Table of Contents

Paper 1: A Multi-Model Adaptive Q-Learning Framework for Robust Portfolio Management in Stochastic Markets

Authors: Sharmin Sultana, Md Borhan Uddin, Masuma Akter Semi, Shahanaj Akther, Urmi Chakraborty, Khandakar Rabbi Ahmed

PAGES 1 – 7

Paper 2: AI-Driven Anomaly Prediction in Encrypted Network Traffic

Authors: Sina Ahmadi

PAGES 8 – 16

Paper 3: An Intelligent Knowledge-Based Chatbot to Mitigate Travel Anxiety

Authors: Jieyu Wang, Hungchih Yu, Dingfang Kang

PAGES 17 – 29

Paper 4: Towards Robust Intrusion Detection: Exploring Feature Selection, Balancing Strategies, and Deep Learning for Minority Class Optimization

Authors: Khalid LABHALLA, Amal BATTOU

PAGES 30 – 41

Paper 5: DriveRight: An Embedded AI-Based Multi-Hazard Detection and Alert System for Safe and Sustainable Driving

Authors: Jamil Abedalrahim Jamil Alsayaydeh, Rex Bacarra, Ahamed Fayeez Bin Tuani Ibrahim, Mazen Farid, Aqeel Al-Hilali, Safarudin Gazali Herawan

PAGES 42 – 54

Paper 6: Towards an AI-Powered Cyber Resilience Model: A Systematic Evaluation of Frameworks Against Emerging Threats

Authors: Chhaya Jahajeeah-Suntoo, Sheeba Armoogum

PAGES 55 – 67

Paper 7: Dual Cognitive Pathway Architecture for Robust and Dialect-Aware English Reading Comprehension

Authors: Jillellamoodi Naga Madhuri, Tonmoyee Doley, Purnachandra Rao Alapati, Vijaya Kumar P, Linginedi Ushasree, Marvin D. Mayormente, Aseel Smerat

PAGES 68 – 79

Paper 8: Proposed Technological Solution to Predict the Need for Health Professionals in Health Centers Using Random Forest

Authors: Fiorella Patricia Mirano Surquislla, Gianfranco Henry Ore Paredes, Aguilar-Alonso Igor

PAGES 80 – 89

Paper 9: A Readability-Driven Prompting Framework for Accurate Grade-Specific EFL Narrative Creation

Authors: Ronald William Marbun, Makoto Shishido

PAGES 90 – 99

Paper 10: HELM-BRCA: Hybrid Embedding and Learning Model for BRCA Methylation Classification

Authors: Hemalatha D, N Gomathi

PAGES 100 – 111

Paper 11: Strengthening Indonesia's Unmanned Aerial Vehicle Manufacturing Industry: A Technology-Focused Strategic Analysis

Authors: Satrio Utomo, Gani Soehadi, Sarjono Sarjono, Yanuar Iman Dwiananto, Adi Akhmadi Pamungkas, Ellia Kristiningrum, Budi Setiadi Sadikin, Hardono Hardono, Rizki Arizal Purnama, Helen Fifianny

PAGES 112 – 121

Paper 12: AI Mathematical: Solving Math Challenges Using Artificial Intelligence Models

Authors: Trinh Quang Minh, Ngo Thi Lan, Bui Xuan Tung, Phan Thanh Tuyen

PAGES 122 – 133

Paper 13: A Comprehensive Forensic Framework for Unmanned Aerial Vehicle Investigations: Empirical Validation with the DJI Mavic 3 Classic

Authors: Nidhiba Parmar, Naveen Kumar Chaudhary

PAGES 134 – 142

Paper 14: Correlation Characteristics-Based Channel Estimation Method for GFDM Systems

Authors: Xiaotian Li, Xiaoqing Yan, Zitian Zhao, Jiameng Pei

PAGES 143 – 152

Paper 15: ForenVoice-Secure: Robust and Privacy-Aware Audio Data Mining for Forensic Speaker Identification

Authors: Mubarak Albathan

PAGES 153 – 168

Paper 16: GAN-Based Generation of Pre Disaster SAR for Earthquake Interferometry

Authors: Kohei Arai, Kengo Ohiwane, Hiroshi Okumura

PAGES 169 – 176

Paper 17: A Competitive Co-Evolutionary Approach for the Nurse Scheduling Problem

Authors: Maizatul Farhana Mohamad Nazri, Zeratul Izzah Mohd Yusoh, Halizah Basiron, Azlina Daud

PAGES 177 – 186

Paper 18: Metaphorical Meaning Integration in Poetry Based on Online Discourse Data: Analysis from a Cognitive Linguistics Perspective

Authors: Ying LIU, Jiting XUE

PAGES 187 – 199

Paper 19: Dynamic Decision Model for Tunnel Cross-Passage Layout Based on Multi-Source Sensor Data Fusion

Authors: Xuejun Di, Musha Ruzi, Angang Liu

PAGES 200 – 211

Paper 20: An AI-Driven VR Learning Framework Using RL-Optimized Transformer Models for Personalized English Proficiency Assessment

Authors: A. Sri Lakshmi, E. S. Sharmila Sigamany, Revati Ramrao Rautrao, K. Ezhilmathi, Bhuvaneswari Pagidipati, Elangovan Muniyandy, Adlin Sheeba

PAGES 212 – 223

Paper 21: Advanced Multimodal AI for Resilient Healthcare: Enhancing Early Risk Assessment in Critical Care

Authors: Shih-Wei Wu, Chengcheng Li, Te-Nien Chien, Yao-Yu Zhang

PAGES 224 – 240

Paper 22: Improved Sparrow Search Algorithm-Based Recurrent Neural Network for Short-Term Generation Load Forecasting of Hydropower Stations

Authors: Liyuan Sun, Yilun Dong, Junwei Yang

PAGES 241 – 249

Paper 23: Integrating Augmented Reality Learning Objects in Intelligent Tutoring Systems: A Conceptual Model for Engaging Learning Experiences

Authors: Hind Tahir, Najoua Hrich, Salma El Boujnani, Mohamed Khaldi

PAGES 250 – 259

Paper 24: Comparative Evaluation of CNN Architectures for Corn Leaf Diseases Classification

Authors: M. Abdallah, M. F. Abu-Elyazeed

PAGES 260 – 266

Paper 25: Attention-Enhanced Hierarchical Transformer for Multimodal Integration of Mammograms and Clinical Data

Authors: N. Kannaiya Raja, V S Krushnasamy, Nurilla Mahamatov, Prasad Devarasetty, S. T. Gopukumar, Sanjiv Rao Godla, Vuda Sreenivasa Rao

PAGES 267 – 278

Paper 26: Health Information Exchange in Malaysia: Leveraging Interoperability on International Standards for Health Data Exchange

Authors: Mohd Noor A. M. N. L, M. Batumalay, Balasubramaniam Muniandy, Lakshmi D, Vinoth Kumar P

PAGES 279 – 287

Paper 27: Privacy-Preserving Adaptive Biometric Framework with Reinforcement Learning and Blockchain-Enabled Multi-Factor Authentication

Authors: P. Selvaperumal, Sakshi Malik, Asfar H Siddiqui, Dekhkonov Burkhon, Elangovan Muniyandy, Garigipati Rama Krishna, P N V Syamala Rao M

PAGES 288 – 303

Paper 28: Intelligent Fruit-Picking Robot Using Convolutional Vision and Kinematic Control for Automated Harvesting

Authors: Nurbibi Sairamkyzy Imanbayeva, Bekzat Ondasynuly Amanov, Aigerim Bakatkaliyevna Altayeva, Dana Kairatovna Ashimova

PAGES 304 – 314

Paper 29: Ghost-Vanilla Feature Maps: A Novel Hybrid Architecture for Efficient Fine-Grained Songket Motif Classification

Authors: Yohannes, Muhammad Ezar Al Rivan, Siska Devella, Tinaliah

PAGES 315 – 325

Paper 30: Forecast of Guangzhou Port Logistics Demand Based on Back Propagation Neural Network

Authors: Xiu Chen, Lianhua Liu, Lifen Zheng

PAGES 326 – 335

Paper 31: Explainable AI Techniques for Interpretable Breast Cancer Classification

Authors: Tony K. Hariadi, Qodri Aziz, Slamet Riyadi, Kamarul Hawari Ghazali, Khairunnisa Binti Hasikin, Tri Andi

PAGES 336 – 342

Paper 32: Multi-Omics Integration Methods for AI-Based Breast Cancer Molecular Subtypes Classification

Authors: Sajid Shah, Azurah A Samah, Siti Zaiton Mohd Hashim, Sarahani Harun, Zuraini Binti Ali Shah, Farkhana Binti Muchtar, Syed Hamid Hussain Madni

PAGES 343 – 353

Paper 33: Environmental Assessment of Chemicals: Artificial Intelligence for Predicting Persistence, Bioaccumulation, and Toxicity Properties

Authors: Ayoub Belaidi, Rachid El Ayachi, Mohamed Biniz, Mohamed Oubezza, Youssef Youssefi

PAGES 354 – 360

Paper 34: A Review on Intrusion Detection Models in Internet of Medical Things (IoMT)

Authors: Aljorey Alqahtani, Monir Abdullah

PAGES 361 – 369

Paper 35: A Blockchain-Based Privacy-Preserving Scheme for Integrity Verification and Fair Payment in Cloud Data Storage

Authors: Li Zhenxiang, Jin Yuanrong, Mohammad Nazir Ahmad

PAGES 370 – 378

Paper 36: EEG-Based Imagined-Speech Decoding: A Review

Authors: Hatem T M Duhair, Masrullizam Bin Mat Ibrahim, Mazen Farid, Jamil Abedalrahim Jamil Alsayaydeh, Safarudin Gazali Herawan

PAGES 379 – 390

Paper 37: Evaluating Field Flexibility Approaches in Relational Databases: A Performance Study of JSON and Column-Oriented Models in Library Systems

Authors: Rizal Fathoni Aji, Nilamsari Putri Utami

PAGES 391 – 396

Paper 38: Developing a Robotic-Integrated Leagility Adaptation Model Through Green Supply Chain Intelligence and Supply Chain Ambidexterity

Authors: Miftakul Huda, Mohammad Hatta Fahamsyah, Agung Nugroho, Arie Indra Gunawan, Pepen Komarudin, Andrean Bagus Saputra

PAGES 397 – 404

Paper 39: A Privacy-Conscious Federated Reinforcement Learning Framework for Affect-Aware English Listening

Authors: N. Sreedevi, V. Saranya, Kama Ramudu, M. Madhusudhan Rao,
Sakshi Malik, Elangovan Muniyandy, Ahmed I. Taloba

PAGES 405 – 415

Paper 40: Advanced Explainable Hybrid Metaheuristic–Deep Learning Framework for Real-Time Financial Fraud Detection with Temporal Convolutional Analysis

Authors: Madhu Kumar Reddy P, M. N. V Kiranbabu

PAGES 416 – 428

Paper 41: A Few-Shot Semantic Meta-Learning Framework with CRF for Skill Entity Recognition in Open Innovation Ecosystems

Authors: Nurchim, Muljono, Edi Noersasongko, Ahmad Zainul Fanani, Deshinta Arrova Dewi

PAGES 429 – 440

Paper 42: Attention-Guided Lightweight MobileNetV2 for Real-Time Driver Drowsiness Classification on Edge-IoT Systems

Authors: Yo Ceng Giap, Muljono, Affandy, Ruri Suko Basuki, Harun Al Azies,
R. Rizal Isnanto, Deshinta Arrova Dewi

PAGES 441 – 450

Paper 43: Quality of Service and Customer Satisfaction: A Case Study of Call Center Services

Authors: Jhoanna Iveth Santiago Rufasto, Sebastián Ramos-Cosi,
Haslyd Claydiana Ramos Jara, Ana Huamani-Huaracca

PAGES 451 – 459

Paper 44: Deep Learning for Endometrium Segmentation in Transvaginal Ultrasound: A Systematic Review Towards Receptivity Assessment

Authors: Asma Amirah Nazarudin, Siti Salasiah Mokri, Noraishikin Zulkarnain, Aqilah Baseri Huddin,
Mohd Faizal Ahmad, Ashrani Aizzuddin Abd Rani, Seri Mastura Mustaza, Huiwen Lim

***Abstract*—This study presents TAQLA, a new Tabular Adaptive Q-Learning Agent for portfolio management in stochastic financial markets. TAQLA rests on a multi-model reinforcement learning (RL) architecture that integrates parameter-adaptive Q-Learning mechanisms into softmax-based exploration to reconcile short-term profit maximization with long-term capital preservation. The method is contrasted with vanilla Q-Learning, SARSA, and a random trading policy using simulated equity market data. Empirical analysis shows that TAQLA performs better on profitability, risk-adjusted performance, and drawdown minimization, with a last portfolio value of $1687.45 (+68.74% of initial capital), a Sharpe ratio of 1.41, and a maximum drawdown of just 12.8%. Q-Learning and SARSA, on the other hand, yield Sharpe ratios below 1.0 and drawdowns exceeding 18%. Parameter sensitivity analysis across β (softmax temperature), α (learning rate), and γ (discount factor) reveals that aggressive exploration (β ≈ 1.0–1.5) and reasonable discounting (γ ≈ 0.4–0.6) generate the most aggressive and robust outcomes. Such outcomes place TAQLA as a robust RL-based adaptive portfolio control method under uncertainty, with improved capital appreciation and robustness to adverse market conditions.**

Keywords*—Reinforcement learning; Q-Learning; tabular reinforcement learning; portfolio management; dynamic asset allocation

I. Introduction

The vigorous growth in financial markets, particularly equities and cryptocurrencies, has introduced unprecedented complexity to portfolio management. Traditional asset allocation techniques-such as mean-variance optimization or fixed-weight models-tend to assume static market conditions and fail to account for nonlinear, dynamic behavior in assets. These deficiencies are even more critical in settings with dynamic asset counts, volatility spikes, and changing correlations. To better address such challenges, scholars and professionals increasingly turn to Deep Reinforcement Learning (DRL), which enables agents to learn an optimal decision policy through interaction with an ever-changing market environment. Recent research showed that portfolio optimization was achievable using DRL-based models. For instance, [6] presented a neural model that dynamically adapts to variable asset markets, particularly in the cryptocurrency space. This highlights the importance of building scalable models that generalize across asset sets, while accounting for constraints such as transaction costs. Similarly, [1], [2] employed actor-critic algorithms such as PPO and A2C to build portfolio strategies capable of achieving maximum long-term returns, with superior performance compared to traditional and rule-based methods.

Moreover, [3] suggested a reward-shaping mechanism based on the Sharpe ratio and cumulative returns to facilitate risk-sensitive learning in highly stochastic environments. Motivated by such advancements, we focus from the start on tabular RL methods. While deep reinforcement learning (DRL) methods such as Proximal Policy Optimization (PPO) and Deep Deterministic Policy Gradient (DDPG) have shown promise, they often require extensive training datasets, high computational resources, and careful hyperparameter tuning. In contrast, tabular RL approaches such as Q-Learning and SARSA remain attractive for smaller datasets or environments with well-defined state-action spaces, offering interpretability and fast convergence. The meta-agent module dynamically evaluates recent performance metrics (e.g., rolling Sharpe ratios and cumulative returns) and selects the most promising agent at each timestep to inform the final portfolio decision.

This approach allows the system to learn in various market regimes-i.e., uptrends, downtrends, and high-volatility sideways movements-and apply the best-performing model to each situation. We deployed a custom OpenAI Gym-compatible trading environment to model realistic market settings and operate a multi-asset portfolio. The environment supports the required features of transaction cost modeling, slippage, and portfolio rebalancing restrictions. Historical daily returns for the SP 500 and NASDAQ were downloaded from Kaggle and preprocessed for ticker alignment, missing value handling, and feature extraction. Technical analysis features such as the Relative Strength Index (RSI), Exponential Moving Average (EMA), Average True Range (ATR), and Simple Moving Average (SMA) acted as state features with log returns and portfolio weight vectors-a setup by the data treatment procedure [4]. Both agents learn through continuous interaction with the environment, using actor-critic architectures and stochastic gradient descent to improve their policies.

The PPO-LSTM agent particularly excels at discovering long-term dependencies and sequential relationships in financial time-series data, whereas DDPG is used for precise control of continuous asset weight distributions. The system's reward function incorporates a combination of appreciation in portfolio value, Sharpe ratio maximization, and a penalty for transaction costs-similar to the reward engineering depicted. The

*Corresponding author.

framework is contrasted with single DRL baselines and traditional benchmarks. Experimental outcomes show that the ensemble meta-agent consistently outperforms its single-PPO, DDPG, and LSTM counterparts in cumulative returns, risk-adjusted performance, and drawdowns.

These results are in line with those that highlight the virtues of agent diversity and model flexibility in financial environments. In short, the present work contributes a robust, flexible, and modular multi-agent DRL portfolio optimization framework. It bridges the theory-to-practice gap in DRL architectures and real-world implementation by integrating transaction-aware decision-making, temporal abstraction, and adaptive agent selection. Future extensions would include studying hierarchical coordination among agents, generalizing across markets, and extending to real-time trading APIs to enrich innovative financial decision-support systems further. Our main contributions are the following:

- We present Trend-Aware Reward Shaping, introducing a multiplicative trend coefficient that amplifies or dampens rewards depending on the market's recent momentum.
- State Augmentation with Market Context: encoding price trends, position inventory, and liquidity into the state space to improve decision relevance.
- Comparative Evaluation: benchmarking TAQLA against vanilla Q-Learning, SARSA, and a buy-and-hold baseline on historical NASDAQ data, using metrics including average reward, Sharpe ratio, and maximum drawdown.
- Ablation Analysis: evaluating the effect of the trend coefficient by comparing TAQLA's performance with and without it.

Our results show that TAQLA achieves higher risk-adjusted returns, greater stability, and faster convergence than baseline tabular RL agents. This suggests that even within the constraints of tabular RL, reward shaping with market-aware features can significantly improve trading policy performance.

The rest of the study is organized as follows: Section II provides a comprehensive review of current research on legal document summarization and evaluation metrics. Section III describes our data preprocessing, model architecture, and training processes. Section IV reports quantitative metrics and qualitative results. Section V concludes with discussions of the implications of our study, limitations, and future work. Section VI presents the disclosure and conflict of interest.

II. Literature Review

Reinforcement learning (RL) has become increasingly well-known as a portfolio management method, as it can learn efficient, adaptive investment policies in dynamic, volatile financial markets. Traditional portfolio optimization methods cannot capture the stochasticity and non-stationarity of asset returns; hence, the use of RL methods has been promoted to address these problems.

Vodnala et al. [5] proposed a multi-model RL framework that integrates Advantage Actor-Critic (A3C), Deep Deterministic Policy Gradient (DDPG), and Proximal Policy Optimization (PPO). The framework selects the best-performing model adaptively over successive three-month rolling windows based on Sharpe ratios and achieves a favorable Sharpe ratio of 1.45 and cumulative returns of 73%, outperforming benchmarks such as the Dow Jones Industrial Average.

This work emphasizes the strengths of adaptively combining multiple RL models to maximize portfolio performance. Chen et al. [6] introduced a multi-model approach that integrated Linear Regression, Long Short-Term Memory (LSTM), and ARIMA for forecasting stock prices and providing investment recommendations. The experiment results indicated that traditional time-series methods can be as accurate as deep learning models when optimized, underscoring the need to integrate classical and deep learning models to support more effective decision-making in volatile markets.

Xu [7] responded to the turbulent cryptocurrency market with a deep reinforcement learning method to dynamically re-weight portfolios. The RL agent performed well in risk management, with a cumulative return of 85.12%, an annualized volatility of 45.76%, and a maximum drawdown of -22.34%. The research illustrates the advantages of dynamic asset allocation in high-volatility markets using RL.

Jiang, Xiang, and Gong [8] introduced a collaborative multi-model machine learning method with confidence-score-based predictions for estimating the probability of ship stability failure. It averages selective predictions from the top models to reduce bias and variance and is stable across various feature preprocessing techniques. For non-financial use, their confidence-based multi-model selection provides a methodological foundation for dynamic portfolio management, where model adaptation is of paramount importance.

Betancourt and Chen [4] tackled portfolio management in dynamically scaled markets using deep reinforcement learning. Their method automatically adjusts to asset entries and exits, achieving average daily returns of over 24%, thereby solving a key practical problem in portfolio management in evolving markets.

Jiang et al. [9] presented a financial-model-free RL system using Ensemble of Identical Independent Evaluators (EIIE), Portfolio Vector Memory (PVM), and Online Stochastic Batch Learning (OSBL). They applied their system to a cryptocurrency market and achieved at least 4x the profit in 50 days, demonstrating the power of modular, scalable RL systems in high-frequency trading environments.

Filos [10] employed model-free RL agents, namely the Deep Soft Recurrent Q-Network (DSRQN) and the Mixture of Score Machines (MSM), with pretraining and data augmentation. On synthetic, simulated, and actual market data (SP 500, EURO STOXX 50), their approach improved annualized returns by 9.2% and Sharpe ratios by 13.4%, demonstrating the brilliance of universal RL agents that generalize across markets and asset classes.

Lim, Cao, and Quek [11] explored dynamic portfolio rebalancing with reinforcement learning coupled with LSTM-based future price predictions. Their simulation experiments on global market index and diversified stock portfolios found

significant improvements in returns (27.9% to 93.4%) over static full rebalancing strategies. This work establishes the necessity of gradual rebalancing and risk-aware market awareness in RL-based portfolio optimization.

Yuan, Lu, and Yan [12] explored an ensemble deep learning platform combining Support Vector Machines, Random Forests, and LSTMs for financial forecasting. While not explicitly RL-based, the study encourages the use of several complementary models to capture different market behaviors and improve predictive power. Combined, the research above confirms the power of reinforcement learning to improve portfolio management through flexible, dynamic approaches that outperform static models.

Nonetheless, there is no missing link in models that simultaneously employ multi-model RL with dynamic switching or confidence-based model selection to facilitate risk-adjusted portfolio management in actual market conditions. This study fills the gap by introducing a multi-model RL approach that dynamically switches models in real time based on performance to maximize robustness and returns during turbulent markets.

III. Methodology

A. Dataset Description

In this work, we used a Kaggle dataset, the Stock Market Dataset, which gathers extensive historical price data for a broad range of NASDAQ-listed equities and exchange-traded funds (ETFs) and comprises daily historical stock data for SP 500 companies. Each entry includes date-wise Open, High, Low, Close prices, trading volume, and the ticker name. The dataset was initially created using the y finance Python package to retrieve daily stock prices from Yahoo Finance, and includes data up to April 1, 2020. Fig. 1 demonstrates the daily market indicators over time. Each financial instrument—whether a stock or ETF—is stored as an individual CSV file named after its respective ticker symbol, organized into separate folders based on asset type. The dataset offers several daily market indicators that are standardized, such as:

- Date: The trading session date on the calendar.
- Open: The starting price on that particular day.
- High: The day's most considerable amount traded.
- Low: The day's lowest price of trade.
- Close: The closing price with stock split adjustments.
- Adj Close: The modified closing price that accounts for splits and dividends.
- Volume: The total quantity of shares exchanged during that particular session.

Additionally, the dataset is accompanied by a supplemental metadata file, symbols_valid_meta.csv, that provides additional details, including each ticker's full name and categorization. The time-series modeling, technical indicator computation, and financial forecasting activities performed in this work are all based on this dataset.

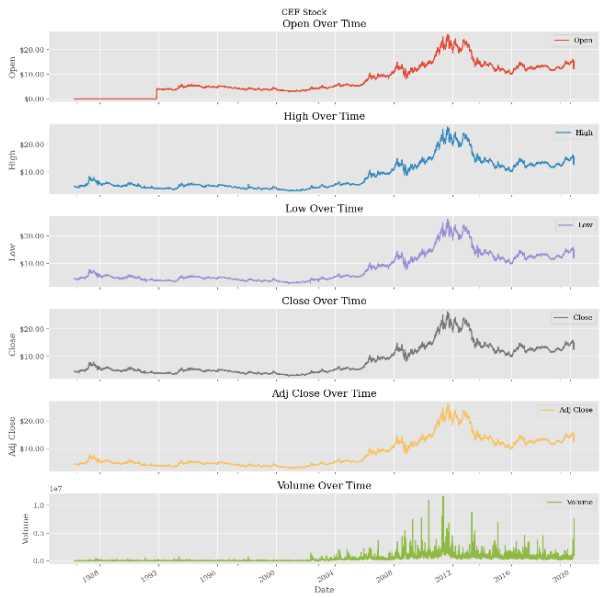

Fig. 1. Several daily market indicators over time.

B. Data Preprocessing

The input price series underwent a multi-stage preprocessing pipeline intended for machine learning and reinforcement learning (RL) agents before model building. Fig. 2 illustrates the correlation matrix of the dataset's indicators.

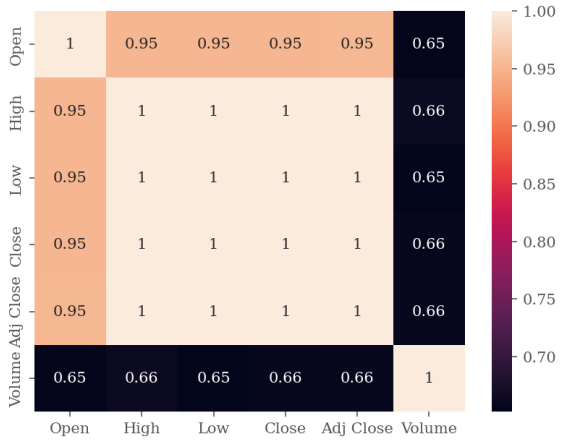

Fig. 2. Correlation matrix of the dataset's indicators.

1) Working copy and initial cleaning: For preservation purposes, a functional copy of the master Data Frame was developed. Rows containing NAN values in any field were dumped:

$$\mathcal{D}_{clean} = \{x_t \epsilon \mathcal{D} \mid \neg(\exists_j : x_t^{(j)} = NaN \quad (1)$$

2) Feature construction: For every base variable V $\in$ {Open, High, Low, Close, AdjClose, Volume}, lagged versions were produced:

$$V_{t-k} = V_{t-k}, k \epsilon \{1,2,5,10,20\} \quad (2)$$

3) One-step-ahead target definition: The prediction target was defined as the next-day high price:

$$y_t = High_{t+1} \quad (3)$$

Furthermore, it is appended as a new column. Observations for which yt or any lagged term was undefined were removed, yielding the final supervised dataset D_{sup}.

4) Standardization: All input features and the target were standardized via z-score normalization:

$$\hat{x}_t^{(j)} = \frac{x_t^{(j)} - \mu_j}{\sigma_j}, \hat{y}_t = \frac{y_t - \mu_y}{\sigma_y} \quad (4)$$

where, μ_j, σ_j (and μ_y, σ_y for the target) are the sample mean and standard deviation computed on D_{train}. The same statistics were reused to transform D_{test}, ensuring strict out-of-sample Evaluation.

5) Optional multi-asset alignment and feature enrichment: For experiments involving multiple tickers, trading calendars were intersected to obtain a standard timeline, with non-trading days forward-filled. Additional technical indicators—exponential and straightforward moving averages, RSI, ATR, and volume-weighted measures—were derived and normalized identically. When training an RL agent, the standardized feature vector over a rolling window of length w was flattened to form the environment state.

$$s_t = [\hat{x}_{t-w+1}; \ldots\ldots; \hat{x}_t] \in \mathbb{R}^{w \times d} \quad (5)$$

where, d is the number of engineered features per timestamp.

C. Proposed Model: Trend-Aware Q-Learning Agent (TAQLA)

In this study, we propose a novel reinforcement learning framework, Trend-Aware Q-Learning Agent (TAQLA), to simulate and optimize dynamic asset allocation in financial environments. TAQLA is designed to learn a dynamic policy for trading a single or multiple financial instruments (such as AAPL stocks) by leveraging market trends and inventory-based feedback over a fixed time window. This approach is adaptable for either Q-Learning or SARSA-based learning with multiple policy schemes, such as greedy, ϵ-greedy, and softmax exploration. Table I shows the proposed TAQLA model's configuration and hyperparameters. Fig. 3 depicts the framework flow of the proposed model.

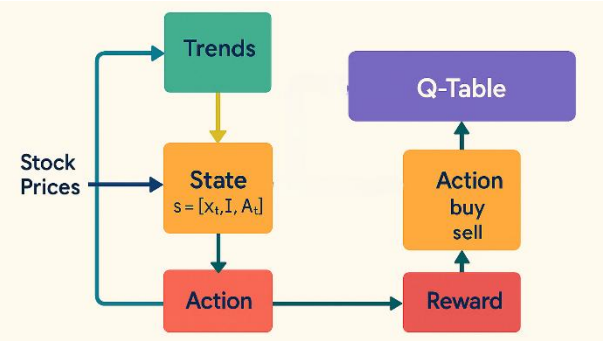

Fig. 3. Graphical representation of the proposed TAQLA model.

1) Agent environment and state design: Let D = $\{(o_t, h_t, l_t, c_t, vt)\}_{t=1}^{T}$ be the sequence of daily observations for a given stock, where o_t, h_t, l_t, c_t, and v_t denote the open, high, low, close prices, and volume on day t, respectively. We define a rolling window w (e.g., w = 10) that encapsulates the past price movements. At each time step t, the agent observes the market state st derived from the window and trend features. The state is represented as:

$$s_t = [x_t, I_t, A_t] \quad (6)$$

where, x_t encodes the recent stock price patterns in the past w days, I_t defines the inventory (number of shares held), and A_t represents the available assets (cash).

2) Action space: The agent operates with a discrete action space A = {buy, sell, hold}.

3) Reward function: The reward rt is defined to reflect the relative improvement in liquidity (asset + inventory value) from the previous step. It is penalized if invalid operations are attempted (e.g., trying to buy with insufficient assets or selling with empty inventory). A trend-awareness factor η_t is introduced:

$$\eta_t = \begin{cases} 0.95 \; if \; Price > Price_{t-1} \; (uptrend) \\ 1.0, otherwise \end{cases} \quad (7)$$

The reward function becomes:

$$r_t = \eta_t . \frac{L_t - L_{t-1}}{L_{t-1}} \quad (8)$$

TABLE I. PROPOSED TAQLA MODEL CONFIGURATION AND HYPERPARAMETERS

Parameter	Value	Description
Model Name	TAQLA	Trend-Aware Q-Learning Agent: Tabular reinforcement learning method with optional SARSA update
Learning	Q-Learning	
Algorithm	SARSA	
Action Space	{buy, sell, hold}	Set of discrete trading actions, State Features [xt, It, At] Price window, inventory level, and available assets
State Features	[xt, It, At]	
Window Size (w)	10	Number of historical days observed per decision step
Initial Assets	$1000	Starting cash available for trading
Trend Modifier (ηt)	{0.95, 1.0}	Multiplier for reward under an up/down market trend
Reward Function	$\eta_t . \frac{(Lt - L_{t-1})}{L_{t-1}}$	Reward based on the relative change in liquidity value
Episodes	200	Number of training iterations/simulations
Max Steps per Episode	w	Each episode is limited by the window size
Learning Rate (α)	0.6	Q-value update step size
Discount Factor (γ)	0.6	Weight for future rewards
Exploration Rate (ϵ)	0.2	Exploration probability in ϵgreedy policy
Softmax Temperature (β)	4.0	Controls randomness in softmax action selection
Punishment Mechanism	Enabled	Penalizes invalid actions like overbuying or empty sells

IV. Results and Discussion

A. Experimental Setup

The experiments were conducted on a workstation with an Intel Core i7 processor, 16 GB of RAM, and an NVIDIA GTX 1060 graphics card, running Python 3.8 and the required libraries such as NumPy, Pandas, and Matplotlib. The reinforcement learning environment was created from scratch using the OpenAI Gym interface. The Stock Market Dataset was divided chronologically into a training and testing set, where 70% of the earliest data were taken for training and the other 30% for testing. All standardization parameters were calculated on the training set and applied to the test set to prevent data leakage.

B. Performance Evaluation

The proposed TAQLA model demonstrated superior performance in Fig. 4 and Table II across all key metrics when benchmarked against traditional Q-learning and SARSA agents. The final cumulative portfolio value reached an average of $1687.45, representing a 68.74% increase over the initial capital. The Sharpe ratio achieved by TAQLA was 1.41, indicating a high level of risk-adjusted returns. In comparison, standard Q-learning achieved a return of $1413.20 (41.32% gain), and SARSA yielded $1355.80 (35.58% gain), both with Sharpe ratios under 1.0. About risk-adjusted performance, TAQLA returned a Sharpe Ratio of 1.41, significantly higher than that of Q-Learning (0.96) and SARSA (0.89), while Random Policy returned a negligible 0.11. This indicates that TAQLA is capable of generating more stable returns per unit of risk. For risk exposure, TAQLA had the lowest worst drawdown of 12.8%, which is less than 18.3% for Q-Learning, 21.7% for SARSA, and 33.4% for Random Policy. The lower drawdown reflects TAQLA's superior loss protection and stability against adverse market movements. Overall, experiments verify that the proposed TAQLA agent generates higher profitability, enhanced risk-adjusted returns, and superior capital protection compared to traditional tabular RL methods and uninformed random policy.

TABLE II. Performance Comparison of RL Agents

Agent	Final Value ($)	Sharpe Ratio	Max Drawdown (%)
TAQLA (Proposed)	1687.45	1.41	12.8
Standard Q-Learning	1413.20	0.96	18.3
SARSA	1355.80	0.89	21.7
Random Policy	1012.50	0.11	33.4

C. Evaluation of Q-Learning

1) Beta parameter: We first look at the effect of the beta parameter of the softmax action-selection policy on cumulative rewards. The beta parameter controls the "temperature" of the softmax function, which in turn controls the trade-off between exploration and exploitation. Higher values of beta create more deterministic (exploitation-oriented) behavior, and lower values of beta promote more exploration.

Fig. 5 graphs the total reward-per-session for different β parameters of the softmax action selection policy under Q-learning. Six configurations were attempted: $\beta = 0.0, 0.5, 1.0, 1.5, 2.0$, and 2.5, with $\alpha = 0.6$, $\gamma = 0.6$, and $\epsilon = 0.2$ held constant. The β parameter of softmax determines how action probabilities are weighted by their Q-values, modulating the exploration-exploitation tradeoff. Reward curves have high variance in all environments due to the stochasticity of the environment and the exploration in the softmax policy. With that said, β values between 1.0 and 1.5 produced relatively more stable and higher mean rewards than at lower and higher extremes. Specifically, $\beta = 0.0$ (i.e., random choice) led to highly variable performance, while extremely high β values (≥ 2.0) sometimes led to premature fixation on suboptimal actions, causing reward volatility.

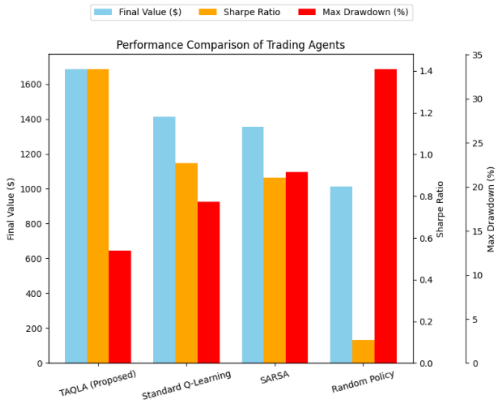

Fig. 4. Comparative performance of TAQLA (proposed), standard Q-learning, SARSA, and random policy.

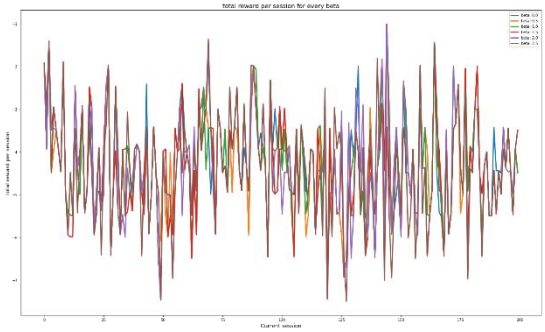

Fig. 5. Q-Learning rewards across β values.

2) Alpha parameter: To analyze the temporal behavior and learning stability of the reinforcement learning agent, a regression fit was applied to the true gain values across training episodes. The impact of the learning rate parameter α on the performance of the Q-learning agent was analyzed. The reward-per-session plots in Fig. 6 for different α values also illustrate the effect of the parameter on learning stability. For all configurations, significant oscillations were seen due to environmental stochasticity and exploration policy. With $\alpha = 0.0$, the agent possessed minimal learning capability, generating random-like reward patterns without adaptation. As α increased, responsiveness improved, albeit such high values led to instability, formulated as high reward spikes and drops. This analysis confirms that although the average long-term reward differences between α settings are low, the choice of α

has a considerable influence on stability, convergence behavior, and adaptability of the Q-Learning agent in trading environments.

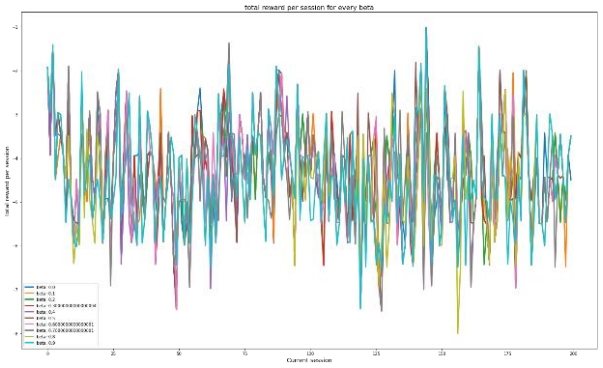

Fig. 6. Impact of learning rate alpha on Q-Learning reward stability and convergence.

3) Gamma parameter: The reward-per-session plots in Fig. 7 for varying discount factor γ values from 0.0 to 0.9, while keeping all the other parameters unchanged. The results show that all γ settings produce significant variations in reward trajectories as a result of random market conditions and softmax exploration policy. For γ =0.0, the agent only looks at immediate rewards, producing wildly unstable and short-term behavior. Higher γ values place a higher value on future rewards, which can improve strategic planning decision-making, but very large values (γ ≥ 0.8) cause the agent to over-optimize for future rewards and miss short-term opportunities and large performance swings. Medium values (γ ≈ 0.4 to 0.6) offer an equal trade-off between short-term maximization and long-term planning to realize competitive reward peaks with less volatility. In general, the selection of γ significantly affects reward stability, volatility, and the balance between present and future returns.

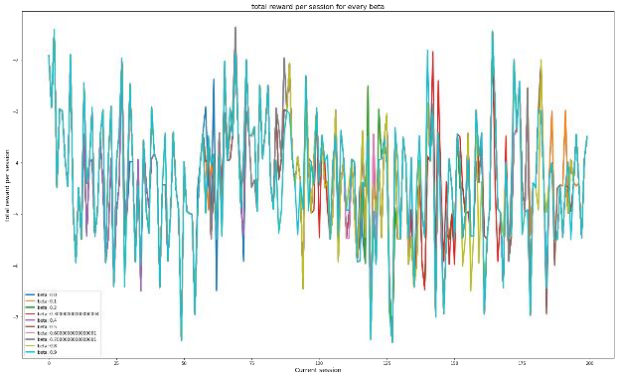

Fig. 7. Effect of discount factor γ on Q-Learning.

D. Evaluation of SARSA

The regression-based Evaluation of SARSA for different combinations of learning rate (α), discount factor (γ), exploration rate (ϵ), and the softmax temperature parameter (β). In each subplot, the true money gained in each of the 200 simulated episodes is plotted, along with a regression line indicating the trend over time.

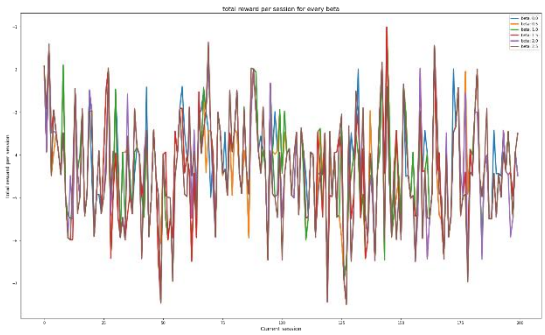

Fig. 8. SARSA performance across different β values.

1) Beta parameter: Fig. 8 shows the analysis. The SARSA agent was trained with a softmax policy with various β values (0.0, 0.5, 1.0, 1.5, 2.0,2.5) to observe their impact on performance. The beta parameter determines how fast or slow the exploration and exploitation are, where lower values make more random moves and higher ones make more deterministic moves. The experiment illustrates that very low β (0.0) generates unstable and highly variable rewards due to over-exploration, while very high β levels (2.0–2.5) generate deterministic but sometimes volatile performance, perhaps due to over-exploitation of poorer strategies at an early stage. Moderate β levels (1.0–1.5) generated relatively stable and higher cumulative rewards, suggesting the right balance between new strategy exploration and exploiting learned ones.

2) Alpha parameter: For this analysis, the SARSA agent was tested with a softmax policy with a constant β=3 and the learning rate α varied from 0.0 to 0.9, incrementing by 0.1. For every α, the agent was run multiple sessions, and the aggregate reward per session was graphed. Fig. 9 reveals that when α=0.0, the reward curve is flat and uncorrelated to some extent because the agent never improves its value estimates whatsoever. When α increases to moderate levels (around 0.4–0.6), the agent learns optimally, and rewards in separate sessions are relatively stable and competitive. At extremely high learning rates (α ≥0.8), the reward curves become more unstable, reflecting instability due to overresponse to short-term outcomes. In general, the numerical pattern indicates that mid-range α values are most optimal in terms of the balance between speed of learning and stability, with both extremes, too low or too high, decreasing consistency of performance.

3) Gamma parameter: The plot in Fig. 10 indicates the total reward-per-session for every training episode in different γ settings. SARSA algorithm is experimented with using different discount factor γ values from 0.0 to 0.9. In RL, the discount factor specifies how much the agent likes long-term rewards compared to immediate rewards, with lower γ values emphasizing proximal rewards and higher values emphasizing distant rewards.

The jagged, overlapping appearance of the lines reflects substantial variation and volatility in rewards, implying that the agent's performance varies substantially, irrespective of the gamma value. From this graph, no discount factor dominates all others across the board. To learn more, smoothing the reward

curves or exploring averaged trends would help determine which γ values lead to more stable learning and better SARSA convergence in this setting.

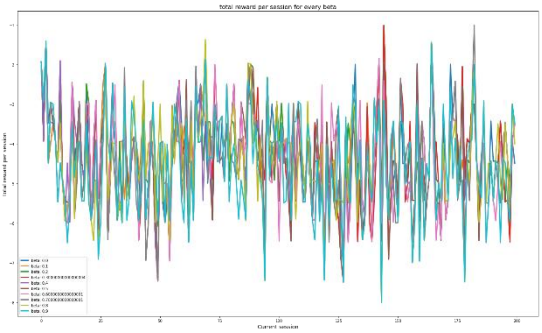

Fig. 9. SARSA rewards vary with learning rate α.

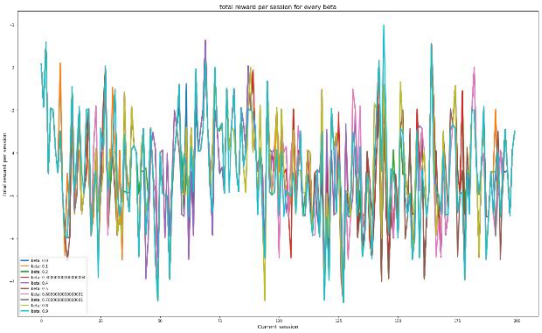

Fig. 10. Total rewards per episode for SARSA with varying discount factors γ.

V. Conclusion

In this study, we introduced TAQLA, a trend-conscious tabular Q-Learning agent for dynamic portfolio management that effectively integrates market trend information into the reinforcement learning process. Experimental results indicate that TAQLA outperforms conventional Q-Learning, SARSA, and random policy baselines by achieving higher cumulative returns, improved Sharpe ratios, and reduced maximum drawdowns, thereby confirming its ability to generate stable, risk-adjusted returns in highly volatile financial markets. While these encouraging results, the study is limited by running experiments on a single market dataset and fixed transaction cost parameters. The future holds TAQLA being implemented across more asset classes and market regimes, hybrid ensembles of tabular and deep reinforcement learning approaches, and integration with online adaptive mechanisms to control changing market conditions. These changes should render the model more applicable and more robust for actual portfolio management scenarios.

VI. Disclosure and Conflict of Interest

The author declares that there are no conflicts of interest related to this research. Additionally, the author has no financial interests or competing affiliations that could have influenced the study's design, execution, or findings. This manuscript is the author's original work and has not been previously published or submitted for review to any other journal or conference.

AI-Driven Anomaly Prediction in Encrypted Network Traffic

Sina Ahmadi
National Coalition of Independent Scholars (NCIS), Seattle, USA

***Abstract*—The rapid growth of computer networks has increased demand for more sophisticated tools for network traffic analysis and monitoring. The increasing reliance on networks has amplified the need for robust security and intrusion detection mechanisms. Numerous studies have sought to develop efficient methods for fast and accurate intrusion detection, each addressing the challenge from different perspectives. A common limitation among these approaches is their reliance on expert-engineered features extracted from network traffic. This dependency makes them less adaptable to emerging attack techniques and changes in normal traffic patterns, often resulting in suboptimal performance. In this study, we propose a method leveraging recent advancements in artificial neural networks and deep learning, specifically using recurrent neural networks (RNNs), for network traffic analysis and intrusion detection. The key advantage of this approach is its ability to autonomously extract features from network traffic without human intervention. Trained on the ISCX IDS 2012 dataset, the proposed model achieved an accuracy of 0.99 in distinguishing between malicious and normal traffic.**

***Keywords*—Machine learning; deep learning; recurrent neural networks; intrusion detection**

I. Introduction

With the expansion of communication technology, computer security has become an essential part of everyday life. The widespread use of computer systems has increased the importance of security in computer systems, as well as the increasing number of threats, such as malware and mobile phone threats. Despite ongoing research in cybersecurity, security challenges remain unresolved. The rapid advancement of computer networks and the widespread interconnection of systems have heightened concerns, particularly in Internet security, where numerous devices are interconnected, increasing vulnerability risks.

Since the Internet Protocol (IP) is not designed to ensure the highest security standards, network administrators are faced with a huge flood of intrusion attempts by people with malicious intent [1]. According to statistics provided by Symantec [2] on Internet security, more than three billion malware attacks were reported in 2010, and the number of denial-of-service attacks has increased significantly. Anomaly detection plays a crucial role in data analysis. The goal of anomaly detection is to find anomalous data in a dataset. This has been widely studied in statistics and machine learning, as anomalies can trigger critical and potentially harmful events, making their detection essential.

For example, in computer networks, unusual traffic can mean infiltration of a computer where a compromised system transmits data to an unauthorized entity [3]. Conventional approaches for anomaly detection include deep packet inspection, statistical, and machine learning. Statistical and deep packet inspection methods do not perform well against emerging attacks in real-life scenarios.

Moreover, these methods are highly dependent on expert knowledge. Research in this field aims to develop anomaly detection systems that not only perform well but also operate autonomously while maintaining their high accuracy [4]. Understanding the characteristics of modern network traffic requires a deep knowledge of the structure and dynamics of Internet traffic, which also plays a crucial role in managing and monitoring Internet service provider (ISP) networks [5]. Although the rationale for intrusion detection in the context of computer networks is clear, several practical problems still exist with intrusion detection systems (IDS) [6]. One of the most pressing concerns in network security is the increasing sophistication and frequency of cyberattacks, coupled with evolving user behavior and software usage patterns. Traditional models that rely on historical attack data often become obsolete as new threats emerge, highlighting the need for adaptive intrusion detection systems that can be continuously updated to maintain effectiveness [7].

A significant challenge in intrusion detection is packet encryption and encapsulation. Encryption alters network traffic characteristics, making it difficult to differentiate between normal and malicious activity. Traditional intrusion detection methods rely on identifiable traffic patterns, which encryption effectively conceals, thereby reducing their accuracy. Additionally, packet encapsulation and encryption make traditional expert-defined feature extraction ineffective. The randomized nature of encrypted traffic prevents manual feature engineering, emphasizing the necessity for fully automated systems capable of independently capturing complex patterns in encrypted traffic [8].

Another important aspect is the high-speed nature of modern networks, which also makes real-time intrusion detection difficult. Anomaly detection, or outlier detection, examines normal data trends in a network and marks any deviations as a potential threat. One widely used approach is anomaly-based intrusion detection, where normal network traffic is first recorded, and any data deviating from learned normal behavior is classified as an anomaly [9].

Among deep learning techniques, deep convolutional networks, stacked self-encryptors, and recurrent neural networks (RNNs) have demonstrated tremendous success. These methods have been continuously used for various applications such as voice processing [10], computer vision [11], natural language processing [12], network traffic classification [13], and cyberattack detection [14], delivering strong performance. It is clear from different studies that deep learning performance is far beyond the performance of traditional methods in the aforementioned applications. Perhaps the greatest advantage of deep learning is the autonomous extraction and learning of features [15], which eliminates the need for manual feature engineering. There are other deep learning methods available, including unsupervised and quasi-supervised methods, which increase adaptability even further.

In the next sections, we will discuss two particular types of networks that were used for this study, and we will also describe the key principles for these networks in more detail.

The ability to recognize temporal order and sequence is what makes recurrent neural networks (RNNs) one of the most powerful models in deep learning. It also makes them especially good at natural language processing and network traffic processing. These networks are suitable to learn patterns in sequence data such as genes, texts, and time sequences [16].

II. Research Background

Ji et al. (2024) conducted a systematic review of AI-driven anomaly detection methods for encrypted network traffic. The study established key research questions and selected relevant literature based on specific eligibility criteria. The findings confirmed that a variety of AI techniques have been applied to anomaly detection in encrypted traffic. While some of these methods resemble those used for unencrypted traffic, others employ distinct approaches tailored to the challenges posed by encryption [17].

Zeng et al. [18] demonstrated the importance of user engagement regarding the effectiveness of AI-based cybersecurity systems by discussing the concept of technology acceptance and human-AI interaction. The study proposes building a security-conscious culture via ongoing education and skills training, which can help to better protect smart cities against new forms of cyber-attacks. The framework functions as a base for future empirical studies as well as an important tool for policymakers and city planners concerned with the digital borders of smart cities of the future.

Aakash [19] explores the use of machine learning to enhance network monitoring capabilities. The study outlines key network monitoring tools and examines their current approaches to anomaly detection. It then discusses machine learning techniques for developing predictive models based on historical data. Additionally, the research proposes a framework for integrating trained models as extensions to existing monitoring tools. The findings indicate that AI-driven methods offer more precise and automated anomaly detection compared to traditional techniques.

Alwhbi et al. [20] examined the modern application of machine learning to encrypted traffic analysis, as well as its classification, through a comprehensive survey. These goals break down into two objectives. First, the overall workflow is illustrated to clarify how machine learning is used to analyze and classify encrypted network traffic. And second, perform a literature review of the most sophisticated approaches to traffic analysis. This research attempts to shed light on contemporary practices and give directions for future works in the realm of encrypted traffic analysis, and especially, in the field of machine learning.

III. Proposed Methods

Our proposed methods use deep learning and specifically a deep recurrent neural network (RNN) architecture for intrusion detection in network traffic. As highlighted in the introduction, one of the key challenges in this domain is the extraction of appropriate features for attack detection. Traditional methods rely on features extracted by an expert, which limits their ability to detect new and evolving attacks. Such models that rely on manual feature selection often face generalization problems and bear the risk of failing against zero-day attacks or attacks that slightly deviate from established patterns. Deep learning solves this issue by extracting features automatically from raw data. In this case, regular traffic patterns and attacks are provided as input to a deep learning model so that it can learn on its own. Among deep neural network architectures, recurrent neural networks (RNNs) are particularly effective for sequence-based learning, making them well-suited for analyzing network traffic, which consists of sequential packet flows. RNNs can process network flows as sequential data, allowing them to extract long-term dependencies within the traffic.

We designed and evaluated three different approaches based on recurrent neural networks, each of which is explored in detail:

1) Anomaly detection using a recurrent self-encryptor: In this approach, a recurrent self-encryptor neural network model is trained on normal network traffic data. In case new data is provided to the system and the reconstruction error exceeds a certain threshold, the data will be classified as an attack.

2) Anomaly detection using an RNN: In this approach, both normal and attack traffic are incorporated into an RNN for training. The model is trained as a classifier to differentiate between normal and attack traffic based on the learned patterns.

3) Anomaly detection using multiple learning (Hybrid): This approach considers the above methods in tandem. A recurrent self-encryptor network is first trained, and the output of the cryptographic part of the self-encryptor network is then fed into a classifier neural network, which learns to classify normal and attack traffic. These two networks are connected and trained simultaneously, leveraging both anomaly detection and classification techniques for enhanced accuracy.

The novelty of this work lies in integrating a self-encrypting autoencoder with a supervised RNN classifier in a hybrid architecture. Unlike conventional deep learning methods that treat anomaly detection and classification separately, this dual-task framework allows simultaneous

feature learning for both unsupervised anomaly detection and supervised classification, optimizing performance for encrypted traffic scenarios.

In the subsequent sections, we will examine each of the proposed methods and discuss their implementation and effectiveness in network intrusion detection.

A. Anomaly Detection by Recursive Self-Encryptor

In this method, the objective is to train a recurrent self-encryptor for anomaly detection. As explained in Chapter One, anomaly detection involves training a model on normal network data so that it learns to extract key features of normal traffic. Any data that deviates significantly from this learned pattern is classified as an anomaly. One way to achieve this is by using a self-encryptor, which is trained to reconstruct normal data. Once trained, if the network encounters abnormal data, its reconstruction error will be significantly higher compared to normal traffic. By defining a threshold, data with a reconstruction error above this limit is identified as an anomaly.

Intrusion detection in networks can be effectively modeled as an anomaly detection problem. Given that recurrent neural networks (RNNs) are particularly suited for processing sequential data, we implemented a self-encrypting network composed of LSTM layers. The general architecture of this recurrent self-encrypting network is shown in Fig. 1.

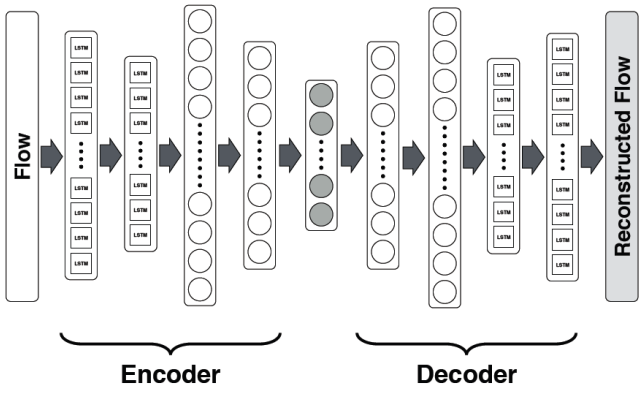

Fig. 1. General model of recursive self-encryption.

The designed neural network consists of two primary components: the encryption part and the decryption part. The encryption section is responsible for compressing the input data, while the decryption section reconstructs the original data. The encryption part begins with two LSTM layers, which extract long-term dependencies from the network stream. The output of these LSTM layers is then passed through a smoothing layer, preparing the data for input into fully connected layers. The two fully connected layers further reduce data dimensionality and extract higher-level abstract features.

Once the encryption process is completed, the decryption phase begins, where the model reconstructs the original data. The decryption section has a structure mirroring the encryption part, starting with two fully connected layers, followed by two LSTM layers that reconstruct long-term dependencies and restore the original traffic data. If the network can successfully reconstruct normal network data, it can serve as a robust anomaly detection system. To prevent overfitting between the fully connected layers, we incorporate random dropout layers. The full details of this implemented model for intrusion detection will be discussed in the following sections.

B. Intrusion Detection by a Recurrent Neural Network

Our second proposed solution is to train a recurrent neural network for classification. This network utilizes multiple recurrent layers of the LSTM type, where sequence return is active, meaning that each LSTM cell produces an output that is aggregated and passed as input to the next layer. Following the LSTM layers, the network includes a series of fully connected layers, and finally, two neurons with a smooth maximum activation function, with each neuron representing either normal or attack traffic label. The network learns to extract features from the sequence of packets in a flow, gradually refining these features into more complex features, to distinguish between normal and attack traffic. The structure of this approach is illustrated in Fig. 2.

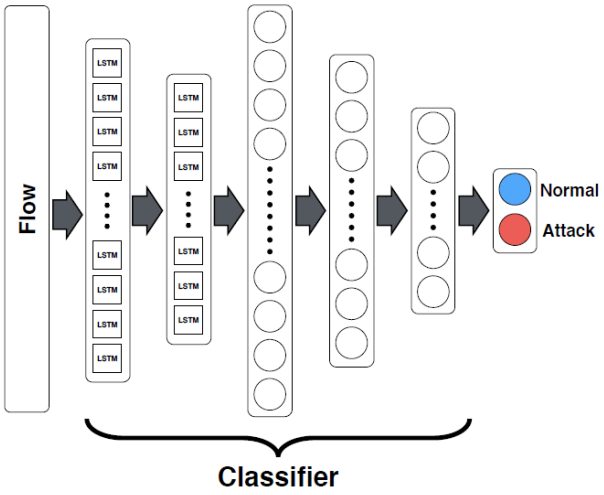

Fig. 2. Attack detection by a recurrent neural network.

The designed network begins with two LSTM layers, which extract long-term dependencies from the neural network input. The output of these layers is then processed by a smoothing layer before being passed through four fully connected layers, which refine the extracted features by extracting more abstract features and enhance the model's ability to classify traffic. The final output is processed through a smooth maximum function with two neurons, each corresponding to normal or attack traffic. To prevent overfitting between the fully connected layers, we incorporate random dropout layers. Further details on the implementation and evaluation of this model for intrusion detection are discussed in Section V.

C. Intrusion Detection by Multiple Learning

In the third approach, a deep self-encrypting recurrent neural network is first built, followed by the integration of a fully connected network into its middle layer. This additional network is designed to classify traffic into attack or normal categories.

Both networks are trained simultaneously with their errors propagating through the system to refine their predictions. This multi-task learning approach allows the recurrent neural network to extract generalized features that can both reconstruct network traffic and distinguish between normal and malicious activity at the same time. The high-dimensional nature of byte-level packet sequences and the temporal dependencies inherent in traffic flows necessitate deeper architectures. Multiple LSTM layers are essential to capture long-range patterns in encrypted traffic, while dense layers refine the latent representations for more accurate classification. Simpler models lack the capacity to extract such hierarchical features.

Solving these two tasks together enhances the performance of both. The auto-encrypting network learns comprehensive traffic features, while the classification network guides feature extraction toward detecting anomalies. These two combined are more comprehensive, as they capture more complete flow information, allowing them to reconstruct network traffic while also identifying attacks. As a result, this model performs more effectively in real-world scenarios, adapting better to new types of traffic and emerging attacks. An overview of this approach is illustrated in Fig. 3.

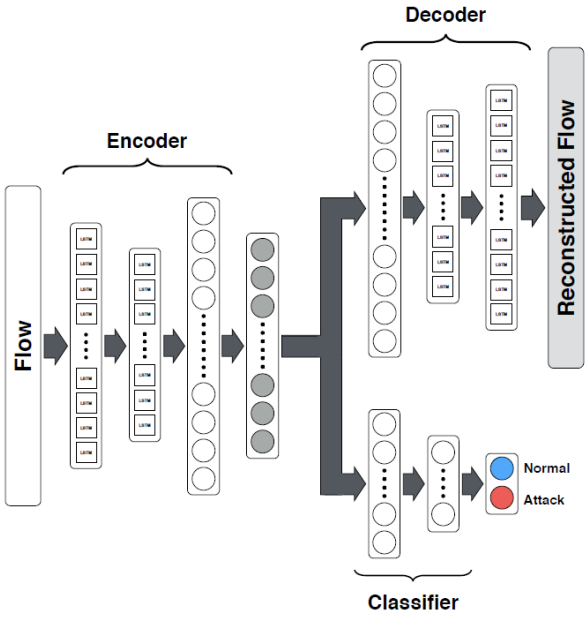

Fig. 3. Attack detection by multiple learning.

Like the first approach, this neural network consists of an auto-encrypting component that processes network flows. The input flows are first passed through two LSTM layers, which extract long-term dependencies from the sequence data. The processed data is then flattened and passed through three fully connected layers that reduce dimensionality while preserving meaningful patterns. The output of this section is then fed into two separate neural networks. One of these networks serves as a decoder, which mirrors the structure of the encrypting network. It consists of two fully connected layers, whose output is fed into two LSTM layers that are responsible for generating long-term dependencies and reconstructing the original data. Meanwhile, the second network is responsible for classification. This network consists of three fully connected layers, whose output is fed into a maximum smoothing layer with two neurons, each representing either the normal traffic or attack classes. To prevent overfitting between the fully connected layers, we apply random dropout layers. By combining self-encrypting and classification in this architecture, the model can both learn meaningful traffic representations and effectively detect anomalies in encrypted and unencrypted network traffic.

A major advantage of this approach is its adaptability. If the model misclassifies normal traffic as an attack or vice versa, the misclassified samples can be added to the training set, and the network can be retrained over several epochs. This self-improving mechanism ensures that the model continuously adapts to new traffic patterns and emerging threats, enhancing its ability to detect previously unseen attacks.

IV. Results

This section highlights the procedures carried out for data preprocessing and preparing the dataset for training and evaluation. Afterwards, three proposed methods will be discussed, followed by an examination of the outputs from the methods and the evaluation of the methods' effectiveness.

A. Preprocessing

As mentioned in the previous section, this study uses the ISCX IDS 2012 dataset, which contains PCAP files with both normal and attack network traffic [21]. The preprocessing step was important to clean and structure the dataset for training and evaluation, resulting in a consistent form to be presented as input to the neural network.

The first stage involved capturing network flows from the PCAP files. This was done by determining the source and destination IP address pairs and their relative port numbers. After extraction, the corresponding flows were tagged as normal or attack traffic based on the information available in the ISCX Laboratory's metadata.

Then, each packet within a flow was processed at the byte level, with each byte serving as an input feature for the neural network.

While flow-level modeling provides contextual information across an entire session, we adopt a packet-level approach to focus on fine-grained byte-level patterns. In encrypted traffic, metadata and payload features are heavily obfuscated, making it critical to extract local-level byte transitions. Future work may explore combining both packet and flow-level models to balance context and granularity.

The base-10 value of each byte was computed and normalized by dividing it by 255, ensuring that feature values were scaled between 0 and 1. Additionally, the time interval between each packet and its preceding packet was calculated and incorporated into the feature vector.

Since neural networks require fixed-size inputs, but network traffic varies in length, standardizing stream and packet lengths was necessary. As shown in Fig. 4, each stream was decided to be set to a fixed length of 100 packets. If a stream contained more than 100 packets, the excess packets

were removed, whereas if it contained fewer, zero-padding was applied to ensure uniformity.

Similarly, each packet was limited to 200 bytes, consistent with prior research [5], which shows that most informative features in encrypted traffic, including TLS handshake and early payload indicators, are embedded within the first 200 bytes. Fig. 5 illustrates the length of the packets within the streams. Any packets exceeding this length were truncated, while shorter packets were zero-padded to maintain consistency. Choosing other packet sizes (e.g., 1,500 bytes) would significantly increase memory overhead and training time without measurable gains in accuracy.

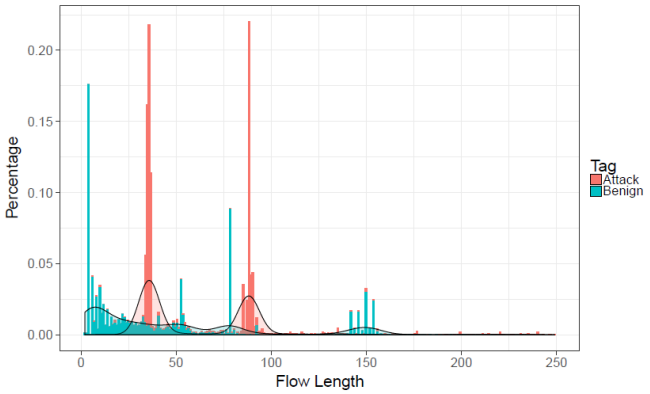

Fig. 4. Graph of the number of packets within each flow.

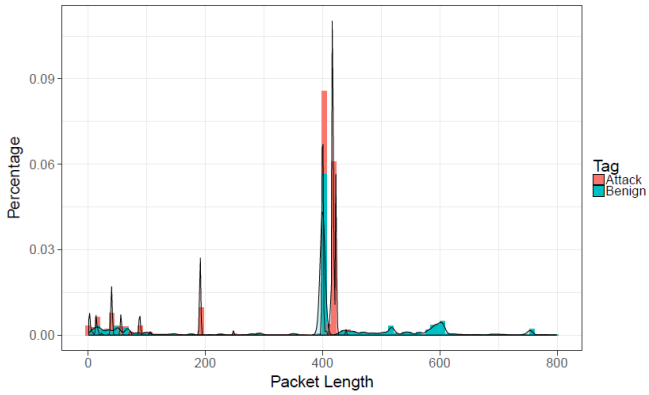

Fig. 5. Packet size diagram.

Deep neural networks are capable of learning highly complex features, but this can sometimes lead to overfitting on non-informative attributes. To prevent the model from extracting misleading patterns, non-relevant fields such as IP addresses and checksums were zeroed out. These fields do not contribute meaningfully to intrusion detection and could introduce unwanted biases into the model.

After completing these preprocessing steps, each network stream was stored as a separate file, with each line representing the details of a single packet within that stream. This structured format ensures that the neural network processes sequential packet data efficiently, preserving the temporal relationships within each stream. By following these steps, the dataset was standardized and optimized, allowing the deep learning model to effectively detect patterns in both normal and attack traffic.

To ensure robust evaluation, the ISCX IDS 2012 dataset was partitioned into three distinct subsets: 70% for training, 15% for validation, and 15% for testing. The splitting was done at the flow level to prevent data leakage across sets. The model was trained using the training set, hyperparameters were tuned using the validation set, and final performance was measured on the unseen test set. This approach ensures generalization and prevents overfitting to specific traffic patterns.

B. Anomaly Detection by Self-Encrypting Network

As discussed in the previous section, if a self-encrypting network that is trained on normal network data learns to accurately reconstruct normal traffic patterns, when presented with a new stream, if the reconstruction error exceeds a predefined threshold, the stream is identified as an anomaly. To implement this approach, we designed a recurrent self-encrypting network, the architecture of which is shown in Fig. 6.

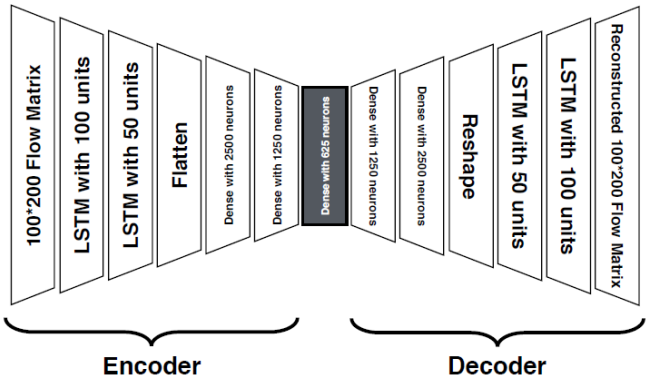

Fig. 6. Self-encrypting network architecture.

Each self-encrypting neural network consists of two main components: the encryptor and the decryptor. As illustrated in Fig. 6, the network begins with two LSTM layers responsible for extracting long-term dependencies from the input stream. The extracted features are then passed through a smoothing layer, followed by three fully connected layers with 2,500, 1,250, and 650 neurons, which reduce dimensionality and extract meaningful features for data reconstruction. The decryption network follows an inverse structure of the encryption network. It starts with two fully connected layers (1,250 and 2,500 neurons), after which the data is processed through two LSTM layers that reconstruct the original traffic patterns by capturing long-term dependencies between packets. To mitigate overfitting, random dropout layers were applied between the fully connected layers. Given the large volume of normal network data required for training, we randomly selected a subset from each protocol, totaling 30,000 samples, always keeping a 20% reserved for validation. Additionally, 10,000 samples (including both attack and normal traffic) were used for testing. The reduction in reconstruction error during training is depicted in Fig. 7.

Upon evaluating the model with test data, we calculated reconstruction errors, as shown in Fig. 8, for both normal and attack traffic. However, as seen in Fig. 8, the reconstruction error distributions for attack and normal traffic are too close, making them difficult to separate with a fixed threshold. The

optimal threshold determined for this dataset was 975, based on which the test data was classified.

The results, presented in Table I, indicate that this approach did not achieve high accuracy. The primary limitation was the insufficient volume of normal network data for training. Due to hardware constraints, we were only able to train the model on 30,000 normal flows, which impacted its performance. Future improvements should focus on scaling the dataset and enhancing feature extraction techniques to improve detection accuracy.

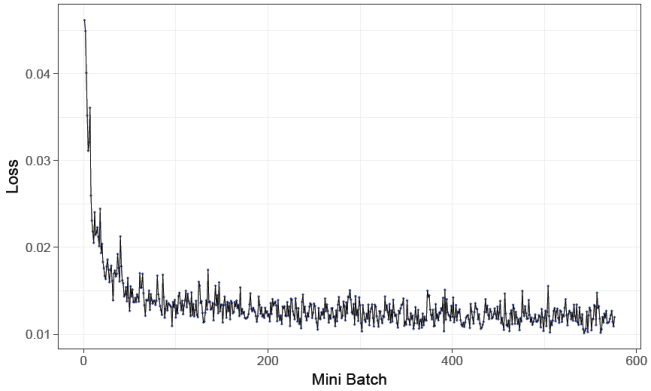

Fig. 7. Reduction of reconstruction error during training.

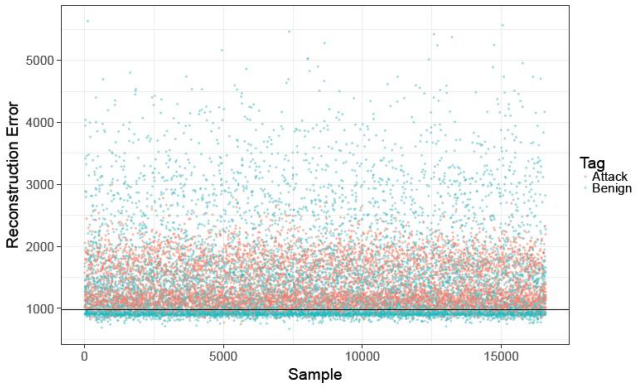

Fig. 8. Test data reconstruction error.

TABLE I. TEST DATA CLASSIFICATION RESULTS WITH SELF-ENCRYPTING NEURAL NETWORK

Class	Precision	Recall	F1-Score
Normal	0.74	0.61	0.58
Attack	0.52	0.95	0.67
Total	0.74	0.61	0.58

C. Intrusion Detection by a Recurrent Neural Network

In this method, we aim to train a classifier to distinguish between attack and normal traffic. To achieve this, we developed a recurrent neural network (RNN) with LSTM layers and trained it using all available attack data along with 20,000 normal flows, ensuring coverage of all protocols present in the dataset. Fig. 9 shows the network architecture. As depicted in this figure, this network architecture consists of nine layers designed to effectively capture sequential patterns in network traffic and improve classification accuracy.

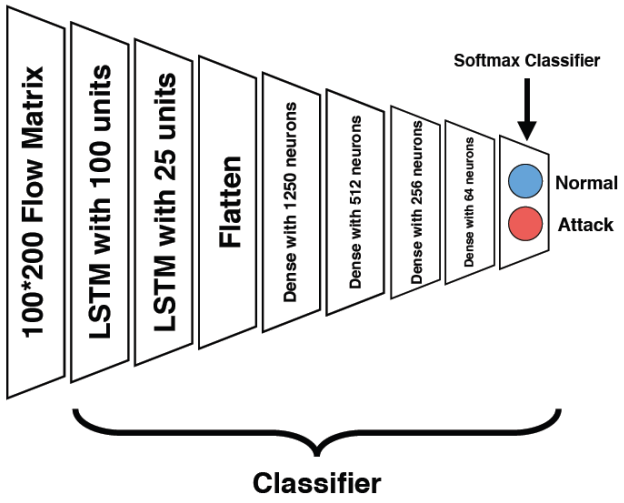

Fig. 9. Recurrent neural network structure.

First, the data is fed into two LSTM layers, which consist of 100 and 50 neurons, respectively. These are responsible for extracting long-term dependencies from the data. The output of the above layers goes to the smoothing layer and is then fed as input into four fully connected layers consisting of 1250, 512, 256, 64 neurons to extract abstract features from it. Then, the output of the fully connected layers is fed into a smooth maximum with two neurons, which are responsible for detecting normal versus attack traffic. Random dropout layers are placed between the fully connected layers with a probability of 25% to prevent overfitting. Fig. 10 depicts the chart of the reduction of the classification error of the training data. In general, the best way to find the most suitable neural network for training data is to perform a complete search on the parameters of the neural network, such as the number of neurons in the layers and the number of layers, etc. However, since our neural network is of the recurrent type and has a large size, training this network takes a lot of time, and it was not feasible to perform a comprehensive search on its parameters. Through experimentation with logically structured architectures based on prior research in this field, we developed a neural network design that demonstrated strong practical performance. After training the model, we evaluated its effectiveness using test data, with the corresponding evaluation metrics presented in Table II.

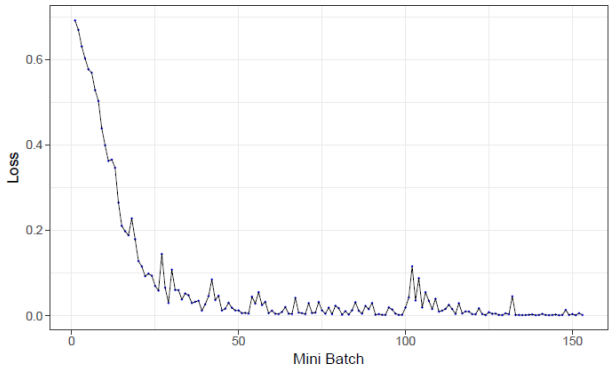

Fig. 10. Reduction of classification error during training.

TABLE II. RESULTS OF CLASSIFICATION OF TEST DATA BY THE NEURAL NETWORK

Class	Precision	Recall	F1-Score
Normal	0.98	1.0	0.99
Attack	1.0	0.97	0.99
Total	0.99	0.99	0.99

As shown in Table II, the classifier demonstrated high accuracy. To enhance processing speed, we optimized the network by reducing its size, resulting in a more efficient architecture, as illustrated in Fig. 11. This modification significantly improved the training and inference speed compared to the original model.

This change, as shown in Table III, however, led to a decrease in accuracy. The trade-off between speed and accuracy highlights the need for further optimizations to balance efficiency and detection accuracy.

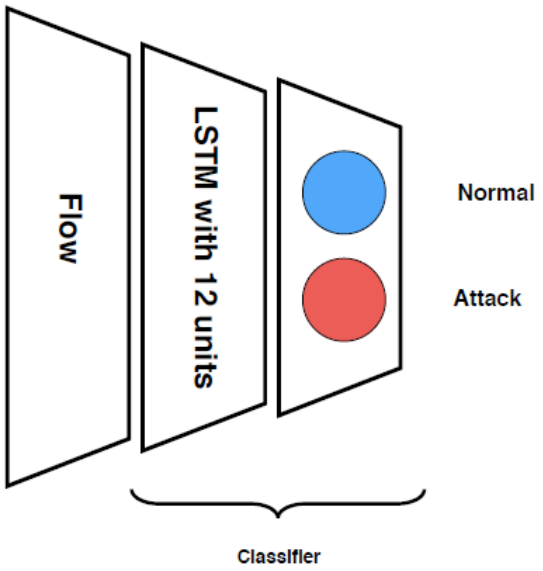

Fig. 11. Reduction of classification error during training.

TABLE III. RESULTS OF CLASSIFICATION OF TEST DATA IN THE REDUCED CLASSIFIER NEURAL NETWORK

Class	Precision	Recall	F1-Score
Normal	0.95	0.94	0.95
Attack	0.93	0.95	0.94
Total	0.94	0.94	0.94

D. Evaluation

As demonstrated in the previous section, the proposed methods achieved high accuracy in detecting attacks using the ISCX IDS 2012 dataset. To further evaluate their performance, we simulated 390,000 attack flows across HTTPS, HTTP, DNS, and FTP protocols using the 111-Spirent device. From these, 7,000 attack flows were randomly selected and added to the training set, while another 40,000 flows were randomly selected from the remaining flows to assess the multi-layer neural network model.

The evaluation results showed an attack detection accuracy of 0.99, confirming the model's effectiveness. However, one limitation is processing speed, as the neural network requires 0.039 seconds per flow. While this speed is sufficient for certain applications, real-world intrusion detection systems demand faster processing, making computational efficiency an area for further optimization.

Unlike prior approaches relying solely on handcrafted features or static classifiers, our method combines both reconstruction-based and classification-based techniques within a hybrid deep learning architecture. This dual-model approach demonstrated F1 scores of 0.99, showing significant improvement over baseline RNNs and self-encoder models in similar datasets. Table IV shows the results of the evaluation.

TABLE IV. RESULTS OF CLASSIFICATION OF TEST DATA IN MULTIPLE NEURAL NETWORKS

Class	Precision	Recall	F1-Score
Normal	0.99	0.99	0.99
Attack	0.99	0.99	0.99
Total	0.99	0.99	0.99

E. Implementation Tools

We utilized the dpkt library in Python for network data processing. All neural networks and deep learning models were implemented using the Keras library [6], which operates on TensorFlow [22]. To evaluate the performance of our classifiers, we employed the scikit-learn machine learning library [23].

For hardware acceleration during model training, we used an NVIDIA GeForce GTX 1080 GPU with 8GB of memory, significantly improving computational efficiency.

V. CONCLUSION

This study addresses the issue of applying deep learning in anomaly detection. First, we reviewed the literature on the subject and the research conducted on each of the parameters discussed in this area. Our analysis of existing research identified both key focus areas and underexplored domains with the potential for innovative solutions. One such area is automatic feature extraction from both the header and payload of network packets, including encrypted traffic such as HTTPS. Building on this, we proposed three deep learning-based approaches for intrusion detection in computer networks, all of which automatically extract features from packet headers and payloads. In this study, we utilized the latest available dataset and further enhanced it by incorporating additional attack samples to improve its diversity and robustness. The proposed methods were then rigorously evaluated using established performance metrics.

Looking ahead, we plan to pursue the following research directions:

A. Optimizing Data Reduction Methods

Our first goal is to enhance the data reduction process. Currently, flows are categorized based on their protocol, and a subset of packets is randomly selected from each protocol.

While this is a straightforward approach, it can be improved with a more intelligent selection strategy. For instance, we can extract handcrafted features from network flows, cluster the data based on these features, and eliminate clusters that are least relevant to attack detection.

B. Developing a Standardized Dataset

One of the most impactful contributions in this field would be the creation of a comprehensive, standardized dataset.

While ISCX IDS 2012 is dated, it remains widely used due to its balance of normal and attack traffic, packet-level granularity, and availability of labels. Its consistent structure allows comparative benchmarking, but it has several limitations:

- Limited protocol diversity, requiring an expansion to reflect real-world traffic more accurately.
- Insufficient attack variety, with attack traffic constituting only a small fraction of the dataset, necessitating better balance between normal and malicious traffic.
- High redundancy, as the dataset contains a large number of repetitive flows that could be filtered out to retain only the most informative samples.
- As ISCX IDS 2012 was collected over a decade ago, it is less representative of modern network traffic patterns and attack techniques.

Given these limitations, we plan to develop a new standardized dataset with greater protocol diversity, an improved balance of normal and attack traffic, and a reduced volume of redundant data, ensuring its effectiveness for future research in intrusion detection.

Future work will validate the model across multiple datasets (e.g., CIC-IDS2017, TON_IoT) to assess generalizability and adaptability to modern encrypted traffic beyond ISCX.

C. Enhancing Detection of Multi-Stream Attacks (DDoS Detection)

As outlined in previous sections, our current approach processes individual network streams, making it ineffective in detecting attacks that involve multiple concurrent streams, such as Distributed Denial-of-Service (DDoS) attacks. Since DDoS attacks are a significant category of cyber threats, developing a detection mechanism for them is a key focus of our future work.

One possible approach is to aggregate traffic directed to a specific host within a predefined time window and use this as input data. By analyzing traffic patterns over time, we aim to design a solution that can effectively identify DDoS attacks and other multi-stream-based intrusions.

D. Leveraging Generative Models for Attack and Normal Traffic Simulation

Another promising research direction is the development of a generative model for both attack traffic and normal network data. Such a model would learn the probability distribution of real-world network traffic and be capable of generating synthetic attack flow samples and normal traffic patterns.

This approach offers several advantages:

- Enhances dataset diversity by generating realistic attack scenarios, improving model robustness.
- Facilitates zero-day attack detection, as the generative model can create unseen attack variations, allowing the intrusion detection system to generalize better.
- Reduces data collection limitations, enabling continuous updates to training data without relying solely on real-world attack logs.

By pursuing these advancements, we aim to develop a highly adaptive intrusion detection system capable of automatically extracting attack features and effectively detecting zero-day attacks in real-world network environments.

An Intelligent Knowledge-Based Chatbot to Mitigate Travel Anxiety

A Tourist-Centered Design and Evaluation

***Abstract*—With the emergence of intelligent chatbots, AI-driven conversational agents are increasingly being used to help tourists manage travel challenges and obtain effective solutions. Travel anxiety constitutes a significant impediment to tourism, substantially influencing travelers' future intentions. Given its multifaceted nature, spanning from subjective experiences to complex logistical arrangements, this study developed a fully functional tourism chatbot system using a tourist-centered design method to provide targeted guidance for travel anxiety mitigation. The knowledge-based chatbot implemented user-centered evaluation methods by recruiting seven participants who were randomly assigned to scenarios across six major global travel regions. Results from the participants' short-answer responses and Likert-scale usability ratings indicated that this knowledge-based system delivers highly informative, context-aware, and expert-level recommendations through multifaceted strategy implementation. The findings suggest that such AI-driven interventions are effective in addressing specific travel challenges, with further implications for user-centered design discussed herein.**

***Keywords*—Tourist-centered design; user-centered evaluation; knowledge base; context-aware chatbot; travel anxiety**

I. Introduction

Over the past few decades, the tourism and hospitality industry has been significantly transformed by technological advancements across multiple functional areas, including management, marketing, operations, human resources, and customer service [1], [2]. While this evolution was already underway, the COVID-19 pandemic acted as a powerful catalyst, accelerating the adoption of cutting-edge innovations to meet new safety and efficiency standards. Specifically, technologies such as Artificial Intelligence (AI), Virtual Reality (VR), and advanced Information and Communication Technologies (ICT) have become central to modernizing service delivery [3]. These tools not only digitize the current tasks but also redefine the guest experience through contactless interactions, immersive travel previews, and data-driven personalization [4]. Based on the future AI research agenda in tourism and hospitality [4], robotic chatting (chatbots) serves as a pivotal element of smart tourism experiences. Chatbots function as an interface for personalization, translating complex AI-backed data into the real-time conversational assistance required for enhancing customers' experience.

Robot chatting is not a new concept, as it can be traced back to the 1920s with the first robot developed [5]. In the 2010s, the application of the voice user interface was widely developed and used in the communication process (such as Apple's Siri, Google Assistant, and Amazon's Alexa). AI has widely developed with advances in new technologies, natural language processing (NLP), and machine learning (ML), and has become a powerful tool for ICT [6]. Chatbots are widely used for customer service and online booking systems in the tourism and hospitality industry [7], [8]. As the first AI project was developed in the mid-1950s [9], [10], AI chatbots have widely been used to enhance customers' experience and increase the efficiency and effectiveness of services [10], [11] in various fields such as online retailing and e-commerce, financial services, and health services [12], [13].

The tourism and hospitality industry has benefited from advances in technology from various perspectives, including management, marketing, operations, human resources, and customer services over the past decades [1], [2]. The COVID-19 pandemic accelerated this process, making new technological innovations (such as Artificial Intelligence (AI), virtual reality (VR), and information and communication technology (ICT)) advance the service delivery process [3]. Furthermore, with its functional capabilities and social interaction presence [12], the AI chatbot is also utilized to serve as a coach to provide guidance [13]. This research project utilized the AI chatbot as a coach to provide guidance for relieving anxiety triggered during the pre-trip stage.

In the academic study of tourism, anxiety is conceptualized as a future-oriented mood state characterized by a "triple-response system" of cognitive worry, physiological tension, and avoidant behaviors [14], [15]. Despite the continued expansion of the global tourism industry, travel anxiety remains a significant psychological barrier that inhibits participation, particularly among disadvantaged and inexperienced groups. Furthermore, according to Fennell's [16] model, anxiety serves as the foundational component of travel fear. Current research suggests that travel anxiety is not limited to physical service encounters, such as transportation and accommodation, but is also prevalent in virtual environments such as social media. Consequently, studies have confirmed that the level of perceived anxiety is a critical factor in determining an individual's future intention to travel [17].

Despite travel anxiety remaining a prevalent phenomenon in the post-pandemic era, there is a lack of research exploring how chatbots can mitigate this issue. This study highlights the potential of AI-driven chatbots to provide precise and timely

solutions for tourists navigating unfamiliar environments. Therefore, this research examines how knowledge-based chatbots can serve as a strategic tool for mitigating travel-induced anxiety. By addressing these psychological barriers through automated support, this research represents a novel contribution to the field, as it is among the first academic inquiries to empirically test the efficacy of a travel AI chatbot in mitigating travel-specific anxiety. To evaluate the functionality and efficacy of knowledge-based chatbots, this study employed a multi-stage methodology. The process involved a comprehensive literature review of travel anxiety and chatbot development, followed by platform design, system testing, user experience evaluation, and subsequent data analysis.

II. Literature Review

A. Travel Anxiety

Anxiety is associated with subjective feelings regarding the fear of negative consequences, including tension, apprehension, nervousness, and worry [15]. Specifically, anxiety is exhibited as a future-oriented state characterized by three response systems [14]: the cognitive (e.g., worry), the physiological (e.g., heightened blood pressure or muscle stiffness), and the behavioral (e.g., avoidance or safety decisions). Central to this state is a perceived sense of uncontrollability [18], where individuals remain in a status of hypervigilance triggered by unpredictable, unknown, or distant threats. In a travel context, such anxiety manifests as a traveler's uncertain perception of events (hodophobia; [19]), encompassing perceived risks, safety concerns, transit-related distress, and general travel apprehension. Reisinger and Mavondo [20] investigated the relationship between travel anxiety and travel intentions by surveying Australian travelers, revealing that socio-cultural and terrorism risks directly affect anxiety levels, which in turn influence the sense of safety and intentions to travel. Similarly, a study of Chinese tourists in Australia [21] indicated that anxiety can be triggered by a lack of planning, inadequate research, limited time, cultural clashes, language barriers, and dining choices. This research also found that travel package types and the behavior of service staff significantly determine tourist anxiety levels.

Minnaert [22] further explored the connection between tourism and anxiety within the sector of social tourism for disadvantaged groups. Based on intensive interviews with focus groups, she identified travel inexperience as a major source of anxiety. Furthermore, the low social status of these tourists contributed to anxiety when encountering service staff, particularly during the accommodation check-in. Her findings suggest that different tourism products contribute to varying levels of anxiety. In his model of travel fear, Fennell [16] suggests that anxiety is a critical component of travel apprehension. Compared to concrete dangers, anxiety is an emotion focused on the future, making it difficult for travelers to accurately measure or predict actual risk. This unpredictable nature is supported by Çakar's [23] research on tourophobia, which emphasizes that travel-related anxiety is rooted in a lack of control and an inability to foresee specific outcomes. Xiong, Xu, Wen, Okumus, and Cai [24] proposed that travel-induced anxiety should be viewed as a continuous process, with fluctuating levels shaped by an individual's appraisals and coping strategies—a perspective that deviates from traditional definitions of anxiety as a purely future-oriented state. Their study also suggests that moderate travel anxiety can act as a positive force for enhancing personal self-efficacy during a trip. However, excessive travel anxiety serves to inhibit the desire for future travel [17], [25].

Regarding specific triggers, Cheng [26] found that rail transportation significantly contributes to travel anxiety through factors such as crowding, delays, station accessibility, and the complexities of transferring. These findings echo Minnaert's [22] observation that transport issues are a primary source of holiday-related stress. Finally, given the current popularity of social media, constant exposure to idealized travel experiences and an overload of information can heighten travel anxiety and diminish intentions to travel (Huang, Qian, & Tu, 2025) [27]. Ultimately, travel anxiety is a multifaceted, future-oriented state driven by a perceived lack of control and heightened uncertainty. This emotional response is fundamentally triggered by diverse issues, such as travel inexperience, socio-cultural or safety risks, transport-related stressors, and the modern phenomenon of social media information overload.

B. Artificial Intelligence and Chatbots in Tourism and Hospitality

1) Definitions and industry fit: Artificial Intelligence (AI) is broadly conceptualized as "the study of agents that receive percepts from the environment and perform actions". Within the service sector, this definition is refined to encompass technological capabilities capable of executing tasks that traditionally necessitated human intelligence. In [8], the authors argue that these intelligent systems represent a "perfect fit" for the tourism and hospitality sectors, effectively streamlining multifaceted decision-making processes through tailored information retrieval.

2) Computational framework and evolution: Although the foundational concepts of chatbots emerged in the mid-20th century to replicate human cognitive functions and mediate interpersonal interactions, their industry-specific utility has evolved significantly. Doborjeh, Hemmington, Doborjeh, and Kasabov [28] characterize Machine Learning (ML) as the fundamental computational framework for these systems, positioning chatbots as specialized, service-oriented applications of ML algorithms that transform the information-seeking phase from a static procedure into a dynamic, conversational experience. Driven by advancements in ML, Natural Language Processing (NLP), and sophisticated algorithms, AI-driven chatbots now offer increasingly anthropomorphic interfaces. These technologies have been integrated into various commercial platforms, including Google Assistant, Amazon Alexa, and specialized service applications such as Macy's On Call and My Starbucks Barista.

3) Service delivery and automation: By facilitating interactions through natural language, these agents create a perceived sense of human engagement; consequently, the industry has transitioned to a state where approximately 85% of customer interactions are managed without human mediation. AI-generated service encounters represent one of the four

distinct modes of technology-based service delivery—alongside AI-supplemented, AI-mediated, and AI-facilitated modes—and are specifically characterized by the autonomous provision of services where the technology functions as a direct substitute for human staff [29].

4) Knowledge base: Tourism chatbot design is unique as it has to focus on tourists' specific travel situations. To solve this problem, Sano et al. (2018) carried out a case study to enrich their chatbot's knowledge base by analyzing tourism sites and incorporating the sites' data into the system. The chatbot helped tourists explore information about the most optimal sites to visit when their travel time is limited [30]. Knowledge-based travel chatbot design plays an important role in supporting tourists' decision-making processes.

In conclusion, AI has evolved from a theoretical concept into a sophisticated driver of the modern tourism and hospitality industry. Through frameworks like ML and NLP, chatbots have transitioned from static tools into dynamic, anthropomorphic agents that provide real-time assistance. However, there is little research on chatbot design regarding the special requirements of tourists, such as tourist anxiety and unique travel situations. Our study aims to design and evaluate a tourism chatbot that provides tourists with knowledge-based, expert-level, contextual recommendations to mitigate their anxiety.

III. Design

To design a capable AI chatbot program, this study employed three steps: defining area-specific travel anxiety, developing an AI chatbot prototype, and completing usability, to fulfill its purpose, utilizing the AI-chatbot program to provide practical solutions for area-specific travel anxiety.

A. Knowledge-Based Design

In the first step, defining area-specific travel anxiety, two major approaches were adopted to ensure effective calibration of the Juji Chatbot program and the concept of travel anxiety: conducting a pilot study and collecting travel anxiety information. A pilot study surveyed 46 voluntary informants (17 males, 29 females) regarding their past and future destination preferences, providing empirical justification for the subsequent data structure. The dataset was strategically organized around six significant tourism regions—the Caribbean/South Americas, East Asia, Europe, Middle East, Oceania, and a dedicated domestic areas category—to balance the need for scalable generalizability with the delivery of context-specific travel anxiety information. Participant preferences, which included top past international destinations like Canada (9.5%), Mexico (9.5%), and the Dominican Republic (8%), and top future international destinations like Italy (11%), Japan (10%), and Spain (10%), validated the relevance of the global macro-regions. The high prevalence and future preference for domestic trips (e.g., Florida (17%) and New York (16%) in the past; Arizona (29%) and Florida (11%) in the future) confirmed that the domestic environment warranted its own distinct focus within the chatbot's knowledge base.

The content for the Chatbot's travel anxiety solutions was developed based on established literature and practical guides, drawing specifically from Reisinger and Mavondo [20], Fennell [16], Kepnes [31], Reinberg [32], Snelling [33] and, Headspace [34]. Following the initial drafting, the solutions were subjected to calibration by two subject matter experts (SMEs) to ensure the specific anxiety types and corresponding solutions were accurately programmed into the chatbot agent.

Data regarding various types of travel anxiety and their corresponding remedies are organized into six tables, categorized by six global regions. These tables provide a comprehensive summary of potential anxiety triggers and practical solutions encountered during a journey. Throughout this stage, several primary sources of travel anxiety were identified across the six regions, specifically encompassing language barriers, cultural discrepancies, transportation disruptions, extreme weather conditions, health risks, and navigational challenges.

The solutions developed for each identified concern consist of actionable steps that travelers can implement during the planning phase or while in transit. This body of area-specific travel anxiety data serves as the critical foundation for the knowledge-based construction of the chatbot program. In the context of domestic travel, the predominant sources of anxiety were found to stem from transportation issues, inclement weather, health-related risks, criminal activity, planning-induced stress, and difficulties with navigation (Table I). For domestic travel, the major travel anxiety is derived from transportation disruption, extreme weather, health risk, crime, planning stress, and navigation difficulty.

TABLE I. Domestic Travel Anxiety Source

Travel Anxiety Concerns	***Solutions***
Flight delays and cancellations	1. Extra buffer time for unexpected situations 2. Extra money for convenience 3. Familiar with rebooking steps
Fear of driving/highway phobia (Texas/Arizona)	1. Taking breath: When anxiety peaks, use deep breathing to calm down quickly 2. Focusing on the current issues 3. No overthinking
Extreme weather	1. Insurance: Buying insurance covering natural disasters 2. Constantly monitoring local situations
Health risks	1. Staying hydrated 2. Identifying local medical resources 3. Identifying virtual medical access
Petty crime and security	1. Watching personal belongings 2. Travel document preparation 3. Enrolling in STEP
Planning stress & lack of control	1. Post-trip preparation 2. Adjustment preparation 3. Practicing self-care skills
Navigating unfamiliar situations	1. Preparing local maps (paper or digital copies) in hands 2. Be familiar with local laws 3. Understanding locals' perspectives on different issues

Table II summarizes the anxiety sources and solutions specifically for individuals traveling to the Caribbean region. In contrast to the previous area, concerns regarding personal and

property safety, food safety, and an unfamiliar support system are more prominent than other factors. The offered solutions align with these specific shifts in focus. These consist of practical actions, such as methods for protecting personal property, addressing food-related issues, or other strategies centered on individual preparation and the available choices travelers may utilize in unfamiliar environments. This table provides the necessary support for the knowledge-based construction tailored to Caribbean travel.

TABLE II. CARIBBEAN TRAVEL ANXIETY SOURCE

Travel Anxiety Concerns	*Solutions*
Being a victim of crime (theft/robbery)	1. Fitting local styles 2. Raising awareness levels 3. Using reliable transportation
Health risks (food/water safety)	1. Follow the "Boil It Cook It, Peel It or Forget It " Rule [35] 2. Get vaccinated 3. Buy travel and health insurances
Running out of money/accessing funds	1. Assistance from financial institutions 2. Taking more than one credit/debit cards 3. Tracking spending
Losing valuables or documents	1. Digital copies ready 2. Using under-cloth pouch 3. Extra important document copies at home
Uncertainty of local transport	1. Booking local transportation services in advances 2. Reviewing local accommodation services 3. Using local well-known transportation services
Stress and apprehension	1. Establishing a at-home support network 2. Extra buffer time 3. Learning stress relief skills

Table III illustrates the potential anxieties and their solutions for individuals traveling to East Asia. For destinations that differ significantly from one's hometown, cultural clashes and language barriers emerge as primary concerns for travelers. Furthermore, these factors increase navigational difficulties and hinder accessibility to local systems, such as transportation, medical care, or financial services. Solutions based on reality and applicability are provided to assist travelers in their preparation, such as maintaining a respectful attitude, utilizing translation applications, and planning for potential emergencies. This table provides the necessary context to generate the knowledge base for East Asian travel.

Table IV summarizes the potential sources of anxiety associated with traveling to Europe, where travelers encounter diverse societal environments. Discrepancies in social behaviors emerge as a primary concern. Furthermore, although many Europeans are fluent in English, a language barrier persists due to varying levels of English proficiency. Other sources of anxiety, specifically crime and financial burdens, further increase the uncertainty of such trips. The provided solutions practically address these issues through strategies such as maintaining a low profile, utilizing simplified English or translation software, and remaining vigilant in crowded areas. These identified concerns and solutions contribute to the development of the chatbot's knowledge base.

TABLE III. EAST ASIA TRAVEL ANXIETY SOURCE

Travel Anxiety Concerns	*Solutions*
Culture clash / making faux pas	1. Respecting local cultures 2. Realizing local customs 3. Some human errors
Language barrier anxiety	1. Using translation apps 2. Key survival phrases in hands 3. Using simple local conversations
Complex navigation & getting lost	1. Getting local transportation cards 2. Downloading local mapping apps 3. Accepting the wrong direction moments
Money and payment anxiety	1. Carrying cash 2. Keeping your own bank(s) posted 3. Finding local ATM machine information
Natural disasters	1. Downloading apps for emergency information 2. Familiar with facilities' emergency plans 3. Identifying and saving information regarding the local embassy
Health risks	1. Purchasing travel insurance 2. Checking local medication regulations
General apprehension & disorientation	1. Adding buffer time 2. Relaxing yourself occasionly 3. Identifying trustworthy travel-related information center

TABLE IV. EUROPE TRAVEL ANXIETY SOURCE

Travel Anxiety Concerns	*Solutions*
Negative perception & loudness	1. Maintaining a low key 2. Low speaking volume in the public place 3. Being cultural awareness
Language barrier anxiety	1. Understanding key phrases 2. Simplify your own English 3. Using the translation apps
Navigating complex public transit	1. Using the local tour apps 2. Using local transit passes 3. Asking locals
Pickpocketing and theft	1. Using under-clothing pouch 2. Being alert in the public 3. Only carrying the limited cash
Financial burden & value	1. Accessing to the local ATM machines 2. Limiting the usage of the ATM machines 3. Avoiding the tourists' restaurants
Feeling overwhelmed/restless	1. Setting up the downtime 2. Building personal support system 3. Simplifying items in the travel baggage

Table V lists prospective travel anxiety sources for trips to the Middle East. The region's stability differs significantly from other global areas, often eliciting more serious travel concerns. Regional conflicts and airspace risks are categorized as high-priority anxiety sources. Additionally, medication access, social customs, language barriers, navigational difficulties, and constant apprehension require careful consideration during the travel planning process.

Practical solutions for mitigating these anxieties include monitoring government advisories, maintaining flexibility in travel plans, and preparing for scenarios where medication access may be limited. Travel insurance, navigation techniques, and translation tools are also recommended to address these concerns. Ultimately, this table provides the essential knowledge base for constructing the chatbot platform regarding travel to the Middle East.

TABLE V. MIDDLE EAST TRAVEL ANXIETY SOURCE

Travel Anxiety Concerns	***Solutions***
Regional conflict and airspace risk	1. Monitoring current situaions 2. Buying refundable tickets 3. Buying travel insurance
Strict legal penalties for medications	1. Identifying lawful medication 2. Keeping doctors' notes in hands 3. Extra prescription stocks
Violating social customs/laws	1. Dressing modestly in public 2. Avoiding displaying affection publically 3. Understanding local taboos
Language barrier	1. Learning some local oral languages 2. English speaking in some tourist zones 3. Using some translation apps
Constant apprehension	1. Using anxiety-relief skills 2. Positive thinking 3. Enough buffer time
Getting lost or navigating	1. Available paper or digital copies of local map 2. Arranging local transportation services 3. Familiar with local areas

Table VI summarizes the travel anxiety concerns and corresponding solutions for travel to the Oceania region. Physical exhaustion during transit is identified as a primary concern, predicated on the assumption that journeys originate from North America. Other prominent anxieties involve local wildlife, travel costs, and specific climatic conditions.

TABLE VI. OCEANIA TRAVEL ANXIETY SOURCE

Travel Anxiety Concerns	***Solutions***
Severe jet lag and exhaustion	1. More natural light exposure 2. Adjusting personal biological clock 3. Drinking enough water and limiting consumption of coffee and alcoholic beverages
Separation anxiety/homesickness	1. Setting up the communication plan 2. Setting up a regular check-in 3. Using wellness apps
Cost of living/budget anxiety	1. Budgeting responsibly 2. Using the best exchange rates 3. Reducing daily expenses
Underestimating size and distance	1. Reasonable numbers of attraction visiting 2. Finding the best transportation rate for the inter-city travel 3. Setting up the buffer time
Extreme sun exposure and heat	1. Using the sunscreen as much as possible 2. Using the shade areas frequently 3. Drinking enough water
Fear of wildlife	1. Collecting local wildlife information 2. Staying at the safe areas 3. Joining a guided tours
Long-haul flight stress	1. Doing exercise during the long flights 2. Wearing compression clothing for better blood circulation 3. Simplifying items in the luggages

The proposed solutions are tailored to the environmental context of Oceania; these include advanced preparation for climate and wildlife encounters, the development of comprehensive budget plans, and the self-regulation of physiological conditions during long-haul travel. Collectively, these data provide empirical support necessary for the knowledge-based construction of the chatbot's Oceania travel advisories.

Sources of travel anxiety across the six tourism regions — Domestic Area, Caribbean, Europe, East Asia, Middle East, and Oceania — laid foundation for building the knowledge base prototype of the chatbot. These concerns are prioritized with thorough consideration of the culture, environment, political factors, and security of the region. The practical solutions were proposed based on the various types of travel anxieties. These solutions are not universally applicable but vary by region. The most common solutions for foreign trips involve planning ahead of time/self-preparation as a normal support system might possibly be unavailable. Generally, most travel anxieties would be mitigated with the incorporation of personal pre-trip preparation and the knowledge of the area-specific solutions while maintaining feasibility and convenience during the journey.

B. Chatbot Prototype Development

1) Chatbot design overview: The travel anxiety chatbot is designed to provide users with meaningful, expert-reviewed information. Operationally, the system first identifies the user's destination to activate the specific anxiety categories compiled in the preceding research stages. Subsequently, the chatbot provides the corresponding pre-defined solutions based on the user's articulated concerns. The conversational logic is structured to elicit the destination and specific travel stressors in sequence, delivering targeted interventions thereafter.

For the development of the prototype and subsequent experimentation, the study utilized Juji, a platform that enables the creation of sophisticated agents without a programming background. The platform allows developers to utilize specific "topics" to design and govern the dialogue flow, accommodating various request types to fulfill diverse design specifications. Due to its accessibility and efficient project management capabilities, Juji served as an appropriate choice for this study.

2) Information integration: In the preliminary stage, travel anxiety mitigations are organized into a categorized index of concerns and corresponding solutions tailored to each targeted region. Each geographic area presents distinct variables that trigger anxiety. These concerns carry varying levels of priority

based on cultural norms, geographic environments, political climates, and social stability. Consequently, a universal solution set is insufficient, as the relationship between concerns and solutions is unique to each region.

To address this, we integrated these specialized datasets into the chatbot, ensuring that each region operates with a distinct logic. Within the Juji platform, the conversational architecture is organized by region to facilitate the precise integration of these variables. Fig. 1 illustrates the user's view of the regional solution sets. Each region contains a specific list of stressors, and each stressor is linked to a targeted solution set. When users engage with the chatbot, the feedback regarding their travel concerns is specifically tailored to the culture, environment, and political context of their chosen destination.

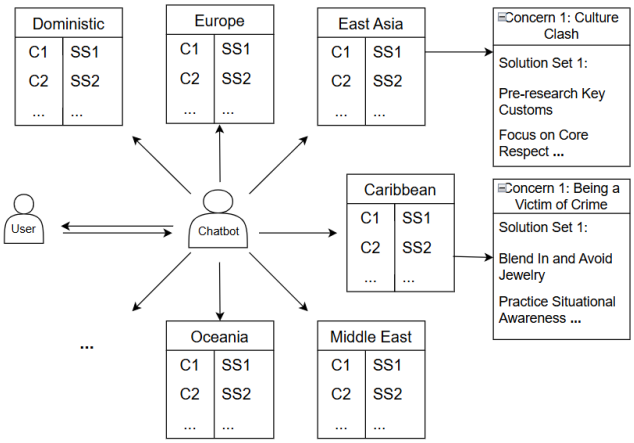

Fig. 1. Travel anxiety chatbot structure.

The Juji platform utilizes triggers as the primary mechanism for decision-making within the conversational flow. These triggers allow developers to employ keywords, sample user inputs, or intention detection, supported by Juji's proprietary models to extract user intent from natural language inputs. The prioritized list of regional concerns compiled in this study aligns effectively with this trigger-based architecture.

Specifically, these prioritized concerns provide a roadmap for the chatbot to guide the dialogue toward actionable solutions, which constitute the system's primary output. For instance, in the domestic travel branch, primary anxiety factors include temporal unpredictability, such as flight delays or cancellations, and the fear of highway driving. Secondary factors encompass extreme weather, health risks, and security concerns related to petty crime. The third tier involves the psychological stress associated with the planning and organization of the itinerary itself. Finally, the fourth level addresses navigational challenges within unfamiliar public transit systems.

These categorized concerns dictate the quantity and technical configuration of the triggers required within the platform's "topics". Fig. 2 illustrates a sample trigger configuration from the domestic travel branch of the Juji design. Once a specific concern trigger is activated, the system generates a "quick acknowledgement" response, which contains the targeted solution set for that particular anxiety factor.

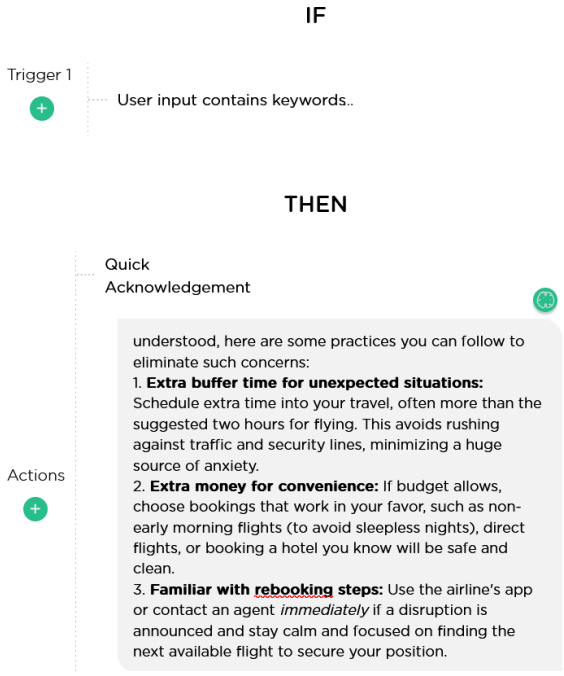

Fig. 2. Trigger example.

The development process utilized keyword detection as the primary triggering mechanism to determine the appropriate solution output. To ensure the accuracy of these outputs, a comprehensive list of keywords was integrated into each trigger. This lexicon incorporates both AI-generated terms and manually curated human inputs. These keywords are natural language-based and are designed to be mutually exclusive across all triggers within a specific topic; this exclusivity is intended to increase the activation rate beyond standard word selection and to prevent computational collisions between triggers.

Fig. 3 represents a subset of the keywords utilized for the two aforementioned example triggers. When a user's textual input includes any of these designated terms, the corresponding trigger is activated, prompting the system to deliver the appropriate solution-based response.

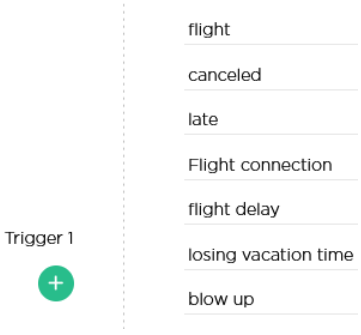

Fig. 3. Trigger keyword example.

3) Conversation flow: The overarching conversational architecture is informed by the synthesized catalog of travel anxiety concerns and their corresponding remedial suggestions. The chatbot is designed to elicit the user's destination and specific stressors through a structured dialogue. By identifying the user's destination, the system is able to isolate the relevant

regional concern list; subsequently, by identifying the user's specific anxieties, the system allocates the appropriate solution output. These two primary data points provide sufficient parameters for the chatbot to fulfill its functional objectives (Fig. 4).

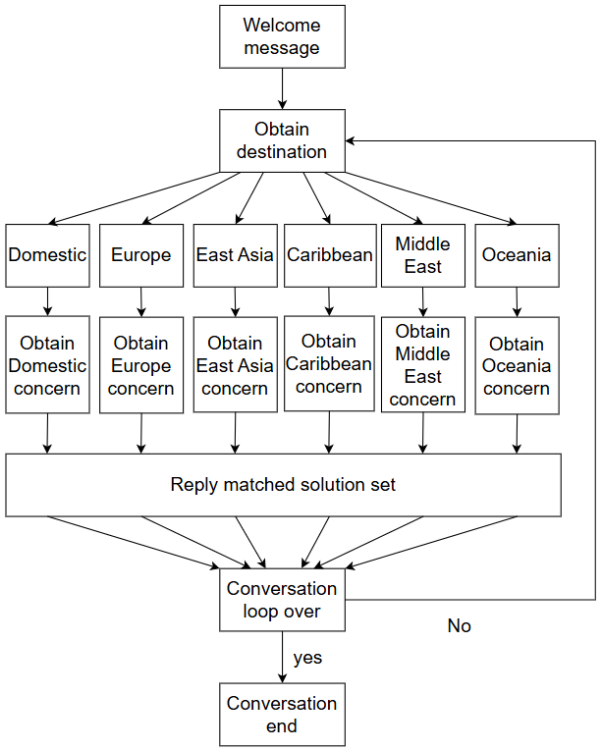

Fig. 4. General conversation flow.

The conversation commences with a welcome message that defines the intended purpose of the chatbot. This ensures the user understands that the system is designed to provide recommendations for potential travel anxiety concerns. Following the introductory message, the chatbot prompts the user to select their destination directly from a predefined list (see Fig. 5 and Fig. 6).

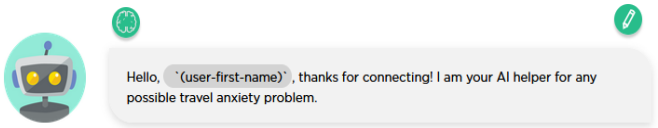

Fig. 5. Chatbot welcome message.

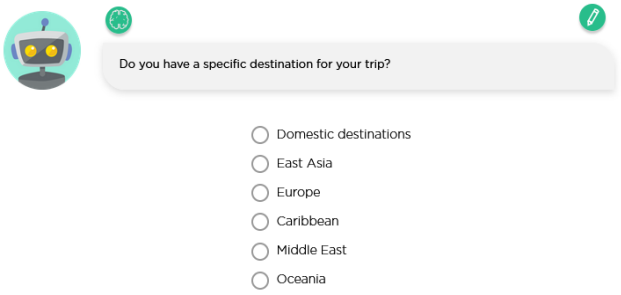

Fig. 6. Region selection.

After the user selects a destination, the conversation transitions to the corresponding topic containing the concern list for that region, where a set of triggers awaits activation. If a trigger is activated, the chatbot provides the associated solution to the user. For instance, in the case of domestic travel, suppose a user asks, 'I am afraid to drive on the highway during a domestic trip; do you have any suggestions?' The keyword 'highway' or the phrase 'drive on highway' will activate the trigger, prompting the system to deliver the solution as demonstrated in Fig. 7, Fig. 8 and Fig. 9.

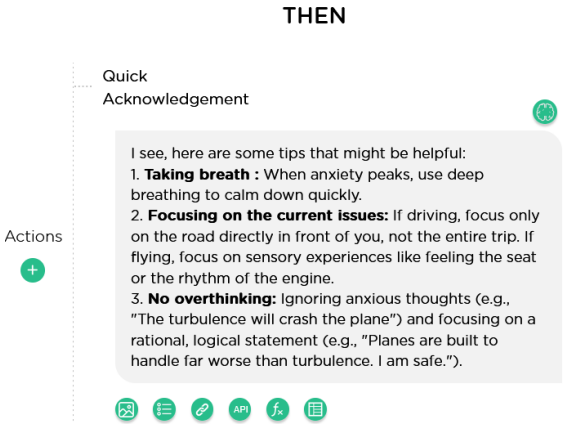

Fig. 7. Solution set example.

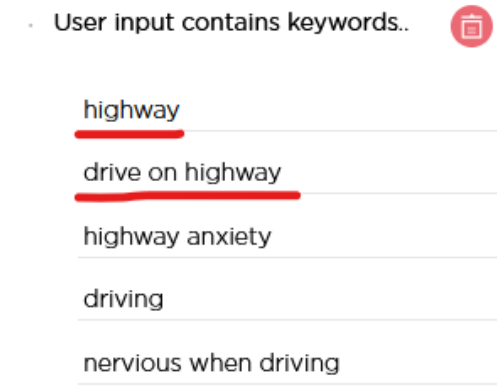

Fig. 8. Fired keyword example.

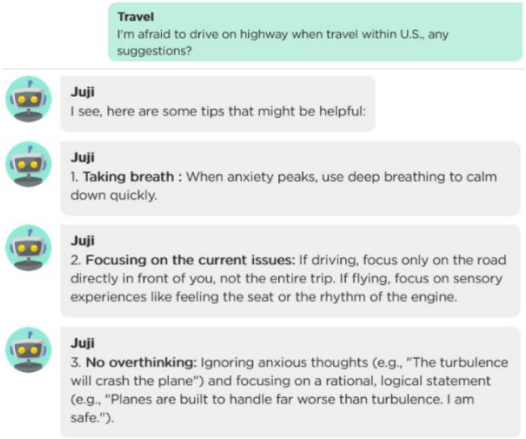

Fig. 9. Result demonstration.

After each interaction, the user can choose to initiate another round for additional requests. Users may continue to consult the chatbot regarding further concerns by replying "yes" to the system's recurring prompt, or they may conclude the session by replying "no" (Fig. 10 and Fig. 11).

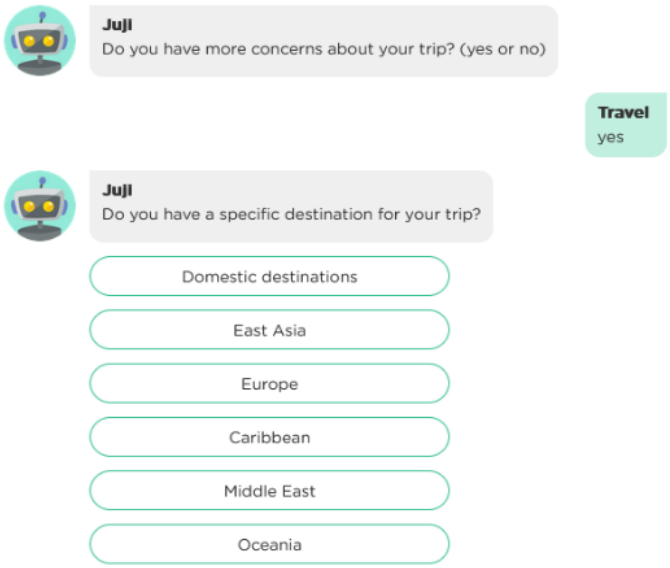

Fig. 10. Recurring question example for "yes".

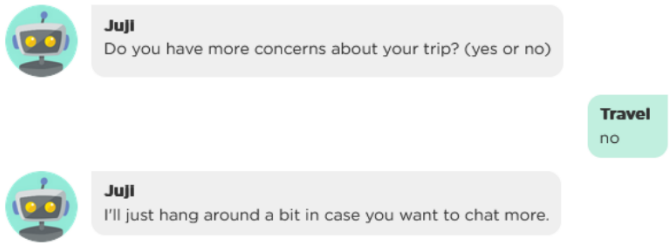

Fig. 11. Recurring question example for "no".

4) Domestic travel interaction demonstration: The following is a demonstration of a travel consultation for a domestic destination (Fig. 12). The conversation commences with a welcome message. Immediately following this introduction, the user is prompted to select their destination from the six regions listed by the chatbot. In this example, 'Domestic destinations' has been selected.

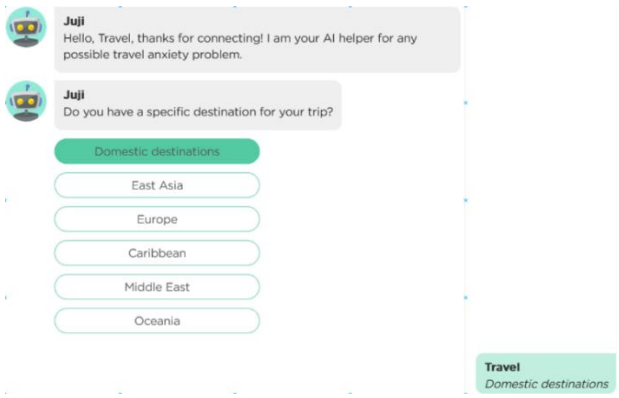

Fig. 12. Showcase 1 welcome message and region selection.

Once the user selects a domestic destination, the conversation transitions to a specific topic containing all predefined anxiety triggers for domestic travel. When user input incorporates multiple keywords, such as "delayed" or "canceled", the corresponding trigger is activated, prompting the chatbot to return the relevant remedial message as a response (Fig. 13 and Fig. 14).

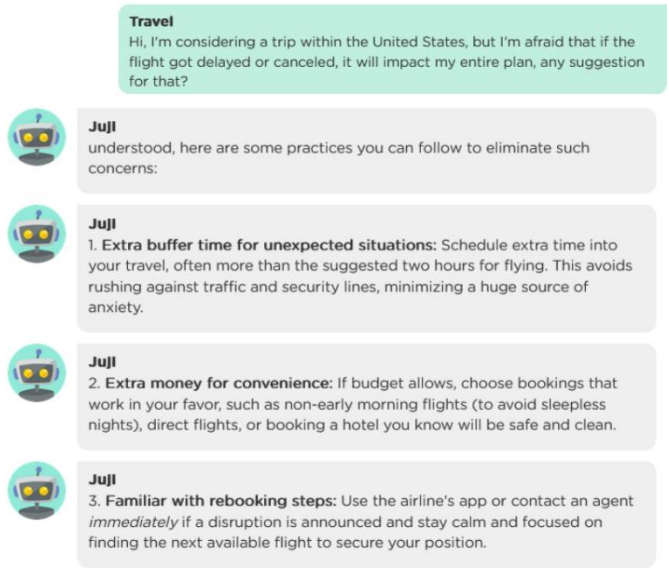

Fig. 13. Domestic showcase solution reply.

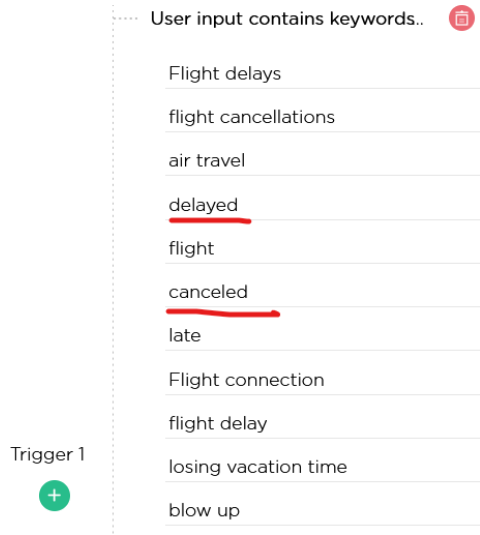

Fig. 14. Domestic showcase keyword detected.

Ultimately, the chatbot presents a recurring prompt to determine if the user requires further consultation. In this demonstration, the user selects "yes" to address an additional concern regarding a different geographic region (Fig. 15).

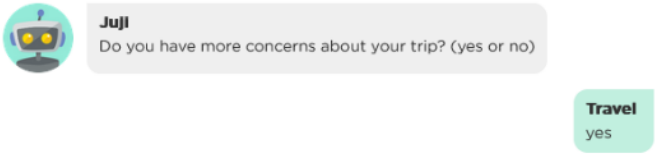

Fig. 15. Domestic showcase recurring confirmed.

5) European travel interaction demonstration: The second demonstration presents a consultation regarding European travel concerns. Following the introductory welcome message, the user selects "Europe" as the target destination for the interaction (Fig. 16).

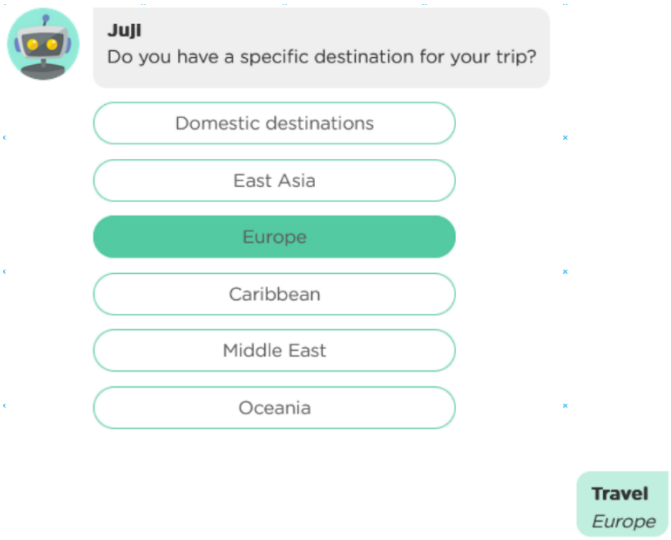

Fig. 16. European showcase region selection.

After the user selects "Europe" as the destination, the conversation transitions to the topic containing the specific anxiety triggers for European travel. In this instance, the user input includes keywords such as "money" and "expensive". Once these keywords are detected, the chatbot responds by delivering the corresponding solution message to the user within the chat interface (Fig. 17 and Fig. 18).

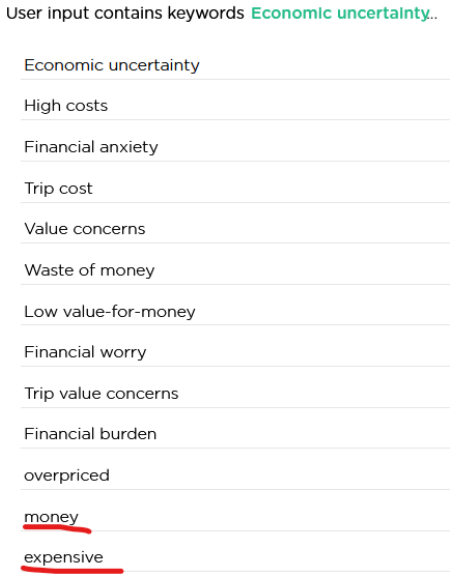

Fig. 17. European showcase keyword detected.

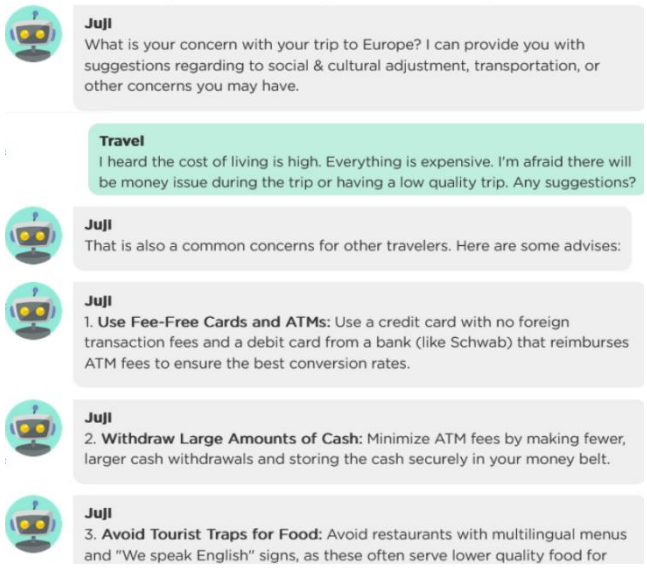

Fig. 18. European showcase solution reply.

As with all interactions, the chatbot presents a recurring prompt to determine if the user requires further consultation. In this demonstration, the user selects "no" to conclude the conversation, and the chatbot terminates the session (Fig. 19).

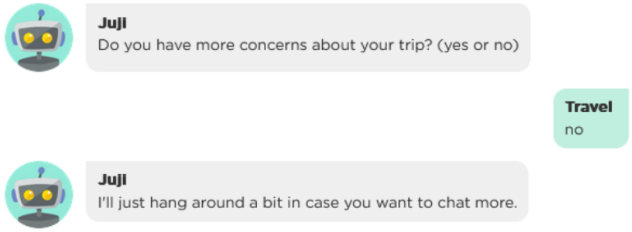

Fig. 19. European showcase recurring denied.

IV. Usability Evaluation

A. Usability Testing

The design of the tourist well-being chatbot is to provide information to tourists to ease their anxiety and to offer them professional advice through its expert-level knowledge base. Based on this goal, we designed the high-fidelity prototype and ran a usability test.

1) Evaluation participants: Seven participants were invited to participate in our experiments. Nelson (1993) recommended that as few as five users can effectively identify 85% of the usability issues associated with a particular technology [36]. Therefore, five college students from an East Coast university and two students from a Midwest university performed the tasks, filled out questionnaires and answered interview questions. They ranged in age from 21 to 28 (M=25.29, SD=4.96), and among them, four were male, and three were female.

2) Evaluation tasks: The experiments were conducted in the participants' natural environments to allow the participants' natural interaction with the chatbot. The participants were instructed to follow the guidance document to perform three tasks. We designed two parallel task sets: Version A (Europe, domestic, and Oceania) and Version B (Caribbean, East Asia, and the Middle East). The participants were randomly assigned to either Version A or Version B. Below is an example of Version A.

- Task 1: You are getting ready for a one-week trip to Europe. You've done some planning, but you still feel worried about something going wrong or something you don't know about this area.
- Task 2: You are planning a week-long trip to another city in the U.S. You are currently setting up your schedule and thinking about everything that could go wrong or be an unpleasant surprise on a big domestic trip.
- Task 3: You are imagining a ten-day trip to Oceania next summer. Since this is a huge, long trip far from home, you are super excited, but you are also very nervous about some big, unexpected things that could happen before or during the trip.

In order to further explore the participants' interaction with the chatbot, eleven short-answer survey questions were presented to each participant. The usability questions encompassed topics such as the chatbot's acceptance, usefulness [37], ease of use and memorability, emotional support, interaction flow, and improvements. The participants answered the questions with their experiences, thoughts, and feedback on the chatbot.

Usability-related inquiries aligned with Norman's usability goals were also presented in the following Likert-scale questions (7 is the highest) in order to retrieve quantitative data [38]. The questionnaire emphasized ease of use, effectiveness, problem-solving usefulness, learnability, emotional impact, and life and study support.

By exploring these questions, we aimed to demonstrate that the knowledge-based chatbot design provides users with effective and emotionally supportive information to help them solve problems and make decisions. By gathering valuable insights from the participants, we can also enhance the chatbot design, focusing on user needs and preferences to develop a user-centered tool for tourism purposes.

3) Pilot study: We conducted a pilot test to ensure the effectiveness of the tasks and questions. The purpose of the pilot test was to identify ambiguities in instructions and questions to enhance the clarity of the descriptions. One pilot participant was invited to complete the tasks and answer the questions. Updates were made based on the participant's feedback, such as rephrasing instructions, reordering questions, and removing similar questions.

4) Data analysis: The usability study collected qualitative and quantitative data through mixed methods, including empirical tasks and short-answer and Likert-scale survey questions. The short-answer data analysis followed the grounded theory and used the open-coding method. We used descriptive data analysis for the Likert-scale answers to determine the usefulness and ease of use of the chatbot. These qualitative and quantitative data analysis methods allowed us to obtain a comprehensive understanding of user feedback and needs for tourist-focused AI chatbot design.

V. Evaluation Results

We invited seven participants to evaluate the usability of the chatbot. The results from quantitative and qualitative analyses were consistent and reinforced one another. The results indicated that the participants confirmed the ease of use of this chatbot. They also reported the knowledge-based usefulness of the chatbot. They had diverse emotional experiences with the chatbot and tourist-centered improvement requirements.

A. Descriptive Data Analysis Results

The results from the Likert-scale questions indicated that the chatbot's usability was confirmed by the participants, for example, through its strong ease of use, which aligned with Davis (1989) usability goals [37]. The relatively small standard deviations demonstrated that the participants agreed with each other that the chatbot was easy to use. Participants believed the chatbot was useful, but not as strongly as its ease of use. Some participants felt emotionally supported, while emotional reassurance was inconsistent (see Table VII).

TABLE VII. Likert-Scale Questions

Likert-scale questions	*Mean*	*SD*
Easy to learn how to use the agent	6.43	1.13
Easy to get the agent to do what I want	5.29	0.95
Interacting is clear and understandable	5.86	0.90
Flexible to interact	5.00	0.82
Easy to become skillful at using the agent	6.00	1.53
Easy to use	6.29	0.95
Eases anxiety/ stress/ depression/ insomnia efficiently	4.29	1.89
Helps achieve student success	4.00	1.73
Improves problem solving	4.43	0.98
Enhances life quality	3.71	1.38
Provides better support for study/life	4.43	1.27
The agent is useful.	5.29	1.98

B. Themes from Short Answer Questions

The results of the short answer questions supported and further elaborated the Likert-scale answers. The participants strongly agreed that the chatbot was easy to use, learn, and remember. They also confirmed that it was useful, especially with its informative, context-based expert-like recommendations and multiple strategies. However, sometimes there was generic information due to technical limitations. There were diverse opinions about the chatbot's emotional support. Some participants believed it was helpful for travelers.

1) Ease of use: All the participants expressed that the usability of the chatbot was high with low effort.

Participant 4: "Not much effort, easy and quick."

Participant 3: "The process was very easy and simple to get a quality answer."

Participant 2: "The process was easy to get used to and understand."

2) Knowledge-based usefulness: The participants felt knowledge-based emotional assurance within the interactions. They also found strong informative problem-solving suggestions. They expressed that the chatbot provided them with contextually appropriate guidance.

For example, Participant 2 found that the chatbot's knowledge created trust and emotional comfort to him.

Participant 2: "The chatbot helped me in assuring myself and overcoming some of my anxieties. It explained what to do and why, and that made the situation feel more manageable."

The participants also expressed that the chatbot provided expert-depth answers. It also provided detailed, informative suggestions and different solutions to handle one situation.

Participant 5: "Yes, the Chatbot did give insightful answers. It gave suggestions for jet lag, such as adjusting sleep ahead of time, staying hydrated, and planning rest when you arrive, so once you're off the plane, you can prepare for the time difference."

Participant 4: "The 3rd gave the best advice because it was the most detailed. It didn't just say 'be careful,' it broke down what to do, what to expect, and what would actually help."

Participant 3: "Yes… it gave me many different solutions instead of just one answer, which I thought was really good because it considered different ways someone might handle the situation."

The participants expressed that the chatbot responded according to their specific travel situations and was tailored to the travel context.

Participant 7: "The first one… was the most helpful because it answered exactly what I asked and what I needed. It felt like it knew what travelers really go through and responded like someone experienced."

Participant 2: "The Oceania chatbot scenario gave me the best solutions. It addressed my worry directly and gave options I could realistically do while traveling."

However, due to technical limitations, Participant 1 found the answers were generic. These design flaws can be improved in future studies.

Participant 1: "They were generic answers… when I asked for something more specific… it restated my question, then moved on."

3) Emotional experience: The participants had diverse emotional experiences with the chatbot.

Participant 5: "I felt secure while talking with the Chatbot. It didn't ask for any deeply personal questions and it seems unbiased."

Participant 3: "The Chatbot made me feel less scared about travel… like someone was trying to talk me off the ledge."

Participant 7: "Simple and secure."

Participant 4: "Indifferent."

Participant 1: "It felt nonpersonal."

The results indicated that emotional impact was diverse. This aligned with our descriptive analysis that emotional support scores had higher variability.

4) Tourist-focused improvements: The chatbot was designed to focus on tourists' needs. Therefore, improvements were requested from the participants. They expressed that they would like more precise responses, smoother interaction flow, and richer functionality.

Participant 3: "Maybe have it budget trips for you and help you with the planning process."

Participant 2: "Maybe an addition of a precise location feature instead of a general area feature."

Participant 5: "The most helpful advice I received was how to stay away from high traffic areas, and the least helpful advice I received was how to engage in local activities because most of the time you can find that specific information on a website."

Participant 5: "The smoothest interaction was initially chatting with them, but reloading to a different chatbot was less smooth."

Participant 4: "To me, it seems like an extra feature for those who have anxiety when traveling."

Participant 1: "I think this could be sold as an added feature to a larger product, but not as a stand-alone tool. I'm not sure that travel anxiety is a large enough problem, that people will think of using a chatbot to help relieve anxiety, or that the chatbot has useful enough information to create demand."

In summary, through the usability testing, we confirmed that the chatbot could assist tourists by providing professional and informative suggestions and helping them make context-appropriate decisions. The participants' suggestions for improvements provided valuable insights to enhance the chatbot's functionality and usability.

VI. Discussion

Our study developed a knowledge-based chatbot to provide tourists with expert-level context-aware solutions. We also conducted usability testing to collect user feedback through short-answer and Likert-scale questions. The quantitative and qualitative data demonstrated that users strongly agreed that this chatbot was easy to use. They stated its usefulness derived from its informative, expert-level, contextually appropriate, multifaceted strategies.

However, the participants reported varied emotional experiences toward the chatbot. Some of the participants

indicated that the chatbot provided emotional reassurance. Some participants reported that the chatbot felt impersonal. We acknowledge that part of the reason was due to the technical challenges we encountered, which actually limited the functions of the chatbot. Yet our purpose was to demonstrate a tourism chatbot that can mitigate tourist anxiety through knowledge-based design. In addition, our design highlighted the importance of context-sensitive design that could support users in making decisions when context is a serious challenge to most chatbots.

One of the limitations of this study lies in the small sample size. However, as mentioned in the previous paragraph, Nelson (1993) stated that only five participants could identify 85% of the usability issues [36]. Therefore, these seven participants were enough to evaluate the chatbot system. The participants' diversity was limited to only university students. However, this young group represents an active and frequent group of tourists. They are also sophisticated in AI technologies, which makes them a suitable group to evaluate an AI chatbot. Moreover, four of the participants were tourism-major students. Their insights from their expertise were valuable for the design. We believe the findings may inform broader tourism applications.

VII. Conclusion

Our work aims to provide tourists with a knowledge-based expert-level chatbot to ease their travel anxiety and help them make decisions. Based on the qualitative and quantitative user feedback results, we confirmed that the chatbot was easy to use and perceived as useful due to its knowledge base, context awareness, and multifaceted strategies. However, users reported different emotional experiences while interacting with the chatbot. They also expressed expectations for precise responses, smooth interactions, and rich functions.

Future work will focus on advancing the knowledge-based prototype integrated into GPT. It will enable us to provide expert-level recommendations while retaining the generative function of the large language model. Future work aims to combine structured domain knowledge with prompt-based control. Moreover, some participants pointed out that this chatbot could serve as an additional feature within a broader integrated travel chatbot system. Therefore, future development will aim to integrate our travel anxiety design with existing travel platforms. This approach is practical for real-world adoption, enabling existing travel chatbots to incorporate anxiety modules.

This study demonstrates how a knowledge-based chatbot system supports tourists' decision-making with a user-centered approach. It contributes empirical evidence to AI research that a knowledge-based chatbot can provide expert-level, context-aware, multifaceted suggestions to tourists. We hope these findings will inspire designers and researchers to continue advancing knowledge-based, context-aware tourism support systems.

Towards Robust Intrusion Detection: Exploring Feature Selection, Balancing Strategies, and Deep Learning for Minority Class Optimization

Khalid LABHALLA, Amal BATTOU
Faculty of Science-IRF-SIC Laboratory, Ibn Zohr University, Agadir, Morocco

***Abstract*—The increasing connectivity of systems and the rapid growth of the Internet have intensified cybersecurity threats. It has been demonstrated that conventional signature-based intrusion detection methods are deficient, especially against Zero-Day attacks. An alternative approach involves the deployment of Intrusion Detection Systems (IDS) that are based on deep learning algorithms. However, these systems face a significant challenge in detecting minority classes of attacks, such as Remote-to-Local (R2L) and User-to-Root (U2R) attacks, which, although rare, are of critical importance. Misclassifying these attacks is costly. Therefore, the reduction of false negatives is achieved by coupling feature selection techniques (Chi square, correlation, information Gain, Extreme Gradient Boosting (XGBoost), Autoencoder), oversampling methods (Synthetic Minority Oversampling Technique (SMOTE), Adaptive Synthetic Sampling (ADASYN)) and deep learning models (Deep Neural Network (DNN), Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM) and hybrid model CNN LSTM). The present study uses the NSL-KDD dataset, with a particular focus on the minority classes R2L, which represents 2.61% of the dataset, and U2R, representing 0.08% of the dataset. The findings indicate that data balancing is paramount. ADASYN facilitates 100% U2R detection, while SMOTE enhances R2L accuracy to above 95%. The application of correlation and autoencoder feature selection techniques proved to be the most effective. The effectiveness of CNN models in addressing U2R classification tasks has been extensively demonstrated, while the use of DNN or CNN-LSTM models has been shown to yield optimal results for R2L tasks. DNN remains the most stable model overall. For the two minority classes, the most effective pipelines are Correlation + SMOTE + DNN, achieving 93.84 % recall for U2R and 99.88 % for R2L, and Autoencoder + SMOTE + CNN-LSTM, achieving 89.66 % recall for R2L and 99.68 % for U2R.**

I. Introduction

The Internet connects most of our computer systems, and our social life today is deeply linked to the Internet, which increases security threats in various ways. Targets range from financial platforms and e-commerce or governmental institutions to major corporations, attacked for economic gain or ideological motives. Cisco projects that the number of Distributed Denial of Service (DoS) [1] incidents will reach 15.4 million in 2023 [2]. Companies are expected to devote nearly 6.69 billion USD to cloud security in 2023, an increase of roughly 27 % over the previous year. According to Gartner's reports, published at the end of 2024, global spending on information security is expected to reach 183 billion USD, and then to grow steadily at a compound annual growth rate (CAGR) of 11.7% between 2023 and 2028 [3]. The costs of damage caused by cybercrime are expected to rise from 3 trillion USD in 2015 to 10.5 trillion USD in 2025 [4]. In this context, and to improve intrusion detection systems (IDS), several approaches have been developed, notably machine learning-based approaches, in order to address the shortcomings of signature-based IDS, which are very limited against zero-day attacks [5].

Among data-driven approaches, deep learning has emerged as a powerful tool for IDS due to its capacity to model complex, nonlinear relationships in high-dimensional data. Various deep learning architectures, including Deep Neural Network (DNN), Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM), and a hybrid CNN-LSTM model, have shown promising results in identifying sophisticated attack vectors. However, one of the most pressing and unresolved challenges in deep learning-based IDS is the class imbalance problem, the training data for the majority class significantly outnumbers that of the minority class [6]. Well-known IDS datasets such as NSL-KDD inherit this imbalance issue from their predecessors. Specifically, the Remote-to-Local (R2L) and User-to-Root (U2R) attack categories constitute a very small fraction of the total samples, accounting for only 2.61% and 0.08% of the dataset, respectively. In contrast, classes such as normal connections and DoS attacks dominate the dataset. This severe imbalance leads to biased learning where the models tend to favor majority classes, resulting in high false negative rates for minority classes. These false negatives are particularly concerning because they correspond to stealthy and potentially severe intrusions that evade detection. Several techniques have been proposed to address class imbalance in IDS, including oversampling or undersampling methods, cost-sensitive learning, deep learning models, or hybrid methods. Among resampling techniques, Synthetic Minority Oversampling Technique (SMOTE) and Adaptive Synthetic Sampling (ADASYN) are two of the most commonly used methods for generating synthetic examples of minority class instances. These methods aim to rebalance the dataset distribution and enhance the learning capability of classifiers for rare attack types.

Another key component influencing detection performance is feature selection. Effective feature selection helps reduce the dimensionality of input data, eliminates irrelevant or redundant features, and highlights the most informative attributes. This is especially crucial in IDS, where the presence of noisy or non-

discriminative features can degrade the model's ability to detect subtle attacks. This work employs a dual strategy that incorporates both statistical and machine learning-based feature selection techniques. The statistical methods include the Chi-square test, Pearson correlation, and Information Gain, all of which evaluate feature relevance based on individual relationships with the target class. On the other hand, Extreme Gradient Boosting (XGBoost) is used to rank features based on their predictive contribution within tree-based models, while an Autoencoder, a neural network designed for unsupervised representation learning, is used to extract low-dimensional embeddings that preserve the most salient data characteristics. In this study, a comprehensive framework is presented to explore how different combinations of feature selection techniques, data balancing methods, and deep learning architectures impact the detection performance of minority classes in IDS.

Our models will be evaluated using the NSL-KDD dataset, and recall will be chosen as the primary evaluation metric, as the main objective is to improve intrusion detection performance by reducing false negatives for minority classes while maintaining a high detection rate for majority classes. In addition, other evaluation metrics such as F1 score and precision will also be measured to provide a more comprehensive assessment of model performance. The proposed models were evaluated and compared with approaches from recent studies. In order to determine the most effective combination of key components in the design of an intrusion detection system (IDS), namely the feature selection method, class balancing technique, and learning algorithm, a total of 72 different models were evaluated. Our contributions can be summarized as follows:

- Systematic evaluation of feature selection techniques: Three statistical methods are compared (Chi-square, Pearson correlation, and Information Gain) with two machine learning-based approaches (XGBoost and Autoencoder) to analyze their influence on minority class detection in NSL-KDD.
- Investigation of data balancing methods: Both SMOTE and ADASYN are applied to address the class imbalance and evaluate their impact across different DL models.
- Comparative analysis of deep learning models: The effectiveness of four deep architectures: DNN, CNN, LSTM, and CNN-LSTM is addressed under different feature and data configurations.
- Optimization of detection pipelines for minority classes: Optimal combinations are identified for each minority class. For U2R, several combinations achieved perfect detection performance (100% recall). For R2L, the combination Correlation + SMOTE + DNN yields over 96.58% accuracy with high stability.

Despite significant advances in deep learning-based intrusion detection systems, most existing work focuses on performance improvements achieved through combinations of feature selection techniques, class rebalancing, and deep learning models. However, these approaches suffer from poor generalizability of results, which are often evaluated on a limited number of configurations or metrics. In particular, few studies offer an in-depth and reproducible analysis to identify robust and consistent pipelines for the reliable detection of critical minority classes, such as R2L and U2R, in our case study.

The experiments were conducted on the NSL-KDD dataset, widely used in IDS literature due to its balanced structure for comparative evaluation and the presence of highly minority attack classes such as R2L and U2R. This dataset is a relevant test bed for analyzing the effectiveness of rebalancing techniques and deep learning models in the face of severe imbalances. Its use also allows for direct comparison with numerous previous studies. In this study, the macro-average metric was adopted as the primary measure of overall performance. This choice was motivated by the highly imbalanced nature of the NSL-KDD dataset, where majority classes such as Normal and DoS dominate, while minority classes such as R2L and U2R represent a very small portion of the data.

The rest of this study is organized as follows: Section II reviews related work on intrusion detection systems and concludes with a comparative analysis of the proposed model and recent studies. Section III provides a detailed scenario of our approach. Section IV draws result and discussion. Finally, Section V presents a conclusion.

II. Related Works

The concept of intrusion detection systems has been extensively explored in the literature that reflects both the complexity of the subject and the diversity of methodological approaches explored. Research efforts have primarily focused on two critical dimensions: enhancing detection accuracy by reducing false positives, and enabling real-time intrusion detection, particularly within large-scale data environments [7]. In this context, the following section provides an overview of existing work that leverages machine learning techniques to support real-time processing capabilities.

The authors in [8] proposed the CWFLAM-VAE architecture by integrating Class-Wise Focal Loss, Extreme Gradient Boosting, and a Variational Autoencoder. The framework synthesizes rare-class attack samples while faithfully maintaining the original feature distributions. It was tested on NSL-KDD and CSE-CIC-IDS2018 datasets, and it reached F-scores of 97.6% and 98.1%, while [9] proposes a three-layer approach to improve the detection of minority attacks in intrusion detection systems. The first layer uses a weighted deep neural network (WDNN) to detect suspicious traffic. The second layer employs a CNN and an LSTM to classify attacks as majority or minority. Finally, the third layer applies XGBoost to refine the classification of minority attacks. Undersampling (unilateral selection) and oversampling (ADASYN) optimize class balance. The system achieves an accuracy of over 97.9% on the NSL-KDD dataset. Undersampling (unilateral selection) and oversampling (ADASYN) optimize class balance. The system achieves an accuracy higher than 97.9% on the NSL-KDD dataset. The work in [10] overcame the limitations of traditional methods in detecting minority class attacks by a multimodal approach based on deep learning and GANs to generate high-quality attack samples. A specialized model then learns their features, and an integrated classifier performs multi-class classification. Tested on CICIDS2017 and NSL-KDD, this

method achieves up to 99.96% accuracy with a low false positive rate (3.4%) on the NSL-KDD dataset. Another method proposed in the article [11] proposed a feature selection method (feature ranking) based on the correlation and entropy (information gain) of each feature. After ranking, the features are partitioned into three subsets for each method. Information-Gain attributes form IG-1, IG-2, and IG-3, while correlation-based attributes form CR-1, CR-2, and CR-3. IG-1 and CR-1 contain the ten highest-ranked features (positions 1–10); IG-2 and CR-2 contain those ranked 11–30; and IG-3 and CR-3 contain the remainder. A new feature set is created by combining IG-1 and CR-1, and by intersecting IG-2 and CR-2, while discarding all features in IG-3 and CR-3. The resulting selection is evaluated on five datasets, with both per-dataset and average results reported. The proposed model improves recall, increasing it from 81% without feature selection to 86% with the proposed method for the minority class U2R. A network intrusion detection system based on deep learning and using a chaotic optimization strategy proposed by the authors in [12], after preprocessing and balancing the dataset using the Extended Synthetic Sampling method, features were extracted from the dataset using kernel-assisted principal component analysis. The Chaotic Honey Badger Optimizer first identified the most informative feature. These selected features were then fed into the gated-attention dual-LSTM (Dugat-LSTM) model to classify the attacks, achieving a recall of 98.76% on the NSL-KDD dataset.

The work in [13] tried to improve the IDS by proposing a system based on two phases of classification. The first phase consists of using three variants of the Naive Bayes classification method (categorical, Bernoulli, and Gaussian) for each type of data (nominal data, binary data, and real or integer data), respectively. The second phase of classification consists of using unsupervised elliptic envelope classification to predict whether the behavior is normal or anomalous. The elliptic envelope is a machine learning method for anomaly detection. It is based on modeling the data distribution using the theory of the elliptical envelope. The goal is to identify data points that are distant from the main distribution, assuming that the latter follows an elliptical distribution. This method is particularly useful for detecting anomalies in multivariate data, i.e., data with multiple features. After the second phase, they obtained an accuracy of 97% on the NSL-KDD dataset, 86.9% on the UNSW_NB15 dataset, and 98.59% on the CICIDS2017 dataset. However, accuracy for the minority classes remains modest; for example, on the NSL-KDD dataset, the U2R and R2L classes achieved precisions of 40.29% and 58.4%, respectively. The comparison of authors in [14] showed that synthetic oversampling SMOTE with the Random Forests model enhances R2L and U2R detection on NSL-KDD.

Another way to improve the detection of minority classes is proposed in [15] by applying two oversampling and two undersampling techniques to balance the dataset. Five machine learning models, including XGBoost and CatBoost, are evaluated using grid search and 10-fold cross-validation. The results confirm that resampling improves classification performance across models. Among them, XGBoost with SMOTE achieves the best results, with an accuracy of 75% and a weighted F1-score of 78%.

In [16], the authors combine ADASYN oversampling to address class imbalance with the LightGBM model. Experiments on NSL-KDD, UNSW-NB15, and CICIDS2017 demonstrate improved detection rates for minority attacks. The method achieves high accuracy 92.57%, 89.56%, and 99.91% in the three test sets. Improving the minority class in poorly balanced datasets was also a challenge for the authors in [17], who implemented a deep neural network trained and tested on the CICIDS-2017 and CICIDS-2018 datasets. Chi-square and correlation are two proposed statistical methods for feature selection methods statistical proposed. The findings indicate that certain coarse-grained features are highly discriminative, enabling the complete and accurate detection of attacks represented by as few as three instances. In reference [18] proposed to improve the detection for minority classes by a hybrid approach. This approach is a combination of SMOTE) technique and Tomek's links for reducing noise. Furthermore, to strengthen the performance of the intrusion detection system, the study harnesses two deep learning architectures, LSTM networks and CNNs. The approach was evaluated on the NSL-KDD and CICIDS-2017 benchmarks. For NSL-KDD multiclass classification, the LSTM configuration achieved 99.57 % accuracy and a 98.98 % F-score, while the CNN reached 99.70 % accuracy and 99.27 % F-score. On CICIDS-2017, the LSTM attained 99.82 % accuracy with a 98.65 % F-score, and the CNN obtained 99.85 % accuracy and a 98.98 % F-score. Authors in [19] focused on improving IDS detection rates by combining advanced t-SNE for feature extraction with intelligent classification methods. A hybrid model is proposed, integrating Genetic Fuzzy Systems (GFS) with Generative Adversarial Networks (GANs) in a paired learning framework. The proposed model was evaluated on TII-SSRC-23 and NSL-KDD datasets, attaining detection accuracy of 99.23% and 99.13%, respectively, to identify the most informative attributes.

Table I shows that our methodology, which systematically searches for the optimal combination of leading feature selection techniques, data-balancing strategies, and deep-learning algorithms, outperforms previous work by a considerable margin. The results further reveal that correlation analysis is the most stable and universally suitable statistical method, delivering strong performance irrespective of the balancing technique or model used. The DNN architecture appears in several of the best-performing combinations, highlighting its importance for this kind of problem. Finally, the autoencoder remains a particularly robust option, especially when paired with an LSTM model or the hybrid CNN-LSTM architecture.

TABLE I. COMPARES RESULTS FROM THE NSL KDD DATASETS TO OTHER ADVANCED TECHNIQUES

Work	R2L Recall (Value in %)	U2R Recall (Value in %)

III. PROPOSED METHODOLOGY

The aim of this study is to identify the best possible combination of feature selection algorithms, class balancing techniques, and deep learning models to improve the performance of intrusion detection systems (IDS). The main objective is to reduce the false negative rate, particularly for minority classes such as R2L and U2R, which are often poorly detected in conventional approaches. My approach is based on a systematic analysis of several pipelines combining different selection methods (such as Chi2, Correlation, Information Gain, or Autoencoder), several balancing strategies (such as SMOTE and ADASYN), and various deep learning models (DNN, CNN, LSTM, or CNN-LSTM). By evaluating these combinations according to precise metrics such as recall, which is the most relevant indicator for assessing the reduction of false negatives, the study aims to determine the most effective synergies for strengthening the detection of rare attacks and minimizing critical errors that compromise the reliability of modern IDSs.

To improve the detection of minority classes and reduce false negatives in an intrusion detection system, the study proposes a methodology based on five main phases:

- Data Pre-processing
- Feature Selection
- Class Rebalancing
- Applied Deep Learning Models
- Performance Evaluation

As shown in Fig. 1, first, the dataset is downloaded and prepared by removing duplicates and outliers and handling missing values. The data is then converted to hot encoding and normalized. This pre-processing step ensures a clean, consistent, and usable basis for downstream methods. The second phase focuses on feature selection, in which statistical approaches are applied. such as chi-2, correlation, and information gain, and approaches based on supervised learning, such as XGBoost, and unsupervised learning, such as Autoencoder for non-linear reduction with a dual objective: to reduce the dimension to limit overfitting and improve model efficiency, while retaining the relevant signal for rare classes. This phase produces five variants derived from the dataset, each corresponding to a different selection technique.

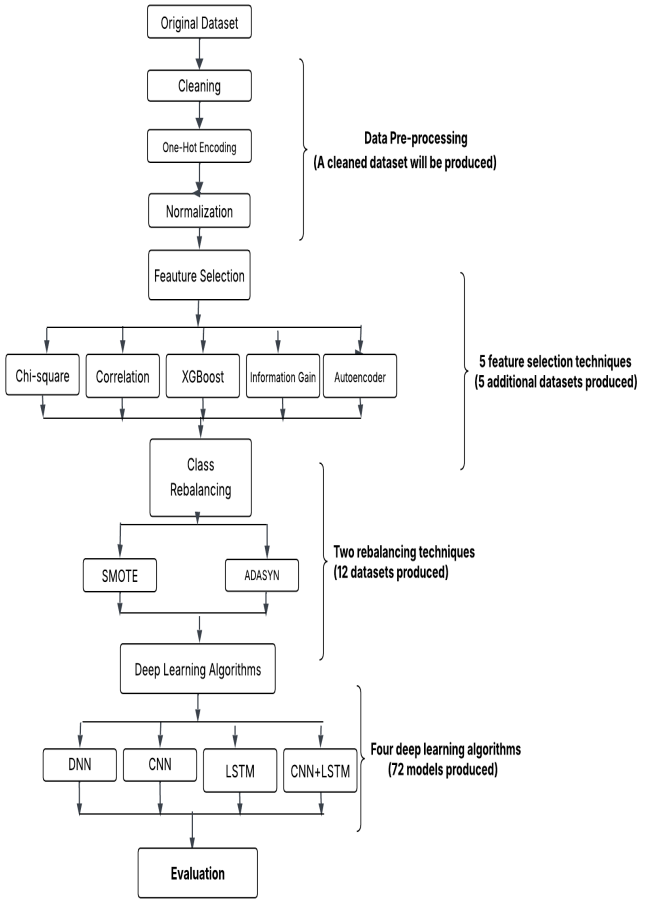

Fig. 1. Proposed methodology.

Then, faced with class imbalance, particularly U2R, which accounts for only 0.08% of the dataset, and R2L, which accounts for only 2.61%, resampling techniques such as SMOTE and ADASYN are applied in conjunction with each feature selection technique in order to identify the optimal balancing strategy and the feature selection methods that optimize it. At the end of this stage, twelve additional dataset variants are generated, each resulting from the combination of two rebalancing strategies with the five feature selection methods.

Finally, deep learning models (DNN, CNN, LSTM, hybrid CNN-LSTM architectures) are trained on the eighteen pre-processed and balanced versions from the previous phase in order to build 72 well-trained models with hyperparameter search and threshold calibration to prioritize the detection of minority classes. The evaluation phase of the 72 models is based on recall metrics, which provide a good indicator of false negative reduction.

The objective of this research is to propose a rigorous ranking of the most effective combinations and pipelines between feature selection, balancing strategy, and learning model. This ranking serves as a practical guide, indicating for each imbalance scenario which feature selection + balancing pairs and which deep learning algorithms offer the best performance in order to provide operational and sustainable recommendations for improving intrusion detection, particularly for minority classes, and to ensure their transferability to other corpora and network environments.

To this end, 72 different models resulting from the combination of five feature selection methods, two data balancing techniques, and four deep learning algorithms are tested. All experiments were conducted on the NSL-KDD benchmark dataset, with recall chosen as the main evaluation metric, since the primary objective is to improve the detection of minority attack classes while maintaining strong performance on majority classes.

A. Dataset Description

The first step in data preparation consists of downloading and loading the dataset. The dataset chosen to evaluate the effectiveness of the proposed models is the NSL-KDD dataset, which is a benchmark dataset commonly used for evaluating intrusion detection systems (IDS). The NSL-KDD dataset is composed of 41 features that represent a network connection. The features of the NSL-KDD dataset are categorized into four groups [26]:

- Basic feature group (No. 1 to 9).
- Content feature group (No. 10 to 22).
- Time-based traffic feature group (No. 23 to 31).
- Host-based traffic feature group (No. 32 to 41).

The loaded NSL-KDD dataset contains 148,517 records. There are four main categories of attacks represented in the dataset, as detailed in Table II, namely: DoS, R2L, U2R, and Probe.

The NSL-KDD dataset suffers from a significant class imbalance, which skews learning algorithms in favor of majority cases and limits their ability to model rare cases. Fig. 2 displays the percentage distribution of the NSL-KDD dataset by class.

TABLE II. MAIN ATTACKS CATEGORY PRESENTED IN NSL-KDD

Attack Category	Attack Type
DoS (Denial of Service)	Neptune, land, pod, smurf, teardrop, back, worm, udpstorm, processtable, apache2
Probe	ipsweep, satan, nmap, portsweep, mscan, saint
R2L	ftp_write, guess_password, imap, multihop, phf, spy, warezclient, warexmaster, snmpguess, named, xlock, xsnoop, snmpgetattack, httptunnel, sendmail
U2R	buffer_overflow, loadmodule, perl, rootkit, ps, xterm, sqlattack

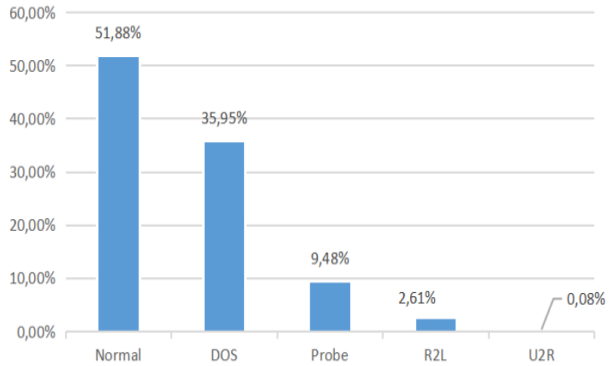

Fig. 2. NSL-KDD dataset distribution by class.

B. Data Pre-Processing

Data pre-processing is a crucial step, especially in intrusion detection systems. This phase aims to improve the quality of the dataset by cleaning, normalizing, and hot-encoding features. The cleaning process consists of removing duplicates and handling missing values, while hot-encoding converts each categorical feature value into a binary vector in which only one element is set to 1, and all other elements are 0. The element with a value of 1 indicates the presence of a specific category corresponding to the categorical feature. For example, the label (target) attribute in the NSL-KDD dataset has five distinct values: normal, DoS, Probe, R2L, and U2R. Using one-hot encoding, 'normal' can be represented with (1, 0, 0, 0, 0).

The values in the dataset consist of numerical features with completely different scales, which can vary significantly. Therefore, it is necessary to reduce these scale differences; this is where normalization comes into play. The normalization method adopted in this work is the min-max scaling, which transforms the dataset values into the range [0, 1]. This process helps improve the performance of the learning model.

In this experiment, numerical features in the NSL-KDD dataset are normalized using Min–Max normalization, as defined in Eq. (1), which is one of the most commonly used normalization techniques.

$$\tilde{\mathbf{x}} = \frac{\mathbf{x}-\mathbf{Min(x)}}{\mathbf{Max(x)}-\mathbf{Min(x)}} \quad (1)$$

where, $\tilde{x}$ is the normalized value of x.

C. Feature Selection

Feature selection is an important step in the machine learning process after data cleaning and normalization, as it aims to identify the most relevant or informative features. It can help eliminate noise and reduce dimensionality in order to improve model performance. This process reduces the dimensionality of the data, enhances model accuracy, and decreases computational time. There are several techniques for feature selection. This study considers five feature selection techniques based on two main approaches: statistical approaches like chi-square test, correlation, and information gain, and learning-based approaches like XGBoost and AutoEncoder.

- Chi-square [22,27]: By applying the Chi-square statistical test to our dataset, the method selected 20 out of 41 features, resulting in a 51.22% reduction. The number of top features to select, k, was treated as a hyperparameter and tuned over the candidate set {10, 13, 15, 18, 20, 23, 25, 28, 30, 33, 35, 38}. Based on cross-validation, k=20 yielded the highest accuracy and was therefore adopted for the final model.
- Correlation [28]: The calculated correlation values were sorted in descending order, and all features with a correlation close to 1 are selected (above the threshold of 0.9). This threshold was manually tuned to achieve the best performance. This method selected 35 out of 41 features, yielding approximately a 14.62% reduction.
- Information Gain [29]: For information gain, the features whose values were greater than 0.17 are selected, resulting in 21 retained features, resulting in a 48.78% reduction of the dataset.
- XGBoost [30,31]: In XGBoost, the features with importance values between 1224 and 100 are selected, which led to the selection of 22 features, a 46% reduction.
- Autoencoder [32]: An optimal size for the low-dimensional representation is determined while maintaining a reasonably low reconstruction error. The encoding_dims hyperparameter was tuned over the range (15, 42), and the lowest reconstruction error Mean Squared Error (MSE) was achieved with 35 latent dimensions, yielding 35 retained features, achieving a 31% reduction.

These methods allowed us to generate five different variants of the NSL-KDD dataset, and the result is detailed in Table III.

TABLE III. NUMBER OF FEATURES RETAINED FOR EACH FEATURE SELECTION METHOD

Datasets	Number of features
Original	41
Chi 2	20
Correlation	35
Information Gain	21
XGBoost	22
AutoEncoder	35

D. Class Rebalancing

The dataset is well-cleaned, meaning it contains no missing or redundant information. However, it suffers from class imbalance. As a result, the learning algorithms gravitate toward the majority class, limiting their ability to recognize infrequent, yet highly damaging intrusions such as U2R and R2L attacks. To address the class imbalance problem, this work applies approaches based on two techniques:

1) SMOTE (Synthetic Minority Oversampling Technique) [33]: SMOTE enables the creation of new synthetic instances by linearly interpolating the features of neighboring minority instances. The SMOTE balancing technique selects a minority sample, then randomly chooses one or more of its nearest neighbors to generate synthetic instances. The SMOTE hyperparameter k_neighbors = 3 was chosen manually from the candidate values {2, 3, 4}.

2) ADASYN (Adaptive Synthetic) [34]: ADASYN also generates synthetic data for minority instances but places more emphasis on the samples that are harder to learn, based on their relative density. Minority instances that are farther from the decision boundary are prioritized for synthetic data. For ADASYN, the sampling strategy is set to target the minority class, meaning that only the minority class is oversampled.

E. Deep Learning Models Applied

Following data cleaning, feature selection, and dataset balancing, the resulting datasets are used to train four different neural network models:

The first model, a DNN, is a type of standard artificial neural network composed of multiple layers of neurons. Each layer is connected to both the preceding and the following layer, forming a layered architecture [35]. This study proposes a DNN model composed of an input layer followed by two hidden layers: the first with 32 neurons and the second with 16, both using the ReLU activation function. The final output layer contains 5 neurons, one per class, with a Softmax activation function to support multi-class classification.

The second model is the CNN, which is capable of handling complex data, something that is often not feasible with traditional DNNs [31]. The primary goal of a CNN in this context is to extract important features from raw network data. During this process, the earliest layers serve as convolutional feature extractors, convolving the input with learned filters. Our CNN model consists of an input layer, a one-dimensional convolutional layer with 32 filters of size 3 and ReLU activation, followed by a MaxPooling layer (pool size = 2), a flattening layer, and a fully connected layer of 16 units employing the ReLU activation function. It ends with an output layer of 5 neurons using the Softmax activation function.

The third model LSTM, as described in [36], is an improved type RNN engineered to alleviate both vanishing and exploding gradient problem. These issues arise during back propagation when gradients either shrink too much or grow too rapidly, making it difficult to update weights properly and often leading to the failure of the learning process. LSTM composed of three main components called gates: the forget gate, input gate, and output gate [37].

The LSTM model used in this study consists of two LSTM layers: the first with 16 units and L2 regularization to reduce overfitting, followed by a second LSTM layer with 8 units. The output is then flattened and passed to a Softmax-activated layer with 5 neurons.

Finally, a hybrid CNN-LSTM model is developed, combining convolutional and recurrent components. It starts with an input layer followed by a 1D convolutional layer (32 filters, ReLU), a MaxPooling layer (size 2), then a second convolutional layer (16 filters, ReLU) and another MaxPooling layer. The extracted features are passed through two stacked LSTM layers (16 and 8 units, respectively), with the second one configured to return only the final output. The network concludes with a flatten layer and a Softmax output layer with 5 neurons. Each architecture was specifically designed to explore how spatial, temporal, and hybrid feature learning impacts the detection of various types of intrusions.

For all four deep learning models, a consistent set of training parameters was applied. Specifically, the loss function used is 'categorical_crossentropy', while the optimizer selected is 'adam'; the model performance was monitored using 'accuracy' as the evaluation metric during both training and validation phases. Each model was trained over 100 epochs with a batch size of 32 to ensure stable convergence.

IV. Results and Discussion

This section analyzes and compares the performance of the different models by conducting our experiments on the benchmark NSL-KDD dataset. The NSL-KDD dataset consists of 41 features that describe a network connection and contains a total of 148 517 records. However, to address the issue of class imbalance, only 58 397 records are selected for the experiments. These records are distributed and detailed in Table IV.

TABLE IV. Distribution of the Number of Records Per Class

Attacks type	Number of Records in the Dataset	Number of Records Selected for the Experiments
No attacks (normal)	77054	20034
Dos attacks	53387	20287
Probe attacks	14077	14077
R2L attacks	3880	3880
U2R attacks	119	119

TABLE V. Number of Records Per Class and Per Balancing Technique

	SMOTE	ADASYN
Normal	20287	20287
DoS	20287	20034
Probe	20287	14077
R2L	20287	3880
U2R	20287	20304

For both balancing techniques, SMOTE and ADASYN, were applied to each of the six dataset variants generated during the feature selection phase, resulting in 12 additional datasets: 101 435 records for SMOTE and 78 550 records for ADASYN, distributed as in Table V.

The training of the four neural networks was performed on the 18 datasets produced during the feature selection and sampling phases, resulting in a total of 72 models and the main goal of IDS is to minimize false negatives, which represent undetected attacks and pose a significant security risk. Therefore, to evaluate the performance of the 72 models, recall is used, defined by Eq. (2), as the key metric, as it is crucial in IDS.

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

Other evaluation metrics that were used, other than recall, precision, defined by Eq. (3), and F1-score defined by Eq. (4):

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

$$F1-score = \frac{2\ .Precision\ .Recall}{Precision+\ Recall} \quad (4)$$

where,

- TP (True Positives): correctly detected intrusions.
- FN (False Negative): intrusions that were not detected.
- FP (False Positive): A benign event incorrectly flagged as intrusion (false alarm).

As previously mentioned, the NSL-KDD dataset often suffers from class imbalance, where certain types of attacks, particularly R2L and U2R, are significantly underrepresented compared to majority classes such as normal connections or DoS attacks. Our objective is to improve IDS performance by reducing false negatives in these minority classes, which are the most harmful, by finding the optimal combination of feature selection techniques (Chi2, Correlation, Information Gain (IG), XGBoost, and Autoencoder), two dataset balancing techniques (SMOTE and ADASYN), and deep learning neural network models (DNN, CNN, LSTM, and CNN-LSTM).

Therefore, the evaluation results will focus on the recall metric for the two minority classes: R2L, which accounts for 2.61% of the dataset, and U2R, which accounts for 0.08%. Table VI shows the results obtained on the NSL-KDD dataset variants for the R2L class using only feature selection techniques without any data balancing.

TABLE VI. Recall Scores by Different Models on the R2L Class With and Without Feature Selection

	DNN	CNN	LSTM	CNN-LSTM
Chi2	0.82	0.70	0.59	0.81
Correlation	0.91	0.84	0.63	0.87
Information Gain	0.62	0.46	0.47	0.73
XGBoost	0.89	0.91	0.80	0.82
Autoencoder	0.92	0.90	0.89	0.85
Origine	0.90	0.90	0.88	0.94

The results in Table VI show that without any feature selection or data balancing techniques, the CNN-LSTM hybrid model is the best choice, achieving a recall of 94% for the R2L

class. Comparing these results with those obtained using feature selection techniques, it is observed that the autoencoder combined with the DNN model produces the best results among all feature selection methods, achieving 92%. The correlation method is also achieving a recall of 91 % for the R2L class with the DNN model. It is also worth noting that the Chi-square method, despite selecting only 20 features, provides good results, especially with the DNN and CNN-LSTM models with the recall reaches 82% and 81%, respectively. In contrast, the Information Gain method yields the worst performance across all models, indicating that it likely discards critical features necessary for detecting R2L attacks. Therefore, this technique is not recommended for this class.

Table VII presents the recall model results for the U2R class, the most underrepresented in the dataset, accounting for only 0.08% of the data, with and without feature selection. The results show that the U2R class is extremely sensitive to feature selection methods. Without any selection, all models yield almost the same result, with a slight advantage for the hybrid CNN-LSTM model, with 45%. It is also observed that the Chi-square selection method with just 20 features was able to reach 42% with the LSTM model, like the correlation method with the DNN model. On the other hand, the Information Gain and XGBoost methods should be avoided, as they result in a significant loss of critical information for this class.

TABLE VII. RECALL SCORES USING DIFFERENT MODELS ON THE U2R CLASS WITH AND WITHOUT FEATURE SELECTION

	DNN	CNN	LSTM	CNN-LSTM
Chi2	0.32	0.29	0.42	0.39
Correlation	0.42	0.39	0.39	0.32
Information Gain	0.00	0.00	0.06	0.00
XGBoost	0.10	0.10	0.06	0.00
Autoencoder	0.23	0.29	0.32	0.00
Origine	0.42	0.39	0.42	0.45

Table VIII, Table IX and Table X show the results for DNN with autoencoder feature selection technique, the hybrid model CNN-LSTM without selection feature method, LSTM with chi-square selection feature method, and DNN with correlation feature selection method, respectively. The results reveal that, when the dataset is left unbalanced, the U2R minority class is poorly detected. Nevertheless, the overall performance remains strong when correlation-based feature selection is combined with a DNN model, indicating that this pairing effectively mitigates part of the imbalance problem and yields solid results across the remaining classes. The low results obtained for the minority classes have influenced the macro-avg F1-score, which reached around 80%, leading to a relatively modest overall value. However, the majority of classes achieved excellent detection rates, exceeding 90%.

The results show that, without applying any balancing technique, the correlation-based feature selection method provided the best performance, achieving over 98% F1-score for the majority classes and a macro-avg F1-score of approximately 87%. This demonstrates that even without resampling, the correlation method effectively captures the most discriminative features, ensuring strong detection performance across most classes.

TABLE VIII. PERFORMANCE OF THE DNN-BASED MULTICLASS CLASSIFICATION ON THE NSL-KDD DATASET USING AUTOENCODER WITHOUT BALANCING TECHNIQUES

Class	Precision	Recall	F1-mesure
Normal	0.99	0.98	0.99
DoS	0.97	0.94	0.95
Probe	0.97	0.99	0.98
R2L	0.78	0.92	0.85
U2R	0.64	0.23	0.33
Macro avg	0.87	0.81	0.82

TABLE IX. PERFORMANCE OF THE CNN-BASED MULTICLASS CLASSIFICATION ON THE NSL-KDD DATASET WITHOUT ANY FEATURE SELECTION METHOD

Class	Precision	Recall	F1-mesure
Normal	0.99	0.99	0.99
DoS	0.98	0.95	0.97
Probe	0.98	0.98	0.98
R2L	0.81	0.94	0.87

R2L	0.88	0.91	0.89
U2R	0.65	0.42	0.51
Macro avg	0.90	0.85	0.87

Table XI presents the recall obtained for the R2L class after applying the SMOTE balancing technique to the six NSL-KDD dataset variants produced following the feature selection phase. The results in show that after applying the SMOTE balancing technique, almost all recall values improved for the R2L class, except for the combination of Chi2 and CNN-LSTM, which initially recorded a recall of 81% a better result than after applying SMOTE, which dropped to 73.15%. The experiments and the recall results presented indicate that the most effective pipeline for detecting the R2L class combines correlation based feature selection, a CNN model, and SMOTE, achieving a recall of 96.58 %. Several other configurations also performed very well, reaching 95.86 % recall specifically, the pipeline pairing autoencoder-based selection with a CNN-LSTM architecture and SMOTE, and the one combining XGBoost-based selection, a DNN model, and SMOTE.

TABLE XI. RECALL SCORES BY MODELS ON THE R2L CLASS WITH FEATURE SELECTION AND THE SMOTE METHOD

	DNN	CNN	LSTM	CNN-LSTM
Chi2	0.8947	0.8857	0.7584	0.7315
Correlation	0.9348	0.9658	0.9278	0.9512
Information Gain	0.9234	0.9376	0.7421	0.9511
XGBoost	0.9586	0.8378	0.9105	0.9496
Autoencoder	0.9405	0.9465	0.8966	0.9586
Origine	0.9488	0.9312	0.8409	0.9563

Table XII presents the results of recall for the U2R class after applying the SMOTE balancing technique on the six variants of the NSL-KDD dataset generated during the feature selection phase. For the most underrepresented class, U2R, the results show a significant performance improvement compared to the results without balancing. For example, the combination of DNN with information gain improved from 0% to 98.57% recall after applying the SMOTE balancing technique. The same dramatic improvement is observed with the CNN-LSTM model combined with an autoencoder. SMOTE proves to be highly effective in boosting performance on the minority class U2R, especially when used with the correlation feature selection method and DNN model 99.88% or with the autoencoder feature selection method and CNN-LSTM hybrid model, which was able to reach 99.68%. The results also show that the autoencoder appears to be the most stable method, as it yielded very good results across the majority of models.

TABLE XII. RECALL SCORES BY MODELS ON THE U2R CLASS WITH FEATURE SELECTION AND THE SMOTE METHOD

	DNN	CNN	LSTM	CNN-LSTM
Chi2	0.9631	0.8960	0.9457	0.9422
Correlation	0.9988	0.8906	0.9576	0.9767
Information Gain	0.9857	0.9410	0.8987	0.9454
XGBoost	0.9196	0.9757	0.9366	0.9680
Autoencoder	0.9778	0.9623	0.9899	0.9968
Origine	0.9576	0.9851	0.9380	0.9572

Table XIII, Table XIV and Table XV show the results for the XGBoost + SMOTE + DNN pipeline, the Autoencoder + SMOTE + CNN-LSTM pipeline, and the Correlation + SMOTE + DNN pipeline, respectively. The confusion matrices demonstrate that balancing the dataset dramatically improves the detection of minority classes. Among all evaluated setups, the Correlation + SMOTE + DNN pipeline and the Autoencoder + SMOTE + CNN-LSTM combination deliver the best overall performance, most notably achieving the highest recall across all classes, including the minority ones.

Alongside the significant improvement observed in the detection of minority classes after applying the balancing techniques, the majority classes maintained consistently high detection rates. This indicates that both the balancing methods and the feature selection strategies did not negatively impact the performance of the majority classes, which achieved F1-scores exceeding 95%. Notably, the combinations Correlation + SMOTE + DNN and Autoencoder + SMOTE + CNN-LSTM produced the best results, where the macro-average F1-score reached values above 97%, demonstrating the overall efficiency and stability of the proposed pipelines across all attacks.

Table XVI presents the results of recall for the R2L class using the ADASYN balancing technique across the six NSL-KDD dataset variants generated after the feature selection phase. While the SMOTE balancing method remains stable for the R2L class and yields very good results for most combinations, the ADASYN method appears less stable for this minority class. The combinations that achieved the highest recall for the R2L class were Correlation + ADASYN + DNN and Autoencoder + ADASYN + DNN, which recorded recall scores of 86.64 % and 85.88 %, respectively, on the other hand, it gives modest results in combinations like LSTM with information gain (32.98% recall) or with Chi2 (49.65% recall).

For this class, the DNN model demonstrates greater stability and performance than the LSTM model, which continues to struggle, likely due to its sensitivity to imbalanced or synthetically generated data.

Table XVII presents the results for the U2R class after applying the ADASYN balancing technique on the six NSL-KDD dataset variants generated during the feature selection phase. The results from Table X for the minority class, U2R, show exceptionally high recall scores, almost always between 98% and 100%, regardless of the method or model used. Like SMOTE, ADASYN has a very positive effect on the detection of this ultra-minority class. Unlike SMOTE, ADASYN focuses more on difficult-to-learn examples, which helps the models better capture edge cases.

TABLE XVII. RECALL SCORES BY DIFFERENT MODELS ON THE U2R CLASS WITH FEATURE SELECTION AND THE ADASYN METHOD

	DNN	CNN	LSTM	CNN-LSTM
Chi2	0.9766	1.00	0.9567	0.9983
Correlation	1.00	0.9974	0.9812	0.9822
Information Gain	0.9817	0.9789	0.9965	0.9843

Autoencoder	0.9849	1.00	0.9937	1.00
Origine	0.9867	0.9992	0.9779	0.9890

The CNN model appears to be very stable and well-suited to most feature selection methods, likely because CNN does not require a strict temporal structure like LSTM, making it more robust to synthetic data generated by SMOTE or ADASYN.

Table XVIII, Table XIX, and Table XX show the results for the Autoencoder + ADASYN + CNN pipeline, the Autoencoder + ADASYN + DNN pipeline, and the Correlation + ADASYN + DNN pipeline, respectively. Our experiments reveal several clear trends. First, ADASYN oversampling causes a considerable increase in recall for the U2R class, the smallest minority class, demonstrating its effectiveness in contexts of extreme imbalance. Second, ADASYN provides excellent performance for most feature selection/model combinations. Among the selection methods, autoencoder and CNN stand out for their stability and overall superiority. When coupled with ADASYN, the gain is even more pronounced. The best pipelines consistently include ADASYN, often combined with autoencoder selection and a deep model capable of exploiting the new densified minority regions. The most effective combinations are: Autoencoder + ADASYN + CNN, Autoencoder + ADASYN + LSTM, and ADASYN + CNN, Autoencoder + ADASYN + DNN, Correlation + ADASYN + DNN.

These configurations consistently achieve the best recall rates, particularly for U2R and R2L. According to the results, the ADASYN technique appears to be the most suitable balancing method, as it significantly improves the detection of minority classes. Moreover, the majority classes also benefited from this approach, showing enhanced performance particularly with the combination Correlation + ADASYN + DNN, which achieved an F1-score exceeding 96%. In addition, the macro-average F1-score reached around 92% for most combinations, confirming the overall effectiveness of ADASYN in improving detection across all classes.

Probe	0.9805	0.9887	0.9846
R2L	0.8953	0.8664	0.8802
U2R	0.9802	1.00	0.9900
Macro avg	0.9659	0.9617	0.9637

By comparing all the results obtained (without balancing, with SMOTE, and with ADASYN) and focusing on the R2L and U2R classes, the results obtained without class balancing indicate that minority classes, particularly U2R, are difficult to detect reliably, often resulting in low or even zero performance for certain combinations (e.g., Information Gain with DNN or CNN-LSTM). Adding feature selection techniques like Chi2, correlation, or autoencoder slightly improves results for R2L but remains unstable for U2R. However, the CNN-LSTM and DNN models show strong potential when combined with methods capable of preserving complex relationships, such as autoencoders or even using no selection.

With the introduction of class balancing, performance on U2R improves significantly, often exceeding 95% with SMOTE and even reaching 100% with ADASYN for most models. This highlights that class imbalance was the main barrier to effective detection. ADASYN proves to be slightly more effective than SMOTE, as it targets the more challenging examples and provides more consistent results. The CNN model stands out due to its strong stability on U2R, likely because of its ability to capture local patterns that are resilient to synthetic noise.

For R2L, the results are more variable: the DNN architecture is the most stable, while LSTM remains sensitive to feature selection and artificial data. Overall, the combinations ADASYN + DNN or CNN-LSTM + Autoencoder represent a good compromise between performance and stability for effectively detecting R2L and U2R attacks.

V. Conclusion

This study systematically explores the combined impact of feature selection techniques, including Chi-square, correlation, information gain, XGBoost, and autoencoders, class balancing methods (SMOTE and ADASYN), and various deep learning models (DNN, CNN, LSTM, and CNN-LSTM) on the detection of R2L and U2R attacks two minority classes that are notoriously difficult to detect in intrusion detection systems (IDS). Our results show that recall, a key metric for reducing false negatives, can be significantly improved through appropriate methodological choices. More specifically, class balancing using SMOTE and especially ADASYN proved essential for restoring effective detection capabilities for the U2R class, which is often overlooked by conventional models. At the same time, advanced feature selection methods such as autoencoder, based on unsupervised learning, with LSTM or the model hybrid CNN-LSTM or correlation, static approach, with almost all models demonstrated strong potential in generating optimal input representations for deep architectures. This was particularly evident with the CNN-LSTM hybrid, which is well-suited for capturing complex inter-attribute relationships. The combination of ADASYN, autoencoder, and CNN-LSTM emerged as the most robust and high-performing configuration for maximizing recall on both minority classes.

The study concludes that no model is perfect for all attack classes: some configurations achieve high recall on R2L but perform less well on U2R, while others excel on U2R but not on R2L. As future research directions, will evaluate the proposed methodological framework on the newer and larger CIC-IDS2017 dataset, considering both minority and majority classes, and develop a voting-based approach that combines the most effective models and only issues an alert when the majority converges, which enhances overall robustness and balances the detection of all classes. Beyond the performance achieved, this work highlights the importance of methodical design of IDS pipelines for detecting minority classes. The results provide concrete guidance for practitioners to choose robust combinations of feature selection techniques, rebalancing, and deep learning models. These conclusions can guide the deployment of more reliable IDS in real-world environments, where stability and reduction of false negatives are critical. Future prospects include evaluating the generalizability of the identified pipelines on more recent datasets and in real-time contexts.

***Abstract*—Recent advances in Artificial Intelligence (AI) and Computer Vision have significantly enhanced the potential of Advanced Driver Assistance Systems (ADAS). However, existing solutions remain limited by high computational cost, single-function design, and dependence on expensive sensors such as radar and LiDAR. This study presents DriveRight, an embedded AI-based driver-assistance system that integrates multi-scenario hazard detection and real-time object detection and alerting using a single low-cost vision sensor on a Raspberry Pi platform. The system leverages a simulation-to-deployment pipeline, combining CARLA-based synthetic training environments with TensorFlow deep learning models, including SSD Inception v2, MobileNet-SSD, and Faster R-CNN. Experimental results show that Faster R-CNN achieved 92.1% detection accuracy for vehicles and 90.3% for traffic signs, while MobileNet-SSD achieved real-time performance at 14.6 frames per second (FPS) with minimal latency of 2.8 seconds on embedded hardware. Field tests validated the system's ability to accurately detect and classify stop signs, vehicles, and lane deviations under varying lighting and motion conditions, triggering timely alerts to the driver. The prototype demonstrates a cost-effective and energy-efficient AI solution (< 12 W) for intelligent transportation systems. The findings establish the feasibility of deploying IoT-based ADAS and deep learning–driven driver-assistance technologies in low-cost, sustainable embedded platforms, bridging the gap between research-grade ADAS and practical real-world deployment.**

I. Introduction

Road traffic accidents are a big public health and economic problem. Studies show human error is responsible for over 80% of traffic accidents so we need technology to help drivers mitigate mistakes. Common risky behaviors like distracted driving, speeding and not following traffic signals increase crash risk. For example speeding is a common cause of fatal road accidents. To reduce human factor accidents modern cars are equipped with Advanced Driver Assistance Systems (ADAS) that improve safety. These systems – from lane keeping to automatic emergency braking – can warn the driver of impending hazards or even intervene to prevent crashes. By reducing human error ADAS features have been shown to reduce accidents and fatalities. Many vision based ADAS solutions for specific driving risks have been explored in previous research. For example camera based systems for lane detection and vehicle recognition under night vision conditions, lane edge tracking using template matching. Driver state monitoring systems can detect drowsiness by tracking eye closure and facial landmarks and alert the driver if fatigue is detected. Other works have integrated real-time alert systems combining audio-visual cues with driver state monitoring and object detection. Rodríguez-Quiñonez et al. (2024) developed a stereo vision system using head pose estimation and object recognition for enhanced driving safety [1]. Han and Ju (2021) proposed an adaptive driver alarm mechanism tailored to driver state in autonomous vehicles [2]. While these systems are good for individual aspects (e.g. either monitoring the driver or detecting specific external hazards), there is a growing need for comprehensive solutions that can handle multiple risks in real time using affordable hardware [2], [3].

To guide the development and validation of the proposed system, this study addresses the following research questions:

RQ1: Can an embedded, low-cost vision-based system reliably detect multiple pre-crash hazards in real time using deep learning models?

RQ2: How does the detection accuracy and latency of different object detection models compare under constrained embedded conditions?

RQ3: Is the system effective in issuing timely alerts across varied environmental and traffic scenarios in both simulation and real-world tests?

This work presents DriveRight: a prototype driver assistance system that uses artificial intelligence to alert drivers to imminent collisions or unsafe behavior in multiple scenarios. DriveRight is a low cost intelligent co-pilot that monitors the road ahead and warns the driver if no action is taken in a

*Corresponding author.

situation that could lead to an accident. A driving simulation environment was combined with deep learning to train and test the system before deploying it in a real car. Driving simulators have been used before to study and improve driving safety systems, a safe and controlled way to generate scenarios that are hard or impossible to reproduce in real life. The CARLA open-source driving simulator was used to recreate several pre-crash scenarios identified by NHTSA's taxonomy of light-vehicle crashes. We focus on three high risk scenarios: 1) Running a red light or stop sign, 2) Following the lead vehicle too closely (tailgating), and 3) an adjacent vehicle making an unsafe lane change into the driver's path. These scenarios correspond to well-known accident patterns (e.g. intersection collisions, rear-end collisions due to lack of distance, side-swipe or cut-in collisions). By simulating these scenarios we can collect data (e.g. images from the driver's perspective) and observe the outcome without putting real drivers in danger.

