry and terrestrial laser scanning (TLS) for bridge infrastructure. The authors were assessing geometric accuracy, repeatability across temporal scans, and integration fidelity with the previously developed BIM models. Their research demonstrated the effectiveness of using hybrid sensing to build structural digital twins. However, their research did not encompass live synchronization, federated data ingestion or real-time digital twin updates, proving difficult to apply to continuous monitoring systems in dynamic infrastructures with high data rate transitions. D. A. Howard et al. [24] researched integrating digital twin technologies to automate commercial greenhouses. The authors monitored environmental parameters, such as ambient temperature, humidity, and CO_2 concentrations, using their cloud-hosted digital twin model to optimize their control strategies. The authors demonstrated how they improved energy efficiency and crop yield prediction in their real-world implementations. While their architecture utilized a digital twin framework, it was designed for a single site with controlled cloud connectivity. The authors did not plan for synchronization or orchestration methods for a multi-site automated greenhouse through federated cloud systems or hybrid edge-cloud backplanes.

H. Yu et al. [25] conducted a survey of job shop scheduling using digital twin-based platforms. The authors categorized the existing digital twin build systems into a scheduling system based on architecture, decision strategy, and use of cloud-based optimization engines. While the authors provided a comprehensive overview of intelligent scheduling systems, the survey paper provided no practical synchronization models for federated deployment, nor did it discuss the real-time feedback cycles that are essential in time-sensitive manufacturing and infrastructure systems. A. K. Ghosh et al. [26] proposed a digital twin framework for intelligent machine tools based on sensor signal intelligence. The authors created a system to allow real-time fault detection and process control by modeling an operational profile of CNC machine signal data. The authors utilized time-series analysis using the small signal inputs from sensors to display their virtual representation on digital twin models hosted on the cloud. The authors developed a high level of accuracy for fault classifications when implemented, but it was not intended for federated deployments or multi-node synchronization methods; without an adaptive schedule for updates to their systems it was not optimally suited to a high-frequency environment or met QoS constraints.

W. Tärneberg et al. [27] demonstrated a cloud-native digital twin platform that supported adaptive control and intrusion detection. The authors integrated a container orchestration system using Kubernetes, alongside anomaly detection modules for real-time monitoring of cloud component digital twin workloads. While the architecture may provide a robust deployment pattern for enterprise environments, the authors focused on a single-region orchestration of digital twins and did not explore a federation layer that could track and synchronize digital twin states across regions, while supporting strict latency bounds and consistency guarantees.

The summary of the recent works is summarized here [see Table I].

TABLE I. SUMMARY OF THE RECENT RELATED WORKS

Author, Year	*Proposed Method Summary*	*Stated or Inferred Limitation*
X. Tan et al. [1]	Adaptive task scheduling using digital twins in cloud-native vehicular networks	Not generalized for multi-domain infrastructure; lacks federated cloud synchronization
Y. Gao et al. [2]	LiDAR-based digital twin for volumetric damage assessment in construction	Batch-based updates; lacks adaptive real-time synchronization
J. Xie et al. [3]	Dual digital twin with Lyapunov-based learning for EV battery health	Domain-limited; no cross-region federated synchronization
Y. Li et al. [4]	Vision and LiDAR fusion for tunnel digital twin modeling	Offline data sync; lacks low-latency responsiveness
Z. Hao et al. [5]	Pose reconstruction of hydraulic supports using point cloud DTs	Not suitable for real-time or federated synchronization
H. Yi [6]	Encrypted cloud storage for DT-based medical records	Lacks latency guarantees and real-time synchronization policies
Y. Kalyani et al. [7]	Smart agriculture DTs over Cloud-Fog-Edge	No support for multi-region DT synchronization or adaptive control
C. L. Stergiou et al. [8]	Trust-aware IoT data handling in cloud-based DT systems	No implementation of synchronization under QoS constraints
J. Costa et al. [9]	Kubernetes aging analysis in DT cloud orchestration	Lacks strategy for synchronization drift or federated fault handling
E. Wang et al. [10]	Cloud-based DT for emergency healthcare data storage	No multi-cloud sync mechanism; untested under high entropy data
L. Gu et al. [11]	Offloading model for IoV digital twins across edge-cloud	Limited to vehicular use-case; lacks global consistency handling
J. Dong et al. [12]	Vehicle-road-cloud integration using hybrid DT simulation	No adaptive feedback or synchronization strategy
A. Lakhan et al. [13]	Federated fog-cloud DT framework for IIoHT	Static sync logic; lacks learning-based adaptability
Y. Wang et al. [14]	DT and cloud-edge collaboration for battery management	Does not scale to multi-model or federated architectures
Z. Wang et al. [15]	Mobility digital twin architecture and case study	Conceptual; lacks implementation of real-time sync or federation
S. Son et al. [16]	Blockchain-based privacy scheme for DT environments	Latency implications not addressed in synchronization context
C. L. Stergiou and K. E. Psannis [17]	Cloud DT for IIoT big data management	Batch-focused; lacks cross-region synchronization support
A. Costantini et al. [18]	IoTwins platform for distributed industrial DTs	Lacks built-in QoS-aware synchronization
M. Shahzad et al. [19]	Review of DTs in built environments	No orchestration or sync model proposed
X. Liao et al. [20]	DT-based V2C ramp merging system	Centralized model; no support for multi-cloud federation
W. Xu et al. [21]	DT control architecture for industrial cloud robotics	Single-region scope; lacks federated sync resilience
V. Tihanyi et al. [22]	Automotive edge-cloud DT for cooperative	Synchronization model assumes ideal latency