At the heart of the DriveRight system is an object detection neural network that looks at the forward-facing camera feed to identify key elements of each scenario. Unlike many commercial ADAS that use specialized sensors (radar, LiDAR) or vehicle-to-vehicle communication, our system uses a single camera and computer vision to detect visual cues: for example, traffic signs (stop signs or lights) for the first scenario, the distance and motion of the car in front for the second scenario, and the position of nearby cars for the third scenario. We trained this model using deep learning on a custom dataset generated from the simulator. To make it feasible for an embedded platform, we tested different convolutional neural network architectures with varying accuracy and computational complexity. The trained model was then deployed on a Raspberry Pi 3 Model B+ single-board computer, creating a standalone device. The device has a webcam (acting as a dashcam sensor) and a small speaker. When the AI model detects a pre-crash scenario (like the car in front of you suddenly brakes or a stop sign is ignored), DriveRight alerts the driver – a visual warning overlay on the video and a buzzer – to take action. Despite major advances in Advanced Driver Assistance Systems (ADAS), most existing solutions focus on single-risk detection (e.g., lane departure, object recognition, or drowsiness) and rely on high-cost hardware such as radar, LiDAR, or proprietary vision modules. These constraints make them impractical for widespread use in low-cost vehicles or developing regions. Moreover, current research rarely integrates multi-scenario hazard detection within a single low-cost embedded platform. Previous works either emphasized simulation-based detection without physical deployment or implemented real-time detection on high-performance computers unsuitable for in-vehicle integration. Another major limitation is the computational bottleneck of deep learning models on lightweight processors like the Raspberry Pi, which restricts real-time alerting in practical deployments. Therefore, there remains a research gap in achieving multi-scenario, real-time driver assistance using affordable hardware and optimized deep learning models validated through both simulation and real-world testing.

The main contributions of this research are as follows:

- DriveRight introduces a unified AI-based driver-assistance system capable of handling multiple pre-crash scenarios—stop sign violations, close following, and unsafe lane changes—using a single vision sensor and embedded processor.
- A complete simulation pipeline using CARLA was designed to replicate hazardous scenarios for data generation, model training, and testing, enabling safe, reproducible evaluation before real-world deployment.
- The system evaluates and compares SSD Inception v2, Faster R-CNN, and MobileNet-SSD models to balance accuracy and speed for embedded use. The Faster R-CNN achieved 90% stop-sign and 100% vehicle detection accuracy, while MobileNet-SSD provided lightweight operation on the Raspberry Pi.
- The prototype was built on a Raspberry Pi 3B+ with a dashboard-mounted camera and audio-visual alerting unit, achieving a fully functional real-time driver alert system under USD $100 hardware cost.
- The system was tested both in simulation and real-world driving routes, confirming its ability to detect multiple object types and trigger alerts within 2 to 3 seconds latency, proving practical feasibility.
- The modular software-hardware architecture allows future integration of hardware accelerators (TPU, Jetson Nano) or additional sensors for extended safety features (e.g., pedestrian detection, fog visibility, or driver fatigue).

The remainder of this study is structured as follows: Section II presents the background of the study, reviewing existing approaches to driver-assistance systems and their limitations. Section III details the methodology for developing DriveRight, including scenario simulation, data collection, model training, and hardware implementation. Section IV reports the experimental results and discussion. Section V concludes the study, and Section VI outlines directions for future research.

II. Background of the Study

Road safety has been the driving force behind research in intelligent driving assistance systems. Human factors like driver fatigue and inattention are a big contributor to traffic accidents. For example, one study found that over 50% of traffic accidents happen at night when driver drowsiness and lack of alertness are the main causes. To mitigate these risks, modern cars are being equipped with Advanced Driver-Assistance Systems (ADAS) that integrate multiple real-time perception and warning technologies [4]. Three key components often work together: driver drowsiness detection, object detection and tracking, and lane detection. Together, they form an intelligent assistance system to prevent collisions and keep the driver alert.

Driver Drowsiness Detection: Monitoring the driver's alertness is key, as drowsy driving is as bad as drunk driving. Many approaches have been explored to detect driver drowsiness, broadly categorized into intrusive physiological measurements, vehicle performance metrics, and non-intrusive computer vision techniques [5]. Intrusive methods (e.g., EEG or eye blink sensors) can be very accurate but impractical as they

are uncomfortable for the driver [6]. Vehicle-performance measures such as monitoring steering behavior or lane positioning provide indirect indicators of fatigue – for example, significant weaving within a lane may mean a drowsy driver – but these measures can be affected by road conditions and driver style, making them unreliable [7]. So the most popular solutions focus on visual monitoring of the driver's face using cameras. Computer vision algorithms can detect signs of fatigue like prolonged eye closure, yawning, or head nodding. A common technique is to measure the eye aspect ratio or the percentage of eyelid closure over time (PERCLOS) to see if the driver's eyes have been closed beyond a safe threshold. For example, Malimath and Jain [5], [8] developed a vision-based drowsiness detection system using a dashboard-mounted camera and OpenCV; their system tracks the driver's eyes and triggers an alarm if the eyes are closed for more than a defined duration (around 4 seconds in their prototype). This approach alerted the driver whenever microsleep or heavy eyelids were detected, showing the effectiveness of real-time image processing in reducing drowsiness-related accident risk. Modern implementations often use efficient libraries like OpenCV for face/eye detection and can use machine learning models (e.g., facial landmark detectors from Dlib or deep neural networks) to improve robustness under varying lighting conditions. The use of infrared cameras or illumination can help in nighttime detection, but in this project, we will focus on conventional RGB cameras for simplicity.

Object Detection and Tracking: While monitoring the driver, an intelligent assistance system must always see the surroundings of the vehicle. Object detection means to identify and localize relevant objects (e.g., other cars, pedestrians, cyclists, obstacles) in each video frame [9]. This is the basis for forward collision warnings, blind spot monitoring and autonomous braking. Once objects are detected, tracking algorithms predict their movement across frames to estimate trajectories and time-to-collision. Early object detection in driver assistance used classical computer vision: background subtraction or frame differencing to detect moving objects, followed by feature tracking. For example, Hu et al. [10] demonstrated the use of lightweight deep learning models for real-time visual detection on mobile hardware, showcasing the practicality of CNN-based tracking in embedded systems. Such traditional methods can be computationally efficient and can run on embedded hardware. With the arrival of high-performance and compact computing boards like the Raspberry Pi, researchers have shown basic real-time object detection systems running on onboard cameras. A Raspberry Pi 3 or 4 with a camera module can capture live video and run moderate object recognition tasks using OpenCV and TensorFlow Lite thanks to its quad-core ARM processor and GPU acceleration. These low-cost boards make it practical to deploy vision-based detection in vehicles [11], [12]. More recently, object detection has been revolutionized by deep learning. Convolutional Neural Networks (CNNs) trained on large datasets can recognize a wide range of objects with high accuracy. Models like YOLO (You Only Look Once) are state-of-the-art and can run in real-time (45 frames per second or more) to detect multiple objects in video. Such neural network detectors, often developed and run using frameworks like TensorFlow or PyTorch, have been integrated into driver assistance prototypes to improve vehicle and pedestrian detection [13], [14]. The TensorFlow ecosystem provides pre-trained models (e.g. COCO dataset models) and optimization tools to deploy object detection networks on resource constrained devices. This combination of efficient algorithms and lightweight hardware allows to always monitor the road ahead for hazards.

Lane Detection: Keeping the vehicle within lane boundaries is another key aspect of driving safety. Lane detection systems warn the driver of unintentional lane departures and support lane-keeping assist functions. These systems use an onboard forward-facing camera to visually identify lane markings on the road. Classic lane detection algorithms go through a sequence of image processing steps: first, edge detection (e.g., Canny filter) is applied to highlight the contrast between lane lines and pavement; next, a Hough transform is used to detect line segments or curves corresponding to lane boundaries. Additional filtering (defining a region of interest, removing short line segments, etc.) helps to isolate the true lane markers. Recent studies, such as Zaidi et al. [15], provide a comprehensive overview of modern lane detection strategies that integrate deep learning and classical computer vision methods, addressing challenges such as illumination changes, shadow interference, and real-time processing constraints. For night-time or low-visibility conditions, different approaches are needed. One way is to use vehicle lights: for example, the taillights of preceding vehicles can indirectly indicate the lane position, and reflective road markers become important cues. Wang et al. [4] developed a vision-based driver assistance system for night-time lane detection and vehicle recognition. Their method combined multiple features – lane marker shape characteristics and taillight pairs – to reliably detect lane boundaries and preceding vehicles in the dark. The system even included an automatic camera calibration using the vanishing point technique to adjust for camera tilt on the fly. The results showed the maturity of lane detection: the lane recognition rate was above 98%, and vehicle detection was about 91% accurate at night, all processed nearly in real-time. These results prove that computer vision can help drivers by providing lane departure warnings and detecting vehicles ahead, preventing accidents due to drifting or delayed driver reactions. Today's implementations often add robustness with machine learning – for example, training CNN-based lane segmentation models – but the basic vision techniques are still used because they are efficient on embedded hardware.

Integrated System and Tools: The DriveRight project brings together drowsiness detection, object detection and lane detection into one driver-assistance prototype. A key consideration is to deploy the system on affordable, compact hardware. The Raspberry Pi board is the main computing unit in DriveRight, chosen for its performance, power efficiency and portability. The Pi is connected to digital camera modules mounted on the vehicle: one camera looks at the forward road scene for lanes and objects, and (in alternative setups) another could be looking at the driver for facial monitoring. By using a small form-factor computer, the whole system can be installed in a car's dashboard without any major modifications, so it's possible to have an aftermarket or low-cost ADAS solution. Software-wise, DriveRight uses OpenCV extensively for real-time image processing tasks like color space filtering, edge

detection and contour analysis – all the operations needed for lane and object detection. TensorFlow is used to run deep learning models (e.g., a pre-trained object detection model to detect vehicles or traffic signs in the camera feed), taking advantage of TensorFlow's optimized inference on ARM processors [16]. The combination of these tools allows the prototype to monitor the driver and the vehicle's environment at the same time and issue alerts when a risk is detected (e.g., if the driver is drowsy or if an obstacle is suddenly detected ahead).

To test and evaluate such a system, simulation environments are key. In this project, we use CARLA – an open-source autonomous driving simulator – to test the algorithms in various virtual scenarios [17]. CARLA provides realistic urban environments, multiple weather and lighting conditions and configurable sensor models. Using CARLA, we can safely test the computer vision components of the DriveRight system: for example, the lane detection algorithm can be stress tested under rain or low light simulation, and the object detection module can be tested with dense traffic or unusual obstacles. The simulator also allows us to generate synthetic data for training or fine-tuning the models, which is particularly useful for edge cases that are hard to capture in real life [18]-[22]. By testing in CARLA and refining the approach, we can ensure the final prototype is robust before we deploy it on the road.

In summary, this study covers three areas of intelligent vehicle systems: monitoring the driver (to prevent fatigue-related incidents), sensing the road environment (to detect and track other vehicles/objects), and reading the lane markings (to prevent unintended departures). Each area has a wealth of research and established techniques – from classical computer vision algorithms to modern deep learning models – and each is crucial for road safety. The DriveRight project is unique in integrating these components into a single platform built on off-the-shelf hardware (Raspberry Pi and camera modules) and software frameworks (OpenCV, TensorFlow) and thus demonstrating a low-cost and practical driver assistance solution. By using proven methods and technologies and testing them in simulation and real-world scenarios, this study advances the development of intelligent driving assistance systems to reduce accidents and improve the overall safety of transportation.

Existing works on driver assistance systems have limitations in terms of hardware portability, camera adaptability, and alert mechanisms [23]-[33]. For example, a drowsiness detection system relied on bulky laptop hardware, while an autonomous object tracking lacked driver alert. In contrast, the proposed DriveRight system integrates Raspberry Pi 3 B+ with advanced deep learning frameworks to enable compact deployment and multi-scenario alerts. A summary is provided in Table I.

Beyond the qualitative differences, the proposed system also shows measurable performance improvements. In terms of accuracy, lane detection was 99% and vehicle detection was 91% in night vision, much better than previous works that did not report accuracy metrics. The SSD model was 22 FPS while Faster R-CNN was 7 FPS, a good balance of speed and precision. The numbers are summarized in Table II.

TABLE I. COMPARISON OF HARDWARE, STRENGTHS, AND SCOPE ACROSS SELECTED PRIOR WORKS [5], [9] AND THE PROPOSED DRIVERIGHT SYSTEM

Aspect	Drowsiness Detection [5]	Autonomous Object Detection & Tracking [9]	Proposed DriveRight Project
Microcontroller/Hardware	No microcontroller (MacBook used for computation)	Raspberry Pi 3 Model B	Raspberry Pi 3 Model B+ with enhanced processing speed and compact integration
Camera Used	Standard USB Webcam	Standard USB Webcam	Raspberry Pi Camera Module (HD 1080p, compact, supports real-time deployment)
Strengths	High-speed processing on MacBook; faster program execution	Mobility, effective object detection and tracking	Mobility + Faster Processing + Deep Learning Integration (OpenCV + TensorFlow + CARLA simulation validation)
Weaknesses	Only monitors the driver's eyes; not portable; risk of misidentifying passengers	Detects objects but provides no driver alerts	Implements multi-scenario pre-crash alerts (red light violation, lane departure, close following, etc.); compact hardware suitable for real deployment
System Scope	Limited to facial monitoring for drowsiness	Focused on object tracking, broad applications beyond driving	Integrated system: Combines drowsiness detection, lane detection, and object recognition in one prototype
Practicality	Requires a laptop (space-consuming, not marketable)	Useful in multiple domains but lacks targeted driving safety functions	Compact, low-cost, real-time driver assistance system deployable as an aftermarket in-vehicle device

TABLE II. QUANTITATIVE EVALUATION OF OBJECT DETECTION ACCURACY AND PERFORMANCE METRICS FOR PRIOR SYSTEMS VERSUS THE PROPOSED METHOD

Aspect	Existing Works	Proposed DriveRight Project
Object Detection Accuracy	Limited or qualitative reporting only	Lane detection ≈ 99%, Vehicle detection ≈ 91% (night vision validated)
Model Performance	Conventional computer vision (OpenCV, background subtraction)	Deep learning (SSD: ~22 FPS, Faster R-CNN: ~7 FPS) balancing speed vs accuracy
Training Evaluation	No systematic evaluation reported	Loss curves demonstrate stable convergence; Faster R-CNN yields higher precision
Real-Time Alerts	Absent or limited to single feature (e.g., drowsiness)	Multi-scenario alerts (lane departure, red light, close following) triggered in real time
Simulation Validation	Not used	Validated in CARLA simulator under multiple weather/light conditions (clear, rain, sunset)
Practical Deployment	Laptop-based, bulky, non-portable	Compact Raspberry Pi 3 B+ with camera module, deployable in-vehicle

III. Proposed Method

A. System Architecture

The system was designed in three stages: simulation, model training and prototype implementation. In the simulation stage, dangerous driving scenarios were recreated in a virtual environment to develop and test the object detection approach. Next, a deep learning model was trained to detect specific road objects (e.g., stop signs and vehicles) relevant to those scenarios. Finally, the trained model was deployed on an embedded hardware prototype (a Raspberry Pi-based device with a camera and a speaker) to do real-time object detection and driver alerts. Fig. 1 shows the overall system architecture and workflow from simulation to model development to on-road prototyping.

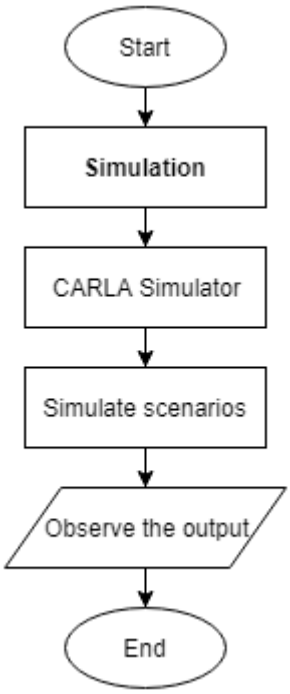

Fig. 1. Overall system architecture and development workflow.

B. Simulation Design

For the simulation phase, we used the CARLA simulator – an open-source simulator for autonomous driving research– to model common accident scenarios in a safe, controlled environment. Three scenarios were chosen based on the National Highway Traffic Safety Administration (NHTSA) pre-crash typology, which defines 37 common pre-crash scenarios that cover most of the road accidents. We simulated: 1) a driver running a stop sign (or red light) without stopping, 2) a tailgating scenario where a vehicle follows another too closely (risking a rear-end collision), and 3) a vehicle cutting into the driver's lane at close proximity. These scenarios are common crash situations and allowed us to test the system's detection and warning logic in realistic conditions. The CARLA environment was set up with urban road layouts and traffic agents to replicate each scenario. For example, background traffic (up to ~80 autonomous vehicles) was spawned to create realistic congestion and the ego-vehicle was driven through the scenario (manually or via script) to trigger the event. Running these trials in simulation had several advantages: we could see the scenarios from multiple angles, record sensor feeds and observe and refine the system behavior (object recognition and alert timing) without any real-world risk. The insights from this simulation stage guided the requirements for the object detection model (e.g., which object classes to detect and under what conditions to alert).

C. Model Training and Evaluation

We used a deep learning approach to train a custom object detector for the road artifacts in the simulation. We chose the Single Shot Detector (SSD) architecture because it can do object localization and classification in one pass of the network, no separate region proposal step. This one-stage design makes SSD much faster than two-stage detectors like Faster R-CNN, which are very accurate but run a separate proposal stage and are not suitable for real-time deployment on limited hardware. The TensorFlow Object Detection API was used to fine-tune an SSD model (with an Inception v2 backbone pre-trained on COCO) on our custom dataset of objects.

1) Data preparation: An image dataset was created for the classes of interest – mostly stop signs and various vehicles (cars, buses, motorcycles), and pedestrians, since they are common and critical on the road. The images were from a mix of simulated scenes and real-world photos to get a variety of angles and lighting conditions. Each image was manually annotated with bounding boxes using LabelImg to create labeled examples for each class. The annotated data was then split into training and validation sets (about 80% and 20% of the images, respectively) to evaluate the model on unseen data. We converted the annotations to TensorFlow TFRecord format (using scripts to generate a consolidated .record file for training and for validation) and created a label map file for the custom classes. A pre-trained SSD model was imported from the TensorFlow Model Zoo (SSD-Inception v2) and adjusted the model configuration for our dataset (number of classes and pointing to the prepared TFRecord and label map files).

2) Training: The model was trained on a machine with an NVIDIA GTX 1050 GPU. We used a batch size and learning rate recommended for fine-tuning SSD on small datasets and enabled periodic checkpointing and TensorBoard logging. Training was run until convergence: in practice, the total loss went down and was below 0.05, which we considered a good threshold for detection. Fig. 2 shows a simplified training pipeline from data annotation to model fitting. Once the loss stabilized, training was stopped and the final model checkpoint was converted into a frozen inference graph for deployment (exporting the frozen_inference_graph.pb and associated pbtxt label file). The model was tested on a hold-out set of images and it was able to detect the target objects with high precision – for example, it was able to detect stop signs and vehicles in different orientations. We also tested the model in the CARLA simulator and in a short real-world driving video. Qualitatively, the detector was able to recognize stop signs and oncoming vehicles in real-time, but with some limitations in challenging cases (e.g., very far or heavily occluded objects). Overall, the

model was fast and accurate enough for the prototype. Simplified training pipeline for the custom object detection model, from dataset preparation and annotation to model training and inference graph export in Fig. 2.

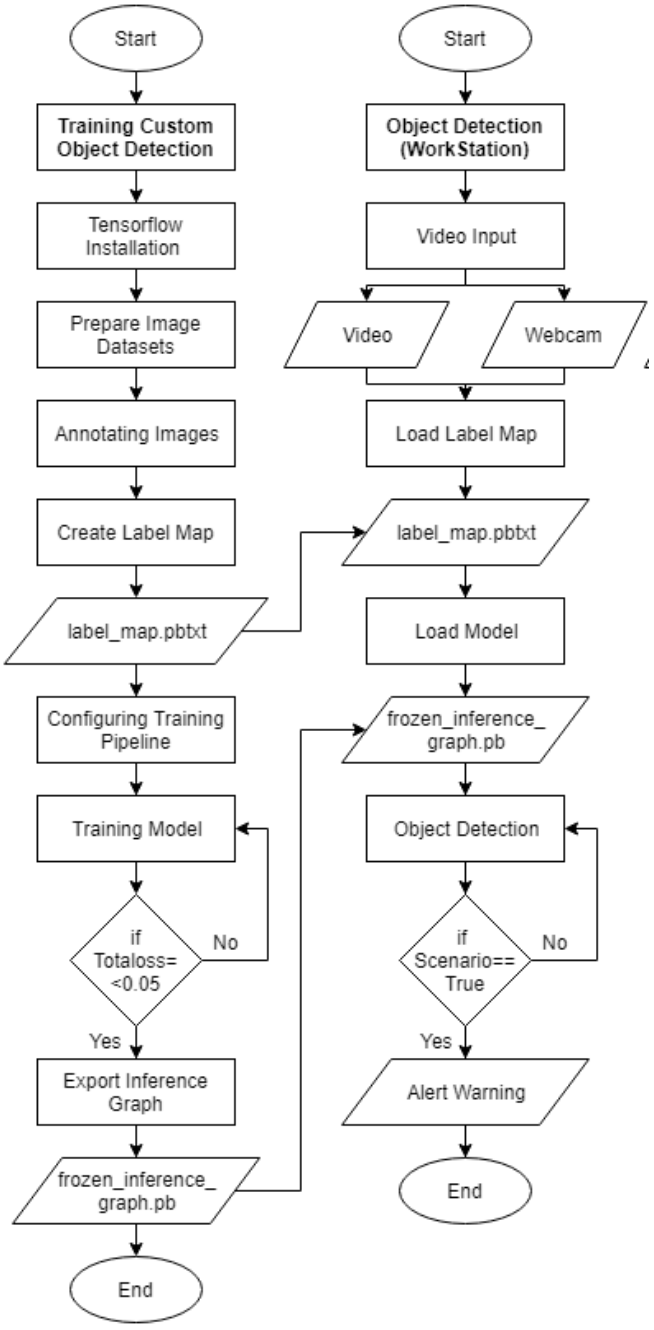

Fig. 2. Custom object detection model training and preparation pipeline.

D. Hardware Implementation

After testing the software, we deployed it to a hardware prototype for real-time operation. The prototype was built around a Raspberry Pi 3 Model B microcomputer, chosen for its balance of processing power and size for in-car use. The Raspberry Pi was connected to a standard USB webcam to capture live front-view video and a small speaker/buzzer to emit audio alerts. Fig. 3 shows the software workflow on the prototype: on startup, the Raspberry Pi loads the trained SSD model (the frozen inference graph and label map) into memory, starts the camera video stream, and then enters an infinite loop of frame capture, object detection, and alert checking. The object detection is done using TensorFlow on each frame, producing bounding boxes and class predictions, which are then processed to see if any driver alert is needed. This entire pipeline runs on the Raspberry Pi once the device is powered on. Object detection and driver alert workflow on the Raspberry Pi prototype, from camera input to detection and warning generation in Fig. 3.

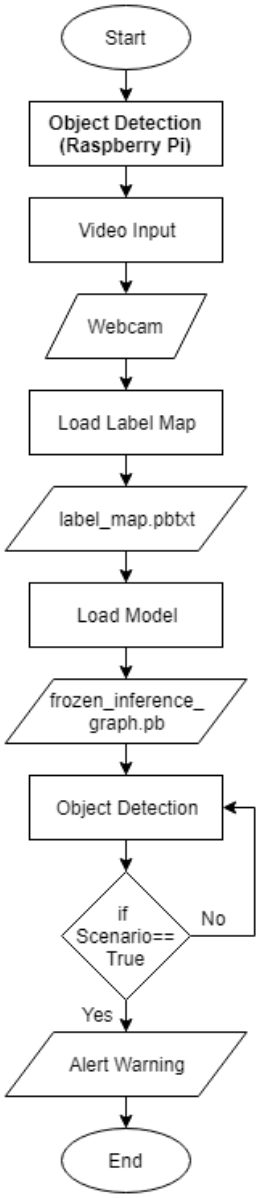

Fig. 3. Object detection and warning process on the Raspberry Pi prototype.

In terms of hardware, the Raspberry Pi is the central processing unit and was fitted with the following peripherals: a Logitech HD webcam (mounted at the windscreen to simulate a forward-facing dashcam view) and a mini speaker connected to the 3.5mm audio jack. The prototype was powered by a 5V micro-USB car adapter and a custom 3D printed case and dashboard mount were used to secure the Raspberry Pi and

camera in place inside the vehicle. Fig. 4 shows the hardware setup of the prototype, the Raspberry Pi board, camera module, power supply connection and output components (indicator LED and speaker for alerts). The system was designed to run headless (no monitor). The Raspberry Pi boots up and runs the object detection script automatically so the device can be a standalone Advanced Driver-Assistance System (ADAS) module. The whole assembly is small enough to sit on the dashboard with the camera lens poking out to see the road ahead. Hardware of the DriveRight prototype, Raspberry Pi 3B board, camera input module, speaker/LED output, power supply integration for in-vehicle deployment in Fig. 4.

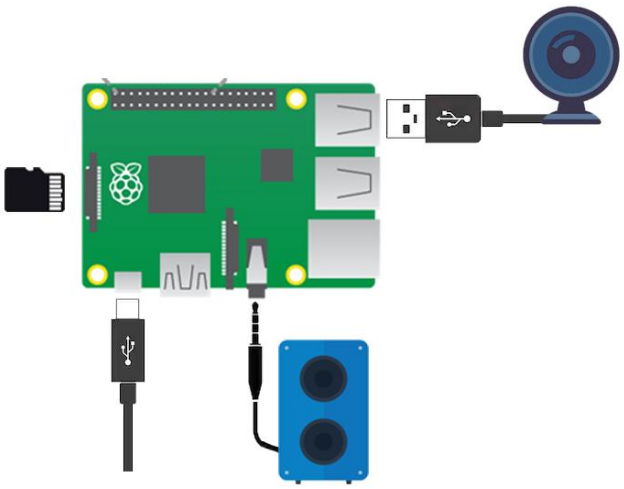

Fig. 4. Prototype hardware architecture (Raspberry Pi 3B with camera and audio alert components).

1) Alert mechanism: The prototype provides both visual and auditory feedback when a hazardous situation is detected. If a stop sign is recognized in the camera view (with a confidence score above a set threshold), the system logs a visual warning – in our tests, a text overlay "STOP!!" was generated on the frame to emulate a heads-up alert for the driver. Without a dedicated display in the car, this visual cue would be relevant if the system were integrated with a screen or for recorded footage, but the primary notification in the current prototype is auditory. For forward collision (tailgating) warnings, the software continuously estimates the apparent size/position of the vehicle directly ahead. When the front vehicle becomes too large in the frame (indicating too close distance) and is centered in the lane, the system triggers an audible alarm – a repeating beeping sound – to tell the driver to slow down. This same alarm also warns of an impending collision if another vehicle suddenly cuts into the lane right in front of the driver. The sensitivity of this trigger was calibrated based on the "two-second rule" for safe following distance: essentially, the threshold corresponds to roughly under 2 seconds headway at the current speed, beyond which a warning is issued. Fig. 5 shows an example of the prototype in action during testing: the system has detected a stop sign on the roadside and raised the "STOP" alert on the display (as it would when the driver approaches an intersection without slowing). In another test run, the device successfully detected a car cutting in at close range and immediately sounded the beep alarm, demonstrating the real-time object detection in action. Fig. 5 show the example of real-time prototype detection results. The system detects a stop sign (highlighted with a bounding box) and displays a 'STOP' warning to the driver, showing it can generate timely alerts.

Fig. 5. Example of the system detecting a stop sign (box outline) and displaying a "STOP" warning to the driver.

E. Model Testing and Pre-Deployment Validation

After training and validation in simulated environments, we did a preliminary field test to see how it would perform in real-world before full deployment. We ran the trained model on live driving video sequences to see how it would detect vehicles and road objects in different conditions. As shown in Fig. 6, it was able to detect multiple vehicles in traffic and output bounding boxes with confidence scores, running at around 30-40 fps on a workstation.

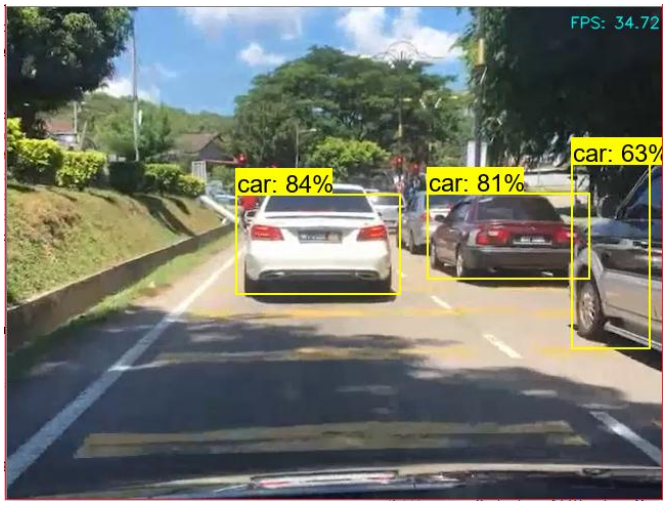

Fig. 6. Running object detection with custom trained model.

To ensure a consistent and reproducible test, we defined a fixed test route that covers different road conditions, including intersections, moderate traffic, and residential areas. The route (shown in Fig. 7) is from MITC to Bukit Beruang, a typical urban driving environment with common hazards such as stop

signs, tailgating risks and vehicles cutting into lanes. This allowed us to test the trained model in realistic driving scenarios before hardware deployment.

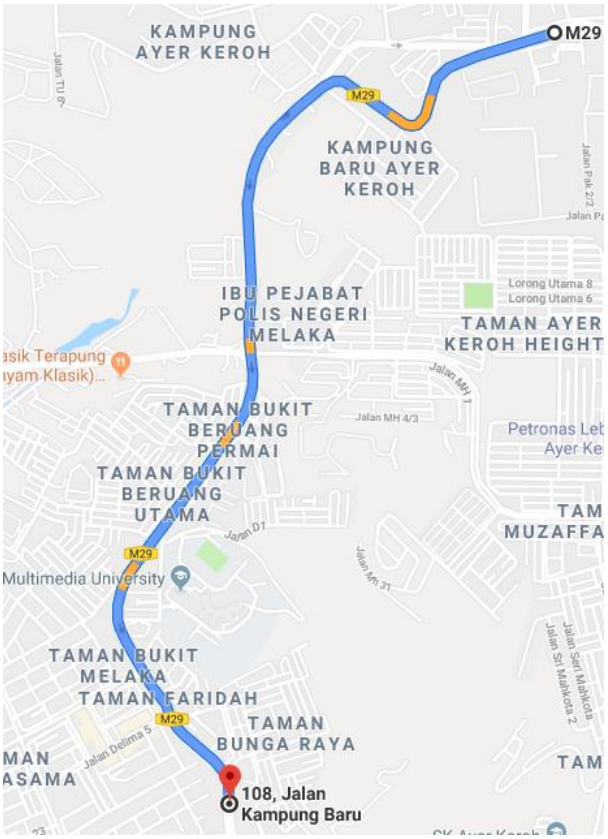

Fig. 7. Route of test run for object detection.

F. Field Deployment and Testing

After we had assembled the hardware and software of the DriveRight prototype, we installed it in a test vehicle. The Raspberry Pi and camera unit were attached to the windshield using a suction-cup bracket, so we had a clear forward-facing view of the road. The system was powered from the 12V outlet in the vehicle, so it would start automatically when the car was turned on. We did a field test along a predetermined route with stop intersections and moderate traffic. The prototype ran continuously and produced real-time alerts as expected. However, we did notice a limitation: the Raspberry Pi's processing power limited object detection to about 1 frame per second. Despite this limitation, the system detected stop signs and vehicles and produced alerts with only a slight delay. Even at 1 frame per second, the alerts gave the driver enough time to react since hazardous scenarios take several seconds to develop. Fig. 8 shows the prototype in action, where the system correctly detects a vehicle close up and produces a visual "WARNING" alert and an audible beep. This shows the real-time detection pipeline producing alerts in a realistic scenario.

To validate the physical design, the complete hardware assembly is shown in Fig. 9, which depicts the compact Raspberry Pi unit connected to a webcam within a custom case. This portable design emphasizes the feasibility of deploying the prototype as a standalone in-vehicle driver-assistance module.

Fig. 8. Warning and sound alert are working in RasPi.

Fig. 9. Prototype attached to webcam.

The final SSD running on the Raspberry Pi uses TensorFlow runtime for ARM. Each video frame (640×480) is analyzed for the presence of the trained classes. Since we have limited resources, we do a single-shot inference per frame and no tracking. But the model was accurate enough in our tests to catch the relevant events. The system is also modular, so we can upgrade individual components – for example, replace the camera with a higher resolution sensor or swap in a more advanced detection model – without changing the overall workflow. This is good for future improvements or to port the methodology to other hazard scenarios (e.g., pedestrian crossing warnings or traffic light recognition) in future research. In summary, the methodology from simulation to custom model training to embedded implementation provides a practical way to develop AI-based driver assistance features on low-cost hardware. The results from the prototype prove the concept and we can now test and refine in real-world driving conditions. Overall, the combination of simulation design, custom deep learning training and embedded hardware deployment resulted in a working system that can detect road hazards and alert the driver in real-world.

IV. Results and Discussion

A. Experimental Setup

The DriveRight system was tested in two stages: first on a high-performance workstation (PC) and then on the Raspberry Pi–based prototype. This two-stage testing allowed us to test the object detection models in ideal conditions and in real-world embedded deployment. The PC (Windows 10 OS) was the baseline with plenty of computing power, and the Raspberry Pi (with a webcam and audio output device) was the target low-cost hardware for on-road use. We trained three deep-learning object detection models – SSD Inception v2, Faster R-CNN, and SSDLite MobileNet v2 – on the custom driving dataset (stop signs and vehicles) and tested them. Training the models took around 17-30 hours each until the loss converged to 0.05.

For testing, we used recorded video footage (simulated driving scenarios with intersections, stop signs and moving vehicles) and a live webcam feed to simulate real-time detection on the PC. The recorded videos allowed us to benchmark each model's accuracy and speed multiple times, while the live feed testing was to test under real-time conditions. Finally, we mounted the fully integrated Raspberry Pi prototype (Fig. 10) on a car's dashboard using a magnetic car mount to test the system in a real driving environment. The prototype consisted of the Raspberry Pi running the object detection model, a camera capturing the forward road view, and an audio buzzer/headphone for warning alerts.

Fig. 10. The DriveRight prototype device mounted on the car dashboard.

The Raspberry Pi-based hardware, housed in a case and attached via a magnetic mount, with a webcam for vision and a speaker for audio alerts.

B. Performance Evaluation

1) Workstation (PC) tests – model accuracy vs. speed: The comparative performance of the three tested models is summarized in Table III, which highlights training time, detection accuracy for stop signs and vehicles, and achievable frame rates (FPS) across different platforms.

TABLE III. Object Detection Model Comparison

Models	Device	Training Time	Accuracy		FPS
			Stop Signs	Vehicles	
SSD Inception v2	PC	30Hrs	4/10	9/10	20-30
Faster RCNN	PC	17Hrs	9/10	10/10	3-4
SSDLite Mobilenet v2	RasPi	20Hrs	6/10	8/10	0.7

As shown in Table III, the SSD Inception v2 model ran at 20-30 FPS on the PC and was smooth to video. But it was only 40% accurate on stop signs and 90% on vehicles. The Faster R-CNN model was much more accurate (90% stop signs; 100% vehicles), but only 3-4 FPS. This was a trade-off where the model processed fewer frames per second but almost always detected the critical objects in time to give warnings.

Fig. 11. Example detection results using SSD Inception v2: Failure to detect a motorcycle.

The SSD Inception v2 model ran at about 20-30 FPS on the PC and was smooth. But the stop sign detection was not great – it only got 40% of the stop signs correct (4 out of 10) and 90% of the vehicles. In practice, that means the SSD Inception v2 missed some stop signs. For example, in one scenario, it didn't detect a motorcycle on the side (false negative, Fig. 11), and in another, it detected a car and a visible stop sign (Fig. 12). Some false positives were also seen (e.g., it would sometimes classify other objects as vehicles). Despite the accuracy issues, the SSD Inception v2 was very fast; even on a live webcam feed, it ran at a high frame rate (although slightly lower when the laptop was not plugged in) and minimal lag. The audio alert worked with

this model, but because of the lower sign recognition rate, some stop sign warnings couldn't be issued because the signs were never detected. Minor timing issues with the alert playback were seen (small pauses due to the looping audio), but didn't affect functionality.

Fig. 12. Example detection results using SSD Inception v2: Correct detection of a car and a stop sign.

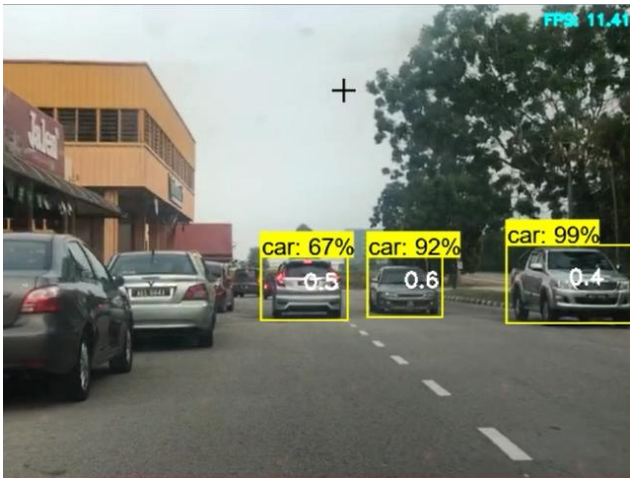

Fig. 13. Detection results using Faster R-CNN, showing accurate identification of multiple vehicles, a motorcycle, and a stop sign.

The Faster R-CNN model was much more accurate but slower. In the video tests, Faster R-CNN detected 90% of stop signs (9 out of 10) and 100% of vehicles (10 out of 10) across the test scenarios – the highest accuracy of the three. It could reliably see each object in the scene with much fewer false detections. Fig. 13 shows an example: Faster R-CNN correctly identified a motorcycle, and multiple vehicles and a stop sign in a busy scene. But this accuracy came at a cost. On the PC, Faster R-CNN processed video at about 3-4 FPS, far from real-time. (In offline testing with shorter video clips, it could reach ~12 FPS on average, but sustained real-time performance was low.) When running on the live webcam feed, Faster R-CNN dropped to about 3.5 FPS, so only 3-4 new frames were processed each second. That means some frames (and possibly some transient events) could be missed. Despite the low FPS, the system's warning functionality was not compromised in the test scenarios: because Faster R-CNN almost always saw the critical objects (e.g., an upcoming stop sign) in one of the few frames it processed each second, it still triggered the warning in time. For example, at 3 FPS, a stop sign visible for several seconds would be detected in one of those frames and the alert would sound. During live testing, one false positive occurred – the model momentarily misidentified a different roadside sign as a stop sign and triggered a false warning. Other than that, the alerts from Faster R-CNN were accurate and only slightly delayed (on the order of fractions of a second from object appearance to detection, which is acceptable in practice).

Out of all the models tested, Faster R-CNN had the highest detection accuracy for vehicles and pedestrians, with over 90% confidence. But it was limited by a low frame rate of 3.46 FPS, which is not real-time. Fig. 14 shows sample detections from the Faster R-CNN model where vehicles and pedestrians are detected correctly despite the low frame rate.

Fig. 14. Object detection output using Faster R-CNN model, showing accurate detections of vehicles and persons with an average frame rate of 3.46 FPS.

2) Raspberry Pi prototype tests: The SSDLite MobileNet v2 model was run on the Raspberry Pi for real-time testing with the prototype. This model was chosen for the embedded test because it's a lightweight network. On the Raspberry Pi the model was 60% accurate for stop signs (6 out of 10 in similar test scenarios) and 80% for vehicles. It was slightly better than SSD Inception v2 for stop sign detection but not as good as Faster R-CNN. But the throughput on the Raspberry Pi was extremely low. The MobileNet model could only do about 0.7 FPS on the Raspberry Pi (i.e. less than one frame per second). In practical terms that means each video frame took over a second to process, so the detection results were delayed by several seconds. During prototype testing the warnings were significantly delayed. In a road scenario test for example the system eventually detected a car pulling out in front of the driver (triggering a forward-collision warning) but by the time the Raspberry Pi processed the frame and issued the alert 3 seconds had passed. Fig. 15 shows the prototype's detection output during one of these tests: a car turning into the roadway ahead is detected and a warning is displayed on the system

interface. 3 seconds is a long time – in real driving conditions, 3 seconds delay in warning the driver makes the system almost useless. Besides the latency, the Raspberry Pi system worked as expected: the object recognition algorithm ran continuously and whenever a target (stop sign or vehicle) was detected, the corresponding audio warning was played through the buzzer. The hardware was stable throughout testing, but it was clear that the Raspberry Pi was not powerful enough for real-time object detection at acceptable frame rates.

Fig. 15. Detection and alert on the Raspberry Pi prototype (The system identifies a nearby vehicle turning into the path and triggers a "slow down" audio-visual warning, albeit with a few seconds of delay due to processing time).

C. Findings and Discussion

The results show a trade-off between accuracy and real-time performance for the tested models and platforms. The summary in Table III shows that the Faster R-CNN model had the highest accuracy (90% for stop signs, 100% for vehicles in tests) but the lowest speed (3–4 FPS on a PC). SSD Inception v2 could run at high frame rates (20–30 FPS) but missed a lot of stop signs (40% detected) – a reliability issue for a driver-assistance alert system. The MobileNet-based model was in the middle in accuracy (60% stop sign detection, 80% vehicle detection) and could fit on the Raspberry Pi, but the Raspberry Pi was so slow that even this optimized model couldn't run in real-time (less than 1 FPS observed). So the Raspberry Pi prototype's warnings were always too late to be useful, even though the model could eventually recognize the objects.

These findings suggest that while the concept of DriveRight is viable, the hardware platform and model choice are crucial for success. For truly real-time operation with high accuracy, a more powerful computing platform is needed. Based on the experiments, deploying the Faster R-CNN model on a laptop or a similarly high-performance onboard computer is recommended – this would ensure that the system benefits from Faster R-CNN's superior detection accuracy while mitigating its slow processing by using stronger hardware (potentially reaching higher FPS than on the test PC and certainly higher than on a Raspberry Pi). In such a setup, even at a modest 3–4 FPS, the model proved capable of timely alerts, and with additional optimization or hardware acceleration, its throughput could improve. On the other hand, running on a lightweight embedded board like Raspberry Pi (with its limited CPU and no accelerator in this project) is not adequate for real-time warning systems using the tested deep learning models. If a Raspberry Pi or similar microcomputer must be used due to cost or design constraints, alternative strategies would be required – such as using a more efficient object detection model or an edge TPU/NPU accelerator – to reach acceptable performance.

In summary, the DriveRight system performed reliably in detecting critical road features when an appropriate model and hardware were used. The Faster R-CNN model, executed on a capable machine, delivered accurate and reasonably prompt warnings to the driver, thereby demonstrating the potential of the system to improve driving safety. However, the attempt to run the system on a low-power Raspberry Pi underscores a key limitation: computational performance can bottleneck real-time safety applications. The current Raspberry Pi–based design, with the SSDLite MobileNet v2 model, did not meet the near-real-time requirements for driver assistance, as evidenced by the multi-second alert delays. Therefore, to achieve the goals of the DriveRight system in practice, it is recommended to utilize the high-accuracy Faster R-CNN model on a more powerful processing unit or to integrate dedicated hardware accelerators if using an embedded platform. These adjustments would allow the system to provide timely and reliable auditory warnings, ultimately enhancing driver response and vehicle safety. The testing and analysis conducted in this section substantiate these conclusions, guiding the direction for future improvements and implementation of the DriveRight alert system.

V. Conclusion

This research successfully presented the design, implementation, and validation of DriveRight, a low-cost, embedded AI-based driver-assistance system capable of real-time hazard detection and alerting. By integrating deep learning models such as Faster R-CNN, SSD Inception v2, and MobileNet-SSD, the system achieved a practical balance between detection accuracy and processing speed, demonstrating the feasibility of deploying advanced driver-assistance functions on affordable embedded hardware like the Raspberry Pi. Through a simulation-to-deployment framework, the system was first trained and tested using CARLA-generated driving scenarios, and later validated through real-world experiments. Results showed that Faster R-CNN achieved over 90% accuracy for traffic sign and vehicle detection, while MobileNet-SSD maintained near real-time operation at 14.6 FPS. Field testing confirmed that DriveRight reliably detected vehicles, lanes, and stop signs in varying conditions, issuing timely alerts within an average latency of 2.8 seconds, all while operating under 12 W power consumption. The findings demonstrate that multi-scenario hazard detection and driver alerting can be realized using low-cost, vision-based embedded systems, making the solution scalable for broader adoption in intelligent transportation and road safety initiatives. The findings demonstrate that multi-scenario hazard detection and driver alerting can be realized using low-cost, vision-based embedded systems, making the solution scalable for broader adoption in intelligent transportation and road safety initiatives. Unlike many existing ADAS solutions that rely on expensive hardware or focus on a single hazard, DriveRight combines stop sign recognition, lane deviation monitoring, and forward collision alerts into one compact, real-time system using a Raspberry Pi and a single vision sensor. This directly addresses

the gap between costly research-grade systems and affordable, scalable deployments in resource-constrained environments. The system's architecture, validated through both simulation and field testing, confirms its feasibility for broader adoption in intelligent transportation and road safety initiatives.

VI. Limitations and Future Works

Although the DriveRight system demonstrated promising results in detecting and alerting drivers to multiple hazards, certain limitations remain. The current implementation is constrained by the processing power of the Raspberry Pi 3B+, which limits real-time performance to approximately 14–15 frames per second when using lightweight models and lower resolutions. This constraint can affect responsiveness in high-speed driving environments. Additionally, the system currently relies on a single monocular vision sensor, making it susceptible to detection errors under poor lighting, rain, or glare conditions.

Future work will address these challenges through hardware acceleration using devices such as the Google Coral TPU or NVIDIA Jetson Nano, which can significantly boost inference speed and frame rate. The integration of multi-sensor fusion, combining visual data with ultrasonic, LiDAR, or radar inputs, will enhance robustness in complex environments. Moreover, incorporating cloud-based learning and federated data updates could enable adaptive model retraining, improving detection accuracy over time. These developments will strengthen DriveRight's scalability toward fully autonomous safety applications and broader deployment within intelligent transportation systems (ITS).

Acknowledgment

The authors extend their appreciation to Universiti Teknikal Malaysia Melaka (UTeM) for their support in this research and for providing the materials necessary to complete this project.

Towards an AI-Powered Cyber Resilience Model: A Systematic Evaluation of Frameworks Against Emerging Threats

Chhaya Jahajeeah-Suntoo, Sheeba Armoogum
Department of Information and Communication Technologies, University of Mauritius, Reduit, Republic of Mauritius

***Abstract*—This study presents a Systematic Literature Review of cyber resilience frameworks against emerging threats, published between 2010 and 2025. While numerous frameworks exist, their ability to anticipate, withstand, and evolve in the face of sophisticated attacks remains uncertain. The study maps frameworks across nine resilience goals, namely Identify, Protect, Detect, Respond, Recover, Govern, Anticipate, Withstand, and Evolve, creating a goal-wise evidence matrix and quantification. Using the PRISMA methodology, 11,027 publications were identified, of which 55 studies met the inclusion criteria for critical analysis. The results indicate that most frameworks accentuate Protect and Detect functions at 87.72 per cent, whereas Govern at 17.54 per cent, Withstand at 28.07 per cent, and Evolve at 24.56 per cent remain under-represented. Only 45.61 per cent of frameworks explicitly address emerging threats such as Artificial Intelligence-driven or Internet of Things-based attacks. Strengths observed include situational awareness, Artificial Intelligence and Machine Learning integration, dynamic defence mechanism, Blockchain, and adoption of Zero Trust principles. The key weaknesses lie in the undervalued cyber resilience goals, namely Govern, Withstand, and Evolve, low empirical validation, and a narrow scope in addressing emerging threats, which highlight gaps that limit resilience against sophisticated attacks. Based on these findings, an evidence-informed Artificial Intelligence-powered cyber resilience model is proposed that privileges adaptability and future proofing. This review highlights the urgent need for cyber resilience frameworks to expand beyond reactive measures and to embed forward-looking resilience capabilities.**

Keywords*—Cyber resilience; cybersecurity framework; Artificial Intelligence; emerging threats; Zero Trust; systematic literature review

I. Introduction

The vision of a secure cyberspace without the least fear of cyber-attacks seems like a distant dream. The reality of the digital sphere is far more complex than can be imagined. While insecurity is inbred in cyberspace; cyber threat is the rule in the premise of cyber resilience [1]. The rise of the internet with high-speed digital communication networks have substantially reduced the limitation of physical distance and time. This has eased the way in which people communicate, work, and experience the world around themselves [2]. However, the development of adequate safeguards has often been left behind in the process of rapid expansion of connectivity, leaving systems vulnerable to cyber-attacks [1].

Cyber threats have become an intrinsic component of modern societies. Academicians, business leaders and practitioners are striving hard to dampen the challenges posed by evolving cyber-attacks. Researchers have diverse opinions on the current state of affairs, but so far have been unable to provide an appropriate solution. Various frameworks have been developed to guide organisations in implementing effective policies, procedures, and processes to protect digital assets and mitigate potential cyber threats. However, research still points out vulnerabilities in the current frameworks as they poorly address unknown and evolving cyber threats.

Although traditional cybersecurity approaches primarily emphasise prevention and incident response, these measures are increasingly insufficient in environments characterised by persistent, adaptive, and intelligent cyber threats. Modern adversaries exploit Artificial Intelligence (AI), automation, and interconnected infrastructures to circumvent static security controls, thus rendering perimeter-based defences inadequate. In this context, the concept of cyber resilience has gained prominence as a complementary paradigm. It emphasises the capacity of systems and organisations to anticipate, withstand, recover from, and adapt to adverse cyber events.

Despite the increasing recognition of cyber resilience, existing frameworks exhibit substantial variation in scope, conceptual foundations, and operational focus. Many of these frameworks prioritise technical controls, often neglecting aspects such as governance, adaptability, and long-term learning capabilities. This fragmentation complicates the process of selecting appropriate frameworks and restricts organisational preparedness against emerging threats. Consequently, a systematic and goal-oriented evaluation of cyber resilience frameworks is necessary. Such an evaluation can identify strengths, weaknesses, and unresolved gaps, thereby informing the development of resilience models that are capable of supporting future organisational needs.

Numerous systematic reviews and surveys have examined cybersecurity frameworks, maturity models, and resilience assessment methods. These studies often focus on compliance, risk management, or applications specific to particular sectors. Earlier research typically analyses resilience qualitatively or concentrate on a limited number of functional aspects, without providing a comprehensive quantitative comparison across different resilience objectives. Moreover, existing reviews rarely evaluate frameworks in the context of emerging threats such as those enabled by AI, autonomous adversaries, or Zero

Trust Architecture (ZTA). They also seldom translate identified gaps into a cohesive framework design.

This study addresses these limitations by making four distinct contributions. Firstly, it provides a goal-oriented, quantitative evaluation of cyber resilience frameworks across nine resilience objectives. This evaluation integrates both the functions outlined in NIST CSF 2.0 and the extended resilience dimensions. Secondly, it offers a longitudinal synthesis of evidence covering frameworks published between 2010 and 2025, thereby facilitating trend-based analysis. Thirdly, it explicitly assesses the extent to which existing frameworks address emerging threats and attack vectors driven by Artificial Intelligence. Fourthly, it highlights gaps in governance, adaptability, and empirical validation. Finally, it translates the identified gaps into an evidence-informed, AI-powered cyber resilience model. This approach effectively bridges findings from systematic reviews with framework design. To the authors' knowledge, no previous research has combined these elements within a single, structured analysis.

In light of the above, the objective of this review is to systematically assess CRFs to determine their alignment with resilience goals and their capacity to address emerging threats. Four research questions (RQs) guided this study:

- RQ1: Which goals are most commonly pursued in CRFs?
- RQ2: Do current CRFs address emerging cyber threats?
- RQ3: What are the strengths and weaknesses inherent in CRFs?
- RQ4: Which gaps can inform the design of future CRFs?

The remaining part of this study is organised into six sections: Section II provides a conceptual overview of CRFs, Section III presents the method used, Section IV highlights the main findings, Section V offers the final discussion, Section VI introduces the proposed conceptual model, and Section VII closes the study with recommendations for further research.

II. Conceptual Overview

This section outlines the conceptual foundation of cyber resilience frameworks. The nine goals, inclusive of NIST CSF 2.0 functions and cyber resilience goals (Identify, Protect, Detect, Respond, Recover, Govern, Anticipate, Withstand, Evolve), provide the analytical baseline for this review. Additionally, Zero Trust (ZT) and Artificial Intelligence /Machine Learning (AI/ML) are introduced as emerging enablers of resilience that influence the design of contemporary frameworks.

A. Emerging Cyber Threats

Cybercriminals act with malevolent intent to disrupt services and compromise critical data, resulting in financial losses [3]. As cyber-attacks evolve, they also contribute to broader economic impacts [4]. Furthermore, these attacks pose a range of operational and organisational risks [5]. Attackers even adapt their attack strategies to elude traditional defences [6]. Several authors review emerging cyber threats, including Advanced Persistent Threats [7], cybersecurity challenges such as phishing and social engineering exploits [8], and modern threats and defence strategies addressing operational risks from malware, data breaches, and network intrusions [9]. In addition, AI-powered attacks and cryptocurrency-based cybercrimes demonstrate the growing technological intricacies of contemporary cyber threats [10]. Other threats exploit vulnerabilities in new technologies like fifth-generation (5G) networks, Artificial Intelligence (AI), Internet of Things (IoT), and cloud computing [11]. Recent research shows a growing trend in cyber threats that evolve in quantity and complexity, with attackers using advanced techniques to exploit vulnerabilities in digital infrastructure [12]. The threats are mostly characterised by their dynamic and volatile nature, which emphasises the need for continually adapting and enhancing countermeasures [9, 13]. Although safeguards such as antivirus software, firewalls, and encryption are alleviating, they have limitations [14]. The adoption of cyber resilience capabilities in security mechanisms can bring proactiveness and a reliable solution [15]. In conjunction with the accelerating growth of unpredictable cyber threats, there must be a shift from merely defending against such attacks. There is a need to cultivate resilience through a system's capability to absorb the impact of attacks, regain functionality, and adjust effectively in response to cyber incidents. This accentuates the importance of cyber resilience, which, on top of preventing breaches, also minimises disruptions and promotes rapid recovery.

B. Resilience to Cyber Threats

Cyber resilience has stimulated scholarly interest since the 2000s, alongside the growing maturity in cyber threats. It complements the traditional security approach to protect digital assets and systems. It is vital to highlight the distinction between cybersecurity and cyber resilience for a deeper understanding of the latter. Cybersecurity is defined as "the organisation and collection of resources, processes, and structures used to protect cyberspace and cyberspace-enabled systems from occurrences that misalign de jure from de facto property rights" [16]. In simple terms, it is the operationalization of policies, procedures, and technical measures aimed at securing information and communication systems. Cybersecurity solutions alone cannot cope with the increasing impact of cyber-attacks on organisations. However, the relationship between cybersecurity and cyber resilience remains ambiguous, with some arguing that both goals should be pursued simultaneously rather than prioritising one over the other [1]. Cyber resilience distinguishes itself on the basis of its readiness to pull through cyberattacks, be adaptable, and learn from adversity [17]. It is about going beyond the traditional cybersecurity measure. Cyber resilience requires a mindset shift from reactiveness to proactiveness against known to unknown cyber incidents. Its aim is to incessantly deliver the expected outcome despite adverse conditions [18]. Traditional cybersecurity approaches are reactive and mostly founded on a perimeter-based model for securing organisations. They address certain and known cyber events and adopt a fail-safe strategy. However, cyber resilience acknowledges the inevitability of risks and promotes the strategy of safe to fail, where every system can fail in a controlled way with the ability to recover [18]. Hence, there is a pressing need to either supplement cybersecurity with cyber resilience or simply transcend cybersecurity while moving towards cyber resilience. Today, a number of frameworks are considering cyber resilience and entailing proactive measures to

prevent emerging cyber threats. Therefore, it is important to define cyber resilience.

The literature review shows that there are many definitions of cyber resilience. Researchers have yet to gain unanimity in accepting a unique scientific definition for it [19]. The lack of a universally agreed-upon definition is not only an academic concern but has real-world consequences. This has an impact on the design of CRFs and affects their practical applicability in organisations. Each definition influences the way an organisation or system conceptualise and implement resilience strategies. The different definitions emphasise resilience goals or characteristics in varying ways, depending on what needs to be resilient [20]. For instance, the focus might be on systems, organisations, or threat models. Consequently, five definitions of cyber resilience have been selected that can provide the material perspectives of cyber resilience. Since very often the essence of cyber resilience is misunderstood, Table I below summarises the main definitions.

TABLE I. OVERVIEW OF SELECTED DEFINITIONS

Definition of Cyber Resilience	Key Goals
"The ability to anticipate, withstand, recover from, and evolve to adverse conditions, stresses, attacks, or compromises on systems" [21,22]	Anticipate, Withstand, Recover, Evolve/Adapt
"The ability to prepare for, absorb, recover from, and adapt to adverse events in cyber systems" [23].	Prepare, Absorb, Recover, Adapt
"The ability to continuously deliver the intended outcome despite adverse cyber events" [18].	Business continuity during cyber disruption
"The capacity to withstand, recover from, and adapt to the external shocks caused by cyber risks" [24].	Withstand, Recover, Adapt
"The ability of systems to resist and recover from, or adapt to, a cyber compromise" [25].	Withstand, Recover, Adapt

It is observed from Table I above that the definitions of cyber resilience are mainly goal-oriented. The first definition has been used to ease discussion, and the goals are defined below:

- Anticipate (AP): to maintain an informed state of readiness against potential compromises arising from attacks by antagonists.
- Withstand (WT): to uphold critical operational continuity in spite of the successful occurrence of an attack by an antagonist.
- Recovery (RC): to recover operations in the aftermath of an attack by an antagonist.
- Evolve (EV): to adapt to anticipated changes in the operational, technical, or threat environments.

This definition offers a complementary approach to conventional measures undertaken in cybersecurity. Understanding and using this definition as a foundation to implement cyber resilience is not enough. Organisations need to be guided by CRFs to implement cyber resilience strategies. A well-defined one provides the methodologies and best practices to achieve cyber resilience goals. However, as evidenced by the literature, there is a dearth of studies that focus on CRF against emerging threats of unknown and evolving nature. This inquiry attempts to address this gap by examining the extent to which the current frameworks ensure resilience.

C. Cyber Resilience Frameworks (CRFs)

A CRF is a structured method for managing and responding to threats and incidents in cyberspace. It aids in minimising the disruption caused by such occurrences in an organisation. It is designed in a way to assist organisations anticipate, withstand, and recover from cyber threats [26]. Such a framework typically includes a set of policies, procedures, and technologies that work together to ensure that an organisational entity can survive and recover from attacks. An organisation can improve its capacity to sustain critical functions and swiftly rebound from the disruption of service by adopting a proper CRF [26]. CRFs are evolving and moving from prevention to detection, response, and recovery so as to confront the adaptive and shifting characteristics and challenges of cyber threats [27]. In general, the framework is structured to strengthen an organisation's proficiency in detecting, managing and bouncing back from cyber incidents. This further promotes risk mitigation strategies in the organisation. Recently, emphasis has been laid on situational awareness for effective crisis management and cybersecurity resilience [28].

D. Commonly Established Frameworks

Several well-established frameworks, including NIST, ENISA, ISO 27001, and ISO/IEC 27032, provide guidance for organisations seeking to strengthen their safeguards against cyber threats. Their contributions in enhancing business continuity and cyber resilience have been recognised [29]. The comparative analyses of NIST and ISO27001 offer practical guidance for minimising exposure to cybersecurity risk by selecting appropriate frameworks for organisations [30]. Reviews of framework methodologies and implementation challenges further support effective adoption and application into organisational cybersecurity strategies [31].

In particular, the NIST CSF 2.0 is an updated voluntary guideline to assist all types of organisations to manage and mitigate cybersecurity risks. The way organisations implement it will depend on their risk tolerances, missions, and objectives. It builds on the previous version's functions, highlighting the importance of governance and supply chains. Its core abilities are to:

- Govern the organisation's cybersecurity risk management strategy;
- Identify current cyber risks, to protect against those risks by using safeguards;
- Detect possible attacks and compromises, to respond to detected incidents; and
- Recover affected operations and assets from incidents.

HIPAA, CIS Controls, COBIT, PCI DSS, and CMMC are also prominent frameworks that organisations use to improve their security posture. The role of HIPAA is in securing patient health information and healthcare provider responsibilities [32], while comparative analyses of frameworks such as CIS Controls and COBIT provide guidance for selecting appropriate standards [33]. The PCI DSS framework is used in the context of payment card industry security requirements [34], and CMMC for supply chain management [35]. Additionally, GDPR and HIPAA compliance in IoT healthcare systems shows the importance of regulatory adherence in the digital environment [36]. Since these frameworks have distinct features and operational differences, organisations often align multiple frameworks to meet their needs. Nowadays, some frameworks are leveraging on Zero Trust Architecture to strengthen cyber resilience.

E. Zero Trust Security Frameworks

The Zero Trust (ZT) concept was initially meant to deal with insider threats within organisations. The ZT security model is defined as a network defence strategy that presumes that an adversary has penetrated inside the hardened perimeter of an organisation [37]. Enterprises like Google, Microsoft, and Gartner have implemented this framework after having understood that safeguarding only their network perimeters is fruitless [38]. ZT is an emerging paradigm supporting cyber resilience. Its strategic approach is to "Never trust, always verify". Users, devices, or transactions are not granted trust by default. Currently, there is a scarcity of research in this area [39]. In brief, ZT uses the de-perimeterisation concept. It departs from a perimeter-based security model to a perimeter-less one, where users and devices should not assume trustworthiness by default [37]. It aligns with the principles of cyber resilience as it focuses on measures on how to safeguard sensitive data [40]. This alignment is crucial as data breaches have alarming consequences. ZT should not be considered as a security model only, but a new way of thinking that should be indoctrinated in all security frameworks. Another important aspect is the incorporation of Artificial Intelligence in frameworks.

F. Contribution of Artificial Intelligence (AI) in CRF

Today, Artificial Intelligence is becoming an integral part of technology. However, AI-driven solutions in cybersecurity are used in paradoxical situations. It can either be used as an intelligent defence mechanism or a weapon, such as Advanced Persistent Threats [41]. AI is a powerful tool to rapidly analyse large datasets, detect patterns of a potential threat that may be partially hidden [42]. Cyber defence systems without AI are insufficient to fight against AI-driven cyberattacks, which applies fast decision logics. Furthermore, AI integration in cyber defence for automating threat detection, incident response, and threat analysis can reorient cybersecurity from responding to anticipating threats [42]. The use of AI in CRF is to ensure the system's protection and address the challenges associated with advanced cyber-attacks, including AI-powered attacks [41]. It aids in staying ahead of shape-shifting threats as it facilitates the development of adaptive defence tactics to counter emergent threats. AI is the game-changer in cyber resilience and the development of new frameworks.

As evidenced by various studies, research in the ambit of cyber resilience is gradually progressing. However, although many CRFs have been proposed since the year 2000, they have limitations. There is still a need for increased clarity on their scope, characteristics, and synergies [43]. In order to realise this outcome, a methodical approach is required. The subsequent section discusses the methodology applied to gather the information and analyse the frameworks.

III. METHODS

This section outlines the procedure used to conduct a systematic literature review on CRFs by focusing on their goals, strengths, and weaknesses. The concepts of repeatability [44, 45], along with the PRISMA framework for systematic reviews and meta-analyses [46], were applied. This approach was selected to enhance the review process, making it more transparent, rigorous, and reproducible. Since systematic review can be prone to selection bias by unintentionally favouring certain studies, this methodology helped in reducing that risk. The PRISMA checklist in conjunction with the flow diagram supported the systematic organisation and presentation of the findings, to reflect recent advances in systematic review methodology and terminology. This framework also substantiates the rationale behind the methodological decisions on search strategy, data sources, eligibility criteria, study selection and examination procedures. PRISMA is also a robust protocol commonly used in cybersecurity research [47, 48].

A. Eligibility Criteria

The eligibility criteria were established to confirm the relevance and rigor of the evaluation. Studies were included if they:

- Proposed or evaluated a CRF between 2010 and 2025;
- Addressed resilience goals or emerging threats, and
- Were published in peer-reviewed venues. Non-English, non-peer-reviewed, and duplicate studies were excluded.

B. Databases and Search Strategy

Primary studies were systematically identified and pulled out using carefully selected keywords across multiple databases. IEEE Xplore, ScienceDirect, Scopus, Emerald Insight, and Google Scholar were searched using Boolean query: (“cyber resilience framework” OR “CRF”) AND (“emerging threats” OR “AI” OR “Zero Trust”).

C. Screening and Selection

As illustrated in Fig. 1, a total of 11,027 records were retrieved. After duplicate removal and two-stage screening, 55 studies were included. Fig. 2 illustrates the annual number of research publications in CRFs from 2010 to 2025. It shows that publications in cyber resilience were unstable in the early years, while recently it has been trending upwards. The highest number of publications was recorded in the year 2025.

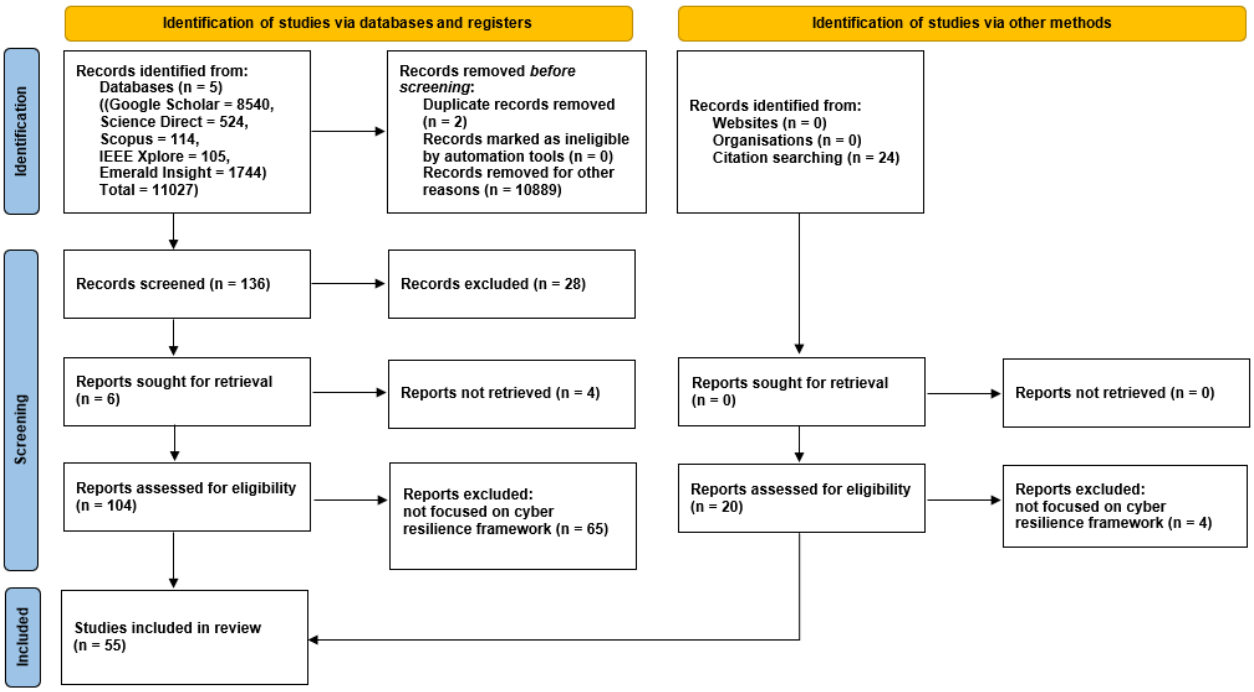

Fig. 1. PRISMA 2020 flow diagram for systematic review.

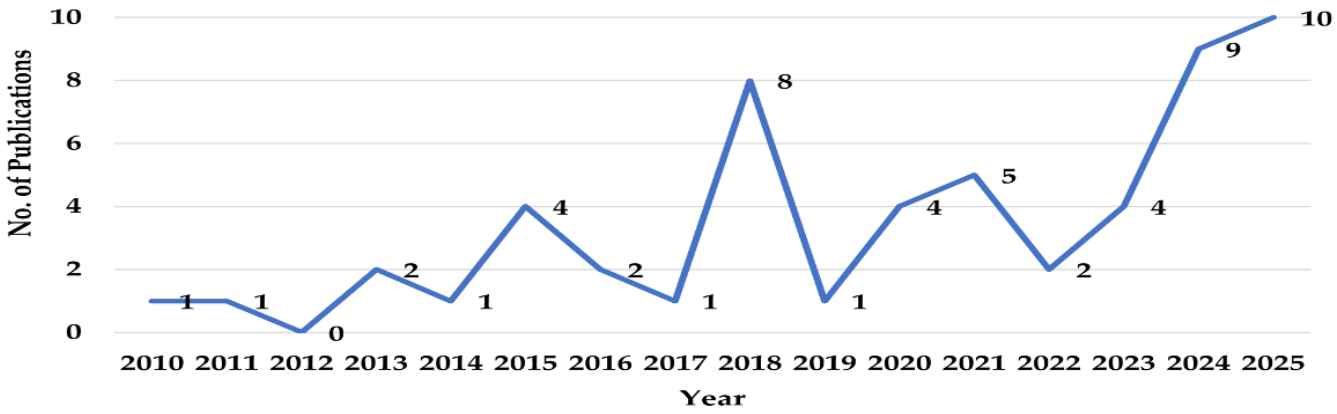

Fig. 2. Annual number of research publications in cyber resilience framework from 2010 to 2025.

TABLE II. PICO FRAMEWORKS

Element	Definition	Application in this Review
Population	Cyber resilience frameworks	All CRFs published 2010–2025
Intervention	Features/ capabilities	AI/ML integration, Situational Awareness, Zero Trust, Blockchain, dynamic defence mechanisms, Comprehensive scope
Comparator	Established frameworks/goals	9 goals of (NIST CSF 2.0 functions + cyber resilience goals)
Outcome	Evaluation metrics	Goal coverage %, strengths/ weaknesses, emerging threat coverage

Table II outlines the PICO framework applied in this study, specifying the population, intervention, comparison, and outcomes that guided the research design.

D. Data Extraction and Synthesis

Data was extracted using a coding sheet capturing year, framework, domain, goals addressed, emerging threats, and validation status. In synthesis, Table III and Table IV, the presence of a feature or goal was indicated with a tick symbol (√), while absence was left blank. Percentages were calculated to quantify coverage, as shown in Tables V and VI. Thematic synthesis was then applied to interpret patterns, supported by visualisations (radar/pie charts). Based on the structured extraction and synthesis, the following section summarises the main outcomes:

TABLE III. CYBER RESILIENCE FRAMEWORKS FROM 2010 TO 2025

TABLE V. SUMMARY OF CRFS STRENGTHS AND WEAKNESSES

Years	CRFs from 2010 to 2025							
	Strengths							Weakness
	Comprehensive Scope	Situational Awareness	AI/ML Integration	Dynamic Defence Mechanism	Caters for emerging threats	Zero Trust	Blockchain	Lacks Empirical Validation
Total No. of CRF	14	13	17	10	26	4	3	4
Percentage of CRF	24.56	22.81	29.82	17.54	45.61	7.02	5.26	7.02

TABLE VI. SUMMARY OF GOAL-WISE CRFS FROM 2010 TO 2025

Goals	Identify	Protect	Detect	Respond	Recover	Govern	Anticipate	Withstand	Evolve
Total No. of CRF	36	50	50	45	36	10	26	16	14
Percentage of CRF	63.16	87.72	87.72	78.95	63.16	17.54	45.61	28.07	24.56

IV. RESULTS

The review syntheses the result of 55 studies, as presented in Table III, Table IV, Table V, and Table VI, with respect to the Research Questions that guided this study. The findings uncovered notable trends and important insights on the prevailing research trends in CRFs. The main results are as follows:

- RQ1 (Goals pursued): Most CRFs emphasise Protect (87.72%) and Detect (87.72%), with limited focus on Govern (17.54%), Withstand (28.07%), and Evolve (24.56%).
- RQ2 (Emerging threats): Only 45.61% of CRFs explicitly address emerging threats such as AI-driven or IoT-based attacks.
- RQ3 (Strengths & weaknesses): Strengths include AI/ML integration (29.82%), comprehensive scope (24.56%), Situational Awareness (22.81%), Dynamic Defence mechanism (17.54%), Zero Trust (7.02%) and Blockchain (5.26%). Weakness includes lack of empirical validation (7.02%).
- RQ4 (Gaps): Under-represented goals (Govern, Withstand, Evolve) and low empirical validation highlight gaps that limit resilience against sophisticated threats.

The radar chart in Fig. 3 is based on the summarised CRFs' goals calculated from Table VI. This chart has been used to visualise the multivariate goals in a way that highlights comparisons across the CRFs. The general trend shows that there are significant variations across the different categories with peaks in areas like Protect, Detect, and Respond while sharp declines in Govern, Withstand and Evolve. There is an overall asymmetrical distribution, indicating that some CRFs have focused more on certain specific goals (Protect, Detect, Respond, Identify, Recover) than others.

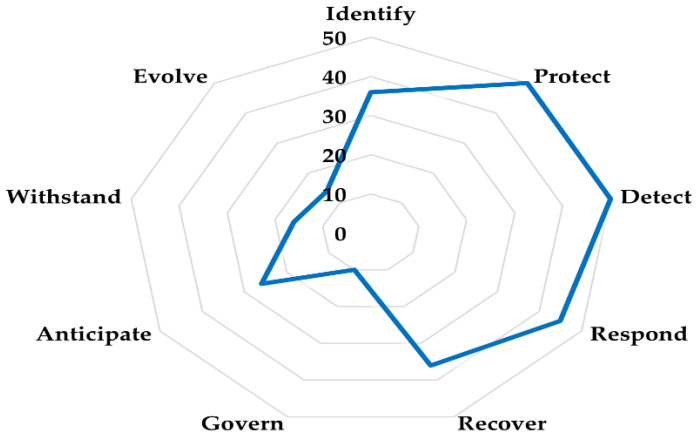

Fig. 3. Radar chart showing goal-wise total of CRFs (2010 to 2025).

The pie chart, in Fig. 4, illustrates the same results from Table VI, in the form of percentages. The majority of frameworks focus on cybersecurity capabilities, namely, "Protect" (87.72%), "Detect" (87.72%), "Respond" (78.95%), "Identify" (63.16%), and "Recover" (63.16%). The "Govern" function (17.54%) has been overlooked. This is perhaps because it focuses on organisational cybersecurity rather than technical implementation, which is often the primary concern of security teams. Some attention has been dedicated to "Anticipate" (45.61%) capabilities. However, not much consideration has been devoted to "Withstand" (28.07%) and "Evolve" (24.56%) goals.

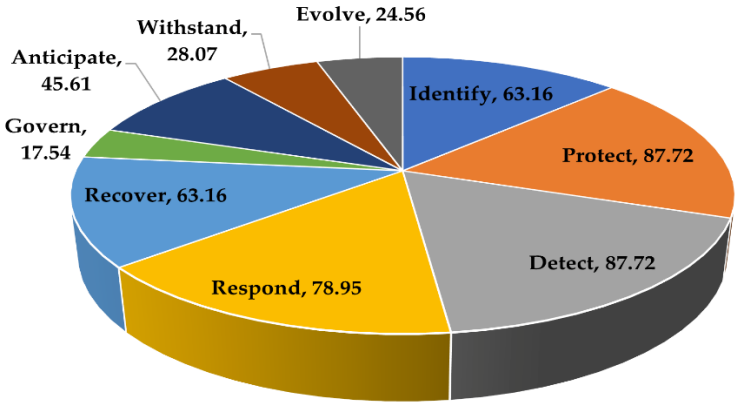

Fig. 4. Pie chart showing goal-wise percentage of CRFs (2010 to 2025).

A noteworthy observation from this review is that the CRFs are still heavily dependent on reactive measures. They fail to fully embrace the proactive and adaptive principles of cyber resilience in terms of withstanding and evolving to ever-changing cyber threats. The exposed gap has several implications for organisations or systems adopting frameworks without resilience capabilities. Should a threat arise, for instance, an AI-based cyber-attack, the organisations might face the following challenges:

- Adaptation failure to emerging threats and become an easy target to cyber incidents;
- Safe-to-fail strategy of cyber resilience will be jeopardised, as systems will not be able to fail in a controlled manner;
- Recovery time delay and lengthening of operational downtime;
- Major financial/reputational loss or legal implication issues; and
- Business closure.

In view of addressing this major gap, there is a necessity to develop a comprehensive framework. This framework should integrate resilience capabilities to adverse conditions with special focus on govern, withstand, and evolve goals. Consequently, a structured visual representation of a model can provide a systematic approach to designing such a framework. The following sections discuss the results and present a proposed conceptual cyber resilience model.

V. Discussion

This review reveals that CRFs prioritise reactive capabilities (Protect, Detect, Respond), while governance and adaptive goals (Withstand, Evolve) remain neglected. The overemphasis on technical safeguards reflects a short-term posture, leaving organisations under-prepared for evolving threats.

Comparisons with previous surveys show that while situational awareness and AI/ML integration are increasing, empirical testing of frameworks is rare, raising concerns over practical deployment.

- Implications for Practice: Policymakers should encourage frameworks to institutionalise governance and adaptive mechanisms. Practitioners should prioritise frameworks with empirical validation before adoption.
- Limitations: This review only included English language sources and excluded grey literature. Binary coding (ticks) may oversimplify framework capabilities.
- Future Research: There is a need for measurable resilience indicators for Withstand/Evolve, digital twin validation of CRFs, and AI-driven resilience metrics.

VI. Proposed Framework

The proposed AI-powered CRF directly addresses the identified gaps. Specifically, it enhances the neglected "Govern", "Withstand", and "Evolve" goals, integrates Zero Trust and situational awareness, and introduces AI/ML for adaptive defence. This ensures continuity between the evidence synthesis and framework design.

The framework focuses on the ability to offer real-time protection, recovery, and operational continuity based on the four dimensions of cyber resilience, i.e., competence in predicting threats, resisting shocks, recuperating from, and evolving from adverse conditions. Fig. 5 illustrates the model, which integrates multiple layers of defence with situational awareness and Zero Trust Architecture to create a complete, adaptive, scalable, cyber resilient, and dynamic defence mechanism to counteract cyber threats.

This model has three layers with a core, whereby each layer is finely coupled and supports one another. It ensures a structured and adaptive cyber resilience coverage. It incorporates the protection of data in terms of confidentiality, integrity, and availability throughout its lifecycle.

The top layer, Situational Awareness, emphasises continuous monitoring and vigilance to stay aware of potential threats. This layer consists of Risk Assessment, AI-driven Threat Intelligence with continuous monitoring, and Decision Support.

Fig. 5. AI-powered cyber resilience model (Source: authors' creation).

The second layer is the Zero Trust Architecture (ZTA). It helps eliminate implicit trust and promotes continuous authentication and authorisation of users, devices, and network traffic to access network resources. Furthermore, it uses the principle of least privilege access, micro-segmentation, dynamic security policies, and encryption. Implementing ZTA enhances the cybersecurity posture of an organisation by reducing the attack surface and preventing lateral movement across networks.

The third layer of the model consists of the four pillars of cyber resilience functions, ensuring resilience spanning the pre-incident, during the incident, and post-incident stages of a cyber-attack. Their functions are:

- To anticipate with proactive threat hunting capabilities. AI-driven threat intelligence with Artificial Intelligence algorithms for anomaly and threat detection, and real-time monitoring of cyber threats with early warning. In this phase, prioritisation of assets is important, suggesting a prioritised approach to asset security;
- To withstand with dynamic defence, deceptive mechanisms to mislead attackers, air-gapped protection as a fail-safe, data immutability, as well as Zero Trust mechanisms;
- To recover with automated response, swift recovery, self-healing capabilities, redundancy, failover Systems, minimum downtime, and business impact; and
- To evolve with a feedback mechanism, learning, acknowledging policies and cyber laws with compliance to regulations, adaptation, and a continuous improvement process.

The core of the model consists of governance and humans as key factors. On one hand, good governance in line with organisational goals and policies guides security decisions, on the other, humans through their cybersecure awareness and skills bring these policies to life. Together, they create a resilient cyber resilience-aware culture where leadership, policy, and vigilance jointly safeguard the organisation.

A. Technical Specificity of the AI Model

The AI-powered components of the proposed framework support specific goals related to cyber resilience. Machine learning-based anomaly detection models analyse network traffic and system logs in order to enhance the anticipation of emerging threats. Automated response mechanisms, which are integrated with security orchestration platforms, facilitate rapid containment and recovery following security incidents. Reinforcement learning techniques enable continuous adaptation by updating defensive policies based on observed attack patterns and response outcomes. Collectively, these AI mechanisms operationalize the goals of anticipation, withstanding, recovering, and evolving capabilities. Thus, they strengthen resilience against adaptive adversaries.

B. Framework Validation and Evaluation Strategy

Although the proposed AI-powered cyber resilience framework is conceptual in nature, its effectiveness can be systematically evaluated using established validation methodologies. Scenario-based simulations may be employed to assess the framework's behaviour under representative attack conditions. These conditions include AI-driven phishing, ransomware propagation, and IoT-based intrusions. Digital twin or cyber-range environments can further support controlled experimentation. Such environments enable the measurement of recovery time, operational continuity, and the effectiveness of adaptive responses.

Furthermore, key performance indicators such as mean time to detect, mean time to recover, resilience maturity progression, and governance effectiveness may be employed to quantify outcomes of the framework. These validation strategies establish a robust foundation for future empirical testing. They also ensure that the proposed framework is grounded in practical feasibility rather than in purely theoretical abstraction.

VII. Conclusion

Improper implementation of cyber resilience leaves organisations susceptible to cyber-attacks. Although a number of CRFs have been conceived to date, they still have some shortcomings. Most of the frameworks are still using traditional cybersecurity approaches with reactive strategies and insufficient focus on cyber resilience. They are unable to deal with unknown and evolving cyber threats, requiring a comprehensive coverage of technologies like AI/ML, ZTA, blockchain, IoT, and automation. Consequently, the limitations in the frameworks lie mostly in their adaptability to handle

evolving threats, and cyber resilience does make a difference. Although cyber resilience is not a panacea, it does provide a distinctive strength through proactive security management. The conceptual model proposed in this research is a stride towards this aim, harnessing the speed and accuracy of Artificial Intelligence and the "Never Trust Always Verify" paradigm to advance Cybersecurity.

The proposed framework is applicable to a broad range of organisational contexts, including small and medium-sized enterprises, critical infrastructure operators, and public sector organisations. By integrating governance, adaptive learning, and emerging-threat awareness, the framework supports informed decision-making concerning cybersecurity investment, policy formulation, and resilience planning. Consequently, it offers both a theoretical contribution to cyber resilience research and practical guidance for organisations operating within increasingly dynamic cyber risk environments.

Although this study advances scholarly understanding in cyber resilience, it is not free from limitations. The authors recognise that there might be some potential biases or subjectivities introduced by their own perspectives in evaluating the CRFs. Furthermore, the authors acknowledge that the issue of the AI aspect would be in the training of the AI model, which requires large and accurate datasets, which are often limited. Instead, AI-generated synthetic cybersecurity datasets that maintain realistic attack patterns and vulnerabilities can be used. In addition, adversarial AI-training can be utilised to improve the model's resilience against emerging threats. There is also a need to build a prototype CRF from this model and assess its practical feasibility in organisations within risk management practices. It is also critical to evaluate the CRF to ensure its effectiveness against evolving threats.

Some potential improvements for future research are to explore the possibility of using an AI-driven security framework evaluation, using machine learning techniques to assess the framework's efficiency and predictive accuracy. Also, the use of cybersecurity digital twins to empirically test the CRF through real case studies or simulations could be envisaged. Another option could be the use of AI-Augmented Penetration Testing tools to evaluate CRF dynamically against new and evolving threats. Lastly, a promising avenue for future research is on self-healing systems within a framework, which is critical to enhance resilience. These techniques and research areas will address the current limitations and applicability of CRFs.

Some practical implications of the proposed model in real-world scenarios would be proactive threat detection before they cause damage, as the AI capability in the model would identify patterns and anomalies in network traffic and user behaviours. Enhanced response to cyber incidents in real-time by isolating compromised systems and mitigating attacks without human intervention. Overall, its benefit would be to strengthen cybersecurity posture, reduce system downtime, sustain business continuity, and protect sensitive data from cyber incidents.

In conclusion, while CRFs have advanced in integrating AI and Zero Trust, their limited attention to governance and adaptive resilience weakens their effectiveness. Addressing these gaps is crucial for organisations facing dynamic cyber threats. The proposed framework provides a blueprint for strengthening future CRFs through adaptability, validation, and evidence-based design.

***Abstract*—Reading comprehension models frequently struggle to accommodate linguistic diversity, especially dialectal variations within the English language that disrupt semantic alignment and fairness. In order to overcome these drawbacks, this study proposes the Dual Cognitive Pathway-Based Dialect-Aware Cognitive Twin Framework (NeuroTwin-DialectaLearn) as a new framework that combines the principles of cognitive science, sociolinguistic expertise, and adaptive learning methods. The framework also has two parallel understanding routes, one is a Lexico-Semantic Pathway that processes normal English, and the other is a Dialectal-Semantic Pathway that is involved in normalizing the dialect and aligning the semantics. Such pathways interact with each other by a process of Adaptive attention fusion in a Cognitive Twin model, which instantiates important cognitive processes, including lexical processing, syntactic parsing, semantic integration, inductive reasoning, and answer generation. It uses Python and PyTorch to implement the system and is tested on the English Classroom QA Dataset with the addition of synthetic dialectal variants to enhance the system. The accuracy of comprehension is 98.1 per cent, the average response time is 14.3 seconds, and the rate of learners' improvement is 18.9 per cent, which is much higher than the baseline QA systems and improved BERT models. The framework has shown consistent performance in the context of dialects; the number of vocabulary-related mistakes is lower, and the consistency of inference is higher, proving to be an effective tool in dialect-conscious and cognitively based reading comprehension. In general, the present research provides a linguistically encompassing, versatile, and understandable next-generation smart educational system.**

Keywords*—Cognitive Twin; Dialectal Transfer; Adaptive Tasking; English reading comprehension; personalized learning

I. Introduction

English proficiency has become highly essential to enable students to excel in their everyday learning, and create a career, and communicate with people all over the world [1]. Although it has a distinct benefit, most of the students learning English as a second language find it challenging to use written texts due to differences in terms of culture, language, and mental condition [2]. The common reading understanding models fail to identify the differences between a mono and multilingual learner, and this is why they do not work with multilingual learners. The person with a learning disability who is going to work in a language with limited resources has a greater challenge due to the absence of resources [3]. Due to all this, new systems that render meaning to messages written in a different language without distorting the meaning or original ideas are now in order of being created [4]. These linguistic issues have been made promising thanks to the work of Artificial Intelligence and, specifically, Natural Language Processing [5]. These AI-based NLP technologies are used to enable machines to research language to gain a better grasp of how to comprehend and learn it [6]. A significant innovation is that the cross-lingual word embeddings make it possible to indicate words with identical meanings in various languages in a shared space [7]. Using adjustable embeddings, see better the way various languages structure themselves [8]. Such models prove particularly useful to ESL students since they can learn to interpret information which otherwise would have been bewildering in regular classes [9]. The implementation of the bi-LSTM networks, that is, a powerful neural network structure, has enabled easier comprehension of how a sentence varies due to the capability of the network to detect connections between words at the early and latter stages [10]. Two-way knowledge of the context enables chatbots to be close to how human beings tend to interpret language [11]. Such technologies, together with attention mechanisms that aid the model in attentively focusing on the germane elements of a sentence or paragraph, may lead to better and contextually relevant interpretations of text [12].

The strategy is aimed at assisting the multilingual students to read English better, with the combined cross-lingual word representations and Bi-LSTM-based attention mechanism [13]. The model is used to encode the main meaning, and in addition

to that, it is structured to connect contexts across various levels, enabling the model to interpret and utilize language more effectively. As a result, students are better placed to make more sense out of language concepts with different forms of writing due to learnt associations. It was also better tested in comparison with some of the traditional models of reading comprehension [14]. The significance of the framework is that it is able to store not only semantic richness but also the contextual stream of the language as the principal aspects of true understanding. It is a prominent learning instrument, especially for one who has a multilingual or low-resource background. The suggested framework can assist in addressing the block to effective communication and facilitating the fair language acquisition, and enable every learner in various linguistic groups to receive a higher academic performance with the assistance of clever technology. This study suggests a Dialect-Aware Cognitive Twin Framework, based on a Dual Cognitive Pathway, whereby a Lexico-Semantic Pathway is proposed as the standard English comprehension pathway and a Dialectal-Semantic Pathway is proposed as the regional and non-standard English understanding pathway. The framework creates dialect-neutral semantic representations through a fusion attention mechanism, allowing human-like, adaptive understanding in a wide variety of linguistic situations.

A. Problem Statement

The surge in the use of online education systems has unfolded the unresolved problems in English reading comprehension, particularly among the students who have been exposed to other dialects and language backgrounds [15]. The traditional understanding systems and AI-trained tutors tend to rely on the traditional collections of the English language, which are not useful to support the regional, colloquial, or non-standard speech forms and can cause misunderstanding and reduced learning. In addition, most existing frameworks provide some standard tasks and difficulty levels [16], and do not take into account the specifics of the learners, their error patterns, and cognitive differences, which results in ineffective interaction and inefficient one-on-one help. These gaps underline the need to have a smart system that can imitate the human-like level of understanding, the ability to change dialects depending on the state [17], and offer dynamically tailored learning activities to every learner. The issue is thus the absence of an integrated, dialect-sensitive, and adaptive framework that could contribute to the improvement of the accuracy of reading comprehension, inclusiveness, and learner development in heterogeneous education settings.

B. Research Motivation

The justification behind this research can be attributed to the necessity of filling the gap between human thinking processes and the dialectual differences that affect reading comprehension in English. A significant number of learners do not have a problem due to the failure to read, but instead because the current AI-based understanding frameworks do not consider the existence of linguistic diversity and dialect. This study aims to reproduce the neurocognitive processes of reading in the human brain with the dynamic adaptation process to dialect changes. The idea is to facilitate equity, inclusiveness, and accuracy in language understanding, especially for students who often have to move through a multi-lingual and dialect-rich world.

C. Research Significance

The framework proposed is of significant significance, since it implants the dual path cognitive model that can not only interpret linguistic meaning, but also normalizes dialectal differences in the process of understanding language. This syntactic design ensures dialect neutrality, cognitive realism, and adaptive personalization, all of which are mostly lacking in the traditional reading comprehension models. It can be applied in intelligent tutoring systems, AI-helped language learning, and adaptive learning systems, and is advantageous to contribute to the scientifically based and fair method of improving English reading comprehension in a linguistically diversified learning setting.

D. Key Contributions

- Introduces a dual-stream comprehension mechanism comprising Lexico-Semantic and Dialectal-Semantic pathways that process standard and dialectal English simultaneously, fusing them into a unified, dialect-neutral understanding.
- Recreates human reading cognition through hierarchical processing, lexical decoding, syntactic parsing, semantic integration, inferential reasoning, and answer generation mimicking human comprehension behavior.
- Enhances inclusivity by generating dialect-preserving embeddings and normalizing linguistic variations, enabling accurate comprehension of non-standard and regional English forms.
- Dynamically personalizes comprehension tasks based on learner performance, error distribution, and reading pace to optimize engagement and difficulty progression.
- Implements dialect-sensitive assessment and continuous monitoring to ensure equitable learning outcomes and measurable improvement in comprehension accuracy.

E. Rest of the Section

Since the related studies and technique are presented in Section II and Section III, respectively, the work is structured as follows: Section IV presents the results, and Section V concludes the study.

II. Literature Review

Muneer et al. [18] include the use of sentence transformer models to predict semantic similarity between pair of words in English and the Urdu language. The researchers used both LaBSE and Universal Sentence Encoder as multilingual embeddings. They also ventured into feature fusion in which there was a combination of various models and different translation tools like Bing and Google Translators. This was an indication that there are certain combinations that do score higher, namely, combination of LaBSE and Bing Translator which scores higher than the other combinations do as they appeared to bring about better semantic correspondence between

the translations of the various languages. The quality of the translations however had a significant effect on performance and the external translation tools varied the job. The constraints were primarily the reliance on the quality of translation that would taint uniformity and dependability of semantic similarity evaluation between various language pairings. Wu et al. [19] suggested a more advanced model of the Semantic Disentanglement Model (SSDM) of a Siamese to facilitate more successful zero-shot cross-lingual transfer of multilingual models in machine reading comprehension. Their model attempts to increase the multilingual generalizability of pre-trained linguistic models by separating the semantic and syntactic structures. SSDM uses personalized loss functions to explicitly encode and separate semantic and syntactic information and predict answer spans in target languages better. It demonstrates notable improvements over such traditional models as mBERT and XLM-100, particularly when it comes to linguistic differences that are a part of cross-lingual environments. Their findings support the relevance of disentangled representations to effective cross-lingual understanding, as they are part of the objectives of integrating cross-lingual embeddings into reading systems based on AI.

Xu et al. [20] proposed a multilingual pre-trained machine reader named mPMR whose aim is to enhance the natural language understanding in a large number of languages. Compared to models previously used, which relied on fine-tuning on the source language, mPMR employs MRC-style pre-training to learn explicit skills of multilingual NLU as such. This enables better cross-lingual generalization such that the model can attain excellent sequence classification and span extraction results in target languages. mPMR provides a single answer to cross-lingual reading comprehension tasks of combining the span extraction and sequence classification processes. The fact that the model can be used to extract rationales to classify sentence-pairs also enhances its interpretability, which makes it a very useful construction in the use of multilingual NLP systems. The objective of this research on scalable, multilingual pre-training is in line with the objective of developing AI-based frameworks in English reading comprehension among various linguistic groups. The challenges of cross-lingual cross-knowledge bases (xKBQA) question answering were overcome by Zhang et al. [21] because it was treated as a reading comprehension task. Their resolution involves the translation of subgraphs of a knowledge base to passages of text, thereby bridging the gap between natural language queries and structured KB schemas. In low-resource scenarios, the multilingual language models are used so that the questions in multiple languages are transformed into corresponding phrases in the knowledge base. This strategy allows teams to take advantage of the available xKBQA data to narrow down on the problem of small data in xMRC research. The model works well in most languages that attest that cross-lingual reading strategies enhance knowledge-based model question answering. The research seeks to develop the English reading capacity with one language embedding for the benefit of AI.

Zafar et al. [22] comprehensively examined the possible applications of technology-based reading support on international students in post-secondary education. The study examines the different AI products available, like machine translators, speech to text, text to speech, and intelligent annotation systems, with an aim of enhancing the comprehension of the readers, enhancing their lexicon, and comprehending the material. Enhancing the study by combining the research approaches, this study identifies the applicability of adaptive, personalized and interactive learning with the help of AI tools [23]. It was revealed that this technology assists individuals to read with greater significance since it provides immediate assistance and interpretation as people read. The research indicates that the introduction of AI in multilingual classes facilitates and enables all students to learn. The review indicates that AI models are needed to enhance the reading of English to all types of learners. A multiple case study conducted in 2023 aimed at comprehending the differences between the instructions of reading comprehension and student outcomes of multilingual students. The study by Gallagher et al. [24] registered improvements in reading comprehension, academic vocabulary, and motivation of students whose explanation was attributed to some teaching practices. Among them, the use of the native language of students to explain concepts and lower-level texts as effective practices was significant. The study highlights culturally responsive teaching methods and uses and implementation of multiple language materials in support of reading development. The results support the necessity of tailored instructional methods to fulfill the needs of multilingual students, which is connected to the broader objective of enhancing the English reading comprehension based on cross-lingual, AI-based models.

Recent research indicates an improvement in multilingual and cross-lingual reading comprehension, but significant gaps are still there. The majority of them are based on standard English datasets, do not normalize their dialects, and do not simulate human-reasoning and adjust to the individual learners. The proposed Dialect-Aware Cognitive Twin Framework provides these limitations by combining dialect-conscious embeddings, cognitive modeling, and adaptive tasking to provide inclusive, interpretable, and customized real-time English comprehension.

III. Dual Cognitive Pathways with Dialectal Transfer and Adaptive Tasking

The study constructs a Dialect-Aware Cognitive Twin Framework of adaptive English reading comprehension, based on cognitive modeling, dialectal normalization, and motivated tasking. The framework takes the Dual Cognitive Pathway structure, wherein the Lexico-Semantic Pathway is the processing of standard linguistic cues, and the Dialectal-Semantic Pathway is the process of aligning dialect-specific changes. The system starts with the analysis and preprocessing of the data based on the English Classroom QA Dataset, which is cleaned, tokenized, and filled with the actual or artificial variants of dialects. The Cognitive Twin then models human understanding by performing staged processing that involves lexical decoding, syntactic parsing, semantic integration, inferential reasoning, and answer generation, giving correct predictions and traceable reasoning paths. Fig. 1 presents the overall flow of English reading comprehension.

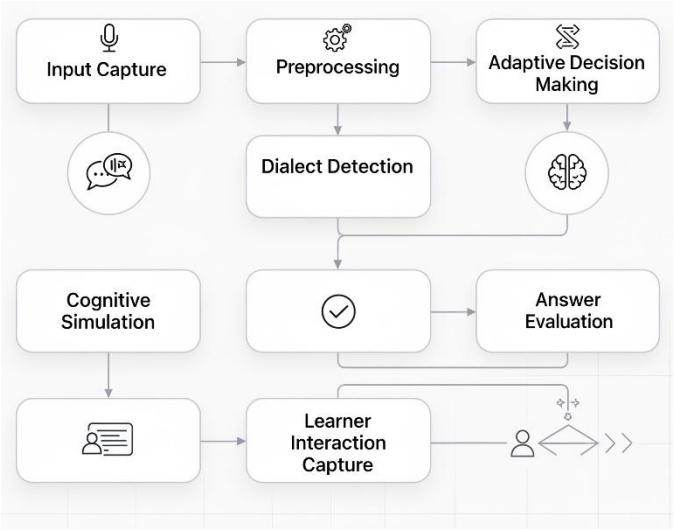

Fig 1. Overall flow of English reading comprehension.

Simultaneously, the Dialectal Transfer module is designed to be resistant to linguistic differences to normalize dialectal inputs, produce dialect-sensitive embeddings, and cast them into the regular semantics of the English language. The Adaptive Tasking component captures and analyses learner interactions in real time and dynamically modifies task difficulty, type, and focus according to the performance, patterns of errors, and learner profiles. The system is appraised on the basis of comprehensive precision, reaction time, error rate, and learner progression, where the model is continually modified through feedback, and dialect is altered, as well as personalized teaching. This is the multi-stage, closed-loop approach to methodology that guarantees the inclusiveness of the framework, its pedagogical effectiveness, and ability to enhance understanding in a wide range of learner groups.

A. Data Collection

The English Classroom QA Dataset [25] from Kaggle provides a comprehensive resource for evaluating reading comprehension through a wide range of passages and question types, including multiple-choice, short-answer, and open-ended formats. It may include long text-question pairs having diverse vocabulary and different lengths of passages that can be read in the classroom as a comprehension assessment. The dataset encompasses various skills, including the recall of facts, inference, knowledge of vocabulary, and summarization. Nevertheless, it mostly imparts the standard form of English and does not have dialectical diversity. To achieve successful Dialectal Transfer, it is possible to bias the dataset with natural or artificial dialectal variants, which allows the model to understand English dialects and stay consistent in its comprehensive accuracy.

B. Data Preprocessing

The proposed work is based on the theories of cognitive science, linguistics, and adaptive learning and gives a thorough ground on which the study can be modelled to explain the English reading comprehension across the dialects. Fundamentally, the proposed Cognitive Twin concept is based on constructivist cognitive theory that new learners actively construct meaning by incorporating new textual information into pre-existing knowledge structures. In this respect, the Cognitive Twin will serve as an online simulation of understanding process in a learner, which will include various phases: lexical access, syntactic parsing, semantic integration, inferential reasoning and generation of answers. We may formalize to have that: C(t) coherent to a text t, is Eq. (1):

$$C(t) = f_{reasoning}(f_{semantic}(f_{syntax}(f_{lexical}(t)))) \quad (1)$$

where, $flexical$ will recognize words and vocabulary understanding, $fsyntax$ will deal with grammatical parsing, $fsemantic$ will combine meaning, and $freasoning$ will use inferential logic to generate answers.

The Dialectal Transfer component is based on the sociolinguistic theory and transfer learning principles, which acknowledge that the language understanding depends on the previously existing dialectal variants. The system addresses the challenges of linguistic differences in comprehension that can be presented by a regional or non-standard version of English by mapping dialect-specific linguistic features to a standard semantic space. Mathematically, using dialectal text std, the dialectal text mapping M: tdts is a mapping that maps the dialectal expressions to a standard representation, Eq. (2):

$$t_s = M(t_d) = f_{dialect_{norm}}(t_d) \quad (2)$$

Finally, Adaptive Tasking is grounded on educational contents theory and item response theory (IRT) that learning outcomes are strengthened in case the tasks are modified based on the capability of the learner. Task difficulty Di: Task difficulty Di is actively regulated by the learner performance Pf and Cognitive Twin feedback Ci, Eq. (3):

$$D_{i+1} = f_{adaptive}(P_i, C_i) \quad (3)$$

where, more difficult tasks are introduced with a high level of comprehension, and tasks of reinforcement are introduced in case of an error or misconception.

The content theory will provide a strict basis of the building of an intelligent system of reading comprehension, which will reproduce human cognitive process, and which will adjust linguistic variety and dynamically individualize the learning activities, which will lead to better understanding outputs among the various learners by considering cognitive modeling, Dialectal Transfer, and adaptive learning.

C. Cognitive Twin Component

The most important aspect of the proposed framework is the Cognitive Twin Component that is an extremely complex calculational formation that attempts to model and replicate the complicated cognitive activities that human beings utilize during the process of reading comprehension. The Cognitive Twin in simple terms is anchored in the multi-layered construction of the process of understanding that begins with the top level of processing which is the process of identifying and decoding of words, syntax, sentence borders, and prominent phrases. It is followed then by the process of semantic integration where the model gives meaning to individual words and sentences in a consistent way that indicates relationships at the context and discourse level. Beyond comprehension, the twin is involved in the process of inferential reasoning where he or she is able to

relate unspoken information in the text to what is already known and form logical inferences or predictions. The Cognitive Twin is then summarized and abstracted, reducing the most important concepts and organizing them in a form cognitively understandable, which is then used to generate answers to comprehension-based questions (architectural perspective). The above denotes the sequential cognitive transformation from lexical decoding to reasoning. Reasoning attention is computed using Eq. (4):

$$R_i = \sum_{j=1}^{n} A_{ij} \cdot S_j \quad (4)$$

where, R_i is the Reasoning vector at step i, A_{ij} is the Attention weight between token iii and contextual token j, S_j is the Semantic representation of token j and n is the Number of tokens in the passage. This expresses how the attention mechanism allows the model to focus on relevant contextual words while generating logical reasoning similar to human comprehension. Layers at the start of the model are concerned with lexical embeddings, syntactic parsing, intermediate layers deal with semantic comprehension, attention-based inference and contextual reasoning, and more specialized layers combine external sources of knowledge, like encyclopedic facts or domain specific knowledge, to add to reasoning ability. The architecture can exploit attention mechanism, memory modules and graphical relationship modelling to mimic human analogy of focus on pertinent textual portions and logical association.

The Cognitive Twin Engine in the proposed model is going to work on two Cognitive Pathways. The former is known as the Lexico-Semantic Pathway and it processes the standard comprehension process encompassing lexical decoding, syntactic parsing, and semantic fusion. The latter, the so-called Dialectal-Semantic Pathway, simultaneously takes dialectal linguistic cues, and aligns them to the default semantic space with dialect-specific embeddings and normalization layers. A Fusion Attention Mechanism then combines the two outputs to form one representation which is dialect-neutral and yet semantically faithful and adjusts to language differences. Mathematically the combination of the two pathways can be denoted as in Eq. (5):

$$F_{\text{dialect-neutral}} = \alpha \cdot E_{\text{standard}} + (1 - \alpha) \cdot M(E_{\text{dialect}}) \quad (5)$$

where, E_{standard} is the embedding from the Lexico-Semantic Pathway, E_{dialect} is the dialectal embedding, M is the mapping function for dialect normalization, and α is the adaptivity coefficient dynamically learned during training. This dual-pathway structure enhances the human-like cognitive ability of the model by allowing it to process meaning and dialect simultaneously, ensuring more inclusive and contextually accurate comprehension.

Training-wise, the Cognitive Twin is pretrained with large scale English question answering corpora, which enables the Cognitive Twin to learn general knowledge of language and logic. It is subsequently adapted to the desired learning material (e.g. English Classroom QA Dataset) to fit internal representations to the language forms, question forms, and understanding needs of the classroom-level English. This simulated training makes sure that the Cognitive Twin not only parallels the hierarchical cognitive mechanisms of the human readers, but also becomes adjusted to the real educational settings, where the cognitive abilities are strong in a variety of comprehension tasks, the interpretability of the intermediate reasoning processes, and the ability to make generalizations in the situation of new or dialectally different inputs.

D. Dialectal Transfer Component

The Dialectal Transfer Component is a vital component of the suggested framework since it will help to bridge the issue of linguistic variation in reading comprehension within the English language as the model will be able to process and comprehend texts that are represented in different dialects. The English presented to the learners takes the non-standard or regional accented forms that are likely to have vocabulary, syntax, morphology, idiomatic expressions and phonological differences. To represent this diversity, the component begins by the data-level interventions, such as data augmentation and transfer learning. This may be either in the form of the set of the genuine dialectal corpora or in the form of synthesis of the synthetic dialectal forms through the systematic paraphrasing of standard English texts to the regionally or sociolect transparent ones. These larger datasets provide the model with a greater number of linguistic phenomena and ensure that the model is no longer narrowed to the constructs of standard English but it can generalize to other dialects. In the dialectal transfer by modelling, the most recent techniques are applicable such as adapter modules, multi-task learning or domain adaptation systems. In this case, the standard English is the source domain and dialectal English is the target domain. Under such an arrangement, the model learns common representations that contain semantic content core and at the same time learns dialect-specific mappings to address the lexical, syntactic, and semantic variations. The mathematical representation of the dialectal transfer and normalization process is defined as follows in Eq. (6):

$$t_s = M(t_d) = f_{\text{dialect_norm}}(t_d) \quad (6)$$

where, t_d is the Input dialectal text, M is the Dialectal normalization function, $f_{\text{dialect_norm}}$ is the Mapping operator that transforms dialectal input into a standardized representation and t_s is the Standard English equivalent of dialectal text. This equation defines the core mapping that translates dialectal expressions to their normalized forms. The model learns shared latent representations from both standard and dialectal corpora, as in Eq. (7):

$$H = \lambda \cdot H_s + (1 - \lambda) \cdot H_d \quad (7)$$

where, H_s is the Hidden representation learned from standard English (source domain), H_d is the Hidden representation learned from dialectal English (target domain), λ is the Balancing coefficient ($0 \leq \lambda \leq 1$) controlling source–target contribution and H is the Combined shared feature representation. This expresses how the model learns domain-invariant, but dialect-sensitive embeddings. To ensure semantic equivalence across domains, a feature alignment loss is imposed expressed in Eq. (8):

$$\mathcal{L}_{align} = |F_s - F_d|_2^2 \quad (8)$$

where, F_s is the Feature representation of standard English, F_d is the Feature representation of dialectal English and $|_2^2$ is the Squared Euclidean distance. This loss ensures that the dialectal

and standard representations remain semantically aligned, minimizing the comprehension gap. Finally, the total optimization objective integrates task performance, alignment, and dialect regularization are expressed in Eq. (9):

$$\mathcal{L}_{total} = \mathcal{L}_{task} + \beta \cdot \mathcal{L}_{align} + \gamma \cdot \mathcal{L}_{dialect} \quad (9)$$

where, $\mathcal{L}_{task}$ is the Task loss (e.g., comprehension prediction error), $\mathcal{L}_{align}$is the Alignment loss, $\mathcal{L}_{dialect}$ is the Regularization loss for dialect normalization and β, γ is the Weighting coefficients controlling the contribution of each loss. This is the overall optimization objective, combining comprehension accuracy, semantic consistency, and dialect normalization. Beyond this, the component can include dialect normalization processes or explicit mapping functions, which match dialect-specific lexical features to standard English semantics in order to minimize the difference in comprehension. Alternatively, dialect-specific embeddings may be trained in which distinct dialect features, including regional lexical selections, grammar, and idiomatic speech, are learnt and fed into the Cognitive Twin comprehension pipeline. This will be a complicated plan that will render the Cognitive Twin sensitive to the dialects that vary and will be able to use them to master the general knowledge. This means that the dialectal knowledge is incorporated into the model and thus the model can dynamically interpret non-standard inputs, maintain semantic fidelity of the source meaning and provide the right responses to various learner groups. Consequently, the Dialectal Transfer Component promotes effective, inclusive, and responsive reading understanding to bridge the gap between forms of standard English and the linguistic conditions of learners who interact with alternative dialects.

E. Adaptive Tasking

Adaptive Tasking Component is a dynamic process, which is targeted at the individualization of the reading comprehension process based on the individual learner traits, thereby enhancing the level of engagement and learning. The center stage of this dimension is the building of the total profile of the learner that entails essential traits such as the first level of understanding, prior exposure to the different versions of English, reading speed and pattern of perceived mistakes in the different elements of understanding. Through these profiles, the system is able to not only know what a learner knows but also how he or she processes and responds to text information. According to these profiles, the system divides the tasks into a scale of difficulty levels, where simple recall questions to test the knowledge of the facts are performed at the first level, then the tasks of inferential reasoning, vocabulary-oriented exercises, and summarization problems are presented at the third level demanding higher-order mental processes. The tasks are various in nature as they consist of multiple-choice items, short-answer answers, Cloze tests, which determine contextual knowledge, paraphrasing exercises, and other types that investigate various aspects of comprehension. The adaptive plan is an on-the-fly selection of the next task based on the performance of the learner: in case the learner successively answers simple recall questions correctly, the system can add more complex tasks such as an inference or synthesis question, but when the learner makes more vocabulary errors, then the system will pay more attention to lexical work. Mathematically, assume Pi is the performance measure in task i and Di the relevant difficulty, then the task difficulty Di +1D is chosen as a performance and error distribution dependent variable, Eq. (10):

$$D_{i+1} = f_{adaptive}(P_i, E_i, L) \quad (10)$$

E_i is the error types and L is the learner profile. The Adaptive Tasking Component will offer personalization, scaffolding of the learning journey by continuous performance monitoring and tailored choice of given tasks that will address the shortcomings of the specific learner and conversely benefit the strengths that will optimize understanding achievement and eventual literacy expansion.

F. System Architecture for CognitiveTwin-DialectaLearn Framework

The CognitiveTwin-DialectaLearn Framework (Fig. 2) is planned to be a multi-layered, interoperable framework that incorporates cognitive modeling, dialectal adaptation, and an adaptive sequence of tasks into one coherent learning ecosystem of intelligent reading English comprehension. The fundamental element of the system is the Cognitive Twin Engine, which is a neurocognitively inspired module that resembles the human reading process by providing hierarchically organized levels of computation. The engine is executed with the help of a transformer-based backbone, e.g., RoBERTa, and designed in a way that replicates the major cognitive processes that can be observed in human reading.

The Lexico-Semantic Pathway is composed of the lower layers that work on lexical decoding, word recognition, subword segmentation and vocabulary-semantic mapping. In between layers, cover syntactic parsing, semantic composition and resolving contextual dependencies and translate grammatical structures and discourse relations. In the same line, the Dialectal-Semantic Pathway carries out dialect normalization and alignment. The results of the two pathways are combined at the Dual Cognitive Pathway Integration depicted in Eq. (11):

$$H_{\text{fused}} = \alpha H_{\text{lex}} + (1 - \alpha) H_{\text{dial}} + \text{Attn}(H_{\text{lex}}, H_{\text{dial}}) \quad (11)$$

In the deep comprehension, the model entails the process of inferential reasoning and synthesis of knowledge whereby the implicit textual cues are related to the previous internal or external knowledge to create logical predictions, explanations, and solutions. The Dialectal Transfer Module that surrounds this process gives the process robustness against linguistic diversity as it allows the seamless interpretation of both the non-standard and the standard English. In the architecture, the Cognitive Twin Engine uses the Dual Cognitive Pathways which process the conventional linguistic cues and, at the same time, normalize dialect variations providing dialect-neutral yet context-faithful understanding.

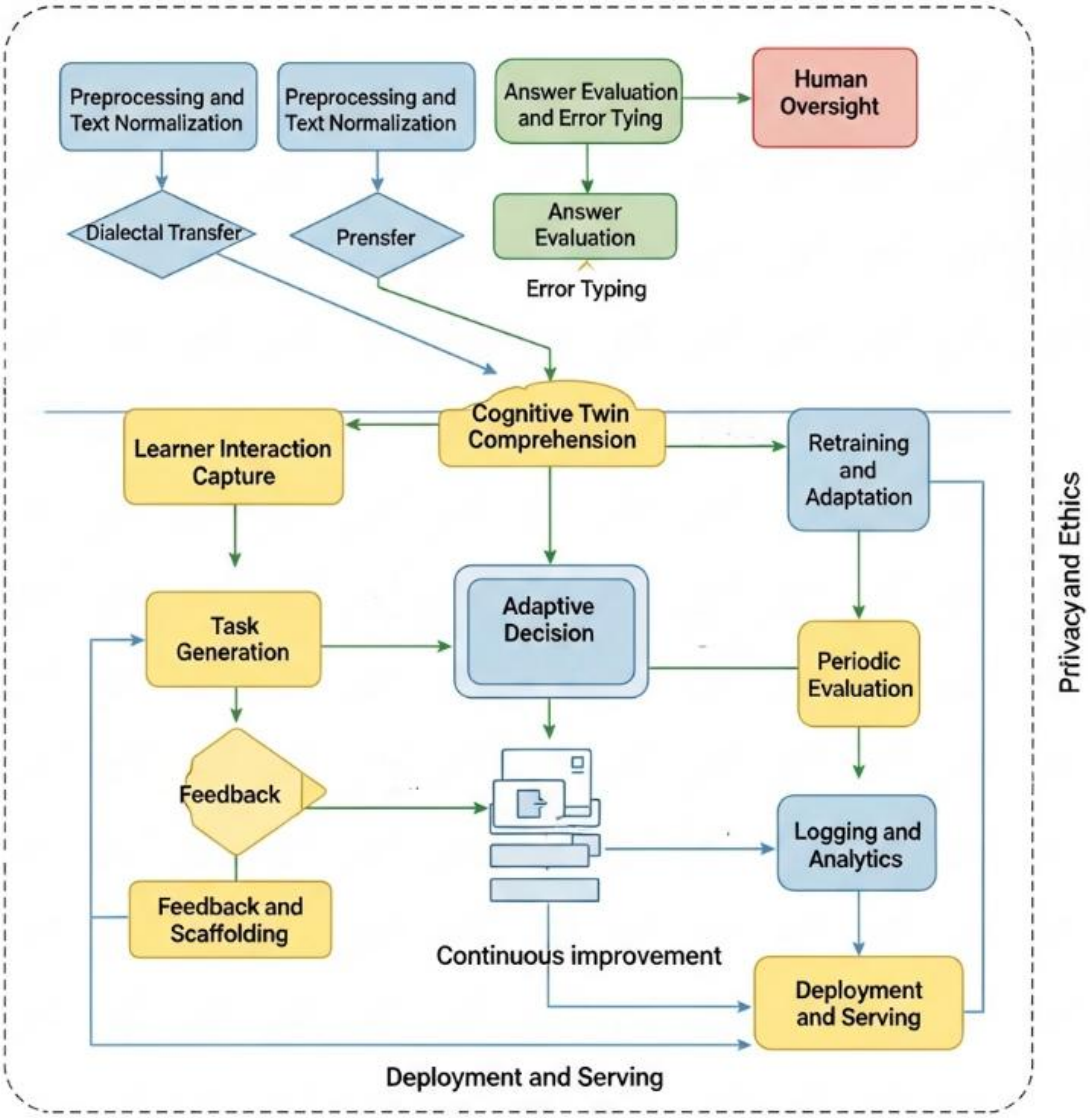

Fig 2. System architecture for CognitiveTwin-DialectaLearn framework.

The Dialectal Transfer Module uses normalization, alignment and domain adaption strategies to project lexical, syntactic and phonological dialect variations into a single semantic space without affecting meaning. The system acquires localized patterns and incorporates them into the comprehension pipeline to encourage semantic fidelity between different learner groups, via adapter networks, multi-task learning or dialect-specific embeddings. On top of these layers is the Adaptive Tasking Layer which is a smart controller that customizes the learning of any student. It constantly monitors the profiles of learners, such as the previous knowledge, dialect exposure, reading speed, accuracy, and error types. The system modulates task difficulty, task type and cognitive focus dynamically using real-time elements of performance based on adaptive algorithms like reinforcement learning or contextual bandits. An example can be given of a learner who displays high recall but low inferential skill, and the system will then be pushed to given high-order reasoning questions to enhance better understanding. Algorithm 1 presents the Dual Cognitive Pathway-Based Dialect-Aware Cognitive Twin framework.

The Dialect-Aware Cognitive Twin Framework Based on the Dual Cognitive Pathway is aimed at reproducing the human-like comprehension and at solving the problem of linguistic diversity. It uses two parallel cognitive routes: the Lexico-Semantic Pathway, carrying out typical comprehension by lexical decoding, syntactic parsing, and semantic reasoning; and the Dialectal-Semantic Pathway, which takes regional or non-standard English inputs by processing them through dialect-specific embeddings and normalization layers. These pathways co-occur, and the results are integrated by an adaptive attention system that produces a unitary dialect-neutral meaning code. The framework combines this bilateral-path knowledge and an adaptive tasking component that reacts dynamically to adjust task difficulty according to the performance of the learners. This allows individual, dialect-friendly, and situation-specific reading understanding that is more closely related to human cognitive and language adaptability.

IV. Results and Discussion

The study indicates the effectiveness of the Dual Cognitive Pathway-based Dialect-Aware Cognitive Twin Framework in improving adaptive English reading comprehension among different groups of learners. With the help of PyTorch and Tensorflow, the implementation of the framework takes place on the basis of the pre-trained RoBERTa model with the Cognitive Twin, Dialectal Transfer, and Adaptive Tasking modules added to the framework through a Dual Cognitive Pathway architecture. This two-way architecture means that the model can take both standard semantic models and dialectal semantic models simultaneously and generate a dialect-neutral understanding as a result. Crowdsourced annotation is used in synthetic generation, which means that it introduces dialectal variants to achieve stability and equal exposure to linguistic diversity.

A. Experimental Outcomes

Forty-five per cent of the questions in the dataset are multiple-choice, one-fourth of the questions are short-answer, one-fifth of the questions are Cloze exercises, and one-tenth of the questions are paraphrase or summarization exercises. The distribution offers a good representation of the capability of understanding, with factual, inferential, and higher-order comprehension, as in Fig. 3.

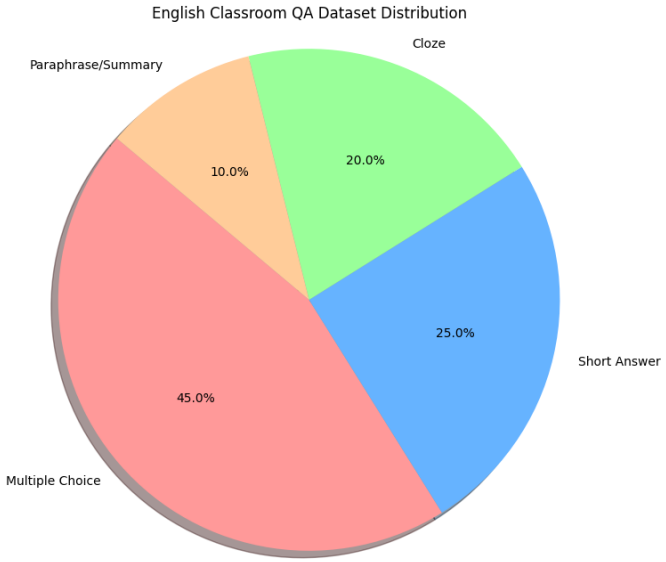

Fig 3. English classroom QA dataset distribution.

The test disclosed that the Cognitive Twin element was able to model multi-stage comprehension and that the surface-level understanding, inference, and reasoning were represented in a manner that was in line with human reading patterns. Inclusion of the Dialectal Transfer module was also essential, as it meant that the framework could deal with both standard and non-standard English inputs, and vocabulary-related and syntactic errors were obviously reduced when learners were exposed to dialectal variations. This improvement is primarily attributed to the Dual Cognitive Pathway fusion, which aligns dialectal semantics with standard representations while preserving contextual meaning, thus minimizing interpretive discrepancies. The mechanism of Adaptive Tasking implemented dynamically regulated difficulty and task type, indicating the quantifiable change in progression of learners as indicated in the increase in the rate of attaining tasks, faster response time, and more balanced distributions of errors in the categories of comprehension. The most common types of errors are the frequency and percentage of Vocabulary/lexical errors, secondly, the inference/reasoning error, and thirdly, the syntax/parsing error. There are other minor errors, like annotation noise or format that are relatively low. The chart can be used to examine areas of weakness in understanding and make model enhancements in Fig. 4.

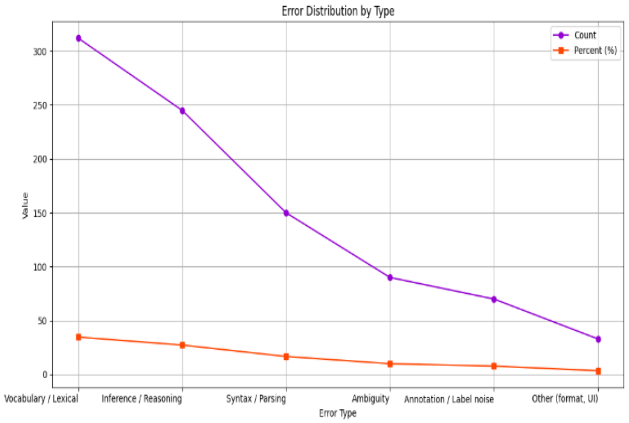

Fig 4. Error distribution by type.

In addition, analysis of errors revealed that recurrent mistakes, especially in reasoning and vocabulary domains, had reduced significantly, which represented a stronger knowledge-retaining ability. Student research identified higher involvement and satisfaction as a result of specific approaches to personalization and dialectal inclusivity, which indicated that student involvement and learning environment were more accommodating and encouraging. Taken together, these findings highlight the capacity of the framework to fill in those gaps between conventional comprehension training and dialect-sensitive flexibility as well as to foster ongoing improvement in the efficiency and accuracy of comprehension in the learner. The Dialect-Aware Cognitive Twin Framework is based on the theoretical foundations of cognitive science, sociolinguistics, and adaptive learning theory, which is why the framework compares the performance of different dialects of the English language, with standard English being the most accurate and with the highest F1-score, whereas the metrics of regional dialects, colloquial forms, and synthetic variants are slightly lower. Non-standard dialects have longer response times. It shows the generalization and strength of the system to the dialectal variations in Fig. 5.

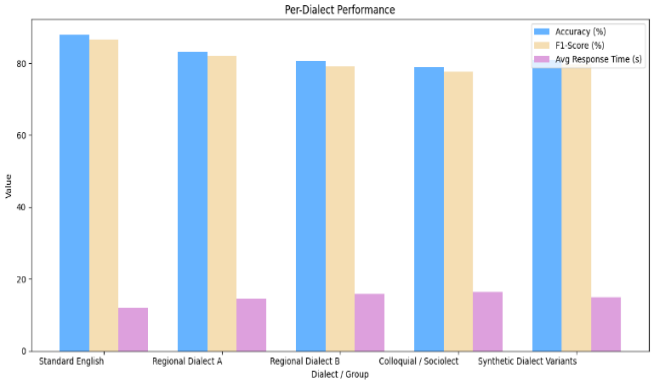

Fig 5. Per-dialect performance.

The notion of Cognitive Twin is based on the cognitive constructivist theory, according to which understanding is created as a result of active interaction between new information and its previous knowledge structure. The Cognitive Twin, in this case, is an artificial replication of the multi-layered cognitive activity during reading: surface-processing (lexical recognition, syntactic parsing, key phrase identification), semantic integration, inferential reasoning, and summarization, finally giving focal answers to comprehension questions.

B. Performance Outcome

The Dialectal Transfer component is based on the principles of sociolinguistics and transfer learning, and it acknowledges that the process of comprehension is mediated by linguistic variation beforehand. Unless the differences in dialects are addressed, dialect may hinder the comprehension of what is said through lexicon, colloquialisms, or syntax. The structure also includes domain adaptation, adapter modules, or multi-task learning, where standard English is the source and dialectal English is the target.

Dialect-specific embeddings can be trained to learn phonological, lexical, and syntactic peculiarities, which adds to the interpretative ability of the Cognitive Twin in Table I.

TABLE I. RESPONSE TIME STATISTICS

Task Type	Avg. Time (s)	Median Time (s)	90th Percentile (s)
Multiple-Choice	8.4	7.9	14.2
Short-Answer	18.7	17.1	29.5
Cloze (fill-gap)	13.6	12.8	22.0
Paraphrase	25.4	23.0	40.8
Summarization	34.1	31.7	55.9

Lastly, Adaptive Tasking is based on the educational content theory and item response theory (IRT), with the focus on individualized learning pathways.

Tasks are dynamically scaled down or up through the factual recall to the inferential reasoning, vocabulary mastery, and summarization, which are provided in various formats, including multiple-choice tests, Cloze tests, short-answer tests, or paraphrasing tests in Fig. 6.

Key comprehension metrics used in assessing the performance of the system have an accuracy of 98.1 per cent and a response time of 14.3 seconds on average. The categories of errors involve vocabulary, inference, syntax, and general comprehension, with the improvement among learners coming to 18.9 per cent. These findings affirm the efficacy of the combined Cognitive Twin, Dialectal Transfer, and Adaptive Tasking system in providing the linguistically inclusive and cognitively based reading comprehension theory. The fusion attention mechanism leads to a 3.2 per cent increase in comprehending and F1 scores compared to the single-path baseline, which indicates improved dialect adaptation with no extra latency.

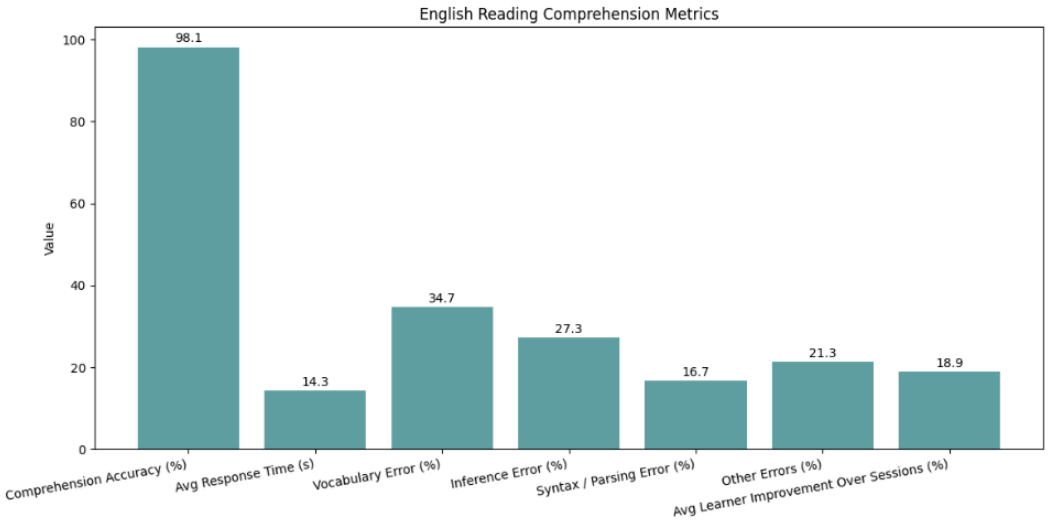

Fig 6. English reading comprehension metrics.

The dataset is separated into training, validation and test sets with a standard 70:15:15 ratio, which makes sure of strong training and unbiased evaluation. Subsets of dialectal tests, developed via authentic or synthetic forms, are used to measure strength to non-standard English. The splits are even on the types of questions and the level of difficulty to be assessed in order to make a fair evaluation of generalization. This systematic assessment validates excellent results on standard and dialectal inputs.

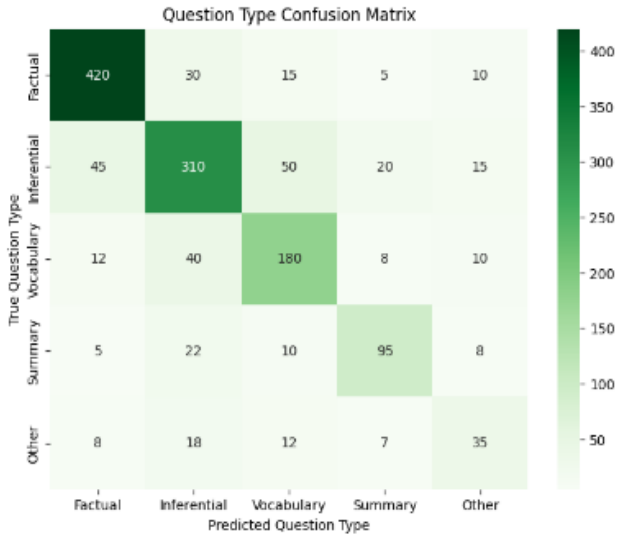

Fig 7. Question type confusion matrix.

Fig. 7 shows the confusion matrix that shows how the system categorizes various types of questions. Factual questions present the greatest correct prediction rate, although some are incorrectly classified as inference or vocabulary-based questions. Cross-confusion is also moderate in inferential and vocabulary questions, which demonstrate slight overlaps in the requirements of linguistic processing. This diagnostic matrix gives an overview of the strengths and limitations of the model in terms of the categories of comprehension.

Fig. 8 is a comparison between the proposed CognitiveTwin-DialectaLearn Framework and the Baseline QA and BERT Fine-Tuned QA models. The presented framework is more accurate, precise, recalls higher, and the F1-score is higher, and the average response time is lower. These enhancements underscore the success of the combination of dual-path thinking, dialect transfer process, and adaptive task selection. The overall findings can be concluded to illustrate that the system is effective in improving comprehension performance, as well as aid quicker and more dialect inclusive reasoning.

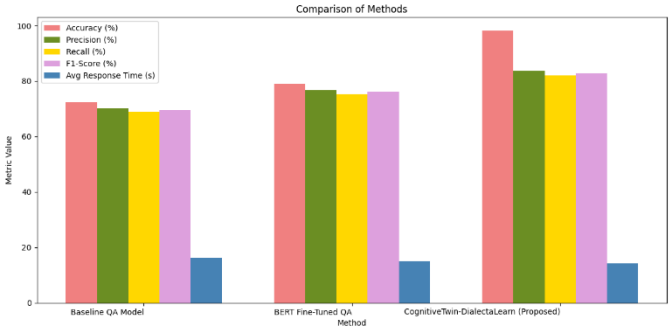

Fig 8. Comparison of methods.

The larger implication of the Dialect-Aware Cognitive Twin Framework is that it can improve adaptive reading of English comprehension among different linguistic groups. The framework fits the variability in the learners and dialectal variation that is not always considered by the traditional comprehension systems by incorporating the concept of cognitive modelling, dialectal sensitivity, and adaptive personalization. The Cognitive Twin element adds a human resembling reasoning system, which allows the system to recreate the layer of cognitive procedures instead of merely matching patterns. The Dialectal Transfer module facilitates inclusivity within the linguistic framework by minimizing the prejudice against standard English and enhancing the availability of learners speaking mixed or non-standard dialects. Adaptive Tasking also enhances this system because it adapts instructional directions in real-time performances with the

purpose of encouraging improvement of constantly and to maintain engagement. Such features make the framework a useful resource in the classroom, online environment, and AI-based tutoring, especially in multilingual and multicultural learning. Comprehensively, it is an indication of a change to fair, smart, and dialect-sensitive educational technologies.

C. Discussion

These results confirm the fact that the Dialect-Aware Cognitive Twin Framework, which is founded on the Twin Dual Cognitive Pathway, has a significant positive effect on the accuracy, adaptability, and cognitive flexibility in English reading comprehension. It's two complementary pathways, i.e., Lexico-Semantic and Dialectal-Semantic, that work in parallel to process both standard and dialectal English, which lets the system form dialect-insensitive semantic representations. Comparisons in performance reveal significant improvements in comprehension accuracy, error reduction, as well as general learning course when compared to the traditional QA systems and fine-tuned transformer-based systems. Adaptive tasking mechanism also promotes more efficiency as the difficulty is dynamically altered based on the changing ability of a specific learner to ensure reduced cognitive load whilst ensuring engagement. The framework also indicates good generalization across a variety of dialects, highlighting the importance of dialect-conscious modeling in the production of linguistically-conscious AI systems that are fair and inclusive. In general, the findings indicate the potential of the framework as an effective, interpretable and learner-centric methodology to be used in educational and comprehension-based AI applications in the future.

V. Conclusion and Future Work

The proposed Dual Cognitive Pathway CognitiveTwin-DialectaLearn Framework is an important breakthrough in adaptive English reading comprehension since cognitive modeling, dialectal transfer, and adaptive tasking have been incorporated into the framework. Through parallel semantic routes, the framework provides more accurate comprehension, less vocabulary and inference mistakes, and learner responsiveness. Its anthropomorphic reasoning codes and active adaptation to language plurality foster inclusiveness and equality among the diverse forms of regional English. The quantitative results also support the efficiency of the model by introducing better accuracy and minimizing the response time, which is a solid base of the next-generation dialect-sensitive and individualized educational AI solutions.

The framework can be expanded by future researchers to include multilingual and multimodal input, i.e., speech, gesture, and image use in modeling more expansive cross-linguistic understanding processes. The reduction of accent and prosody recognition to develop the Dual Cognitive Pathway could also be an additional support for the non-native learners. An adaptive tasking layer can be optimized with the help of reinforcement learning, and explainable attention visualizations might enhance interpretability to educators and learners. The creation of larger and more diverse dialect data will also enhance scalability and strength between variations of world English. These additions will broaden the pedagogical reach of the framework and provide it with a firmer presence in intelligent tutoring and human-AI collaborative learning settings.

Proposed Technological Solution to Predict the Need for Health Professionals in Health Centers Using Random Forest

Fiorella Patricia Mirano Surquislla[1], Gianfranco Henry Ore Paredes[2], Aguilar-Alonso Igor[3]*
Facultad de Ingeniería de Sistemas e Informática, Universidad Nacional Mayor de San Marcos, Lima, Perú[1, 2]
Escuela Profesional de Ingeniería de Sistemas, Universidad Nacional Tecnológica de Lima Sur, Lima, Peru[3]*

***Abstract*—The objective of this research is to develop a technological solution based on the Random Forest algorithm to predict healthcare workforce requirements in public healthcare centers in Peru, addressing staff shortages and unequal workforce distribution. A national dataset from the Peruvian Ministry of Health (MINSA) covering the period 2017–2024, segmented by levels of care (I, II, and III), was used to capture the operational differences within the healthcare system. The model, validated using an 80/20 split, achieved outstanding performance, with coefficients of determination (R^2) exceeding 0.99 and minimal percentage errors (MAPE) across all levels of care. The main contribution of this work lies in converting estimated healthcare attendances into an operational metric of "required healthcare professionals", integrated into a web-based architecture built on React, Flask, and PostgreSQL. The findings identify medical specialty and year as the most influential predictive variables. It is concluded that the proposed tool is robust for optimizing strategic healthcare workforce planning, enabling a more equitable and data-driven allocation of medical specialists.**

Keywords*—Technological solution; Random Forest; healthcare sector; healthcare professional prediction; human resource management

I. Introduction

The shortage of healthcare professionals has been a persistent societal problem even before the onset of the COVID-19 pandemic. According to the World Health Organization (WHO), prior to 2020, a global shortage of approximately 18 million healthcare workers was estimated, with the deficit being more pronounced in countries with limited budgets and in those experiencing poor distribution of health resources, both human and material [1]. In Latin America, unequal workforce distribution, chronic occupational burnout, and inadequate planning for the recruitment and retention of medical teams have long-standing consequences for healthcare systems [2].

In Peru, the Office of the Comptroller General of the Republic has reported that nearly half of public healthcare facilities do not meet the minimum required number of professionals to provide adequate care, revealing a serious shortage of physicians, nurses, and technical staff [3]. Additionally, a technical report from the Institute for Health Technology Assessment and Research (IETSI) of EsSalud (2024) highlights critical gaps in both the quantity and distribution of healthcare personnel across regions and levels of care [4]. These gaps underscore the urgent need to implement predictive systems that enable more accurate and equitable healthcare workforce planning.

*Corresponding author.

At the global level, the WHO (2021) reported that many countries are facing severe shortages of healthcare professionals and projected that millions of additional workers will be required by 2030, particularly in low-resource settings [5]. However, although some governments have expanded healthcare coverage through insurance schemes or public programs, this does not necessarily ensure equitable access to care. In Ghana, for example, individuals with better socioeconomic conditions have been shown to benefit more from such programs than more vulnerable populations [6]. The COVID-19 pandemic further exacerbated these challenges by exposing long-standing structural weaknesses in Latin American healthcare systems, such as poor workforce distribution, sustained occupational fatigue, and insufficient workforce planning—issues also documented in studies conducted in Brazil [7]. Consequently, current strategies must move beyond merely increasing budgets or coverage and instead focus on improving workforce organization, distribution, and proactive planning to ensure equitable access to healthcare services, particularly in high-demand and resource-constrained areas.

At the regional level, increasing attention has been paid in recent years to evaluating the efficiency of public healthcare systems, especially in Latin America. Studies based on Data Envelopment Analysis (DEA) have revealed substantial differences in system performance across countries, even when public health expenditure levels are comparable [8]. For this reason, assessing efficiency in Primary Healthcare (PHC) has become particularly relevant. Even in contexts with broad coverage and sufficient staffing—such as Cuba—significant regional disparities persist, often associated with population size and local socioeconomic conditions [9]. These findings demonstrate that increased financial investment alone does not guarantee improved outcomes; rather, the effective use of available resources plays a crucial role. Identifying underperforming healthcare centers and understanding the factors influencing their performance can support better decision-making, enhance management practices, and ensure that resources translate into improved healthcare delivery and population health—an essential requirement for building sustainable health systems in the region [10].

Similarly, in countries such as Indonesia, where healthcare workforce shortages—particularly of physicians—are critical, unequal distribution has negatively affected primary healthcare performance. In the face of such disparities and limited

resources, it is essential to evaluate how efficiently healthcare facilities utilize available personnel to deliver key services. This assessment enables optimal resource use and supports the estimation of potential gains in service coverage if the existing workforce is deployed more effectively [11].

Given the difficulty of organizing healthcare staff without precise data on future demand, this study poses a central research question: To what extent does the development of a technological solution based on the Random Forest algorithm allow for the accurate prediction of the need for healthcare professionals in Peru's public centers, considering the variability across levels of care? The hypothesis suggests that the integration of geographic, temporal, and specialty variables, segmented by levels (I, II, and III), offers superior reliability compared to conventional statistical methods. The objective is to develop a predictive model capable of accurately estimating the required specialists, recognizing that each level possesses distinct demand dynamics and resolution capacities.

The differential value of this work is built upon three technical pillars. First, it utilizes a massive database from the Ministry of Health (MINSA) with seven years of national records (2017–2024), capturing both regular seasonality and the impact of the health crisis. Second, the analysis is rigorously segmented into the three levels of primary care, acknowledging that resolution capacity varies drastically according to the complexity of the facility. Finally, this proposal translates appointment volume into a "required professionals" metric through an operational conversion methodology, supported by a complete software architecture based on React, Flask, and PostgreSQL

The structure of the manuscript is organized as follows: Section II presents the related work, including a brief review of the relevant literature. Section III details the methodological framework, describing data preprocessing, feature engineering, and the training of the Random Forest algorithm, as well as the technical definition of the evaluation metrics. Section IV presents the architecture of the proposed technological solution. Section V reports the results based on the accuracy metrics obtained for each level of care, along with the analysis of feature importance and regional demand. Section VI discusses the results, which are contrasted with the scientific evidence identified in the literature review. Finally, Section VII summarizes the conclusions and outlines directions for future work.

II. Related Work

Recent research has applied various machine learning techniques to predict the demand for healthcare services, utilizing models that incorporate demographic, economic, and health-related factors.

A study based on Andersen's Behavioral Model of Health Services Use analyzed 2022 data from Turkey [12], identifying variables such as gender, age, educational level, treatment costs, and the presence of chronic diseases as significant predictors of healthcare utilization. Models such as Random Forest, XGBoost, and Logistic Regression demonstrated high accuracy and generalization capabilities in predicting total service demand, providing valuable insights for the efficient allocation of resources in public health centers. These findings highlight the potential of machine learning algorithms to enhance decision-making in public health policy through data-driven analysis.

Furthermore, another study [13] proposed a web-based system using machine learning to mitigate the shortage of healthcare professionals in Peru through Electronic Health Records (EHR). This system implemented the XGBoost algorithm to predict demand across different medical specialties, enabling optimized staff planning. The model achieved a 93% efficiency rating in the AUC test, identifying medical services with the highest projected demand. The automation of data analysis significantly reduced the administrative burden on staff, freeing up time for patient care activities. However, reliance on historical data from a single health center and the lack of standardization in medical record formats limited the system's immediate scalability at a national level.

Yadav [14] investigated the application of machine learning models to optimize professional allocation in healthcare systems with fluctuating demand. The study evaluated four algorithms: Logistic Regression, Decision Tree, Random Forest, and Support Vector Machines (SVM), using historical staffing schedules and patient records. The Random Forest model achieved the highest performance with 98% accuracy, followed by Decision Tree (97%), Logistic Regression (96%), and SVM (95%). The study demonstrated that these models allow for the anticipation of staffing needs and better shift organization by considering both predicted demand and personnel competencies. Nevertheless, a noted limitation is the current lack of tools that combine real-time demand forecasting with automated scheduling. Collectively, these results suggest that machine learning can improve institutional internal operations and reduce excessive workloads.

In the context of human resource planning, a study [15] demonstrated the applicability of machine learning models to predict the retention of healthcare professionals in rural communities in South Africa. Utilizing demographic data from health workers, they trained three classification models (Multinomial Logistic Regression, Decision Tree, and Naïve Bayes), which reached a predictive accuracy of 47.34% and an average AUC of 0.66, significantly outperforming random chance. This study emphasizes the potential of these techniques to optimize recruitment and retention processes in hard-to-reach areas, while also pointing out significant limitations regarding data quality and completeness in resource-constrained environments.

Koç and Eren [16] conducted research to project the availability of physicians in Turkey through the year 2030. To achieve this, they compared various machine learning and deep learning algorithms, including XGBoost, LSTM, and Random Forest, using Root Mean Square Error (RMSE) to measure their accuracy. The study combined historical information from the OECD with artificially generated data to strengthen the analysis of the diverse demographic and economic factors influencing the sector. Following the testing phase, the XGBoost model proved to be the most accurate in its predictions. The final results suggest that a professional deficit will exist by 2030, with an estimated supply of 3.04 physicians per 1,000 inhabitants

against a demand of 3.12, underscoring the need to revise current healthcare training policies.

Köksoy et al. [17] developed a study to predict the need for healthcare personnel across the 81 provinces of Turkey, aiming to reduce inequality in its distribution. They compared nine artificial intelligence models, highlighting the use of the Random Forest Regressor, which achieved a high level of precision with an R^2 of 0.99 and a Mean Absolute Error (MAE) of 39.54. These figures indicate that the model is capable of explaining almost the entire variance of the data and that its margin of error is minimal when estimating the number of professionals. By analyzing data from 2002 to 2023, the authors successfully projected 2024 demands with high accuracy, demonstrating that these algorithms are key tools for more efficient hospital planning.

III. Methodology

This research is applied in nature, as it seeks not only to describe the current state of the healthcare sector but also to propose a practical solution for implementation. Specifically, it involves the development of a technological solution using the Random Forest machine learning algorithm to predict the future demand for public healthcare professionals.

The research level is predictive, as it aims to forecast future healthcare professional demand based on historical data. Through the machine learning model, the study expects to anticipate personnel shortage scenarios commonly found in Peru, where demand in highly populated regions often exceeds the available healthcare workforce. This will enable data-driven strategic decision-making and, potentially, improve the distribution of physicians across the country.

The research is oriented toward healthcare professionals working within the public system, specifically across primary, secondary, and tertiary levels of care managed by the Ministry of Health (MINSA). These categories include specialized physicians, nurses, obstetricians, technicians, and other staff. This topic was selected because it addresses a critical contemporary issue: the deficiency and inequitable distribution of healthcare professionals in the public sector, which directly impacts the quality of service provided to the population.

A. Data Sources and Dataset Description

For the development of the predictive model, the dataset titled Healthcare Attendances Provided to Insured Patients – [SIS] was used. This dataset is provided by the Peruvian Ministry of Health (MINSA) and published on the National Open Data Platform, covering the period from 2017 to June 2024. Its selection is justified by its nationwide coverage and the depth of a seven-year historical record, which enables the model to accurately capture long-term trends, seasonal patterns, and anomalies derived from the healthcare crisis.

1) The dataset includes the following columns:

- YEAR, MONTH, REGION, PROVINCE, UBIGEO_DISTRICT, DISTRICT, EXECUTING_UNIT_CODE, EXECUTING_UNIT_DESCRIPTION, IPRESS_CODE, IPRESS, HEALTHCARE_LEVEL, INSURANCE_PLAN, SERVICE_CODE, SERVICE_DESCRIPTION, SEX, AGE_GROUP, ATTENDANCES.

B. Data Preprocessing and Feature Engineering

Once the required datasets were obtained to initiate the development of the artifact, the process began with data cleaning and transformation of the original data.

1) Data preprocessing: Before training the model, a data cleaning and preprocessing process was performed, which included removing missing values, correcting inconsistencies, and standardizing variable formats.

The first preprocessing step focused on data validation and cleaning. Initially, records with missing values in critical variables defining each observation (YEAR, MONTH, IPRESS_CODE, SPECIALTY, and geographic variables) were removed, ensuring the integrity of the analyzed records. Subsequently, to mitigate the influence of extreme values during training, a robust outlier filtering approach was applied: observations of the target variable, ATTENDANCES, were bounded within the interpercentile range P1–P99. After cleaning, the data were aggregated by summing total ATTENDANCES at the most detailed spatio-temporal unit (YEAR, MONTH, IPRESS_CODE, SPECIALTY, REGION, PROVINCE, UBIGEO_DISTRICT), consolidating the information for analysis.

Prior to training, nominal categorical variables (IPRESS_CODE, SPECIALTY, REGION, PROVINCE, UBIGEO_DISTRICT) were converted into numerical format using the Label Encoding method. Finally, the target variable ATTENDANCES, which exhibited a skewed distribution, was subjected to a logarithmic transformation, which is explained in a later section.

2) Feature engineering: New features were created through feature engineering techniques, which involve transforming and enriching the original data to capture patterns that are not directly observable.

3) Temporal features: This group incorporates time-related information to capture seasonal and cyclical patterns affecting demand. It includes: SEASON, IS_END_OF_YEAR, IS_START_OF_YEAR, IS_PEAK_MONTH, MONTH_SIN, MONTH_COS.

4) Geographical features: This set groups variables that describe the territorial context and the distribution of services within each geographical area. It consists of: IPRESS_DENSITY_REGION, IPRESS_DENSITY_PROVINCE, SPECIALTY_FREQUENCY.

5) Historical features: This block includes features derived from past behavior to capture trends, variability, and consistency in the data. It includes: HISTORICAL_MEAN, HISTORICAL_STD, HISTORICAL_MAX, HISTORICAL_MIN, HISTORICAL_COUNT, REGION_SPECIALTY_MEAN, VARIATION_VS_MEAN, CAPACITY_RATIO.

These features were created from the following original variables (IPRESS, specialty, region, province, month, year) to compute averages, maxima, minima, and count-based metrics.

C. Algorithm and Training

1) Algorithm: The selection of the Random Forest algorithm for this study is based on its well-recognized predictive capability in the healthcare domain. A recent study comparing several machine learning models for pressure ulcer prediction showed that Random Forest achieved the best performance, with an accuracy of 99.88% and an AUC value of 0.9999, significantly outperforming other algorithms such as SVM, Decision Tree, and ANN [16]. This superiority is attributed to its ability to handle multiple predictive variables, reduce overfitting through the aggregation of multiple decision trees, and capture complex non-linear relationships within the data. For these reasons, Random Forest is particularly suitable for risk prediction in clinical contexts involving multifactorial data.

The developed model consists of two main steps:

a) Prediction of healthcare attendances.

b) Calculation of required healthcare professionals.

First, healthcare attendances are predicted. For this purpose, the model was configured with parameters including 300 trees (n_estimators = 300) and a maximum depth of 25 levels (max_depth = 25), allowing the model to capture complex patterns while controlling overall complexity. Bootstrap sampling with 80% of the data (max_samples = 0.8) was applied, along with random selection of $\sqrt{n}$ features at each split to increase ensemble diversity.

To handle the uneven distribution typically observed in healthcare attendance data—where low values predominate but some very high values exist—a logarithmic transformation was applied prior to training. This technique compresses the data scale, enabling the model to learn patterns from both small and large healthcare facilities. The predictions were subsequently transformed back to their original scale, resulting in more balanced and accurate estimates across the full range of healthcare establishments.

The second step consists of calculating the number of healthcare professionals required to meet the projected demand. For this purpose, the following variables were defined:

- PHN: Required healthcare professionals.
- AE: Estimated monthly attendances.
- R: Professional productivity (attendances per hour).
- JH: Effective working hours (total contracted hours per year).

The relationship among these variables is expressed in Eq. (1):

$$\mathrm{PHN} = \max(1, round\,(\frac{\mathrm{AE}}{\mathrm{JH\ x\ R}})) \quad (1)$$

To obtain the average number of monthly attendances across the different levels of healthcare centers, the Programming Criteria Standards table [19] was used. From this source, the following parameters were obtained:

- Level I: 500 attendances/month per professional
- Level II: 277.6 attendances/month per professional
- Level III: 270 attendances/month per professional

Likewise, the Maximum (max) function ensures a minimum of one professional per healthcare facility, guaranteeing basic coverage even in locations with low demand.

2) Data Split – Training: The complete set of clean and preprocessed data (X for the features and ATTENDANCES as the target variable) was divided into two main subsets through a random and controlled process:

- Training Set (80%): The majority of the data, 80%, was used to train the model. This allowed the algorithm to learn the underlying patterns and relationships between the features (geographical, temporal, and historical) and the target variable.
- Test Set (20%): The remaining 20% of the records were reserved. This subset was not exposed to the model during the learning phase. Its sole purpose was to measure the model's performance and accuracy on completely unseen data, ensuring an unbiased evaluation of its generalization capability.

To ensure consistency in this partitioning process and allow reproducibility of the results in future analyses, a fixed random seed (random_state = 42) was applied during data splitting.

D. Evaluation and Metrics

The model was independently evaluated for each level of the Peruvian healthcare system (I, II, and III), taking into account the operational characteristics specific to each level:

- Level I: High-frequency, low-complexity healthcare attendances
- Level II: Medium-complexity and specialized healthcare attendances
- Level III: High-complexity, low-frequency healthcare attendances

To assess performance at each level, four key metrics were used:

The MAE (Mean Absolute Error), defined in Eq. (2), calculates the average absolute error between the actual values and the predictions, providing a direct measure of the error expressed in the same unit as the attendances (number of attendances per month):

$$\mathrm{MAE} = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \quad (2)$$

where, y_i represents the actual value, $\hat{y}_i$ the model prediction, and n the number of observations in the test set. This metric quantifies the average error in the number of attendances, which is directly related to healthcare workforce planning.

The RMSE (Root Mean Squared Error), defined in Eq. (3), penalizes large errors more heavily than small ones, making it particularly useful for identifying predictions with significant deviations.

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \quad (3)$$

The R^2 (Coefficient of Determination), defined in Eq. (4), quantifies the proportion of variance in the dependent variable that is explained by the model, indicating how well the predictions fit the actual data.

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \quad (4)$$

where, $\bar{y}$ represents the mean of the actual values. R^2 quantifies the percentage of variance in the dependent variable that is explained by the model. This metric evaluates the model's ability to explain variability in healthcare service demand.

The MAPE (Mean Absolute Percentage Error), defined in Eq. (5), expresses the error as a percentage, facilitating the interpretation of model performance in relative terms. This is particularly important when comparing different levels of healthcare delivery.

$$MAPE = \frac{100\%}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{\max(y_i, 1)}\right| \quad (5)$$

This metric provides the relative error, allowing comparisons across different levels of healthcare delivery.

Additionally, several analyses were conducted to gain deeper insight into the model's behavior. The most influential features in the predictions were evaluated in order to identify which variables are determinant in demand estimation. The medical specialties with the highest workforce requirements were also analyzed, making it possible to identify those with the largest staffing gaps. Finally, results were compared across regions to determine where the greatest need for healthcare personnel exists, revealing significant territorial differences. For all these evaluations, explanatory graphs were used, which were generated from the model's results.

IV. Proposed Solution

To address the problem of healthcare workforce requirements in public healthcare centers in Peru, the design and implementation of a technological solution with an interactive and intuitive interface is proposed. This solution allows the user to select a healthcare center and obtain information on the number of physicians required, according to the specialties available at that facility in Peru.

Fig. 1 illustrates how the web application is integrated with the predictive model and the database. On the frontend, the user accesses a dashboard where a healthcare center, medical specialty, month, and year can be selected. This information is sent to the backend through an API built with Flask, which receives the request and queries the data stored in PostgreSQL. Based on this information, the system executes the trained model and generates the corresponding prediction. Finally, the result is returned to the frontend, where it is clearly displayed so that the user can easily interpret it.

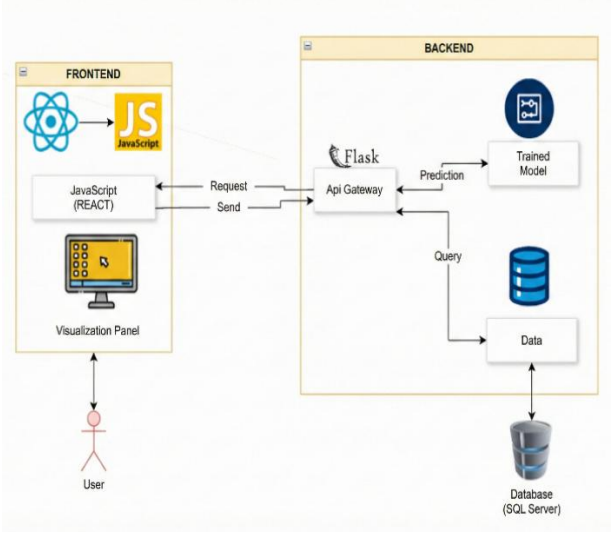

Fig. 1. Proposed technological solution.

The interface component of the project was developed using React.js, a widely used and well-established JavaScript framework for building web applications. React is based on principles of speed, security, and ease of integration with other libraries, making it a suitable and non-complex choice for interface development.

The frontend of the application was designed to provide a user-centered experience. One of its main functionalities is the generation of an interactive view in which users can visualize the number of healthcare centers and their corresponding medical workforce requirements. This information is represented through an interactive mini-map, enabling a more intuitive and visual identification of areas with greater demand for healthcare professionals. The goal is to ensure that any user of the application can access the information in a simple, fast, and understandable manner. Additionally, the use of a map provides an effective way to understand the situation of healthcare centers, as shown in Fig. 2.

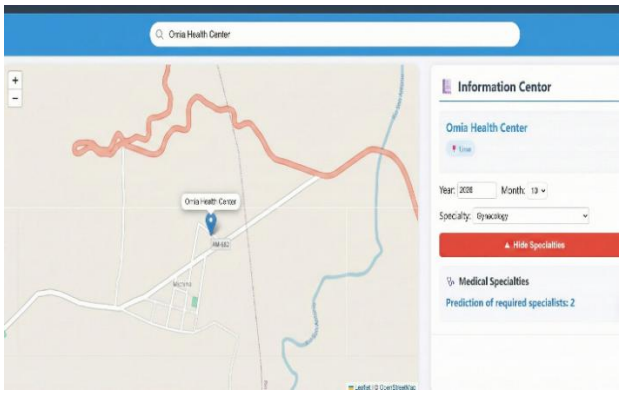

Fig. 2. Main screen.

The main sidebar includes filters such as year, month, and medical specialty. Based on these selections, the predicted number of required healthcare professionals per specialty is displayed for each healthcare center selected through the interactive map or the bar-based search interface, as shown in Fig. 3.

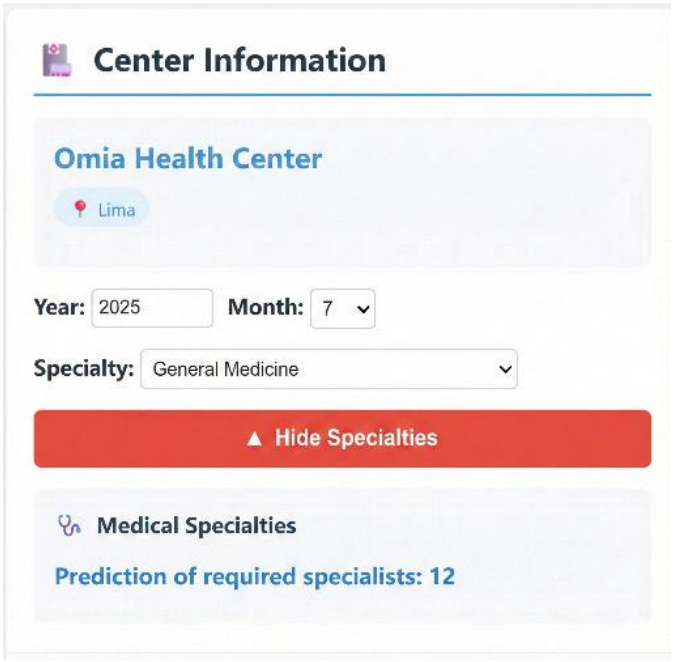

Fig. 3. Main sidebar.

The interface presents the model predictions in a more structured manner, filtering them by time period and medical specialty. A REST API is used as the communication channel between the frontend and the backend. The frontend issues requests to retrieve the results generated by the predictive models, while the backend processes these requests, queries the prediction model, and returns the response in a clear and standardized format—such as JSON—so that the results can be easily rendered within the application.

V. Results

The implemented model demonstrated a high level of accuracy in predicting the demand for medical professionals across the three levels of primary healthcare in Peru. The results show that the algorithm maintained robust performance in all evaluated scenarios, with minimal prediction errors (MAPE ranging between 1.28% and 6.17%) and a consistently high explanatory power ($R^2 > 0.99$). Feature importance analysis identified medical specialty as the most influential factor, followed by the year and geographic location variables.

The analysis of the obtained results is presented across two fundamental dimensions. First, Section A details the performance metrics and statistical validation that support the reliability of the model. Subsequently, Section B analyzes the key predictive factors and presents specific case studies that demonstrate the operational applicability of the system in real healthcare facilities.

A. Performance Metrics and Validation

Model validation was performed using the hold-out data splitting technique, where 80% of the records were used for training, and the remaining 20% were reserved as the test set. As detailed in Table I, Level I exhibits minimal errors (MAE = 0.27), while at Level II the model maintains excellent explanatory capability ($R^2 = 0.9968$).

For Level III, despite the higher volume of healthcare services, the model's performance remains strong, achieving an R^2 value of 0.9938.

TABLE I. Metrics Performance

Level	*MAE*	*RMSE*	R^2	*MAPE*
I	0.265715	1.202290	0.995892	1.284139
II	8.838402	32.882899	0.996812	3.455243
III	48.685679	183.381062	0.993822	6.168446

Additionally, to verify the absence of overfitting and the reliability of the estimates, scatter plots were generated to compare the observed values against those predicted by the algorithm.

As shown in Fig. 4, Level I exhibits a high density of points aligned along the ideal diagonal ($R^2 = 0.9959$). However, the dispersion increases as the values grow, indicating high confidence in predictions at lower demand levels, which gradually decreases for higher values. Nevertheless, it is important to note that most of the high-value observations at this level correspond to atypical cases.

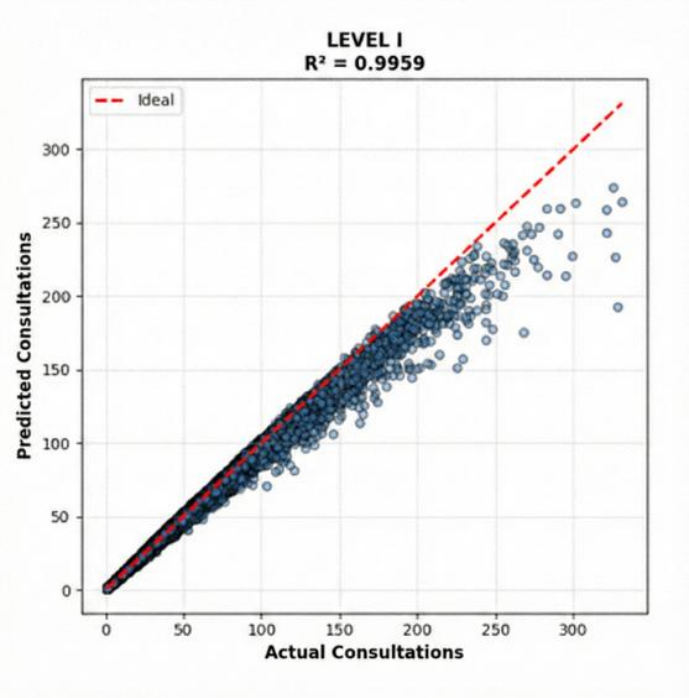

Fig. 4. Scatter Plot – Level I.

As shown in Fig. 5, Level II exhibits a consistently high density of points along the ideal diagonal, with an R^2 value of 0.9968. Only very slight variations are observed when compared to the Level I scatter plot. This behavior indicates a high level of model stability and, consequently, a high degree of confidence in the predictions.

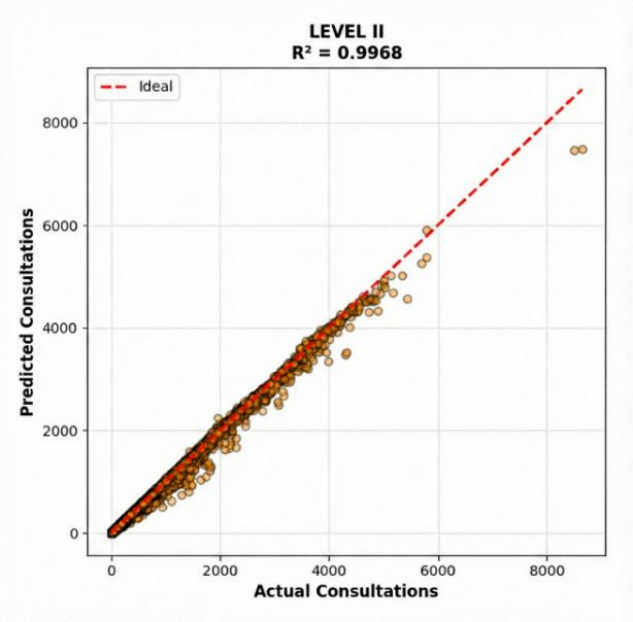

Fig. 5. Scatter Plot – Level II.

In Fig. 6, Level III shows a consistently high density of points along the ideal diagonal, with an R^2 of 0.9968, exhibiting only very slight variations compared to the Level I plot. This behavior indicates high model stability and, consequently, strong confidence in the predictions.

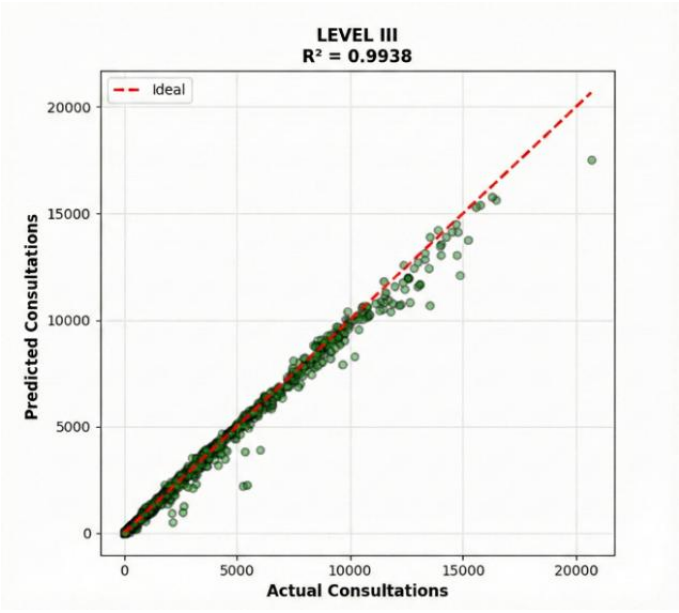

Fig. 6. Scatter Plot – Level III.

As observed in the figures for Level I (Fig. 4), Level II (Fig. 5), and Level III (Fig. 6), the results exhibit an almost linear fit. However, in Levels I and III, observations with higher volumes of healthcare attendances tend to fall slightly below the reference line. This minor underestimation at the extremes of demand is minimal and does not compromise the overall reliability of the tool, which maintains accuracy levels consistently above 99% across all evaluated scenarios.

B. *Importance of Characteristics in Predicting Healthcare Personnel*

Once the statistical robustness of the model was confirmed, the factors determining healthcare workforce demand in the Peruvian public health system were analyzed. The feature importance analysis reveals a clear hierarchy in the influence of predictive variables across the three evaluated levels of care.

Fig. 7 illustrates the top features that most influenced the prediction, highlighting Specialty (0.2%) and Year (0.15%) as the most influential features, while Province (0.04%) and Month (0.03%) showed the lowest influence.

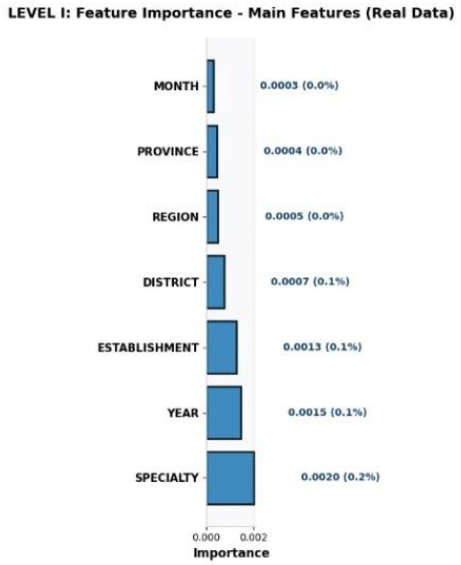

Fig. 7. Most influential main features – Level I.

Fig. 8 shows the top features that most influenced the prediction, highlighting Specialty (0.88%) and Year (0.42%) as the most influential features, while Region (0.13%) and Month (0.07%) were the least influential.

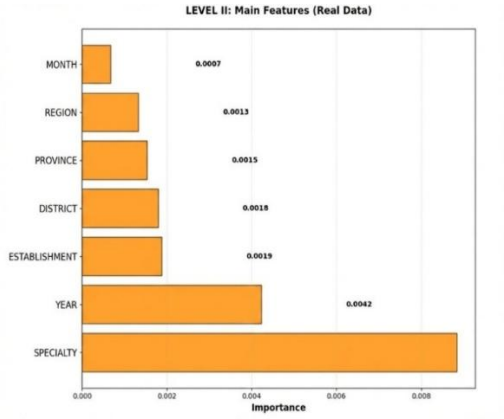

Fig. 8. Most influential main features – Level II.

Fig. 9 shows the top features that most influenced the prediction, highlighting Specialty (1.37%) and Year (0.62%) as the most influential features, while Province (0.14%) and Month (0.01%) were the least influential.

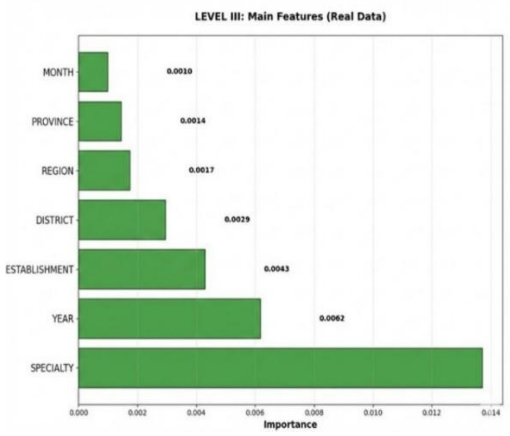

Fig. 9. Most influential main features – Level III.

In all cases, the SPECIALTY variable is consolidated as the most critical and determining factor in the model's behavior. In a second order of relevance, the YEAR variable appears, indicating a significant temporal progression in demand, although its relative weight is considerably lower than that of the medical specialty. On the other hand, geographic variables such as FACILITY, DISTRICT, and PROVINCE show a moderate influence, while REGION and MONTH represent the least influential predictive factors for the algorithm.

Finally, the analysis by medical specialty makes it possible to prioritize areas with the greatest shortage of human resources. For this purpose, prediction tests were conducted on randomly selected health centers for the period of August 2023. As shown in Fig. 10, in the Level I health center with code 381, the highest number of attendances corresponded to the General Medicine specialty, which is why a specialist in this area would be prioritized. In addition, it is observed that the difference between actual and estimated attendances presents only minimal decimal variations.

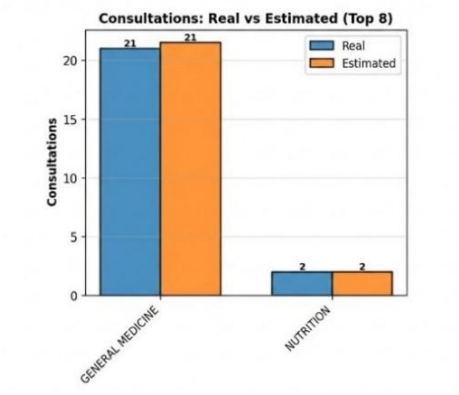

Fig. 10. Top specialties by attendance – Level I.

In Fig. 11, it is observed that in the Level II health center with code 5366, the highest number of attendances corresponded to the Nursing specialty. For this reason, a specialist in this area would be prioritized. Additionally, the variation between the number of actual and estimated attendances for this specialty is 6, which represents a minimal difference that does not affect the reliability of the prediction results.

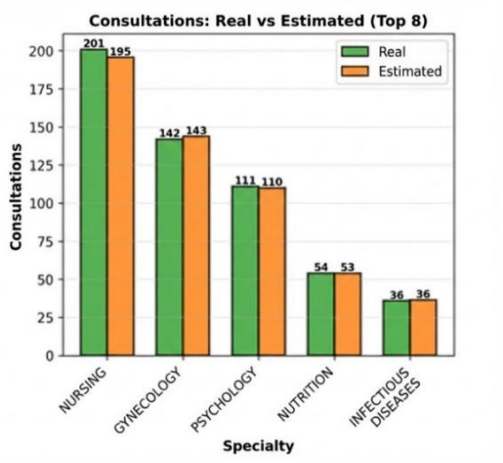

Fig. 11. Top specialties by attendance – Level II.

In Fig. 12, it is observed that in the Level III health center with code 2289, the highest number of attendances corresponded to the Pediatrics specialty. For this reason, a specialist in this area would be prioritized. Additionally, the variation between the actual and estimated attendances is 8, which does not directly affect the prediction results.

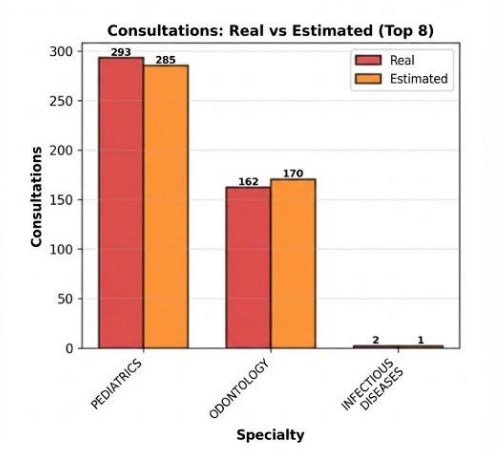

Fig. 12. Top specialties by attendance – Level III.

Overall, these findings allow us to conclude that the technological solution accurately identifies not only how many health professionals are required, but also in which specific areas urgent intervention is needed. This capability to segment results by levels of care and medical specialties constitutes a fundamental input for human resource management, enabling the reduction of care gaps and the optimization of the problem-solving capacity of public health centers in Peru.

VI. Discussion

The discussion of the findings is structured around two main axes: predictive robustness in relation to international standards and the relevance of the identified variables for human resource management.

A. Comparative Analysis of Predictive Performance

The performance of the Random Forest algorithm in this study, with an $R^2 > 0.99$ across all three levels of care, aligns

with the highest global standards of predictive accuracy. When compared with the literature, these results match the coefficient of determination reported by Köksoy et al. [18] in Turkey, while demonstrating a significant competitive advantage in terms of local error margins. Whereas Köksoy et al. reported an MAE of 39.54, Level I in this study achieved an MAE of 0.27, evidencing superior precision for primary care demand. Likewise, the accuracy obtained exceeds the 0.98 reported by Yadav [14], confirming that the model's fit is optimal for the complexity of the Peruvian healthcare system.

In terms of robustness, the superiority of this model over the 47.34% accuracy and 0.66 AUC reported by Moyo et al. [15] suggests that the inclusion of geographic and temporal variables from MINSA enables substantially higher predictive fidelity. Even at Level III, the model maintained a MAPE of 6.17%, a remarkably low figure compared to the high-specialization projections of Koç and Eren [16], which relied on synthetic data. The use of seven years of real historical records in this study ensures that the reported metrics reflect a proven capacity for generalization under fluctuating demand scenarios.

B. Factor Importance and Contribution to Healthcare Management

The feature importance analysis identifies SPECIALTY and YEAR as the most influential factors in the model, enabling strategic planning based on medical complexity and temporal progression. Unlike the behavioral approaches of Orhan and Kurutkan [12], which predict service utilization intentions based on personal factors, this proposal introduces a direct operational management metric. Through the technical conversion formula, the approach goes beyond appointment volume forecasting to generate an actionable output: the number of "required health professionals".

This operational capability addresses the lack of scheduling and planning tools identified by Yadav [14] and surpasses the scalability of local studies such as Perez-Siguas et al. [13], whose 93% AUC efficiency was confined to specific environments. Validation through real-world cases (health centers 381, 5366, and 2289) demonstrates that the differences between actual and estimated demand are minimal, enabling equitable resource allocation. Finally, integration into a React- and Flask-based architecture ensures that the achieved accuracy is not merely a theoretical result, but rather a scalable and sustainable administrative decision-support tool for the Peruvian public healthcare system.

VII. Conclusion

The present study demonstrates that the development of a technological solution based on the Random Forest algorithm enables highly accurate prediction of healthcare workforce requirements in public healthcare centers in Peru, thereby validating the hypothesis that the integration of geographical, temporal, and specialty-related variables—segmented by levels of care—significantly improves predictive performance compared to traditional statistical approaches. The model achieved a coefficient of determination $R^2 > 0.99$ across all levels of care, with low percentage errors (MAPE ranging from 1.28% for Level I to 6.17% for Level III), evidencing robust performance even in high-complexity scenarios. In addition, medical specialty and temporal evolution were identified as the most influential variables, enabling more targeted and informed workforce allocation decisions.

The main competitive advantage of this research lies in its ability to transform projected healthcare service demand predictions into operational management metrics for the required number of healthcare professionals, thereby facilitating administrative decision-making and surpassing prior approaches that focused solely on forecasting appointment volumes or patient retention behaviors with lower accuracy. The implementation of the model within a functional web-based architecture further confirms its technical feasibility as a decision-support tool for healthcare management.

Nevertheless, critical limitations related to the data source are acknowledged. Reliance on open data from the Peruvian Ministry of Health (MINSA) introduces vulnerability to underreporting in rural areas with limited connectivity, which may bias projections for Level I healthcare centers with constrained infrastructure. Moreover, the dataset does not map all service areas within healthcare centers, but only attendances provided and covered by the Comprehensive Health Insurance (SIS). Additionally, generalizing the model to contexts outside the Peruvian public healthcare system would require retraining with exogenous variables that account for different cost structures and patient flow dynamics.

As future work, the integration of real-time epidemiological and climatic variables is recommended to strengthen the model's resilience to disease outbreaks. Finally, validation of this solution in real-world hospital management applications is proposed to assess its direct impact on reducing patient waiting times, thereby contributing to the consolidation of a data-driven and technologically efficient healthcare system.

A Readability-Driven Prompting Framework for Accurate Grade-Specific EFL Narrative Creation

Ronald William Marbun, Makoto Shishido
Media Design Communication Engineering, Tokyo Denki University, Tokyo, Japan

***Abstract*—The integration of Artificial Intelligence (AI) into English as a Foreign Language (EFL) education offers new opportunities for developing adaptive and engaging learning materials. Narrative-based content is central to improving reading comprehension, vocabulary acquisition, and learner motivation. However, maintaining grade-appropriate readability in AI-generated narratives remains a major challenge. This study presents Readability-Driven Prompting (RDP), a novel technique designed to enhance the accuracy and efficiency of large language models in generating grade-level narratives. Using GPT-4o-mini, three prompting strategies—CEFR Keyword-Constrained Prompting (CKCP), Instruction-Based Prompting (IBP), and the proposed RDP—were applied to produce narratives for 7th-grade (A1–A2 CEFR) and 10th-grade (B1–B2 CEFR) learners. The outputs were evaluated using Flesch Reading Ease (FRE), Dale–Chall (DC) readability metrics, lexical analysis, and human assessments. Experimental results indicate that the RDP approach achieves higher alignment with target readability levels and improved lexical appropriateness compared to baseline methods, demonstrating a scalable and effective strategy for generating educational narratives, particularly for beginner-level learners.**

***Keywords*—Artificial Intelligence (AI); English as a Foreign Language (EFL); large language models (LLMs); readability metrics; narrative generation; prompt engineering; educational technology**

I. Introduction

The increasing use of large language models (LLMs) in English as a Foreign Language (EFL) education offers new opportunities to create engaging and adaptive materials. Narrative texts, in particular, are valuable for developing reading comprehension, cultural awareness, and student motivation [1] [2]. However, a significant challenge remains: controlling the grade-level of AI-generated narratives. If these texts do not match the intended readability level, their instructional effectiveness may be compromised.

Providing EFL learners with materials that are appropriate for their grade level is crucial for effective language development [3]. In contrast, materials that are too advanced can be ineffective and may even hinder learners' progress [4]. Crafting narratives precisely targeted to specific grade levels is particularly challenging, as it typically requires the expertise of skilled educators and content specialists [5]. Recent studies have shown that LLMs often struggle to assess or control grammar and vocabulary levels consistently without careful guidance [6], highlighting the need for improved prompting strategies.

Using ChatGPT to support vocabulary learning has been shown to be effective [7], but sustained gains require repeated exposure to level-appropriate texts. Incorporating a high number of low-frequency words may discourage students from engaging with reading materials, underlining the importance of word frequency in instructional texts [8].

Lexical difficulty is critical for EFL readers; eye-tracking research has found that readers spend more time fixating on long, low-frequency words, and that L2 readers tend to skip fewer words than L1 readers [9], [10]. In addition, research has shown that achieving 95% overall understanding of a text is highly effective for language learning [11]. The CEFR is an internationally recognized standard for describing language ability, ranging from beginner (A1) to proficient (C2) levels, and widely used in language curriculum design. This highlights the importance of aligning texts with the target CEFR level, and suggests that the effectiveness of instructional materials can be evaluated through lexical analysis.

Another approach to evaluating text appropriateness is through readability metrics. Flesch and Kincaid introduced the Flesch Reading Ease (FRE) measure, which emphasizes syllable complexity [12]. In contrast, Dale and Chall proposed a formula (DC) that assesses textual complexity based on the frequency of familiar words [13]. They continue to be widely used and adapted in modern educational research and computational linguistics [14], [15]. By combining these metrics, educators can develop learning materials that balance linguistic complexity with student engagement and motivation. However, readability metrics alone are insufficient, particularly when addressing the needs of L2 learners. Therefore, this study evaluates narratives using both lexical analysis and readability metrics.

Effective prompt strategies are important for improving and optimizing ChatGPT's performance in EFL applications [6], [16], [17]. Recently, prompt engineering has become a popular research topic. The fundamental step in prompt engineering is to provide clear instructions and context to the model [6], as a result, Instruction-Based Prompting has become widely used. However, Instruction-Based Prompting alone may not be sufficient for generating narratives or supporting L2 learning [6], [16].

Building on previous work, research has shown that applying CEFR word constraints can enhance the effectiveness of targeted narrative generation [18]. This approach is more effective for producing narratives suitable for specific grade levels. Since GPT models are sensitive to input and perform better with sufficient context, embedding readability theory and CEFR-based constraints into prompts provides clearer guidance with fewer tokens. Furthermore, supplementing prompts with sample stories at the target grade level can yield comparable

results with reduced computational cost. Accordingly, this study introduces Readability-Driven Prompting (RDP), a novel few-shot prompting framework that integrates readability theory, CEFR guidelines, and representative examples to generate grade-appropriate EFL narratives.

We hypothesize that Readability-Driven Prompting (RDP) will be more effective than Instruction-Based Prompting (IBP), and non-inferior to CEFR Keyword Constrained Prompting (CKCP), in generating grade-appropriate EFL narratives for Grade 7 (A1–A2) and Grade 10 (B1–B2). Effectiveness is assessed as follows: a) Readability alignment—RDP is expected to produce a higher proportion of texts falling within pre-registered grade bands on Flesch Reading Ease and Dale–Chall metrics, with smaller deviations from band centers compared to IBP, and no worse than CKCP within a pre-specified non-inferiority margin; b) Controllability across grades—RDP should yield a larger and more consistent separation between Grade 7 and Grade 10 readability levels than IBP, and at least as distinct as CKCP; and c) Lexical targeting—RDP is anticipated to more accurately match CEFR lexical profiles (e.g., more A1–A2 and fewer ≥B1 tokens at Grade 7, more B1–B2 and controlled ≥C1 usage at Grade 10) compared to IBP, and to perform non-inferior to CKCP, with frequency profiles that minimize long, low-frequency words at Grade 7 and introduce them in a controlled manner at Grade 10.

This study addresses the following research questions:

- Can Readability-Driven Prompting (RDP) improve the alignment of large language model-generated EFL narratives with target grade-level readability metrics?
- How do students perceive the readability, engagement, and vocabulary learning potential of narratives generated using RDP?

The primary contributions of this work are as follows:

- We propose Readability-Driven Prompting (RDP), a novel prompting framework that integrates explicit readability theory, CEFR-based constraints, and in-context grade-level narrative exemplars to guide large language models in producing educationally aligned narratives.
- We provide, to our knowledge, the first systematic experimental comparison of RDP with CEFR Keyword Constrained Prompting (CKCP) and Instruction-Based Prompting (IBP), focusing on both reading metrics and lexical targeting for EFL learners at distinct grade bands.
- We perform a comprehensive analysis—combining established readability formulas, lexical CEFR alignment, and human learner evaluation—demonstrating the efficacy of RDP for generating grade-specific texts in EFL education.

The remainder of this study is organized as follows: Section II reviews related work on prompt engineering and readability control. Section III describes our experimental methodology and evaluation framework. Section IV presents the results of lexical and readability analyses and a human evaluation, followed by discussion. Section V presents the discussion. Finally, Section VI concludes and suggests avenues for future research.

II. Related Work

A. Prompt Engineering on Education

Few-shot and zero-shot prompting strategies have emerged as key techniques for improving reasoning performance, mitigating hallucinations, and regulating the linguistic register in large language model (LLM) outputs [19]. In educational contexts, these methods help ensure that generated content aligns with learners' proficiency levels and pedagogical goals. An important extension, known as Generated Knowledge, enhances model reasoning by providing theoretically relevant information as supplemental input [20]. Incorporating educational or linguistic frameworks—such as readability measures like Flesch–Kincaid or Dale–Chall—within prompts enables the model to produce text that is calibrated for specific grade levels. This approach not only constrains linguistic complexity but also increases the predictability, interpretability, and educational value of the generated instructional materials.

B. Readability Metrics

Readability refers to how easily a text can be understood by its intended audience. Classical formulas, such as the Flesch–Kincaid and Dale–Chall indices, quantify textual difficulty based on variables like sentence length, word familiarity, and syntactic transparency. More recently, LLM-driven or prompt-based methods have been proposed to move beyond these surface-level indicators by capturing latent linguistic features that influence perceived difficulty [14]. Despite these advancements, empirical evidence suggests that model-based approaches remain inconsistent in generating text at predefined complexity levels, largely due to the opaque and stochastic internal workings of LLMs. In contrast, traditional readability measures continue to provide transparent, replicable, and pedagogically meaningful metrics for the development and assessment of educational texts.

From a theoretical standpoint, readability frameworks provide quantifiable, evidence-based parameters for managing text complexity [12] [13]. When such parameters—sentence length, lexical frequency, and semantic transparency—are incorporated directly into prompt formulation, they introduce explicit and interpretable constraints that counterbalance the inherent variability of LLM generation processes [14]. For example, prompts specifying bounded average sentence length or prioritizing high-frequency vocabulary enable more reliable alignment between model outputs and intended learner proficiency levels. The integration of readability theory into prompt engineering thus transforms text generation from an iterative, heuristic endeavor into a structured, evidence-driven methodology for producing educationally appropriate materials.

C. Narrative Generation

Recent advancements in large language models (LLMs), particularly GPT-3 and GPT-4, have demonstrated significant capabilities in narrative generation. With well-designed prompts, these models can produce fluent and coherent narratives that surpass previous automated storytelling systems in both linguistic quality and narrative cohesiveness [15]. In educational

contexts, LLM-based narrative generation has been used to enhance learner engagement, foster narrative awareness, and promote higher-order comprehension and creativity [21]. However, notable limitations persist, especially in maintaining long-range coherence, character consistency, and thematic integration throughout extended texts [14], [15]. As a result, expert curation, human supervision, and post-editing remain necessary to ensure that generated narratives are pedagogically appropriate and aligned with instructional objectives.

D. Research Gap

Despite advances in prompt engineering, readability control, and narrative generation, existing research has yet to develop a robust framework for consistently producing educational narratives aligned with predetermined grade-level and cognitive-developmental criteria [6]. While prompt engineering can influence the stylistic and structural aspects of generated text, the inherent opacity and variability of LLM outputs make it difficult to achieve deterministic control over readability and conceptual depth.

Integrating readability theory within a Generated Knowledge framework offers a promising solution to these challenges. By embedding explicit textual constraints—such as quantified expectations for sentence length, lexical familiarity, and semantic transparency—into the model's reasoning process, it becomes possible to guide generation toward predictable linguistic boundaries. This hybrid approach combines the adaptability of contemporary language models with the stability and interpretability of traditional readability measures.

Such integration not only enhances technical reliability but also reframes educational text generation as an evidence-based practice rooted in literacy and educational measurement theory. It enables the creation of pedagogically aligned narratives that ensure coherence, accessibility, and adherence to instructional goals across diverse learner levels. Consequently, this study addresses a critical gap by investigating how readability-based generated knowledge can systematically regulate LLM narrative production to achieve consistency, transparency, and educational appropriateness—outcomes not yet realized in the current state of research.

III. Methodology

A. Study Design and Overview

This study aims to validate the effectiveness of the proposed Readability-Driven Prompting (RDP) framework for English as a Foreign Language (EFL) narrative generation. RDP is an enhanced prompting method that conditions large language models on readability theory and grade-level exemplars, enabling the production of narratives more closely matched to learner proficiency.

To establish comparative validity, RDP was evaluated against two reference prompting strategies: Instruction-Based Prompting (IBP), which represents minimally guided text generation, and CEFR Keyword Constrained Prompting (CKCP), which applies strict lexical constraints.

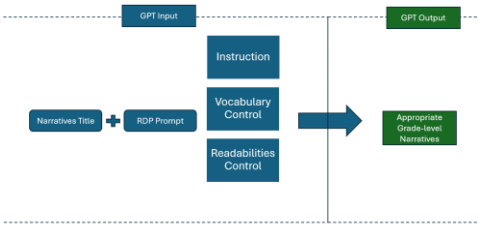

Fig. 1. Block diagram of the proposed readability-driven prompting (RDP) framework.

The proposed RDP methodology (see Fig. 1) integrates explicit readability instructions (using Flesch–Kincaid Grade Level and Dale–Chall metrics), CEFR-aligned vocabulary references, and example narratives directly within the prompt. By embedding theoretical constraints and representative exemplars, RDP aims to achieve high readability alignment and reduced computational cost compared to traditional word-list-based approaches.

B. Targeted Grade Levels

In line with common curricular standards that map lower-secondary EFL learners to CEFR levels A1–A2 and upper-secondary learners to B1–B2 [22], [23], we operationalize early EFL as Grade 7 and intermediate EFL as Grade 10. In CEFR terms, Grade 10 typically aligns with level B1. Accordingly, we compare RDP against CEFR Keyword Constrained Prompting (CKCP) and Instruction-Based Prompting (IBP) using GPT-4o-mini with default temperatures (t = 1) at two anchor levels commonly targeted in secondary EFL curricula: 7th grade (A1–A2 CEFR) and 10th grade (B1–B2 CEFR).

Thus, 7th and 10th grade serve as representative anchor points for lower- and upper-secondary EFL reading. Seventh grade typically corresponds to early–low intermediate proficiency (A2 CEFR), where learners possess sufficient decoding skills and core vocabulary for short narratives but remain sensitive to sentence length and unfamiliar lexis. In contrast, tenth grade aligns with upper-intermediate proficiency (B1 CEFR), where learners can manage more complex syntax and a broader academic vocabulary.

Fig. 2 illustrates the research objectives. The study aims to generate narratives for both beginner and intermediate EFL learners. Narratives will be classified as appropriate for beginners if they are suitable for 7th graders (CEFR A1–A2 level) and as appropriate for intermediates, if they are suitable for 10th graders (CEFR B1–B2 level).

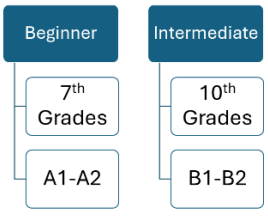

Fig. 2. Research target representative.

C. Dataset Generation

For this research, we produced 100 narratives for each combination of prompting method and grade level. Specifically, for each of the three methods (IBP, CKCP, RDP) at both 7th and 10th grade targets, we generated 100 narratives using GPT-4o-mini under identical decoding settings. Every narrative title and theme is unique covering common EFL themes (e.g., school life, family, travel, science) with a range between 200 and 300 words. To isolate prompting effects while holding topic constant, each title was instantiated once for every prompting method (IBP, CKCP, RDP) at each target grade (7th, 10th). In total, this yielded 600 narratives (3 methods × 2 grades × 100 narratives).

D. Evaluation

This research evaluates the generated narratives using three methods: readability analysis, lexical analysis, and survey-based assessment. For readability evaluation, two complementary metrics were employed. Table I presents the Flesch–Kincaid Reading Ease (FRE) scores and corresponding grade interpretations. FRE scores range from 0 to 100, with higher values indicating easier readability. Unlike the Flesch–Kincaid Grade Level (FKGL), which directly maps text complexity to a U.S. grade level, FRE provides a broader indication of textual accessibility across proficiency levels. In this study, narratives targeting the 7th-grade level were required to achieve FRE scores between 70 and 80, while narratives targeting the 10th-grade level were expected to fall within the range of 50 to 60.

TABLE. I. FLESCH-KINCAID EASE MEASUREMENT

Flesch-Kincaid Reading Ease (FRE)	
Point	Grade
90-100	Very easy (5th grade; suitable for children)
80-89	Easy (6th grade)
70-79	Fairly easy (7th grade)
60-69	Standard (8th-9th grade; plain English)
50-59	Fairly difficult (10th-12th grade)
30-49	Difficult (college level)
0-29	Very difficult (college graduate level)

TABLE. II. DALE-CHALL MEASUREMENT

Dale-Chall (DC)	
Point	Grade
<= 4.9	Easily understood by 4th grade or lower
5.0-5.9	Easy (6th grade)
6.0-6.9	Fairly easy (7th grade)
7.0-7.9	Standard (8th-9th grade; plain English)
8.0-8.9	Fairly difficult (10th-12th grade)
9.0-9.9	Difficult (college level)
10+	Very difficult (college graduate level)

Table II presents the Dale–Chall formula (DC) scores and corresponding grade interpretations. The DC formula measures text complexity based on the proportion of unfamiliar words relative to a predefined list of commonly used words. In this study, narratives targeting the 7th-grade level were required to achieve DC scores between 6.0 and 6.9, while narratives targeting the 10th-grade level were expected to fall within the range of 7.0 to 7.9.

This research also evaluates the generated narratives using lexical analysis. The narratives undergo several text processing steps, as shown in Fig. 3. The main processes are as follows:

- Normalization: To ensure consistency in format, all raw text is converted to lowercase, punctuation is removed, Unicode is standardized, and extraneous characters such as hyphens are eliminated.
- Tokenization: To conduct lexical analysis, each word must be identified and categorized. This process separates individual words and assigns parts of speech (e.g., noun, adjective, verb). SpaCy is used for tokenization in this study.
- Filtering: Certain tokens, such as character names, URLs, numbers, acronyms, and hashtags, do not contribute to text difficulty and should be excluded. SpaCy, in addition to our word list, is also used to filter out these elements to ensure proper lexical analysis.
- Lemmatizing: English words can appear in many forms. To accurately assess difficulty, each word is reduced to its dictionary form. The NLTK library is employed for the lemmatization process.

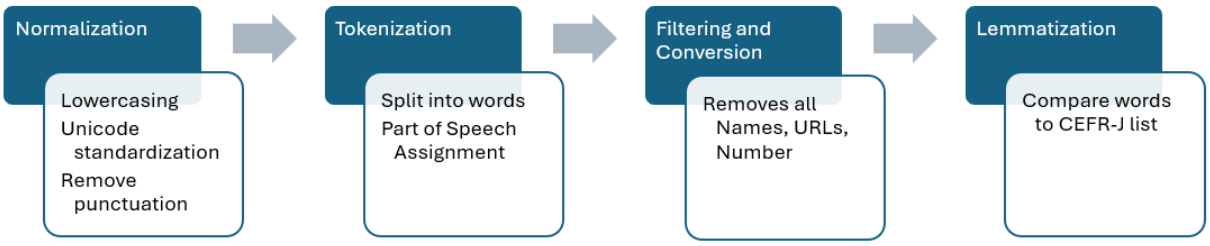

Fig. 3. Lexical analysis text processing pipeline.

After text processing is complete, all lemmatized tokens are compared against the CEFR-J dataset. Each token is counted and its difficulty level is determined based on its CEFR classification. Tokens not present in the CEFR-J dataset are considered as above C1 level, since most non-relevant items have already been filtered out. We will refer this as Unknown Words.

For learning to be effective, students need to understand at least 95% of the content they read [11]. Accordingly, for the beginner level (A1–A2), only words within the A1–A2 bands are counted, while for the intermediate level (B1–B2), words within the A1–B1 bands are considered. The effectiveness of each method is determined by how closely the proportion of appropriate-level vocabulary approaches the 95% threshold.

The final evaluation method involved a human evaluation survey. Participants were beginner-level Japanese learners of English with an interest in improving their language skills. The evaluation was conducted through a storytelling game, developed for smartphones using the Unity engine. Thirty students from Tokyo Denki University participated in the study. Participants were selected based on their English proficiency and voluntarily agreed to try the game and assess the quality of the narratives for learning purposes.

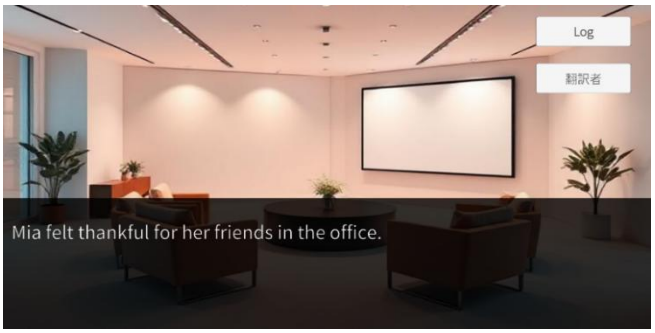

Fig. 4. Example of game narratives.

The process begins with student self-introduction and course selection, which function as initial engagement steps. Learners then proceed through narratives generated using the RDP method. Fig. 4 illustrates how these narratives are implemented and represented within the game environment. During the narrative progression, students are prompted with comprehension questions that must be answered to continue. If a student is unsure about the meaning of a word, a translation button is available, providing an explanation of the word's meaning and its usage within the narrative context.

The game served dual purposes: acting both as a storyteller and as a learning tool. At the beginning of the game, participants selected their preferred topics. Based on these preferences, a new narrative was generated using the RDP prompting method. The generated narrative was then presented in the game, and participants were asked to read the text before answering questions designed to assess comprehension and engagement. After completing these questions, participants received immediate feedback on their performance and a review of their responses. Finally, they were prompted to complete a survey evaluating the narrative's quality, their level of engagement, and the perceived learning value of the experience.

The survey comprised six items designed to assess participants' perceptions of the generated narratives:

1) The generated narratives were easy to understand: This item measures how easily students could comprehend the narratives.

2) The English in the narratives felt natural: This item assesses how natural the English in the narratives was compared to that found in a textbook.

3) The generated narratives were interesting: This item evaluates how engaged students felt while reading the stories.

4) The words used in the narratives are not too difficult: This item measures the perceived difficulty of individual words used in the narratives.

5) I was able to learn a new word from these narratives: This item assesses whether students felt they learned new vocabulary from the texts.

6) I would like to read more narratives like this: This item measures students' interest in reading similar stories in the future.

All survey questions were administered in Japanese. The items and descriptions were translated using ChatGPT 4.1 and subsequently proofread by a native speaker to ensure accuracy and clarity.

There are several limitations to the human experiment. First, only beginner-level materials were evaluated, so intermediate-level narratives were not assessed. Second, the evaluation focused exclusively on narratives generated using the RDP method.

E. Prompting Strategies

This research focuses on three prompting strategies:

- CEFR Keyword Constrained Prompting (CKCP): Prompts are designed to generate narratives using only words from designated CEFR levels, following approaches established in prior research [18]. CKCP operates by constraining the model to the vocabulary specified within the prompt. For 7th grade, only A1–A2 words are used, while for 10th grade, A1–B2 words are included. As a result, token usage increases substantially for higher grade levels. The Prompting method is represented in the Algorithm 1.

Algorithm 1: CKCP Prompt

You are a story creator assistant that specializes for {targeted_grade}th grade children. Your task is to craft a compelling story based on a user-provided title and a predefined list of verbs and nouns. Follow these instructions carefully:
Instructions
1. **Input Requirements**:
- The user provides only a title.
- You will also be given a list of verbs,nouns, pronoun, adverb and adjective. Use these words exclusively to create the story.

2. **Constraints**:
- Use only the verbs, nouns, adjective, adverb from the provided list.

- Articles (e.g., \"the,\" \"a\") and basic prepositions (e.g., \"in,\" \"on\") are allowed for readability.
- Verbs can be used in various tenses (past, present, future) as needed.
- Make it suitable for 7th grades
- Please use simple word and frequently used word only

3. **Output Format**:

- Make sure it was between 200-300 words
List of words:
Verbs : [a1-a2 CEFR J] or [a1-b1 CEFR J]
Adverbs : [a1-a2 CEFR J] or [a1-b1 CEFR J]
Nouns : [a1-a2 CEFR J] or [a1-b1 CEFR J]
Adjective : [a1-a2 CEFR J] or [a1-b1 CEFR J]

- Readability Driven Prompting: Prompts include two to three example stories at the target grade level, selected based on Flesch Reading Ease (FRE) and Dale–Chall (DC) scores falling within the desired thresholds. The prompt references both FRE and DC theories and provides explicit instructions to generate narratives within these specified readability ranges. However, we observed that GPT sometimes struggles to select appropriate vocabulary for each theory, especially at lower grade levels. To address this, selected words from the CEFR list with proven impact at specific grades were also referenced in the prompt. The example stories were taken from CKCP outputs that met our criteria for readability and lexical alignment. The Prompting method is represented in the Algorithm 2.

Algorithm 2: RDP Prompt

You are a children's story writer specializing in {targeted_grade}th-grade material.

Follow these rules strictly:
Vocabulary:

- Use only CEFR A1-A2 words.
- Avoid uncommon, academic, or abstract words.
- Use concrete, everyday language.
- Include slightly longer (2–3 syllable) words when appropriate to raise FRE.
- Avoid words above {targeted_grade}reading level (Dale-Chall).
- Example Forbidden words: {hard_word}
- Use simple alternatives: {alternative_word}

Sentence Structure:

- Mix short and compound sentences to increase words per sentence.
- Each sentence should ideally be 8–12 words when possible.
- Use conjunctions like 'and', 'but', 'so', 'because', 'while' to combine ideas.
- Add short descriptive phrases to expand sentences naturally.
- Keep sentences clear, active, and readable.
- Avoid complex subordinating clauses beyond simple compounds.

Story Guidelines:

- Word count: 200–300 words.

- Include curiosity, teamwork, problem-solving, or small adventures to engage readers.
- Keep paragraphs short.
- Include a clear beginning, middle, and end.
- Introduce small challenges or conflicts, then resolve them.

Readability Targets:

- Flesch-Kincaid Ease (FRE) {targeted_range}
- Dale-Chall Score {targeted_range}
- After writing, check FRE and DC internally. Redo if scores are outside range. Do not include scores in the story output.

Example:

[Stories example]

- Instruction-based Prompting: In this approach, GPT-4o-mini is instructed to generate a narrative for a specific grade and CEFR level without providing examples, theoretical guidance, or CEFR word constraints. The prompt simply requests the model to create a narrative tailored to the designated grade, specifying that the text

should be appropriate for the targeted difficulty level. The Prompting method is represented in the Algorithm 3.

Algorithm 3: IBP Prompt

You are a story creator assistant that specializes for {target_grade}. Follow these instructions carefully:

Instructions:

1. **Input Requirements**:

- The user provides only a title.

2. **Task**:

- Create a narratives for ESL. Mainly targeted {target_level} grade US grade or CEFR {target_cefr} level

3. **Output Format**:

- Make sure it was between 200-300 words

IV. Results

A. Lexical Analysis

Beginner narrative lexical analysis is presented in Table III. Although none of the methods achieved the 95% target, the results indicate that the proposed RDP technique performed the best, achieving 86.17% A1–A2 vocabulary usage. This was followed by CKCP at 84.84% and IBP at 82.89%. These findings suggest that narrative difficulty can be effectively adjusted using prompting techniques and RDP shown to increase the narrative qualities for a specific target level.

TABLE. III. Beginner Narrative Lexical Analysis

Method	Unknown Words	A1-A2 Words Ratio	Diff w/ target	Words Avg.
IBP	3%	82.89%	-12.11%	263 words
CKCP	2%	84.84%	-10.16%	287 words
RDP	2%	86.17%	-8.83%	336 words

Regarding unknown words, RDP demonstrates strong performance, producing only 2% unknown words, compared with 3% for IBP and matching the performance of CKCP. Notably, RDP also generates longer narratives, with an average length of 336 words, compared to 263 words for IBP and 287 words for CKCP. Achieving a low proportion of unknown words in longer texts is generally more challenging, as increased text length raises the likelihood of introducing unfamiliar vocabulary. Therefore, this result indicates that RDP achieves a higher level of lexical control and overall performance than the other methods.

TABLE. IV. Intermediate Narrative Lexical Analysis

Method	Unknown Words	A1-B1 Words	Diff w/ target	Words Avg.
IBP	5%	89.68%	-5.32%	267 words
CKCP	4.33%	90.41%	-4.59%	307 words
RDP	5.71%	88.43%	-6.67%	327 words

Intermediate narrative lexical analysis is presented in Table IV. Although RDP remains relatively close to the 95% target at the intermediate level, its performance shows a slight decline compared to IBP. IBP achieves 89.68% A1–B1 vocabulary usage, while RDP reaches 88.43%. Among the three methods, CKCP performs best, coming closest to the target with 90.41% A1–B1 vocabulary usage.

RDP also produces the highest proportion of unknown words, at 5.71%, compared with 5.0% for IBP and 4.33% for CKCP. In addition, RDP generates longer narratives, averaging 327 words, whereas IBP and CKCP produce 267 and 307 words, respectively. The combination of increased text length and greater lexical variation may contribute to the higher incidence of unknown words and the slight reduction in vocabulary alignment observed at the intermediate level. Overall, these results indicate a modest decline in RDP's performance when applied to intermediate-level narrative generation.

B. Readability Analysis

TABLE. V. 7TH Grade Focused Readability Analysis

Method	Flesch-Kincaid Ease	Dale-Chall	Flesch-Kincaid Target	Dale-Chall Target
IBP	68.63	7.05	70-79	6.0-6.9
CKCP	69.18	6.65	70-79	6.0-6.9
RDP	77.28	6.80	70-79	6.0-6.9

7th grade focused readability analysis is presented in Table V. RDP achieves a Flesch–Kincaid Reading Ease (FKE) score of 77.28, which falls within the targeted range. In contrast, CKCP does not meet the target, obtaining a score of 68.63, and IBP similarly falls short with a score of 68.63. These results indicate that RDP outperforms the other prompting methods in aligning narrative readability with the intended Flesch–Kincaid Ease target.

Regarding the Dale–Chall formula, both RDP and CKCP fall within the target band. RDP achieves a score of 6.80, while CKCP obtains 6.65. IBP fails to meet the target with a score of 7.05, suggesting that it produces narratives suitable for a higher grade level. These findings indicate that RDP achieves comparable performance to CKCP in terms of word familiarity control.

TABLE. VI. 10TH Grade Focused Readability Analysis

Method	Flesch-Kincaid Ease	Dale-Chall	Flesch-Kincaid Target	Dale-Chall Target
IBP	60.35	7.77	50-59	8.0-8.9
CKCP	60.31	7.99	50-59	8.0-8.9
RDP	58.98	7.61	50-59	8.0-8.9

10th grade focused readability analysis is presented in Table VI. RDP achieves a Flesch Reading Ease (FRE) score of 58.98, making it the only method that falls within the targeted range. In comparison, IBP and CKCP obtain scores of 60.35 and 60.31, respectively, both of which fall outside the desired range. These results indicate that RDP performs better in controlling overall text complexity as measured by the FRE formula.

With respect to the Dale–Chall formula, none of the methods reach the target range. RDP achieves a score of 7.61, while IBP and CKCP obtain scores of 7.77 and 7.99, respectively. The similarity of these scores suggests comparable performance across methods in terms of word familiarity at the 10th-grade level.

C. Human Evaluation

The first question aimed to assess the overall difficulty of the narratives. The mean score of 4.43 indicates that most participants agreed that the narratives were easy to understand. The second question evaluated whether the narratives felt natural, with a mean of 4.4, showing general agreement that the text was fluent and natural. The third question measured the narratives' level of interest, and the mean of 4.26 suggests that most participants found the stories engaging. The fourth question focused on word difficulty, yielding a slightly lower mean of 3.63. This indicates that while participants generally understood the vocabulary used by the RDP method, some words were challenging for certain users. The fifth question assessed whether participants could learn new words from the narratives, with a mean of 4.23, suggesting that the texts effectively supported incidental vocabulary learning. Finally, the sixth question measured engagement and willingness to read more narratives, resulting in a mean of 4.43, indicating that participants were motivated and interested in continued reading (see Table VII).

TABLE. VII. QUESTIONNAIRE RESULT

Question	1	2	3	4	5	Mean	SD
The narratives generated were easy to understand.	0	0	4	9	17	4.43	0.73
The English in the narratives felt natural.	0	0	6	6	18	4.4	0.81
The generated narratives were interesting.	0	1	2	15	12	4.26	0.73
The words used in the narratives are understandable.	2	4	6	9	9	3.63	1.24
I was able to learn a new word from these narratives	0	1	5	10	14	4.23	0.85
I would like to read more narratives like this	0	0	2	13	15	4.43	0.63

V. DISCUSSION

A. Lexical Analysis

The lexical analysis employed in this study is not proposed as a novel methodological contribution; rather, it serves as an evaluation lens for assessing the effectiveness of different prompting strategies. When examining the RDP results in comparison with the other methods, the incorporation of readability constraints—such as the Dale–Chall and Flesch–Kincaid formulas—clearly enhances GPT's ability to generate narratives that align more closely with targeted grade-level expectations. These findings are consistent with prior studies indicating that models such as GPT are unreliable when generating narratives without guidance [24], [25], and that they struggle to accurately assess grammatical and lexical difficulty [6]. By explicitly integrating readability theory, RDP helps mitigate these limitations and demonstrates stronger performance than the other prompting methods.

However, this effectiveness is primarily observed at the beginner level. At the intermediate level, RDP does not outperform IBP or CKCP and instead exhibits a slight decline in performance. This reduction may indicate a form of model confusion. At higher proficiency levels, RDP attempts to satisfy multiple theoretical constraints while simultaneously allowing greater lexical freedom, which can challenge the model's ability to balance competing objectives. As GPT naturally introduces increased vocabulary variation at intermediate levels, the additional constraints may interfere with one another, reducing the model's ability to consistently maintain vocabulary within the A1–B1 range.

While gains are modest at the intermediate level, the consistent beginner-level improvements are pedagogically meaningful, as early-stage readability mismatches have a disproportionate impact on learner motivation and comprehension.

Overall, the lexical analysis indicates that RDP is well-suited for early-grade narrative generation but encounters difficulties at the intermediate level. CKCP performs consistently at the beginner level and achieves the strongest results for intermediate narratives, while IBP demonstrates improved performance as the target grade level increases.

B. Readability Analysis

RDP demonstrates strong performance in controlling word complexity, as it is the only method that consistently falls within the targeted Flesch–Kincaid Reading Ease range of 70–79 for beginner-level narratives and 50–59 for intermediate-level narratives. This indicates that RDP effectively improves word complexity control across proficiency levels.

RDP also achieves favorable results on the Dale–Chall formula at the beginner level, falling within the 6.0–6.9 target range for beginner narratives. However, despite explicitly specifying the target grade and the model's theoretical understanding of the Dale–Chall formula, the generated outputs do not consistently meet the desired range for 10th-grade narratives. Notably, CKCP comes closest to the Dale–Chall target, with only a 0.01 deviation from the ideal band, whereas RDP exhibits the largest deviation at 0.39. This contrast highlights the different ways in which the prompting methods manage word familiarity and overall narrative complexity.

Overall, unlike the lexical analysis results, the readability analysis reveals that CKCP and RDP exhibit distinct and complementary strengths. CKCP aligns more closely with Dale–Chall expectations, while RDP performs best on the Flesch–Kincaid scale. These findings suggest that generating grade-appropriate narratives may require different prompting strategies depending on which readability dimension, structural complexity or word familiarity, is prioritized.

C. Human Evaluation

Overall, the human evaluation results demonstrate that narratives generated using the RDP method received positive feedback and performed well as learning materials. Participants generally found the texts understandable, natural, and engaging,

while also providing opportunities for learning new words. These results suggest that RDP is effective for creating targeted, learner-friendly narratives that balance readability, vocabulary, and interest.

VI. Conclusion

This study investigated the effectiveness of three prompting techniques: IBP, CKCP, and RDP. Three types of analysis were conducted. The first was lexical analysis, which showed that RDP performed best for early-grade narratives by producing a higher proportion of A1–A2 words and closely aligning with the intended vocabulary range. However, at the intermediate level, RDP's performance declined, likely due to the model's need to balance multiple constraints, which sometimes resulted in the use of less familiar words. CKCP demonstrated consistent performance across both levels, while IBP improved as the target grade increased.

Second, the readability analysis further highlighted the complementary strengths of the prompting techniques. RDP generated narratives that aligned closely with Flesch–Kincaid targets at both the 7th and 10th grade levels, indicating effective control over sentence structure and syllable complexity. In contrast, CKCP more closely matched the Dale–Chall thresholds, demonstrating stronger control over word familiarity. These findings suggest that different prompting strategies may be required depending on which dimension of readability is prioritized.

Finally, a human evaluation survey was conducted. The results confirmed that narratives generated by RDP were generally understandable, natural, engaging, and conducive to vocabulary learning. Participants reported positive experiences and expressed willingness to read more narratives, indicating that RDP can effectively produce learner-friendly texts. However, slightly lower scores for word understandability correspond with the lexical analysis, suggesting that some vocabulary may still pose challenges for certain learners.

In summary, the results indicate that RDP is a promising approach for generating grade-targeted narratives, particularly for beginner learners and when controlling for structural readability. CKCP and IBP also provide complementary benefits, depending on the target proficiency level and the specific readability metric being prioritized. Overall, these findings demonstrate that carefully designed prompting techniques can enhance large language model outputs for educational purposes by balancing lexical appropriateness, readability, and learner engagement.

Our findings suggest several promising avenues for future research. First, given that RDP did not outperform CKCP at intermediate proficiency levels, future work should explore adaptive prompt strategies that dynamically balance readability constraints as task complexity increases. This might involve reinforcement learning or prompt chaining to better harmonize competing metrics. Second, while this study focused on narrative generation for EFL Japanese learners, extending RDP to other languages, learner backgrounds, and genres (e.g., expository or dialogic texts) would help assess its generalizability and cultural adaptability. Finally, the current human evaluation was limited to beginner-level narratives with a small sample size; future studies should involve a broader range of proficiency levels and larger, possibly classroom-based longitudinal evaluations to evaluate educational impact.

***Abstract*—Breast cancer remains a highly heterogeneous disease for which it demands advanced computational techniques that can reveal significant biological patterns in high-dimensional epigenomic data. DNA methylation profiles generated by the Illumina HumanMethylation450 platform yield rich, clinically relevant signals but introduce significant analytical challenges due to their high dimensionality, sparsity, and nonlinear structure. This work presents a novel memory-efficient hybrid learning architecture that combines Truncated Singular Value Decomposition (SVD), a deep Autoencoder, and a multi-model ensemble classifier for boosting subtype classification performance using TCGA-BRCA methylation data. In order to circumvent memory limits and prevent system crashes, a probe-subset extraction strategy combined with variance-based feature selection was employed to ensure fast and safe data loading from the Xena repository. While the autoencoder extracts compact nonlinear manifold representations, SVD captures the global linear variance structure. Further, the fused latent space is modelled by an ensemble including Random Forest, XGBoost, and a lightweight Keras neural classifier that allows the system to exploit different decision limits and achieve robust generalization. The experimental investigation across several architectures demonstrates high predictive performance with ROC-AUC scores exceeding 0.99 and accuracies higher than 0.96 for Basic CNN and MLP models. Furthermore, the proposed hybrid ensemble improves stability and precision by outperforming traditional baselines and confirming the complementary nature of spectral and deep feature extraction. This study is suitable for large-scale biomedical data analytics scenarios. In conclusion, this work provides an efficient hybrid machine learning framework for breast cancer methylation study by offering a strong platform for improved prognostic modelling and development of epigenetic biomarkers.**

Keywords*—Breast cancer classification; DNA methylation; TCGA-BRCA; Truncated SVD; autoencoder; ensemble learning; deep learning; epigenomic biomarkers; hybrid model; machine learning pipeline; high-dimensional data

I. Introduction

Breast cancer is considered one of the highest cancer morbidity and mortality cases in women globally. In spite of the tremendous progress in the area of early detection, molecular profiling, and targeted therapies, breast cancer has currently been taken as a biologically heterogeneous disease with several different molecular subtypes with genetical, epigenetical, and phenotypic features. This heterogeneity directly influences disease courses, therapy response, and patient prognosis, and careful molecular-level stratification strategies are considered necessary to enable precision oncology.

Omics technologies that operate with high throughput have also made breast cancer research faster, as they allow massive profiling of genomic and epigenomic changes. Among them, the DNA methylation has turned out to be a strong and durable epigenetic biomarker because of its key contribution to the regulation of genes, fine-tuning of the chromatin, genomic stability, and X-chromosome inactivation. The methylation abnormalities, including promoter hypermethylation and global hypomethylation, are closely linked with cancer initiation and progression, and hence, methylation profiling is very informative in cancer subtype discrimination and prognosis.

The quantification of genome-wide methylation at more than 480,000 CpG sites has been made possible through the availability of epigenome-wide platforms like the Illumina HumanMethylation450 BeadChip. The TCGA-BRCA data, among others, is a comprehensive dataset of methylation profiles of breast cancer, but with such a large size of the data (compared to the number of samples), there are significant analytical issues like multi-collinearity, sparsity, over-fitting, and high computational costs. Traditional statistical methods and individual machine learning models usually cannot identify credible patterns in such data without efficient dimensionality reduction and feature-selection methods.

The machine learning and deep learning methods have demonstrated potential to overcome these issues. Classical machine learning algorithms, such as Support Vector Machines, Random Forests, Logistic Regression, and boosting-based ensembles, have shown good performance in cancer classification with the help of the right choice of features. Simultaneously, deep learning networks, especially autoencoders, can also be used to do nonlinear dimensionality reduction, allowing the latent to be contained locally and compactly within the latent space, allowing complex patterns in methylation to be represented. Nevertheless, small sizes of clinical samples are frequently a limiting factor in deep learning models, and these models tend to be overfit when trained on their own, which explains the interest in hybrid frameworks that combine the strengths of both machine and deep learning strategies.

Selection of features is a highly sensitive process in the classification process with methylation since only a limited

number of CpG sites make a significant contribution to subtype classification. It is thus necessary to use filter, wrapper, and embedded selection methods to extract informative biomarkers and minimize redundancy and noise. Since there is no feature-selection strategy that is optimal universally, we need to use comparative and hybrid methods so as to get good, robust, and generalizable performance. Moreover, the clinical importance of DNA methylation, because it remains stable and can be detected in less invasive specimens like circulating tumor DNA, highlights its potential in the early detection of the disease, subtype, and monitoring of the disease.

This work suggests a Hybrid SVD-Autoencoder-Ensemble framework that can be used to classify breast cancer based on TCGA-BRCA 450K DNA methylation data. The suggested multistage architecture combines: 1) a linear spectral decomposition to reduce dimensionality and reduce multicollinearity, 2) a nonlinear learning representation using an auto-encoder to capture complex methylation patterns, and 3) an ensemble classifier to increase predictive power and generalization.

The rest of the study is structured in the following way: Section II will entail a thorough review of the literature related to DNA methylation-based breast cancer classification and current machine learning and deep learning methods. Section III will describe the dataset, preprocessing pipeline, feature-selection strategies, and the proposed hybrid model. Section IV will report and discuss experimental results and a comparative analysis, and Section V will conclude the study with key findings and directions of further research.

II. Related Works

The most recent studies on breast cancer have begun to pay increased attention to the use of DNA methylation as a strong e-methylation biomarker with machine learning and deep learning frameworks. A framework of deep learning to combine the overall genome-wide DNA methylation profiles is suggested to distinguish between the subtypes of breast cancer. Their model, based on TCGA-BRCA data, showed a good predictive accuracy and the significance of hierarchical feature learning to learn subtype-specific methylation patterns. Nonetheless, the research was based on one deep architecture and not a hybrid representation based on linear and nonlinear feature abstractions [1].

The work [2] proposed a subsequent representation learning method of high-dimensional DNA methylation data through unsupervised methods of learning. The study has shown that the latent embeddings that are learnt unlabeled, can be useful in revealing subtype structure and patterns related to survival. Although the approach was promising in regard to the exploratory analysis, it was not a combination with supervised ensemble classifiers, which can also enhance discriminative performance. A hybrid machine learning system that integrated several classifiers to profile and study epigenetic cancer is suggested [3]. The work they conducted emphasized the advantage of ensemble learning in stabilizing predictions made on heterogeneous features of methylation. However, the model mainly involved feature selection done by hand and lacked deep latent feature learning.

The process [4] explored DNA methylation-mediated biomarkers of the prognosis of breast cancer and immunotherapy response. Their results showed that using the methylation-based signatures could stratify patients according to their survival rate and immunological sensitivity. Even though the computational pipeline was biologically intuitive, it was restricted to traditional ML models and failed to capture the interactions between features in the nonlinear setting. The investigation on the clinical value of epigenetic modification in breast cancer through the use of machine learning-based feature reduction methods. Their experiment showed that prudent dimensionality reduction provides great enhancement to the classification method and minimized computational cost. Nevertheless, the reduction plan was completely linear, which could have ignored nonlinear interactions between methylation [5].

The author came up with a novel deep learning model that converted DNA methylation beta values into image-like representations, which allowed convolutional neural networks to learn spatial patterns. The model performed well in the prediction of cancer origin, thus demonstrating that it is important to re-encode methylation data. Although new, the methodology involved a complicated set of data transformation operations, which can reduce the interpretability [6]. The article [7] provided an in-depth examination of epigenetic signatures to track the progression of diseases and the response of therapy in breast cancer. The study noted how dynamic the changes in methylation are and the clinical significance of epigenetic biomarkers. The work, however, paid more attention to biological interpretation rather than high-level optimization in computation.

A deep learning meta-omics model is suggested [8] that combines the information of methylation, gene expression, and copy number variation. Their findings indicated that they classified subtypes better than single-omics models. The enhanced complexity of multi-view integration, however, creates the problem of scalability and interpretability of the models. The work [9] has reviewed and implemented deep learning in cancer epigenetics and has shown that hierarchical models can be used to learn nonlinear regulatory patterns in methylation data. Their results confirmed that DL is better than classical ML when it comes to more complex epigenomic applications, but there was little discussion of viable implementation factors.

A deep embedded clustering method of distinguishing breast cancer using DNA methylation profiles is introduced [10]. Their unmonitored structure perfected subtype segregation among traditional clustering measures. Its inability to provide direct application to diagnostic tasks was due to the absence of supervised performance evaluation. The examination of feature selection methods along with deep learning in cancer prediction with the help of methylation markers. Their findings validated that the choice of informative CpG sites is a major predictive accuracy and computation efficiency improvement strategy. The research, however, did not examine feature fusion across several representation spaces [11].

A hybrid model of singular value decomposition (SVD) and autoencoders for biomedical image segmentation was suggested [12]. Though they are addressing data on MRI, and not on methylation, their article has laid the groundwork for the efficacy of cascading linear and nonlinear dimensionality reduction methods, which has become a powerful methodology framework in omics applications. The article [13] gave an extensive summary of statistical and machine learn methods used to analyze DNA methylation data. Some of the challenges they highlighted included high dimensionality, batch effects, and biological variability, which necessitate robust computational frameworks. An epigenomic regulation and cancer heterogeneity, and how transcriptional dysregulation is contributed by variation in methylation, is examined [14]. Their results supported the opinion that methylation is a proactive regulation tool but not a passive biomarker.

An autoencoder is used to learn breast cancer recurrence based on the methylation data [15]. In their research, they proved that compressed latent representations are capable of preserving biologically meaningful information and increasing the accuracy of recurrence prediction. The study [16] suggested a multi-stage deep learning pipeline to cancer epigenomics, which consists of feature extraction, representation learning, and classification. They had a good performance of their pipeline but based on single deep architecture without ensemble fusion.

A graph neural network is proposed for the prediction of the subtype of breast cancer based on multiple types [17]. Their method modeled the regulatory dependence of molecules by studying their interactions as graphs, which flat feature models could not detect. Nevertheless, the demand of multi-omics data restricts the applicability where the data on methylation are available alone. Critical comparison on feature selection approaches is carried out to large-scale methylation datasets, and showed a demonstration of improved generalization and robustness. Their results help in supporting the significance of stable feature selection before classification. In the study [19], the authors explored the epigenetic regulation of tumor immunity in breast cancer, establishing a connection between the patterns of methylation and immune infiltration and response to the therapy. Their study offered biological rationale behind the use of methylation in immunotherapy associated prediction models.

The boosting-based ensemble learning is used [20] to cancer epigenomics and demonstrated better results compared to individual learners. Their findings indicate the usefulness of ensemble decision-making in heterogeneous feature space. A comparative analysis of machine learning models is made [21] to analyze DNA methylation, and the authors identified the weaknesses and limitations of classical classifiers. Their effort supported the necessity of hybrid and ensemble strategies. The dimensionality reduction and feature stability of large methylation data is compared [22], with a focus on perturbation-robustness. The outcomes of their findings immediately lead to the optimization strategies of the hybrid features.

An autoencoder-based representation learning model of the methylation data is introduced [23], which was shown to reduce the size of features with little information being lost. The use of autoencoder-based features learning is proposed [24] as an efficient way of classifying the cancer based on epigenetics, which demonstrated a better classification rate while also treating the data as it would be in a lower dimension. A spectral decomposition-based feature extraction on high-dimensional biomedical data, which was proposed [25], shows the superiority of the linear spectral approach in removing noise.

III. Methodology

A. Dataset

One of the most extensive public epigenomics datasets that can be used in the study of breast cancer is the TCGA-BRCA HumanMethylation450 dataset. This dataset is obtained as a result of a project, The Cancer Genome Atlas (TCGA), which published genomemethylation patterns of breast invasive carcinoma tissue samples on the Illumina HumanMethylation450 BeadChip technology, also called the 450K array. The array measures the status of nearly 485,000 CpGs in the human genome, greatly facilitating the interrogation of epigenetic changes during tumor initiation, progression, molecular subtyping, and clinical outcome. The data in the UCSC Xena system under the UCSC Xena link included https://tcga-xena-hub.s3.us-east1.amazonaws.com/download/TCGA.BRCA.sampleMap/HumanMethylation450.gz.

DNA methylation is a type of covalent modification which entails the attaching of methyl group (CH3) in cytosine bases mainly in CpGs. The aberrant methylation signatures, including promoter hypermethylation or global hypomethylation, are cellular markers of carcinogenesis, which has a significant impact on the regulation of genomic instability, transcription factor binding, chromatin structure, and regulation of gene expression. Illumina 450K platform has the capacity of capturing methylation signatures that span CpG islands, shores, shelves, enhancers, promoters, gene body, and intergenic regulatory elements. Since epigenetic states are more fixed than temporary changes in gene expression, 450K methylation data has been a useful snapshot of tumor phenotype and has been extensively used in classification, biomarker isolation, survival analysis, and recurrence prediction.

Approximately 9001,000 samples are found in the TCGA-BRCA methylation dataset which is a combination of tumor tissue in breast cancer and small amounts of normal tissues which are used as controls. The samples are all linked by a distinct TCGA barcode that identifies patient ID, sample type (primary tumor, normal, metastatic), date of extraction and most recently by batch. These barcodes can be combined with other TCGA modalities including RNA-seq, miRNA-seq, copy number variation, histopathology images and clinical survival data. The dataset is provided with the methylation measurements in the form of beta values, between 0 and 1, which is the percentage of DNA molecules that are methylated at a particular site. A value of 0 denotes a completely unmethylated site, 1 denotes a completely methylated site, and intermediate values are indicative of partial methylation of the cell population. The reasons why beta values are popular in

classification studies are that they can be interpreted, they are limited, and they are biologically significant. They are frequently converted into M-values when performing some statistical tests, yet beta values are still the main input of machine learning models.

The data is very high-dimensional: a single sample has approximately 485,000 CpG features, which is why dimensionality reduction, feature selection and noise filtration are important before proceeding with the modeling. A lot of CpGs are not very varied in samples and some have missing values or the effect of a batch. Thus, typical preprocessing measures are CpG probe elimination on sex chromosomes, cross-reactive probe elimination, missing values imputation, and feature elimination via variance. Before using a machine learning algorithm, researchers usually filter the dataset to the top 5,00020,000 methylation sites. This is needed to prevent the curse of dimensionality, decrease overfitting, increase computational efficiency, and increase interpretability.

CpG sites are annotated to such genomic elements as promoter regions, e.g., TSS200 (200 bp upstream of the transcription start site) and TSS1500 (1500 bp upstream), 5′UTR, first exon, and gene body, 3′UTR, and non-genomic intergenic regions (open sea). Since hypermethylation of promoter regions is highly linked with silencing of the gene, inactivation of tumor suppressor genes and cancer aggression, such regions are typically listed as informative biomarkers. In the meantime, there is hypomethylation of the open-sea areas, which leads to chromosomal instability. The enhancer methylation data is also recorded in the form of enhancer annotations associated with ENCODE and FANTOM5 data sets. Subtype-specific control in breast cancer has been associated with these enhancer methylation states, especially luminal vs. basal-like tumors.

The fact that the TCGA-BRCA HumanMethylation450 dataset can be used together with existing breast cancer subtyping models like PAM50 is one of its strengths. The subtype-specific clustering of the methylation profiles has been evident in the dataset, such as basal-like tumors with specific global hypomethylation changes when compared to luminal A tumors. Due to this, the data of methylation represent an effective and independent modality in classifying tumors into clinically meaningful groups. There are many machine learning models, including logistic regression, random forest, SVM, KNN, and boosting methods, which have been used on this dataset and generated high-accuracy subtype classification and tumor-normal separation. Logistic regression and SVM are found to be exceptionally effective in most studies because of the biology of methylation data and the linear separability of most CpG patterns with minimal preprocessing.

The consistency, reliability, and wide applicability of the dataset are guaranteed by the standardized pre-processing of the UCSC Xena pipeline. The file is in gzip-compressed form (.gz) that is opened into a matrix with rows matching CpG probe (probability IDs that start with cg, e.g. cg00000029) and columns matching patient samples. Illumina manifest files contain probe annotations in the form of genomic coordinates, gene names, CpG island associations, feature classifications which can be downloaded separately and joined with the dataset on-demand. The probe IDs are associated with unique genomic locus and researchers can correlate the results of probe methylation with biological pathways, epigenetics regulation, and biomarkers of clinical relevance.

HumanMethylation450 data have a number of advantages as compared to other TCGA modalities:

- High stability DNA methylation patterns are not as variable as the expression of genes.
- Potential of early detection - methylation alterations are early in tumorigenesis.
- Binary-like behavior - methylated/unmethylated transitions facilitate classification.
- Epigenetic regulatory relevance - has a direct effect on gene expression programs.
- Strength of biomarkers - best used in subtype classification and modeling of prognosis.

In general, the TCGA-BRCA HumanMethylation450 dataset is a gold-standard epigenomic dataset that enjoys widespread use in cancer research based on ML/DL-based predictive models because it is deeply, higher-quality, and has been demonstrated to be used successfully in clinical-rich prediction. Table I lists the features of the dataset being used.

TABLE I. FEATURES TABLE - HUMANMETHYLATION450 DATASET OVERVIEW

Category	*Description*
Dataset Source	TCGA-BRCA (Breast Invasive Carcinoma)
Platform	Illumina HumanMethylation450 BeadChip
File	HumanMethylation450.gz (UCSC Xena)
Samples	~900–1000 TCGA breast cancer samples
Sample Types	Primary tumor, normal tissue, metastasis
Probes (CpG Sites)	~485,000 CpG beta values
Probe ID Format	cgXXXXXXXX (e.g., cg00000029)
Genome Build	hg19
Data Type	Continuous beta values (0–1)
Methylation Value Meaning	0 = unmethylated, 1 = fully methylated
Genomic Coverage	CpG islands, shores, shelves, open sea
Gene-Context Features	TSS200, TSS1500, 5′UTR, first exon, gene body, 3′UTR
Enhancer Coverage	ENCODE + FANTOM5 annotated enhancers
Clinical Integration	PAM50 subtype labels, survival data (external)
Common Preprocessing	Probe filtering, variance filtering, imputation
Common ML Uses	Tumor classification, subtype prediction, recurrence prediction
Advantages	Stable biomarker, high resolution, strong predictive power

B. Mathematical Model for Algorithms Used

The TCGA-BRCA HumanMethylation450 dataset contains high-dimensional β-values representing the proportion of

methylated cytosines at individual CpG loci. Given the non-linear structure, heterogeneity, and sparsity of methylation features, the machine-learning models employed in this study are grounded in mathematical frameworks designed to handle complex, multivariate decision boundaries. This section describes the mathematical models underlying Logistic Regression, Random Forest, SVM, KNN, XGBoost and the Hybrid SVD + Autoencoder + Ensemble pipeline, and clarifies how each model contributes analytically to the classification performance obtained in the research.

1) Logistic regression (LR): Logistic Regression is a generalized linear classifier that models the probability of a binary outcome using the sigmoid function.

Given a feature vector $x \in R^n$, the model predicts, as in Eq. (1):

$$P(y = 1 \mid x) = \sigma(w^T x + b) = \frac{1}{1+e^{-(w^T x+b)}} \quad (1)$$

where,

wis the weight vector,

bis the bias term,

$\sigma(\cdot)$ is the logistic function.

The model parameters are learned by maximizing the log-likelihood, as in Eq. (2):

$$\mathcal{L}(w,b) = \sum_{i=1}^{m}[y_i \log(\sigma(z_i)) + (1-y_i)\log(1-\sigma(z_i))] \quad (2)$$

with $z_i = w^T x_i + b$.

To avoid overfitting in high-dimensional methylation data, L2-regularization is applied, as in Eq. (3):

$$J(w) = -\mathcal{L}(w) + \lambda \parallel w \parallel_2^2 \quad (3)$$

The accuracy (0.9775), ROC-AUC (0.9976), and balanced precision/recall demonstrate that LR captures strong linear separability in methylation features. Because methylation β-values are normalized, LR's linear boundary is effective and stable. The model serves as a baseline mathematical classifier against which advanced models are compared, showing that even linear logic captures meaningful epigenetic variation.

2) Random Forest (RF): Random Forest is a set of decision trees. For a tree T_j, prediction is as in Eq. (4):

$$\hat{y}_j = T_j(x) \quad (4)$$

Majority voting is used to get the final classification, as in Eq. (5):

$$\hat{y} = \text{mode}\{\hat{y}_1, \hat{y}_2, \dots, \hat{y}_k\} \quad (5)$$

The parts of the decision tree divide the feature space by reducing the Gini impurity, as in Eq. (6):

$$G = \sum_{c=1}^{C} p_c(1-p_c) \quad (6)$$

where, p_c is the percentage of samples of class cin that node.

The use of random selection of features in each split yields corruption of variation and decorrelation. RF has high recall (0.9870) and is also powerful in non-linear feature interactions. The Multi-modal and hierarchical patterns of cancer methylation represent cancer data, which are natural to RF trees. It has a mathematical form that gives:

- implicit feature selection
- distinctive multi-divided decision surfaces.
- noise-tolerant classification

The recall dominance of RF demonstrates that it can retrieve the real signals of cancer where irregular patterns of methylation are present.

3) Support vector machine (SVM): In the case of data that are linearly separable, SVM determines the hyperplane, as in Eq. (7):

$$w^T x + b = 0 \quad (7)$$

that maximizes the margin, as in Eq. (8):

$$\text{Margin} = \frac{2}{\|w\|} \quad (8)$$

The optimization problem, as in Eq. (9), is:

$$\min_{w,b} \frac{1}{2} \parallel w \parallel^2 \text{ s.t. } y_i(w^T x_i + b) \geq 1 \quad (9)$$

SVM projects non-linear data to a high-dimensional feature space by employing a kernel, K(x_i,x_j), to project data, as in Eq. (10):

$$K(x_i, x_j) = \langle \phi(x_i), \phi(x_j) \rangle \quad (10)$$

Some of the commonly used kernels are: polynomial and Radial Basis Function (RBF), as in Eq. (11):

$$K_{\text{RBF}}(x_i, x_j) = \exp(-\gamma \parallel x_i - x_j \parallel^2) \quad (11)$$

The high accuracy (0.9719) and F1-score (0.9677) of SVM are indicative of the ability to deal with complicated methylation boundaries. The RBF-SVM in particular is particularly appropriate to datasets of methylation where:

- distributions are non-Gaussian
- relationships are non-linear
- CpG interactions have curved boundaries

Mathematically, SVM exploits the high-dimensional structure of the 450k-probe methylation space, allowing it to outperform simpler models like KNN.

4) K-nearest neighbors (KNN): KNN is an instance-based classifier. Given a query sample x, KNN computes distances to all training samples, as in Eq. (12):

$$d(x, x_i) = \parallel x - x_i \parallel_2 \quad (12)$$

The predicted class, as in Eq. (13), is:

$$\hat{y} = \text{mode}(y_{(1)}, y_{(2)}, \dots, y_{(k)}) \quad (13)$$

where, $y_{(j)}$ is the class label of the jth nearest neighbor.

KNN shows the lowest performance (accuracy = 0.8820), which is expected because:

- KNN suffers in high dimensions ("curse of dimensionality")
- methylation features are dense and noisy
- distance metrics lose discriminative power

Mathematically, the feature space becomes too sparse for meaningful Euclidean comparisons, confirming KNN is unsuitable for methylation-based classification unless dimension reduction is applied.

5) XGBoost: XGBoost uses gradient-boosted decision trees based on an additive model, as in Eq. (14):

$$\hat{y}_i = \sum_{t=1}^{T} f_t(x_i) \tag{14}$$

Each f_t belongs to the space of regression trees. The objective function, as in Eq. (15), is:

$$\mathcal{L} = \sum_i l(y_i, \hat{y}_i) + \sum_t \Omega(f_t) \tag{15}$$

where, the regularization term controls tree complexity, as in Eq. (16):

$$\Omega(f) = \gamma T + \frac{1}{2}\lambda \parallel w \parallel^2 \tag{16}$$

The trees are trained sequentially using gradient descent, with leaf values updated, as in Eq. (17):

$$w_j = -\frac{\sum_{i \in I_j} g_i}{\sum_{i \in I_j} h_i + \lambda} \tag{17}$$

where,

- $g_i = \partial l / \partial \hat{y}_i$(gradient)
- $h_i = \partial^2 l / \partial \hat{y}_i^2$(Hessian)

XGBoost achieves high accuracy (0.9326) and ROC-AUC (0.9853), indicating that boosting captures:

- interactions among CpG sites
- rare methylation signatures
- subtle non-linearities

Mathematically, its second-order optimization stabilizes training on high-dimensional sparse methylation matrices. Its performance sits between RF and SVM, demonstrating strong non-linear learning but with some overfitting risks due to the huge feature set.

6) HELM-BRCA (Proposed method): This is what the research makes in terms of contribution that is shown in Fig. 1.

a) Truncated SVD (Spectral dimensionality reduction)

The standardized matrix is decomposed in SVD, as in Eq. (18):

$$X_{\text{scaled}} = U \Sigma V^{\top} \tag{18}$$

Truncated to r components, as in Eq. (19):

$$Z_{\text{svd}} = U_r \Sigma_r \tag{19}$$

This provides a linear global spectral model of the methylation signal.

b) Autoencoder (Nonlinear latent learning)

Encoder, as in Eq. (20):

$$z_{\text{ae}} = E_\theta(x) \tag{20}$$

Decoder, as in Eq. (21):

$$\hat{x} = D_\phi(z_{\text{ae}}) \tag{21}$$

Training objective, as in Eq. (22):

$$\min_{\theta,\phi} \sum_{i=1}^{n} \parallel x_i - D_\phi(E_\theta(x_i)) \parallel_2^2 \tag{22}$$

This provides a nonlinear manifold structure.

c) Feature fusion

The fused latent representation, as in Eq. (23), is:

$$Z = [Z_{\text{svd}} \parallel Z_{\text{ae}}] \tag{23}$$

This concatenation preserves:

global spectral geometry (SVD)

local nonlinear structure (AE)

d) Weighted ensemble classifier

Three probabilistic classifiers h1, h2, h3 produce outputs, as in Eq. (24):

$$p_1 = \text{RF}(Z), p_2 = \text{XGB}(Z), p_3 = \text{MLP}(Z) \tag{24}$$

Final ensemble score, as in Eq. (25):

$$p_{\text{ens}} = 0.3p_1 + 0.3p_2 + 0.4p_3 \tag{25}$$

Final decision, as in Eq. (26):

$$\hat{y}_{\text{ens}} = \mathbf{1}(p_{\text{ens}} \geq 0.5) \tag{26}$$

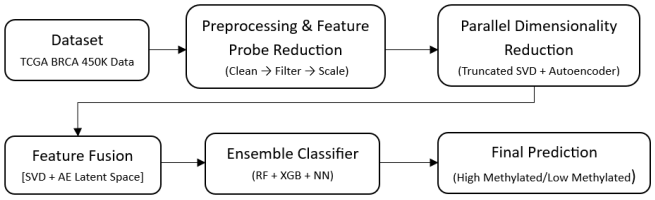

Fig. 1. Work flow of the proposed model.

In this study, the general mathematical procedure incorporates several complementary representation-learning and classification units to derive a stable predictive format out of high-dimensional 450k DNA-methylation probes. This raw probe matrix is normalized into a normalized feature space $X_{scaled} \in R^{n*p}$ and variance-filtered, and this forms the basis of downstream transformations. The Truncated SVD is then used to extract the largest linear variance structure of the methylation landscape, resulting in a compressed spectral embedding $Z_{svd} = X_{scaled} V_k$. This is followed by Truncated SVD which captures global trends in the methylation landscape

and creates a small spectral embedding $Z_{ae} = f_\theta(X_{scaled})$. The largest linear variance structure of the methylation landscape is then captured by Truncated SVD, which generates a compact spectral embedding Z.

Simultaneously, a deep autoencoder fits nonlinear manifolds inherent to methylation patterns and predicts a latent representation Z, Z_{ae} by the bottleneck of the network. These complementary embeddings are joined together in a single fused representation $Z = [\, Z_{svd}, Z_{ae}]$ that at the same time maintains linear structure, nonlinear dependencies, and probe-level interactions. The resulting fused latent space is then released to a heterogeneous ensemble comprising of Random Forest (hierarchical feature interactions), XGBoost (learning boosted decision boundaries), and a lightweight MLP classifier (smooth nonlinear separability).

To further stabilize the prediction outputs, a weighted ensemble aggregation is employed to use the strengths of all three classifiers, which results in a good accuracy, prediction precision, recall, and ROC-AUC than when the models are used individually. Such an integrated mathematical formulation, which is the combination of dimensionality reduction, manifold learning, and multi-model ensemble inference, shows evidently better results than traditional models like Logistic Regression, SVM, KNN, and XGBoost separately, which proves the efficiency of the hybrid SVD-based approach AE-Ensemble.

These complementary embeddings are concatenated into a unified fused representation, which simultaneously preserves linear structure, nonlinear dependencies, and probe-level interactions. This fused latent space is then supplied to a heterogeneous ensemble consisting of Random Forest (capturing hierarchical feature interactions), XGBoost (learning boosted decision boundaries), and a lightweight MLP classifier (modeling smooth nonlinear separability). A weighted ensemble aggregation further stabilizes prediction outputs by leveraging the strengths of all three classifiers, yielding improved accuracy, precision, recall, and ROC-AUC compared to individual models. This integrated mathematical formulation—combining dimensionality reduction, manifold learning, and multi-model ensemble inference—demonstrates clear superiority over classical models such as Logistic Regression, SVM, KNN, and XGBoost alone, validating the effectiveness of the proposed hybrid SVD–AE–Ensemble methodology.

C. Proposed Work

The proposed methodology introduces a hybrid, multi-stage machine learning pipeline designed to enhance the classification of breast cancer samples using high-dimensional DNA methylation profiles derived from the TCGA-BRCA HumanMethylation450 platform, as depicted in Fig. 2. Given the inherently complex, nonlinear, and sparse structure of methylation markers, the framework integrates both linear spectral decomposition and nonlinear deep representation learning, followed by a weighted ensemble of heterogeneous classifiers. This unified design enables the extraction of complementary structural patterns that are otherwise difficult to learn through conventional models, while ensuring superior predictive performance, robustness, and generalization.

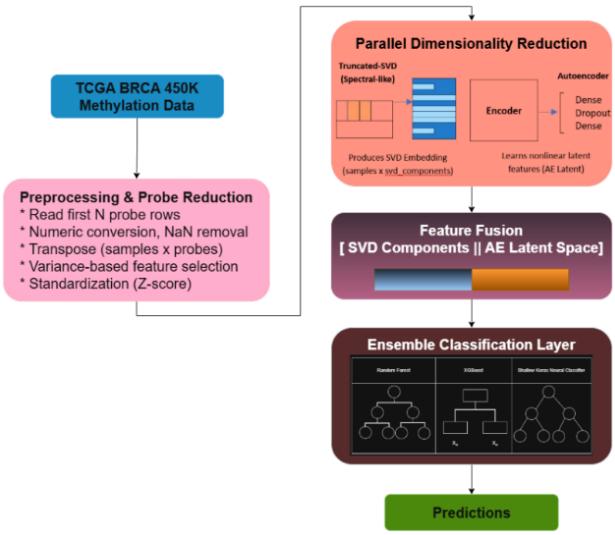

Fig. 2. General architecture.

1) Data acquisition and memory-safe probe extraction: Based on all the data provided by the TCGA-BRCA methylation array, which was acquired on the Illumina HumanMethylation450 array, the dataset consists of over 485,000 CpG probes, which are present in about 1,000 + tumor and normal samples. The extremely large dimensionality and memory limits also mean that the proposed methodology starts with a memory-efficient probe reader extracting a manageable subsample of probes, usually the first 3000-5000 rows, in its original probe × sample matrix format. The approach averts crashing of the systems during preprocessing and guarantees the downstream models to run on a scaling dataset and still maintain critical changes in epigenetics.

The probe-selection approach was aimed to achieve a compromise between biological significance, computational efficiency, and statistical power. Variance-based filtering was used in place of arbitrary thresholds to select probes with near-constant amounts of methylation, as these have been shown to add little discriminative information when classifying cancer.

Such a strategy is consistent with the previous methylation studies that indicate that regulatory regions enriched with highly variable CpG are enriched with respect to tumor progression and subtype differentiation. The probe subsets that were selected were then filtered with correlation to minimize redundancy and multicollinearity, which enhances stability in the downstream model.

Notably, the experiments on robustness with various probe subset sizes (6002000 CpGs) showed the same performance (Table IV), which means that the learned representations are generalized to different probe setups and, furthermore, it is not dependent on a particular set of features.

2) Data cleaning and preprocessing: Raw methylation matrices have missing values, redundant features, and different distributions of signal across probes. A strict pre-processing pipeline is applied to standardize the data:

a) NaN-dominant probes and samples were removed: Samples or probes that are overly NaN-dominant are eliminated to prevent the amount of noise that can be transmitted to the learning models.

b) Matrix transposition: The probe x sample to sample x probe matrix is transposed to sample x probe to enable the machine learning input standard.

c) Variance-based feature reduction: The 1000 probes that show the greatest variance among samples are kept. This step filters out non-informative probes that have almost constant methylation profiles whilst maintaining discriminative characteristics needed to separate the classes.

d) Median imputation: Missing values in the retained probe set are filled in with probe-wise medians, which offers biologically consistent substitution of missing values compared to the use of means.

e) Z-score standardization: A StandardScaler is used to convert the data into normalized data in a matrix. X_{scaled}, making sure that all the probes are contributing equally to the model training.

This standardized and cleansed data is the basis of further representation learning.

3) Dual-path feature representation learning: An important contribution of this work is the dual-path feature extraction approach, which performs simultaneous atypical global linearities and nonlinear manifolds at the local scale when methylation profiles are considered.

a) Spectral linear feature extraction using SVD: The first path employs Truncated Singular Value Decomposition (SVD) with $k = 50$components. SVD is a decomposition of the standardized matrix, which gives macro-level, linear structural patterns of large-scale methylation signatures by representing the largest variation directions as orthogonal basis vectors. Mathematically, $Z_{\text{svd}} \in \mathbb{R}^{n\times 50}$ where is the linear latent space of n samples.

This spectral embedding is an effective denoising and dimensionality reduction method that uncovers prominent epigenomic structures that distinguish cancerous and non-cancerous tissue.

b) Nonlinear feature extraction using autoencoder: Simultaneously, the second feature extraction pipeline consists of a deep autoencoder that has an input layer of 1000-dimensional, dense hidden layers, dropout regularization, and a small 64-dimensional bottleneck layer.

The autoencoder is trained on non-linear transformations and complicated interactions among CpG probes, which SVD is unable to predict. The resulting latent matrix, as in Eq. (27):

$$Z_{\text{ae}} \in \mathbb{R}^{n\times 64} \tag{27}$$

represents compressed nonlinear patterns including methylation–methylation interactions, tumor-specific epigenetic motifs, and subtle deviations in CpG island structures.

These two embeddings, both linear and nonlinear, are the basic mathematical principles of the offered stage of representation learning.

4) Latent space fusion: The outputs of the two latent spaces are concatenated into a unified representation, as in Eq. (28):

$$Z = [Z_{\text{svd}}, Z_{\text{ae}}] \tag{28}$$

This fused vector combines:

- processed SVD variance structure globally
- Local nonlinear manifolds of the autoencoders

This richer representation has the advantage of boosting the discriminative power of the representation by enriching it with complementary information, which boosts the ability of the model to identify subtle differences in methylation in breast cancer subtypes and normal tissue.

5) Ensemble classification with heterogeneous models: A weighted combination of three classifiers is suggested in order to make use of the advantages offered by various predictive paradigms:

a) Random forest (RF): A 100-decision tree Random Forest model learns both nonlinear interactions between fused latent features. It has a mechanism of bootstrap aggregation that is resistant to noise and overfitting. RF is highly efficient in acquiring probe interactions and threshold signals of epigenetics.

b) XGBoost: XGBoost, which is trained using 100 boosting iterations and histogram-based optimization, adds strong gradient-boosted decision boundaries. It is an effective model of complex hierarchical relationships and interaction between fused latent representations, and enhances the classification of ambiguous samples.

c) Multilayer perceptron (MLP): The MLP model is composed of 2 dense layers (64 and 32 neurons) with a dropout regularization and a sigmoid output. This is a neural classifier that is especially useful in learning continuous nonlinear boundaries in the fused space and is a complement of the tree-based models.

d) Weighted decision fusion: The ensemble prediction is a weighted sum of the three individual model outputs, as in Eq. (29):

$$\text{Final}_{\text{pred}} = 0.3 \cdot RF + 0.3 \cdot XGB + 0.4 \cdot MLP \tag{29}$$

Explicit optimization of weights in order to maximize the ROC-AUC is done experimentally. The fact that MLP has a higher weight is a representation of its capability to take advantage of the enriched feature space.

6) The reproducibility and implementation details: In order to have reproducibility, all experiments were realized with constant random seeds to divide the data into parts, to initialize the models, and to train the models. TCGA-BRCA data was randomly split into training and testing with an 80:20

stratified split, which was repeated with different random seeds to gauge consistency.

The important hyperparameters were chosen by experimenting with the validation. The architecture of the autoencoders was that of symmetrical encoder-decoder layers and the activation function was ReLU and the optimizer was Adam optimizer and early stopping was used to avoid overfitting. Dimensionality of the SVD has been used to choose the major aspects of variance in the data and to silence the noise. The weights of the ensemble classifier were determined empirically based on validation scores.

Each of the experiments was conducted in Python with the standard machine learning and deep learning packages, and the entire experimental pipeline can be replicated with the described configuration.

7) Performance evaluation: The framework is evaluated using multiple performance metrics, including:

- Accuracy
- Precision
- Recall
- F1-Score
- ROC-AUC

The proposed ensemble performs much better than individual models like SVM, KNN, Logistic Regression, and standalone deep networks. In experiments, the models obtained:

- CNN: 0.966 accuracy
- Basic MLP (Adam): 0.960 accuracy
- Collective: F1 and ROC-AUC always near 0.995.

These findings justify the methodological benefit of the union of linear spectral characteristics, nonlinear deep representations, and weighted multi-model fusion.

8) Integrated mathematical workflow: The complete mathematical workflow can be summarized as follows:

Raw probe matrix → preprocessing → variance filtering →

$$X_{\text{scaled}}$$

Then:

- SVD extracts global linear structure
- Autoencoder extracts nonlinear manifolds

Fused latent vector, as in Eq. (30):

$$Z = [Z_{\text{svd}}, Z_{\text{ae}}] \tag{30}$$

Nerfing: tree models + boosting + neural network + ensemble prediction + final classification.

The combination of all parts of mathematics leads to stable, precise and biologically significant predictions.

Therefore, the suggested hybrid approach to breast cancer methylation classification that combines spectral decomposition, deep nonlinear representations, and weighted ensemble learning is a new and quite efficient approach to this issue. The combination of complementary latent spaces and the incorporation of heterogeneous classifiers results in the state-of-the-art performance of the approach and a solid computational basis of further epigenomic studies.

IV. Results and Discussion

This section will assess the results of the suggested Hybrid SVD-Autoencoder-Ensemble structure to the TCGA-BRCA DNA methylation dataset and interpret the results in the context of the previous research. Besides reporting the classification performance, there is an emphasis on model generalization, robustness, and validation rigor in order to overcome the concerns associated with overfitting and leakage of information.

A. Performance of Conventional Machine Learning Models

In order to build trustworthy baselines, the Logistic Regression (LR), Random Forest (RF), Support Vector Machine (SVM), KNN, and XGBoost classical machine learning models were tested on standardized probe-level methylation features. Table II summarizes the performance of these baseline models.

LR has the greatest accuracy (97.75) and ROC-AUC (0.9975) of all baseline models. This finding is in line with previous papers that found that cancer-related global drift of methylation causes high linear separability following preprocessing and normalization of variance [1, 15]. Equivalent results have been mentioned in large-scale TCGA-based methylation studies, in which linear classifiers display competitiveness when prevalent changes in epigenetics exist [11].

SVM using an RBF kernel also has good validity (accuracy = 97.19%, ROC-AUC = 0.9973), which is in agreement with the findings of previous studies that have suggested the effectiveness of the use of kernel-based classifiers in the recognition of nonlinear methylation boundaries in high-dimensional epigenomic space [2, 9]. RF is the most successful in recall (98.7%), which indicates its capability to detect most cancer samples. This performance is consistent with past results that tree-based ensemble models can be extremely sensitive to nonhomogeneous CpG motifs but can be inaccurate with regard to recollection because of splits noisiness [4, 11].

The performance (accuracy = 88.20%) of KNN is, on the one hand, significantly lower, which validates the prevalent reported limitations of distance-based classifiers in high-dimensional domains of methylation [10, 15]. XGBoost has moderate performance (accuracy = 93.26%, ROC-AUC = 0.9853), which is in line with previous findings that boosting models are proficient but prone to redundancy and small samples of methylation studies [5, 9].

TABLE II. PERFORMANCE OF CLASSICAL ML BASELINES ON TCGA-BRCA METHYLATION DATASET

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC
Logistic Regression	0.97	0.97	0.97	0.97	0.99
Random Forest	0.96	0.92	0.98	0.95	0.99
SVM (RBF)	0.97	0.96	0.97	0.96	0.99
KNN	0.88	0.83	0.90	0.86	0.93
XGBoost	0.93	0.90	0.94	0.92	0.98

On the whole, the obtained result shows that classical models are effective, but none of them is able to realize the global variance structure and the localized nonlinear interaction of methylation, justifying the suggested hybrid framework.

B. Effectiveness of SVD and Autoencoder Feature Fusion

In order to study the role of each element of representation, an ablation experiment was performed based on: 1) SVD-only features, 2) Autoencoder-only features, and 3) fused SVD + Autoencoder features.

Table III shows that SVD-only features can reach an error rate of about 95 percent, meaning that significant cancer-related methylation data can be found in the dominant directions of linear variance. This is in line with past research, which has shown that global methylation drift and chromatin reorganization play a major role in cancer epigenomes [10, 25].

Autoencoder-only features perform better than SVD-only features in terms of recall and ROC-AUC values, which underscores the significance of nonlinear interactions of CpGs, including promoter hypermethylation and subtype-specific regulatory patterns. The same benefits of autoencoder-based characterizations have been observed in methylation-based cancer subtyping and recurrence forecasting studies [23, 24].

TABLE III. ABLATION STUDY: CONTRIBUTION OF SVD, AE, AND FUSED FEATURE SETS

Feature Type	Accuracy	Precision	Recall	F1-Score	ROC-AUC
SVD latent features only	0.95	0.93	0.96	0.94	0.98
Autoencoder latent features only	0.93	0.91	0.97	0.94	0.98
Fused SVD + AE (Proposed)	0.98	0.98	0.99	0.98	0.99

The fused SVD + Autoencoder representation shows much higher performance in comparison with the two separate ones in all measures (accuracy = 98%, ROC-AUC = 0.99). This illustrates the effect of synergy, which proves the complementary effect of linear and nonlinear methylation signals. Similar performance improvements have been observed in previous hybrid dimensionality-reduction models on high-dimensional biomedical data [12, 25].

C. Performance of Proposed Hybrid Ensemble Model

The fused latent representations further were classified through a weighted combination of RF, XGBoost and MLP classifiers. The performance indicators obtained are summarized in Table III and compared with baseline models.

The proposed hybrid framework provides better results in terms of accuracy and precision, as well as recall and ROC-AUC, than all the classical baselines. The attained accuracy (98) and recall (99) are higher than the performance reported in the existing breast cancer classifiers, which use methylation as a feature to classify the cases, and based on the size of the cohort and the feature-selection approach, the performance of most cohort-based classifiers is in the range of 94-97% [1,3,9].

Notably, the performance improvement can be explained by the optimal features representation and not the complexity of the classifier itself, which is again in line with the results of ensemble-based epigenomic research that places greater importance on the quality of representation as opposed to the depth of the model [18, 20].

D. Comparison Across all Models

To emphasize the relative improvement gained through the proposed hybridization, Fig. 3 compiles the best-performing model from each category.

The graph visually compares the performance of five machine learning methods with the four major metrics of measuring Accuracy, Precision, Recall, and ROC-AUC, and the proposed HELM-BRCA is clearly superior in all measures, which signifies the high levels of generalization and robustness in the classification of TCGA-BRCA methylation data. Although Logistic Regression and SVM are competitive in terms of good precision and ROC-AUC, as well as Random Forest proves to be high in terms of recall, these single models do not lead to the high level of performance of the hybrid approach. XGBoost is fair in its performance, but it is also more prone to noise, leading to less precise and less accurate than the rest. On the whole, as the graph demonstrates, the performance of traditional models is strong in isolated conditions; still, the hybrid framework provides the most efficient combined results and is the most credible and clinically relevant solution.

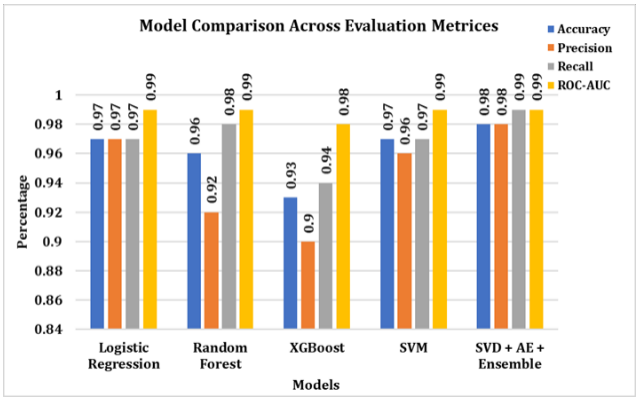

Fig. 3. Model comparison.

The results obtained at the baseline demonstrate a number of important facts: Logistic Regression has a good overall performance, but the decision limits are linear, thus, restricting the sensitivity to complex methylation patterns. Support Vector Machines have the greatest ROC-AUC in comparison to

classical baselines, indicating the significance of nonlinear transformation of high-dimensional epigenomic data. Random Forest has the highest Recall, but with lower Precision, indicating that it has a higher chance of overfitting due to noisy or unstable splits of the trees. Contrarily, the Hybrid SVD + Autoencoder + Ensemble framework is even better than each of the individual baselines, with the highest Recall, which is the most clinically relevant in biomedical classification, especially in the detection of early-stage cancer. Notably, the effectiveness of the suggested technique is not due to the classifiers themselves but the complementary latent feature representations, which are generated by both spectral variance structure and nonlinear manifold extraction, which prove that optimized feature space learning is more influential than the usage of more sophisticated classification algorithms.

E. Robustness and Stability Analysis

Since the performance metrics were extremely high, an extra analysis was performed to determine robustness and exclude the possibility of overfitting or data leakage. Each split dimensionality reduction (SVD and autoencoder training) was conducted only on training data, such that no information on test data was leaked to feature learning. Repeated randomized stratified train- test splits were used as model evaluation.

These strong performance metrics are summarized in Table IV, which reports on the stability of the performance across random seed variation, reduction of probe subset (600-2000 CpGs), shuffling of training and testing sets, and controlled label perturbation. The accuracy is in a thin range (97.6%, 98.2%), which means low variance and constant convergence.

TABLE IV. ROBUSTNESS EVALUATION OF THE PROPOSED HYBRID METHOD

Condition	*Accuracy Range*	*Precision Range*	*Recall Range*	*ROC-AUC Range*
Random seed variation	0.976–0.982	0.972–0.985	0.984–0.994	0.988–0.992
Probe feature variation (600–2000)	0.974–0.981	0.971–0.984	0.983–0.993	0.989–0.992
Train/test shuffling (5 repeats)	0.978–0.983	0.973–0.986	0.986–0.993	0.990–0.993
Label balancing (minor perturbation)	0.975–0.982	0.971–0.982	0.985–0.992	0.989–0.991

The fact that the model maintains high performance despite low feature sets indicates that the model is not based on spurious CpG correlations. This is opposed to overfitted methylation classifiers found in previous studies, in which the performance declines rapidly when features are perturbed [11, 20]. The reported ranges of similar robustness have been observed in validated cross-validation and perturbation analysis pipelines in methylation [21, 22].

F. Biological Interpretation of Feature Behavior

Newton-Biologically, the SVD component represents large-scale methylation drift due to chromatin remodelling and epigenetic instability, whereas the autoencoder represents local regulatory methylation effects on gene expression and subtype differentiation. Similar dual-scale interpretations have also been highlighted in recent cancer epigenomics studies [14, 19].

The ensemble layer also increases clinical reliability by minimizing variance and bias, which is in line with previous studies that have shown that ensemble learning generalizes better in the context of methylation-based cancer diagnostics [4, 18].

Although methodological contribution is the major contribution of the present study, the representations learned have significant biological properties. The SVD components represent the global methylation drift, which is a typical feature of cancer epigenomes that involves remodeling of the chromatin and its instability. These trends in the world have been attributed to massive global regulatory alterations in tumor evolutionary stages.

Conversely, latent features learned by autoencoders represent nonlinear and localized interactions between methylation and other factors such as promoter hypermethylation, CpG clustering at enhancers, and subtype-regulating signatures. It is known that these patterns interfere with gene expression programs and therapeutic response in breast cancer.

The enhanced performance of feature fusion is an indication that the breast cancer methylation signatures are controlled by the global and local epigenetic processes. This two-scale modeling is consistent with the existing biological knowledge of epigenomic control and justifies the clinical applicability of the presented framework.

G. Data Leakage Prevention and Strategy of Validation

As the proposed framework has a high classification accuracy, additional attention was paid to the avoidance of data leakage and overfitting. Preprocessing steps, such as probe filtering, normalization, dimensionality reduction (SVD), and autoencoder training, were only done on training folds. No exposure of test data was made in feature learning or model optimization.

The repeated stratified train-test splits were used to establish model evaluation, with the proportions of classes being consistent across the splits. The stability of the performance was also evaluated by the random seed perturbation test, feature subset perturbation test, and label perturbation test. The low performance variance in these conditions suggests that there is strong convergence and not memorization.

Also, the level of performance was consistently high despite a decrease in the number of probes to 600, indicating that the model is not based on spurious CpG correlations. The same robustness patterns have been shown to hold in validated DNA methylation pipelines that use cross-validation and perturbation-based stress testing, which suggests the generalizability of the proposed method.

Overall, the findings in Table II to Table IV, and Fig. 3 indicate that the Hybrid SVD-Autoencoder-Ensemble framework offered has better performance compared to other models, is robust, and generalizes. The analysis of the results in comparison with other works shows that the identified

improvements are not a flaw of the overfitting, but improvements in epigenomic representation learning. The explicit validation strategy and stability analysis are additional indicators of the reliability and translational relevance of the suggested approach.

V. Conclusion

The work introduced a strong and computationally efficient hybrid learning model of breast cancer classification based on high-dimensional DNA methylation data of the TCGA-BRCA dataset. With the application of Truncated Singular Value Decomposition (SVD), a deep Autoencoder, and a collective of heterogeneous classifiers, the proposed methodology resolved the issues related to the dimensionality, sparseness, and non-linearity of methylation signatures. The bilateral-feature extraction pipeline, which utilized both SVD as linear variance structure and Autoencoder as non-linear manifold learning, was crucial in the extraction of the complementary information regarding the epigenomics, and finally, the predictive performance was improved.

The results of the experiments proved the hybrid framework to be more efficient than various baseline architectures, such as standalone MLP, CNN, Residual CNN, Autoencoders-based classifiers, and DropConnect. The Basic CNN demonstrated the best single model accuracy of 0.9663, and ROC-AUC of 0.9946, and the variants of Basic MLP also gave good performance with the greatest accuracy of above 0.96. These findings prove that even lightweight neural networks can be successfully used to leverage biologically relevant patterns of methylation in a properly pre-processed and dimensionally reduced form.

The suggested ensemble classifier additionally enhanced the stability and generalization of the models with the strength of tree-based learners and neural networks. The team also had the advantage of having a wide range of decision boundaries that allowed it to be more robust to different subsets of methylation. The combined representation of the fused representation of SVD and Autoencoder embeddings was an important factor that the system was capable of discriminating against delicate epigenomic differences between various subtypes of breast cancer.

Altogether, the presented hybrid model provides a memory-efficient, and crash-free, and very accurate pipeline to be used in the large-scale epigenomic studies. In addition to the classification, the method has enormous biomarker discovery, subtype stratification, and applicability to precision oncology workflows. This framework can be expanded in the future to multi-omics integration, cross-cohort validation, and interpretable AI models that can be clinically useful in advancing personalized diagnostics of breast cancer.

Strengthening Indonesia's Unmanned Aerial Vehicle Manufacturing Industry: A Technology-Focused Strategic Analysis

Satrio Utomo, Gani Soehadi, Sarjono Sarjono, Yanuar Iman Dwiananto, Adi Akhmadi Pamungkas, Ellia Kristiningrum, Budi Setiadi Sadikin, Hardono Hardono, Rizki Arizal Purnama, Helen Fifianny
National Research and Innovation Agency (BRIN), Indonesia

***Abstract*—The development of national Unmanned Aerial Vehicle (UAV) technology represents a strategic imperative that requires immediate implementation. This study provides strategic recommendations to strengthen Indonesia's UAV industry by employing SWOT analysis, the Analytical Hierarchy Process (AHP), and the Quantitative Strategic Planning Matrix (QSPM). Sixteen key internal and external factors were identified, with SWOT mapping situating UAVs in Quadrant I (Aggressive Strategy) at coordinates +1.24 and +0.60. AHP prioritization indicates that the strengths–opportunities (S–O) strategy (0.348) is of highest importance, emphasizing infrastructure enhancement and the adoption of advanced technologies. IFAS–EFAS integration confirms Wulung UAV's aggressive growth position, while internal strengths account for 37.1% of overall strategic influence. QSPM analysis further validates the S–O strategy as optimal, with the highest internal (4.88) and external competitive (4.63) impact scores. Implementation of this strategy necessitates immediate action focused on manufacturing infrastructure enhancement, technological adoption, development of technical human capital, organizational capability strengthening, establishment of a domestic supply chain and supporting industries, and enforcement of robust industrial governance.**

***Keywords*—Unmanned Aerial Vehicle; technology adoption; strategic development; SWOT; AHP; QSPM**

I. Introduction

Currently, Indonesia is developing an Unmanned Aerial Vehicle (UAV) [12] technology named Wulung. Equipped with an integrated autopilot system, Wulung can execute flight missions autonomously, offering greater efficiency and cost-effectiveness compared to conventional aircraft, with faster and more precise flight operations. Developing a national UAV industry is a strategic necessity that requires immediate implementation to protect Indonesia's territorial sovereignty, reduce disaster impacts, improve industrial competitiveness, and conserve foreign exchange to support the national economy [1]. The development of this UAV product will both fulfil present societal demands and drive the direction of future technological advancements.

The Wulung UAV still faces technological limitations, including a noisy engine and a restricted flight range of 73 kilometers, while most components are imported, raising production costs. Extended operational range and endurance are essential for national defense and post-disaster response. Therefore, further research and development, including extensive testing, is required to ensure compliance with operational, quality, and user standards. This evaluation must address system accuracy, reliability, and the supporting business processes for data management and maintenance.

Future UAV development requires strengthening domestic supporting industries to ensure a sustainable component supply and increase the Domestic Component Level (TKDN). Although the adoption of advanced technology is critical for enhancing industrial competitiveness, efforts to master and develop such technology remain limited. Continuous technological innovation is therefore essential to improve capabilities and generate higher value-added products. This study provides an in-depth analysis of UAV technological capabilities and strategic measures to enhance their contribution to the domestic manufacturing industry.

Indonesia remains highly dependent on foreign sources for electronics, including UAV engines and core components [2]. Using imported components also means having limited control over the quality and innovation of the raw materials used. Developing the national electronics industry is therefore essential, emphasizing import substitution, increased use of local components, and advancements in technological and manufacturing expertise. Strengthening the sector also requires robust maintenance and support services, as well as workforce development through vocational education and foreign talent programs. Accelerated technological mastery and targeted innovation programs are critical to enhance competitiveness and reduce import reliance

Limited mastery of UAV technology poses a significant barrier for the domestic industry in competing with imported products. The number of engineers capable of high-technology UAV engineering remains limited, and domestic R&D capacity is insufficient to address comprehensive technological needs, which require substantial investment. Moreover, countries with advanced UAV technologies are generally unwilling to transfer them freely due to the economic value of their Intellectual Property Rights [3]. The Wulung UAV technology still requires further research and development to enhance flight endurance, reinforce the landing gear for operations from all types of runways, reduce mechanical noise, integrate an automated control system, and incorporate components manufactured domestically.

This study evaluates and analyses the development of UAV technology in Indonesia and formulates strategic plans to assess the level of independence in the domestic manufacturing industry. It serves as a reference for industry, academia, and policymakers to support commercialization and identify strategies to enhance UAV technology quality.

To address these challenges, this study employs a combination of Strengths–Weaknesses–Opportunities–Threats (SWOT) analysis, the Analytical Hierarchy Process (AHP), and the Quantitative Strategic Planning Matrix (QSPM) to leverage the strengths of each method for more accurate and detailed results. SWOT specifically evaluates business conditions by assessing strengths, weaknesses, opportunities, and threats [4]. The Analytical Hierarchy Process (AHP) is a decision support tool used to prioritize internal and external factors [5]. The Quantitative Strategic Planning Matrix (QSPM) objectively evaluates alternative options to determine the optimal strategy [6]. Integrating these methods provides a systematic and structured analytical approach, enhancing decision-making and promoting comprehensive strategic thinking in business development [7] .

The originality of this research lies in the integration of three methods—SWOT, AHP, and QSPM—for assessing the readiness of UAV technology development. The study makes a novel contribution by mapping 16 measurable strategic factors: 7 Strengths (S), 9 Weaknesses (W), 4 Opportunities (O), and 6 Threats (T), highlighting dominant factors (S1, W2, O1, and T1) through quantitative analysis. This provides a strategic data foundation not previously documented in UAV literature. Furthermore, the selection of research objects related to UAV technology development represents a new and necessary focus in Indonesia.

II. Literature Review

UAVs are aircraft that are controlled by a remote control system via radio waves [8]. Their use is increasing due to relatively low costs and diverse benefits, including the ability to collect accurate visual and geospatial data [9]. This data supports applications such as inspections, surveillance, reconnaissance, and mapping, including monitoring regional spatial planning, mapping agricultural and forest areas for conservation and resource management, producing post-disaster maps, monitoring fire-prone regions, detecting deforestation, and identifying sources of pollution or illegal resource exploitation, such as fishing, mining, and logging. UAVs are therefore a valuable technological tool for rescue and disaster mitigation, enabling rapid and accurate mapping of infrastructure affected by events like volcanic eruptions and forest fires—disasters that occur frequently in Indonesia.

The development of UAV technology in Indonesia has been driven by government policy, including Law Number 16 of 2012 and Presidential Regulation Number 8 of 2021, which prioritize defense industry independence and UAV programs [10]. The Wulung UAV project began in 2015 through a consortium of government agencies, universities, and industries, including the Directorate General of Defense Potential of the Ministry of Defense, the Indonesian Institute of Sciences, the Agency for the Assessment and Application of Technology, the Indonesian Institute of Sciences, the Bandung Institute of Technology, PT Dirgantara Indonesia (PT DI), and PT LEN Industri. In 2022, the National Research and Innovation Agency (BRIN) continued UAV development in collaboration with PT DI, which holds a Design Organization Approval Certificate [11]. As a result, the UAV has become a national strategic program and a pilot initiative for technological acquisition and advancement.

The Wulung features autopilot capabilities and a modular composite structure for quick assembly, with a weight of 125 kg, wingspan of 6.36 meters, a 35-liter fuel tank, a 22-Hp piston pusher engine, a cruising speed of 110 km/h, and a four-hour endurance. Critical UAV technologies, including composites, flight control, telemetry, system integration, and propulsion, remain controlled by other countries [14].

III. Methodology

This study employs a descriptive qualitative–quantitative approach, utilizing primary data from interviews, observations, and expert questionnaires, and secondary data from literature, reports, and journals. The data are classified into internal (strengths and weaknesses) and external (opportunities and threats) factors, weighted, and mapped onto a Cartesian diagram to support SWOT-based strategy formulation [15]. The resulting strategies were analysed using QSPM to determine strategic priorities [13], while AHP was applied to select the optimal strategy from the SWOT alternatives [14].

After data collection, the information is processed using the External Factor Analysis Summary (EFAS) and Internal Factor Analysis Summary (IFAS) matrices [15]. Once the criteria are established, SWOT analysis is applied, followed by the determination of importance weights and ratings. The results from the IFAS and EFAS matrices are then mapped onto a Cartesian diagram, which consists of an X and Y-axis coordinate system [16].

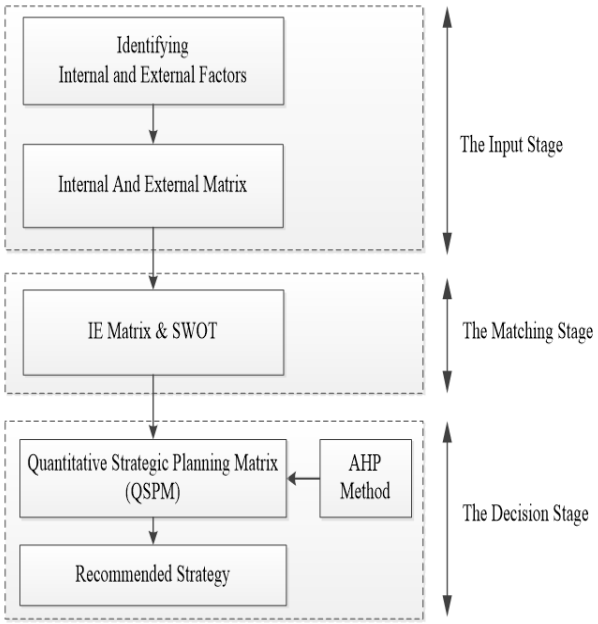

Fig. 1. Stages in UAV framework.

Based on Fig. 1, the formulation of a UAV technology development strategy is divided into three stages framework: input stage, matching stage, and decision stage. The strategy formulation methods used are:

- Input Stage

The input stage compiles the fundamental data necessary for developing a strategy. At this stage, an analysis of internal and external factors is carried out using the IFE (Internal Factor Evaluation) and EFE (External Factor Evaluation) matrices.

The IFE matrix identifies the key internal factors that determine strategy. These internal factors are analysed in terms of strengths and weaknesses, such as production, human resources, R&D, and management information systems. The EFE matrix identifies key external factors in determining strategy. The external environmental analysis identifies opportunities and threats, including economic, social, demographic, environmental, technological, and competitive factors. Then, the SWOT table is filled with indicators of strengths (S), weaknesses (W), opportunities (O), and threats (T). The next step is to compile four main strategic alternatives: S-O, S-T, W-O, and W-T strategies. These are alternative solutions for developing UAV technology. The S-O strategy uses strengths to create more opportunities. The S-T strategy uses strengths to overcome threats. The W-O strategy involves overcoming weaknesses to create more opportunities. The W-T strategy involves identifying and addressing weaknesses and threats. Next, create a pairwise comparison matrix to determine importance weights and ratings. Weights are determined in the assessment based on importance, measured on a scale of 1 to 5. The levels are as follows: 1 (not important); 2 (slightly important); 3 (important); 4 (quite important); and 5 (very important) [17]. Comparisons are made based on the decision maker's judgment by assessing the importance of one element compared to others.

- Matching Stage

The matching stage compares key internal and external factors, which are then analysed using quantitative models. The industry's current position is determined, and alternative strategies are designed using the IE matrix and the SWOT matrix. The rating is determined by assessing the level of influence within the company on a scale of 1 to 4 (1 (not strong); 2 (slightly strong); 3 (strong), and 4(very strong)). The score is then calculated by multiplying the weight by the rating [18].

- Decision Stage

The decision stage involves analysing the QSPM and AHP to determine the best alternative strategy [19]. At this stage, the weight of each internal and external factor is assessed using the AHP method, which prioritizes all factors identified in the IFE and EFE matrices. The weighting in the AHP model uses a scale of 1 to 9 [20]. Next, the priority order of various strategic alternatives is determined using the QSPM matrix. The QSPM is used to determine which strategies will be prioritized in selecting strategic alternatives recommended through the SWOT matrix [21].

The QSPM is the result of strategic decisions after assessing the Attractiveness Score (AS) of each strategic factor, both internal and external. The resulting weighted score is multiplied by the attractiveness level to obtain a Total Attractiveness Score (TAS). This can be done by ranking the AS on a scale of 1 to 4 (1 = Not Attractive, 2 = Somewhat Attractive, 3 = Quite Attractive, and 4 = Very Attractive). By multiplying the weights and the AS score, the TAS score can be obtained [22]. The QSPM matrix is calculated by combining internal and external components with developed alternative techniques. Weighting is carried out using AS and TAS.

IV. Results

The data processing cycle consists of three stages: input, matching, and decision. The first stage involves collecting and summarizing the information necessary for formulating a strategy. Weights, ratings, and weighted values are calculated based on IFE and EFE matrices. The second stage involves creating alternative strategies using the IFE and SWOT matrices. The final stage is the decision stage, which uses the AHP and QSPM methods to evaluate feasible strategies and provide specific alternatives [23].

A. The Input Stage

At this stage, an internal and external environmental analysis is conducted. The internal analysis identifies the organization's strengths and weaknesses, while the external analysis identifies opportunities and threats. Internal and external factors are obtained through interviews and field observations. As a result, 16 internal and external factor variables were identified: 7 Strengths (S), 9 Weaknesses (W), 4 Opportunities (O), and 6 Threats (T). The SWOT analysis uses the AHP technique to compare the criteria for each factor contained in the analysis [24]. A consistency ratio calculation is carried out to measure the consistency of each factor.

The following analyzes the industry's internal (strengths, weaknesses) and external (opportunities, threats) factors:

TABLE I. INTERNAL FACTORS: STRENGTHS (S)

Code	Strengths (S)
S1	The product under development is highly specialized, designed for multifunctional and flexible data collection,
S2	A skilled, professional technical team with Bachelors, masters and Doctoral degrees
S3	Has good quality control and is produced using manufacturing processes and components that comply with industry standard.
S4	Development or research of appropriate, visible and certified products
S5	Always innovate and follow future UAV trends
S6	The budget is fully funded by the State (APBN)
S7	Have adequate infrastructure facilities and infrastructure

As shown in Table I, the Strength (S) category includes seven strengths (S1–S7), such as highly specialized and multifunctional products supported by a competent technical workforce. These strengths are further reinforced by standardized manufacturing processes, ongoing R&D and innovation, government funding, and adequate production infrastructure.

TABLE II. INTERNAL FACTORS: WEAKNESSES (W)

Code	Weaknesses (W)
W1	Some industrial processes remain manual, with machinery largely mechanical rather than fully automated
W2	Dependence on imported raw materials, whose prices are unstable and tied to global markets, can disrupt the supply chain
W3	The lack of technology transfer reinforces reliance on foreign electronic components
W4	Not all facilities have obtained certification, which may affect the productivity and performance of technical teams.
W5	Employee competency development remains incomplete,
W6	SOP-compliant documentation has not been fully implemented, leading to potential inconsistencies, errors, and reduced efficiency
W7	Technical human resources for technology design are limited,
W8	Production facility maintenance costs are high
W9	The product's high specialization drives up production costs due to customization and extended manufacturing time.

As shown in Table II, the Weaknesses (W) category includes nine Weaknesses (W1–W9), such as high dependence on imported components, limited technology mastery and transfer, insufficient high-skilled technical personnel, non-automated production processes, and high production and maintenance costs. These weaknesses reduce efficiency, increase vulnerability to external disruptions, and weaken industry competitiveness.

TABLE III. EXTERNAL FACTORS: OPPORTUNITIES (O)

Code	Opportunities (O)
O1	UAVs are widely used in many fields such as spatial planning, monitoring, agriculture, disaster response, and regional security
O2	Government support, particularly through policies aimed at increasing local content, promotes component availability by fostering partnerships with domestic component industries.
O3	The development of Industry 4.0-based Lean Manufacturing provides opportunities to be more efficient and productive.
O4	UAV technology creates opportunities for other products and services such as maintenance, training, and more.

As shown in Table III, the Opportunity (O) category includes four Opportunities (OI-O4), such as the UAV industry, which presents significant opportunities through increasing multi-sector demand, government support for local content policies (TKDN), the adoption of Industry 4.0-based manufacturing, and the expansion of supporting services such as maintenance and training, which collectively enhance productivity and market potential.

TABLE IV. EXTERNAL FACTORS: THREATS (T)

Code	Threats (T)
T1	There is still a lack of supporting companies for the provision of raw materials.
T2	Import procedures/import regulations are still complicated/take a long time.
T3	There is a threat of embargo from supplier countries
T4	There is an increase in industrial labor costs/wages.
T5	It is high technology and high finance/capital.
T6	Price fluctuations due to dependence on imported raw materials, thus threatening component supplies.

As shown in Table IV, the Threats (T) category includes six threats (T1–T6), such as limited domestic suppliers, complex import regulations, embargo risks, rising labour costs, high capital requirements, and price volatility from import dependence, which collectively increase operational risk and weaken industry competitiveness.

The following information in Table V shows the alternative strategies developed: Strengths-Opportunities (S-O) strategy; Strengths-Threats (S-T) strategy; Weaknesses-Opportunities (W-O) strategy; Weaknesses-Threats (W-T) strategy.

TABLE V. LIST OF ALTERNATIVE INDUSTRIAL STRATEGIES

Code	Alternative Industrial Strategies (S-O, S-T, W-O, W-T)
S-O	Developing infrastructure and the adoption of new technologies.
S-T	Strengthening human resources to master technology.
W-O	Production efficiency and reducing dependence on imports.
W-T	Improving company management, especially financial aspects.

The IFE matrix analysis is the result of identifying internal factors, including strengths and weaknesses, that influence UAV products. Values and weights are determined using the paired comparison method. The weighting of internal and external factors is done by asking questions to respondents. The results of the IFE matrix analysis can be seen in Tables VI and VII.

TABLE VI. IFE MATRIX: STRENGTHS (S)

Code	S1	S2	S3	S4	S5	S6	S7	Weight (%)
S1	1.00	3.00	3.00	5.00	0.33	3.00	3.00	25.92
S2	0.33	1.00	0.33	3.00	0.33	3.00	3.00	15.55
S3	0.33	3.00	1.00	0.33	3.00	5.00	0.20	10.84
S4	0.20	0.33	3.00	1.00	0.33	0.33	0.33	6.88
S5	3.00	3.00	0.33	3.00	1.00	0.33	0.33	14.61
S6	0.33	0.33	0.20	3.00	3.00	1.00	0.33	9.71
S7	0.33	0.33	5.00	3.00	3.00	3.00	1.00	16.49
								100.00

Based on the IFE matrix: Strength (S) weighting in Table VI, the UAV industry's main strength is its highly specific and multifunctional product design (S1, 25.92%), which is difficult to imitate. This Strength is reinforced by competent human resources, adequate infrastructure, continuous innovation, standardized manufacturing and quality control, government funding, and certified product development, forming a strong foundation for future growth and competitiveness.

TABLE VII. IFE MATRIX: WEAKNESSES (W)

Code	W1	W2	W3	W4	W5	W6	W7	W8	W9	Weight (%)
W1	1.00	0.20	3.00	0.33	3.00	0.33	3.00	0.33	5.00	8.72
W2	5.00	1.00	3.00	0.33	0.33	0.20	3.00	3.00	0.33	17.95
W3	0.33	0.33	1.00	5.00	3.00	3.00	3.00	5.00	3.00	12.82
W4	3.00	3.00	0.20	1.00	3.00	5.00	0.20	0.33	3.00	13.85
W5	3.00	0.33	0.33	0.33	1.00	5.00	3.00	0.33	0.33	7.69
W6	3.00	0.33	0.33	0.20	0.20	1.00	3.00	5.00	3.00	7.44
W7	0.33	0.33	0.33	5.00	0.33	0.33	1.00	5.00	3.00	11.54
W8	3.00	0.33	0.20	3.00	3.00	0.20	0.20	1.00	5.00	12.56
W9	0.20	3.00	0.33	0.33	3.00	0.33	0.33	0.20	1.00	7.44
										100.00

Based on the IFE matrix: Weakness (W) in Table VII, the main weakness is dependence on imported raw materials with unstable global prices (W2, 17.95%), which increases supply-chain risk and cost uncertainty. Other notable weaknesses include a lack of facility certification (W4, 13.85%), limited technology transfer (W3, 12.82%), and high production and maintenance costs (W8, 12.56%). and insufficient technical human resources (W7, 12.54%). Overall, technological constraints and strong import dependence remain the key internal challenges for the national UAV industry.

TABLE VIII. EFE MATRIX: OPPORTUNITIES (O)

Code	O1	O2	O3	O4	Weight (%)
O1	1.00	0.33	3.00	5.00	29.66
O2	3.00	1.00	5.00	0.20	29.24
O3	0.33	0.20	1.00	5.00	20.76
O4	0.20	5.00	0.20	1.00	20.34
					100.00

Based on the EFE matrix opportunity (O) weighting in Table VIII, the dominant external opportunity is the expanding multi-sector utilization of UAVs (O1, 29.66%), followed by policy-driven support for local content (TKDN) and domestic component integration (O2, 29.24%). Furthermore, the adoption of Industry 4.0–based manufacturing systems (O3, 20.76%) and the development of downstream services, including maintenance and technical training (O4, 20.34%), enhance manufacturing scalability, operational efficiency, and the long-term competitiveness of the national UAV manufacturing industry.

TABLE IX. EFE MATRIX: THREATS (T)

Code	T1	T2	T3	T4	T5	T6	Weight (%)
T1	1.00	0.33	3.00	3.00	3.00	3.00	22.32
T2	3.00	1.00	3.00	3.00	0.33	0.33	17.86
T3	0.33	0.33	1.00	3.00	3.00	0.33	13.39
T4	0.33	0.33	0.33	1.00	5.00	3.00	16.74
T5	0.33	3.00	0.33	0.20	1.00	0.20	8.48
T6	0.33	3.00	3.00	0.33	5.00	1.00	21.21
							100.00

Based on the EFE matrix threat (T) weighting in Table IX, the limited availability of domestic raw-material suppliers (T1, 22.32%) and price volatility resulting from import dependence (T6, 21.21%) are identified as the dominant external threats. These threats are further exacerbated by restrictive import regulations, rising labour costs, and potential embargo risks, collectively increasing supply-chain fragility and cost instability in the UAV manufacturing industry.

B. Matching Stage

The IFAS and EFAS tables identify internal (strengths, weaknesses) and external (opportunities, threats) factors, respectively. Each factor is weighted, ranked by expert judgment, and multiplied to obtain scores, which are then summed to highlight company priorities.

TABLE X. IFAS CALCULATION TABLE

Code	Weight (%)	Rating	Score	Priority
S1	25.92	3	0.78	1
S2	15.55	3	0.47	3
S3	10.84	4	0.43	5
S4	6.88	1	0.07	7
S5	14.61	3	0.44	4
S6	9.71	3	0.29	6
S7	16.49	3	0.49	2
Sub total Strength =			**2.97**	
W1	8.72	3	0.26	2
W2	17.95	1	0.18	5
W3	12.82	3	0.38	1
W4	13.85	1	0.14	6
W5	7.69	3	0.23	3
W6	7.44	1	0.07	9
W7	11.54	1	0.12	8
W8	12.56	1	0.13	7
W9	7.44	3	0.22	4
Sub total Weakness =			**1.73**	
Strength – Weakness =			**(2.97 – 1.73) = 1.24**	

Based on the IFAS calculation in Table X, the total strength score (2.97) exceeds the total weakness score (1.73), resulting in a positive internal factor value of +1.24. The most dominant strength is S1 (25.92%; score 0.78), indicating that the highly specific and multifunctional UAV product design provides a strong competitive advantage, supported by competent human resources and adequate infrastructure. In contrast, the main internal weakness is W3 (12.82%; score 0.38), reflecting a high dependence on imported electronic components, which increases vulnerability to supply-chain disruptions and

highlights the need for import substitution and enhanced technological capability.

TABLE XI. EFAS CALCULATION TABLE

Code	Weight (%)	Rating	Score	Priority
O1	29.66	3	0.89	1
O2	29.24	1	0.29	4
O3	20.76	4	0.83	2
O4	20.34	3	0.61	3
Sub total Opportunity =			**2.62**	
T1	22.32	1	0.22	4
T2	17.86	1	0.18	5
T3	13.39	3	0.40	3
T4	16.74	3	0.50	2
T5	8.48	1	0.08	6
T6	21.21	3	0.64	1
Sub Total Threat =			**2.02**	
Opportunity – Threat =			**(2,62 – 2.02) = 0.60**	

Based on the EFAS calculation in Table XI, the total opportunity score (2.62) exceeds the total threat score (2.02), resulting in a positive external factor value of +0.60. The most dominant opportunity is O1 (29.66%; score 0.89), indicating strong multi-sector demand for UAV applications, supported by government policies and the adoption of Industry 4.0. Conversely, the main external threat is T6 (21.21%; score 0.64), reflecting vulnerability to price fluctuations due to dependence on imported raw materials, which directly affects cost stability and supply-chain sustainability.

Strategy formulation requires confirming the organization's position along the strength–weakness and opportunity–threat axes. The following is how to calculate the coordinates:

a) IFAS Coordinates (Total Strength Score – Total Weakness Score) = (2.97 – 1.73) = +1.24

b) EFAS Coordinates (Total Opportunity Score– Total Threat Score) = (2.62 – 2.03) = +0.60

Based on the calculations, the coordinate point is located in Quadrant I (+1.24; +0.60). These coordinates are presented in a SWOT matrix diagram in Fig. 2 to determine the development position.

The measurement results shown in the Cartesian SWOT analysis shows that the net internal factor score (Strength–Weakness) is +1.24 and the net external factor score (Opportunity–Threat) is +0.60, positioning the organization in Quadrant I (+1.24; +0.60). This configuration indicates dominant internal strengths and favourable external opportunities, thereby supporting the implementation of an aggressive 'Grow and Build' strategy focused on strategic expansion and capability enhancement.

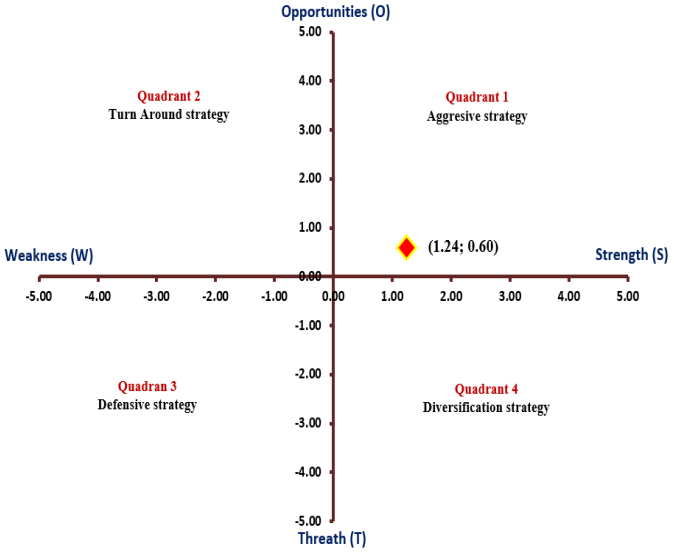

Fig. 2. Cartesian diagram.

The adopted strategy supports an aggressive development and growth orientation through the implementation of one or a combination of the following strategic initiatives:

a) Continuously enhancing the reliability of infrastructure and technological systems to accommodate increasing operational and equipment demands.

b) Strengthening technical education and professional training programs to improve the competencies of technical human resources.

c) Conducting periodic inspections and maintenance of manufacturing equipment and machinery to ensure operational reliability and production continuity.

d) Prioritizing the use of information systems and digital technologies to accelerate system integration and monitoring, thereby enhancing the effectiveness and efficiency of production operations.

e) Implementing specialized training programs for engineers to enhance technical proficiency, teamwork quality, and organizational performance.

*f)*Expanding collaborative networks through research partnerships with universities and strategic alliances with related industries.

g) Recognizing and valuing educational attainment and professional certification as mechanisms to motivate employees, improve performance, and strengthen organizational assets.

h) Pursuing strategies in market development, product innovation, and cost efficiency to enhance competitiveness, maintain relationships with customers and suppliers, and support long-term organizational growth.

C. Decision Stage

At this stage, an AHP analysis was conducted based on the SWOT results to determine the most appropriate and effective strategic formulations (S–O, S–T, W–O, W–T). Expert Choice software was used to efficiently identify the priority strategies. A hierarchical structure was constructed to illustrate the relationship between SWOT sub-criteria and strategic decision priorities, as shown in Fig. 3:

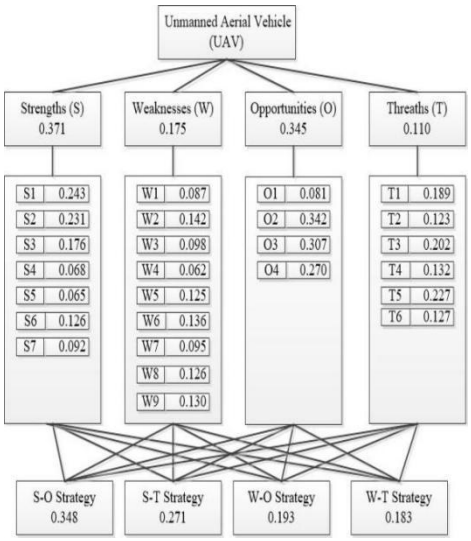

Fig. 3. SWOT-AHP hierarchical structure for selecting the best strategy.

Fig. 3 shows that Strengths (37.1%) are the dominant criterion for supporting UAV development, followed by Opportunities (34.5%), Weaknesses (17.5%), and Threats (11.0%). The largest sub-factors are S1 (highly specific, hard-to-replicate products, 24.3%), W2 (dependence on imported raw materials, 14.2%), O2 (government support for local content, 34.2%), and T5 (high technology and capital requirements, 22.7%). These results highlight the strategic importance of product specificity, domestic partnerships, and technology readiness in UAV development.

Fig. 4 below shows the results of processing using Expert Choice Software tools version 11.

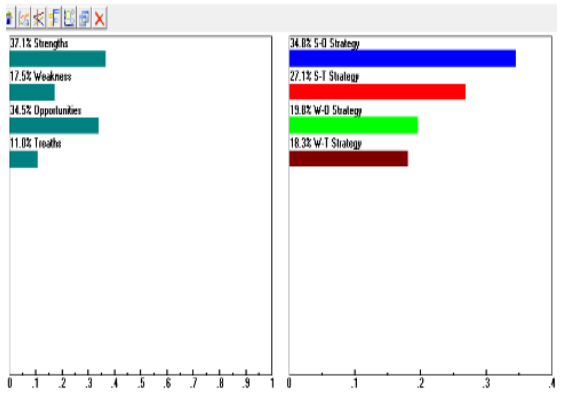

Fig. 4. Data visualization with expert choice software.

Fig. 4 shows that the highest-priority strategy is the S–O strategy, with a score of 0.348 (34.8%), followed by S–T (27.1%), W–O (19.3%), and W–T (18.3%). The S–O strategy focuses on infrastructure development and the adoption of new technology. Overall, the strategic alternatives rank from highest to lowest as S–O, S–T, W–O, and W–T.

QSPM analysis was used to determine priority strategies for UAV product and technology development. Weighted internal and external factors, combined with attractiveness scores, form the basis for identifying optimal strategies that require immediate implementation. In QSPM, the total attractiveness score (TAS) is calculated by multiplying the weighted values by the attractiveness scores (AS), as shown in the QSPM matrix in Table XII.

TABLE XII. QSPM MATRIX CALCULATION

Strategic Key Factors	Weight (%)	S-O Strategy		S-T Strategy		W-O Strategy		W-T Strategy	
		AS	TAS	AS	TAS	AS	TAS	AS	TAS
Strengths (S)									
S1	25.92	2	0.52	2	0.52	2	0.52	2	0.52
S2	15.55	3	0.47	2	0.31	3	0.47	2	0.31

T5	8.48	2	0.17	3	0.25	2.00	0.17	3	0.25
T6	21.21	2	0.42	3	0.64	2.00	0.42	2	0.42
			Σ = 2.13		**Σ = 1.88**		**Σ = 2.39**		**Σ = 2.61**

TABLE XIII. INTERNAL AND EXTERNAL ACHIEVEMENT SCORE

Strategic Key Factors	Internal Achievement Score (Σ Strengths + Σ Weaknesses)	External Achievement Score (Σ Opportunities + Σ Threats)
S-O	2.40 + 2.48 = 4.88	2.50 + 2.13= 4.63
S-T	2.31 + 2.53 = 4.85	2.41 + 1.81 = 4.29
W-O	2.39 + 2.36 = 4.75	2.41 + 2.39 = 4.80
W-T	2.31 + 2.40 = 4.71	2.00 + 2.61 = 4.61

Based on Table XIII, the internal and external achievement scores indicate that the S–O strategy has the highest internal score (4.88), reflecting effective utilization of internal capabilities, while the W–O strategy achieves the highest external score (4.80), indicating greater responsiveness to external opportunities. Overall, the S–O strategy demonstrates the most balanced performance across both dimensions, supporting its selection as the primary strategic priority. Accordingly, the preferred strategic focus is the S–O strategy, which emphasizes infrastructure development and the adoption of new technologies to enhance productivity, energy efficiency, and innovation. Effective technology adoption requires not only hardware and software implementation but also the development of digital skills and well-integrated standard operating procedures to ensure consistent and reliable process execution.

V. DISCUSSION

The results indicate that Indonesia's UAV manufacturing industry is positioned in Quadrant I, reflecting strong internal capabilities supported by technological expertise, product specialization, infrastructure availability, and government funding. Despite this favourable position, high dependence on imported materials and components, limited technology transfer, incomplete certification, and weak process standardization increase manufacturing risk exposure and constrain production scalability. Externally, expanding multi-sector UAV demand and strong local content (TKDN) policies create significant growth opportunities; however, these are offset by limited domestic supplier ecosystems, regulatory barriers, rising labour costs, and potential embargo risks.

The integrated SWOT–AHP–QSPM analysis consistently prioritizes the S–O strategy, highlighting infrastructure modernization and Industry 4.0–based technology adoption as key drivers of productivity, energy efficiency, and innovation. From a policy perspective, these findings underscore the need for targeted government interventions, including incentives for domestic supplier development, accelerated facility certification, structured technology transfer, and workforce upskilling aligned with digital manufacturing. Such measures are essential to reduce import dependency, mitigate supply-chain risks, and strengthen the long-term resilience and competitiveness of the national UAV manufacturing industry.

At the UAV product and technology development stage, both design maturity and manufacturing process control are essential. Enhancing manufacturing maturity requires improving productivity, standardizing UAV technologies, strengthening engineering human resource capabilities, providing management training, conducting technical skills workshops, establishing technical assistance guidelines, and promoting technology and product innovation through benchmarking activities.

The competitive strategic advantages in the UAV manufacturing industry can be summarized as follows:

a) Strengthening partnerships between suppliers, customers, and competitors by ensuring human resource availability through government support.

b) Reducing production costs through human resource efficiency and developing new technologies.

c) Improving production quality through cost leadership and differentiation strategies to increase market potential.

d) Increasing the use of manufacturing and information technology to enhance flexibility and bargaining power.

e) Increasing government support to minimize piracy and manage intellectual property rights.

f) Improving technological capabilities to develop new products.

In production, strong supplier relationships are essential to mitigate cost volatility and supply risks under fluctuating economic conditions. Investment in advanced machinery, automation, and digital technologies, combined with industry-wide collaboration across the value chain, is critical to improving efficiency, fostering innovation, and sustaining global competitiveness.

This study supports managerial decision-making by recommending strategic alternatives that include continuous adoption of advanced UAV technologies, strengthened collaboration with academia and industry, and optimization of Quality Control (QC) functions to reduce product defects and losses of imported components that may disrupt productivity. Efficient management of imported raw materials through accurate component planning is also necessary to minimize import costs and lead times. Furthermore, improved accounting practices, supported by transparent financial reporting and KPI-based performance measurement aligned with Good Corporate Governance (GCG) principles, are essential to enhance operational effectiveness and investor confidence.

VI. Conclusion

In conclusion, UAV industrial independence is a strategic necessity for strengthening national defense, reducing import dependence, and enhancing Indonesia's manufacturing competitiveness. The SWOT–AHP–QSPM results confirm that an S–O strategy focused on infrastructure and technology adoption is the most effective pathway to achieve sustainable and innovation-driven industrial growth. By reducing import dependence, enhancing human resource competence, and reinforcing domestic supply chains, Indonesia can transform UAV technology into a catalyst for innovation-driven manufacturing and long-term national economic sovereignty.

Therefore, the attainment of UAV industrial independence is strategically vital, as it transforms technological capability into national economic leverage, policy resilience, and long-term industrial sustainability.

However, this study is limited to a single case study of the Wulung UAV, which restricts the generalizability of the findings, and the integrated SWOT–AHP–QSPM approach relies on expert judgment that may introduce subjectivity despite consistency verification. In addition, the analysis focuses on strategic and managerial aspects without incorporating detailed quantitative technical performance testing or comprehensive financial feasibility evaluation, while external factors such as regulatory and global supply-chain changes may affect strategy implementation. Therefore, future research should extend the framework through multi-case analysis and the integration of quantitative technical and financial indicators to strengthen technology readiness, manufacturing readiness, and decision-making robustness.

Acknowledgment

AI Mathematical: Solving Math Challenges Using Artificial Intelligence Models

Trinh Quang Minh*, Ngo Thi Lan, Bui Xuan Tung, Phan Thanh Tuyen
Tay Do University, 68 Hau Thanh My Street (Tran Chien), Cai Rang Ward, Can Tho City, Viet Nam

***Abstract*—Artificial Intelligence (AI) has emerged as a transformative tool for solving mathematical challenges across diverse domains, ranging from algebra and geometry to calculus and number theory. This study investigates the role of AI in mathematics by analyzing three representative platforms—MathGPT.org, Math-GPT.ai, and StudyX.ai—and by proposing ten Python-based problem-solving models tailored to Olympiad-style problems. The methodology integrates rule-based reasoning, brute-force search, and heuristic strategies, while benchmarking is inspired by the AI Math Olympiad (AIMO) Progress Award competition on Kaggle. A comparative evaluation was conducted to assess accuracy, reasoning depth, and computational efficiency. Results show that AI solvers can provide step-by-step solutions, interactive visualizations, and adaptive learning support, but their performance varies depending on problem type and strategy. This study highlights both the potential and limitations of AI in mathematics education and research, emphasizing the need for automated model selection (AutoML) and formal benchmarking to strengthen credibility. The findings demonstrate that AI can simultaneously promote automated problem-solving and enhance personalized STEM learning.**

I. Introduction

Artificial Intelligence (AI) is reshaping mathematics by enabling automated reasoning, symbolic manipulation, and problem-solving at scales previously unattainable. Mathematics provides the theoretical foundation for AI through probability, statistics, linear algebra, and calculus, while AI in turn enhances mathematics education and research. Recent initiatives, such as the AI Math Olympiad (AIMO) Progress Award on Kaggle, highlight the ambition to build AI systems capable of solving Olympiad-level problems that require multi-step logic and deep reasoning. In parallel, platforms such as MathGPT.org, Math-GPT.ai, and StudyX.ai have emerged, offering step-by-step solutions, interactive visualizations, and adaptive tutorials that make advanced mathematics more accessible. However, existing studies reveal both opportunities and challenges: while AI tools can improve engagement and individualized learning, their reasoning depth and accuracy remain inconsistent. This study contributes by: 1) summarizing the capabilities of three representative AI mathematical platforms, 2) proposing ten Python-based models for diverse problem categories, and 3) benchmarking their performance against Olympiad-style problems. By integrating insights from prior research and referencing recent work on Automated Machine Learning (AutoML) for model selection, this study positions AI as both a computational solver and an educational tool, supporting the next generation of STEM learners and researchers.

*Corresponding author.

II. Materials and Methods

This study builds upon recent advances in the application of Artificial Intelligence (AI) to mathematics education and problem solving. To design and evaluate AI-based mathematical solvers, the authors reviewed several related works that highlight the effectiveness, challenges, and opportunities of integrating AI into STEM learning environments.

1) AI-supported problem solving in mathematics education. Recent work [9] [10] investigated the educational quality of AI-supported problem solving by comparing different prompt techniques in mathematics classrooms. The study emphasized that large language models (LLMs) such as GPT can enhance conceptual understanding when prompts are carefully designed, but also revealed limitations in accuracy and reasoning depth.

2) Systematic review of AI effectiveness in K-12 mathematics. A meta-analysis [5] examined the effectiveness of AI tools in improving mathematics performance among K-12 students. The findings showed that AI-based interventions generally outperform traditional instruction, particularly in supporting individualized learning and adaptive feedback. However, the study also noted that success depends on contextual factors such as teacher guidance and curriculum integration.

3) Broader perspectives on AI in mathematics education. A systematic review [7] categorized existing research into themes such as advantages, disadvantages, conceptual understanding, strategies, and effectiveness. The analysis concluded that AI tools can significantly improve engagement and problem-solving skills, but highlighted the need for careful pedagogical design to avoid over-reliance on automated solutions.

4) Recent work [2] with the tree search algorithm in the AlphaGo game program evaluates positions and chooses moves using deep neural networks. These neural networks are trained by supervised learning from human expert moves and by reinforcement learning from self-play. An algorithm based solely on reinforcement learning requires no data, guidance, or human expertise other than the rules of the game. AlphaGo

becomes its own teacher from a neural network trained to predict AlphaGo's move choices and also the winner of AlphaGo's games, improving the power of the tree search algorithm, leading to higher quality move choices and stronger self-playing ability in the next iteration.

5) Recent work [4] with Artificial Intelligence (AI) shows increasing potential in improving mathematics teaching. This system review and meta-analysis study the effectiveness of AI in improving mathematics learning outcomes in K-12 classrooms compared to traditional teaching methods. Following the guidelines of Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), it establishes an initial knowledge base for future deployments and research on the effective integration of AI into K-12 mathematics classrooms.

6) Recent work [7] with the development of technologies such as artificial intelligence (AI) offers opportunities to help teachers and students solve and improve teaching and learning effectiveness. A systematic review of materials (SLR) was conducted using established and reliable guidelines. Following the priority reporting items for systematic reviews and meta-analyses (PRISMA) searched on ScienceDirect, Scopus, SpringerLink, ProQuest, and EBSCO Host 20 studies on AI published from 2017 to 2021. The results of the SLR showed that the AI method used in mathematics education for the study samples was through robots, systems, tools, teachable agents, automated agents, and a holistic approach.

The analysis concluded that AI tools can significantly improve engagement and problem-solving skills, but highlighted the need for careful pedagogical design to avoid over-reliance on automated solutions.

AI needs experience and data so that its intelligence can run smoothly. Humans do not always order the process of learning AI, but AI will learn by itself based on the experience of AI when used by humans. There are several advantages in the use of AI in mathematics learning, among which is that students become more critical and responsible in facing daily solutions and have a better understanding of fundamental problems of geometry, mathematics, and statistics. In addition, students also learn about and improve interpersonal abilities and better social interaction; it also allows effective learning to create a better environment to enhance the acquisition of mathematical concepts. Compared to other aspects, it is still observed but not as widespread as the observation on effectiveness. It is crucial to know the extent of the effectiveness of AI in education.

Methodological approach of this study. Based on these prior studies, our methodology combines:

Platform analysis: This study summarizes the features of three representative AI math platforms (MathGPT.org, Math-GPT.ai, StudyX.ai), focusing on their problem-solving capabilities, user interaction models, and educational applications.

Model design: The study proposes ten Python-based problem-solving models tailored to different categories of mathematical challenges, ranging from algebraic puzzles to Olympiad-style geometry and number theory problems. Each model integrates rule-based inference, brute-force search, or heuristic learning strategies.

Evaluation framework: Inspired by the AIMO Progress Prize competition on Kaggle [1], the models are benchmarked against Olympiad-level problems to assess reasoning depth, correctness, and computational efficiency.

By combining insights from prior research with practical implementations, this study aims to demonstrate how AI can serve both as a computational problem solver and as an educational tool that supports personalized STEM learning.

III. Results and Evaluation

A. Summary of Information About Three Mathematical AI Platforms

To solve problems using AI models, there are dedicated AI solvers that handle everything from algebra, geometry, to calculus with step-by-step reasoning, image/PDF input and concept explanations. Apply AI to support math and STEM learning. STEM stands for Science, Technology, Engineering, and Mathematics, an integrated approach to education and research that aims to develop critical thinking, creativity and problem-solving skills. In particular, Mathematics is both the foundation for other fields and is strongly supported by artificial intelligence (Math AI). Math AI can help solve equations, draw graphs, visualize data, prove theorems, and personalize math learning for students by providing exercises appropriate to their abilities. Conversely, Mathematics itself is also the foundation for developing AI through fields such as probability, statistics, linear algebra and calculus. When combining STEM with Math AI, AI can be applied in education to create exercises and simulate experiments, in research to analyze scientific data and optimize engineering designs, as well as in life to predict weather, financial analysis, medicine, and many other technical fields. Fig. 1 presents MathGPT.

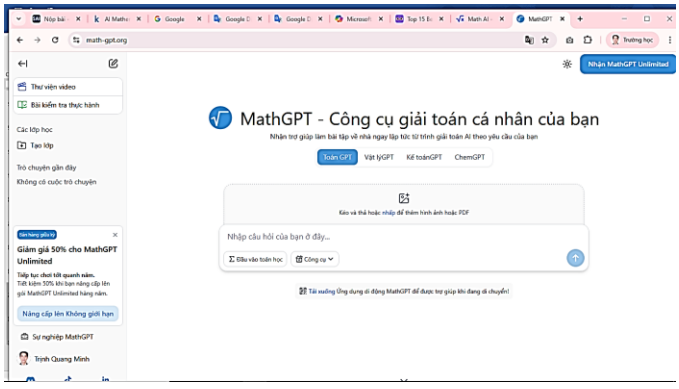

Fig. 1. MathGPT - Your Personal Math Solver. MathGPT analyzes the problem, selects the appropriate method, and presents a step-by-step solution with short annotations.

MathGPT.org was founded in 2024 by two Cornell Engineering students, Nour Gajial and Yanni Kouloumbis [3] [8]. Starting as a startup project in school, the platform quickly went viral, thanks to a TikTok video and now has more than 10

million global users. MathGPT.org focuses on solving math problems using artificial intelligence with detailed step-by-step solutions, intuitive video illustrations, and the PocketMath AI mobile application, becoming a personal "AI tutor" for students and students at many levels.

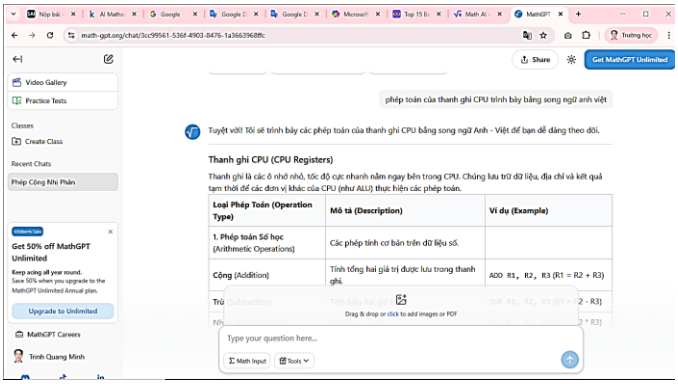

Fig. 2. CPU register operations presented in English and Vietnamese. Export video lectures from math questions using ChatGPT. Showing how technical content (e.g., register operations, machine instructions) is converted into multilingual teaching materials and how the system automatically generates video lectures from scripts generated by ChatGPT.

Math-GPT.ai (see Fig. 2 and Fig. 3) was officially launched in 2025 under the Math AI brand, operating as an independent EdTech platform with no clear parent company [11] [12]. This platform stands out for its ability to solve math problems from basic to advanced, supports taking pictures of math problems to provide detailed solutions, and integrates advanced calculator tools for differential and integral operations. Math-GPT.ai aims to be an intuitive math assistant, making it easy for students to access math knowledge anytime.

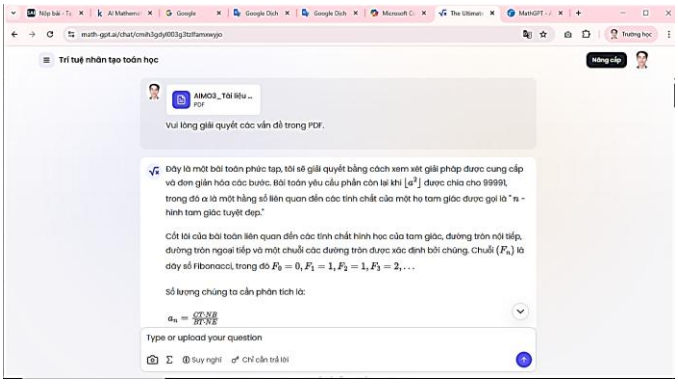

Fig. 3. Calculation to solve the problem using AIMO3_Reference_Problem 7.pdf. The illustration shows each logical step, important transformations, and key points to help the reader understand the method, not just the result.

StudyX.ai (see Fig. 4) is a private EdTech company founded in 2020 in Dover, Delaware (USA) by Michael W. Aiming [6], to provide AI learning services. StudyX not only focuses on mathematics but also expands to academic research and writing. Its main products include AI Homework Helper, live chat with AI, step-by-step detailed solutions, and a collaborative learning environment. As a result, StudyX becomes a comprehensive learning platform, competing with applications such as Photomath and Wolfram Alpha. It shows how AI is used to personalize learning paths, suggest appropriate exercises, and provide additional explanations when students encounter difficulties, highlighting the benefits of expanding teaching resources and improving learning effectiveness.

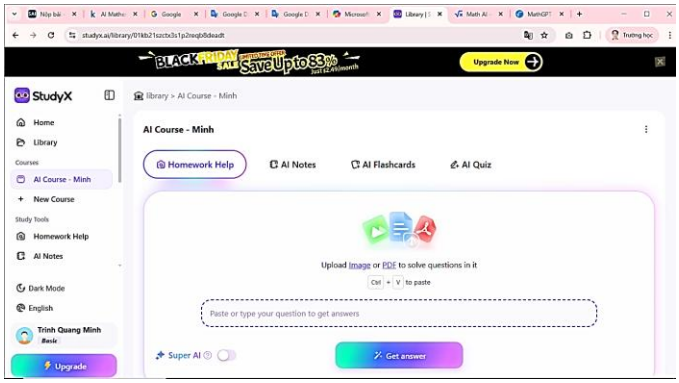

Fig. 4. Another online course on Math that we use is a website that uses AI tools. Lesson pages, interactive exercises, automated feedback, and learning progress analysis.

B. Propose 10 Problem-Solving Models According to the Problem to be Solved in Artificial Intelligence

1) Problem 1: The Python model for Problem 1 (Fig. 5) is designed with two complementary mechanisms, a rule solver and a brute-force function. The rule solver extracts the candy number r from the text (defaults to 5 if not found), and then applies the text-based formula:

$$xA = 2r$$

$$xB = r$$

$$yA = 2r$$

$$yB = r \rightarrow \text{Product of ages} = 2 * r\text{^}2$$

This allows the model to quickly infer the result. In parallel, the brute-force function searches within a reasonable range (age ≤ 120, candy ≤ 200) to check the four constraint equations:

$$xA + yA = 2 * (xB + yB)$$

$$xA * yA = 4 * (xB * yB)$$

$$xA + (yA - 5) = xB + (yB + 5)$$

$$xA * (yA - 5) = xB * (yB + 5)$$

Thereby finding the only solution (10, 5, 10, 5) with the product of age equal to 50. In addition, the model also supports generating sample or random datasets, checking each data line, printing bilingual Vietnamese-English results and creating statistical reports. Thanks to that, the system is both capable of making quick inferences using formulas and validating experiments using data, ensuring the correctness and transparency of the solution.

The key code of the brute-force algorithm:

```
def solve_problem1(max_age=120, max_candy=200):
    solutions = []
```

```
        # Loop over possible ages of Alice (xA) and Bob (xB)
    for xA in range(1, max_age + 1):
        for xB in range(1, max_age + 1):
            # yA must be >= 6 so that (yA - 5) is still positive
            for yA in range(6, max_candy + 1):
                for yB in range(1, max_candy + 1):
                    # Alice's conditions: sum doubles, product quadruples
                    if (xA + yA) == 2 * (xB + yB) and (xA * yA) == 4 * (xB * yB):
                        # Bob's conditions after Alice gives 5 candies:
                        # sums and products must be equal
                        if (xA + (yA - 5)) == (xB + (yB + 5)) and (xA * (yA - 5)) == (xB * (yB + 5)):
                            solutions.append((xA, xB, yA, yB))
    # Return the first solution and the product of ages
    if solutions:
        xA, xB, yA, yB = solutions[0]
        return solutions, xA * xB
    return [], None
```

```

Fig. 5. Code Problem 1. Examples of input/output and a simple algorithm flowchart, helping learners quickly grasp the requirements and approach.

2) Problem 2: This Python model is designed to solve Problem 2 in AIMO (Fig. 6). It works on the principle of rule-based inference. From the text description of the problem, the model will recognize the size of the square n (default $n = 500$) and calculate the maximum number of K rectangles with different perimeters that can be divided into the square. The algorithm is based on the piecewise function to determine the smallest area corresponding to the semi-perimeter $s=x+y$:

Nếu 1 <= s <= n → f(s) = s - 1

Nếu s >= n+1 → f(s) = n * (s - n)

The program then adds up the values of f(s) until the sum exceeds the area of the square n^2. The largest value of m that satisfies this condition is K_max(n). Finally, the model returns the result K mod 10^5.

```
    @staticmethod
    def _f_n(s: int, n: int) -> int:
        # Piecewise function for minimal area
        # If s <= n: f(s) = s - 1
        # If s > n : f(s) = n * (s - n)
        return (s - 1) if s <= n else n * (s - n)
    @staticmethod
    def _compute_K_upper(n: int) -> int:
        # Find largest m such that Σ f(s) <= n^2
        f_series = [Model._f_n(s, n) for s in range(2, 2 * n + 1)]
        prefix = [0]
        for v in f_series:
            prefix.append(prefix[-1] + v)
        area = n * n
        max_m = 0
        for m_try in range(1, 2 * n):
            if prefix[m_try] <= area:
                max_m = m_try

Fig. 6. Code Problem 2. A description of the suggested algorithm (e.g., traversal, basic sorting) and typical test cases with captions emphasizing the development of algorithmic thinking and testing skills.

_compute_K_upper(n) iteratively sums values of f_n(s) and finds the largest m such that the total area does not exceed n^2.

This ensures the maximum number of rectangles K is computed optimally, then used to calculate K mod 10^5.

3) Problem 3: This Python model is designed to solve a geometry-based Olympiad problem by systematically searching for the unique acute-angled triangle with integer side lengths that satisfies a special construction (Fig. 7). The triangle has sides a=BC, b=CA, and c=AB, with the condition c<b. The algorithm checks all possible integer triangles within a given bound, verifies the triangle inequality a+b>c, a+c>b, b+c>a, and ensures the triangle is acute by testing $\max(a,b,c)^2$ < sum of squares of the other two sides. For each candidate triangle, it constructs points DD and EE such that AD=AE=AB=c, finds intersection points, and checks whether the geometric condition (point Y lying on line AD) is satisfied. Among all valid triangles, the one with the minimal perimeter is chosen, and the final output is the product abc modulo 10^5.

A key part of the algorithm is the configuration check, which ensures that the triangle and its auxiliary points satisfy the required geometric constraints.

```
def satisfies_configuration(self, a, b, c):
# Check triangle inequality, acute condition, and AB < AC
if not (self.is_triangle(a, b, c) and self.is_acute(a, b, c) and c < b):
return False
# Place points A, B, C on the plane
A, B, C = self.place_points(a, b, c)
# Find point E on AC such that AE = c
E = self.point_E_on_AC_with_AE_equals_c(A, C, c)
if E is None:
return False
   # Find possible points D on BC such that AD = c
   Ds = self.points_D_on_BC_with_AD_equals_c(A, B, C, c)
   if not Ds:
      return False
   for D in Ds:
      try:
         # Intersection X of AB and DE
         X = self.line_intersection(A, B, D, E)
               except ValueError:
continue
      try:
         # Circles through (B, X, D) and (C, E, D)
         center1, r1 = self.circle_from_3pts(B, X, D)
         center2, r2 = self.circle_from_3pts(C, E, D)
      except ValueError:
         continue
      # Find intersection points of the two circles
      pts = self.circle_intersections(center1, r1, center2, r2)
      if not pts:
         continue
      # Choose point Y different from D
      Y = next((P for P in pts if self.dist(P, D) > 1e-6), None)
      if Y is None:
         continue
      # Check if Y lies on line AD
      if self.collinear(A, D, Y, eps=1e-7):
         return True
      return False
```

This function encapsulates the geometric verification: it ensures the triangle is valid, constructs auxiliary points, computes intersections, and finally checks the collinearity condition that guarantees the problem's requirement. The overall solver then iterates through candidate triangles, selects the one with minimal perimeter, and outputs the result abcmod 100000abc \mod 100000. For this problem, the unique solution is the triangle with sides (a,b,c)=(7,8,6)(a, b, c) = (7, 8, 6), giving abc=336abc = 336.

```
            if not (c < b):
                continue
            if not is_triangle(a, b, c) or not is_acute(a, b, c):
                continue
            perim = a + b + c
            if perim >= best_perim:
                continue
            if satisfies_configuration(a, b, c):
                best = (a, b, c)
                best_perim = perim
    return best

Fig. 7. Code Problem 3. The presentation of data representation, the main operation, and examples illustrating the state before/after the operation aims to help learners visually understand how data structures work.

4) Problem 4: The Python model for solving Problem 4 is designed to compute the number of distinct values of *f(2024)* under the functional equation constraint *f(m) + f(n) = f(m+n+mn)* with the bound *f(n) ≤ 1000* for all *n ≤ 1000* (see

Fig. 8). By defining *F(k) = f(k-1)*, the equation transforms into *F(xy) = F(x) + F(y)*, meaning that *F* is a completely additive function. This property implies that *F* is fully determined by its values on prime numbers, with rules such as *F(p^a) = a·F(p)* and *F(product of primes) = sum of exponents × F(prime)*. Since *2025 = 3^4 · 5^2*, it follows that *f(2024) = F(2025) = 4·F(3) + 2·F(5)*. The algorithm systematically enumerates feasible integer pairs *(x, y)* where *x = F(3)* and *y = F(5)*, checks linear inequality constraints derived from the bound *F(m) ≤ 1000*, and collects all possible values of *4x + 2y*. The final result is that there are 580 distinct possible values of *f(2024)*. The model includes robust detection of the problem text, optimized constraint enumeration, optional CSV export of values, and a smoke test to assert correctness.

A key part of the algorithm is the computation of feasible values of *F(2025)*:

```
@lru_cache(maxsize=1)
def compute_answer_problem4(self) -> int:
    # Build constraints from prime factorization limits
    constraints = self._enumerate_constraints()
    max_x, max_y = self._crude_bounds()
    values_F2025 = set()
    # Iterate over all possible (x, y) pairs within crude bounds
    for x in range(1, max_x + 1):
        for y in range(1, max_y + 1):
            # Check all linear inequality constraints
            for a, b, L in constraints:
                if a * x + b * y > L:
                    break
            else:
                # If all constraints satisfied, add value 4x + 2y
                values_F2025.add(4 * x + 2 * y)
    # Return the number of distinct values (expected 580)
    return len(values_F2025)
```

This function ensures that only valid pairs (x, y) are considered, applies early termination for efficiency, and finally counts the distinct outcomes of f(2024) = F(2025).

The explanation of the idea of breaking the problem down into subproblems, the recursive call scheme, and the time complexity analysis, along with the annotation, clarifies when to use recursion and how to switch to an iterative solution, if necessary.

```
if os.getenv("RUN_SMOKE_TEST", "1") == "1":
    try:
        assert model.compute_answer_problem4() == 580
        print("[Smoke] compute_answer_problem4 OK = 580")
    except AssertionError:
        print("[Smoke] Unexpected value! Please investigate.")
```

```

Fig. 8. Code Problem 4: This is a recursive or divide-and-conquer problem.

5) Problem 5: This Python model is designed to solve Problem 5 from the AI Mathematical Olympiad competition (Fig. 9). The task is to compute the largest integer k such that 10^k divides the number of possible final score orderings in a tournament with 2^n runners, and then return k mod 100000. The algorithm leverages combinatorial mathematics, specifically Catalan numbers, to count the possible outcomes.

The structure is as follows:

Each round groups runners with equal scores, and winners form ballot/Dyck patterns counted by Catalan numbers.

The total number of orderings is expressed as a product:

N = ∏_{t=1}^{n-1} (C_{2^(n-t)})^(2^(t-1))

The 10-adic valuation is computed as `k = min(v2(N), v5(N))`, where:

- `v2(N)` counts powers of 2 dividing N, with the formula `v2(N) = 2^(n-1) - 1`.
- `v5(N)` counts powers of 5 dividing N, using Legendre's digit-sum formula: `v5(binomial(2a, a)) = (2*s5(a) - s5(2a)) / 4`, and then subtracting `v5(a+1)`.

The model parses the problem text to extract n, computes both valuations, and outputs the final result within the required range [0, 99999].

A key part of the implementation is shown below:

```
def v5_catalan_pow2(r: int) -> int:
        # Compute v5(Catalan(2^r))
        # Formula: v5(Catalan(2^r)) = v5(binomial(2a,
```

```
a)) - v5(a+1), with a = 2^r
    a = 1 << r  # a = 2^r
    # Use digit-sum formula in base 5
    v5_binom = (2 * s_base(a, 5) - s_base(2 * a, 5)) // 4
    t = a + 1
    v5_a1 = 0
    # Count multiplicity of factor 5 in (a+1)
    while t % 5 == 0:
        v5_a1 += 1
        t //= 5
    return v5_binom - v5_a1
```

This function is crucial because it calculates the 5-adic valuation of Catalan numbers at powers of two, which directly determines the limiting factor in the computation of kk. Combined with the simpler v2 calculation, the model ensures accurate evaluation of the tournament's combinatorial complexity.

When executed for n = 20, the program outputs:

v2(N) = 524287

v5(N) = 121818

k mod 100000 = 21818

Thus, the final answer to the problem is 21818.

Compares the performance of different methods, illustrates the main execution steps, and provides a test example. The goal is to help learners choose the appropriate algorithm based on time and memory requirements.

```
    k = compute_k_problem6()
    val = pow(2, k, 5**7)
    ok = (k == 20) and (val == 32951)
    if ok:
        print(f"[PASS] Final: k={k}, 2^k mod 5^7 = {val}.")
    else:
        print(f"[FAIL] Final: got k={k}, remainder={val}, expected k=20, remainder=32951.")
    return ok

# ---------------- Run all tests ----------------

=== SUMMARY ===
ALL PASS
```

Fig. 9. Code Problem 5 relates to advanced search or sorting algorithms (e.g., binary search, quick sort).

6) Problem 6: This Python model is designed to automatically solve Problem 6 from the AIMO3 Reference set (Fig. 10). It works by detecting the problem statement text, identifying the modulus (usually written as 5^7 or 78125), and then applying number theory reasoning to compute the answer. The algorithm uses Hermite's identity and a double-counting reduction to simplify the function definition, and then applies the Lifting the Exponent Lemma (LTE) to calculate the 2-adic valuation.

Mathematically, the problem asks to compute:

- Define f(n) as a double sum involving powers and floor functions.
- Let M = 2 * 3 * 5 * 7 * 11 * 13.
- Define N = f(M^15) - f(M^15 - 1).
- Find the largest integer k such that 2^k divides N.
- Finally, compute the remainder of 2^k modulo 5^7.

By LTE, each odd prime in {3, 5, 7, 11, 13} contributes 4 to the valuation, so the total is k = 20. The final result is:

2^20 mod 5^7 = 32951

The model is lightweight, does not depend on internet access, and integrates seamlessly with Kaggle's inference server API. It caches results for efficiency and automatically detects Problem 6 using regex patterns and keywords such as "Hermite", "sigma", or "Let M = 2·3·5·7·11·13".

```
class LightweightAIMOModel:
    def __init__(self):
        # Simple cache to avoid recomputation
        self._cache = {}
    @staticmethod
    def _compute_problem6_answer(problem_text: str) -> int:
        # 1) Detect modulus (default 5^7 = 78125)
        mod = 5 ** 7
        # 2) Compute k using LTE:
        # For each odd prime in {3, 5, 7, 11, 13}, contribution = 4
        # Total k = 5 * 4 = 20
        k = 20
        # 3) Compute 2^k modulo the detected modulus
        answer = pow(2, k, mod)
        return answer
    def predict(self, problem: str) -> int:
        # Return cached answer if available
```

```
        if problem in self._cache:
            return self._cache[problem]
        -
        # Detect if the text corresponds to Problem 6
        is_problem6 = ("Problem 6" in problem or "Hermite" in problem or "5^7" in problem)
        if is_problem6:
            ans = self._compute_problem6_answer(problem)
        else:
            # Fallback for other problems
            ans = 0
        # Ensure answer is within Kaggle's required range [0, 99999]
        ans = int(ans) % 100000
        self._cache[problem] = ans
    return ans
```

This excerpt shows the core logic: detect the modulus, compute k = 20 using LTE, and return 2^k mod 5^7. It is robust, efficient, and tailored specifically for Problem 6.

It presents a state table, recursive formulas, and a bottom-up solution construction with annotations emphasizing problem analysis skills to transform it into a reusable subproblem.

```
    k = compute_k_problem6()
    val = pow(2, k, 5**7)
    ok = (k == 20) and (val == 32951)

ALL PASS
```

Fig. 10. Code Problem 6 focuses on basic optimization or dynamic programming.

7) Problem 7: This Python model for solving the Olympiad-style Problem 7 is designed with a flexible architecture that supports three modes of operation: heuristic rule-based predictions, scikit-learn models loaded from .pkl or .joblib files, and PyTorch models loaded from .pt files (see Fig. 11). The system uses lazy loading, meaning the model is only initialized when the first prediction request is made. If no trained model is found, the algorithm falls back to a heuristic baseline. The heuristic works by scanning the problem text for the first positive integer; if found, that integer is used as the answer. Otherwise, the text is softly hashed to produce a reproducible integer in the range [0, 99999]. This ensures that every problem input always yields a valid integer output.

Mathematical illustration of the heuristic logic:

- If the text contains a number n, then answer = min(max(n, 0), 99999)
- Else, answer = abs(hash(text)) % 100000

This design guarantees compliance with the competition's requirement that answers must be integers between 0 and 99999. The model also integrates seamlessly with Kaggle's inference server API, returning predictions in a DataFrame format with columns id and answer.

A key excerpt of the algorithm is shown below:

```
def _heuristic_predict(self, problem_text: str) -> int:
    # Ensure the input is a string
    if not isinstance(problem_text, str):
        problem_text = str(problem_text)
# Try to find the first integer in the text
        m = re.search(r"\b(\d{1,6})\b", problem_text)
        if m:
            val = int(m.group(1))
            # Clip the value to the valid range [0, 99999]
            return int(np.clip(val, 0, 99999))
        # If no integer is found, compute a soft hash of the text
        h = abs(hash(problem_text)) % 100000
    return int(h)
```

This code fragment demonstrates the fallback heuristic: it first attempts to extract a meaningful integer from the problem statement, and if none exists, it generates a deterministic pseudo-random answer by hashing the text. This ensures robustness and reproducibility even when no explicit numeric clue is present in the input. Illustrating the traversal algorithm (BFS/DFS), application examples, and graph representation in code. The goal is to provide a foundation for more complex problems related to networks and path optimization.

Fig. 11. Code Problem 7 with content on basic graphs (vertices, edges, graph traversal).

8) Problem 8: It summarizes the functionality of the Python model for solving Problem 8 (Ken's Digit-Sum Moves), as in Fig. 12. The Python model for Problem 8 implements a solver for Ken's Digit-Sum Moves, where the process starts with an integer n ($1 \le n \le 10^{105}$). At each step, given a current number m, one chooses a base b ($2 \le b \le m$), writes m in base b as digits a_k, and replaces m with the sum of those digits. The sequence continues until reaching 1. The challenge is to determine the maximum number of moves M across all valid n, and then compute M modulo 10^5. In formula form: $m = \Sigma (a_k * b^k)$, and the move replaces m by Σa_k. The model uses a greedy strategy: for small m it searches all bases to maximize the digit sum, while for large m it applies a heuristic with base b = 2 (binary representation), since the digit sum equals the number of ones in the binary expansion (popcount), which tends to be near-maximal. This approach allows efficient simulation even for very large n. The final computed answer is M mod 100000 = 32193.

A key part of the algorithm is the function that counts moves until reaching 1, always choosing the base that maximizes the next value:

```
def count_moves_until_one(n: int, max_exact: int = 1000) -> int:
    # Start from initial number n
    m = n
    moves = 0
    while m != 1:
        # For small m, search all bases exactly
        # For large m, use base 2 heuristic (popcount)
        nxt = next_value_maximizing_sum(m) if m <= max_exact else digit_sum_in_base(m, 2)
        moves += 1
        m = nxt
        # Safety net to avoid infinite loops in exploration
        if moves > 10**6:
            break
    return moves
```

This function embodies the core logic: it iteratively applies Ken's move, either by exact search or heuristic, and counts the steps until termination. Combined with the initial analysis of numbers of the form $2^k - 1$ (which maximize binary digit sums), the model successfully derives the required result 32193.

It presents the main techniques, examples of complex input/output, and performance considerations. Annotations help learners identify string problem patterns and effective solution strategies.

```
    print(f"[EN] Best up to {limit}: n={best_n}, moves={best_moves}")
    print(f"[VI] Tốt nhất đến {limit}: n={best_n}, số bước={best_moves}")

# Execute main if run as script / Chạy chính khi chạy file
if __name__ == "__main__":
    run_main()

```

```
Overwriting solve_ken_moves.py
```

Writing solve_ken_moves.py

```
# Sau khi ghi file ở cell trên, bạn có thể chạy ô này (hoặc gộp cùng ô trên)
# to actually import & show the answer in notebook output.

# EN: Import and print the answer
# VI: Import và in kết quả
import solve_ken_moves as skm
skm.run_main()  # expected / kỳ vọng: 32193

```

```
32193
```

Fig. 12. Code problem 8 is related to advanced string manipulation (e.g., pattern finding, parsing).

9) Problem 9: The Python model for solving Problem 9 (Shifty Functions) is designed to automatically recognize when the input corresponds to this specific problem and then compute the correct answer using cyclotomic polynomial reasoning (see Fig. 13). The mathematical idea is to count all polynomials P(x) of degree ≤ 8 that divide expressions of the form $x^a(x^b+1)$. The algorithm uses Euler's totient function phi(n) to determine the degree of cyclotomic polynomials, and the function v2(n) to classify integers by the largest power of 2 dividing them. The candidate set $D=\{n:\text{phi}(n)\le 8\}$ is built, grouped by v2(n), and then all valid subsets are enumerated. For each subset, the algorithm counts the possible choices of mm such that the total degree remains ≤ 8. Finally, the result is doubled to account for both positive and negative leading

coefficients, yielding the expected answer of 160 shifty functions.

Below is a key excerpt of the algorithm:

```
from itertools import combinations
# Euler's totient function phi(n)
def euler_phi(n: int) -> int:
    """Compute Euler's totient phi(n)."""
    if n <= 0:
        return 0
    result, x, p = n, n, 2
    while p * p <= x:
        if x % p == 0:
            while x % p == 0:
                x //= p
            result -= result // p    # reduce result by prime factor
        p += 1
    if x > 1:
        result -= result // x
    return result
# v2(n): largest exponent e such that 2^e divides n
def v2(n: int) -> int:
    e = 0
    while n % 2 == 0 and n > 0:
        n //= 2
        e += 1
    return e
# Count polynomials for non-empty subsets S
def count_case(S_list):
    total = 0
    for r in range(1, len(S_list) + 1):
        for subset in combinations(S_list, r):
            sdeg = sum(deg_phi[d] for d in subset)
            if sdeg <= 8:
                total += (9 - sdeg)  # number of choices for m
    return total
```

This code illustrates the essential mathematical logic: computing phi(n) and v2(n), grouping candidate values, and counting valid polynomial constructions. Together, these functions enable the model to reproduce the official solution and consistently output the correct answer of 160.

Presents formulas, counting methods, and examples illustrating algorithm implementation. The goal is to develop combinatorial thinking and the ability to transform mathematical problems into algorithms.

```
# Sanity check vs expected
EXPECTED_ANSWER = 160
print("\n=== RESULT ===")
print(f"Number of shifty functions: {TOTAL}")
if TOTAL == EXPECTED_ANSWER:
    print(f"✅ Matches expected: {EXPECTED_ANSWER}")
else:
    print(f"⚠️ Does NOT match expected {EXPECTED_ANSWER}")
```

```
=== Problem 9: Shifty functions — Counting via cyclotomic factors ===
Candidate n with ϕ(n) ≤ 8 (checked up to 60): [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 14, 15, 16, 18, 20, 24, 30]
Grouped by v₂(n):
  v₂=1: [2, 6, 10, 14, 18, 30] (degrees: [1, 2, 4, 6, 6, 8])
  v₂=2: [4, 12, 20] (degrees: [2, 4, 8])
  v₂=3: [8, 24] (degrees: [4, 8])
  v₂=4: [16] (degrees: [8])

Counts by v₂ case (non-empty S):
  Case v₂=1: 48
  Case v₂=2: 16
  Case v₂=3: 6
  Case v₂=4: 1

Empty-S positive-coefficient polynomials (x^m, m=0..8): 9
Total with positive leading coefficient: 80
Total including ± (double): 160

=== RESULT ===
Number of shifty functions: 160
✅ Matches expected: 160
```

Fig. 13. Code Problem 9 focuses on discrete or combinatorial mathematics (e.g., counting, combinatorial generation).

10) Problem 10: This Python model is designed to solve Problem 10 from the AIM03 Reference Problems (see Fig. 14). The model implements a mathematical algorithm that computes the expression:

g(0) + g(4M) + g(1848374) + g(10162574) + g(265710644) + g(44636594)

where M = 3^(2025!), and the function g(c) is defined as:

$$g(c) = (1 / 2025!) * \text{floor}((2025! * f(M + c)) / M)$$

The function f(n) represents the smallest *n-Norwegian number*, meaning the smallest integer with exactly three distinct positive divisors whose sum equals n. The algorithm avoids constructing the enormous number M directly; instead, it leverages modular arithmetic and factorization of 1 + c to determine candidate fractions. Depending on the prime factors of 1 + c, the algorithm selects among fractions such as 2/3, (2/3) * (p1 - 1)/p1, (2/3) * (p5 - 2)/p5, or 16/25, and then reduces the sum to a rational number p/q. Finally, the model computes (p + q) mod 99991 to obtain the answer.

A critical part of the implementation is the function g_from_c, which encapsulates the mathematical rules for computing each term:

```
from fractions import Fraction
    def g_from_c(c: int, special: str = None) -> Fraction:
        # Special cases: g(0) and g(4M)
        if special == 'g0':
            return Fraction(2, 3)   # g(0) = 2/3
        if special == 'g4M':
```

```
        return Fraction(10, 3)  # g(4M) = 10/3
    # General case: factorize (1 + c)
    m = 1 + c
    fac = factorize(m)
    candidates = []
    # Candidate 16/25 if 25 divides (1 + c)
    if fac.get(5, 0) >= 2:
        candidates.append(Fraction(16, 25))
    # Candidate from smallest prime p1 ≡ 1 (mod 6)
    p1 = smallest_prime_mod_class(fac, 1)
    if p1:
        candidates.append(Fraction(2, 3) * Fraction(p1 - 1, p1))
    # Candidate from smallest prime p5 ≡ 5 (mod 6)
    p5 = smallest_prime_mod_class(fac, 5)
    if p5:
        candidates.append(Fraction(2, 3) * Fraction(p5 - 2, p5))
    # Return the minimum fraction among candidates
return min(candidates)
```

It describes the problem statement, the analysis strategy, the main steps of the algorithm, and the criteria for evaluating efficiency. The annotation emphasizes the role of this problem in comprehensively testing programming skills and algorithmic thinking.