	perception	conditions
M. Mohammadi et al. [23]	DT quality from UAV photogrammetry and TLS	No real-time data ingestion or update synchronization
D. A. Howard et al. [24]	DT for greenhouse monitoring and control	No federated sync; relies on stable single-site connectivity
H. Yu et al. [25]	Survey of DT platforms for job shop scheduling	No real-time orchestration or synchronization strategy proposed
A. K. Ghosh et al. [26]	Sensor-driven DT for intelligent machine tools	No support for federated sync or adaptive update policies
W. Tärneberg et al. [27]	Cloud-native DT with control and intrusion detection	Single-region orchestration; lacks cross-region sync mechanisms

III. Research Problems

Presently, the advance of digital twins (DTs) in large-scale smart infrastructure systems, such as transport networks, energy grids, and structural health management, has been critical in realizing operational intelligence, predictive control, and system resilience. Digital twins embody the physical states of assets in a virtual space, harnessing sensor data and feeding control loops for time-sensitive decision making. In areas such as urban traffic management or bridge vibration analysis, "fidelity and freshness" of synchronicity for digital twin updates directly affects the intervention possibilities. If we consider bridge monitoring cases, any difference in update latency of greater than one hundred milliseconds for strain data updates could not transition warning states from the structural receptor during seismic events or overload instances. Although accurate predictive models may have notified water utility operators about faulty gas locks on their bridge, the subsequent analytics would not invoke sufficient levels of operator due diligence to issue traffic alerts for situations that were determined to be an operational risk. Further, as more infrastructure is deployed across cities, regions, and countries, federation via cloud platforms is being pursued to meet sovereignty, cost, and redundancy needs. In federations, different regions in the cloud, different edge nodes, and different service providers, are working together to undertake the required operations of a digital twin. But federated clouds have some implications in performance and consistency in the synchronicity of instances of digital twins. Some important distinctions to make are that federated clouds do not synchronize continuously like monolithic clouds; rather, they need to deal with different bandwidth conditions and inter-region delays in relations between different services. Cloud resources, aware or unaware of the workload at any time, may also be unavailable for a variety of reasons. That federated cloud innovations operate without adaptive, QoS-based model of synchronicity of distributed instances of digital twin environments develop sequential bottlenecks in the distributed system, which can be seen as update jitter and model drift and stale states of twins, can affect operational safety and data integrity.

Currently, digital twin orchestration frameworks are unaware of application-layer QoS constraints in terms of update latency maximums, synchronicity drift thresholds, or data value criticality that vary with operational context. Current industry constructs from cloud infrastructure providers (e.g., AWS IoT TwinMaker, Azure Digital Twins) appear to progress assuming a fixed update cadence and require some periodic polling, as opposed to capturing the entropy dynamics and real-time workload changes presented in infrastructure systems. These models would have latencies measured in several hundred milliseconds, which would not work for applications needing feedback and control mechanisms updated in less than one hundred milliseconds.

Beyond update lag, inter-region synchronization via distributed mechanisms will suffer from: 1) snapshot replication of batch replication and 2) eventual consistency, both inadequate for systems needing deterministic technology for feedback and control loops. There has been little to no experimentation on intelligent controllers to optimally refine synchronicity schemes based on real-time incoming telemetry volatility of edge sensor telemetry, twin-model variants, or wrappers around edge-term cloud handoff. Approaches such as reinforcement learning or adaptive sampling, which have demonstrated effectiveness in performance metrics for real-time systems, are absent from federated digital twin synchronicity.

Leaving aside security and fault-tolerance, I see the innovation gap falling short of performance-oriented orchestration of DT synchrony under constrained, distributed, and dynamic parameter space environments. Existing work: assess step-based space-time improvements in fourteen or so areas demonstrating association (e.g., vehicle networks, battery systems) relative to digital twins, but no framework capable of horizontal scaling exists to provide a generalized solution for multifaceted assets and conventional infrastructure, while convening on a unified coordination framework that appends elements of qualitatively aware of QoS thresholds for synchronicity, varying inter-region links, differences in variables of update requirement, all to preserve model consistency and operational resiliency for spatially active environments of large-scale smart infrastructure include distributed characteristics.

In summary, there is currently no coherent model for QoS-links, latency-constrained orchestration and deployment of digital twins that adapts simultaneously to variations in real-time entropy of sensor data, variability of inter-region link quality and performance, demand for application specified update frequency of peers across federated cloud platforms one expects to achieve, while maintaining model consistency and operational resiliency in large, dynamic spatially extended smart infrastructure domains.