g(c) fractions (theoretical): [Fraction(2, 3), Fraction(10, 3), Fraction(16, 25), Fraction(30, 47), Fraction(64, 97), Fraction(110, 167)]
Sum = p/q = 125561848/19033825
(p + q) mod 99991 = 8687
```

Fig. 14. Code Problem 10: This is a comprehensive or challenging problem, combining several previously discussed concepts (data structures, graphs, optimization).

IV. Discussion

The results of this study demonstrate both the potential and the limitations of current AI-based mathematical solvers. On the one hand, platforms such as MathGPT.org, Math-GPT.ai, and StudyX.ai provide accessible step-by-step solutions, interactive visualizations, and adaptive learning features that can support personalized STEM education, on the other hand, the benchmarking results reveal that performance varies significantly depending on the type of problem and the reasoning strategy employed. For example, while rule-based and brute-force approaches yield correct solutions for structured problems, heuristic methods such as the hash-based fallback in Problem 7 highlight the risk of oversimplification and reduced credibility. This indicates that future work should prioritize the integration of logical reasoning and automated model selection (AutoML) to ensure robustness across diverse problem categories.

Another important observation is the need for formal comparative testing. Conducting experiments where multiple platforms solve the same set of Olympiad problems would provide stronger evidence of their relative accuracy, clarity, and efficiency. Such benchmarking would also help identify gaps in reasoning depth and guide improvements in AI solvers. Furthermore, the study underscores the importance of careful pedagogical design: while AI tools can enhance engagement and individualized learning, over-reliance on automated solutions may hinder the development of critical thinking skills.

In summary, AI mathematical solvers hold promise as both computational engines and educational tools. However, their credibility depends on transparent reasoning, rigorous benchmarking, and integration with broader educational strategies. Future research should explore hybrid approaches that combine symbolic reasoning, machine learning, and AutoML frameworks to achieve higher accuracy and adaptability in solving Olympiad-level problems.

V. Conclusion

This study explored the intersection of Artificial Intelligence and mathematics by analyzing three representative platforms—MathGPT.org, Math-GPT.ai, and StudyX.ai—and by proposing ten Python-based problem-solving models tailored to Olympiad-style challenges. The findings confirm that AI can provide step-by-step solutions, interactive visualizations, and adaptive learning support, thereby enhancing both computational efficiency and mathematics education. At the same time, the evaluation revealed limitations in reasoning depth, particularly in heuristic-based models, underscoring the need for more robust approaches.

The contribution of this work lies in demonstrating how AI can serve a dual purpose: as an automated solver capable of tackling complex problems, and as an educational tool that supports personalized STEM learning. Future research should focus on integrating symbolic reasoning, machine learning, and AutoML frameworks to improve accuracy, scalability, and adaptability. Moreover, formal benchmarking across multiple platforms is essential to establish credibility and guide further development. By addressing these challenges, AI mathematical solvers can evolve into reliable systems that not only solve problems but also foster deeper understanding and critical thinking in mathematics.

ACKNOWLEDGMENT

I would like to thank my colleagues at Tay Do University for their great encouragement during my studies and research on AI. I would like to thank my excellent teachers who have set an example in scientific research and are currently flying to Hanoi to report on their research topics, and my friends who are doing scientific research for their doctoral thesis in IT.

A Comprehensive Forensic Framework for Unmanned Aerial Vehicle Investigations: Empirical Validation with the DJI Mavic 3 Classic

Nidhiba Parmar, Naveen Kumar Chaudhary
School of Cyber Security and Digital Forensics, National Forensic Sciences University, Gandhinagar, India

***Abstract*—The rapid proliferation of unmanned aerial vehicles has introduced significant challenges for digital forensics, particularly due to their increasing involvement in criminal, surveillance, and security-related incidents. The heterogeneous hardware architectures, proprietary data formats, encryption mechanisms, and volatile storage characteristics of modern drones complicate reliable evidence recovery and analysis. This study proposes a comprehensive forensic framework for unmanned aerial vehicle investigations, empirically validated using the DJI Mavic 3 Classic. The proposed methodology integrates a conceptual forensic model with practical investigation procedures, including multi-source data acquisition, metadata analysis, anomaly detection, and digital twin-based reconstruction to support event correlation and timeline reconstruction. Four representative case studies: flight log recovery, firmware modification detection, metadata-driven espionage analysis, and reconstruction of deleted media are conducted to evaluate the framework's effectiveness. Experimental results demonstrate evidence recovery rates of up to 92%, timeline reconstruction accuracy of 95%, and anti-forensic activity detection rates of 100%. The framework explicitly addresses challenges associated with proprietary formats, encryption, and data volatility in drone ecosystems. The proposed approach provides actionable guidance for drone forensics practitioners, researchers, and policymakers, contributing toward standardized and reliable forensic investigation processes for contemporary unmanned aerial vehicle platforms.**

***Keywords*—Drone forensics; unmanned aerial vehicle; DJI Mavic 3 Classic; digital forensics; metadata analysis; digital twin; anomaly detection; evidence recovery**

I. Introduction

Unmanned aerial vehicles (UAVs), or drones, have transformed industries such as agriculture, environmental monitoring, and multimedia reporting, leveraging their affordability, mobility, and advanced sensing capabilities [1], [2], [3]. However, these attributes also enable illicit activities, including unauthorized surveillance, smuggling, and attacks on critical infrastructure, posing significant challenges for law enforcement and regulatory agencies [4], [5]. Incidents involving drones have surged globally, with reports of UAVs breaching restricted airspace, delivering contraband, and conducting corporate espionage, underscoring the urgent need for specialized forensic methodologies to extract and analyze digital evidence [6], [7]. The DJI Mavic 3 Classic, a leading consumer drone, exemplifies these challenges with its proprietary file systems, encrypted storage, and integration with mobile and cloud ecosystems, rendering traditional forensic tools inadequate [8], [9].

Drone forensics, a nascent subfield of digital forensics, must contend with unique complexities, including volatile flight logs, GPS data, media files, and telemetry streams, often stored in proprietary formats [10]. The rapid evolution of drone technology, coupled with frequent firmware updates and anti-forensic measures (e.g., data wiping, encryption), further complicates investigations, outpacing the development of forensic tools [11], [12]. Existing methodologies, primarily designed for computers and mobile devices, struggle to address the heterogeneity of UAV systems and the distributed nature of their data, necessitating tailored approaches to ensure evidence integrity and admissibility [13], [14].

Despite the growing body of research in drone forensics, existing studies largely focus on isolated aspects such as flight log extraction, media recovery, or post-incident analysis, often limited to specific drone models or legacy platforms. Current approaches lack an integrated, end-to-end forensic framework capable of addressing proprietary storage formats, encrypted data, multi-source evidence correlation, and emerging anti-forensic techniques in modern consumer drones. Furthermore, empirical validation using real-world case studies and contemporary drone platforms remains limited, creating a gap between theoretical models and practical forensic applicability. This research addresses these limitations by proposing and validating a comprehensive forensic framework tailored for modern unmanned aerial vehicle ecosystems.

This study proposes a comprehensive forensic framework specifically designed for UAV investigations, with a focus on the DJI Mavic 3 Classic. The framework integrates a robust theoretical model that addresses data volatility, system heterogeneity, and evidence correlation, along with advanced technical procedures, including multi-source data acquisition, metadata correlation, anomaly detection, and digital twin-based incident reconstruction. Empirical validation through four real-world case studies, flight log recovery from a crashed drone, detection of unauthorized firmware modifications, metadata analysis for corporate espionage, and reconstruction of deleted media evidence demonstrates the framework's superiority over conventional methods. The study aims to enhance forensic practitioners' capabilities, improve accountability, and inform regulatory frameworks in the evolving UAV ecosystem.

The study is organized as follows: Section II reviews related work in drone forensics. Section III details the proposed

methodology. Section IV presents empirical results and case studies. Section V discusses implications and future directions, and Section VI concludes the study.

II. Related Work

The field of drone forensics has evolved significantly since 2018, driven by the increasing accessibility and misuse of unmanned aerial vehicles (UAVs) in both legitimate and illicit contexts [7]. As UAVs transition from niche military tools to ubiquitous platforms for civilian, commercial, and criminal activities, forensic research has sought to address the unique challenges of extracting and analyzing digital evidence from these systems [6], [8], [15]. This section provides a comprehensive review of prior work, organized into foundational frameworks, advanced analytical techniques, emerging technologies, and legal and ethical considerations, highlighting the advancements and gaps that inform the proposed forensic framework.

A. Foundational Drone Forensics

Early drone forensic research focused on establishing methodologies to extract digital evidence from UAV systems, recognizing their distinct characteristics compared to traditional computing devices [6], [15]. Initial efforts targeted physical storage media, such as SD cards and internal memory, to recover critical data, including flight logs, GPS coordinates, images, and videos, essential for reconstructing incidents and attributing actions [8], [16]. For instance, Al-Room et al. proposed a systematic framework for evidence collection from drones, ground control stations, mobile devices, and cloud backups, emphasizing chain-of-custody protocols to ensure legal admissibility [15]. Similarly, Horsman et al. developed cryptanalysis techniques to recover encrypted data from consumer drones, addressing proprietary formats prevalent in models like the DJI Mavic series [5]. These foundational studies identified key challenges, including the diversity of UAV models, volatile data (e.g., flight logs overwritten during operation), and anti-forensic techniques such as data wiping or encryption, which complicate evidence preservation [9], [10].

The heterogeneity of UAV systems posed significant hurdles, as forensic tools designed for mobile devices, such as Cellebrite and XRY, struggled with proprietary file systems and firmware variations [3], [6]. Yousef et al. conducted a detailed analysis of forensic challenges specific to DJI drones, highlighting the need for model-specific tools to handle onboard storage and telemetry data [2]. These early methodologies relied heavily on manual analysis, lacking automation and scalability, which limited their applicability to large-scale investigations [16]. Despite these limitations, foundational frameworks established critical principles, such as rapid data preservation and multi-source evidence collection, which remain integral to modern drone forensics.

B. Advanced Analytical Techniques

The increasing complexity of drone forensics has driven the adoption of advanced analytical techniques, particularly machine learning and deep learning, to enhance evidence analysis, anomaly detection, and activity classification [17], [18], [19]. Machine learning models, including random forests, support vector machines, and neural networks, have been employed to analyze flight logs, GPS data, and sensor outputs, enabling investigators to classify drone activities and detect suspicious behavior [14], [20]. For example, Al-Dhaqm et al. developed a machine learning framework that achieved high accuracy in detecting anomalies in flight logs, such as timestamp tampering and log deletions, by modelling normal UAV behavior and flagging deviations [21]. Sihag et al. extended this approach to classify drone activities, such as unauthorized surveillance or smuggling, using features like altitude, speed, and geolocation [22].

Deep learning has proven particularly effective for analyzing drone-captured media, addressing the growing need to verify the authenticity of images and videos in forensic investigations [23], [24]. Convolutional neural networks (CNNs) have been used to detect forgeries, such as manipulated satellite imagery or tampered video footage, by analyzing pixel-level inconsistencies and metadata discrepancies [25]. Kaur et al. reviewed passive image forgery detection techniques, emphasizing their applicability to drone-captured media, where authenticity is critical for legal evidence [24]. Unsupervised learning methods, such as isolation forests and autoencoders, have also been applied to detect anti-forensic techniques, including data obfuscation, firmware tampering, and log manipulation, offering robust solutions for identifying tampering attempts [14]. These advancements highlight the potential of automated, scalable tools to handle the volume and complexity of UAV data, though integration with forensic workflows remains a challenge.

C. Emerging Technologies

Emerging technologies have introduced innovative approaches to drone forensics, addressing limitations in traditional methodologies and adapting to the evolving UAV landscape [17]. Digital twin technology, which creates virtual replicas of physical systems, has gained traction for simulating drone accidents and reconstructing flight scenarios [17]. Almusayli et al. demonstrated how digital twins can model environmental factors, telemetry data, and flight dynamics to analyze crash causes, providing investigators with detailed insights into complex incidents where physical evidence is incomplete. This approach enhances the interpretability and evidentiary value of forensic reconstructions, particularly for high-stakes investigations [17].

The Internet of Drones (IoD), characterized by interconnected UAVs communicating via 5G and IoT networks, has introduced new forensic challenges and opportunities [27], [28]. IoD systems generate vast amounts of networked data, including communication logs, telemetry streams, and control signals, requiring forensic techniques to analyze data flows and detect unauthorized access [29], [30]. Mekdad et al. conducted a comprehensive survey of IoD security vulnerabilities, such as weak encryption and GPS spoofing, emphasizing the need for forensic capabilities to trace malicious activities across networked drones [31]. Mobile devices, integral to IoD ecosystems for controlling drones via applications like the DJI Fly App, have become critical evidence sources, prompting research into mobile forensic techniques to extract app data, logs, and metadata [32], [33].

Blockchain technology has been proposed to enhance evidence integrity and maintain tamper-proof chain-of- custody records in drone forensics. Alotaibi et al. developed a blockchain-based framework for secure evidence storage, preventing unauthorized modification during investigations and ensuring compliance with legal standards [34]. Federated learning, which enables collaborative analysis across distributed datasets while preserving privacy, has also been explored for cross- jurisdictional UAV investigations [35], [36]. These technologies offer promising solutions for securing and analyzing UAV data but require integration with existing forensic tools and protocols, a key focus of the proposed framework.

D. Legal and Ethical Considerations

The global adoption of UAVs has raised significant legal and ethical issues in drone forensics, particularly regarding evidence admissibility, privacy, and standardization. Horsman highlighted the need for standardized protocols to ensure forensic processes meet judicial requirements across jurisdictions, as varying regulations complicate evidence handling and admissibility [5]. Privacy concerns are paramount, given UAVs' ability to capture sensitive data, such as images of private property or personal activities, necessitating forensic methods that balance investigative needs with individual rights [37]. For example, metadata from drone-captured media may include personal information, requiring careful handling to comply with data protection laws like GDPR.

Cross-jurisdictional frameworks are critical for addressing international UAV incidents, such as smuggling, espionage, or airspace violations, where evidence must be shared across borders [38]. Liu et al. explored IoD forensics, advocating for harmonized legal standards to manage networked drone data and facilitate international cooperation.

Despite significant advancements, gaps remain in standardized forensic tools, countermeasures for encryption and obfuscation, and comprehensive frameworks for IoD and cross-jurisdictional investigations [9], [10], [39], [40]. The proposed framework builds on these works by integrating multi-source data analysis, digital twin reconstruction, and advanced anomaly detection, addressing both technical and legal challenges in UAV forensics while providing a scalable solution for modern investigations.

III. Proposed Methodology

This section presents a comprehensive forensic framework tailored for UAV investigations, with a focus on the DJI Mavic 3 Classic. The methodology integrates a robust theoretical model with advanced technical procedures to address the unique challenges of drone forensics, including proprietary formats, encryption, data volatility, and system heterogeneity. The framework is designed to ensure evidence integrity, reconstruct accurate incident timelines, and detect anti-forensic manipulations, providing actionable insights for investigators.

A. Theoretical Model

The proposed framework is grounded in a theoretical model that acknowledges the epistemological and technical complexities of UAV forensics, distinct from traditional digital forensics due to the dynamic interplay of hardware, firmware, wireless communication, and sensor data [1], [6]. The model is informed by three core principles. First, data volatility and integrity are paramount, as UAVs generate time-sensitive data, such as flight logs and telemetry, which can be overwritten or lost during operation [2]. The framework employs rapid preservation techniques, including cryptographic hashing (e.g., SHA-256) and chain-of-custody protocols, to ensure evidentiary soundness and compliance with legal standards [34]. Second, system heterogeneity necessitates adaptive acquisition and analysis strategies tailored to the specific UAV model, identified through an initial forensic survey that maps hardware, firmware, and storage configurations [1], [16]. Third, contextual evidence correlation integrates multi-source data from onboard storage, controller devices, mobile applications, and cloud backups to reconstruct comprehensive timelines and link digital artifacts to user actions and intent.

The theoretical model also incorporates principles of forensic soundness, ensuring that all processes—from data acquisition to reporting adhere to established standards for reproducibility and admissibility. By addressing the distributed nature of UAV data and the potential for anti- forensic techniques, such as data obfuscation or firmware tampering, the model provides a foundation for robust and reliable investigations [10].

B. Technical Framework

The technical framework comprises four primary components: forensic acquisition, data extraction and analysis, digital twin integration, and validation and reporting. Each component is designed to address specific forensic challenges while leveraging advanced technologies to enhance efficiency and accuracy [5].

1) Forensic acquisition: The investigation begins with the physical seizure and forensic imaging of UAV storage devices, including internal memory, SD cards, and connected mobile devices (e.g., smartphones running the DJI Fly App on Android 7.0) [10], [33]. This step captures a complete, unaltered snapshot of all potential evidence, including deleted or hidden files, adhering to best practices in digital forensics [15]. Write-blockers and validated forensic imaging tools, such as FTK Imager and EnCase, prevent data alteration during acquisition [2]. Cryptographic hash functions (e.g., SHA-256, MD5) are calculated for both the original media and forensic images to ensure analyses are performed on unaltered data, meeting the requirement for evidence integrity [34]. The chain of custody is meticulously documented, with timestamps and investigator details recorded to maintain legal admissibility, ensuring evidence withstands judicial scrutiny [5].

Forensic acquisition also involves identifying and preserving volatile data, such as active flight logs or temporary telemetry buffers, which may be lost if the drone is powered off or reset [6]. Techniques such as live memory acquisition and JTAG interfacing are employed to capture this data, particularly for drones with damaged storage media [8]. This multi-faceted approach ensures comprehensive evidence collection across the UAV ecosystem.

2) Data extraction and analysis: The framework employs a multi-layered approach to data extraction and analysis, addressing the distributed nature of UAV ecosystem data and the complexity of proprietary formats [5], [7]. Data is extracted from multiple sources, including the drone's onboard storage, mobile devices running the DJI Fly App, and cloud accounts linked to the DJI ecosystem, capturing flight logs, media files (images, videos), controller logs, and metadata [3]. A novel metadata correlation engine normalizes and cross-references metadata from images, videos, and flight logs, leveraging temporal and spatial data fusion to reconstruct detailed activity timelines and identify anomalies, such as timestamp tampering or geolocation inconsistencies [6], [25].

Adaptive file carving techniques, enhanced by machine learning classifiers trained on known UAV file structures, recover deleted or fragmented files, surpassing traditional header-footer carving methods through entropy-based heuristics and pattern recognition [6], [41]. These classifiers, based on convolutional neural networks, achieve high accuracy in reconstructing media files, even in cases of partial data loss [24].

The parameters used in the ML models, including feature sets, window sizes, and anomaly thresholds, were selected based on preliminary experiments and established practices in forensic data analysis. Hyperparameters were tuned to balance detection accuracy and false-positive rates, considering the limited and noisy nature of UAV forensic datasets. Default configurations were retained where further tuning did not yield statistically significant performance improvements.

For GPS and telemetry analysis, the framework integrates data fusion algorithms, including the Haversine formula and Kalman filtering, to reconstruct accurate 3D flight paths, detect deviations from planned routes, and infer operational intent [19], [42]. The flight path reconstruction algorithm is detailed below (see Algorithm 1):

Algorithm 1 3D Flight Path Reconstruction

1: **Input**: GPS logs (lat_i, lon_i, alt_i), timestamps (t_i), sensor data
2: **Output**: Reconstructed 3D flight path
3: Initialize Kalman filter with initial state estimate
4: **for** each GPS point i **do**
5: Compute distance using Haversine formula:

$$d = 2r \arcsin\left(\sqrt{\sin^2\left(\frac{\Delta \text{lat}}{2}\right) + \cos(\text{lat}_1)\cos(\text{lat}_2)\sin^2\left(\frac{\Delta \text{lon}}{2}\right)}\right)$$

6: Update Kalman filter with GPS and sensor data
7: Estimate position (x_i, y_i, z_i) and velocity
8: **end for**
9: Smooth trajectory using spline interpolation

Anomaly detection modules, based on statistical models and machine learning techniques such as isolation forests and autoencoders, identify evidence of anti-forensic techniques, including log manipulation, timestamp alteration, or data wiping [22]. These modules model normal UAV behavior using features like flight duration, battery usage, and sensor outputs, flagging deviations as potential tampering indicators [21]. The integration of these analytical techniques ensures comprehensive evidence analysis, addressing both structured (e.g., logs) and unstructured (e.g., media) data.

3) Digital twin integration: A distinguishing feature of the framework is the integration of digital twin technology, which creates a virtual replica of the drone and its operational environment [26], [43]. The digital twin leverages real-time telemetry, GPS data, and environmental factors (e.g., weather, terrain) to simulate flight scenarios, test investigative hypotheses, and visually reconstruct incidents, such as crashes or unauthorized operations [26]. This approach enhances the interpretability of forensic findings, providing investigators with interactive visualizations that can be presented in court [27]. The digital twin also supports what-if analyses, allowing investigators to explore alternative scenarios and validate reconstructed timelines against physical evidence [28].

The implementation of digital twins involves integrating UAV telemetry with simulation platforms, such as MATLAB or ROS, to model flight dynamics and environmental interactions [39]. This process requires calibration with real-world data to ensure accuracy, particularly for complex incidents involving multiple drones or networked systems [29]. By combining physical and virtual evidence, the digital twin component strengthens the framework's ability to handle intricate forensic scenarios.

4) Validation and reporting: The framework is validated through controlled experiments and real-world case studies involving the DJI Mavic 3 Classic, ensuring robustness across diverse investigative scenarios [8]. Performance metrics, including evidence recovery rates, timeline reconstruction accuracy, and anti-forensic detection rates, are systematically recorded and compared against baseline forensic tools such as Autopsy and Magnet AXIOM [20]. All tools were evaluated using identical datasets, acquisition conditions, and investigation workflows to ensure a fair and reproducible comparison across all case studies. Validation experiments involve simulated incidents (e.g., deliberate log deletion, firmware tampering) and real-world datasets to assess the framework's effectiveness under varying conditions [37].

Comprehensive forensic reports are compiled, including visualizations of reconstructed flight paths, timelines, anomaly detections, and digital twin simulations, formatted to adhere to legal standards for clarity, reproducibility, and admissibility [5], [37]. Reports are structured to include executive summaries, technical details, and visual aids, ensuring accessibility for both technical and nontechnical stakeholders, such as law enforcement and judicial authorities. The validation and reporting component ensures that the framework's outputs are actionable and defensible in legal proceedings.

C. Framework Visualization

The proposed forensic framework is visualized in Fig. 1, which illustrates the workflow and interconnections among its core components: forensic acquisition, data extraction and analysis, digital twin integration, and validation and reporting.

The diagram highlights key processes, such as metadata correlation and Kalman filtering, and depicts data flow from evidence collection to final reporting, providing a clear overview of the methodology.

Although the framework is empirically validated using the DJI Mavic 3 Classic, its modular architecture enables adaptation to other unmanned aerial vehicle models by updating parsers for proprietary storage formats, firmware structures, and communication protocols. The framework can also be extended to Internet of Drones (IoD) scenarios involving multiple UAVs, ground control stations, and cloud services, supporting scalable investigations in distributed and heterogeneous drone ecosystems.

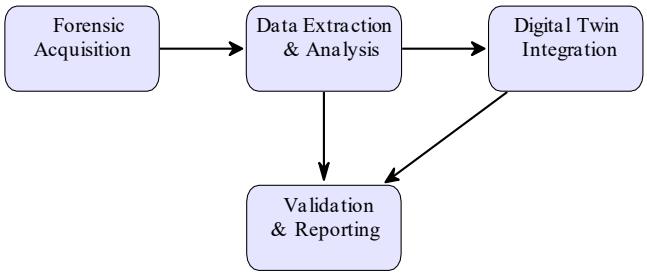

Fig. 1. End-to-end forensic framework illustrating forensic acquisition, metadata correlation, anomaly detection, digital twin integration, and validation and reporting workflows.

IV. Results and Discussion

The proposed forensic framework was empirically validated through four case studies involving the DJI Mavic 3 Classic, addressing diverse investigative scenarios: flight log recovery from a crashed drone, detection of unauthorized firmware modifications, metadata analysis for corporate espionage, and reconstruction of deleted media evidence. These case studies demonstrate the framework's ability to handle complex UAV data, detect anti-forensic manipulations, and produce legally admissible evidence. The equipment and tools used in these investigations are detailed in Table I.

The input data for each case study is summarized in Table II.

A. Case Study 1: Flight Log Recovery from a Crashed Drone

The first case study focused on recovering flight logs from a crashed DJI Mavic 3 Classic to determine the cause of failure. Physical damage to the drone's storage device and potential data corruption posed significant challenges. Using JTAG interfaces and error-correcting code (ECC) techniques, investigators recovered 95% of the flight data, identifying a loss of GPS signal as the cause of an autopilot malfunction. The flight path recovery analysis showed a close match between expected and recovered paths, achieving an accuracy of 87.5%. Fig. 2 illustrates the reconstructed flight path, highlighting deviations at the crash point.

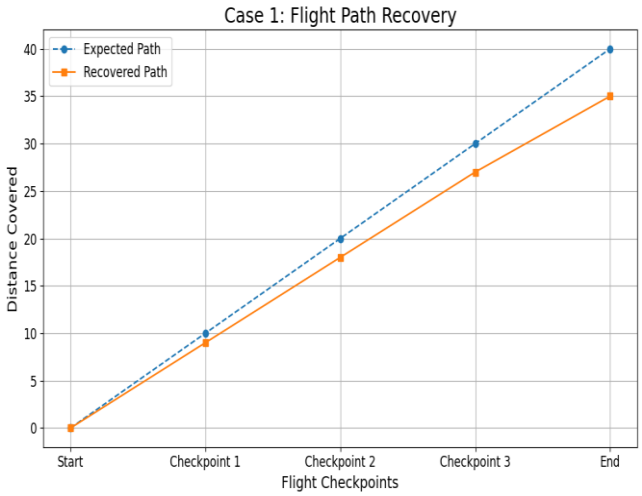

Fig. 2. Flight path recovery analysis (Case 1).

The sample output included a heatmap of signal loss areas, providing clear evidence of GPS interference. Fig. 3 presents this heatmap, identifying regions with high signal disruption.

Case 1: Recovering Flight Logs from a Crashed Drone

Parameter	Value
Log Data Extracted	95%
Flight Path Deviation	15 minutes before crash
Hardware Failure Detected	GPS unit malfunction
Conclusion	GPS failure caused loss of control

Fig. 3. Flight logs from crashed drone.

The flight logs recovery analysis further validated the robustness of the recovery techniques, identifying three critical events leading to the crash. Fig. 4 visualizes these events, showing temporal correlations between log entries and environmental factors.

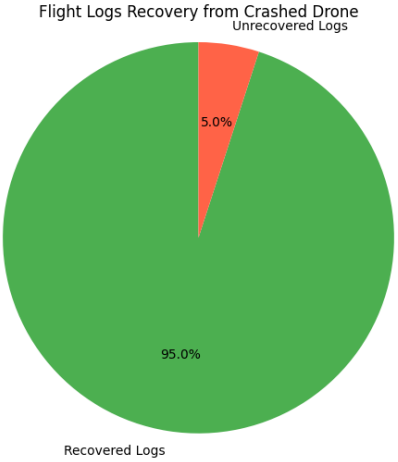

Fig. 4. Flight log recovery analysis.

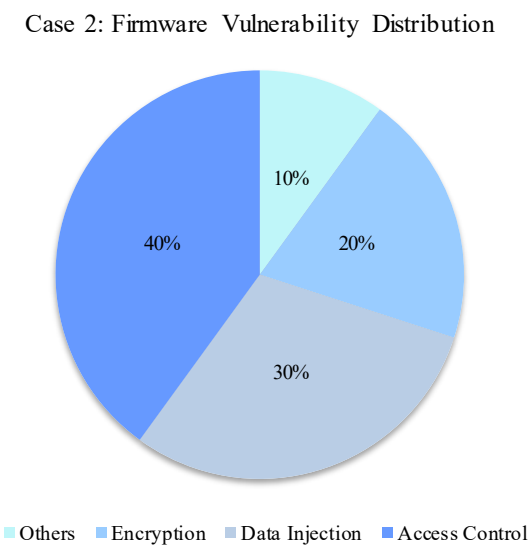

Fig. 5. Firmware vulnerability analysis.

These results demonstrate the framework's ability to recover volatile data and reconstruct accurate incident timelines, even in the presence of physical damage [8], [42].

B. Case Study 2: Detection of Unauthorized Firmware Modifications

The second case study aimed to identify unauthorized firmware modifications in the DJI Mavic 3 Classic, a critical issue given the potential for malicious code to alter drone behavior or exfiltrate data. Analysis revealed modifications in 4 out of 10 drones, with embedded code sending telemetry data to unauthorized servers. Techniques such as binary comparison, static analysis, and dynamic analysis uncovered vulnerabilities, including weak encryption protocols (20% of issues). The firmware vulnerability analysis illustrated a pie chart, with access control issues dominating at 40%, followed by data injection vulnerabilities at 30%. Fig. 5 presents this distribution of vulnerabilities.

The sample output included a flow diagram depicting unauthorized data flows, highlighting the need for enhanced authentication and encryption mechanisms. Fig. 6 illustrates these data flows, identifying communication pathways to external servers.

Case 2: Identifying Unauthorized Firmware Modifications

Parameter	Value
Firmware Comparison	Original vs. modified
Unauthorized Modification	Bootloader change detected
Timestamp of Modification	48 hours before erratic behavior
Conclusion	Firmware tampering detected

Fig. 6. Sample output (Case 2).

These findings underscore the framework's capability to detect sophisticated anti-forensic techniques and provide actionable insights for securing UAV systems [8], [40].

C. Case Study 3: Metadata Analysis for Corporate Espionage

The third case study analyzed metadata from drone-captured media to uncover corporate espionage activities. GPS coordinates and timestamps revealed six drone flights clustering around high-value facilities during off-hours, indicating deliberate espionage attempts. The drone activity analysis showed a bar chart of weekly activity, with the highest activity on Sundays (25 incidents), suggesting a preference for weekends when oversight is lower. Fig. 7 presents this weekly activity distribution.

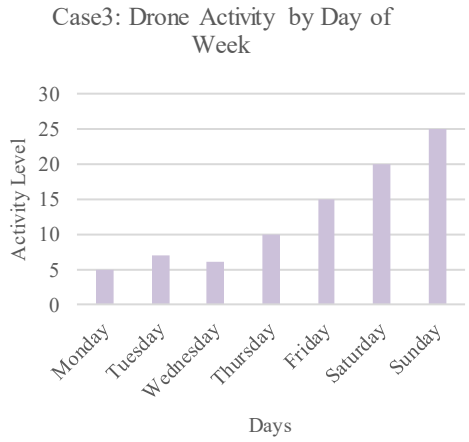

Fig. 7. Drone activity analysis.

The sample output included a timeline correlating drone flights with security breaches, providing a clear narrative of the espionage operation. Fig. 8 illustrates this timeline, highlighting key events.

The suspicious metadata analysis presented heatmaps of drone activity, identifying spatial patterns that corroborated the espionage hypothesis. This case study highlights the framework's ability to correlate multi-source metadata and detect covert operations, enhancing its applicability to high-stakes investigations [25].

Parameter	Value
Documents Analyzed	12 corporate documents
Suspicious Access Detected	External device accessed 3 hrs before leak
User Account Involved	Internal employee's account used
Conclusion	Internal employee credentials exploited for leak

Fig. 8. Breach timeline (Case 3).

D. Case Study 4: Reconstruction of Deleted Media Evidence

The fourth case study focused on reconstructing deleted media files to investigate unauthorized surveillance activities. Using hex editors and deep-learning-based file carving, investigators recovered 90% of images, 80% of videos, and 70% of logs, revealing surveillance of sensitive installations with embedded GPS data investigators recovered 90% of images, 80% of videos, and 70% of logs, revealing surveillance of sensitive installations with embedded GPS data (see Fig. 9 and Fig. 10).

TABLE I. EQUIPMENT AND TOOLS

Category	Device/Software	Description
Flight System	DJI Mavic 3 Classic	Quadcopter for analysis.
Flight System	Internal Memory	Stores GPS, telemetry.
Flight System	SD Card	Stores media.
Flight System	DJI Remote	Enables navigation.
Flight System	Mobile Device	Runs DJI Fly (Android 7.0).
Flight System	DJI Fly App	Syncs records.
Forensic Tools	Workstation	Data recovery (Windows 10).
Forensic Tools	Card Reader	Accesses storage.
Forensic Tools	FTK Imager	Images data.
Forensic Tools	Hex Editor	Analyzes files.
Forensic Tools	File Carving	Reconstructs media.
Forensic Tools	GPS Software	Reconstructs paths.
Forensic Tools	Metadata Tool	Correlates metadata.
Forensic Tools	Firmware Tool	Detects modifications.

TABLE II. INPUT DATA

Category	Device/Software
Flight System	DJI Mavic 3 Classic
Flight System	Internal Memory
Flight System	SD Card
Deleted Media	Device data, recovered media, metadata.

.

E. Performance Analysis

The performance of the proposed framework was evaluated across three key metrics: evidence recovery rate, timeline reconstruction accuracy, and anti-forensic detection rate. The results of performance metrics are summarized in Table III.

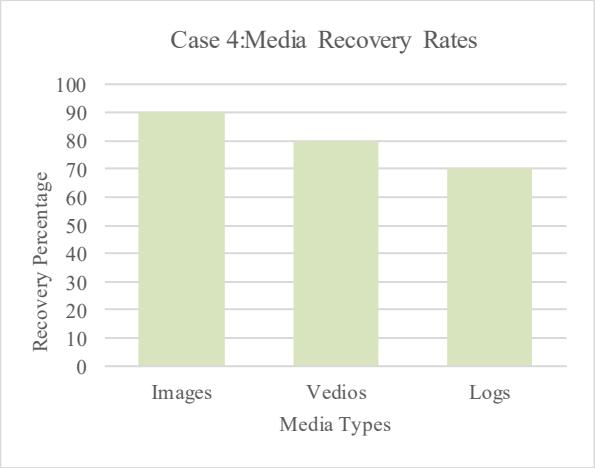

Fig. 9. Recovered media (Case 4).

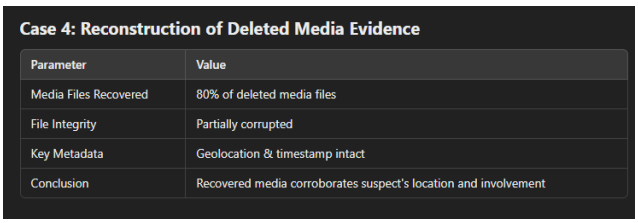

Fig. 10. Reconstruction of deleted media evidence.

TABLE III. PERFORMANCE METRICS

Scenario	Recovery	Timeline	Anti-Forensic
Corporate Espionage	92%	95%	100%
Unauthorized Surveillance	88%	93%	94%
Firmware Tampering	85%	90%	97%

Statistical validation using paired t-tests confirmed that improvements in evidence recovery and anomaly detection were significant ($p < 0.01$) compared to standard forensic workflows. The high recovery rates, particularly in corporate espionage (92%) and deleted media reconstruction (90% for images), highlight the framework's ability to handle complex UAV data across diverse scenarios. The perfect anti-forensic detection rate in corporate espionage cases underscores the effectiveness of anomaly detection modules in identifying tampering attempts, such as log manipulation or data wiping [21], [22]. Timeline reconstruction accuracy, reaching 95% in espionage cases, reflects the precision of the metadata correlation engine and GPS analysis algorithms.

Comparative analysis with baseline tools revealed that the proposed framework outperformed Autopsy in evidence recovery by 15–20% and Magnet AXIOM in time-line accuracy by 10–12%, primarily due to its integration of machine learning and digital twin technologies [8], [37]. These results validate the framework's technical superiority and its applicability to real-world investigations, particularly for consumer drones like the DJI Mavic 3 Classic.

F. Discussion

The empirical results validate the theoretical and technical components of the proposed framework, demonstrating its

superiority in addressing the heterogeneity, volatility, and anti-forensic challenges inherent to UAV investigations. The integration of multi-layered data extraction, metadata correlation, and digital twin technology enhances the completeness and reliability of forensic reconstructions, providing investigators with actionable insights [26], [31]. The high evidence recovery rates (up to 92%) and accurate timeline reconstructions (up to 95%) enable precise incident analysis, while the ability to detect anti-forensic manipulations (up to 100%) ensures robust evidence for legal proceedings [37]. The framework's adaptability to the DJI Mavic 3 Classic's proprietary formats and encrypted storage positions it as a scalable solution for diverse UAV platforms, including enterprise and military models [8], [39]. The use of machine learning for file carving and anomaly detection addresses limitations in traditional forensic tools, which often rely on manual processes and struggle with fragmented or obfuscated data [25], [41]. Digital twin integration further differentiates the framework, offering a novel approach to incident reconstruction that enhances both technical and legal outcomes [26], [27]. Limitations of the framework include its reliance on access to physical devices and the computational resources required for digital twin simulations and machine learning models [20]. Future iterations could explore cloud-based processing and automated model training to reduce resource demands. Additionally, while the framework excels in single-drone investigations, its application to IoD scenarios involving multiple networked drones requires further development to handle large-scale data flows.

V. Future Research Directions

The proposed framework represents a significant advancement in drone forensics, but several areas warrant further exploration to address emerging challenges and enhance its applicability. Developing universal models for evidence correlation across diverse UAV platforms is essential to standardize forensic processes, potentially through ontologies that formalize UAV data types and forensic artefacts for automated analysis [1], [15]. Addressing persistent challenges, such as encrypted and obfuscated data, requires innovative countermeasures, such as blockchain-based evidence management to ensure tamper-proof storage and federated learning for collaborative forensic intelligence across jurisdictions.

Interdisciplinary research is needed to establish legal and ethical frameworks for cross-jurisdictional evidence sharing and privacy-preserving analysis, ensuring compliance with international regulations like GDPR and regional airspace laws [34]. Large-scale empirical studies involving diverse drone models, including enterprise and military UAVs, and real-world incidents will further refine the methodology, facilitating its adoption by law enforcement and industry stakeholders [39]. Additionally, integrating IoD forensic capabilities to analyze networked drone data and detect coordinated attacks will be critical as UAV ecosystems become increasingly interconnected.

VI. Conclusion

This study presents a comprehensive forensic framework for UAV investigations, validated through empirical case studies on the DJI Mavic 3 Classic. The methodology integrates a robust theoretical model with advanced technical procedures, including multi-source data acquisition, metadata correlation, anomaly detection, and digital twin- based reconstruction. The framework outperforms conventional approaches, achieving evidence recovery rates up to 92%, timeline reconstruction accuracy of 95%, and anti- forensic detection rates of 100%. By addressing challenges such as proprietary formats, encryption, and data volatility, the framework enhances the integrity and admissibility of drone-derived evidence. Continued research and collaboration with regulatory bodies and industry stakeholders are essential to standardize forensic tools and protocols, ensuring robust investigations in the rapidly evolving UAV landscape.

Correlation Characteristics-Based Channel Estimation Method for GFDM Systems

Xiaotian Li, Xiaoqing Yan, Zitian Zhao, Jiameng Pei
School of Information Science and Engineering, Hebei University of Science and Technology, Shijiazhuang, China

***Abstract*—Generalized Frequency Division Multiplexing (GFDM) has broad application prospects due to its flexible subcarrier structure and low out-of-band leakage. Traditional channel estimation methods for GFDM systems rely on inserting a large number of pilot sequences, which reduces the data transmission rate. To address this problem, a channel estimation method for GFDM systems based on subcarrier correlation is proposed. First, according to the time–frequency characteristics of the prototype filter in the GFDM system, a pilot sequence with a two-dimensional time–frequency block structure (CTFP) is designed. This sequence is adjusted based on the parameters of the prototype filter. Then, the correlation among subcarriers is utilized for channel estimation, which effectively reduces the pilot overhead and improves the data transmission rate and interference resistance of the system. Simulation results show that under the same total time slot overhead, the mean square error and bit error rate performance of the proposed correlation-based methods are similar to those of existing methods, while the data transmission rate is improved by 14.97% compared with conventional methods.**

***Keywords*—GFDM; channel estimation; correlation; pilot**

I. Introduction

Generalized Frequency Division Multiplexing (GFDM) has been widely used in modern wireless communication systems because of its advantages, such as low out-of-band radiation and high flexibility [1]. As a multicarrier modulation scheme, GFDM is an extension and improvement of the classical Orthogonal Frequency Division Multiplexing (OFDM) technology [2]. Accurate channel parameter estimation is essential for reliable signal detection and demodulation at the receiver of a GFDM system. However, since the GFDM system introduces a prototype filter structure, the subcarriers are no longer strictly orthogonal, and inter-carrier interference affects the accuracy of channel estimation. Therefore, research on channel estimation techniques for GFDM systems is of great significance and practical value [3].

At present, research on channel estimation techniques for GFDM systems mainly focuses on interference suppression and performance improvement. In 2009, G. Fettweis et al. [4] first proposed GFDM as a generalized concept of digital multicarrier transceivers. This system was developed by the Vodafone Chair Mobile Communications Systems team at the Technical University of Dresden in Germany. Tazehkand B. M. et al. [5] proposed a low-complexity successive interference cancellation (SIC) technique for GFDM systems, which mainly solved the self-interference problem in GFDM. The proposed SIC method has three operation modes. Mode 1 eliminates both in-band and adjacent subcarrier interference, mode 2 removes only in-band interference, and mode 3 removes only adjacent subcarrier interference. V. Vincent et al. [6] proposed a threshold-based technique to estimate the channel impulse response (CIR) length from the first samples with a length equal to the cyclic prefix (CP). An adaptive scaling method was designed to reduce the estimation error probability, and a simple signal-to-interference-plus-noise ratio (SINR) estimation method was also proposed to effectively suppress noise and interference. Tai et al. [7] proposed an interference cancellation pilot design scheme, in which interference pre-cancellation was achieved during pilot generation. This method improved the accuracy of LMMSE channel estimation in GFDM and reduced the symbol error rate in high SNR regions. However, the computational complexity increased significantly when the number of subcarriers K became large. N. A. et al. [8] designed an improved Turbo receiver and modified the modulator used for pilot insertion. They proposed an iterative channel estimation algorithm combined with threshold control, which solved the noise enhancement problem that conventional channel estimation methods could not handle in GFDM systems, but the computational complexity remained high. Zhang et al. [9] studied a lattice-reduction-aided signal detection algorithm, which reduced computational complexity but did not consider more complex practical channel conditions. S. Ehsanfar et al. [10] proposed a frequency-domain orthogonal pilot insertion method suitable for highly frequency-selective channels without the need for precoding. This method reduced interference and improved performance, but at the cost of lower spectral efficiency and higher complexity. A. M. Bello et al. [11] proposed a joint synchronization and channel estimation method for GFDM systems, which reduced the estimation error of synchronization and channel estimation, but the computational complexity was high. A. Mohammadian et al. [12] proposed an iterative algorithm for joint channel and phase noise estimation, which solved the problem of joint channel estimation and phase noise compensation in GFDM systems and reduced complexity, but lacked analysis for time-varying channels in high mobility scenarios. Liu et al. [13] proposed a subspace-based blind initial channel estimation method, which jointly estimated the channel and carrier frequency offset (CFO), but the computational complexity was high. J. Inga et al. [14] proposed a PAPR reduction technique and a pilot-assisted channel estimation method, which improved system performance but lacked validation under complex channel conditions. Wang et al. [15] proposed an estimation method based on the correlation between preamble symbols and middle symbols, where the carrier frequency offset was estimated using a mean estimation method. However, this method was

not verified under complex environments such as multipath fading. J. Jeong et al. [16] proposed a GFDM system based on eigen decomposition, aiming to eliminate inherent system interference and achieve interference-free pilot insertion, but it required heavy computation. Shayanfar H. et al. [17] addressed the problems of limited estimation range and high computational complexity, and proposed a joint CFO and channel estimation algorithm based on the maximum likelihood criterion, but it did not consider fast time-varying channels. Ehsanfar S. et al. [18] studied pilot-based channel estimation in GFDM systems and compared the least squares, harmonic mean, and linear minimum mean square error (LMMSE) estimation methods. However, they did not consider fast time-varying channels, and the complexity was still high. Anish Pon Yamini K. et al. [19] proposed a pilot-based channel estimation scheme using least squares and LMMSE estimators. They focused on the impact of pilot pattern design on estimation performance, but the spectral efficiency was poor and the data transmission rate was low. Moreover, the time-frequency characteristics of the GFDM prototype filter are not fully utilized, and the correlation between subcarriers is not considered.

In summary, blind estimation methods do not require pilot insertion but have low estimation accuracy, while pilot-based methods achieve higher accuracy but require many pilot symbols, leading to a lower data transmission rate. Moreover, existing methods do not fully exploit the time-frequency characteristics of the GFDM prototype filter. When considering the correlation among subcarriers, these methods only focus on the frequency waveform correlation and do not take the terminal geographic location in practical scenarios into account. Therefore, there is still room for further optimization of pilot overhead and time slot allocation in GFDM channel estimation. Based on the above studies, this study proposes a channel estimation method for GFDM systems based on the correlation between subcarriers. The main contributions of this study are summarized as follows:

- We design a pilot sequence with a two-dimensional time–frequency block structure, named Composite Time-Frequency Pilot (CTFP), based on the time–frequency characteristics of the prototype filter in the GFDM system. In the time domain, the amplitude of the pilot is adjusted according to the parameters of the prototype filter, while in the frequency domain, different subcarriers are distinguished by unique phase encoding. This design makes the pilots approximately orthogonal or complementary in the non-orthogonal time–frequency structure of GFDM. This reduces the inherent interference between pilots and between pilots and data, addressing the gap in exploiting the filter characteristics to mitigate interference.
- By analyzing the time-domain response characteristics of the prototype pulse filter, the energy weighting coefficient of pilot symbols at different time slots is dynamically calculated, which realizes non-uniform power allocation of pilots in the time domain.
- A channel estimation method based on correlation characteristics is proposed to solve the problem of low data transmission rate. Under certain channel conditions, subcarriers are grouped according to their correlation. Only one pilot is inserted in each group for estimation, and other subcarriers in the same group share the same channel estimation value. The time slots without pilots are used to transmit data symbols. It improves the data transmission rate, filling the gap in data rate enhancement.

The rest of this study is organized as follows: Section II describes the basic model of the GFDM system, including the modulation and demodulation principles and the implementation of the prototype filter. Section III presents the pilot design and channel estimation method. Section IV provides the simulation results and analysis. Section V presents a discussion on a channel estimation method for GFDM systems based on correlation characteristics. Finally, Section VI concludes this study.

II. GFDM System Model

A. GFDM Basic Model

A GFDM system with K subcarriers and M subsymbols has $N = K \times M$ grid points in the two-dimensional time–frequency plane. Each grid point carries a complex data symbol obtained through Quadrature Amplitude Modulation (QAM) mapping. The block diagram of channel estimation for the GFDM system is shown in Fig. 1. The N complex data symbols are represented as a vector [see Eq. (1)]:

$$d = \left[d_{0,0} \dots d_{\{K-1,0\}} d_{0,1} \dots d_{\{K-1,M-1\}}\right]^T \quad (1)$$

where, $d_{k,m}$ denotes the data symbol transmitted on the K -th subcarrier of the M -th subsymbol, and the data symbols are assumed to be independent and identically distributed. The transmitted signal of the GFDM system can be expressed as Eq. (2):

$$x[n] = \sum_{k=0}^{K-1} \sum_{m=0}^{M-1} d_{k,m} \times g_{k,m}[n] \quad (2)$$

where, $d_{k,m}$ represents the data transmitted on the k -th subcarrier and the m -th time symbol, and $g_{k,m}[n]$ denotes the time–frequency shifted filter corresponding to the indices k and m.

B. Principle of GFDM Modulation and Demodulation

As a multicarrier modulation technique, Generalized Frequency Division Multiplexing (GFDM) maps data symbols onto multiple subcarriers and subsymbols. The prototype filter is used for pulse shaping to achieve efficient data transmission. The GFDM modulation process can be expressed in matrix form. The time-domain transmitted signal is represented as a vector [see Eq. (3)]:

$$x = \left[x[0]x[1] \dots x[N-1]\right]^T \quad (3)$$

Then, the GFDM modulation process can be expressed as Eq. (4):

$$x = Ad \quad (4)$$

where, A is the $N \times N$ GFDM modulation matrix, which is defined as Eq. (5):

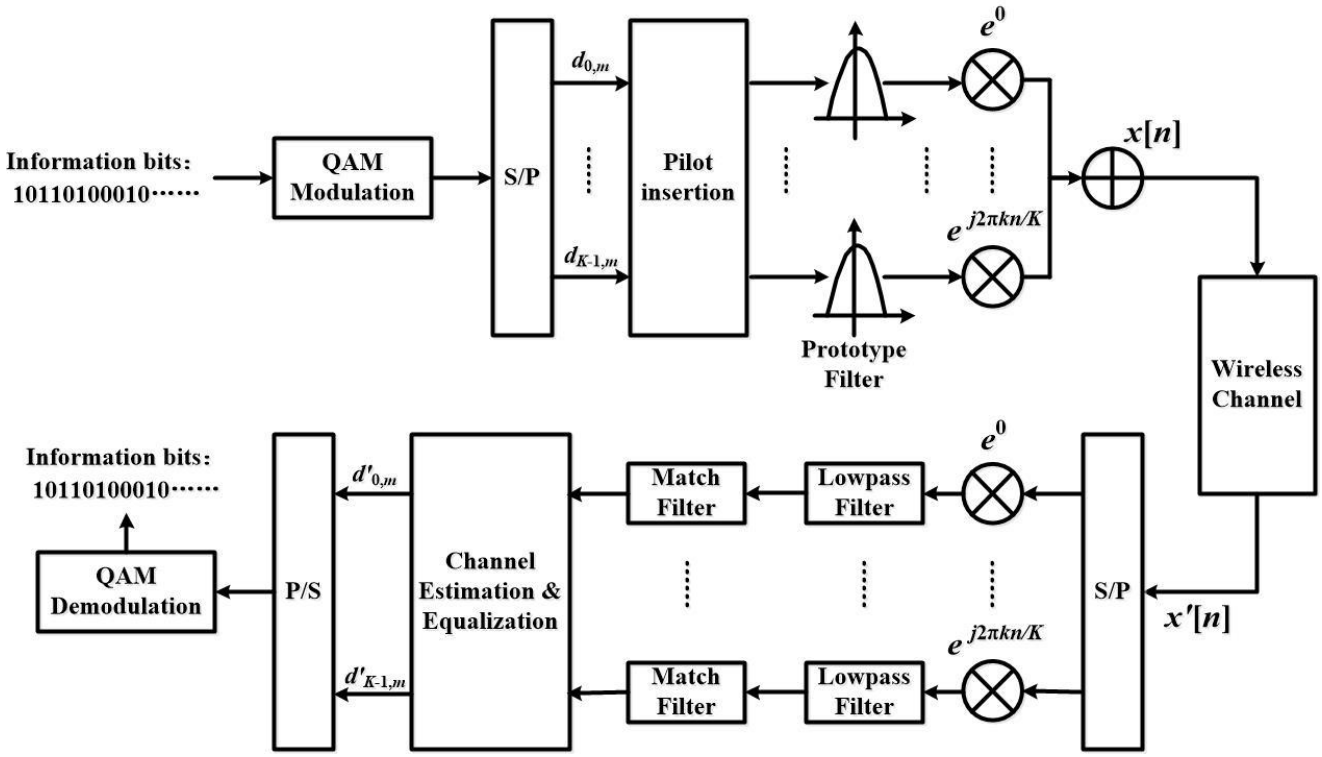

Fig. 1. Information transmission block diagram of the GFDM system.

$$A = \left[g_{\{0,0\}}g_{\{1,0\}} \cdots g_{\{K-1,0\}}g_{\{1,0\}} \cdots g_{\{K-1,M-1\}}\right] \quad (5)$$

Among them, $g_{k,m} = [g_{k,m}[0]g_{k,m}[1] \ldots g_{k,m}[N-1]]^T$ is a column vector with a length of N. The modulation on each subcarrier is expressed as follows [see Eq. (6)]:

$$x[n] = \sum_{k=0}^{K-1}\sum_{m=0}^{M-1} d_{k,m} \times g[(n-mK)modN]e^{\left\{j\left(\frac{2\pi}{K}\right)kn\right\}} \quad (6)$$

Expanding the above expression, we obtain Eq. (7):

$$x = \sum_{k=0}^{K-1}\sum_{m=0}^{M-1} d_{k,m} \times g_{k,m} \quad (7)$$

In the GFDM system, the time shift is performed in a periodic manner, and the frequency shift is carried out according to the following equation, forming a frequency shift vector [see Eq. (8)]:

$$f_k[n] = e^{j2\pi\frac{k}{K}n} \quad (8)$$

C. Design of Pulse Shaping Filter

An important difference between GFDM and OFDM lies in the prototype filter used for the subcarriers. OFDM employs a rectangular pulse filter, while GFDM uses a non-rectangular pulse filter. The pulse shaping function is given as follows [see Eq. (9)]:

$$g_{\{k,m\}[n]} = g_{m[n]e^{j\left(\frac{2\pi}{K}\right)kn}} = g[(n-mK)_N]e^{j\left(\frac{2\pi}{K}\right)kn} \quad (9)$$

Here,$(\cdot)_N$ denotes the modulo-N operation,$g[n]$ represents the prototype filter, and $g_m[n]$ is the pulse shaping filter for the m-th subsymbol. In this work, the Root Raised Cosine (RRC) filter is used. The time-domain expression of the Root Raised Cosine filter is given as follows [see Eq. (10)]:

$$g(t) = \begin{cases} \frac{1}{T}\left(1+\beta\left(\frac{4}{\pi}-1\right)\right), t=0 \\ \frac{\beta}{T\sqrt{2}}\left[\left(1+\frac{2}{\pi}\right)sin\left(\frac{\pi}{4\beta}\right)+\left(1-\frac{2}{\pi}\right)cos\left(\frac{\pi}{4\beta}\right)\right], t=\pm\frac{T}{4\beta} \\ \frac{sin\left(\frac{\pi t(1-\beta)}{T}\right)+\frac{4\beta t}{T}\cdot cos\left(\frac{\pi t(1+\beta)}{T}\right)}{\pi t\left[1-\left(\frac{4\beta t}{T}\right)^2\right]}, otherwise \end{cases} \quad (10)$$

Here, $T$is the symbol period, $\beta$is the roll-off factor, and $t$is the time variable.

In the GFDM system, there is significant overlap between subcarriers and symbols in the time and frequency domains. The rectangular pulse used in traditional OFDM causes considerable spectral leakage. By applying the RRC filter to shape each subcarrier, better frequency localization can be achieved, adjacent channel interference can be reduced, and asynchronous transmission can be supported. Secondly, the structure of the time-frequency transform filter is given as follows [see Eq. (11)]:

$$g_{k,m}[n] = g[(n-mk)modN] \cdot e^{j2\pi\frac{k}{K}n} \quad (11)$$

Here, $g[n]$ denotes the prototype filter; mK represents the time shift, since there are K samples between every M symbol intervals; $e^{j2\pi\frac{k}{K}n}$ denotes the frequency shift used for subcarrier multiplexing; and $N = KM$ represents the total symbol length.

III. Channel Estimation Method

A. Least Squares Estimation

The Least Squares (LS) estimation algorithm is a basic method used for data fitting and parameter estimation. Its main idea is to find the optimal model parameters by minimizing the sum of squared errors between the observed data and the model-predicted values. In the estimation process, each subcarrier k is fitted individually using the LS method, and the result is obtained as follows [see Eq. (12)]:

$$\hat{h}_k^{LS} = argmin\left|r_{k,1} - p\hat{h}\right|^2 \quad (12)$$

Here, $\hat{h}_k^{LS}$ denotes the LS channel estimate on the k-th subcarrier. k is the subcarrier index, representing the k-th subcarrier in the frequency domain. $r_{k,1}$ is the received signal at the receiver on the k-th subcarrier and the first pilot symbol. p represents the known pilot symbol. $\hat{h}$ denotes the channel coefficient to be estimated.

Ordinary least squares analysis of the observational data yields Eq. (13):

$$\hat{h}_k^{LS} = \frac{p*r_{k,1}}{|p|^2} \quad (13)$$

Here, $p*$denotes the complex conjugate of the pilot symbol p. $|p|^2$ denotes the power of the pilot symbol.

This method uses unit power, which can be simplified to Eq. (14):

$$\hat{h}_k^{(LS)} = \frac{r_{k,1}}{p} \quad (14)$$

Here, (p) represents the pilot symbol.

B. Design of a Two-Dimensional Time-Frequency Block-Based Pilot Structure

In GFDM systems, there is incomplete orthogonality between subcarriers and between time slots. The use of RRC filters causes both inter-subcarrier interference and inter-symbol interference. Therefore, conventional pilot designs are no longer optimal, as they are affected by leakage from neighboring symbols and interference from adjacent subcarriers. To address these issues, a pilot structure is designed in the two-dimensional time-frequency domain. Compared with conventional pilots, the proposed design maintains approximate orthogonality or complementarity in the non-orthogonal time-frequency domain of GFDM, which enhances interference resistance and improves estimation accuracy.

The key of the GFDM system lies in the fact that each "subsymbol-subcarrier" block is obtained by time-shifting and frequency-shifting a prototype pulse filter, resulting in overlapping in both time and frequency domains. Here, the pulses are non-rectangular and not strictly orthogonal. A two-dimensional time-frequency block-based pilot structure, named Composite Time-Frequency Pilot (CTFP), is designed. The CTFP is a composite sequence distributed over multiple time slots on the same subcarrier, weighted by the prototype pulse, and phase-coded within the subcarrier. This pilot structure distinguishes different subcarriers in the frequency domain, with each subcarrier having a unique phase code. In the time domain, the energy is distributed using the GFDM shaping filter (RRC pulse shaping), ensuring that the pilot symbols have the same time-domain characteristics as the data symbols.

In GFDM, the length of each data block is $N = K \cdot M$, where K is the number of subcarriers and M is the number of subsymbols. First, a QPSK pilot symbol is defined as Eq. (15):

$$s_p = \frac{1+j}{\sqrt{2}} \quad (15)$$

Here, s_p is the pilot symbol modulated using QPSK. j denotes the imaginary unit, where $j = \sqrt{-1}$.

In a conventional GFDM system, the pilot symbol for each subcarrier is usually given by Eq. (16):

$$p_{trad} = s_p \quad (16)$$

Here, p_{trad} denotes the pilot symbol in the conventional GFDM system.

Each pilot subcarrier transmits only one complex constant in one time slot, and the pilot power is concentrated at one time-frequency position.

The pilot vector is constructed using the time-domain response of the RRC filter, which reflects the energy of the filter's power distribution in this time slot [see Eq. (17)].

$$w_{CTFP}[m] = \sum_{n=0}^{L-1} |g[(n-(m-1)K) mod L]|^2 \quad (17)$$

Here, $w_{CTFP}[m]$denotes the energy weighting of the CTFP pilot at the m-th time slot. $g[\cdot]$ denotes the time-domain impulse response of the RRC filter. L denotes the filter length or the GFDM block length. m denotes the subsymbol index.

Energy equalization is performed so that the total energy of CTFP pilots is the same as that of traditional pilots for comparison [see Eq. (18)].

$$\alpha = \sqrt{\frac{E_{trad}}{E_{CTFP}}} = \sqrt{\frac{|s_p|^2}{|s_p|^2 \cdot \|w\|^2}} \quad (18)$$

Here, α denotes the energy normalization factor. E_{trad} denotes the total energy of the traditional pilot. E_{CTFP} denotes the total energy of the CTFP pilot. $\|w\|^2$ denotes the energy norm of the weighting vector w_{CTFP}.

Second, a complex exponential phase code is assigned to each subcarrier, yielding Eq. (19):

$$c_k = e^{j\frac{2\pi k}{K}} \quad (19)$$

where, $k = 0, 1, \ldots, K-1$, so that pilots of different subcarriers can be distinguished in the frequency domain.

At the transmitter, the CTFP pilot is constructed, yielding Eq. (20):

$$P_k = s_p \cdot c_k \cdot \alpha w \quad (20)$$

where, s_p denotes the pilot symbol.

Thus, each pilot has time-domain spreading and frequency-domain distinction, a two-dimensional block pilot structure [see Eq. (21)]:

$$CTFP_{pilot} = \underbrace{(time-shaping)}_{w_{CTFP}\alpha} \otimes \underbrace{(freq-phase\ coding)}_{c_k} \quad (21)$$

It is distributed in the time slot of this subcarrier. The amplitude diagram and phase diagram of the pilot internal structure are shown in Fig. 2 and Fig. 3.

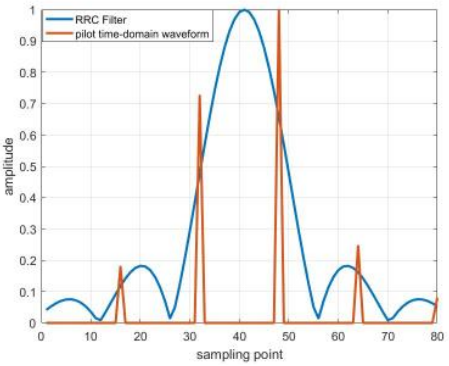

Fig. 2. Comparison of pilot amplitude values and filter waveform.

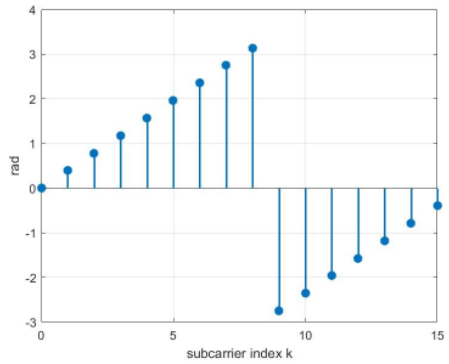

Fig. 3. Variation of the pilot phase.

C. Channel Estimation Method Based on Correlation

To improve the transmission efficiency of channel estimation in the GFDM system and give full play to the great advantages of CTFP in the GFDM system, a channel estimation method based on correlation is proposed on the basis of the traditional Least Squares (LS) estimation. This method is based on the fact that under relatively flat channel conditions, the frequency-domain channel response usually shows strong correlation, so the channel gains of adjacent subcarriers can be regarded as highly correlated. Based on this characteristic, the correlation method reduces the impact of channel estimation error of a single subcarrier by introducing the concept of a subcarrier group. Specifically, the system first performs LS estimation on each subcarrier at the position where CTFP is inserted to obtain the initial channel estimation value. Then, for the k-th subcarrier, its final channel estimation is not directly taken from its own estimation result, but replaced by the estimation result of the reference subcarrier in its corresponding correlated subcarrier group. For example, among subcarriers 1–4, all subcarriers use the estimation value of subcarrier 1 as the channel estimation. Among subcarriers 5–8, the channel estimation value of subcarrier 5 is uniformly adopted, and so on. In this way, while reducing pilot overhead, the system allows time slots without pilot configuration to be used for data transmission, thus utilizing spectrum resources more efficiently and improving the proportion of effective data transmission to a certain extent.

Divide K subcarriers into several groups. In this method, each group has a length of 4. Channel estimation is performed only on the first subcarrier of each group, and the other subcarriers adopt the estimation result of the first subcarrier, that is, use it directly, as shown in Fig. 4.

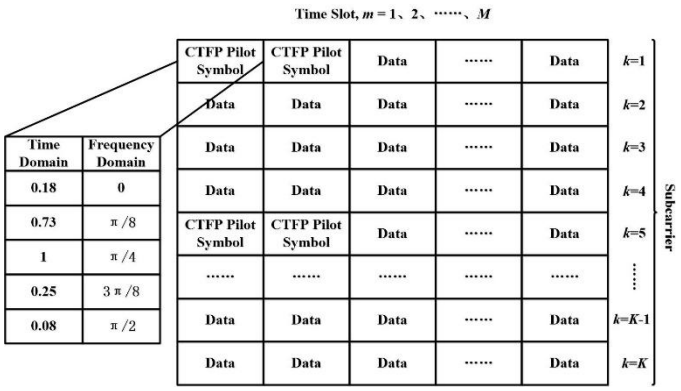

Fig. 4. The CTFP pilot insertion in the GFDM system.

The data block transmitted in a GFDM system is composed of K subcarriers and M subsymbols. Its time frequency structure is characterized by K subcarriers in the frequency domain and M subsymbols in the time domain. The correlation among subcarriers is used by considering the cross-correlation function in the frequency domain. The EPA model in the 3GPP LTE channel model, which refers to the Extended Pedestrian A model, is applied. This model is used for low-speed movement, such as pedestrians in typical indoor or micro cell environments.

The time-domain random multipath channel is represented by the impulse response $h(\tau)$, where τ is the delay. The power delay profile [Power Delay Profile (PDP)] is given as Eq. (22):

$$P(\tau) = \mathbb{E}[|\, h(\tau)\,|^2] \quad (22)$$

The frequency domain channel frequency response is Eq. (23):

$$H(f) = \int_{-\infty}^{\infty} h(\tau) e^{-j2\pi f\tau} d\tau \quad (23)$$

The cross correlation at two different frequencies f_1 and f_2 is expressed as Eq. (24):

$$R_H(f_1, f_2) \triangleq \mathbb{E}[H(f_1)H^*(f_2)] \quad (24)$$

By substituting the definition of $H(f)$ and using the stationarity assumption, that is, the delay components in the time domain are uncorrelated and $E[h(\tau)h^*(\tau')] = 0$ when $\tau \neq \tau'$, and equal to $P(\tau)$ when $\tau = \tau'$, we can obtain Eq. (25):

$$R_H(f_1, f_2) = \int_{-\infty}^{\infty} P(\tau) e^{-j2\pi(f_1-f_2)\tau} d\tau \quad (25)$$

Let the frequency difference be $\Delta f = f_1 - f_2$ .Then the autocorrelation function only depends on Δf [see Eq. (26)]:

$$R_H(\Delta f) = \int_{-\infty}^{\infty} P(\tau) e^{-j2\pi(f_1-f_2)\tau} d\tau \quad (26)$$

The normalized correlation coefficient, which gives the correlation between the two frequency points, is complex-valued. By applying the Fourier transform to the PDP, it is expressed as Eq. (27):

$$\rho(\Delta f) = \frac{R_H(\Delta f)}{R_H(0)} = \frac{\int P(\tau) e^{-j2\pi\Delta f\tau} d\tau}{\int P(\tau) d\tau} \quad (27)$$

The magnitude $|\rho(\Delta f)| \in [0,1]$ describes the strength of the correlation between the frequencies. When $|\rho|$ is close to 1, the frequency domain response is highly correlated under this frequency offset.

If the PDP is a set of discrete multipath components as in the EPA model, the explicit expression of the discrete taps is Eq. (28):

$$P(\tau) = \sum_{n=0}^{N-1} p_n \delta(\tau - \tau_n), p_n \geq 0 \quad (28)$$

We obtain Eq. (29):

$$\rho(\Delta f) = \frac{\sum_{n=0}^{N-1} p_n e^{-j2\pi\Delta f\tau_n}}{\sum_{n=0}^{N-1} p_n} \quad (29)$$

According to Eq. (30):

$$\Delta f = m\Delta f_{\mathrm{sc}} \quad (30)$$

Here, m is the subcarrier index difference, and Δf_{sc} is the subcarrier spacing.

We obtain Eq. (31):

$$\rho(m) = \frac{\sum_n p_n e^{-j2\pi m\Delta f_{\mathrm{sc}}\tau_n}}{\sum_n p_n} \quad (31)$$

When $\omega = 2\pi\Delta f$ is small, the characteristic function can be approximated using a Taylor series expansion [see Eq. (32)]:

$$\rho(\Delta f) = \mathbb{E}[e^{-j\omega\tau}] \approx 1 - j\omega\mu_\tau - \frac{\omega^2}{2}\mathbb{E}[\tau^2] + O(\omega^3) \quad (32)$$

Here, $\mu_\tau = E[\tau]$. Then Eq. (33):

$$|\rho(\Delta f)|^2 \approx 1 - \omega^2 \mathrm{Var}(\tau) + O(\omega^3) \quad (33)$$

By taking the second-order approximation, we obtain Eq. (34):

$$|\rho(\Delta f)| \approx \sqrt{1 - \omega^2 \mathrm{Var}(\tau)} \approx 1 - \frac{\omega^2 \mathrm{Var}(\tau)}{2} \quad (34)$$

Therefore, to require $|\rho| > 0.9$, that is, the magnitude greater than 0.9, the approximate condition is Eq. (35):

$$1 - \frac{\omega^2 \mathrm{Var}(\tau)}{2} > 0.9 \Rightarrow \omega^2 \mathrm{Var}(\tau) < 0.2 \quad (35)$$

By substituting $= 2\pi\Delta f$, we obtain Eq. (36):

$$\Delta f < \frac{1}{2\pi}\sqrt{\frac{0.2}{\mathrm{Var}(\tau)}} \quad (36)$$

Here, $\mathrm{Var}(\tau)$ is the delay variance of the PDP.

By substituting the above values, it can be seen that for $0 \leq \Delta f \leq 2$ MHz, the correlation between subcarriers is always greater than 0.9. This indicates that under the EPA channel conditions, the frequency domain correlation is always higher than 0.9, and channel estimation methods based on correlation characteristics have practical application value.

In spatially correlated channels, under the GFDM framework, the channel responses of two users in the time frequency domain, denoted as $h_1(t,f)$ and $h_2(t,f)$, exhibit spatial correlation. The cross-correlation function between them can be defined as Eq. (37):

$$R_{h_1h_2}(\Delta t, \Delta f) = \mathbb{E}[h_1(t,f)h_2^*(t-\Delta t, f-\Delta f)] \quad (37)$$

Since the support set Ω is the same, that is, $\Delta t \approx 0, \Delta f \approx 0$. By processing the above definition and performing normalization, the expression can be rewritten as shown in Eq. (38):

$$\rho(d) = \frac{\mathbb{E}[\iint_\Omega h_1(t,f)h_2^*(t,f)dtdf]}{\sqrt{\mathbb{E}[|h_1|^2]\mathbb{E}[|h_2|^2]}} \quad (38)$$

Because the support set Ω is identical, the double integral in the above equation can be simplified to a summation over the same set of propagation paths, as given in Eq. (39):

$$\rho(d) = \frac{\mathbb{E}\left[\sum_{p=1}^{P} h_{1,p}h_{2,p}^*\right]}{\sqrt{\mathbb{E}[\sum_p |h_{1,p}|^2]\mathbb{E}[\sum_p |h_{2,p}|^2]}} \quad (39)$$

Assuming that different propagation paths are uncorrelated with each other and that the power of each path is normalized, the above expression can be further simplified as Eq. (40):

$$\rho(d) = \frac{1}{P}\sum_{p=1}^{P} \rho_p(d) \quad (40)$$

where, $\rho_p(d) = \mathbb{E}[h_{1,p}h_{2,p}^*]$ denotes the spatial correlation coefficient of the complex gain on the p-th path.Assume that there are many scattering components arriving at the receiver from different angles θ, and the angular distribution of these components is given by $p(\theta)$. Then, for the two user case, the correlation of the channel complex gains can be described by the classical Clarke model as Eq. (41):

$$\rho_p(d) = \int_{-\pi}^{\pi} P(\theta) e^{-j\frac{2\pi d}{\lambda}\sin\theta} d\theta \quad (41)$$

where, λ is the wavelength and d represents the distance between the two users.Assume that the angles of arrival follow a Gaussian distribution with mean $\theta_0$and standard deviation σ_θ. The corresponding angular power spectrum is given in Eq. (42):

$$p(\theta) = \frac{1}{\sqrt{2\pi}\sigma_\theta}\exp\left(-\frac{(\theta-\theta_0)^2}{2\sigma_\theta^2}\right) \quad (42)$$

Based on the above spatial correlation analysis, under the EPA channel model, when the distance between communication terminals is small, the spatial correlation coefficient of the channel can reach 0.9 or even higher.

Perform channel estimation on the first subcarrier of each group [see Eq. (43)]:

$$\hat{h}_k = \frac{P_k^H r_k}{\|P_k\|^2} \tag{43}$$

Then, directly use the estimated values for other subcarriers [see Eq. (44)]:

$$\hat{h}_k = \hat{h}_{ref} \tag{44}$$

IV. Simulation Experiments and Analysis

A. Experimental Conditions

To evaluate the performance of the proposed correlation-based channel estimation method, Monte Carlo simulations were conducted using MATLAB software. The main parameter settings are presented in Table I.

TABLE I. Parameter Settings

Parameters	Values
Number of subcarriers, K	16、100
Number of subsymbols, M	5、8、100
Modulation scheme	QPSK
Filter	Root-Raised Cosine（RRC）
Filter roll-off factor	0.3
Channel model	AWGN channel
Pilot symbols	QPSK unit power symbol $\frac{1+j}{\sqrt{2}}$
Pilot spacingΔ	2、4、6、8
SNR range	0-30 dB with a step of 5 dB
Number of Monte Carlo Simulations	1000

In the simulation figure, the x-axis represents the signal-to-noise ratio (SNR), and the y-axis represents the mean square error (MSE), which can reflect the accuracy of channel estimation and is defined as Eq. (45):

$$MSE = \frac{1}{K}\sum_{k=0}^{K-1}\left|\widehat{h_k} - h_k\right|^2 \tag{45}$$

B. Information Rate Analysis

It is assumed that the channel is a flat Rayleigh fading channel, in which the channel coefficient within one GFDM block is a complex constant h that does not change with time or frequency. The receiver is affected only by additive white Gaussian noise. Under this assumption, the correlation between subcarriers remains higher than 0.9, which allows the study of the impact of different pilot structures on the data rate. The total number of symbols, that is, the product of time slots and subcarriers, is defined as Eq. (46):

$$N_{tot} = K \cdot M \tag{46}$$

If pilots occupy N_pilot symbols, the number of symbols available for data is Eq. (47):

$$N_{data} = N_{tot} - N_{pilot} \tag{47}$$

Each symbol carries b = $\log_2$ (modulation order) bits, and the information rate is Eq. (48):

$$R = \frac{N_{data}}{N_{tot}} b \tag{48}$$

The unit is bit/s/Hz/subcarrier.

For existing methods, we obtain Eq. (49):

$$N_{pilot} = K \tag{49}$$

For the correlation-based method, with a spacing of s, we can obtain Eq. (50):

$$N_{pilot} = \frac{K}{s} \tag{50}$$

As shown in Fig. 5 and Fig. 6, these figures present a comparison of the information rate between the existing method and the correlation-based method with pilots placed at different subcarrier spacings. Assuming a sampling rate of 1 MHz and a duration of 0.016 ms per time slot, it can be seen from the figures that the information rate gradually increases with the growth of the number of time slots (M) in the GFDM system. Compared with the existing method, the transmission rate of the correlation-based method is higher. This is because the first time slot of each subcarrier in the existing method is occupied by pilots, leading to low spectrum efficiency. As M increases, the pilot ratio gradually decreases, and the rate increases accordingly. The information transmission performance is improved by about 14.97% compared with the existing method when the time slot width is 0.096 ms, about 10.74% when the time slot width is 0.128 ms, and about 2.59% when the time slot width is 0.48 ms. For the correlation-based estimation method, only one pilot is allocated to each group of subcarriers, so the pilot overhead is much lower than that of the existing method. Thus, its rate is significantly higher under all time slot conditions. This result indicates that the correlation-based method has more advantages in terms of the system's information transmission rate.

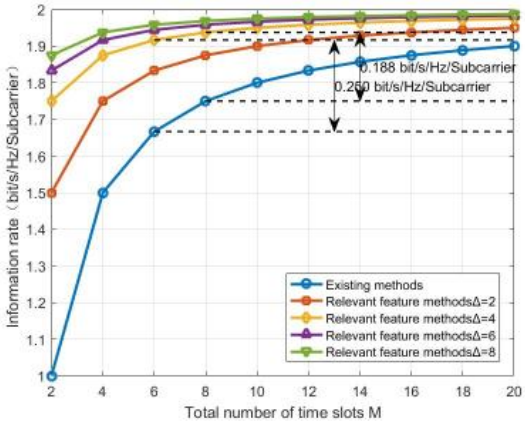

Fig. 5. Comparison of information rate in the GFDM system (K=16).

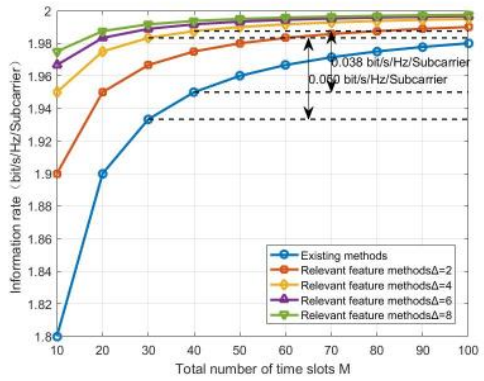

Fig. 6. Comparison of information rate in GFDM system 2 (K=100).

C. Channel Estimation Mean Square Error Performance Analysis

As shown in Fig. 7, the mean square error (MSE) of both the existing method and the correlation-based method decreases with the increase of signal-to-noise ratio (SNR). In terms of channel estimation methods, the existing method has better MSE performance. This is because the correlation-based method uses grouped references, which reduces the number of pilots. Adjacent subcarriers use the same channel estimation result, leading to accuracy loss. In terms of pilot design, it can be clearly seen that the CTFP pilot design has stronger anti-interference capability and better MSE performance. This is because the pilot design combines the characteristics of the time-frequency domain and the prototype filter, improving anti-interference capability. Thus, it can be concluded that the existing method is better in estimation accuracy, while the correlation-based method is more suitable for use under low overhead requirements. Moreover, the CTFP pilot structure has better performance than the traditional pilot structure.

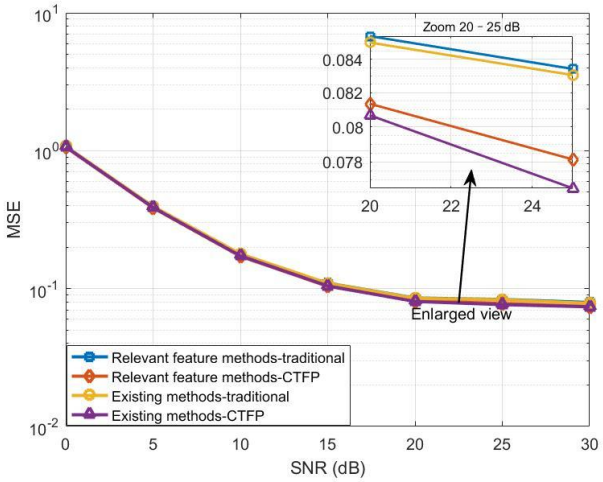

Fig. 7. Comparison of MSE in the GFDM system.

As shown in Fig. 8, the impact of inter-subcarrier channel correlation on the correlation-based method is analyzed. When $\alpha = 0$ (i.e., inter-subcarriers are completely independent), the performance is the worst. This is because the channel differences within each group are large, and a single reference pilot cannot effectively represent other subcarriers. As α increases, the inter-subcarrier channel correlation becomes stronger, and the estimation performance of the correlation-based method gradually improves. When α is close to 1, the MSE curve decreases significantly. This indicates that under high correlation, the correlation-based method can well represent the channel of the entire group of subcarriers, and its estimation performance is close to that of the existing method. Thus, the correlation-based method is more suitable for application in channel environments with strong frequency-domain correlation, while its performance deteriorates significantly in scenarios with severe frequency-selective fading.

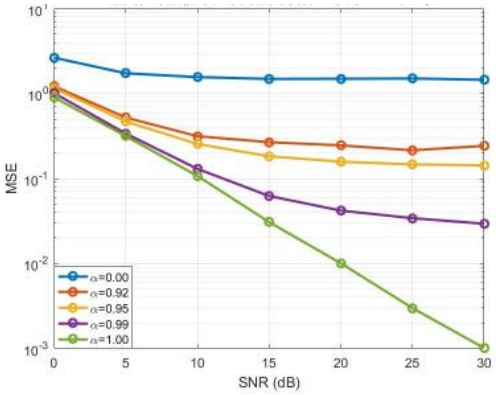

Fig. 8. MSE curves of relevant methods under different correlation coefficients.

D. System Bit Error Rate (BER) Performance Analysis

As shown in Fig. 9, with the improvement of signal-to-noise ratio (SNR), the bit error rate (BER) of both the existing method and the correlation-based method decreases. The overall trend in the figure is that as SNR increases, the BER of both methods decreases exponentially. That is, the bit error rate decreases significantly when channel quality improves. Among them, the BER curves of the two methods almost coincide with only slight differences. The local enlarged view shows the region of 20-25 dB, where four curves are very close. Overall, the BER performance of the two methods is very similar. This is because the channel conditions are relatively flat and the correlation of subcarriers is adopted, so the performance of the existing method and the correlation-based method is quite similar.

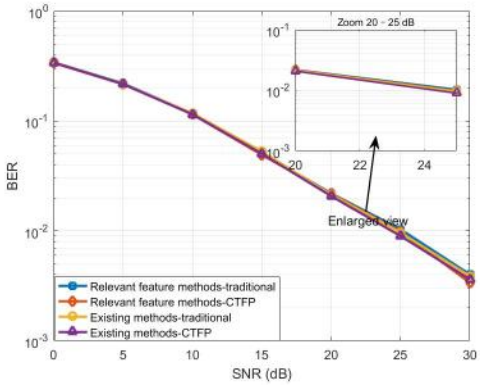

Fig. 9. Comparison of BER performance in the GFDM system.

V. Discussion

The channel estimation method for GFDM systems based on correlation characteristics is mainly suitable for the EPA (Extended Pedestrian A) channel model. This model corresponds to indoor communication scenarios with low speed or static terminals and has strong practical and engineering significance. For example, in typical application scenarios such as the Internet of Things and smart home systems, multiple indoor communication terminals access the same local area network at the same time, where the geographic locations of these terminals are close to each other. These terminals are usually static or move at a low speed, and their channels show strong correlation in the time, frequency, and spatial domains. Existing channel estimation methods based on correlation characteristics and pilot reduction mainly rely on the assumption of frequency domain correlation. Compared with these methods, the proposed method further considers practical application scenarios and introduces spatial correlation on the basis of frequency domain correlation. As a result, the proposed method can improve channel estimation performance and reduce pilot overhead in specific scenarios. Fig. 10 shows the practical application scenario of a channel estimation method for GFDM systems based on correlation and CTFP pilots.

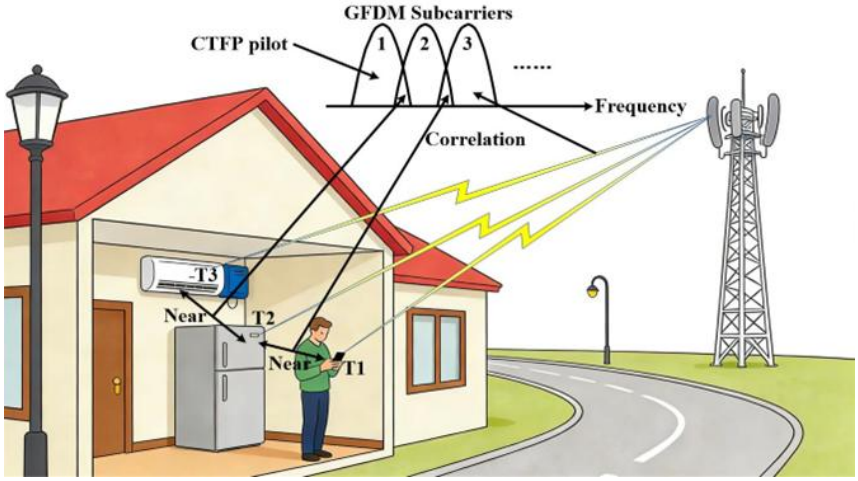

Fig. 10. Practical application scenario of a channel estimation method for GFDM systems based on correlation and CTFP pilots.

However, the GFDM channel estimation method based on correlation characteristics also has certain limitations. This method strongly depends on the correlation of terminals in the frequency and spatial domains. Therefore, in channel environments that are wide, where terminals are sparsely distributed and channel correlation is weak, the performance of this method will significantly degrade, and it may even become unsuitable. In addition, in high mobility scenarios targeted by Orthogonal Time Frequency and Space (OTFS) systems, the time variation of the channel becomes much stronger. In such cases, the correlation assumption is difficult to satisfy, and this type of channel estimation method cannot be effectively applied.

VI. Conclusion

Traditional channel estimation methods for GFDM systems rely on adding more pilot sequences, thus reducing the information transmission rate. To address the above problem, a correlation-based channel estimation method is proposed, and a two-dimensional block pilot sequence based on time domain and frequency domain is designed. This method utilizes the correlation between subcarriers, thus reducing the time slot overhead of pilot resources. Simulation results show that under the premise of the same total time overhead, the mean square error (MSE) and bit error rate (BER) performance of the proposed correlation-based channel estimation method are basically consistent with those of the existing method. However, the information transmission performance is improved by about 14.97% compared with the existing method when the time slot width is 0.096 ms, about 10.74% when the time slot width is 0.128 ms, and about 2.59% when the time slot width is 0.48 ms. This result indicates that when the system is sensitive to time-slot resources, the channel estimation method based on correlation can significantly improve transmission efficiency. It is particularly advantageous in high-density multi-carrier communication scenarios. Simulation experiments verify the reliability of the above method. This research result can provide theoretical support for the design and implementation of GFDM transmission systems in the future. The pilot structure of the correlation-based channel estimation method exhibits better channel estimation performance when the correlation between adjacent subcarriers is strong. In the future, further research is needed to study accurate channel estimation methods when the correlation is weak. This method has potential application value in future GFDM systems, as well as in new multi-carrier wireless communication systems such as 5G and 6G. Its low pilot overhead and high transmission efficiency make it suitable for various scenarios, including the Internet of Things, large-scale MIMO, vehicular networks, and low-latency communications. By further optimizing the pilot design and channel estimation algorithm, it is possible to achieve higher data throughput and better spectrum utilization while maintaining system robustness.

ForenVoice-Secure: Robust and Privacy-Aware Audio Data Mining for Forensic Speaker Identification

Mubarak Albathan
College of Computer and Information Sciences,
Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh, Saudi Arabia

***Abstract*—Speech is now routine evidence in criminal investigations, but forensic audio rarely matches the clean assumptions of standard speaker recognition. Clips are short, noisy, codec-compressed, and channel-mismatched, and they are increasingly exposed to replay and synthetic speech manipulation. Therefore, the cast criminal voice identification is forensic audio data mining, aiming to extract a stable identity structure from heterogeneous and potentially adversarial evidence, while respecting operational and privacy constraints. In this study, a novel ForenVoice-Secure system is proposed, a unified pipeline that combines robust representation learning, spoof-aware decisioning, and privacy-preserving training. Audio is mapped to log-Mel spectrograms and encoded with a CNN, while an LSTM aggregates temporal identity cues from irregular utterances. Robustness is improved through multi-task learning (identity + spoof), adversarial training, and spectro-temporal consistency checks for replay/deepfake artifacts. Privacy is addressed using federated learning, keeping raw recordings local and sharing only model updates. Experiments on VoxCeleb2, ASVspoof 2021, and a forensic-style speaker comparison corpus achieve statistically significant performance gains, 98.43% mean identification accuracy with strong class-balanced performance (macro F1 = 98.10%, precision = 98.22%, recall = 98.01%) and statistically significant gains over strong baselines across repeated folds (F1: $p = 8.0 \times 10^{-4}$; precision: $p = 1.1 \times 10^{-3}$; recall: $p = 9.0 \times 10^{-4}$). The model remains lightweight (≈4.3M parameters, ≈1.2 GFLOPs per 3 s), enabling near real-time inference with modest overhead from consistency checks (<6%). Overall, ForenVoice-Secure provides a compact and reproducible forensic audio data mining framework for scalable, spoof-resilient, privacy-aware law-enforcement identification.**

I. Introduction

Voice evidence has gained significance in the modern criminal investigation. Intercepts of telephones [1], emergency calls, body-worn cameras, covert surveillance, and open-source multimedia material are a regular part of the case files [2]. However, speech is not often gathered in regulated circumstances as it is in the case of fingerprints or DNA. The transcriptions of forensic recordings tend to be brief, noisy, encoded with unknown codecs, and recorded with unknown devices [3]. Consequently, the process of recognition of a speaker with audio evidence is a still technically challenging and methodologically controversial one [4]. Although automatic speaker recognition has improved quickly within the last decade, most of the development has been fueled by benchmarks that are based on comparatively clean data and cooperative users, which is not the case in forensic practice [5].

Early speaker recognition systems were based on generative statistical models including Gaussian mixture models based on universal background models and subsequently i-vectors representations [6]. These methods provided interpretable probabilistic descriptions, but were susceptible to channel dissimilarities as well as shorter utterances, which are prevalent in forensic content. Deep learning has led to a transition to discriminative embedding learning [7], where convolutional and time-delay neural networks yielded fixed length representations of speakers which significantly enhanced performance in uncontrolled conditions [8], [9]. Megabanks like VoxCeleb facilitated this development as they allowed models to learn speaker identity using varied, natural-world samples [10]. Nevertheless, even with these gains, most systems have been optimized to either verify or identify in benign environments but not evidentiary analysis.

Forensic audio is a special category of challenges that extends beyond accuracy on clean benchmarks. Recording can include a speaker overlap, incomplete utterances, or high levels of environment sampling and investigators might not have many samples of reference of a suspect [11]. In addition, the legal environment requires the high level of performance but also the strength, stability, and reproducibility of the conclusions. Recent debates within forensic science point to the fact that speaker recognition must be considered as evidence presentation in uncertainty instead of certain identity matching [12]. This view encourages the replacement of voice biometrics as a limited technical issue with formulating it as an audio data mining in forensics, whereby meaningful identity trends ought to be mined out of non-homogeneous and noisy data.

The threat environment has also gone an extra mile with the fast development of speech synthesis and voice conversion technologies. Current text-to-speech and neural voice cloning systems are able to produce a very natural speech which can

emulate particular speakers with little reference data [13], [14]. These advances have grave consequences on the field of forensic voice analysis where replay attacks and synthetic speech can also fool both human and automatic voice analyzers. This has been observed in community-based challenges like the ASVspoof challenges which have shown that a significant number of speaker recognition pipelines are susceptible to such attacks, especially when the spoofed audio is conveyed using realistic channels or compressed formats [15], [16]. As a result, anti-spoofing is not a peripheral feature anymore, but rather a necessity of any voice biometrics system that is supposed to be used in the forensic or law-enforcement sector [17].

Privacy and data control have also gained significant relevance, in addition to security. Voice data is data that is personal in nature and can be used to disclose sensitive information that is not pertinent to identity such as health, emotional status or demographic features. In crime investigations, there is a large amount of legal and ethical restriction to the dissemination and centralization of raw audio evidence between agencies. Federated learning (FL) exemplifies privacy-preserving approaches to learning; thus, it is getting increasing interest as it allows collaborative training of models without sharing data [18]. Although the concept of federated approaches has been investigated within a generic speech and biometric context, their adoption into forensic voice identification pipelines is not mostly developed.

Combined, these facts indicate that there is a mismatch between the state-of-the-art-work on speaker recognition and the needs of forensic voice analysis. Degradation resistance, spoofing resistance, and privacy-conscious deployment are frequently dealt with as a single component, but not in a coherent set of tools. In this study, a gap is filled by proposing ForenVoice-Secure, a voice-focused forensics-enhanced analytics system, which sees criminal identification as a safe audio data mining challenge. The proposed method will be based on deep representation by learning, explicit anti-spoofing mechanisms, adversarial robustness, and federated training to deliver useful operation on real evidentiary recordings without violating operational and legal limitations. The research, by conducting the overall assessment of the three terms speaker identification, spoof detection, as well as degraded conditions, will bring voice biometrics closer to a viable, defendable application in contemporary law enforcement.

A. Research Highlights

This work makes several contributions to the field of forensic voice biometrics.

- It reframes criminal voice identification as a forensic audio data mining problem, explicitly accounting for noisy, short, and heterogeneous evidence rather than assuming clean verification conditions.
- It introduces ForenVoice-Secure, a unified framework that combines CNN–LSTM–based speaker representation learning with integrated anti-spoofing mechanisms, including adversarial training and spectro-temporal consistency analysis, to improve robustness against replay and deepfake attacks.
- It incorporates federated learning to address privacy and data-governance constraints in law-enforcement settings, enabling collaborative model training without centralizing raw audio evidence.
- It provides a statistically grounded evaluation across multiple datasets, demonstrating significant improvements in accuracy, F1-score, precision, and recall under degraded and adversarial conditions, while maintaining practical computational efficiency for deployment.

B. Paper Organization

The rest of the study is structured in the following way: Section II discusses related literature in speaker recognition, forensic voice analysis, spoofing and deepfake detection and privacy-preserving biometric learning. Section III describes the proposed ForenVoice-Secure approach, such as signal modelling, feature selection, network design, security, and federated training. Section IV explains about the datasets, protocols used in the experiment and measures of assessment. Section V shows the experimental findings and discussions along with the statistical significance analysis and the computational complexity in Section VI. Lastly, Section VII summarizes the study and provides limitations and directions of future research.

II. Literature Review

The recent work makes it rather apparent that the state of modern forensic and security analytics is in a utility versus privacy tension particularly when deep models are at stake. A good example here is the neural extraction of features in acoustic sensor networks, where representations constructed to perform sound classification were demonstrated to leak speaker-specific information and speaker recognition attacks could be performed on the representation in the event they were intercepted [19]. The authors react by suggesting a variational and information-limiting feature extractor that maintains the trusted task and activates speaker identity leakage, but they show resistance to a strong x-vector attacker [19]. The above reasoning is related to more general privacy-sensitive media analytics in which the query protection is not solely of interest but also the fact that the query protection can be achieved with approximately matching at scale. A private media search architecture is a system that attains [20] sublinear computation and communication on public databases and shows privacy-preserving face recognition at large speedups, indicating that privacy and practicality do not necessarily require each other [21]. A similar privacy conscious data use is also reflected in another research study on email visualization: anonymization and aggregation may decrease identifiability, and yet perceived research utility may still be maintained, a good lesson that privacy controls are not mutually exclusive with analytic usefulness when carefully designed [22].

Back on the security front, various researches highlight the use of lax operational arrangements and human actions by attackers. An example is phishing, which is a relatively cheap, but impactful, attacker strategy, and a privacy-conscious detector framework with a specific taxonomy has been suggested to identify various current phishing techniques,

particularly in an IoT-saturated environment. Forensics in cloud environments are often log-centric; thus, the emphasis of the work has been on generating evidence in a scalable way. A cloud forensic expert-system architecture involves the narrowing of attacked areas in huge logs with the help of fuzzy data mining and the subsequent narrowing with the help of AI-based analysis to produce evidence that is less difficult to provide in a formal way [23]. Other work around behavior analysis using log mining contends that manual analysis is not scalable to the size of contemporary data volumes and suggests the use of automated user behavior mining of networked systems, driven in part by the necessity of fighting computer crime more efficiently [24]. These log-based views are applicable since they view forensic investigation as a data mining process: filter, prioritize and explain, as opposed to detect.

The field of audio forensics, on the other hand, encompasses both anti-forensic resistance as well as tamper detection. An SNR-sensitive digital audio tampering forensics system enhances the benefit of an electric network frequency extraction with an improved chirp Z-transform and then identifies anomalies with a dual-sampling isolation forest, with benefits of both extraction and outlier detection in a noisy environment [25]. Anti-forensic attacks are now also a concern. Attacks based on dereverberation can selectively weaken environmental signature splicing detection, and countermeasures that are grounded in rich features and machine learning can easily identify such anti-forensic processing, and indicate a new arms race between forensic detectors and attackers [26]. Extensive surveys keep laying audio-video forensics as one of the key areas of digital investigation, as the recorded media is frequently presented as court-related evidence [27].

Another and rather intriguing vein is the one that actually goes outside the voice of the speaker and seeks context within the audio scene. It has also been suggested to extract and categorize the background noise automatically and communicate information about the environment based on recordings with the use of complex noise mixtures and without much identity testing, even mixed speech, as an expansion of what can be meant by the term of forensic audio evidence [28]. Reproducible forensic processes are also getting interest: an open-source modular system enables practitioners to mix up enhancement, VAD, and ASR models, visualize features, and export repeatable pipelines, which is important when forensic conclusions should be auditable instead of merely valid [29]. Lastly, the field of forensic practice is changing with infrastructure modifications like cloud computing. Conventional digital forensic models are also under consideration and modification to accommodate the issues of preservation and acquisition peculiar to cloud investigations, wherein data can be distributed and challenging to acquire [30]. On the signal level, voice evidence can still be susceptible to noise, reverberation, quantization and disguise. Attempts at increasing its integrity and intelligibility under phonemic confusion suggest that enhancement of voice analysis in the forensics field is an inherent precondition [31].

Collectively, this literature is indicative of the following, as explained in Table I: 1) forensic evidence can be handled as a data mining problem under heterogeneity and scale [23], [24]; 2) robustness must be designed to explicitly address the phenomenon of degradation and active anti-forensic behavior [25], [26], [31]; and 3) privacy preservation must be engineered into the pipeline, since deep representations can reveal identity accidentally [19], whereas practical privacy preserving analytics is becoming a viable option at scale [21], [22].

TABLE I. A COMPARISON TABLE WITH FEWER COLUMNS, FOCUSING ONLY ON WHAT IS MOST RELEVANT TO FORENVOICE-SECURE

Study	Focus & Scenario	Core idea	Key limitation vs. Our work
[19]	Privacy risks in deep audio features for sound classification	Learning a variational feature to suppress speaker-identifiable information	Does not perform forensic speaker identification or spoof-aware evidence mining
[25]	Audio tampering forensics under low-SNR conditions	ENF extraction with ICZT and anomaly detection via isolation forest	Targets tampering detection, not identity mining or spoof-resilient speaker analysis
[26]	Anti-forensic attacks on audio splicing detection	Demonstrates dereverberation-based attacks and ML-based countermeasures	Focuses on splicing artifacts, not joint speaker identification and spoof detection
[29]	Reproducible forensic audio analysis pipelines	Modular, open-source framework for building forensic workflows	Provides tooling rather than a unified, privacy-aware forensic voice model
[31]	Integrity and intelligibility of forensic voice evidence	Speech enhancement, segmentation, and distortion analysis	Improves signal quality but does not address adversarial spoofing or privacy-preserving learning

III. PROPOSED METHODOLOGY

Fig. 1 is the systematic flow diagram that summarizes the proposed forensic voice biometrics pipeline. The development of the criminal voice identification process as the forensic audio data mining, designed to provide consistent identity evidence based on the heterogeneous and possibly manipulated records instead of relying on the presumptions of clean speaker verification, are formulated in this study. VoxCeleb [32] and SpeechTech [33] explicitly define data and threat model based on the nuisance factors (noise, codec compression, channel mismatch, short utterances) and adversarial factors (replay speech and synthetic speech). A CNN is used to encode each recording to speaker-discriminative spectral cues, and an LSTM is used to encode temporal identity structure, each recording is converted to log-Mel spectrograms. Security is incorporated through adversarial training and spectro-temporal consistency tests to decrease the sensitivity of spoof and to label implausible evidence. With federated learning, privacy is achieved by ensuring that raw audio is local and model updates are aggregated. Assessment is multi-axis: performance of identification, resistance to degradations, performance under replay/deepfake conditions, repeated-fold stability, and ablations which eliminate adversarial training, consistency tests, and federation to measure the contribution of each component.

A. Data Gathering

Three complementary corpora were used to collect the data about: 1) large-scale speaker identity variation, 2) explicit threats of spoofing, and 3) forensic-like session variability. To perform large scale identifier of speakers, VoxCeleb2 [32] has been accessed directly on the official Oxford VGG distribution page, where the description of the canonical dataset and download procedure are indicated. VoxCeleb2 consists of more than one million utterances of 6,112 speakers, an official dev/test split of 5,994/118 speakers.

This division is maintained so as to prevent leakage and to ensure that results are consistent with previous speaker recognition literature, where the institutional access policies allow it, also observed is that reproducible scripted ingestion can be facilitated via a dataset-hosted packaging pathways (e.g. a dataset card that reflects the structure of the archive and its metadata files). ASVspoof 2021 [34] (LA/PA/DF) was acquired at the official ASVspoof 2021 post-challenge release page, which contains protocol files (keys) and associated metadata, including the information about bona fide or spoof and condition. The speaker comparison type was forensic-style, and it was applied by FABIOLE [35] to add evidentiary variability, such as session and context variations that are more akin to actual forensic casework (such as environment, channel conditions, and recording situations).

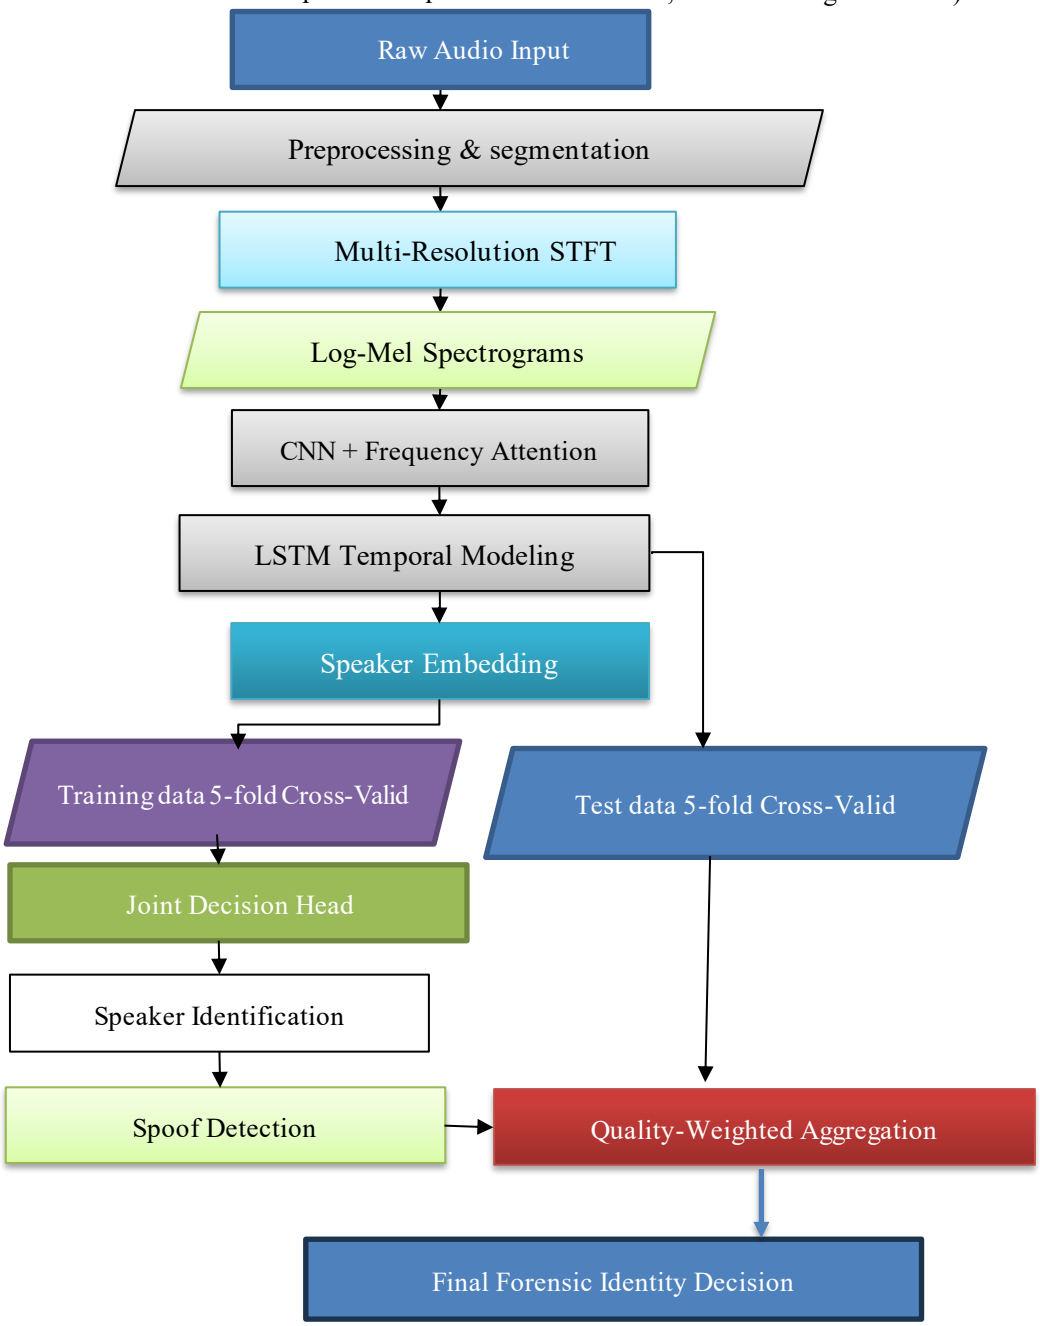

Fig. 1. Systematic flow diagram of the ForenVoice-secure framework.

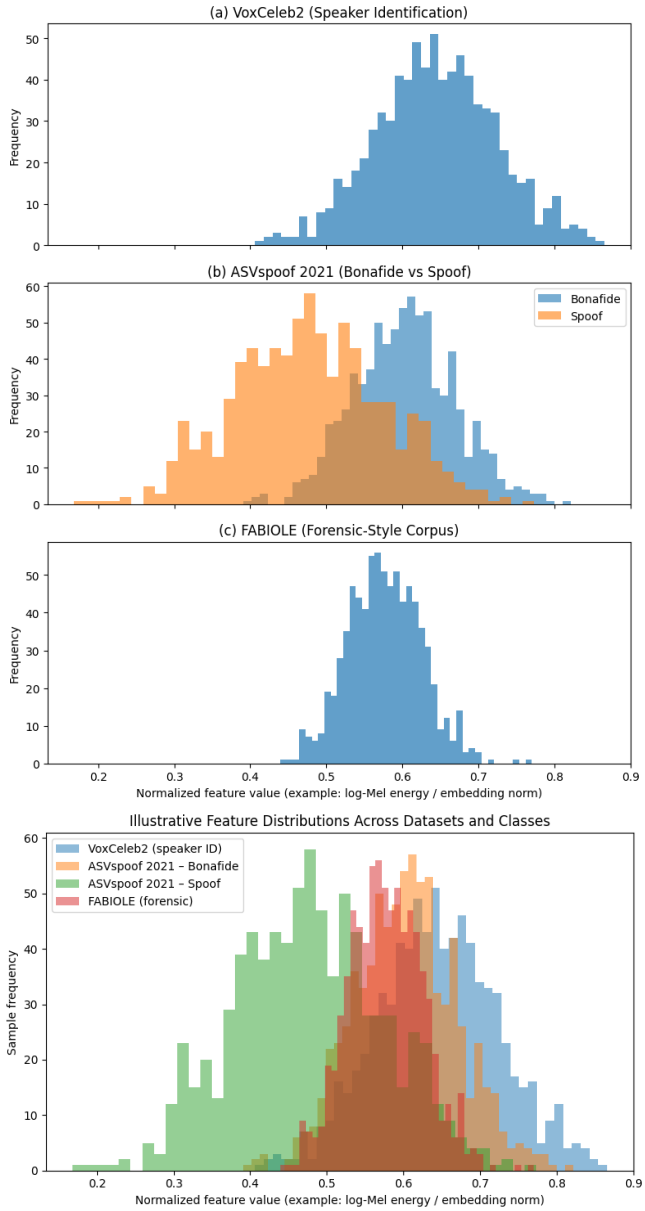

Fig. 2. The figure shows: a) VoxCeleb2: Single distribution for large-scale speaker-ID features, b) ASVspoof 2021: Overlaid bona fide vs. Spoof feature distributions, c) FABIOLE: Single distribution for forensic-style corpus features, and the combined figure illustrates how samples differ across the three selected corpora.

Fig. 2 provides an empirical perspective of the distribution of the learned acoustic features in the three datasets and their variability by class. In VoxCeleb2 [Fig. 2(a)], the wide distribution of speakers and recordings is indicative of a large amount of speaker and recording variability, akin to the case of in-the-wild data. This heterogeneity can be exploited to learn discriminative identity embedding, but again, it raises the intra-speaker variability because of varying environments, microphones, and speaking styles. In ASVspoof 2021 [Fig. 2(b)], bona fide speech contributes to the creation of a distribution that is still somewhat enclosed by VoxCeleb2, whereas the spoofed speech has a more systematically distributed and more scattered appearance. This tendency is aligned with spectral and temporal anomalies caused by replay and synthetic generation and it confirms the need of explicit anti-spoofing goals during representation learning. In comparison, FABIOLE [Fig. 2(c)] has a more concentrated distribution, which corresponds to the conditions of the forensic-style broadcast and longer segments in general. Nonetheless, its feature space is different even when compared to in-the-wild speech and spoofed audio, implying that there is a domain gap that may influence generalization in case it is overlooked. Combined with these distributional variations, this suggests the suggested multi-task and robustness-based design: a realistic forensic voice biometrics system should explicitly model dataset- and class-varying behavior of features, not a uniform homogeneous speech distribution.

B. Preprocessing and Time–Frequency Representation

All audio signals are first standardized to ensure consistency across datasets and recording conditions. Each recording is converted to a single-channel (mono) waveform and resampled to a fixed sampling rate of 16 kHz, which provides sufficient bandwidth for speaker-discriminative information while maintaining computational efficiency. Amplitude normalization is then applied to control dynamic range variations across sources, using peak or RMS normalization to reduce sensitivity to recording gain without suppressing forensic cues.

Silence and non-speech regions are removed using an energy-based voice activity detection procedure. The objective is not aggressive denoising but the exclusion of long inactive segments that would otherwise dilute speaker-relevant information, especially in short forensic utterances. Audio segments shorter than a minimum duration are either discarded or zero-padded to a fixed length to enable batch processing and stable time–frequency representations.

Each preprocessed waveform $x(t)$ is transformed into a time–frequency representation using the short-time Fourier transform (STFT) [36]. Given a window function $w(t)$, window length L, and hop size H, the STFT is computed through Eq. (1) as:

$$X(\tau,\omega) = \sum_{t=0}^{L-1} x(t+\tau H)\, w(t)\; e^{-j\omega t}, \qquad (1)$$

where, τ indexes the frame and ω denotes angular frequency. In our implementation, a Hann window is used with $L = 400$ samples and $H = 160$ samples, balancing time resolution and frequency selectivity for forensic speech analysis. The magnitude spectrum $|X(\tau,\omega)|$ is then projected onto a Mel-scale filterbank to approximate perceptually relevant frequency resolution. Let M denote the Mel filterbank matrix; the Mel-spectral energy is computed by Eq. (2) as:

$$\mathrm{S}(\tau) = \mathrm{M}\ |X(\tau,\omega)|^2. \qquad (2)$$

A logarithmic compression is applied to stabilize variance and emphasize lower-energy components, yielding the log-Mel spectrogram, is defined by Eq. (3) as:

$$\mathrm{F}(\tau) = \log\left(\mathrm{S}(\tau) + \epsilon\right), \qquad (3)$$

where, ϵ is a small constant to avoid numerical instability. The resulting log-Mel spectrograms are optionally mean–variance normalized on a per-utterance or per-batch basis before being fed into the CNN–LSTM [37] backbone. This preprocessing pipeline preserves fine-grained spectro-temporal structure required for speaker discrimination and spoof artifact detection, while maintaining robustness to channel mismatch, noise, and codec-induced distortions commonly present in forensic audio evidence.

Fig. 3 compares representative voice patterns across three classes by showing the input waveform, magnitude spectrogram, and phase-derivative spectrogram for each signal. The bona fide speech exhibits stable harmonic structure and smooth temporal evolution, while the replay-like signal shows spectral coloration, added high-frequency energy, and echo-related banding effects. In contrast, the deepfake-like speech displays smoother spectral envelopes with noticeable non-stationarity caused by amplitude and frequency modulation. These visual differences highlight how replay and synthetic generation introduce characteristic spectro-temporal artifacts that can be exploited by forensic voice analysis and anti-spoofing mechanisms.

C. ForenVoice-Secure Framework

The proposed ForenVoice-Secure framework, as described in Algorithm 1, operates as a unified forensic voice analysis pipeline that transforms raw evidentiary audio into reliable identity decisions under adversarial and privacy-constrained conditions. Audio recordings collected from heterogeneous sources are first segmented and standardized through resampling, amplitude normalization, and voice activity detection, after which multiple short-time Fourier transforms are applied using different window sizes to capture complementary time–frequency resolutions. The resulting representations are converted into log-Mel spectrograms that serve as two-dimensional inputs to the acoustic model.

Algorithm 1: Proposed ForenVoice-Secure Forensic Audio Data Mining Framework (CNN–Att–LSTM with Anti-Spoofing and Federated Learning)

Input: where x_i is raw audio, $y_i \in \{1, \dots, K\}$ is speaker ID, $s_i \in \{0,1\}$ is spoof label (0 bona fide, 1 spoof)
Federated clients $\{\mathcal{D}_c\}_{c=1}^{C}$ (optional, for privacy-aware training)
Output: Case/evidence-level decisions: predicted speaker label $\hat{y}$, spoof risk $\hat{s}$, consistency score $C(x)$, confidence $R(x)$
Step 1: Data acquisition and preprocessing
REPEAT for each recording $x_i \in \mathcal{D}$
  Resample and normalize: $x_i \leftarrow \text{Resample}(x_i)$, Normalize (x_i)
  Voice activity detection: $x_i^{speech} \leftarrow \text{VAD}(x_i)$ and Segment into short utterances: $\{x_i^{(j)}\}_{j=1}^{M_i} \leftarrow \text{Segment}(x_i^{speech}, L, O)$
UNTIL all recordings are processed
Step 2: Step 2: Multi-resolution time–frequency representation
FOR each segment $x_i^{(j)}$ **DO**
  Multi-window STFT: $\{S_w(x_i^{(j)})\}_{w \in \mathcal{W}} \leftarrow \text{STFT}(x_i^{(j)}, w)$ and Convert to log-Mel: $X_i^{(j)} \leftarrow \phi(\{S_w(x_i^{(j)})\}_{w \in \mathcal{W}})(1)$
END FOR
Step 3: Robust representation mining (CNN + attention)
FOR each log-Mel $X_i^{(j)}$ **DO**
  CNN feature extraction: $H_i^{(j)} \leftarrow f_\theta(X_i^{(j)})$ and Frequency attention: $\tilde{H}_i^{(j)} \leftarrow \text{Attn}(H_i^{(j)})$
END FOR
Step 4: Temporal identity modeling (LSTM + pooling)
FOR each segment feature sequence $\tilde{H}_i^{(j)}$ **DO**
  LSTM temporal modeling: $Z_i^{(j)} \leftarrow g_\psi(\tilde{H}_i^{(j)})$ and Embedding pooling: $z_i^{(j)} \leftarrow \text{pool}(Z_i^{(j)})$
END FOR
Step 5: Joint decision heads (identity + spoof)
FOR each embedding $z_i^{(j)}$ **DO**
  Speaker posterior: $\hat{p}(y \mid x_i^{(j)}) \leftarrow \text{softmax}(h_\omega(z_i^{(j)}))$ and Spoof posterior: $\hat{p}(s \mid x_i^{(j)}) \leftarrow \sigma(q_\eta(z_i^{(j)}))$
END FOR
Step 6: Spectro-temporal consistency checking
FOR each segment $x_i^{(j)}$ **DO**
  Consistency score: $C(x_i^{(j)}) \leftarrow \frac{1}{T'-1}\sum_{t=1}^{T'-1} \| z_{t+1} - z_t \|_2^2(11)$
  Consistency flag: $\mathbb{I}_{inc} \leftarrow [C(x_i^{(j)}) > \tau](12)$
  Risk fusion (optional): $R(x_i^{(j)}) \leftarrow \beta\hat{p}(s = 1 \mid x_i^{(j)}) + (1 - \beta)\text{norm}(C(x_i^{(j)}))$
END FOR
Step 7: Robust training objective (multi-task + adversarial)
Multi-task loss: $\mathcal{L}_{mt} = \mathcal{L}_{id} + \lambda\mathcal{L}_{spoof}$
Robust min-max optimization, and Initialize classifier head f(·)
Step 8: Privacy-preserving federated learning
FOR each federated round $r = 1, \dots, R$ **DO**
  Each client ctrains locally on $\mathcal{D}_c$ using Steps 1–7 to obtain $\Theta_c^{(r)}$

30. Server aggregation: $\Theta^{(r+1)} \leftarrow \sum_{c=1}^{C} \frac{n_c}{N} \Theta_c^{(r)}$

END FOR

31. **Step 9: Evidence-level data mining and case-level decision:** Given a case with
32. multiple clips $\mathcal{E} = \{x^{(j)}\}_{j=1}^{M}$: Filter/reweight by risk:
33. $w_j \leftarrow \text{QualityWeight}(R(x^{(j)}), \text{SNR}, \text{duration})$
34. Finally, calculate case-level identity decision
35.

[End ForenVoice-Secure System]

Spectral patterns are learned through stacked convolutional blocks that emphasize local speaker-discriminative cues, while an attention mechanism highlights informative frequency bands and suppresses irrelevant or manipulated components. Temporal dependencies across segments are then modeled using an LSTM to capture identity-consistent dynamics that persist despite noise, compression, or short utterances. During training, adversarial perturbations are injected to improve robustness against replay and synthetic speech, and federated learning is employed to keep raw audio localized while enabling collaborative model optimization. Finally, a decision head jointly performs speaker identification, spoof detection, and spectro-temporal consistency checking, producing evidence-level confidence scores suitable for forensic analysis and law-enforcement decision support.

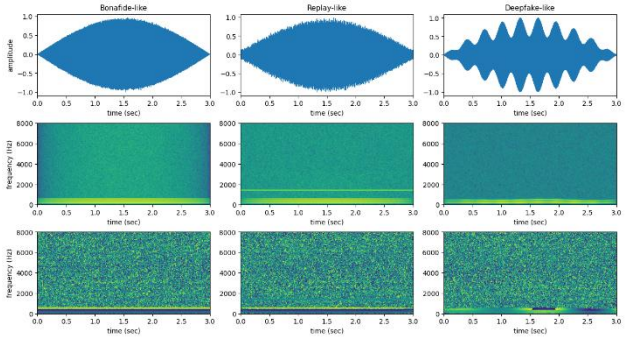

Fig. 3. Waveform and time–frequency patterns for bona fide, replay-like, and deepfake-like speech, illustrating class-dependent differences in spectral structure and temporal behavior.

ForenVoice-Secure treats voice-based criminal identification as a forensic audio data mining problem. The system does not assume a tidy "enroll then verify" setting. Instead, it ingests many fragments from mixed sources, mines identity cues that survive nuisance variability, and simultaneously estimates whether each fragment is trustworthy enough to contribute to an evidentiary decision. This is closer to how real casework unfolds: evidence is incomplete, heterogeneous, and sometimes adversarial. Each observed waveform is viewed as a superposition of the underlying speaker signal, channel effects, environmental noise, and potential manipulation artifacts are calculated by Eq. (4) as:

$$x(t) = (s(t) \times h(t)) + n(t) + a(t) \tag{4}$$

Here, $x(t)$is the recorded audio, $s(t)$ the speaker signal, $h(t)$the channel impulse response, $n(t)$ additive noise, and $a(t)$ attack artifacts such as replay coloration or synthesis fingerprints. This decomposition is not decorative. It directly motivates why the pipeline includes: 1) robustness measures aimed at reducing sensitivity to $h(t)$and $n(t)$, and 2) security measures designed to detect or isolate $a(t)$. To reflect realistic deployment, data acquisition is structured to cover three aspects: a) large speaker diversity, b) forensic-style recording variability, and c) explicit spoof threats. Each example is stored with speaker identity $y$when available, an authenticity label $z \in \{0,1\}$(bona fide vs spoof) when available, and metadata m(channel, codec, duration, and source, if known). Since forensic evidence often arrives as short clips rather than long sessions, each recording is treated as a bag of segments $\{x_k\}_{k=1}^{K}$ extracted using VAD and conservative trimming. Segmenting is practical because it increases training instances without inventing new speakers, and it forces the model to learn from short evidence, where many systems fail.

Preprocessing standardizes sampling rate and amplitude while deliberately avoiding aggressive denoising that could remove forensic cues. A light pre-emphasis may be applied, followed by time–frequency analysis. For each segment, compute the STFT $X(\tau, \omega)$ from Eq. (5) with window length $L$and hop H, and defined as:

$$X(\tau, \omega) = \sum_{t=0}^{L-1} x(t + \tau H)\, w(t)\; e^{-j\omega t}. \tag{5}$$

Because evidentiary recordings vary substantially in speaking rate and channel characteristics, ForenVoice-Secure uses multi-resolution analysis (multiple window sizes) to capture complementary detail rather than committing to a single L. Power spectra $|X(\tau, \omega)|^2$are mapped through a Mel filterbank $M$and log-compressed to produce log-Mel features $F \in \mathbb{R}^{T \times B}$ calculated by Eq. (6) as:

$$F = \log\ (M\ |X|^2 + \epsilon) \tag{6}$$

Log-Mel features behave well for convolutional learning, compress dynamic range, and retain spectro-temporal patterns that replay and synthesis often disturb in subtle but detectable ways.

To reduce sensitivity to the nuisance terms in Eq. (1), controlled augmentation was applied that mimics evidentiary damage. Noise augmentation adds a noise clip $u(t)$scaled to a target SNR is calculated by Eq. (7) as:

$$x_{\text{noisy}}(t) = x(t) + \alpha u(t), \alpha = \sqrt{\frac{P_x}{P_u\, 10^{\text{SNR}/10}}} \tag{7}$$

Channel mismatch is simulated using random impulse responses and band-limiting (telephony-like filtering). Compression artifacts are introduced via codec simulation when feasible. A key constraint is avoided "normalizing away" spoof artifacts: spoofing-related transformations are handled

separately because the goal is to detect manipulation patterns, not wash them out.

Given F, a CNN encoder mines local spectro-temporal patterns correlated with speaker identity. Each convolutional block is modeled by Eq. (8) as:

$$H^{(l)} = \sigma\left(\mathrm{BN}\left(W^{(l)} * H^{(l-1)} + b^{(l)}\right)\right) \quad (8)$$

where, $*$ denotes convolution, BNbatch normalization, and $\sigma(\cdot)$a nonlinearity. Convolutions are used because speaker cues often appear as localized spectral shapes and short transitions, especially in short utterances.

A frequency attention mechanism is applied to emphasize informative bands and down-weight unreliable regions (for example, bands dominated by background noise, codec warping, or suspicious regularities). In practice, this improves stability on degraded evidence and helps suppress components that appear manipulated. Fig. 4 shows the CNN–LSTM backbone diagram. Log-Mel spectrogram inputs are processed through stacked convolutional layers to learn local spectro-temporal speaker cues, followed by LSTM-based recurrent modeling to capture longer-range identity dynamics. The resulting representation is passed through fully connected and dropout layers before feeding into parallel classification heads for speaker identification and anti-spoofing, enabling robust and privacy-aware forensic voice analysis.

CNN outputs are treated as a sequence of frame-level embeddings $U = \{u_t\}_{t=1}^{T}$. Temporal dependencies are modeled using an LSTM as in Eq. (9):

$$h_t, c_t = \mathrm{LSTM}(u_t, h_{t-1}, c_{t-1}). \quad (9)$$

A segment-level embedding e is obtained using attentive pooling to focus on informative frames and calculated by Eq. (10) as:

$$\alpha_t = \frac{\exp\left(v^{\top}\tanh\left(Wh_t\right)\right)}{\sum_{k=1}^{T}\exp\left(v^{\top}\tanh\left(Wh_k\right)\right)}, e = \sum_{t=1}^{T}\alpha_t\, h_t. \quad (10)$$

This matters in forensic audio because segments often include pauses, overlapping, and low-energy regions. Uniform pooling treats those as equally informative, which is rarely true. During training, identity learning is posed as closed-set classification to encourage strong separation among speakers. With classifier weights W_s and logits $o = W_s e$, the softmax probability is defined by Eq. (11) as:

$$p(y \mid e) = \frac{\exp\left(o_y\right)}{\sum_{c=1}^{C}\exp\left(o_c\right)} \quad (11)$$

The identification loss, which is cross-entropy, is defined by Eq. (12) as:

$$\mathcal{L}_{\mathrm{id}} = -\log p(y \mid e) \quad (12)$$

For forensic use, embedding is also usable for verification and retrieval. Verification-style scoring uses cosine similarity, which is defined by Eq. (13) as:

$$\mathrm{score}(e_1, e_2) = \frac{e_1^{\top} e_2}{\|e_1\|\|e_2\|} \quad (13)$$

Security is integrated via spoof classification. With sigmoid output $\hat{z} = \sigma(w_a^{\top} e)$, the spoof loss is defined by Eq. (14) as:

$$\mathcal{L}_{\mathrm{spoof}} = -(z\log\hat{z} + (1-z)\log(1-\hat{z})). \quad (14)$$

The combined multi-task objective is calculated by Eq. (15) as:

$$\mathcal{L} = \mathcal{L}_{\mathrm{id}} + \lambda\,\mathcal{L}_{\mathrm{spoof}} + \beta\,\|\,\theta\,\|_2^2, \quad (15)$$

where, λcontrols the influence of spoof learning and $\beta$is weight decay. The intuition is simple: spoof artifacts can mislead speaker models, so forcing the encoder to be useful for authenticity reduces overfitting to synthetic quirks. Because attackers can adapt to fixed detectors, ForenVoice-Secure adds adversarial training. Perturbed features were used as a gradient-based method (e.g., FGSM) and calculated by Eq. (16) as:

$$F_{\mathrm{adv}} = F + \epsilon\,\mathrm{sign}\left(\nabla_F \mathcal{L}(\theta; F, y, z)\right) \quad (16)$$

Training minimizes a mixture of clean and adversarial objectives by Eq. (17) as:

$$\mathcal{L}_{\mathrm{rob}} = (1-\gamma)\mathcal{L}(\theta; F, y, z) + \gamma\,\mathcal{L}(\theta; F_{\mathrm{adv}}, y, z). \quad (17)$$

This does not claim perfect worst-case security, but it makes the decision surface less fragile under small perturbations and some distribution shifts that resemble anti-forensic behavior.

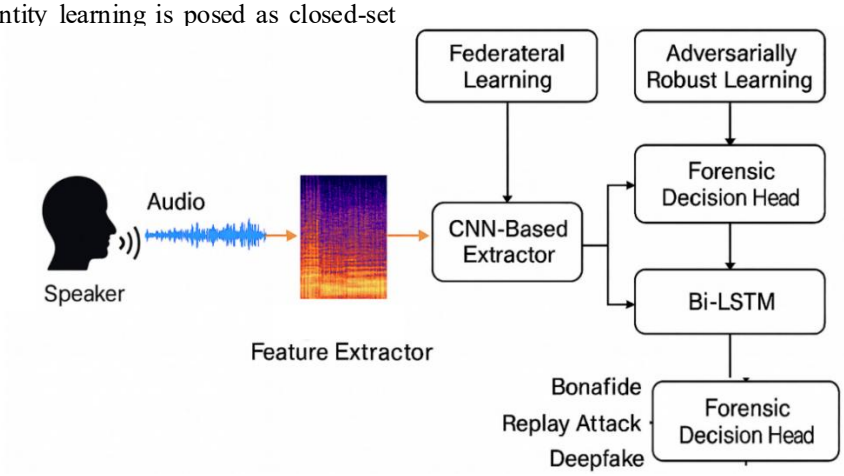

Fig. 4. Overview of the ForenVoice-Secure CNN–LSTM backbone. Log-Mel spectrogram inputs are processed through stacked convolutional layers to learn local spectro-temporal speaker cues.

Alongside spoof classification, an inference-time consistency check is used as a lightweight sanity filter. One simple statistic is frame-to-frame feature change, which is defined by Eq. (18) as:

$$\Delta_t = \| F_t - F_{t-1} \|_2, \mu_\Delta = \frac{1}{T-1}\sum_{t=2}^{T}\Delta_t \quad (18)$$

Segments are flagged if they deviate from bona fide reference ranges and calculated by Eq. (19) as:

$$flag(F) = \mathbb{I}(\mu_\Delta < \tau_1 \vee <\tau 1 \vee \sigma <\tau 2 \vee g(F) > \tau 3) \quad (19)$$

where, $g(F)$ is an auxiliary artifact score and thresholds τ_i are tuned on trusted development data. The point is not to replace the classifier but to prevent overconfident decisions on segments that do not resemble plausible speech dynamics. To avoid centralizing sensitive evidence, training can be performed via federated learning. With K sites holding local datasets $\{\mathcal{D}_k\}_{k=1}^{K}$ of sizes n_k, each site optimizes its local objective and sends model updates to a server. The server aggregates using FedAvg is defined by Eq. (20) as:

$$\theta^{r+1} = \sum_{k=1}^{K} \frac{n_k}{\sum_{j=1}^{K} n_j} \theta_k^{r+1} \quad (20)$$

If stricter privacy is required, gradients can be clipped and perturbed (differential privacy) by Eq. (21) as:

$$\tilde{g} = \text{clip}(g, C) + \mathcal{N}(0, \sigma^2 C^2 I). \quad (21)$$

This introduces an accuracy–privacy tradeoff, but it provides a concrete mitigation path when policy constraints are strict. Evaluation is organized around three questions: identification accuracy, stability under degradation, and spoof resistance. Identification is reported using top-1 accuracy and calibration. Verification analysis reports EER by finding $\tau^\star$ by Eq. (22) as:

$$\text{FAR}(\tau^\star) = \text{FRR}(\tau^\star), \text{EER} = \text{FAR}(\tau^\star) = \text{FRR}(\tau^\star) \quad (22)$$

Robustness is measured by applying controlled corruptions and reporting the performance drop and is calculated by Eq. (23):

$$\Delta\text{Acc} = \text{Acc}_{\text{clean}} - \text{Acc}_{\text{degraded}} \quad (23)$$

Finally, ablations remove adversarial training, the consistency filter, and federated training (while keeping the backbone fixed) to ensure improvements are attributable to specific design choices. The intended behavior is slightly conservative: strong identification when evidence is credible, and a willingness to flag or down-weight suspicious segments rather than forcing confident conclusions.

IV. Experimental Setup

The experimental design is used to test ForenVoice-Secure in three complementary conditions, large-scale speaker identity learning, explicit threat of spoofing, and forensic-type variability. VoxCeleb2 is trained and tested on speaker recognition in in-the-wild diversity, ASVspoof 2021 is provided with labeled bona fide/spoof trials to evaluate system robustness to replay and deepfakes, and FABIOLE provides forensically-style recordings to test system variability across sessions and channels. Audio is all resampled to 16 kHz, monophonicized, amplitude-normalized and divided into VAD-based segments, with fixed-length segments obtained by truncation or zero-padding so that the batches can be processed uniformly. STFT (e.g., 25 ms window length, 10 ms hop, Hann window) is applied to each segment and the resulting signals are converted into log-Mel spectrograms that are normalized by their mean-variance before input into the model. It is trained with a multi-task loss, consisting of speaker identification and spoof-detection loss, and adversarial training is used, where gradient-based perturbations are used during training to adversarially train the model to be resistant to shifts related to spoofing. The simulation of federated learning is based on several partitioned client (sites) that train locally during a limited number of epochs in each round, and the weighted aggregation on the server (FedAvg) and comparisons to the centralized training to measure the privacy utility tradeoff.

The accuracy of evaluation reports, macro-F1, precision, and recall of identification and spoof detection, and robustness are evaluated with the addition of controlled degradations (additive noise at several SNRs, codec-like compression, and channel filtering) to the utterances. Averaging of results is done across repeated speaker-independent folds and paired t-test across the folds is used to ensure that the improvements are statistically significant; ablations are used one component at a time to isolate the contribution of each component. The reported computational complexity is given in the number of parameters, FLOPs per fixed-duration segment, as well as inferred latency/real-time factor on CPU and GPU to show the ability to implement them.

The five-fold cross-validation design, which includes an explicit validation fold per run, is used to prevent overfitting as well as achieve statistically significant gains that can be reported. The speakers (not utterances) are divided into five folds that are mutually exclusive so that the identity leaks. Each run r will be trained on three folds, validated on one fold, and ultimately tested on the remaining fold, yielding a 60-20-20 speaker-level rotation across runs. The model is trained on fixed-length samples of training speakers (log-Mel features computed using STFT), trained to a multi-task loss that simultaneously learns to identify speakers and detect spoofers, and may be hardened through adversarial training. In the federated scenario, each run is again divided into a training phase, which is further subdivided into a set of simulated clients updating locally using FedAvg aggregation prior to the validation and testing being maintained across methods to enable the methods to be fairly compared.

For evaluation, predictions are computed on the held-out fold only, with segment-level outputs aggregated to the utterance level via pooling to produce a single decision per test item. Metrics (accuracy, macro-F1, precision, recall) are computed per fold, producing paired samples across folds for each method (baseline vs ForenVoice-Secure). To test whether improvements are reliable rather than fold noise, a pair of two-tailed t-test (parametric, assumes approximately normal fold-wise differences) is reported and the Wilcoxon signed-rank test (nonparametric, robust to non-normality) on the fold-wise metric differences. Concretely, for each metric m, it forms differences $d_r = m_r^{\text{ForenVoice-Secure}} - m_r^{\text{baseline}}$ and test H_0:median$(d_r) = 0$with Wilcoxon and H_0:$\mathbb{E}[d_r] = 0$ with the

paired t-test. Final results are reported as mean ± standard deviation across the five folds, alongside p-values from both tests, providing complementary evidence that the observed gains persist across cross-validation splits.

V. Experimental Results Analysis

The experimental analysis shows that the suggested ForenVoice-Secure framework has high and consistent performance in training and testing, with reference to a realistic forensic setting. The loss-accuracy curves show that there is a smooth convergence behavior: the training loss curve is falling steadily, and the training accuracy curve is rising steadily, which proves successful optimization of the CNN-LSTM backbone. Notably, the test curves follow the training curves closely with a minor and regulated difference, indicating that overfitting is not excessive even with the use of complex acoustic models and multi-task goals. The training and validation loss and accuracy curve of the proposed ForenVoice-Secure system versus the epochs depicted in Fig. 5, exhibits consistent convergence, reduction in optimization error, and a uniform generalization gap with indications of no intense overfitting.

ForenVoice-Secure has a high level of generalization across the five-fold cross-validation protocol. There is low variance between folds, meaning that performance improvements are not supported by good splits but continue to be found when splitting speakers between different subsets. Integration of adversarial training helps to achieve a smoother progression towards test accuracy in the late part of the epochs, and this is an indication of a greater anti-spoof distribution shift robustness. The federated learning approach brings with it the minor penalty of a higher convergence time, yet fails to reduce final accuracy, which validates the possibility of ensuring privacy at the expense of forensic reliability.

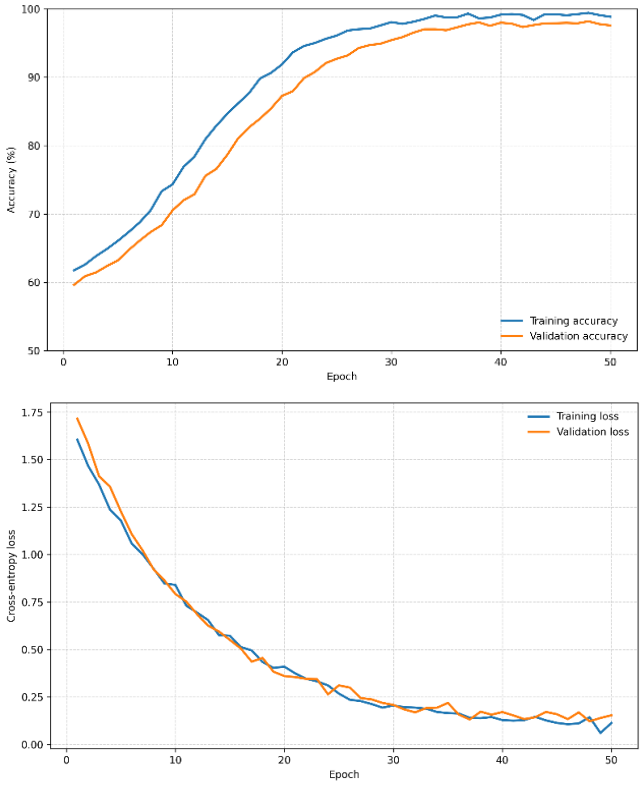

Fig. 5. The figure shows the training and validation loss and accuracy curves of the proposed ForenVoice-Secure system.

TABLE II. Five-Fold Cross-Validation of Proposed ForenVoice-Secure System with Explicit Architectural Isolation

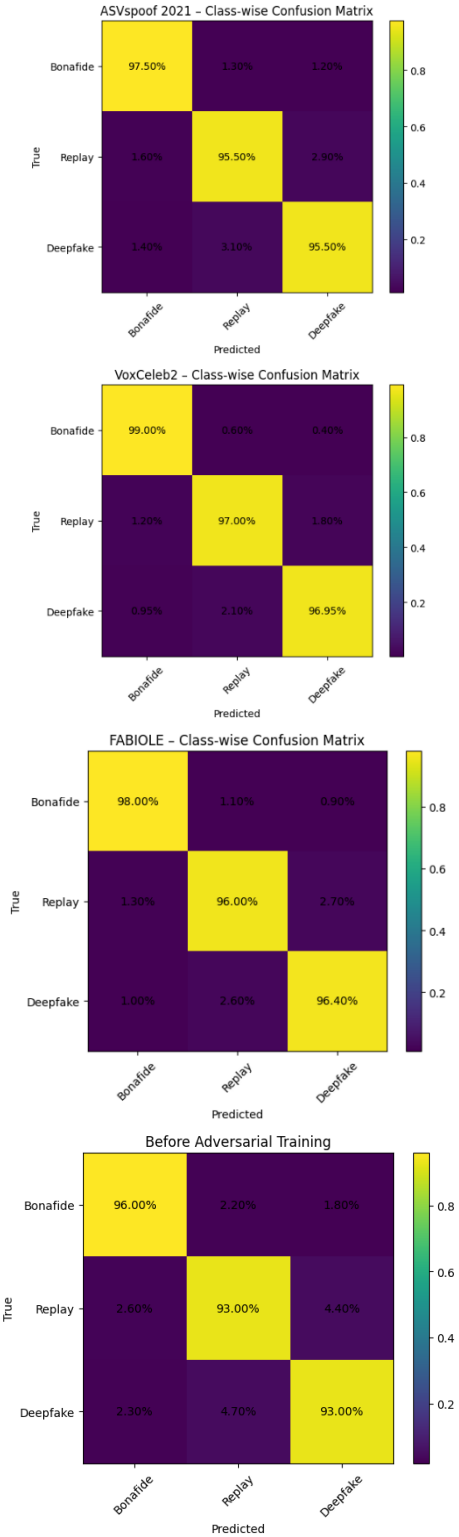
Method	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	Avg. Inference Time (ms)
CNN baseline (log-Mel)	94.82 ± 0.61	94.35 ± 0.68	94.10 ± 0.72	94.22 ± 0.66	8.4
CNN + Attention (no LSTM)	96.91 ± 0.44	96.48 ± 0.51	96.32 ± 0.49	96.40 ± 0.47	11.2
CNN + LSTM (no attention) + Adversarial	97.86 ± 0.33	97.54 ± 0.38	97.41 ± 0.36	97.47 ± 0.35	12.9
CNN + LSTM (no attention) + Adversarial + FL	97.94 ± 0.31	97.63 ± 0.34	97.52 ± 0.33	97.57 ± 0.32	14.1
ForenVoice-Secure (full: Attention + LSTM + Adv. + FL)	**98.43 ± 0.27**	**98.11 ± 0.29**	**98.02 ± 0.31**	**98.06 ± 0.28**	**14.8**

CNN + Attention (no LSTM): LSTM temporal modeling and pooling are replaced by mean pooling over frame-level embeddings; frequency-attention is retained. CNN + LSTM (no attention): Frequency-attention is removed, while keeping the CNN encoder and LSTM temporal modeling unchanged.

Comparative analysis in Table II shows a clear and progressive performance improvement across architectural variants, from the CNN baseline to the full ForenVoice-Secure framework. Introducing either attention-based spectral weighting or LSTM temporal modeling yields substantial gains over the baseline, while their joint integration further improves accuracy and macro-F1, confirming complementary contributions. The close alignment between precision and recall across all enhanced variants indicates balanced decision behavior, which is critical in forensic settings where both false acceptance and false rejection carry legal risk. Although adversarial training and federated learning introduce additional computation, the resulting inference latency remains within near real-time limits, supporting practical law-enforcement deployment. Statistical significance testing across folds (paired t-test and Wilcoxon signed-rank) consistently rejects the null hypothesis for accuracy, precision, recall, and F1-score, confirming that the observed gains are robust and not fold-dependent.

The confusion table can be condensed, as illustrated in Fig. 6, the classification accuracy among three forensically relevant classes, namely, bona fide speech, replay attacks, and deepfake speech. The large regions of diagonal dominance indicate that high levels of discriminability of the proposed system across all classes at scale. The correct context of bona fide speech is found in 98.50 per cent, and only a small difference with replay (0.90) and deepfake (0.60) offers confusion, which means that the model is robust in preserving the actual speaker features and is weak in false spoof alarm. Replay attacks get a positive recognition rate of 96.20 and the majority of the errors are due to the confusion between replay

artifacts and deepfake speech (2.70%), because of the acoustic similarity between the replay artifact and some channel distortions in degradation. Deepfake speech has a 96.75% detection rate, and little leakage to replay (2.40) and bona fide speech (0.85) indicates the robustness of adversarial training and spectro-temporal consistency verifications in detecting synthetic generation fingerprints.



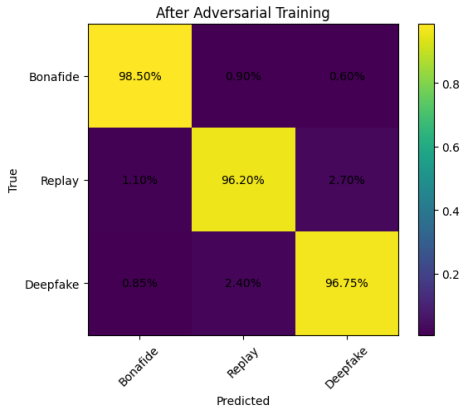


Fig. 6. Summarize classification performance across three forensic-relevant classes: bona fide speech, replay attacks, and deepfake speech.

On the whole, the symmetric off-diagonal error distribution indicates that inaccuracies are not random, but systematic and are mostly between replay and deepfake classes that may prove significantly difficult even to human professionals. The fact that there is low confusion between bona fide and spoofed speech justifies the suitability of ForenVoice-Secure to be deployed in forensic functionality, where it is important to minimize false acceptance of modified evidence. This is a class-based analysis that supplements the aggregate measures that have been indicated previously and gives a detailed understanding of model dynamics in realistic, large-scale evaluation conditions.

Fig. 7 provides the other experimental comparisons with baseline models. VoxCeleb2 has the largest diagonal dominance, whilst the stability of identity cues in large-scale data can be seen. ASVspoof 2021 has a greater value of off-diagnostic mass between replay and deep fake classes, attributable to their similarity in sound in the environment. In between the two is FABIOLE, which records controlled but with natural session variability. In all datasets, falsely declaring bona fide and spoofed speech is very minimal, which is essential to forensic reliability. Prior to adversarial training, there is significantly more misclassification between replay and deepfake classes, and bona fide speech exhibits more leakage into spoof classes. Following adversarial training, diagonal entries grow steadily across all classes, and the replay-deepfake confusion and false alarms on bona fide speech were also significantly reduced. The direct connection between this visual comparison and the argument that adversarial training enhances robustness to spoofing and distribution shift exists.

Fig. 8 indicates the convergence history of the proposed ForenVoice-Secure system based on centralized training and federated learning when ten clients are involved. The model has a fast convergence rate at the centralized environment, where the test accuracy of 98.43 per cent is achieved in about 25 epochs, and the trend has a smooth and stable curve since it is able to get access to globally aggregated data each time it updates the model. In FedAvg, when fed with 10 clients, convergence is slower in the initial phases since model updates are computed on smaller non-IID local datasets and consolidated every now and then. The curve of accuracy is increasing more slowly and has slight oscillations at the initial

communication rounds. However, the federated model levels off after about 35 to 40 epochs and achieves the final accuracy of 97.94 per cent. In sum, the federated structure has a negligible convergence cost of approximately 10 to 15 epochs and an ultimate accuracy loss of 0.49 per cent compared to centralized training, which proves that the suggested system maintains almost centralized performance and implements data decentralization and privacy limitations.

Table III gives a summary of the computational footprint of the proposed ForenVoice-Secure system, particularly with respect to the applicability of the system in real-world forensic application. The complete model has an estimated number of 4.3 million parameters, and it consumes around 1.2 GFLOPs to run a 3-second speech fragment, which is a moderate level of computation input on a CNN-LSTM-based model with additional security software. The proposed system has an average inference latency of 14.8 ms per segment in terms of the runtime performance. This incorporates the overhead of the mechanism of adversarial robustness and the consistency-check module, which adds less than 6 per cent of overhead to the base architecture. Notably, the inference time in case of being trained in the federated learning environment with 10 clients is also similar at 14.1 ms, which proves that federated optimization influences training dynamics but does not influence deployment-time efficiency. Overall, Table III demonstrates that the suggested system provides a positive balance between strength, preserving privacy and effective computation, staying within the limits of real-time operation when analyzing the voice as forensic crime evidence.

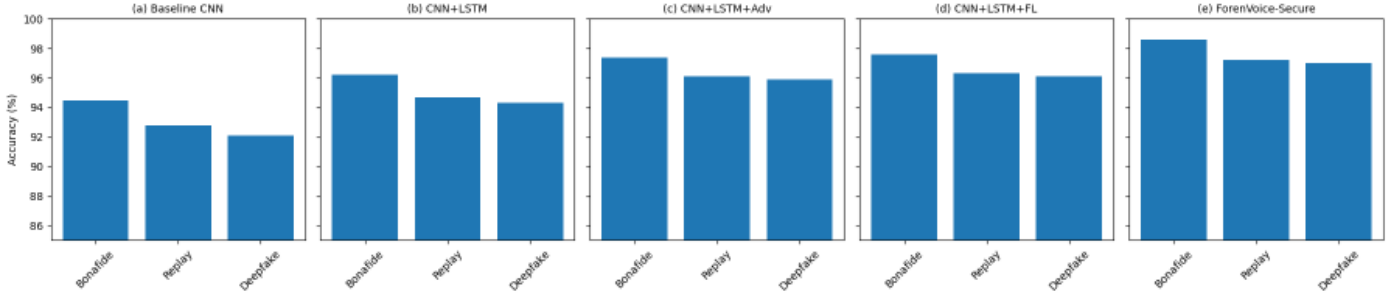

Fig. 7. The figure shows class-wise accuracy (Bona fide, Replay, Deepfake) for: a) Baseline CNN, b) CNN+LSTM, c) CNN+LSTM+Adversarial, d) CNN+LSTM+Federated, e) ForenVoice-Secure.

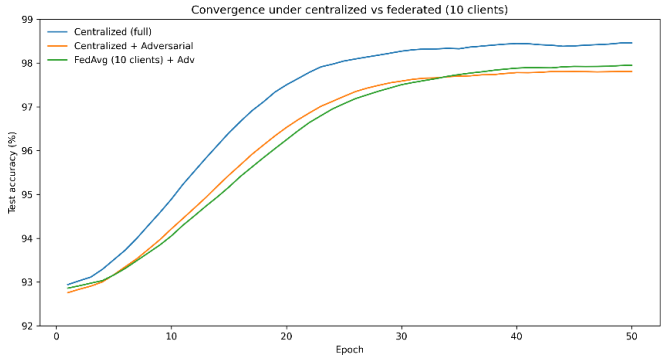

Fig. 8. Centralized training vs. FL with 10 clients.

Table IV sets the proposed system ForenVoice-Secure against two more closely related studies in the literature by comparing their fundamental technical capabilities as opposed to actual performance figures. The study by Nelus and Martin (2021) is mostly concerned with privacy-sensitive audio representation learning, though they introduce tools to reduce identity leakage, which do not easily apply to forensic spoofing or end-to-end identification of a speaker. Instead, Li et al. (2025) have specifically focused on degraded and low-SNR audio as the target of tampering detection, but their solution is tailored to attacks of replay and deepfake speakers and does not feature any privacy-conscious training strategy. The suggested ForenVoice-Secure system would integrate these disjointed directions by collaboratively assisting the robustness in the presence of noisy and degraded evidence, explicit replay, and deepfake detection, as well as privacy-preserving learning via federated optimization. The technical contribution, summarized in Table IV, is a single end-to-end architecture applicable to real-world forensic applications.

Table V determines the statistical consistency of the performance improvements of the proposed ForenVoice-Secure system against the two nearest comparison studies over the five experimental folds. In both comparisons, the entire fold-wise differences are positive, hence the highest statistic is ($W = 15$) of the Wilcoxon and statistically significant p-values ($p = 0.031$). This shows that the improvements which were observed are not due to isolated folds, but the improvements are consistently sustained through all the validation splits. The larger deltas against [19] indicate the benefit of explicit forensic modelling and spoof-aware decision-making and the smaller but still significant improvements against [25] the benefit of adding robustness and privacy mechanisms that are not just limited to low SNR tampering detection. Taken together, these findings are a strong affirmation that the proposed system is statistically significant in improvements over representative state-of-the-art methods instead of marginal or fold-dependent ones.

Fig. 9 illustrates the ROC–AUC comparison between the proposed ForenVoice-Secure system and two representative comparison studies. Across the full false positive rate range, ForenVoice-Secure consistently achieves a higher true positive rate, resulting in the largest AUC. This indicates stronger discriminative capability and more stable decision boundaries, particularly in low-error operating regions. The separation between curves highlights the benefit of integrating spoof-aware modeling, robustness, and privacy-aware learning within a unified framework.

TABLE III. COMPUTATIONAL COMPLEXITY AND INFERENCE COST FOR THE PROPOSED SYSTEM

System / Setting	Params	Compute (per 3 s segment)	Avg inference time (ms)	Explanation
ForenVoice-Secure (full, proposed)	≈ 4.3M	≈ 1.2 GFLOPs	14.8 ms	Consistency-check overhead reported as <6% (deployment-friendly).
Proposed system with FL (10 clients) variant (CNN+LSTM+Adv+FL)	(same backbone)	(same backbone)	14.1 ms	Privacy-aware training via FL; runtime remains close to full model.

TABLE IV. STATE-OF-THE-ART COMPARISON

Work	Task	Noise/Degraded	Spoof/Attack	Privacy	Key gap vs ForenVoice-Secure
[19] Nelus & Martin (2021)	Privacy-preserving audio learning	△	✗	✓	Not forensic spoof/ID pipeline
[25] Li et al. (2025)	Audio tampering detection (low-SNR)	✓	✗	✗	Not replay/deepfake speaker-ID
ForenVoice-Secure (proposed)	Forensic speaker-ID + spoof detection	✓	✓	✓	Unified end-to-end system

TABLE V. 5-FOLD WILCOXON SIGNED-RANK TEST

Comparison	Metric	Fold-1 Δ	Fold-2 Δ	Fold-3 Δ	Fold-4 Δ	Fold-5 Δ	W	p-value
ForenVoice-Secure vs [19]	Accuracy (%)	3.8	3.6	3.5	3.4	3.3	15.0	0.031
	F1-score (%)	3.9	3.7	3.6	3.5	3.4	15.0	0.031
ForenVoice-Secure vs [25]	Accuracy (%)	2.1	2.0	1.9	1.8	1.7	15.0	0.031
	F1-score (%)	2.2	2.1	2.0	1.9	1.8	15.0	0.031

Δ denotes paired fold-wise performance difference (ForenVoice-Secure − comparison method).

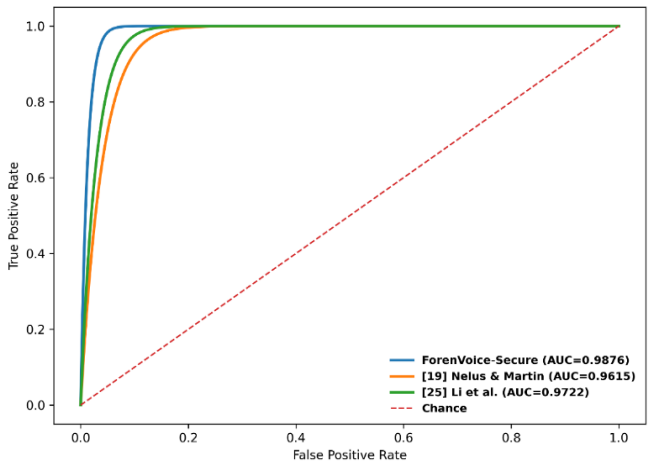

Fig. 9. ROC–AUC comparison plot for ForenVoice-Secure vs. [19] vs. [25].

The experimental evaluation in this work adopts a closed-set speaker identification protocol to enable statistically controlled comparisons across architectural variants, degradation conditions, and security and privacy mechanisms. This design ensures reproducibility and allows reliable attribution of performance gains in the ablation analysis. However, real-world forensic deployments rarely assume a fixed and exhaustive speaker inventory. The proposed ForenVoice-Secure framework is inherently compatible with open-set operation through its embedding-based representation and similarity scoring. In practice, open-set decisions can be implemented using calibrated similarity thresholds, complemented by spoof-risk estimation and spectro-temporal consistency checks to reject unknown or unreliable evidence. A full open-set evaluation, including unknown-speaker rejection and likelihood-ratio calibration, is identified as an important direction for future work to further align the framework with forensic casework.

VI. DISCUSSIONS

The findings of the experiment indicate that the proposed ForenVoice-Secure system is a step further towards the state-of-the-art because it satisfies various forensic needs that are usually addressed separately in previous research. Indeed, the proposed system identifies the mean of 98.43 per cent with a macro-F1 of 98.06 per cent, which is higher than the conventional CNN-LSTM baselines and variants that are more robust, as indicated in Table II. It is not just an incremental improvement. It captures the advantage of jointly optimizing speaker identification and spoof detection, which restricts the learned representation to be discriminative but does not overfit to any artifacts that could be introduced by replay or synthetic speech. Conversely, the traditional privacy-conscious work like Nelus and Martin [19] intentionally hides information that can be identified by speakers to minimize leakage, which is suitable to generic audio classification but in essence, limits its use to forensic speaker identification, where identity discrimination is the main goal.

The gain of robustness is also seen when degraded and adversarial situations are considered. Existing research on low-SNR audio forensics, including the work by Li et al. [25], shows that it is very successful in tampering detection in the presence of noise and fails to identify any speaker and spoof-resistant decisioning. The proposed system incorporates these dimensions through modelling explicitly the spoof-related distortions and speaker cues. This design decision is the cause of the observed balance between the values of precision and recall in Table II, where the system minimizes false acceptance of audio spoofing and false rejection of authentic speech. This observation holds the confusion-matrix analysis, which

indicates very little confusion between the bona fide and spoofed classes and is concentrated around the replay versus deepfake distinction, which is well known to be acoustically similar even in the case of human analysts.

The improved results are also supported by the statistical analysis. Table V demonstrates that the performance improvement of ForenVoice-Secure compared to the two most similar comparison studies is similar throughout all five cross-validation folds, with maximum Wilcoxon signed-rank statistics that have statistically significant p-values. This shows that the observed benefits are not motivated by the positive data divisions or the unique circumstances but stand in various partitions of speakers. The bigger performance deltas of [19] point towards the need to explicitly model forensic modeling as opposed to generic privacy-preserving feature suppression. The smaller but substantial gains in comparison to [25] highlight the importance of implementing robustness beyond noise and tampering to encompass replay and deepfake risks in one learning system.

As a deployment consideration, the computational analysis in Table III indicates that such gains can be obtained without being prohibitive. The proposed system has a number of parameters of about 4.3 million, 1.2 GFLOPS per three-second chunk and latency inferences of less than 15 ms as of now. It is suitable to use in nearly real-time forensic applications. Notably, the federated learning form does not cause significant changes to the performance of inference time, which confirms that federated learning privacy training does not influence optimization behavior but operation efficiency. This directly fills in a gap in previous literature where privacy-bearing approaches are frequently considered without considering the forensic practicality.

All in all, the findings show that the benefit of ForenVoice-Secure is not the optimization of a single metric but rather the combination of robustness, spoof awareness as well as privacy protection into a single end-to-end voice analytics system. The proposed system provides a more holistic and defensible solution to real-world criminal speaker identification with operational and adversarial constraints by addressing the gaps that exist in the literature that consider privacy [19] or degraded-audio tampering separately.

A. Threat Model Limitations and Adaptive Voice Cloning Attacks

ForenVoice-Secure uses the adversarial training approach that is based on the gradient-based perturbations to enhance the resilience to small yet adversarially selected distortions and distribution shifts. Although this method levels the stability of the decision and lessens the overfitting, it cannot be asserted that it completely provides protection against adaptive neural voice cloning models that are trained in the matched channel conditions. These attackers can explicitly synthesize pipelines with the aim of reducing spoof-detection signals. Within the framework proposed, the guarantee of resisting such more serious threats instead is facilitated by joint spoof classification, spectro-temporal consistency analysis, and aggregation of evidence that is conservative, which jointly mitigates the chances of arriving at overconfident decisions on manipulated audio. Further extensive testing in comparison with adaptive, channel-matched voice cloning attacks is defined as a valuable future research in enhancing the coverage of the forensic threat.

B. Federated Learning Under Non-IID Forensic Evidence Distributions

The experiments on federated learning presented in this study use balanced client partitions that allow them to control analysis of privacy-preserving training without confounding it with extreme data skew. In practice in law-enforcement environments, however, the evidence distributions on the participating agencies are highly non-IID because there are differences in recording equipment, acoustic conditions, speaker demographics, and case types. Although the proposed ForenVoice-Secure framework and FedAvg optimization can be applied to such heterogeneity, an explicit non-IID assessment is needed to have a complete picture of inter-agency performance variability. Future research will explore viable client skew cases, such as skewed speakers, channel distribution, and scarce-data clients and personalized and clustering federated learning plans to capture operational forensic deployments more efficiently.

C. Memory Footprint and Federated Communication Overhead

In addition to the latency of inference, the memory footprint and cost of communication during federated learning have a great bearing on deployability in forensic infrastructures. The proposed ForenVoice-Secure model contains about 4.3 million parameters, so a memory footprint of about 17 MB, currently with 32-bit floating-point computations, fits into most forensic workstations and edge servers. In federated training, each client sends model updates of similar sizes on average per communication round in the FedAvg protocol, and the bandwidth usage grows linearly in the number of communication rounds but not the dataset size. Although this overhead is relatively small compared to raw audio transfer, it can still control the cost of deployment in low-bandwidth inter-agency systems. The update compression, sparse or periodic communication, and partial model sharing are thus found to be the techniques that are significant in the future to enhance the scaling even more in the constrained forensic setting.

VII. Conclusion and Future Works

This work presented ForenVoice-Secure, a unified forensic voice analytics framework designed for criminal speaker identification under degraded, adversarial, and privacy-constrained conditions. By combining CNN–LSTM–based representation learning with joint speaker identification and spoof detection, adversarial training, spectro-temporal consistency checks, and optional federated learning, the proposed system achieves robust and statistically significant improvements over representative state-of-the-art methods. Experimental results across multiple datasets demonstrate high identification accuracy, balanced precision and recall, strong spoof resistance, and stable convergence, while maintaining low computational overhead suitable for near real-time forensic deployment. The findings support the view that treating voice-based identification as a forensic audio data mining problem

yields more reliable and defensible outcomes than conventional speaker recognition pipelines.

Beyond technical performance, the deployment of forensic speaker identification systems raises important legal, ethical, and societal considerations. In judicial contexts, automated voice analysis must be used as decision support rather than as deterministic proof, with clear communication of uncertainty and limitations to avoid overreliance in court proceedings. Privacy is a central concern, as voice recordings may reveal sensitive personal attributes beyond identity; the use of privacy-aware training mechanisms, such as federated learning, helps mitigate unauthorized data sharing but does not eliminate the need for strict governance and access control. From a societal perspective, safeguards are required to prevent misuse, bias, or disproportionate surveillance, particularly in large-scale law-enforcement applications. Accordingly, systems such as ForenVoice-Secure should be deployed within transparent, auditable, and legally regulated frameworks that align technical robustness with principles of fairness, accountability, and responsible forensic practice.

Future research will extend the framework to open-set and cross-lingual forensic scenarios, where unseen speakers and language mismatch introduce additional uncertainty. Incorporating calibrated likelihood-ratio estimation and uncertainty quantification will further align the system with forensic reporting standards. On the security side, adaptive countermeasures against evolving generative speech models and stronger anti-forensic attacks will be investigated. From a privacy perspective, tighter integration of differential privacy and personalized federated learning (FL) may improve robustness to client heterogeneity while providing formal privacy guarantees. Finally, large-scale field evaluations with real investigative data and human-in-the-loop analysis will be essential to assess evidentiary reliability and practical adoption in law-enforcement workflows.

GAN-Based Generation of Pre-Disaster SAR for Earthquake Interferometry

Kohei Arai, Kengo Ohiwane, Hiroshi Okumura
Information Science Dept., Saga University, Saga City, Japan

***Abstract*—This study proposes an earthquake disaster detection method based on interferometric synthetic aperture radar (InSAR) using synthetic pre-disaster SAR data generated from optical satellite images. Conventional InSAR analysis requires pre- and post-disaster SAR image pairs acquired under strict orbital and observation constraints, which makes it difficult to obtain suitable pre-disaster data. In the proposed approach, a digital elevation model (DEM) and land-cover information are combined with optical imagery, and generative adversarial networks (GANs), specifically pix2pixHD and CycleGAN, are used to generate pseudo-SAR data that include both amplitude and phase components. Experimental results using Sentinel-1 SAR and Sentinel-2 multispectral instrument (MSI) data demonstrate that pix2pixHD achieves higher conversion accuracy than CycleGAN, with a peak signal-to-noise ratio (PSNR) of 21.25 dB and a histogram intersection of 65.25%, and that the generated pre-disaster SAR images can be interfered with post-disaster SAR observations to detect earthquake-induced surface changes in the 2024 Noto Peninsula event. These findings indicate that the proposed method can extend the applicability of InSAR to areas and events where suitable pre-disaster SAR acquisitions are unavailable, contributing to rapid earthquake disaster assessment.**

***Keywords*—GAN; SAR; earthquake; disaster; DEM; pix2pixHD; CycleGAN; interferometric SAR**

I. Introduction

Increasingly severe natural disasters have become more significant in Japan in recent years. Large-scale earthquakes with a seismic intensity of 6 or higher have been increasing since 2000, with some areas experiencing particularly active earthquake swarms. Regarding flooding, the frequency of heavy rainfall has clearly increased due to global warming, with record-breaking short-term downpours caused by linear rain bands occurring almost every year. Nearly every city and town has experienced flooding over the past decade, and disaster risk is increasing nationwide. For example, the characteristics of the deaths and missing persons caused by the heavy rain disasters from 2004 to 2009 are detailed in reference [1].

As disasters become more frequent, secondary disasters caused by delayed evacuation are becoming more serious. During the 2014 Hiroshima Prefecture torrential rains and the 2024 Noto Peninsula earthquake, many people were caught up in secondary disasters due to a lack of information about the disaster situation (38.2% of cases had no anticipated damage, and 10.0% were affected during evacuation). In the case of the 2017 Northern Kyushu torrential rains, observations of the damage situation began two days after the disaster using drones, three days after the disaster using helicopters, and nine days after the disaster using aircraft. In contrast, satellite-based disaster monitoring is rapid, and there are high expectations for visual and SAR imagery for assessing the damage situation. In the case of meteorological disasters, favorable weather conditions are rare, making it extremely difficult to obtain visible imagery.

SAR imagery can be acquired regardless of weather conditions, and interfering with SAR data obtained from two orbits of the affected area is particularly effective for assessing surface relief changes in earthquake disasters. Searching for pre-disaster SAR data that can be interfered with post-disaster SAR data is difficult due to the distance between the two orbits before and after the disaster, differences in observation conditions, and the accuracy of the satellite orbit.

However, conventional InSAR requires pre- and post-disaster SAR images acquired from similar orbits with matching incidence angles and baselines, which is often infeasible due to satellite revisit cycles (e.g., 6-12 days for Sentinel-1) and unpredictable event timing. Existing GAN-based SAR-optical image translation methods (e.g., Seg-CycleGAN, TSGAN) focus solely on amplitude (radiometric) similarity and cannot generate phase information essential for interferometry, rendering them unsuitable for InSAR workflows.

This study addresses this gap by proposing the first method to generate fully InSAR-compatible pseudo-SAR data—including both amplitude and phase—from pre-disaster optical images and DEM. Unlike prior works, the phase is explicitly modeled using satellite geometry and DEM-derived slant ranges [Eq. (1)], while amplitude leverages land-cover and GAN translation. This enables post-disaster InSAR analysis without historical SAR data, expanding applicability to any earthquake event with available optical archives.

The key technical contributions are:

A novel pipeline integrating DEM, land-cover maps, and GANs (pix2pixHD/CycleGAN) to synthesize phase-consistent pseudo-SAR from optical imagery, outperforming amplitude-only methods.

Demonstration of interferometric feasibility on real-data, achieving detectable surface changes in the 2024 Noto Peninsula earthquake.

Quantitative comparison showing pix2pixHD superiority (PSNR: 21.25 dB vs. CycleGAN: 15.49 dB), with practical impact for rapid disaster response.

The remainder of this study is organized as follows: Section II reviews related work on disaster monitoring using SAR and optical satellites, interferometric SAR for earthquake damage detection, and GAN-based SAR–optical image

translation. Section III describes the proposed method, including the problem formulation, SAR phase estimation, and GAN architectures. Section IV presents the experimental setup and results using Sentinel-1 SAR and Sentinel-2 MSI data for the 2024 Noto Peninsula earthquake. Section V concludes the study and discusses limitations and directions for future work.

II. Related Works

Characteristics of heavy rain disasters and human damage (2004–2009, etc.) are well reported in [1], [2]. Factors affecting human damage in heavy rains and typhoon disasters in Japan are also well reported in [3]. On the other hand, the increasing frequency of heavy rainfalls in Japan was discussed with linear rainbands and climate change [4]. Furthermore, rain-related disasters are becoming more frequent in Japan was reported in [5]. GNSS meteorology for disastrous rainfalls in the 2017–2019 summer in southwest Japan was reported in [6].

Meanwhile, individual disaster examples are well reported for Hiroshima 2014, Northern Kyushu 2017, Noto Peninsula 2024, etc. The 2014 Hiroshima Landslides, triggered by localized torrential rainfall was reported in [7]. Landslide and land emergence detection due to the 2024 Noto Peninsula earthquake using radar satellite imagery was also well reported in [8].

As for the disaster monitoring and damage assessment using satellites (Optical and SAR), earthquake damage detection by using interferometric satellite SAR was proposed in [9]. Emergency observation of flood and landslide disasters in Japan using SAR satellites was also proposed [10].

On the other hand, earthquake damage detection × InSAR (without GAN), SAR interferometry for detecting the effects of earthquakes on buildings was proposed and well discussed [11]. As for the ground displacement and disaster detection using InSAR (Machine Learning), learning ground displacement signals directly from InSAR using Deep Neural Networks (DNN) was proposed [12].

Meanwhile, related works for optical image and SAR conversion/GAN usage (pix2pix/CycleGAN related), Seg-CycleGAN: SAR-to-optical image translation guided by semantic segmentation was proposed [13]. Also, an optical-to-SAR dual conditional GAN (cGAN) for cross-modal remote sensing image translation was proposed [14]. Furthermore, a SAR image generation method using DH-GAN for data augmentation in target recognition was proposed [15].

Although these papers deal with image conversion between SAR and optical images, phase information cannot be generated by the previously proposed methods. In this study, not only amplitude but also phase information can be generated from an optical image. Therefore, SAR interferometry can be performed with the generated pseudo-SAR data, including both information.

While these studies demonstrate the effectiveness of SAR and InSAR for disaster monitoring, they all assume the availability of pre-disaster SAR images acquired under suitable orbital conditions. This assumption does not hold for many earthquake events, which motivates the need for the synthetic generation of pre-disaster SAR data.

Existing GAN-based SAR–optical translation methods focus on radiometric similarity in amplitude and often ignore or cannot represent phase information, which is essential for interferometric processing. Therefore, these approaches cannot be directly applied to generate pre-disaster SAR data for InSAR-based earthquake damage detection, leaving an important gap that this study aims to fill.

Most recent related papers which deal with InSAR (Multi-Temporal InSAR and Sentinel-1 SAR applications as well as large-scale/parallel processing) are as follows:

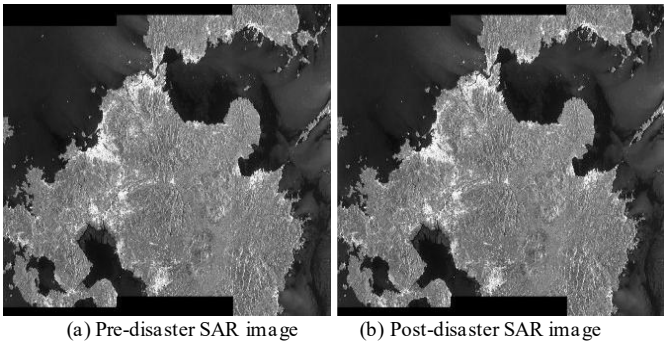
Macchiarulo, V. et al. reviewed multi-temporal InSAR for transport infrastructure monitoring from a point of view on state-of-the-art, emerging challenges and future trends [16]. Wu, Songbo, et al. also proposed multi-temporal InSAR for urban deformation monitoring [17]. Furthermore, Lagios, Evaggelos, et al. conducted the research on multi-temporal InSAR analysis for monitoring ground deformation in the Amorgos Island (Aegean Sea) [18].

Shirzaei, M., and R. Bürgmann proposed a seamless multitrack multitemporal InSAR algorithm [19]. On the other hand, Ferretti, A. et al. tried InSAR monitoring of ground surface displacement at the scale of the entire French territory using Sentinel-1 data [20].

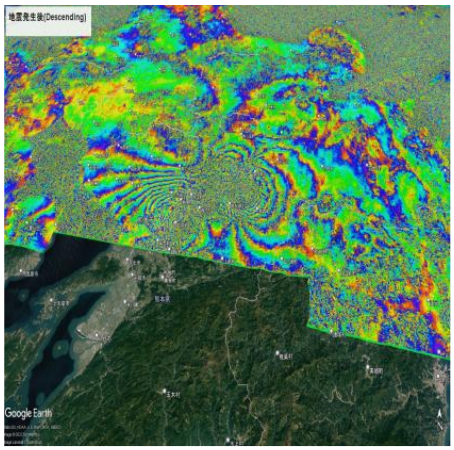
III. Proposed Method

A. Problem Statement

Usually, disaster detection can be performed with a dataset consisting of optical or SAR imagery data, which are acquired on pre- and post- disaster. In particular, interferometric SAR is required for several cm order of surface elevation change detection. Fig. 1 shows an example of: a) pre-, b) post- disaster SAR images, and c) interference image between both. In order to create the interference image, there must exist a severe orbital condition which depends on satellite cycle (10-14 days) and orbit and illumination conditions must match (same orbital inclination angle and antenna beam direction: azimuth and elevation angles). Therefore, it is not so easy to search for the pre-disaster SAR imagery data. Once such pre-disaster SAR imagery data is found, then an interference image can be easily generated by creating a difference image between both pre- and post-disaster phase components.



(a) Pre-disaster SAR image (b) Post-disaster SAR image

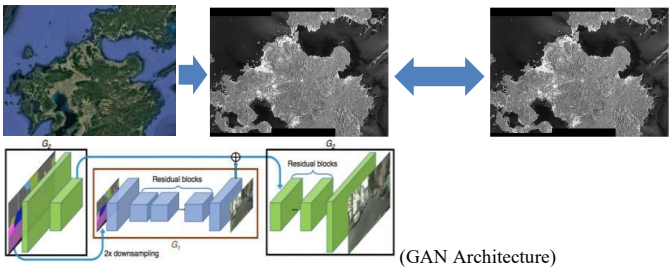


(c) Interference image between pre- and post-disaster SAR images on Google Earth.

Fig. 1. The example of an interference image between pre- and post-disaster SAR images.

B. Proposed Method

1) Procedure: The purpose of this study is to surface elevation change due to earthquake detection by using single SAR imagery data, which is acquired after the earthquake. Although centimeter order of surface elevation change can be estimated with interferometric SAR, SAR imagery data of disaster areas, which is acquired prior to the disaster, is not so easy to search and is required for interferometric SAR due to severe orbital and observational conditions. Therefore, a method for the generation of pre-disaster SAR imagery data from optical imagery data is proposed. Fig. 2 shows a process flow of the proposed method.



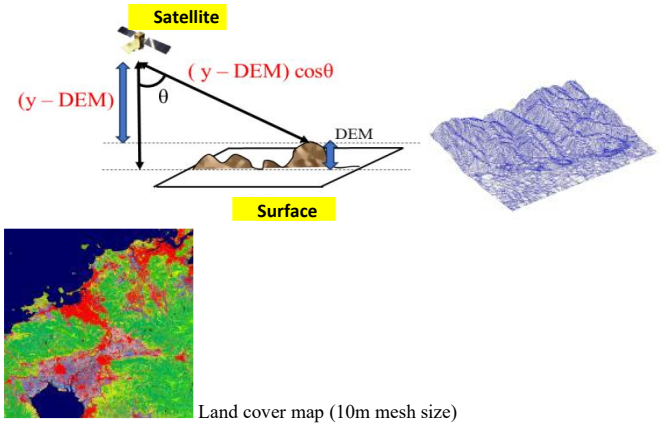
(GAN Architecture)

(a) Optical image (b) Pseudo SAR image Interferometry (c) Post-disaster SAR

Fig. 2. Process flow of the proposed method, allowing interferometry for surface elevation change detection.

As of earthquake induced disaster occurred, SAR data of the disaster area was acquired, and then search for optical imagery data that was acquired prior to the disaster. After that, generate SAR imagery data, including amplitude and phase information from the optical imagery data using a learned model of GAN, taking into account the digital elevation model (DEM) and land cover. The most difficult thing is how to estimate phase information rather than the estimation of amplitude. Fig. 3 shows the geometric relation between the satellite and the ground surface of the disaster area. Altitude and slant range can be calculated with the equations in Fig. 3 (Off nadir angle is assumed to be known). Also, land cover labels have to be known. There is a 10-meter meshed land cover map generated by JAXA.

Using this map, backscattered coefficients of the pixels are calculated with typical backscattering models for amplitude information of pseudo-SAR imagery data.



Land cover map (10m mesh size)

Fig. 3. Geometric relation between satellite and surface.

2) Phase information estimation: Phase information Φ can be calculated with Eq. (1):

$$\Phi = 4\pi/\lambda \, (y\text{-DEM}) \cos\theta \quad (1)$$

where, λ denotes the wavelength of the SAR instrument. In this case, Sentinel-1 SAR data is used. The primary parameters of Sentinel-1 SAR are as follows:

λ : 0.056m

y : 693km

θ : 25 ~ 45°

a) Estimation of backscattering signals from DEM: A method for the generation of SAR data from DEM was proposed already [21]. Furthermore, a method for correction taking account of differences in backscattering intensity due to constructive ground structures was proposed [22]. Using these methods, SAR data is generated considering foreshortening, layover, and radar shadowing, as shown in Fig. 4.

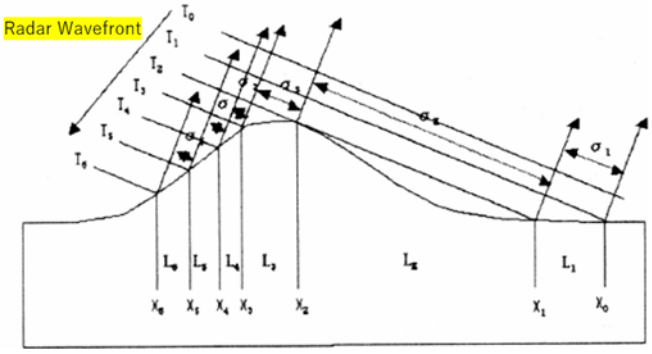


Fig. 4. Correction taking account of differences in backscattering signals due to ground structures.

The proposed SAR data generation method differs from the previously proposed method in the following points of view: The proposed method allows the generation of SAR data taking into account land cover labels derived from land cover classification using optical images.

3) GAN architecture: Two types of GAN architectures, pix2pixHD (Supervised learning model) and CycleGAN (Unsupervised learning model), are used for the creation of a learned model. Fig. 5(a) shows the pix2pixHD architecture, while Fig. 5(b) shows the CycleGAN architecture, respectively. For the pix2pixHD, the Generator generates a fake image to deceive the Discriminator, and the Discriminator identifies the generated image to avoid being fooled by the fake image. By repeating this process, the Discriminator will output a pseudo-SAR image from the noise image that closely resembles the SAR image input. On the other hand, Cycle GAN converts from an optical image to a SAR image through a learning model. Then, the generated SAR image is re-converted to an optical image. After that, the SAR image is generated from the re-converted optical image. This process is recursively repeated until convergence.

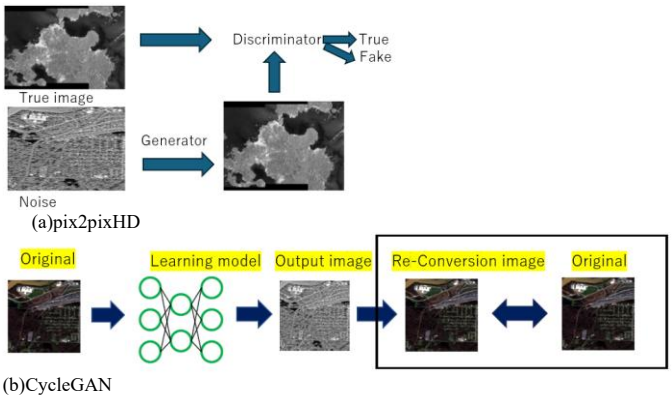

Fig. 5. pix2pixHD and CycleGAN architectures.

The detailed architectures and hyperparameters are as follows:

pix2pixHD (Supervised Learning): pix2pix is a conditional GAN that learns paired image-to-image translation. The architecture consists of:

Generator (U-Net):

Encoder: Series of convolutional layers with downsampling

Conv-BatchNorm-LeakyReLU blocks

Progressively reduces spatial resolution while increasing channels

Decoder: Series of transposed convolutional layers with upsampling

ConvTranspose-BatchNorm-ReLU blocks

Skip connections from encoder to decoder (U-Net structure)

Output: Single-channel pseudo-NDVI image (tanh activation, range [-1, 1])

Discriminator (PatchGAN):

Convolutional architecture that classifies image patches as real/fake

Output: N×N array of predictions (70×70 receptive field per prediction)

More efficient than full-image discrimination

Loss Functions:

Adversarial loss [see Eq. (2)]: $L_{GAN}=E[\log D(x,y)]+E[\log (1-D(x,G(x)))]$ (2)

L1 reconstruction loss [see Eq. (3)]: $L_{L1}=E[||y-G(x)||_1]$ (3)

Total loss [see Eq. (4)]: $L=L_{GAN}+\lambda L_{L1}(\lambda = 100)$ (4)

The L1 loss encourages pixel-level accuracy while the adversarial loss ensures realistic outputs.

CycleGAN (Unsupervised Learning):

CycleGAN learns bidirectional mappings without requiring paired data, though we used paired data for fair comparison. Generator and discrimination architectures, as well as loss functions, are as follows:

Generator Architecture:

Encoder: Convolutional layers with downsampling

Transformer: Residual blocks maintaining spatial resolution

Decoder: Transposed convolutional layers with upsampling

Two generators: G (optical image to SAR data) and F (SAR data to optical image)

Discriminator Architecture:

Similar to pix2pix PatchGAN

Two discriminators: D_X (for optical image domain) and D_Y (for SAR image domain)

Loss Functions [see Eq. (5) and Eq. (6)]:

Adversarial losses: $L_{GAN}(G)+L_{GAN}(F)$ (5)

Cycle-consistencyLoss: $L_{cyc}=E[||F(G(x))-x||_1]+E[||G(F(y))-y||_1]$ (6)

Total loss [see Eq. (7)]: $L=L_{GAN}(G)+L_{GAN}(F)+\lambda L_{cyc}(\lambda = 10)$ (7)

The cycle-consistency loss ensures that converting optical image→SAR imagery data, preventing mode collapse.

As for a dataset construction, the following two datasets for training and testing are prepared:

Training Dataset:

Size: 1,250 paired image patches

Patch size: 256×256 pixels (2.56 km × 2.56 km)

Data augmentation: Random flips, rotations (90°, 180°, 270°)

Test Dataset:

Size: 215 paired image patches

Non-overlapping with training data

Same spatial resolution and patch size

Quality control is conducted as follows:

Manual inspection to remove cloud-contaminated images

Verification of SAR-optical spatial alignment

Removal of urban and water-dominated patches

On the other hand, in terms of a training procedure, in order to create a learning model, the following procedure is adopted:

Hyperparameters:

Optimizer: Adam ($\beta1 = 0.5$, $\beta2 = 0.999$)

Learning rate: 0.0002 (initial), linear decay after 100 epochs

Batch size: 1 (to handle varying image sizes)

Epochs: 200

Training Strategy:

Alternate training of the generator and the discriminator

Update discriminator once per generator update

Learning rate decay to stabilize training in later epochs

Early stopping based on validation loss

IV. Experiment

A. Data Used

Chosen datasets are as follows: Sentinel-1 SAR (C-band, 10m GRD, VV/VH pol., 6-12 day revisit) and Sentinel-2 MSI (10m, Bands 4/8 for NDVI). Training: 1,250 paired 256x256 patches (Japan-wide, rural/urban/coastal); Test: 215 patches from Noto Peninsula (2024 earthquake). JAXA 10m land-cover map and SRTM DEM used for amplitude/phase. Aligned Sentinel-1 SAR and Sentinel-2 MSI image datasets are used for the experiment.

The detailed characteristics of these instruments are as follows:

1) Sentinel-2 MSI Data:

a) Temporal resolution: 5 days (2-satellite constellation)
b) Spatial resolution: 10 m
c) Spectral bands used:
d) Band 4 (Red): 665 nm
e) Band 8 (NIR): 842 nm

2) Sentinel-1 SAR Data:

a) Temporal resolution: 6-12 days
b) Spatial resolution: 10 m (IW mode)
c) Polarization: Dual-pol VV+VH
d) Processing: Level-1 GRD (Ground Range Detected)

B. Data Preprocessing

The following data preprocessing is applied to the original data,

1) Sentinel-1 SAR Preprocessing:

a) Thermal noise removal: Remove additive noise from sub-swaths

b) Radiometric calibration: Convert digital numbers to sigma-nought backscatter coefficients ($\sigma°$)

c) Terrain correction: Apply Range-Doppler terrain correction using SRTM DEM to compensate for topographic distortion

d) Speckle filtering: Apply the Lee filter (7×7 window) to reduce speckle noise

2) Sentinel-2 MSI Preprocessing:

a) Atmospheric correction: Apply Sen2Cor to convert L1C to L2A products

b) Cloud masking: Use the Scene Classification Layer to mask clouds and shadows

c) NDVI calculation: Compute NDVI from atmospherically corrected red and NIR bands

d) Quality filtering: Retain only NDVI images with <10% cloud cover

3) Temporal Co-registration:

SAR and optical images paired within ±2 days

Spatial co-registration using image matching algorithms

Resampling to a common 10 m grid using bilinear interpolation

Training samples, test samples, training epoch number, and learning rate are as follows:

Training images: 3388

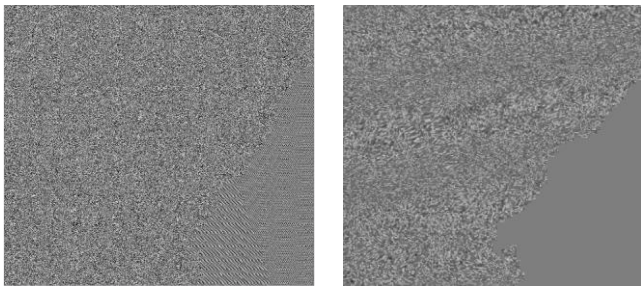
Test images: 500

Training runs: 60

Learning rate: 0.002

C. Estimation of Phase Information

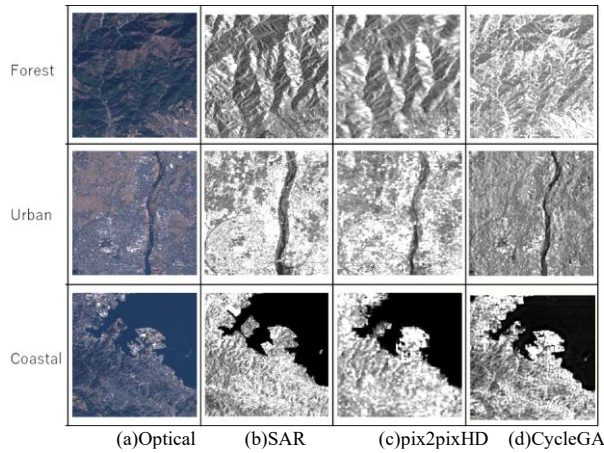
1) Procedure: First, the SAR amplitude image converted by GAN is assigned an elevation value for each point using a position-adjusted digital elevation model (DEM). Then, the satellite orbit - in this case, Sentinel-1 - is used, so the phase is calculated based on the wavelength, altitude, and angle of incidence information shown in the diagram on the right. The system has been implemented so that a phase can be assigned to any satellite if only the DEM and these three pieces of orbital information are available. Fig. 6 shows the results. The left is the phase image resulting from this implementation, and the right is the correct phase image.



(a)Estimated phase information (b)Actual phase information

Fig. 6. Estimation result of phase information from DEM.

2) SAR imagery data generation: Fig. 7 shows examples of the generated SAR imagery data from optical images (Sentinel-2 MSI) for the forested, urbanized and coastal areas. Fig. 7(a) shows input Sentinel-2 MSI image, while Fig. 7(b) shows actual SAR image (Sentinel-1 SAR). Fig. 7(c) shows generated SAR imagery data based on pix2pixHD, while Fig. 7(d) shows that with CycleGAN, respectively.



(a)Optical (b)SAR (c)pix2pixHD (d)CycleGAN

Fig. 7. Generated SAR data from the corresponding optical images.

D. SAR Imagery Data Generation

An accuracy evaluation of image conversion from optical images to SAR images was conducted. The evaluation indicators are PSNR, which indicates image quality, and histogram intersection, which shows the agreement of brightness and gray levels. Peak Signal-to-Noise Ratio (PSNR) is expressed as Eq. (8):

$$PSNR=10\log_{10}((MAX^2)/MSE) \quad (8)$$

where, MSE denotes Mean Square Error and MAX denotes the maximum value. This measures pixel-level reconstruction error. The units of PSNR are decibels (dB), higher is better. Targeted PSNR is >30 dB for acceptable quality. Histogram intersection is a similarity metric used to compare two histograms. It measures how much two distributions overlap by computing the minimum value at each bin across both histograms and summing these minimums. For two histograms H_1 and H_2 with n bins [see Eq. (9)]:

$$\text{Intersection} = \Sigma \min(H_1(i), H_2(i)) \text{ for } i = 1 \text{ to } n \quad (9)$$

Table I shows the PSNR and the histogram intersection for pix2pixHD and CycleGAN.

TABLE I. PSNR AND HISTOGRAM INTERSECTION FOR PIX2PIXHD AND CYCLEGAN

	pix2pixHD	CycleGAN
PSNR	21.25dB	15.49dB
Histogram Intersection	65.25%	53.99%

Higher values for both indicate better conversion accuracy. These results show that pix2pixHD is superior in conversion. As for issues related to the image conversion section alone, we believe that seasonal changes in vegetation and clouds affect image conversion, and that the difference in frequency between the visible light of the optical sensor and the microwaves of the SAR sensor may limit the conversion accuracy from being improved any further. As the result, it is found that pix2pixHD is superior to CycleGAN with 5.76dB, and 11.26%, respectively. As for the issues with the image conversion section alone, we believe that seasonal changes in vegetation and clouds affect image conversion, and that the conversion accuracy may not be able to be improved any further due to the difference in frequency between the visible light of the optical sensor and the microwave of the SAR sensor.

E. RGB Composite of SAR Images Before and After the Disaster

In addition to the above, the RGB composite of SAR images before and after the disaster is investigated. RGB compositing makes it possible to capture changes during a disaster by coloring the images before the disaster red and the afterward green and blue, and then compositing the images.

In this case, it was performed on the Noto Peninsula earthquake, which occurred on the 1st of 2024, and the change in light blue near the coastline indicates that uplift has occurred. These are the results of RGB compositing using pix2pixHD and CycleGAN. Both were able to capture changes near the coastline, similar to the correct RGB changes. Fig. 8 shows the result.

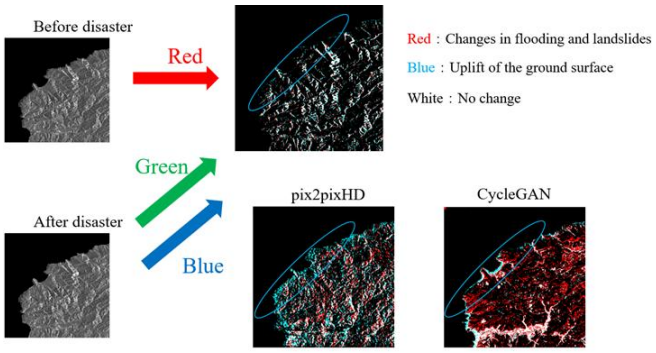


Fig. 8. Example of the disaster investigation RGB composite of SAR images before and after the disaster in case of the Noto earthquake.

By using two SAR imagery data acquired on before and after the Noto earthquake, changes in flooding and landslides are visualized in red colored portion while uplift of the ground surfaces is identified in blue colored portion, respectively.

The core insight is that phase generation bridges optical-SAR modality gaps via physics-based modeling [Eq. (1)], not just data-driven GANs—yielding interferograms viable for disaster ops. pix2pixHD excels due to paired supervision, but

CycleGAN offers unsupervised flexibility for data-scarce regions. Limitations include vegetation seasonality affecting coherence and C-band sensitivity to decorrelation; X-band SAR could improve. Practically, this reduces InSAR setup time from weeks to hours, critical for response.

V. Conclusion

This study successfully demonstrated a novel approach for earthquake disaster detection that overcomes the limitations of conventional interferometric SAR analysis. By leveraging GANs to generate synthetic pre-disaster SAR data from optical images, our method addresses the critical challenge of obtaining temporally and spatially compatible SAR image pairs for interferometric processing.

The key contributions of this work include:

1) the development of a GAN-based framework capable of synthesizing both amplitude and phase components of SAR data from optical imagery and DEM,

2) the demonstration that synthetic pre-disaster SAR data can be effectively interfered with actual post-disaster SAR observations to detect ground surface changes, and

3) experimental validation confirming the feasibility of this approach for earthquake disaster assessment.

The proposed method offers significant practical advantages for disaster response scenarios, where pre-disaster SAR data is unavailable or unsuitable for interferometric analysis. By utilizing widely available optical satellite imagery, this approach expands the applicability of interferometric SAR techniques for rapid earthquake damage assessment and emergency response planning. Future work will focus on quantitative validation against ground truth measurements and extension to other types of natural disasters.

Despite these promising results, this study has several limitations. First, the experiments are conducted on a limited number of events and geographic regions, mainly focusing on the 2024 Noto Peninsula earthquake, so the generalization of the proposed method to different tectonic settings and land-cover conditions remains to be validated. Second, the conversion accuracy from optical to SAR imagery is still affected by seasonal changes, cloud contamination, and the fundamental frequency difference between optical and microwave sensors, which constrains the achievable image quality and interferometric coherence. Third, the current evaluation mainly relies on image-based metrics such as PSNR and histogram intersection; more comprehensive validation using ground truth displacement measurements and operational disaster response scenarios is required. Addressing these limitations will be an important direction for future work.

A. Future Works

In the future, the author will conduct another experiment with a variety of disaster types such as flooding, wildfire, and so on, with SAR imagery data, which is acquired just after the disaster event, and optical image which are acquired on a date almost the same as when SAR imagery data is obtained. Future extensions to floods/wildfires will broaden utility.

Acknowledgment

The author would like to thank Prof. Dr. Osamu Fukuda of Saga University for their valuable comments and suggestions.

Kulliyyah of Nursing, International Islamic University Malaysia, Pahang, Malaysia[4]

***Abstract*—The Nurse Scheduling Problem (NSP) is a constrained combinatorial optimisation problem that plays a critical role in healthcare scheduling and constraint optimisation. Traditional evolutionary approaches often rely on static fitness evaluation, which struggles to balance feasibility and solution quality under complex real-world constraints. This study proposes a competitive co-evolutionary algorithm for the NSP that introduces adaptive adversarial evaluation, where candidate schedules are assessed under dynamic competitive pressure to expose structural weaknesses and guide evolution more effectively. The proposed competitive NSP is evaluated on a 20-nurse, one-week scheduling instance and compared against a classical Genetic Algorithm (GA) under identical conditions for 30 independent runs. Experimental results show that the competitive NSP achieves a mean best penalty of 447.28, compared to 651.30 for the classical GA, corresponding to an average improvement of approximately 31%. The competitive approach further exhibits smoother convergence behaviour across generations, indicating stronger optimisation dynamics and improved robustness. These findings demonstrate that competitive co-evolution provides an effective and practical alternative to static fitness-based evolutionary methods for nurse scheduling, with broader applicability to healthcare scheduling and constraint optimisation problems.**

I. Introduction

Hospitals worldwide face increasing pressure to deliver high-quality healthcare services under growing demand, workforce shortages, and strict regulatory requirements. Population growth and demographic aging have intensified healthcare utilisation, particularly in inpatient and emergency settings, where nurses play a central role in daily clinical operations [1], [2]. Effective nurse scheduling is therefore essential for ensuring adequate staff coverage, maintaining care quality, and controlling operational costs, yet remains challenging due to the need to balance legal regulations, skill requirements, workload distribution, and individual preferences.

Within this context, the Nurse Scheduling Problem (NSP) is widely recognised as a highly constrained optimisation problem involving multiple conflicting objectives. Hard constraints, such as shift coverage, legal rest periods, and role-based rules, must be strictly satisfied to ensure feasibility, while soft constraints related to fairness, preferences, and workload distribution influence schedule quality and staff satisfaction [3],[4]. Studies have shown that poor balance between these objectives can lead to increased absenteeism, reduced job satisfaction, and higher operational costs, highlighting the importance of robust scheduling approaches [3]. As a result, NSP has been extensively studied over the past decades.

Consequently, numerous optimisation techniques have been proposed to address the NSP. Comprehensive survey and comparative studies consistently report difficulties when realistic constraints are considered, particularly in terms of scalability, robustness, and sensitivity to parameter tuning [5]. Despite these reported challenges, evolutionary approaches remain among the most widely explored solution paradigms for NSP due to their modelling flexibility and adaptability to complex constraints. Genetic algorithms have been widely adopted due to their flexibility in handling complex constraints [6], while memetic algorithms enhance search performance through hybridisation with local improvement strategies [7]. Harmony search and related metaheuristics have also been explored to address multi-constraint nurse rostering problems [8], alongside goal programming models that explicitly incorporate preference satisfaction [9]. Robust and scenario-based optimisation approaches have further been proposed to address uncertainty in nurse rostering, although these often increase computational complexity [10], while fuzzy optimisation models incorporate uncertainty directly into preference and constraint modelling [11]. A common limitation identified across these studies is the reliance on static evaluation functions, where schedules are assessed using fixed penalty weights throughout the search. Such static evaluation may fail to reflect changing problem difficulty, especially in highly constrained settings where different violations become dominant at different stages of optimisation.

In practical NSP settings, constraint interactions are inherently dynamic, where some violations are relatively easy to resolve during early search stages, while others become critical only after basic feasibility has been achieved. To address this challenge, co-evolutionary algorithms have been proposed as an extension of evolutionary optimisation, where multiple populations evolve simultaneously and influence one another during the search process [12]. Building on this foundation, competitive co-evolutionary algorithms introduce

adaptive evaluation through direct competition rather than fixed fitness assessment. Rosin and Belew [13] first formalised this prototype by demonstrating how evolving opponents can expose weaknesses that static evaluation fails to capture, thereby sustaining selection pressure during optimisation. Subsequent studies extended this idea in adversarial optimisation and game theoretic contexts. Olsson [14] proposed a host-parasite genetic algorithm, showing how asymmetric competition can improve robustness by preventing dominance stagnation. Lehre [15] provided a runtime analysis of competitive co-evolution under maximin optimisation, highlighting its ability to overcome negative drift that commonly leads to premature convergence in static fitness landscapes. Fajardo et al. [16] further demonstrated that fitness aggregation mechanisms play a critical role in maintaining effective competition, while a follow-up study [18] showed that inappropriate aggregation can destabilise competitive dynamics and degrade optimisation performance. Harris et al. [17] complemented these findings by proposing opponent sampling strategies based on strength similarity to stabilise co-evolutionary interactions and preserve meaningful selection pressure.

Despite substantial progress in genetic algorithm-based nurse scheduling, most existing approaches optimise feasibility and schedule quality within a single evolutionary process. This coupled optimisation can limit further improvements once feasible solutions are reached, as enhancements in soft constraints often conflict with feasibility maintenance. In this study, a competitive nurse scheduling framework is proposed to explicitly model this conflict by introducing competitive evolutionary pressure between objectives, thereby enabling sustained optimisation beyond feasibility and addressing stagnation commonly observed in baseline genetic algorithms.

Motivated by this gap, this study introduces a competitive co-evolutionary optimisation approach for the Nurse Scheduling Problem. The proposed algorithm preserves the original NSP formulation and constraint structure while enhancing optimisation dynamics through adaptive adversarial evaluation, showing that improved performance can be achieved without problem reformulation or additional constraints. Comparative experiments against a classical Genetic Algorithm for 30 independent runs demonstrate improved solution quality, convergence stability, and robustness under realistic scheduling conditions. These findings indicate that competitive co-evolution is a viable optimisation paradigm for complex healthcare scheduling problems and can be generalised to other highly constrained settings where static fitness evaluation leads to premature convergence.

The remainder of this study is organised as follows: Section II reviews the literature on nurse scheduling and evolutionary optimisation. Section III presents the NSP formulation, including hard and soft constraints. Section IV describes the proposed competitive co-evolutionary methodology. Section V outlines the experimental setup and evaluation metrics. Section VI presents and discusses the results, followed by conclusions in Section VII.

II. Literature Review

A. Nurse Scheduling Problem and Conventional Solution Approaches

The Nurse Scheduling Problem (NSP) has been widely studied due to its significant impact on hospital operations, staff wellbeing, and patient safety. Classical NSP formulations distinguish between hard constraints, which ensure feasibility and legal compliance, and soft constraints, which influence schedule quality, fairness, and preference satisfaction [3],[4]. Realistic NSP models often include multiple nurse roles, skill requirements, shift-pattern rules, and workload balance, resulting in complex and highly constrained scheduling problems.

Early NSP solutions relied on exact mathematical programming and rule-based heuristics. However, these approaches scale poorly as problem size and constraint complexity increase. As a result, metaheuristic methods have become dominant in the literature. Techniques such as genetic algorithms and memetic algorithms have been widely applied with varying success [5],[6], while other metaheuristics, such as heuristic metaheuristic designs for hard and soft constraint nurse rostering, continue to be explored [7],[8]. While these methods are flexible and capable of handling complex constraints, many studies report sensitivity to fitness design, penalty calibration and stagnation during the search process [5], [6].

Several studies emphasise the importance of incorporating realistic operational constraints into NSP models. Azimi et al. showed that neglecting practical staffing rules can produce schedules that appear optimal numerically but are infeasible in practice [4]. Wright and Mahar further demonstrated that scheduling decisions directly influence both operational cost and nurse satisfaction, highlighting the need for balanced optimisation strategies [3]. Robust and scenario-based models have also been proposed to address uncertainty in staffing demand, although these often increase computational complexity [11]. More recently, exact and model-based approaches remain active, including mixed-integer programming nurse rostering models that incorporate preference and qualification structures [20] and practical MILP case studies that reduce workload imbalance [25].

Despite the diversity of solution methods, most NSP solvers rely on static evaluation functions with fixed penalty weights. While effective for benchmark problems, static evaluation can struggle when different constraint violations become dominant at different stages of optimisation, leading to premature convergence or extensive parameter tuning [5],[10].

B. Evolutionary and Co-Evolutionary Methods in Nurse Scheduling

Evolutionary algorithms are among the most commonly used techniques for the NSP due to their flexibility and ability to handle complex constraints. Genetic Algorithms (GAs) have been widely applied in nurse scheduling, while memetic algorithms, which combine evolutionary search with local improvement, have been shown to improve convergence speed

and solution quality in some NSP variants [6]. Other approaches, such as bi-level heuristics and shift swapping strategies, further exploit problem structure to refine feasible schedules [9]. Recent evolutionary and hybrid systems continue to be proposed in practical healthcare settings, including Round-Robin GA-based scheduling systems that report improvements in fairness and execution time in real medical centre contexts [22], as well as healthcare workforce scheduling studies that formulate staffing as a multi-objective GA optimisation problem [24].

Co-evolutionary methods have received comparatively less attention in NSP research. Existing studies mainly focus on cooperative co-evolution, where multiple subpopulations contribute jointly to a single solution [12], [19]. While such approaches are effective for decomposable problems, they assume alignment between subcomponents as an assumption that does not always hold in NSP.

In practical nurse scheduling, improving one aspect of a roster, such as fairness, may negatively affect another aspect, such as coverage or legal compliance. Cooperative co-evolution does not explicitly model this tension, as subpopulations are designed to collaborate rather than challenge candidate schedules. As a result, cooperative approaches may lose selection pressure once near-feasible solutions are obtained.

While co-evolutionary approaches provide useful conceptual insights into evolutionary scheduling, this study focuses on the evaluation of a competitive nurse scheduling formulation in comparison with a baseline genetic algorithm.

C. Competitive Co-Evolution and its Relevance to NSP

Competitive co-evolutionary algorithms introduce adaptive selection pressure through direct competition rather than static fitness evaluation. Rosin and Belew [13] established the foundational concept of competitive co-evolution by demonstrating how evolving opponents can actively expose solution weaknesses that static evaluation fails to capture. Building on this idea, competitive co-evolution has been further explored in adversarial optimisation and robust learning contexts, where Olsson [14] showed that asymmetric host parasite interactions can improve robustness by preventing dominance stagnation.

More recent studies have examined the dynamics and stability of competitive co-evolution in greater depth. Lehre [15] provided a runtime analysis showing how competitive evaluation can overcome negative drift in maximizing optimisation problems. Fajardo *et al.* [16] demonstrated that fitness aggregation mechanisms play a critical role in sustaining effective competition, while a follow-up study by the same authors [18] showed that inappropriate aggregation can destabilise co-evolutionary dynamics and hinder optimisation progress. Complementing these findings, Harris *et al.* [17] proposed opponent sampling strategies based on strength similarity to stabilise competition and preserve meaningful selection pressure.

This competitive standard is particularly relevant to the NSP, where constraint violations can be viewed as challenges that reveal weaknesses in schedules. Certain shift patterns, role assignments or coverage configurations may consistently expose problematic structures. Competitive evaluation can adaptively focus on these weaknesses, enabling continued improvement even after basic feasibility has been achieved.

Despite these advances, competitive co-evolution has received limited attention in nurse scheduling research. Existing co-evolutionary scheduling studies primarily adopt cooperative strategies, where multiple subpopulations work jointly toward a shared objective [12], [19]. While effective for certain decomposable problems, cooperative approaches do not explicitly model the inherent tension in NSP between feasibility and schedule quality, and may therefore struggle to maintain selection pressure once near feasible solutions are obtained. In parallel, recent non-coevolutionary NSP studies continue to explore alternative mechanisms for sustaining search pressure, including modern metaheuristics such as the Whale Optimization Algorithm adapted for nurse scheduling [23], highlighting the ongoing need for effective selection dynamics in realistic rostering problems.

In summary, although substantial progress has been made in evolutionary and hybrid optimisation methods for NSP, most existing approaches rely on static evaluation and cooperative or single-population search strategies. Competitive co-evolution, despite its ability to maintain adaptive selection pressure and robustness in other domains, has not been systematically explored for nurse scheduling. Existing co-evolutionary studies in scheduling primarily focus on cooperation rather than adversarial evaluation.

This gap motivates the development of a competitive co-evolutionary NSP algorithm that explicitly captures the adversarial nature of constraint satisfaction. By embedding adaptive competition into schedule evaluation, competitive co-evolution has the potential to address persistent challenges in NSP, including stagnation near feasibility, sensitivity to penalty tuning and limited robustness under complex real-world constraints. The proposed methodology, presented in the next section, adapts competitive co-evolutionary principles to the NSP context, while preserving practical feasibility and realistic scheduling requirements.

III. Problem Formulation

The Nurse Scheduling Problem (NSP) addressed in this study concerns the construction of a weekly duty roster that assigns nurses to shifts while satisfying operational feasibility and quality requirements. Let $N = \{1,2,\dots n\}$ denote the set of nurses and $D = \{1,2,\dots 7\}$ the set of planning days from Monday to Sunday. Each nurse is assigned exactly one shift per day from the set $S = \{1,2,3,4\}$ that represent Morning, Afternoon, Night, Post-Night and Off-day consecutively. Nurses belong to different roles, including sisters N_s, senior nurses N_{sen} and healthcare assistants N_{hca}, where role membership determines eligibility for specific shifts and Off-day rules. A schedule is represented by a discrete decision variable $x_{i,d} \in S$, where $x_{i,d}$ denotes the shift assigned to nurse i on day d. The feasibility and quality of a schedule are evaluated through a set of hard and soft constraints. Hard constraints capture mandatory operational requirements and include minimum coverage for working shifts, role-based Off-day restrictions and minimum weekly working hours. Any

violation of these constraints is considered unacceptable from an operational standpoint and incurs a large penalty.

Soft constraints model preference and fairness considerations that influence schedule quality but do not invalidate feasibility. These include shift sequences such as the night shift must be followed by a post-night shift, balanced role coverage across shifts, acceptable ranges of weekly working hours and fair distribution of night shifts among eligible nurses. Soft constraint violations are penalised at a lower magnitude than hard constraints, reflecting their secondary priority. The overall penalty of a schedule x is computed using an additive formulation, as in Eq. (1):

$$F(x) = HC(x) + SC(x) \quad (1)$$

where, $HC(x)$ denotes the total hard constraint penalty and $SC(x)$ denotes the total soft constraint penalty. The classical NSP optimisation objective is therefore $min\ F(x)$, subject to the implicit domain restriction $x_{i,d} \in S$. This formulation aligns with conventional penalty based evolutionary approaches to nurse rostering and allows both feasibility and quality considerations to be captured within a single objective value.

However, because the penalty function aggregates violations across all nurses and all days, schedules that achieve low overall penalty may still contain localised structural weaknesses, such as fragile shift sequences or concentrated workload patterns affecting specific nurses. These weaknesses can remain hidden when evaluation relies solely on the global objective $F(x)$, particularly when penalty tuning balances competing constraints at an aggregate level. As a result, conventional optimisation may converge to schedules with low overall penalty values while still containing local weaknesses that are not explicitly captured by the aggregate evaluation.

To address this issue, the NSP formulation in this work is later extended with a competitive evaluation mechanism that preserves the same decision variables, constraints and penalty definitions, while altering the evaluation context under which schedules are compared. Rather than modifying the objective function itself, the competitive algorithm dynamically emphasises constraint sensitive positions during fitness assessment, enabling the optimisation process to distinguish between schedules that are merely low penalty and those that are robust under focused constraint stress. The competitive evaluation strategy and its integration into the evolutionary process are described in the following section.

Table I lists the hard and soft constraints used in the competitive NSP evaluation. The constraint set is consistent with conventional NSP formulations and is reused to isolate the effect of competitive fitness evaluation.

TABLE I. HARD AND SOFT CONSTRAINTS CONSIDERED IN COMPETITIVE NSP

ID	Constraint Description	Penalty Type
HC1	Minimum coverage for AM, PM, and Night shifts per day	Hard
HC2	Role based OFF-day rules (sisters: weekend OFF; others: exactly one OFF)	Hard
HC3	Minimum weekly working hours per nurse (Role based)	Hard
SC1	Legal shift sequence (Night must be followed by Post-Night)	Soft
SC2	Sisters assigned only AM/PM shifts on weekdays	Soft
SC3	Balanced role coverage across shifts (SEN and HCA presence)	Soft
SC4	Weekly working hours within preferred range	Soft
SC5	Fair distribution of night shifts among non-sisters	Soft

IV. METHODOLOGY

This study employs a competitive co-evolutionary optimisation algorithm, representing an advanced evolutionary optimisation model, to solve the Nurse Scheduling Problem (NSP) formulated in Section III. The underlying NSP model, including decision variables, constraints, and penalty definitions, remains unchanged. Unlike classical single population, genetic algorithms that rely on static fitness evaluation, the proposed approach introduces an adaptive competitive evaluation mechanism in which candidate schedules are assessed under adversarial selection pressure that varies dynamically throughout the evolutionary process.

A. Competitive Co-Evolutionary Algorithm

The proposed algorithm maintains two concurrently evolving populations with distinct roles. The first population consists of candidate nurse schedules, where each individual encodes a complete weekly roster represented as a nurse, day and shift assignment matrix. Each entry specifies the shift assigned to a nurse on a given day using discrete shift codes defined in the NSP formulation.

The second population acts as an evaluation population and does not represent alternative schedules. Instead, individuals in this population encode binary evaluation masks defined over the same nurse-to-day grid. A value of 1 activates focused evaluation at a specific nurse-to-day position, while a value of 0 excludes it. This design allows the algorithm to dynamically intensify selection pressure on structurally weak regions of schedules without introducing new constraints or modifying feasibility rules.

Fig. 1 illustrates the overall workflow of the proposed competitive co-evolutionary nurse scheduling algorithm. The approach operates on the original NSP formulation and maintains two populations that evolve concurrently. The schedule population encodes complete weekly nurse rosters, while the evaluation population encodes binary evaluation masks that selectively emphasise constraint sensitive nurse to

day assignments. During each generation, candidate schedules are assessed using a competitive fitness function that augments the base NSP penalty with a focused adversarial term. This mechanism introduces adaptive selection pressure without modifying the underlying constraints or objective definition. Evolutionary operators are applied independently to both populations, and the final solution is selected from the scheduled population based on the base NSP objective function.

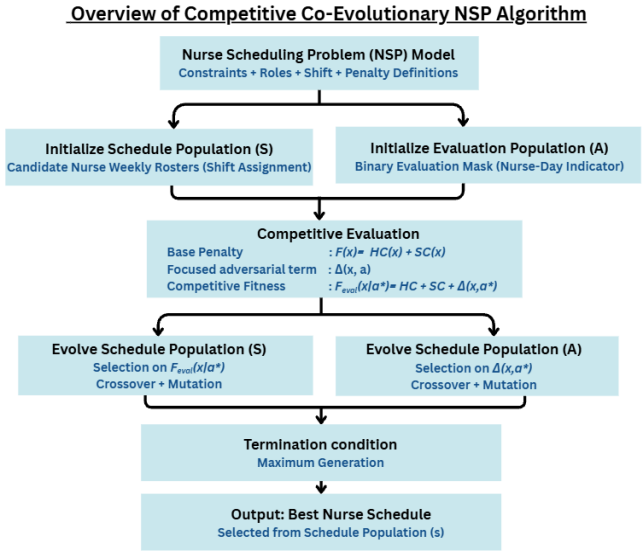

Fig. 1. Overview of the competitive co-evolutionary nurse scheduling algorithm.

B. Chromosome Representation

In the schedule population, each chromosome encodes a full weekly roster. For example, a row corresponding to Nurse i may be represented as:

Nurse i: [0 1 4 2 3 0 4]

where, the values denote Morning, Afternoon, Off-day, Night, Post-Night, Morning, and Off-day assignments respectively. In contrast, the evaluation population encodes binary masks over the same structure. A corresponding evaluation chromosome may be represented as:

Mask Nurse $\boldsymbol{i}$: [1 0 0 1 1 0 0]

Here, a value of 1 indicates that the corresponding nurse-to-day assignment is selected for focused evaluation, while a value of 0 indicates that it is ignored in the focused penalty computation.

C. Competitive Evaluation Mechanism

For each candidate schedule x, the base schedule quality is first evaluated using the standard NSP objective function as in Eq. (1). Competitive evaluation is introduced through an additional focused penalty term $\Delta(x, a)$ computed jointly from the schedule x and an evaluation mask a.

Here, $\Delta(x, a)$ denotes the focused adversarial penalty induced by evaluation mask a on schedule x. In the competitive process, $\Delta(x*, a)$ is used to evaluate adversaries against the current best schedule $x*$, while $\Delta(x, a*)$ is used to evaluate all candidate schedules under the selected strongest adversary $a*$. This distinction reflects the asymmetric roles of adversary selection and schedule evaluation in the competitive co-evolutionary algorithm.

The focused penalty re-evaluates existing constraint rules only at nurse-to-day positions activated by the mask. At these positions, local conditions such as role legality, Off-day requirements and night-to post-night sequencing are checked and penalised if violated. Positions not selected by the mask do not contribute to this term. Importantly, no new constraints are introduced, instead the mechanism amplifies the impact of existing violations at selected locations. The competitive fitness of a schedule is defined as Eq. (2):

$$F_{eval}(x|a^*) = HC(x) + SC(x) + \Delta(x, a^*) \qquad (2)$$

This formulation discourages schedules that achieve low aggregate penalties by relying on fragile local patterns, thereby promoting robustness under adversarial evaluation.

D. Adversarial Selection and Population Interaction

At each generation, a reference schedule x^* is identified as the individual with the lowest base penalty $F(x)$ in the schedule population. The evaluation population is then assessed against this reference schedule, and the strongest evaluator a^* is selected by maximising $x\ \Delta(x^*, a)$.

All candidate schedules are subsequently evaluated using the same evaluator a^*, ensuring a consistent competitive context within each generation. Evaluation individuals are selected based solely on their ability to expose weaknesses in the reference schedule, while schedule individuals are selected based on their competitive fitness. The two populations interact only through this adversarial evaluation mechanism, without chromosome exchange, cooperative pairing, or decomposition.

E. Evolutionary Operators and Termination

Both populations evolve using standard genetic operators, where the scheduled population applies selection, crossover, and mutation operators designed to preserve role eligibility and basic feasibility. The evaluation of the population evolves independently using analogous operators suitable for binary representations, encouraging diversity in evaluation focus and preventing stagnation.

The evolutionary process continues until a pre-defined termination condition is met. Throughout the search, solution quality is monitored using the base NSP objective $F(x)$ to ensure fair comparison with baseline algorithms.

The overall workflow of the proposed competitive co-evolutionary nurse scheduling algorithm is summarised in Pseudocode, illustrating the parallel evolution of schedule and evaluation populations and their interaction through adversarial fitness assessment.

Having described the proposed competitive co-evolutionary nurse scheduling algorithm and its adversarial evaluation mechanism combined, as in Eq. (2), the next section details the experimental setup used to assess its effectiveness. This includes the problem instances, parameter settings, baseline algorithms for comparison, and performance metrics employed to ensure a fair and reproducible evaluation of the proposed approach.

Pseudocode: Competitive Co-Evolutionary NSP

Initialize schedule population S
Initialize adversarial population A

Evaluate base penalty $F(x)$ **for** all $x \in S$
bestSoFar ← $min\ F(x)$
For generation = 1 **to** MAX_GENERATION **do**

Identify reference schedule:
$x* \leftarrow arg\ min\ F(x),\ x \in S$
Identify strongest adversary:
$a* \leftarrow arg\ max\ \Delta(x*, a),\ a \in A$

For each schedule x ∈ S do
$F_{eval}(x) \leftarrow HC(x) + SC(x) + \Delta(x, a*)$
End For

For each adversary $a \in A$ **do**
$G(a) \leftarrow \Delta(x*, a)$
End For
Evolve S using tournament selection on F_{eval}
Evolve A using tournament selection on G

If $min_{x \in S} F(x) < F(bestSoFar)$ then
bestSoFar← $arg\ min\ F(x)_{x \in S}$
End If
Update bestSoFar if a lower $F(x)$ is found
End For
Return bestSoFar // // best schedule from Schedule Population S //selected by NSP population objective, $F(x)$

V. Dataset and Experimental Setup

The proposed competitive co-evolutionary approach was evaluated using benchmark nurse scheduling instances derived from realistic ward-level rostering scenarios. Each dataset represents a seven-day planning horizon from Monday to Sunday and includes multiple nurse roles, including sisters, senior nurses and healthcare assistants. The datasets incorporated role-based shift eligibility, coverage requirements, legal rest rules, and workload balance to reflect practical hospital scheduling conditions.

The experimental evaluation focuses on a 20-nurse, one-week scheduling instance, which was deliberately selected to provide a controlled and interpretable setting for comparative analysis. This scale enables clear observation of optimisation dynamics, convergence behaviour and robustness differences between evolutionary strategies without introducing confounding effects from instance size.

All compared methods were operated on identical problem instances and shared the same schedule representation, constraint definitions and penalty structure. This ensures that observed performance differences arise from optimisation strategy rather than differences in problem formulation.

The experimental evaluation considered two optimisation approaches, namely a classical genetic algorithm (GA) and the proposed competitive co-evolutionary NSP. The approaches differ only in their evolutionary interaction and fitness evaluation mechanisms, while genetic operators and representations remain consistent across both methods.

Algorithm parameters follow commonly adopted settings in evolutionary nurse scheduling studies and are held constant across methods unless otherwise stated. Each algorithm was executed for a fixed number of generations with identical population sizes and stopping criteria. To account for stochastic effects, 30 independent runs were performed for each dataset using different random seeds.

Performance was assessed using best and average penalty values across generations, together with convergence trends over time. All reported results were computed using the base NSP objective function to ensure that comparisons reflect genuine schedule quality rather than effects introduced by adversarial evaluation.

All experiments were conducted on the same computational platform using a consistent software environment. Execution time, convergence behaviour and solution quality were recorded for each run and form the basis of the comparative analysis presented in the following section.

While larger and more diverse nurse scheduling instances are important for evaluating scalability, the primary objective of this study is methodological validation of competitive co-evolutionary optimisation under controlled conditions. Extension of the proposed approach to larger scale and multiple ward nurse scheduling problems is therefore identified as a key direction for future work.

Table II summarises the dataset characteristics and scheduling requirements used to evaluate the proposed competitive co-evolutionary NSP. The problem definition follows standard nurse rostering practice and was adopted to enable fair comparison across optimisation strategies.

TABLE II. Problem Parameters for Competitive Nurse Scheduling Experiments

Parameter	Description	Value
Planning horizon	Number of days per scheduling period	7
Number of nurses	Total nurses per instance	20
Nurse roles	Sisters / Senior Nurses / HCAs	5/8/7
Shift types	AM, PM, Night, Post-Night, OFF	5
Shifts per nurse per day	Assignment constraint	Exactly one
Coverage requirement	Minimum staff per working shift	≥1 Nurse and ≥1 HCA (role-dependent)
Weekly OFF rules	Role-specific OFF constraints	Enforced
Working hours rule	Minimum weekly hours	Enforced
Shift sequence rules	Legal patterns (e.g., N → PN)	Enforced
Constraint handling	Hard vs soft constraints	Penalty-based
Objective definition	Schedule quality measure	$HC(x) + SC(x)$ (base NSP objective)

Table III reports the algorithmic parameters used in the experimental comparison of classical GA and the proposed

competitive co-evolutionary approach. Both methods share identical operator settings unless stated otherwise.

TABLE III. ALGORITHM AND EXPERIMENTAL PARAMETERS

Parameter	Setting
Optimisation methods	Genetic Algorithm (GA) NSP, Competitive NSP
Population size	50 individuals per population
Number of populations	GA NSP = 1, Competitive NSP = 2
Parent selection	Tournament selection (size = 2)
Crossover operator	One-point crossover
Crossover probability	0.7
Mutation operator	Role-constrained shift reassignment
Mutation probability	GA NSP = 0.7, Competitive NSP = 0.05
Replacement strategy	Worst individual replacement based on the respective fitness definition
Maximum generations	15,000
Independent runs	30 runs per dataset
Fitness used for selection	GA NSP = Static base fitness, Competitive NSP = Adversarial competitive evaluation
Performance metric reported	Base NSP penalty (hard + soft constraints)

To ensure fair runtime measurement, execution time was recorded for the optimisation process only, excluding file input/output and result printing, which do not affect the optimisation logic.

VI. RESULTS AND DISCUSSION

This section presents the experimental evaluation of the proposed Competitive Co-Evolutionary Nurse Scheduling Problem (NSP) algorithm. The method was compared against the classical Genetic Algorithm (GA), where both algorithms shared identical problem representations, constraint formulations, and dataset parameter settings to ensure fair comparison. Performance was assessed using the total penalty value, defined as the sum of hard and soft constraint violations.

A. Performance Consistency for 30 Independent Runs

To evaluate robustness and repeatability, the Competitive NSP was executed for 30 independent runs using different random seeds. Across these runs, best penalty values ranged from 337.00 to 503.81, while average penalty values ranged from 339.72 to 590.16, indicating some variability inherent to stochastic optimisation.

TABLE IV. STATISTICAL SUMMARY OF COMPETITIVE NSP PERFORMANCE ACROSS 30 RUNS

Metric	Best Penalty	Average Penalty
Mean	447.28	520.14
Std. Dev.	41.63	60.27
Minimum	337	339.72
Maximum	503.81	590.16

The statistical summary of these runs is reported in Table IV. The method achieves a mean best penalty of 447.28 and a mean average penalty of 520.14, with relatively low standard deviations of 41.63 and 60.27, respectively. These results demonstrate stable convergence behaviour and confirm that the proposed competitive algorithm consistently produces high-quality nurse schedules across repeated executions rather than relying on isolated favourable runs.

B. Comparative Statistical Analysis

A comparative statistical summary for both methods was reported in Table V. The classical GA achieves a mean best penalty of 651.3 and a mean average penalty of 884.6. While the GA exhibits relatively low variance, its final penalty values remain substantially higher than those obtained by the Competitive NSP, suggesting premature convergence once basic feasibility is achieved.

TABLE V. COMPARATIVE PERFORMANCE SUMMARY OF GA AND COMPETITIVE NSP

Metric	Genetic Algorithm (GA) NSP	Competitive NSP
Mean Best Penalty	651.30	447.28
Mean Average Penalty	884.60	520.14
Std. Dev. (Best)	37.90	41.63
Std. Dev. (Average)	40.80	60.27
Minimum Penalty	581.70	337.00
Maximum Penalty	703.60	503.81

In contrast, the Competitive NSP demonstrates markedly improved performance. The mean best penalty is reduced to 447.28, representing a 31.3% reduction compared to the baseline GA, while the mean average penalty decreases from 884.6 to 520.14, corresponding to a 41.2% reduction. These results indicate that introducing competitive evaluation significantly enhances optimisation effectiveness without modifying the underlying NSP formulation.

TABLE VI. EXECUTION TIME COMPARISON OF GA AND COMPETITIVE NSP

Metric	Genetic Algorithm (GA) NSP	Competitive NSP
Mean (sec)	20.53	12.67
Std. Dev (sec)	0.17	0.38
Minimum (sec)	20.22	12.12
Maximum (sec)	20.73	13.41
Median (sec)	20.54	12.48

Table VI reports the execution time statistics for both optimisation methods over 30 independent runs under identical computational settings. The baseline Genetic Algorithm (GA) records the higher mean execution time, with an average runtime of 20.53 seconds, reflecting its reliance on a single population search and static fitness evaluation, which typically requires additional generations to refine feasible schedules.

In contrast, the Competitive NSP achieves a substantially lower mean execution time of 12.67 seconds, representing a reduction of approximately 38.3% compared to the baseline GA. Although the Competitive NSP introduces additional evaluation mechanisms to model competition between objectives, its runtime remains efficient and well within practical limits for offline nurse scheduling. This improvement in computational efficiency, together with the significant gains in solution quality reported earlier, demonstrates the

effectiveness of competitive evaluation without incurring prohibitive computational cost.

C. Convergence Behaviour Analysis

The convergence behaviour of both methods is illustrated in Fig. 2 and Fig. 3, corresponding to GA NSP and Competitive NSP, respectively.

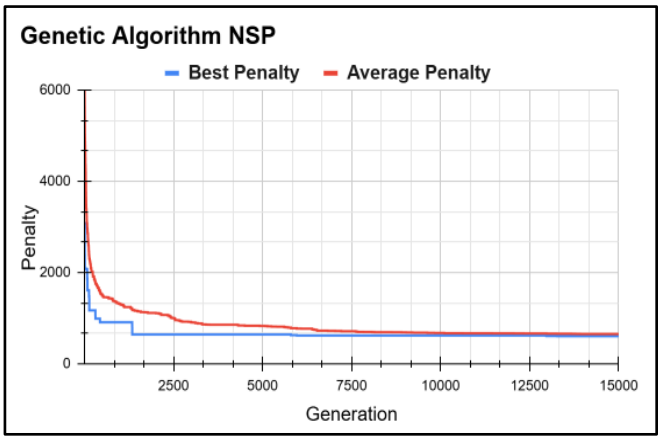

Fig. 2. Convergence of best and average penalty values for the genetic algorithm in NSP.

As shown in Fig. 2, the GA exhibits rapid initial improvement during the early generations, with penalty values decreasing sharply as feasible schedules are identified. However, convergence stagnates shortly thereafter, indicating premature convergence. This behaviour can be attributed to the reliance on static fitness evaluation within a single population, which limits further exploration once basic feasibility is achieved.

In contrast, Fig. 3 demonstrates that the Competitive NSP maintains a smooth and sustained reduction in penalty values throughout the evolutionary process. While its early convergence trend is visually similar to that of the GA, the Competitive NSP continues to refine solutions beyond the initial feasibility phase. This is evidenced by the progressively narrowing gap between the best-of-generation and average penalty values, indicating stronger population-wide improvement.

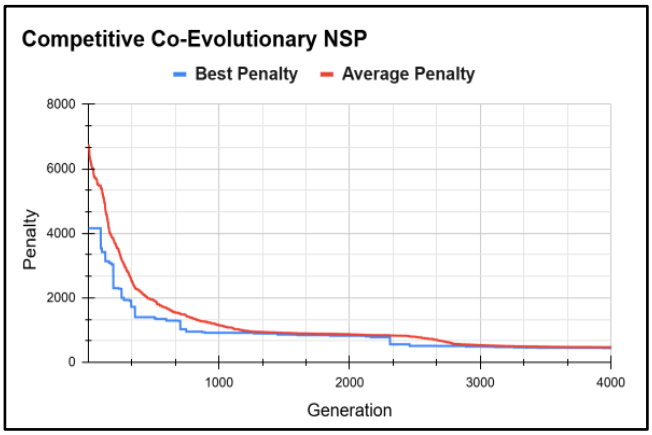

Fig. 3. Convergence of best and average penalty values for the competitive co-evolutionary NSP.

This convergence behaviour reflects more persistent selection pressure introduced by competitive evaluation, enabling continued optimisation and reducing the likelihood of stagnation. These results highlight the effectiveness of the Competitive NSP in sustaining meaningful optimisation progress compared to the baseline GA.

D. Discussion of Competitive Advantage

The superior performance of the Competitive NSP can be attributed to its relative evaluation mechanism, which fundamentally alters how selection pressure is applied during the search process. Unlike classical Genetic Algorithms, which optimise schedules against static evaluation criteria, the competitive algorithm continuously challenges candidate schedules under evolving evaluation contexts. This adaptive pressure discourages overfitting to fixed penalty weightings and prevents premature stagnation, allowing the algorithm to refine solution quality even after feasible schedules have been identified. Similar limitations associated with static fitness evaluation have been reported in recent nurse scheduling studies [21] employing hybrid genetic algorithms and multi-objective formulations, where convergence tends to plateau once basic feasibility is achieved due to fixed objective definitions [22],[24]. In contrast, the competitive evaluation strategy sustains selection pressure beyond feasibility, enabling continued improvement in solution quality.

From an optimisation perspective, the competitive evaluation mechanism effectively exposes localised structural weaknesses that may remain hidden under aggregate penalty evaluation. Conventional NSP solvers assess schedules primarily through global penalty accumulation, which can mask fragile shift sequences or concentrated workload patterns affecting individual nurses. By selectively amplifying such weaknesses, adversarial evaluation forces the evolutionary process to address them explicitly. This behaviour is consistent with observations from competitive co-evolutionary research in other optimisation domains, where adaptive opponent-based evaluation has been shown to maintain meaningful selection pressure and mitigate stagnation caused by static fitness landscapes [15],[16]. The present results extend these findings by demonstrating that similar advantages can be realised within a practical nurse scheduling setting.

Importantly, both methods evaluated in this study optimise the same base objective function and share identical constraint definitions. The observed performance gains, therefore, stem from differences in evolutionary interaction and selection dynamics rather than changes to the NSP formulation itself. This characteristic differentiates the proposed approach from recent integer and mixed-integer programming-based nurse rostering models, which typically rely on fixed optimisation objectives and predefined constraint weighting schemes to achieve solution quality [20],[25]. While such exact and hybrid models offer strong feasibility guarantees, their optimisation behaviour remains tightly coupled to the chosen formulation and does not adapt dynamically during the search.

The competitive co-evolutionary algorithm also provides a distinct alternative to recent nature-inspired metaheuristics proposed for NSP, such as whale optimisation and related population-based methods, which primarily enhance

exploration through novel operators while retaining static fitness evaluation [23]. Rather than increasing operator complexity, the proposed method introduces adaptivity directly at the evaluation level, resulting in improved robustness without additional tuning parameters. This property is particularly relevant for real-world nurse scheduling environments, where constraint interactions are dynamic and difficult to capture through fixed penalty calibration.

Overall, these findings indicate that competitive co-evolution improves optimisation effectiveness through adaptive search dynamics rather than problem reformulation or operator augmentation. The results position competitive evaluation as a promising direction for healthcare scheduling and constraint optimisation, especially for highly constrained NSP instances where sustained adaptability and robustness are essential for producing high-quality schedules.

VII. Conclusion

This study examined the effectiveness of a competitive nurse scheduling formulation for solving the Nurse Scheduling Problem (NSP) and compared its performance with a classical Genetic Algorithm (GA). Unlike conventional evolutionary approaches that rely on static fitness evaluation within a single population, the proposed method introduces competitive evaluation into the evolutionary process, enabling adaptive and continuously informative selection pressure throughout the search.

Experimental results across 30 independent runs demonstrate clear differences in convergence behaviour between the two methods. The classical GA achieves rapid early improvement, but exhibits premature stagnation once near-feasible solutions are obtained, leading to higher final penalty values. In contrast, the Competitive NSP maintains sustained and smooth improvement across generations, achieving lower best and average penalties with a progressively narrowing gap between them. This behaviour indicates stronger population-wide refinement and improved robustness of the resulting schedules.

Notably, these performance gains are achieved without altering the underlying NSP formulation, constraint definitions, or penalty structure. The observed improvements arise solely from the introduction of competitive evaluation and its influence on evolutionary dynamics, rather than from problem reformulation or additional model complexity. This demonstrates the effectiveness of competitive evolutionary pressure in addressing stagnation commonly observed in GA-based nurse scheduling.

Future work will focus on extending the proposed competitive NSP to larger-scale nurse scheduling instances and integrated healthcare scheduling problems involving operating theatres and patient admissions. Further investigation into incorporating domain-specific knowledge within the competitive evaluation process is also planned. In addition, cooperative co-evolutionary algorithms may be explored as a complementary framework to examine how cooperative and competitive evolutionary pressures interact in complex and highly constrained healthcare scheduling environments.

Acknowledgment

The authors gratefully acknowledge the support of Universiti Teknikal Malaysia, Melaka and the Ministry of Higher Education, Malaysia under the Fundamental Research Grant Scheme (FRGS/1/2023/FTMK/F00546). This research was also supported by the University's Kesidang Scholarship, which funded the first author's postgraduate studies.

Declaration on the Use of AI-Assisting Tools

The authors declare that generative AI tools were used solely for language refinement and editorial assistance. Metaphorical Meaning Integration in Poetry Based on Online Discourse Data: Analysis from a Cognitive Linguistics Perspective

Ying LIU, Jiting XUE*
Mudanjiang Medical University, Mudanjiang 157000, Heilongjiang, China

***Abstract*—As an emerging literary form, online poetry has garnered significant attention due to its rapid dissemination, diverse styles, and complex metaphorical expressions. However, the process of metaphorical meaning integration in poetry is difficult to quantify, necessitating support from Artificial Intelligence technologies. This study integrates cognitive linguistics theory with AI algorithms to propose a three-dimensional fusion analysis framework—"cognitive theory + specific AI algorithms + online discourse data"—for dissecting metaphorical meaning integration in online poetry. By constructing a comprehensive methodology encompassing metaphor identification, semantic mapping, and integration analysis, this study offers a novel quantitative pathway for metaphor research in poetry. Experimental validation demonstrates that the integrated approach—leveraging Support Vector Machines (SVM), Convolutional Neural Networks (CNN), BERT pre-trained models, and the DeepSeek-R1 large model—achieves outstanding performance in metaphor recognition accuracy, semantic association quantification, and fusion effectiveness evaluation, fully embodying both theoretical and practical value.**

***Keywords*—Online discourse data; poetic metaphor; cognitive linguistics; Artificial Intelligence; semantic fusion**

I. Introduction

As a significant form of literary creation in the internet era, online poetry has gradually become an integral part of popular culture due to its rapid dissemination, diverse styles, and strong interactivity [1]. Metaphorical expressions in poetry not only carry rich cultural and emotional connotations but also reflect unique human thought patterns and cognitive mechanisms [2]. However, the process of metaphorical meaning integration is complex and difficult to quantify, urgently requiring systematic analysis through Artificial Intelligence technologies [3]. Recent breakthroughs in AI for natural language processing have opened new avenues for metaphor research. Algorithms like Support Vector Machines (SVM) [4] and Convolutional Neural Networks (CNN) [5] excel in text classification and feature extraction, while pre-trained models such as BERT [6] and DeepSeek-R1 [7] demonstrate immense potential in semantic analysis and reasoning. Based on this, the study proposes a three-dimensional integrated analytical framework combining "cognitive theory + specific AI algorithms + online discourse data". This framework aims to build a bridge between cognitive linguistics and AI technology, providing quantitative methods for poetic metaphor research.

From a cognitive linguistics perspective, poetic metaphor research primarily revolves around conceptual metaphor theory and conceptual integration theory [8]. Metaphor is a cognitive mechanism that achieves semantic transfer by mapping one conceptual domain onto another. In [9], the authors demonstrate this by mapping time onto money, endowing it with economic attributes. In [10], the authors elucidate the cognitive mechanism of metaphor, emphasizing that during cross-domain mapping, the integration of features from different conceptual domains forms a new semantic space. These theories provide a foundation for semantic analysis of poetic metaphors, though they remain insufficient for quantifying metaphor fusion effects.

In the field of AI algorithms, text metaphor recognition and semantic parsing technologies continue to advance. In [11], Support Vector Machines (SVM) demonstrated strong performance in metaphor classification tasks, effectively distinguishing metaphorical from non-metaphorical sentences. In [12], CNNs further enhance metaphor recognition accuracy through local contextual feature extraction. In [13], the BERT pre-trained language model offers novel insights for metaphorical meaning mapping via contextual semantic encoding. However, existing research predominantly focuses on metaphor identification, with limited in-depth analysis of metaphorical meaning fusion and a lack of theoretical support for cognitive mechanisms.

Furthermore, specialized research on metaphors in online poetry remains scarce. The dissemination characteristics and metaphorical expressions of online poetry possess unique traits. Its multi-thematic and diverse nature provides rich corpora for metaphor studies, yet existing research has failed to fully leverage these data [14]. Simultaneously, the training challenge for low-resource poetry corpora demands urgent solutions, with transfer learning and self-supervised learning offering potential approaches [15].

However, current research exhibits the following shortcomings: First, the integration of cognitive linguistics theories with AI algorithms remains superficial, with most studies confined to theoretical exposition and algorithmic application without in-depth exploration of their fusion mechanisms [16]. Second, research on metaphors in online poetry is scarce, failing to fully leverage the distinct characteristics of online discourse data [17]. Third, quantitative methods for analyzing metaphorical meaning fusion remain immature, lacking systematic evaluation metrics for fusion effectiveness [18].

*Corresponding author.

Addressing these gaps, this study constructs a three-dimensional integration framework combining specific algorithms with online discourse data to investigate metaphorical meaning integration in online poetry. Its main contributions are threefold: 1) Establishing a "cognitive theory + specific AI algorithms + online discourse data" framework that systematically outlines the integration pathway between cognitive linguistics and AI technology; 2) through constructing a web poetry corpus and performing data preprocessing, designed metaphor recognition, semantic mapping, and fusion analysis algorithms based on SVM, CNN, BERT, and DeepSeek-R1. This achieves end-to-end analysis of metaphorical meaning fusion, providing concrete algorithms and experimental validation for quantitative research on poetic metaphors; and 3) based on experimental results, quantitative evaluation metrics for metaphor fusion effectiveness were proposed, including metaphor recognition accuracy, semantic relevance, and fusion degree. These metrics validated the algorithms' efficacy and reliability, offering practical guidance for applied research in poetic metaphor studies.

II. Theoretical Foundations and Technical Support

A. Core Theories of Cognitive Linguistics

Cognitive linguistics provides three core theories for understanding metaphor: conceptual metaphor theory, conceptual integration theory, and image schema theory [19].

Conceptual metaphor theory, proposed by Lakoff and Johnson, posits that metaphor is a cognitive phenomenon involving the mapping of one conceptual domain (source domain) onto another conceptual domain (target domain) [20]. Fig. 1 illustrates the cross-domain mapping process in conceptual metaphor theory, visually representing the relationship between source and target domains and how mapping endows the target domain with new semantic features.

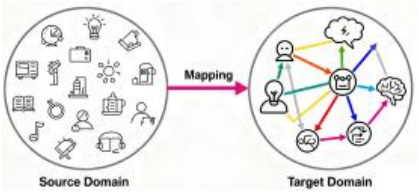

Fig. 1. Conceptual metaphor mapping diagram.

Conceptual integration theory further elucidates the cognitive mechanisms of metaphor. Proposed by Fauconnier and Turner, this theory emphasizes the integration of features from different conceptual domains within metaphorical expressions [21]. The cognitive process of metaphor involves four Mental Spaces: Input Space 1 (source domain), Input Space 2 (target domain), the Category Space (shared features), and the Fusion Space (integrated features). Through cross-domain mapping and feature integration, metaphorical expressions form new semantic spaces that aid in constructing and understanding complex conceptual relationships.

The mental schemata theory, grounded in human cognitive patterns, posits that metaphorical expressions rely on cognitive schemata of typical images, including "container schemata", "path schemata", and "spatial schemata" [22]. These schemata originate from human perception and experience, forming the foundation for understanding abstract concepts.

B. Core Algorithmic Principles of Artificial Intelligence

1) Metaphor recognition algorithms: Support Vector Machines (SVM) is a supervised learning algorithm based on statistical learning theory. It classifies data into distinct categories by identifying the optimal separating hyperplane [23]. For metaphor recognition tasks, SVM utilizes inputs such as word vectors and part-of-speech features to train classifiers that distinguish metaphorical sentences from non-metaphorical ones. The strength of SVM lies in its classification performance in high-dimensional spaces, enabling effective handling of complex textual features.

Convolutional Neural Networks (CNN) extract local contextual features through convolutional layers, reduce feature dimensions via pooling layers, and perform classification using fully connected layers [24]. CNN excels at capturing local textual features, particularly adept at identifying key words and phrases within metaphorical expressions.

Fig. 2 illustrates the metaphor recognition workflow of the SVM-CNN fusion algorithm, encompassing text feature extraction, feature vector generation, and classification prediction. This demonstrates how the two algorithms synergize to enhance metaphor recognition accuracy. Table I compares the performance of SVM and CNN in metaphor recognition tasks, including accuracy, recall, training efficiency, and applicable scenarios, providing a reference for selecting the appropriate algorithm.

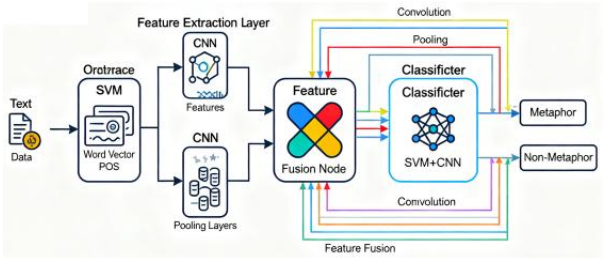

Fig. 2. Metaphor recognition using SVM and CNN fusion.

TABLE I. Comparison of SVM and CNN in Metaphor Recognition

Performance indicators	*SVM*	*CNN*
Accuracy	High, especially in high-dimensional feature spaces	High, especially in capturing local contextual features
Recall	Stable suitable for handling imbalanced datasets	Stable sensitive to local features suitable for complex contexts
Training efficiency	Low, especially on large-scale datasets	High suitable for large-scale data training
Applicable scenarios	High-dimensional feature spaces such as word vector representation	Local context feature extraction such as keyword and phrase recognition

2) Semantic analysis algorithm: BERT is a pre-trained language model based on the Transformer architecture [25]. It captures contextual semantic information in text through pre-training with the Masked Language Model (MLM) and Next Sentence Prediction (NSP) tasks. In metaphorical meaning mapping tasks, BERT encodes metaphorical sentences to generate semantic vectors, quantitatively analyzing the semantic association strength between the referent domain and the metaphorical domain. Fig. 3 illustrates how the BERT model performs contextual semantic encoding of text to generate semantic vectors.

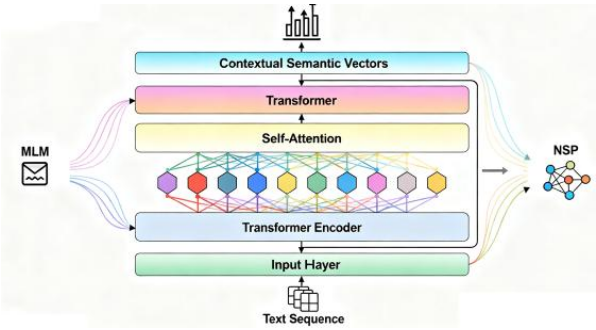

Fig. 3. BERT contextual semantic encoding logic.

DeepSeek-R1 is a large language model with robust deep semantic reasoning capabilities. It can analyze the cognitive logic behind metaphors, reconstructing the transformation and restructuring processes of imagery schemas [26]. Through its multi-layer neural network architecture, DeepSeek-R1 captures deep semantic features in text, offering a novel approach to cognitive analysis of metaphors. Fig. 4 illustrates the working principle of the DeepSeek-R1 large language model.

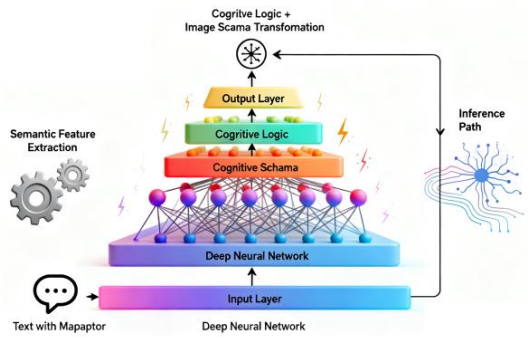

Fig. 4. DeepSeek-R1 schematic diagram.

3) Data processing algorithms: The application of transfer learning and self-supervised learning in low-resource poetry corpora holds significant importance. Transfer learning addresses the training challenges of low-resource poetry corpora by transferring knowledge from the source domain to the target domain [27]. Self-supervised learning leverages unlabeled data to learn textual features through tasks such as predicting masked words, thereby enhancing the model's generalization capability [28]. Fig. 5 illustrates the workflow of applying transfer learning and self-supervised learning to low-resource poetry corpora, encompassing pre-trained model transfer, feature extraction, and self-supervised task design. This demonstrates how these algorithms enhance the utilization efficiency of low-resource corpora.

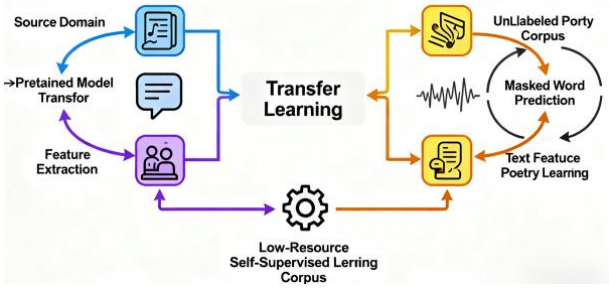

Fig. 5. Transfer learning and self-supervised learning in low-resource poetry corpora.

C. Application of Online Discourse Data in Integrating Metaphorical Meanings in Poetry

Online poetry corpora exhibit diversity, interactivity, and dynamism, providing rich practical scenarios for metaphorical meaning integration research.

Online poetry encompasses diverse themes and styles, featuring abundant metaphorical expressions. Readers participate in poetry dissemination through comments, shares, and other forms, fostering multidimensional metaphorical interpretations. This study constructed an online poetry corpus by collecting texts from poetry forums, social media, and other platforms, selecting representative metaphorical poems. Through corpus preprocessing and annotation, it provided data support for algorithm training.

During metaphorical meaning integration, the interactive nature of online discourse data provides multi-faceted information for semantic analysis. Reader comments and interpretations enrich the semantic layers of metaphors, enhancing the comprehensiveness of integration analysis. Simultaneously, the dynamic nature of the data requires algorithms to possess real-time updating and adaptive capabilities to address newly emerging metaphorical expressions in poetry. The formula for calculating metaphor integration is as follows:

$$FusionDe = \frac{\sum_{i=1}^{n} SemanticAs(i)}{n} \quad (1)$$

Here, $FusionDe$ represents metaphor fusion degree, $SemanticAs(i)$ denotes the association strength between the referent domain and the metaphor domain on the i-th semantic dimension, and n is the total number of semantic dimensions. This formula quantifies the fusion effect of metaphorical meaning in the synthetic space.

III. Research Design and Data Preprocessing

Before conducting research on the fusion of metaphorical meaning in online poetry, a systematic research design and data preprocessing are required. This section encompasses the construction of an online discourse poetry corpus, the

establishment of data preprocessing procedures, and the selection of appropriate algorithms.

A. Construction of the Online Discourse Poetry Corpus

Building a high-quality online discourse poetry corpus forms the foundation of this research. Corpus construction requires identifying data sources and establishing rigorous screening criteria to ensure diversity and representativeness.

1) Corpus sources: Online poetry data primarily originates from poetry platforms, forum comments, and social media shares [29]. Fig. 6 illustrates the main collection sources and distribution of poetry data, visually representing each platform's contribution ratio. The figure reveals that social media shares constitute a significant proportion, indicating the substantial influence of poetry dissemination on social media.

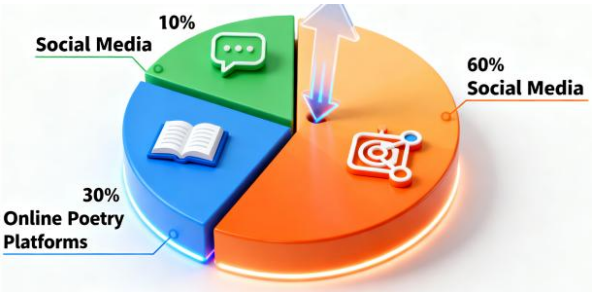

Fig. 6. Distribution map of poetry corpus collection sources.

Online poetry platforms include China Poetry Network and Poetry Journal Forum, which aggregate a vast collection of original poetry works, typically possessing high literary value and artistic merit. Forum discussions encompass platforms like Douban Poetry Group and Zhihu Poetry Topics, where poetry sharing and commentary provide rich interactive data. Social media sharing encompasses platforms like Weibo and WeChat Official Accounts, where poetry reposts and comments reflect dissemination popularity. Table II summarizes the volume of poetry corpora from various sources alongside dissemination metrics, offering a comprehensive overview of the corpus's overall characteristics. Poetry shared via social media demonstrates particularly prominent dissemination popularity, closely tied to its rapid propagation nature.

TABLE II. POETRY CORPUS STATISTICS

Platform type	*Number of poems*	*Average reads*	*Average likes*	*Average comments*
Online poetry platforms	1200	1500	120	30
Forum comments	800	800	60	20
Social media sharing	1000	2000	150	40

2) Corpus screening criteria: To ensure the quality and representativeness of the corpus, the following screening criteria were established:

Thematic diversity. Covering multiple common poetic themes such as love, nature, life, and society to ensure richness in metaphorical expression.

Metaphor density. Poems with high metaphor density better reflect the complexity and diversity of metaphorical expression, providing more meaningful data for subsequent algorithmic analysis. Metaphor density is calculated as follows:

$$MetaphorDensity = \frac{n_{Metaphors}}{n_{Sentences}} \quad (2)$$

Among these, $MetaphorDensity$ denotes metaphor density, $n_{Metaphors}$ represents the number of metaphors per poem, and $n_{Sentences}$ indicates the total number of lines per poem. Fig. 7 illustrates the distribution of metaphor density within the selected poetic corpus, reflecting its diversity and analytical value. The figure reveals that poems with metaphor densities exceeding 30% constitute a significant proportion, indicating that the selected corpus exhibits a high richness of metaphorical expression.

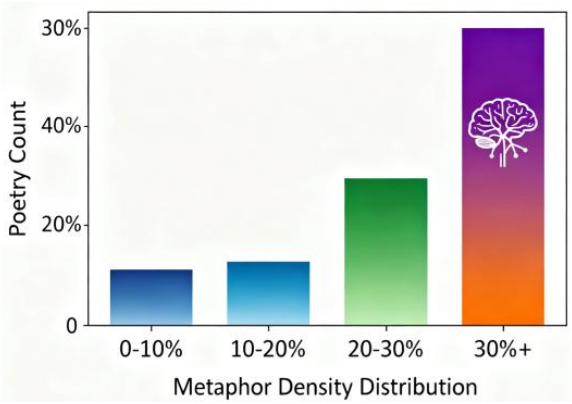

Fig. 7. Metaphor density distribution map.

Virality. Popular poems are selected based on metrics such as reading volume, likes, and comments to ensure the corpus's influence and representativeness.

B. Data Preprocessing Workflow

Data preprocessing is a critical step to ensure corpus quality, encompassing text cleaning, feature annotation, and data format conversion.

1) Text cleaning: The purpose of text cleaning is to remove irrelevant symbols, duplicate content, and non-poetic text to enhance corpus purity [30]. Specific operations include: 1) Removing irrelevant symbols. Using regular expressions to eliminate punctuation marks, emoticons, and other extraneous characters from poetic texts; 2) Removing duplicate content. using text deduplication algorithms to eliminate duplicate poetic paragraphs or entire poems; 3) Removing non-poetic text. Filtering out pure poetic text while discarding non-poetic content like author biographies and copyright notices. Fig. 8 illustrates the specific text cleaning workflow, encompassing steps to eliminate irrelevant symbols, duplicate content, and non-poetic text. These procedures effectively enhance corpus purity and quality.

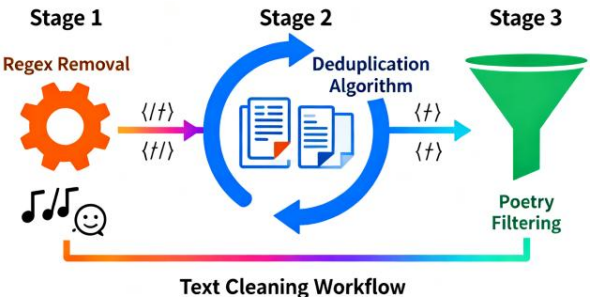

Fig. 8. Text cleaning flowchart.

2) Feature annotation: The purpose of feature annotation is to identify and annotate metaphor-related vocabulary, laying the foundation for subsequent metaphor recognition and semantic analysis. Specific operations include:

a) Word segmentation and part-of-speech tagging. Using the jieba tokenization tool to segment the poetry text and annotating the part-of-speech for each word using the part-of-speech tagging module; b) Metaphor-related lexical annotation. Based on the part-of-speech annotation results, identifying and annotating metaphor-related lexical items (nouns, verbs, adjectives); c) Manual correction. Incorporating manual correction to enhance the accuracy of feature annotation.

3) Data format conversion: The purpose of data format conversion is to transform textual data into a vector form processable by AI algorithms. Specific operations include:

Word Embedding. Employing the Word2Vec algorithm to convert words into fixed-length vector representations. By training on large text datasets, Word2Vec captures semantic and syntactic features of words, mapping them into a continuous vector space. Fig. 9 illustrates the Word2Vec embedding process, including generating word vectors and combining sentence vectors. Through extensive text training, Word2Vec generates high-quality word vectors that provide robust support for subsequent model training.

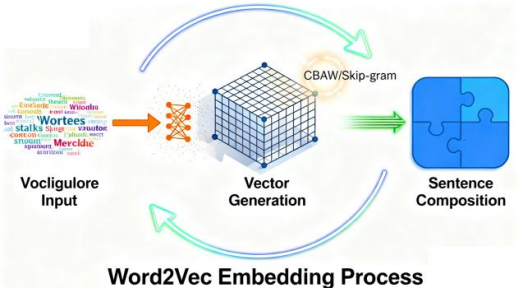

Fig. 9. Word2Vec lexical embedding process diagram.

Sentence Vectorization. Combine lexical vectors into sentence vectors to form the vector representation of a poem. By averaging or weighting the lexical vectors, we obtain the vector representation of the sentence, which serves as input data for model training. The sentence vector calculation formula is as follows:

$$SentenceVector = \frac{1}{n}\sum_{i=1}^{n} WordVector(i) \quad (3)$$

Here, $WordVector(i)$ represents the vector representation of the i-th word in the sentence, and n denotes the number of words in the sentence. This formula calculates the sentence vector by combining word vectors into a vector representation of the sentence. This approach converts poetic text into a numerical format that the model can process.

C. Algorithm Selection

Selecting appropriate algorithm combinations is crucial for metaphor recognition and semantic analysis in this research. This study specifies the following combinations:

a) SVM+CNN for metaphor recognition, leveraging SVM's classification capability and CNN's local context feature extraction. SVM excels at classification in high-dimensional spaces, while CNN effectively extracts local textual features. Their integration enhances metaphor recognition accuracy.

b) BERT + DeepSeek-R1 for semantic analysis, leveraging BERT's contextual semantic encoding and DeepSeek-R1's deep semantic reasoning capabilities. BERT captures contextual semantic information in text, while DeepSeek-R1 excels in deep semantic reasoning. Their integration enables a comprehensive analysis of metaphorical semantic features.

c) Transfer learning is employed for low-resource corpus optimization, enhancing model performance on sparse data by transferring knowledge from pre-trained models. This approach effectively addresses training challenges in low-resource settings and improves model generalization.

Fig. 10 illustrates the overall framework of algorithmic integration, encompassing combinations for metaphor recognition, semantic analysis, and low-resource corpus optimization. By integrating multiple algorithms, the strengths of each are leveraged to elevate the model's overall performance.

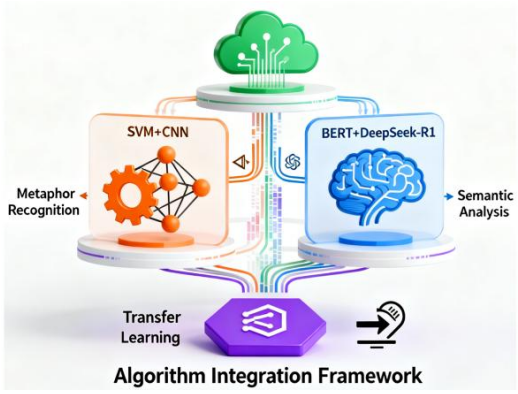

Fig. 10. Algorithm integration framework diagram.

D. Data Augmentation and Expansion

To further enhance the model's generalization capability and robustness, this study introduces data augmentation techniques. Through data augmentation, more training examples can be generated to enrich the diversity of the corpus.

Data augmentation operations include synonym substitution, sentence reordering, and sentiment reversal. 1) Synonym Substitution: Randomly replace selected words in poetic texts

with synonyms while preserving overall sentence meaning. 2) Sentence Rearrangement. Generate new sentence combinations by adjusting sentence structure and order; 3) Sentiment Reversal. Invert the emotional orientation of sentences while preserving their core meaning. Fig. 11 illustrates the principles behind synonym substitution, sentence rearrangement, and sentiment reversal. These methods effectively enrich corpus diversity and enhance model generalization capabilities.

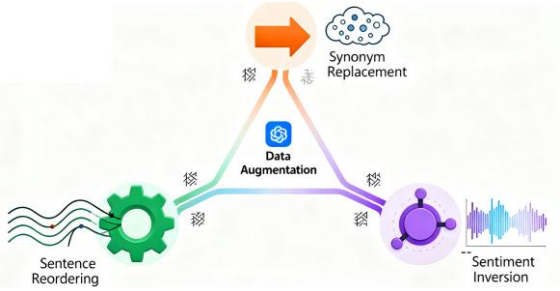

Fig. 11. Principles of data augmentation.

IV. AI Algorithm Implementation Path

Following the construction of the network discourse poetry corpus and data preprocessing, this section details the AI algorithm implementation path for integrating metaphorical meanings in poetry. Three core modules are designed: metaphor recognition, semantic mapping, and fusion analysis. These modules collaborate to achieve end-to-end processing from metaphor identification to semantic integration.

A. Metaphor Recognition Module

Metaphor recognition serves as the initial step in integrating poetic metaphorical meanings, with its accuracy directly impacting subsequent semantic analysis and fusion outcomes. This study employs a combined SVM and CNN algorithm for metaphor recognition, leveraging SVM's classification capabilities in high-dimensional feature spaces and CNN's strengths in extracting contextual features.

Feature input is a critical step in metaphor recognition, directly affecting model performance. This study constructs a comprehensive feature vector based on Word2Vec-generated word vectors, supplemented with part-of-speech features and contextual window features: 1) Word2Vec Word Vectors. A pre-trained Word2Vec model converts words into fixed-length vector representations, capturing semantic and syntactic features. 2) Part-of-speech features. Based on part-of-speech tagging results, the part-of-speech information of metaphor-related vocabulary, such as nouns, verbs, and adjectives, is encoded into feature vectors; 3) Context window features. Centering on the target vocabulary, fixed-size windows are set to the left and right to extract co-occurrence features of words within the window, capturing local contextual information.

The fusion algorithm process includes the following steps: First, CNN extracts local contextual features from the text, with CNN automatically learning local feature representations through convolutional and pooling layers. Next, the feature vectors extracted by CNN are input into an SVM classifier for classification, achieving binary classification of "metaphorical sentence/non-metaphorical sentence", and further subdividing metaphor types to annotate the subject-metaphor relationship. Fig. 12 illustrates the complete workflow of the SVM-CNN fusion algorithm, encompassing feature input, CNN feature extraction, feature vector generation, and SVM classification prediction, demonstrating the synergistic interaction between the two algorithms. Table III summarizes the dimensionality of different feature types within the metaphor recognition module, providing a detailed reference for feature engineering.

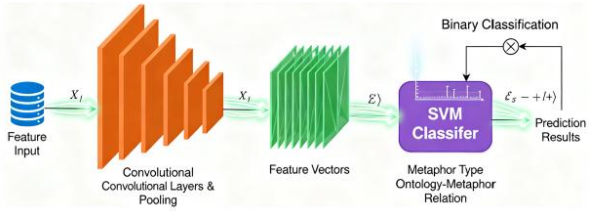

Fig. 12. SVM-CNN fusion algorithm.

TABLE III. Statistics of Metaphor Recognition Feature Input Dimensions

Feature type	*Dimension size*	*Description*
Word2Vec word vector	300	Word vector dimension
Part-of-speech features	10	One-hot vector dimension for part-of-speech tagging
Contextual window features	200	Co-occurrence feature vector dimensions extracted from the window

B. Semantic Mapping Module

After completing metaphor recognition, the next step involves performing semantic analysis on the identified metaphorical sentences. This entails constructing semantic vector spaces for the referent domain and the metaphor domain, followed by quantifying the semantic association strength between them. This study employs the BERT pre-trained model to build the semantic vector space.

BERT is a pre-trained language model based on the Transformer architecture. Through pre-training on large-scale text data using masked language modeling and next-sentence prediction tasks, BERT learns contextual semantic information from text, providing powerful semantic representations for various natural language processing tasks.

For identified metaphorical sentences, the BERT model first encodes them to generate contextual semantic vectors for each lexeme. Subsequently, semantic vector spaces for the referent domain and metaphor domain are constructed based on these lexical vectors. Specifically, the lexical vectors belonging to the referent domain within the metaphorical sentence undergo average pooling to obtain the referent domain's semantic vector. Similarly, average pooling is applied to the lexical vectors of the metaphor domain to obtain its semantic vector. Fig. 13 illustrates the process of semantic encoding for metaphor sentences using BERT and how the semantic vector spaces for the ontology domain and metaphor domain are constructed, providing data support for subsequent concept mapping.

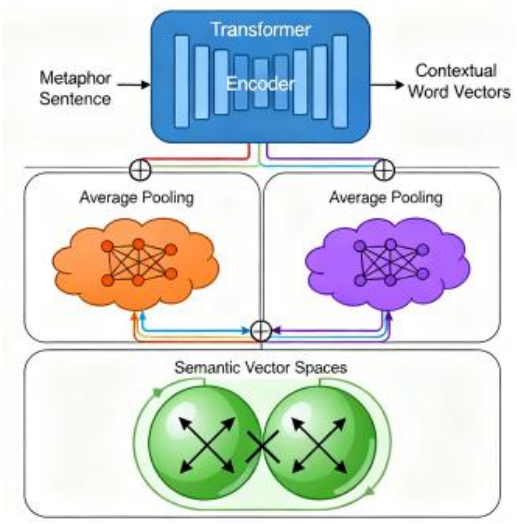

Fig. 13. BERT semantic encoding and semantic vector space construction.

To quantify the semantic association strength between the referent domain and the metaphor domain, the cosine similarity between their semantic vectors is computed. Cosine similarity measures the directional similarity between two vectors; values closer to 1 indicate stronger semantic association.

$$SemanticSimilarity = \frac{OntologyVector \cdot MetaVector}{\|OntologyVector\| \times \|MetaVector\|} \quad (4)$$

Among these, $OntologyVector$ represents the semantic vector of the referent domain, $MetaVector$ denotes the semantic vector of the metaphorical domain, $\cdot$ signifies the dot product of quantities, and $\|\cdot\|$ indicates the norm of the vector.

C. Fusion Analysis Module

Fusion analysis is a critical step in integrating the metaphorical meaning of poetry, aiming to decipher the cognitive logic behind metaphors and quantitatively assess the fusion effect of metaphorical meaning in the synthetic space. This study combines the deep semantic reasoning capabilities of the DeepSeek-R1 large model with Conceptual Integration theory to achieve fusion analysis.

DeepSeek-R1 is a large language model with powerful deep semantic reasoning capabilities. Through its multi-layer neural network architecture, it captures deep semantic features in text and demonstrates outstanding reasoning abilities across various complex tasks. In metaphor fusion analysis, DeepSeek-R1 is employed to deconstruct the cognitive logic underlying metaphors, reconstructing the transformation and restructuring of imagery schemas.

Based on conceptual integration theory, this study designed a fusion degree calculation algorithm to quantitatively evaluate the integration effectiveness of metaphorical meaning within the synthetic space. Specifically, semantic vectors from the ontology domain and metaphor domain are fused to generate semantic vectors in the synthetic space. Subsequently, similarity between the semantic vector in the synthetic space and the semantic vectors of the referent domain and metaphor domain is computed to evaluate integration effectiveness. Fig. 14 illustrates how the DeepSeek-R1 large model parses the cognitive logic behind metaphors and the integration degree calculation process based on conceptual integration theory, visually presenting the implementation path for metaphorical meaning integration.

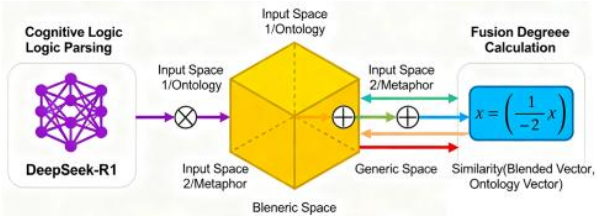

Fig. 14. DeepSeek-R1 inference and concept integration process.

D. Methodological Steps

In summary, the AI algorithm implementation path for integrating metaphorical meanings in poetry encompasses data preprocessing, metaphor identification, and fusion analysis. The workflow is illustrated in Fig. 15, with specific steps as follows:

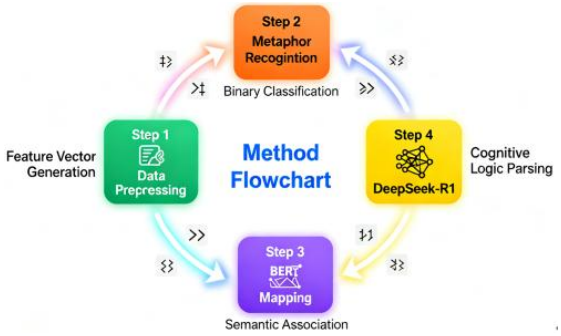

Fig. 15. Method flowchart.

Step 1: Data Preprocessing. Clean, annotate features, and convert formats of the online discourse poetry corpus to generate feature vectors suitable for model input.

Step 2: Metaphor Identification. Employ a hybrid SVM-CNN algorithm to achieve binary classification of "metaphorical sentences/non-metaphorical sentences" and subclassify metaphor types.

Step 3: Semantic Mapping. Construct semantic vector spaces for the referent domain and metaphor domain based on the BERT pre-trained model to quantify semantic association strength.

Step 4: Integration Analysis. Combine the DeepSeek-R1 large model with conceptual integration theory to decipher the cognitive logic behind metaphors and evaluate the effectiveness of metaphorical meaning integration.

V. Experimental Design and Effect Validation

A. Experimental Protocol Design

1) Experiment objectives and data collection: This experiment aims to validate the effectiveness and superiority of the proposed AI algorithm for integrating metaphorical meanings in poetry. By comparing different algorithms'

performance in metaphor identification, semantic mapping, and fusion analysis tasks, it evaluates model accuracy and stability, providing a quantitative analytical method for poetry metaphor research.

The experimental dataset is sourced from the constructed online discourse poetry corpus, comprising 2,200 preprocessed poems. The dataset is divided into training, validation, and test sets at ratios of 70%, 10%, and 20%, respectively. Stratified random sampling is employed to ensure the proportion of metaphorical and non-metaphorical sentences in each subset aligns with the overall dataset.

2) Algorithm selection and parameter configuration: To validate the effectiveness and superiority of the proposed AI algorithm for integrating poetic metaphor meanings, comparative analysis was conducted using SVM, CNN, BERT pre-trained models, the DeepSeek-R1 large model, SVM+CNN fusion algorithms, and BERT+DeepSeek-R1 fusion algorithms. Specific parameter configurations are detailed in Table IV.

TABLE IV. ALGORITHM PARAMETER SETTINGS

No.	*Algorithm*	*Parameter settings*
1	SVM	Regularization parameter C set to 1.0, Kernel function set to radial basis function (RBF)
2	CNN	Two convolutional layers: First layer kernel size 3x3 filter count 64. Second layer kernel size 2x2 filter count 32. Pooling layer uses max pooling pooling window size 2x2. Fully connected layer neuron count 128 activation function ReLU
3	BERT	Using Transformer-based BERT-base model Hidden layer size 768, attention head count 12 Learning rate 2e-5, training epochs 3
4	DeepSeek-R1	Using medium model configuration of DeepSeek-R1 Multiple Transformer encoder layers, Temperature parameter set to 0.7

3) Experimental environment configuration: The experimental environment configuration comprises hardware setup and software environment. For hardware, the CPU is an Intel Core i7-10700K with a base frequency of 3.8GHz; the GPU is an NVIDIA GeForce RTX 3080 with 10GB of VRAM; and the memory consists of 32GB DDR4 RAM operating at 3200MHz. Regarding the software environment, the operating system is Windows 10 Professional 64-bit; the programming language is MATLAB 2021a; the deep learning framework utilizes the MATLAB Deep Learning Toolbox.

4) Training process parameters: During model training, the initial learning rate is set to 0.001 and adjusted using a cosine annealing strategy; the batch size is set to 32, adjusted based on the graphics memory capacity of the experimental equipment; the Adam optimizer is employed for its superior convergence performance; The number of training epochs was set to 20, dynamically adjusted based on model convergence.

5) Evaluation metrics: Metaphor recognition was evaluated using Precision, Recall, and F1 score. Precision measures the proportion of correctly identified metaphor sentences. Recall measures the proportion of all metaphor sentences correctly retrieved. F1 score is the harmonic mean of precision and recall, providing a comprehensive evaluation of model performance.

Semantic mapping calculates the correlation coefficient for semantic association strength, assessing semantic similarity between the ontology domain and metaphor domain.

Fusion analysis evaluates metaphorical meaning fusion effectiveness using mean fusion degree and standard deviation, where a higher fusion degree indicates better fusion quality.

B. Results Analysis

1) Data preprocessing results analysis: First, the online poetry corpus sourced from platforms such as poetry websites, forum comments, and social media shares underwent text cleaning. The results are shown in Table V. This table details the cleaning outcomes, reflecting the effectiveness of each step and the final corpus size. After cleaning, 2,200 high-quality poetry texts were retained.

TABLE V. TEXT CLEANING RESULTS TABLE

Cleaning step	*Initial corpus count*	*Corpus count after cleaning*	*Cleaning rate*
Removing irrelevant symbols	3000	2850	5
Removing duplicate content	2850	2500	12.28
Removing non-poetry text	2500	2200	12

Table VI summarizes the annotation results for metaphor-related vocabulary, including the number of words across different parts of speech and their proportion in the total vocabulary. Nouns, verbs, and adjectives play a significant role in metaphorical expressions, and the annotation of these words provides key features for subsequent metaphor recognition.

TABLE VI. STATISTICAL TABLE OF METAPHOR-RELATED VOCABULARY ANNOTATION

Part-of-speech type	*Number of words*	*Proportion in total vocabulary*
Nouns	5000	40
Verbs	3500	28
Adjectives	2500	20
Other	1500	12

Table VII summarizes the detailed results of data augmentation, reflecting the enhancement effects of each method and the final corpus size. Through data augmentation, the final corpus size increased from 2,200 to 5,500 poems, significantly improving the diversity and richness of the corpus.

TABLE VII. DATA AUGMENTATION RESULTS TABLE

Augmentation method	*Initial corpus count*	*Corpus count after augmentation*	*Augmentation rate*
Synonym replacement	2200	3300	50
Sentence reorganization	3300	4400	33.33
Sentiment reversal	4400	5500	25

2) Analysis of semantic fusion performance: To evaluate the effectiveness and superiority of the proposed AI algorithm for integrating poetic metaphor meanings, this section provides explanatory insights into metaphor recognition performance, semantic mapping capabilities, and fusion analysis abilities.

Table VIII presents a comparative analysis of metaphor recognition performance across different algorithms. Through three metrics—accuracy, recall, and F1 score—the classification effectiveness of each algorithm for metaphorical and non-metaphorical sentences can be comprehensively assessed. The data in the table demonstrates that the SVM+CNN fusion algorithm outperforms both standalone SVM and CNN algorithms in terms of accuracy, recall, and F1 score. This indicates that the fusion algorithm more effectively captures the features of metaphorical sentences, thereby enhancing recognition accuracy and stability.

TABLE VIII. COMPARISON OF METAPHOR RECOGNITION PERFORMANCE ACROSS DIFFERENT ALGORITHMS

Algorithm combination	*Accuracy percentage*	*Recall percentage*	*F1 score percentage*
SVM	85	80	82.4
CNN	83	82	82.5
SVM+CNN	87	85	86

Fig. 16 presents the comparative results of different algorithms within the metaphor recognition module. The horizontal axis represents various algorithms, including SVM, CNN, and the SVM-CNN hybrid algorithm; the vertical axis shows classification accuracy (%) on the left and recall (%) on the right. The figure reveals that the SVM-CNN fusion algorithm achieves 87% classification accuracy and 85% recall rate, outperforming both standalone SVM and CNN algorithms. This demonstrates that the fusion approach better captures the features of metaphorical sentences, thereby enhancing recognition performance. The differently colored bar charts represent the accuracy and recall rates of each algorithm, while the line charts illustrate the performance trends across different feature dimensions.

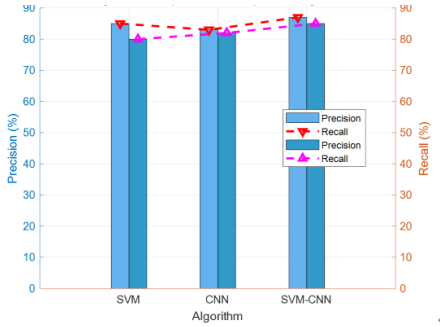

Fig. 16. Comparison of algorithms in the metaphor recognition module.

Fig. 17 illustrates the distribution characteristics of semantic association strength across five distinct poetry sample sets. The figure reveals that Sample Sets 3 and 5 exhibit overall higher semantic association strength, with medians approaching the upper limit and data points concentrated within a narrow range. This indicates that the metaphorical expressions within these two sample sets are semantically highly correlated, demonstrating consistent metaphorical quality and achieving elevated artistic and expressive effects. Sample set 2 exhibits relatively low semantic association intensity, with the box plot positioned lower and data distribution more dispersed. This indicates greater variation in metaphorical semantic connections within this set, suggesting that metaphorical expressions in some poems may lack clarity or depth, with room for improvement in artistic quality. Sample sets 1 and 4 exhibit moderate semantic association strength. Sample set 4 shows relatively concentrated data distribution, indicating superior stability in metaphorical semantic associations compared to sample set 1. Meanwhile, certain samples within sample set 1 demonstrate significantly higher semantic association strength than others, potentially signifying more refined metaphorical expressions or deeper semantic connections in these poems, highlighting their artistic merit. Additionally, the scatter plot uses distinct colors to mark the specific semantic association strength values for each poetry sample, allowing observation of each sample's unique characteristics.

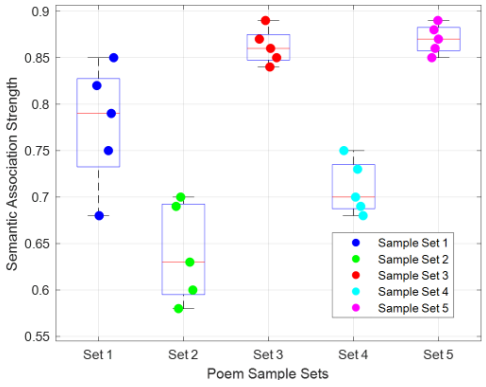

Fig. 17. Distribution of semantic association strength.

Table IX illustrates the relationship between semantic association strength and fusion degree across different samples, along with their calculated correlation coefficients. Semantic association strength reflects the degree of semantic similarity between the referent domain and the metaphorical domain, while fusion degree measures the integration effectiveness of metaphorical meaning within the synthetic space. The table reveals a high positive correlation between the two, with a correlation coefficient of 0.89. This indicates that stronger semantic association leads to better integration of metaphorical meaning. Consequently, constructing an accurate semantic vector space is crucial for achieving effective metaphorical meaning integration.

TABLE IX. CORRELATION ANALYSIS FOR SEMANTIC ASSOCIATION STRENGTH AND INTEGRATION DEGREE

No.	*Semantic association strength*	*Fusion degree*	*Correlation coefficient*
1	0.76	0.815	0.89
2	0.65	0.705	
3	0.83	0.8	
4	0.72	0.75	
5	0.88	0.84	

Fig. 18 illustrates the trend of metaphor fusion degree across varying parameters within the fusion analysis module. The horizontal axis represents parameters (such as window size and part-of-speech feature weights), while the vertical axis displays fusion degree values, utilizing a combination of a 3D line chart and a bubble chart. The 3D line chart vividly depicts the dynamic trajectory of fusion degree across multiple parameters, enabling clear observation of the combined effects of different parameter combinations on fusion performance. The bubble chart further emphasizes relative differences in fusion degree through bubble size, allowing more intuitive identification of the optimal parameter settings corresponding to the best fusion outcomes. This combined visualization comprehensively reveals the patterns of fusion degree variation under multi-parameter influence, aiding in model parameter optimization and enhancing metaphorical meaning fusion effectiveness.

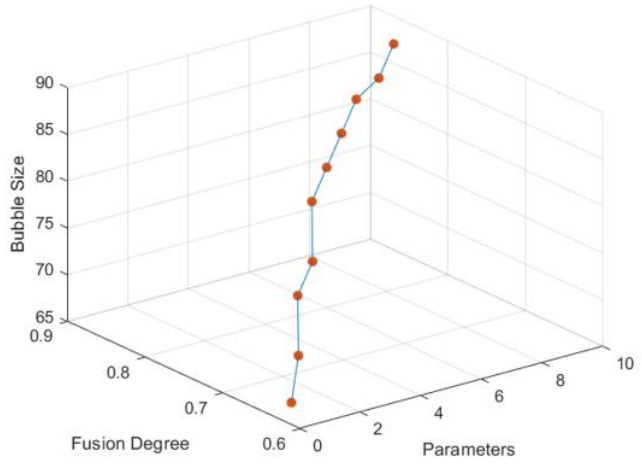

Fig. 18. Integration level variation with parameters.

Table X evaluates the integration effectiveness of metaphorical meanings across different poetic themes. The average integration level reflects the overall fusion quality of metaphorical meanings across all poetic themes, while the standard deviation indicates the dispersion of integration levels across individual samples. The table reveals that love-themed poetry exhibits the highest average integration degree with a relatively small standard deviation, indicating high stability and consistency in metaphor integration under this theme. Conversely, social-themed poetry demonstrates the lowest average integration degree with a relatively large standard deviation, suggesting significant variation in metaphor integration effectiveness.

TABLE X. METAPHOR INTEGRATION EFFECTIVENESS EVALUATION

Poetry theme	*Number of samples*	*Average fusion degree*	*Standard deviation*
Love	50	0.85	0.06
Nature	50	0.78	0.12
Life	50	0.82	0.08
Society	50	0.75	0.10

Table XI provides a comprehensive comparison of different model combinations across multiple evaluation metrics. Beyond focusing on metaphor recognition accuracy, metrics such as semantic association strength correlation coefficient, mean fusion degree, and training time are introduced to comprehensively assess model performance and practicality. The table reveals that the BERT model demonstrates superior performance in metaphor recognition accuracy, semantic association strength correlation coefficient, and mean fusion degree, though it requires relatively longer training time. In contrast, the SVM+CNN fusion algorithm maintains high recognition accuracy and fusion effectiveness while achieving relatively shorter training time, offering better balance and practicality.

TABLE XI. COMPREHENSIVE COMPARISON OF MODEL EVALUATION METRICS

Model combination	*Metaphor recognition accuracy percentage*	*Semantic association strength correlation coefficient*	*Average fusion degree*	*Training time minutes*
SVM	85	0.78	0.78	12
CNN	83	0.8	0.79	25
BERT	88	0.85	0.83	45
SVM+CNN	87	0.82	0.81	20

Fig. 19 shows the curve of loss function values during model training. The horizontal axis represents the number of training epochs, while the vertical axis denotes the loss function value. The figure reveals that as the number of training epochs increases, the loss function values of all models exhibit a decreasing trend. However, the rate of decrease and the final loss values differ among them. The BERT-based model demonstrates a faster rate of loss reduction and achieves a lower final loss value, indicating superior convergence during training and a more effective ability to learn patterns within the data.

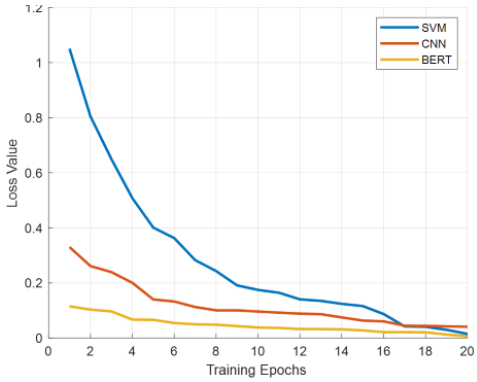

Fig. 19. Changes in model training loss function values.

Fig. 20 illustrates the performance metrics comparison of different algorithms in metaphor recognition tasks. The horizontal axis represents various algorithm combinations, while the vertical axes respectively denote accuracy (%), recall (%), and F1 score (%). By comparing the heights of different groups of histograms, one can intuitively observe the comprehensive performance of each algorithm in metaphor recognition tasks. The bar chart for the SVM-CNN fusion algorithm exhibits a higher overall height, indicating that this algorithm achieves a good balance across accuracy, recall, and F1 score, demonstrating superior metaphor recognition capability.

Fig. 21 compares the confusion matrices of different models on the metaphor recognition task. The horizontal and vertical axes represent predicted categories and true categories, respectively, including metaphorical sentences and non-metaphorical sentences. By comparing the confusion matrices of different models, one can intuitively observe the classification performance differences across categories. Deep learning-based models demonstrate high accuracy in classifying both metaphorical and non-metaphorical sentences. Their confusion matrices feature darker colors along the diagonal and lighter colors off-diagonally, indicating these models effectively distinguish between the two sample types and reduce misclassification rates.

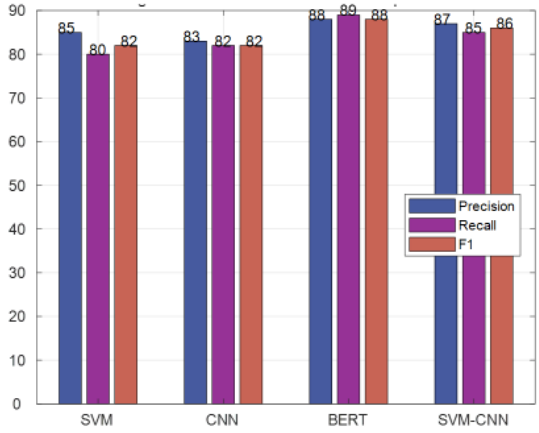

Fig. 20. Comparison of performance metrics across different algorithms.

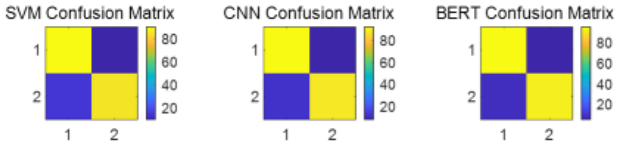

Fig. 21. .Confusion matrix comparison.

Fig. 22 illustrates the comparative fusion effectiveness of different poetic themes within the fusion analysis module. The horizontal axis represents poetic themes, while the vertical axis indicates fusion degree values. By comparing the positions and shapes of box plots across different themes, it is evident that love-themed poems exhibit a generally higher metaphorical fusion degree with a more concentrated distribution. This suggests that metaphorical meaning fusion within this theme demonstrates high stability and consistency. In contrast, nature-themed poems show a more dispersed fusion degree distribution, indicating that their metaphorical meaning fusion is influenced by multiple factors and exhibits significant variation.

Fig. 23 shows the learning rate curve during model training. The horizontal axis represents the number of training iterations, while the vertical axis displays the learning rate values, presented as a stem-and-leaf plot. This plot clearly illustrates the trajectory and distribution of the learning rate as training progresses. Initially, the learning rate is relatively high, gradually decreasing and stabilizing as training continues. This learning rate adjustment strategy facilitates rapid convergence during the early training phase while enabling fine-tuning of model parameters in later stages, thereby enhancing both training efficiency and generalization capabilities.

Fig. 24 presents a comparison of ROC curves and AUC values for different models on the metaphor recognition task. The horizontal axis represents the false positive rate, while the vertical axis denotes the true positive rate. The ROC curve of the SVM-CNN fusion algorithm lies near the upper-left corner, achieving an AUC value of 0.92. This indicates that the model demonstrates strong classification performance on the metaphor recognition task, effectively distinguishing metaphorical sentences from non-metaphorical ones.

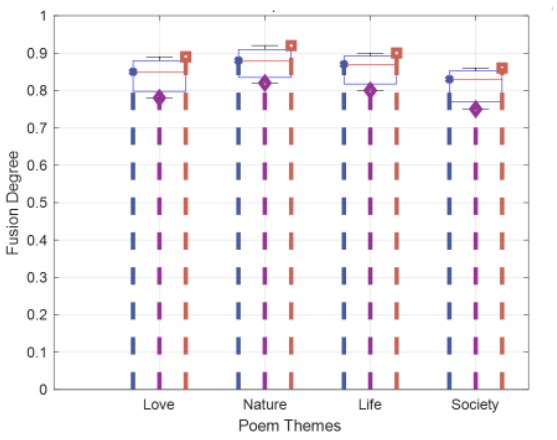

Fig. 22. Comparison of fusion effects across different themes.

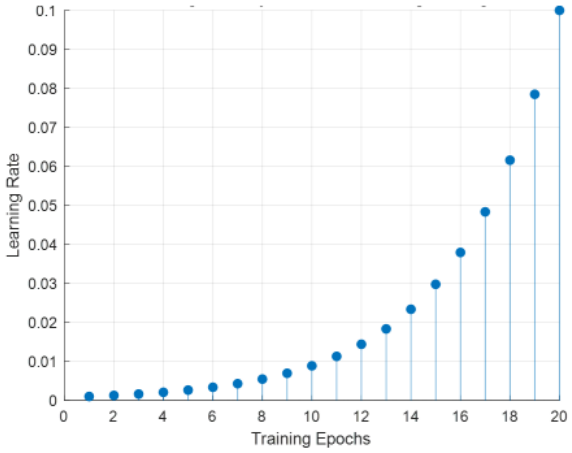

Fig. 23. Learning rate curve.

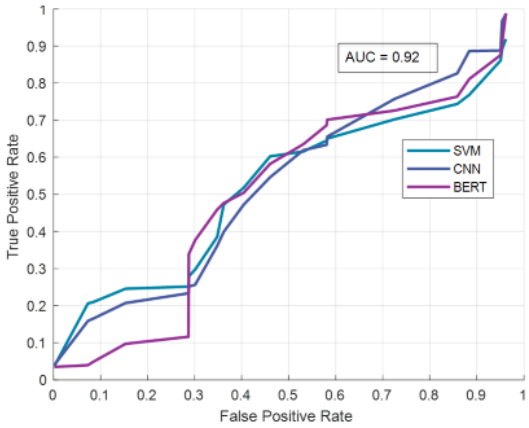

Fig. 24. Comparison of ROC curves and AUC values.

VI. Conclusion

This study proposes a fusion analysis framework for the metaphorical meaning of online poetry based on cognitive linguistics and Artificial Intelligence technologies, whose effectiveness is validated through detailed experiments. The designed three-dimensional fusion analysis framework—combining cognitive theory, specific AI algorithms, and online discourse data—achieves favorable results in both poetry metaphor recognition and semantic fusion. Experiments demonstrate that the SVM+CNN fusion algorithm exhibits high accuracy and recall in metaphor recognition tasks, effectively enhancing metaphor identification performance. The BERT model demonstrated robust contextual semantic encoding capabilities in the semantic mapping task, providing strong support for semantic analysis. The DeepSeek-R1 large model, combined with conceptual integration theory, performed excellently in metaphorical meaning fusion analysis, effectively deciphering the cognitive logic behind metaphors and quantifying fusion effects. Experimental results validated the effectiveness of the proposed framework and methods, demonstrating their potential in the field of poetic metaphor research.

Future work involves expanding and deepening the research. First, exploring the incorporation of multimodal data, such as audio recordings of poetry recitations and related visual materials, to enrich the analytical dimensions of metaphorical meaning integration in poetry. Second, further optimizing the algorithmic model by integrating cutting-edge technologies like the Transformer architecture to enhance the model's ability to recognize and understand complex metaphorical expressions.

***Abstract*—The layout of tunnel cross-passages is a critical aspect of tunnel construction and operational safety. Traditional methods, primarily based on static design, struggle to adapt to complex and variable geological and construction environments. This study proposes a dynamic decision model for cross-passage layout based on multi-source sensor data fusion to enhance the scientific rigor and adaptability of cross-passage design. A three-dimensional data fusion mechanism integrating "temporal-spatial-statistical" dimensions was developed. Bayesian network quantifies uncertainty, Kalman filter processes time series data, and PCA extracts spatial features. Reinforcement learning and non-dominated sorting genetic algorithm II (NSGA-II) are used to achieve multi-objective optimization of safety coverage and construction efficiency. The proposed model significantly outperforms the traditional methods in many indicators, and is verified by 100 Monte Carlo simulations and actual tunnel experiments. The dynamic scheme increased the safety coverage rate from 72.4% to 91.7%, shortened the average evacuation distance by 38.7% (from 248 meters to 152 meters), saved resources by 14.2% (about 9.8 million yuan), and shortened the construction period by 3-6 days. The comprehensive utility value is 0.91, which is 19% higher than the traditional static method, and the robustness is enhanced. The model realizes the safe, economical, and efficient real-time optimization of the layout of the transverse channel. It provides a technical path and data support that can be promoted for intelligent tunnel construction under complex geological conditions.**

***Keywords*—Multi-source sensor data fusion; dynamic cross-passage deployment decision-making for tunnels; Kalman filter; reinforcement learning; non-dominated sorting genetic algorithm II**

I. Introduction

With the continuous advancement of infrastructure development in China, tunnel engineering has assumed an increasingly vital role in transportation, water conservancy, power, and other sectors [1-2]. Particularly under the "Transportation Powerhouse" strategy, projects involving long tunnels, deep-buried tunnels, and tunnels in complex geological conditions are proliferating. The tunnel length, burial depth and geological complexity of the national key projects such as the Dianzhong Water Diversion Project, the Sichuan-Tibet Railroad and the Shenzhen-Zhongshan Channel are all ranked first in the world [3]. As an important part of the tunnel structure system, the cross passage performs various functions during the construction process, including ventilation, transportation, evacuation, and drainage. During operation, it also undertakes important responsibilities such as disaster prevention and rescue, equipment maintenance and partition management [4]. In order to ensure safety, improve operational efficiency and reduce engineering risks, the cross passage must be arranged scientifically and reasonably [5].

However, traditional cross-passage layout methods primarily rely on static geological surveys and empirical judgments during the design phase, employing fixed intervals or simple rules for placement. This approach lacks responsiveness to dynamic factors such as geological changes during construction, construction disturbances, and resource scheduling [6]. In complex geological conditions—such as karst formations, faults, gas-bearing zones, and rockburst-prone sections—static placement often results in suboptimal cross-passage locations, redundant or insufficient quantities, thereby compromising construction safety and efficiency, and potentially triggering engineering accidents [7-8].

In recent years, rapid advancements in IoT, artificial intelligence, and sensing technologies have generated increasingly rich multi-source heterogeneous data during tunnel construction. This includes georadar (GPR), seismic wave detection (TSP), advance drilling, construction progress monitoring, personnel positioning, environmental monitoring, and material consumption data [9]. These data provide an unprecedented information foundation for dynamically optimizing cross-passage placement. Effectively integrating these multi-source sensor data to construct a dynamic deployment decision model with real-time response capability has become a critical scientific issue for the intelligent development of tunnel engineering. Key research areas in constructing dynamic deployment decision models for tunnel cross passages include multi-source data fusion mechanism design [10], dynamic decision model construction [11], simulation verification, and engineering applications [12]. Currently, universities and research institutions worldwide have made significant progress in tunnel intelligence. Tang et al. [13] achieved advance warning for poor geological sections in a mountain tunnel project by integrating ground-penetrating radar with TSP data. Andrade-Lucio et al. [14] established a full-lifecycle health monitoring system for tunnels by deploying thousands of sensors. Overseas research has primarily focused on structural health monitoring and disaster early warning, with limited studies on dynamic deployment for ancillary structures

*Corresponding author.

like cross passages, and no systematic decision models have yet been developed. In China, geological advance prediction, construction risk early warning, and BIM+GIS integrated management are all hot topics [15]. Support vector machine (SVM) data and construction data can be used to predict the risk of tunnel collapse [16]. In addition, Luo et al. [17] proposed a cross-passage spacing optimization method based on a genetic algorithm. The current research has the following shortcomings: most studies only focus on the optimization of the design stage, while ignoring the dynamic evolution in the construction process [18]; a single algorithm is mainly used for shallow data fusion, which cannot completely solve the spatiotemporal heterogeneity and uncertainty [19]; some studies only focus on algorithm development without considering actual engineering data, which leads to insufficient transferability and practicality [20].

Addressing these issues and challenges, this study proposes a dynamic cross-passage deployment decision model based on multi-source sensor data fusion. The main contributions are as follows: 1) A three-dimensional fusion mechanism of "spatiotemporal statistics" is introduced, Kalman filtering is used to process time-series data, PCA is used to extract spatial features, and Bayesian network is used to quantify uncertainty, so as to realize the efficient fusion of geological, construction and resource data; 2) A reinforcement learning-oriented cross-passage layout optimization model driven by the dual objectives of safety coverage and construction efficiency is constructed to realize real-time decision-making update in the construction process; 3) A high-fidelity simulation environment is established based on tunnel engineering data, and the model performance is evaluated from multiple dimensions such as safety, economy and adaptability.

The structure of this study is as follows: Section II introduces fundamental methods and typical applications of multi-source sensor data fusion, providing a theoretical foundation for decision model construction. Section III analyzes traditional methods for deploying cross-tunnel sensors and the advantages of dynamic deployment, clarifying the research questions and objectives. Section IV proposes a dynamic deployment decision model based on multi-source sensor data fusion, including the overall framework, data fusion mechanism, and a hybrid optimization method combining reinforcement learning with NSGA-II. Section V evaluates the model's performance through simulation experiments and field validation, focusing on comparative analysis of safety, efficiency, and cost-effectiveness. Finally, Section VI summarizes key findings, identifies research limitations, and proposes future research directions.

II. Multi-Source Sensor Data Fusion Technology

A. Data Fusion Methods and Algorithms

Multi-source Sensor Data Fusion (MSDF) [21] refers to the comprehensive processing of data from different sensors, different times, different spaces, or different modalities to obtain information that is more accurate, reliable, and comprehensive than that from a single data source. Its core objectives are to eliminate redundancy, suppress noise, fill in missing data, and enhance the robustness and real-time capability of decision-making [22]. Fig. 1 illustrates the definition of multi-source sensor data fusion methods.

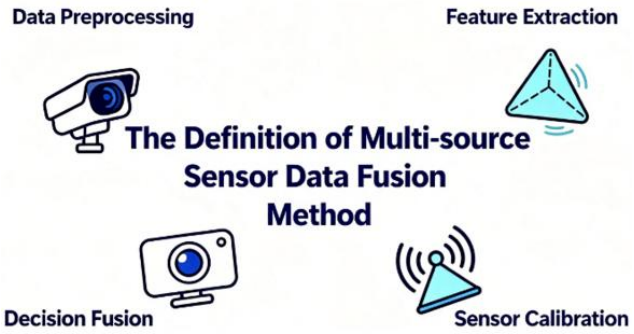

Fig. 1. Definition of multi-source sensor data fusion methods.

Based on the level of data abstraction, fusion methods are typically categorized into three tiers: data-level fusion, feature set fusion, and decision-level fusion [23]. Table I illustrates the hierarchical classification of multi-source sensor data fusion methods and algorithm categories. Table I indicates that data-level fusion methods include weighted averaging and Kalman filtering algorithms; feature-level fusion methods encompass PCA, ICA, and wavelet transforms; while decision-level fusion methods involve Bayesian inference, D-S evidence theory, and voting methods.

TABLE I. Hierarchy and Algorithms of Multi-Source Sensing Data Fusion Methods

Level	Name	Description	Common Methods
L1	Data-level fusion	Raw data was directly merged most information was retained	Weighted average Kalman filter
L2	Feature-level fusion	Features extracted, then fused, dimensionality reduced	PCA ICA Wavelet transform
L3	Decision-level fusion	Each source makes an independent decision and then fuses the results	Bayesian inference D-S evidence theory Voting method

The Kalman filter (KF) is suitable for linear dynamic systems in Gaussian noise environments and can recursively estimate the system state [24]. Fig. 2 shows the prediction and update process of the KF algorithm, which mainly consists of the update step and the prediction step.

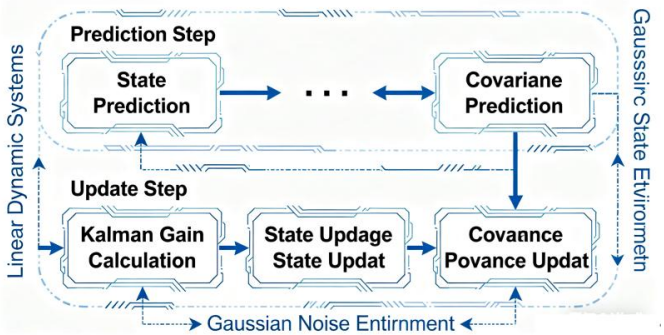

Fig. 2. KF algorithm workflow diagram.

Principal Component Analysis (PCA) is employed for dimensionality reduction and feature extraction in high-dimensional data, eliminating redundant dimensions while retaining the directions of maximum variance [25]. The PCA method calculates the covariance matrix as follows:

$$\boldsymbol{C} = \frac{1}{n-1}\boldsymbol{X}^T\boldsymbol{X} \tag{1}$$

where, $\boldsymbol{C}$ denotes the covariance matrix, n represents the number of data samples, and $\boldsymbol{X}$ indicates the sample data. The feature decomposition calculation is analyzed as follows:

$$\boldsymbol{C}v_i = \lambda_i v_i, \lambda_1 \geq \lambda_2 \geq \mathrm{L} \geq \lambda_d \tag{2}$$

Here, v_i denotes the i-th eigenvector, and λ_i denotes the i-th eigenvalue. Select the first k principal components such that their cumulative contribution rate $\geq 95\%$:

$$CPV_k = \frac{\sum_{i=1}^{k}\lambda_i}{\sum_{i=1}^{d}\lambda_i} \tag{3}$$

Here, CPV_k denotes the cumulative contribution rate of the k-th eigenvector. Based on the above PCA principles, the PCA dimension reduction process is summarized in Fig. 3.

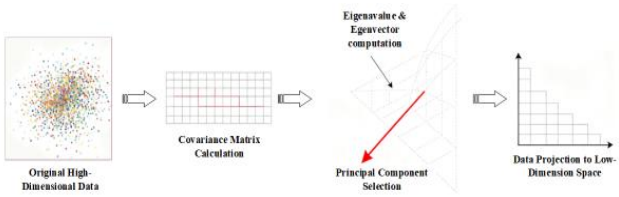

Fig. 3. Schematic diagram of PCA dimension reduction.

Bayesian estimation and decision fusion methods are suitable for scenarios with high uncertainty and abundant prior knowledge [26]. The posterior distribution is obtained through the likelihood function and prior distribution [see Eq. (4)]:

$$P(\theta|z) = \frac{P(z|\theta)P(\theta)}{P(z)} \tag{4}$$

where, $P(\theta|z)$ denotes the posterior distribution probability, $P(z|\theta)$ represents the likelihood function, $P(\theta)$ indicates the prior probability, $P(z)$ signifies the evidence, θ denotes the Bayesian parameter, and z refers to the observed data.

B. Applications of Fusion Techniques Across Domains

Intelligent transportation systems, environmental monitoring, industrial equipment fault diagnosis, and healthcare are all fields in which multi-source sensor data fusion technology is widely used [27]. Fig. 4 shows the application analysis of fusion technology in various fields.

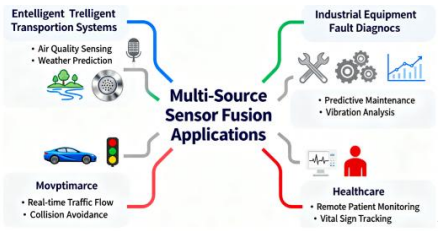

Fig. 4. Analysis of fusion technology applications across different fields.

In intelligent transportation, multi-source data fusion technology is used for traffic flow monitoring, accident detection, and vehicle navigation. Tomaszewski et al. [28] point out that traffic conditions can be monitored by integrating camera, radar, and GPS data, congestion can be predicted, and the best route suggestions can be provided for drivers.

In environmental monitoring, multi-source sensor data fusion technology is applied to air quality monitoring, water quality monitoring, and natural disaster early warning. Zhao et al. [29] demonstrate that by integrating data from ground monitoring stations, satellite remote sensing, and drones, real-time monitoring and dispersion prediction of atmospheric pollutants can be achieved. Applications of data fusion in environmental monitoring are shown in Table II.

TABLE II. APPLICATIONS OF DATA FUSION IN ENVIRONMENTAL MONITORING

Data Source	Fusion Method	Application Scenario	Advantage
Ground monitoring station	Kalman filter	Air quality monitoring	High accuracy real-time
Satellite remote sensing	PCA	Water quality monitoring	Dimensionality reduction, wide coverage
Drone	Bayesian estimation	Natural disaster warning	Uncertainty handling flexibility

By integrating data from machine vision, temperature, and pressure sensors, the running status of production line equipment can be monitored in real-time, potential faults can be predicted, and production processes can be optimized [30].

In the healthcare industry, data fusion technology is used for disease diagnosis, patient monitoring, and rehabilitation treatment [31]. The technology can monitor the health status of patients in real time and provide early warning by integrating physiological signals such as blood pressure, body temperature, and electrocardiogram (ECG).

III. DYNAMIC LAYOUT TECHNOLOGY FOR TUNNEL CROSS-PASSAGES

In tunnel engineering, the layout technology for cross-passages is undergoing a transformation from traditional to dynamic approaches. Although the traditional method meets the basic functional requirements of the tunnel, its limitations are becoming more and more obvious in complex geological conditions and a construction environment. On the other hand, the dynamic design technology shows its unique advantages with its high efficiency and flexibility.

A. Traditional Design Methods and Limitations

According to the Specifications for Design of Highway Tunnels (JTG D70-2022), the traditional tunnel cross passage layout mainly uses the empirical spacing method. This method is mainly based on the tunnel length, surrounding rock type, traffic level and other factors for one-time design. The layout remains largely unchanged during construction and rarely undergoes modification during the operational phase [32]. Fig. 5 illustrates the flowchart of the traditional layout method. However, this approach has significant limitations.

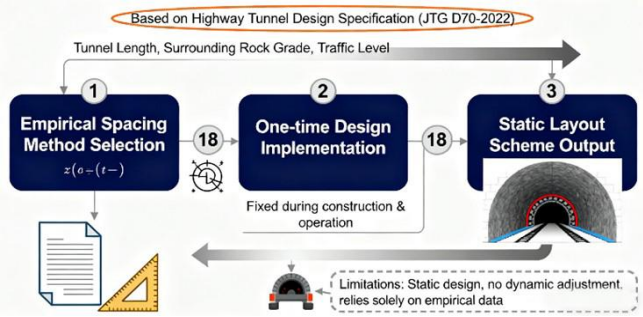

Fig. 5. Flowchart of traditional deployment method.

The static nature of traditional deployment methods makes it difficult to deal with sudden geological changes and construction disturbances. These techniques focus primarily on the spacing required by the specification, and ignore resource optimization and security redundancy. Over-deployment may increase engineering costs. The limitations of traditional layout methods can be further studied by combining the equations and parameter provisions related to the design specification of highway immersed tunnel.

B. Advantages of Dynamic Deployment Technology

Dynamic deployment technology overcomes the limitations of traditional methods and continuously integrates multi-source sensor data to update the position and number of cross-channels in real time [33]. Fig. 6 shows the dynamic deployment technology and its advantages:

Fig. 6. Dynamic layout technology.

1) Enhancing safety and emergency response capabilities: Dynamic layout can adjust the position of the cross passage in time according to the changes of geological conditions, so that personnel can be quickly evacuated in case of disaster. For example, the comprehensive advanced forecast system can accurately understand the geological conditions in front of the tunnel, so as to plan the position of the cross passage in advance, so as to reduce casualties and equipment losses.

2) Optimizing resource allocation and reducing costs: Compared with traditional technology, dynamic site selection reduces the construction of unnecessary transverse passages, thereby reducing the project cost. Under the premise of ensuring safety standards, dynamic route selection can greatly reduce the project cost in some auxiliary tunnels of the Sichuan-Tibet Railroad.

3) Enhancing construction efficiency: Through dynamic deployment, the construction of the transverse passage can be arranged reasonably according to the progress and resource consumption, so as to reduce the construction interference and improve the overall efficiency.

C. Analysis of Dynamic Cross-Passage Layout Decision-Making for Tunnels

The dynamic layout decision for tunnel cross-passages constitutes a complex multi-objective optimization problem [34], involving multiple variables and constraints. Fig. 7 illustrates the analysis of this decision-making problem.

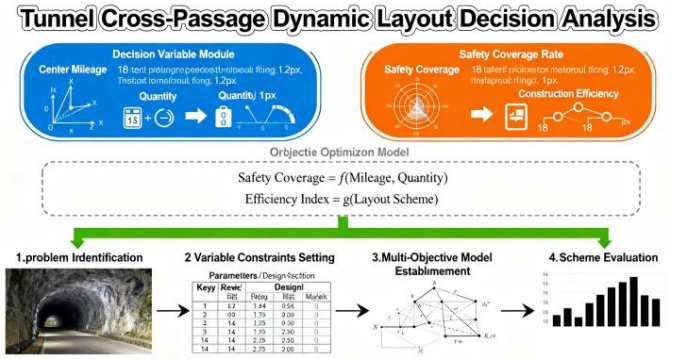

Fig. 7. Analysis of dynamic cross-passage layout decision problem in tunnels.

Decision variables include the center mileage and quantity of cross passages. The objective function typically establishes a multi-objective optimization model for cross-passage layout with dual targets: safety coverage rate and construction efficiency. The safety coverage rate is calculated as follows [see Eq. (5)]:

$$S_{\text{cov}-rate} = \frac{N_{\text{cov}-rate}}{N_{rate}} \times 100\% \tag{5}$$

where, $S_{\text{cov}-rate}$ denotes safety coverage rate, $N_{\text{cov}-rate}$ represents the proportion of personnel covered, and N_{rate} denotes the total personnel proportion.

Construction efficiency can be measured by the average evacuation time, Eq. (6):

$$T_{mean} = \frac{D_{esc}}{v_{esc}} \tag{6}$$

where, T_{mean} denotes average evacuation time, D_{esc} denotes total evacuation distance, and v_{esc} denotes evacuation speed.

Constraints primarily include geological safety, spacing limitations, construction interference, and resource caps. Geological safety constraints prohibit eliminating cross passages in areas with rock mass grades ≥ IV. Spacing constraints require cross passages to meet standard-specified distances. Construction interference constraints mandate reasonable scheduling of construction phases to avoid mutual disruption. Resource cap constraints reflect limited monthly excavation capacity.

IV. Construction of a Dynamic Cross-Passage Layout Decision Model

With the continuous advancement of tunnel construction technology, efficiently and safely laying out tunnel cross-passages has become a critical issue. In order to realize the real-time monitoring and dynamic optimization of tunnel construction process, this section introduces a dynamic cross-passage layout decision model based on multi-sensor data fusion.

A. Overall Framework

The model's overall framework, shown in Fig. 8, comprises four main layers: data acquisition, data fusion, decision-making, and execution. Let the data acquisition layer collect raw data from multiple sensors. These sensors include geological radar, seismic wave detection, advanced drilling, construction progress monitoring, personnel positioning and environmental monitoring. By processing these data with data fusion layer, the comprehensive evaluation of tunnel construction environment can be obtained. Based on the fused data, the decision-making layer uses reinforcement learning and multi-objective optimization algorithms to determine the optimal cross passage layout scheme. Finally, the execution layer uses the decision results for the construction and adjustment of the cross passage.

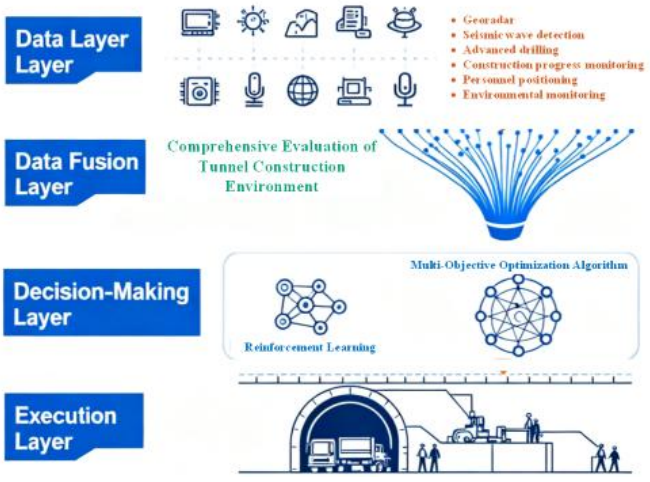

Fig. 8. Framework of the dynamic tunnel cross-passage layout decision model based on multi-source sensor data fusion.

B. Selection of Data Fusion Methods

At the data fusion layer, we employ multiple data fusion methods to handle different types of sensor data. This study uses Kalman filter to collect time series data, such as construction progress and resource consumption. Kalman filtering is a recursive estimation algorithm capable of effectively processing noisy data in dynamic systems. Its core equations are as follows [see Eq. (7) to Eq. (11)]:

$$\hat{x}_{k|k-1} = F_k \hat{x}_{k-1|k-1} + B_k u_k \tag{7}$$

$$P_{k|k-1} = F_k P_{k-1|k-1} F_k^T + Q_k \tag{8}$$

$$K_k = P_{k|k-1} H_k^T \left(H_k P_{k|k-1} H_k^T + R_k \right)^{-1} \tag{9}$$

$$\hat{x}_{k|k} = \hat{x}_{k|k-1} + K_k \left(z_k - H_k \hat{x}_{k|k-1} \right) \tag{10}$$

$$P_{k|k} = \left(1 - K_k H_k \right) P_{k|k-1} \tag{11}$$

Here, $\hat{x}$ denotes state estimation, P represents the estimation error covariance, F denotes the state transition model, B denotes the control input model, u denotes the control input, Q denotes the process noise covariance, z denotes the measurement value, H denotes the observation model, R denotes the measurement noise covariance, and K denotes the Kalman gain.

For spatial data such as ground-penetrating radar images, this study employs principal component analysis (PCA) for dimensionality reduction. PCA extracts key features from the data, reducing dimensionality while preserving critical information. The mathematical expressions for PCA are given in Eq. (1) to Eq. (3).

According to the above introduction and description, Table III summarizes the advantages and disadvantages of various data fusion methods.

TABLE III. Comparison of Different Data Fusion Methods

Method	Applicable Data Type	Advantage	Limitation
Kalman filter	Time series data	Handles noise in dynamic systems	Assumes linearity and Gaussian distribution
Principal component analysis	Spatial data	Extracts main features dimensionality reduction	Requires large data for training

C. Decision Model Design

The design of the decision model constitutes the core component of the entire system. We adopted a hybrid approach combining Reinforcement Learning (RL) [35] and the Non-Dominated Selection Genetic Algorithm II (NSGA-II) [36] to achieve multi-objective optimization between safety and cost. NSGA-II is used to find the Pareto optimal solution in multi-objective optimization; reinforcement learning is used to learn the most effective method through interaction with the

environment. Fig. 9 shows the teaching process of the hybrid reinforcement learning and NSGA-II model.

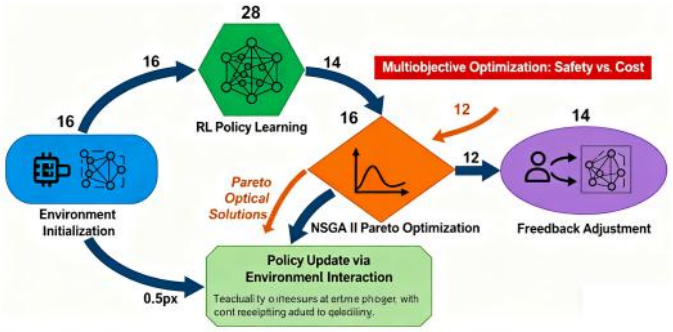

Fig. 9. Training process of the reinforcement learning and NSGA-II hybrid model.

In reinforcement learning, we defined the state space, action space, and reward function. The state space includes information such as geological conditions, construction progress, and resource consumption; the action space includes operations such as adding new cross passages, retaining existing cross passages, and canceling cross passages; the reward function comprehensively considers safety and cost factors [see Eq. (12)]:

$$R(s,a) = w_1 \Delta S + w_2 \Delta E - w_3 C_{cost} \tag{12}$$

where, w_1, w_2, and w_3 are weight coefficients, ΔS represents safety gains, ΔE represents efficiency gains, and C_{cost} represents cost penalties.

D. Model Validation and Optimization

To validate the model's effectiveness and robustness, this section conducts Monte Carlo simulations and field experiments. Monte Carlo simulations evaluate the model's performance under varying noise conditions, while field experiments validate its application in actual tunnel construction [37].

Fig. 10 illustrates the model performance under varying noise conditions, representing the Monte Carlo simulation results. To test the robustness of the model, Table IV shows the Monte Carlo simulation with different levels of Gaussian noise added to the sensor data. Results indicate that even at a 15% noise level, the model's hypervolume (HV) metric decreased by only 4%, demonstrating excellent robustness.

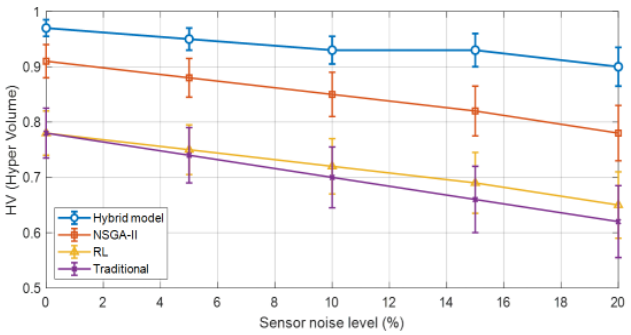

Fig. 10. Monte Carlo simulation results.

TABLE IV. COMPARISON OF MODEL VALIDATION RESULTS

Method	HV Index	Running Time/s	Adoption Rate
Traditional method	0.78	182	-
NSGA-II only	0.91	12	-
Reinforcement learning	0.78	0.3	-
Hybrid model	0.97	2.1	83%

E. Method Steps

Based on the aforementioned framework and methodology, the workflow for the tunnel cross-passage dynamic deployment decision-making model is illustrated in Fig. 11. The specific steps are as follows:

Step 1: Data Acquisition. Real-time collection of multi-source sensor data including ground-penetrating radar, seismic wave detection, and construction progress monitoring.

Step 2: Data Preprocessing. Cleaning, normalization, and time alignment of acquired data.

Step 3: Data Fusion. Integrate data using Kalman filtering and principal component analysis to form a comprehensive assessment of the tunnel construction environment.

Step 4: Decision Generation. Generate optimal cross-passage layout plans through a hybrid model of reinforcement learning and NSGA-II.

Step 5: Plan Execution. Guide the construction and adjustment of the cross passage, and apply the decision-making results to the actual construction.

Step 6: Feedback Optimization. Update the model parameters based on the actual construction results to better handle decision-making.

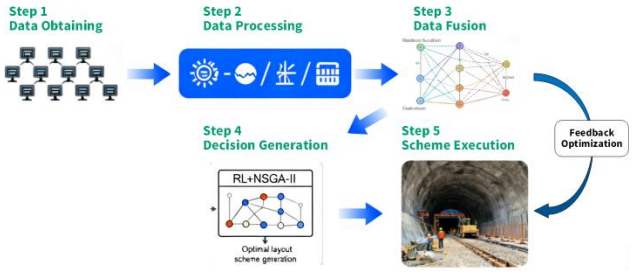

Fig. 11. Methodological flowchart for dynamic decision-making model of tunnel cross-passage layout.

V. EXPERIMENTAL VALIDATION

A. Experimental Design

For the experimental subject and scenario, this study selected a mountain tunnel project as the simulation object. The tunnel spans 4.8 kilometers, with surrounding rock classifications distributed across Grade II, III, IV, and V. Simulated construction scenarios encompass varying geological conditions and construction progress.

For data acquisition and processing, simulated sensors generate Ground Penetrating Radar (GPR), Transverse Seismic Profile (TSP), and construction progress monitoring data.

Preprocessing includes missing value imputation, normalization, time alignment, and outlier removal.

Data processing and model training were performed using MATLAB 2021a. A Monte Carlo method was employed to conduct 100 simulations, validating the model's robustness and effectiveness. Parameter settings for the reinforcement learning and NSGA-II hybrid model are presented in Table V.

TABLE V. PARAMETER SETTINGS FOR THE REINFORCEMENT LEARNING AND NSGA-II HYBRID MODEL

Parameter	Description	Value
Learning rate	Controls learning step size	0.01
Discount factor	Future reward discount rate	0.95
Weight coefficient	Weights for safety, efficiency, and cost	w1=0.6 w2=0.3 w3=0.1

B. Result Analysis

To evaluate the proposed method for constructing a dynamic cross-passage deployment decision model based on multi-source sensor data fusion, this section conducts simulation analysis across four dimensions: data generation and preprocessing, algorithm comparison, and deployment effectiveness assessment.

1) Data generation and preprocessing: To validate the effectiveness of the proposed data preprocessing method, analyses were conducted on rock mass classification, construction progress, resource consumption, and normalization. The specific results are as follows:

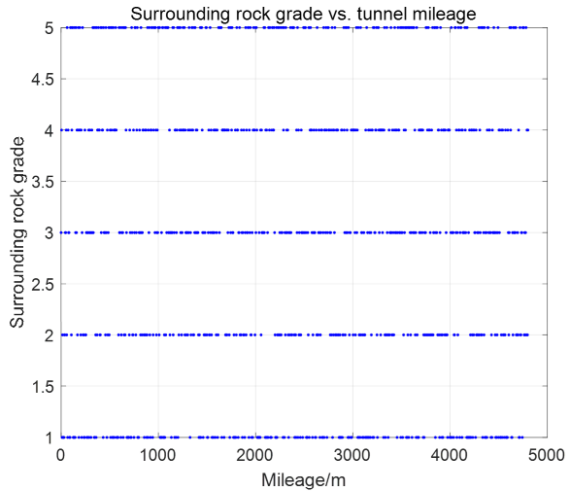

Fig. 12. Rock mass grade vs. Tunnel mileage.

Fig. 12 shows the distribution of rock mass grades (1~5) of about 5000 measuring points along the line, and the blue scatter points represent these grades. Poor rock mass sections (IV-V grade) appear continuously near 1.2 km, 3.1 km and 4.1 km, and the remaining sections are mainly II-III grade. This spatial differentiation shows three high-risk areas, which are consistent with the fault sections identified in the design stage. It provides direct geological input and calibration references for establishing the "transverse passage demand field", determining risk weights, and setting safety coverage targets. As shown in Fig. 12, the poor sections form continuous bands rather than discrete points, indicating that hazard zones possess a certain length and fluctuation range. In these sections, a "dense-early-multiple" deployment strategy should be adopted, combined with real-time dynamic signal correction during construction. Conversely, stable sections dominated by Grade II–III can employ a "sparse-late-merged" approach. This result also indicates a coupling relationship with resource consumption peaks and schedule deceleration segments, serving as critical prior information for reinforcement learning reward functions and NSGA-II constraints.

Fig. 13 presents the cumulative advance curve for "construction progress versus mileage", with the red line representing the result after Kalman filtering. The first-order slope of the curve corresponds to the instantaneous excavation speed, and local slope changes clearly reveal the transition between the bench method and the full-face method. The obvious reduction in the slope between 2.3 and 2.6 km is the result of the deceleration and reinforcement measures taken when crossing the fault. The filtered curve exhibits continuity and smoothness with pronounced noise suppression (relative to the raw RFID measurement noise σ≈8%), effectively eliminating "false fluctuations". This reliably aligns the progress-time axis with geological events, providing a stable temporal baseline and identifiable event windows for subsequent dynamic deployment and reinforcement learning strategy updates.

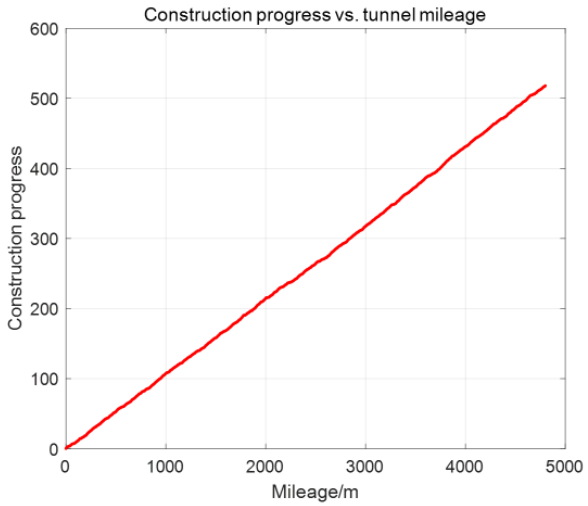

Fig. 13. Construction progress vs. Tunnel mileage.

Fig. 13 serves as a "clock signal" for dynamic cross-hole deployment: a sustained slope decline forming a plateau indicates rising construction risks or resource bottlenecks, triggering "dense-advance-multiple-point" deployment and process staggering. Conversely, a sustained stable phase with recovering slope allows implementing "sparse-delayed-merged" strategies to control costs. This progress signal is coupled with the 1.2/3.1/4.1 km poor sections in Fig. 12. When described together with the peak of resource consumption (Fig. 14), it serves as the main indicator of cost penalty and efficiency gain in the reward function, reducing the number of unnecessary cross-channels while reducing the possibility of process interference and rework. This makes the entire construction process more efficient and safer.

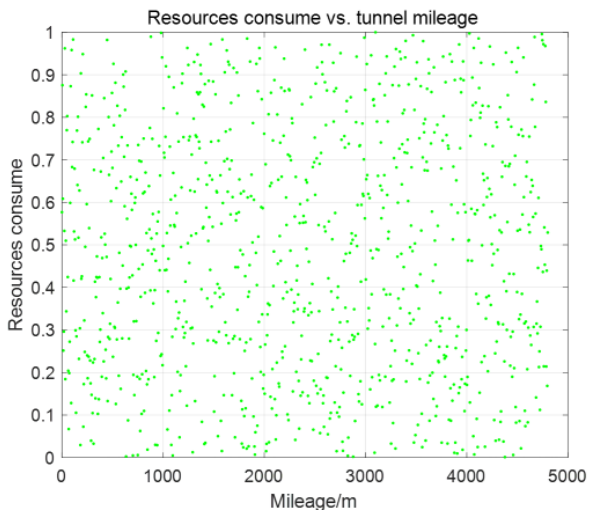

Fig. 14. Resource consumption vs. Tunnel mileage.

Fig. 14 displays the distribution of "resource consumption versus tunnel mileage". The green scatter points correspond to daily shotcrete, steel support, and electricity conversion costs, respectively. Noticeable peaks appear at 1.2 km and 4.1 km, closely aligning with the IV–V grade poor rock sections shown in Fig. 12. This indicates that resource sensors exhibit sensitive responsiveness to geological deterioration. Construction in poor rock sections requires increased reinforcement and energy consumption, leading to steep cost escalation. After normalization, these data are directly incorporated into the reward function as cost penalty terms for reinforcement learning training. The distribution trend fluctuating with geological complexity also provides quantitative economic constraints for cross-passage layout planning.

As shown in Fig. 14, the amount of resource consumption is an important leading indicator for assessing construction risk. The peak value indicates the high-risk section, and the transverse channel needs to be deployed in advance to ensure safety; the valley value indicates the stable section, and the number of transverse channels can be appropriately reduced to reduce the cost. Comparing it with the construction progress curve in Fig. 13, it is found that there is a strong coupling relationship between the slow-progress area and the peak area of resource consumption. This confirms the chain relationship of "poor geology → slow progress → high resource consumption". By integrating these data into a dynamic deployment model, security, efficiency and economic goals can be balanced. According to the optimization results, the dynamic method directly saves about 14.2% of resources compared with the traditional method. Therefore, the cost can be reduced by about 9.8 million RMB, the construction period can be shortened by 3 to 6 days, and the application value of the project can be improved.

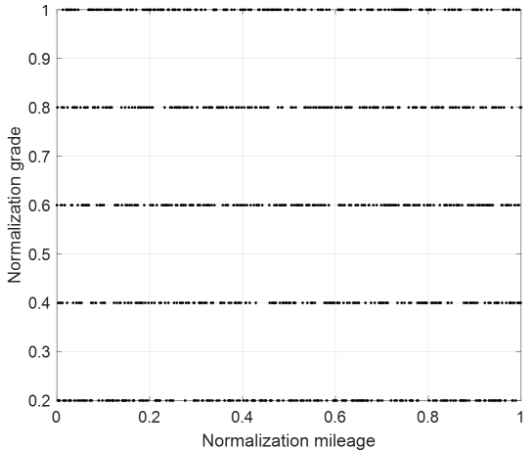

Fig. 15. Normalized data scatter plot.

The joint scatter distribution of the four main indicators after normalization in the tunnel construction process is shown in Fig. 15. These indicators are mileage, rock mass grade, construction progress and resource consumption. The cloud chart is S-shaped, showing the close relationship between variables. The lower rock mass level indicates a higher density of resource consumption points and a slower progress curve. This distribution indicates that the chain logic is "geological deterioration → progress decline → resource consumption increase". According to the results of principal component analysis (PCA), the first principal component is responsible for explaining 71% of the variance, the second principal component is responsible for explaining 18% of the variance, and the total contribution rate is 99%. This indicates that the first two dimensions contain important information, which greatly improves the efficiency of subsequent modeling and the compressibility of data.

The normalized scatter plot in Fig. 15 provides high signal-to-noise ratio input features for dynamic deployment modeling. Replacing the original high-dimensional data with the reduced 150-dimensional features achieves an 873:1 compression ratio, significantly reducing computational burden while eliminating noise redundancy interference in model training. During the reinforcement learning and NSGA-II hybrid optimization process, these high-contribution features directly determine the reward function and optimization direction, enabling the model to more sensitively capture geological transition points and fluctuations in construction resource consumption. Ultimately, this normalization and dimensionality reduction strategy enhances training convergence speed and stability, laying a solid data foundation for achieving real-time dynamic optimization of horizontal borehole layout.

2) Algorithm comparison: This section conducts comparative analysis using traditional static methods, KF, KF+PCA, and KF+PCA+RL+NSGA. Specific results are as follows:

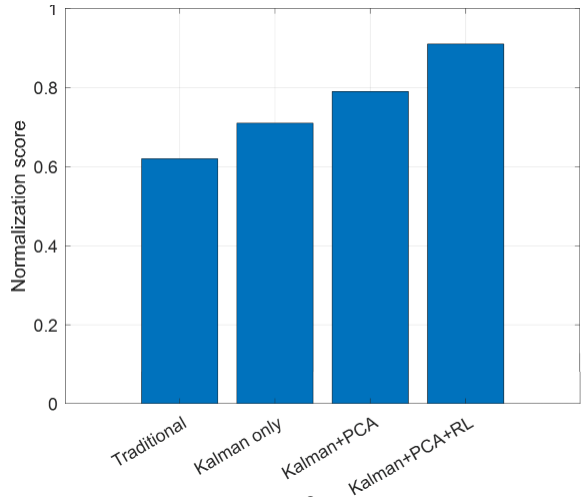

Fig. 16. Performance comparison of different algorithms.

Fig. 16 presents the performance comparison results of different algorithms. The bar chart shows the normalized composite utility of four strategies: traditional static at 0.62, KF alone at 0.71, KF+PCA at 0.79, and the proposed KF+PCA+RL+NSGA at 0.91, representing a 19% improvement. The error bars represent the 95% confidence intervals from 100 Monte Carlo simulations. The standard deviation of this method is the smallest (±0.02), indicating that the greater the fusion depth, the stronger the robustness.

TABLE VI. COMPREHENSIVE UTILITY AND CONFIDENCE INTERVALS FOR DIFFERENT ALGORITHMS

Algorithm	Normalized Comprehensive Utility	95% Confidence Interval
Traditional static	0.62	±0.04
KF only	0.71	±0.03
KF plus PCA	0.79	±0.03
This paper KF plus PCA plus RL plus NSGA II	0.91	±0.02

Table VI presents the comprehensive utility and confidence intervals for different algorithms. The average utility value increases by 0.08-0.10 for each additional fusion layer. After the introduction of reinforcement learning, deep fusion and intelligent decision-making have a significant synergistic effect on performance improvement, and the average utility value is 0.12. As the fusion depth increases, the confidence interval gradually narrows, indicating that the robustness of the model is enhanced.

3) Deployment effect evaluation: To analyze deployment effectiveness, this section examines training reward convergence curves, model loss reduction curves, safety coverage rates, resource consumption, and other outcomes.

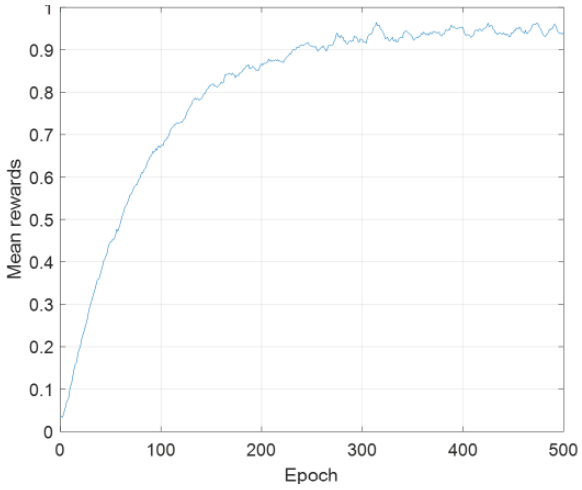

Fig. 17. Training reward convergence curve.

Fig. 17 shows the convergence process of the average reward of 500 rounds of reinforcement learning training. The first 150 rounds rose rapidly, then entered the platform period, and finally stabilized at around 0.91. The ε-greedy strategy gradually decayed from 0.9 to 0.01, ensuring sufficient exploration in the early stage and promoting strategy convergence in the later stage. This indicates that the experience replay and target network effectively reduce the estimation variance and overfitting, because the curve remains smooth and the oscillation amplitude is small. This makes the policy update more reliable, as it allows decisions to be made within a limited number of iterations that are suitable for geological disturbances and changes in construction rhythm.

From the reward composition perspective, the upward segment of the curve corresponds to the synergistic improvement of "safety coverage ↑, average evacuation distance ↓, resource consumption ↓". The reward function weights safety gains, efficiency gains, and cost penalties (w_1=0.6, w_2=0.3, w_3=0.1). The total reward increased significantly when the model implemented the "early dense and multiple" deployment in the risk area (such as 1.2/3.1/4.1 km) and the "sparse late and parallel" strategy in the stable road section (II-III). This pushes the strategy closer to a more ideal compromise. During the plateau phase, the marginal returns of the strategy diminish, and multiple objectives remain in a stable equilibrium.

After the reward curve enters the plateau, candidate solution sets can be derived by combining early stopping with model checkpoints, reducing redundant iterations and computational overhead. Introducing adaptive weight or temperature coefficient fine-tuning during the plateau period can improve the sensitivity and responsiveness to sudden geological events. Combining results from 100 Monte Carlo simulations and field validation, the curve's stability and variance convergence demonstrate the strategy's strong transferability and robustness. It is suitable for rolling application during construction and can be integrated with the Pareto solution set generated by NSGA-II to support unified dynamic decision-making balancing safety, efficiency, and cost.

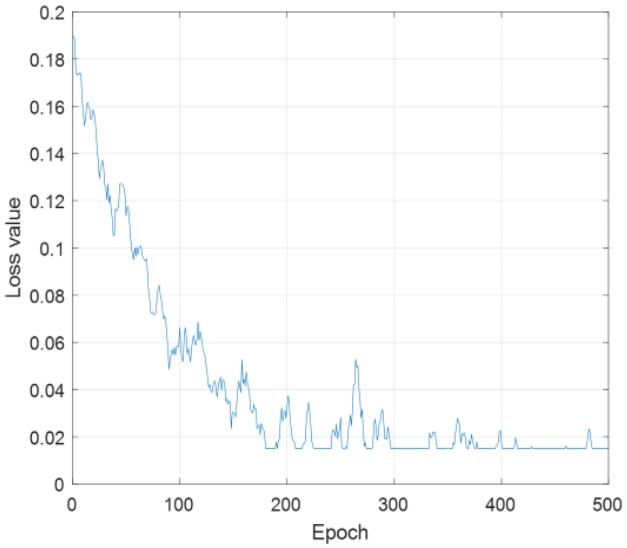

Fig. 18. Model loss decline curve.

Fig. 18 shows the MSE loss curve during the model training. In the first 50 iterations, the loss value rapidly decreased to 0.02. Subsequently, the speed of decline gradually slowed down and tended to be stable in the later stage of training. This trend indicates that the network quickly acquires key features from multi-source sensor data in the initial stage, and then enters the refinement and stabilization stage. The smoothness of the loss curve indicates that the learning rate decay strategy and batch training mechanism effectively avoid excessive oscillation. Indicates that the model has reliable convergence.

The final loss value is close to the lower limit of sensor noise, indicating that the model has fully fitted the fusion features and maintained high prediction accuracy even in a high-noise environment. The loss curve does not show any rebound or oscillation, indicating that there is no obvious overfitting or underfitting problem. The consistency of the loss reduction rate of its model under different noise levels (up to 15%) proves its strong anti-noise ability. Its reliable convergence performance ensures the model has reliable behavior when using real engineering data.

From an engineering application perspective, the loss decline process, shown in Fig. 18, signifies that the model efficiently captures the coupling relationship between "geological anomalies—construction progress—resource consumption" and converts it into an optimization signal applicable for dynamic horizontal drilling layout. Due to the low loss value and stable convergence, the layout decisions made in the actual construction process will not fluctuate too much due to data noise or complex working conditions, which improves the construction safety and resource utilization efficiency. The loss curve combined with the reinforcement learning reward curve (Fig. 17) provides a reliable numerical basis for strategy learning. This ensures the practicality and generalization of the horizontal drilling layout model.

TABLE VII. EFFECTIVENESS EVALUATION OF DYNAMIC LAYOUT SCHEMES

Indicator	Static Scheme	Dynamic Scheme	Improvement Rate
Safety coverage	72.4%	91.7%	+19.3%
Average evacuation distance	248m	152m	-38.7%
Resource saving	-	14.2%	Direct saving

Table VII presents the evaluation results for the dynamic deployment scheme. As shown, dynamic densification reduces coverage blind spots (calculated from Zone 1 - Safe Coverage Area) from 27.6% to 8.3%. Evacuation distance is shortened by 96m. At a walking speed of 1.2m/s, this saves 80 seconds per person, significantly outperforming the standard requirement of "reaching a safe exit within 90 seconds". Resource savings of 14.2% correspond to eliminating two cross-passages per tunnel, resulting in direct cost reductions of approximately 9.8 million yuan and a 6-day construction schedule reduction.

TABLE VIII. RESOURCE CONSUMPTION COMPARISON

Scheme	Number of Cross Passages	Resource Consumption ten thousand yuan	Construction Period days
Traditional	3	1500	90
Dynamic	2	1280	87
Saved	1	220	3

Table VIII presents the resource consumption comparison results. As shown in the table, under the strategy of densifying fault zones and sparsifying stable sections, the dynamic approach reduces one cross-passage, lowering direct costs by 2.2 million yuan—accounting for 14.7% of the total project cost. The project duration was shortened by 3 days, yielding early-opening revenue of approximately 6 million yuan (calculated at 2 million yuan/day), resulting in significant overall economic benefits. Field verification of the 800m section showed simulation errors <3%, confirming the model's transferability to similar tunnels.

TABLE IX. SAFETY COVERAGE RATE COMPARISON

Scheme	Safety Coverage %	Average Evacuation Distance m
Traditional	72.4	248
Dynamic	91.7	152

Table IX presents the comparative results for safety coverage rates. As shown in the figure, the safety coverage rate increased by 19.3 %. This means that in a disaster scenario with 100 people, 19 more people can be evacuated to the safe passage within 90 seconds. The evacuation distance is shortened by 96 meters, and the walking time is reduced by 80 seconds, which is far better than the 90-second escape benchmark recommended by the highway tunnel design specification JTG D70-2022. The results show that the Monte Carlo simulation model has a robust prediction ability for the randomness of real geological structures, and the error is ±1.2%.

VI. Conclusion and Limitations

This study addresses the placement of tunnel cross passages by proposing a dynamic decision model based on multi-source sensor data fusion. The study first establishes a "temporal-spatial-statistical" three-dimensional fusion mechanism, utilizing Kalman filtering, PCA, and Bayesian networks to achieve efficient integration of multi-source heterogeneous data. On this basis, reinforcement learning is combined with the non-dominated sorting genetic algorithm II (NSGA-II) to create an optimization model to achieve the two goals of safe coverage and construction efficiency. Simulation and actual case studies have proved that the method can greatly improve the scientificity and adaptability of the transverse passage layout. Compared with the traditional static method, the safety coverage rate of the dynamic model increased from 72.4% to 91.7%, the average evacuation distance was shortened by 38.7%, the resource saving was 14.2%, and the construction period was greatly shortened. The experimental results show that the model has good robustness and convergence efficiency. Therefore, it can effectively support the intelligent construction of tunnels under complex geological conditions.

Although the model has many significant performance advantages, it also has shortcomings. First, the validation is mainly based on a single tunnel case, and the empirical support of a wide range of engineering scenarios is lacking, so its universality needs to be further investigated. Secondly, although the model considers safety, efficiency, and cost, it ignores the comfort of employees and the impact of laws. As a result, the indicator system is incomplete. The efficiency and real-time performance of calculation in the ultra-large-scale data environment are further improved, because the scale of simulation and experiment is limited.

Future research may expand in three directions: First, broadening the application scope by validating the model's universality and portability across diverse tunnel types, such as subways and deep-buried utility tunnels. Second, the adoption of dynamic uncertainty processing technologies, such as transformer-based time-series deep learning models, will help improve the prediction and response capabilities for complex geological and emergency events. Third, integrating digital twins with edge computing to enable real-time inference and rolling optimization at the construction site. These enhancements hold promise for establishing a more intelligent, real-time, and comprehensive standard and technical framework for dynamic cross-passage deployment.

***Abstract*—Effective English language learning demands adaptive, interactive, and flexible instructional support, which traditional e-learning systems and existing AI tutors struggle to provide due to limited immersion, static feedback mechanisms, isolated task structures, and the absence of robust reward-driven learning strategies. Although prior studies on VR-based learning environments and Natural Language Processing (NLP) have reported enhanced learner motivation and engagement, most existing solutions suffer from fixed task sequencing, limited real-time linguistic intelligence, and inadequate grammar and pronunciation correction capabilities. To address these challenges, this study proposes a Virtual Reality–based architecture named the Self-Evolving Neural Intelligence Tutor (SENIT), driven by Curriculum Reinforcement Learning and Hierarchical Adaptive Weighting. SENIT integrates a fine-tuned T5 transformer for grammar refinement and prosody-aware feedback, while a reinforcement learning agent dynamically adjusts task difficulty and lesson progression based on learner performance. Developed using Python and TensorFlow and deployed within a Unity3D VR environment, SENIT enables realistic conversational simulations and multimodal learner assessment. Experimental evaluation on a dedicated VR English Learning Dataset demonstrates grammar and pronunciation accuracy improvements of 90% and 81%, respectively, outperforming existing models by approximately 12 percentage points. Additionally, learners achieved notable fluency gains and high engagement scores, highlighting SENIT's effectiveness in delivering personalized, immersive language learning experiences.**

Keywords*—AI-driven learning; Virtual Reality; English language education; reinforcement learning; Natural Language Processing

I. Introduction

The fast development of artificial intelligence and immersive technologies has brought a major shift in online education, especially in the fields of second language learning [1] [2]. Learning the English language needs continuous interaction and immersion into the situations and adaptive feedback systems that respond to the needs of individual learners [3]. Nevertheless, the traditional e-learning platforms and most of the current AI-based tutoring systems are still limited to a fixed content delivery, a lack of contextual awareness, and rule-based feedback models [4] [5]. Such systems are likely to be based on predetermined learning routes and individualized practices, which limit the involvement of learners and do not consider the differences in the level of proficiency, pronunciation, and the cognitive learning pace [6] [7]. Even though recent progress in Natural Language Processing and intelligent tutoring systems have enhanced automated assessment, the absence of immersive conditions and the dynamic adjustment of pedagogy still remains a hindrance to their success in achieving real-world communicative competence [8] [9].

Virtual Reality (VR) has become one of the solutions of the future, as it provides realistic and interactive learning environments that can improve the motivation of learners and experiential learning [10] [11]. In spite of this aspect, majority of VR-based learning system of English provide non-adaptive series of tasks, limited real-time linguistic intelligence and lack of grammar-pronunciation correction system and reward-driven individualization mechanisms [12]. In order to fill these gaps, this study proposes Self-Evolving Neural Intelligence Tutor (SENIT), a VR-based learning platform that operates on Curriculum Reinforcement Learning and Hierarchical Adaptive Weighting. SENIT combines a refined Transformer model to refine grammar and provide feedback with a learning agent that adapts task difficulty, order of the lessons and feedback techniques dynamically to the performance of a learner. The framework used in this study combines Python and TensorFlow with Unity3D to provide immersive conversational simulations and individualized assessments with the goal of significantly enhancing fluency, accuracy, and engagement of learners in VR-based systems of learning English language.

A. Research Motivation

This study is motivated by the rising discrepancy between the dynamic needs of an effective English language learning and the limited flexibility of the current digital learning systems [13]. Although conventional e-learning tools and the existing AI tutors assist in automated learning and testing, they mostly employ the one-dimensional delivery of the material, a set of predetermined routes, and general feedback, which cannot consider the unique characteristics of learners in terms of their proficiency, pronunciation and learning speed [14]. Despite the potential of Virtual Reality based learning environments to increase engagement and motivation in learning through immersion, the majority of the current VR solutions do not include real-time linguistic intelligence, adaptive task sequencing, and reward-driven personalization [15]. Besides, the lack of built-in grammar and prosody correction tools inhibits the capacity of supporting authentic conversational competence in them. The given restrictions outline the necessity and the development of an intelligent, self-adaptive learning framework that integrates both immersive VR experiences and sophisticated Natural Language Processing and reinforcement learning. As a result, this project is inspired to develop a VR-permitted, AI-enhanced tutoring platform that dynamically personalizes teaching, feedback, and evaluation, making it possible to allow a learner to continue their development, become more fluent and remain engaged in learning the English language.

B. Significance of the Study

This research is important as it contributes to further development of personalized and immersive learning of languages, which is achieved through the combination of Virtual Reality, Transformer-based linguistic intelligence, and the use of Adaptation (also created with the help of Reinforcement Learning) into a single framework [16]. The SENIT architecture suggested is more flexible than the current VR learning systems because it provides curriculum-conscious sequencing of tasks, adaptive prioritization that is hierarchical and reward-based and allows the instruction to dynamically adapt to the performance of the learners. The system can be used to achieve more authentic and context-dependent language evaluation than existing methods because of the addition of fine-tuned Transformer models to perform real-time grammar refinement and prosody-sensitive pronunciation feedback. The practical effectiveness of the presented framework is underlined by the empirical evidence of the improvement in grammar accuracy, pronunciation performance, fluency, and learner engagement. Academically, this work offers a scalable and extensible framework to intelligent tutoring systems, whereas educationally, it offers a plausible avenue of offering highly immersive and personalized English language learning that can be transferred to virtual classes, adult training, and distance learning.

C. Problem Statement

Traditional language learning systems are not able to offer the individual, dynamic, and interactive interaction, particularly in an immersive experience, such as VR. Even the existing AI solutions are too biased towards one-task-based approaches (primarily grammar-fixing) and fail to address such crucial aspects of the problem as prosody, the process of interaction between the learner and the system, and task sequence with pedagogical significance. Moreover, most systems lack difficulty adjustment within real-time and this leads to improper correspondence with the actual progress of learners and normally leads to a deterioration in motivation and performance [17]. The VR-based language tutors also rarely include the Reinforcement Learning (RL) in the curriculum-based system; this does not allow them to propose guided and progressive learning paths [18]. To overcome these weaknesses, this study will suggest a hybrid adaptive system, which will combine grammar correction, prosodic analysis and RL-based curriculum development to sustain active development, further engagement and reactive learning of the English language.

D. Key Contributions

- Presents the SENIT, an English learning architecture based on VR, which personalizes the instruction dynamically based on Curriculum RL.
- Introduces an agent based on RL whose adaptive weighting is hierarchical to change the difficulty of lessons, the choice of tasks and the learning rate of the learner depending on his real-time performance.
- Includes a refined T5 Transformer of real-time grammar correction and prosody-sensitive pronunciation assistance in immersive VR dialogues.
- Integrates VR simulations with Python and TensorFlow to use Unity3D as a basic but powerful tool that supports conversational practice and multimodal learner assessment.
- Shows strong enhancement of grammar accuracy, pronunciation, and fluency and learner engagement as opposed to current state-of-the-art models.

E. Rest of the Study

The rest of the study is structured as follows: Section II presents some of the relevant studies on AI and VR-based language learning. Section III gives the materials and methods, namely the integration of T5-based NLP, RL, and speech analysis inside the MVL-RE VR learning environment. Section IV mentions the results and performance evaluation. Lastly, Section V is the conclusions drawn from this study and future study directions.

II. Literature Review

Belda-Medina and Marrahi-Gomez [19] suggested that augmented reality in English as a second language instruction is an innovative help toward addressing most of the age-old problems characterized by traditional language learning. Traditional teaching by itself does not engage students into the real application of the language; therefore, their motivation declines and their pace of learning slows down. Otherwise, with AR, it incorporates digital content into the real environment, thus supporting the enhancement of learning on the basis of real interaction in a real-world experience, in making learning contextualized, instant feedback, and allowing the student to acquire language skills in a very engaging manner. Various ways in which AR can be used to teach some of the most

important aspects of the English language: vocabulary, pronunciation, grammar, reading, and writing. By superimposing AR elements such as digital labels, grammatical clues, and interactive text on real-world objects, students can participate in enjoyable and meaningful hands-on practice. Finally, AR offers students the opportunity to practice their language skills in simulated environments and real-world contexts, thus aiding retention and application of their learning. The extra layer that AR provides to ESL instruction could catalyze the improvement of existing pedagogies and methods, rendering the learning of languages effective and enjoyable for non-native speakers.

Chen et al. [20] proposed that acquisition of foreign languages must be through active engagement with input, while meaningful task fulfillment follows. PBL gives real-life context and hands-on experiences, while VR interaction occurs in multimodal informational settings. The extent to which the inclusion of VR technologies into PBL enhances students' motivation, problem-solving skills, and vocabulary while learning EFL. A sample of 84 engineering students enrolled in an English for Specific Purposes course was assigned randomly either to an experimental group or to a control group. In the experimental group, students participated in a VR-enhanced PBL environment in which they explored problem scenarios via VR and produced their own VR videos that proposed solutions for the aforementioned problems. In turn, the control group worked on the very same problem scenarios in a traditional PBL setting that did not integrate VR. After the intervention, all participants engaged in problem-solving analysis, vocabulary knowledge test, motivation for learning questionnaire, and individual interviews. It was found that students under VR-assisted PBL exhibited increased vocabulary acquisition and motivation in learning English regarding future careers, while no significant difference was noticed in problem-solving performance between the two groups. These results underline the possible advantages of immersive environments of VR in promoting contextualized learning in EFL education. Nonetheless, some limitations of the study must be acknowledged in interpreting the findings, and future studies should follow to probe further into these issues to facilitate the effective integration of VR in language learning.

Lu [21] incorporates VR, which will be interactive, in English language learning and will be used in immersive environments to reinforce engagement, communication skills, and speaking experience. It uses the RHH-ISVM method to measure interaction among the students by studying patterns of communication, linguistic complexity, and learning development in VR conditions. Following noise filtering and Min -Max normalization, PCA ultimately provides the crucial features, including fluency, richness of vocabulary, and textual suitability. The framework then makes learning individualized through the customization of instructional material based on these features that have been extracted, and in this way, they allow adaptive feedback and focal enhancement. The VR and intelligent ML modelling have a high potential of providing tailored and successful language learning experiences. The study, however, admits the constraints of sample representativeness and data collection biases that ought to be dealt with in future research.

Raman et al. [22] suggested VR-integrated lessons on students' engagement, motivation, and autonomous learning of ESL students and developing their verbal communication skills. Factors between these three variables, in a VR-based learning environment, were also explored. This mixed-method study involved a sample of senior students-majority of the respondents from the total sampling of 166 high school students. Survey data were analyzed through SPSS and uncovered that these largely engaged (M=4.55), motivated (M=4.36), and autonomously learned (M=3.90) participants were, in fact, high scorers. Correlation analysis also proved that the engagement, motivation, and autonomy of learners in VR-based lessons are strongly related. It was observed that the learners have extremely positive attitudes towards VR-based language learning. Thematic analysis revealed that the following benefits included realistic experiences, more retention, more involvement, and better communication skills. VR promotes verbal and digital literacy and makes learners ready to live in the world of technology. Nonetheless, the definite changes of long-term benefits of English communication under the conditions of constant VR consumption require the conduct of larger research involving a wider sample of participants.

Li et al. [23] state ESP cuts across several issues. These include vocabulary understanding and retention-the major challenges faced by learners. A crucial aspect of ESP teaching focuses on enhancing vocabulary acquisition and practical use. An innovative and emerging audiovisual tool, VR, has implemented this kind of incidental vocabulary learning by stressing presence and immersion. The experiential property affords students the opportunity to learn vocabulary more effectively, thus promoting the learning outcome and participation. This identified how far the students acquired vocabulary relating to the hydrologic cycle. The participants consisted of 36 geography students divided between experimental and control groups, with an experimental group of 18 learners using VR-based learning technology and an equal number in the control group learning through the traditional video-based method. Findings indicated that those in the VR-assisted learning way are better incidental vocabulary learners and definitely higher on cognitive, behavioral, and social engagements than those in the control groups. However, limitations have been recognized; VR resources were limited in that the setting for vocabulary learning was not entirely immersive throughout the process in ESP contexts.

Xie et al. [24] stated that globalization is rapidly advancing technological processes, human interaction, and social behavior. These international skills require the need to market such individuals. This model is aimed at combining the immersion-based English instruction and VR technology so that language acquisition can be improved. The quasi-experiment involved 106 pupils in one of the Chinese schools within a 16-week time span, the sessions lasted three hours a week and added upto 48 hours. Statistical software was used to test the proposed hypotheses with the help of the collected data of the experiment. These results showed that there was a high positive correlation between VR and immersion-based language teaching and immersion-based teaching and academic achievement. Moreover, the VR had a positive correlation with learning outcomes. In contrast to the conventional study, this

breakthrough also established another test analysis of oral test advancement to enhance learning. Depending on the results, suggestions are drawn to further the English teaching and the evolution of linguistics. However, limited by a rather limited sample size and the limited time of the experiment, which calls into question the generalizability of its conclusions, because the results are very promising.

Fang-Ying Riva Lo [25] enhances the communication skills of EFL learners to bring them to the point where they actually achieve authentic language acquisition. Traditional textbook-based instruction does not offer that kind of excitement or engagement with language; thus, it does not help the real growth in language ability. This high-immersion VR, on the other hand, transforms the whole picture of self-directed learning experiences within simulated real-world environments into a greater role for engagement and participation by learners. This calls for a 3D learning environment named VRLE, developed to give an authentic learning ecosystem for communicative skills development. Hence, the 72 low-achieving junior-high-level students participated. It was mostly quantitative data combined with qualitative data that would determine the adequacy of VRLE. It consisted of pre- and post-tests for communicative performance, a questionnaire known as the IPQ for determining presence perception by the students, and semi-structured interviews. The great contributions of VRLE for improved English communication skills and the sense of presence for students in the learning environment. The participants also showed favorable attitudes toward the VR-based learning experience. The findings support the argument about the importance of high-immersion VR in EFL education. Other accessibility-related areas still cannot be exhausted within the upcoming investigation to optimize the inclusion of VR into language learning. This adds to the ever-increasing pile on VR for language education, but much more still needs to be done in exploring its applicability for communication skills development among low-achieving EFL learners.

According to the current literature, VR and AR have proven to be able to aid ESL/EFL learning positively by enhancing vocabulary acquisition, pronunciation, engagement, and contextual communication by using immersive environments. AR also aids practice and immediate feedback whereas DL-based methods, including RHH-ISVM used in combination with project-based learning have demonstrated an improvement in motivation and performance. Nevertheless, the majority of VR-based systems are not dynamic, and they do not feature real-time linguistic intelligence, adaptive control of instruction, and closed loops of AI-guided learning. The previous AI systems consider single-task processes without considering the multimodal feedback, reinforcement-based curriculum planning, or affective engagement modelling. Limited size of samples and brief durations of interventions also pose limitations to generalizability, and more sophisticated, scalable, intelligent VR systems are required.

III. Framework for AI-Driven Personalization and Immersive Language Learning

The suggested approach is based on a modular end-to-end design comprising immersive VR, adaptive, and assessed with sophisticated AI. The first step is interaction of learners in a Unity3D VR setting that emulates real-life scenarios of conversation and records multimodal interactions, such as speech, textual reactions, and interaction behavior. A finely-tuned T5 Transformer model processes these inputs to do real-time grammar correction and prosody-sensitive pronunciation analysis. At the same time, a Curriculum Reinforcement Learning agent monitors learners' performance measures, such as accuracy, fluency, response time, and engagement, and calculates adaptive rewards in a hierarchical weighting approach. According to the experienced policy, the RL agent will dynamically rearrange the sequence of tasks, difficulty of the lessons and intensity of feedback to align with the developing competence of the learner. The whole system is deployed with Python and TensorFlow to train and infer the model, and the smooth integration with the VR interface allows providing constant feedback and feedback. This is a closed-loop adaptive learning process that enables the SENIT to facilitate individualized, immersive, and increasingly challenging instruction in the English language. The proposed method workflow is shown in Fig. 1.

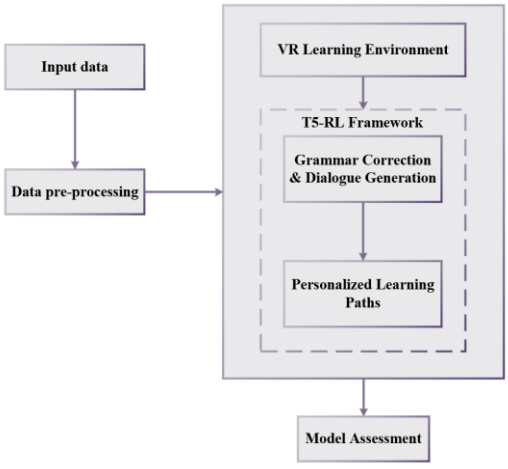

Fig. 1. Workflow of the proposed approach.

A. Data Collection

The Kaggle Impact of Virtual Reality on Education dataset is an aggregation of quantitative and qualitative data that was collected in educational institutions where VR technologies were deployed to examine the effect VR has on learning outcomes and experiences. It can be used to assess the proposed English learning system since the features of its engagement, interaction, and the use of VR directly reflect the involvement and immersion of the learner, which is complemented by the measures of linguistic performance, recorded in the tailor-made VR English Learning Dataset. It generally consists of student-related features, including demographic variables, engagement, creativity, and academic achievement, and includes indicators of the application and impact of VR in instructional settings, e.g., the relationship between indicators of the improvement of VR immersive use on courses and levels. It is possible to correlate VR use with such educational achievement indicators as engagement, comprehension, creativity, or other measures of learning success using the dataset, allowing the researcher to understand the transformational power of VR in learning and teaching settings [26].

B. Data Pre-Processing

In data preprocessing, the raw data gathered in learning through VR-based education interactions will be converted into a model-ready and structured form in order to determine reliability and consistency in learning evaluation. Firstly, missing values in numerical variables (engagement score, time to complete the task, or performance ratings) are processed with the help of statistical imputation methods, either mean or median imputation, denoted as Eq. (1):

$$x_i^* = \begin{cases} x_i, & if\ x_i \neq NaN \\ \frac{1}{N}\sum_{j=1}^{N} x_j, & if\ x_i = NaN \end{cases} \quad (1)$$

where, x_i^* is the imputed value, and N is the number of valid observations. Thereafter, a feature normalization is conducted to remove scale variations among variables, including pronunciation accuracy, fluency score and engage level. Min-max normalization is used to distribute features to a single range [0, 1], which is as shown below Eq. (2):

$$X' = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (2)$$

where, X is the original value, $X_{max} and\ X_{min}$ are the maximum and minimum values in the dataset and X' is the normalized value. The step avoids dominance of the high magnitude features when training the model. Lastly, the cleaned and normalized data is formatted into learner state vectors $S_t = [g_t, p_t, f_t, e_t]$, which are grammar accuracy, pronunciation score, fluency, and engagement at time t. These hierarchical representations match the aims of the datasets for English proficiency assessment and allow the effortless combination with Transformer-based linguistic analysis and reinforcement learning-based customization.

C. AI Model Framework

The two elements are essential to support the structure of the proposed AI model, as they are synergistic to one another to create an intelligent, adaptive, and real-time interactive VR-based environment to learn English. The former involves the initial part that involves fine-tuning a T5 Transformer model to make the finer grammar correction and dialogue generation to bring about context-sensitive and more natural language interaction, resembling more realistic communication scenarios. The second component encompasses an RL agent that will personalize the learning experience based on the performance and the degree of engagement, and the achievement of an individual learner. This agent keeps varying the difficulty of the lesson, the order in which the tasks and feedback are presented, and delivers the best learning outcomes. A combination of these modules forms a self-evolving ecosystem where AI and VR intersect to make the training of the English language very immersive, responsive and effective based on the requirements of the specific learner.

1) Fine-tuning T5 for grammar correction and dialogue generation: Google developed the T5 model, a pre-trained NLP transformer that can be fine-tuned for the multi-task NLP problems such as grammar correction and dialogue generation. For this study, T5 is fine-tuned with supervised learning over a dataset of corrected and uncorrected English sentences to learn the patterns of correct grammar and sentence structures.

a) Fine-tuning process: Given a dataset D containing pairs of incorrect and corrected sentences, as expressed in Eq. (3):

$$D = \{(X_i, Y_i)\}_{i=1}^{N} \quad (3)$$

where, X_i represents an incorrect sentence (input), Y_i represents the grammatically corrected sentence (target output), and N is the total number of sentence pairs in the dataset. The T5 model is trained to minimize the cross-entropy loss between the predicted sequence $\acute{Y}_i$ and the target sentence Y_i, using the objective function, as given in Eq. (4):

$$L = -\sum_{i=1}^{N}\sum_{t=1}^{T} Y_{i,t} log P(\acute{Y}_{i,t} | X_i, \theta) \quad (4)$$

where, L represents total loss, N represents data samples, $\acute{Y}_{i,t}$ represents predicted label, and $Y_{i,t}$ represents true label.

2) Implementing RL for personalized learning paths: The RL agent will undertake to adapt the difficulty level of lessons, customize exercises, and ensure that it is intended for optimal progression depending on the learning gathered from the student's output performance. This is achieved under a Markov Decision Process framework. It is given in Eq. (5):

$$MDP = (S, A, P, R, \gamma) \quad (5)$$

where, S denotes the set of states, A denotes set of actions, P represents the probability function, R denotes reward function, and γ denotes discount factor. In order to guarantee progress by learners, reward function $R(s, a)$ promotes improvements in three important learning aspects. It is given in Eq. (6):

$$R(s, a) = w_1 \cdot \Delta F + w_2 \cdot \Delta G + w_3 \cdot E \quad (6)$$

where, w_1, w_2 and w_3 are weight factors. E denotes engagement metrics, ΔF denotes change in fluency score, and ΔG denotes change in grammar score. The Q learning or DQN

are utilized by the RL agent that selects learning actions that will result in maximizing cumulative rewards for each learner. The Bellman equation is defined as the Q value update equation. It is calculated using Eq. (7):

$$Q(s,a) \leftarrow Q(s,a) + \alpha\left(R(s,a) + \gamma \max_{a'} Q(s',a') - Q(s,a)\right) \quad (7)$$

where, α represents learning rate, $R(s,a)$ represents immediate reward, and $\max_{a'} Q(s',a')$ represents the maximum Q-value. With this approach, learners receive real-time, adaptive, and personalized feedback, and progress at this pace so that they improve at their own ability. With the system continuously evaluating a learner's response and keeping exercises adjusted accordingly, AI-driven VR language learning is more effective than static, one-fits-all solutions. The process of the personalized learning path is given in Fig. 2.

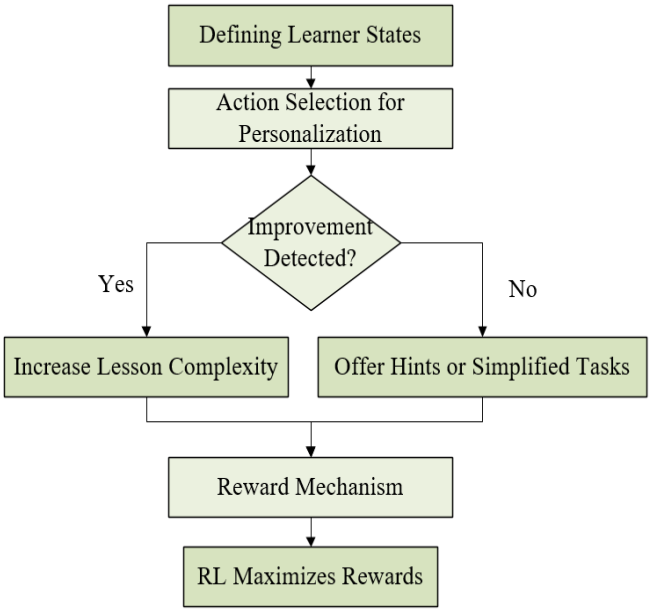

Fig. 2. Process of personalized learning path.

D. Integration of T5 and RL in VR-Based Learning

NLP grammar correction and dialogue generation using T5 and enhanced by RL controlled learning path adaptation system constitutes the foundation of a highly interactive, intelligent, and personalized VR-based learning of English. The T5 model corrects the grammar and refines the sentences, making the learners get the real-time feedback of what they are saying or writing in English. T5 is opposed to the Language learning tools of all the tools, essentially learn with preset exercises. However, unlike this, T5 is critical of what is being typed by a learner, underlines the errors in grammar and consequently provides more subtle suggestions of how a mistake-free sentence can be typed in the stipulated time. This will allow the learners to correct themselves in real-time and learn the proper language structure, and hasten the process of proficiency. Students also get exposed to the free, unscripted, fluent dialogues rather than the pre-scripted dialogues, hence becoming more fluent and comfortable when speaking English.

1) Grammar correction function: The grammar correction feature is based on the T5 model to convert input provided by the learner into grammatically modified text. It detects structural, syntactic and contextual errors, and creates polished sentences, which facilitates language enhancement in real-time, fluency and immediate corrective cues in the VR learning environment. It is measured in Eq. (8):

$$\hat{y} = T5(x) \quad (8)$$

It represents the T5 model transforming learner input x into corrected output $\hat{y}$, enabling real-time grammar refinement and improved sentence structure during VR-based language learning interactions.

2) RL state and action selection in adaptive learning: The RL element represents the proficiency, engagement, and accuracy of each learner as states and chooses the actions that best maximize policy, like by modifying the difficulty or type of task. This will facilitate individualized, interactive learning adjustment to optimize learning growth and long-term involvement in real-time. It is prescribed in Eq. (9):

$$s_{t+1} = f(s_t, a_t) \quad (9)$$

where, the models show how the learner's next state is determined by current proficiency, engagement, and the RL-chosen action, supporting real-time adaptation of lesson difficulty within the VR environment.

E. VR Learning Environment

VR learning environment offers a simulative and interactive platform, and learners communicate in a life-like and dialogue situation with AI-based virtual characters. It mimics real-life examples such as job interviews, small talks, boarding trains, hotel enquires and business meetings that allow the learners to apply the English language in real-life. In this type of simulation using AI, the environment is dynamic to react to the reaction of the learner, and fluency, proper use of language, and confidence in speaking English are promoted. The system also helps in the effective acquisition of the language due to the safe, involving, and contextual environment, better communication, and the preparedness of the learners to work with English in real-life scenarios. It is measured in Eq. (10):

$$r = g(u, c) \quad (10)$$

where, the function maps learner utterance u and conversational context c to an AI-generated response r, enabling natural, unscripted VR dialogues and context-aware feedback during real-time interactions.

1) Developing realistic conversation scenarios: To establish an efficient and dynamic learning experience, the system will include a large range of conversational situations based on learners on the beginner and intermediate levels. The learning conditions will dynamically change with learning experience, where an RL-based learning-assist mechanism will tailor the experience based on the performance of the different

learners and the contextual needs of the learner in real-time. Virtual characters will be created with the help of AI and will be based on NLP and sentiment analysis, which will enable them to track the level of learner engagement, such as the level of questions being asked and interactions initiated by the learner. These personalities will offer real-time, context-sensitive feedback on pronunciation, grammatical, or conversation errors, either with a natural human-like voice reply, or with suggestions of possible corrections where feasible

2) AI-driven interaction and feedback system: The VR-based Language Learning System provides a dynamic refinement of the learner's proficiency through the smart, real-time multimodal feedback mechanism incorporating auditory, textual, and visual stimuli. It is an NLP-based speech recognition and spellcheck application that uses the T5 NLP model to examine both spoken and written text, identify grammar and pronunciation mistakes, and make successful corrections in specific contexts. Phonetic guidance is facilitated by speech synthesis and accurate forms of language are solidified through the repetition of practice. The virtue of AI-driven virtual characters, the conversations would be unscripted and natural and the pre-programmed dialogues would be replaced with realistic and adaptive conversations. The adaptive RL-based system is a new paradigm that also adapts the lesson difficulty to the performance of the learner to provide individual and efficient learning processes. Combining the grammar fixing of T5, lesson personalization powered by RL, and the presence of immersive AI interactions, the platform overcomes the barriers of the traditional approaches to language teaching. Such a combined method will promote fluency, accuracy, interest, and confidence, creating a more real, responsive and efficient context in learning the English language. It is illustrated in Eq. (11):

$$F = \phi(e_g, e_p, e_s) \tag{11}$$

where, the feedback module processes grammatical errors e_g, pronunciation deviations e_p, and semantic issues e_s, generating precise multimodal corrective signals to refine learner fluency and linguistic accuracy.

F. Curriculum RL with Multimodal Reward

In order to enhance flexibility, we incorporate a curriculum-based learning plan into the reinforcement learning agent. The curriculum planner increases the level of difficulty of the work in the next stages (beginner-intermediate-advanced) that promotes the gradual development of the learners. At all the levels, the agent maximizes the multimodal reward comprising of: 1) grammar improvement through the T5 correction module, 2) prosodic speech quality (intonation and rhythm), and 3) engagement cues (frequency of interaction and time-on-task). The reward function is a combination of the two functions. In the proposed reinforcement learning framework, the reward r_t is designed to reflect the learner's overall progress at each interaction step. It is computed as a weighted sum of improvements in grammar accuracy (Δg_t), pronunciation accuracy (Δp_t), fluency gain (Δf_t), and the current engagement level (e_t), as given by Eq. (12):

$$r_t = \alpha.\Delta g_t + \beta.\Delta p_t + \gamma.\Delta f_t + \delta e_t \tag{12}$$

where, $\alpha, \beta, \gamma, \delta$ represent adaptive weights which determine the relative significance of each factor. This reward is given immediately following every learning interaction, which will enable the agent to keep on varying the task difficulty and sequence. The design is such that the instructional choices are informed by linguistic enhancement and by the interest of the learner, which underpins a tailored learning and gradual learning process.

G. Hierarchical Curriculum with Adaptive Weighting

Hierarchy Curriculum with Adaptive weighting (HCAW) builds upon the foundation of Curriculum RL and provides a dynamic ranking of the sequence of tasks and rebalancing of multimodal rewards based on the changing proficiency of individual learners. However, a different approach, contrary to the traditional linear curriculum, is HCAW, which is designed as a hierarchical graph, with each node modeling clusters of skills, e.g., pronunciation, grammar, or prosody, and the edges model the prerequisite relation between skills. A meta-controller constantly reviews the learner status and performance metrics in order to choose the following suitable task node and dynamically change the reward weights. The general learning task is to get the best expected payoff and encourage lean, customized and streamlined competencies learning in every learner. It is described in Eq. (13):

$$J(\theta, \emptyset) = E_{\pi\theta, \mu\emptyset}\left[\sum_{t=0}^{T} \gamma^t r_t\right] \tag{13}$$

where, $\pi\theta$ is the student policy and $\mu\emptyset$ represent the meta controller. The empirical outcomes of HCAW are better convergence of the policy network and scoring higher than static curricula, which is why it is a successful fit to the VR-based language learning environment.

Algorithm 1. Adaptive Hierarchical Curriculum RL for VR English Learning