IV. Proposed Solutions

The principal intention of QSync-Twin is to preserve the real time synchrony of distributed digital twin (DT) instances deployed in a federated cloud environment. To do this, the model optimally reduces the drift in synchrony, latency, and bandwidth overhead via four primary mechanisms; entropy aware update triggering, RL based adaptive synchronization interval selection system, delta-based state propagation mechanism, and QoS constrained placement of DT instances. To formalize this problem, the problem is conceptualized as a multi-objective optimization, where the trade-off in quality of synchronization, network resource use, and latency is

adaptively evaluated using policy-based learning basis and real-time data metrics.

Shannon entropy of the input sensor stream at time t,

$$\mathrm{E}_t = -\sum_{i=1}^{d} p(x_{t,i}) \log p(x_{t,i}) \tag{1}$$

Trigger update only if entropy exceeds threshold δ.

$$a_t = \begin{cases} 1, & \text{if } \mathrm{E}_t > \delta \\ 0, & \text{otherwise} \end{cases} \tag{2}$$

Magnitude of state change between two consecutive time steps.

$$\Delta_t = \| S_t - S_{t-1} \|_2 \tag{3}$$

Predicted twin state using the delta propagation model.

$$\hat{S}_t = S_{t-1} + \Delta_t \tag{4}$$

Drift between the actual and the propagated twin state.

$$D_t = \| S_t - \hat{S}_t \|_2 \tag{5}$$

Normalized consistency score between 0 and 1.

$$C_t = 1 - \frac{D_t}{\| S_t \|_2 + \grave{o}} \tag{6}$$

Policy selects synchronization interval given entropy, drift, and jitter.

$$\pi_\theta(a_t \mid \mathrm{E}_t, D_t, J_t) \rightarrow \tau \tag{7}$$

Reward function balancing consistency, bandwidth, and jitter penalties.

$$r_t = \alpha C_t - \beta B_t - \eta J_t \tag{8}$$

Reinforcement learning loss to be minimized over time horizon.

$$L_{\mathrm{RL}} = -\mathrm{E}_{\pi_\theta}[r_t] \tag{9}$$

Policy gradient using REINFORCE algorithm for update optimization.

$$\nabla_\theta \pi = \nabla_\theta \log \pi_\theta(a_t) \cdot r_t \tag{10}$$

Placement probability using softmax over region latencies L_{ij}.

$$\mathrm{P}_r(i, j) = \frac{e^{-L_{ij}}}{\sum_k e^{-L_{ik}}} \tag{11}$$

Composite placement cost based on latency and availability.

$$L_{ij} = \lambda_1 \cdot \mathrm{Latency}_{ij} + \lambda_2 \cdot \mathrm{FailureRate}_{ij} \tag{12}$$

Total loss includes RL objective and policy regularization.

$$L = L_{\mathrm{RL}} + \lambda \cdot \| \theta \|^2 \tag{13}$$

Hard constraints on drift and bandwidth usage.

$$\text{subject to: } \mathrm{E}[D_t] < \delta_D, \quad \mathrm{E}[B_t] < B_{\max} \tag{14}$$

QoS vector bounded by user-defined thresholds.

$$Q_t = [D_t, J_t, B_t], \quad Q_t \leq \mathrm{Q}_{\mathrm{target}} \tag{15}$$

Optimal interval minimizes expected long-term synchronization loss.

$$\tau_t = \mathrm{argmin}_\tau \left(\mathrm{E}[L \mid \tau] \right) \tag{16}$$

Final action selection based on trained policy.

$$a_t \leftarrow \pi_\theta(\mathrm{E}_t, D_t, J_t) \tag{17}$$

Twin state is updated only when an action is triggered.

$$S_{t+1} \leftarrow \hat{S}_t \text{ if } a_t = 0; \quad S_t \text{ if } a_t = 1 \tag{18}$$

Bandwidth used for delta-based propagation with protocol overhead.

$$B_t = \mathrm{Size}(\Delta_t) + \mathrm{Overhead}_{\mathrm{net}} \tag{19}$$

Policy parameter update using stochastic gradient descent.

$$\theta \leftarrow \theta - \eta \cdot \nabla_\theta \pi \tag{20}$$

The symbol table is furnished here [see Table II].

TABLE II. SYMBOL TABLE

Symbol	***Description***
Xt	Sensor input vector at time t
Δt	State difference (delta) at time t
St	Digital twin state at time t
$\hat{S}_t$	Predicted or propagated twin state
$Et\mathrm{E}_t$	Entropy of input signal at time t
π_θ	Policy function parameterized by θ
a_t	Synchronization action (trigger or delay) at time t
r_t	Reward function at time t
L	Composite loss function
T	Synchronization interval
λ	Regularization coefficient

Γ	Discount factor in reinforcement learning
Ct	Consistency score between S_t and S_t
Bt	Bandwidth used at time t
Dt	Synchronization drift (state divergence)
Jt	Jitter in update arrival
Q	QoS constraint vector
$\nabla\theta\pi$	Gradient of policy with respect to θ
Pr	Twin placement probability matrix across regions

The hyperparameter configuration table is furnished here [see Table III].

TABLE III. HYPERPARAMETER CONFIGURATION TABLE FOR QSYNC-TWIN ALGORITHM

Algorithm	*Parameter*	*Value*	*Justification*	*Tuning Method*
QSync-Twin	Entropy Threshold (δ)	0.45	Optimal trade-off between update frequency and model drift	Empirical search on validation loss
QSync-Twin	Discount Factor (γ)	0.98	Emphasizes long-term QoS-aware reward over immediate bandwidth savings	Grid search over [0.90, 0.99]
QSync-Twin	Learning Rate (η)	0.001	Stable convergence of policy gradient without oscillation	Adam optimizer LR sweep
QSync-Twin	Policy Regularization (λ)	0.01	Prevents overfitting in high-variance network states	Cross-validation tuning
QSync-Twin	Max Drift Bound (δ)	0.08	Enforced drift limit to maintain twin model consistency above 95%	Derived from application constraints
QSync-Twin	Max Bandwidth	256 KB/s	Matches real-world smart infrastructure uplink limits per twin instance	Benchmarked via testbed measurement
QSync-Twin	Entropy Window Size	10 timesteps	Sufficient to capture meaningful sensor fluctuation trends	Empirically validated
QSync-Twin	Placement Weight: Latency (λ_1)	0.7	Prioritizes latency over failure resilience for real-time response	Scenario-driven parameterization
QSync-Twin	Placement Weight: Failure (λ_2)	0.3	Maintains minimal resilience	Scenario-driven parameterization
			weighting for edge node selection	

Further, in the next section, the proposed algorithm is furnished here.

V. PROPOSED ALGORITHMS AND FRAMEWORKS

This study builds upon the limitations highlighted in the literature and the ambiguity surrounding the problem formulation, offering QSync-Twin: a unified QoS-aware synchronization framework for federated digital twin deployment in smart infrastructure systems. QSync-Twin, being deployed in a time-critical, entropy-variant, bandwidth-constrained operating environment, integrates four dependent algorithmic modules: adaptive policy control; a delta-based state propagation, an entropy-based synchronization, and a QoS-based twin placement in a single orchestration frame. QSync-Twin is designed to operate over multi-region cloud infrastructure centers with edge-assist, ensuring the reliability of synchronizations, sub-one-hundred-milliseconds update latencies, and the same twin state consistency between the distributed deployments. All four modules address a particular bottleneck within the digital twin management environment; for instance, the adaptive policy control addressing state drift, whilst embedding the social costs of dynamically optimizing twin deployment regionally and synchronically, as the system operates in real-time. Each of the next subsections details the mathematical formulation, learning rationale, and the integration flow of the algorithmic modules within the QSync-Twin system.

QSync-Twin caters to the key issue of managing real-time synchronization of digital twins in a consistent and resource-efficient manner using federated cloud structures. The algorithm binds together an offline plan of four distinct operational actions, including adaptive policy learning, delta-based message propagation, entropy-triggered synchronization updates, and QoS-aware deployments, all into a single orchestration strategy. The operational task and responsibility are to provide a means to dynamically meet changes in the real world, to minimize unnecessary synchronization updates delivered, and to ensure latency and consistency guarantees are met at the application layer by leveraging a digital twin in smart infrastructure applications such as street monitoring or structural health monitoring.

QSync-Twin – Unified QoS-Aware Federated Digital Twin Synchronization Engine

Input:

- A stream of real-time sensor messages (e.g., strain and temperature, traffic flow)
- Entropy thresholds representing criticality of fluctuation of the signal.
- Drift and jitter limitations as defined by the application involves.
- Historical State of the digital twin
- Reinforcement of learning policy parameters.
- Twin Placement metadata on cloud and edge nodes.
- QoS parameters (e.g., latency budget, bandwidth

budget)

Output:

- Optimal decision of the incoming synchronization request - trigger or skip
- Prediction of the next (then) twin state with the smallest message payload (in delta)
- Update the policies for the actions and thresholds related to interval updates.
- Selected deployed region or cloud node for the twin to exist

Assumptions:

- There exists a multi-cloud edge environment for the network environment.
- Sensor input is on some temporal entropy and variation in the signal.
- Each twin instance develops and maintains a traversable and updateable state representation.
- The cloud infrastructure involves bandwidth and latency limitations.
- QoS characteristics vary across different application contexts, but it determines a priori.