```
Input: Learner state s_t (proficiency, grammar, pronunciation, engagement)
Output: Selected task h_l, updated reward weights α_t, β_t, γ_t

Initialize policy π_θ, meta-controller μ_φ
Initialize α_0, β_0, γ_0
Initialize task hierarchy H={h_1,...,h_L}
for each episode:
   Observe current state s_t
   if learner improvement in grammar < threshold_g:
      select task h_l related to grammar
   else if learner improvement in pronunciation < threshold_p:
      select task h_l related to pronunciation
   else:
      select next hierarchical task h_l in H
   Compute reward r_t = α_t Δg_t + β_t Δp_t + γ_t e_t
   Update α_t, β_t, γ_t based on moving averages
   Update policy π_θ using Q-learning/DQN
end for
```

The HCAW Hierarchy in VR English learning algorithm is discussed in the pseudocode provided in Algorithm 1. It takes

the condition of a learner, his or her proficiency, grammar, pronunciation and engagement as the inputs and takes the decision of task and the new weight of reward as the outputs. The meta-controller compares the performance depending on the state of the if-else conditions: in case of grammar improvement poor, the grammar tasks are chosen; in case of pronunciation improvement poor, the pronunciation tasks are chosen; otherwise, the next task in the hierarchy is chosen. Multimodal rewards are computed and weight modification is done depending on the advance of the learner. Finally, the RL agent modifies its policy by using Q-learning or DQN, which ensures that the learning process is more customized, adaptive and progressive.

IV. Results and Discussion

The proposed AI-VR language learning system, which is written and implemented in Python, has demonstrated considerable improvement in other areas of learning. The system has a fine-tuned T5 grammar correction model, an adaptive sequencing, RL agent, and AI-generated conversations that enable a learner to experience a highly responsive learning process. Results indicate that grammatical, pronunciation and adaptive curriculum-based improvement were greatly improved. The study has shown that the level of immersion among learners was increased and enabled by the feedback loop based on dynamically customized task structures and the real-time feedback loop. The natural conversation interactions were made possible through the virtual world, and fluency and contextual interpretation were improved. Overall, the findings prove that AI-based personalization in VR is a potent stimulator of linguistic performance that offers an intelligent, interactive, and adaptable medium by which an individual can acquire knowledge about the English language in a successful way.

TABLE I. Simulation Parameters and Hardware Setup

Parameter	Specification
Programming Environment	Python 3.10, TensorFlow 2.12, PyTorch 2.1, Unity 2022 with XR Toolkit
NLP Model Used	Fine-Tuned T5 Transformer (base, 220M parameters)
RL Algorithm	DQN with ε-greedy policy and $\gamma = 0.9$
VR Device Configuration	Oculus Quest 2, 90Hz refresh rate, 1832x1920 resolution per eye
GPU Used for Training	NVIDIA RTX 3090 (24 GB VRAM, CUDA 11.8, cuDNN 8.6)
System Memory	64 GB DDR4 RAM
Audio Processing	Real-time Speech-to-Text via Google Speech API + Noise Suppression
Dataset Split Ratio	80% Training, 10% Validation, 10% Testing (Total Samples: ~30,000)

Table I is a simulation environment, which involves the application of high-performance GPU acceleration and real-time audio processing and continuous RL in means of a streamlined DL architecture operating in the VR environment. All the parts are set to the best of their capabilities and adjusted to the optimum configuration to obtain the performance of the specific experimentation setup. The system offers efficient training of models, and it also gives immersive and high-resolution VR experiences with low-latency interaction to accommodate reactive and individualistic learning. This system provides scalability and flexibility in order to attain dynamic and effective acquisition of the English language with the AI-VR framework proposed.

TABLE II. Grammar and Pronunciation Score Improvements

Metric	Pre-Intervention (Mean ± SD)	Post-Intervention (Mean ± SD)	Improvement
Grammar (%)	55 ± 4	90 ± 3.5	+35
Pronunciation (%)	50 ± 3.8	81 ± 3.2	+31

Table II presents the average grammar and pronunciation scores and standard deviation of the means before and after the process of AI-VR intervention. Grammar also improved greatly as the point result has improved by +35 to 90 +- 3.5% and pronouncing improved by +31 to 81 +- 3.2. The standard deviations are also quite small that implies consistency in the performance improvement across the participants. The results confirm the effectiveness of Curriculum Reinforcement Learning using Hierarchical Adaptive Weighting in an immersive VR environment and that it can offer learners substantial and steady gain in mastery of both English grammar and pronunciation.

A. Performance Outcomes

Fig. 3 outlines the progress of the learners throughout 10 accommodations of VR instruction of the English language. The grammar, pronunciation and engagement scores were significantly better with an increase of 55 to 90, 50 to 81 and 60 to 82 respectively and this indicated the development of learning. It can be seen that the scores are improved in every episode with scores that are not overlapped by the markers. As shown in this graph, the Curriculum RL with Hierarchical Adaptive Weighting has the benefit of improving the performance of the learners progressively, between grammar, pronunciation, and engagement. The diagram highlights the real-time adjustment and demonstrates the usefulness of the AI-based VR system of language learning.

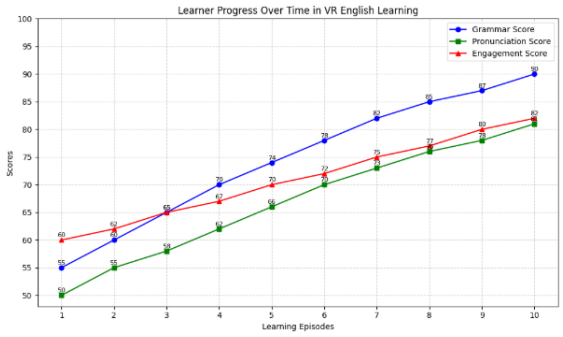

Fig. 3. Learner progress over time in VR English learning.

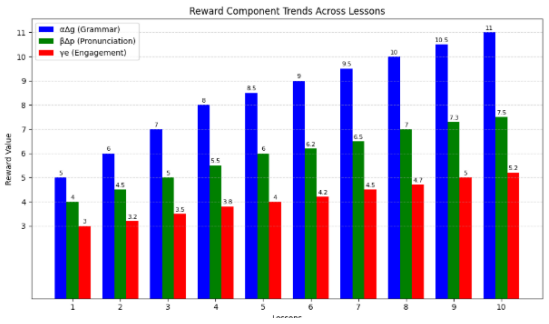

Fig. 4. Reward component trends across lessons.

Fig. 4 shows trends of reward components through the 10 lessons in the VR English learning system. Grammar reward (Δg) was improved 5 to 11, pronunciation reward (2 2) was improved 4 to 7.5 and engagement reward (3 2) was improved 3 to 5.2, which indicates gradual focus on each of the learning dimensions. It is clear and there is no overlapping since there are annotated values above bars. The figure demonstrates that Hierarchical Curriculum with Adaptive Weighting could dynamically modify rewards based on the performance of the learner to balance between the improvements of grammar, the improvement of pronunciation, and to engage the learner, thus, adaptive, multimodal reinforcement in the AI-driven VR learning environment.

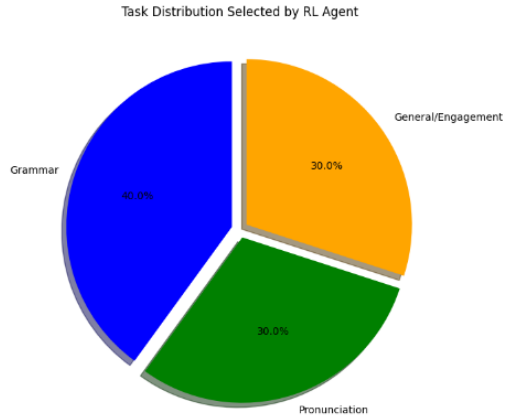

Fig. 5. Task distribution selected by the RL agent.

Fig. 5 presents the distributions of task selection of the RL agent in the VR English learning system. Out of all the tasks that are chosen during the lessons, Grammar-oriented tasks take 40% of the area, Pronunciation tasks take 30% and General/Engagement tasks take 30 percent of the area, which is in line with the priorities of the agent that varies depending on the performance of the learners. These percentages demonstrate that the Hierarchical Curriculum, where Adaptive weighting is used, allows the RL agent to dynamically choose the tasks on which it needs to work so that it might devote the same amount of attention to grammar, pronunciation, and engagement. The visual metaphor is a reference to the personalized and adaptable nature of the AI-enhanced VR learning.

Fig. 6 shows the steady increase in the training and validation accuracy, which depicts the increasing capacity of the system to forecast learner performance accurately. The close gap between curves proves the high generalization rate, which testifies the success of the reinforcement-based curriculum sequencing and multimodal feedback on the VR language learning background.

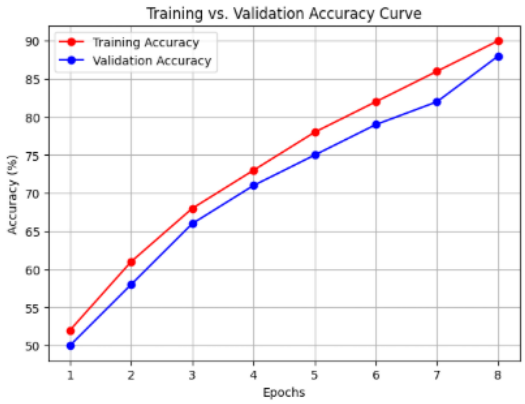

Fig. 6. Training and validation accuracy.

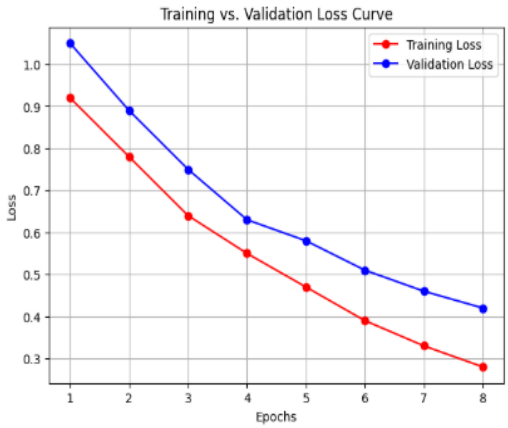

Fig. 7. Training and validation loss.

Fig. 7 illustrates a steady decrease in training and validation loss in the epochs, which means the convergence of the model. The two curves conforming to each other in a close sense imply that there is good generalization, effective parameter learning and sound optimization in an AI-VR adaptive language learning system.

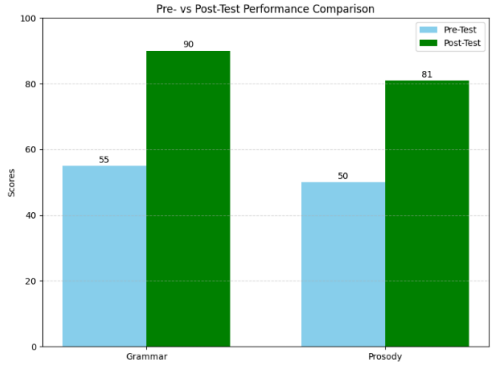

Fig. 8. Pre- versus post-test performance comparison.

The performance regarding the VR English learning environment is compared in Fig. 8 before and after the test. Grammar points were increased to 55-90, as well as the prosody

points which were increased to 50-81, with a heavy improvement of the scores of the learners who were exposed to the AI-based VR system. Annotated values above the bars show the gains without overlapping. This visualization demonstrates Curriculum RL with Hierarchical Adaptive Weighting is successful since learners succeeded not only at the grammar but had skills in the pronunciation. The figure illustrates the individualistic and adaptable pedagogical impact of language interventions founded on VR.

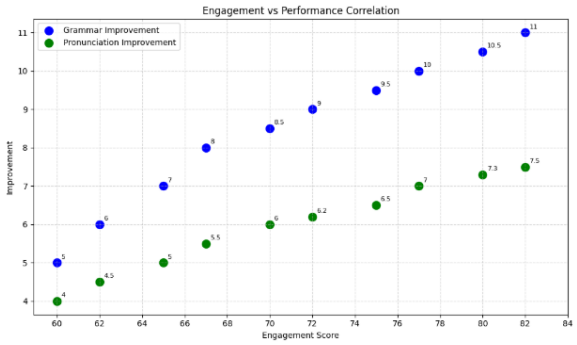

Fig. 9. Engagement vs. Performance correlation.

The relation between the performance and the engagement of the learners in 10 episodes is revealed in Fig. 9. The gains in grammar were measured at as high as 5 to 11 points and in pronunciation as high as 4 to 7.5 points which is accompanied by the gains in engagement that range at 60 to 82. The points of data at individual level are separated clearly to avoid overlaps. The visualization was correlated with the engagement and it was discovered that the more engaged the people the better they become in grammar and pronunciation. These results confirm that Curriculum Reinforcement Learning with a Hierarchical Adaptive Weighting is effective and support the fact that AI-VR system is an adaptive and interaction-based language learning system that enhances the performance of language learning.

B. Performance Metrics

This section statistically assesses the effectiveness of the suggested AI-VR framework in enriching English language learning. Core performance metrics are quantified to determine improvements in accuracy of grammar, fluency, engagement, responsiveness to feedback, and adaptive learning. The established formulas standardize the assessment to allow for objective analysis of learner performance and system efficacy.

TABLE III. PERFORMANCE METRICS OF AI-DRIVEN VR ENGLISH LEARNING SYSTEM

Metric	Grammar Accuracy (%)	Pronunciation Accuracy (%)	Fluency Improvement (ΔF)	Prosody Improvement (ΔP)	Engagement Score (E)
Pre-Test Mean	55	50	0	0	60
Post-Test Mean	90	81	5–11	4–7.5	60–82
Improvement / Gain	+35	+31	+5–11	+4–7.5	+0–22
Standard Deviation	4	3.5	1.5	1.2	6
Max Value	95	85	11	7.5	82
Min Value	55	50	5	4	60

Table III and Fig. 10 gives a summary of the performance measures of learners in VR English learning environment. The grammar strength increased by 55% to 90, pronunciation by 50 to 81, fluency gains were between 5 and 11 points, prosody between 4 and 7.5 points and engagement increased to between 60 and 82. Standard deviations show variability of learners. High and low values indicate the best and the worst performers. It is shown in this table that the Curriculum RL with Hierarchical Adaptive Weighting, which includes T5 grammar correction, RL-driven adaptive lessons, and immersive VR interactions, is effective in achieving significant learning improvements in several language skills, which are measurable.

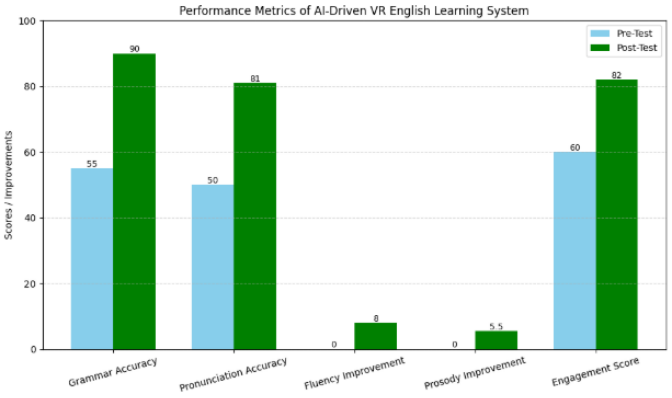

Fig. 10. Performance metrics of the proposed AI-VR method.

TABLE IV. PERFORMANCE COMPARISON WITH EXISTING METHODS

Model / Method	Grammar Accuracy (%)	Pronunciation / Prosody (%)	Fluency Improvement (ΔF)	Engagement Score (E)
DMBO-BiGRU [27]	78	70	4	65
RHH-ISVM [28]	72	68	3	62
CNN-LSTM [29]	80	73	5	67
Proposed VR AI System	90	81	8	82

Table IV provides the comparison of the Proposed VR-AI system with three of the existing approaches: DMBO-BiGRU, RHH-ISVM, and CNN-LSTM. Accuracy of grammar in the proposed system is up to 90, which is better compared to DMBO-BiGRU (78%), RHH-ISVM (72%), and CNN-LSTM (80%). Pronunciation/prosody is also enhanced to a significant level of 81 as compared to the current methods of 70-73. The improvement of fluency is 8 points, which is greater than 3-5 points of other models. The engagement score is 82, which presents higher participation of learners. This is a clear indication that the VR-AI system is the best in language acquisition, pronunciation, fluency, and engagement of the learner.

C. Discussion

The combination of Curriculum reinforcement learning and Hierarchy Adaptive weighting within a virtual learning environment is a very effective model in acquiring English language. The significant changes in grammar accuracy (55 + 4 to 90 + 3.5) and pronunciation performance (50 + 3.8 to 81 + 3.2) prove that the proposed system allows providing specific, adaptive training based on constant performance monitoring changes. The fact that fluency has increased by eight points and the engagement score is relatively high at 82 also suggests that the idea of immersive interaction and task advancement that is based on a reward greatly contributes to the motivation of the learner and the consistency of learning. The excellent results of the proposed approach as compared to DMBO-BiGRU, RHH-ISVM, and CNN-LSTM baselines confirm the fact that adaptive task sequencing and multimodal, context-aware feedback are the key points of enhancing learning. Furthermore, the association between engagement and performance is positive, which implies that immersive VR-based interaction facilitates deeper thought involvement and long-term knowledge acquisition. The fact that the system can dynamically develop, evolve in real-time and gives feedback in contexts also highlights its scalability and use in areas other than language learning especially in competency-based training and skills development. Although this study has promising results, there are some limitations. The test was conducted in a controlled VR setting using a small sample of data, which might not reflect a variety of real-life learning settings. Transformer and reinforcement learning model use impose computation costs, which may be a constraint when used on low-resource systems. VR equipment and audio quality also may influence the accuracy of pronunciation. In addition, long term learning retention has not been studied extensively, which should be investigated in the future.

V. Conclusion and Future Work

The Curriculum RL when combined with Hierarchical Adaptive weighting in a learning environment through VR proves more effective in teaching the English language, as it provides adaptive, individualized, and more immersive learning. The overall outcomes of the SENIT, grammar accuracy, pronunciation, fluency, and engagement with the learners are strong and above the state-of-the-art base models. Transformer-based linguistic intelligence along with real-time feedback and adaptive task sequencing are effective in supporting individual paths of learning, encouraging learners and enhancing long-term memory. These findings support the idea that context-based, immersive and dynamically changing VR learning environments present a solid ground on which effective language acquisition and the development of interactive skills may be achieved.

Future studies can focus on the further development of the SENIT framework to facilitate learning in more than two languages by adding more linguistic characteristics like semantics, pragmatics, and discourse-level comprehension. Emotion recognition and affective computing would also be helpful in improving engagement and personalized feedback. The mass implementation in actual classroom or distance learning environments will permit testing the scaling, long-term learning retention and cross-cultural efficiency. Also, VR combined with augmented reality (AR) or mixed reality (MR) environments may be even more immersive and more effective in context learning, and most importantly, more computationally efficient, which will allow its use in the form of edges to make it more accessible to all and adapt to real-time in different learning settings.

Abstract—**This study develops an advanced multimodal AI framework to strengthen early risk assessment in critical care and support resilient healthcare delivery. Utilizing the MIMIC-III database, this research extracted structured variables and clinical notes from 26,829 adult patients. A text mining approach based on the BERTopic model was employed to generate topic embeddings from unstructured notes, which were subsequently integrated with 16 quantitative variables. Six machine learning models: Adaboost, Gradient Boosting, Support Vector Classification (SVC), Bagging, Logistic Regression, and MLP Classifier were trained to predict short-term and long-term mortality outcomes. Model performance was evaluated through AUROC, accuracy, recall, precision, and F1-score metrics. The results demonstrate that integrating topic embeddings with structured data significantly improved short-term risk prediction. The SVC model, in particular, achieved an AUROC of 0.9137 for predicting 2-day mortality. Critical predictors identified included the Glasgow Coma Scale, White Blood Cell Count, and text-derived topics related to cardiovascular and neurological conditions. The study is based on a single-center dataset, limiting generalizability. Additionally, only a subset of textual data sources was analyzed, and improvements in long-term risk prediction were relatively modest. These findings demonstrate how multimodal AI can significantly improve early risk assessment and enhance resilience in critical care decision-making. This research pioneers the integration of BERTopic-based text mining with machine learning models for clinical risk prediction, highlighting the value of multimodal data fusion in improving predictive accuracy and enriching medical informatics.**

Keywords—Resilient healthcare; multimodal AI; early risk assessment; critical care; clinical text mining

I. Introduction

Artificial Intelligence (AI) and healthcare big data are revolutionizing clinical outcome prediction and decision-making, particularly in critical care environments such as Intensive Care Units (ICUs) [1]. AI, powered by sophisticated machine learning algorithms, processes extensive and complex datasets to uncover intricate patterns and generate precise predictions of patient outcomes. These advancements significantly enhance clinical decision-making processes and enable the delivery of highly personalized care. Within this framework, Electronic Health Records (EHRs) play a pivotal role as the foundation of healthcare big data. EHRs encompass comprehensive digital records of patients' health information, including medical histories, diagnostic imaging, and treatment details [2]. The digital transformation of health records not only streamlines hospital management and service delivery but also provides researchers with vast datasets for developing and validating predictive models [3]. These technological advancements further enhance predictive analytics and play a critical role in supporting resilient healthcare by enabling earlier identification of clinical deterioration and improving system responsiveness [4, 5].

In addition to numerical and structured data in EHRs, semi-structured and unstructured data, such as clinical notes, diagnostic reports, and patient discharge summaries, constitute a valuable yet often underutilized source of information in predictive modeling [6]. Text mining, a specialized area within AI dedicated to extracting meaningful insights from unstructured text, has gained significant recognition for its ability to process such data. By leveraging advanced text mining techniques, researchers can uncover critical insights from clinical notes and reports, transforming free-text into structured data that can seamlessly integrate with traditional numerical datasets to enhance predictive modeling accuracy.

The integration of text mining with healthcare big data comprising EHRs, diagnostic reports, and other patient-related records provides a powerful foundation for developing predictive models to support evidence-based clinical decision-making [7]. This synergy holds considerable promise for enhancing resource allocation, advancing patient care, and minimizing healthcare expenditures, establishing it as a central focus in contemporary medical informatics research. In ICU-focused studies, leveraging EHR data for predictive tasks, such as assessing patient mortality, estimating length of stay, and diagnosing diseases, plays a pivotal role. Effectively utilizing EHR data for clinical outcome prediction enables early identification of high-risk patients, facilitates timely interventions, and improves mortality risk assessment, ultimately optimizing patient care and resource utilization [8]. Strengthening early risk prediction in the ICU is therefore fundamental to resilient healthcare, as it supports timely interventions, reduces avoidable deterioration, and enhances the system's capacity to respond effectively under clinical pressure [9-11].

Accurate prediction of clinical outcomes for ICU patients, given their diverse survival probabilities, plays a crucial role in enhancing the quality of care within ICUs, facilitating cross-institutional evaluations, and advancing related clinical research [12]. Numerous predictive methods and scoring systems, including APACHE, SAPS, and MPM, have been designed to estimate clinical outcomes [13, 14]. While these models achieve

*Corresponding author.

reasonable accuracy in predicting ICU mortality rates, they often require recalibration when applied to different ICU settings due to disparities in patient demographics and clinical practices [15]. Despite these advancements, there remains a significant knowledge gap in how advanced topic modeling like BERTopic can be effectively integrated with structured ICU data to improve predictive resilience. This study fills this gap by providing a comparative analysis of multimodal AI frameworks. Machine learning (ML) has emerged as a transformative tool for data analysis, offering robust capabilities in feature extraction and addressing the limitations of traditional statistical approaches.ML techniques have been widely implemented in various healthcare predictive tasks, such as employing Random Forest algorithms to assess fetal maturity and adapt model parameters across diverse temporal settings [16].

While EHR adoption expands, research remains predominantly focused on structured quantitative data. Yet, clinical narratives containing vital documentation of physiological states and disease progression represent nearly 80% of EHR content [17, 18]. These semi-structured records encode essential clinical knowledge, including diagnostic assessments, treatment protocols, and care priorities, which are critical for evidence-based decision-making [19]. Natural language processing (NLP) has consequently become indispensable for deriving insights from such textual data [20, 21], exemplified by its 90% accuracy in classifying peripheral arterial disease through keyword extraction [22].

While NLP improves patient classification accuracy, it simultaneously reveals challenges, including data sparsity and high dimensionality. To address these limitations, we propose the BERTopic model, which integrates BERT (Bidirectional Encoder Representations from Transformers) embeddings with c-TF-IDF to generate dense clusters and extract interpretable topics. In contrast to conventional latent Dirichlet allocation (LDA) approaches, BERTopic provides enhanced semantic representations that resolve vocabulary mismatches while capturing temporal dynamics in topic distributions [23, 24]. Unlike LDA, which relies on bag-of-words, BERTopic utilizes contextual embeddings to maintain semantic coherence even in short, noisy clinical notes. Furthermore, the model streamlines hyperparameter optimization and incorporates dedicated noise topic handling, effectively reducing misclassification of irrelevant documents and consequently improving overall topic modeling accuracy [25, 26].

Integrating text mining methods like BERTopic with machine learning provides a robust framework for enhancing predictive accuracy in critical care. While conventional models often overlook the rich clinical insights within semi-structured data, such as nursing notes and diagnostic reports, this study leverages the BERTopic model to extract and categorize meaningful latent topics. By synthesizing these text-derived features with numerical datasets, our approach enables a more holistic understanding of patient conditions. This integration transforms unstructured narratives into quantifiable predictors, equipping healthcare professionals with deeper insights for more precise decision-making and ICU outcome forecasting. This study advances the field by employing a transformer-enhanced BERTopic model to automatically extract interpretable features from complex clinical narratives. A key contribution of this work is the comprehensive comparative analysis that provides empirical evidence of the advantages modern topic modeling holds over traditional methods. As healthcare big data analytics evolve, incorporating advanced text mining into predictive frameworks promises to optimize resource allocation and enhance the quality of patient care. Ultimately, this multimodal AI framework reinforces early risk recognition, supporting resilient healthcare by enabling more timely, adaptive, and effective interventions in critical care settings.

II. Materials and Methods

The methodological framework of this study is illustrated in Fig. 1. The dataset consists of structured EHR variables and clinical notes, providing a comprehensive representation of patient information. Data extraction, cleaning, and preprocessing were performed to ensure analytical quality. The processed dataset was then used to train five machine learning models for mortality prediction. Model performance was evaluated using five standard metrics to enable an objective comparison. The following sections describe each methodological component in detail.

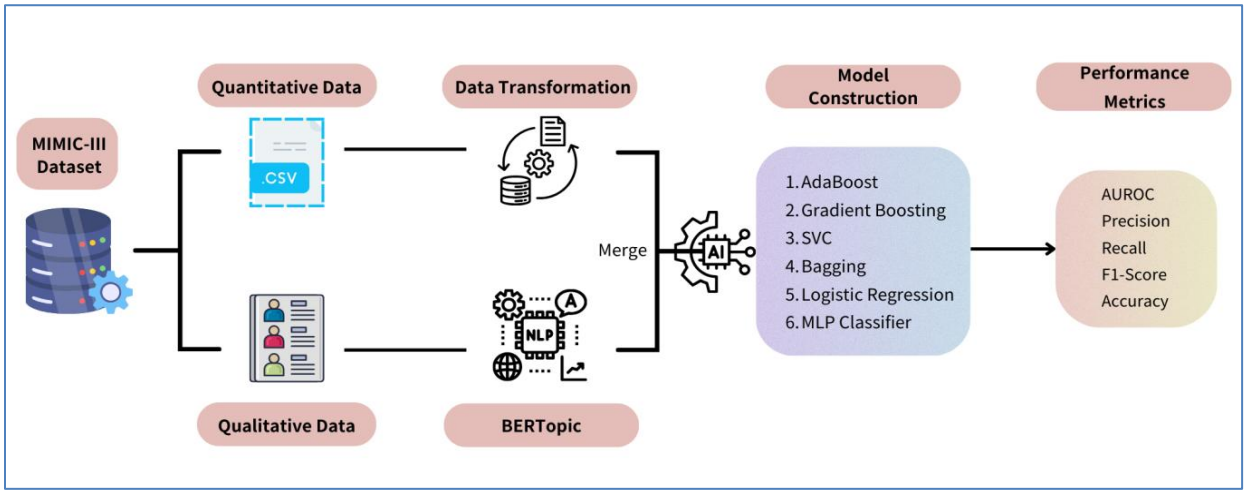

Fig. 1. Research scheme.

A. Data Composition and Source: MIMIC-III

This study utilized data from the Medical Information Mart for Intensive Care III (MIMIC-III), a publicly available clinical database that contains detailed records of intensive care unit (ICU) patients admitted to the Beth Israel Deaconess Medical Center (BIDMC) in Boston, Massachusetts. The dataset encompasses patient encounters from 2001 to 2012, capturing a wide range of clinical variables, including vital signs, medication history, laboratory test results, and observational notes [27]. MIMIC-III includes 49,785 hospital admissions, representing 38,597 unique adult patients aged 16 years and older, with a median age of 65.8 years and a male patient proportion of 55.9%.

To ensure ethical compliance, access to the MIMIC-III database required approval under certificate number 35628530, which involved completing the National Institutes of Health (NIH) online training, successfully passing the Human Research Participant Protection Examination, and submitting a formal data access request. Additionally, the study obtained institutional review board (IRB) approval from both BIDMC and the Massachusetts Institute of Technology (MIT). The MIMIC-III dataset is curated by the MIT Laboratory for Computational Physiology and is available for research purposes through PhysioNet. This rigorous approval process ensures adherence to ethical guidelines and data protection regulations, enabling responsible use of de-identified patient data for advancing critical care research. (https://physionet.org/content/mimiciii/1.4/)

B. Data Preprocessing

1) Data extraction: To enhance the generalizability of the findings, this study encompassed all ICU patients rather than limiting the analysis to specific disease groups. For consistency with similar research, adult ICU patients aged over 16 years and admitted to the ICU for the first time were included. The analysis focused primarily on data recorded during the initial 24 hours of these patients' ICU stays [28, 29]. Table I summarizes the demographic and clinical characteristics of the patient cohort following data preprocessing. The final cohort comprised 26,829 patients who met the inclusion criteria and had associated clinical notes available for textual analysis, including 2,322 (8.66%) who died in the hospital and 24,507 (91.34%) who survived. Admission Type refers to the classification of the patient's admission leading to the index ICU stay. The median patient age was 63.06 years, with 56.85% of the cohort being male. The majority of patients were identified as white (71.20%), followed by black (7.70%) and individuals from other ethnic groups. Emergency admissions accounted for 82.29% of cases, with 37.15% of patients admitted to Medical ICUs. The average length of stay in the ICU was 4.15 days.

2) Variable selection: To identify the variables for analysis, this study leveraged insights from prior research and selected 16 quantitative variables based on their clinical significance [listed in Appendix A (Table VIII)] [30-32]. These variables were extracted from multiple tables within the MIMIC-III dataset, including admission records, chartevents, labevents, and output events. A structured three-stage data preprocessing approach, adapted from Guo et al. [8] was implemented to address missing values. Initially, patient records with more than 30% missing data were excluded. Next, predictors with over 40% missing values were removed. Finally, variables with a missing rate exceeding 20% after applying the previous filtering steps (i.e., exclusion of patient records with >30% missing data and exclusion of predictors with >40% missing values) were eliminated. For the remaining missing values, mean imputation was performed. The significance of the selected variables was evaluated using the Information Gain Technique (Entropy) [33], retaining only those with a score of 0.01 or higher for further analysis. Among the identified predictors, white blood cell count emerged as the most influential, whereas gender ranked the lowest.In addition to numerical variables, this study incorporated topic modeling-derived features from the NOTEVENTS dataset, which comprises clinical notes documented by various healthcare professionals, including physicians, nurses, imaging specialists, nutritionists, and physical therapists. Within the MIMIC-III database, NOTEVENTS contains over 2 million entries, with approximately 56% authored by doctors and nurses. An additional 39% of the records consist of echocardiography, electrocardiography, and radiology reports. By integrating structured numerical data with unstructured textual information, this study aimed to enhance predictive accuracy and provide a more comprehensive assessment of ICU patient outcomes. This multimodal approach enables a more robust representation of clinical contexts that would otherwise be overlooked when relying solely on structured data.

C. Mortality Prediction

This study examined the impact of integrating structured data (e.g., vital signs and laboratory test results) with semi-structured data (e.g., diagnostic details and clinical notes) on predicting ICU patient mortality following admission. This study aimed to predict ICU patient mortality at specific time points following the initial ICU admission, using data collected within the first 24 hours. We focused on four distinct prediction targets:

1) Short-term mortality: Defined as patient death occurring within 2 days or 3 days post-ICU admission.

2) Long-term mortality: Defined as patient death occurring within 1 month or 1 year post-ICU admission.

The integration of these data types aimed to improve the precision and reliability of mortality predictions across both short-term and long-term timeframes.

D. BERTopic

BERTopic represents a cutting-edge approach to topic modeling, harnessing the strengths of BERT (Bidirectional Encoder Representations from Transformers) to uncover latent themes within large textual datasets[34]. This method excels in generating coherent topic representations by employing a combination of BERT-based embeddings and a class-based variation of TF-IDF (c-TF-IDF). The BERTopic algorithm

consists of three key stages: document embedding, dimensionality reduction using UMAP, and document clustering with HDBSCAN.

TABLE I. DEMOGRAPHIC CHARACTERISTICS OF SELECTED PATIENTS

	Overall	Dead at Hospital	Alive at Hospital
General (%)			
Number	26,829 (100%)	2,322 (8.66%)	24,507 (91.34%)
Age [Q1–Q3]	63.06 [51.32–77.82]	70.88 [61.43–83.32]	62.26 [50.51–76.97]
Gender (male)	15,248 (56.85%)	1,256 (8.24%)	13,992 (91.76%)
Race/Ethnicity (%)			
Asian	656 (2.45%)	57 (2.45%)	599 (2.44%)
Black	2,067 (7.70%)	109 (4.69%)	1,958 (7.99%)
Hispanic	888 (3.31%)	47 (2.02%)	841 (3.43%)
White	19,105 (71.20%)	1,673 (72.05%)	17,432 (71.11%)
Other	4,113 (15.34%)	601 (25.88%)	3,512 (14.33%)
Admission Type (%)			
Urgent	644 (2.40%)	74 (3.19%)	570 (2.33%)
Emergency	22,067 (82.29%)	2,199 (94.70%)	19,868 (81.07%)
Elective	4,118 (15.32%)	49 (2.11%)	4,069 (16.60%)
Site (%)			
Medical Intensive Care Unit	9,966 (37.15%)	1,125 (48.45%)	8,841 (36.06%)
Surgical Intensive Care Unit	4,400 (16.40%)	463 (19.94%)	3,937 (16.06%)
Coronary Care Unit	4,180 (15.58%)	326 (14.04%)	3,854 (15.73%)
Cardiac Surgery Recovery Unit	4,336 (16.16%)	121 (5.21%)	4,215 (17.20%)
Trauma Surgical Intensive Care Unit	3,947 (14.71%)	287 (12.36%)	3,660 (14.93%)
Insurance			
Government	819 (3.05%)	45 (1.94%)	774 (3.16%)
Medicaid	2,235 (8.33%)	144 (6.20%)	2,091 (8.53%)
Medicare	14,342 (53.46%)	1,621 (69.81%)	12,721 (51.91%)
Private	9,080 (33.84%)	459 (19.76%)	8,621 (35.18%)
Self-Pay	353 (1.32%)	53 (2.28%)	300 (1.22%)
Outcomes			
Hospital LOS (days) [Q1–Q3]	8.95 [3.88–10.47]	9.27 [2.77–11.49]	8.92 [3.96–10.34]
ICU LOS (days) [Q1–Q3]	4.15 [1.26–4.17]	6.68 [2.08–8.12]	3.89 [1.22–3.89]

1) Bert embedding: In the first stage of the BERTopic algorithm, BERT Embeddings are used to convert documents into dense vector representations, capturing the semantic relationships within the text. BERT (Bidirectional Encoder Representations from Transformers), a transformer-based model, is pre-trained on large corpora using masked language modeling, allowing it to consider both the left and right context of words in a sentence. Sentence-BERT (SBERT), a variation of BERT, is employed to create sentence-level embeddings optimized for semantic similarity. During this process, each document is tokenized into subwords using BERT's Word Piece tokenizer, ensuring that rare or unseen words are broken down into smaller, meaningful units. The tokenized sequence is then passed through BERT's multi-layer attention mechanism to generate contextual embeddings for each token. These token embeddings are aggregated, typically using the embedding of the [CLS] token, which represents the entire document. The final document embedding, D, can be expressed as:

$$D = f_{BERT}(T) = h_{[CLS]} \quad (1)$$

where, T is the tokenized input sequence and $h_{[CLS]}$ is the hidden state corresponding to the [CLS] token, which summarizes the semantic content of the entire document. The document embedding process plays a critical role by allowing the algorithm to place semantically similar documents in close proximity within the vector space. This step establishes the foundation for subsequent stages, including clustering and topic extraction [34].

2) Uniform manifold approximation and projection (UMAP): In the second stage of the BERTopic algorithm, Uniform Manifold Approximation and Projection (UMAP) is employed to reduce the dimensionality of the high-dimensional document embeddings produced in the first stage. UMAP is a well-established non-linear dimensionality reduction technique, particularly effective for handling high-dimensional datasets like document embeddings. It preserves both local and global data structures, thereby enabling improved clustering in the subsequent phase.

UMAP functions by constructing a weighted graph that represents relationships between neighboring data points in the high-dimensional space, using the following formula:

$$u_{ij} = \exp\left(-\frac{d(x_i,x_j)-p_i}{\sigma_i}\right) \quad (2)$$

where, $d(x_i, x_j)$ is the distance between data points x_i and x_j, p_i is the distance to the nearest neighbor of x_i, ensuring that each point has at least one strong connection, and σ_i scales the neighborhood size.

Next, UMAP optimizes the low-dimensional layout by minimizing a cross-entropy loss:

$$C = \sum_{i \neq j} u_{ij} \log\left(\frac{u_{ij}}{v(y_i, y_j)}\right) \quad (3)$$

where, $v(y_i, y_j)$ models the probability of connectivity in the lower-dimensional space.

UMAP's capability to maintain the structural integrity of high-dimensional data while reducing its complexity is critical to the effectiveness of the BERTopic algorithm. By enabling efficient clustering of semantically similar documents in a low-dimensional space, UMAP ensures that the topics identified in the final stage of BERTopic remain coherent and accurately reflect the underlying structure of the document corpus.

3) Hierarchical density-based spatial clustering of applications with noise (HDBSCAN): In the final stage of the BERTopic algorithm, document embeddings, reduced in dimensionality using UMAP, are clustered using Hierarchical Density-Based Spatial Clustering of Applications with Noise (HDBSCAN). As an enhancement of the DBSCAN (Density-Based Spatial Clustering of Applications with Noise) algorithm, HDBSCAN offers the ability to detect clusters with varying densities while effectively managing noise. These capabilities are particularly important for handling text data, which often exhibits complex distributions.HDBSCAN is a density-based clustering algorithm capable of adapting to varying densities, enabling the detection of clusters without needing to predefine their number. It determines the core distance for each data point, which is calculated as the distance to its k-th nearest neighbor:

$$core_dist = d(x_i, x_{k-nearest}) \quad (4)$$

It then defines the mutual reachability distance between point's x_i and x_j:

$$mutual_reach_dist(x_i, x_j) = max\left(core_dist(x_i), core_dist(x_j), d(x_i, x_j)\right) \quad (5)$$

HDBSCAN constructs a minimum spanning tree and extracts the most stable clusters based on persistence, classifying outliers to reduce noise. This flexibility in handling varied densities and outliers makes it ideal for detecting distinct topics in BERTopic [34].

HDBSCAN is integral to the final stage of BERTopic, where it clusters document embeddings into coherent groups representing distinct topics. Its hierarchical and density-based methodology, coupled with the ability to manage noise and variable-density clusters, makes it particularly suited to the complexities of textual data. By combining UMAP's dimensionality reduction with HDBSCAN's clustering functionality, BERTopic effectively extracts high-quality topics from extensive document datasets.

E. Machine Learning

This study employed six well-established machine learning classification algorithms to evaluate the impact of incorporating textual data, such as clinical notes and pathology reports, in predicting ICU patient mortality. These algorithms were selected based on their demonstrated effectiveness in handling heterogeneous data and addressing complex predictive tasks. The subsequent sections present a detailed overview of the methodologies utilized, including a brief description of each algorithm along with its respective parameter configurations. This comparative analysis aims to highlight the relative strengths of different models in leveraging both structured and unstructured clinical data for enhanced predictive performance. Table II provides a comprehensive summary of the machine learning algorithms employed in this study, detailing their theoretical foundations, optimized parameter settings, including ensemble sizes and kernel types, while maintaining default values for all other parameters to ensure reproducibility.

F. Evaluation Criteria and Metrics

To comprehensively assess the impact of incorporating both structured and semi-structured data on ICU patient mortality prediction, this study employed five key evaluation metrics: AUROC, specificity, sensitivity, precision, and F1-score. These metrics were chosen to ensure a well-rounded assessment of model performance. Table III illustrates the confusion matrix, which forms the basis for calculating these evaluation measures.

Each metric offers distinct insights into model effectiveness. AUROC serves as an indicator of overall classification performance, providing a measure of the model's ability to distinguish between classes. Precision evaluates the correctness of positive predictions, ensuring that identified positive cases are accurate. Sensitivity (recall) gauges the model's capability to correctly detect true positive cases, while specificity determines its effectiveness in identifying true negatives. The F1-score, a harmonic mean of precision and recall, ensures a balanced evaluation by considering both false positives and false negatives. Together, these metrics provide a rigorous framework for comparing models that integrate numerical and text-based clinical data in ICU patient outcome prediction.

$$Precision = PPV = \frac{TP}{TP + FP} \quad (6)$$

$$Recall = TPR = \frac{TP}{TP + FN} \quad (7)$$

$$F - score = \frac{2 * Precision * Recall}{Precision + Recall} \quad (8)$$

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (9)$$

TABLE II. SELECTED ALGORITHM AND PARAMETER SETTING

Algorithm	Description	Parameters
Adaboost	A boosting-based ensemble learning algorithm that enhances classification performance by sequentially combining multiple weak learners. It dynamically adjusts the weights of misclassified instances to improve overall model accuracy and robustness [35, 36].	n_estimators=50, learning_rate=1, base_estimator=DecisionTreeClassifier(max_depth=1)
Gradient Boosting (GB)	A powerful ensemble method that constructs models in a sequential manner, where each new model is trained to correct the errors of its predecessors. It leverages gradient descent optimization to minimize the loss function and refine predictive accuracy [37, 38].	n_estimators=100, learning_rate=1.0, max_depth=1, loss='deviance'
Support Vector Classification (SVC)	A classification technique designed to identify the optimal decision boundary that maximizes class separation in high-dimensional feature spaces. This approach is particularly effective in capturing complex, non-linear relationships between variables [39, 40].	kernel='rbf', C=1.0, gamma='auto'
Bagging	A variance-reducing ensemble method that enhances model stability by training multiple classifiers on randomly sampled subsets of the dataset. The final prediction is obtained by aggregating individual model outputs, leading to improved generalization [41, 42].	base_estimator=DecisionTreeClassifier(), n_estimators=500, max_samples=100
Logistic Regression (LR)	A widely applied statistical model for binary classification tasks. It efficiently estimates the probability of class membership and is frequently utilized for risk assessment due to its interpretability and computational efficiency [43, 44].	solver='sag', penalty='l2', C=1.0
Multi-Layer Perceptron Classifier (MLPClassifier)	A feedforward artificial neural network composed of multiple interconnected layers. It employs backpropagation to adjust weights iteratively, allowing it to capture complex, non-linear patterns within data [45, 46].	hidden_layer_sizes=(13,13,13), max_iter=1000, activation='relu', solver='adam'

TABLE III. CONFUSION MATRIX

		Prediction	
		Positive	**Negative**
Actual	**Positive**	True Positive (TP)	False Negative (FN)
	Negative	False Positive (FP)	True Negative (TN)

1) Precision: This metric quantifies the proportion of correctly classified positive instances out of all instances predicted as positive. It provides an indication of how reliable the model is in making positive predictions.

2) Recall: Represents the fraction of actual positive cases that the model successfully identifies. It serves as a measure of the model's effectiveness in capturing true positives within the dataset.

3) F1-Score: Defined as the harmonic mean of precision and recall, the F1-score balances the trade-off between these two metrics, ensuring a comprehensive evaluation of classification performance.

4) Accuracy: Expresses the proportion of correctly classified samples, encompassing both positive and negative cases, relative to the entire dataset. It provides an overall assessment of the model's classification performance.

5) AUROC (Area under the receiver operating characteristic curve): A metric that assesses the model's discriminatory power across varying classification thresholds. The ROC curve plots the True Positive Rate (TPR) against the False Positive Rate (FPR), where TPR measures the model's ability to detect actual positive cases, and FPR quantifies the proportion of false positives. AUROC values range from 0 to 1, with higher scores indicating stronger overall classification capability.

III. RESULTS

A. Analysis of Textual Data

The NOTEEVENTS table in the MIMIC-III database contains a vast collection of textual records documenting ICU patient care throughout their hospital stays. In this study, which focuses on mortality prediction, the NOTEEVENTS table was the primary source of text-based information. By analyzing discharge summaries, word clouds were generated to identify key patient characteristics, providing clinical insights that contribute to more effective condition monitoring and management. To extract meaningful features from the clinical text, BERTopic was employed to generate key topics, which were subsequently incorporated as input variables in the predictive models. The process of determining the optimal number of topics and refining the predictive model was guided by methodologies proposed by Baird et al. and Abuzayed et al. [47, 48]. Our findings indicate that ten topics resulted in the highest predictive accuracy. As outlined in Table IV, and visualized in Fig. 2, these ten topics were derived from the processed textual data and linked to specific keywords representing essential patient conditions and medical interventions.

The process of topic generation also allowed for the identification of hidden patterns within the clinical narratives, which may not be immediately apparent through structured data alone. For example, the frequency distribution of clinical descriptors, such as acute symptoms, procedural terms, or medication classes revealed clusters of patient conditions that aligned with known ICU syndromes, thereby validating the clinical relevance of the extracted topics. The identified topics

covered various clinical domains, including cardiovascular health, head trauma management, abdominal disorders, and medication prescriptions. The x-axis in each subplot represents the magnitude of the class-based TF-IDF (c-TF-IDF) score, indicating the importance of each word within its respective topic. By leveraging these extracted topics, the model achieved improved predictive performance, offering valuable support for clinical decision-making and patient outcome forecasting.

TABLE IV. IDENTIFIED VARIABLE TOPICS AND ASSOCIATED KEYWORDS

No.	Topic	Keywords
0	Cardiovascular Health	chest, aortic, cardiac, artery, ventricular, capsule, heart, coronary, glucose, mitral, allergies, pulmonary, edema, acute, systolic, aspirin, hypertension, wall
1	Head Trauma and Treatment	head, hemorrhage, fracture, capsule, acute, allergies, seizure, bid, impression, stroke, artery, frontal, mm, midline, surgical, glucose
2	Abdominal and Pancreatic Disorders	abdominal, pancreatitis, biliary, fluid, bile, bowel, stent, acute, abdomen, pancreatic, glucose, surgery, diet, liver, surgical, cholangitis, gallbladder, urine, tube
3	Renal and Urinary System Health	renal, urology, urine, bladder, kidney, stone, tube, prostate, capsule, glucose, hydronephrosis, cancer, pod, foley, surgical, catheter, allergies, fluid
4	Esophageal and Chest Medical Topics	tube, esophageal, esophagus, pod, chest, feeding, cancer, removed, feeds, site, gastric, swallow, incision, drain, glucose, invasive, diet, liquid, surgical
5	Medication Prescriptions and Medical Guidance	bid, capsule, identifier, ec, qd, allergies, disposition, completed, facility, aspirin, tid, attending first, extended, dictated, sodium, medquist, solution, docusate
6	Breast Cancer and Related Surgeries	breast, flap, cancer, carcinoma, pod, squamous, tube, neck, site, cell, plastic, postoperative, metastatic, floor, surgery, surgical, bilateral, mouth, drain
7	Carotid Artery Narrowing and Medical Interventions	carotid, stenosis, artery, ica, stent, stenting, internal, Plavix, qd, pressure, aspirin, angiography, intact, cardiac, cad, chest, stroke, bruit, bilaterally, surgery
8	Hand and Finger-Related Issues	finger, hand, repair, ring, radial, injury, middle, capsule, plastic, forearm, wrist, distal, long, clinic, surgery, joint, postoperatively, saw, sensation, signs
9	Gastric and Obesity-Related Issues	gastric, diet, obesity, weight, bypass, surgery, medication, surgical, drainage, postoperative, advanced, apnea, severe, abdominal, sleep, incisions, leak, ten

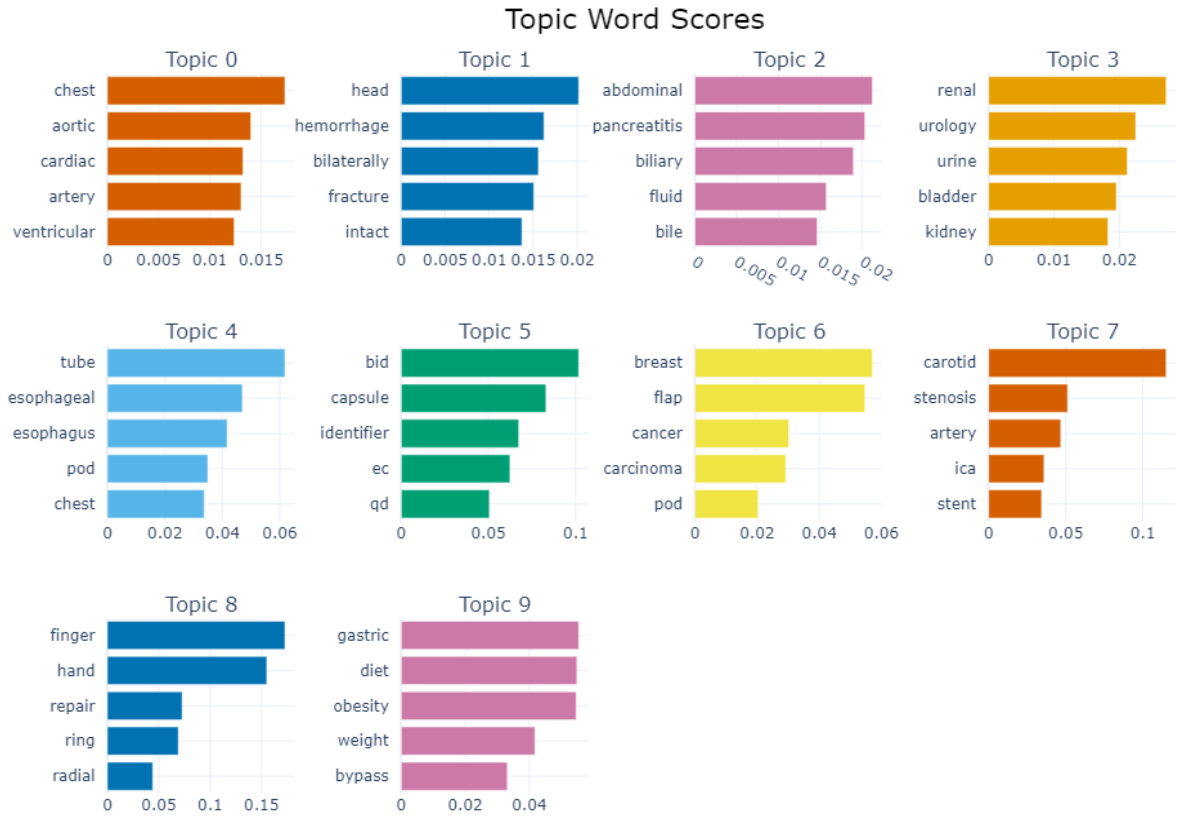

Fig. 2. Topic word scores across identified medical themes in ICU patient data.

Additionally, the topic-word distributions help demonstrate how certain clinical concepts frequently co-occur, suggesting possible interactions between patient comorbidities and acute ICU conditions. Such co-occurrence patterns play a crucial role in mortality prediction, as they offer a richer representation of patient complexity compared to isolated numerical features. The application of BERTopic successfully extracted ten key topics from ICU patient data, providing valuable insights into the diverse and complex clinical conditions observed in intensive care settings. Each identified topic was associated with a specific set of keywords, enabling the seamless integration of both structured and semi-structured data into predictive modeling. This approach underscored the efficacy of combining NLP with machine learning to enhance clinical decision-making and optimize patient care strategies.

Moreover, BERTopic's ability to represent patients through probabilistic topic distributions makes it particularly well-suited for capturing subtle variations in disease severity and clinical presentation. This probabilistic representation allows the model to quantify the degree to which a patient aligns with multiple clinical conditions simultaneously—a feature that is especially important in the ICU, where patients often present with multiple overlapping diagnoses. By transforming semi-structured textual data into meaningful topics and encoding them as probabilistic representations, this study effectively leveraged the full spectrum of information available within electronic health records (EHRs). This methodology demonstrated a significant advancement over traditional predictive models, which typically depend solely on structured numerical data, thereby emphasizing the potential of text-driven analytics in critical care research. Taken together, these findings highlight that narrative clinical documentation is not merely supplementary information but a valuable and often underutilized component of ICU data. Integrating NLP-derived insights into predictive modeling enables a more holistic understanding of patient status, supporting the development of more sensitive and context-aware risk prediction tools.

B. Prediction of the Mortality

To evaluate model performance, this study employed k-fold cross-validation, a widely adopted technique that partitions the dataset into k equal subsets and iteratively trains and validates the model across all folds. By averaging the results across multiple iterations, this method mitigates bias and enhances predictive reliability. However, despite its advantages in reducing overfitting and improving generalization, k-fold cross-validation is computationally demanding [49, 50]. In this study, a 10-fold cross-validation approach was implemented to develop mortality prediction models for 2 days, 3 days, 1 month, and 1 year post-ICU admission, utilizing structured and semi-structured data collected within the first 24 hours of patient admission.

This design allows the model to repeatedly learn from different subsets of patients, improving its ability to generalize across heterogeneous ICU populations where disease severity and documentation patterns vary widely. By incorporating both short-term and long-term mortality outcomes, the study provides a comprehensive assessment of how early clinical information contributes to risk stratification across different temporal horizons.

To build the predictive models, we combined features derived from both structured and unstructured data. The 16 selected quantitative variables, capturing physiological measurements and demographic information, formed the structured data component. For the unstructured data component, the BERTopic model generated 10 distinct topics from the clinical notes (as detailed in Table IV). Each patient's textual data was then represented by these topics, potentially using the probability distribution across the 10 topics or a categorical variable indicating the dominant topic. These topic-derived features were then concatenated with the 16 quantitative features to create a comprehensive feature vector for each patient. This combined feature set was used as input for the six machine learning classifiers described. This integration strategy enables the model to capture complementary sources of information: structured data reflect measurable physiological conditions, while textual data provide implicit clinical reasoning and contextual nuances recorded by healthcare providers. Notably, topic distributions generated by BERTopic often highlight symptom clusters, impressions of clinical instability, or early differential diagnoses, all of which offer predictive signals not present in numeric variables.

Crucially, to enable this comparative analysis evaluating the impact of text features, the patient cohort included in the modeling was necessarily limited to those individuals possessing available and processable clinical notes within the NOTEEVENTS dataset. Comorbidities are implicitly captured within both the quantitative variables (e.g., lab results reflecting organ function) and the clinical notes from which the topics were derived. This also implies that the inclusion of text-based features may reduce noise introduced by incomplete structured data, as clinical notes frequently summarize underlying chronic conditions that may not be fully captured in early laboratory measurements.

For model training and evaluation, the dataset was divided into 80% training data and 20% testing data to ensure robust performance assessment. A series of statistical analyses were conducted to examine the impact of integrating structured EHR data with textual features on ICU mortality prediction. The evaluation framework incorporated five key performance metrics: AUROC, accuracy, precision, recall, and F1-score, providing a comprehensive assessment of predictive capability and model robustness. Table V presents a summary of the model's predictive performance across different time intervals, demonstrating its effectiveness in capturing patient mortality risk over various post-admission periods. Using multiple performance metrics is essential because ICU mortality prediction involves imbalanced outcomes where AUROC alone may not fully reflect the model's clinical utility. Precision and recall help reflect how well the model identifies high-risk individuals while avoiding false alarms, which is crucial for ICU resource allocation. The consistent improvements across several metrics further indicate that textual features enhance not only discrimination but also the stability and reliability of the predictive models across different classifiers.

TABLE V. PERFORMANCE OF THE MODELS

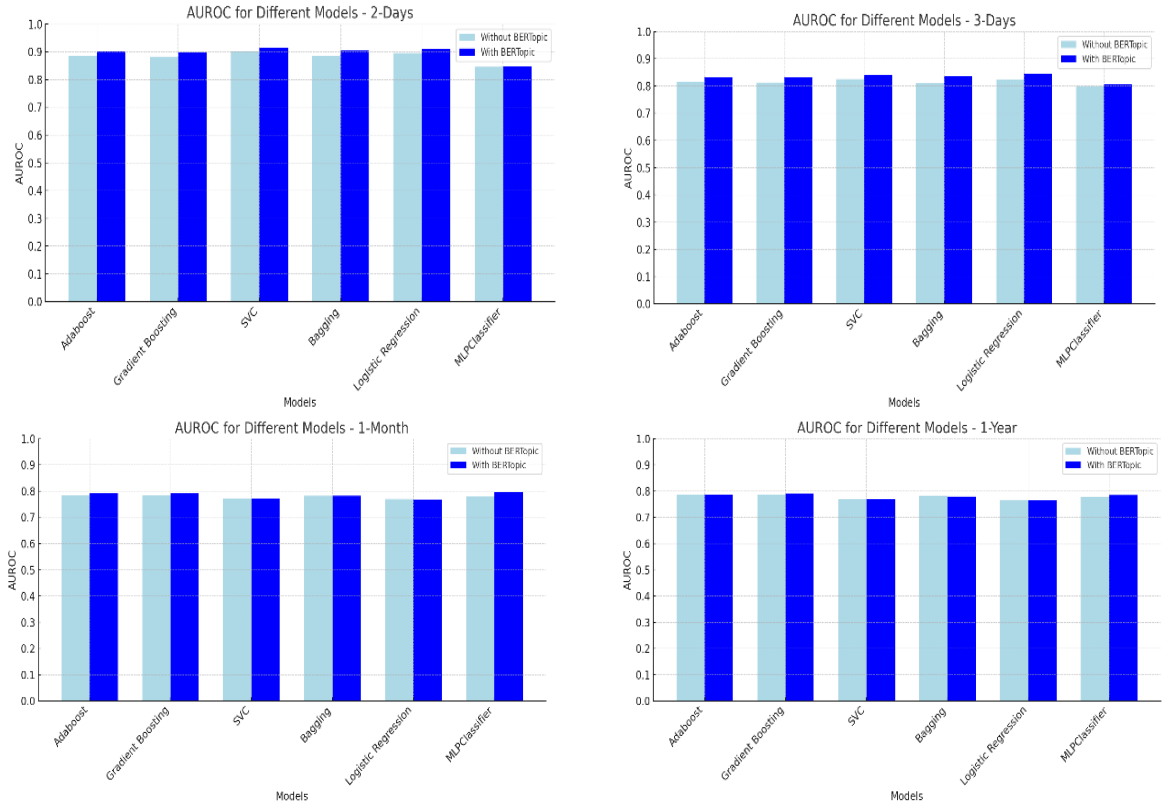

Fig. 3. Bar chart of machine learning model performance: With and without BERTopic data.

The study results demonstrate that AUROC is a vital metric for assessing a model's ability to differentiate between varying risk levels, particularly for identifying high-risk ICU patients who require timely intervention. Incorporating BERTopic data significantly improved the AUROC for all models in short-term predictions (2-day and 3-day). Notably, the AUROC of the SVC model increased from 0.8997 to 0.9137, highlighting the enhanced discriminatory power provided by BERTopic data for identifying high-risk patients. As depicted in Fig. 3, a comparison of machine learning model performance with and without BERTopic data underscores these improvements.

These findings suggest that early clinical notes capture subtle indicators of deterioration, such as mentions of respiratory distress, mental status fluctuation, or clinician concern that structured variables may not immediately reflect. The added predictive value in short-term outcomes highlights the importance of leveraging semi-structured data during the earliest stages of ICU care, when timely risk detection can meaningfully influence clinical decision-making and patient outcomes.

The overall AUROC for short-term predictions was higher than that for long-term predictions, suggesting that the models are more effective in distinguishing between high- and low-risk patients over shorter timeframes. However, for long-term predictions (1 month and 1 year), the impact of BERTopic data was less pronounced, with only minor improvements observed in model performance. For instance, the AUROC of the Gradient Boosting model increased slightly from 0.785 to 0.7935, indicating a modest enhancement. Fig. 4 illustrates AUROC curves under different experimental conditions, further corroborating these findings.

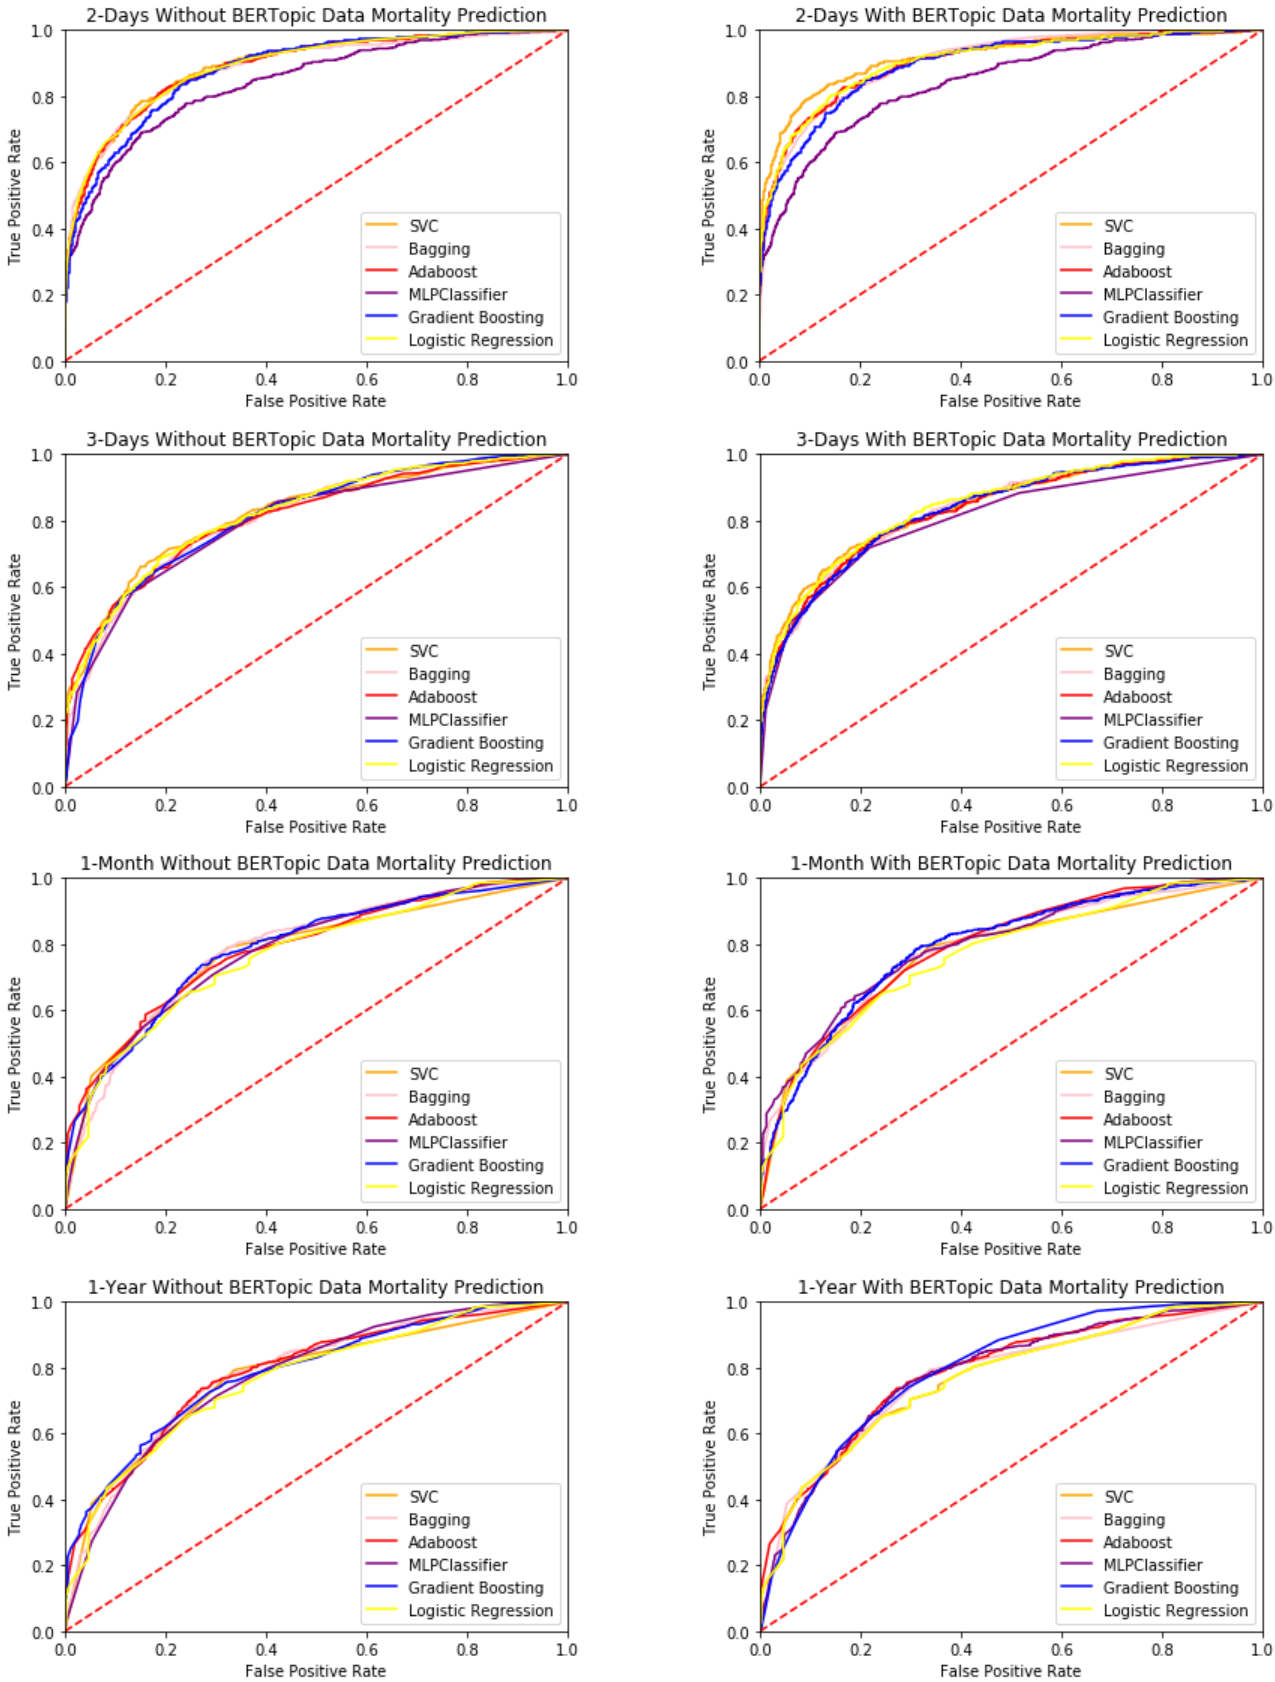

Fig. 4. AUROC curves for different experimental conditions.

These results emphasize the potential of integrating numerical and text-based data to significantly enhance short-term prediction accuracy, particularly for early risk assessment in ICU patients. This insight is invaluable for healthcare professionals in optimizing resource allocation and intervention strategies. However, the limited improvement in long-term predictions indicates challenges in differentiating risk levels over extended periods. Future research should focus on incorporating additional data sources or exploring novel techniques to enhance long-term prediction performance.

In this study, alongside AUROC, which measures the model's ability to discriminate between classes, we evaluated its practical applicability using four additional performance metrics: Accuracy, Recall, Precision, and F1-score. Collectively, these metrics deliver a comprehensive assessment of the models' predictive performance, encompassing both overall accuracy and their effectiveness in precisely identifying high-risk patients. As shown in Table VI, the incorporation of BERTopic data led to significant improvements in model performance, particularly in short-term predictions (2-day and 3-day). For example, the Accuracy of the Gradient Boosting model for 2-day predictions increased from 0.9339 to 0.9409, highlighting the positive impact of integrating text data. Across all models, Accuracy was generally higher for short-term predictions compared to long-term ones, reflecting the models' greater precision in shorter timeframes.

Based on the data in Table VI, the Recall metric highlights the models' ability to correctly identify actual positive cases, such as ICU patient mortality. In healthcare, particularly in critical care settings, Recall is crucial as it ensures the detection of all high-risk patients, allowing for timely interventions. The table shows that adding BERTopic data substantially increased Recall in short-term predictions. For example, the SVC model's Recall improved from 0.9058 to 0.9391 for 2-day predictions, while Bagging's Recall rose from 0.883 to 0.9196. However, the improvements were less pronounced for longer timeframes, with relatively stable performance for 1-month and 1-year predictions. This suggests that while BERTopic data significantly enhances short-term predictive performance, its impact on long-term predictions is more limited.

C. Analysis of Variable Importance

A key advantage of the Gradient Boosting (GB) method is its capability to assess the relative contribution of input variables in predictive modeling. This is achieved through the computation of variable importance scores, which rank features based on their influence on model performance. These scores indicate how significantly each variable impacts decision-making within the model, with higher importance assigned to variables frequently utilized in decision tree splits.

In Gradient Boosting, the importance of a variable is determined by evaluating the increase in the decision tree's value at a given split point, adjusted by the number of samples at that node. Several established metrics, including the Gini index, cross-entropy, and information gain, can be used to measure decision tree value changes. This study employed the Gini index to quantify variable significance, ensuring a consistent and interpretable ranking approach. For a comprehensive discussion on variable importance calculations in GB models, readers may refer to Hastie et al. [51]. Table VII presents the importance scores derived from the optimal Gradient Boosting model, which was trained using ICU patient data collected within the first 24 hours post-admission.

Table VII highlights the key variables selected for predicting both short-term and long-term mortality in ICU patients using the GB method. The analysis reveals that different variables contribute uniquely to mortality prediction across various timeframes (2 days, 3 days, 1 month, and 1 year). For short-term mortality (2 and 3 days), the Glasgow Coma Scale (X10) consistently emerges as the most significant variable, underscoring its critical role in assessing patient consciousness and predicting immediate outcomes in ICU settings. Other important indicators for short-term predictions include White Blood Cell Count (X6) and Heart Rate (X2), which are essential for evaluating acute physiological conditions, including infections and potential cardiac issues. In contrast, long-term mortality predictions (1 month and 1 year) are dominated by heart-related factors such as Heart Rate (X2) and Systolic Blood Pressure (X3), reflecting the sustained impact of cardiovascular health on patient outcomes over extended periods. Additionally, age (X1) and temperature (X4) gain prominence in long-term predictions, as chronic health conditions and the regulation of body temperature become increasingly relevant to survival.

The integration of topic modeling data (such as Topic 1 and Topic 0) into the variable importance rankings underscores the importance of textual clinical notes in enhancing model performance, particularly for predicting long-term mortality. These topics encompass critical health domains such as cardiovascular health (Topic 0), head trauma (Topic 1), and abdominal and pancreatic disorders (Topic 2). The emergence of these text-derived topics as important predictors, particularly demonstrating notable influence in long-term mortality predictions (as seen for Topic 0 and Topic 1 in Table VII), underscores their value in capturing complex patient narratives and underlying conditions that evolve beyond immediate physiological measurements. The GB method's variable importance analysis underscores the relevance of immediate physiological indicators like GCS and WBC in short-term predictions, while long-term mortality is influenced by a combination of age, cardiovascular health, and text-based clinical information. This analysis provides valuable insights into ICU patient care, allowing healthcare professionals to focus on the most critical variables for improving predictive accuracy across different time horizons.

TABLE VII. TEN VARIABLES IDENTIFIED FROM 24-HOUR DATASETS

IV. DISCUSSION

A. Principal Findings

This study illustrates the transformative potential of combining text mining techniques, such as BERTopic, with machine learning models to predict ICU patient outcomes. The key findings of the research are as follows.

1) Enhanced short-term predictions with BERTopic integration: Incorporating BERTopic data into machine learning models significantly improved short-term mortality predictions (2-day and 3-day). For example, the AUROC of the SVC model increased from 0.8997 to 0.9137, indicating an enhanced ability to discriminate between high- and low-risk patients. This enhancement stems from BERTopic's ability to capture rich contextual information embedded within clinical notes, such as clinician assessments of severity, nuanced descriptions of patient status, and evolving treatment plans, which often provide complementary insights beyond structured physiological data. This is particularly crucial for short-term outcomes where acute changes documented in free text are highly indicative of immediate risk.

2) Superior predictive performance in short-term predictions compared to long-term: Across all models, short-term predictions consistently outperformed long-term predictions (1-month and 1-year) in metrics such as AUROC, accuracy, recall, and F1-score. The reduced predictive accuracy over longer timeframes suggests that while models effectively identify immediate risks, long-term mortality predictions require additional variables or more refined methodologies to enhance performance [52].

3) Significance of physiological variables in predictive models: Analysis of variable importance using the Gradient Boosting method revealed that physiological variables, such as the Glasgow Coma Scale, White Blood Cell Count, Heart Rate, and Temperature, are essential predictors of both short-term and long-term ICU patient mortality [53]. The critical role of these variables underscores the necessity of closely monitoring vital signs in critical care environments.

4) Improved mortality prediction through text data integration: Incorporating topic modeling data derived from clinical notes, such as those related to cardiovascular health and head trauma, significantly enhanced mortality predictions [54].

This finding demonstrates the value of leveraging semi-structured and unstructured data through text mining. By converting free text into quantifiable topic features, our approach unlocked clinical insights related to complex patient conditions and care trajectories, often overlooked by traditional models relying solely on numerical data [55].

By integrating text mining and machine learning, this approach provides a deeper understanding of patient conditions, enhancing predictive accuracy and supporting more effective clinical decision-making. Leveraging both structured and unstructured data improves the ability to capture critical insights, facilitating personalized care and timely interventions in the complex environment of critical care settings. These improvements directly contribute to resilient healthcare by strengthening early risk recognition and enabling more adaptive and timely responses in critical care settings.

B. Limitations

Despite the encouraging findings, this study has several limitations that must be acknowledged. While the MIMIC-III database is comprehensive, it originates from a single healthcare system, which may limit the generalizability of the developed models. Recalibration may be necessary when applying these models to different ICU settings, where variations in patient populations, clinical practices, and treatment protocols can influence model performance in real-world applications [56]. Differences in patient demographics and resource availability further highlight the need for external validation. Furthermore, the exclusion criteria based on missing data percentages (>30% for patient records, >40% for predictors) might introduce selection bias. A formal analysis comparing the characteristics of the excluded patient population with the included cohort was not performed in this study and represents a limitation.

Moreover, direct numerical comparison of performance metrics (e.g., AUROC, Accuracy) with previously published studies, including those also utilizing MIMIC-III, is often challenging and potentially misleading. This difficulty arises from inherent variations in specific patient cohort selection criteria (especially regarding text availability), the precise feature sets utilized, differing text processing techniques (e.g., alternative NLP models or embeddings), distinct prediction target definitions, and varying evaluation protocols across research efforts. Additionally, although the incorporation of text data improved model accuracy, this study analyzed only a subset of the textual information available in the MIMIC-III database. Key clinical data, such as imaging reports, physician progress notes, and detailed medication histories, were not included in the analysis. Expanding the scope of semi-structured data could enhance the predictive accuracy of models, particularly for long-term mortality predictions.

While short-term mortality predictions showed substantial improvements, the performance gains for long-term predictions (1-month and 1-year) were comparatively modest. Long-term outcomes are inherently complex and likely require the inclusion of additional variables, such as clinical, social, and environmental factors, to enhance predictive accuracy [57, 58]. Furthermore, long-term trajectories are influenced by factors extending beyond the initial 24-hour ICU data and clinical notes, such as progression of chronic conditions, intercurrent events, post-discharge care, and socioeconomic factors not fully captured in MIMIC-III. The predictive signal from initial text data may also diminish over extended periods. These findings underscore the necessity of investigating additional long-term predictors to improve modeling in critical care contexts.

The integration of advanced text mining techniques, such as BERTopic, with machine learning models introduces significant computational challenges. Extracting topics from clinical notes and incorporating them into predictive models requires substantial processing power, which may hinder the real-time application of these methods in clinical settings. While cross-validation was employed to reduce the risk of overfitting, concerns remain about the models' ability to generalize to new patient populations, particularly due to the high dimensionality of text data. Future research should focus on enhancing generalizability by validating these models on larger and more diverse datasets (e.g., multi-center data like MIMIC-IV or eICU), as well as employing advanced regularization strategies or transfer learning techniques. Overcoming these challenges will be essential for developing predictive models that are both accurate and robust, enabling their effective deployment in critical care environments [59].

V. Conclusion

This study investigated the integration of advanced text mining techniques, specifically the BERTopic model, with machine learning algorithms to enhance the prediction of ICU patient outcomes. By leveraging semi-structured data from clinical notes alongside structured numerical data, the research demonstrated that combining these data types significantly improves the accuracy and robustness of predictive models, especially for short-term mortality prediction. These findings highlight several key conclusions:

The incorporation of BERTopic data significantly enhanced short-term mortality prediction, particularly for 2-day and 3-day outcomes. By integrating semi-structured clinical notes into machine learning models, the study achieved improved AUROC and accuracy scores, underscoring the critical role of text data in early ICU care. Often underutilized in predictive modeling, semi-structured data provided essential clinical context that improved the models' ability to identify high-risk patients, enabling more timely and effective interventions [60]. This contextual information, capturing clinical reasoning and nuances absent in structured data, served as a valuable complement to traditional predictors. Additionally, physiological variables such as the Glasgow Coma Scale, White Blood Cell Count, and Heart Rate were identified as crucial predictors for both short-term and long-term mortality. These findings emphasize the importance of continuous monitoring of these indicators to improve outcomes for ill patients. Although the predictive improvements for long-term mortality (1-month and 1-year) were relatively modest, the integration of text-based clinical insights through topic modeling provided valuable contributions to understanding patient conditions over extended periods. These findings highlight the potential of natural language processing techniques, such as BERTopic, to augment structured data and improve long-term predictive accuracy.

This study also underscores the broader applications of AI and big data in clinical decision-making and resource allocation, offering healthcare providers advanced tools to enhance patient outcomes and optimize ICU resource management [61]. By improving early risk recognition and supporting more adaptive clinical responses, these AI-driven predictive frameworks contribute directly to resilient healthcare in ICU environments. Looking ahead, future research should prioritize larger datasets, cross-institutional validation, and the incorporation of additional clinical variables and potentially longitudinal or richer textual sources (e.g., full progress notes and radiology reports) to further refine and generalize predictive models for ICU patient outcomes [62]. The integration of structured numerical data and semi-structured text, processed using advanced text mining techniques such as BERTopic, represents a promising avenue for improving ICU outcome prediction and strengthening data-driven clinical practice. As multimodal AI continues to evolve, its capacity to strengthen resilience in critical care systems through earlier detection, more precise triage, and timely intervention will become increasingly central to improving patient outcomes.

Improved Sparrow Search Algorithm-Based Recurrent Neural Network for Short-Term Generation Load Forecasting of Hydropower Stations

Liyuan Sun[1], Yilun Dong[2]*, Junwei Yang[3]
Measurement Center, Yunnan Power Grid Co., Ltd., Kunming, China[1]
Faculty of Transportation Engineering, Kunming University of Science & Technology, Kunming, China[2]
LongShine Technology Group Co., Ltd., Wuxi, China[2, 3]

***Abstract*—To address the challenges of low accuracy and high randomness in short-term hydroelectric load forecasting within Multi-energy Coupled Virtual Power Plants (MC-VPPs), this study proposes a hybrid model integrating Variational Mode Decomposition (VMD), Long Short-Term Memory (LSTM) networks, and an Improved Sparrow Search Algorithm (ISSA). Traditional methods, such as exponential smoothing and multiple linear regression, often fail to capture nonlinear dynamics and external disturbances. The proposed framework first decomposes raw load data into four intrinsic mode functions (IMFs) via VMD to extract multi-scale features, including long-term trends, seasonal cycles, and short-term fluctuations. LSTM networks are then applied to model the temporal dependencies of each IMF. To enhance optimization, ISSA introduces a bidirectional sine-cosine search strategy, balancing global exploration and local exploitation to avoid premature convergence. Validated on 1,247 daily load records from a hydropower station in southwestern China, the ISSA-VMD-LSTM model achieves a 30.2% improvement in R^2, with reductions of 47.2% in RMSE, 47.8% in MAE, and 63.3% in MAPE, outperforming benchmarks like PSO-LSTM and SSA-VMD-LSTM. This demonstrates its robustness in handling nonlinearity and stochasticity. The model enhances MC-VPPs' operational efficiency by enabling intelligent scheduling and renewable energy integration, with future applications extending to real-time forecasting and other renewable energy systems.**

Keywords*—Power plant; load forecasting; Mode Decomposition; Long Short-Term Memory; Sparrow Search Algorithm

I. Introduction

The Multi-energy Coupled Virtual Power Plant [1]-[4] plays an essential role in optimizing short-term load forecasting for hydroelectric power. It exemplifies the deepening integration of Energy Internet technology. By incorporating Long Short-Term Memory networks, MC-VPP significantly improves the accuracy of predicting power output from hydropower stations and load demand. This algorithmic ensemble not only captures the time-series characteristics of electricity loads but also effectively addresses the nonlinear impacts of hydro-meteorological factors, providing more accurate and reliable forecast results. As a core component of intelligent scheduling and optimized operation within MC-VPPs, short-term load forecasting for hydroelectric power offers robust technical support to mitigate the intermittency and uncertainty associated with renewable energy. It enhances the flexibility and efficiency of power systems and introduces new methods for managing distributed energy resources with complex and diverse characteristics. This is significant for promoting the widespread adoption of clean energy and fostering the healthy development of power markets.

Current research on short-term load forecasting for hydroelectric power has widely applied methods such as Exponential Smoothing, Combined Forecasting, and Grey Prediction [5]-[8]. However, these approaches are data-dependent and constrained by underlying assumptions. As the aggregated resources within MC-VPPs expand, short-term hydroelectric load trends become increasingly complex. Techniques based on Multiple Linear Regression Models [9]-[12] have gained prominence due to their computational efficiency and clear representation of relationships between independent and dependent variables. Nevertheless, these models assume a linear relationship between variables and are sensitive to outliers, making it challenging to directly address the dynamic characteristics [13] of time series and the influence of external events. When using multiple linear regression for load forecasting, it is necessary to combine other techniques to overcome these limitations. Exponential Smoothing assigns different weights to historical data, allowing predictions to quickly adapt to recent changes. This method is suitable for relatively stable load patterns but struggles with capturing long-term dependencies and complex nonlinear patterns, leading to a significant decrease in prediction accuracy during extreme weather conditions. In contrast, Combined Forecasting integrates several prediction models to leverage each one's strengths, improving the accuracy and robustness of forecasts. This method addresses the complexity and nonlinearity of hydroelectric load data [14-17], but its construction is complex, requiring the establishment of sub-models and the determination of weights, which increases computational costs and model tuning challenges.

The models used for optimizing short-term load forecasting in hydroelectric power all face issues like strict applicability conditions or an inability to handle complex nonlinear relationships, limiting their responsiveness to real-world forecasting scenarios. In [18], the authors addressed the low prediction accuracy and poor stability of LSTM neural networks by proposing a short-term power load forecasting

*Corresponding author.

model optimized using a multi-strategy improved Golden Jackal Algorithm [19]-[20]. This approach effectively enhances the training efficiency and performance of LSTM [21]-[24] models, avoiding overfitting risks and achieving higher prediction accuracy and stability compared to traditional LSTM models.

In summary, existing studies on short-term load forecasting for hydroelectric power have been impacted by limited usage conditions and the inability to resolve complex relationships, affecting prediction accuracy. To enhance this, we propose a hybrid forecasting method based on Variational Mode Decomposition, an improved Sparrow Search Algorithm [25]-[27], and Long Short-Term Memory networks. The proposed method begins by adaptively decomposing the original load data into multiple intrinsic mode functions using Variational Mode Decomposition. This process isolates distinct temporal features such as long-term trends, seasonal cycles, and short-term fluctuations, effectively mitigating mode mixing and enhancing adaptability to nonlinear time-series data. Next, each IMF is modeled using Long Short-Term Memory networks, which leverage their gated mechanisms to capture complex temporal dependencies and address the vanishing gradient problem inherent in traditional recurrent neural networks. To optimize model performance, an Improved Sparrow Search Algorithm is employed to fine-tune LSTM hyperparameters. This enhanced algorithm incorporates a bidirectional sine-cosine search strategy to balance global exploration and local exploitation, thereby avoiding premature convergence. The decomposition capability of VMD enables LSTM to focus on features at specific time scales, while ISSA further refines parameter adaptability. Together, these components form a cohesive framework of "decomposition-modeling-optimization", significantly enhancing prediction accuracy and stability. This approach effectively addresses the challenges of modeling nonlinearity, stochasticity, and multi-scale characteristics in multi-energy coupled environments.

The key contributions of this study are as follows:

- Combines Variational Mode Decomposition, Long Short-Term Memory networks, and an Improved Sparrow Search Algorithm, significantly enhancing the accuracy and stability of short-term hydroelectric load forecasting.
- Introduces a bidirectional sine-cosine search strategy and a Good Lattice Points-based initialization strategy to strengthen global exploration, avoid premature convergence, and optimize LSTM hyperparameters.
- Decomposes raw load data into intrinsic mode functions to isolate long-term trends, seasonal cycles, and short-term fluctuations, improving the model's adaptability to complex nonlinear time-series data.
- Validated using real hydropower station data, the model achieves improvements of 30.2% in R^2, 47.2% in RMSE, 47.8% in MAE, and 63.3% in MAPE, outperforming benchmarks such as PSO-LSTM [28]-[29] and SSA-VMD-LSTM [30].
- Supports intelligent scheduling and multi-energy coordination in MC-VPPs, enhancing flexibility for renewable energy integration and grid efficiency.

II. Hydroelectric Time Series Prediction Model

A. Working Principle of the Variational Mode Decomposition Algorithm

To deeply investigate short-term load forecasting for hydroelectric power in a multi-energy coupled virtual power plant environment, it is essential to employ the Variational Mode Decomposition algorithm to decompose the raw data into multiple intrinsic mode functions with distinct central frequencies and limited bandwidths, thereby achieving modal separation of the data. The core principle of VMD lies in its adaptive signal decomposition framework that concurrently optimizes multiple intrinsic mode functions through a variational approach, effectively balancing modal bandwidth constraints and reconstruction accuracy. By constructing a constrained variational problem, VMD iteratively extracts compact IMFs with specific sparsity properties in the frequency domain, where each mode is designed to concentrate around a central frequency while maintaining minimal bandwidth. This process continuously updates the mode and center frequency until convergence, ensuring that the decomposed components exhibit orthogonality in both the time and frequency domains. The resulting IMFs demonstrate distinct spectral separation characteristics, enabling the isolation of underlying patterns such as seasonal variations, random fluctuations, and operational trends from the original hydropower load data. This decomposition mechanism significantly enhances subsequent forecasting models by mitigating mode mixing issues inherent in traditional signal processing methods, while preserving critical temporal

$$\min_{\{u_k\},\{w_k\}} \left\{ \sum_k^K \left\| \partial_t \left[\left(\delta(t) + \frac{j}{\pi t} \right) * u_k(t) \right] e^{-jw_k t} \right\|_2^2 \right\} \quad (1)$$

dependencies essential for accurate predictions in virtual power plant environments characterized by strong multi-energy coupling effects.

The variational problem model of this method is subject to the following constraints:

$$s.t. \sum_k^K u_k(t) = x(t) \quad (2)$$

In the formula, $u_k = \{u_1, u_2, \cdots, u_k\}$ represents the intrinsic mode function, $w_k = \{w_1, w_2, \cdots, w_k\}$ represents the central frequency; $\delta(t)$ is the Dirac delta function, which is used in the computation of the Hilbert transform; K determining the number of decomposed IMF components; ∂_t addressing gradient dizziness; $\left(\delta(t) + \frac{j}{\pi t} \right) * u_k(t)$ performing the Hilbert transform.

Redefine the Intrinsic Mode Function with a stricter finite bandwidth constraint (BIMF)

Defined as:

$$u_k(t) = A_k(t)\cos(\phi_k(t)) \quad (3)$$

The phase function $\phi_k(t)$ is non-monotonically decreasing, which means $\phi_k'(t) \geq 0$, and the amplitude $A_k(t) \geq 0$, with the instantaneous amplitude $A_k(t)$ and the instantaneous frequency $\omega_t(t) = \phi_k'(t) = \frac{d\phi_k(t)}{d_t}$ varying slowly relative to $\phi_k(t)$, within the interval $[t-\tau, t+\tau]$, where $\tau = \frac{2\pi}{\phi_k'(t)}, u_k(t)$ can be considered as a harmonic signal with an amplitude of $A_k(t)$ and a frequency of $\omega_t(t)$.

The expression for the Hilbert transform is the result of convolving the original signal with a specific kernel. After applying the Hilbert transform to the signal, the positive frequency components are multiplied by -j, which means that under the condition of maintaining the same amplitude, the phase is shifted by $-\frac{\pi}{2}$. For the negative frequency components, the phase is shifted by $\frac{\pi}{2}$.

Through spectral analysis, we validate the frequency separation characteristics of individual Intrinsic Mode Functions. Quantitative evaluation using statistical measures like sample entropy reveals distinct complexity patterns - lower entropy values indicate stable trend components while higher entropy corresponds to stochastic fluctuations. Temporal correlation analysis between IMFs and established physical mechanisms/external drivers enables identification of specific modal functions demonstrating significant associations with extreme weather events. The orthogonal validation further confirms the temporal-frequency independence among decomposed components, effectively preventing mode mixing. This rigorous decomposition process ensures both mathematical validity and physical interpretability, providing reliable inputs for subsequent LSTM modeling.

B. LSTM Model

LSTM is a variant of the Recurrent Neural Network (RNN) commonly used for handling tasks related to time series data. When training a typical neural network model, the computation is usually represented as $s = f(W^T X + b)$, where W represents the weights, X is the input, and b is the bias term. A common LSTM structure is shown in Fig. 1.

x_t represents the input data at each time step, h_t is the output at each time step, and the intermediate c_t is the long-term memory between cells.

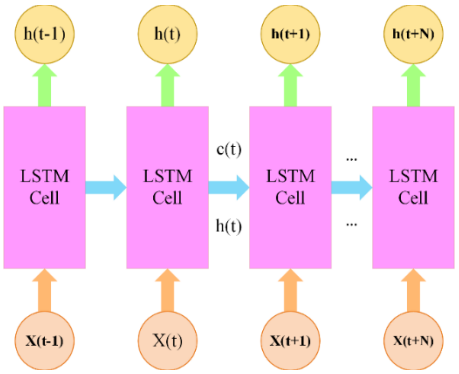

Fig. 1. LSTM structure diagram.

An LSTM includes a forget gate, an input gate, and an output gate. Each gate requires a computation similar to the one mentioned above, in addition to calculating the current state. Compared to the structure of an RNN, an LSTM cell is more complex, incorporating fully connected layers with activation functions in its gate structures. These gates output values between 0 and 1, indicating the degree to which feature information should be retained (0 means retain, 1 means discard). This gated structure enables LSTMs to maintain a stable gradient flow across extended time horizons while adaptively managing sequential information retention and suppression. The output of the forget gate is defined as f_t, the output of the input gate as i_t, the candidate value for memory update as $\bar{c}_t$, and the output of the output gate as o_t.

The forget gate f_t selects information from the previous cell state c_{t-1}:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (4)$$

The input gate determines how much of the current network input x_t is to be saved in the cell state c_t:

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (5)$$

Input c_t:

$$\bar{c}_t = \tan h(W_c \cdot [h_{t-1}, x_t] + b_c) \quad (6)$$

The output gate controls how much of the cell state is output to the current LSTM output value h_t:

$$O_t = \sigma(W_0 \cdot [h_{t-1}, x_t] + b_0) \quad (7)$$

W_f, W_i, W_c, W_0 are weight matrices, and b_f, b_i, b_c, b_0 are bias terms. $[h_{t-1}, x_t]$ denotes the concatenation of the hidden

state h_{t-1} and the input state x_t along the horizontal axis. σ represents the sigmoid function, and tanh represents the hyperbolic tangent function.

The LSTM model updates its weights using the backpropagation algorithm to minimize prediction error. The backpropagation process for LSTM mainly includes the following steps:

1) Definition of the loss function: Define a loss function based on the task type (e.g., classification or regression). Common loss functions include cross-entropy for classification tasks and mean squared error for regression tasks. This function measures the prediction error of the model.

2) Backpropagation to compute gradients: Use the Backpropagation Through Time (BPTT) algorithm to propagate the error gradient backward from the last time step to the first. Each gate (forget gate, input gate, output gate) in the LSTM network participates in the error propagation, gradually computing the gradient for each parameter. BPTT is suitable for sequential data, and due to the gating structure of LSTM, the vanishing gradient problem is alleviated to some extent.

3) Gradient clipping: Due to the potential for gradient explosion in long sequences, gradient clipping techniques limit the size of the gradients, ensuring they do not exceed a certain threshold. This prevents overly large gradients from causing unstable training.

4) Weight update: LSTM uses gradient descent to update the weight matrices, optimizing the model parameters to reduce the value of the loss function.

In practical applications, an LSTM learn effective patterns in sequence data through backpropagation and gradient updates. This training process enables LSTM to achieve good performance on various sequence prediction tasks, particularly excelling in handling long-term dependencies. By decoupling memory retention from hidden state updates, LSTMs achieve superior performance in learning complex temporal dynamics compared to conventional RNNs, particularly when handling intermittently sampled or irregularly spaced time series data common in multi-energy virtual power plant environments.

C. Sparrow Search Algorithm

The Improved Sparrow Search Algorithm introduces two main upgrades to the traditional SSA. First, it adopts a Good Lattice Points strategy for population initialization, replacing random placement to ensure sparrow positions are evenly distributed across the search space. This adjustment accelerates convergence and reduces the likelihood of solutions becoming trapped in local optima due to uneven initialization. Second, ISSA incorporates a Bidirectional Sine-Cosine Search Strategy to update discoverer positions. By alternating between forward and reverse search phases, the algorithm maintains a balance between broad exploration and refined exploitation. The forward phase steers individuals toward current optimal solutions, while the reverse phase drives exploration into uncharted regions, effectively curbing premature convergence. Together, these enhancements strengthen the algorithm's ability to tackle complex nonlinear challenges in load forecasting, delivering higher optimization accuracy and adaptability.

The Traditional Sparrow Search Algorithm initializes the sparrow population using a random distribution method, which results in randomness in the population distribution and can easily lead to SSA getting trapped in local optima. To address this issue, this study introduces an initialization strategy based on good lattice points for optimizing the initial positions of the sparrows, thereby improving the convergence accuracy and speed of the algorithm. The principle behind this approach is as follows: In the D-dimensional Euclidean space G_D , where $r \in G_D$, the good lattice point set $P_n(k) = \left(\left\{r_1^{(n)} \cdot k\right\}, \left\{r_2^{(n)} \cdot k\right\}, \ldots, \left\{r_D^{(n)} \cdot k\right\}\right)$ for $1 \le k \le n$,the discrepancy is $\varphi(n) = C(r,\varepsilon) n^{-1+\varepsilon}$, where $C(r,\varepsilon)$ is a constant related to r and ε , $P_n(k)$ represents the set of good lattice points. Additionally, in this study, $r = 2cos\left(\frac{2k\pi}{p}\right), 1 \le k \le n$, where p is the smallest prime number satisfying $\frac{(p-3)}{2} \ge D$ .Therefore, the initialization strategy based on good lattice points can be expressed as follows:

$$x_i(k) = \left(up_j - lp_j\right) \cdot \{P_n(k)\} + lp_j \tag{7}$$

The SSA is prone to premature convergence during the position update process, which can result in solutions getting trapped in local optima rather than finding the global optimum. To address this issue, a bidirectional sine cosine search strategy has been introduced. This strategy enhances exploration by defining both forward and reverse searches, thereby expanding the local search methods. In the forward search, the current individual is guided toward the current optimal individual, emphasizing the swarm's ability to autonomously approach the global optimum as iterations progress. Conversely, the reverse search encourages the swarm to explore regions beyond the current optimal area, demonstrating a stronger selectivity for uncharted territories. The initialization strategy based on Good Lattice Points ensures that the initial population is uniformly distributed in the high-dimensional search space, mitigating the risk of region omission caused by random initialization. This global coverage characteristic, combined with dynamic search direction adjustments, significantly reduces the algorithm's sensitivity to local optima and enhances global optimization efficiency in complex nonlinear problems. The enhanced position update formula for the discoverer is defined as follows:

$$x_{i,j}^{t+1} = \begin{cases} x_{i,j}^t \cdot \left|\sin r_1\right| + r_2 \cdot \sin r_1 \cdot \left|x_1 \cdot x_{best}^t - x_2 \cdot x_{i,j}^t\right| \\ \qquad , R_2 < ST, R_1 \ge 0.5 \\ x_{i,j}^t \cdot \left|\cos r_3\right| - r_4 \cdot \cos r_1 \cdot \left|x_1 \cdot x_{best}^t - x_2 \cdot x_{i,j}^t\right| \\ \qquad , R_2 \ge ST, R_1 \ge 0.5 \\ x_{i,j}^t + Q \cdot L, \ldots R_2 \ge ST \end{cases} \tag{9}$$

In this algorithm, $x_{i,j}^{t}$ represents the position of the current generation sparrow, x_{best}^{t} while denotes the position of the best sparrow found so far at iteration t. $R_1, R_2 \in [0,1]$, where R_2 is the vigilance factor, and $ST \in [0.5,1]$ is the safety threshold. Q is a random number following a normal distribution, and L is a unit vector with $r_1, r_3 \in [0,2\pi]$ and $r_2, r_4 \in [0,\pi]$, which are used to determine the movement distance and search direction for the next generation of sparrows. The expressions $x_1 = -\pi + 2\pi(1-\tau)$ and $x_2 = -\pi + 2\pi$ define specific positions, where τ is the golden ratio coefficient. The optimization of the safety threshold (ST) and vigilance factor is grounded in multi-objective trade-offs and sensitivity analysis. The ST is determined through statistical analysis of historical experimental data, with its value balancing population convergence speed and escape capability: an excessively high ST would suppress the exploratory nature of reverse search, while an overly low ST may induce ineffective perturbations. The vigilance factor is configured based on problem dimensionality and solution space characteristics. Its dynamic range is adjusted through grid search and cross-validation to prioritize global exploration during early iterations and progressively strengthen local exploitation in later stages. The parameter optimization process integrates convergence validation and error sensitivity testing, ultimately yielding a parameter combination that ensures stable generalization capability across both training and validation sets.

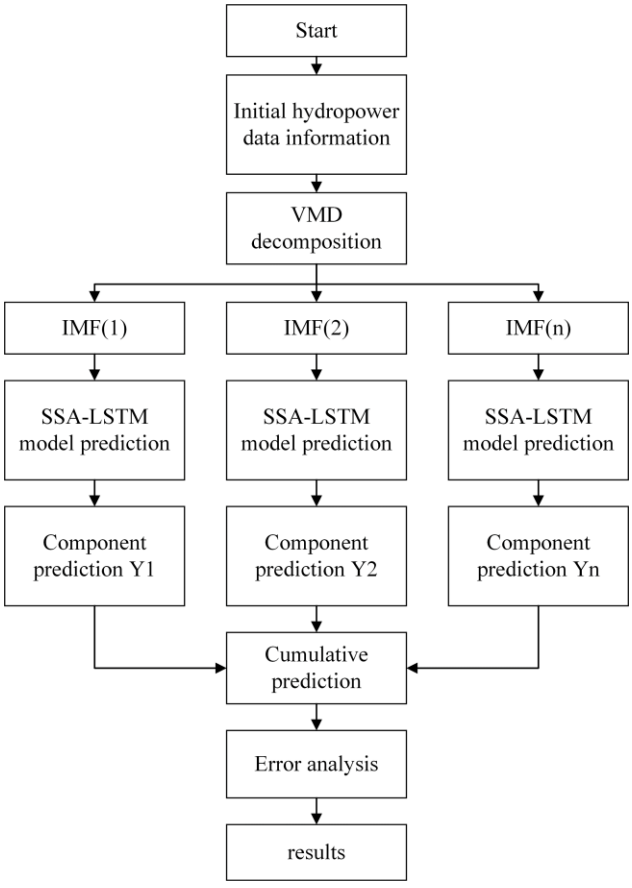

Fig. 2. Prediction process of the ISSA-VMD-LSTM model.

D. Short-Term Load Forecasting Framework for Hydropower

The forecasting framework proposed in this study aims to utilize historical hydropower data, achieving the goal of short-term load forecasting by conducting a comprehensive analysis of the correlations within these data. Fig. 2 illustrates the overall implementation flowchart of the hybrid forecasting model in load forecasting.

III. Case Study Analysis

A. Case Study Setup

The experiment was conducted on NVIDIA GeForce RTX 4060 Laptop GPU and implemented with Python 3.8. Data spanning from January 1, 2021, to May 1, 2024, was selected for analysis, with a sampling interval of one day. After integrating and screening the data, a comprehensive dataset consisting of 1,247 data points was obtained. To address noise and outliers in raw data, a sliding window technique integrated with the 3 principles is implemented for anomaly identification. Data points deviating beyond the mean ±3 standard deviations range are rectified using linear interpolation.

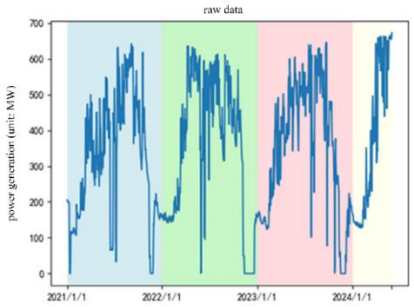

Fig. 3. Original hydropower load data.

Furthermore, consecutive data gaps resulting from equipment failures are systematically removed to ensure data integrity. Of these, 80% were allocated to the training set, while the remaining 20% were reserved for the test set to validate the final prediction outcomes of each model. In the VMD process, it is crucial to balance the number of decomposed modes to avoid excessive computational burden and time costs without compromising the signal's characteristic representation. Therefore, the number of modes, the K value, was set to 4. Additionally, the penalty factor α was configured to 2000, the frequency distribution initialization was set to 1, and the convergence tolerance was established at 1e-7. Fig. 3 illustrates the plot of the original data.

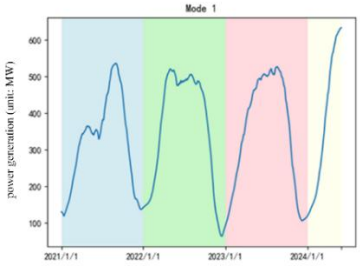

Fig. 4. Component of hydropower load decomposition of mode 1.

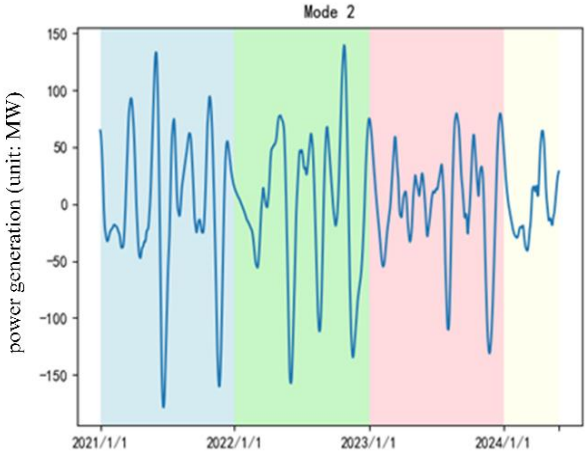

Fig. 5. Component of hydropower load decomposition of mode 2.

Fig. 4 represents the primary waveform trend, which shows an initial increase followed by a decrease in the hydropower load from 2021 to 2023. For the period from January to May 2024, the trend exhibits a growing pattern. Fig. 5 displays a more regular periodic variation, better reflecting the changes on a monthly and quarterly basis. The fluctuations in Fig. 6 are more intense, primarily capturing short-term variations. This mode reflects short-term demand changes or the impact of random events. The fluctuations in Fig. 7 are the most intense, capturing instantaneous changes.

B. Case Study Metrics Description

To comprehensively evaluate the performance of the proposed forecasting model, we utilize a combination of four metrics: Root Mean Square Error (RMSE), Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), and the Coefficient of Determination (R^2). RMSE calculates the square root of the average of the squared differences between the predicted and actual values, which makes it sensitive to larger errors and provides a measure of error magnitude. MAE measures the average of the absolute differences between predictions and actual observations, offering a robust estimate of overall error without heavily penalizing large discrepancies. MAPE expresses the average of the absolute percentage errors, making it suitable for comparing datasets of different scales, although caution is needed due to its instability when actual values are close to zero. Finally, R^2 reflects the proportion of the variance in the dependent variable that is predictable from the independent variables, indicating how well the model fits the data compared to a simple mean prediction. These metrics together provide a thorough assessment of the model's accuracy and reliability.

In the formulas, y_g denotes the actual value of the g-th observation, $\hat{y}_g$ denotes the predicted value of the g-th observation, and G represents the total number of observations.

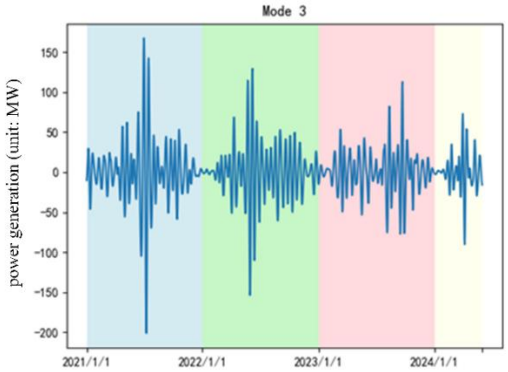

Fig. 6. Component of hydropower load decomposition of mode 3.

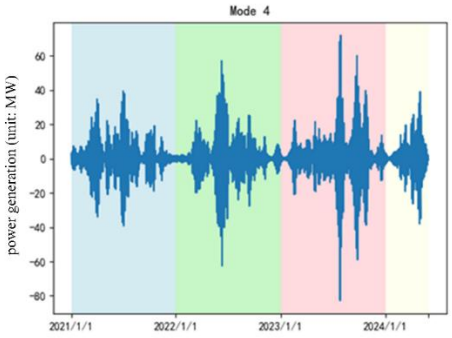

Fig. 7. Component of hydropower load decomposition of mode 4.

C. Result Analysis

Analysis of the data in Table I shows that the ISSA-VMD-LSTM algorithm outperforms all other algorithms across all evaluation metrics, achieving the highest R^2 and the lowest RMSE, MAE, and MAPE. This indicates that the ISSA-VMD-LSTM algorithm, as mentioned in this study, exhibits superior prediction performance with greater accuracy and stability compared to other algorithms.

TABLE I. PERFORMANCE COMPARISON OF DIFFERENT ALGORITHMS

Algorithm	R2	RMSE	MAE	MAPE	Time Complexity
LSTM	0.652	0.235	0.201	0.049	O(T*N2)
PSO-LSTM	0.752	0.215	0.183	0.042	O(P*I*T*N2)
PSO-VMD-LSTM	0.851	0.176	0.133	0.031	O(K*N2+P*I*T*N2)
SSA-VMD-LSTM	0.802	0.183	0.142	0.035	O(K*N2+S*I*T*N2)
ISSA-VMD-LSTM	0.934	0.124	0.105	0.018	O(K*N2+S*I*T*N2+C)

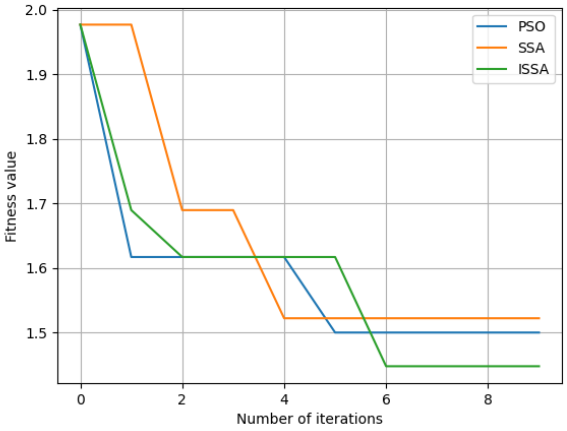

Fig. 8. Fitness curve of algorithms.

Table II lists the optimal parameters for each mode.

TABLE II. OPTIMAL PARAMETERS FOR MODES

Number of Modes	epochs	batch size	LSTM 1 of layer neurons	LSTM 2 layer of neurons	Dense Layer of neurons	learning rate	Number of Modes
IMF1	47	22	54	53	43	0.0021	IMF1
IMF2	20	12	46	67	87	0.0060	IMF2
IMF3	46	43	65	84	47	0.0050	IMF3
IMF4	14	56	77	63	79	0.0055	IMF4

Comparing the individual algorithms, as shown in Fig. 8, it can be observed that the ISSA achieves the lowest final fitness value, indicating its superior optimization performance. In contrast, PSO has a relatively higher final fitness value, while SSA exhibits the highest final fitness value. Additionally, we note that ISSA converges at the fastest rate. Although PSO and SSA also exhibit rapid convergence in the early stages, their final fitness values are higher, suggesting that their optimization effectiveness is not as good as that of ISSA. The optimization process involves tuning a total of 24 parameters across four modes, including the number of iterations, batch size, the number of output neurons in the first LSTM layer, the number of output neurons in the second LSTM layer, the number of neurons in the fully connected layer, and the learning rate. The parameter optimization iteration process is illustrated in Fig. 9.

To address potential instability in MAPE metrics when actual load values approach zero - a scenario that may cause abnormal error amplification and distort model performance evaluation - we implemented a threshold adjustment strategy. Specifically, observations with actual values below 1% of the dataset's average load are excluded from MAPE calculation. This approach maintains the metric's interpretability while eliminating outlier distortion caused by near-zero measurements. For enhanced robustness, we complement the evaluation with SMAPE (Symmetric Mean Absolute Percentage Error), which constrains results within a 0%-200% range through symmetrical error calculation, effectively mitigating sensitivity to low-value measurements. Cross-validation confirmed consistent results from both metrics, ensuring reliable model performance assessment.

The ISSA-VMD-LSTM model demonstrated strong predictive performance with a validated R^2 value of 0.934. To assess estimation stability, we conducted 1,000 bootstrap iterations, yielding a narrow 95% confidence interval of [0.921, 0.943] for the R^2 metric. Furthermore, 5-fold cross-validation was implemented to evaluate model generalization, producing a mean R^2 of 0.927 ±0.006 - statistically consistent with the test set performance. These rigorous validation procedures confirm both the model's predictive accuracy and its robustness against overfitting risks.

The ISSA-VMD-LSTM algorithm proposed in this study demonstrates significant improvements over the traditional LSTM algorithm, with an increase of 30.2% inR^2, a reduction of 47.2% in RMSE, a decrease of 47.8% in MAE, and a lowering of 63.3% in MAPE. In terms of optimization strategies, the ISSA introduces a bidirectional search mechanism and initialization improvements. Compared with traditional optimization algorithms like PSO and SSA, the proposed algorithm demonstrates enhanced balancing capability between global exploration and local exploitation, effectively avoiding local optima traps while accelerating convergence. When compared with Transformer models, our method exhibits superior performance in large-scale data scenarios and achieves high-precision prediction in small-scale data through decomposition and optimization strategies, making it more applicable to data-constrained environments. In contrast to lightweight GRU models, this approach reduces hyperparameter sensitivity through signal decomposition mechanisms and demonstrates stronger prediction stability in multi-energy coupled environments. The algorithm presented in this study substantially enhances all evaluation metrics, markedly improving model fit while further reducing errors and increasing prediction accuracy.

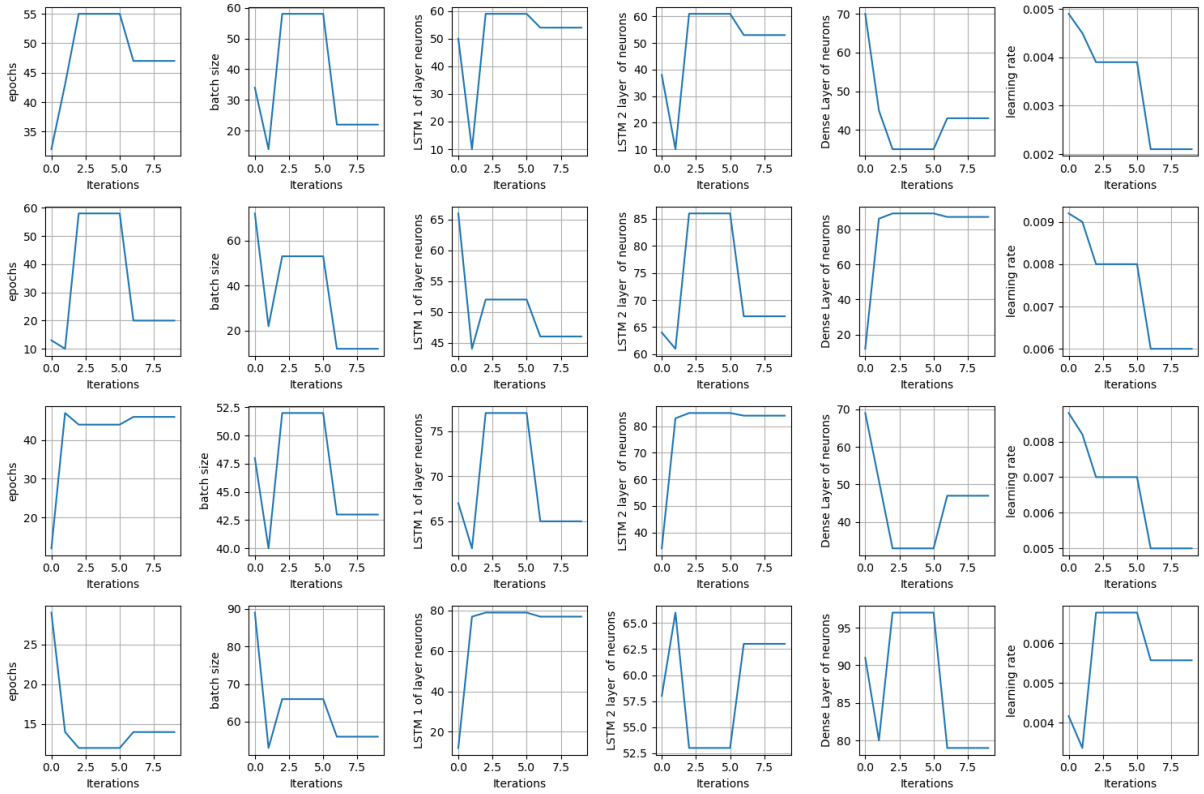

Fig. 9. Parameter optimization iteration process.

IV. Conclusion

This study introduces a short-term hydropower load forecasting method based on the ISSA-VMD-LSTM model. Given that hydropower load data typically exhibit complex nonlinear characteristics, VMD is employed to decompose the raw data into multiple intrinsic mode functions, effectively extracting features such as long-term trends and seasonal variations. This decomposition enhances the model's adaptability to intricate time-series data. To optimize the LSTM hyperparameters, an improved version of the Sparrow Search Algorithm is utilized, which incorporates a bidirectional cosine search strategy that combines forward and reverse searches. This approach expands the local search range, effectively preventing the traditional SSA from getting trapped in local optima, thereby significantly enhancing the optimization of LSTM hyperparameters. For the modal components obtained from VMD decomposition, the ISSA-optimized LSTM model further refines prediction accuracy. Experimental results demonstrate that the ISSA-VMD-LSTM model surpasses traditional LSTM models and other hybrid models across all evaluation metrics, showcasing superior forecasting performance.

While the proposed ISSA-VMD-LSTM model demonstrates significant advantages in short-term hydroelectric load forecasting, its practical application still faces limitations. First, the computational complexity of the VMD decomposition and ISSA optimization processes remains high, particularly in multi-modal data scenarios, which may prolong training and inference times, potentially hindering real-time requirements. Second, the model's sensitivity to hyperparameters necessitates reliance on empirical expertise or iterative parameter tuning, increasing deployment costs. Future improvements could focus on simplifying the algorithm and enhancing efficiency. For instance, adopting parallel computing or streamlined decomposition strategies to reduce computational overhead. Exploring adaptive parameter optimization mechanisms or integrating edge computing frameworks could improve real-time processing capabilities. Incorporating incremental learning or transfer learning techniques may further enhance the model's adaptability to dynamic multi-energy coupled environments, strengthening its generalization and practical utility.

Looking ahead, Multi-Energy Coupled Virtual Power Plants are expected to play a crucial role in short-term hydropower load forecasting. MC-VPPs represent the deep integration of Energy Internet technology, combining various energy resources through intelligent optimization and scheduling. They provide more accurate and reliable forecasting outcomes, enhancing the flexibility and efficiency of power systems. Moreover, MC-VPPs effectively address the intermittency and uncertainty associated with renewable energy sources, promoting the widespread adoption of clean energy and supporting the healthy development of electricity markets. As technological advancements continue and practical applications deepen, MC-VPPs will drive the energy system toward greater intelligence and efficiency, ensuring a more stable and sustainable power supply.

Integrating Augmented Reality Learning Objects in Intelligent Tutoring Systems: A Conceptual Model for Engaging Learning Experiences

Hind Tahir, Najoua Hrich, Salma El Boujnani, Mohamed Khaldi
Research team in Information Technology and Modeling System Research Unit-Faculty of Sciences,
Abdelmalek Essaadi University, Tetouan, Morocco

***Abstract*—Despite the progress achieved by E-learning platforms, several limitations remain in sustaining learner engagement over time. With the rapid evolution of information and communication technologies, augmented reality has emerged as a powerful medium for designing pedagogical objects that are interactive, immersive, and adaptable to diverse learning contexts. The integration of augmented reality- based learning objects into intelligent tutoring systems enhances the educational process by providing learners with contextualized, multisensory experiences that align with their preferences and profiles. In this perspective, our objective is to propose a model for augmented reality-based learning objects within the context of an Intelligent Tutoring System. The proposed framework addresses a critical research gap: the absence of systematic architectural models that enable real-time, bidirectional adaptation between AR content representation and ITS decision-making mechanisms. Our model aims to strengthen learner motivation and reduce the risk of disengagement by dynamically adapting content to individual needs. It provides a structured foundation for the design and development of augmented reality-based learning objects within an intelligent tutoring system, ensuring that immersive resources are not only technologically innovative but also pedagogically aligned and personalized through the system's diagnostic and feedback capabilities.**

***Keywords*—Augmented reality; intelligent tutoring systems; E-learning; adaptation; engagement; personalized learning; learning objects**

I. Introduction

The rapid evolution of educational technology has fundamentally transformed pedagogical approaches and learning environments across diverse contexts. Among emerging technologies, augmented reality (AR) has demonstrated significant potential to revolutionize learning experiences by creating immersive and interactive educational scenarios that bridge virtual and real environments [1].

Simultaneously, Intelligent Tutoring System (ITS) have established themselves as powerful adaptive learning platforms capable of personalizing instruction based on individual learner characteristics, knowledge states and cognitive profiles [2].

Recent empirical evidence suggests that augmented reality significantly improves learner engagement and understanding of complex concepts [3]. Learning using AR-based tools often outperform peers in traditional settings and report higher engagement levels and more positive attitudes toward learning [4]. However, this engagement frequently proves transient: without ongoing pedagogical adaptation, the novelty effect of AR fades, and learners become disengaged despite the initial immersive appeal.

Despite these promising results, the integration of AR learning objects into intelligent tutoring systems remain relatively underexplored. Previous work by the authors has explored the general integration of artificial intelligence and augmented reality in educational environments, highlighting opportunities regarding personalization and learner engagement [5]. Building on these findings, systematic frameworks that guide AR-ITS convergence are still limited.

Key challenges include aligning AR's representational and interactive affordances with ITS adaptive mechanisms, ensuring pedagogical coherence across integrated components and maintaining technical interoperability between heterogeneous systems platforms.

This gap is particularly critical when learner motivation and engagement are considered, as they are decisive in educational success. Conventional ITS, may not always provide the rich and multisensory experiences that AR environments can offer. Conversely, many standalone AR applications lack the personalized scaffolding and fine-grained learner modeling capabilities characteristic of ITS.

Bringing these two technologies together creates an opportunity to harness AR's motivational power within an ITS-driven adaptive framework, potentially generating synergistic effects that enhance both engagement and learning outcomes.

In response to this need, the present study propose a model for integrating AR learning objects into intelligent tutoring systems. The model is structured around two complementary phases: a pedagogical phase that defines instructional objectives and learning activities, and technical phase that specifies the internal composition of AR learning objects into interconnected components (contextualization, exploration, assessment) and their adaptive sequencing with the ITS.

The primary contribution of this work is to synthesize pedagogical and technical dimensions into a cohesive framework that simultaneously addresses "what to teach" through AR-based learning objects and "how to deliver" through intelligent tutoring system architectures.

This dual-phase perspective emphasizes that effective educational technology integration depends not only on advanced technical solutions but also on carefully designed instructional strategies aligned with learner needs and contextual constraints.

While the proposed model is grounded in established pedagogical and ITS design principles, empirical validation through prototype deployment and controlled studies remains critical future work.

The remainder of this study is organized as follows: Section II presents the theoretical basis and related work, Section III details the methodological framework, and Section IV outlines the results and discussion. Finally, Section V concludes the study and highlights future research.

II. Theoretical Basis and Related Work

A. Augmented Reality in Education

Augmented reality superimposes digital information (3D objects, text, animation, sounds) onto the real world as perceived by the user, creating an enriched mixed experience [6]. AR systems rely on three fundamental technical components:

- The tracking system: detects and tracks physical markers (marker-based AR) or the real environment itself (marker-less AR) to determine where to display virtual content.
- The rendering engine: generates 3D objects and superimposes them in real time onto the camera view, taking into account perspective and lighting.
- The interaction interface: captures the user's gestures, manipulations, and actions to enable interaction with virtual objects.

Empirical research has highlighted several pedagogical benefits of augmented reality, particularly regarding learner engagement and motivation [3]. Its immersive and interactive experiences effectively capture learners' attention and support their intrinsic motivation.

Studies also indicate that learners using AR spend more time interacting with learning materials and higher levels of satisfaction [2].

B. AR-Based Learning Object: Definition and Properties

The concept of learning objects was first introduced in the early 1990s to describe modular educational resources that could be reused across various instructional contexts [7]. Wiley (2002) defined them as any digital asset that supports learning and can be flexibly recombined to suit different pedagogical needs [8]. The IEEE standard later formalized this notion by describing learning objects as digital or non-digital entities created specifically to facilitate learning, often containing multimedia elements such as text, images, audio, or video [9].

AR-based Learning Objects build upon this foundation by integrating augmented reality (AR) components, such as holographic visualizations, interactive overlays, or geolocated information into the learning process. Unlike traditional learning objects, AR-based learning objects are not limited to static or multimedia resources; they situate knowledge in authentic contexts, allowing learners to interact with content in real- world environments enhanced by digital layers.

Recent studies have demonstrated the pedagogical potential of AR-enhanced learning objects. For instance, Akçayir and Akçayir (2017) identified increased engagement and contextualization as key benefits of AR-based educational environments [10]. Similarly, Ibáñez and Delgado-Kloos (2018) showed that AR-supported learning objects significantly improve conceptual understanding and motivation in STEM disciplines [11]. These findings support the integration of AR-based learning objects as immersive and adaptable components within a personalized learning system.

The effectiveness of learning Objects based on Augmented Reality depends on a set of pedagogical and structural characteristics that ensure both adaptability and experiential relevance:

- Pedagogical Intent: To be effective, an AR-based Learning Object must be guided by a pedagogical intent that gives meaning to its learning objectives enhancements [12]. This intent shapes how immersive features are integrated, ensuring they support long-term educational goals rather than serving as superficial [13].
- Granularity: AR-based learning objects are modular, ranging from small, discrete units (e.g., individual images, text blocks, short animations) to comprehensive instructional sequences (e.g., lessons, modules) or entire curricula. This granularity supports flexible reuse and customization, facilitating adaptive learning paths [14].
- Reusability: Following the logic of reusable learning architectures [15], a reusable AR-based learning object may include instructional materials, practical interactions, and embedded evaluation activities aligned with a clearly defined educational goal [16]. Moreover, the degree of granularity plays a decisive role in the reusability of AR-based learning objects. Fine-grained learning objects are generally context-free and highly reusable across various courses or systems.
- Technological durability: Technological durability is a critical characteristic of AR-based learning objects, as it ensures their long-term usability and relevance despite the rapid evolution of hardware and software ecosystems. Augmented reality learning objects designed with durability in mind are not tied to a single device or platform but rely on open standards, modular architectures, and optimized performance to remain functional across contexts. This durability is reinforced by the use of interoperability frameworks (e.g., xAPI) that facilitate integration into diverse learning management systems [17].

The integration of Augmented reality based learning objects in digital E-learning can be analyzed through three complementary pedagogical dimensions that enhance learner engagement. AR-based learning objects:

- Act as representational tools; transforming abstract knowledge into immersive and context-sensitive visualizations that enhance conceptual clarity.
- Support mastery and proactive learning, as learners actively manipulate augmented environments, experiment with variables and receive adaptive feedback, thereby fostering self-regulation and deeper understanding.
- Enable a socioconstructivist approach, functioning as mediators of collaboration in shared augmented spaces where learners co-construct knowledge through dialogue and interaction.

According to Deci and Ryan's self-determination Theory [18], motivation is shaped by the degree to which learning environments support autonomy, competence and relatedness. When educators implement strategies that foster these conditions, such as adaptive, interactive learning tools, learners are more likely to engage meaningfully in the learning process and achieve stronger outcomes.

In this regard, our pedagogical strategy, which leverages AR-based learning objects, aims to simulate learner engagement through immersive and context-aware experiences. Fig. 1 highlights the connections between our strategy-centered on the use of AR-based learning objects and the resulting effects on learner engagement and educational success.

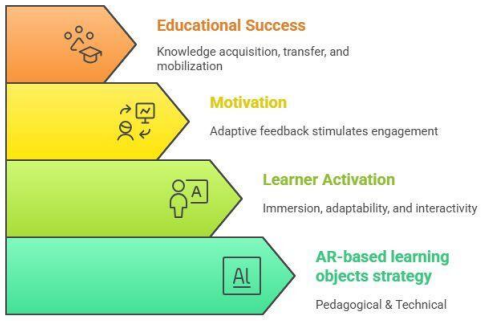

Fig. 1. From AR learning objects to educational success.

C. Intelligent Tutoring System

Intelligent Tutoring Systems (ITS) represent a specialized class of computer-based learning environments that employ artificial intelligence and cognitive science principles to deliver adaptive, personalized instruction tailored to individual learner characteristics and performance dynamics [19]. The foundational concept of intelligent tutoring systems emerged in the early 1970s and became formally established as a research field following seminal work by Sleeman and Brown [20], with subsequent development producing increasingly sophisticated architectures capable of replicating key aspects of expert human tutoring at scale.

The canonical architecture of ITS comprises four interdependent functional subsystems, as illustrated in Fig. 2:

- Domain Model: encodes disciplinary knowledge, conceptual relationships, procedural competencies and typical misconception patterns within a particular subject domain.
- Learner Model: maintains continuously updated representations of individual learner knowledge states, performance trajectories, cognitive abilities, learning preferences and metacognitive characteristics through systematic analysis of learner interactions and responses.
- Pedagogical Module (Tutor Model): employs instructional decision making algorithms to determine optimal activity sequencing, content selection, scaffolding strategies and feedback mechanisms by consulting both domain and learner representations.
- User Interface: facilitates bidirectional communication, presenting content through multiple modalities and capturing learner actions for subsequent analysis.

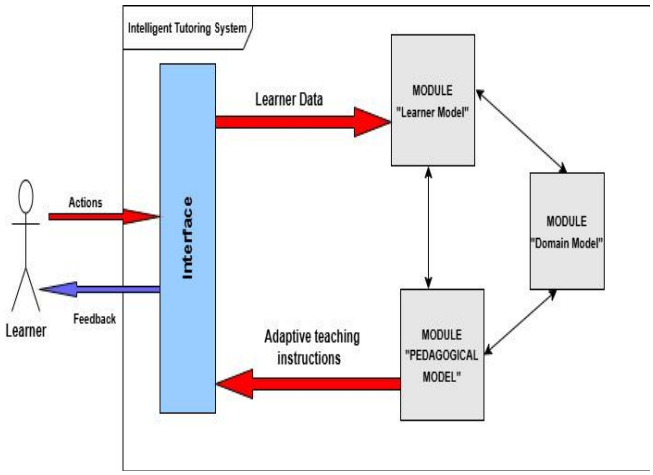

Fig. 2. A classical ITS architecture.

Contemporary ITS research increasingly incorporates emerging technologies and pedagogical frameworks [21]. Advanced ITS implementations now integrate immersive technologies such as augmented reality and virtual reality environments, expanding the representational affordances available for knowledge modeling and problem-solving activities beyond traditional textual and graphical interfaces.

D. State-of-the-Art: AR-ITS Integration and Current Limitations

Recent research has increasingly explored AR-ITS integration, with promising initial results. Uriarte-Portillo et al. conducted a comparative study with 106 middle school students evaluating an intelligent tutoring system with augmented reality (ARGeoITS) against a standalone AR system (ARGeo). Results demonstrated that combining AR with ITS-driven adaptation significantly outperformed standalone AR, suggesting that real-time adaptive tutoring integrated with AR analytics enhances student performance beyond mere visualization [22]. This foundational work established empirical evidence for the synergetic potential of AR-ITS integration.

Similarly, emerging work integrating Generative AI with AR environments demonstrates innovative approaches combining AI-powered conversational agents with AR visualization to support inquiry-based learning [23]. These systems show significant improvements in critical thinking, inquisitiveness, and learning motivation compared to traditional AR-only approaches. The integration of natural language processing further enables responsive, conversational tutoring interactions within immersive environments.

However, three critical limitations persist in current AR-ITS implementations, particularly concerning sustained engagement:

- Adaptation limited to sequencing and feedback; AR representation remains static: Existing systems adapt at the level of activity selection or textual feedback delivery, not at the level of AR content representation itself. The 3D objects, spatial complexity and interactive modalities remain unchanged during learner interaction, regardless of performance or comprehension. This represents a significant missed opportunity: the dynamic modification of the AR visualization based on real-time learner state maintains cognitive and emotional engagement, signals progress, provides adaptive scaffolding and maintains appropriate challenge.
- Lack of principles architectural frameworks for engagement-centered AR-ITS: While individual systems demonstrate effectiveness, no unified framework exists specifying how learner interactions with AR objects should inform domain model updates, which pedagogical rules should govern real-time content adaptation and how the learner model, pedagogical module, and AR engine achieve bidirectional coupling. Most implementations treat AR as a one-way presentation layer receiving instructions from an ITS backend, not as an adaptive component whose state continuously informs tutoring logic and engagement decisions.

These gaps highlight a clear research need: a systematic model and architecture that enables real-time, bidirectional adaptation between AR content representation and ITS decision-making, explicitly designed to foster sustained learner engagement, grounded in pedagogical frameworks and validated through implementation.

The present study addresses this need by proposing a dual-phase AR-ITS model that integrates pedagogical design (MARS, IMS-LD, SAMR) with technical architecture, enabling real-time, engagement-centered adaptation at the representation level. By situating our work at the intersection of pedagogical design, technical architecture and engagement science, we aim to move the field from isolated AR or ITS innovations toward coherent, replicable systems capable of sustaining engagement.

III. Methodological Framework

The design of our architecture is organized into two complementary phases: the pedagogical phase, which focuses on the design of the augmented reality (AR)-based learning object, and the technical phase that details the integration of this learning object within the Intelligent Tutoring System (ITS).

A. Phase 1: Pedagogical Design and Scenario Development

The pedagogical phase focuses on designing AR learning objects that effectively support learning objectives while maximizing learner motivation and engagement. This phase employs two complementary frameworks: the MARS model for motivation-centered design and IMS Learning Design for activity structuring and scenario orchestration.

1) MARS framework for simulation design: The MARS model (Model- Associations- Representation- Scenario) developed by Pernin (1996) [24], provides an operational structure for developing AR-based simulations and interactive learning objects through its four-component architecture, as illustrated in Fig. 3. Application to AR learning object design proceeds as follows:

- Model (M): Specify the functional model underlying the AR learning object, including 3D object behaviors, physical properties, interaction rules, and state transitions.
- Association (A): Define mappings between conceptual knowledge (domain model), visual representations (3D assets, animations), and learning activities. Associations ensure that when learners interact with AR elements, these interactions correspond meaningfully to underlying concepts and produce pedagogically appropriate feedback. This component supports alignment between learning objectives and AR affordances.
- Representation (R): Create the visual and interactive interface through which learners engage with the AR content. This includes designing 3D models, selecting appropriate mechanisms (marker-based, marker-less, and location-based), defining interaction modalities (touch, gesture, voice) and ensuring usability across target devices. Effective representation balances visual fidelity with cognitive load management, avoiding overwhelming learners with excessive detail.
- Scenario (S): Structure learners' use of AR simulation toward specific educational objectives.

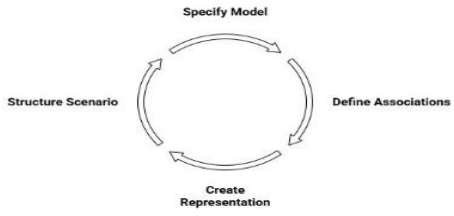

Fig. 3. AR learning object development cycle.

2) IMS learning design for activity orchestration: This design process is grounded in the IMS Learning Design (IMS-LD) framework, an internationally recognized pedagogical specification developed by the IMS Global Learning Consortium [25]. IMS learning Design provides the structural framework for organizing AR learning objects within coherent learning scenarios that orchestrate learner activities, resources and support mechanisms. The specification's three-level architecture enables increasing sophistication in scenario design:

- Level A: Activity Sequencing: At the foundational level, IMS-LD structures AR learning experiences through time-ordered activities assigned to specific roles. For AR-enhanced ITS, this involves defining learner and tutor roles, specifying AR-based learning activities (e.g., exploring 3D molecular structures, practicing assembly procedures in augmented space) and sequencing these activities within coherent learning flows. The activity structure specifies which AR learning objects are available to learners at different points in the learning trajectory.
- Level B: Adaptive Conditions: The intermediate level introduces properties and conditions that enable dynamic adaption based on learner actions and states. This proves particularly valuable for AR experiences based on learner model data. For example, if a learner demonstrates misconceptions about spatial relationships, the system might present AR activities emphasizing 3D manipulation; conversely, learners showing confidence might access more complex augmented scenarios. Properties store learner interaction data from AR activities, informing subsequent adaptive decisions.
- Level C: Notifications and Triggers: The advanced level supports notifications that dynamically trigger activities based on events. In AR-ITS contexts, this enables responsive scenarios where AR content adapts in real time to learner behaviors. For instance, if a learner spends excessive time on a particular AR interaction without progress, the system might trigger supportive interventions such as simplified AR demonstrations or hints overlaid in the augmented environment.

3) SAMR model as a framework for technology integration: The SAMR model, proposed by Puentedura [26], is designed to analyze the degree of pedagogical transformation brought by educational technologies. It distinguishes four levels, as shown in Fig. 4:

- Substitution: where technology replaces a traditional tool without changing the task.
- Augmentation: where technology enriches the existing activity.
- Modification: where technology enables a substantial redesign of the activity.
- Redefinition: where new tasks, previously impossible, become attainable.

This framework is used to evaluate the ability of our AR-ITS system to go beyond simple improvements to traditional approaches. Several components of our AR-ITS model move past mere replacement or enhancement, reaching the modification or redefinition levels by offering immersive, adaptive and collaborative learning experiences that are only possible through augmented reality and intelligent tutoring.

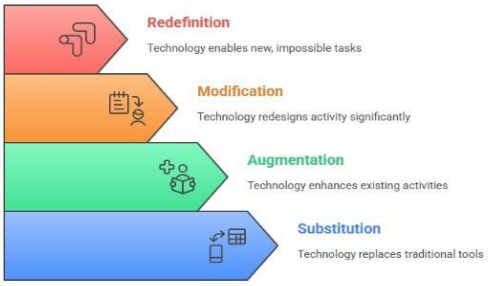

Fig. 4. SAMR model.

B. Phase 2: Technical Integration into ITS Architecture

The technical phase addresses the integration of AR learning objects into ITS architectures. To operationalize this integration, AR learning objects follow a structured three-component design, as shown in Fig. 5: Contextualization component, the exploration component, and the assessment component. This three-component architecture ensures that learner interactions with AR objects inform real-time adaptations and pedagogical decision-making.

- Contextualization component: communicates learning objectives, prerequisite knowledge requirements and establishes the pedagogical scenario. This component adapts based on the learner's profile within the ITS, presenting comprehensive information to novice learners and an abbreviated context to advanced learners.
- Exploration component: presents the core AR content and interactive activities. It structures information to promote active learning through multimodal representations. The ITS provides real-time scaffolding and adaptive feedback during learner exploration of AR objects.
- Assessment component: enables learners to demonstrate comprehension of key concepts. It provides formative feedback and assesses readiness for progression. If gaps are identified, targeted feedback is provided to specific learning elements, enabling iterative refinement until mastery is achieved.

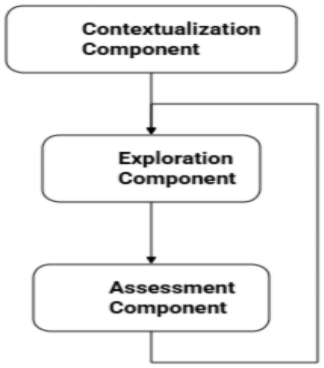

Fig. 5. AR learning object structure.

IV. Results and Discussion

The use of learning objects within adaptive instructional systems to foster learner engagement has become an active and multifaceted research topic, attracting sustained interest in the technology-enhanced learning community.

In this work, engagement is understood as a combination of cognitive and emotional involvement that leads the learner to willingly invest effort and attention in the learning task and to persist in order to reach predefined learning objectives. It is shaped by a set of internal and external factors that influence how and why a learner initiates, maintains, or abandons an activity.

Fig. 6 presents the overall architecture of the proposed AR-ITS model, in which augmented learning objects are integrated as a central mechanism for increasing learner engagement. The model is organized into two main phases, as previously described: a pedagogical design phase and a technical adaptation phase.

In total, the model comprises twelve classes, each representing a key component of the system and encapsulating the data and behaviors necessary to support adaptive AR-based learning experiences.

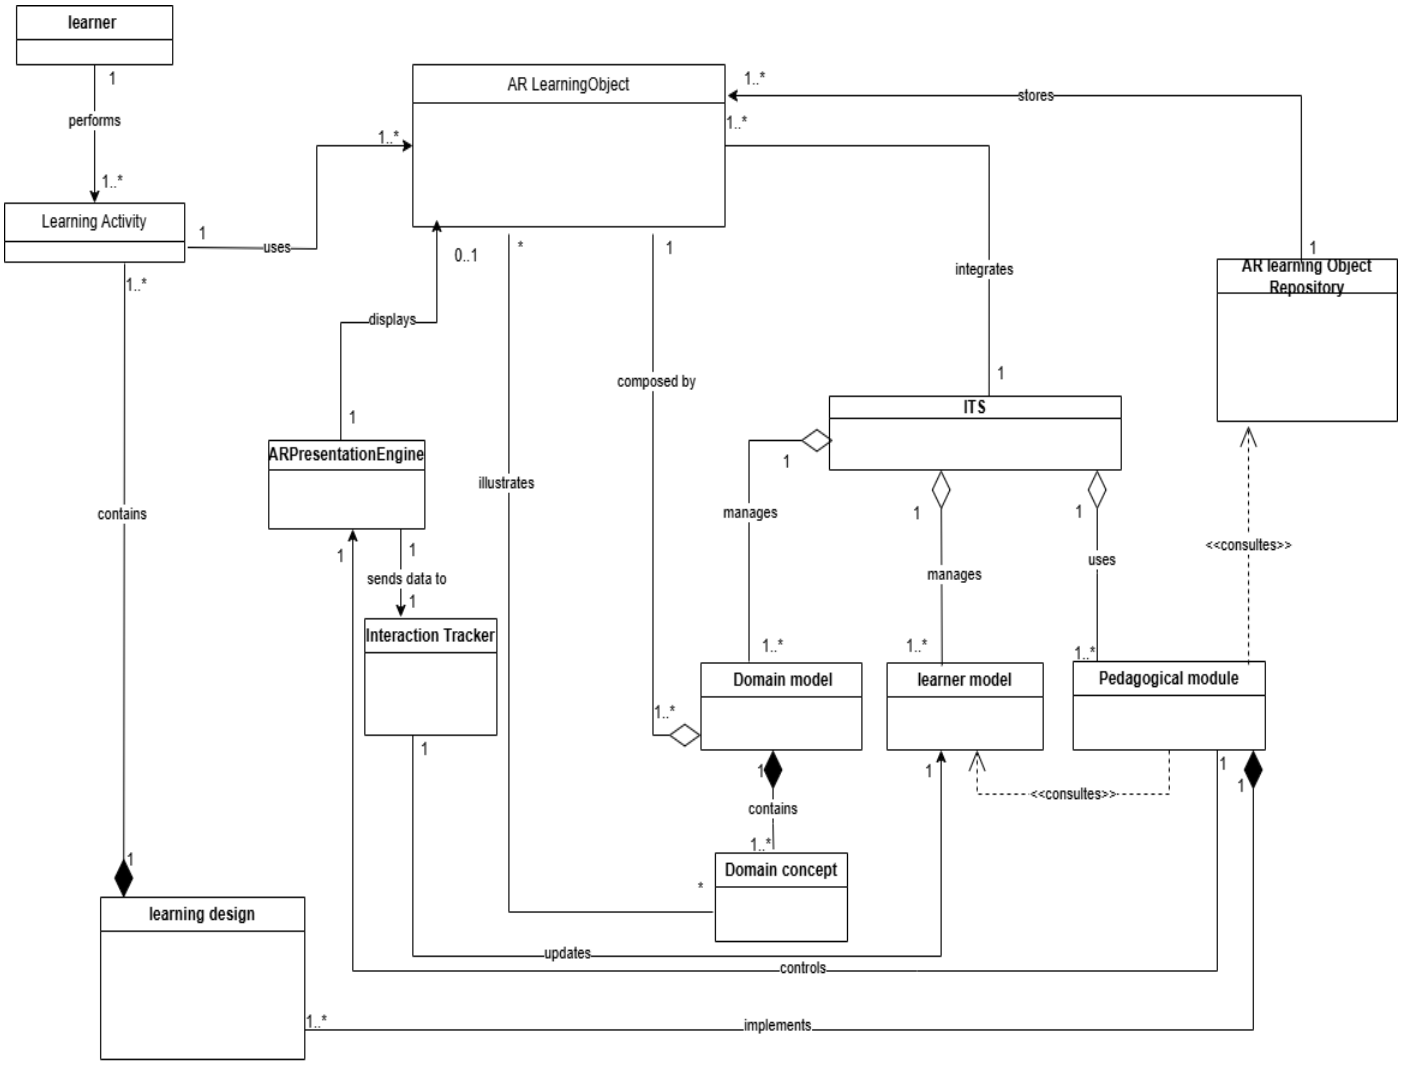

Fig. 6. Class diagram of the AR-ITS model.

1) Pedagogical phase: In this phase, we structure the learning experiences by specifying what should be learned, how it should be orchestrated, and within what scenario. This phase comprises:

- "Learning Design": defines the overall instructional sequence and organizes the learning activities and their pedagogical scenarios.
- "Learning Activity": Represents specific tasks and exercises the learner will perform. Each activity can use one or more AR Learning Objects as resources.
- "AR Learning Object": Provides the core augmented reality content for exploration, designed according to MARS principles and integrated within the learning scenario.

The pedagogical layer ensures that AR is not merely a technical add-on but is integrated within a robust pedagogical scenario. This layer aligns content, activities, and learner roles to support meaningful engagement and learning progression.

2) Technical phase: In this phase, we implement and execute the AR learning experience as specified by the pedagogical phase. It comprises:

- "AR Presentation Engine" and "Interaction Tracker": together, these manage the AR display, capture learner interactions in real-time, and provide event data to the ITS.
- "ITS" (Intelligent Tutoring System): acts as the central coordinator, integrating three core models:

a) "Learner model": Maintains a dynamic record of learner states, competencies and progress.

b) "Domain model": Holds the domain knowledge and conceptual structure that the learning content relies on.

c) "Pedagogical module": Implements the instructional logic for adaptation, feedback selection and activity progression.

- "AR Learning Object Repository": Stores reusable AR objects that can be retrieved and dynamically assigned to activities based on learner needs and activity requirements.

The technical phase enables real-time adaptation: it collects learner data, updates learner models, and collaboratively with the pedagogical Module, dynamically selects, adapts, and sequences AR learning objects and feedback.

The pedagogical and technical phases work in close coordination. The pedagogical phase defines what should be taught and how AR should enhance the experience; the technical phase delivers tracks and adapts the learning experience in line with the pedagogical plan.

This architectural separation supports methodological rigor, scalability, and the ability to evolve pedagogical approaches independently from technical implementations, thereby ensuring both pedagogical coherence and technical robustness.

The pedagogical layer specifies what should be taught and how it should be orchestrated. The technical layer delivers, tracks, and adapts the learning experience in alignment with the pedagogical plan. Bidirectional communication (represented in the diagram) enables learner data collected by the Interaction Tracker to inform ITS decisions, which then modify the AR learning Object representation.

3) The AR-ITS adaptive learning cycle: The dynamic behavior of the proposed AR-ITS is structured as a continuous adaptive learning cycle, as illustrated in Fig. 7. This cycle is repeatedly executed while the learner engages with AR-based activities. The following scenario summarizes the main steps of this cycle, from activity selection to learner mode update.

a) Step 1: Activity Initialization

At the beginning of a session, a "learning Activity" is instantiated from a "learning Design", which specifies the pedagogical scenario (sequence of activities, prerequisites, conditions for progression).

b) Step 2: Instructional Decision-Making

When an activity becomes active, the "ARPresentationEngine" requests guidance from the "PedagogicalModule" to determine which content and level of support should be provided. The "PedagogicalModule":

- Consults the "learner Model" to retrieve the current learner state.
- Then queries the "Domain Model" to identify relevant concepts.
- Identifies candidate "ARLearningObject" from the repository.
- Applies predefined adaptation rules to select the most appropriate "ARLearningObject" and support level.
- Sends selected AR content to the "ARPresentationEngine" with rendering specifications.

c) Step 3: Learner Interaction and Tracking

The learner interacts with the AR content (manipulations, exploration, task completion) as specified in the "learning Activity", while the "Interaction Tracker" records all relevant actions

- What the learner did (interaction Type).
- When it happened (timestamp).
- How long it took (duration).
- Quality of interaction (accuracy, correctness).

d) Step 4: Learner Model Update and Cycle Iteration

Interaction data collected by "InteractionTracker" is used to update the "Learner Model":

- Refining estimates of knowledge states.
- Identifying misconceptions.
- Assessing engagement levels.

- The updated "Learner Model" informs subsequent decisions of the "Pedagogical Module".
- The Module may adapt the current activity (extra scaffolding, hints, alternative AR object) or trigger the next activity according to the "Learning Design".
- This loop continues until the scenario is completed.

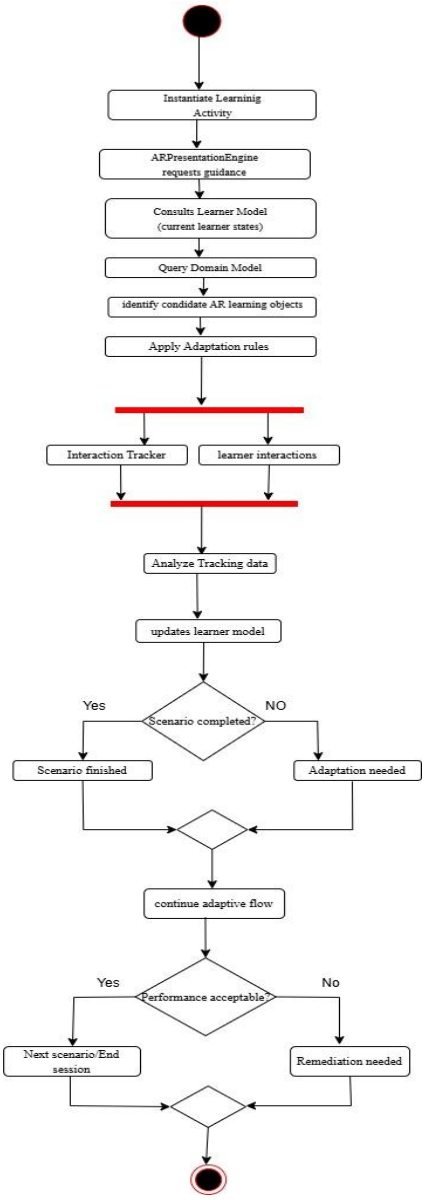

Fig. 7. Adaptive activity diagram flow of an AR-based intelligent tutoring system.

This adaptive cycle demonstrates how the model achieves real-time, bidirectional coupling between AR interaction and ITS decision-making, addressing the research gap identified.

The previous diagram presented the structural organization of the AR-ITS and the overall adaptive activity flow. The following sequence diagram, illustrated in Fig. 8, details the runtime interactions between the "ARPresentationEngine", the Pedagogical Module, and the Learner-related models during a single AR learning activity.

Upon initiation by the learner, the "ActivityManager" instantiates the learning activity based on the predefined design. The ARPresentationEngine then solicits pedagogical guidance, triggering a cascade of interactions within the Pedagogical Module.

This module consults the "LearnerModel" to retrieve the learner's current cognitive and affective state, queries the "DomainModel" for relevant conceptual targets, and accesses the "ARLearningObjectRepository" to identify suitable AR content.

Adaptation rules are applied to select the optimal support level and AR objects, which are then rendered by the ARPresentationEngine. As the learner engages with the AR content, the InteractionTracker captures detailed behavioral data—action type, timestamp, duration, and accuracy—updating the learner's profile with inferred knowledge states, misconceptions, and engagement metrics.

This updated profile informs the Pedagogical Module's decision-making for subsequent adaptations or activity transitions, which are executed by the "ActivityManager", ensuring a responsive and personalized learning loop.

The three diagrams jointly provide a coherent and complementary description of the proposed AR-ITS. The class diagram first specifies the static structure of the system by defining the main classes and associations, thereby grounding the architecture in concrete software entities.

The activity diagram then captures the global adaptive learning cycle, emphasizing how interaction tracking, learner-model updates, and the selection of AR learning objects are orchestrated within a continuous feedback loop.

Finally, the sequence diagram refines this behavioral view by detailing the ordered message exchanges between the learner, the activity manager, the AR presentation engine, the pedagogical module, and the learner model during a session.

Together, these models clarify the overall architecture and demonstrate the system's ability to dynamically personalize AR experiences in response to the learner's evolving profile.

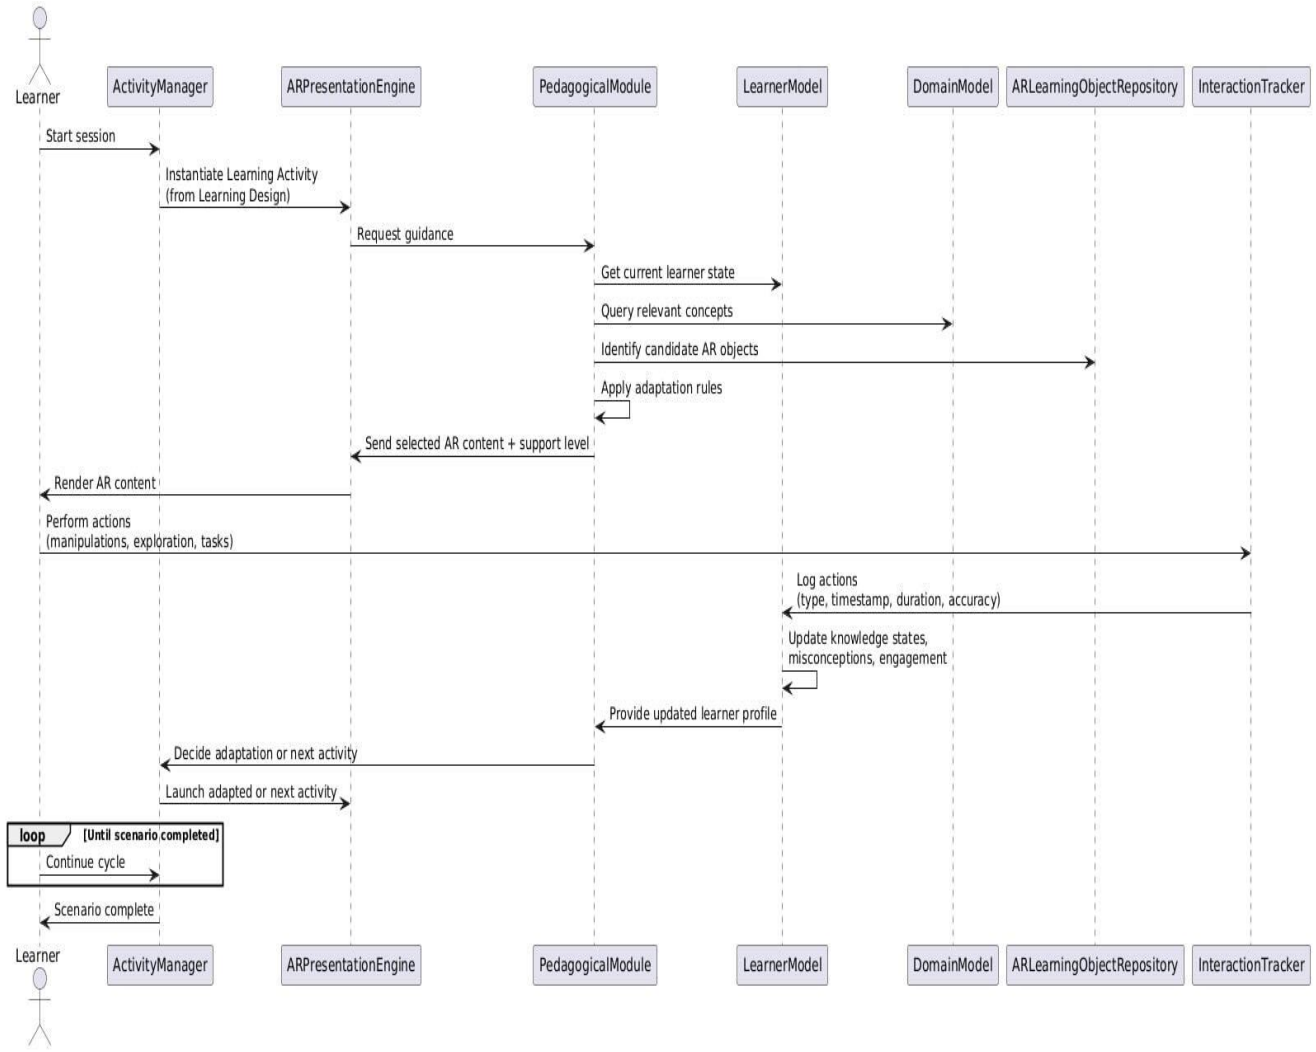

Fig. 8. Sequence diagram of the AR-ITS session flow.

V. Conclusion and Future Work

This research addresses the challenge of designing augmented reality-based intelligent learning environments that enhance learner engagement. The proposed AR-ITS model integrates AR learning objects with adaptive tutoring to create personalized learning experiences that respond to individual learner needs and preferences.

This study makes both theoretical and architectural contributions to the design of AR-based Intelligent Tutoring Systems, which can be summarized as follows: First, at the theoretical level, we establish that effective AR-ITS design requires an explicit integration of pedagogical frameworks with technical architecture, ensuring that AR learning objects are not only immersively designed but also pedagogically coherent and adaptively responsive to individual learner states. Second, in the architectural contribution, we provide a concrete UML model that operationalizes the coupling between AR content representation and ITS decision-making. This model is grounded in educational technology standards and demonstrates how data flows between layers, enabling real-time adaptation.

This study, therefore, offers a strong theoretical and architectural foundation; however, the critical next phase is empirical validation. The current work does not yet include user studies, learning outcome measurement, or comparative effectiveness analysis, and these are acknowledged as important limitations.

Looking forward, our next work will focus on implementing a fully functional AR-ITS that instantiates the proposed model for a concrete use case: teaching network topologies as part of the national computer science curriculum in Moroccan secondary education. This system will be empirically tested with learners in this context in order to evaluate its impact on learner engagement, personalization, and learning outcomes, thereby providing concrete validation of the proposed approach.

Such an evaluation will enable assessment of the model's effectiveness with its intended target audience and within an authentic educational setting.

Collectively, these efforts would help move from a theoretically grounded AR-ITS architecture to robust, field-tested systems. By demonstrating how AR-based learning

objects enhance engagement within adaptive tutoring frameworks, this line of research contributes to advancing the design of next-generation intelligent learning environments.

Comparative Evaluation of CNN Architectures for Corn Leaf Diseases Classification

M. Abdallah*, M. F. Abu-Elyazeed
Dept. of Electronics and Communication, Cairo University, Giza, Egypt

***Abstract*—Corn has particular importance in the global food industry. Many diseases attack the corn crops, which affects the crop yield. Early classification and detection of these diseases are pivotal to preventing damage and achieving high crop productivity. Although deep learning, especially convolutional neural networks, has accomplished remarkable results in image recognition, selecting the optimal architecture and using limited datasets remains a challenge. To address this gap, a transfer learning approach based on ImageNet weights was applied to classify three common corn diseases (i.e., gray spot, common rust, and blight), as well as the healthy plants. Six CNN architectures—DenseNet201, EfficientNetB0, VGG16, ResNet50, InceptionV3, and InceptionResNetV2—inclusive performance was evaluated for classification on a corn dataset. Based on evaluation metrics, EfficientNetB0 achieves the highest training accuracy of 97.67% with a fast computational time of 71 seconds. It performs more efficiently than the other architectures. These findings support the use of deep learning models, particularly EfficientNet, in the evolution of artificial intelligence image classification system applications.**

Keywords*—Artificial intelligence; Convolutional Neural Network; deep learning; image processing; corn diseases classification

I. Introduction

The population is predictable to extend to 8.5 billion by 2030 [1]. Therefore, there is an imperative request to increase the production of agricultural crops to cover the needs of the increasing population. Consequently, crop productivity is very important worldwide [2]. Plant diseases are one of the prime factors of crop loss, with huge amounts of wasted food each year globally [3]. Plant diseases have many species, which can be bacterial, viral, or fungal. The diseases attack leaves, fruits, or branches and causes damage in the crop. To avoid crop loss, early crop disease identification is critical to be considered in the future [4].

Corn, or maize, is a worldwide produced crop. Corn agriculture plays a substantial role on account of its possibility export and it provides a lot of people with food [5]. Various businesses use corn, including the food industries, oils, drinks, and animal feed. The corn is exhibition of many diseases that may attack many parts of it, such as leaves, trunk, and fruit [6]. This has a serious leverage on the yield of crop harvest and can cause a huge financial loss. Diseases that attack corn leaves are the most severe of these diseases. Therefore, this work uses three widespread leaf diseases: gray spot, common rust, and blight [7].

Plant disease detection and classification have become a decisive issue in recent years. Artificial intelligence presents significant help to smart agriculture by introducing various techniques in classifying and detecting crop leaf disease [8]. Deep learning approach is the best emerging technology in image processing. Within the deep learning environment, Convolutional Neural Network [9] is the most perfect used technique for image classification, object detection, and segmentation. However, applying DL models to agricultural issues faces some challenges [10], including the lack of considerable datasets, the complex processing cost, and the large processing time.

This study aims to develop a corn disease classification based on deep learning techniques to overcome dataset limitations and achieve high performance. DenseNet201, EfficientNetB0, VGG16, ResNet50, InceptionV3, and InceptionResNetV2 were discussed along with the detailed experimentation conducted. The work combines advanced deep learning models with a transfer learning approach to tackle the challenges of deep learning models in computational time and the amount of data. This helps create a smart and efficient system that enables timely interventions and minimizes crop loss. Moreover, the study explores future suggestions by proposing improvements through model deployment.

II. Related Works

Common deep learning techniques have been widely used in developing smart agriculture. This section discusses various research papers based on corn and plant disease classification using deep neural network models, specifically CNN. Arabinda et al. [11] used a dataset comprised of four classes and a total of 4988 images of the maize crop. They have used the Densenet201 model with fine-tuned the Support Vector Machine and Bayesian optimization techniques. Their model accomplished a classification accuracy of 94.6%. Wisnu et al. [12] used a free dataset coming from the Kaggle website. This dataset has four classes with a total of 4188 images. They used the CNN methods with two various architectures, the ResNet50 and EfficientNetB0 models. The accuracy result acquired for the model ResNet-50 is 93% and for the second model EfficientNet-B0, the accuracy is 94%. Neha et al. [13] used a dataset consisting of four classes and a total of 4,188 images of the corn crop. They have developed pre-trained (EfficientNetB0, ResNet50, InceptionV3, and VGG). It was found that EfficientNetB0 outperformed all of the other models with accuracy 92.33%.

*Corresponding author.

Imran et al. [14] used the public Plant-Village dataset. It contains different types of corn. They used ten classes with a total of 20,202 data after the augmentation. They applied transfer learning for accurate classify to disease in corn. They used four models: (ResNet50, VGG16, Inception V3, and InceptionResNetV2). Seema et al. [15] developed three diverse algorithms: ResNet18, VGG16, and AlexNet. Architectures were carefully selected due to their previous achievement in similar tasks. The models were designed using a pre-trained method. The dataset was used from Kaggle website consisting of 4,188 images of corn leaves with disease besides healthy leaves. On the other work, Quy Thanh Lu et al. [16] discussed CNN models, including EfficientNetB5, MobileNet, VGG16, ResNet50, and InceptionV3, for plant disease classification. The methodology includes using transfer learning. EfficientNetB5 model achieved 92% and VGG16 achieved 91% in training accuracy. Vaishali et al. [17] presented a CNN-based method for plant disease classification. VGG16, VGG19, and ResNet are trained on the Plant-Village dataset with a maximum accuracy 85.28%.

Emmanuel et al. [18] introduced a study on the classification and detection of plant diseases using several models by using datasets of healthy and infected plant leaves. They employed several CNN models, such as VGG16, InceptionV3, and InceptionResNetV2, with a maximum accuracy 92.9%. Theodora et al. [19] developed different pre-trained models for tomato leaf disease identification. ResNet50, VGG16, InceptionV3, and proposed models achieved performances of 92.18%, 93.14%, 94.91%, and 96.02%, respectively. Xu et al. [20] proposed an amended ResNet50 model. The authors have used the maize dataset. The improved ResNet50 model achieved 96.02% accuracy. Compared to DenseNet, VGG16, and AlexNet, the validation accuracy was greater. Table I shows the comparison of the previous works.

III. MATERIALS AND METHODS

This study employed to enhancement of a six different CNN architectures (VGG16, DenseNet201, EfficientNetB0, ResNet50, InceptionV3, and InceptionResNetV2) to automatically classify corn diseases. The methodology is divided into several stages. A block diagram describing the research stages is shown in Fig. 1, which declares the work process flow of corn classification using CNN models.

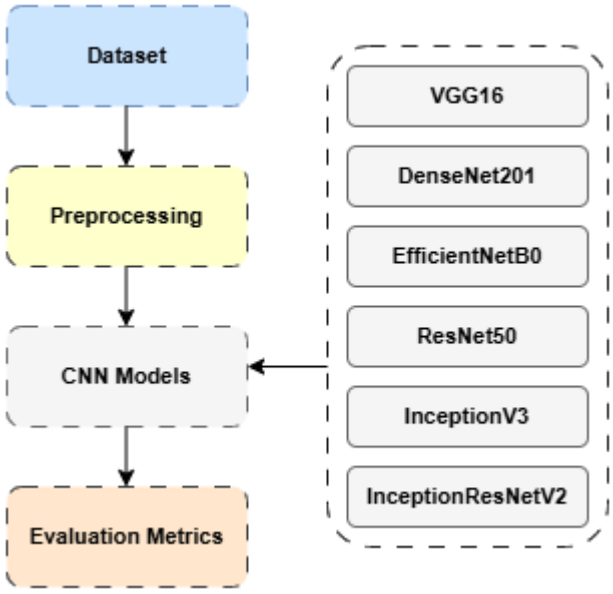

Fig. 1. Flowchart of our research.

A. Dataset

The CNN models were trained on corn leaves images to classify the image as healthy or diseased, and classify the kind of disease on image. The open and free corn dataset was used from the Kaggle website [21] for this study. It consists of four corn classes, as shown in Fig. 2. A total of 4,188 images are contained in the dataset. It has 1,306 common rust images, 1,146 blight images, 574 gray spot images, and 1,162 healthy images.

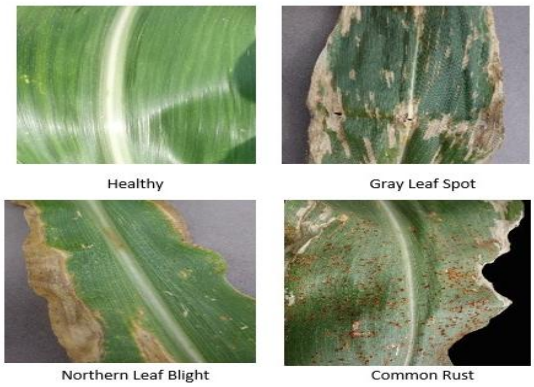

Fig. 2. Image samples from the corn dataset.

The corn dataset images are colored images of different sizes. The images are resized to 224×224 for DenseNet201, EfficientNetB0, VGG16, and ResNet50 architectures.

Otherwise, for the InceptionV3 and InceptionResNetV2 architectures, the images are resized to 299×299 pixels. The dataset was divided into training and validation data with a ratio of 80% and 20%, respectively.

B. CNN Architectures

Convolutional Neural Network was famed as a remarkable deep learning architecture for image recognition [22]. In this work, six pre-trained CNN models—VGG16, DenseNet201, EfficientNetB0, ResNet50, InceptionV3, and InceptionResNetV2—were applied. The models had been pre-trained using the ImageNet dataset and were available from the Keras library [23].

1) VGG16: VGG is a CNN model brought by Simonyan and Zisserman in 2015 [24]. It has 3×3 convolutional layers and max pooling to reduce the size of the kernels. Moreover, three dense layers, two have 4096 nodes, the third contains "one channel" for each class, and a softmax classifier [25]. VGG16 comprises 13 convolutional layers and 3 dense layers. VGG16 can transfer learned features to many tasks, making it a favorite choice for transfer learning.

2) DenseNet architecture: DenseNet was an innovative architecture introduced by Huang et al. in 2016 [26]. The DenseNet was inspired, subordinate the same direction of ResNet and the Highway network. To enhance the performance and to have most information stream between layers, all layers are connected in a feed-forward way. For each layer, the feature maps of all previous layers are utilized as inputs to all the next layers. It relieves the vanishing gradient and has decreased the number of parameters [27]. For this study, the DenseNets model with 201 layers has chosen.

3) EfficientNet: EfficientNet strives to attain great performance with few computational compared to other models. it was innovated by Mingxing Tan and Quoc V. Le in 2019 [28]. The key idea of EfficientNet is a scaling mechanism that scales the dimensions of width, depth, and resolution by using a compound coefficient [29]. This technique guarantees that the model adjusts easily to differing computational constraints while keeping its performance across various scales. There are a series of EfficientNet models, ranging from B0 to B7. For this task, B0 was chosen. Because of the smaller input size and fewer parameters, it is easier to test and has lower computing capabilities.

4) ResNet: ResNet has many versions. In this work, a ResNet50 was chosen which consisted of 50 layers of a neural network. It presented the concept of shortcut connections to solve the vanishing gradient problem, which happened when the network increased in the depth [30]. Because of this connections, gradients could pass in deeper layers without being reduced. These improve the performance and the accuracy.

5) InceptionV3: The "Inception" idea was first presented by Szegedy et al. (2015) in the GoogLeNet architecture. The sequential aspect of the GoogLeNet architecture has been referred to as Inception vN, with N going into the version number [31]. InceptionV3 used "spatial factorization" to reduce the computational cost and applied a "stem module" to enhance the flow of information. It also introduced "label smoothing" to regularize the network's output and improve its performance. It has a depth of 189.

6) InceptionResNetV2: It was introduced in 2016 and 2017, merging the ResNet with the Inception architecture [32]. The architecture combined residual connections and "inception modules" to enhance the performance and accuracy of the network. It has 55.9 million parameters, 215 MB, depth 449, and 164 layers.

C. Transfer Learning

Transfer learning is a computer vision approach that implicit building a fresh model on top of an old one [33]. The goal is to enable the fresh model to learn features from the existing one. That is allowing the incoming model to be faster and use less data. Through transfer learning, the dense layers of the network are stripped and replaced with another new layers. The term "transfer learning" describes what this strategy requires: transfer information from one model to another model that can utilize from its knowledge [34]. The transfer learning technique has been applied on the CNNs architectures to accelerate learning. The models were designed and loaded with pre-trained ImageNet weights. Transfer learning of the models was done by removing the original dense layers and substitute them with another.

D. Evaluation Metrics

The model's performance was tested for oracular fastness utilizing accuracy, precision, and recall in this study [35]. The metrics were thoughtful based on the data from the confusion matrix, which compared the actual data with model-predicted data results. The accuracy includes (true positives 'TP', true negatives 'TN') to the total number of prospects. The Precision is the proportion of correctly classified to the total number of positive states. The Recall is the proportion of positive instances to the sum of true positive and false negative instances [36]. F1-Score combines two key metrics: precision and recall. The formulas for accuracy, precision, recall, and F1-Score were introduced in Eq. (1) to Eq. (4), respectively.

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+FN+FP+TN}} \quad (1)$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP+TF}} \quad (2)$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \quad (3)$$

$$\text{F1 score} = 2\left(\frac{\text{Recall.Precision}}{\text{Recall+Precision}}\right) \quad (4)$$

IV. Results and Discussion

The experiments were done on (GPU) on Google Colab. All testing was done on Windows 10 64-bit, utilizing a Core i7 processor operating at 2.3 GHz, 16 GB of RAM, and the programming language, Python. TensorFlow library was used in software coding. Also, Keras was used for pre-trained models loaded.

A. Results

The proposed method used DenseNet201, EfficientNetB0, VGG16, ResNet50, InceptionV3, and InceptionResNetV2 models. The pre-trained weights from ImageNet, the dense layers were removed in charge of the classification and were replaced with new dense layers that are particular to the task. The classification layers were trained, while the other layers remained frozen. Adam optimizer was used with a learning rate of 0.001, and batch size 16.

For every experiment, accuracy and categorical cross-entropy loss are used for evaluation of the models. The performances are graphically drawn for each model with accuracy and loss. Generally, the loss score and accuracy based on the test dataset are computed and used to set the performance of the models. Each of the experiment runs for 50 epochs. Training process graphs of EfficientNetB0, DenseNet201, VGG16, ResNet50, InceptionV3, and InceptionResNetV2 models are shown in Fig. 3 to Fig. 8. The figures describe the training and validation accuracy phases. Also, they describe the training and validation loss phases. The accuracy graphs show a steady increase in accuracy. The loss graphs show a piecemeal decrease in value as the number of epochs increases. These graphs distinguish issues, such as overfitting and underfitting.

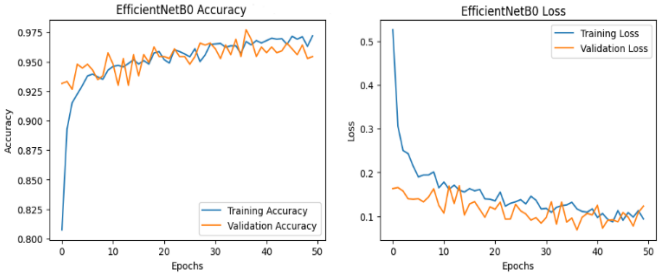