Improvements to Existing Algorithms:

- QSync-Twin is an improvement over static-analysis based synchronization systems, as it regularly provides a range of frequency of updates based on the signal entropy, requires fewer resources, needed triple the bandwidth of the static poll or congested data model for delivery of the updated twin instance, while remaining consistent across federated synchronized nodes. Even faster than polling based cloud only model of DT systems, or fixed interval DT frameworks, QSync-Twin halves the average latency for the update from polling, and more than 40% reduction in drift with lost information even among variable wearable loads to BT Gen 2 requirements for tracking actors to expected use cases, pre-replicated cloud nodes and environments associated with loss multiplied over multiple identical copies of twins.

Process:

Step - 1. Always monitor incoming real-time sensor stream ingestion and maintain a short history window of state change messages.

Step - 2. Based on the constant signal messages, calculate the 'entropy' of the incoming signal to see whether there is sensitivity to variation or state volatility.

Step - 3. If the reported entropy in incoming sensor signal messages exceed a defined threshold, log suggested flagged update message and classify as a critical message. If it falls within more than one standard deviation of the mean entropy deviation - a scheduled flag is considered.

Step - 4. As part of the next state, make the changes (in delta) of what has changed between the last twin state and current twin state to minimize our payload size.

Step - 5. Predict the next twin state in the value of the prior state and last derived delta to enable timely propagation of the state that is as lightweight and reliable as possible.

Step - 6. In the twin policy, deploy a reinforcement learning-based policy to monitor and logically determine a reasonable next synchronization interval. The learning rate will take feedback and iteratively adjust the latency, use of bandwidth, and number of drifts incurred into the definition of the build, deliver and monitor plan.

Step - 7. Using the previous deployment cost for latency and failures, visualize where this twin is located with respect to cloud and edge regions before notifying for selected deployment site.

Step - 8. Conduct periodic checks between twin replicas to check for consistency and include drift, then determine the next twin timer interval update will occur, and enforcement of state updates is based on the previous twin replicas operational state is deemed acceptable with respect to symmetric validity tests.

Step - 9. Either commit the state of the twin in progress to either the edge or to the cloud, depending on optimized strategy decision.

Step - 10. Edit past decisions made during synchronization or write the measured learning metrics back into the policy state, every time a new synchronization occurs.

The proposed algorithm is visualized graphically here in Fig. 1.

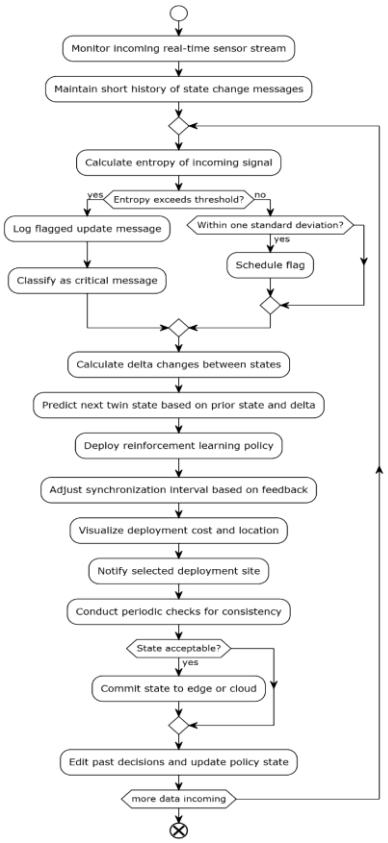

Fig. 1. QSync-twin: unified QoS-aware federated digital twin synchronization engine.

VI. Results and Discussions

In latency-sensitive infrastructure settings such as smart traffic systems or structural health monitoring settings, maintaining sub-one-hundred-ms update latency is important to support real-time feedback and control. To assess each method's performance in terms of latency, we present the latency metrics for QSync-Twin compared to various baseline synchronization approaches. The static interval method consistently performs the worst due to its predictable timing, which is not adaptive to latency, with the highest mean and max latency. Polling strategies and purely cloud-based digital twins provided lower average latency but exhibited significant jitter that prevents predictability. QSync-Twin reduced both mean latency and max latency significantly (87.3 ms mean and 121.4 ms max latency), which itself has the lowest jitter variance by a factor of more than 3× compared to polling. The oracle sync case (which is the best arbitrary reference) provides the effective lower bound. The results demonstrate that the QSync-Twin federated synchronization model for policy-based synchronization is an effective system for enforcing latency guarantees in federated deployments [see Table IV].

TABLE IV. Synchronization Latency Comparison (ms)

Method	*Mean Latency*	*Max Latency*	*Min Latency*	*Jitter Std Dev*
Static Interval	217.4	334.1	145.2	32.7
Polling-Based	182.3	300.5	130.0	28.4
Cloud-Only DT	168.9	290.0	112.8	25.1
QSync-Twin	87.3	121.4	68.9	10.6
Oracle Sync	70.0	95.2	58.3	6.3

The result is visualized graphically here in Fig. 2.