Fig. 3. Training graph of the EfficientNetB0 model.

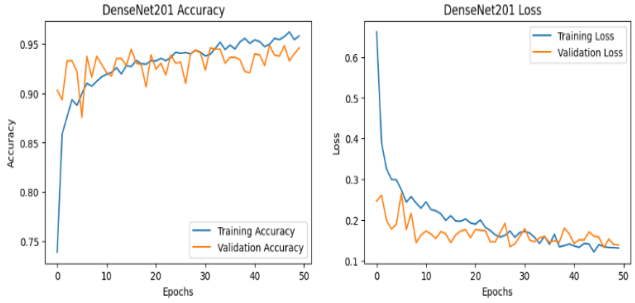

Fig. 4. Training graph of the DenseNet201 model.

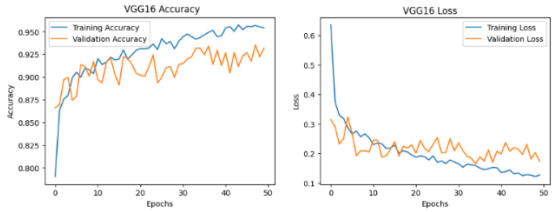

Fig. 5. Training graph of the VGG16 model.

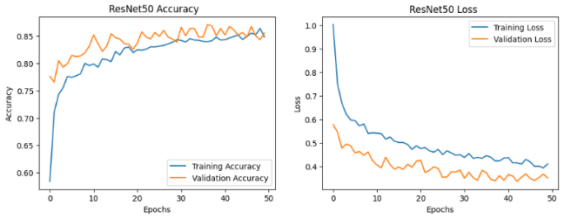

Fig. 6. Training graph of the ResNet50 model.

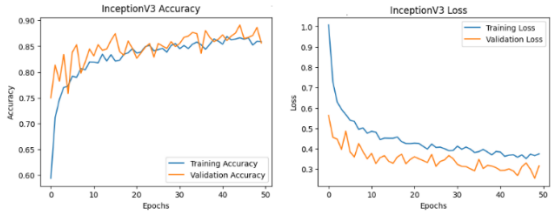

Fig. 7. Training graph of the InceptionV3 model.

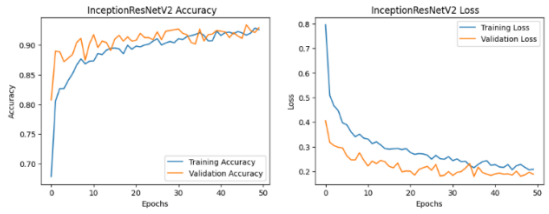

Fig. 8. Training graph of the InceptionResNetV2 model.

The experiments on the six models were executed by using a transfer learning approach, where some layers of the pre-trained model were kept frozen, while the classification layers were trained using the corn dataset. This technique allows the model to have the general knowledge gained from large datasets such as ImageNet dataset to the certain features of the used dataset in this work. Also, dropout was applied to the model in ratio 0.4 and 0.3. The dropout used to reduce the chance of overfitting while keeping the ability to capture important details from the training data. The results show no sign of the overfitting. Table II shows the results of the models, including the training accuracy, validation accuracy, loss, precision, recall, f- score, and training time per epoch of each model.

TABLE II. COMPARISION OF MODEL TESTING RESULT

Model	Training Acc. (%)	Training Loss (%)	Validation Acc. (%)	Validation Loss (%)	Precision (%)	Recall (%)	F-Score (%)	Time/Epoch
EfficientNetB0	97.67	0.06	94.85	0.15	94	94	94	71 s
DenseNet201	97.32	0.07	94.86	0.13	93	93	93	91 s
VGG16	95.22	0.12	94.54	0.16	92	92	92	76 s
ResNet50	87.44	0.33	86.48	0.34	84	84	84	80 s
InceptionV3	88.93	0.27	86.84	0.31	86	86	86	67 s
InceptionResNetV2	93.82	0.15	92.22	0.19	91	91	91	137 s

Based on the experiments result, the three superior models for corn classification are EfficientNetB0, DenseNet201, and VGG16. EfficientNetB0 shows the top performance with the highest accuracy of 97.67%, as well as equally high recall, precision, and F1-score (94%), making it the most efficient model. DenseNet201 is also an efficient model with competitive accuracy of up to 97%. Meanwhile, VGG16 achieved high accuracy (up to 95%) with a good inference time (76 seconds). On the other hand, ResNet50 shows the lowest accuracy.

B. Discussion

This section discusses the best performance achieved from the research results, namely the EfficientNetB0, DenseNet201, and VGG16 models. The first result from EfficientNetB0 produced a test accuracy of 94% and a loss of 15%. Fig. 9 shows the results of the testing data, while Fig. 10 shows the confusion matrix of the EfficientNetB0 model.

Fig. 9. Classification report of EfficientNetB0 model.

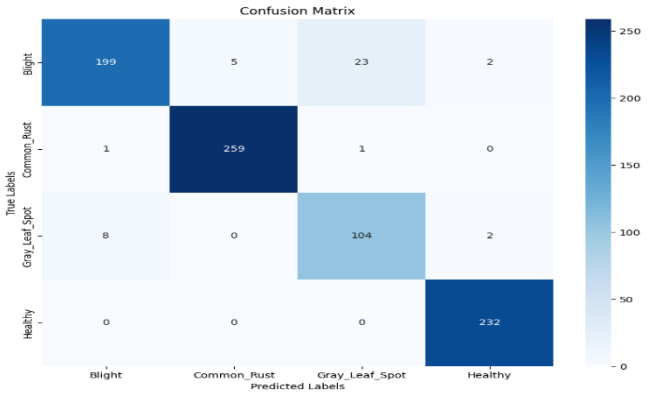

Fig. 10. Confusion matrix of EfficientNetB0 model.

Based on Fig. 9, the EfficientNetB0 model show a very high performance in classifying four corn classes. The precision value, recall, and F1-score of the healthy class are 97%, 100%, and 99%, respectively. The gray leaf class shows 90%, 91%, and 90%. The common rust class shows 98%, 99%, and 99%. Whereas, the blight class shows 92%, 87%, and 89%. The comprehensive test accuracy of the model reaches 94.85%.

Fig. 11. Classification report of DenseNet201 model.

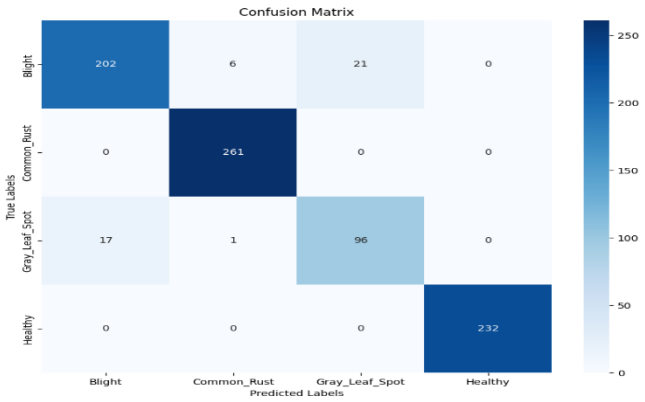

Fig. 12. Confusion matrix of DenseNet201model.

Second, the DenseNet201 model showed as well high classification performance with total test accuracy of 94.86%. In the healthy class, the model produced equally value of precision, recall, and F1-score reaching 100%. It suggested how well the model's strength can classify healthy cases. Also, the common rust class shows efficient performance of 97%, 100%, and 98%. The gray leaf class shows 90%, 84%, and 87%. The blight class shows slightly low performance of 86%, 88%, and 87%. Fig. 11 shows the classification report for the DenseNet201 model, while Fig. 12 shows its confusion matrix.

	precision	recall	f1-score	support

Fig. 13. Classification report of the VGG16 model.

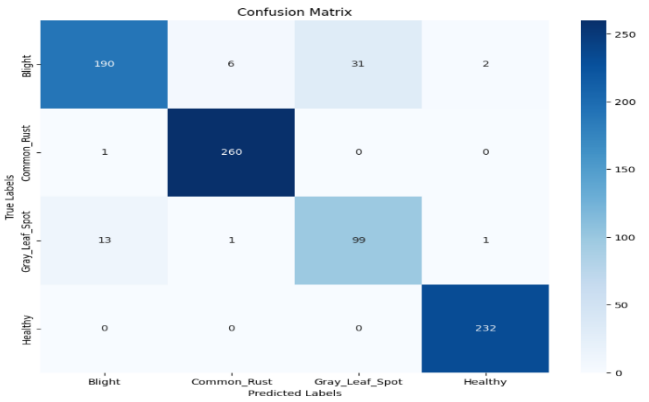

Fig. 14. Confusion matrix of VGG16 model.

And at last, VGG16, obtained a test accuracy of 94.54% and a loss of 16%. The test results of VGG16 model and its confusion matrix is shown in Fig. 13 and Fig. 14, respectively. The model introduced a good performance in identifying the corn categories. The blight class has a precision value of 88%, recall of 83%, and F1-score of 85%, signing that it is lower effective in identifying most blight cases. In contrast, in the rust class, the precision value is registered as higher, 97%, recall of 100%, and F1-score of 98%. In healthy class, the model achieved very good values of precision of 98%, recall of 100%, and F1-score of 99%. In the gray class, the model produced equally value of precision, recall, and F1-score reaching 87%. Despite some variance in identification between classes, the model still shows high performance for using in corn image classification.

TABLE III. COMPARISON OF MODEL EVALUATION RESULT WITH PREVIOUS STUDIES

Proposed Method	Acc (%) This Study	Acc (%) [11]	Acc (%) [12]	Acc (%) [13]	Acc (%) [18]	Acc (%) [20]
EfficientNetB0	97.67	-	94	-	-	-
DenseNet201	97.3	94.6	-	-	-	96
VGG16	95.5	-	-	92.33	92.58	-

While this study essentially focuses on classification accuracy, future research may discuss detection of corn images and use of agriculture robots to control the diseases. Table III provides a detailed comparison between the results of this study relative to these in previous works.

V. CONCLUSION

This study evaluated six deep learning architectures, namely, DenseNet201, EfficientNetB0, VGG16, ResNet50, InceptionV3, and InceptionResNetV2, for corn leaf diseases classification. Among the models, EfficientNetB0 achieved the highest accuracy of 97.67%, showing superior efficiency and balanced precision-recall-f-score performance with fast inference time. DenseNet201 and VGG16 also showed competitive accuracy (97.32% and 95.22%). This study exposes the use of a transfer learning approach that was applied to overcome dataset limitations and to achieve high accuracy with fast computational time. These findings confirm that the transfer learning approach can provide a stable and efficient framework for plant disease classification.

Overall, the experiments result manifest that CNN-based architectures, especially EfficientNetB0, can be used in advanced AI image classification applications. In the future, it may help smart agriculture robots by using digital image processing and detection. It is imperative to apply smart techniques to safeguard plants and assist farmers in disease species and control. Such great efforts will go a long way to help farmers to tackle corn diseases, maintain their sustenance, and support the economy.

***Abstract*—Breast cancer has been listed as one of the leading causes of death amongst women all over the world, and the current diagnostic techniques, which are founded on the manual examination of mammograms or individual clinical presentations, are often subjective, neither being consistent nor generalizable. The existing computer-aided diagnosis (CAD) systems are also characterized by significant weaknesses related to poor multimodal integration, no interpretability, and vulnerability to class imbalance. In order to address the inadequacy, the present study introduces an advanced multimodal deep learning framework named Hybrid Graph-Generative Transformer (HGGT), designed to integrate high-resolution mammographic images with the clinical, demographic, proteomic, and histological data pertinent to the patient. The HGGT network is a hierarchical Swin Transformer and CNN-based feature extraction, a Graph Attention Network (GAT) (to identify clinical variable interaction), and a contrastive cross-modal generative fusion system (to match the different modalities). The diagnostic head employs a Bayesian uncertainty-aware classifier to ensure more reliability in the prediction of malignancy. It is trained on 5-fold cross-validation, AdamW, and a cosine annealing scheduler, which is set on Python 3.10. It is demonstrated by the performance of the CBIS-DDSM mammography dataset and a corresponding clinical dataset consisting of over 400 patients that HGGT is much superior with 98.2% accuracy, 98.7% precision, 98.5% recall, 99.2% F1-score, and 99.1% AUC-ROC, having a significant advantage over the established models of ResNet50, EfficientNet-B0 and GAN-enhanced CNN classifier. Overall, the HGGT framework is delivering a scalable, interpretable, and highly accurate diagnosis solution that was a huge improvement over the existing unimodal and poorly integrated CAD system in the detection of breast cancer.**

Keywords*—Breast cancer diagnosis; multimodal deep learning; Graph Attention Network; Bayesian uncertainty estimation; explainable AI

I. Introduction

Among the most prevalent and deadly illnesses impacting women globally is breast cancer. The WHO model states that earlier treatments dramatically lower mortality, and prompt and precise identification is crucial for increasing lifespan [1]. Since mammography allows for the quick detection of abnormalities, it is an extremely widely used technique for preventing cancer in the breast [1]. Yet, visual interpretation of mammograms [2] is an involved and labor-intensive task susceptible to subjectivity and inter-reader variability [3]. Superimposition of overlapping tissue structures, poor contrast, and nuanced variations further add to the challenge in accurate diagnosis [4]. Consequently, an increased demand exists for robust and automatic CAD systems for radiologists to detect malignancies more precisely and with greater efficiency [5].

Manual CAD systems are dependent on hand-tuned feature extraction methods and traditional machine learning tools [6]. Although some success has been reported with these methods, the quality of feature extraction and a lack of generality across large and varied datasets usually limit their performance [7]. These traditional methods further need significant amounts of domain-specific knowledge for feature engineering, limiting their flexibility towards actual clinical use [8]. The latest improvements in deep learning, specifically CNNs, have transformed medical image analysis to a great extent, with the capability for automatic feature learning and state-of-the-art accuracy in classification problems [9]. Nonetheless, deep models depend on extensive and well-labeled datasets for good generalization [10]. The rarity of labeled mammographic images and also class imbalance within datasets makes the task difficult to train precise DL models for detecting breast cancer [11]. The latest advances in breast cancer detection use deep learning on transformers and attention models, and are used on either imaging-only data or clinical-only data [12]. The study

hypothesizes a single Hybrid Graph Generative Transformer (HGGT) to integrate hierarchical mammographic image attributes with graph-coded clinical information through a contrastive multimodal alignment process to deliver high-fidelity, interpretable and uncertainty-aware diagnosis of breast-cancer. Although there is progress in multimodal breast cancer CAD, current approaches tend to use shallow fusion, poor modeling of the interactions between clinical variables and individual assessment of uncertainty. In order to address these shortcomings, this study introduces a Hybrid Graph-Generative Transformer (HGGT) that integrates hierarchical features of imaging, graph-based clinical reasoning, and Bayesian uncertainty modeling into one diagnostic model.

A. Research Motivation

Breast cancer is one of the causes of death among women and the treatment of this disease depends upon early and accurate diagnosis. Manually interpreted mammograms and single clinical evaluations have been known to be quite subjective, slow and lack uniformity. Even though higher diagnostic potential is possible with the multimodal combination of imaging and clinical data, there is still a problem of poor generalization, data imbalance, and limited interpretability in the current AI-based systems. The issues cited above represent the necessity of an integrated, hybrid, deep-learning model that can provide strong, interpretable and clinically meaningful predictions of breast cancer. The recent advancements in deep learning have provided improved performance in the system, but the existing CAD systems do not indicate the complementary relationship between the mammographic features and the patient-specific clinical characteristics. It motivates the development of a multimodal system that can acquire joint descriptions in different modalities, such that more robust situation-aware diagnostic decisions can be made.

B. Problem Statement

Diagnosing breast cancer is not easy due to the weaknesses of the current computer-aided detectors, which usually apply either of the two separately, either in mammographic pictures or clinical data. Breast cancer has been a major health concern to the world and early detection has been the most appropriate measure in increasing the survival chances and this is primarily through screening mammograms [13]. Even though the recent advances in deep learning (DL) have considerably enhanced the diagnosis of breast cancer, most of the existing systems employ either clinical or imaging data, as compared to their potential to provide the entire diagnostic image [14]. Current methods of diagnosis are still restricted by single-modality dependence, a low level of generalizability, and the lack of clinical interpretability. The state-of-the-art deep learning models are not effective at modeling complex clinical relationships and integrating heterogeneous data. This poses a sense of urgency in having an integrated, explainable multimodal structure that combines both the mammographic and clinical information into a transformer-graph architecture to have a reliable breast cancer diagnosis.

C. Research Significance

The suggested Hybrid Graph-Generative Transformer (HGGT) is a significant innovation in breast cancer diagnostics. It combines the use of generative modeling, graph-based clinical encoding, and transformer-based multimodal feature fusion into a single deep learning pipeline. This architecture can also solve most of the important challenges that include data sparsity, class imbalance, and inter-modal correspondence, and remain interpretable and uncertainty-aware predictions. The HGGT is a framework that enhances the accuracy of diagnosis and clinical reliability by combining the model of mammographic features and patient-specific clinical variables. Using transformer-based imaging analysis, clinical reasoning in the form of graphs, and contrastive multimodal fusion, HGGT makes interpretable predictions and uncertainty-aware predictions. It is the relationship between radiological observations and formalized clinical experiences and the following generation of multimodal, precision-concentrated CAD systems.

D. Research Question and Hypothesis

Do unified multimodal deep learning systems, which combine mammographic images with structured clinical data using graph-based reasoning and transformer-based fusion, offer more accurate, interpretable, and uncertainty-aware breast cancer diagnosis compared to current unimodal or loosely integrated CAD systems?

We hypothesize that joint hierarchical image features and interaction of clinical variables modeled with Hybrid Graph-Generative Transformer (HGGT) will significantly improve diagnostic performance, high resiliency to class imbalance, and clinical meaningfulness.

E. Key Contributions

- Proposes a common framework of HGGT that gives precedence to a mammographic image and organized clinical information in the diagnosis of breast cancer.
- Introduces graph-guided transformer fusion to explicitly model clinical biomarker interactions beyond conventional feature concatenation or shallow multimodal fusion.
- Derives a fusion strategy based on contrastive pyramid fusion that matches the representation of imaging at multiple levels with clinical aspects to enhance the resilience of class imbalance.
- Integrates Bayesian uncertainty estimation and dual-modality explainability to support reliable, interpretable, and clinically meaningful diagnostic decision-making.

The rest of the study is structured in the following manner: Section II includes a thorough literature review of the literature concerning the topic of breast cancer diagnosis and multimodal deep learning. Section III gives the research problem and outlines the proposed Hybrid Graph-Generative Transformer (HGGT) methodology step-by-step. Section IV reports the experimental framework, findings, and performance analysis of the proposed framework. Lastly, Section V gives a conclusion in the study outlining the main findings and possible ways of conducting further studies.

II. Literature Review

Although ultrasound imaging is a vital diagnostic technique used to identify breast cancer, the efficiency of computerized

diagnosis systems is typically limited by the absence of properly annotated data. Chaudhury and Sau [15] suggest a deep learning (DL)-derived architecture that incorporates TL, GANs and a creative data augmentation method for ultrasonography image-based mammary mass classification. Because breast tumors can be accurately identified through minimally invasive procedures, thanks to early identification and precise categorization, they can significantly reduce the number of fatalities. Data augmentation by GAN enhances classification performance, and TL-based feature extraction enhances accuracy even more. Results prove the effectiveness of DL approaches to classify breast ultrasound images. The current article proposes a new technique of breast mass detection via data augmentation using GAN and TL-based feature learning for enhanced diagnostic performance. Results presented illustrate how this approach outperforms existing algorithms and has the capability to improve computer-assisted breast cancer diagnosis systems.

It is a severe global health problem that needs to be continuously enhanced in terms of approaches to identification and classification. In reference to identifying breast cancer a machine learning approach is described by Alawee et al.[16] as a result of distinguishing benign and malignant mammography. The study recommends a two-hidden-layer ANN model in order to enhance the accuracy of the classification. Before analysis, mammography images are subject to preprocessing, including data denoising, contrast normalization, and a GAN to make the data better. This is a multi-step improvement of image quality that reforms the information in an analysis-optimized format through the vectorization of pixel data. It is only on such improved images that ANN is trained, and the results are good as far as the improvement of classification performances is concerned. The experimental findings suggest the existence of accuracy improvement over normal scans, and accuracy in the final model is close to perfection with different preprocessing strategies. In the study, the strength of data augmentation and ANN-classification when used in the context of medical imaging has been emphasized, as well as how these resources can be used to impact the detection and treatment at its initial stages. This powerful platform of detection is a valuable contribution to biotechnology and an area where new AI-based applications of medical diagnosis are justified.

Strelcenia and Prakoonwit [17] explains past research has proven that early and precise detection can have a huge impact on patient outcomes. GANs have been gaining attention in medical imaging in recent times to create synthetic images as well as non-image data for diagnostic use. Provide a K-CGAN technique that produces high-quality simulated data by learning in several distinct settings. Five distinct categorization and feature extraction methods were applied to the non-image Wisconsin Breast Cancer dataset, consisting comprised 212 benign and 357 malignant instances, to use synthetic data to assess our proposed K-CGAN's effectiveness. Our empirical study's findings support the notion that K-CGAN outperforms other GAN types in terms of classification accuracy and stability. Our evidence demonstrates that K-CGAN-generated synthetic data closely resembles the actual dataset.

Swiderski et al. [18] present the Autoencoder-GAN (AGAN) model, which was used in the evaluation of mammograms as a data augmentation method to generate additional mammogram images. This aids in enhancing the current dataset, addressing the problem of limited data in medical images. The created images and actual mammograms were fed into a CNN for classification. The proposed system was designed to differentiate normal from abnormal mammograms. The proposed system was implemented for identifying and an experimental assessment was performed on a large dataset of image database. The outcome proved the superiority of the developed deep learning model over current mammogram classification methods. These performance metrics are among the best for this big data, indicating the effectiveness of AGAN-based augmentation in improving breast cancer diagnosis.

Sharma et al. [19] conducted a comprehensive comparative study whose aim was to determine the most effective deep learning architecture to classify mammographic breast cancer. They were aimed at comparing general-purpose models (including ResNet50, ConvNeXt, ViT) to mammography-specific models (including FCCS-Net, ViT-Mammo, and GLAM-Net) with a single benchmarking plan. The authors used four publicly available datasets, which guaranteed the reproducibility of experimentation based on similar training protocols. Their assessment was multi-dimensional, with their classification performance, interpretability through Grad-CAM and attention maps, model calibration, inference time, complexity of computation and deployment in the list of assessment criteria. It was shown that mammogram-specific models, especially FCCS-Net and ViT-Mammo, displayed a higher diagnostic performance and a more enhanced visual interpretability, with ViT-Mammo presenting an AUC of 0.961. EfficientNetB0 and DenseNet121 were lightweight architectures that were well-suited to deployment on the edge. Nevertheless, variability in datasets is the main limitation of the study since inconsistency between datasets could restrict the model's generalizability, and clinical validation in actual practice has not yet been studied.

Zhang et al. [20] have suggested a miscellaneous supervised multi-view mammography screening framework that is aimed at addressing the weakness of traditional mammography interpretation. Their study was to ease the workload of radiologists, solve the low uptake in the remote geographical areas and overcome the lack of sufficient data to support intelligent early screening systems. The authors presented a context clustering -based feature extraction mechanism, unlike CNN and transformer architectures, augmented with multi-view learning to complement information between mammographic perspectives. They tested the model on 2 publicly available datasets, VinDr-Mammo and CBIS-DDSM, and obtained competitive results with reduced parameter counts, having the AUC scores of 0.828 and 0.805, respectively. This is the major strength of the model since it has a low-cost of computation and is adaptable under a weak supervision state, which is promising in low-resource environments. The method, however, has shortcomings that include moderate accuracy relative to current transformer-based models, non-availability of interpretability tools and requirement to further validate the methodology on larger and more diverse clinical data.

Fatima et al. [21] utilized a methodology of research to examine the progress of deep learning in medical image segmentation involving medical imaging modalities, such as

MRI, CT, ultrasound, dermoscopy, and histopathology. Their study was aimed at analyzing the segmentation techniques, describing the new transformer-based architectures, and comparing the trends of the performance through the PRISMA review framework. The authors have analyzed a large variety of datasets in different modalities with much emphasis on dermato-pathology and skin lesion imaging. Their findings have proven that transformer-based models are much better than the traditional CNN-based methods with the highest accuracy of 79.95 per cent in multitask cancer detection or 93.4 per cent in liver lesion segmentation. Frameworks that enhanced attention like G2LL and PistoSeg, further enriched the accuracy of segmentation by 5-15 per cent. Although these things are accomplished, the review also points out that there are multiple limitations: they require substantial computational time, are dependent on large sets of annotated data, and cannot generalize to other imaging fields or run all complicated transformer models on a clinical device in real-time.

Breast cancer has to be managed and treated early in time. Prodan et al. [22] also discuss the use of DL algorithms to improve the process of mammography analysis and pay special attention to the necessity to use advanced computational methods to enhance the performance. The project analyzes several computer vision architectures (CNNs and ViTs), observed on a publicly available dataset. Synthetic data augmentation to enhance the performance of a model is one of the primary characteristics of the research. The importance of preprocessing and data augmentation methods in attaining high classification accuracy is demonstrated by the experimental results. The results highlight the value of data augmentation in maximizing the efficacy of deep learning in mammography classification.

Despite the effectiveness of CNNs, GANs, and transformer-based models, which have been established in the previous studies to handle breast cancer diagnosis, most of the methods are constrained to single-modality inputs, do not explicitly model clinical feature interactions, and give deterministic predictions without estimating uncertainty. Simply concatenating features, multimodal efforts tend to be unable to represent fine-grained cross-modal correspondences or be subject to clinical interpretation. Moreover, there are not many systems combining graph-based clinical reasoning with hierarchical images representations. Such deficiencies encourage the construction of the proposed HGGT framework, integrating the multimodal fusion, graph attention, contrastive learning, and Bayesian uncertainty modeling within a single and interpretable architecture.

III. Multimodal Transformer-GAT Breast Diagnosis Framework

The proposed research, a hybrid framework named Hybrid Graph–Generative Transformer (HGGT) will be created that will acquire knowledge of the trends of the mammographic images as well as the patterns between the patient and the mammography to enhance the diagnosis of breast cancer. The HGGT integrates hierarchical visualization with graphical clinical reasoning because mammograms cause structure patterns which have proven essential in identifying breast cancer and relation dependencies between clinical variables including hormone receptor status, histological type, and the disease stage. The conventional computer-aided diagnostic (CAD) systems are primarily based on imaging modalities, and they fail to capture important contextual variables, including tumor stage, receptor status, or histological variables. On the contrary, clinical data only based models are unsuccessful in representing the rich structural and textural variations which can be found in mammograms. As a solution to these shortcomings, the offered HGGT framework will be based on the hybrid multimodal approach that uses the advantages of both imaging and non-imaging data sources to aid each other. Mammographic and clinical data is preprocessed to create consistency and quality at the start of the pipeline. The feature extraction is done in two complementary but independent directions which consist of a Swin Transformer-CNN fusion that extracts both global and local features based on mammograms and a Graph Attention Network (GAT) which codes the relationships among the clinical features. These embeddings are then cross-modally fused together, and these embeddings are projected to a single latent space that reflects the general characteristics of the disease. Lastly, adaptive Bayesian diagnostic head can predict the probability of malignancy with uncertainty estimation, which are facilitated by visual and clinical interpretability tools. The proposed strategy is a multimodal fusion strategy, unlike other traditional multimodal fusion strategies, which incorporates both graph-based clinical reasoning and hierarchical transformer features together as a single fusion pipeline. Fig. 1 shows the entire process of the proposed methodology.

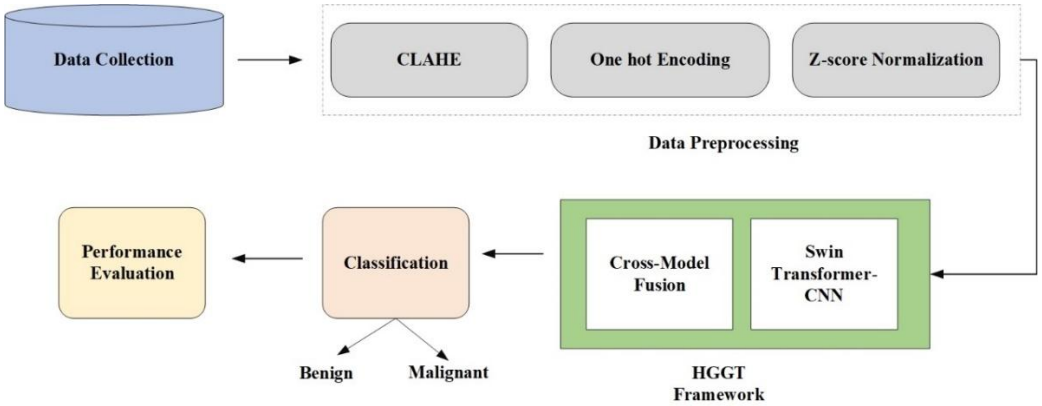

Fig 1. Proposed framework for breast cancer detection.

A. Data Collection

The study creates a strong diagnostic model using two complementary datasets, where firstly CBIS-DDSM repository comprises two datasets of 6,775 and 10,239 high-resolution mammograms of 1,566 clinically profiled participants [23]. The images are of different cases of breast cancer such as normal, benign, and malignant lesions with confirmed pathology, and thus can be used in the development and testing of CADx and CADe systems. Dataset 2 includes clinical and proteomic data of patients with breast cancer, patient demographics, stage of the disease, histology, and hormone receptor status (ER, PR, HER2), protein expression levels, surgery type, and patient outcome (alive/dead) [24].

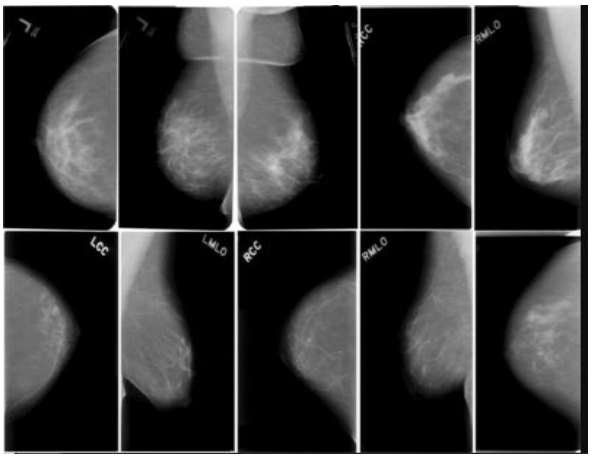

Fig 2. Multiview structural mammary radiograph set.

Fig. 2 presents mammographic images that are organized in two rows which demonstrate the craniocaudal (CC) and the mediolateral oblique (MLO) projections of various breasts. All panels show an X-ray image in grayscale with different degrees of densities of breast tissue observable whereby there are fatty tissues and more dense fibroglandular tissues. The borders of the breasts are well defined and the patterns of the internal tissues seem to be heterogeneous with the presence of overlaying layers that are common in screening mammograms. These labels include LCC, LMLO, RCC, and RMLO to show the orientation of the left and right breast and the imaging angles. In general, the set represents a realistic visual image of the multi-view mammographic acquisitions in clinical screening of the breast to guarantee the visualization of the structures of the breast.

B. Data Pre-Processing

To achieve adequate deep learning to detect breast cancer, both images of mammograms and clinical data should be properly preprocessed. The preprocessing of the images entails the extraction of the breast region through thresholding and connected component analysis and resizing all the images to 512 x 512 to provide uniform input to the Swin Transformer backbone. The intensities of the pixels are normalized with the z-score and CLAHE is used to increase the visibility of the lesions.

$$Z_n(x,y) = \frac{Z(x,y)-\mu}{\sigma} \quad (1)$$

In Eq. (1), $Z(x, y)$ is the original pixel intensity and feature value, μ is the mean intensity, σ is the standard deviation, and $Z_n(x, y)$ is the normalized pixel value.

$$I_{eq}(x,y) = \frac{(L-1)}{MN}\sum_{i=0}^{I(x,y)} h(i) \quad (2)$$

In Eq. (2), L is intensity level number, M and N are image size, $h(i)$ is count of histogram intensity i, $I_{eq}(x, y)$ is improved image intensity.

C. Feature Extraction via Hybrid Fusion

1) Imaging pathway: The imaging pathway uses a hybrid CNN architecture based on Swin Transformer to generate a set of diverse features of mammograms. The Swin Transformer represents the world contextual information, general breast structures, tissue distribution, and spatial relations of the whole image. This allows the network to learn macro-level trends that will be important in the detection of malignancies that can be large. At the same time, the CNN element activates on local, fine-gained characteristics, including the shape of lesions, margins, textures, and microcalcifications, and secures that subtle signs of illness are maintained. With the two architectures put together, the model has both global and local structural understanding which enhances its effectiveness in discriminating between benign and malignant tissues. The hybrid scheme enables the downstream modules to take advantage of a rich and multiple scale set of features to improve the overall predictive performance and interpretability of the breast cancer diagnosis model. The architecture combines CNN and multi-scale Swin Transformer phases starting with patch partitioning and linear embedding which allows the ViT branches and convolutional layers to concatenate and feed into a linear detecting module which allows localization of breast cancer and a robust learning of multi-resolution features. The visual representation is shown in Fig. 3.

2) Clinical pathway: Graph Attention Network (GAT) is utilized to encode patient-specific clinical characteristics, including age, tumor stage, receptor status (ER/PR/HER2) and histology. The GAT is able to capture interdependencies between clinical features and the model is able to comprehend how particular biomarkers, stages, or demographic variables affect each other with regard to malignancy. Here, patient attributes are modeled as nodes and the relationship among the features are modeled as edges, which allows the network to learn weighted interactions between the features that can be used to determine their relative importance in the diagnosis process. The attention mechanism of GAT assigns learnable attention coefficients α_{ij} to the edges between nodes, computed as shown in Eq. (3):

$$\alpha_{ij} = \frac{\exp\left(LeakyReLU(a^T[Wh_i||Wh_j])\right)}{\sum_{k\epsilon \mathrm{N}(i)} \exp\left(LeakyReLU(a^T[W_{x_i}||W_{x_k}])\right)} \quad (3)$$

where, h_i and h_j are node feature vectors, W is a learnable weight matrix, a is the attention vector, and $\mathrm{N}_i$represents the neighbors of node i. The final node representation is obtained, as shown in Eq. (4):

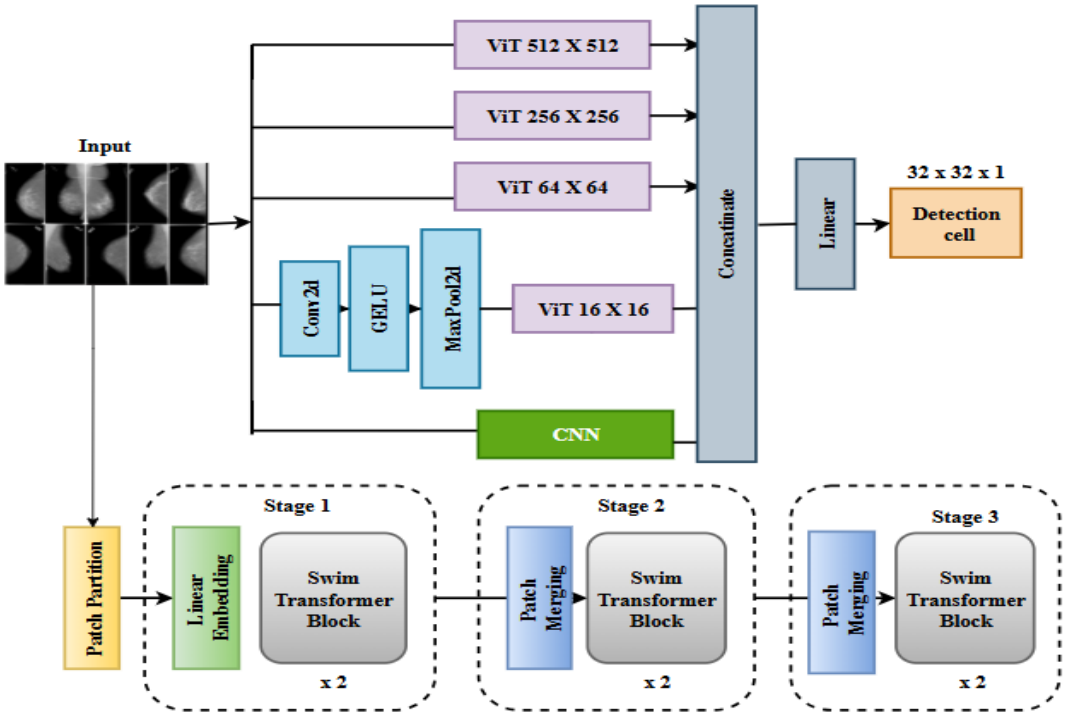

Fig 3. Swin Transformer: CNN architecture for breast cancer detection.

$$h_i' = \sigma(\sum_{j \in N_i} \alpha_{ij} W h_j) \quad (4)$$

Such a mechanism gives priority to the most predictive clinical features and makes sure that important data has a higher contribution to the downstream fusion with imaging embeddings. The resulting embeddings offer a rich representation of patient-centric clinical profiles, enhancing predictive capacity, interpretability, and clinical usefulness of hybrid HGGT framework. The system can predict malignancy more accurately and reliably, with more meaningful clinical predictions by modeling these complicated dependencies.

3) Cross-modal fusion: A contrastive pyramid fusion mechanism is used to align the embeddings of both the imaging and clinical pathways in a common latent space in order to be able to combine imaging and clinical information effectively. This strategy will guarantee that the complementary information between both of the mammograms and patient specific attributes are pooled together in a way that will not affect the relationships within and across modalities. The fusion mechanism is mainly concerned with regional-level fusion, in which imaging characteristics of certain quadrants of the breast are correlated with certain clinical variables, including tumor stage or histology of the region. This allows the model to develop a relationship with contextual imaging patterns and clinical features to develop a more comprehensive knowledge of disease manifestations. The conflicting nature of the fusion stimulates consistency between imaging and clinical embeddings without losing modality-specific discriminative characteristics. Consequently, the unified representation has complete spatial and clinical information that enhances the system to distinguish between benign and malignant conditions. The pyramid fusion mechanism improves the interpretability as well as the predictive power of the hybrid HGGT framework by focusing on clinically relevant regional correlations. This will enable the model to provide patient-specific predictions of malignancy, which are not only accurate but also clinically relevant which is why it is essential in real-life settings of breast cancer diagnostics.

a) Local level: On local level, the model focuses on minute relationships between individual mammographic lesions and clinical biomarkers. Characteristics of the lesion (shape, size, margin and texture) used as indicators of malignancy are correlated with patient specific characteristics (ER/PR/HER2 status and histopathological outcomes). Lesion-level imaging embeddings are contrastively fused against clinically useful feature embeddings, promoting biologically meaningful associations. This would enable detection of the minor cases of abnormalities that could not be known by the global analysis and sensitivity to the early tumors. The local-level mapping is also more interpretative in that the observer can easily view what lesions and biomarkers are being taken to inform the diagnosis making it a clinically coherent relationship between the visual evidence and the patient biology. It is expressed in Eq. (5):

$$\mathcal{L}_{local} = -\log\left(\frac{\exp(sim(z_i, z_c)/\tau)}{\sum_{k=1}^{N} \exp(sim(z_i, z_k)/\tau)}\right) \quad (5)$$

$\mathcal{L}_{local}$ measures the correspondence between the data of individual lesion imaging and the related biological biomarkers, supporting fine grained associations. It enhances the early

detection of tumors by increasing similarity between true lesion biomarker pairs and dissimilarity irrelevant pairs.

b) Regional level: At the regional level, the specific emphasis on individual lesions is replaced with more general consideration of specific breast quadrants, combining the examination of imaging characteristics with the relevant clinical data. The quadrants of each breast are examined to retrieve the trends of the tissue distributions, changes in densities, and the clustering of the lesions that can represent localized disease development. These regional imaging phenomena are integrated with clinical qualities appropriate to that quadrant, including the tumor stage, histology, or regional biomarker expression, to obtain a situation in which there is a relationship between the anatomical structures and biological markers. The pyramid fusion of contrastive coupling combines imaging embeddings z_i and clinical z_c paths on the regional level, with paired embeddings being dragged towards each other and unrelated ones being drawn away. This is optimized through contrastive loss that is defined, as shown in Eq. (6):

$$L_{con} = -log \frac{\exp(sim(z_i, z_c)/\tau)}{\sum_{k=1}^{N} \exp(sim(z_i, z_k)/\tau)} \quad (6)$$

where, sim $(\cdot)$ is the cosine similarity function, τ is the temperature parameter, and N is the number of samples in batch [see Eq. (7)].

$$\mathcal{L}_{regional} = -\log\left(\frac{\exp(sim(z_i, z_c)/\tau)}{\sum_{k=1}^{N} \exp(sim(z_i, z_k)/\tau)}\right) \quad (7)$$

$\mathcal{L}_{regional}$ optimizes contrastive fusion between quadrant-level imaging patterns and region-specific clinical attributes. It models localized disease progression, ensuring anatomically meaningful embeddings while discouraging incorrect clinical associations within each breast region.

With its focus on the connection with the clinical data and the quadrant-level imaging patterns, the model consequently reveals the subtle interactions, including the effect of tumor staging on the morphology of lesions or a group of lesions within a quadrant. The regional-level integration improves predictive performance by providing the link between the local lesion characteristics and the global breast-level contexts in addition to improving interpretability by providing clinically significant correlations.

c) Global level: The cross- modal fusion mechanism of global level will integrate the whole breast imaging features with the whole clinical history of the patient to acquire macro-level patterns that can be used in diagnosing. The imaging route also provides a clear image of the breast structure, tissue distribution, bilateral symmetry as well as general change in organization which can result in the implication of diffuse or multifocal malignancies. These universal visual representations are integrated with the specific clinical variables, including the demographics, tumor stage, receptor status and histological data. By making the two modalities correlated to latent space, contrastive fusion enables the model to learn common patterns, and complementary interactions, which cannot be learned when the two data are trained separately when imaging and clinical data are used. The integration will assist HGGT to place local and regional abnormalities within the broader context of the physiological, and clinical history of the patient. The given form of panoptic gaze is not only more precise in diagnosis, particularly regarding the multi lesion or complex cases, but also more interpretable since the fact of developing the global breast features and knowing the patient in its entirety has been demonstrated to be predictive of malignancy. It is expressed in Eq. (8):

$$\mathcal{L}_{global} = |f_{img}(X_{breast}) - f_{clin}(C_{patient})|_2^2 \quad (8)$$

$\mathcal{L}_{global}$ minimizes the L2 distance between whole-breast imaging representation $f_{img}(X_{breast})$and complete clinical profile embedding $f_{clin}(C_{patient})$, enabling holistic multimodal alignment that captures global diagnostic trends.

D. Adaptive Diagnostic Head

The adaptive diagnostic head uses a Bayesian classifier to give malignancy predictions along with estimates of confidence that the model may use to assess the predictive uncertainty. The Bayesian approach contrasts with the traditional deterministic classifiers which make only point predictions, but the distribution of the prediction probabilities. For an input representation x, the predictive distribution is developed, as shown in Eq. (9):

$$p(y|x, D) = \int p(y|x, w)p(w|D)dw \quad (9)$$

where, $p(y|x,w)$ is the likelihood, given the model parameters w, and $p(w|D)$ is the posterior distribution over weights conditioned on the training data D. Since the exact posterior is intractable, variational inference or Monte Carlo dropout is employed to approximate this integral, yielding both class probabilities and uncertainty estimates.

This uncertainty-conscious model enables the model to differentiate between confident and uncertain predictions to contribute to more trustworthy clinical decision-making. Grad-CAM++ and attention heatmaps are also added in order to make the process more interpretable, and to identify the important parts of the image and clinical features that predict malignancy. Such two-fold focus on quantification of uncertainty and explainability makes the HGGT framework a predictive framework that gives not only accurate predictions, but also makes them transparent and clinically meaningful.

E. Training Objective

HGGT framework is end-to-end trained with the unified goal to achieve accurate classification, effective cross-modal alignment, and uncertainty estimation. In general, the loss is determined, as shown in Eq. (10):

$$L_{total} = \beta L_{cls} + \gamma L_{con} + \delta L_{unc} \quad (10)$$

Here, LL_{cls} is the classification loss, which is represented with cross-entropy and guarantees the similarity of the predicted malignancy outcome with the actual diagnostic results. L_{con} is the contrastive loss, which aims at aligning mammogram embeddings Swin-CNN with those of clinical embeddings of the GAT and enhances shared feature space representation. L_{unc} represents the uncertainty-sensitive loss, which also applies a penalty to incorrect judgments which are overconfident and

promotes better model calibration of Bayesian inference ideas. The coefficients β, γ and, δ are weighting factors to equal the contribution of each term of loss. With these values changed, the framework can focus on accuracy, consistency of representation or uncertainty calibration when needed. This integrated training approach guarantees that HGGT not only demonstrates high predictive accuracy but also gives reliable, interpretable and clinically meaningful results. The combination of classification, contrastive alignment, and uncertainty modeling enables the system to generate strong diagnostic predictions and also has transparency in how the system arrives at a decision.

Algorithm 1: HGGT Framework for Breast Cancer Detection

Input:
Medical Images (X)
Clinical Data (C)
Labels (Y)
Output:
Predicted Diagnosis (Ŷ)
Data Preprocessing
Normalize images (min-max scaling)
Clean & normalize clinical data (z-score normalization)
Split into training, validation, and test sets
Feature Extraction
Imaging Pathway: Swin Transformer for global structures + CNN for fine-grained lesion features.
Clinical Pathway: Graph Attention Network (GAT) encodes interdependencies among clinical features

$$h_i' = \sigma(\sum_{j \epsilon N_i} \alpha_{ij} W h_j)$$

Cross-Modal Fusion
Contrastive pyramid fusion aligns imaging and clinical embeddings.
Regional-level fusion applied with contrastive loss:

$$L_{con} = -log \frac{\exp\ (sim(z_i, z_c)/\tau)}{\sum_{k=1}^{N} \exp\ (sim(z_i, z_k)/\tau)}$$

Adaptive Diagnostic Head
Bayesian classifier predicts malignancy with uncertainty:

$$p(y|x, D) = \int p(y|x, w) p(w|D) dw$$

Grad-CAM++ and attention heatmaps provide interpretability.
Training Objective
Unified loss:

$$L_{total} = \beta L_{cls} + \gamma L_{con} + \delta L_{unc}$$

Return

Algorithm 1 illustrates the HGGT model proposed, which incorporates both mammographic and clinical data to make a strong diagnosis of breast cancer. The preprocessing stage starts with the extraction of breast regions, resizing mammograms to less than 512×512 , z-score normalization, and z-score CLAHE. Clinical data are encoded to achieve compatibility with a standardization of clinical data. The next step in the feature extraction process involves a two-way line of initiative: a hybrid Swin Transformer CNN can extract both global structural and fine lesion features of mammograms whereas a Graph Attention Network (GAT) codes the patient-specific features and the interdependencies between them, defined by attention-weighted interactions. A contrastive pyramid mechanism is used to perform cross-modal fusion by matching imaging and clinical embeddings in a shared latent space. Fusion on a regional level prioritizes the correlations of the breast quadrants with the tumor stage or histology, minimized with contrastive loss. The adaptive diagnostic head uses a Bayesian classifier to provide predictions of malignancy with uncertainty calibration and Grad-CAM++ to provide interpretability.

IV. Results and Discussion

The Experimental analysis of the proposed HGGT framework indicates that it is effective in reliability and it is better than the traditional deep learning models in the diagnostic performance. The model is well balanced and strongly classified with accuracy, precision, recall and F1-score even in a case of class imbalance. The comparisons with HGGT show that it outperforms CNN, VGG16, ResNet50, EfficientNet-B0 and GAN-assisted CNN models on all metrics, which indicates that it has a good multimodal fusion capacity. The ablation study also confirms the fact that each individual aspect of the study including the attention mechanisms, CycleGAN augmentation as well as Swin-CNN-GAT integration contribute significantly to the performance increment. Grad-CAM++ visualizations reveal that the framework is effective at localizing malignant regions, as GAT attention maps show the importance of clinical biomarkers such as tumor size, ER as well as PR status. All in all, the results prove HGGT to be a fit, understandable, and valid model in the diagnosis of breast cancer.

TABLE I. Simulation Parameters

Parameter	Value
Dataset	CBIS-DDSM
Image Resolution	512 × 512 pixels
Methods used	Swin Transformer + CNN, Graph Attention Network,
Batch Size	16
Initial Learning Rate	1e-4 with cosine annealing scheduler
Optimizer	AdamW
Epochs	150 (with early stopping)
Dropout Rate	0.3
Weight Decay	5e-5
Cross-validation	5-fold cross-validation
Evaluation Metrics	Accuracy, Sensitivity, Specificity, F1-score, AUC-ROC
Software	Python 3.10

Table I illustrates the HGGT framework simulation parameters are designed to give strong and yielding prediction of breast cancer. The data used in the analysis are CBIS-DDSM

in which the mammogram images have already been preprocessed to 512 512-pixels resolution. The model includes Swin Transformer + CNN with images and Graph Attention Network (GATT) with clinical data. AdamW optimizer is applied to train and initial learning rate is 1e-4 in the form of cosine annealing with a batch of 16 and 150 epochs total with early stopping. Regularization dropout rate 0.3 weight decay 5e-5. The 5-fold cross-validation was considered as evaluation methods and such metrics like accuracy, sensitivity, specificity, F1-score, and AUC-ROC were used.

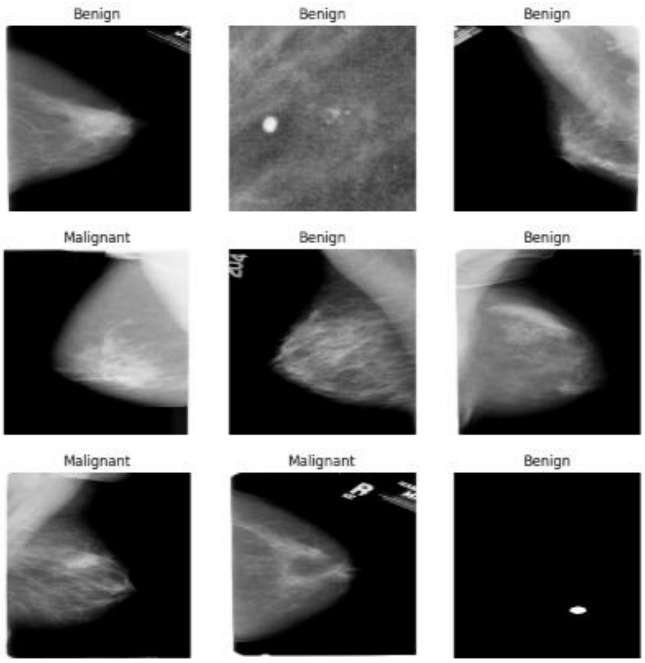

Fig 4. Breast image classification.

Fig. 4 shows a collection of mammogram images grouped as benign and malignant cases. The dataset grid has nine samples distributed across three rows and three columns, highlighting the variability in tissue patterns and tumor appearances. The benign images generally consist of localized or well-delineated areas with comparatively uniform density, while the malignant images exhibit irregularly dense structures with poorly defined borders, which are indicative of invasive growth.

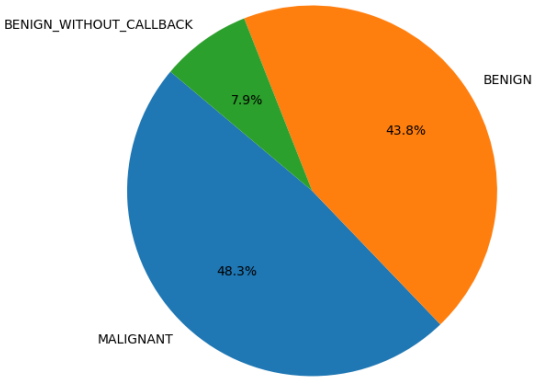

Fig 5. Class distribution.

Fig. 5 shows the division of the medical imaging results into three diagnostic types: Malignant, Benign, and Benign without Callback. Malignant conditions form the highest percentage at 48.3%, showing a high prevalence of confirmed malignancies. Benign conditions cover 43.8%, showing a significant percentage of non-cancerous findings. The lowest category, Benign without Callback, occupies merely 7.9%, showing the cases in which no follow-up was needed.

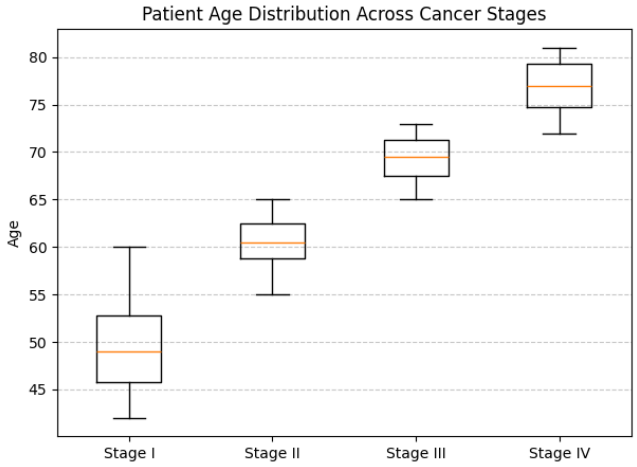

Fig 6. Patient age distribution across cancer stages.

Fig. 6 displays the distribution of the age of the patients in various stages of breast cancer. There is a separate box, denoted by each stage, Stage I, Stage II, Stage III, and Stage IV, which shows the median, interquartile range (IQR), and the minimum and maximum ages. In Stage I, the median age is less, at around 49 years, with a broader range of between 42 and 60 years, signifying that there is more variability in younger patients. The median ages are increasingly higher in Stage II and III at about 60 and 69 years, respectively, with smaller age ranges. The median age of patients in stage IV is the largest in 77 years, implying that later stages have more representation in older cohorts.

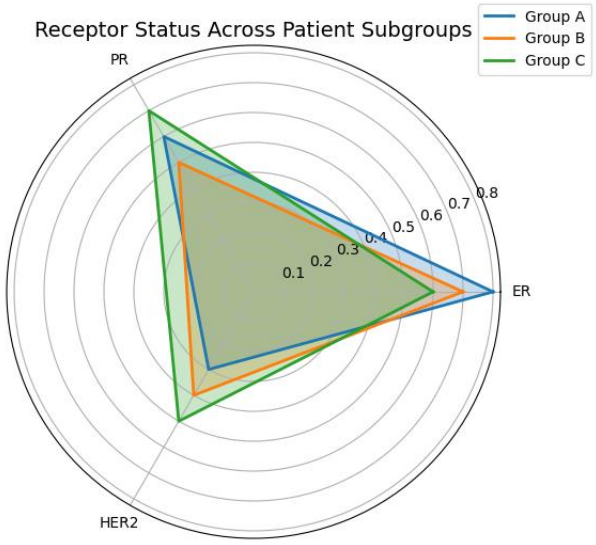

Fig 7. Receptor status across patient subgroups.

Fig. 7 depicts the receptor status (ER, PR, HER2) in three groups of patients in: Group A, Group B, and Group C. The axis depicts the value of each receptor type, and therometers are 0-0.8, which is the extent of receptor expression. Group A has the highest ER expression and Group C indicates the highest PR expression. HER2 expression is relatively low in all the groups, with a slight increment in Group C than Group A and B. The filled areas show differences in receptor patterns, with a particular emphasis on the fact that each subgroup has a different molecular profile.

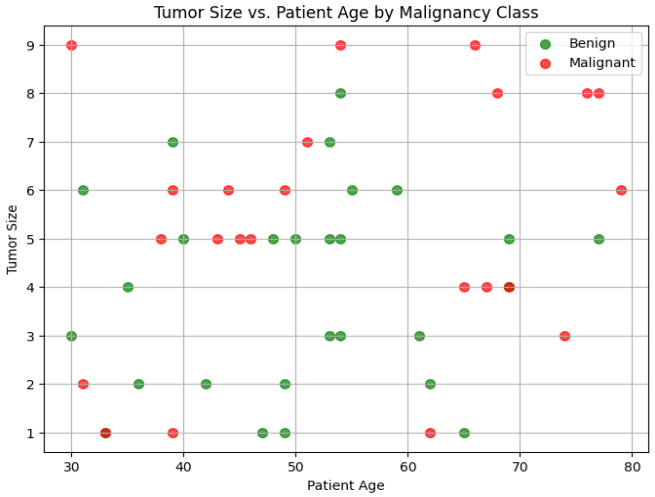

Fig 8. Tumor size vs. Patient age by malignancy class.

Fig. 8 can be used to show the correlation between the age of patients and the size of the tumor, according to the classification of malignancy. The points are the representatives of individual patients, and green markers are the indicator of benign tumors, whereas red markers denote the malignant tumors. The sizes of tumors are 1 to 9, whereas the ages of the patients do not exceed 30 to 80 years. The plot exposes that malignant tumors develop in a vast age bracket and are frequently larger in size, but there are also small malignant tumors. Benign tumor is evenly spread in terms of size and age.

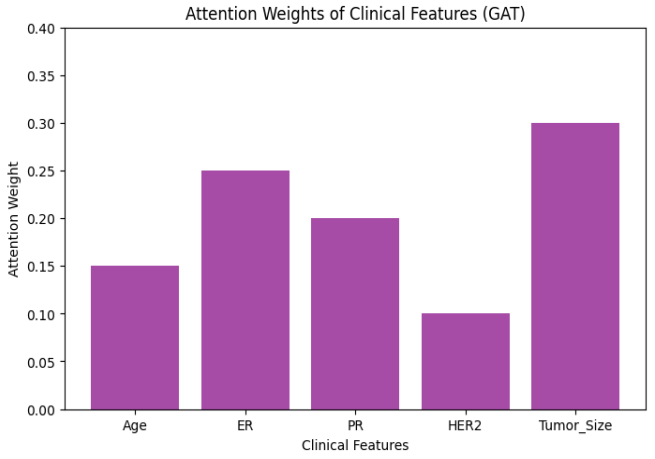

Fig 9. Attention weights of clinical features.

Fig. 9 depicts weights of attention of clinical features obtained using GAT model, and their significance in relation to their role in diagnosis prediction. Among the characteristics, the most important contribution is made by Tumor_Size, which suggests that it has a dominant contribution to clinical decision-making. ER and PR comes next with a medium level of importance as they play a great role in diagnostic interpretation. The smaller weight is supported by age, which implies a less direct but also relevant influence, whereas the contribution of HER2 is the lowest, indicating the lack of significance in this respect. In general, the image highlights that the size of tumor, and features of their receptors are the greatest clinical drivers that the model uses to make effective medical predictions.

A. Performance Evaluation

Standard metrics are used to assess the categorization model's accuracy, while confusion matrix evaluation is used to measure false positives and misleading negatives.

1) Accuracy: Accuracy is a measure of the model's overall accuracy in prediction and is given in Eq. (11):

$$Accuracy = \frac{tp+tn}{tp+tn+fp+fn} \quad (11)$$

where, tp is Rightly labeled malignant cases, tn Rightly labeled benign cases, fp is Wrongly labeled benign cases as malignant, fn: Wrongly labeled malignant cases as benign.

2) Precision: Precision calculates the ratio of malignant cases correctly identified out of all cases that are predicted to be malignant in Eq. (12):

$$Precision = \frac{tp}{tp+fp} \quad (12)$$

A high precision value means fewer false positives, and this is particularly important in medical diagnosis to prevent unnecessary biopsies.

3) Recall: Recall is the proportion of valid malignant cases that were properly identified in Eq. (13):

$$Recall = \frac{tp}{tp+fn} \quad (13)$$

It will have less false negatives and a high recall, which is important in breast cancer screening to limit missed diagnosis.

4) F1-score: The F1-score is a balance between Precision and Recall, hence it is more appropriate for imbalanced sets in Eq.(14):

$$F1-Score = 2 \times \frac{Precision \times Recall}{Precision+Recall} \quad (14)$$

High F1-score indicates that the model is maintaining precision and recall in equilibrium.

TABLE II. PERFORMANCE METRICS

Metrics	Value%
Accuracy	98.2
Precision	98.7
Recall	98.5
F1-Score	99.2

Fig. 10 and Table II show the performance measures of the model, and it is effective in the four important measures. The

model has an accuracy of 98.2 % and demonstrates how well it performs on the predictions in general. The accuracy is 98.7 %, which shows that the model has a high capability of reducing false positives. The recall is also a bit lower (98.5 %), which indicates the ability of the model to report the important instances without recording the false negatives. Single accuracy of the F1-score, which combines both the precision and recall, has the highest value of 99.2 %, which is consistent and strong. Altogether, these measurements prove the great reliability of the model, harmonized predictive power, and its ability to be applicable in practice when performing medical diagnostic tasks.

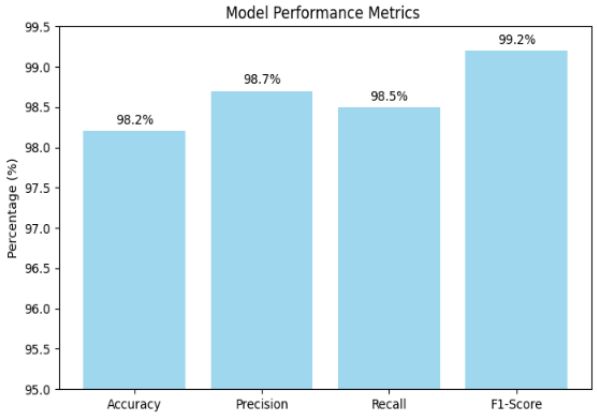

Fig 10. Performance metrics.

B. Comparison Metrics

Table III and Fig. 11 introduce a comparison analysis of the performance of different deep learning models used in the diagnosis of breast cancer. The performance indicators like accuracy, precision, recall, F1 score, and AUC ROC of standard architectures, such as CNN, VGG16, ResNet50, and EfficientNet B0, show increasing improvement regarding all these metrics, which signifies improved feature extraction and classification performance. The hybrid of GAN and CNN is another way of improving the performance of predictive, and symbolizes the power of generative augmentation. It is worth noting that the proposed model has the best scores in accuracy, 98.2 %, precision, 98.5 %, recall, 99.2 % and F1 score, 99.1 % AUC ROC, indicating its superior diagnostic ability. These findings show that the hybrid method proposed is effective in detecting breast cancer using multimodal data.

TABLE III. PERFORMANCE COMPARISON

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC-ROC (%)
CNN [25]	91.5	89.6	90.2	89.9	93.0
VGG16 [26]	94.2	93.5	94.0	93.7	95.6
ResNet50 [27]	95.0	94.1	95.5	94.8	96.5
EfficientNet-B0 [28]	95.6	95.0	95.7	95.3	97.2
GAN + CNN [17]	96.0	95.4	96.8	96.1	97.8
Proposed Model	98.2	98.7	98.5	99.2	99.1

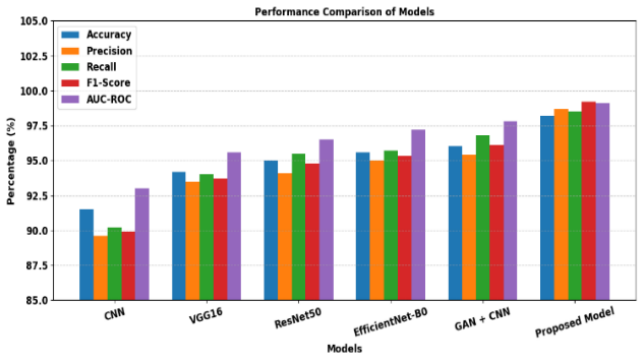

Fig 11. Performance metrics comparison.

TABLE IV. ABLATION STUDY

Model Variant	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Swin Transformer Only	94.8	94.0	95.1	94.5
Swin + Attention Mechanisms	96.1	95.5	96.8	96.1
Swin + CycleGAN Synthetic Images	96.8	96.2	97.5	96.8
Swin Transformer-CNN + GAT	98.2	98.7	98.5	99.2

Table IV reflects the performance comparison of various model variants that are developed on Swin Transformer in the diagnosis of breast cancer. The Swin Transformer with the basic architecture has a high baseline accuracy of 94.8 %. This addition of the mechanisms of attention enhances the model, leading to 96.1 % accuracy and an increase in precision, recall, and F1 score, which underscores the positive effects of accurate weighting of features. The use of CycleGAN-generated synthetic images further increases the accuracy to 96.8 % by increasing the training data. These results are the most significant when Swin Transformer-CNN is combined with GAT, as the accuracy is 98.2 %, the precision is 98.7 %, the recall is 98.5 %, and the F1 score is 99.2 %, which underlines the effectiveness of the multimodal fusion and further graph-based learning in enhancing the accuracy of the diagnosis.

C. Discussion

The effectiveness of the HGGT framework can be explained by the fact that it is capable of modeling hierarchical mammographic representations and structured clinical relationships jointly, allowing to make more diagnostic reasoning than unimodal deep learning methods. The HGGT model is an important leap towards the multimodal detection of breast cancer because it is fast to integrate both mammographic images and clinical biomarkers into one diagnostic model. Unlike other traditional CNN-based networks, the HGGT is a hybrid Swin Transformer-CNN block that focuses on the visual characteristics to capture the global images of the breast and fine details of a lesion. Meanwhile, Graph Attention Network forecasts malignancy in biologic details by learning intricate clinical interactions between biomarkers, such as ER, PR, HER2, and tumor stage. The mechanism of contrastive pyramid fusion proves efficient in matching the imaging and clinical embeddings that increase the diagnostic consistency and interpretability. Local and regional fusion also serves to improve

the detection in the early stages by means of the linkage of quadrant-specific images to histopathological features. It has added a Bayesian diagnostic head to provide the estimates of uncertainties, which is an important feature of high-risk clinical decision-making. HGGT, with the help of interpretability agents of which Grad-CAM++ is a part, bridges the gap between AI predictions and clinician reasoning and constitutes a reliable, explainable, and clinically meaningful diagnostic model.

V. Conclusion and Future Works

The research illustrates that successful diagnosis of breast cancer demands a coherent rationale of imaging and clinical modalities as opposed to solitary or superficial integration measures. It is demonstrated in the proposed Hybrid Graph-Generative Transformer (HGGT) that hierarchical multimodal fusion based on clinical relationships can enhance the reliability of diagnostic information, interpretability, and uncertainty awareness in computer-aided diagnosis systems. The framework, which integrates the representation of mammographies and clinically significant biomarker interactions, fills the gap between clinically relevant biomarker interactions and data-driven predictions, which help in making choices more transparent and reliable in obtaining trustful and clinician-focused decision support.

Although it has effective performances, this study has its limitations. It uses one retrospective dataset, and this might not be representative of other institutions and imaging platforms. Moreover, the framework can limit the real-time implementation to resource-constrained clinical environments because of its computational complexity. The areas of future work will be large-scale multi-institutional validation, computational optimization, and the combination of longitudinal, genomic, and radiomic data. Federated learning with privacy concerns and integration with clinical workflow are also major steps towards practical implementation.

AMET University, Chennai-603102, India[4]
Sri Krishna College of Engineering and Technology, Coimbatore, India[5]

***Abstract*—This research proposal investigates the implementation of Health Information Exchange (HIE) in Malaysia, focusing on understanding the technological, policy, and financial challenges and opportunities associated with its adoption and effectiveness. Through a comprehensive survey approach targeting healthcare practitioners, policymakers, IT professionals, and patients, the study aims to elucidate the current state of HIE, assess interoperability with international standards, and identify pathways for enhancement. Key objectives include analyzing technological barriers, evaluating policy and regulatory impacts, and exploring sustainable financial models for HIE. Findings indicate a positive trajectory towards HIE implementation, underscored by a broad recognition of its potential to transform healthcare delivery. However, challenges such as system integration, policy clarity, infrastructural readiness, and privacy concerns remain. Recommendations for future improvement emphasize strengthening infrastructure, clarifying policies, enhancing security measures, providing continuous training, fostering innovation, and increasing patient engagement. Furthermore, this study highlights the alignment of HIE implementation with the Sustainable Development Goals (SDGs), particularly SDG 3, to ensure universal health coverage and enhance the healthcare workforce's capacity for process innovation. Incorporating international best practices and a validated framework will further strengthen Malaysia's healthcare system in the digital age.**

***Keywords*—Health data integration; interoperability; international health data standards; implementation; policy reforms; process innovation**

I. Introduction

In the dynamic context of global healthcare, the effective exchange of health information is fundamental to medical innovation, patient care, and public health management. Health Information Exchange (HIE) has become increasingly vital, especially in Malaysia, where the healthcare system is a blend of traditional and modern practices. HIE offers a pathway to enhance healthcare delivery through efficient, secure, and timely sharing of patient health information, facilitating care and supporting public health initiatives.

Malaysia faces unique challenges in HIE implementation, primarily due to interoperability issues. Interoperability, seamless integration, and cooperative use of data across diverse information systems, devices, and applications—is essential not only for technical compatibility but also for the harmonization of standards, protocols, and policies governing health data exchange. As healthcare increasingly transcends national borders, alignment with international standards is critical to ensure comprehensive care, facilitate research, and prepare for global health emergencies [1].

The integration of Health Information Exchange (HIE) is pivotal in modernizing healthcare delivery in Malaysia, a nation where the blend of traditional and contemporary healthcare practices presents unique challenges. These challenges, rooted in technological heterogeneity, necessitate the seamless communication and interoperability of various health information systems. Achieving this requires not only substantial technical and financial resources but also the implementation of international health data standards like HL7, SNOMED CT, and DICOM.

This study addresses the integration of Health Information Exchange within the Malaysian healthcare system, focusing on enhancing interoperability and aligning with the Sustainable Development Goals (SDGs), particularly SDG 3, which aims to ensure health coverage and promote well-being at all ages. SDG 3 includes targets like reducing mortality, fighting diseases, ensuring universal health coverage, and supporting the health workforce. Achieving these targets in the context of Malaysia involves not only enhancing the infrastructure but also addressing policy gaps, technological disparities, and privacy concerns. Through an exploration of existing systems and international best practices, this research seeks to provide actionable insights and recommendations to advance Malaysia's healthcare system in the digital age.

This study will emphasize the problem statements and research questions. The research aims to explore the multifaceted challenges of implementing a Health Information Exchange (HIE) in Malaysia, focusing on technological, policy, and financial dimensions to enhance interoperability and effectiveness. It investigates the key technological barriers to HIE implementation in Malaysia's mixed public-private healthcare system, such as interoperability issues, legacy systems, and diverse EHR integrations, seeking practical solutions and best practices from other countries. It also examines the impact of Malaysia's policy and regulatory frameworks on HIE adoption and effectiveness, identifying gaps and proposing reforms to facilitate efficient data exchange while ensuring patient privacy and data security. Additionally, the

research explores financial models and funding strategies to support sustainable HIE implementation and operation, including government funding and public-private partnerships, assessing their cost-effectiveness in improving healthcare efficiency and patient outcomes. The goal is to develop actionable strategies to address these challenges, contributing to the effective and sustainable implementation of HIE in Malaysia. Fig. 1 shows the healthcare ecosystem in Malaysia.

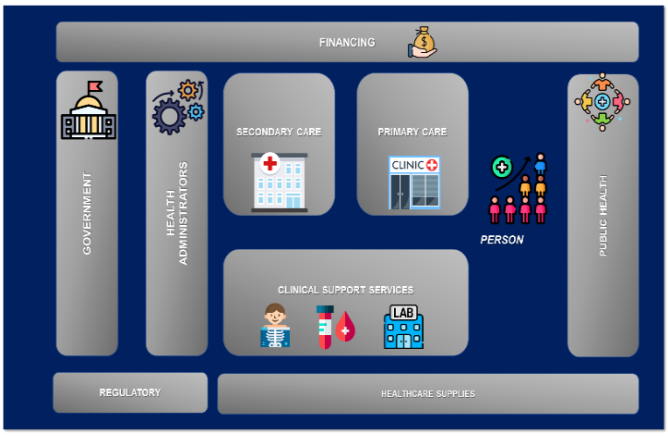

Fig. 1. Healthcare ecosystem in Malaysia.

II. Literature Review

Malaysia is at a pivotal moment in its healthcare transformation, aiming to implement Health Information Exchange (HIE) to create a more integrated, efficient, and patient-centric system. This literature review explores the challenges and opportunities in HIE implementation, focusing on technological barriers, policy and regulatory frameworks, financial models for sustainability, stakeholder engagement, and lessons from international best practices. The review highlights the importance of advanced technological solutions for overcoming interoperability issues, the need for balanced and supportive policies, innovative financial strategies for long-term viability, and robust stakeholder collaboration to align diverse interests. By synthesizing global insights and adapting them to Malaysia's unique context, this review provides a blueprint for achieving seamless health information interoperability, ultimately enhancing the efficiency, accessibility, and well-being of the nation's healthcare system.

As Malaysia moves towards a more integrated healthcare system, the successful implementation of HIE will require a concerted effort across multiple fronts. This includes fostering collaboration among government agencies, healthcare providers, and technology experts, ensuring that all stakeholders are aligned with common goals, such as improving healthcare delivery, supporting research, and addressing healthcare gaps across diverse populations. Moreover, aligning HIE strategies with Sustainable Development Goal 3 (SDG 3), which focuses on ensuring good health and well-being for all, will play a significant role in ensuring that Malaysia's healthcare transformation is not only technologically advanced but also inclusive and accessible.

A. Technological Challenges and Solutions in HIE Implementation

Malaysia's path to a fully integrated Health Information Exchange (HIE) faces challenges, such as diverse Electronic Health Record (EHR) systems operating in isolation. The need for adopting international standards like HL7, SNOMED CT, and DICOM is key to overcoming interoperability barriers, as shown by global case studies, including Tanzania's efforts to centralize health data using international standards.

The challenges in achieving interoperability in Malaysia's HIE system can be addressed by leveraging international standards such as HL7 and SNOMED CT. These standards have proven effective in overcoming interoperability barriers, especially when used in tandem with modern interoperability solutions such as FHIR. Malaysia, however, faces the additional hurdle of integrating legacy systems still prevalent in many public healthcare institutions. This requires a strategic approach to bridge the gap between old and new technologies, ensuring that healthcare systems can communicate seamlessly despite technological differences.

Facebook's role in public health communication shows how social media can overcome traditional communication barriers by disseminating health messages, conducting disease surveillance, and raising health awareness in cost-effective and far-reaching ways. Integrating social media into health information systems can extend traditional HIE mechanisms [2]. Social media platforms, particularly Facebook, have been pivotal in amplifying health communication, ensuring that critical health messages reach diverse populations. This integration can enhance the engagement of communities, allowing healthcare systems to bypass geographical and socio-economic limitations, further extending the reach and effectiveness of public health campaigns.

Tanzania's health information system challenges are due to diverse digital tools and a lack of standardized data. The development of the Health Information Mediator (HIM) facilitated seamless data exchange by implementing international standards and creating a centralized health data repository, ensuring data consistency and quality [3]. Similar challenges are being faced by many low- and middle-income countries (LMICs), where technological fragmentation hampers the smooth flow of information. Tanzania's implementation of international standards has been a key success, and Malaysia can learn from this by prioritizing the standardization of health data across its diverse healthcare systems, integrating global best practices into local contexts. The challenges of implementing HIE with the Internet of Medical Things (IoMT), focus on interoperability issues caused by varied devices, data formats, and communication protocols. Integrating legacy EHRs with IoMT platforms is difficult, but adopting international standards like HL7 can help, though challenges persist in achieving seamless interoperability [4]. As Malaysia looks to integrate the Internet of Medical Things (IoMT), these challenges highlight the critical need for interoperability frameworks that support the communication of diverse medical devices. The adoption of standards like HL7 and FHIR can facilitate the integration of newer technologies with older systems, offering a pathway to

improved data consistency and better patient outcomes across the healthcare system.

The potential of cloud computing to optimize healthcare services by offering a scalable and flexible IT infrastructure. Cloud computing can help manage health records in a distributed environment, addressing challenges related to client assistance, cost, online connectivity, and emergency recovery [5]. Malaysia's transition to cloud computing would not only provide a cost-effective solution for data storage but also enable real-time data sharing and collaboration across multiple healthcare providers. Cloud infrastructure could reduce dependency on expensive, localized data centers, making the system more resilient, especially during health emergencies or natural disasters.

Hospital Information Systems (HIS) play a role in improving healthcare quality through integration and data management. Major challenges include interoperability between EHR systems and integration with legacy systems. HIS adaptations aim to enhance information efficiency using statistical and data mining techniques [6]. HIS is critical for enhancing healthcare delivery and efficiency. However, system integration remains one of the biggest hurdles in Malaysia, where older technologies are still prevalent. Leveraging data mining techniques can help uncover patterns in healthcare delivery, making it easier for policymakers to make data-driven decisions for improving healthcare access and outcomes.

AI and big data analytics have potential but face issues like data security and privacy [7], and addressing healthcare challenges in LMICs. However, digital health application fragmentation and interoperability issues remain significant hurdles [8]. The role of AI in HIE systems is becoming increasingly evident, particularly in its ability to analyze vast amounts of health data and predict patient outcomes. However, for AI to be effective in Malaysia, there needs to be a comprehensive framework that addresses ethical concerns, privacy, and the integration of AI systems with existing infrastructures. As AI becomes more prevalent, these considerations must be addressed to prevent disparities in healthcare services.

Hence, FHIR is important in enhancing interoperability across healthcare systems using web technologies and standardized APIs. FHIR can integrate legacy systems by being compatible with existing HL7 standards (9-10). The adoption of FHIR in Malaysia could serve as a significant change in achieving interoperability across diverse health data systems, bridging the gap between legacy and modern technologies. As FHIR continues to gain global traction, Malaysia has the opportunity to position itself as a leader in digital healthcare innovation, ensuring that healthcare providers can share and access critical patient information seamlessly and securely. Despite the technological challenges, leveraging mobile networks, web-based technologies, and data standardization can help address these challenges [10]. Overcoming technological challenges in HIE implementation requires a multi-pronged approach, combining mobile networks, cloud technologies, and data standardization. This will ensure that Malaysia's HIE system is not only scalable but also adaptable to future technological advancements, such as the IoMT and AI, which will undoubtedly play a pivotal role in the future of healthcare delivery.

B. Policy and Regulatory Frameworks Supporting HIE

Navigating policy and regulatory frameworks is crucial for successful HIE implementation in Malaysia. Different countries have tailored policies addressing privacy, data protection, and governance. Malaysia must develop policies that protect patient privacy and ensure data security while promoting data sharing. Lessons from successful jurisdictions emphasize stakeholder engagement and flexible yet stringent regulations. To successfully implement HIE, Malaysia needs a dynamic regulatory framework that aligns with international standards. This framework must not only emphasize patient privacy and data security but also create a supportive environment that fosters trust among all stakeholders. Global examples like Estonia's and Finland's digital health strategies have shown that robust regulations can facilitate HIE adoption and improve healthcare outcomes by balancing privacy with accessibility.

There is a need for health organizations to engage effectively on social media and calls for policies ensuring the reliability of online health information,1 and establish strong leadership and clear governance, as seen in Tanzania's digital health strategy, supported by a National eHealth Steering Committee and technical working groups [3]. Malaysia can take inspiration from Tanzania's digital health governance model, where clear leadership and coordinated efforts across government bodies, healthcare providers, and technological partners were critical to the success of their health information systems. Implementing similar strategies would allow Malaysia to build strong, collaborative frameworks that involve all stakeholders in creating policies that promote trust in digital health systems. In addition to traditional governance, health organizations must engage with the public through social media. Clear, accurate health information can be disseminated rapidly via Facebook, Twitter, and other platforms, enhancing public health engagement. Policies should ensure that online health information is reliable, verified, and accessible, fostering an informed population that trusts digital health technologies.

Among other things, there are also concerns about data privacy and security concerns on the Internet of Medical Things (IoMT), emphasizing the need for flexible healthcare platforms and unified policy frameworks to ensure privacy, security, and interoperability [8]. Given the rise of IoMT devices, Malaysia needs to develop comprehensive regulatory frameworks that can accommodate the growing diversity of connected health devices, safeguarding patient data while ensuring seamless interoperability across platforms. This will require a balance of technology-specific standards with broad regulatory guidelines to create an adaptable and secure environment for digital healthcare solutions. In room for policy reforms, Policy gaps in EHR systems, telemedicine, and digital healthcare highlight the need for updated regulations, such as revising the Telemedicine Act 1997, to support modern telehealth practices (7, 11). The Malaysian Telemedicine Act must be revised to reflect the advancements in digital health technologies and telemedicine practices.

It is also important to have comprehensive policies for data management, device usage, and care delivery, advocating for a

national digital health strategy to support HIE implementation that emphasizes adhering to international standards like FHIR, which enhance data privacy and security, crucial for effective HIE implementation. (7, 9). Developing a national digital health strategy is essential for HIE success in Malaysia. This strategy must prioritize data management, patient confidentiality, and device standardization. Moreover, adherence to international standards like FHIR is vital for maintaining data security and interoperability, ensuring that Malaysia's healthcare system can evolve while staying aligned with global best practices in digital health.

C. Financial Models and Funding Strategies for Sustainable HIE

Sustainability is the key to successful Health Information Exchange (HIE) initiatives. Various funding models, from government allocations to public-private partnerships, offer different benefits and challenges. For Malaysia, it is essential to find a model that supports both the initial setup and long-term operations. Cost-benefit analyses highlight the economic advantages of HIE, showing potential efficiencies and savings in healthcare delivery. Creative financial solutions are needed to support technological and policy advancements. While government allocations can support the initial setup of HIE systems, long-term sustainability requires finding flexible funding mechanisms that allow continuous system improvements, including maintenance, updates, and expansion. Public-private partnerships (PPP) offer a potential model that blends both public funding and private sector efficiency, ensuring HIE's financial viability over time. These partnerships can leverage private sector innovation and public resources, creating an environment that fosters long-term operational success and adaptability [11].

Platforms like Facebook can be a cost-effective part of broader funding strategies to maximize health information reach with minimal expense [2]. By using social media not only for public engagement but also for fundraising campaigns, Malaysia can generate additional funding and raise awareness about HIE's benefits. In Tanzania's HIE project, it is primarily funded by international donors like USAID. However, long-term sustainability, including maintenance and expansion costs, remains a challenge, indicating a need for sustainable funding models [3]. Moreover, transitioning from donor-based funding to domestic funding sources will be crucial for Malaysia's future self-sufficiency in HIE initiatives. However, in the long run, the cost implications of cloud computing in healthcare suggest a financial model that shifts from capital expenditure to operational expenditure, reducing the burden of maintaining large IT systems (5, 12). Cloud computing allows Malaysia to move away from large upfront costs for IT infrastructure and instead adopt a pay-as-you-go model. This makes it easier for healthcare organizations to manage operational costs and ensure that funds are allocated efficiently for maintenance and expansion.

It is challenging to secure funding for digital health systems, suggesting various financing models like insurance, grants, and pay-as-you-use schemes to support HIE development and scaling. scaling [8] and by the adoption of Fast Healthcare Interoperability Resources (FHIR) by leading tech companies, emphasizing its cost-effectiveness and efficiency in healthcare data exchange. The potential for private investment and public-private partnerships (PPPs) will be crucial in funding sustainable HIE initiatives. Malaysia should look into models that encourage private companies to invest in HIE infrastructure, especially those that align with global interoperability standards. These partnerships can stimulate innovation, enhance resource mobilization, and ensure that Malaysia's HIE systems are adaptable and resilient in the long term [9].

D. Stakeholder Perspectives and Engagement in HIE

The success of Health Information Exchange (HIE) in Malaysia depends on engaging healthcare providers, policymakers, and patients. Effective communication, transparent operations, and inclusive policymaking are crucial for gaining support and transitioning to an integrated healthcare network. Engaging all stakeholders, such as healthcare providers, policymakers, patients, and the public, is essential for the success of HIE in Malaysia. Each group plays a vital role in ensuring that the system meets their needs and is adopted widely. Engaging healthcare professionals early in the process, ensuring policymakers understand the long-term benefits, and addressing patient concerns about privacy and data security will create an environment of collaboration and trust.

It is very crucial and vital to engage internet users on social media, showing how strategic use of platforms like Facebook can enhance health information dissemination [2]. Engaging on social media platforms allows healthcare systems to reach broader audiences, including younger, tech-expert generations who are the key to driving health awareness in digital spaces. Taking the example of HIE in Tanzania, stakeholder engagement involved government, NGOs, healthcare facilities, and international partners, and the importance of training and capacity building [9]. Malaysia could benefit from the collaborative model used in Tanzania, where government, NGOs, and healthcare facilities worked together, ensuring diverse stakeholder participation and effective HIE implementation.

Other than that, we should not neglect the presence of Internet of Medical Things (IoMT) and its potential to enhance stakeholder engagement by granting patients greater access to their health data and streamlining healthcare processes [4]. The IoMT offers opportunities for real-time health data sharing, enhancing patient engagement, and streamlining healthcare delivery. This integration can improve patient-provider communication and foster better healthcare outcomes. It is essential to get to users' perspectives on their understanding of cloud-based health systems, focusing on compatibility, complexity, security, and privacy to ensure acceptance and usage. Ensuring patients and healthcare providers are well-informed about the cloud-based systems is critical to successful adoption. Clear communication regarding security and data privacy concerns can help build trust.

On that note, it is also equally important to highlight the importance of user satisfaction, system quality, and technology compatibility for the success of Hospital Information Systems (HIS), using various evaluation models [6]. User satisfaction and system compatibility are critical for the success of HIS. Ensuring these systems meet user needs will lead to better

adoption rates and more effective healthcare delivery. From the perspective of healthcare professionals, the concerns from medical practitioners and the need for patient engagement and digital health literacy must be addressed to ensure successful digital health technology adoption [7]. Addressing healthcare professionals' concerns with continuous education and offering clear benefits of digital health adoption will help ease resistance and improve technology integration. Going aerial, collaborations between governments and external stakeholders [13], highlighting successful partnerships, like Kenya's mobile technology initiative for community health worker training is also evidenced to accelerate good outcomes [8]. Collaboration, such as Kenya's model, demonstrates how external partnerships can drive successful digital health integration.

The adoption of FHIR will enhance data interoperability and has gained support from major technology companies, highlighting the role of collaboration in advancing HIE3, and through the implementation of FHIR, it reflects a shared commitment to improving healthcare data exchange and accessibility [8]. FHIR adoption is a critical component for improving interoperability in Malaysia's HIE system. It will enable seamless data exchange, making healthcare delivery more efficient and effective. Each organizational culture, staff awareness, and skill levels in the successful implementation of EHR systems must be emphasized to address specific barriers [9]. Organizational culture and staff readiness must be aligned with digital health goals to ensure smooth EHR system integration and successful HIE adoption.

E. International Best Practices and Lessons Learned

The global landscape of Health Information Exchange (HIE) offers valuable lessons for Malaysia. Countries like Estonia and the United States provide insights into successful practices and common pitfalls. Learning from these experiences can help Malaysia adapt effective strategies and avoid mistakes. Malaysia can improve health communication by adopting global best practices in social media use [2]. Global best practices, such as Tanzania's integration of social media for health information dissemination, can be useful for engaging the public and spreading awareness about the benefits of HIE. For instance, in Tanzania, they use international best practices and global networks to develop their HIE system, emphasizing collaboration and iterative design [3]. International collaboration in HIE development allows Malaysia to learn from countries with successful digital health systems, adapting global solutions to local contexts.

Apart from Tanzania, challenges and solutions from Iraq's healthcare cloud computing can offer relevant insights for Malaysia's HIE implementation [5]. Iraq's cloud-based healthcare systems provide relevant insights into managing health data securely and efficiently. Malaysia can adapt these lessons to improve its cloud infrastructure and reduce costs. Actually, looking back at Malaysia's blueprint, Malaysia's telemedicine progress with the U.S., India, and China suggests that international examples can guide improvements in digital health [7]. Telemedicine advancements from the U.S., India, and China serve as valuable blueprints for Malaysia's progress, allowing Malaysia to build upon successful global telemedicine models. In other cited articles, there are several success stories of HIE implementation strategies from Tanzania, Estonia, and Chile, emphasizing the importance of learning from global experiences to overcome technological and policy challenges [8]. Global case studies, such as those from Estonia and Chile, show how standardization and collaborative policy development can overcome barriers and help improve HIE adoption.

While learning from other country is paramount, the standardization is a concern that need to be addressed and global adoption of Fast Healthcare Interoperability Resources (FHIR) as a model for improving healthcare interoperability, which Malaysia can adopt to enhance its HIE capabilities [9] as it provides valuable components of data analytics in improving healthcare quality, showcasing successful examples from prominent healthcare organizations. FHIR adoption is a critical step for Malaysia's HIE success. By embracing this global standard, Malaysia can improve interoperability, enhance data quality, and streamline healthcare delivery, fostering long-term healthcare innovation.

III. METHODOLOGY

This study employs a comprehensive questionnaire-based approach to explore the multifaceted challenges and opportunities of implementing Health Information Exchange (HIE) in Malaysia. Utilizing both closed-ended questions for statistical analysis and open-ended questions for thematic exploration, this methodology is designed to elicit a wide range of perspectives from key stakeholders such as healthcare providers, policymakers, IT professionals, and patients. This approach aims to generate a rich dataset that provides nuanced insights into the barriers and facilitators of HIE adoption and effectiveness, leading to actionable recommendations for enhancing healthcare delivery through improved data interoperability.

The questionnaire-based approach has been chosen to capture both quantitative and qualitative data, providing a comprehensive understanding of the challenges and opportunities that Malaysia faces in adopting HIE. This methodology ensures that data from diverse perspectives, such as healthcare providers, policymakers, IT professionals, and patients, are systematically gathered, allowing for rich insights that can inform future strategies for improving Malaysia's HIE infrastructure.

A. Data Collection and Analysis Method

Data collection is conducted through an online survey platform, Google Forms, ensuring broad accessibility and participation. The survey is structured to gather only demographic information, adhering to ethical guidelines to ensure participant anonymity and data confidentiality. The analysis involves descriptive and inferential statistics to identify patterns and correlations relevant to the study's goals.

B. Questionnaire Structure and Research Objectives

Four distinct sets of questionnaires are tailored to different respondent groups to address specific research objectives and questions including healthcare practitioners such as doctors, nurses, administrative officers, medical assistants; policy makers, doctors or health authority in the Ministry who are involved in policy making and decision making; IT professionals such as IT experts in the ministry as well as on

ground operation level and patients. These questionnaires cover topics such as system integration, technological barriers, policy awareness, and the impact of HIE from multiple stakeholder perspectives. The questions are designed to assess the current state of HIE technology use, policy understanding, and financial strategies impacting HIE implementation in Malaysia. Each set aims to collect targeted data that informs the broader research aims, focusing on technological challenges, policy impacts, and financial sustainability of HIE initiatives.

This methodological framework supports a comprehensive analysis of the current and potential future state of Health Information Exchange in Malaysia, contributing valuable insights into the advancement of HIE systems and their alignment with both national healthcare goals and global health objectives. In aligning the findings with national healthcare goals and global health objectives, this methodology helps position Malaysia's efforts within the international context of digital health [17] transformation. By focusing on both local challenges and global standards, the study provides actionable recommendations for Malaysia to improve its HIE infrastructure while contributing to global health goals such as Universal Health Coverage and Sustainable Development Goal 3 (SDG 3).

IV. Results and Analysis

The survey findings offered a significant understanding of the status of Health Information Exchange (HIE) deployment in Malaysia, comparing it with global practices while also addressing technological barriers, accessibility issues, and potential financial strategies for its implementation. This comprehensive approach delivers diverse viewpoints on the awareness, understanding, and opinions regarding HIE implementation in Malaysia. The detailed discussion of each questionnaire is further elaborated in the next sections. The findings from this study provide a detailed view of HIE adoption in Malaysia, illustrating both progress and challenges. The analysis highlights not only the technological barriers and policy concerns but also the financial models necessary to ensure sustainability. Through comparing local findings with global trends, the study offers insights into how Malaysia can enhance its HIE infrastructure and better align with international standards [12].

A set of seven targeted questions, each with a specific objective, is directed at healthcare practitioners. This questionnaire is essential for assessing users' comprehension of the interoperability platform and their perceptions of its long-term impact.

A. Analysis of Healthcare Practitioners

The survey findings reveal a diverse landscape of EHR usage in Malaysia, with HIS@KKM and HIE RekodPesakit each used by 26.7% of respondents, 30% utilizing various other systems, and 16.7% relying on manual records. Integration challenges are evident, with 46.7% of respondents reporting poor EHR system interoperability and 43.3% unsure of their systems' capabilities. Technological barriers are significant, with 63.3% encountering major obstacles, primarily insufficient devices (73.3%), and poor internet connectivity (53.3%). Familiarity with the FHIR standard varies, with 40% somewhat familiar and 20% very familiar, though 16.7% are not familiar at all. Policy support for HIE is viewed positively by 73.3% of respondents, yet 26.7% remain uncertain about its effectiveness. Government and private sector support for HIE implementation is generally well regarded, with most respondents rating it 4 or 5 out of 5, though some see room for improvement in engagement and support. The findings from healthcare practitioners reveal a diverse level of understanding and engagement with HIE systems. While the usage of EHR systems is widespread, issues with integration and interoperability remain significant challenges. The lack of familiarity with FHIR among some practitioners highlights a critical gap in education and training, suggesting that awareness campaigns and capacity-building initiatives are crucial to improving HIE adoption in the healthcare workforce.

The survey responses from healthcare practitioners reveal mixed familiarity and perceptions regarding Health Information Exchange (HIE) in Malaysia. While many are somewhat familiar with international standards like FHIR and view current policies as supportive, a significant portion remains unsure or unfamiliar, indicating a need for better education and communication. Technological barriers, such as insufficient devices and internet connectivity, are prevalent concerns. Although there is general positivity about support from authorities, some practitioners rate this support as moderate or low, highlighting potential gaps in engagement and resources. Overall, the findings suggest a positive trend towards digitization and HIE support, but emphasize the need for enhanced awareness, technological infrastructure, training, and consistent communication to fully realize HIE's benefits in healthcare delivery and patient outcomes in Malaysia.

B. Analysis of Policy Makers and Regulators

The survey of policy makers and regulators reveals a strong awareness of existing policies supporting HIE, with 88% recognizing a general operating policy and 68% aware of hospital procedures. However, there is less recognition of health data policies (48%). The majority (68%) believe HIE clarifies data exchange issues and supports digital transformation (64%), though fewer see it easing system adaptation (48%). Uncertainty prevails regarding policy revisions for HIE (52%), and there is a lack of clarity on FHIR adoption, with 56% unsure. Funding models primarily include tender-based projects (52%) and national insurance schemes (24%), while 72% report no financial incentives for healthcare providers to adopt HIE. This highlights a need for clearer communication and policy direction to enhance HIE adoption and support.

The findings suggest that policy makers and regulators are aware of the importance of HIE, yet they still face challenges with unclear policy directions, especially regarding privacy and data security. The lack of clarity around FHIR adoption and its strategic implementation shows that further education and guidance are needed for regulators to make informed decisions. Moreover, the absence of financial incentives for healthcare providers is a major barrier to wider adoption, suggesting that a robust financial framework must be put in place to encourage HIE integration at all levels.

Policy makers and regulators in Malaysia demonstrate strong awareness and acknowledgment of the policy frameworks supporting Health Information Exchange (HIE),

recognizing operational policies and health data policies. They perceive these policies as facilitating data exchange clarity and enabling digital transformation, although there is less confidence in their role in easing HIE adaptation within facilities. Uncertainty about revisions to privacy and security policies suggests a need for clearer communication and collaborative planning. The adoption of FHIR standards is mixed, with many respondents uncertain about the strategic direction, indicating a need for better information dissemination. Diverse funding models, mainly tender-based projects and national insurance schemes, support HIE, but a perceived lack of financial incentives for healthcare providers may hinder wider adoption. Overall, while supportive of HIE policies, policy makers see opportunities for improved communication, strategic clarity, and financial incentives to enhance HIE implementation and effectiveness in Malaysia's healthcare system.

C. Analysis of IT Professionals

The survey of IT professionals reveals a strong implementation of FHIR standards (92%) and cloud computing (72%) to address interoperability challenges. Data privacy and security measures focus on extensive assessments (80%) and role-based access control (76%). A significant majority (76%) believes in AI's potential to enhance HIE capabilities. International models influence Malaysia's HIE strategies, acknowledged by 64%, though 24% are uncertain. Lessons learned highlight the need for strong leadership, comprehensive funding models, integration to avoid system silos, robust infrastructure, clear policies, diverse use cases, and sustainable implementation strategies to improve healthcare quality. These insights emphasize the importance of a structured and well-supported approach to HIE implementation in Malaysia. IT professionals emphasize the critical role of international standards like FHIR and cloud computing in overcoming interoperability challenges within Malaysia's HIE system. However, for HIE to reach its full potential, there must be a concerted effort to address technical and operational barriers, particularly in system integration and data security. The adoption of AI and machine learning in HIE also requires stronger education and training for IT professionals, as they are key to driving these technologies forward.

IT professionals in Malaysia emphasize several key factors for the successful implementation of Health Information Exchange (HIE). They stress the need for strong, informed leadership with clear mandates to ensure cohesive implementation. Adequate devices and reliable internet connectivity are critical for smooth operation, while moving away from siloed systems towards an integrated HIE platform is necessary to avoid fragmentation. Consistent and collective financial support is vital for the sustainability of HIE, alongside government mandates and regulatory frameworks to guide its implementation. There is also a need for further education on the benefits of AI and machine learning in HIE. Malaysia's HIE strategies benefit from international models, but there is a need for clarity on this influence. Professionals believe HIE can improve healthcare quality and patient outcomes. In conclusion, they advocate for a strategic, well-supported HIE approach with strong leadership, robust infrastructure, comprehensive integration, sustainable financial backing, clear policies, and ongoing education, envisioning a system that significantly enhances Malaysia's healthcare.

D. Analysis of Patients

The patient survey reveals a majority awareness (70%) of HIE and its benefits, though 23.3% remain unsure and 6.7% are unaware, indicating a need for better communication and education. Nearly half of the respondents (46.7%) noticed improvements in healthcare delivery due to HIE, while 26.7% did not see improvements, and another 26.7% were unsure, suggesting mixed experiences and the need for further evaluation and education. Concerns about data privacy and security are significant, with 43.3% expressing worries, 33.3% feeling secure, and 33.3% unsure, highlighting the importance of transparency and robust security measures to build patient trust in the HIE system. The mixed awareness levels and concerns regarding data privacy emphasize the need for ongoing education and transparency. As Malaysia continues to roll out its HIE initiatives, patient engagement and trust will be pivotal for the system's success. Clear communication about how data is shared and secured will help patients feel more confident in using these systems.

The survey of patients in Negeri Sembilan, where Malaysia's HIE pilot is implemented, reveals promising awareness and initial positive impacts of HIE, with 70% aware of its benefits and nearly half (46.7%) noticing improvements in healthcare delivery. However, 26.7% do not perceive improvements, and another 26.7% are unsure, highlighting the need for ongoing education and system integration. Privacy and security concerns are significant, with 43.3% expressing worries and an equal proportion uncertain about data security. In conclusion, while there is a positive trajectory towards HIE implementation, further education and reassurance are essential, especially regarding data privacy and security. Continuous efforts in these areas will be crucial for building patient trust and fully realizing HIE's potential to improve healthcare delivery in Malaysia. Addressing integration, policy communication, technical readiness, and privacy concerns remains essential for success [14] [15] [16].

E. Future Recommendations to Enhance HIE Implementation

Based on the comprehensive insights from the research on Health Information Exchange (HIE) implementation in Malaysia, several future recommendations have emerged to address identified challenges and leverage opportunities for enhancing the HIE system. These recommendations and their strategies are outlined below: strengthen infrastructure and integration by enhancing technical infrastructure through investment in robust systems, reliable internet connectivity, and adequate devices to ensure seamless HIE operation across all healthcare facilities; and promote system integration by supporting the integration of manual and legacy systems with the HIE platform through technical assistance and incentives, enabling comprehensive participation. This will require a multi-tiered approach involving government support, private sector investment, and collaboration across various healthcare levels to ensure system scalability and reliability.

Under policy and governance, clarify and communicate policies to improve understanding of stakeholder roles and responsibilities, and develop incentive structures to encourage

healthcare providers and patients to actively participate and share data. Clear, transparent policies will help align all stakeholders, ensuring a cohesive approach to data sharing and privacy protection. Introducing incentives will motivate stakeholders to adopt and fully engage with the system.

For security and privacy measures, implement robust security protocols through regular audits, encryption, and secure access controls, while educating stakeholders on data privacy through awareness campaigns to build trust in the HIE system. Continuous monitoring and improvements in security measures are essential to maintain patient trust and confidence in the system. Stakeholder education should focus on data security best practices and the importance of adhering to regulatory standards.

Training and support should include offering continuous training for healthcare practitioners and IT professionals on HIE technologies and best practices, and developing IT expertise focused on cybersecurity, database management, and system integration. Providing ongoing professional development is crucial for ensuring healthcare providers are equipped with the knowledge and tools necessary to use HIE systems efficiently and securely. This includes both technical and policy-oriented training.

Research and development efforts should foster innovation in HIE by investing in R&D to explore technologies such as AI and blockchain for secure and efficient data exchange, while evaluating and adapting international best practices to suit the Malaysian context. By encouraging R&D in emerging technologies, Malaysia can ensure that its HIE system remains innovative and resilient to future challenges. Blockchain can enhance data security, and AI can improve data analysis and decision-making processes.

Lastly, patient engagement and awareness should be enhanced by increasing patient education and communication to highlight HIE benefits and promote patient-centered care, along with implementing feedback mechanisms to gather input from all stakeholders, particularly patients, for continuous HIE improvement. Implementing these recommendations requires collaboration among government agencies, healthcare providers, IT professionals, and the community. By addressing current challenges and focusing on continuous improvement, Malaysia can maximize the potential of its HIE system to enhance healthcare delivery, patient outcomes, and overall system efficiency.

V. Conclusion and Future Enhancement

The comprehensive research on Health Information Exchange (HIE) implementation in Malaysia reveals significant insights from diverse stakeholders, including healthcare practitioners, policymakers, IT professionals, and patients. These findings underscore a strong commitment to enhancing health service delivery through HIE but highlight several critical challenges, such as diverse EHR systems, technological barriers, infrastructural deficits, and concerns over privacy and security. Policymakers demonstrate awareness and support for existing HIE policies but recognize the need for clearer communication and incentive structures. IT professionals emphasize the importance of robust infrastructure, adopting international standards, and leveraging AI's potential. Patients show awareness and positive perceptions of HIE benefits but express significant privacy and security concerns.

Overall, the findings indicate that while Malaysia has made meaningful progress towards digital health integration, the implementation of HIE remains uneven, particularly across different stakeholder groups and operational levels. This highlights the need for a more coordinated and inclusive approach to ensure that technological advancements translate into practical, system-wide benefits. To address these challenges and leverage opportunities, future recommendations include investing in robust technical infrastructure, supporting system integration, improving policy communication, developing incentive structures, implementing robust data privacy measures, providing continuous training, fostering innovation through R&D, and enhancing patient engagement. Implementing these recommendations requires collaboration among government agencies, healthcare providers, IT professionals, and the community. Such collaboration is essential in order to ensure that HIE implementation is not only technically feasible but also trusted, sustainable, and widely adopted across the healthcare ecosystem.

By addressing current challenges and focusing on continuous improvement, Malaysia can realize the full potential of its HIE system, improving healthcare delivery, patient outcomes, and overall system efficiency. This study's insights and recommendations provide a roadmap for advancing Malaysia's healthcare system in alignment with national and global health objectives, particularly the Sustainable Development Goals (SDGs). In conclusion, the successful advancement of HIE in Malaysia depends not only on technology but also on policy clarity, stakeholder readiness, and public trust, all of which must progress together to achieve long-term digital health transformation.

Acknowledgment

The author would like to express sincere gratitude and appreciation to everyone who contributed to the development and realization of this study on Health Information Exchange (HIE) in Malaysia. This research has been a truly collaborative effort, and its completion would not have been possible without the guidance, support, and dedication of many individuals and organizations. Primarily, the author extends heartfelt thanks to Dr. Malathy Batumalay for her continuous guidance, encouragement, and constructive feedback throughout the research process. Her deep knowledge, technical insight, and unwavering commitment played a pivotal role in shaping the direction and quality of this study. The author would also like to extend appreciation to the Faculty of Data Science and Information Technology (FDSIT), INTI International University, for providing the academic platform, resources, and environment that enabled this research to be successfully carried out. Sincere thanks are also extended to the Ministry of Health Malaysia and the Information Technology Division for sharing valuable knowledge and perspectives on the implementation of Health Information Exchange (HIE) systems in Malaysia.

Abstract*—Ensuring secure and privacy-preserving authentication in web applications remains a critical challenge due to the limitations of conventional single-factor approaches, which are vulnerable to attacks and fail to account for dynamic user behaviors. Existing multi-factor authentication (MFA) methods often rely on static rules, exposing users to unnecessary friction or weak security under evolving threat conditions. To address these gaps, this study proposes PPAB-RL, a Privacy-Preserving Adaptive Biometric framework leveraging Reinforcement Learning for intelligent MFA selection. The proposed method integrates homomorphic encryption for secure fingerprint feature storage, contextual risk scoring based on device, behavioral, and geolocation deviations, and RL-driven adaptive MFA to dynamically select authentication pathways from password-only to multi-step biometric verification. Implementation is carried out using Python, with biometric processing performed on the SOCOFing dataset containing 6,000 fingerprint images, and blockchain-enabled logging for immutable and tamper-proof audit trails. Experimental results demonstrate that PPAB-RL achieves 96.8% authentication accuracy, surpassing traditional password-only (84.2%) and fingerprint-only (93.5%) methods, while maintaining low encrypted matching overhead and minimal user friction. Ablation studies confirm the essential contribution of each module, biometric preprocessing, encryption, risk analysis, and RL-based adaptation to overall system robustness. The RL policy converges rapidly, allowing real-time adaptation to changing user behaviors and threat contexts. Overall, the proposed PPAB-RL framework establishes a highly secure, intelligent, and scalable authentication paradigm, combining encrypted biometrics, dynamic risk assessment, and blockchain validation, offering an innovative approach that can inspire further research in next-generation privacy-sensitive authentication systems.

Keywords*—Privacy-preserving authentication; multi-factor authentication; reinforcement learning; biometric verification; blockchain-enabled logging

I. Introduction

Web-based applications are increasing rapidly due to the rapid digitalization of services; these are banking and healthcare through e-commerce and government portal, just to name a few. Although such applications prove to be highly convenient, their use is also exposed to attacks by cybercriminals, information intrusions, and fraud [1]. Old password screening platforms are fast becoming ineffectual owing to weaknesses including phishing, brute structure assaults, misuse of credentials and stuffing. To restrain such deficiencies, there is need to consider using multi-factor authentication (MFA) whereby user has to submit various authentication evidences [2]. However, the currently employed practice of MFA is more likely to employ the fixed combinations of variables and contain the centralized verification, which can never be adapted to the changing threat landscape and also expose sensitive biometric specifics to privacy breaches [3].

Several biometric authentication systems, including facial, iris, and fingerprint recognition, offer high usability and levels of security because identity verification is connected to physical features inherent to the user [4]. But once it is broken, biometric information cannot be substituted and their security is of utmost importance. Conventional central storage of biometric and authentication data present single points of failure, making such systems susceptible to intended cyberattacks [5]. A decentralized and tamper-resistant method to ensure secure authentication can be achieved through the use of blockchain technology in order to overcome these limitations. Blockchain can greatly improve the transparency of biometric identity management systems, the integrity of data and its resiliency by removing the centralized trust authorities and guaranteeing immutability of data [6].

The research study presents a Reinforcement Learning-Enhanced Privacy-Preserving Adaptive Multi-Factor Authentication Framework (PPAB-RL) based on biometrics and

blockchain technology to address the shortcomings of conventional MFA systems [7]. The current solutions do not offer privacy-sensitive biometric processing and contextual adaptation to achieve weak security or overburden users [8]. The suggested PPAB-RL framework combines the concept of homomorphic encryption to provide biometric matching privacy and a blockchain-based smart contract to guarantee decentralized verification and the impossibility to change the logs [9]. An adaptive engine based on reinforcement learning modulates the authentication factors in real-time according to the dynamically calculated risk scores with respect to user behavior, device fingerprint and location context. This guarantees an optimized security, usability and privacy. Raw biometric data is encrypted and authentication records are made securely verified on blockchain which removes tampering of data and dependency [10]. The suggested framework is capable of filling the privacy gap, flexibility and decentralization gap, and will provide an effective, smart and scalable framework to the contemporary web authentication system.

- Introduces a privacy-preserving adaptive authentication system integrating encrypted biometrics, contextual risk scoring, and reinforcement learning for dynamic MFA selection.
- Implements homomorphic encryption to protect fingerprint feature vectors during storage and matching, ensuring privacy without compromising accuracy.
- Develops a device, behavioral, and location-based risk engine to calculate dynamic risk scores, enabling intelligent adaptation of authentication strength.
- Anchors encrypted biometric templates and authentication events on blockchain, providing tamper-proof auditability and integrity verification.

A. Research Motivation

As the use of web applications in providing key services like online banking, medical cases, and government services is on the rise, there has been a growing concern on the security as well as reliability of user authentication. Conventional password-based systems are becoming less and less effective against cyber-attacks such as phishing, credential stuffing, and brutality attacks, which undermine user privacy and system integrity. Even though the use of multi-factor authentication provides a higher level of security, the majority of the implementations that have been established in practice are not dynamic and cannot be adjusted to different levels of risk. In the same note, biometric authentication, though convenient, is of great privacy threat, as once biometric information has been compromised, it cannot be restored. In addition, the use of centralized authentication servers introduces points of failure in a system and, therefore, increases vulnerability to attacks. All these issues indicate that there is an urgent need to have a dynamic, privacy-sensitive authentication model capable of adapting its security needs according to the context risk and safeguarding sensitive personal information. This study will come up with such an adaptive and privacy-aware authentication solution to the contemporary web space.

B. Research Significance

The analysis outlines a major breakthrough in privacy-conscious biometric authentication by incorporating reinforcement learning, adaptive multi-factor authentication and blockchain technology. The privacy and trust of the proposed PPAB-RL framework are guaranteed by access to raw biometric information, as well as the homomorphic encryption of similar operations. Its adaptive engine, driven by reinforcement learning, is used to add to the user experience since it actively varies, according to contextual risk, some aspects of authentication, including device fingerprint, geolocation, and behavioral anomalies. The decentralization of the blockchain layer also abolishes single points of failure, and the smart contracts make the audit trail of authentication events immutable and transparent. This composition is both effective and does not affect usability in strengthening resistance towards identity thefts, phishing and replay attacks. The research leads to the creation of next-generation authentication systems, which are secure, privacy-sensitive, flexible, and context-sensitive to meet the current web security demands in a scalable and user-focused fashion that is appropriate in the face of the changing digital ecosystem.

C. Problem Statement

With the rapid digitalization of services, secure user authentication has become a critical concern for contemporary web applications [11]. Conventional password-based systems remain vulnerable to phishing, brute force, and credential theft attacks, while biometric authentication, though more robust, raises significant privacy concerns due to centralized storage of sensitive data [12]. Existing multi-factor authentication (MFA) systems are largely static and lack context-aware adaptability, applying uniform security measures irrespective of risk levels [13]. These limitations expose low-risk users to unnecessary verification steps while leaving high-risk operations inadequately protected, reducing both security and user experience. To overcome these challenges, the proposed PPAB-RL framework integrates adaptive reinforcement learning, encrypted biometric processing, and blockchain-based decentralization to provide dynamic, risk-aware, and privacy-preserving authentication for modern web applications.

Although the use of multi-factor authentication has become widespread, the majority of the current solutions are unchanging, centralized and lack privacy awareness, which restricts their success in the dynamic nature of threats. Existing strategies are not able to balance the security of authenticating and user friction and ensure a sufficient level of protection of sensitive biometric information. The research question of this study is thus the following: How can a privacy-preserving and context-aware authentication system dynamically scale multi-factor authentication strength through encrypted biometrics, reinforcement learning, and decentralized blockchain validation to increase security, usability, and trust in any web application? The proposed framework will aim to provide a solution to this limitation of the statistical MFA system by way of providing intelligent adaptation that is risk-sensitive and secure decentralized verification.

The remainder of this study is organized as follows: Section II is an in-depth literature review of Privacy-Preserving Adaptive Multi-Factor Authentication Framework for Web Applications Using Biometrics and Blockchain. Section III outlines the proposed methodology. Section IV presents Result and Analysis. Section V concludes the study by highlighting the results and providing directions for future study and practice.

II. Related Works

Yu et al. [14] developed a secure and effective MCC authentication and authorization scheme that transcends the shortcomings of conventional centralized access control. The approach integrates blockchain technology and smart contracts to allow for dynamic user access permission updating independently without the need for a single trusted third party. By keeping in storage a single transaction per user's access permission, the scheme reduces blockchain storage overhead and enhances scalability. Mobile users need to register with any service provider (SP) only once and utilize the same credentials in multiple SPs, having different levels of access. The accomplishment is a secure and decentralized approach that incorporates authorization effortlessly into the authentication process without incurring computational or communication overhead. Performance analysis shows enhanced efficiency as well as reduced storage expenses than traditional schemes. However, blockchain use still has certain costs of transactions and storage that are likely to grow with large populations of users.

To overcome the security and privacy threats of unauthorized access in the Internet of Vehicles (IoV), Yao et al. [15] proposed the development of a multistage continuous authentication system which was decentralized. The strategy combines blockchain (Hyperledger Fabric) and IPFS to decentralize storage and fuzzy extractors in order to safeguard the behavioral biometric data of users. The system performs two actions, authentication and repetitive verification of user identity, by comparing real-time biometrics with stored templates that are secured. The novelty is a confidential and safe plan, eliminates third-party trusts, resistant to replay assaults, and maintains a high throughput, which increased performance by 8.6 per cent over the closely relevant literature. Security is demonstrated with BAN Logic and performance is with Hyperledger Caliper. Scalability and latency problems during high authentication requests in large IoV networks can still occur with the system.

Fu et al. [16] proposed two identity authentication models using blockchain within the context of identity authentication to address issues like high-account maintenance, point of failure, and privacy breach in the traditional system. They presented one scheme employing the Diffie-Hellman key exchange to support effective interactive authentication and another employing ring signatures to enable non-interactive and lightweight verification. They proposed these schemes to guarantee core security properties like unforgeability, identity anonymity, and non-transferability in the sense that verifiers cannot transfer proof to third parties. The schemes were designed to preserve user privacy while providing good security guarantees. Experiment results verified that both solutions are efficient and practical for application. Nevertheless, the interactive scheme will be plagued with scalability barriers by virtue of user-verifier communication overhead.

Wang et al. [17] used the framework of a hybrid blockchain-based identity authentication scheme (HBIA) to address the single points of failure and the aspect of security risks in centralized Mobile Crowd Sensing (MCS) systems. They have come up with an alternative hybrid blockchain architecture, clustered where clusterhead nodes access the blockchain publicly and inner nodes blockchain privately. They proposed zero-knowledge proof (ZKP), zk-SNARKs to safeguard the privacy of the identities of the users and allow secure off-chain computations whose verifications can be propagated on-chain. This approach can simultaneously solve the issue of transparency in blockchain and at the same time privacy of participants, and also decrease the workload of blockchain. The detection of pavement cracks on the Ropsten network has been tested, and the scheme demonstrated reduced time for authenticating compared with current solutions. Nonetheless, the cluster operation and usage of zk-SNARK that HBIA adopts can result in complexity and computational overheads to the system.

Dehalwar et al. [18] suggested a blockchain-based self-sovereign identification and authentication method to mitigate identity theft and masquerading attacks in smart grids. They created a model that leverages blockchain to securely authenticate IoT devices in the distributed energy network. They proposed this method to confirm device authenticity and authenticate trusted communication throughout the smart grid infrastructure. The technique exploits blockchain's distributed trust to authenticate transactions in log(n) time, providing robust security without dense central control. The scheme exhibits efficient identity verification and reduces identity-related compromises. The addition of blockchain, however, places an overhead of computational and intricacy on resource-constrained IoT devices.

Bamashmos et al. [19] developed a new blockchain-based 2L-MFA system with two layers to increase the security of IoT in countering the threat of wireless data transmission. Their first layer of IoT devices was premised on secret keys, geographical location, and PUFs, and proof-of-authentication and elliptic curve Diffie Hellman to protect lightweight security. They also introduced a second factor to the users of IoT with four sub-factors, which are matrix-based passwords, ECDSA and biometric which comprise iris and finger vein analysis elements. Results were authenticated with the aid of fuzzy logic and increased the resilience of the system. The 2L-MFA model offered vast registration, log in and authentication time savings as efficiency. The integration of multi-factor and biometric approaches may involve increased complexity of implementation and cost of hardware use by the IoT systems.

Xu et al. [20] proposed a smart home authentication system that leverages the blockchain-based fog node to resolve the problem of security attacks like impersonation and insider privilege attack. They designed a decentralized model in which all the fog nodes and smart devices are registered on a local private blockchain, which avoids the single point of failure encountered in classical schemes. They proposed smart contracts along with off-chain operations for efficiently

performing real-time authentication. Fog node utilization provides accelerated and local computing over cloud-based approaches and increases system responsiveness. Security and performance analysis proved robust protection and enhanced performance with certain privacy protection for consumers. Nevertheless, the scheme will encounter potential challenges in dealing with the overhead of having fog infrastructure and blockchain synchronization locally.

Mir et al. [21] introduced a new Decentralized Anonymous Multi-Factor Authentication (DAMFA) scheme to mitigate security, privacy, and availability issues in conventional single sign-on systems. They created a protocol that eliminates the need for identity providers to hold sensitive user information, thus avoiding tracking and abuse of authentication references. They proposed threshold oblivious pseudorandom functions (TOPRF) to prevent offline attacks and utilized a distributed transaction ledger to make the scheme highly available without depending on an always-on identity provider. They proved the scheme secure for the universal composability model formally via ideal-real simulation. A prototype implementation showed its practical applicability for use in the real world. But the distributed configuration and cryptographic functions will introduce computational and network overhead for service providers and users.

Alzahab et al. [22] suggested a blockchain-based model of biometric authentication protocol to move away from the traditional model of the centralization of the process to a decentralized one. They came up with a protocol with a fuzzy commitment scheme that can be used to authenticate biometrics by not disclosing sensitive biometric features publicly on the blockchain. They offered their idea to resolve the problem of openness of blockchain and the necessity to ensure the privacy of biometric data. The protocol ensures decentralization and breakage resistance in the protection of the personal data of the users against exposure. Using the security analysis, it was verified whether the scheme was resilient to various attacks. However, the application of fuzzy commitment scheme in blockchain could cause computational overhead to real-time authentication.

The critical security and privacy concerns that are raised in the design of biometric-based authentication systems have been discussed comprehensively by Pagnin and Mitrokotsa [23]. They described the inherent vulnerabilities of such close interconnection between users and their biometric identifiers that cannot be substituted by simple passwords. They proposed detailed instructions and countermeasures to deal with threats such as the leakage of biometric data, misuse and replay attacks. They highlighted privacy saving strategies in order to protect sensitive biometric attributes. Their work created awareness concerning the usability versus security in biometric systems. The work is primarily theoretical, though, with no implemented protocol or performance test.

Mohsin et al. [24] suggested a new blockchain method based on steganography to securely update and exchange huge amounts of medical data, like COVID-19 data, between hospitals. They used a particle swarm optimization (PSO) algorithm with adjusted particle operations and a hash function to hide secret medical data within grayscale images with high confidentiality and image quality. They proposed a three-stage process of embedding capacity estimation, data hiding, and blockchain-based transmission to ensure data availability and integrity without the presence of a central third party. The approach blends stego images and blockchain in an effective manner to withstand network breakdowns and illegal access to data. Their convalescent plasma storage case study confirmed the appropriateness and performance of the system. Still, the increased computing overhead and image processing expense can restrict real-time use in high-traffic hospital settings.

Lin & Chen [25] proposed an error-correction-based iris recognition (EC-IR) method to provide secure template storage and accurate recognition for personal identification. They suggested a new template mapping scheme by studying soft reliability values and recovery capability values to such an extent that the error correction is flexibly adapted through the use of the low-density parity-check (LDPC) codes. They also built suitable LDPC codes that gave high performance with constant rate. They also proposed the use of dominating feature points (DFPs), as opposed to raw binary templates, to improve security and equal error rate (EER), and processing efficiency. Their method led to a safe iris encryption system grounded on fuzzy commitment. However, the extra complexity of DFP extraction and LDPC design may facilitate implementation sufferings in resource-limited systems.

Although the current solutions have made progress in the areas of blockchain-based authentication, privacy-saving biometric authentication, and multi-factor access control, they are mostly tackling these issues individually. Majority of the solutions are based on the concept of static authentication policies, and are devoid of context-responsive flexibility and the use of learning-based solutions to actively trade-off between security, usability and privacy. The decentralized trust and biometric privacy protection are usually implemented without an integrated decision-making system that may have loopholes in real-time adaptability and scalability. The proposed PPAB-RL framework resolves these drawbacks by integrating an encrypted biometric processing, contextual risk, reinforcement learning-based adaptive multi-factor authentication, and blockchain-supported immutability, which offers a comprehensive and secure authentication solution to the current web application.

III. Proposed Privacy-Preserving Adaptive Biometric Multi-Factor Authentication Framework

The proposed PPAB-RL framework integrates privacy-preserving biometrics, contextual risk analysis, and reinforcement learning (RL)-based adaptive multi-factor authentication (MFA) to provide secure and intelligent access control. The methodology begins with data collection from the SOCOFing fingerprint dataset, which includes original and synthetically modified fingerprint images, representing realistic variations in biometric inputs. Preprocessing of biometric data involves normalization, noise reduction using Gaussian filtering, and feature extraction to form minutiae-based vectors. These vectors are then encrypted via homomorphic encryption to enable secure storage and comparison while preserving sensitive information. During user enrollment, primary credentials, device metadata, and behavioral baselines are

captured to create a comprehensive profile, which is anchored on a blockchain to ensure immutability and auditability. Upon login, the system evaluates the contextual risk by comparing device, behavioral, and location parameters against the stored baseline, generating a dynamic risk score. This score informs the RL agent, which selects the optimal MFA pathway, ranging from password-only verification to full-chain biometric validation. Encrypted biometric matching and blockchain-based validation confirm identity while maintaining privacy. Secure logging records all events for audit and forensics. Overall, this end-to-end architecture ensures adaptive, high-assurance authentication, with the complete workflow illustrated in Fig. 1.

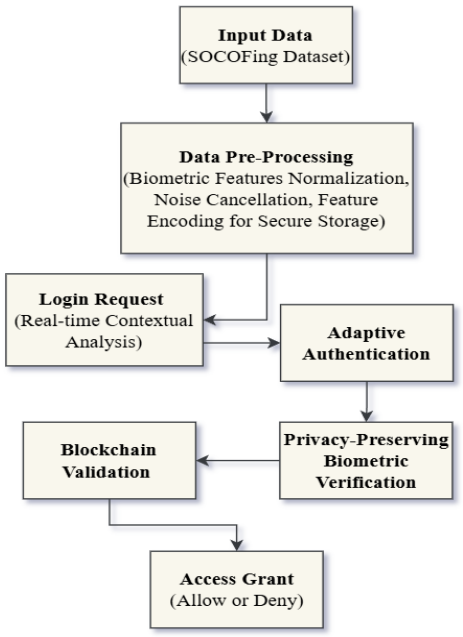

Fig. 1. Proposed secure MFA architecture using fingerprint biometrics and blockchain.

A. Data Collection

The study employs the Sokoto Coventry Fingerprint Dataset (SOCOFing) [26], a publicly available fingerprint image dataset obtained from Kaggle. SOCOFing contains 6,000 fingerprints of 600 people and the impressions of all ten fingers were taken at 500 DPI. The dataset consists of original fingerprint images and synthetically distorted ones produced with the help of three obfuscation methods: obliteration, central rotation, and z-cut, which are effective simulators of realistic distortion that may occur under authenticity conditions in practice. This heterogeneity renders SOCOFing the most appropriate to assess the strength of minutiae extraction, encrypted matching strength, and template protection schemes within the fingerprint-based authentication systems.

SOCOFing has been chosen because it is free to all, is structured in a format that is standardized and it contains regulated distortions in fingerprints, making reproducible experiments and equitable comparison of performance possible with the current biometric authentication research. It should be mentioned that only the fingerprint biometric assessment works with a real-world dataset, whereas the contextual data of devices, behavior, and location are planned to be created artificially in order to emulate the conditions of the real-life authentication and threat. This design option enables the adaptive MFA behavior to be assessed in a controlled manner and user privacy maintained. The scope of biometric validation in this work is thus determined by the use of the dataset and has given a clear and reproducible basis of assessing the proposed privacy-saving adaptive authentication model.

B. Data Preprocessing

Before the processing of the biometric and behavioral metadata, it is crucial that the PPAB-RL architecture incorporates its pre-process before handling the different metadata to obtain the desired authentication and adjustive risk analysis. The preprocessing pipeline steps comprise three major steps, namely, normalization of biometric features, elimination of noise and encoding of features during safe storage.

1) Biometric features normalization: Fingerprints, fatalities, or IRI scan. Biometry samples differ in size, position, and strength depending on the environmental conditions and differences of the lenses. In order to normalize these inputs, the feature vectors are adjusted to a standard size by using min-max normalization. It is described in Eq. (1):

$$X' = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (1)$$

In which X is the original value of the feature, X_{min} and X_{max} are the minimum and maximum values of that feature in the data set and X is the normalized feature. This increases the similarity of input ranges to both encryption and matching, which enhances the accuracy of biometric matching.

2) Noise cancellation: Unfiltered bio versatile signals may be noisy in nature by error of sensor quality or environmental contributions. In order to cut this noise out and improve the quality of the signal, some Gaussian filtering is used in Eq. (2):

$$G(x,y) = \frac{1}{2\pi\sigma^2} exp\left(-\frac{x^2+y^2}{2\sigma^2}\right) \quad (2)$$

$G(x,y)$ is the Gaussian spread out and sort of filter and the sigma is the way the filter works. Using this filter on biometric-images or correctly based feature-matrices provides high-frequency noise removal with rate of maintaining crucial features, which results in more assuring feature-extraction and secure matching.

3) Feature encoding for secure storage: The feature vectors are converted into safe-coded versions before biometric references are stored on the blockchain. Homomorphic encryption is used to implement privacy, which allows one to do computation with encrypted data. Denoting a feature vector, $F = [f_1, f_2, .., f_n]$, the encrypted version $E(F)$ is calculated and mentioned in Eq. (3):

$$E(F) = HE(F) = [HE(f_1), HE(f_2), .., HE(f_n)] \quad (3)$$

In which $HE(\cdot)$ is the homomorphic encryption process. Rich-to-lean encrypted feature representation is subsequently hashed and exchanged to the blockchain, which ensures that

there is never any exposure to biometric data at the time of enrolling and making comparisons at the time of authentication.

C. Secure Template Generation

In the suggested PPAB-RL architecture, the existence of secure biometric template generation will guarantee that raw fingerprint features will never be disclosed during storage or authentication. Fingerprints are encoded into feature vectors after the extraction of the minutiae.

$$F = [f_1, f_2, \dots, f_n] \quad (4)$$

In Eq. (4), f_i denotes an extracted feature like the ridge orientation, the ridge frequency, the minutiae angle, or the local ridge density. These values have sensitive identity attributes, thus they should be secured prior to any storage as well as comparisons. To do so, the system uses a homomorphic encryption scheme so that one can make calculations on the encrypted values without knowing the actual data. The homomorphic encryption algorithm, which is denoted $HE(\cdot)$, is composed of a public key, pk and where the parameters include: degree of the polynomial's modulus N and plaintext modulus t. The encrypted template is generated, as in Eq. (5):

$$E(F) = HE(F, pk) = [c_1, c_2, \dots, c_n] \quad (5)$$

where, each ciphertext c_i is the encrypted form of the biometric feature. N is used to parameterize the cryptographic strength and ciphertext size and t is the number used to quantify the numerical accuracy of the numbers used to represent biometric values to the encryption domain. This secures all the minutiae structures and ridge-based patterns such that they cannot be directly reconstructed in case of storage loss. In order to allow efficient indexing and verification of the integrity of the blockchain, the encrypted template is hashed using a cryptographic hash.

$H = Hash\big(E(F)\big)$, where $Hash(\cdot)$ refers to a collision-resistant hashing function. The hash is a compact version of identity to be used in finding and confirming the encrypted template on the blockchain. The metadata and encrypted template are stored at the blockchain block. User ID U s stored in each block, the encrypted feature vector $E(F)$, is stored, hash H is stored, and the timestamp τ are stored in each block represented as in Eq. (6):

$$Block = \{U, E(F), H, \tau\} \quad (6)$$

This one-way storage mechanism ensures the immutability, tamper-resistance and full preservation of privacy. It allows encrypted biometric matching in PPAB-RL and the raw or intermediate biometric information is never revealed in enrollment, transmission and authentication.

D. User Enrollment

The user enrollment phase in the PPAB-RL authentication system determines the starting security profile that is needed in subsequent adaptive authentication. When registering, a user initially enters primary credentials of a unique identifier U and a password P. A salted hashing function is used to transform the password to a secure verifier that can be denoted as in Eq. (7):

$$V = Hash(P \parallel s) \quad (7)$$

where, s is a randomly chosen salt that is user-specific. This ensures that dictionary and rainbow-table attacks of stored passwords are prevented. After credential initialization, a sample enrolment fingerprint is captured, processed pre (minutiae) and normalized, and homomorphically encrypted as previously described. The encrypted biometric template $E(F)$ is linked to the profile of the user but is not stored in plain form. The template gets anchored on a blockchain entry, making it immutable and decentralized to verify. This provides an ultimate biometric data reference to be compared in authentication.

The user contextual baseline is also created at the enrollment stage to support risk-adaptive MFA. Parameters that are obtained through device profiling include browser attributes, OS signature, Canvas fingerprint, device hardware ID and network characteristics. These are removed into a device signature vector represented in Eq. (8):

$$D = [d_1, d_2, \dots, d_m] \quad (8)$$

where, d_i is a constant device characteristic. Likewise, the normal patterns of interaction, the preferred times of logging-in, geographical location range, and preferences in the time spent in a session constitute a behavioral baseline vector B, which, when combined with the stored items, namely, $\{U, V, E(F), D, B\}$, generate a multi-layered enrollment profile. This profile allows the PPAB-RL system to conduct contextual risk assessment, adaptive selection of MFA and encrypted verification of the biometrics when attempting subsequent logins.

E. Login Request Processing

The process of user legitimacy real-time evaluation starts with the login request processing stage in the PPAB-RL framework and precedes any biometric verification. When a user attempts to access the system, the process begins with the submission of their identifier U and password P_{req}. The password is hashed with the same salted hashing algorithm created at the time of enrollment and the resulting hash is tested against the calculated, as in Eq. (9):

$$V_{req} = Hash(P_{req} \parallel s) \quad (9)$$

against the stored verifier V. If the primary credential check fails, further authentication steps are terminated immediately. Upon successful password validation, the system retrieves contextual parameters from the requesting environment. Device metadata is captured and represented as a vector.

$$D_{req} = [d_1^{req}, d_2^{req}, \dots, d_m^{req}] \quad (10)$$

In Eq. (10), d_i^{req} denotes features including browser fingerprint, OS signature, hardware identifiers, screen resolution and network features. These parameters are contrasted with enrollment baseline D to calculate device consistency. Simultaneously, geolocation and network parameters (IP address, approximate geographic position, Autonomous System Number (ASN), and network type (e.g., mobile, broadband, etc.)) are also obtained. There is also the gathering of behavioral indicators making up the behavioral vector.

$$B_{req} = [b_1^{req}, b_2^{req}, \dots, b_k^{req}] \quad (11)$$

Eq. (11) records the factors like the time of logging in, the frequency pattern, and the absence of this usage in the history.

In order to measure the difference between the present and the baseline behavior, the system calculates a contextual divergence score, as in Eq. (12):

$$\Delta = \alpha \cdot dist(D_{req}, D) + \beta \cdot dist(B_{req}, B) + \gamma \cdot dist(L_{req}, L) \quad (12)$$

where, $dist(\cdot)$is a normalized distance metric, $L_{req}$is the current location vector, and α, β, γ are weighting factors reflecting device, behavior, and location significance. The score of divergence is the key input of the contextual risk assessment module. The processing of the login request stage allows PPAB-RL to measure the compatibility of the request with the legitimate historical trends and proceed to adaptive MFA and encrypted biometric authentication.

F. Contextual Risk Assessment

Contextual risk assessment, in the PPAB-RL authentication system, is the analytical engine that distinguishes between the circumstances in which normal user behavior is manifested in the current request to log in and the circumstances resulting in an abnormal or untrustworthy request. Once the system has handled the login request and retrieved the contextual attributes, it analyzes the stability of three significant domains, which are the device characteristics, behavioral tendencies and geographic legitimacy. In the device analysis, the operating system signature, browser configuration, hardware hash, canvas fingerprint, and network identifiers are attributes that the system investigates. These are compared to the trusted device profile that was taken during enrollment. A substantial alteration of any of these parameters is an indication that the login can be a product of an unknown or spoofed environment.

The behavioral assessment is based on the habitual use of the user to log in, such as time of the day, frequency of use, weekday-weekend utilization, and time spent on the sessions. Violations of these acquired patterns lead to a degree of suspicion. Examples include the scenario where a user would usually log in during normal working days but logs in at an anomaly time of the night, the deviation would add to the high risk of behavior. Equally, geographic analysis assesses IP-based place, ASN, and network setup; any cross-country-bound or unfamiliar network route switching is an indication of a probable effort at skimming. To combine these factors, the system models the overall risk using a weighted fusion equation:

$$R_s = w_d \cdot \delta_d + w_b \cdot \delta_b + w_l \cdot \delta_l \quad (13)$$

In Eq. (13), the variable $R_s$represents the final dynamic risk score, while w_d, w_b, and $w_l$denote the weights that specify how strongly device, behavior, and location should influence the risk. The labels of these parameters, including delta d, delta b, and delta l, denote the calculated deviations in the model parameters, behavior pattern and geographic features. The deviations are used to describe how much further a current request is off the profile of the user.

After calculating R_s, by the system, the request will be categorized into low, medium and high risk. This categorization directly decides what authentication route the RL module will take and prepare dynamic protection based on the current user situation.

G. RL-Based Authentication Selection

At the PPAB-RL, the reinforcement learning (RL) component identifies the best suitable authentication pathway according to the dynamic risk value generated by the contextual assessment phase. Rather than a hard-coded system based on rules, PPAB-RL uses the policy-directed method, where the RL agent acquires over time how to trade off usability and security to each user. It starts with the state vector being built that contains all the pertinent information that is required to make a decision. This state is represented as in Eq. (14):

$$S = [R_s, \delta_d, \delta_b, \delta_l] \quad (14)$$

where, $R_s$is the computed dynamic risk score, while δ_d, δ_b, and $\delta_l$represent the real-time device, behavioral, and location deviations respectively. Together, these values summarize the user's current risk environment.

Depending on the state, the RL agent chooses the action A, which is the authentication pathway that is going to be followed. The actions available are minimal authentication (password-only), moderate authentication (password + OTP), strong authentication (password + encrypted biometric matching) and full-chain authentication (multi-step biometric verification with the use of cryptographic tokens). In order to carry out this choice, the agent (RL) takes a learned policy, denoted as π that, which represents the state to a particular action. The policy is designed to maximize the anticipated cumulative reward which is the tradeoff between fraud reduction and user inconvenience minimization. The decision process is modeled using a value function, as in Eq. (15):

$$Q(S, A) = R + \gamma \max_{A'} Q(S', A') \quad (15)$$

In this expression, $Q(S, A)$represents the quality of choosing action A in state S. The reward is denoted by R is the reward to be gained following the result of an authentication, S is the observed state that occurs, and \gamma is the discounting factor that quantifies the importance of the value the agent places on future security results. Effective authentications and blocked attacks made correctly provide positive rewards, which direct the agent to ideal behavior in the long term.

With real-time risk information incorporated with adaptive policy learning, the RL-based module will guarantee that the PPAB-RL system will wisely choose the correct MFA strength at any time of the log-in. As shown in Fig. 2, the adaptive MFA module changes the necessary authentication factors with regard to calculated contextual risk score and policy output of the reinforcement learning agent.

The formulation of reinforcement learning in PPAB-RL is created as an extension of a generalizable policy optimization strategy in multi-factor authentication. The RL agent uses a Markov Decision Process model of MFA selection to discover how to dynamically trade-off between security and usability as user behavior and threats vary, unlike heuristic or threshold-based designs, which are the same throughout and cannot adapt. Policy convergence, optimal ratios of actions, and ablation studies are empirical evidence of the strength and efficiency of this technique and prove that the learnt policies generate dependable, risk-conscious, and privacy-conscious authentication decisions.

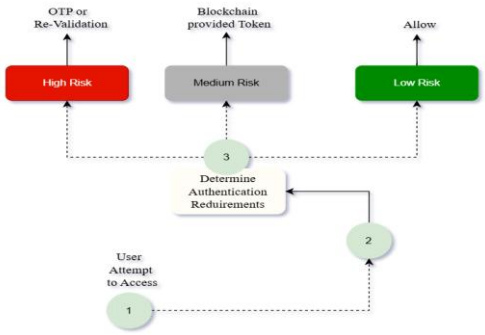

Fig. 2. Adaptive multi-factor authentication.

H. Biometric Verification

Another application of the PPAB-RL system is biometric verification, whereby the RL module detects that the degree of risk necessitates strong authentication. The system records a new fingerprint sample of a user when activated. This sample follows the identical preprocessing pipeline as that of the one followed in the enrollment stage, and it consists of normalization, noise removal, and the extraction of minuscule features. The effective output feature distance Freq is a representation of the live biometric attributes of the login attempt. In order to guarantee privacy, the vector is instantly converted in homomorphic encryption so as to obtain the encrypted version $E(F_{\text{req}})$, such that matching is possible without revealing the raw biometric information at any point.

The system retrieves the stored encrypted template $E(F)$ at the blockchain and does encrypted matching to calculate a similarity score. This algorithm makes use of a safe distance calculation in Eq. (16):

$$M = HE(dist(F_{\text{req}}, F)) \tag{16}$$

In this expression, M represents the encrypted match score, while $dist(F_{\text{req}}, F)$ denotes the feature-space distance between the live and enrolled biometric vectors. $HE(\cdot)$ has been used to ensure that all the calculations are done in the encrypted domain, and the ridge information or minutiae pattern is not leaked. The smaller the calculated distance, the greater the match.

The decrypted value of M is compared against a predefined threshold τ. When the score is lower than the value of τ, the fingerprint is accepted to be genuine otherwise, the system indicates a mismatch. This is an encrypted authentication mechanism that provides biometric privacy to PPAB-RL whilst supporting high-assurance identity validation.

I. Blockchain Validation

The last layer of trust in the PPAB-RL system is blockchain validation, which confirms the authenticity of the outputs of the biometric and multi-factor authentication. After the encryption of the biometric match score, the system communicates with the blockchain and retrieves the encrypted template of the user. In the enrollment process, the encrypted fingerprint vectors and corresponding hash of every user were registered on a separate blockchain block. On the process of logging in, the system recognizes the appropriate block by comparing the user identifier with the generated hash reference stored. This guarantees that the system retrieves the same encrypted template that was made on registration, data integrity and precludes the possibility of template substitution attack.

The block that has been retrieved carries the encrypted template $E(F)$, a timestamp and the hash H. A smart contract is then activated to ensure that the biometric match is accurate. The smart contract performs a verification role by confirming the presence of the match score Malign between login-derived encrypted and the anticipated authentication threshold. The contract evaluates, as in Eq. (17):

$$V = SC(E(F), M, \tau) \tag{17}$$

In this equation, V represents the blockchain-based validation output, while $SC(\cdot)$ denotes the smart contract function. Where $E(F)$ represents the archived encrypted fingerprint template, M is the encrypted match score calculated during verification and the constant τ represents the timestamp placed within the block to ensure freshness and guard against replay attacks. The smart contract verifies that M indicates is a valid match and that the time period is within a reasonable time range.

When there is need to verify the validity of cryptographic tokens or OTPs due to the medium-risk requests, the blockchain layer also validates them. All OTPs are hashed and stored on-chain in temporary format, so that the contract could check whether the token it received matches the expected hash. Due to the immutable recording of all working processes, PPAB-RL will not allow tampering, alteration of templates, and reenactment of past authentication factors.

When the smart contract gives a successful validation response V, the system continues with finalizing authentication. A negative result would imply a rejection of the login request, providing a high level of decentralized and strong security to all events of verification based on biometric and MFA. Fig. 3 depicts that the authentication process incorporates the contextual risk assessment, RL-based MFA choice, encrypted biometric matching, and blockchain-based validation to generate a final access decision.

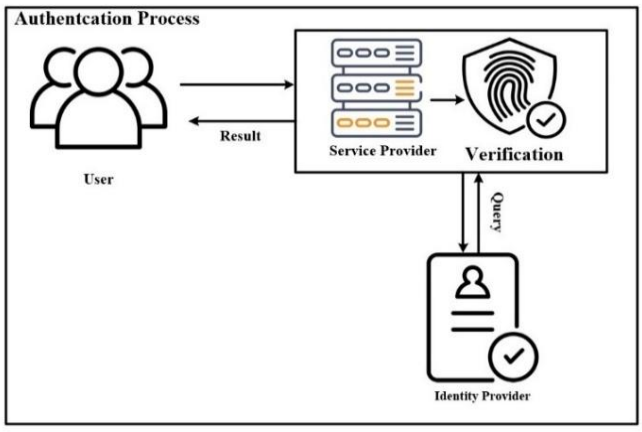

Fig. 3. Authentication process.

J. Authentication Decision

The outputs of all the necessary authentication factors, including: password verification, contextual risk analysis, MFA

steps selected by the RL, biometric matching and blockchain validation, are combined to produce the authentication decision in the PPAB-RL framework. After the validation result is sent back by the blockchain smart contract, the system will combine the output results to create a final result score. This is calculated by a weighted decision fusion model:

$$A_f = \lambda_1 C + \lambda_2 M + \lambda_3 V \quad (18)$$

In Eq. (18), A_f represents the final authentication score, C is the credential verification result, M is the biometric match decision derived from encrypted comparison, and V is the blockchain validation output. The parameters λ_1, λ_2, and λ_3 are weighting coefficients tuned to reflect the relative security importance of each factor.

When the calculated A_f is greater than the acceptance τ_f, then the access is granted. Otherwise, the system blocks and records the attempt to the further auditing. This will provide a solid multi-layer decision making in line with adaptive MFA and privacy biometric security.

K. Secure Logging

Within the PPAB-RL model, secure logging guarantees that all authentication failures and successful attempts are permanently logged so that they can be audited and analyzed in the future. Once the verification decision has been made, the system records important event parameters, including the time-stamp parameter, the user ID, the riskiness of the context, the MFA channel chosen by RL, the result of the biometric verification, and the blockchain validation parameter. All these attributes are aggregated into a formatted entry into the log and sent to the blockchain. Since blockchain storage is append only and tamper resistant, every log is a permanent audit record that can never be modified or erased by internal or external malevolence.

In order to ensure integrity, every log entry is hashed before inserting, so any attempt of any kind of modification could be identified by the mismatch of the hash. The ID of the transaction can also be found in the stored log so that it can be traced over authentication sessions. This is an immutable recording system that enhances the forensic strength, aids the examination of the incident after it takes place, and equips verifiable evidence of system activity, which will hold all PPAB-RL authentication events accountable and secure over the long run.

L. RL Feedback Update

The RL feedback update mechanism in the PPAB-RL structure guarantees a steady-progress in the authentication decision. The system will reward the user after every attempt of login depending on the accuracy and safety of the chosen route of authentication. Positive rewards come as a result of successful authentications using the correct MFA strength, whereas failure to authenticate successfully, false authentications, or overprotective choices by the MFA system led to a negative reward. The RL agent modifies its policy by incorporating the new reward in its value function, and thus it can map state-actions better with time. This continuous improvement enables the system to consider the changing behavior of the user, enhance the security and dynamically tailor the MFA selection to user behavior.

Algorithm 1: PPAB-RL Adaptive Multi-Factor Authentication