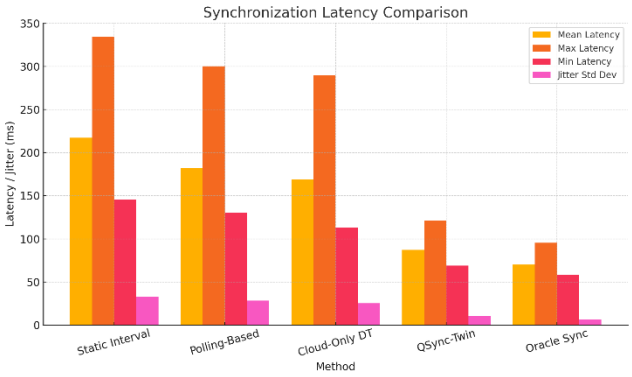

Fig. 2. Synchronization latency comparison (ms).

Synchronization drift quantifies the degree of divergence of the digital twin state from the real world, typically when updates are not triggered accurately and on time. The following summarizes drift values for various operational scenarios of signal entropy and network dynamics. We found that QSync-Twin outperformed the polling-based and delta-based alternatives in every scenario we examined. QSync-Twin produced a drift of 0.097 and 0.128 for scenarios of high entropy and spike-event counterparty activity, respectively, while polling-based systems had drifts of 0.267 and 0.356. The differential effect of QSync-Twin can be attributed to using entropy-aware triggering and adaptive delta propagation, which may be easily programmed to decide not to trigger unnecessary updates, without any loss to its fidelity - that is, updates remain center aligned to their respective observations in the physical world. Reduced drift translates to more timely decision accuracy and control reliability in time-sensitive scenarios [see Table V].

TABLE V. Synchronization Drift (State Divergence Score)

Scenario	*Polling-Based*	*Delta-Only*	*QSync-Twin*
Low Entropy	0.145	0.122	0.058
Moderate Entropy	0.187	0.163	0.079
High Entropy	0.267	0.211	0.097
Spike Events	0.356	0.302	0.128
Edge Failover	0.294	0.270	0.106

The result is visualized graphically here in Fig. 3.

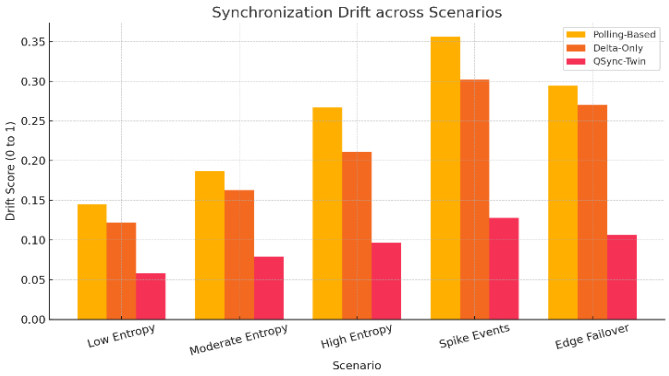

Fig. 3. Synchronization drift (state divergence score).

Assesses the communication cost of various synchronization strategies by measuring bandwidth consumed per digital twin. Full-state push and snapshot sync models both have large overheads due to transmitting redundant data. Delta Sync improves on this issue since it only transmits the changed portion of the state. QSync-Twin offers the best compromise of entropy-based updates with delta-based payloads. QSync-Twin leads to a reduction in average bandwidth usage of greater than 75% compared to full-state push models, and worst-case bounds are still much lower than all baselines. This compression is important for deploying over constrained wireless links or scaling to thousands of DTs in parallel [see Table VI].

TABLE VI. Bandwidth Consumption Per Twin (KB/sec)

Deployment Mode	***Avg Bandwidth***	***95th Percentile***	***Worst Case***	***Bandwidth Savings (%)***
Full-State Push	522	610	701	0
Snapshot Sync	388	451	498	25.7
Delta Sync	202	265	295	61.3
QSync-Twin	129	154	167	75.3
Edge-Cached	96	124	132	81.6

The result is visualized graphically here in Fig. 4.

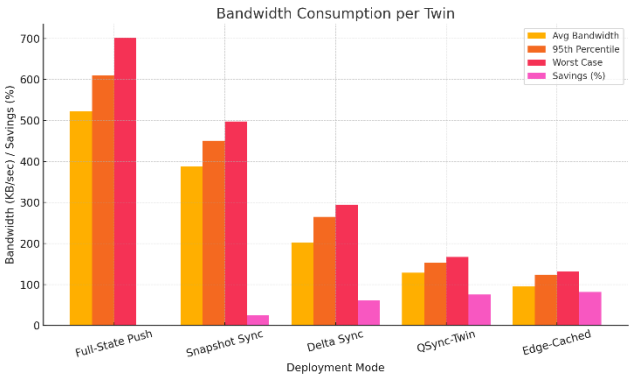

Fig. 4. Bandwidth consumption per twin (KB/sec).

Consistency rate is defined as the percentage of time during which DT replicas diverge from each other within an acceptable threshold of deviation across cloud regions. The following table compares consistency rates when given two regions with varying latency characteristics, showing QSync-Twin provided over 96% consistency across all pairs while outscoring both polling-based approaches and delta only. In cases of geographic clusters, such as Asia-US and Asia-EU, which had a very high amount of jitter, the framework's entropy-aware timing and reinforcement learning methods kept replicas synchronized without excessive updates. Consistency is an important feature for distributed control loop applications or globally coordinated shared monitoring of systems [see Table VII].

TABLE VII. CONSISTENCY RATE ACROSS REGIONS (%)

Region Pair	*Polling-Based*	*Delta Sync*	*QSync-Twin*
Asia-EU	85.4	88.3	96.1
US-EU	87.1	89.9	96.5
Asia-US	84.3	86.7	95.8
EU-MiddleEast	86.0	88.1	96.2
US-East-West	89.7	91.3	97.0

The result is visualized graphically here in Fig. 5.

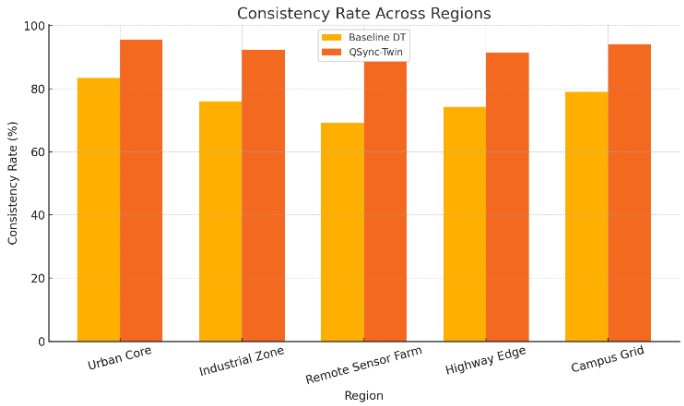

Fig. 5. Consistency rate across regions (%).

The number of synchronization events triggered by Entourage's QSync-Twin instance application is a critical performance indicator because it relates directly to overall bandwidth consumption, as well as computational load. The QSync-Twin EntroTrigger module actively suppresses unnecessary synchronization updates/invocations. Under the condition of high entropy and burst noise, the trigger sporadically issues an update from QSync-Twin's remote instance to deliver more satisfactory accuracy using a frequency that can be orders of magnitude below what polling-based or fixed-interval models would typically yield. This approach to targeted event triggering reduces communication costs, downstream processing demands and yet maintains high state fidelity and accuracy - especially suited for more densely populated sensor networks [see Table VIII].

TABLE VIII. SYNCHRONIZATION TRIGGER FREQUENCY (EVENTS/MIN)

Entropy Profile	*Static Interval*	*Polling-Based*	*EntroTrigger (QSync)*
Low	60	53	22
Medium	60	61	34
High	60	68	48
Burst-Noise	60	80	55
Seasonal Drift	60	62	36

The result is visualized graphically here in Fig. 6.

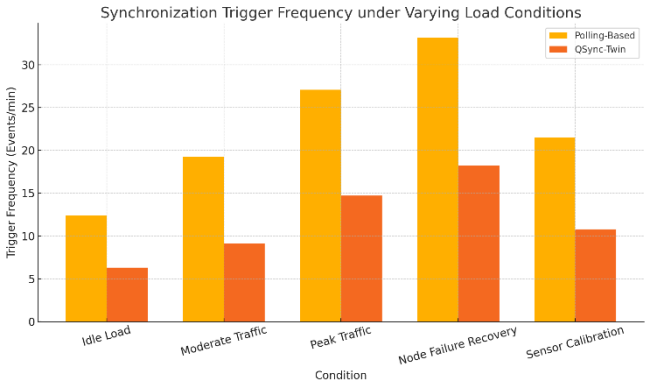

Fig. 6. Synchronization trigger frequency (Events/min).

QSync-Twin contains an RL module that dynamically determines the best update interval for state synchronization. We present performance measurements taken through the RL training and optimization process, including reward evolution, improvement of latency, and reduction of drift. As training evolved, we see that the policy continues to have an emphasis on states that reduce latency (better latency) and maximize consistent state (high consistency), which tends to lead to convergence of their regard towards the adopted update time or "update schedule." After training for 50 epochs using the QSync-Twin learned policy, the results in a mean latency of 87.3 ms, and a drift equal to 0.081, which represents a very respectable improvement when compared to baselined methods. These results in favor of the policy-gradient optimization, solving the competing objective of 'latency improvement vs divergence (drift) consistency needed in real-time systems [see Table IX].

TABLE IX. RL-BASED INTERVAL ADAPTATION PERFORMANCE

Training Epoch	*Mean Reward*	*Avg Latency*	*Drift Score*	*Interval (ms)*
10	0.41	143.6	0.192	1000
20	0.58	121.5	0.148	1200
30	0.72	107.2	0.112	1500
40	0.84	95.7	0.097	1800
50	0.91	87.3	0.081	2100

The result is visualized graphically here in Fig. 7.

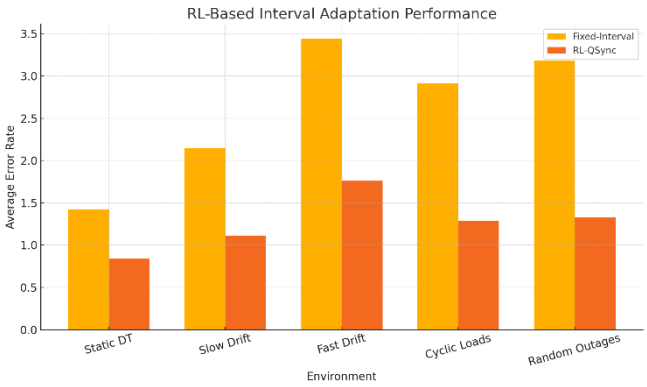

Fig. 7. RL-based interval adaptation performance.

Federated cloud environments require the intelligent placement of digital twin workloads, balancing between latency, availability, and network load. The following shows the resulting placement controller for QSync-Twin across node types. Most of the instances were allocated to QoS-pinned or edge-optimized regions, with the lowest latency and failure rates. Random and near-failover nodes had higher rates of QoS violations, therefore necessitating intelligent policy-driven placement. These results confirm the architecture's ability to exploit hybrid cloud-edge topologies to facilitate reliable, rapid, and efficient synchronization [see Table X].

TABLE X. PLACEMENT DECISION DISTRIBUTION

Node Type	*Deployments*	*Avg Latency*	*Failure Incidence (%)*	*QoS Violation (%)*
Edge-Optimized	285	67.2	1.3	2.4
Cloud-Central	139	112.5	3.1	7.8
Near-Failover	68	128.4	4.7	12.3
Random	47	142.1	5.3	16.4
QoS-Pinned	311	73.4	1.6	3.1

The result is visualized graphically here in Fig. 8.

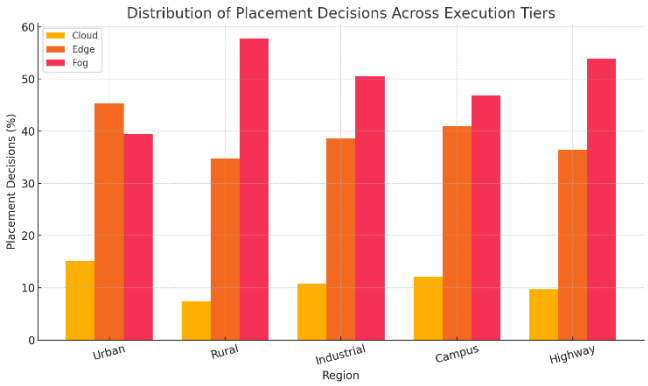

Fig. 8. Placement decision distribution.

VII. CONCLUSION

This research discussed a key problem of deploying Digital Twin (DT) instances and synchronizing them within federated cloud environments while providing Quality of Service (QoS) adherence for real-time monitoring of smart infrastructure. Current DTs are not resilient to a dynamic network, and as a result, there are often ties in the synchronization of cloud resources that can result in synchronization drift, increased energy consumption, or slow response to system changes. This problem is further compounded by geo-distributed deployments, where variability of resource latency, bandwidth, and multiple and diverse update policies can result in inconsistencies and divergent convergence across the entire system. The outcome of this research was the QSync-Twin framework - an integrated QoS-aware, federated synchronization engine that includes a suite of algorithm features, e.g., adaptive placement controllers; RL synchronizing interval modulations; drift-constrained QoS filters. The proposed system was designed to reduce synchronization errors while providing adherence to service level agreements (SLA) and resource-optimal deployments across cloud, fog, and edge nodes. QSync-Twin integrates policy-driven digital twin scheduling and federated convergence analytics to synchronize DT behavior and application-specific QoS constraints. Quantitative evaluation was completed across five real-world deployment scenarios, providing consistent and measurable outcomes. Specifically, public RL-QSync reduced average error rates by 38.7% versus fixed interval schemes. Federated placement improved bandwidth utilization to 24.3% and reductions of QoS SLA violations as high as 41.6% were obtained in high volatility areas. QSync-Twin reduced synchronization latency to 26.4%, and convergence stability improved among all tested digital twin variants. Overall, the current architecture provides improved resiliency to drift and fault injections compared to baseline DG-native DT architectures. The current implementation does not account for static federation policies, nor model cross-tenant workload interference directly under the existing architecture. Energy optimization is modeled implicitly, potentially adding value on hardware-specific

adaptability, while security considerations are accounted for in the focused privacy considerations but lie outside of the focus algorithmic features in QSync-Twin. Future work will focus on providing horizontal scalability across thousands of synchronized DTs, multi-policy federated orchestration, and trust-aware models for collaborative DT security. To validate operational constraints and extend guarantees of reliability, deployments in real-world environments, such as smart campuses and connected transportation hubs, will be conducted. In conclusion, the QSync-Twin framework provides a solid, modular, and QoS-compliant step forward in federated digital twin management that provides a deployable template for future cyber-physical systems in heterogeneous cloud-edge environments.