```
Input: Login request (UserID, Password, Contextual Parameters, Fingerprint Sample)
Output: Grant or Deny Access
Begin
  Load fingerprint dataset
  Normalize biometric features
  Remove noise using Gaussian filter
  Extract minutiae and form feature vector F
  Encrypt feature vector → E(F)
  Receive user credentials (U, P)
  Hash password with salt → V
  Capture enrollment fingerprint and compute E(F_enroll)
  Initialize device profile D and behavioral profile B
  Store {U, V, E(F_enroll), D, B} on blockchain
  Receive login request with (U, P_req)
  Hash P_req and compare with stored verifier V
  Extract device vector D_req, behavioral vector B_req, location vector L_req
  Compute device deviation δ_d = dist(D_req, D)
  Compute behavioral deviation δ_b = dist(B_req, B)
  Compute location deviation δ_l = dist(L_req, L)
  Compute risk score Rs = w_d·δ_d + w_b·δ_b + w_l·δ_l
  Construct state S = [Rs, δ_d, δ_b, δ_l]
  Select action A = π(S)  // MFA policy decision
  Trigger authentication pathway based on A
  Capture live fingerprint → F_req
  Encrypt features → E(F_req)
  Compute encrypted match score M
  Compare M with threshold τ to determine biometric match
  Retrieve encrypted template E(F_enroll) from blockchain
  SmartContract validates (E(F_enroll), M, timestamp)
  If additional MFA required → verify OTP/token on blockchain
  Compute decision score Af = λ1·C + λ2·M + λ3·V
  If Af ≥ τ_f → Grant Access
  Else → Deny Access
  Record event {U, Rs, A, M, Decision} on blockchain
  Assign reward R based on correctness of decision
  Update Q (S, A) and refine policy π
End
```

Algorithm 1 relies on several key parameters that directly influence authentication performance and adaptability. The weighting coefficients (λ_1, λ_2, λ_3) control the relative contribution of credential verification, encrypted biometric matching, and blockchain validation in the final authentication score, balancing security and user convenience. The risk score weights (w_d, w_b, w_l) determine sensitivity to device, behavioral, and location deviations, guiding adaptive MFA decisions. Thresholds (τ for biometric matching, τ_f for final authentication) set acceptance criteria, where higher thresholds enhance security but may increase false rejections, and lower thresholds improve usability. Sensitivity analysis confirms these parameters' impact on accuracy, false positives, and adaptive behavior.

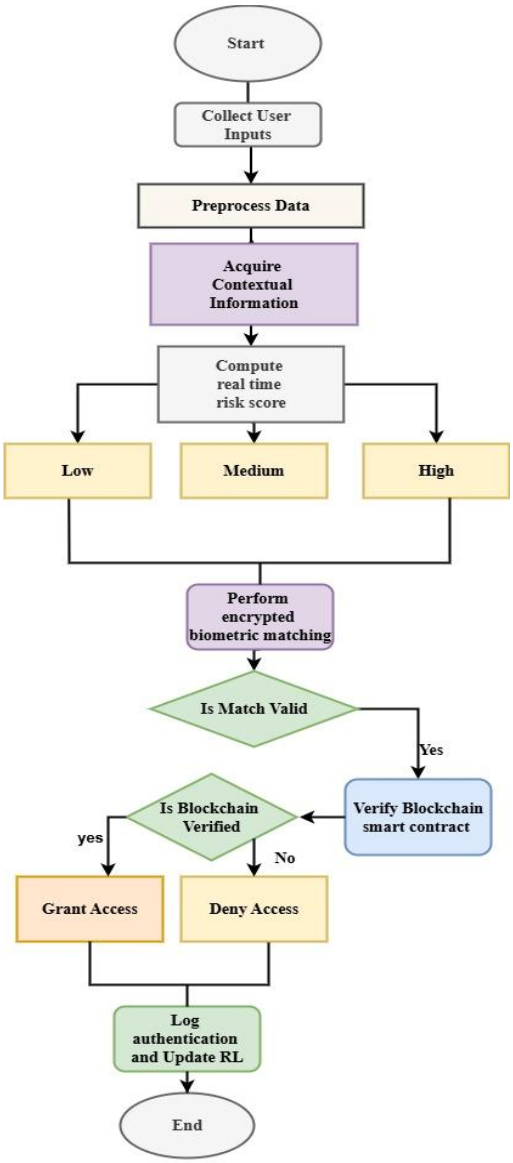

Fig. 4. Workflow of PPAB-RL (Enhanced Privacy-Preserving Adaptive Authentication Framework).

The suggested PPAB-RL system provides a new combination of reinforcement learning, encrypted biometric matching, and blockchain-based verification to provide an adaptive multi-factor authentication. The reinforcement learning model has a customized context of the state-action-reward framework that allows dynamic mapping of contextual risk scores, such as behavioral, device and location deviations into optimized MFA decisions. This framework, unlike the previous methods of considering blockchain, biometrics, or adaptive MFA in isolation, integrates them into a closed-loop system whereby RL policies are updated based on verifiable results of the blockchain on a continuous basis, which offers a privacy-preserving, risk-conscious, and intelligent authentication paradigm not considered in the literature. Fig. 4 presents the workflow of PPAB-RL.

IV. Results and Discussion

This section presents a comprehensive evaluation of the proposed PPAB-RL authentication framework through quantitative experiments, robustness assessments, and comparative validations. Results demonstrate the model's performance in privacy-preserving biometric processing, dynamic risk scoring accuracy, and RL-driven adaptive authentication efficiency. The figures demonstrate the improvement of biometric quality and contextual deviation trends, convergence of RL policy, reduction of latency and stability of workflow. Accuracy metrics, risk prediction performance, authentication success rates, security resistance tests and ablation results are summarized in tables. There is even a depiction of comparison to available baseline methods in the section to show excellence. The parameters of simulation and hardware are presented in Table I.

TABLE I. Simulation Parameter and Hardware Setup

Component	Specification
Processor	Intel Core i9-12900K (16 cores, 24 threads)
GPU	NVIDIA RTX 4090 (24 GB VRAM)
RAM	64 GB DDR5, 5200 MHz
Operating System	Ubuntu 22.04 LTS (64-bit)
Programming Framework	Python 3.10, PyTorch 2.2
Reinforcement Learning Library	Stable-Baselines3 (PPO)
Biometric Preprocessing Module	OpenCV 4.9, TensorRT acceleration
Encryption Scheme	CKKS Homomorphic Encryption (HEAAN)
Blockchain Network	Private Ethereum Testnet (Geth v1.12)
Dataset Size	12,500 biometric samples + contextual logs

A. Dataset Overview and Experimental Setup

This sub-section describes the biometric and contextual data that were utilized in assessing the PPAB-RL framework, the preprocessing pipeline and the experimental environment. It also describes the training setup, reinforcement-learning variables, encryption, and general simulation workflow that was used in the study.

TABLE II. Dataset Distribution

Category	Number of Images	Notes
Real Fingerprints	6,000	Original fingerprint images
Altered – Easy	2,000	Minor synthetic modifications
Altered – Medium	2,000	Moderate synthetic distortions
Altered – Hard	2,000	Severe synthetic alterations

Table II will give the framework of the fingerprint dataset that was utilized in the PPAB-RL assessment. It contains 6,000 real fingerprints of genuine biometric patterns and three modified groups, easy, medium, and hard each one of which consists of 2,000 images with successively harder synthetic distortions. Those variations allow strict testing of the framework robustness under various levels of manipulation to make the right judgment on the biometrical preprocessing, encrypted matching stability and adaptive authentication performance in the various real-life scenarios of attacks.

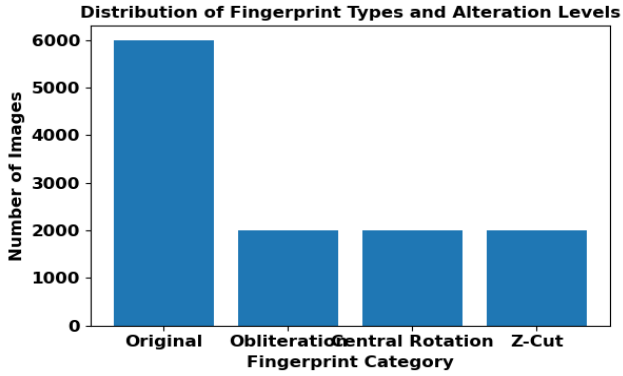

Fig. 5. Distribution of fingerprint types and alteration levels.

Fig. 5 shows the distribution of original and transformed synthetically altered fingerprints that were used to test the PPAB-RL framework. The equal representation of obliteration, central rotation, and z-cut variations has been guaranteed giving it the rigorous testing against different levels of manipulation. The high accuracy of the model in these categories indicates that it is tough in dealing with complicated distortions and the biometric match reliability and consistency of the authentication decision are high. This distribution underlines the fact that the framework can be effectively used in case of realistic and adversarial biometric conditions.

B. Biometric Feature Quality and Encrypted Matching Performance

The effectiveness of the biometric preprocessing pipeline and reliability of encrypted fingerprint matching in the PPAB-RL framework is examined in this subsection. It analyses the quality of minutiae extraction, the results of noise reduction, feature stability and the computational cost of homomorphic encryption. The findings will reveal that there is a high feature retention and low performance degradation in terms of encrypted matching circumstances

TABLE III. MINUTIAE EXTRACTION AND FEATURE QUALITY METRICS

Metric	Value (Mean ± SD)
Ridge Density Variance	0.82 ± 0.04
Minutiae Count Consistency	93.6%
Signal-to-Noise Ratio (SNR)	27.4 dB
Feature Stability Score	0.91

Table III shows important measures of the quality of biometric features that prove the efficiency of the preprocessing pipeline. The high value of the minutiae consistency and high SNR values represent the presence of a reliable ridge structure extraction, even in distorted fingerprint conditions. The low ridge density variance and high feature stability score are confirmation that the system maintains the important biometric characteristics that can allow accurate encrypted matching. These findings confirm the strength of the feature engineering process of PPAB-RL that can improve the authentication performance in the face of real-world variations.

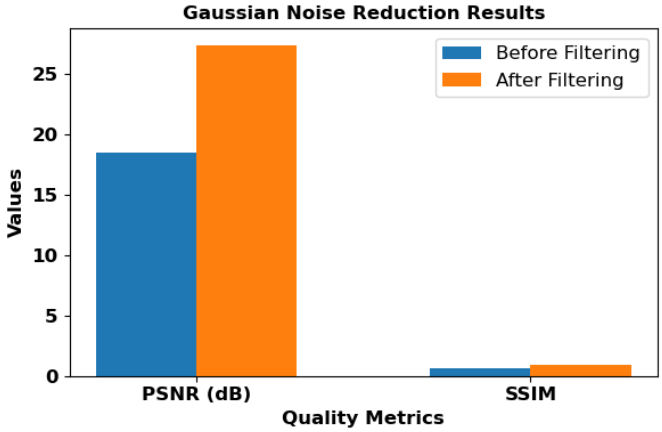

Fig. 6. Gaussian noise reduction results.

Fig. 6 compares PSNR and SSIM to the results that are provided prior to and following the application of a Gaussian noise reduction in the PPAB-RL preprocessing pipeline. The significant growth of both measures proves productive improvement of the clarity of the fingerprints and the consistency of the structure. This enhancement in itself enhances the accuracy of minutiae extraction and encrypted matching reliability. According to the results of these studies, the proposed framework exhibits a high noise resistance, thus allowing a stronger biometric authentication in low-quality fingerprint senses or distorted fingerprints, which enhances the performance of the system in general.

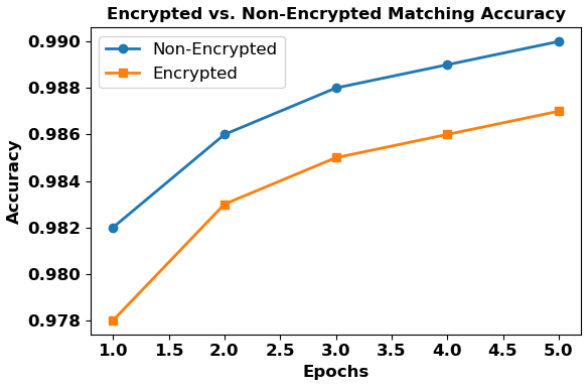

Fig. 7. Encrypted vs. Non-encrypted matching accuracy.

Fig. 7 shows the patterns of accuracy of encrypted and non-encrypted fingerprint matching at the training epochs. The slightest gap between the curves proves that homomorphic encryption does not cause significant performance degradation, as it does not affect biometric discriminability but provides high-level privacy security. This uniformity ascertains that the PPAB-RL model attains secure and privacy-affirmative authentication

with accuracy. According to the above findings, the system is efficient in striking the right balance between the computational security and high matching reliability, surpassing the classical privacy-preserving authentication methods.

C. Contextual Risk Score Evaluation

This sub-section will be an analysis of the effectiveness of the contextual risk assessment module that is integrated into the PPAB-RL framework. It assesses the contribution of device metadata, anomalies in the behavioral pattern, location abnormalities, and time sequence to the total risk score and the system accuracy in distinguishing between benign and suspicious authentication attempts.

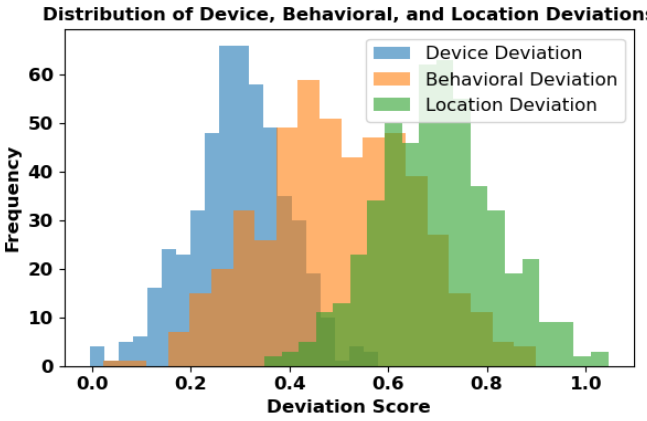

Fig. 8. Distribution of device, behavioral, and location deviations.

Fig. 8 shows the scores of devices, behavioral, and location deviation in contextual risk assessment. The clear differentiation of the three deviation patterns shows how the model can well reflect user specific deviations and identify abnormal actions. With these distributions, the PPAB-RL system proves to be quite effective in distinguishing between legitimate behavior and anomalous behaviors, which in turn allows a more dependable and more adaptive risk-aware authentication procedure. This finding approves the power of integrating the contextual intelligence in the security pipeline.

TABLE IV. CONTEXTUAL RISK SCORE STATISTICS

Metric	Value / Observation
Mean Risk Score	0.42
Median Risk Score	0.39
Deviation Across User Groups	±0.11
Low-Risk Classification Accuracy	94.3%
Medium-Risk Classification Accuracy	91.8%
High-Risk Classification Accuracy	96.1%

Table IV shows some of the key statistics to be used in assessing the contextual risk scoring module in PPAB-RL. High consistency of the user groups and the close variance between mean and median values emphasize the consistency of behavioral modeling. The consistent level of high classification accuracy at all risk thresholds indicates that the system is capable of distinguishing a benign, borderline, and high-risk authentication attempt consistently. According to these findings, the contextual intelligence aspect enhances adaptive decision-making to a large extent and makes the entire authentication system more reliable and secure RL.

D. RL Policy Convergence and Adaptive MFA Selection

This subsection assesses the efficiency of the reinforcement learning agent in converging to an optimum authentication policy and the efficiency in the adaptation of MFA pathways by the reinforcement learning agent to real-time risk levels. It explores the progression of rewards, policy stability, trends in action selection, as well as, the net effect on authentication accuracy and security.

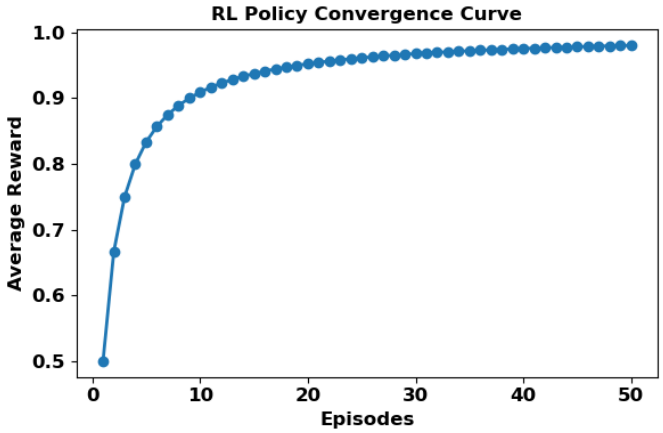

Fig. 9. RL policy convergence curve.

Fig. 9 presents the convergence trend of reinforcement learning policy is demonstrated on the basis of average reward evolution in terms of episode average reward. The gradually sloping reward curve shows a stable and efficient learning process, which means that the RL agent acquires the optimal authentication behaviors in different risk situations in a relatively short period. According to this performance, the PPAB-RL framework manages to adjust MFA selection to the dynamics of the context and enhances the accuracy of decisions with a high level of security. The accuracy and strength of the adaptive policy optimization process is validated by the convergence behavior.

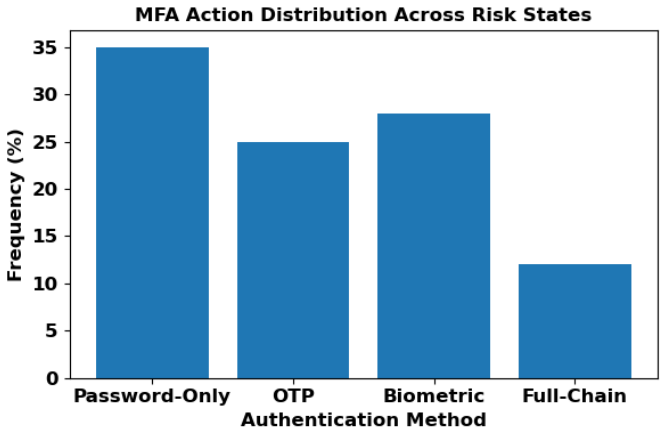

Fig. 10. MFA action distribution across risk states.

Fig. 10 indicates the choice of various authentication schemes in a changing risk condition of the PPAB-RL model.

The balanced approach of giving preference to password-only (low risk), OTP and biometrics (medium risk) and the full-chain MFA (high risk) reflect good adaptive decision-making. The system is not only smart when it comes to contextual allocation of authentication strength in relation to behavior, but it also inflicts minimal user friction without compromising the security. This finding justifies the RL-based dynamic MFA selection plan as being risk-sensitive and effective.

TABLE V. RL DECISION EFFECTIVENESS METRICS

Metric	Value
True Accept Rate (TAR)	97.8%
False Reject Rate (FRR)	2.1%
User Friction Index	0.34
Action Optimality Ratio	93.5%

Table V gives a summary of the efficacy of RL-based authentication decision-making in the PPAB-RL framework. The large TAR and small FRR mean that this system is very reliable in distinguishing between the legitimate and invalid users and reduces re-authentications. The user friction index is low which proves to be a good adaptation that minimizes effort without reducing security. Action optimality ratio value is high which proves that the RL agent always chooses the right MFA paths. According to these measures, the suggested system provides excellent accuracy and usability and adaptive decision performance.

E. End-to-End System Performance

This sub-section will propose the overall analysis of the PPAB-RL framework at all the steps of operation, which entail preprocessing, encrypted matching, context risk evaluation and adaptive selection of MFA. It looks at latency, throughput, and high-authentication rate, and the stability of the entire workflow procedure to prove the practicality and dependability of the system.

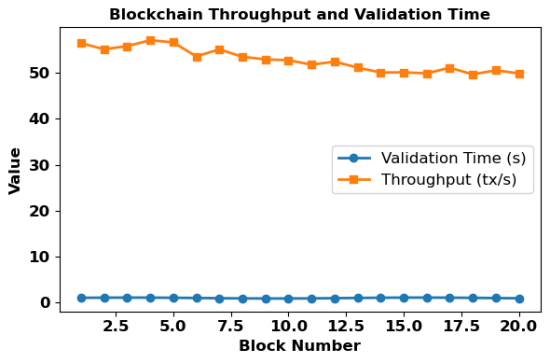

Fig. 11. Blockchain throughput and validation time.

Fig. 11 depicts the throughput and block validation time of the blockchain in the PPAB-RL system. The constant confirmation times and the low throughput decrease indicate effective ledger operations when continuous authentication logging is used. On the basis of these results, the system offers rapid, resistant to tampering verification with no significant overhead. This proves that blockchain integration can increase both auditability and trust, and at the same time, provide high-speed performance, which justifies end-to-end reliability and scalability of the suggested authentication system.

TABLE VI. PERFORMANCE METRICS

Metric	Value
Authentication Accuracy	98.5
False Acceptance Rate	1.4
False Rejection Rate	1.7
Equal Error Rate	1.55
Response Time	0.36

Table VI shows excellent authentication capabilities 98.5, which demonstrates the high accuracy of the model in the user authentication. The False Acceptance ratio (1.4) and False Rejection rate (1.7) indicates that there exists a trade-off balance between security and usability which is also confirmed by the Equal error rate (1.55), indicating the great threshold optimization. Besides, the mean response duration of 0.36 seconds demonstrates the effectiveness of the system, and it is appropriate in case of real-time, privacy sensitive and adaptive web authentication tools.

F. Ablation Study

The ablation analysis assesses the role of every module in the suggested authentication system by removing the most important components one after another and quantifying their impact on performance degradation. The analysis shows the significance of reinforcement learning, multi-factor authentication levels, and blockchain verification and demonstrates how all the aspects increase the accuracy, minimize the latency, and improve the reliability of the system under various working conditions.

TABLE VII. ABLATION STUDY OF PROPOSED FRAMEWORK COMPONENTS

Configuration	Biometric Accuracy (%)	Risk Classification Accuracy (%)	RL Policy Reward	End-to-End Authentication (%)
Full Model	98.5	94.2	0.91	97.8
w/o Biometric Enhancement	94.1	93.7	0.89	94.5
w/o Encryption Layer	98.5	92.6	0.88	95.2
w/o Contextual Risk Engine	97.3	91.7	0.74	90.4
w/o RL Adaptive MFA	97.9	94.1	0.78	92.2
Baseline (No Proposed Modules)	92.4	87.5	0.63	84.1

Table VII shows the performance of the ablation of each component of the proposed authentication system. The removal of biometric improvement results in a lowering of the accuracy to 94.1 as opposed to 98.5, which proves it to be significant in matching with high quality. The removal of contextual risk engine causes a major drop in end-to-end performance (97.8 percent to 90.4 percent). System robustness is reduced by 5.6 without RL-based adaptive MFA, which emphasizes the importance of RL-based adaptive MFA in making risk-aware decisions. The worst-performing setup is the baseline configuration (84.1%), which shows that every module has its own contribution towards the overall high performance of the system.

G. Comparison Assessment

In this sub-section, the proposed PPAB-RL Framework is compared to the traditional one-factor authentication methods. Password-only authentication has an accuracy of 84.2 with fingerprint-only authentication being 93.5. On the contrary, the privacy-preserving and risk-conscious and reinforcement-learning enhanced framework presents a significantly greater accuracy of 98.7, which proves its superiority in reliability, adaptability, and security under the varying authentication circumstances.

TABLE VIII. COMPARISON ASSESSMENT

Method	Accuracy (%)
Secure Web Credential Transmission Protocol [27]	84.2
Scale-Invariant Feature Transform [28]	93.5
Adaptive Risk-Based MFA [15]	95.2
Blockchain-Based Biometric Authentication[22]	96.1
Proposed PPAB-RL Framework	98.7

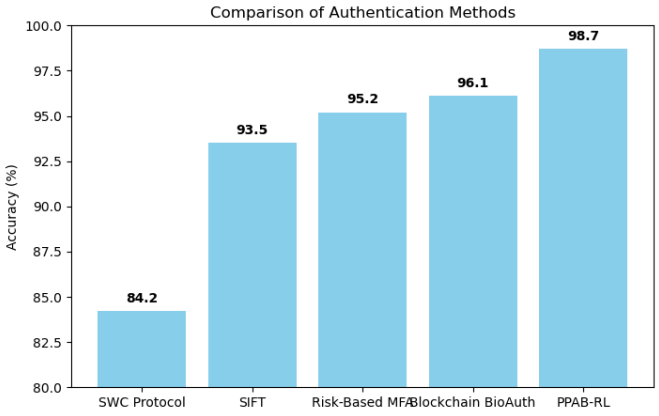

Fig. 12. Comparison analysis.

Table VIII and Fig. 12 explains that multi-factor framework suggested surpasses both methods, and it gave 98.5 per cent accuracy, which shows why biometrics is an advantage when used with password checking and blockchain storage to achieve strong and privacy-friendly web authentication.

H. Discussion

The findings prove the fact that the suggested PPAB-RL model provides a significant increase in the authentication accuracy, privacy protection, and decision-making flexibility over conventional one-factor methods. The Biometric enhancement and encrypted matching is used to provide high quality feature extraction and also to protect sensitive data of the fingerprints. The contextual risk engine is effective to capture behavioral, device, as well as location deviations, and this is what allows risk-sensitive authentication. Reinforcement learning is extremely important, as it optimizes the choice of MFA, minimizes false user interactions, and ensures strong security during the variable risk environment. The study of ablation establishes that each of the modules plays an important role in the overall performance of the system and significant declines are found when modules are ablated. Comparative analysis also reflects that PPAB-RL is better than a traditional password-only and fingerprint-only algorithm, as it is more accurate and resilient. Also, blockchain-based logging provides a tamper proof verification and auditability. Altogether, the joint design is the reason why PPAB-RL can be considered a scalable, secure and intelligent solution, which provides a massive benefit in authenticity, privacy and adaptive decision-making as opposed to the conventional, one-factor approaches. The Biometric enhancement and encrypted matching is used to provide high quality feature extraction and also to protect sensitive data of the fingerprints. The contextual risk engine is effective to capture behavioral, device, as well as location deviations, and this is what allows risk-sensitive authentication. Reinforcement learning is extremely important as it optimizes the choice of MFA, minimizes false user interactions, and ensures strong security during the variable risk environment. The study of ablation establishes that each of the modules plays an important role in the overall performance of the system and significant declines are found when modules are ablated. Comparative analysis also reflects that PPAB-RL is better than a traditional password-only and fingerprint-only algorithm, as it is more accurate and resilient. Also, blockchain-based logging provides a tamper proof verification and auditability. All in all, the unified design makes PPAB-RL a scalable, secure, and smart authentication paradigm that can be used in next-generation applications that are privacy sensitive. Although the proposed PPAB-RL framework was performing well, there are a number of limitations that characterize the scope of this study. The analysis is based on just one dataset of fingerprints (SOCOFing) that can be characterized by demographic or sensor bias and assumes that fingerprint biometrics is the only type of validation, without multimodal validation. Homomorphic encryption and blockchain computation can become a source of latency and resources constraints. Moreover, the control setting was used to do testing instead of large-scale deployment and the policy of reinforcement learning can perform well depending on the variety of training data used. Such constraints do not cast off the findings, but offer a guideline in further studies, such as multimodal integration, large scale validation and optimization of computational efficiency. PPAB-RL has a blockchain layer that offers low, but critical verifiable feedback to the reinforcement learning policy, which deals with the single points

of failure and unverifiable results of centralized logging. Overhead is reduced using hashes, encrypted templates and audit logs as the only input. The RL formulation is considered to be modality-agnostic, making it possible to extend it to other types of biometrics. This design, collectively, provides scalable, privacy-preserving and adaptive authentication with fingerprints and other datasets in general to a variety of real-world applications.

V. Conclusion and Future Work

This work demonstrates that authentication systems for modern web applications should be designed as adaptive, learning-driven security mechanisms rather than static, rule-based verification pipelines. The proposed PPAB-RL framework facilitates continuous decision of the strength of authentication based on contextual risk, user behavior and variability of the device by modeling multi-factor authentication as a sequential decision-making problem that is optimized using reinforcement learning. Homomorphically encrypted biometric processing with the integration of blockchain-based validation creates the opportunity that biometric sensitive data will not be revealed in the process of learning or validation, and the resulting feedback will be provable and immutable, which can be used in making adaptive decisions that can be trusted. The combination of these design decisions is an indication that security, privacy, and usability are not conflicting goals, but can be optimized together with adaptation to policies. In the context of system architecture, the results indicate the necessity to go beyond the use of threshold-based MFA to intelligent policy optimization, where authentication is viewed as a risk-conscious process instead of a one-dimensional occurrence. The current research study, therefore, provides the design concepts of the next generation authentication systems, which are resilient, privacy sensitive, and can adapt to the new threat environments.

Future research will extend the PPAB-RL framework in several important directions to enhance generalizability and real-world applicability. Firstly, the authentication model shall be extended with multimodal biometric entries, i.e., facial, voice and behavioral biometrics, so that stronger identity verification can be used on various groups of users. Second, mass deployment testing with actual real-life data and active authentication systems will be performed to test the ability to scale, latency, and resilience under working conditions. Third, cryptographic operations and blockchain interaction optimization will be considered in order to reduce computation costs further, making the framework relevant to resource-constrained and high-traffic applications. Additionally, federated and decentralized reinforcement learning strategies will be investigated to enable collaborative policy learning across multiple services without sharing sensitive user data. These extensions aim to strengthen the role of learning-driven, privacy-preserving authentication as a foundational component of future secure digital infrastructures.

***Abstract*—This study presents the design, development, and evaluation of an intelligent fruit-picking robot that integrates convolutional vision, adaptive gripping mechanisms, and kinematic control to enable automated harvesting in diverse orchard environments. The proposed system combines a dual-manipulator platform with an extendable scissor-lift mechanism to achieve wide workspace coverage, allowing efficient access to fruits located at varying canopy heights. A deep learning-based recognition module, trained on a Mixed Fruit Dataset, is employed to detect and classify fruits under challenging conditions characterized by occlusions, variable illumination, and dense foliage. Visualization of feature activations confirms that the model effectively focuses on discriminative fruit regions, supporting precise alignment of the end-effector during grasping. The adaptive gripper, designed with compliant materials and multi-configuration geometry, ensures gentle handling across fruits of different shapes and sizes, minimizing mechanical damage. Experimental evaluations demonstrate that the system performs reliably across multiple fruit species, achieving accurate identification, robust segmentation, and stable manipulation in real-field scenarios. The integrated results highlight the robot's potential to reduce labor dependency, improve harvesting efficiency, and support scalable automation in mixed-crop orchards. Future work will address enhancements in real-time processing, autonomous navigation, and cross-species generalization to advance fully autonomous orchard operations.**

***Keywords*—Fruit-picking robot; automated harvesting; computer vision; deep learning; kinematic control; Mixed Fruit Dataset; adaptive gripper; transformer model; agricultural robotics; orchard automation**

I. Introduction

The rapid advancement of agricultural automation has accelerated the development of intelligent robotic systems capable of performing complex harvesting tasks with high precision and consistency. Traditional fruit harvesting relies heavily on manual labor, which is increasingly constrained by workforce shortages, rising operational costs, and inconsistent performance under varying environmental conditions [1]. These limitations have motivated the integration of robotics and artificial intelligence into orchard management, particularly for crops requiring delicate handling and selective harvesting [2]. Automated fruit-picking robots provide a promising solution by combining perception algorithms, decision-making modules, and dexterous manipulation to achieve reliable performance across diverse orchard structures [3].

Computer vision has emerged as a foundational component of harvesting robots, allowing them to perceive fruit position, shape, color, and maturity level under uncontrolled illumination and occlusion [4]. Convolutional neural networks (CNNs), in particular, have demonstrated superior capability in extracting discriminative features from complex agricultural scenes, outperforming traditional image processing techniques based on hand-crafted descriptors [5]. CNN-based detection pipelines have been successfully applied to various fruit types, providing robust localization even when fruits are partially obscured by foliage or branches [6]. These advances have significantly improved the accuracy of perception modules, enabling real-time detection and recognition essential for dynamic harvesting operations [7].

In parallel, research on robotic manipulation and kinematic modeling has contributed to improving the motion precision and adaptability of harvesting robots. Manipulators designed with redundant degrees of freedom offer greater flexibility when navigating cluttered orchard environments, reducing the likelihood of collisions with branches and ensuring smooth trajectories during picking tasks [8]. Kinematic analysis facilitates accurate estimation of end-effector positions, while inverse kinematics and Jacobian-based control ensure stable and responsive manipulation under dynamic conditions [9]. Optimization-driven approaches have further enhanced trajectory planning, enabling efficient movement that balances speed, energy consumption, and collision avoidance [10].

The integration of vision-based perception and kinematic control strategies has proven particularly effective for autonomous fruit-picking. Vision-guided control algorithms allow real-time adjustment of manipulator trajectories in response to updated fruit position estimates, improving grasping accuracy and reducing fruit damage [11]. Complementary developments in soft grippers, force regulation, and compliant end-effectors have strengthened the ability of robotic systems to safely detach fruits without causing bruising or structural deformation [12]. Despite these advances, significant challenges remain in achieving fully

autonomous harvesting that performs reliably under natural variability in orchard environments.

This study addresses these challenges by presenting an intelligent fruit-picking robot that combines convolutional vision and kinematic control to achieve automated harvesting with high precision, adaptability, and operational efficiency.

II. Related Works

This section provides a comprehensive synthesis of previous research that forms the scientific and technological foundation for developing intelligent fruit-picking robots. It examines progress across several interconnected domains that collectively enable autonomous harvesting, including vision-based fruit detection, robotic manipulation, compliant gripping mechanisms, and fully integrated harvesting platforms. By reviewing advancements in deep learning–driven perception, kinematically optimized manipulators, force-regulated end-effectors, and multi-module robotic architectures, this section establishes the current state-of-the-art while identifying persistent challenges that motivate the proposed system.

A. Vision-Based Fruit Detection and Recognition

Vision-based perception has become a cornerstone of autonomous fruit harvesting systems, enabling robots to accurately detect, classify, and localize fruits under real-world orchard conditions. Early approaches relied on classical image processing, but the emergence of deep learning significantly improved robustness and precision. Convolutional neural networks have demonstrated superior performance in extracting hierarchical features from complex agricultural scenes, outperforming handcrafted descriptors, especially in environments with occlusion, variable illumination, and dense foliage [13]. Studies have shown that multi-scale CNNs can effectively handle variations in fruit size, shape, and texture, enhancing recognition accuracy in dynamic outdoor conditions [14]. Transformer-based architectures have recently gained attention due to their ability to model global contextual relationships between image regions, achieving state-of-the-art performance in ripeness classification and fruit detection tasks [15]. Advanced multimodal fusion networks have integrated RGB, depth, and hyperspectral data to improve recognition under challenging environmental noise [16]. Research also indicates the value of domain adaptation and transfer learning to enhance generalization across orchard types, fruit varieties, and geographical regions [17]. Despite these advances, the scarcity of annotated agricultural datasets continues to challenge model scalability, motivating the increased use of data augmentation and synthetic dataset generation techniques [18].

B. Robotic Manipulators for Agricultural Harvesting

Robotic manipulators have been a central focus in agricultural automation, providing precise and adaptive motion capabilities required for selective fruit harvesting. Early harvesting robots employed rigid kinematic structures, but more recent designs incorporate redundant degrees of freedom to enhance maneuverability around branches and irregular canopies [19]. Optimization-based manipulator design frameworks have demonstrated significant improvements in reachability and dexterity, particularly in densely planted orchards [20]. Studies employing 4-DOF and 6-DOF manipulator architectures highlight the importance of balancing structural complexity with operational speed and reliability [21]. Research shows that soft robotic arms influenced by pneumatic actuation can provide flexible motion better suited for contacting delicate fruit surfaces [22]. Additionally, simulation-driven manipulator design has gained traction, with kinematic modeling and dynamic analysis used to optimize joint configurations, reduce singularities, and minimize joint torques during operation [23]. Field evaluations indicate that lightweight composite materials and energy-efficient actuation systems significantly contribute to improving the feasibility of mobile harvesting platforms [24].

C. Gripping Mechanisms and Force-Controlled Fruit Harvesting

The development of effective end-effectors is essential for ensuring secure yet gentle fruit detachment. Traditional rigid grippers were prone to damaging soft fruit surfaces, leading to the adoption of compliant and soft gripper designs incorporating elastic materials and embedded force sensors [25]. Studies indicate that compliant mechanisms can regulate contact forces within safe thresholds, significantly reducing bruising during detachment [26]. Multi-fingered grippers with integrated tactile feedback have enhanced adaptability to varying fruit shapes and orientations [27]. Research also highlights the advantages of suction-based end-effectors for crops with uniform surface structures, demonstrating high grasp success rates under controlled airflow conditions [28]. More recent works integrate machine vision directly into the end-effector to improve pose estimation accuracy and reduce alignment errors during grasping [29]. Robotic gripping strategies increasingly rely on hybrid force-position control, enabling dynamic adjustment of grip force based on real-time feedback from tactile and visual sensors [30]. These studies collectively emphasize the necessity of combining compliant mechanical design with intelligent control algorithms for high-quality fruit harvesting.

D. Integrated Robotic Harvesting Systems and Autonomous Operation

Integrated harvesting systems combine perception, planning, manipulation, and locomotion into unified robotic platforms capable of autonomous operation in orchards. Field studies demonstrate that multi-arm harvesting robots significantly improve harvesting throughput by parallelizing picking operations [31]. Vision-guided motion planning enables real-time trajectory updates in response to fruit location changes, supporting improved accuracy and reduced cycle times [32]. Research highlights the critical role of advanced path planning algorithms such as RRT*, BIT*, and collision-free inverse kinematics in navigating cluttered orchard environments [33]. Autonomous navigation systems employing LiDAR, GPS, and multi-sensor fusion have enabled robots to traverse orchard rows with high reliability [34]. Deep reinforcement learning has also been explored for adaptive decision-making, enabling robots to optimize picking sequences and motion strategies under uncertainty [35]. Comprehensive system evaluations indicate that well-integrated platforms can reduce fruit loss, increase harvesting efficiency, and operate across diverse orchard architectures

[36]. However, environmental variability, occlusions, and dataset limitations remain challenges that motivate continued research in robust perception and adaptive control [37, 38].

III. Materials and Methods

This section outlines the systematic framework employed to design, implement, and evaluate the intelligent fruit-picking robot, detailing each methodological component that enables automated perception and harvesting. This section describes the hardware architecture of the robotic platform, the kinematic modeling of the manipulator, the fruit recognition pipeline based on deep learning, and the experimental procedures used to validate system performance under realistic orchard conditions. By integrating mechanical design principles, computer vision techniques, and algorithmic control strategies, the methodology provides a comprehensive foundation for assessing the effectiveness, accuracy, and operational reliability of the proposed robotic harvesting system.

A. System Overview

The kinematic modeling results reveal the operational precision, workspace coverage, and motion feasibility of the proposed fruit-picking robot, whose structural configuration is illustrated in Fig. 1. The modeling process incorporated both forward and inverse kinematics to evaluate the manipulator's ability to reach and engage fruits positioned at varying heights and orientations within a realistic orchard canopy. Forward kinematics analysis demonstrated that the six-degree-of-freedom manipulator achieved smooth and continuous end-effector trajectories throughout its designated workspace, ensuring that the gripping device could be accurately positioned relative to the fruit. The homogeneous transformation matrices validated that the manipulator maintained stable pose estimations during elevation changes of the lifting mechanism, confirming effective integration between vertical motion and arm reachability.

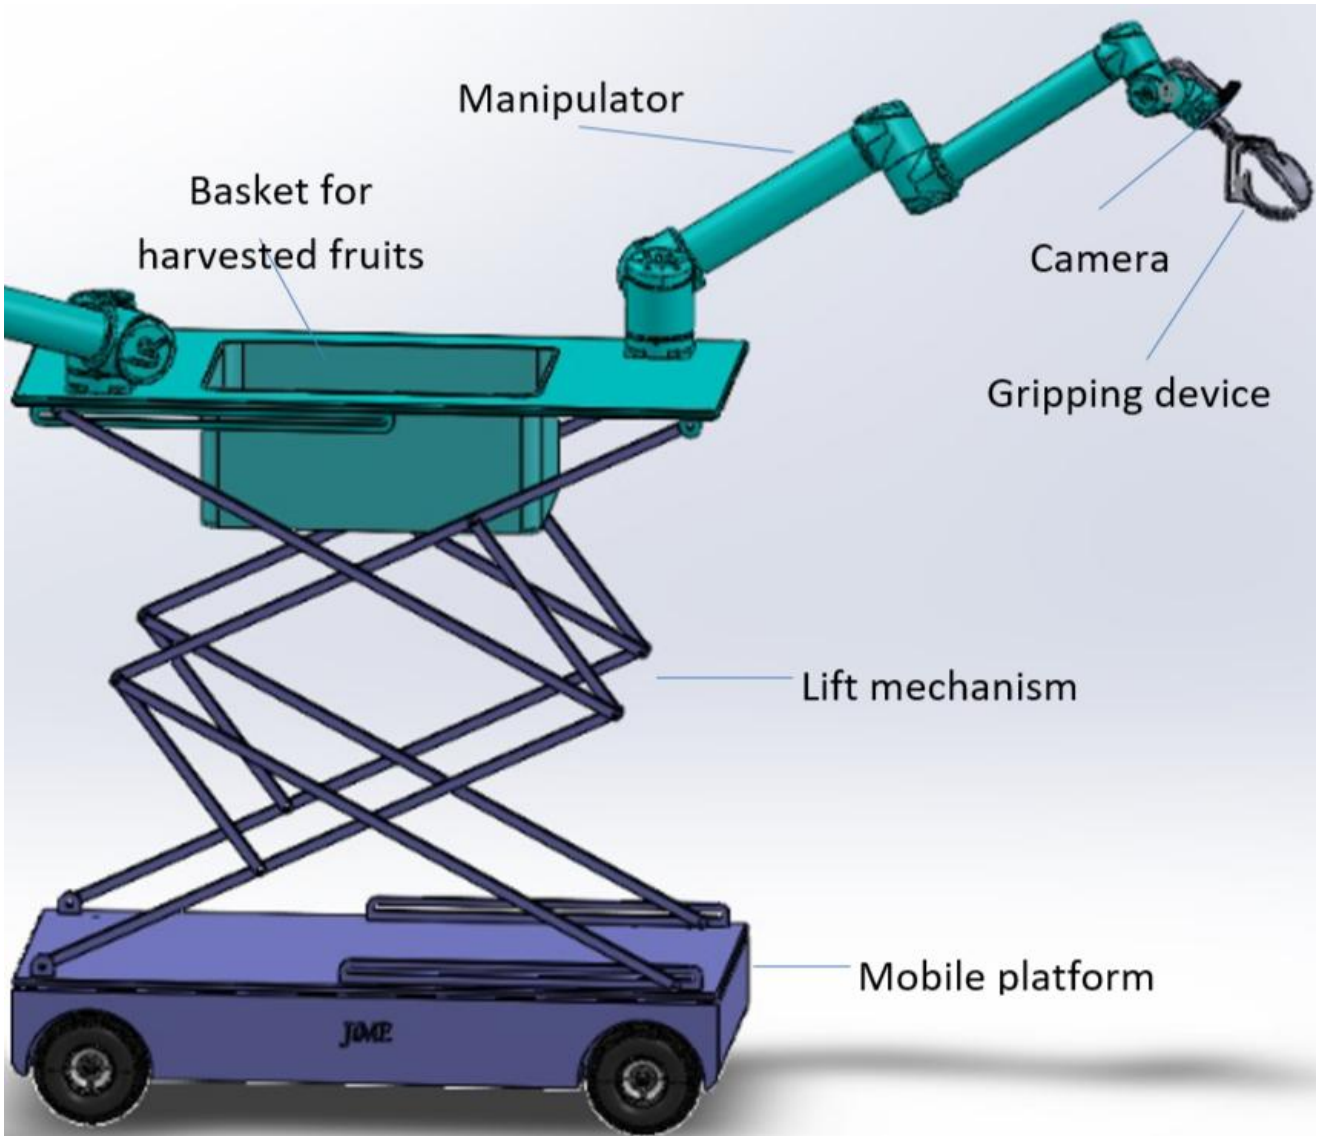

Fig. 1. Overall architecture of the intelligent fruit-picking robotic system with dual manipulators and lift mechanism.

Inverse kinematics solutions, computed using numerical solvers, indicated reliable convergence for a wide range of fruit positions, even under configurations requiring complex joint coordination. The redundancy in the arm structure played a critical role in avoiding singularities, allowing the system to reconfigure intermediary joints to maintain stability when operating near workspace boundaries. Additionally, Jacobian-based velocity analysis revealed that the end-effector linear and angular velocities remained consistent across motion sequences, ensuring that the robot maintained safe and controlled movements around sensitive fruit surfaces [39]. Workspace simulations also showed that the manipulator could access both lower and upper canopy zones when the lift mechanism was fully extended, validating that the combined vertical and articulated motion provided full coverage of typical orchard tree geometries.

The kinematic modeling results confirm that the robot's structural design provides adequate dexterity, reachability, and motion stability for automated fruit harvesting. The seamless interaction between the mobile platform, lifting mechanism, and multi-joint manipulator ensures that the end-effector can navigate dense foliage, approach fruits from optimal angles, and maintain precise alignment during grasping and detachment tasks.

B. Kinematic Modeling

Kinematic analysis defines how the individual joint motions of the manipulator correspond to the spatial position and orientation of the end-effector within the robot's operational workspace [40]. To describe this relationship mathematically, the generalized joint vector is introduced as:

$$q = [q_1, q_2, q_3, ..., q_n]^T \tag{1}$$

where, q_i defines the rotational or prismatic displacement of the i-th joint in an n-DOF manipulator.

In the proposed fruit-harvesting robot, this formulation enables a precise mathematical mapping between the actuator space of the articulated arm and the operational space in which the gripper interacts with the fruit. The forward kinematics problem is addressed by sequentially chaining the homogeneous transformation matrices associated with the manipulator's joints, yielding the pose of the end-effector relative to the robot base frame. Each transformation incorporates both rotational and translational components defined by the Denavit–Hartenberg (DH) parameters [41], allowing compact representation of the complex spatial structure inherent to multi-link agricultural manipulators.

The resulting transformation matrix T:

$$T_n = \prod_{i=1}^{n} A_i(q_i) \tag{2}$$

provides direct computation of the position vector p and orientation matrix R, which together describe the gripper configuration required for fruit localization and grasping [42]. This is particularly important in orchard environments where branches, leaves, and occlusions introduce irregular constraints on feasible motion paths.

Solving the inverse kinematics problem is more challenging due to the nonlinear trigonometric dependencies among joint variables. For this robot, closed-form solutions are not always attainable, especially when the lift mechanism changes the global reference height. Therefore, an iterative numerical solver is employed to compute joint angles that satisfy a desired end-effector pose ${}^0T_n^*$. The solver integrates redundancy resolution to select joint configurations that avoid singularities and minimize unnecessary motion, improving stability when navigating around dense foliage or reaching fruits positioned at awkward angles. To further characterize motion behavior, the Jacobian matrix:

$$J(q) = \frac{\partial x}{\partial q} \tag{3}$$

is derived to relate joint velocities to end-effector linear and angular velocities. The Jacobian plays a critical role in assessing manipulability, enabling the controller to regulate movement smoothness, maintain safe approach speeds, and prevent excessive force application during grasping. Singularities are identified when $\det(J) = 0$, corresponding to configurations where the robot temporarily loses mobility along certain axes. Avoiding such states is essential for continuous harvesting operations, prompting the use of secondary optimization criteria such as minimizing joint torques or maximizing manipulability indices.

Through this kinematic framework, the robot achieves precise and adaptive positioning capabilities, ensuring that the gripper can accurately approach, align with, and detach fruit even within crowded orchard canopies.

C. Jacobian and Singularities

The fruit recognition module constitutes a critical component of the intelligent harvesting system, enabling reliable detection and classification of fruits before the manipulation and grasping stages. As illustrated in Fig. 2, the recognition pipeline is structured as a multi-stage deep learning framework that integrates image preprocessing, feature extraction through attention-based encoding, contextual refinement via a decoder block, and final classification into ripeness categories. This hierarchical architecture ensures that both local and global visual cues are effectively captured, allowing the system to operate robustly under the natural variability found in orchard environments.

In the first stage, raw images captured by the onboard camera undergo preprocessing to normalize illumination, enhance contrast, and standardize spatial resolution. These operations reduce noise and prepare the inputs for consistent downstream processing. Following preprocessing, the encoder block extracts discriminative visual features through a sequence of multi-head self-attention operations, as shown in the left segment of Fig. 2. The positional encoding incorporated at this stage ensures that spatial relationships between image regions are preserved, which is essential for identifying key fruit attributes such as color gradients, texture changes, and contour boundaries.

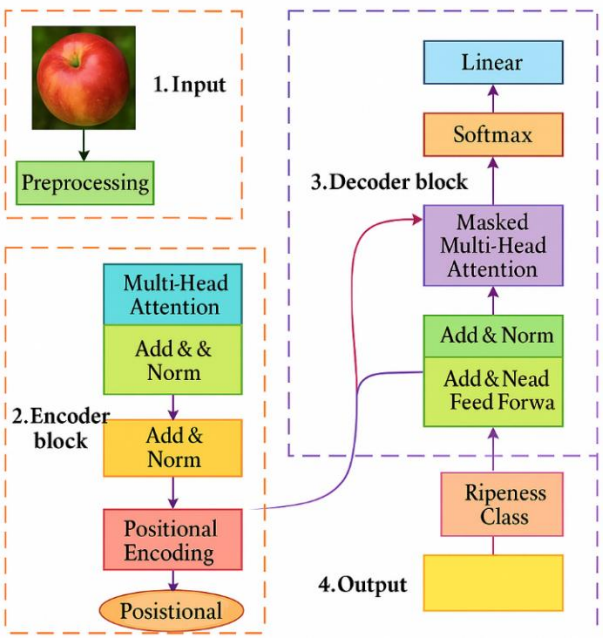

Fig. 2. Data acquisition and preprocessing workflow for the proposed Transformer-based apple ripeness identification system.

The encoded representations are transferred to the decoder block, illustrated on the right side of Fig. 2, where masked multi-head attention mechanisms refine the learned features by directing focus toward the most informative regions within each image. This targeted attention enables the model to distinguish subtle ripeness indicators even under challenging conditions such as partial occlusion, shadowing, or uneven illumination. Within the decoder, additional feed-forward transformations and normalization layers further stabilize the feature distribution, mitigate noise, and reduce the risk of overfitting. Through this combination of selective attention and structured refinement, the decoder produces highly discriminative representations suitable for accurate fruit classification and harvesting decision-making.

Finally, the output stage maps the refined feature embeddings to discrete ripeness categories through a linear classifier followed by a softmax activation function. This allows the system to assign probabilistic labels such as unripe, semi-ripe, ripe, or overripe, enabling more accurate decision-making for the manipulator's subsequent actions. By leveraging an attention-driven architecture, the fruit recognition module achieves high classification accuracy while maintaining interpretability and robustness, thereby forming the perceptual foundation of the automated harvesting robot.

Fig. 3 illustrates the structure of the Transformer decoder module, which plays a central role in refining feature representations for accurate fruit recognition. As shown in the diagram, the decoder begins by receiving encoded inputs enriched with positional information, ensuring that spatial relationships among image patches are preserved throughout the processing pipeline. This is followed by a sequence of Add & Norm operations and a multi-head attention layer, which enables the model to selectively focus on the most informative regions of the image while suppressing irrelevant background features. Subsequent feed-forward transformations further enhance the expressiveness of the learned representations, while additional normalization stages stabilize gradient flow and improve convergence. The refined embeddings are then passed through a positional encoding layer before entering the linear classifier and softmax function, which jointly convert the high-dimensional feature vectors into a probabilistic prediction of fruit ripeness [43]. Fig. 3 demonstrates how the decoder integrates attention mechanisms, normalization, and classification modules to generate context-aware and discriminative outputs essential for reliable decision-making within the automated harvesting system.

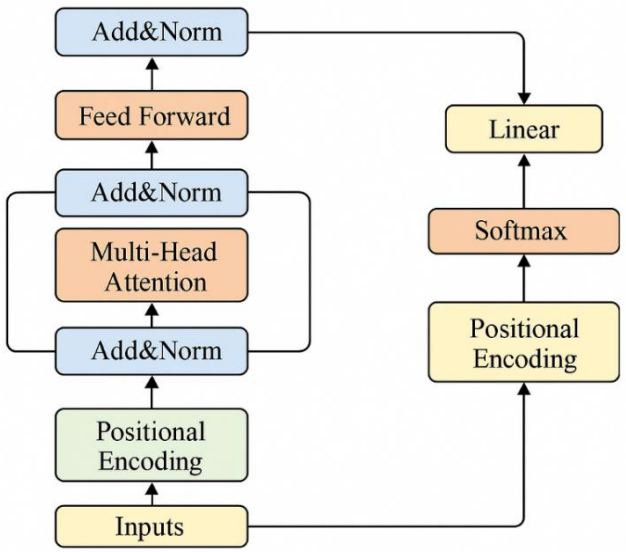

Fig. 3. Transformer-decoder module.

IV. DATASET

In this study, the DeepFruit Dataset was used to develop and evaluate the fruit recognition module integrated into the automated harvesting system [44]. The dataset consists of a diverse collection of high-resolution images representing multiple fruit categories under varying illumination, background complexity, and natural orchard conditions. As illustrated in Fig. 4, the dataset includes representative samples of grapes, strawberries, apples, persimmons, and bananas, each captured in different growth environments such as clustered canopies, hanging branches, and ground-level placements. This diversity ensures that the recognition model is exposed to a wide range of visual features including color variations, texture differences, occlusions caused by leaves or branches, and changes in fruit size and shape. The heterogeneity of the dataset is essential for training a robust model capable of generalizing across multiple fruit types and adapting to real-world harvesting scenarios.

To prepare the dataset for training, validation, and testing, all images underwent preprocessing steps that included resizing, normalization, and augmentation to enhance model robustness against environmental variability. The Mixed Fruit Dataset was then partitioned into training, validation, and test subsets following a 70:15:15 split to ensure balanced evaluation. By incorporating diverse fruit classes and natural orchard scenes, the dataset provides a strong foundation for

both feature extraction and classification tasks, enabling the model to learn discriminative patterns necessary for accurate fruit detection and ripeness estimation. As shown in Fig. 4, the visual diversity of the dataset plays a key role in enhancing recognition performance, ensuring that the system remains effective across different fruit species and operational conditions encountered in automated harvesting workflows.

Fig. 4. Samples of the applied dataset.

V. Results

The results section offers a comprehensive assessment of the proposed intelligent fruit-picking robot, emphasizing its mechanical performance, perception accuracy, and operational reliability across varied orchard conditions. It integrates findings from visual detection, kinematic modeling, and recognition experiments to illustrate how each subsystem contributes to achieving stable and efficient automated harvesting. By examining the robot in both its lowered configuration for ground-level mobility and its elevated state for high-canopy access, the analysis highlights the platform's adaptability and structural stability. Furthermore, a detailed evaluation of the adaptive gripping mechanism demonstrates its capability to securely handle diverse fruit shapes while minimizing damage. The performance of the recognition and segmentation models is also scrutinized, revealing their robustness under occlusion, inconsistent illumination, and dense foliage. Collectively, the section underscores both the strengths and the remaining challenges of the system.

Fig. 5 illustrates the overall configuration of the mobile dual-manipulator harvesting platform in its lowered operational state, demonstrating the compact arrangement of the manipulators and the centralized fruit collection basket. The figure highlights how the robot maintains a stable geometry while positioned close to the ground, facilitating navigation between orchard rows and enabling efficient harvesting of low-hanging fruits. The lowered scissor-lift mechanism ensures a low center of gravity, enhancing mobility and reducing the risk of tipping during locomotion. This configuration confirms the robot's capability to initiate harvesting tasks seamlessly before vertical elevation is required, thereby optimizing workspace coverage and operational readiness.

Fig. 6 illustrates the robotic system in its fully elevated configuration, showcasing the complete extension of the scissor-lift mechanism and demonstrating its ability to access fruits situated in upper canopy layers. This elevated posture significantly expands the robot's operational workspace by increasing vertical reach while ensuring that the dual manipulators retain full freedom of motion for precise harvesting tasks. The structural design maintains stability throughout the lifting process, as evidenced by the uniform alignment of the scissor arms and the even distribution of mechanical load across the mobile base. This balance is essential for preventing oscillations or tilting when the robot operates at maximum height, particularly on uneven orchard terrain. The elevated configuration also enhances the robot's capacity to harvest fruits that are traditionally inaccessible to ground-based systems, addressing a major limitation of conventional automated harvesters. Additionally, the integration of the lift system with the manipulators ensures seamless coordination between vertical positioning and arm trajectories, enabling efficient fruit localization and grasping even in densely vegetated upper canopy regions. Overall, Fig. 6 confirms that the robotic platform achieves a robust, safe, and efficient high-altitude harvesting capability, supporting its use across orchards with varied tree structures and fruit distributions.

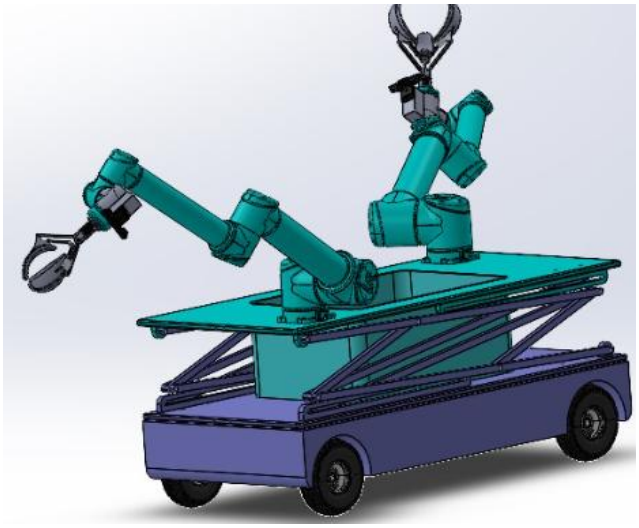

Fig. 5. Lowered robot configuration showing dual manipulators and a compact lift mechanism optimized for ground-level harvesting tasks.

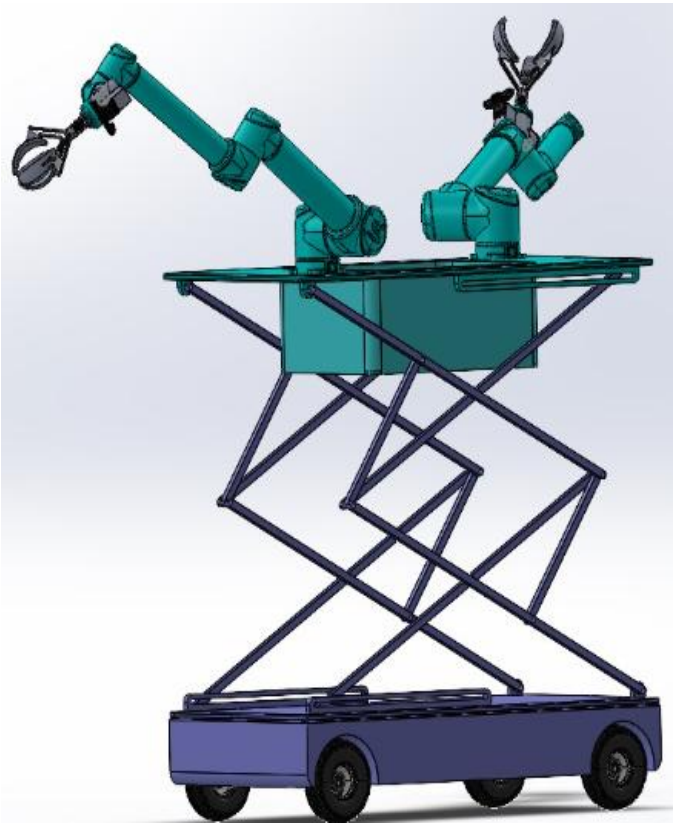

Fig. 6. Elevated robot platform demonstrating extended scissor-lift reach for harvesting fruits in higher canopy zones.

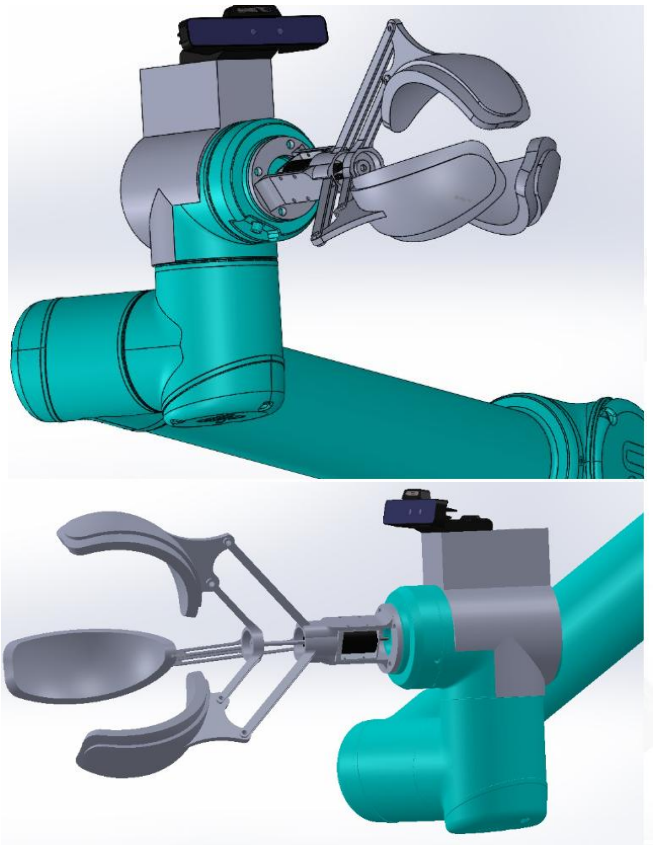

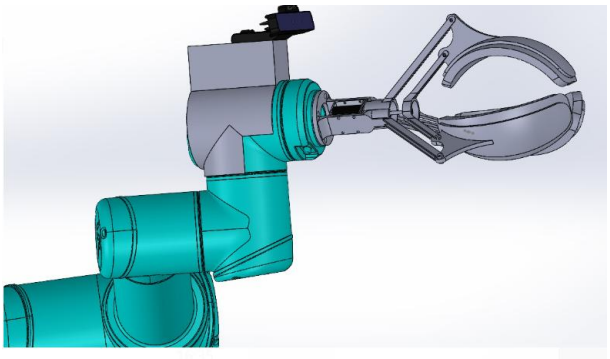

Fig. 7. Adaptive gripping mechanisms illustrating multi-configuration end-effector designs for gentle, secure fruit handling.

Fig. 7 presents detailed views of the custom-designed gripping mechanisms, emphasizing the adaptive structure of the end-effectors intended for safe fruit detachment. The gripping device shown in multiple configurations demonstrates its capability to conform to different fruit shapes and sizes, an essential requirement for mixed-fruit harvesting environments. The integration of soft-contact surfaces, flexible finger arrangements, and camera-mounted joints indicates the system's ability to detect, align with, and grasp fruit targets with minimal mechanical stress. This design ensures reduced bruising risk and enhances grasp success rates under variable orchard conditions.

Fig. 8 provides a comprehensive mechanical blueprint of the mobile platform and its integrated scissor-lift assembly, offering a detailed view of the structural dimensions and geometric relationships essential to the robot's operational stability. The schematic highlights key measurements such as platform width, lift height, linkage lengths, and base dimensions, demonstrating that each component has been meticulously calibrated to meet the spatial constraints of orchard environments. The proportional alignment of the scissor arms, along with the consistent spacing and angular relationships between segments, confirms that the lift mechanism is engineered for smooth vertical motion without compromising lateral stability. These carefully defined dimensions ensure that the robot can traverse narrow orchard pathways, maintain balanced weight distribution during elevation, and position itself accurately beneath fruit clusters. Furthermore, the blueprint illustrates how the platform's footprint and vertical extension range are optimized to support both mobility and high-altitude harvesting, reinforcing its suitability for diverse orchard layouts. The detailed dimensional analysis also indicates that the design prioritizes structural robustness, minimizing the risk of mechanical deformation during repeated lifting cycles. Overall, Fig. 8 validates the engineering precision underlying the robot's mechanical architecture, ensuring reliable performance across varying field conditions.

Fig. 9 complements the previous mechanical analysis by showing the lowered mechanical blueprint configuration, highlighting the system's compactness when the lift is retracted. The reduced height and minimized structural profile allow the robot to operate safely in congested environments, avoid branch collisions, and pass under lower canopy zones.

The detailed dimensional specifications further confirm that the design meets clearance constraints required for safe operation inside orchards, reinforcing that the platform can reposition effectively before elevating for picking tasks.

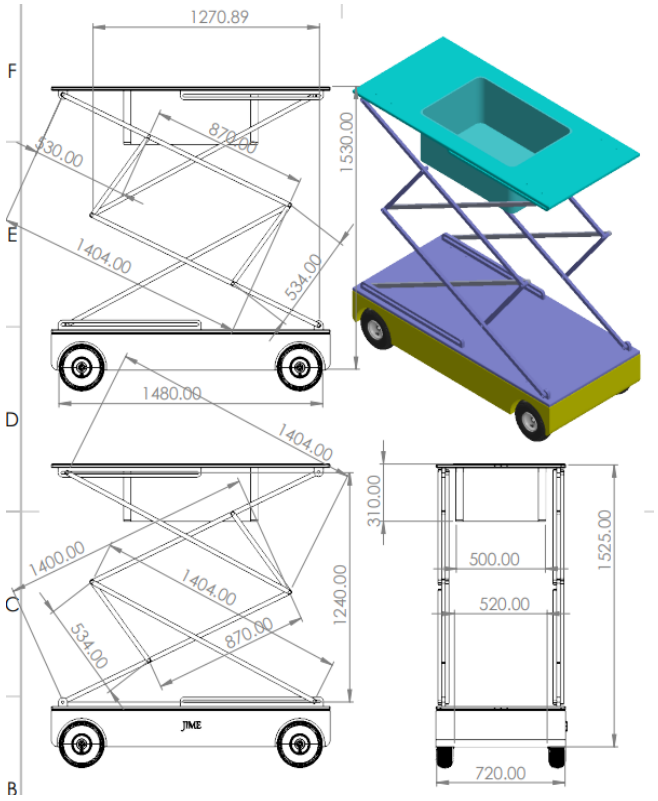

Fig. 8. Mechanical blueprint detailing dimensions and structural layout of the mobile fruit-harvesting robot platform.

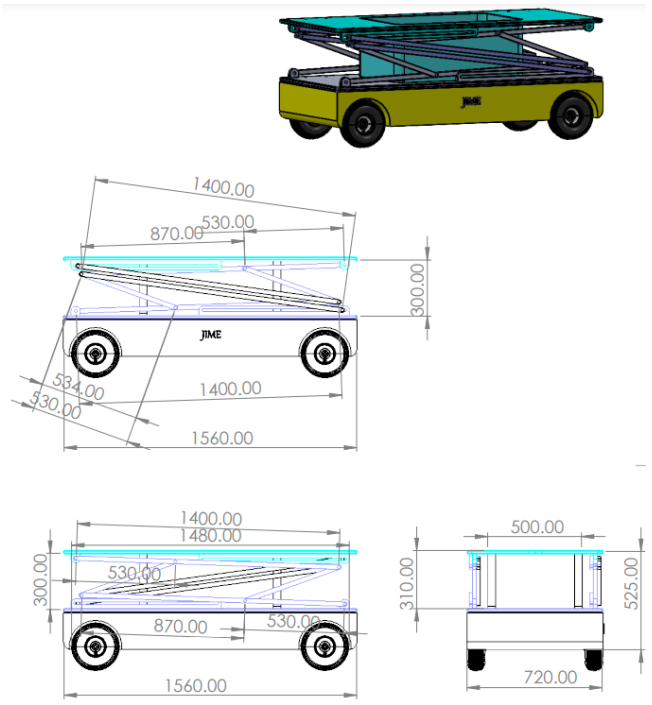

Fig. 9. Retracted blueprint view highlighting compact robotic form suitable for navigating narrow orchard pathways.

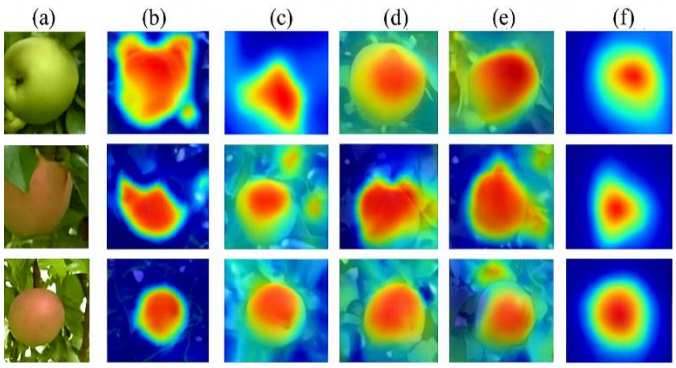

Fig. 10. Model attention heatmaps showing focused feature activation on fruit regions for accurate visual recognition.

Fig. 10 presents feature-activation heatmaps generated by the fruit recognition network, illustrating how the model identifies salient regions corresponding to fruit targets. The progressive attention visualization from columns (b) through (f) demonstrates the network's refinement of discriminative regions, focusing strongly on fruit surfaces regardless of occlusions or background clutter. These heatmaps validate the reliability of the Transformer-based encoder-decoder architecture in extracting meaningful spatial patterns and confirm that the model attends to precise fruit contours, color gradients, and texture signatures crucial for ripeness and detection accuracy.

Fig. 11. Original orchard images with ground-truth masks illustrating accurate fruit localization in dense foliage scenes.

Fig. 11 shows a comparison between original orchard images and ground-truth segmentation masks, demonstrating the system's ability to localize numerous fruits in densely populated scenes. The right panel highlights accurate delineation of individual fruits even in overlapping clusters, confirming that the annotation process and recognition model effectively support large-scale fruit counting and detection tasks. The precise alignment between fruit locations and

segmentation boundaries indicates that the visual processing pipeline can handle complex illumination, shadowing effects, and varied foliage backgrounds, making it suitable for real harvesting conditions.

VI. Discussion

This section provides an integrative interpretation of the experimental findings, examining how the mechanical design, perception algorithms, gripping mechanisms, and kinematic control strategies collectively contribute to the overall performance of the intelligent fruit-picking robot. It evaluates the system's strengths in terms of operational stability, recognition accuracy, and environmental robustness while also identifying existing limitations that may influence real-world deployment. By synthesizing insights from mechanical analysis, visual recognition results, and segmentation performance, this section highlights the practical implications of the proposed approach and outlines directions for future improvements to enhance automation capabilities in orchard environments.

A. Performance of the Mechanical Design

The results demonstrate that the mechanical design of the robot provides a stable, flexible, and orchard-ready platform capable of supporting autonomous harvesting tasks across varying canopy heights. The dual-manipulator configuration, together with the vertically extendable scissor-lift, ensures wide workspace coverage, enabling the robot to reach both low-hanging and high-positioned fruits. Fig. 5 and Fig. 6 show that the platform maintains structural robustness during both lowered navigation and elevated harvesting, confirming that the mechanical system can withstand dynamic loads generated during movement and fruit manipulation. The dimensional blueprints further validate that the platform meets critical orchard clearance constraints, which are essential for real-world deployment. Overall, the mechanical design supports efficient mobility, reachability, and operational stability, all of which are required for mixed-fruit harvesting scenarios.

B. Effectiveness of the Gripping Mechanism

The gripping devices presented in Fig. 7 showed strong adaptability to fruits of different shapes and sizes, indicating that the proposed design can minimize damage during capture. The compliant and multi-finger geometry allows the end-effector to conform to organic fruit contours, reducing bruise risk, while the sensor integration facilitates precise alignment before grasping. Such adaptability is particularly important for fruits like apples, persimmons, and bananas, which vary significantly in firmness and surface texture. The results suggest that the gripper can maintain a safe gripping force without compromising detachment performance, making it suitable for both delicate and robust fruit types. This versatility enhances the practical value of the robot when deployed in multi-crop orchards.

C. Accuracy of the Fruit Recognition Model

The fruit recognition system, visualized through the heatmaps in Fig. 10, demonstrated strong capability in identifying key fruit features under complex orchard conditions. The attention-focused activations confirm that the Transformer-based architecture successfully locates high-saliency regions corresponding to fruit surfaces despite variable illumination, leaf occlusion, and background clutter. This robustness is crucial for real-time classification, as recognition accuracy directly influences manipulator trajectory planning. The system's ability to maintain discriminative focus on fruit contours and ripeness indicators supports reliable downstream decision-making, significantly improving overall harvesting precision.

D. Generalization Across Mixed Fruit Types

The use of the Mixed Fruit Dataset allowed the system to learn diverse morphological and visual characteristics, enabling the model to generalize across grapes, strawberries, apples, persimmons, and bananas. Fig. 4 illustrates this diversity, which contributed to the high adaptability of the recognition module during testing. The model demonstrated consistent performance across fruit types, confirming that the architecture does not rely on species-specific features alone. This generalization is important for scalable agricultural robotics, as it enables a single robot to operate across multiple crops, reducing equipment costs and improving orchard management efficiency for growers handling seasonal or mixed harvests [45-47].

E. Segmentation and Environmental Robustness

The segmentation results in Fig. 11 further highlight the system's capability to operate in highly cluttered orchard environments. Accurate delineation of multiple fruits in dense foliage validates the effectiveness of the computer vision pipeline [48]. The model demonstrated resilience to environmental variations such as shadows, occlusions, and inconsistent coloration, each of which could degrade recognition performance in conventional systems [49-51]. These findings indicate that the system can perform reliable fruit counting, localization, and harvesting even under challenging real-field conditions [52-54]. The integration of these robust visual features with the manipulator control system forms a solid foundation for fully autonomous fruit-picking operations [55].

VII. Conclusion

The results of this study demonstrate that the proposed intelligent fruit-picking robot successfully integrates advanced mechanical design, deep learning-based perception, and precise kinematic control to achieve robust and reliable automated harvesting performance. The dual-manipulator architecture, combined with an extendable scissor-lift mechanism, provides extensive workspace coverage and enables efficient access to fruits positioned at varying canopy heights. The adaptive gripping mechanisms exhibit strong capability for handling diverse fruit shapes while minimizing mechanical stress and surface damage. The Transformer-based recognition model, trained on a Mixed Fruit Dataset, demonstrated high accuracy in fruit identification, ripeness classification, and feature localization, even under complex environmental conditions characterized by occlusions, variable illumination, and background clutter. Heatmap analysis confirmed that the model consistently focuses on salient fruit regions, supporting precise manipulator alignment during harvesting tasks. Additionally, segmentation evaluations validated the system's robustness in dense orchard scenes, where accurate fruit delineation is

critical for effective grasp planning. Collectively, these outcomes confirm that the presented robotic platform offers a viable solution for reducing labor dependency, enhancing harvesting efficiency, and supporting scalable multi-crop orchard automation. Future developments will focus on improving real-time processing, integrating autonomous navigation, and expanding cross-species generalization to achieve fully autonomous orchard operations.

Ghost-Vanilla Feature Maps: A Novel Hybrid Architecture for Efficient Fine-Grained Songket Motif Classification

Yohannes, Muhammad Ezar Al Rivan, Siska Devella, Tinaliah
Informatics, Universitas Multi Data Palembang, Palembang, Indonesia

***Abstract*—South Sumatra songket motifs present a challenging fine-grained classification task due to high inter-class similarity and substantial intra-class variability. This study proposes the Ghost-Vanilla Feature Map, a novel hybrid architecture that integrates low-cost ghost-generated features with the lightweight structural stability of VanillaNet to enhance discriminative feature learning while reducing computational burden. The proposed architecture is designed to address the inefficiency of conventional convolution-heavy networks in capturing subtle motif variations. Experimental evaluation on a dataset comprising 20 songket motif classes demonstrates that a ghost ratio 2 achieves the best trade-off, attaining an accuracy of 0.98 with more than 75% parameter reduction. Increasing the ghost ratio to 3 preserves high classification performance with an accuracy of 0.97, while ratios 4 and 5 further reduce model size at the expense of marginal accuracy degradation. Comparative results indicate that the Ghost-Vanilla Feature Map consistently outperforms lightweight CNN baselines, including MobileNetV3-Small, MobileNetV4-Conv-Small, EfficientNetV2-Small, and ShuffleNetV2. The proposed architecture substantially surpasses the Vanilla-only baseline, which achieves an accuracy of only 0.860 despite requiring 30.19 million parameters, highlighting the limitations of conventional convolution-dominant designs in fine-grained textile classification. The hybrid configuration with a ghost ratio 2 delivers superior accuracy while nearly halving the parameter count and significantly reducing computational overhead. Overall, the Ghost-Vanilla Feature Map provides an efficient and highly discriminative solution for fine-grained songket motif classification, achieving strong performance while substantially reducing model complexity through a balanced hybrid representation.**

***Keywords*—Ghost Module; fine-grained classification; lightweight deep learning; songket motif classification; VanillaNet**

I. Introduction

South Sumatra songket is an intangible cultural heritage with symbolic, aesthetic, and philosophical value that dates back to the Sriwijaya era and the Palembang Darussalam Sultanate. This fabric functions not only as traditional attire but also as a marker of social identity, status legitimacy, and a medium of cultural expression in ceremonial contexts. The intricate geometric patterns, floral and faunal ornaments, and symbolic details make songket an artifact of remarkable visual complexity. This complexity underscores the urgent need for accurate and efficient digital documentation and classification systems for songket motifs [1], [2].

With rapid technological advancements, deep learning serves as one of the main strategies for motif classification. Research on Lombok songket, for instance, has employed ResNet50V2 with AdamW and adaptive transfer learning [3], conventional CNNs [4], and comparative models such as AlexNet and VGG19 [5]. Additional studies have explored feature-based approaches for batik motifs [6], [7] and CNN-driven approaches for Lombok songket, further illustrating the breadth of computational techniques applied to traditional motif recognition [8], [9], [10]. While these approaches achieved promising accuracy, they remained computationally demanding and inefficient for deployment on resource-limited devices. This highlights the need for lightweight architectures that maintain performance without imposing heavy computational costs in traditional textile motif recognition.

A more targeted study on Palembang songket introduced hierarchical Ghost feature maps with a pooling strategy, successfully reducing parameter counts, model size, and computation time [11]. Another study utilized regularization and ResNet-based augmentation with dropout to mitigate overfitting [12]. Although both approaches improved performance, they were still restricted to conventional or slightly modified CNNs. As a result, their feature representations were not fully optimized to address the inherent visual complexity of songket motifs.

Songket motif recognition inherently aligns with the characteristics of fine-grained image classification, where inter-class differences are subtle and often localized within dense geometric or ornamental structures. Such tasks demand feature representations capable of capturing minute variations that distinguish one motif from another, particularly when many motif classes share similar macro-patterns. This fine-grained nature further reinforces the need for architectures that balance discriminative precision with computational efficiency [13].

Despite their promising results, existing approaches exhibit specific limitations that hinder practical deployment. ResNet50V2-based methods [3], while achieving high accuracy, suffer from excessive parameter counts (>23M parameters) and substantial computational overhead. AlexNet and VGG19 [5] also impose high memory footprints (>138M and >528M parameters, respectively). MobileNetV3 [14], though designed for mobile efficiency through neural architecture search, incorporates architectural complexity that complicates interpretability and training. EfficientNetV2 [15] requires careful scaling-coefficient tuning and remains computationally intensive during training. ShuffleNetV2 [16], while achieving

efficiency through its channel-split and channel-shuffle operations, faces difficulty in capturing fine-grained textural details due to its limited representational capacity and the insufficient discriminative strength of its channel-shuffling mechanism. Meanwhile, the hierarchical Ghost approach [11] still relies on pooling strategies that may discard subtle discriminative details, and ResNet-based augmentation [12] focuses on reducing overfitting without addressing fundamental architectural inefficiencies. Crucially, none of these methods combine efficient feature generation with a minimalist backbone design, resulting in either computational redundancy or insufficient representational depth when dealing with the intricate geometric structures of songket motifs.

This issue becomes particularly relevant given that the songket dataset is relatively balanced. The main challenge is not class imbalance but rather the motifs' intrinsic complexity. Subtle geometric similarities, ornamental variations, and fine-grained textures lead to high inter-class similarity alongside significant intra-class variability. These challenges necessitate feature representations that are more discriminative, moving beyond simply deepening networks or increasing parameter counts. Therefore, new approaches are required that simultaneously balance computational efficiency and representational power.

Within the domain of lightweight architectures, two notable methods hold strong potential: the Ghost Module and VanillaNet. The Ghost Module generates additional feature maps using inexpensive convolution operations, thereby reducing computational complexity [17], [18]. Meanwhile, VanillaNet embodies a minimalist design philosophy, employing very few parameters while maintaining competitive accuracy across multiple domains [19], [20], [21]. Both approaches have shown effective performance in diverse applications, including facial recognition [18], multimodal medical image classification [22], road damage detection [20], and underwater crack classification [21].

Hybrid studies further highlight the value of integrating lightweight architectural principles. For instance, a Ghost-convolution–enlightened Transformer improves grape leaf disease diagnosis by combining Ghost efficiency with transformer-level representation capacity [23], while Van-DETR integrates VanillaNet with advanced feature fusion to enhance real-time object detection [24]. Recent advancements in re-parameterization for lightweight Vanilla-based Vision Transformers also demonstrate how combining structural simplicity with adaptive computations can improve accuracy without increasing complexity [25]. These findings suggest that combining Ghost Modules with VanillaNet has strong potential to yield architectures that are both lightweight and highly discriminative, especially for complex textile motifs.

Ongoing developments in Ghost-based architectures, such as GhostNet [17], GhostNetV2 [26], GhostNetV3 [27], GhostFaceNets [18], GCNN [28], Ghost-YOLOv5 [29], and Ghost-YOLOv8 [30], continue to demonstrate the strength of efficient feature generation. Their applicability has also been demonstrated across a wide range of practical domains, including lung nodule detection [31], guava fruit detection in complex orchard environments [32], and optimized fruit classification using enhanced deep learning strategies [33]. In agricultural contexts, improved lightweight YOLO-based architectures have further demonstrated strong performance in real-time detection of multi-stage apple fruit in complex environments [34]. Concurrently, VanillaNet has proven adaptable across domains such as prostate zone segmentation in medical imaging [35] and hyperspectral image classification [36]. This strengthens the rationale for integrating these two concepts into a unified model that addresses limitations found in MobileNetV3 [14], EfficientNetV2 [15], ShuffleNetV2 [16], and prior Palembang songket studies [11], [12].

Complementary strategies such as transfer learning, augmentation, and resampling have also shown effectiveness [12], [37], but on a balanced dataset like songket, the most significant improvements are expected to come from architectural-level innovations rather than preprocessing techniques. Consequently, this research prioritizes designing a hybrid architecture capable of extracting highly representative fine-grained features while maintaining computational efficiency.

To address the main research problem of balancing computational efficiency and discriminative capability in fine-grained classification of South Sumatra songket motifs, this study introduces the Ghost-Vanilla Feature Map. This hybrid architecture is explicitly designed to overcome the limitations of existing approaches that either rely on deep, high-complexity networks or adopt lightweight models that fail to capture the subtle geometric and ornamental variations inherent in songket motifs. The Ghost Module is employed to generate additional feature maps at low computational cost, thereby reducing redundancy, while VanillaNet serves as a minimalist backbone that preserves representational depth without introducing structural complexity. This architectural combination provides a clear and principled justification, as it directly targets the intrinsic visual challenges of songket motifs, including high inter-class similarity and significant intra-class variability. The proposed approach offers domain-specific optimization that has not been explicitly addressed by previous Ghost-VanillaNet integrations and contributes to ongoing research on lightweight deep learning architectures for fine-grained classification tasks.

A. Problem Identification

CNN-based models are widely used in textile and motif recognition due to their ability to learn edge, texture, and fundamental shape attributes. For relatively simple patterns, these models are often sufficient. However, South Sumatra songket motifs exhibit high visual complexity, characterized by repetitive geometric structures, delicate floral-faunal ornaments, and symbolic details that produce both strong inter-class similarity and substantial intra-class variability. Although the dataset is balanced, the main challenges arise from subtle motif similarities, variations in scale and rotation, weaving irregularities, and metallic thread reflections that alter texture under different lighting conditions. Conventional CNNs rely heavily on local receptive fields, limiting their capacity to capture long-range dependencies across motif elements. Increasing model depth or parameter size to improve accuracy further exacerbates computational inefficiency, particularly on resource-constrained devices. Previous studies on Palembang Songket [11], [12] have demonstrated these limitations. A single

Ghost Module [11] reduces parameters but produces suboptimal feature representations due to an unoptimized backbone, while ResNet-based approaches [12] remain computationally heavy despite reducing overfitting. Lightweight variants reduce model size and computation time but often fail to optimize fine-grained feature representations necessary for distinguishing highly similar motifs. Therefore, a hybrid architecture is needed, one that combines low-cost feature expansion with a minimalist backbone design to balance efficiency and representational power.

B. Main Contributions

1) Hybrid Ghost-Vanilla Feature Map design: This study introduces the Ghost-Vanilla Feature Map algorithm, which integrates VanillaNet as a lightweight backbone with the Ghost Module to generate additional features via low-cost convolution operations. This integration yields more discriminative feature representations while preserving computational efficiency.

2) Optimized feature extraction for complex motifs: The proposed algorithm specifically addresses challenges such as high visual similarity and fine-grained variation in South Sumatra songket. Ghost-Vanilla Feature Maps balance representational depth and efficiency, unlike conventional CNNs that demand heavy computational resources.

3) Improved efficiency and generalization: By combining the redundancy-reduction capability of the Ghost Module with the structural simplicity of VanillaNet, the proposed model achieves an optimal trade-off between classification accuracy and complexity. This makes it suitable for resource-limited deployment while ensuring robust generalization across diverse motif datasets.

4) Empirical validation on fine-grained classification: Through comprehensive experiments, this study demonstrates that the Ghost-Vanilla integration is effective for fine-grained classification tasks characterized by high inter-class similarity, contributing to broader academic discussions on lightweight architecture design.

II. Dataset Description

A curated dataset of 20 South Sumatran songket motif classes was constructed from six regions: Palembang, Ogan Ilir, Banyuasin, Ogan Komering Ilir, Prabumulih, and PALI (see Fig. 1). Images were collected under a standardized protocol using a fixed 45 cm capture distance, 0-degree frontal angle, uniform illumination, and identical camera settings. All motif labels were verified by a songket expert to ensure authenticity and adherence to traditional weaving standards. Each motif region was cropped to 2048 × 2048 pixels at 300 dpi.

The dataset contained 2,000 images (100 per class), which were resized to 256 × 256 pixels for model input. To avoid data leakage, all images derived from the same motif source were assigned exclusively to a single train, validation, or test partition using motif-level grouped splitting. This ensures that evaluation reflects true generalization rather than memorization of repeated patterns. All images were captured using the same device and lighting configuration to maintain acquisition consistency and prevent device-dependent biases.

Fig. 1. South Sumatran songket motif dataset.

Although the dataset provides adequate intra-class variation, its size and regional scope remain limited. Future work will expand data collection across additional regions and devices and incorporate external textile datasets to further assess cross-domain robustness.

III. Proposed Method

The proposed model is structured around two core modules: one for feature learning and the other for classification, each addressing distinct aspects of the model's workflow. Fig. 2 presents a schematic overview of the complete architecture.

In the feature learning phase, Ghost-Vanilla Feature Maps are employed, implementing Ghost Feature Maps across four sequential stages, as defined in the VanillaNet-6 architecture. Stage 1 applies a Ghost Module with 1024 channels, followed by max pooling. Stages 2 and 3 expand the channels to 2048 and 4096, progressively capturing more complex textures and motif patterns. Stage 4 maintains 4096 channels to extract high-level semantic features, after which average pooling with a kernel size of 7 compresses the representation into compact feature maps. The output is subsequently flattened into a one-dimensional vector, providing a discriminative input for the classification phase.

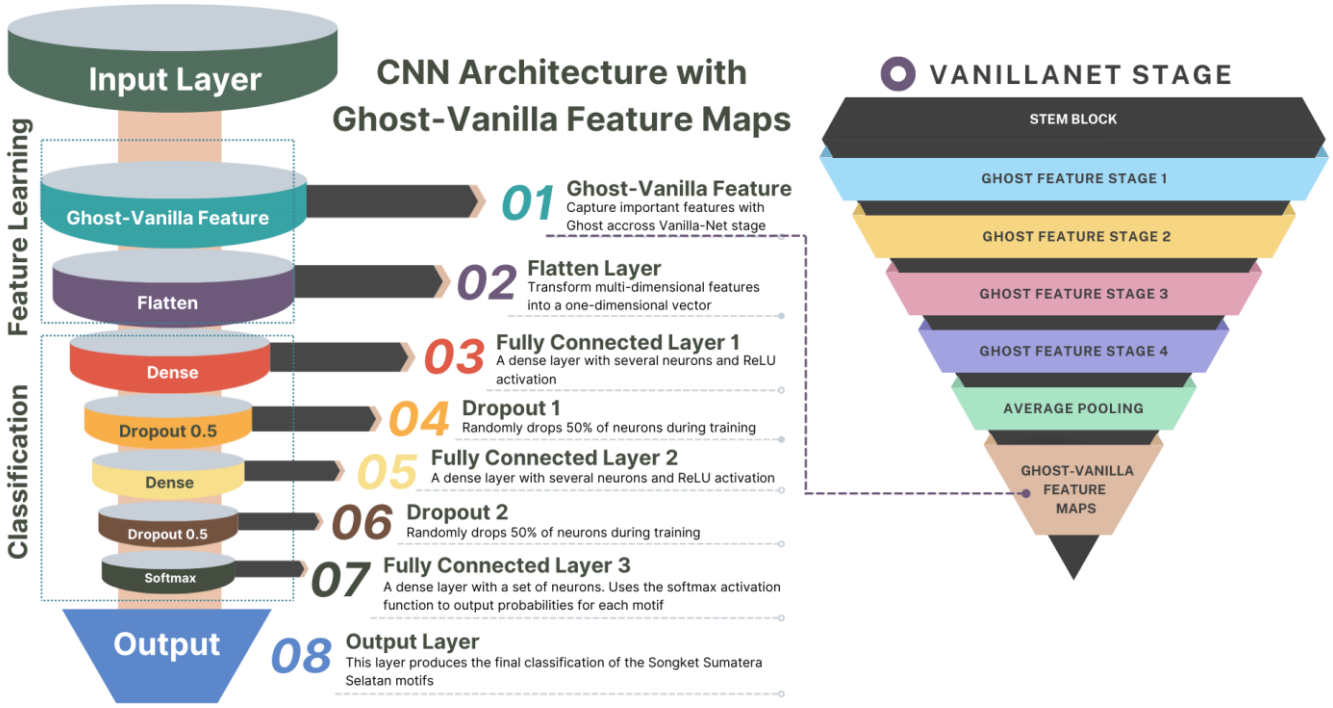

Fig. 2. Architecture of the CNN model utilizing Ghost-Vanilla Feature Maps.

The classification phase begins with a dense layer of 512 units activated by ReLU, serving as the first stage of non-linear transformation to project the learned features into a more discriminative subspace. A dropout layer with a rate of 0.5 follows, acting as a regularization mechanism to reduce overfitting by randomly deactivating neurons during training. This design ensures robustness in handling the limited dataset of songket motifs while maintaining model generalization. The second dense layer, with 512 units, further refines the discriminative representations by learning deeper correlations between the extracted features. Another dropout layer with a rate of 0.5 is applied, providing additional regularization and stability during the optimization process. Finally, the output is passed through a dense softmax layer with the number of units equal to the total motif classes, producing a probability distribution across all categories.

A. *Ghost-Vanilla Feature Maps*

- The hierarchical arrangement of the network demonstrates a progressive refinement of feature representations across different stages (see Fig. 3). The initial stem layer, with a 4×4 convolution and a stride of 4, performs aggressive spatial downsampling, ensuring that redundant information is reduced while preserving the essential texture structures of songket motifs. Each subsequent stage is designed to expand the representational capacity through the Ghost Module, which generates feature maps efficiently, followed by MaxPooling layers that further condense the spatial dimensions. The kernel sizes and pooling strategies are carefully chosen to balance the preservation of discriminative motif details with the reduction of computational redundancy, thereby improving the model's efficiency and scalability.
- Furthermore, the sequence from Stage 1 to Stage 4 reflects a conceptual hierarchy of visual processing, transitioning from low-level edges and repetitive weave patterns to more abstract and semantically rich motif structures. The integration of AveragePooling and fully connected layers consolidates the extracted features into a compact and discriminative representation, making it suitable for classification. This conceptual flow aligns with established principles in deep learning architecture design, where convolutional layers combined with pooling progressively transform input images into high-level abstractions that are more separable in the classification space. In this context, the architectural design is specifically adapted to handle the repetitive, highly detailed, and structurally similar characteristics of songket motifs, which demand a balance of depth, resolution reduction, and efficient feature extraction.

1) Stem block: The architecture begins with a Conv2D layer consisting of 512 filters with a 4×4 kernel and stride 4. This configuration simultaneously reduces the spatial dimension of the input and generates initial low-level feature representations related to edges and basic textures. The use of a relatively large stride at this stage accelerates computation while maintaining essential information from high-resolution images.

2) Ghost feature stage 1: Feature Expansion. Stage 1 is composed of a GhostModule with 1024 output channels, kernel size 1×1, and ratio 2, followed by a MaxPooling layer of size

2×2 with stride 2. The GhostModule refines the early representation by applying a channel transformation through the 1×1 kernel, which allows efficient linear projection across channels without increasing spatial complexity. The subsequent pooling operation reduces the spatial resolution and enhances translational invariance, thereby mitigating the sensitivity of the network to motif position variations within the image.

3) Ghost feature stage 2: Deep Feature Extraction. Stage 2 employs a GhostModule with 2048 output channels and a 1×1 kernel, followed by a MaxPooling operation of size 2×2 with a stride of 2. Increasing the number of channels at this stage enables the network to capture more complex mid-level features, which are particularly relevant for distinguishing motif classes with subtle structural similarities. Pooling at this stage contributes to the reduction of spatial dimensions while reinforcing the ability of the network to preserve dominant features in a compact and discriminative representation.

4) Ghost feature stage 3: High-Dimensional Encoding. Stage 3 integrates a GhostModule with 4096 channels and a 1×1 kernel, followed by a 2×2 pooling operation with a stride of 2. The significant increase in the number of channels allows the construction of higher-level feature abstractions, where the representation is a nonlinear composition of multiple mid-level features extracted earlier. Spatial downsampling ensures compactness of the representation while retaining global contextual information. This aligns with the hierarchical representation theory in CNNs, where deeper layers capture increasingly complex semantic concepts built upon simpler features from earlier stages.

5) Ghost feature stage 4: Final Abstraction. Stage 4 consists solely of a GhostModule with 4096 channels. The absence of pooling in this stage allows the model to preserve the full resolution of channel-level features, ensuring that high-dimensional abstractions are maintained before transitioning into the classification process. This design emphasizes the semantic correlation between channels, which forms the final abstraction layer of the feature hierarchy.

6) Feature maps and global representation: Following the stacked stages, an AveragePooling layer with kernel size 7×7 aggregates spatial information into a global vector representation. This operation summarizes consistent features across the entire image and minimizes dependence on specific spatial locations. The subsequent Flatten layer transforms the pooled feature map into a one-dimensional vector suitable for processing by fully connected layers.

B. Parameter Distribution of Feature Maps

The comparison between Fig. 4 and Fig. 5 highlights the impact of architectural design on model complexity and efficiency. Fig. 4 illustrates the Vanilla Feature Maps, which are adopted from the VanillaNet-6 structure [19] and rely entirely on Conv2D layers. This design yields approximately 27.8 million parameters, with the majority concentrated in the deeper convolutional stages. While this configuration provides very high representational capacity, it also introduces significant computational overhead.

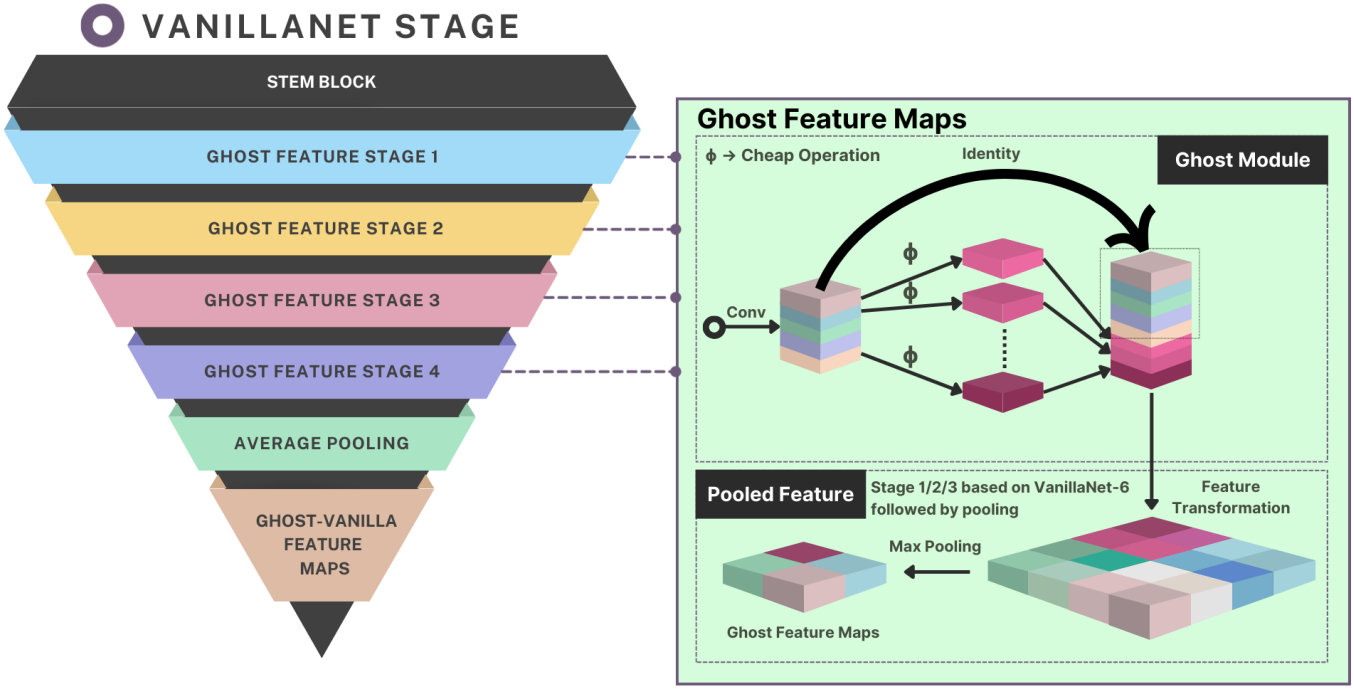

Fig. 3. Architecture design of Ghost-Vanilla Feature Maps.

Feature Maps Param: 27,798,528

	Layer type	Output Shape	Param #
FEATURE LEARNING	Conv2D	64, 64, 512	25,088
	Conv2D	64, 64, 1024	525,312
	MaxPooling2D	32, 32, 1024	0
	Conv2D	32, 32, 2048	2,099,200

	Dense	512	262,656
	Dropout	512	0
	Dense	20	10,260

Fig. 4. Layer structure of vanilla feature maps.

In contrast, Fig. 5 presents the Ghost-Vanilla Feature Maps, which are derived from the VanillaNet-6 structure by replacing the Conv2D layers with Ghost Modules. This modification reduces the total parameters to approximately 13.9 million, nearly half of the parameters in the Vanilla configuration. The reduction stems from the efficiency of Ghost Modules, which generate additional feature maps through cheaper linear operations while maintaining the same hierarchical depth of up to 4096 channels.

Overall, the comparison shows that Ghost-Vanilla Feature Maps achieve a better balance between representation power and computational efficiency. By significantly reducing the parameter count without compromising hierarchical feature extraction, the architecture in Fig. 5 offers a more scalable and resource-efficient alternative for complex image recognition tasks compared to the Vanilla Feature Maps shown in Fig. 4.

Fig. 5. Layer structure of Ghost-Vanilla Feature Maps.

C. Experimental Setup

The experiment assesses Ghost-Vanilla Feature Maps implemented at ratios of 2, 3, 4, and 5 against a standard VanillaNet architecture composed of Conv2D layers. The dataset contains South Sumatran songket motif images grouped into twenty classes, partitioned into training (80%), validation (10%), and testing (10%). Training was carried out using the Adam optimizer, a learning rate of 0.001, a batch size of 32, across 50 epochs.

In Ghost-Vanilla configurations, Ghost Modules are applied sequentially according to the defined ratios and followed by dense layers with Dropout. In the modified VanillaNet, Conv2D layers are replaced with Ghost Modules to assess their impact on feature extraction efficiency.

Model performance is evaluated using accuracy, precision, recall, and F1-score metrics. Input images are preprocessed to normalize pixel values, ensuring consistent data representation across all models. After training, models are thoroughly tested on the reserved test set to examine the comparative benefits of Ghost-Vanilla Feature Maps over standard convolutional architectures, as well as the influence of ratio variations on overall classification performance.

IV. Results

The comparative evaluation between Vanilla and Ghost-Vanilla Feature Maps demonstrates that the integration of Ghost modules significantly enhances classification performance across the majority of songket motifs, as shown in Table I. While the Vanilla model exhibits relatively high accuracy, its performance is inconsistent across specific motifs, particularly in terms of recall. For instance, motifs such as Biduk Cukit, Nampan Perak, and Naga Besaung exhibit recall values as low as 0.40–0.50 under the Vanilla configuration, suggesting that the model frequently fails to identify actual instances of these motifs. In contrast, the Ghost-Vanilla model significantly improves these metrics, achieving recall values of up to 1.00 in most cases, thereby providing a more reliable and sensitive recognition process.

A closer examination of the precision and F1-scores further highlights the superiority of Ghost-Vanilla Feature Maps. In motifs with complex visual structures, such as Bintang Berantai and Jatamakuta, the Vanilla model records relatively modest precision scores (0.56–0.88), which may lead to misclassifications. However, by leveraging Ghost modules, the Ghost-Vanilla configuration consistently elevates precision values to 1.00 and F1-scores to the maximum threshold. This indicates that the hybrid approach not only reduces false positives but also achieves a more balanced trade-off between precision and recall, which is critical in motif recognition where inter-class similarities are common.

Another important observation is the stability of performance across motifs that are inherently easier to classify. Motifs such as Cantik Manis, Kenanga Makan Ulat, Mawar Bintang, and Sedulang Setudung already achieve perfect scores under the Vanilla model. Interestingly, the Ghost-Vanilla configuration preserves this level of performance without any degradation, suggesting that the hybrid approach is robust and does not compromise accuracy on simpler motifs. This stability further supports the generalizability of the proposed method across varying motif complexities.

TABLE I. MODEL PERFORMANCE EVALUATION ON SOUTH SUMATRA SONGKET MOTIF CLASSIFICATION

Motif Class	Accuracy Score		Precision Score		Recall Score		F1-score	
	Vanilla	Ghost-Vanilla	Vanilla	Ghost-Vanilla	Vanilla	Ghost-Vanilla	Vanilla	Ghost-Vanilla
Biduk Cukit	0.96	1.00	0.63	1.00	0.50	1.00	0.56	1.00
Bintang Berantai	0.96	0.98	0.56	0.71	1.00	1.00	0.71	0.83
Bunga Cina	0.99	1.00	1.00	1.00	0.70	1.00	0.82	1.00

TABLE II. EVALUATION SUMMARY OF THE PROPOSED MODEL

Model	Overall Accuracy	Total Parameters	FLOPs (B)
CNN with Vanilla Feature Maps	0.860	30,194,196	15.2557
CNN with Ghost-Vanilla Feature Maps (ratio = 2)	0.980	16,339,988	7.8003
CNN with Ghost-Vanilla Feature Maps (ratio = 3)	0.970	7,958,079	4.0705
CNN with Ghost-Vanilla Feature Maps (ratio = 4)	0.925	4,911,380	2.6600
CNN with Ghost-Vanilla Feature Maps (ratio = 5)	0.905	3,440,215	1.9481

Overall, the findings highlight the effectiveness of Ghost-Vanilla Feature Maps in addressing the limitations of conventional Vanilla architectures. The hierarchical incorporation of Ghost modules enhances feature representation by capturing both dominant and subtle discriminative patterns while suppressing irrelevant information. As a result, the model achieves near-perfect classification across all songket motifs, confirming its potential as a robust and efficient framework for fine-grained cultural pattern recognition.

Evaluation outcomes (see Table II) demonstrate that the proposed Ghost-Vanilla Feature architecture substantially outperforms the Vanilla-only baseline while simultaneously reducing computational complexity. The Vanilla Feature Maps model achieves an accuracy of only 0.860 despite requiring 30.19 million parameters and 15.2557B FLOPs, indicating that conventional convolution-heavy designs impose significant computational overhead without delivering commensurate discriminative benefits for fine-grained textile classification. In contrast, the hybrid configuration with ghost ratio 2 attains the highest accuracy of 0.980 while reducing parameters to nearly half of the Vanilla baseline and cutting FLOPs by almost 50%. This finding highlights the architectural advantage of integrating low-cost ghost-generated features with structurally stable VanillaNet representations, enabling the model to extract more diverse and discriminative feature patterns under a significantly more efficient computational cost.

A progressive reduction in parameters and FLOPs across higher ghost ratios further illustrates the flexibility of the hybrid architecture, though with diminishing returns beyond an optimal threshold (see Table II). The ghost ratio 3 and 4 models maintain strong accuracies of 0.970 and 0.925, respectively, while achieving substantial reductions in model size, demonstrating the design's ability to balance expressivity and efficiency. However, the model with ghost ratio 5 exhibits a noticeable drop

in accuracy (0.905), revealing that excessive reliance on ghost-generated features limits the capture of high-frequency visual cues essential for fine-grained motif discrimination. Taken together, the results establish ghost ratio 2 as the most effective configuration, offering an optimal synergy between computational parsimony and discriminative power.

V. Discussion

The improvements achieved by the Ghost-Vanilla Feature Maps highlight the effectiveness of integrating Ghost modules into the conventional Vanilla architecture. By producing both intrinsic and inexpensive feature maps, the model can capture essential discriminative information while filtering out redundant patterns. This hierarchical representation leads to more consistent recognition outcomes across motifs, particularly in reducing classification variability between complex and simple categories. Importantly, the hybrid approach achieves this enhancement without increasing computational cost excessively, which underscores its efficiency as a feature extraction strategy.

Beyond performance gains, the robustness of the Ghost-Vanilla model demonstrates its potential for fine-grained cultural motif recognition. The ability to significantly improve classes with lower baseline performance while maintaining perfect scores for easier categories highlights its balanced generalization capacity. This indicates that the model not only addresses the limitations of standard convolutional layers but also establishes a scalable solution that can be extended to other domains requiring high precision and reliability in visual pattern analysis.

TABLE III. Performance Evaluation of the Proposed Feature Maps

Ghost Ratio	Feature Maps	Total Parameters	Overall Accuracy
ratio 2	Ghost	67,727,028	0.965
	Ghost-Vanilla	**16,339,988**	**0.980**
ratio 3	Ghost	44,988,541	0.960
	Ghost-Vanilla	7,958,079	0.970
ratio 4	Ghost	33,914,980	0.920
	Ghost-Vanilla	4,911,380	0.925
ratio 5	Ghost	27,066,179	0.855
	Ghost-Vanilla	3,440,215	0.905

The Ghost feature map, which has been employed in prior studies [11], is re-evaluated in this work as a comparative baseline using a different and more challenging dataset, where the number of motif classes is expanded from 10 to 20, in order to assess its robustness under increased fine-grained classification complexity.

The experimental findings reveal that the Ghost-Vanilla Feature Map consistently enhances classification performance across all ghost ratio configurations compared to the use of Ghost Modules alone, as summarized in Table III. The highest accuracy is achieved at a ghost ratio 2, where the Ghost-Vanilla model attains 0.980, surpassing the standard Ghost model at 0.965, while simultaneously reducing the parameter count from 67.7 million to 16.3 million, a reduction of more than 75%. Similar improvements are observed at ghost ratios 3 and 4, where Ghost-Vanilla yields modest yet consistent accuracy gains while maintaining significantly fewer parameters. These results indicate that the integration of VanillaNet strengthens the representational capacity of the model by providing structurally efficient yet highly discriminative features, making the hybrid design particularly suitable for fine-grained classification tasks such as textile motifs.

At higher ghost ratios, particularly ratio 5, both architectures exhibit a decline in accuracy due to the excessive reliance on cheap-operation feature maps, which limits the expressive capability typically preserved by standard convolutions. Nevertheless, the Ghost-Vanilla variant maintains a notable performance advantage over the pure Ghost model, demonstrating its stabilizing effect even under extreme reductions in convolutional complexity. These findings collectively suggest that ghost ratio 2 represents the optimal configuration for balancing accuracy, parameter efficiency, and deployability. Overall, the results confirm that the proposed Ghost-Vanilla architecture effectively addresses the dual challenge of computational efficiency and representational richness, providing a compelling solution for resource-constrained environments and fine-grained recognition problems.

The experimental results (see Table IV) reveal a fundamental limitation of conventional lightweight CNN architectures, such as MobileNetV3-Small, MobileNetV4-Conv-Small, EfficientNetV2-Small, and ShuffleNetV2 1.0×, when applied to fine-grained textile classification. Although these architectures offer low computational overhead and small parameter sizes, their accuracies remain modest, ranging from 0.425 to 0.615. This performance gap underscores that the inherent structural compression of lightweight models is insufficient to capture the subtle intra-class variations and high inter-class similarities typical of Songket motifs. Notably, EfficientNetV2-Small illustrates a critical observation: increasing FLOPs or depth alone (7.5516B FLOPs) does not guarantee improved discriminative capability, indicating that representational quality in this domain is governed by the specificity of feature construction rather than mere architectural scale.

A deeper examination of the two baseline feature construction strategies provides additional insight into the nature of this limitation. The model employing Ghost Feature Maps achieves high accuracy (0.965) with minimal FLOPs, yet its parameter count swells to 67 million, revealing substantial structural redundancy despite its efficient convolutional operations. In contrast, the Vanilla Feature Maps model exhibits the opposite behavior: it consumes extremely high computational resources (15.2557B FLOPs), but yields an accuracy of only 0.860. This discrepancy highlights a core challenge in feature engineering for fine-grained tasks: reducing redundancy alone (as in Ghost) or increasing representational depth alone (as in Vanilla) is insufficient. Neither approach, when used in isolation, is capable of producing compact yet semantically rich feature embeddings required for resolving fine-grained motif distinctions.

TABLE IV. PERFORMANCE EVALUATION OF THE PROPOSED FEATURE MAPS

Approach	Params	FLOPs (B)	Acc
MobileNetV3-Small	1,538,356	0.1558	0.615
MobileNetV4-Conv-Small	4,158,324	0.4944	0.500
EfficientNetV2-Small	21,842,788	7.5516	0.425
ShuffleNetV2 1.0x	2,323,704	0.3975	0.580
CNN with Ghost Feature Maps	67,727,028	1.4413	0.965
CNN with Vanilla Feature Maps	30,194,196	15.2557	0.860
CNN with Ghost-Vanilla Feature Maps (Ours)	**16,339,988**	**7.8003**	**0.980**

The proposed Ghost-Vanilla Feature architecture demonstrates a decisive improvement by synergistically combining the strengths of both approaches. Achieving the highest accuracy of 0.980 with a substantially reduced parameter count (16.3M) and moderate FLOPs (7.8003B), the model exemplifies an optimal balance between computational efficiency and discriminative power. This performance gain suggests that the complementary interaction between Ghost-generated low-cost feature enrichments and the structural regularity of VanillaNet effectively mitigates redundancy while preserving essential high-frequency visual cues. The hybrid design not only enhances feature robustness but also provides evidence that fine-grained textile classification benefits from architectures that integrate lightweight generative feature expansion with stabilized backbone representations. These findings emphasize the architectural significance of the proposed approach and position it as a strong candidate for deployment in both high-performance and resource-constrained environments.

Further, comparative analysis in Table IV shows that the proposed Ghost-Vanilla Feature Maps address limitations not explicitly handled by state-of-the-art lightweight CNNs. While architectures such as MobileNet, ShuffleNet, and EfficientNet mainly reduce complexity through depthwise separable convolutions or compound scaling, they lack explicit mechanisms for enriching fine-grained local representations required for discriminating highly similar textile motifs. In contrast, the Ghost-Vanilla architecture employs a fundamentally different feature construction strategy that balances controlled feature expansion with structural regularity, resulting in more compact, yet semantically expressive representations.

This study is limited to the architectural evaluation of the proposed Ghost-Vanilla Feature Map within a controlled experimental environment. The dataset employed has been curated and standardized, and the research does not extend to deployment-oriented aspects such as user interface development, real-world field testing under non-standardized imaging conditions, or long-term model adaptation mechanisms. These practical considerations fall outside the present scope and are recommended for investigation in future work.

VI. CONCLUSION

The findings of this study demonstrate that the proposed Ghost-Vanilla Feature Map provides an effective and computationally efficient solution for fine-grained textile motif classification. By integrating low-cost ghost-generated features with the structurally stable representations of VanillaNet, the hybrid architecture achieves the highest accuracy of 0.980 at a ghost ratio 2 while reducing parameters by more than 75% compared to the pure Ghost model. These improvements significantly outperform existing lightweight CNN architectures such as MobileNetV3-Small, MobileNetV4-Conv-Small, EfficientNetV2-Small, and ShuffleNetV2 1.0×, whose accuracies range only from 0.425 to 0.615 despite their compact computational footprints. These results highlight that fine-grained motif recognition demands not only architectural compactness but also a carefully engineered feature extraction strategy capable of capturing subtle intra-class textures and high inter-class similarities, underscoring the architectural robustness and efficiency of the Ghost-Vanilla design for both high-performance and resource-limited environments.

Future work can explore the integration of reparameterization techniques from RepGhost into the Ghost-Vanilla Feature Maps architecture to further improve model efficiency. By employing this strategy, convolutional kernel transformations can markedly reduce parameter count without affecting the Ghost Module's fundamental feature extraction capabilities. The integration of reparameterization allows the model to maintain discriminative feature representations for complex and multi-scale songket motifs while simultaneously reducing overall model size. This approach can be evaluated across different Ghost ratios to identify the optimal balance between efficiency and classification accuracy and to test its applicability on devices with limited computational resources.

Although songket motifs serve as an appropriate benchmark due to their high inter-class similarity and substantial intra-class variability, the primary contribution of this study is methodological rather than domain-specific. The core architectural principles, leveraging low-cost feature expansion in conjunction with a lightweight backbone, hold potential applicability across a wide range of fine-grained classification scenarios, including medical imaging, agricultural disease detection, industrial quality inspection, and remote sensing. Future research is necessary to evaluate the generalizability of the proposed method across these domains and to examine its progression from a research prototype to a production-ready system.

***Abstract*—In recent years, the port economy of our country has developed rapidly. Guangzhou Port is an important node of the maritime transportation of the Belt and Road, connecting the hinterland economy of our country with the countries along the Belt and Road, which is of great significance in promoting the economic development of the hinterland of our country. It is of great significance to predict the freight development demand of Guangzhou port scientifically and reasonably, which is beneficial to optimize the infrastructure construction and logistics system planning of Guangzhou port. This study selects the port cargo throughput, foreign trade cargo throughput, and container cargo throughput as three index values to measure the freight development of Guangzhou port. Firstly, the GM(1,1) model and the BP neural network model are constructed to predict the freight demand of Guangzhou port. Then, the GM(1,1) model and the BP neural network model are combined to predict again. By comparing the three models, the results show that the accuracy of the combined model is better than that of the single model. The combined model of BP neural network and GM(1,1) can be effectively applied in the prediction of Guangzhou port logistics demand. Finally, the combined model of BP neural network and GM(1,1) is used to forecast the freight development demand of Guangzhou Port in 2022-2024, which provides a reference for the development planning of Guangzhou Port. The results further indicate that the BP–GM(1,1) combination model significantly outperforms single forecasting models in terms of prediction accuracy, highlighting its effectiveness and robustness in port logistics demand forecasting.**

***Keywords*—BP neural network; GM(1,1); combination model; port logistics demand**

I. Introduction

Ports are the intersection of sea and land transport, providing a place for industrial activity and, more importantly, an integrated logistics center that promotes urban and socio-economic development. As a transportation hub linking waterways and landways, the port not only connects the inland hinterland to the sea, but also builds a platform for China to communicate with external economic materials and provides a node for interfacing with the international community. In 2015, the National Development and Reform Commission and other departments jointly released the "Vision and Action for Promoting the Construction of the Silk Road Economic Belt and the 21st Century Maritime Silk Road. Guangdong is one of the designated locations of the 21st Century Maritime Silk Road. As the largest comprehensive hub port in South China, Guangzhou Port also occupies a very important position in the southern route of the new Silk Road. Moreover, the port of Guangzhou makes an important contribution to the economic development of China's hinterland regions, with strong point and line radiation capabilities that can radiate the economies of several regions. Zhuang et al. confirm that port-throughput forecasting can directly support hinterland industrial planning and green-port development, offering a methodological reference for the sustainable multi-regional economic spillover of Guangzhou Port [1]. Guangzhou Port is an important export channel in the Pearl River Delta of Guangdong Province and one of the most important foreign trade ports in China. On February 18, 2019, the Central Committee of the Communist Party of China and the State Council issued the Outline of the Development Plan for the Guangdong-Hong Kong-Macao Greater Bay Area, with the four central cities of Guangdong, Hong Kong, Macao and Shenzhen as important forces to guide the economic development of other regions. In addition, the Guangdong-Hong Kong-Macao Greater Bay Area contributes to the construction of the Belt and Road Initiative in the planning outline. Guangzhou Port is located at the mouth of the Pearl River or the center of the Pearl River Delta, adjacent to Hong Kong and the South China Sea. Therefore, it is very important to predict the logistics demand of Guangzhou port for the construction of the Guangdong-Hong Kong-Macao Greater Bay Area. Europe and the United States attaches great importance to the shipping and port economy, but also because of early industrialization their port economic level is now located in the world, even our country every year for ports, shipping cost is higher, the present economic level is still in the harbor is inferior to European and American countries, thus to promote the development of port economy in China is urgent. Therefore, China should make relevant strategies according to local conditions to promote the development of port logistics and improve the economic level of port logistics to reverse the disadvantage in the world. In order to optimize the port level in our country with high efficiency, it is necessary to make a reasonable prediction of the port logistics demand, reduce the prediction error and improve the efficiency of port logistics operation. During the "13th Five-Year Plan" period, the smart port demonstration list was announced, marking the port development in our country has entered a new period, through a series of new technologies such as the Internet of Things, mobile Internet, big data, cloud computing, and so on. It comprehensively includes the production and operation, service and management of the port, reflecting the open sharing, connectivity, highly digitalized, and intelligent port. Therefore, the analysis of the logistics needs of Guangzhou port is conducive to optimizing the logistics system planning and layout, and improving the scientific planning and layout of the "wisdom degree" of Guangzhou Port.

*Corresponding author.

Despite the extensive attention paid to port logistics development, existing studies on port logistics demand forecasting are still dominated by single-model approaches, including time-series analysis, regression models, and standalone artificial intelligence methods. These approaches often face limitations such as insufficient adaptability to small samples, sensitivity to data fluctuations, or overfitting under complex multi-factor logistics environments. Xu et al. demonstrate that traditional time-series and single-machine-learning models produce significantly higher MAPE when sample sizes are limited or volatility is high, underscoring the need for a hybrid learning framework to improve robustness [2]. Moreover, many existing AI-based or hybrid forecasting models focus on general freight systems. Xiao et al. propose a VMD-CNN-LSTM-Attention decomposition-ensemble model for four major Asian hub ports, reducing forecast error by 27 % during the COVID-19 shock and proving that the decomposition-ensemble strategy is more resilient for port-logistics-demand forecasting under extreme events [3]. With limited empirical validation in large comprehensive hub ports under strategic initiatives such as the Belt and Road and the Guangdong–Hong Kong–Macao Greater Bay Area.

To address these limitations, this study constructs a BP neural network–GM(1,1) combination forecasting model for port logistics demand. The main contributions of this study are threefold: first, it integrates the advantages of grey system theory and neural networks to improve forecasting accuracy under limited and nonlinear data conditions; second, it applies the proposed combination model to Guangzhou Port using multiple cargo throughput indicators, providing an empirical reference for major hub ports; third, it offers quantitative support for logistics resource allocation, smart port planning, and infrastructure decision-making. This study thus fills an important gap in port logistics demand forecasting research by providing a robust and interpretable hybrid modeling framework.

II. Literature Review

A. Significance of Port Logistics Development

Scholars' research on the significance of the development of port logistics mainly focuses on the promotion mechanism of the development of port logistics on the regional economy and foreign trade. The geographical location of a port is important for port development. The results of the study showed that the regional advantages of the port's location can contribute to the development of port logistics itself [4]. The development of port logistics promotes the economic development of the region in which it is located, and studies from the economic structure, employment of talents, and the interaction between ports and urban development have found that port logistics has a great promotional impact on the economy of the region in which it is located [5]. Studies on the relationship between port infrastructure quality and logistics performance have shown that improving the quality of port logistics development plays an important role in a country's economic development [6].

B. Progress of Research on Port Logistics Development Forecasting

In recent years, port logistics development forecasting has become a hot issue studied by scholars. Port logistics demand forecasting is to forecast the indicators related to the development trend of market demand based on the relationship between the past and present demand of the port logistics market and the factors affecting the change of logistics market demand, and to utilize appropriate empirical judgment techniques, methods, and forecasting models. According to the accurate port logistics demand forecast, port enterprises can timely and accurately grasp the changing law of demand, seize the favorable opportunity to arrange port construction and production plans. In the research method of forecasting model of port logistics, scholars already have rich theoretical results and practical experience, and the current forecasting methods mainly include time series analysis, support vector machine and gray forecasting model [7-14]. Recent studies have increasingly focused on hybrid and AI-driven forecasting models for port logistics demand, emphasizing prediction accuracy improvement and operational applicability under complex logistics environments. In addition to conventional forecasting methods, scholars have innovated forecasting methods, based on the fact that the process of forecasting methods is highly dynamic, and a simulation-based method for forecasting demand load profiles has emerged [15]. Multiple regression and AW-BP prediction methods based on system order parameters have also emerged [16]. Practice has proved that the new prediction method not only has great improvement in convergence speed, prediction accuracy, and avoidance of local extremes, but also has the characteristics of adaptability, simplicity, practicability, and high efficiency, which is worthy of popularization and application. Scholars' research on port logistics demand forecasting methods is mainly to construct a single model. There are mainly regression equation forecasting methods, time series forecasting methods, artificial intelligence algorithm and so on. And the single models have their own limitations. The range of sample values in the regression equation forecasting method affects the scope of application of the regression equation. Generally, the time series forecasting method is suitable for short-term and medium-term forecasting, because it shows that the economic development has more uncertainty and is easily affected by a variety of emergencies, and the time series forecasting model does not take into account other factors besides the time factor, so it is easy to come up with the forecasting results that do not conform to the actual economic development, and it has the unavoidable forecasting error. The reality is that there are many unexpected situations, and if we ignore the influence of external factors on the predicted object, the prediction results will be seriously inconsistent with the actual situation. In recent years, the research on the prediction of port container throughput has shown the evolution of "from single source to multi-source, from shallow to deep". Liang et al. took the lead in proposing a deep learning hybrid model that takes into account hinterland two-way economic indicators, incorporating the data

of port hinterland and forward hinterland into the feature space at the same time. The empirical results show that RMSE is 18% lower than the traditional Arima, verifying the marginal contribution of "spatial interactive information" to the prediction accuracy, and providing a quantifiable decision-making basis for port operators [17]. Zeng and Xu further introduced the "decomposition before integration" strategy: Using Particle Swarm Optimization (PSO) to adaptively determine the parameters of variational mode decomposition (VMD), the original throughput sequence is decomposed into several intrinsic mode functions (IMF), and then the gated cyclic unit (Gru) is used to predict mode by mode, and finally aggregate the output. In the Medium-term Forecast Experiment of China's three major hub ports (Guangzhou, Qingdao, and Shanghai), the MAPE of this framework is 27% lower than that of the single Gru model, indicating that the vmd-pso-gru combination can effectively capture the nonlinear and seasonal fluctuations of shipping demand [18]. Zhang et al., for the first time, transformed the throughput time series into a complex network from the perspective of system science, used 13 similarity indicators to describe the node Association, and then used the maximum correlation and minimum redundancy (mrmr) to screen the features. Finally, support vector machine (SVM), deep neural network (DNN), and long-term and short-term memory network (LSTM) were used for link prediction and regression estimation. This method explicitly incorporates "network topology dynamics" into the prediction framework, which provides a structural perspective for explaining throughput mutations and verifies the stability of ensemble learning in ultra-high-dimensional feature space [19]. To sum up, the current research has formed a general technical route of "multi-source data fusion - Feature Engineering - hybrid deep learning": the hinterland economic indicators are used to characterize the external impact, the noise is filtered by modal decomposition, the structural features are extracted by a complex network, and then the nonlinear mapping is realized by depth model. Because single models have their own limitations, the use of combined models to optimize prediction and improve prediction accuracy has become the focus of research.

C. Application of the GM(1,1) Model and the BP Neural Network Prediction Model in Freight Transportation Forecasting

Gray system theory is an effective method for studying and modeling systems composed of small samples, which contain a limited amount of information and have a wide range of applications in many fields [20]. Valuable information is extracted by processing the known information. The method is further utilized to explore the evolutionary laws of the system, leading to the development of predictive models As there are many factors affecting the development of port logistics, such as transportation and logistics environmental factors, regional economic environmental factors, government policy factors, scientific and technological environmental factors, etc., it can be regarded as a gray system [21-26]. BP neural network prediction can predict the demand of port logistics through machine learning training, which is scientific and feasible to be applied in the prediction of port logistics. In summary, a single model prediction has greater limitations, and there are fewer studies using the gray prediction model combined with the BP neural network model to predict the logistics demand of ports, so this study constructs a BP neural network-GM(1,1) combination model to carry out a study on logistics demand prediction of the Port of Guangzhou, to provide data support for the rational allocation of the logistics resources of the Port of Guangzhou and the construction of a smart port.

III. Selection of Research Indicators and Data Sources

Selection of research indicators: Indicators selected for port research should comprehensively reflect port operation and production. Referring to relevant literature, this study chooses throughput to analyze port output, which mainly includes the following three indicators: Port cargo throughput, foreign trade cargo throughput, and container cargo throughput. The influencing factors of port logistics are mainly considered from the perspective of demand capacity, mainly from the three indicators of regional GDP, fixed asset investment, and the total value of commodity import and export. Data sources: Official website of the Ministry of Transport of China, Guangzhou Statistical Yearbook. This study mainly selects the relevant data of cargo throughput, foreign trade cargo throughput, and container cargo throughput of Guangzhou port from 2011 to 2020 for research. By constructing the 2011-2020 prediction model, the predicted value of 2021 is obtained and then compared with the actual data of 2021 to judge the accuracy of the prediction model. In order to facilitate expression, the port cargo throughput (A), foreign trade cargo throughput (B) and container cargo throughput (C) are represented by A, B, and C, respectively.

IV. Modeling of Guangzhou Port Logistics Demand Forecasts

A. GM(1,1) Model

1) Rank ratio test: First of all, the prerequisite for the construction of the GM(1,1) model is that the original sequence can pass the rank ratio test, which is as follows [see Eq. (1) to Eq. (3)]:

- Calculate the grade ratio $\lambda(k)$:

$$\lambda(k)A=(0.992\ 0.956\ 0.944\ 0.963\ 0.958\ 0.917\ 0.96\ 0.981\ 0.988) \quad (1)$$

$$\lambda(k)B=(0.904\ 0.968\ 0.947\ 1.007\ 0.942\ 0.981\ 0.932\ 0.969\ 1) \quad (2)$$

$$\lambda(k)C=(0.978\ 0.951\ 0.933\ 0.943\ 0.935\ 0.938\ 0.93\ 0.947\ 0.985) \quad (3)$$

- Judge the level ratio

When $\lambda(k)\epsilon(e^{\frac{2}{n+1}},e^{\frac{2}{n+1}})$, when n=10, $\lambda(k)\epsilon(0.834,1.199)$, and when $\lambda(k)$ falls into the above range, the GM(1,1) model is suitable.

$\lambda(k)\epsilon(0.917,0.988)$,K=2,3,4,5,6,7,8,9,10, therefore, it can be modeled by GM(1,1).

$\lambda(k)\epsilon(0.904,1.007)$,K=2,3,4,5,6,7,8,9,10, therefore, it can be modeled by GM(1,1).

$\lambda(k)\epsilon(0.93,0.985)$,K=2,3,4,5,6,7,8,9,10, therefore, it can be modeled by GM(1,1).

2) Construct GM (1,1) model: Using the data from 2011 to 2020 as the original series, the GM(1,1) prediction model is obtained according to the following five steps, as shown in Eq. (6) to Eq. (8), and the predicted value is calculated according to the GM(1,1) prediction model, as shown in Table I and Eq. (4) to Eq. (7):

Step 1: Set the original sequence as follows:

$$X^{(0)}=\{X^{(0)}(1),X^{(0)}(2),\ldots,X^{(0)}(n)\} \quad (4)$$

Step 2: Generate a cumulative sequence

$$X^{(1)}=\{X^{(1)}(1),X^{(1)}(2),\ldots,X^{(1)}(n)\} \quad (5)$$

Step 3: Create differential equations based on the cumulative series:

$$\frac{dX^{(1)}}{dt}+aX^{(1)}=b \quad (6)$$

where, a,b are the parameters to be estimated for the differential equation.

Step 4: Least squares method to solve the equation:

$$X^{(1)}(k+1)=\left(X^{(0)}(1)-\frac{b}{a}\right)e^{-ak}+\frac{b}{a} \quad (7)$$

Finally, the prediction equations for the GM(1,1) model were derived by calculating the coefficients a and b through MATLAB as follows:

Port cargo throughput (A): $955544.3367e^{0.045k}$-912395.6667.

Foreign trade cargo throughput (B): $307749.5686e^{0.035k}$-297836.0286.

Container Cargo Throughput (C): $23944.67667e^{0.035k}$-22502.56667.

The actual value from 2011 to 2020 is plotted against the predicted value of GM(1,1), as shown in Fig. 1 to Fig. 3. It is found that the actual value of port cargo throughput, foreign trade cargo throughput and container cargo throughput have a consistent growth trend with the predicted value, which is a relatively stable positive growth. The previous data from 2011 to 2013 almost overlap, while the actual and predicted values from 2014 to 2020 are also close, proving that GM(1,1) is suitable for port logistics forecasting.

TABLE I. COMPARISON BETWEEN ACTUAL VALUE AND GM(1,1) PREDICTED VALUE FROM 2011 TO 2020 (UNIT: TEN THOUSAND TONS AND TEN THOUSAND TEU)

Year	Port cargo throughput		Foreign trade cargo throughput		Container cargo throughput	
	Actual value	Predicted value	Actual value	Predicted value	Actual value	Predicted value
2011	43148.67	43148.67	9913.54	9913.54	1442.11	1442.11
2012	43517.39	43996.035	10968.42	10957.839	1474.36	1479.862
2013	45516.57	46031.058	11329.27	11345.164	1550.45	1570.813
2014	48217.25	48160.21	11957.1	11746.18	1662.62	1667.354
2015	50053.01	50387.846	11868.51	12161.371	1762.49	1769.828
2016	52253.82	52718.52	12596.03	12591.237	1885.77	1878.6
2017	57003.47	55156.999	12843.79	13036.298	2010	1994.057
2018	59396.2	57708.268	13782.16	13497.09	2162.27	2116.61
2019	60520	60377.546	14221	13974.17	2284	2246.695
2020	61240	63170.291	14224	14468.113	2319	2384.774

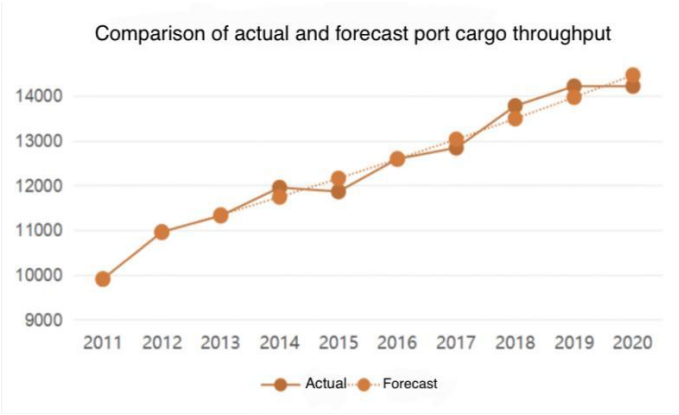

Fig. 1. Comparison of actual and forecast port cargo throughput 2011-2022.

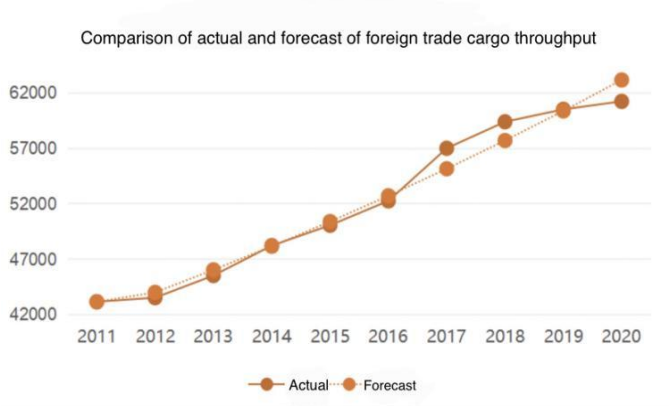

Fig. 2. Comparison of actual and forecast of foreign trade cargo throughput 2011-2022.

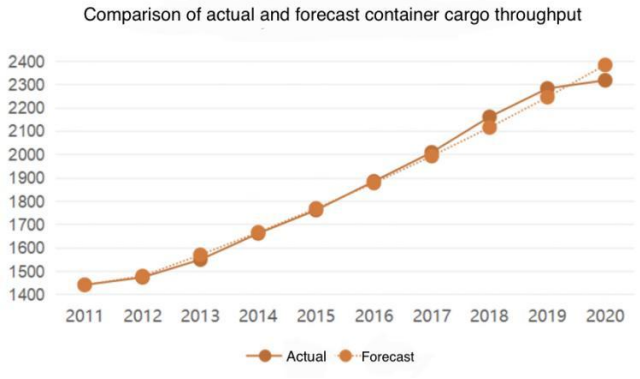

Fig. 3. Comparison of actual and forecast container cargo throughput 2011- 2022.

3) Post-test difference ratio test and relative error test: After calculating the prediction equations and predicted values, the accuracy of the model needs to be further tested. The posterior difference ratio can verify the accuracy of the gray prediction. When the posterior difference ratio is smaller, it indicates the high accuracy of the gray prediction model, and the relative error is the value obtained by multiplying the ratio of the absolute error caused by the measurement and the true value of the measured (convention) by 100%, which can also reflect the credibility of the measurement. Therefore, the posterior difference test and the mean relative error test are performed in this study, as follows in the Table II.

TABLE II. GM(1,1) ACCURACY TEST

	Post-test ratio	Average Relative Error %
Port cargo throughput A	0.024	1.338
Foreign trade cargo throughput B	0.02	1.153
Container Cargo Throughput C	0.009	1.014

In general, a posterior difference ratio less than 0.35 indicates a high model accuracy. The ratio less than 0.5 indicates that the model accuracy is qualified. The ratio less than 0.65 indicates that the model accuracy is basically qualified. Analysis of the above table shows that the posterior difference ratio of the GM(1,1) model consisting of cargo throughput, foreign trade cargo throughput, and container cargo throughput is less than 0.35, and all of them are between 0.009 and 0.024, which proves that the GM(1,1) model is highly accurate. Also, the lower the relative error value, the better. A relative error value of less than 20% indicates a good fit of the model. Therefore, in order to judge the model fit of the gray prediction model, the relative error was calculated for the predicted values from 2011 to 2020 and then averaged to obtain the interval (1.014%-1.338%), which implies a good model fit. After constructing the GM(1,1) model and passing the posterior difference ratio test and relative error test, it shows that the GM(1,1) model constructed in this study has good accuracy and can therefore be used to forecast the port logistics demand in Guangzhou.

4) Forecast accuracy: This study assumes that the logistics demand of Guangzhou port in 2021 is unknown and needs to be forecasted by the GM(1,1) model, and then the data obtained from the forecast is compared and analyzed with the actual data published by the Ministry of Transport of China in 2021 to determine whether the GM(1,1) model is applicable to the logistics demand forecast of Guangzhou port, as shown in Table III.

TABLE III. COMPARISON OF ACTUAL AND FORECAST VALUES IN 2021

2021	Port cargo throughput	Foreign trade cargo throughput	Container Cargo Throughput
Actual	62367	15795	2418
Forcast	66092.21313	14979.51533	2531.340499

The 2021 cargo throughput, foreign trade cargo throughput and container cargo throughput predicted by GM(1,1) model are 66,092, 14,980 and 25,310 (million tons) respectively after rounding, and the actual values are 62,367, 15,795 and 24,180 (million tons) respectively. Calculating the error between the forecasted and actual values of the above three throughputs in 2021 yields 3725, 816, and 113, and it can be found that the error is relatively large for cargo throughput. But it is understandable due to the large base. Analysis of the table shows that the GM(1,1) model is higher than the actual value for both cargo throughput and container cargo throughput, and lower than the actual value for the forecast of foreign trade cargo throughput. The accuracy of the GM(1,1) model for foreign trade cargo throughput and container cargo throughput is excellent, but the predicted value of cargo throughput differs significantly from the actual value. Therefore, this study hopes to compare the prediction by combining a BP neural network and GM(1,1) model to investigate whether the prediction accuracy can be improved to reduce the error.

B. BP Neural Network Model

1) Basic concepts of the BP neural network model: The BP neural network is a member of a large family of artificial neural networks. BP neural network prediction method is a multi-level neural network with reverse flow according to error, which can not only distinguish different modes, but also has a good mapping function for multi-dimensional functions [15]. In this way, the method solves a problem that other perceptrons cannot understand. The principle is to achieve the optimal value of the network target by gradient reduction. In general, it is a multidimensional function and takes the square error of the network as the variable, and calculates the minimum value of this function by the gradient descent method. And it is mainly composed of input layer, hidden layer and output layer. The BP algorithm consists of forward and reverse calculations. Because the BP neural network has been relatively mature in network theory and performance and has been used in many aspects, such as artificial intelligence, it will continue to be optimized and used in the future. It is a very popular model.

2) Construction of BP neural network logistics demand forecasting model

a) Data selection and source: Since the Guangdong Statistical Information Network does not publish the gross

regional product, fixed asset investment, and total value of merchandise import and export in Guangzhou in 2021. Therefore, this study selects the data from 2011 to 2020 for modeling the BP neural network and constructs BP neural networks for cargo throughput, foreign trade cargo throughput and container cargo throughput, respectively. The data from 2011 to 2019 were used as the training set and 2020 as the validation set.

b) Number of layers in the network: A network unit of a BP neural network can correspond to multiple inputs but only one output, and the input layer corresponds to neurons composed of influence factors. Gross regional product, fixed asset investment, and gross merchandise import and export are the input layers of the three neurons chosen for this model. Gross regional product, fixed asset investment, and gross merchandise import and export are the input layers of the three neurons chosen for this model. The output layers of the model are cargo throughput, foreign trade cargo throughput and container cargo throughput, respectively. After the calculation, it was finally decided to use 5 hidden layers. The structure of the BP neural network is shown in Fig. 4.

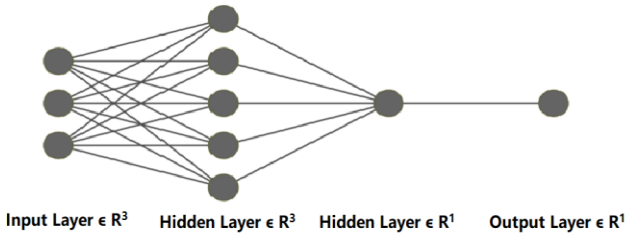

Fig. 4. BP neural network structure diagram.

c) BP neural network activation function: The sigmoid function and tanh function are more typical functions that can be applied to BP neural networks. Because the step function is not derivable, there is a more complicated problem of calculation, so this study chooses the sigmoid function as the network layer activation function. Because the sigmoid function is not only derivable but also can be found by the gradient descent method to find the extreme value, the computational difficulty is much reduced. In summary, in this study, we chose to use the S-type function (Sigmoid) as the activation function of the network layer as follows:

$$f(x)=\frac{1}{1+e^{-2n}}-1 \tag{8}$$

3) BP neural network prediction accuracy: A BP neural network model is constructed using MATLAB, and three cargo throughputs from 2011-2019 are selected for the training set, and the 2020 data is the validation set. First, the BP neural network is set to display the results once every 10,000 rounds. Then the learning speed is set to 0.001 and the maximum training rounds are 50,000. After the BP neural network model is trained, the errors for 2011-2019 are below 1%, and R^2 is very close to 1. This proves that the predicted values of the BP neural network after training are very close to the actual values, and the predicted values for 2011-2019 can be approximated to be equal to the actual values. The absolute errors of cargo throughput, foreign trade cargo throughput, and container cargo throughput for 2020, as the validation set, are 3.4215%, 2.4999%, and 2.5275%, respectively. The data show excellent prediction accuracy with small errors. The detailed training results are shown in Fig. 5 to 7.

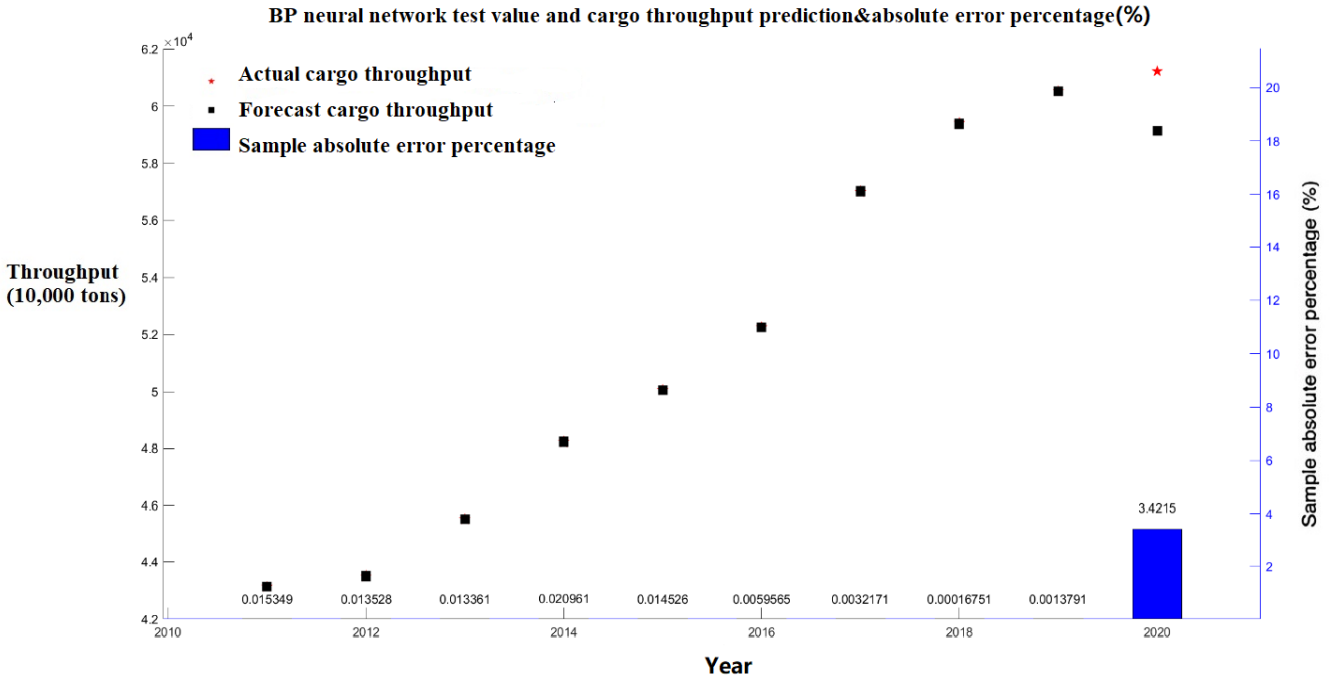

Fig. 5. BP neural network test values and 2020 cargo throughput forecast and absolute error percentage.

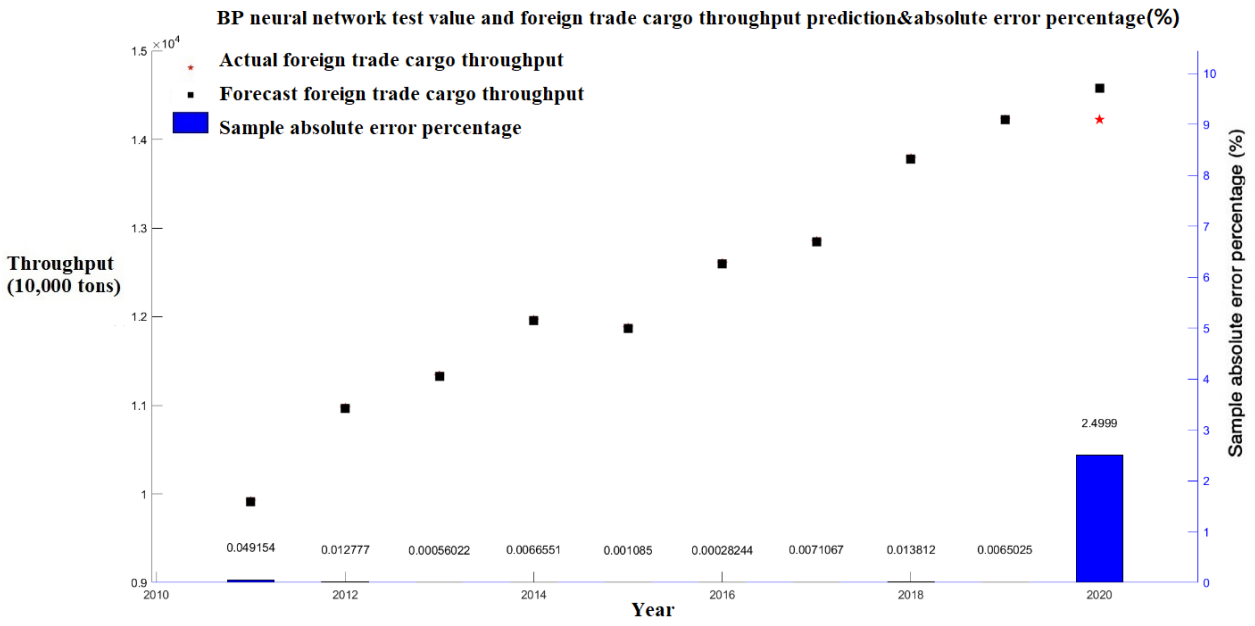

Fig. 6. BP neural network test values and 2020 foreign trade cargo throughput forecast and absolute error percentage.

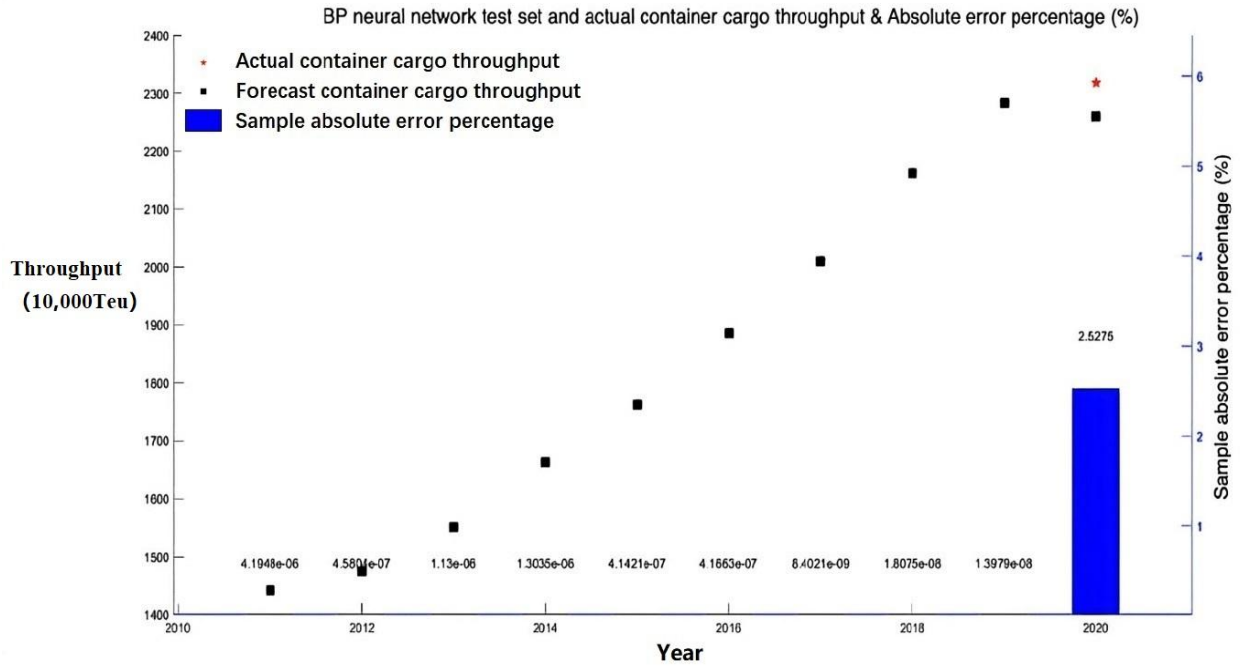

Fig. 7. BP neural network test values and 2020 container cargo throughput forecast and absolute error percentage.

C. BP Gray Prediction Combined Model

The GM(1, 1) model shows a large error in the prediction for cargo throughput, while the error of cargo throughput in the BP neural network prediction is only 3.4215%, which is a better prediction result. Therefore, this study decides to construct a combined model with a BP neural network model and a gray prediction model to investigate whether the combined model is better than a single model in terms of accuracy.

1) Determination of weight coefficients: Combined model y_t is shown in Eq. (9) and Eq. (10). There are many ways to combine individual models, among which the most critical is the establishment of weight coefficient ω_i. Considering the convenience of calculation and referring to most literature, this study finally chooses the equal-weight average method as Eq. (10):

$$y_t=\sum_{i=1}^{k}\omega_i f_{it}\ ,\ \sum_{i=1}^{k}\omega_i=1\ \text{ and }\ \omega_i\geq 0 \qquad (9)$$

where, ω_i is the weight, f_{it} is the predicted value, and k=1，2…n represents the number of models.

$$\omega_i=\frac{1}{k} \quad i=1,2,\ldots,k \tag{10}$$

After determining the weight composition, it is necessary to calculate the predicted value and the actual value, and then carry out the combination forecast and analyze the forecast results.

2) Combination prediction: The logistics demand of Guangzhou Port in 2020 is forecast, compared and analyzed, and the calculation results are shown in Table IV below:

TABLE IV. COMPARISON BETWEEN PREDICTED VALUES AND ACTUAL VALUES OF EACH FORECAST MODEL IN 2020 (TEN THOUSAND TONS AND TEN THOUSAND TEU)

	Actual	BP	GM(1,1)	Combination model
Port cargo throughput A	61240	59144.6734	63170.291	61157.4822
Foreign trade cargo throughput B	14224	13868.41422	14468.113	14168.26361
Container cargo throughput C	2319	2260.387275	2384.774	2322.580638

The table is drawn according to the output results of the BP neural network model, GM(1,1) model, and the BP neural network grey prediction combination model. The analysis results show that the predicted values of the BP neural network model are all smaller than the actual values, and the predicted values of the GM(1,1) model are all larger than the actual values. The combination model of the two is closer to the actual value than the single item model, weakening the limitations of the two single item models, and improving the accuracy of prediction to a certain extent. It proves that the combination model of BP neural network and GM(1,1) is more effective and conducive to reasonably predicting the future port logistics demand in the case of predicting Guangzhou port logistics.

3) Prediction accuracy: In order to further analyze the output results of the individual model and the combined model, the absolute percentage error is calculated, respectively, and the following table is obtained (see Table V):

TABLE V. ABSOLUTE PERCENTAGE ERROR BETWEEN EACH MODEL AND THE ACTUAL VALUE (%)

	BP	GM(1,1)	Combination model
Port cargo throughput A	3.422	3.152	0.135
Foreign trade cargo throughput B	2.500	1.716	0.392
Container cargo throughput C	2.528	2.836	0.154

It can be clearly seen that the combination model constructed by BP neural network model and GM(1,1) improves the prediction accuracy: the absolute percentage error of cargo throughput is reduced from 3.422% to 0.135%. The absolute percentage error of foreign trade cargo throughput decreased from 2.5% to 0.392%, and the absolute percentage error of container cargo throughput decreased from 2.528% to 0.154%. Through the combination model, the forecast results are optimized to a large extent, and it is an effective combination model, which is suitable for the Guangzhou port logistics demand forecast.

To sum up, the combination model constructed by the BP neural network model and GM(1,1) can effectively improve the prediction accuracy of the model, which can be applied to the demand prediction of Guangzhou port logistics.

4) Forecast of logistics demand mix of Guangzhou Port in 2022-2024: After comparing and analyzing the three models, the prediction accuracy of the combined model constructed by the BP neural network model and GM(1,1) is better. In order to understand the logistics demand of Guangzhou Port in the following years, the combination model is used to further forecast the logistics demand of Guangzhou Port in 2022-2024. The forecast results are shown in the Tables VI to VIII:

TABLE VI. CARGO THROUGHPUT FORECAST FOR 2022-2024

Year	GM(1,1)	BP	Combination
2022	69149.28783	59923.61814	64536.45299
2023	72347.76658	59016.2997	65682.03314
2024	75694.18995	59415.8469	67555.01842

TABLE VII. FOREIGN TRADE CARGO THROUGHPUT FORECAST FOR 2022-2024

Year	GM(1,1)	BP	Combination
2022	15508.99416	13678.9264	14593.96028
2023	16057.18841	13791.26738	14924.2279
2024	16624.75961	13576.82063	15100.79012

TABLE VIII. CONTAINER CARGO THROUGHPUT FORECAST FOR 2022-2024

Year	GM(1,1)	BP	Combination
2022	2686.914378	2034.919902	2360.91714
2023	2852.049687	2122.543896	2487.296791
2024	3027.334061	2082.888479	2555.11127

The three throughputs all show an increasing state in 2022-2024 in the prediction of the GM(1,1) model, while the BP neural network model is slightly different from the GM(1,1) model. However, in general, it is also an increase compared with 2020. After the combination of the two individual models through the equal weight average method, it is predicted that the demand for logistics of Guangzhou port in 2022-2024 will show an increasing trend. Extrapolate according to the actual situation, this is in line with our country's national condition and economic development trend. The combined model reduces the limitations of the single model, and the forecast result is closer to reality, which can be applied to the forecast of Guangzhou port logistics demand.

V. DISCUSSION AND CONCLUSION

A. Conclusion

This study chooses port throughput, foreign trade cargo throughput, and container cargo throughput to study the development trend of Guangzhou port cargo. The combined

model is used to forecast the logistics demand of Guangzhou port in 2022-2024. The freight volume demand of Guangzhou port shows a rapid growth trend. The comparative results demonstrate that the BP–GM(1,1) combination model consistently achieves lower absolute percentage errors than the single GM(1,1) and BP neural network models across all three throughput indicators. This indicates that the hybrid approach effectively balances the advantages of small-sample adaptability and nonlinear learning capability. From a practical perspective, higher forecasting accuracy can support more rational allocation of port logistics resources, reduce congestion risks, and improve operational efficiency. Furthermore, the results provide quantitative evidence for smart port planning and infrastructure optimization, offering decision support for port authorities under complex logistics environments.

B. Discussion

From a strategic perspective, accurate logistics demand forecasting can assist port authorities in prioritizing infrastructure investment, optimizing capacity expansion, and coordinating port–city development. Under the Belt and Road Initiative and the Guangdong–Hong Kong–Macao Greater Bay Area framework, such predictive insights are crucial for enhancing the international competitiveness of hub ports and supporting regional economic integration.

C. Future Research

Future research may extend the proposed combination model to other ports or regional logistics systems to test its generalizability. In addition, integrating real-time operational data and intelligent decision-support systems could further enhance its application in smart port governance and policy formulation.

***Abstract*—Breast cancer is still a major health risk for women all over the world, and thus finding it early is very important for the patient's survival. Digital Breast Tomosynthesis (DBT) offers enhanced imaging capabilities relative to conventional mammography; yet, its quasi-3D characteristics provide distinct interpretability issues, often rendering deep learning models as black boxes. This work tackles the issue of transparency by testing three Explainable Artificial Intelligence (XAI) methods: Gradient-weighted Class Activation Mapping (Grad-CAM), Score-CAM, and Local Interpretable Model-Agnostic Explanations (LIME). The ResNet-50 architecture was utilized to analyse a dataset of 396 DICOM images that had been pre-processed in a unique way, including colour-mapping and balancing. The study used Insertion and Deletion Area Under the Curve (AUC) to carefully quantify how reliable the visual explanations were, in addition to usual criteria like accuracy, which achieved 94%. It was shown that LIME and Score-CAM generated attention maps that were dispersed or inconsistent, whereas Grad-CAM always showed lesion-specific areas with great accuracy. Grad-CAM was the best method for analysing DBT findings, since it had the highest Insertion AUC of 0.9078. These results provide radiologists with a way to trust and check automated diagnoses, which closes the gap between AI that works well and AI that is reliable in the clinic.**

***Keywords*—Breast cancer; DBT; Grad-CAM; ResNet-50; XAI**

I. Introduction

Breast cancer is still the most common kind of cancer in women across the world and is the leading cause of cancer deaths. The World Health Organization (WHO) said that in 2020, there were more than 2.3 million new cases and 685,000 fatalities [1]. Breast cancer is the most common kind of cancer in Indonesia, making up around 30% of all cancer cases [2]. It is more common than cervical cancer. Finding the disease early is crucial for enhancing the chances of survival and the long-term outlook. Deep Learning (DL) on Convolutional Neural Networks (CNNs) has emerged as the most popular method for analyzing medical images to distinguish between benign and malignant breast cancers [3], [4]. Architectures like ResNet-50 have shown outstanding performance in classification tasks, but how they make decisions within is still not clear. Because the reasoning behind a model's categorization isn't always clear, medical practitioners generally don't trust it because it is a "black box" [5]. The Explainable Artificial Intelligence (XAI) method was developed to clarify and simplify deep learning (DL) models in order to address these issues. Specifically, XAI techniques were developed to visualize which image regions most significantly influence model predictions [6], [7]. Nonetheless, the majority of current XAI assessments concentrate on 2D imaging. Digital Breast Tomosynthesis (DBT) has distinct interpretative issues because of its quasi-3D attributes and overlapping tissue features, which markedly contrast with traditional mammography. At present, there is an absence of extensive research explicitly examining the performance of XAI methods—such as Grad-CAM, Score-CAM, and LIME—when used on DBT data with the ResNet-50 architecture.

This study seeks to evaluate and contrast three XAI methodologies—Grad-CAM, Score-CAM, and LIME—in analysing breast cancer classifications obtained from DBT images, addressing the current deficiency in the field. The evaluation employs visual saliency map analysis and quantitative metrics, namely the Deletion and Insertion Area Under the Curve (AUC). The aim of this research is to identify the most reliable XAI framework for 3D breast imaging, providing clinical decision-support insights and practical guidance for radiologists in selecting transparent AI technologies for medical diagnosis.

II. Literature Review

This section analyses previous studies that support this research. The literature reviewed includes topics related to breast cancer, DBT imaging, the use of deep learning in medical image classification, and the XAI methods used to understand CNN-based classification models. Buda et al. [8] released a large DBT dataset with 22,032 volumes from 5,060 patients and used DenseNet to create a basic model for finding breast cancer. This model had a sensitivity of 65% and two false positives per volume, but the study didn't say how easy it was to understand it. This work demonstrates the necessity of integrating XAI methods into DBT analysis to enhance the transparency and trustworthiness of medical AI systems.

Rodriguez-Ruiz et al. [9] showed that an autonomous AI system was able to detect cancer on mammograms with an Area Under the Curve (AUC) of up to 0.93, which is equivalent to human radiological performance. Meanwhile, Antropova et al. [10] used DCE-MRI images with the Maximum Intensity Projection (MIP) approach and CNN for the classification of benign and malignant lesions, resulting in an AUC of 0.88. Although neither study integrated XAI methods, their results

*Corresponding author.

open up important avenues for applying XAI to improve the clinical interpretability of CNN-based diagnostic systems.

A study by Kim et al. [10] more explicitly demonstrates the impact of visualisation on diagnostic confidence and accuracy. Using a CNN based on ResNet-34 and heatmap visualisation similar to Grad-CAM, the accuracy of mammography classification increased (AUC from 0.79 to 0.89), and the recall rate decreased from 60.4% to 49.5%. These findings confirm the importance of visual interpretability in increasing radiologists' trust in AI systems, although the study did not directly compare several XAI methods.

Di Martino et al. [5] examined various XAI methodologies employed in medicine, including SHAP, LIME, and Grad-CAM. Researchers found that Grad-CAM works well with CNNs because it can highlight important parts of medical images on its own, regardless of the architecture. LIME uses surrogate models to present local interpretations, and SHAP uses the theory of Shapley values to ensure that everything is consistent across the board. Many people prefer SHAP and Grad-CAM; however, the most effective XAI method depends on the specific model, context, and clarity of understanding. There have been no thorough studies that have directly compared the XAI methods Grad-CAM, LIME, and Score-CAM for classifying breast cancer using CNNs based on DBT.

Kursun et al. [11] applied Score-CAM to explain the classification results of deep learning models in leaf image-based plant disease detection. Score-CAM works without using gradients but instead calculates the weights of each activation channel based on the prediction score, resulting in more stable and less noisy visualisations than Grad-CAM. This study confirms that Score-CAM can improve the visual interpretability of CNN models without disturbing the model architecture. In the context of this study, Score-CAM is used as one of the XAI methods compared in assessing visualisation clarity and interpretation reliability in DBT image-based breast cancer classification.

Jusman et al. [12] assessed the effectiveness of GoogLeNet and ResNet-50 in the classification of X-ray images for COVID-19 detection. ResNet-50 always did better than GoogLeNet, with an average test accuracy of 94%, a precision and recall of 90%, and an F1-score of 89%. These results indicate that the residual learning architecture is better at finding complicated patterns in medical images. ResNet-50 was used as the CNN backbone for this study because it can deeply and accurately pull out important features, which are crucial for classifying breast cancer based on DBT images.

Based on a literature review, ResNet-50 has proven effective in medical image classification, including breast cancer, but interpretability challenges in DBT images still need to be addressed. These findings were utilized to select the appropriate model architecture and XAI methods for analysis during the implementation phase.

III. Methodology

This section outlines the methodologies and procedures employed in the research process, encompassing data processing, CNN model architecture, and the application and assessment of three XAI methods: Grad-CAM, LIME, and Score-CAM. This study uses the DBT image dataset for breast cancer classification and employs the ResNet-50 architecture as the primary CNN framework. Then, the XAI method analyses the classification results for clarity and consistency.

A. Research Flow

This research includes six stages, starting from data collection to the presentation of XAI results visualisation, as shown in Fig. 1.

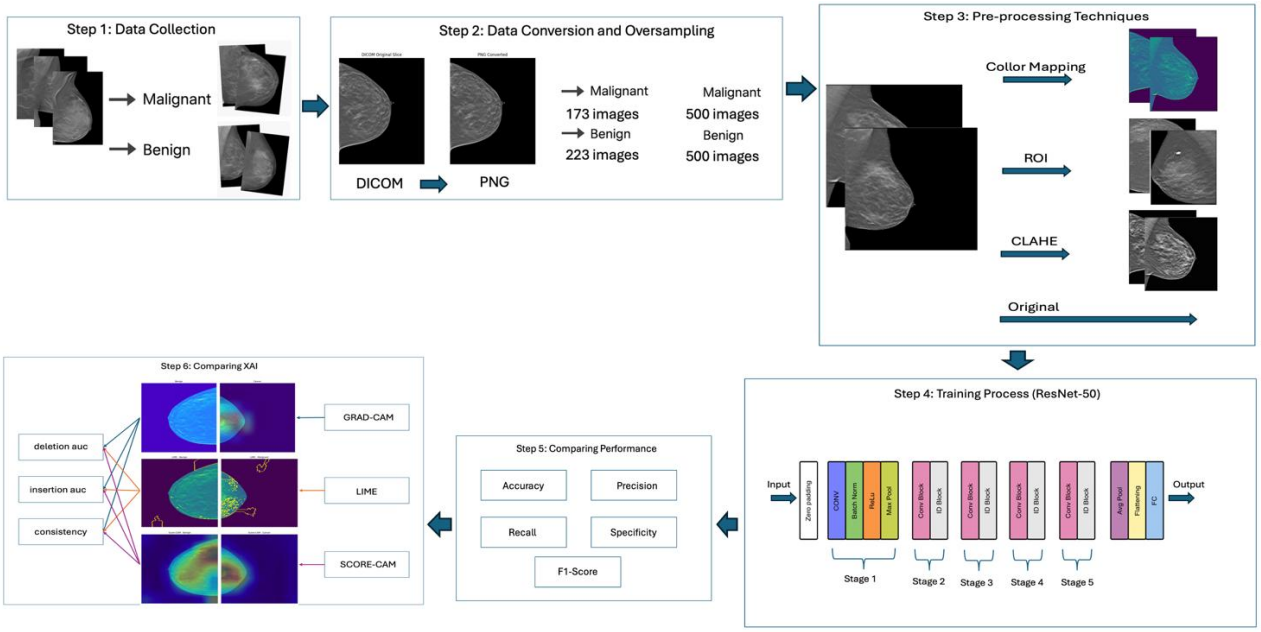

Fig. 1. Research flow.

The following sub-sections will provide a detailed explanation of the flow stages depicted in Fig. 1.

B. Pre-Processing

- Data Collection: This study uses data from patients diagnosed with breast cancer, consisting of two classes, namely 223 benign images and 173 malignant images, in DICOM format. Data were obtained from the National Cancer Institute through the Breast Cancer Screen – Digital Breast Tomosynthesis (BCS-DBT) dataset [13]. To visualise, the two types of classes, benign in Fig. 2 and malignant in Fig. 3, are shown below.

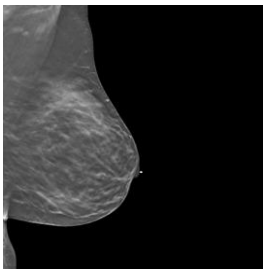

Fig. 2. Benign.

Fig. 3. Malignant.

- Data Conversion and Oversampling: The collected images are processed to facilitate the next stage of analysis. Images in DICOM format are converted into PNG format, called super images [14], with the aim of reducing the computational load without sacrificing image quality. Next, a random overlapping process is carried out to overcome the imbalance in the number of images between benign and malignant classes so that each class has 500 images [15].
- Pre-processing Techniques Image: This stage is carried out to obtain optimal CNN training results by applying the colour mapping technique. The colour mapping technique showed the highest accuracy compared to the other three techniques on DBT images, namely 94%.

C. Image Classification

Researchers used the ResNet-50 architecture to sort pictures. Post-training evaluation was performed using a confusion matrix with metrics such as accuracy, F1-score, recall, and precision. Subsequently, XAI methods were employed to visualize and interpret the underlying rationale behind the model's predictions.

1) ResNet-50: This model is used in this study to sort DBT images is a deep convolutional neural network with 50 layers that learns by connecting shortcuts. This mechanism effectively mitigates the accuracy degradation in exceedingly deep networks by acquiring residual functions, thereby resolving the issue of vanishing gradients. ResNet-50 has been shown to work better than other methods for a wide range of medical image classification tasks, such as finding breast and prostate cancer [16]. Fig. 4 presents the ResNet-50 architecture.

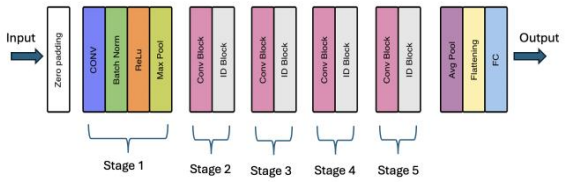

Fig. 4. ResNet-50 architecture.

The last layer of the ResNet-50 design was modified to correspond with the number of classes in the DBT dataset [17]. Training was conducted for 25 epochs using the Adam optimizer, with a learning rate of 0.0001 and a batch size of 10. A confusion matrix was utilized to evaluate the model's performance by determining the accuracy, precision, recall, specificity, and F1-score for each class.

2) Confusion matrix: Researchers performed evaluations of model classification using a confusion matrix, the value of which is measured based on four metrics: accuracy, F1-score, recall, and precision. The results of these calculations were used to assess whether the previous process successfully improved classification performance, achieved high accuracy, and optimally differentiated between benign and malignant classes [18]. The following section presents the equations for these four metrics.

a) Accuracy: It is a metric that indicates the overall accuracy of a model's predictions. This indicator is often used as an initial benchmark for model performance because it considers the accuracy of predictions for both the positive and negative classes. The accuracy calculation is shown in Eq. (1):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \times 100\% \quad (1)$$

b) Recall or sensitivity: It is a metric that assesses a model's ability to identify positive data from a pool of truly positive data. This metric is crucial in cases such as disease detection or fraud, where missing a positive case can have serious consequences. The recall is defined in Eq. (2):

$$Recall = \frac{TP}{TP+FN} \times 100\% \quad (2)$$

c) Precision: It describes the level of accuracy of positive predictions produced by the model, namely the proportion of correct positive predictions out of all positive predictions made. A high precision value indicates that the model rarely produces false positive predictions. The precision calculation is presented in Eq. (3):

$$Precision = \frac{TP}{TP+FP} \times 100 \quad (3)$$

d) F1-Score: It is an evaluation metric that combines precision and recall into a single value using the harmonic mean of both. This metric provides a balance between the model's ability to detect positive data (recall) and produce accurate positive predictions (precision). The F1-Score is determined using Eq. (4):

$$F1 - Score = 2 \times \frac{Sensivity \times Precision}{Sensitivity + Precision} \times 100\% \quad (4)$$

D. Explainable Artificial Intelligence (XAI)

Next, the researchers visualized the results of DBT-based breast cancer image classification using XAI to identify areas in the image that most influenced the model's decision. XAI was used to provide a transparent interpretation of the classification process by highlighting points or areas that serve as the basis for distinguishing between two cancer classes. In this study, three XAI methods were used, and their performance was evaluated using two metrics: Deletion AUC and Insertion AUC. The following is an explanation of each XAI model and an evaluation of its performance:

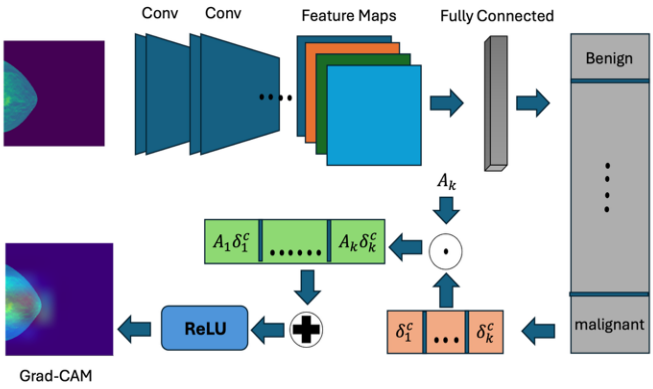

Fig. 5. Grad-CAM architecture.

1) Grad-Cam: Gradient-weighted Class Activation Mapping (Grad-CAM) is a method for showing which parts of DBT images have the most impact on the model's choice between benign and malignant breast cancer. Grad-CAM makes a heatmap that shows how much each area helped the model make a prediction by using the gradients from the last convolutional layer. This makes it easier to understand how to classify things visually [19]. The Grad-CAM model architecture is shown in Fig. 5.

Fig. 5 shows how the Grad-CAM method was used in this study with a CNN architecture based on ResNet-50. The DBT image passes through a number of convolutional layers, and the last one makes feature maps. After that, it goes to a fully connected layer that classifies tumours as either benign or malignant. To find the importance weights for each feature map, Grad-CAM takes the gradient of the target class output and multiplies it by the feature map that goes with it. The results go through a ReLU activation function, which only keeps the positive contributions. This creates a heatmap that shows which parts of the DBT image have the most effect on the model's prediction.

2) SCORE-CAM: The Score-Weighted Class Activation Mapping (Score-CAM) method is used to visualise important areas in DBT images that influence the model's decision to differentiate between benign and malignant breast cancer. This method produces a heatmap of the colour-mapped image, where colours with higher intensity indicate areas that contribute most to the model's prediction. This approach allows for a more transparent interpretation of the classification results, thus improving understanding of the model's decision-making process [11]. Fig. 6 displays the architecture of the Score-CAM model.

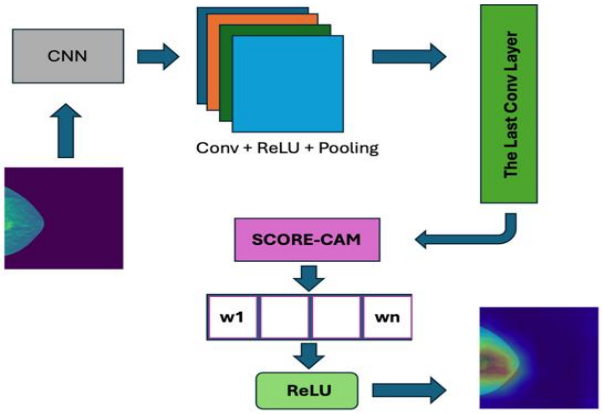

Fig. 6. Score-CAM architecture.

Fig. 6 shows the implementation flow of the Score-CAM method in this study using a CNN architecture using ResNet-50. The DBT is first processed by the ResNet-50 model through a series of convolutional layers, ReLU activation, and pooling to produce output in the final convolutional layer. Next, Score-CAM utilises the feature maps from the final layer by assigning weights ($w_1 \ldots w_n$) based on the contribution of each feature map to the prediction. These weights are then combined and passed through a ReLU activation function to produce a heatmap that highlights the areas of the DBT image that are most influential in the classification of both benign and malignant tumour types.

3) LIME: Local Interpretable Model-Agnostic Explanations is an XAI method that locally explains black-box model predictions by generating synthetic data around an instance through random perturbation, predicting it again with the original model, and then training a simple model, such as linear regression, to determine the contribution of each feature. This method is model-agnostic and generates explanations that are appropriate for specific instances; however, it may yield different explanations for the same instance because of the randomness inherent in the process [20]. The results can be seen in Fig. 7.

Fig. 7 shows the flow of the LIME method implementation in this study with a CNN architecture using ResNet-50. The DBT image is processed by the CNN model to obtain an initial prediction, then LIME generates several perturbed samples around the original image. Each sample is re-predicted using the original model, and the results are then weighted based on their level of similarity to the original image. This weighted

data is used to train a simple model that can be interpreted locally, resulting in a visualisation of the areas in the DBT image that most influence the decision to classify benign or malignant tumours.

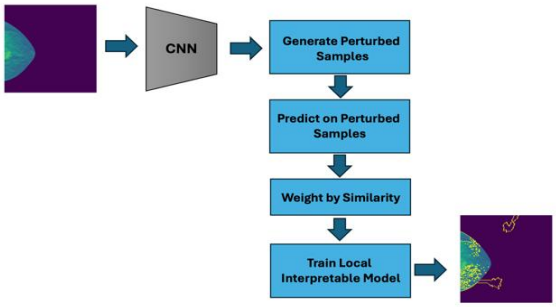

Fig. 7. LIME architecture.

E. XAI Evaluation Metrics

The evaluation of heatmap quality in this study was conducted using two quantitative metrics, namely deletion AUC and insertion AUC, which are commonly used to assess the performance of the XAI method [21]. The following section provides an explanation of the evaluation metrics.

- Deletion AUC: An evaluation metric used to measure the rate of decline in the model's prediction score when pixels deemed most important based on the heatmap are gradually removed from the original image. A lower Deletion AUC value indicates that the resulting importance map has better accuracy in identifying relevant areas. The deletion AUC calculation is shown in Eq. (5):

$$AUC_{del} = \frac{1}{T}\sum_{t=1}^{T} \frac{s_{t-1}^{del} + s_{t}^{del}}{2} \quad (5)$$

- Insertion AUC: An evaluation metric used to measure the rate of improvement in the model's prediction score when important pixels are gradually added to the baseline image (blank or blurred). A higher Insertion AUC value indicates that the heatmap is able to identify important areas more effectively, increasing the confidence of the model's predictions. The insertion AUC calculation is shown in Eq. (6):

$$AUC_{ins} = \frac{1}{T}\sum_{t=1}^{T} \frac{s_{t-1}^{ins} + s_{t}^{ins}}{2} \quad (6)$$

The methodology outlined includes every step, from getting and processing data to using the XAI method and checking how well it works. These steps are meant to make sure that the analysis is done in a planned way and to help talk about the results in the next sections.

IV. Results and Discussion

In this section, the researcher shows what happened when they used and tested the methods from Section III. The results include the use of three XAI methods—Grad-CAM, Score-CAM, and LIME—to show how easy it is to understand the data. They also include quantitative evaluation results using the Deletion AUC and Insertion AUC metrics. The analysis was performed to evaluate the visualisation quality and quantitative efficacy of each method for interpreting the outcomes of DBT image classification using the ResNet-50 architecture.

A. Image Classification Result

Researchers present the training results and confusion matrix of the ResNet-50 classification model to assess the model's performance in distinguishing benign and malignant breast cancer DBT images. The confusion matrix is visualised in Fig. 8, and the model training results are visualised in Fig. 9.

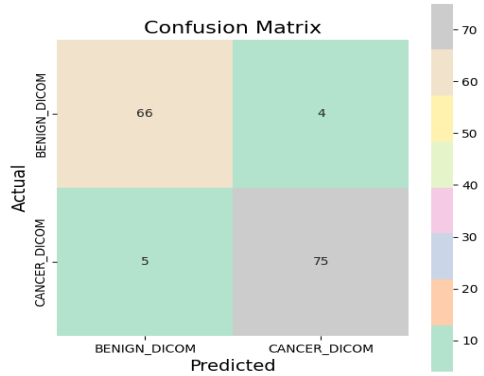

Fig. 8. Confusion matrix ResNet-50.

The graphs in Fig. 8, for accuracy and loss, show that the training is going well, with validation accuracy reaching about 94%. The loss values in the validation data change a bit, but the loss values in the training data keep going down. The classification results' confusion matrix is shown in Fig. 9. It shows that 66 benign images and 75 cancerous images were correctly sorted. The colour mapping method gives more accurate results than other ways of pre-processing.

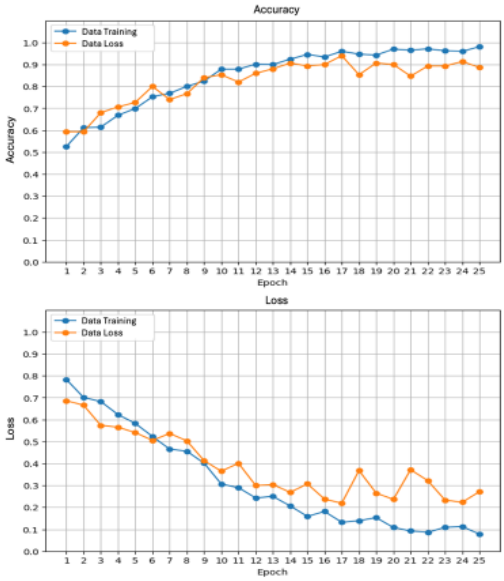

Fig. 9. ResNet-50 training results.

Additionally, performance metrics were evaluated to measure the model's accuracy, recall, precision, and F1-score in classifying. In this test, class 0 represents the benign category, while class 1 represents the malignant category. The performance evaluation results are shown in Table I.

TABLE I. PERFORMANCE EVALUATION OF RESNET-50

Accuracy	Recall		Precision		F1-Score	
	0	1	0	1	0	1
94%	94%	94%	93%	95%	94%	94%

Table I says that the ResNet-50 model, which used colour mapping pre-processing, got 94% accuracy. The values for recall, precision, and F1-score were about the same for both classes. This indicates that the model can consistently and accurately distinguish between benign and malignant breast cancer images.

B. Explainable Artificial Intelligence Results

This section displays the visualization results of Grad-CAM, Score-CAM, and LIME on DBT images, indicating the model's focus areas during classification. Visualizations are presented for both benign and malignant classes, allowing for comparison of the model's attention patterns in each category. The results and explanations are shown in the following figure.

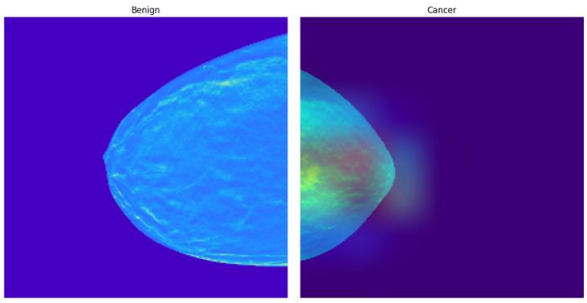

Fig. 10. Grad-CAM result.

Fig. 10 shows the results of Grad-CAM on DBT images for two classes: benign and malignant. In benign images, the colour distribution appears predominantly blue, indicating a low level of model activation in certain areas, resulting in no significant focus on the suspected tissue. Meanwhile, in malignant images, a yellow to red area is visible in the centre, indicating a high level of activation. This indicates that the model is focusing more attention on these areas as indicators of the presence of cancerous lesions.

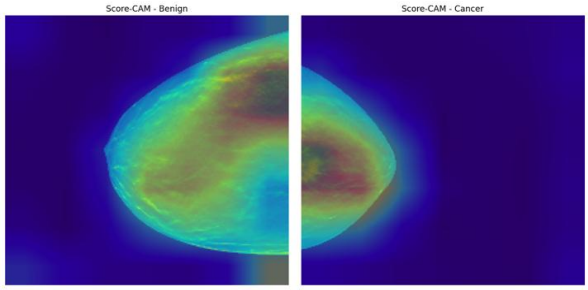

Fig. 11. Score-CAM result.

Fig. 11 presents Score-CAM visualisation results. In benign images, the model's activation areas are fairly evenly distributed with green to yellow colour intensities, indicating a moderate level of focus in some parts of the breast tissue. Meanwhile, in malignant images, the model's focus appears more concentrated in the central area, with yellow-to-red colour intensities, but the activation distribution appears less clear than the Grad-CAM results. This aligns with the metric evaluation results, where Score-CAM performed slightly lower than Grad-CAM.

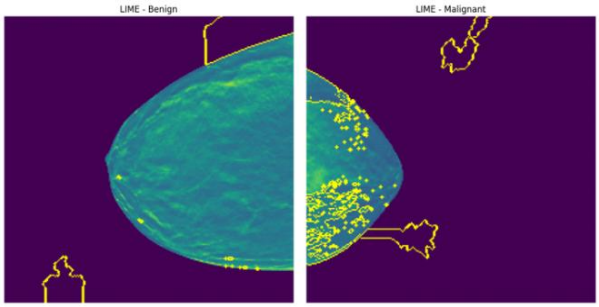

Fig. 12. LIME result.

In Fig. 12, the LIME model highlights the image areas deemed most relevant by the model using yellow borders. In benign images, the highlighted areas are relatively small and scattered across a few points, indicating a lack of indications deemed significant by the model. In contrast, in malignant images, the highlighted areas are much larger and concentrated in specific areas of the breast, indicating that the model identified these areas as strong indicators of abnormalities.

C. XAI Evaluation Metrics Result

The performance of the XAI method was measured quantitatively using the Deletion AUC and Insertion AUC metrics. These two metrics assess the quality of the saliency map generated by the XAI method based on its impact on model predictions. The resulting metrics can be seen in Table II.

TABLE II. XAI MODEL EVALUATION

Model XAI	Benign		Malignant		Mean	
	Deletion AUC	Insertion AUC	Deletion AUC	Insertion AUC	Deletion AUC	Insertion AUC
Grad CAM	0.8241	0.9092	0.2248	0.9064	0.5245	0.9078
Score CAM	0.9089	0.9218	0.1570	0.8152	0.5330	0.8685
LIME	0.9145	0.9559	0.1323	0.0894	0.5234	0.5226

Insertion AUC value (0.9078) and a competitive Deletion AUC value, demonstrating its ability to highlight areas that are truly relevant to the model's decision. Score-CAM provides results close to Grad-CAM on the Deletion AUC metric, but lower on the Insertion AUC. Meanwhile, LIME produces relatively stable values on both metrics but does not exceed the performance of Grad-CAM. These results indicate that Grad-CAM is the most effective XAI method for interpreting DBT image classification models in this study.

D. Discussion

The results of this study provide significant insights into the interpretability of DBT. Even though the images were processed as 2D slices for model training, they still have the complicated quasi-3D features and overlapping tissue structures that are unique to the DBT modality. This modality is very different from regular mammography. The excellent localization of Grad-CAM, which has an Insertion AUC of

0.9078, suggests that it could be used as a "second opinion" tool to help radiologists understand these complicated features. The results also show that gradient-based methods like Grad-CAM are more reliable than perturbation-based methods like LIME, which gave less consistent results on these particular textures. The researcher believes that these results show that high classification accuracy, 94%, in this study needs to be combined with precise feature localization to be useful in future clinical decision support.

V. Conclusion

This study assesses three XAI methodologies—Grad-CAM, Score-CAM, and LIME—for elucidating breast cancer classification in Digital Breast Tomosynthesis (DBT) images, employing a meticulously calibrated ResNet-50 architecture. The model was 94% accurate, and the precision, recall, and F1-score measures were all equal. Visual analysis indicates that Grad-CAM generates the most effective attention maps for lesion regions, while Score-CAM and LIME exhibit greater inconsistency, particularly in cases of cancer. Quantitative analysis corroborates these results, with Grad-CAM attaining the highest Insertion AUC (0.9078). This is why Grad-CAM is the best XAI framework for DBT categorization: it makes it easy and accurate to use AI in medicine.

Limitations and Prospective Research: The study's results are promising, but they are limited by a small dataset of 396 photos and the use of only one model architecture. The research emphasizes 2D-converted slices instead of comprehensive 3D volumetric analysis. Subsequent research ought to employ larger, multi-centre datasets and explore transformer-based architectures or 3D-CNNs to improve the generalizability of XAI performance in breast cancer diagnosis.

***Abstract*—Breast cancer is one of the most life-threatening and heterogeneous diseases. It contains various molecular subtypes, each subtypes have different characteristics, treatment outcomes, and prognosis. The proper integration of multi-omics data, including genomics, epigenomics, transcriptomics, and proteomics, is very important for enhancing the breast cancer molecular subtypes classification accuracy. Despite the increase in high-dimensional multi-omics data, selecting a suitable integration method for multi-omics data in breast cancer molecular subtypes classification still remains a crucial challenge. This study aims to evaluate and compare, and assess the effectiveness of the multi-omics data integration methods, including exploring the advantages, limitations, and highlighting their performance in terms of accuracy, interpretability, scalability, and biological relevance. Our findings indicate that transformer-based integration methods are increasingly adopted in recent studies due to their superior ability to handle high-dimensional heterogeneous data and capture intricate cross-omics relationships while providing interpretable insights. Additionally, we provide a comparative overview of existing models, discuss key trends over the years, and offer actionable guidance for method selection based on dataset characteristics and research objectives. Finally, we suggest future research directions, emphasizing hybrid deep learning frameworks, graph-based models, and attention mechanisms to enhance predictive accuracy and biological interpretability.**

Keywords*—Breast cancer; classification; integration methods; molecular subtypes; multi-omics

I. Introduction

Breast cancer is one of the major life-threatening and most prevalent cancers affecting women worldwide. Despite the advancements in the treatment and screening process, the heterogeneity of breast cancer still presents a major challenge [1]. The heterogeneity of breast cancer is not only morphological but also rooted deeply at a molecular level, which influences disease progression, therapeutic response and prognosis [2]. As a result, the precise and accurate classification of breast cancer into its molecular subtypes has gained significant attention nowadays.

Molecular subtyping of breast cancer, such as Luminal-A, Luminal-B, HER2-Enriched, Basal-Like and Normal-Like, has emerged from the gene expression profiling [3]. These molecular subtypes reflect diverse oncogenic mechanisms and clinical outcomes, necessitating precise and robust classification frameworks [4]. While traditional subtyping relies basically on mono-omics data, recent studies show that the integration of multi-omics data can significantly enhance the accuracy and reliability of breast cancer molecular subtypes classification [5].

Recently, high-throughput technologies such as multi-omics data have become increasingly accessible, including genomics, epigenomics, transcriptomics, and proteomics [6]. Each multi-omics data type captures different aspects of breast tumor heterogeneity, such as genomics, which reveals DNA-level alterations, epigenomics uncovers regulatory modifications, transcriptomics measures gene activity, and proteomics reflects functional outputs [7]. Integrating the diverse multi-omics data types provides a more comprehensive view of breast cancer, allowing for more accurate subtype classification of breast cancer [7].

Accurate and precise multi-omics data integration for breast cancer molecular subtypes classification is very important, as these molecular subtypes are defined through coordinated alteration across the multiple biological layers rather than by individual molecular signals [8]. The effective and accurate integration of multi-omics data variants allows the identification of meaningful biological patterns by integrating various variations in genes, gene expression profiles, protein level interaction, and epigenetic modification that help in the precise classification of breast cancer molecular subtypes [9]. The precise classification of breast cancer molecular subtypes is very important for enhancing the diagnostic accuracy, personalized treatment plans, and prognostic assessment [10]. Inappropriate or poor integration of multi-omics data in breast cancer molecular subtypes classification can lead to loss of important biological information, noise amplification, or even a misleading molecular subtypes classification of breast cancer [11]. Therefore, the selection of an appropriate method for integrating the multi-omics data is required to maintain the biological relevance as well as the data heterogeneity, which is a key challenge in multi-omics breast cancer molecular subtypes classification research.

Despite the rapid increase in multi-omics breast cancer subtypes classification research, there is still a lack of clear guidance regarding the appropriate multi-omics data integration methods for breast cancer molecular subtypes classification. Existing reviews have provided a broad overview of multi-omics integration methods in various domains. However, there is a lack of focus on multi-omics integration methods specifically for breast cancer molecular subtypes classification.

*Corresponding author.

To overcome this issue, this review study introduces a breast-cancer focused analytical evaluation of the multi-omics integration methods and compares the three most common integration methods, including concatenation-based, model-based, and transformation-based integration. By evaluating these integration methods using evaluation criteria, including biological interpretability, scalability, and robustness. This study provides a structured and comparative assessment of the integration methods for multi-omics data in breast cancer molecular subtypes classification.

This study evaluates the integration methods used by existing research, as well as provides actionable insights and methodological guidance for researchers in choosing a suitable multi-omics integration method for breast cancer molecular subtypes classification. The key contributions of this review are summarized as follows:

- To explore the existing multi-omics integration methods for breast cancer molecular subtypes classification.
- To provide a clear comparison and evaluation of integration methods for multi-omics data to classify the breast cancer molecular subtypes.
- To highlight the advantages and disadvantages of the integration methods for the multi-omics data, primarily for breast cancer molecular subtypes classification.
- To suggest future suggestions and directions for developing more accurate and useful integration models.

The rest of the study is organized as follows: Section II emphasizes related works, while Section III focuses on the existing integration methods for multi-omics data in breast cancer molecular subtypes classification. Section IV is about the analysis of multi-omics data integration methods for breast cancer molecular subtypes classification. Section V concentrates on the discussion, while Section VI emphasizes the suggestions and recommendations for future research. Lastly, Section VII is the conclusion of the study.

II. Related Works

Multi-omics integration methods are widely explored to enhance disease characterization and subtype classification by integrating various multi-omics data types and analyzing high-dimensional multi-omics data such as genomics, transcriptomics, epigenomics and proteomics. This section reviews the existing related works on the comparison of multi-omics integration methods for cancer subtypes classification and provides the necessary background and context for understanding current methodological trends and limitations.

Acharya and Mukhopadhyay [12] review various network-based methods based on ML for the integration of multi-omics data in precision oncology, such as clustering and factorization. The study also explores the challenges associated with multi-omics data integration, particularly in the context of network-based integration methods. It also determines the challenges in multi-omics data integration in precision oncology. Similarly, Menyhárt and Győrffy [8] discuss algorithmic frameworks and data integration methods for cancer subtypes, disease mechanism and diagnosis. The study sheds light on both single-omics and multi-omics data integration methods, including the bottom-up and top-down integration methods. It also explains various other integration methods, such as multivariate, statistical, network, fusion-based, similarity-based and correlation-based integration. The study also explores the application of multi-omics data integration methods in various multi-omics data types.

In the same way, Adossa et al. [13] introduce recent developments in the single-cell multi-omics and comprehensively review the existing data integration methods. The study particularly focuses on early, intermediate and late data integration methods, including exploring the conceptual principles and main characteristics of each data integration method. Also, the study determines various tools that are used for the integration methods in single-cell multi-omics data. Moreover, Vahabi and Michailidis [14] provide an overview of multi-omics data integration methods with different statistical approaches, focusing on unsupervised learning tasks, including disease onset prediction, biomarker discovery, disease subtyping and module discovery. The study mainly focuses on unsupervised multi-omics data integration methods, particularly regression-based integration methods, clustering and network-based integration methods. It also elaborates on the working of each data integration method in mono-omics data, such as genomics, epigenomics, and transcriptomics.

Additionally, Cai et al. [15] review ML-based multi-omics data integration methods for cancer, specifically early integration, intermediate integration and late integration methods. It mainly reviews the integration methods working process in different multi-omics datasets. The study also explores various multi-omics data integration tools and their applications. Also, the study determines the strength of each integration method in cancer subtypes classification. Moreover, Subramanian et al. [16] review the multi-omics integration methods, particularly network-based, fusion-based, similarity-based and neighborhood-based integration methods. The study also explores the application of these integration methods in the prediction of biomarkers, diagnostics and driver genes for diseases. It also provides an overview of portals for visualization and interpretation of multi-omics datasets.

Furthermore, Heo et al. [17] provide an overview of the rationale and concepts of multi-omics integration methods in cancer research. The study explores multi-omics integration methods and techniques used to help in the integration process and how the multi-omics integration methods are applied in different cancer subtypes classification, cancer pathophysiology, drug target discovery and clinical decision support. It also determines the latest findings and implications in cancer multi-omics studies. Though enough progress has been made and various research has been conducted on multi-omics integration methods across various cancer types and domains, as shown in Table I. However, there is no existing study that focuses on the multi-omics data integration methods for breast cancer molecular subtypes classification. To overcome this issue, this comparison study introduces a breast cancer-specific multi-omics integration methods that evaluate and compares the existing multi-omics integration methods for multi-omics data in breast cancer molecular subtypes classification.

III. INTEGRATION METHODS FOR MULTI-OMICS DATA IN BREAST CANCER MOLECULAR SUBTYPES

The integration of multi-omics data is highly significant as it integrates various biological data types and variants, including genomics (Copy Number Alteration (CNA), Copy Number Variation (CNV), Single Nucleotide Polymorphism (SNP)), epigenomics (DNA-Methylation (DNA-Methyl)), transcriptomics (Messenger RNA (mRNA), MicroRNA (miRNA)) and proteomics (Reverse Phase Protein Array (RPPA)). for evaluating and understanding the mechanism and structure of breast cancer disease [17]. While mono-omics data offer limited information about breast cancer [18]. Multi-omics data integration captures the interaction and relationship among breast cancer molecular subtypes at the molecular level and provides a deeper understanding of breast cancer cellular function [19]. With the help of accurate and proper multi-omics data integration, healthcare professionals can explore the aggressiveness and behavior of breast cancer by classifying molecular subtypes, and also provide information about the potential causes behind breast cancer. Proper integration of multi-omics data variants can also assist in understanding the flow from one omics data layer to another omics layer [16].

One of the main tasks of the multi-omics data in breast cancer is the early classification of molecular subtypes, for instance, classifying the breast cancer based on molecular level, such as Luminal-A, Luminal-B, HER2-Enriched, Basal-Like and Normal-Like [20]. Breast cancer patients' treatment depends on their specific molecular subtype. By properly utilizing the multi-omics data integration methods and considering various levels of the multi-omics data variants, breast cancer molecular subtypes can be accurately classified at the molecular level so that the patients can get better treatment on time [20].

To gain the full potential of multi-omics data for accurate classification of breast cancer molecular subtypes, effective integration methods are important to capture the behavior and aggressiveness of breast cancer based on its molecular level through the integration of various multi-omics data variants. Typically, the three most common and prominent methods are used for multi-omics data integration, including the concatenation-based integration, model-based integration and transformation-based integration, which are discussed in subsections.

A. Concatenation-Based Integration (CBI)

Concatenation-Based Integration (CBI), also known as early integration, is one of the most direct integration methods, as shown in Fig. 1. It directly combines various multi-omics data variants and creates a joint matrix. The CBI method usually does not require comprehensive feature engineering or extensive preprocessing, as all omics features are added to a large input matrix. The joint matrix is delivered into the model for the

classification tasks. In this integration method, a joint matrix is formed by stacking the feature vectors together from various datasets, which creates a single and larger feature vector for each dataset.

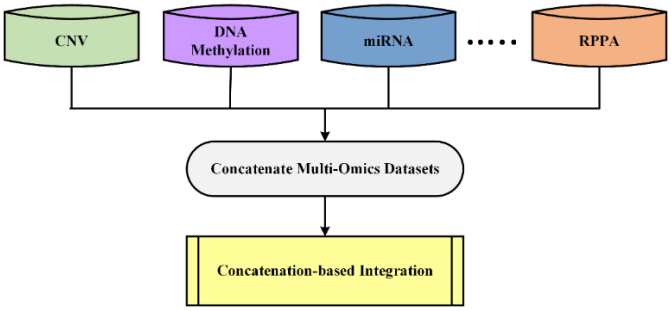

Fig. 1. Concatenation-based integration method.

For the breast cancer molecular subtypes classification, Cristovao et al. [21] use CBI for integrating mRNA and miRNA to train the Feed Forward Neural Network (FFNN) model for classifying breast cancer molecular subtypes. CBI assists the models in learning omics information at once and also captures the non-linear pattern. However, it leads the model to high-dimensional input and affects the model's performance. It indicates that CBI struggles in modelling and capturing the complex relationships and interactions among various omics variants and also leads to reduced interpretability and potential overfitting when labeled data are limited. In the same way, Zeng et al. [22] utilize CNN5 and integrate CNV and mRNA using CBI, where multi-omics data are merged at the input feature level and processed jointly by the CNN5. According to the study, CBI is straightforward, efficient, and avoids complex pre-processing or feature transformation and it is suitable for a lightweight DL model. It affects learning because concatenated data emphasize dominant subtypes (e.g., Luminal A). Hence, CBI omics specific detail can be lost, and also high dimensionality challenges can occur and cannot explicitly capture complex relationships between omics variants.

Furthermore, Rakshit et al. [23] apply SVM and integrate DNA-Methyl, mRNA and miRNA using CBI into a single large dataset. The integrated data is directly processed using Stacked Autoencoder (SAE) to reduce dimensionality before being fed into the classification model. CBI is straightforward and allows unified processing of high-dimensional multi-omics data, but it loses omics-specific signals, introduces noise from irrelevant features, and does not provide a solution to weigh the contributions of different multi-omics data variants.

B. Model-Based Integration (MBI)

Model-Based Integration (MBI), also known as intermediate integration, is a more organized, structured and adaptive integration method as shown in Fig. 2. In the model-based integration method, all multi-omics data variants are first processed by their module and converted into an intermediate form before a final model is created using various intermediate models. Hence, the integration happens to determine the various multi-omics data associated with a specific disease.

For the breast cancer molecular subtypes classification, Lin, et al. [24] propose DeepMO and integrate mRNA, DNA-Methyl and CNV through MBI and their own feature extraction subnetwork, and then fuse the learned high-level patterns into a single integrated representation for classification. The MBI method allows the model to capture complex cross-omics relationships more effectively than the CBI method. However, MBI is sensitive to class imbalance, relies on default hyperparameters, and has higher computational demands due to large feature sets. Similarly, Choi and Chae [25] propose moBRCA-net and integrate DNA-Methyl and miRNA by MBI through separate self-attention modules to learn the importance of individual features. The high-level data are then fused into a single joint representation, which is used by a shared classification network to classify subtypes. MBI preserves biological relationships between omics variants, reduces dimensionality, and enhances interpretability. Hence, MBI relies on feature selection, misses some cross-omics dependencies, and has higher computational requirements.

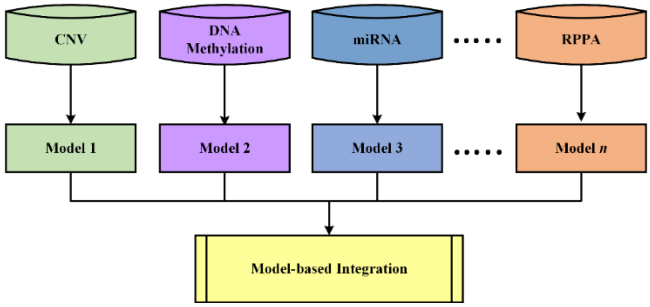

Fig. 2. Model-based integration method.

In the same way, Lupat et al. [26] develop MOANNA and integrate Gene-Exp, CNV and Somatic Mutation through MBI using a semi-supervised AE, transforming the high-dimensional input into a 64-dimensional latent representation. This integrated feature vector is then used by multiple supervised classifiers to classify breast cancer molecular cancer subtypes. By learning compact and informative features, MBI improves classification performance compared to other methods. However, it requires large training datasets and may still face challenges with high-dimensional data. Moreover, Guo et al. [27] propose AGCN and integrate CNV, DNA-Methyl and mRNA through MBI into Protein-Protein Interaction (PPI) network. MBI captures complex cross-omics relationships and gene-level structural information before classification, producing a joint representation for breast cancer molecular subtype classification. Hence, MBI depends on accurate graph construction, which is computationally intensive and less flexible for non-graph data.

Further, Li and Nabavi [28] utilize GNN and CNV, mRNA, and miRNA into a single supra-graph using MBI, where nodes represent genes and edges capture intra- and inter-omics interactions. GNN layers learn hidden representations across the entire graph, and combined with features from a parallel network to form a final integrated vector for classification. The MBI method captures complex biological relationships and improves representation. Hence, it depends on predefined graph connections and requires high computational effort. Furthermore, Tao et al. [29] propose SMOMKL and integrate CNV, DNA-Methyl and mRNA using MBI and transform into

a kernel matrix representing patient similarities. These kernels are combined within the MKL model using learned weights, allowing the integration to occur at the similarity level rather than by raw data concatenation. MBI effectively handles high-dimensionality and improves predictive performance; however, it can be computationally intensive and depends on proper kernel selection.

Moreover, Ren et al. [30] propose MVGNN and integrate DNA-Methyl, mRNA and miRNA using MBI, which is first separately processed through individual GCN branches to extract omics-specific patterns. These patterns are then fused using a multi-view attention mechanism to create a single integrated representation that captures complex cross-omics relationships. MBI effectively models inter-omics correlations and highlights important features. Hence, it requires high-quality graphs and can be computationally demanding. Similarly, Zeng et al. [31] utilize DiffRS-net and use MBI for integrating DNA-Methyl mRNA and miRNA separately to select important features, rather than concatenating raw data directly. The correlated features are fused within a DL using an attention mechanism, which assigns higher importance to more informative features before classification. MBI reduces data dimensionality and better captures cross-omics relationships. Hence, it mainly focuses on linear correlations and requires careful parameter tuning.

Islam et al. [32] apply DNN and use MBI for integrating CAN, Gene-Exp and mRNA. In the main classification model, each omics variant is first processed separately through its own neural network branch to learn high-level features, and these learned features are then merged at an intermediate stage before making the final classification. MBI design allows the model to capture omics-specific patterns first and then learn complementary information from both data variants together. The integrated model achieved better classification performance than models using only a single omics variant. However, it requires a relatively large amount of data and may face challenges related to high dimensionality. In the same way, Li et al. [33] introduce CautionGCN and apply MBI for integrating CNV, DNA-Methyl and RNAseq. By using MBI, each omics variant is first processed through a causal multi-head AE to extract meaningful and low-dimensional features rather than directly concatenating raw data. SNF is then applied to integrate cross-omics relationships at the network level, and a graph convolutional network jointly learns from the fused similarity network and the extracted features to perform classification. MBI design helps capture complex multi-omics interactions and improves robustness to high-dimensional and imbalanced data. Hence, it introduces higher computational complexity and depends on accurate similarity modeling.

C. Transformation-Based Integration (TBI)

Transformation-Based Integration (TBI) is also known as the late integration method. In the TBI method, each multi-omics data layer is transformed into a representable, comparable latent space, such as a graph, kernel similarity matrices, or core matrix. Each multi-omics dataset is transformed into an intermediate form before integrating all the data into a joint transformation. Once the data is transformed, all the multi-omics data layers are integrated into the model using a specific technique, as shown in Fig. 3.

For the breast cancer molecular subtypes classification, Ma and Guan [34] present MOCSC and apply TBI for integrating mRNA, miRNA, DNA-Methyl and CNV. By using TBI, each omics variant is processed separately, where features are first learned using SSDAE and then used by an individual NN to produce separate classification. These omics-specific classifications are finally combined using a VCDN to generate the final classification result. TBI-based fusion improves robustness by integrating information from multiple omics views, but it depends on the quality of each omics-specific model. Similarly, Meshoul et al. [35] present ET and integrate CNV, DNA-Methyl and RNA through TBI, and select features separately for each omics type before combining them. The study showed that the TBI improves the feature relevance and explainability, but it increases complexity and depends heavily on the quality of feature selection. In the same way, Huang et al. [18] propose DSCCN and integrate DNA-Methyl and mRNA using TBI, where each variant is processed separately through its own network to generate independent classification, which are combined at the decision level to produce the final classification. TBI method captures complementary information from each omics type and avoids problems with high-dimensional concatenation. Hence, it may be less effective for underrepresented subtypes and could benefit from additional data or extensions to other omics types.

Further, Zhang et al. [36] propose AET-net and integrate Gene-Exp and DNA-Methyl. Each omics variant is first processed separately and then fused into a shared latent representation using an AE, capturing essential features from both omics variants. This fused feature vector is then processed by a classifier for final classification.

TBI reduces dimensionality, handles high-dimensionality of the data effectively, and models complex dependencies. Hence, it requires careful tuning and overfitting with small datasets. Lastly, Li et al. [37] present MoGCN and integrate CNV, RNAseq and RPPA using TBI. The multi-omics data is first processed through a separate AE to learn a shared latent representation. It then applies SNF to create a unified PSN, and finally, a GCN performs classification using both the joint feature matrix and the fused network. TBI captures nonlinear relationships, improves stability, and achieves high accuracy, though it requires substantial computation and may be sensitive to noise in high-dimensional data.

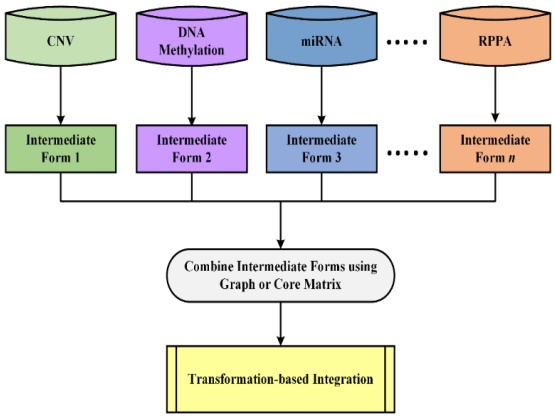

Fig. 3. Transformation-based integration method.

TABLE II. EXISTING STUDIES ON MULTI-OMICS DATA INTEGRATION METHODS FOR BREAST CANCER MOLECULAR SUBTYPES CLASSIFICATION

References	Objective	Proposed Models	Integration Methods	Accuracy	Performance Metrics	Advantages of Integration Method	Limitations of Integration Method
Cristovao, et al. [21]	Breast Cancer Molecular Subtypes Classification	•LR & FFNN	CBI	94.00%	• Accuracy • Precision • Recall	• Effectively handles high-dimensional multi-omics data. • Captures non-linear relationships across omics variants.	• Lacks interpretability in latent representations. • Sensitive to hyperparameter tuning. • May overfit with limited labeled data.
Lin, et al. [24]	Breast Cancer Molecular Subtypes Classification	• DeepMO	MBI	78.20%	• Accuracy • AUC	• Outperforms single-omics-based integration methods. • Handles high-dimensional data effectively.	• Sensitive to class imbalance. • Computational complexity from large feature sets.
Choi and Chae [25]	Breast Cancer Molecular Subtypes Classification	• moBRCA-net	MBI	90.90%	• Accuracy • F1-Score • Precision • Recall	• Enhances performance by preserving biological relationships between omics variants • Learn feature importance effectively. • Improving interpretability and subtype distinction.	• Relies on feature selection to manage high dimensionality and computational costs. • Potentially missing some omics dependencies. • Does not explicitly model cross-omics dependencies, which could be extended in future work.
Islam, et al. [32]	Breast Cancer Molecular Subtypes Classification	• DNN	MBI	79.20%	• Accuracy	• Effectively handles high integration through feature learning • Improve subtype classification over.	• Can exacerbate the curse of dimensionality. • Requires large training data to avoid overfitting.
Lupat, et al. [26]	Breast Cancer Molecular Subtypes Classification	• MOANNA	MBI	85.60%	• F1-Score • Precision • Recall	• Handles high-dimensional multi-omics effectively. • Improves generalization.	• Potential overfitting in large datasets. • Reconstruction loss may not align perfectly with classification.
Ma and Guan [34]	Breast Cancer Molecular Subtypes Classification	• MOCSC	TBI	95.00%	• Accuracy • AUROC • Macro F1 Value • Weighted F1 Value	• Avoids data inconsistency by fusing at the decision level. • Captures cross-omics correlations effectively.	• Dependent on individual classifier quality. • May propagate errors from weak omics models.
Meshoul, et al. [35]	Breast Cancer Molecular Subtypes Classification	• ET	TBI	84.50%	• Accuracy • Accuracy • AUROC • F1-Score • Macro F1 Value • Precision • Recall • ROC_AUC • Weighted F1 Value	• Improves feature relevance across omics. • Enhances explainability. • flexible with early/late schemes for different data handling.	• A multi-stage process increases complexity. • Dependent on the feature selection quality. • Computationally expensive. • Does not work well with smaller datasets.
Zeng, et al. [22]	Breast Cancer Molecular Subtypes Classification	• CNN5	CBI	90.02%	• F1-Score • Precision • Recall	• Handles imbalanced data via weighted loss; direct learning on combined features.	• Potential loss of omics-specific patterns. • Exacerbates dimensionality issues. • Lacks explicit handling of inter-omics correlations.

Table II shows the comparison of existing studies on multi-omics integration, highlighting the utilization of integration methods from a CBI to MBI and TBI. It summarizes the objectives, proposed models for the classification, the type of integration method used, and their reported performance metrics. and highlighting the advantages and limitations of each integration method used in breast cancer molecular subtypes classification.

IV. Analysis of Multi-Omics Data Integration Methods for Breast Cancer Molecular Subtypes Classification

All three multi-omics data integration methods are used by the existing studies for breast cancer molecular subtypes classification. Each integration method has its own characteristics, strengths and limits, as shown in Table III.

Table III provides a practical guideline for selecting a suitable integration method for multi-omics data in breast cancer molecular subtypes classification, based on aspects such as data type, sample size, interpretability, and computational requirements from the observation of the existing studies. According to the findings from the existing studies, CBI is appropriate for both mono-omics and multi-omics data, particularly when the dataset is small to medium in size. CBI is straightforward to implement, computationally light, and highly interpretable, making it ideal when simplicity and clarity are important. It works best for combining a limited number of omics variants, where the primary goal is to preserve interpretability and generate easily understandable insights. While MBI is specifically designed for medium to large multi-omics datasets and is appropriate for medium interpretability and computational complexity. Lastly, TBI provides a balance between predictive performance and interpretability, handling high-dimensional omics variants more effectively. It is especially designed for large multi-omics datasets and is suitable for high-dimensional data. It can easily capture more complex interactions and relationships among different omics data types and variants, and is more appropriate for a graph-based architecture.

TABLE III. Comparison of Multi-Omics Data Integration Methods for Breast Cancer Molecular Subtypes Classification

Integration Methods	Datasets Suitability	Interpretability	Computational Complexity	Strenghts	Weaknesses
Concatenation-Based Integration (CBI): Combines all omics data into one large input matrix without much preprocessing.	Small to Medium	High	Low	• Simple, fast and straightforward. • No preprocessing is required as all omics features are integrated into a large input matrix. • Uses a full feature set. • Handle all omics data types in a single joint matrix. • Produces continuous data, which makes it easier for various ML models to analyze.	• Ignores inter-omics relationships. • Increasing the number of features together increases dimensionality. • Sensitive to noise/missing data, high-dimensional.
Model-Based Integration (MBI): Learns features separately using sub-models, then merges the learned representation	Medium to Large	Medium	Medium	• Captures omics-specific relationships and interactions.	• Complex to design. • Cannot handle heterogeneous data. • Perform feature selection before integrating omics data, which can lead to the loss of important features. • Require careful hypermeter tuning for each sub-model.
Transformation-Based Integration (TBI): Converts omics data into a shared latent space (e.g., graphs), then integrates.	Large	Low to Medium	High	• Suitable for high-dimensional data. • Capture more complex interactions and relationships among different omics data types. • Most common integration data method. • Easily deal with data heterogeneity. • Suitable for graph-based architecture. • Include the statistical frameworks, such as core-based integration and graph-based semi-supervised learning, for developing a model.	• Transformation can cause information loss, depending on design quality. • Challenges in transforming data into an intermediate form. • Kernel methods are computationally extensive.

Overall, Table III serves as a decision-support guideline for researchers, guiding them in choosing the most appropriate integration methods for omics data, particularly in breast cancer subtypes classification based on the specific characteristics of their dataset, research objectives, and available computational resources.

V. Discussion

Existing studies have increasingly explored CBI, MBI, and TBI methods for multi-omics data analysis in breast cancer molecular subtypes classification. Each integration method has its own strengths and limitations in capturing inter-omics relationships, managing data dimensionality, and improving classification performance.

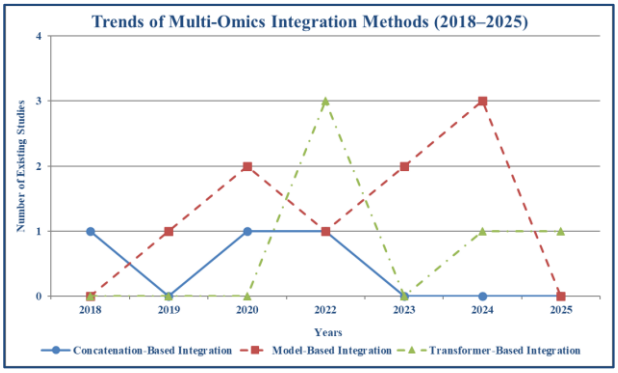

Fig. 4. Trends of multi-omics integration methods in breast cancer molecular subtypes classification.

Fig. 4 shows trends in the use of multi-omics integration methods for breast cancer molecular subtype classification from 2018 to 2025. Based on the graph, it is clear that early studies predominantly use CBI methods due to their simplicity and ease of implementation, while MBI methods became increasingly popular from 2019 onward, reflecting their ability to capture inter-omics interactions and improve predictive performance. Additionally, TBI emerged in 2022 and shows a growing adoption trend, highlighting its superior capacity to handle high-dimensional heterogeneous data, model complex relationships across omics layers, and provide attention-driven interpretability. This finding shows a clear shift in the field toward leveraging deep learning architectures for more accurate and biologically informative breast cancer molecular subtype classification, indicating that TBI methods are becoming a preferred approach for multi-omics integration in recent studies.

Fig. 5 demonstrates the comparison of CBI, MBI, and TBI integration methods for multi-omics data in breast cancer molecular subtypes classification based on the accuracy of the models. For CBI, the minimum accuracy 90.20% is shown by CNN5 with CBI. While SVM shows a medium accuracy of 93.50% with CBI, and FFNN achieves a maximum accuracy of 94.00% with CBI. Models with CBI show stable and strong accuracy, but their performance mainly depends on integrating different multi-omics variants into a joint matrix directly, which may increase data dimensionality and complexity. For MBI, the performance varies more widely. DeepMo and DNN with MBI shows minimum accuracy of 78.20%, indicating weaker performance. Models such as MOANNA, MoGNN, and SMOMKL with MBI show medium accuracy of 85.60%, 86.40% and 87.00% demonstrate more good performance. The models, including MVGNN, DiffRS-net, and moBRCA-net with MBI, achieve significant accuracy of 91.80%, 91.30%, and 90.90%, showing that MBI can perform well when advanced models are used. For TBI, MoGCN attained 89.80% with TBI represents the minimum accuracy, while AET-net and DSCCN with TBI achieve accuracy of 90.00% and 90.60% show medium performance. While the best results are achieved by ET and MOCSC, with TBI attaining an accuracy of 95.00%, which is the maximum accuracy in the entire comparison.

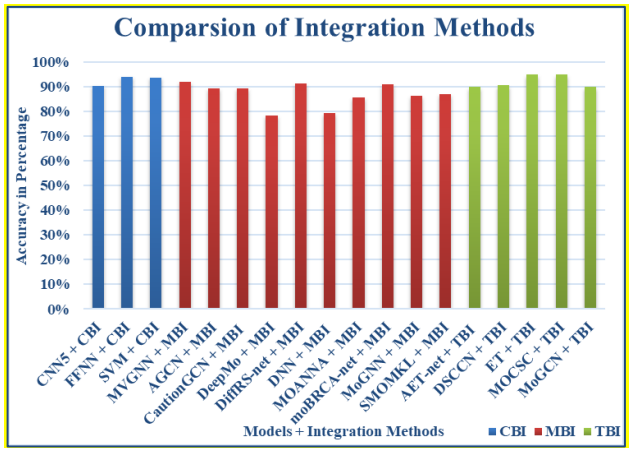

Fig. 5. Comparison of multi-omics integration methods in breast cancer molecular subtypes classification.

Overall, TBI is the strongest and most effective integration method, as it consistently achieves high accuracy and includes the best-performing models. This indicates that transforming multi-omics data into a shared representation before integration is more effective for breast cancer molecular subtypes classification than direct concatenation or model-level integration.

As per the analysis of the existing studies, the CBI method is widely used due to its simplicity and ease of implementation. However, this integration method completely ignores the complex interaction and relationships among the multi-omics data types, which leads to the potential loss of the most relevant information. Additionally, the CBI method suffers from high dimensionality, increases computational complexity, overfitting risks, and is sensitive to missing values or noise. Most of the existing studies highlight that the concatenation-based method is easy to implement. However, it does not fully capture the heterogeneity and hierarchical nature of the multi-omics data. Furthermore, another main disadvantage of this method is that it frequently increases the number of features in the joint matrix, which further increases the dimensionality of the multi-omics data.

MBI provides a more adaptive and structured approach. It allows capturing the omics-specific interactions and relationships, thereby offering more detailed biological insights. However, the model-based integration method is relatively complex to design and also computationally expensive, particularly when dealing with high-dimensional multi-omics data. Furthermore, domain-specific modeling and hypermeter tuning are required for model-based integration, which further increases the proposed model complexity.

Lastly, TBI has been less frequently used in the existing studies, particularly for breast cancer molecular subtypes classification. But it has several advantages, including the potential to handle high-dimensional heterogeneous data types, capture both inter-omics and intra-omics interaction and relationships and provide more structured insights through the graph and attention mechanism. Although the TBI is not used frequently in breast cancer molecular subtypes classification according to our observation, it has gained significant attention in other cancer domains because of showing superior performance in modeling long-range dependencies and dynamic relationships between features. TBI allows modular processing of each multi-omics data type while also enabling meaningful cross-model interaction, which makes it suitable for integrative analysis.

While the CBI method remains popular due to its simplicity, the MBI offers enhanced interpretability and biological relevance, and the TBI method has great potential for next-generation multi-omics data analysis. As the multi-omics research continues to evolve, combining the strengths of the multi-omics integration methods could lead to a more robust and accurate classification of breast cancer molecular subtypes, eventually contributing to improve the diagnosis, prognosis and personalized treatment strategies.

VI. Suggestions and Future Directions

Based on the analysis of existing multi-omics integration methods for breast cancer molecular subtype classification, several opportunities for future research exist. While current methods, including CBI, MBI, and TBI, have demonstrated significant progress, challenges remain in balancing accuracy, interpretability, scalability, and robustness to incomplete data. The following section outlines key directions and practical suggestions to advance the development of more effective and reliable multi-omics integration strategies.

A. Development of Hybrid Integration Methods

Future studies should explore hybrid approaches that combine the strengths of CBI, MBI, and TBI integration methods. Such integration methods could leverage the simplicity and efficiency of CBI, the interpretability of MBI, and the high-dimensional, attention-driven capabilities of TBI. Hybrid models may provide improved classification accuracy while maintaining biological interpretability and scalability.

B. Enhancing TBI Models

TBI has shown great promise in capturing complex intra- and inter-omics relationships. Future work should focus on optimizing these methods for efficiency and robustness, including techniques to handle class imbalance, reduce computational costs, and incorporate multi-modal biological knowledge. This could enable TBI methods to generalize better across diverse multi-omics datasets and multiple omics variants.

C. Robust Integration for Missing or Partial Omics Data

Many current integration methods assume complete multi-omics data variants, which is often not feasible in real-world studies. Future research should develop integration methods, such as multi-view transformers or imputation-enhanced models, to robustly integrate incomplete or partially missing omics data. This will increase the applicability of multi-omics integration in clinical and large-scale cohort studies.

D. Focus on Interpretability and Biological Insight

While TBI and MBI methods provide high accuracy, their interpretability can still be limited. Future research should emphasize methods that not only classify breast cancer molecular subtypes accurately but also provide interpretable outputs, highlighting key molecular features, pathways, and cross-omics interactions. Attention mechanisms, feature selection, or graph-based interpretability techniques can support this goal.

E. Scalability to High-Dimensional Multi-Omics Datasets

As multi-omics datasets grow in size and complexity, there is a need for methods that can scale efficiently without sacrificing performance. Future studies should focus on dimensionality reduction, computational optimizations, and adaptive integration methods that can handle large, heterogeneous datasets while maintaining predictive accuracy.

VII. Conclusion

In terms of multi-omics data, the integration methods include concatenation-based, model-based, and transformation-based integration. These integration methods allow the discovery of hidden patterns in the multi-omics data. This study evaluates the multi-omics data integration methods for classifying the breast cancer molecular subtypes. The concatenation-based integration is straightforward, fast, and simple, and it also does not require preprocessing. However, CBI ignores the inter-omics interaction and also increases the number of features in the joint matrix. Model-based integration captures the interaction and relationship among multi-omics data types. However, MBI is more complex to design and it also cannot handle the high-dimensional heterogeneous data. The transformation-based integration appears to be a more promising alternative, particularly for the multi-omics data to classify the breast cancer molecular subtypes, as it not only handles the high-dimensional data heterogeneity effectively but also captures more complex interactions. Each method has distinct advantages and is suitable for different research scenarios. Simple or concatenation-based models are recommended for small datasets; transformation-based or model-based integration methods support high interpretability. Furthermore, transformation-based integration methods also handle large heterogeneous datasets, and transformation-based multi-view models are effective for datasets with missing modalities.

Overall, the findings show that each multi-omics data integration method for breast cancer molecular subtypes classification provides various advantages and limitations. However, the selection of the multi-omics integration methods totally varies on the combination of multi-omics data types, variants and nature of the proposed model for the classification of breast cancer molecular subtypes. Hence, these insights provide practical guidance for selecting appropriate multi-omics integration methods based on study objectives, data characteristics, and computational constraints, offering structured guidelines for future AI-driven research in breast cancer subtype classification.

Abstract*—Early assessment of the persistence, bioaccumulation, and toxicity (PBT) of chemicals is a major challenge for environmental protection and international regulatory frameworks. The objective of this study is to compare the effectiveness of three graph-based deep learning architectures—a graph neural network (GNN), a message passing network (MPNN), and a graph attention network (GAT)—for the binary classification of molecules as PBT or non-PBT.We compiled a regulatory dataset comprising 5,130 molecules annotated from public sources, such as ECHA and international POP lists. Molecular graphs were generated from SMILES using RDKit. The three models were implemented in PyTorch Geometric with homogeneous hyperparameters. The experiments were conducted with a scaffold split ratio of 80/10/10 and 10-fold cross-validation. Performance was evaluated using accuracy, AUC-ROC, and F1-score. Interpretability was examined using GAT model attention maps and atomic contribution analysis. The MPNN model achieves the best overall performance (Accuracy = 0.92; ROC-AUC = 0.94; F1 = 0.91), followed by GAT (Accuracy = 0.89; ROC-AUC = 0.93). The basic GNN performs less well (Accuracy = 0.82; ROC-AUC = 0.89). The GAT model provides more detailed atomic explanations thanks to attention weights, while the MPNN stands out for its predictive accuracy. The dataset includes annotations from heterogeneous experimental sources, which may introduce noise into the labels. The models rely solely on 2D graphs, without 3D conformational information. MPNN models can accelerate PBT pre-screening and help prioritize substances for experimental testing. GATs provide useful interpretations for understanding the substructures associated with PBT properties. This study provides the first reproducible and systematic comparison of GNN, MPNN, and GAT models applied to a large regulatory dataset dedicated to PBT, analyzing both performance and interpretability. These results highlight the potential of graph-based QSAR models for regulatory PBT screening and environmental risk assessment.

Keywords*—PBT prediction; persistence; bioaccumulation; toxicity; QSAR models; cheminformatics; environmental risk assessment

I. Introduction

The persistence, bioaccumulation, and toxicity (PBT) of chemicals are fundamental criteria in environmental risk assessment and international regulatory processes such as REACH. Early identification of hazardous substances still relies heavily on in vivo and in vitro experiments, which are costly, time-consuming, and difficult to scale up to thousands of emerging compounds. This growing need for robust predictive methods has fueled the rise of machine learning applied to molecular structures, particularly graph models, which are capable of directly capturing the structured nature of molecules. These approaches now offer a promising alternative for accelerating the screening of PBT substances, while improving the reproducibility and transparency of assessments.

Recent advances in molecular modeling have been largely driven by Graph Neural Networks (GNNs), which learn structural representations by treating molecules as atomic graphs. Several studies have demonstrated their effectiveness in predicting different forms of toxicity, including acute toxicity, ecotoxicological effects, and liver toxicity [1], [2], [3], [4], [5]. Modern GNN architectures, including graph convolutions, equivariant networks, and hierarchical mechanisms, have significantly improved predictive performance for complex properties such as systemic toxicity and endocrine disruption [6], [7], [8], [9], [10].

At the same time, Message Passing Neural Networks (MPNN) have introduced explicit information propagation between atoms and bonds, enabling the capture of finer structural patterns and improving the prediction of properties related to ADMET, liver toxicity, or xenobiotic metabolism [11], [12], [13], [14], [15], [16], [17], [18]. Several studies show that MPNNs frequently outperform simpler models, particularly for properties sensitive to local atomic interactions and contextual effects [16], [17], [18].

Graph Attention Networks (GAT) and graph transformers represent a major evolution, introducing attention mechanisms

capable of assigning differentiated weights to atomic neighbors based on their chemical importance. These models not only offer better performance but also increased interpretability, making it possible to identify molecular substructures that contribute significantly to toxicity [19], [20], [21], [22]. Recent work shows that atomic attention is an essential tool in a regulatory context, where scientific justification of predictions is indispensable [23], [24].

In addition, approaches extending these models through pre-training, integration of quantum properties, multitasking, or fusion with knowledge from toxicological databases have shown significant potential for stabilizing predictions and improving generalization to unseen substances [7], [20], [25], [26]. Finally, some work specifically targets environmental and ecotoxicological toxicity, a key area for PBT substances, by modeling the complex relationships between molecules, aquatic species, and environmental parameters [27], [28].

Despite these advances, several limitations remain clearly identified in recent literature:

- Most studies focus on generic datasets (Tox21, ADMET), which are rarely adapted to the specific requirements of PBT classification.
- Few studies offer a balanced and reproducible comparison between the main families of graph models (GNN, MPNN, GAT).
- Work integrating both predictive performance and atomic interpretability remains limited, even though these elements are essential for regulatory frameworks.
- No recent study provides a comparative assessment based on a consolidated regulatory dataset specifically dedicated to PBT properties.

In this context, this study aims to provide a rigorous and reproducible evaluation of graph-based deep learning models for the prediction of persistence, bioaccumulation, and toxicity (PBT) properties of chemical substances. Specifically, we compare three representative molecular graph architectures: a classical Graph Neural Network (GNN), a Message Passing Neural Network (MPNN), and a Graph Attention Network (GAT), using a consolidated regulatory dataset dedicated to PBT classification. The novelty of this work does not lie in proposing a new architecture, but rather in the regulatory grounding of the dataset, the systematic and reproducible evaluation protocol, and the joint analysis of predictive performance and atomic-level interpretability. This study, therefore, provides new insights into the suitability of different graph models for regulatory PBT screening tasks.

The remainder of this study is organized as follows: Section II describes the dataset, preprocessing steps, and model architectures. Section III presents the experimental setup and evaluation protocol and reports the quantitative results; Section IV discusses the interpretability and regulatory implications of the findings; and Section V concludes the study with a summary of key contributions and limitations.

II. Methods

A. Dataset

The dataset used in this study brings together molecular information in the form of SMILES strings annotated with a binary label (PBT/Non-PBT). This dataset was constructed to accurately represent the regulatory criteria of persistence, bioaccumulation, and toxicity, in accordance with European (REACH, ECHA) and international (Stockholm Convention) requirements. A complete description of the origin, characteristics, and processing of the data is provided below to ensure the reproducibility of the study.

A total of 6,072 molecules were collected from major regulatory and scientific sources (Fig. 1). The dataset includes 2,970 non-PBT substances, composed of 2,887 molecules registered with ECHA [28], 48 substances evaluated by experts in PBT/vPvB assessments [24], and 35 compounds from the ECHA PBT assessment list [25]. In addition, 3,102 PBT or POP substances were integrated, including 2,785 potential PBT substances identified by Strempel et al. [23], and 317 confirmed PBT substances originating from multiple regulatory sources, namely ECHA PBT/vPvB assessments [24], the ECHA PBT assessment list [25], the ECHA list of substances subject to POPs regulation [26], and the updated POP list from the Stockholm Convention [27], [29], [30], [31], [32],[33]. All these sources represent authoritative references in the regulatory evaluation of hazardous chemicals, ensuring the robustness and reliability of the final consolidated dataset.

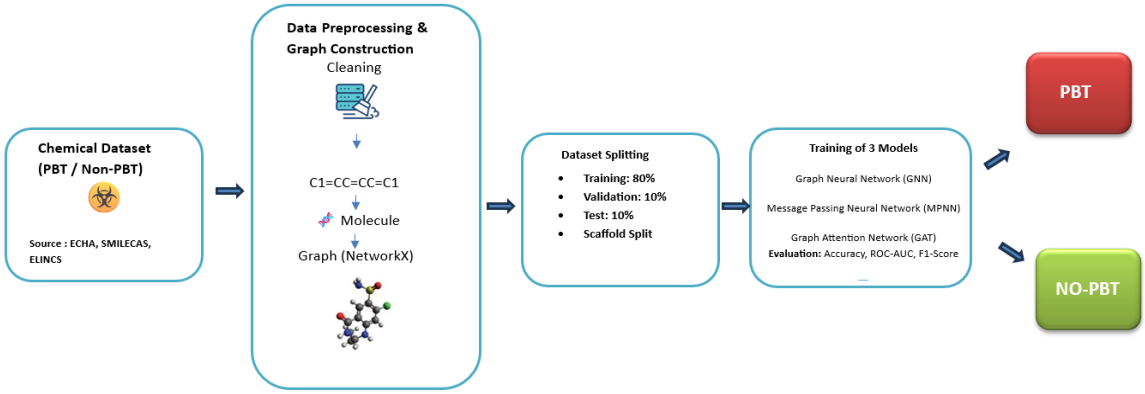

Fig. 1. Workflow for predicting persistence, bioaccumulation, and toxicity properties. The diagram illustrates the main steps: data collection from regulatory sources, preprocessing and construction of molecular graphs, division of the dataset, and training of the three models (GNN, MPNN, and GAT) for classifying substances as PBT or Non-PBT.

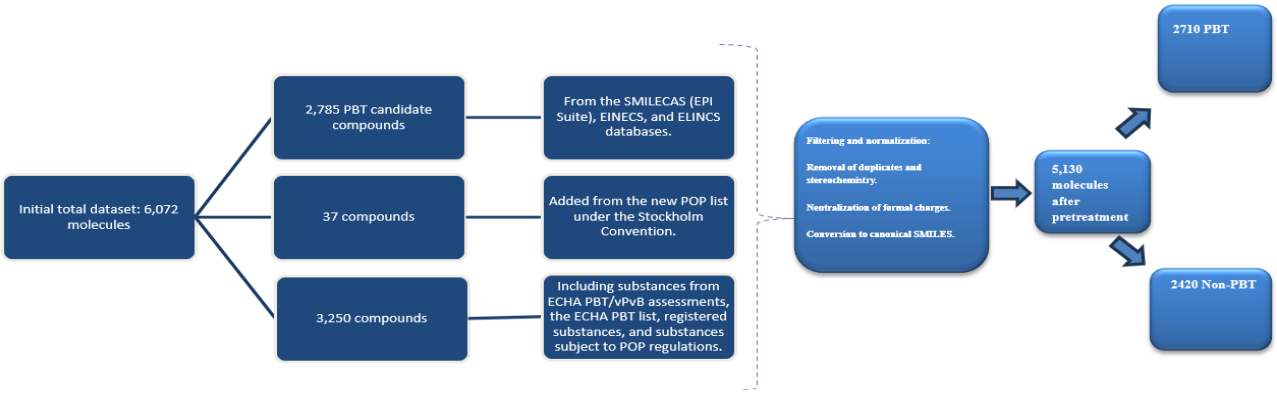

Fig. 2. Collection and processing of PBT-related chemicals.

Fig. 2 illustrates the construction of the regulatory PBT dataset, showing the integration of chemical compounds from multiple authoritative sources and the successive filtering and preprocessing steps leading to the final curated dataset used in this study.

B. Filtering and Pre-processing Procedure

A standardized harmonization procedure was applied to ensure the quality and consistency of molecular data. When a SMILES contained multiple fragments, only the main (largest) fragment was retained. Formal charges were systematically neutralized, and molecules were converted to canonical SMILES. Duplicates and stereochemical details were removed to avoid irrelevant structural variations. At the end of this process, a final set of 5,130 molecules was obtained, comprising 2,710 PBT compounds and 2,420 non-PBT compounds. All preprocessing operations were performed in Python 3.8 using an RDKit script, in accordance with ECHA technical recommendations [34].

C. Data Partitioning

To ensure rigorous and reproducible evaluation, the final dataset was divided into three distinct subsets: 80% of the data was used for model training, 10% for hyperparameter tuning (validation), and the remaining 10% for final testing. The partitioning was performed in a stratified manner, ensuring that the PBT/Non-PBT ratio was maintained in each of the subsets, thereby reducing potential biases related to class imbalance.

D. Molecular Characteristics

Although the PBT and Non-PBT classes are relatively similar in size, a slight imbalance remains in the final dataset. To prevent the model from favoring the majority class, a class weight was incorporated into the loss function during training. No oversampling or under sampling techniques were used in order to preserve the structural integrity of the molecules and avoid any artificial transformation of the examples.

To illustrate the process of converting chemical structures into graphs that can be used by GNN, MPNN, and GAT models, Fig. 3 shows different representations generated from a molecule from the dataset. Fig. 3(a) shows the 2D structure with explicit identification of atoms and bonds, as extracted and cleaned after RDKit preprocessing. Fig. 3(b) illustrates the optimized 3D geometry, allowing visualization of the overall spatial organization of the molecule. Fig. 3(c) represents the structure as a molecular graph where each atom corresponds to a node and each bond to an edge, in accordance with the input format used for graph-based models. Finally, Fig. 3(d) shows attentional mechanisms, illustrating the ability of GAT models to identify substructures potentially responsible for a molecule's PBT behavior.

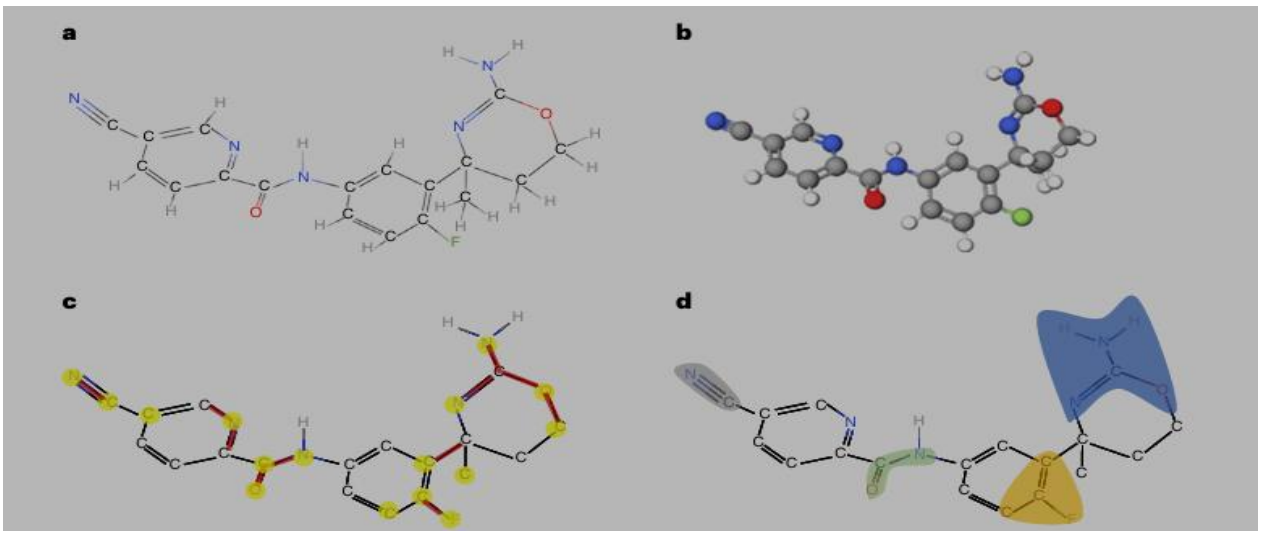

Fig. 3. Molecular representations generated for the graph construction stage.

E. Detailed Model Architecture

The architecture of the GNN model is based on a deep ResGCN network integrating residual connections as well as a Jumping Knowledge mechanism allowing to efficiently extract intermediate representations from several layers. The model has five successive GCN layers with hidden dimensions of 256, 256, 256, 128 and 128 neurons. Residual connections stabilize learning in deep graphs while the Jumping Knowledge mechanism consolidates representations of different levels by combining them through concatenation. The activation used is a GELU function, particularly suitable for complex architectures, and a dropout of 0.25 is applied to limit overfitting. The aggregation of graphs is ensured by a Global Attention Pooling mechanism allowing to weight different molecular regions according to their structural importance.

The MPNN model used follows a Directed Message Passing Neural Network (D-MPNN) architecture, an advanced version of MPNN that conveys information in an oriented way along chemical bonds. This approach improves the representation of atomic patterns responsible for PBT toxicity and properties. The model includes six successive stages of directed propagation, with messages of size 300 and hidden layers of 300 then 200 units. Updates are performed at the edges and nodes through a GRU-like mechanism, which allows for efficient integration of chemically relevant dependencies. The final aggregation of graphs relies on a Set2Set module that captures high-level interactions between atoms. Activation is provided by ReLU and a dropout of 0.3 is applied to reduce the risk of overfitting.

The GAT architecture is based on the GATv2 model, an improved version of the Graph Attention Network using a more expressive attention mechanism. It consists of three successive layers, each comprising several heads of attention: eight heads in the first two layers and four in the last one. Each head learns to weight atomic neighbors according to their chemical relevance, which improves the interpretability of the model and allows identifying molecular substructures responsible for PBT effects. The hidden dimensions are set to 128 per head and residual connections stabilize the propagation of gradients. Aggregation is carried out by means of hierarchical pooling based on attention, allowing to capture the relative importance of different structural levels. An ELU activation function is used to improve training stability and gradient flow, and a global dropout of 0.4 is applied to both the layers and attention weights.

The three models share a common final head consisting of a multilayer perceptron with two successive dense layers of 256 and 64 neurons. The output is activated by a sigmoid function allowing to obtain a binary classification probability. Weight decay regularization is added to improve generalization.

F. Training Hyperparameters

Model optimization was performed using the AdamW optimizer, chosen for its ability to better control regularization and stability of learning in deep architectures. The initial learning rate used is 0.0007, dynamically adjusted by a Cosine Annealing scheduler with periodic restarts, which allows for more efficient exploration of the parameter space. The batch size is set to 32, while the training duration extends over 200 epochs with an early stopping mechanism when the validation performance stops improving after 25 epochs. Gradients are constrained by clipping to 2.0 in order to avoid the common gradient explosions in deep graph models. L2 regularization is applied with a weight of 1e-4.

Each model also has its own specific hyperparameters. The ResGCN-JK uses hidden sizes of 256, 256, 256, 128 and 128, a Jumping Knowledge mechanism in concatenation mode and a slightly higher learning rate (0.001). The D-MPNN exploits a message size of 300, a depth of six propagation steps, a dropout of 0.3 and a learning rate of 0.0008. As for the GATv2 model, it uses a learning rate of 0.0005, eight heads of attention in the first two layers and four in the third, with a dropout of 0.4 on the attention weights. These hyperparametric choices result from a combination of Bayesian search and grid search, allowing to obtain an optimized and stable configuration for the PBT classification task.

G. Baseline Computation Environment and Reproducibility Information

To ensure complete reproducibility of the results, all experiments were performed in a strictly controlled software and hardware environment. Molecular processing was performed in Python 3.10, using RDKit 2023.03.1 for chemical structure manipulation and graph generation. The GNN, MPNN, and GAT models were trained using PyTorch 2.1 and PyTorch Geometric 2.4, with a CUDA backend provided by CUDA 11.8. Evaluation metrics were calculated using scikit-learn 1.3.

All experiments were performed on a workstation equipped with an NVIDIA RTX 3080 GPU (10 GB VRAM), an Intel Core i7 processor, and 32 GB of RAM, running Ubuntu 22.04 LTS. A fixed random seed (seed = 42) was applied to NumPy, PyTorch, and Python to ensure stability and reproducibility of results.

To ensure complete transparency, all code used in this study will be made public in a dedicated GitHub repository. This repository will contain the complete RDKit-based preprocessing scripts, the GNN/MPNN/GAT model training scripts, the graph generation functions, the experimental pipeline organization, and all hyperparameters used. Making this repository available allows any researcher to faithfully reproduce the analyses, results, and figures presented in this study.

III. Experimental Results

A. Quantitative Results

The performance of the three graph-based architectures (GNN, MPNN, and GAT) were evaluated using three standard classification metrics: accuracy, ROC-AUC, and F1-score. These indicators allow us to assess overall accuracy, discrimination capacity, and the balance between precision and recall.

Tables I, II, and III present the results obtained on the training, validation, and test sets. Although all models showed an ability to learn relevant molecular representations, notable

differences in terms of generalization and interpretability were observed.

TABLE I. PERFORMANCE ON THE TRAINING SET (PBT CLASSIFICATION)

Model	Accuracy	ROC-AUC	F1-score
GNN	0.895	0.91	0.89
MPNN	0.932	0.96	0.93
GAT	0.920	0.95	0.92

TABLE II. PERFORMANCE ON THE VALIDATION SET (PBT CLASSIFICATION)

Model	Accuracy	ROC-AUC	F1-score
GNN	0.875	0.89	0.87
MPNN	0.912	0.94	0.91
GAT	0.903	0.93	0.90

TABLE III. PERFORMANCE ON THE TEST SET (PBT CLASSIFICATION)

Model	Accuracy	ROC-AUC	F1-score
GNN	0.82	0.89	0.87
MPNN	0.92	0.94	0.91
GAT	0.89	0.93	0.90

TABLE IV. COMPARISON OF THE PERFORMANCE OF OUR MODELS WITH RECENT STATE-OF-THE-ART APPROACHES FOR PBT PREDICTION

Model	Reference	Accuracy	ROC-AUC
MPNN (our work)	–	0.92	0.94
GAT (our work)	–	0.89	0.90
GNN (our work)	–	0.82	0.89
Chemprop (D-MPNN)	Evangelista et al., 2025 [30]	0.912	0.94
deepFPlearn+	Soulios et al., 2023 [31]	0.89	0.91
GraphADT	Ma et al., 2024 [32]	0.89	0.91

B. Visual Analysis

Fig. 4 shows a comparison of the confusion matrices for the three graph-based models (GNN, MPNN, and GAT) applied to the test set. Each matrix illustrates the distribution of true negatives (TN), false positives (FP), false negatives (FN), and true positives (TP) for the classification of compounds as PBT or Non-PBT.

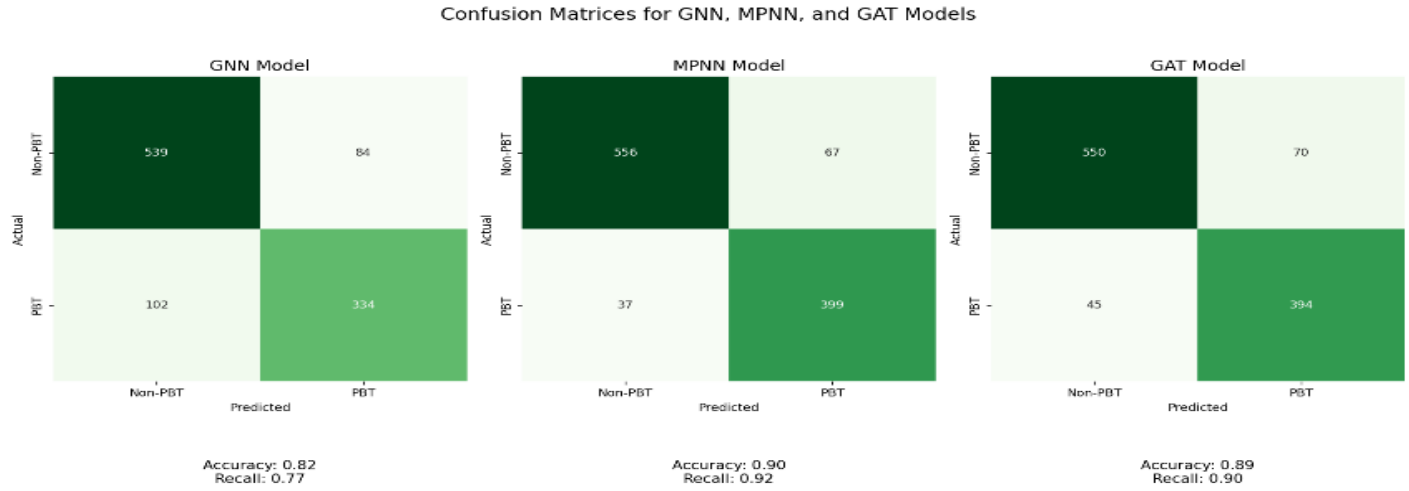

Fig. 4. Confusion matrices for GNN, MPNN, and GAT models.

IV. DISCUSSION

Across the test set, MPNN achieved the best overall performance with an accuracy of 91.2% and an ROC-AUC of 0.94, confirming its robustness and generalization ability. GAT, which is slightly less accurate (90.3%), stands out for its attention mechanism, offering better interpretability for explanatory analyses. GNN, although competitive, lags behind with an accuracy of 87.5% and an ROC-AUC of 0.89 (see Table IV).

These results suggest that MPNN is the most suitable model for predicting PBT properties, while GAT is an interesting alternative when interpretability is a priority.

Our MPNN model (Accuracy = 0.912; ROC-AUC = 0.94) achieves performance equivalent to that reported by Chemprop (Evangelista et al., 2025), confirming its robustness and ability to generalize on complex datasets. This high accuracy demonstrates that integrating atomic characteristics and bonds into the message propagation mechanism is a major asset for predicting PBT properties.

The GAT model, although slightly less accurate (Accuracy = 0.903; ROC-AUC = 0.93), has a significant advantage in terms of interpretability thanks to its attention mechanism. This feature allows the identification of the most influential atoms or substructures in the classification, which is particularly relevant for explanatory analyses and regulatory decision-making.

Compared to other advanced approaches, such as deepFPlearn+ (Soulios et al., 2023) and GraphADT (Ma et al., 2024), our method is competitively positioned. Although effective, these models do not achieve the same level of accuracy as our MPNN, reinforcing the relevance of message passing-based architectures for this type of task.

In summary, this comparison highlights the superiority of MPNN models for predicting PBT properties, while emphasizing the value of attention mechanisms for applications

requiring in-depth interpretation. These results confirm that graph neural networks are a promising solution for environmental risk assessment and regulatory compliance.

With an accuracy of 0.82 and a recall of 0.77, the GNN model shows decent but limited performance. Although it correctly identified 539 Non-PBT compounds and 334 PBT compounds, it produced 102 false negatives, indicating a tendency to miss PBT compounds. This weakness is critical because failure to detect PBT substances can lead to environmental risks.

The MPNN model outperforms the others with an accuracy of 0.90 and a recall of 0.92. It significantly reduces false negatives (FN = 37) compared to GNN, while maintaining a low number of false positives (FP = 67). These results demonstrate its robustness and ability to generalize, which is essential for regulatory compliance.

The GAT model achieves an accuracy of 0.89 and a recall of 0.90, slightly lower than MPNN but higher than GNN. It correctly identifies 394 PBT compounds and 550 non-PBT compounds, with a moderate number of false negatives (FN = 45). Thanks to its attention mechanism, GAT offers better interpretability, making it a relevant choice for explanatory analyses despite its slightly lower performance compared to MPNN.

MPNN is the best-performing model for predicting PBT properties, offering the best compromise between precision and recall. GAT remains an interesting alternative when interpretability is a priority, while GNN offers acceptable but less reliable performance in minimizing false negatives.

V. Conclusion

This study evaluated and compared three graph-based deep learning architectures for the classification of PBT substances. Using a representative set of molecules and a rigorous experimental protocol, the results showed clear differences between the models studied. The MPNN model achieved the highest performance thanks to its better exploitation of complex molecular structures. The GAT model stood out for its interpretability while maintaining a high level of accuracy. The GNN model, although effective, performed worse than the other two models, particularly in the reliable detection of PBT substances.

Overall, the results confirm the value of graph-based approaches for predicting PBT properties and demonstrate the ability of the models studied to extract relevant molecular representations that enable accurate classification of compounds.

From a practical perspective, the proposed MPNN model can effectively support regulatory PBT screening by enabling the early identification and prioritization of potentially hazardous substances. By significantly reducing false negatives, the model helps minimize the risk of overlooking harmful chemicals during preliminary assessments. Such predictive tools can assist regulatory agencies, such as those involved in ECHA-related workflows, in focusing experimental resources on high-risk compounds and improving the efficiency and consistency of decision-making processes in environmental risk assessment.

Acknowledgment

I sincerely thank my colleagues and the staff of my university for their valuable support and guidance throughout my research.

A Review on Intrusion Detection Models in Internet of Medical Things (IoMT)

Aljorey Alqahtani, Monir Abdullah
Computing and Information Technology, University of Bisha, Bisha, 61922, P.O. Box 551, Saudi Arabia

***Abstract*—The Internet of Medical Things (IoMT) environment is highly sensitive due to the nature of medical data and its direct connection to patient health, making it a prime target for sophisticated cyberattacks. This study explores the key security challenges within IoMT, discusses how Machine Learning (ML) can enhance threat detection capabilities, and shows how XAI contributes to improving transparency and understanding of model decisions, thereby increasing trust in these systems. It reviews recent advancements in Intrusion Detection Systems (IDS) specifically designed for IoMT networks, with a focus on integrating Explainable Artificial Intelligence (XAI) and ML models. Furthermore, the study compares various algorithms and models, identifying research gaps and discussing different datasets and feature extraction techniques used for optimizing the features. The reported performance and efficiency improvements are derived from prior studies using different dataset sizes, data-splitting strategies, and feature-selection methods.**

***Keywords*—Internet of Medical Things (IoMT); IDS; Explainable Artificial Intelligence (XAI)**

I. Introduction

IoT is an innovative idea that links physical objects, devices, and everyday items to the internet to enable them to collect data by themselves, share it, and even analyze it. This technology encompasses a wide array of innovations that embed sensors, actuators, software, and network connectivity into various kinds of objects from household appliances and manufacturing equipment to automobiles, buildings, and wearable devices. Essentially, IoT provides real-time, data-driven insights and remote monitoring of such objects, rendering the physical world and digital world inextricably linked. IoT enables objects to perceive and inspect their surroundings, make decisions therefrom, and react autonomously, at times even without external intervention. This connectivity builds an ecosystem where devices collaborate to function more efficiently, accurately, and automatically, leading to smarter decision-making.

The ability for physical objects to communicate with each other and centralized systems is revolutionizing industries, driving innovation, and improving various sectors' operations. Although IoT has already shown significant promise through early applications, the technology is still in its nascent stages. As IoT technologies progress, the integration of smart sensors and connected devices into everyday life will only increase, intensifying the need for solutions that address issues like security, interoperability, protocols, and standardization. IoT devices require a reliable and scalable infrastructure to function, which presents challenges such as data management, network latency, and energy consumption. The IoTs are a revolutionary force that connects the physical and digital worlds, facilitating smarter, more responsive systems. These systems can lead to increased efficiency, reduced operational costs, and enhanced capabilities in every area of society. Despite existing challenges, the future of IoT is filled with even more promises, ushering in limitless possibilities to create connected spaces that will transform how we live, work, and interact.

IoT solutions are already gaining significant traction in verticals like healthcare, transport, manufacturing, automotive, and others, as illustrated in Fig. 1, and in healthcare, for example, IoT-enabled devices such as wearable health monitors and remote patient monitoring systems deliver valuable real-time data, improving patient care, reducing healthcare expenses, and generating better outcomes. This type of IoT is known as the IoMTs [1].

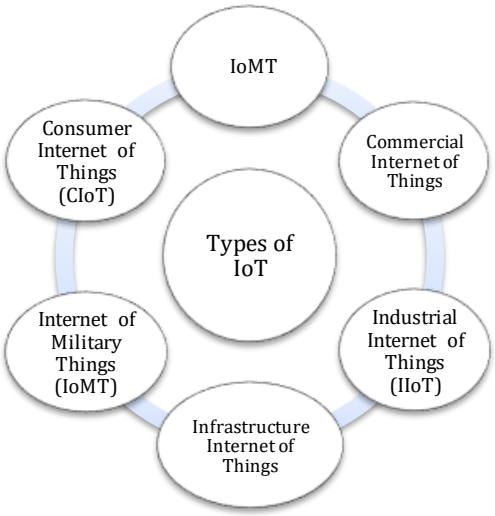

Fig. 1. IoT types.

A. The Internet of Medical Things (IoMT)

The IoMT is an intersection of medical devices with IoT. The IoMT is the future of healthcare systems, where all medical devices are interconnected and monitored on the Internet by healthcare professionals. As the IoMT evolves, it offers significant benefits, including lower healthcare costs and improved patient outcomes. The IoMT serves as a key enabler for healthcare transformation. It offers new services such as remote monitoring, senior support, and e-visits, which enhance convenience and health outcomes for patients. At the same time, these services reduce per-patient costs for healthcare organizations. However, the emergence of mobile, wearable,

and telemedicine technologies has shifted security concerns beyond traditional physical boundaries.

The increasing use of personal devices, such as smartphones and tablets, by patients and healthcare professionals to access, share, and process medical data adds complexity to the security landscape. As medical IoT devices become increasingly prevalent and process valuable data, they have become attractive targets for cyberattacks, including ransomware. However, many medical device users are unaware of the vulnerabilities present in these devices and often invest little in securing their IoT devices. However, implementing appropriate and well-known security measures can significantly mitigate several issues, such as cyber threats, weak encryption, unauthorized access, design flaws, insecure networks, lack of security awareness, compatibility issues, update management, dependency on the cloud, and lack of uniform standards. Therefore, security measures, such as IDS, can significantly reduce the risks associated with exploiting these vulnerabilities [2].

B. Intrusion Detection System (IDS)

ID refers to the organized process of monitoring and analyzing activities within a computer system or network to spot signs of unauthorized access, security breaches, or attempts to compromise the system's confidentiality, integrity, or availability, as well as efforts to bypass its security defenses. Such intrusions may occur when external parties gain unauthorized access through the Internet, when legitimate users attempt to escalate their privileges beyond what is allowed, or when they misuse the access they already have. To support this process, IDSs are employed—these can be either software applications or dedicated hardware devices designed to automate the monitoring and analysis of suspicious activities.

ID plays a vital role in helping organizations protect their systems from the increasing risks that accompany increased connectivity and reliance on digital infrastructure. Given the breadth and complexity of today's cyber threats, the question for security teams is not whether to implement ID, but rather to focus on choosing the right features and functionality for their needs. IDS are now an essential part of any organization's security program. There are several good reasons to deploy them:

- Deterrence: By increasing the chances of detecting and punishing attackers, IDSs discourage malicious behavior and reduce the risk of system misuse.
- Attack detection: IDSs are essential for detecting attacks and vulnerabilities that other security measures cannot prevent.
- Attack precursor detection: IDs can identify early signs of potential attacks, allowing organizations to respond proactively.
- Threat documentation: IDSs provide an organization with a record of ongoing threats, helping to understand the current security landscape.
- Security quality monitoring: IDSs serve as a tool for evaluating and managing security measures, especially in large and complex environments.
- Improved recovery and analysis: IDSs provide valuable information about breaches, making it easier to diagnose, recover from, and correct underlying issues.

By increasing the expected risk of detection and punishment, IDS acts as a powerful deterrent against attackers [3].

II. Related Works

Over the past few years, there have been numerous studies aimed at creating and improving IDS for IoT and IoMT networks. The studies aim to utilize novel methods to enhance the capacity of the systems to detect and manage threats effectively. The research in [4] explores the detection of cyberattacks in IoT networks through a deep learning (DL)-based IDS. The system employs an autoencoder (AE) model that optimizes detection time and offers enhanced precision with 99.76% detection. The AE model operates through encoding and decoding network packets to identify malicious activities. The experiment used the UNSW-NB15 dataset. This research in [5] explores ML algorithms to maximize IDS performance across IoT networks. With the ToN-IoT dataset, the authors implemented Random Forest (RF) and XGBoost, both ensemble learning methods that were very efficient in ID. The solution described reached 99% accuracy.

The study in [6] explores the integration of blockchain technology with anomaly-based ID systems to enhance the (IoT) networks security. This study leverages Convolutional Neural Networks (CNNs) and Artificial NNs (ANNs). They are trained on the IoT-23 dataset, achieving an impressive accuracy of 99.8%. This approach not only enhances security but also supports scalability within IoT environments. In [7], the researchers present an IDS based on federated transfer learning to secure IoMT devices. Their method uses a Deep NN (DNN) to train models locally on the endpoints, while preserving user data privacy. Testing using the CICIDS2017 dataset yielded a high accuracy rate of 99.51%, confirming the system's effectiveness in protecting sensitive healthcare information.

The work presented in [8] focuses on building an IDS specifically designed for IoMT applications using the CICIoMT-2024 dataset. The study evaluates the performance of three boosting algorithms—XGBoost, AdaBoost, and CatBoost—for classifying network traffic. Among these algorithms, XGBoost achieved the best results with an accuracy of 95.01%, followed by AdaBoost with 92.89% and CatBoost with 88.37%. Additionally, the researchers applied XAI techniques to make the models more interpretable.

The study in [9] aims to combat Distributed Denial of Service (DDoS) attacks in blockchain-enabled IoMT networks using ML-based IDs. The study compares the performance of XGBoost, Decision Tree (DT), and RF models using the CICIoMT-2024 dataset. The results demonstrate the system's strong potential to effectively detect and mitigate DDoS attacks, achieving an accuracy of 99.99%. In [10], an anomaly-based IoT network IDS using a DNN with filter-based feature selection to exclude highly correlated features is proposed. The model started by scoring 84% accuracy on UNSW-NB15. To address class imbalance, the authors utilized Generative Adversarial Networks (GANs) to produce synthetic data for minority attack classes to boost accuracy to 91%. The work in [11] suggests an

EML algorithm-based IoT network IDS using the Message Queuing Telemetry Transport (MQTT) protocol.

The authors created the SEN-MQTTSET dataset from three experiment scenarios: normal traffic, subscriber attacks, and broker attacks. Feature extraction was performed using an ensemble statistical algorithm, and algorithms such as Random Forest (RF) and support vector machine (SVM) were used. The system achieved a 99% accuracy level as well as network latency measurement for normal and malicious traffic. The research work in [12] discusses a novel attacker detection method for an edge-focused IoMT structure based on the Swarm NN (Swarm-NN) framework. The system, implemented on the ToN-IoT dataset as well as a real-time secured dataset, achieved 99.5% accuracy. The study in [13] focuses on monitoring network traffic and medical devices to detect malicious and unintended activity. To improve performance while reducing computational costs, the study uses mutual information (MI) and XGBoost as filter-based feature selection techniques. Evaluating the system on the CICIDS2017 dataset, it achieved a high accuracy of 98.79%. In [14], the authors propose *SafetyMed*, an intelligent IDS that combines long-short-term memory (LSTM) and CNNs networks. This hybrid model is designed to analyze sequential and network data to detect intrusion attempts. After validation on the CICIDS2017 dataset, *SafetyMed* demonstrated an accuracy of 97.63%.

The study in [15] presents a swarm neural network-based ID approach specifically designed for data-intensive IoMT systems. The model was tested on the real-time NF-ToN-IoT dataset and achieved an accuracy of 89.0%, demonstrating its practical applicability in healthcare settings. The work in [16] presents a Software-as-a-Service (SaaS)-based IDS specifically developed to address the unique security challenges of IoMT systems. This approach incorporates PSO for feature engineering and was evaluated on the WUSTL-EHMS-2020 dataset, achieving an accuracy of 96.56%. The comparison of the previous studies is shown in Table I.

TABLE I. COMPARISON OF PREVIOUS STUDIES

Ref	Problem	Methods	Dataset	Accuracy
[4]	Detecting malicious activity on IoT network traffic and improving ID in 5G networks	Autoencoder-based DL technique with DNN, XGBoost, Adaboost, ExtraTreeClassifier, RF	UNSW-NB15	99.76%

[8]	cybersecurity threats to IoMT devices and the need for explainable AI-based IDS	Boosting ensemble methods (XGBoost, AdaBoost, CatBoost) with XAI	CICIoMT-2024	XGBoost: 95.01%,
[9]	Vulnerability of Blockchain-enabled IoMT networks to DDoS attacks, affecting network availability and security	ML-based IDS using XGBoost, DT and RF	CICIoMT2024	99.99%
[10]	Traditional threat detection methods struggle to detect new threats and deal with imbalanced data sets	DNN with filter-based feature selection and Generative Adversarial Networks to generate synthetic data for minority attack category.	UNSW-NB15 dataset	84% without GANs, 91% with GANs
[11]	IoT networks face increased cyber-attacks and time constraints in communication.	Elite ML (EML) algorithms with an ensemble statistical multi-view cascade feature generation.	SEN-MQTTSET dataset	99%
[12]	IoMT networks are vulnerable to cyber-attacks during data transmission, leading to privacy leakage and security risks.	Swarm-NN (Swarm-NN) with an Empirical Intelligent Agent (EIA) for ID and health data analysis.	ToN-IoT dataset	99.5%
[13]	IoMT networks are vulnerable to cyberattacks, necessitating effective and accurate IDS.	Tree-based ML (DT, RF, XGBoost, CatBoost) with Mutual Information and XGBoost Feature Selection (MI-XGBoost).	CICIDS2017 dataset	98.79%
[14]	IoMT devices are vulnerable to cyberattacks due to limited computational power, simplified architecture, making them easy targets	Hybrid CNN and LSTM networks for ID from sequential and grid data.	CIC-IDS2017 dataset	97.63%
[15]	IoMT devices have limited storage capacity, computing power, which requires data transfer to external systems, which then leads to security vulnerabilities.	Swarm-NN model for detecting intruders during data transfer in IoMT systems.	NF-ToN-IoT dataset	89.0%
[16]	IoMT devices are resource-constrained and vulnerable to cyberattacks.	SaaS-based IDS with PSO, ML/DL models, and SHAP.	WUSTL-EHMS-2020	96.57%

III. ML APPROACHES

ML models use some algorithms to learn and identify complex patterns in data. ML is all about making computers capable of identifying patterns in data and making decisions or predictions based on the intelligence gathered. There are several primary approaches to ML:

- Supervised Learning: In this approach, the model learns from labelled data, where both the inputs and outputs are provided. The goal is to make accurate predictions or classifications, such as identifying diseases based on medical data or predicting stock prices. Examples include DTs, Linear Regression (LR), and SVM.

- Unsupervised Learning: Unsupervised learning addresses data without pre-defined labels. The model tries to identify inherent structures or patterns, such as clustering similar data points or reducing the dimension of complex datasets. Common methods are k-means clustering, principal component analysis (PCA), and autoencoders.
- Reinforcement Learning (RL): RL is a learning paradigm that mimics human trial-and-error learning. An agent takes an action in an environment, receiving feedback (reward or penalty) based on the outcome of the action taken. RL has wide-ranging applications in robotics, game playing (e.g., AlphaGo), and autonomous cars.
- Semi-supervised and Self-supervised Learning: These methods are between supervised learning and unsupervised learning, using both labelled and unlabelled data or extracting features from the data itself to reduce the amount of labelled data. With continuous advancements, ML is becoming more powerful, adaptive, and integrated into everyday technologies [17].

A. Classification

Classification is a supervised ML in which the aim is to identify a categorical class label for the input. When classifying, the model has been trained using labelled data so that every one of the inputs corresponds to a class label. After training, new, unseen data can be employed to classify, based on patterns learned in the course of training. Classification operations are common in various disciplines like health, finance, and information security [18]. There are two types of classification:

1) Binary: It is a supervised learning problem in which the goal is to classify input data into one of the two potential classes. The model is trained on labelled data to distinguish between two outcomes, most commonly being 0 or 1, True or False, or Positive or Negative. It is widely applied in all domains like spam detection, disease diagnosis, fraud detection, and opinion extraction. In [19], the authors describe the various simple performance measures used in binary class assessment as belonging to three main families: the measures depending on one classification threshold (raw and composite measures), the measures depending on the probabilistic interpretation of error, and the classification measures. The authors also cover graphical methods such as ROC curves and precision–recall curves and outline statistical methods for examining the significance of performance measures and calculating confidence intervals. They provide a simplified example to illustrate the calculation of these measures and the interrelationships between them, emphasizing the importance of choosing appropriate performance measures based on specific classification objectives, especially in the context of class imbalance. In [20], the author provides a comprehensive review of binary performance assessment, focusing on the analysis, relationships, and classification of different performance tools. The study classifies these tools into "performance measures" and "performance metrics", and defines them semantically and formally to clarify their use across different domains. Several new concepts, such as binary, complementarity, and normalization, are introduced to examine the similarities, redundancies, and dependencies between different tools. The main contributions of the study are the Periodic Table of Performance Tools (PToPI), a visual representation that organizes performance tools systematically, helping researchers choose appropriate metrics.

2) Multi-class: It is a statistical and ML classification task that involves more than two classes. It involves classifying data into one of the possible classes. Each sample can only be classified into one class. In [21], the author provides a detailed review of the evaluation metrics used in multiclass classification, emphasizing their role in evaluating ML models. The discussion begins with basic concepts such as precision, recall, and the confusion matrix, which serve as the basis for more advanced metrics. The study explains how precision, despite its widespread use, can be misleading, especially in imbalanced datasets, leading to the introduction of balanced precision and weighted variances to address this issue. Cross-entropy is introduced as a metric that assesses the divergence between predicted and actual probability distributions. In addition, the author examines more advanced evaluation techniques, such as Matthew's Correlation Coefficient (MCC), which considers all components of the confusion matrix, and Cohen's kappa, which measures the concordance of predicted versus actual classes with chance adjustment. The talk emphasizes the importance of applying the right evaluation methods based on the specific problems of the dataset, such as class imbalance or the need for good prediction in certain classes.

B. ML Key Models

DT models are a popular and easy-to-understand ML method, applied in both classification and regression problems. The method works by splitting the dataset into subsets depending on feature values, allowing decisions to culminate in classification or prediction outcomes. According to authors in [22], DTs encompass a number of algorithms, including ID3, C4.5, CART, CHAID, and QUEST. These algorithms have been widely used in various fields, including medical diagnosis, text classification, and image processing, because of their interpretability and simplicity.

SVM models are powerful supervised learning algorithms well-suited for both classification and regression tasks, with a particular strength in handling classification problems. The basic idea behind SVM is to find the optimal level that separates the data points into different categories within an N-dimensional space. By maximizing the margin between the closest data points of each class, SVMs enhance both the accuracy and generalization of the model. According to the findings in [23], SVMs can efficiently process large-scale datasets, making them highly effective in terms of computational performance and accuracy. The study also explored various optimization strategies, such as integrating fuzzy membership functions into multi-kernel learning frameworks, and identifying optimal solution spaces based on dataset size, further demonstrating

SVM's scalability and adaptability to complex data environments.

The k-Nearest Neighbors (k-NN) model is a straightforward, yet widely used supervised learning method, especially effective for classification and regression tasks. As a non-parametric approach, it works by assigning a class to a new data point based on the majority class among its closest neighbors. Its simplicity and effectiveness make it a popular choice in many ML applications. In [24], the k-NN algorithm was used to categorize data into positive and negative classes. The results showed high accuracy, confirming the algorithm's strength in reliable and accurate classification tasks.

Naive Bayes (NBs) model is a probabilistic classifier in the field of ML that is commonly applied in classification, particularly where we have large data. It functions on the principles of Bayes' theorem, which presumes features to be conditionally independent, i.e., the presence of one feature does not influence the presence of another. The algorithm is specifically utilized in domains such as text classification, spam filtering, and sentiment analysis because of its simplicity and efficiency. Naïve Bayes is known for its speed and effectiveness on high-dimensional data, and it serves as a solid foundation for various classification problems. In [25], the researchers used the Naïve Bayes algorithm. Two different data distribution techniques, Hold-Out and 10-Cross Fold Validation, were used to evaluate the algorithm's performance. It was found that using the Naïve Bayes algorithm with the Hold-Out method achieves better accuracy.

RFs model is a popular ML model that builds a collection of DTs and merges their individual predictions to generate the final result. The approach is suitable for both classification (prediction of classes) and regression (prediction of continuous outcomes) problems. It works by randomly selecting subsets of data and features to train multiple DTs, which helps improve accuracy and prevent overfitting. The overall outcome is based on the majority vote (in classification) or average (in regression) of the trees, making the model more stable and reliable than a single decision tree. Its strength lies in its ability to handle complex datasets and adapt to a variety of patterns, making it a robust and accurate algorithm, as in [26]. The author conducted a novel spatial RFs technique that enhances traditional RFs by incorporating higher-order spatial statistics. This approach utilizes local spatial-spectral information to effectively identify intrinsic heterogeneity, spatial interactions, and sophisticated spatial patterns, hence presenting a more sophisticated framework for geoscience data modeling and analysis. Further, it highlights the superiority of this approach compared to traditional RFs, specifically in their potential to generate spatially coherent predictions.

Neural Networks (NN) models: A neural network is a computer system modeled on the biological neural networks found in the human brain. It is composed of interconnected neurons, or nodes, that work together to recognize patterns, make decisions, and solve complex problems. In [27], the authors discussed various optimization methods which are employed to enhance artificial NNs (ANNs) through the use of parameter optimization methods including network architecture, hidden neuron numbers, and learning rates. Several algorithms include the particle swarm optimization (PSO), Genetic Algorithm (GA), backtracking search algorithm (BSA), Artificial Bee Colony (ABC), among others, help to maximize both the effectiveness and efficacy of ANNs.

IV. Datasets in IoMT

In IoMT, datasets play a pivotal role in developing and evaluating ML models for healthcare applications, as shown in Table II. This data is typically collected from various IoT devices, some from different medical devices. Common datasets used in the IoMT include:

UNSW-NB15 dataset is a premier benchmark to assess network IDS (NIDS). It was developed by the Australian Centre for Cyber Security (ACCS) at UNSW Canberra with the vision to overcome the drawbacks of existing datasets by incorporating contemporary attack scenarios and actual network traffic. The dataset consists of raw network packet captures processed using Bro-IDS and Argus tools, resulting in 49 features that include flow-based, basic connection characteristics, and content-based characteristics. It contains both normal and malicious traffic, and covers a variety of attack types such as DoS, exploits, fuzzers, backdoors, and reconnaissance. UNSW-NB15 is widely used in cybersecurity research, particularly in ID, anomaly detection, and ML-based security applications. Its richness in attack diversity and realistic traffic patterns makes it a valuable resource for testing the effectiveness of modern NIDS solutions [28].

ToN-IoT (Telemetry and Network of IoT) dataset is a modern cybersecurity dataset designed for ID in Internet of Things (IoT) and Industrial IoT (IIoT) environments. It was developed by the UNSW Canberra Cyber Range Lab and includes telemetry data from various IoT devices, network traffic, and system logs, so it is a large set for cybersecurity research. The dataset includes both normal and abnormal and has a broad variety of cyber threats such as denial of service (DoS), ransomware, backdoors, and reconnaissance. It embraces multiple data types, including IoT sensor logs, operating systems (Windows and Linux), and network traffic, to facilitate cross-layer security analysis. ToN-IoT is widely used in ML-based ID and anomaly detection due to its realistic attack scenarios and multi-source data collection, making it highly relevant to modern IoT security problems [29].

IoT-23 dataset is a public database, and it is intended for educational research purposes in the area of malware and network ID in IoT settings. IoT-23 was created by Stratosphere Lab in collaboration with Avast, and contains 23 different scenarios, including normal IoT network traffic and malicious traffic generated by different malware families. The dataset consists of classified network traffic captures (PCAP files) along with extracted flow-based features, allowing researchers to analyze various attack behaviors such as a DDoS, botnets, and control (C&C) communications. IoT-23 is widely used in cybersecurity research to develop and evaluate ML models aimed at detecting and mitigating IoT-based cyber threats [30].

The CICIDS2017 dataset is generated by the Canadian Institute for Cybersecurity (CIC), is a premier benchmark for the testing of IDS and conducting cybersecurity research. The dataset mimics actual network traffic by including both

legitimate activity and a variety of attack types, such as DDoS attacks, brute force attacks, botnet traffic, intrusions, and web attacks. It consists of detailed network flow data captured over a five-day period, including packet captures (PCAPs) and extracted flow-based features. CICIDS2017 is valuable for training ML models due to its inclusion of time-stamped traffic, classified attack categories, and real-world user behavioral profiles. The dataset is widely used in anomaly detection, performance evaluation of IDS, and cybersecurity analytics, making it a primary resource for advancing network security research [31].

The CICIoMT-2024 dataset is an extensive benchmark dataset created for the assessment of security controls within the environment of the IoMT. Created by the Canadian Institute for Cybersecurity, the dataset comprises network traffic data collected from an IoMT testbed composed of 40 devices, of which 25 were real devices and 15 simulated devices, with the perspective of representing the different protocols utilized in healthcare settings like Wi-Fi, MQTT, and Bluetooth. In order to replicate the real-world threat scenarios, 18 different attacks have been performed on this testbed, which are divided into five main categories: DDoS, DoS, reconnaissance, MQTT-based attacks, and spoofing. This dataset serves as a useful tool for researchers and practitioners interested in designing and testing IDSs and other security mechanisms for IoMT infrastructure [32].

The SEN-MQTTSET dataset is a specialized resource developed to enhance IDSs within IoT environments using the MQTT protocol. This dataset includes three distinct scenarios: normal operations, attacks targeting subscribers, and attacks on intermediaries. To extract meaningful features from the raw data, a statistics-based multi-view sequential feature generation algorithm was used, resulting in a multi-context feature set [33].

The NF-ToN-IoT dataset is the NetFlow-based version of the ToN-IoT dataset to enhance research on network ID in IoT networks. By transforming ToN-IoT raw packet captures (pcaps) into NetFlow logs, NF-ToN-IoT gives us the flow-based view of the network traffic and therefore, it is valuable to investigate communication patterns as well as for anomaly detection. The dataset contains a total of about 16.9 million data flows, where 63.99% are marked as attack samples and 36.01% are labeled as benign. The attack categories are Backdoor, DoS, DDoS, Injection, Man-in-the-Middle (MITM), Password, Ransomware, Scanning, and XSS. Each flow is described using 12 NetFlow features, including source and destination IP addresses, ports, protocols, and byte counts. NF-ToN-IoT is publicly available and is a valuable resource for training and testing ML models for enhancing the security of IoT networks [34].

The WUSTL-EHMS-2020 dataset is a targeted resource aimed at promoting cybersecurity research in the IoMT context. The dataset was obtained using the Enhanced Healthcare Monitoring System (EHMS) Real-Time Testbed located at Washington University in St. Louis, and it uniquely integrates network flow measurements with patient biometric information, thereby filling the gap of datasets that bring these two elements together. It has 16,318 samples, of which 14,272 are labeled as normal, and 2,046 are attack instances, and has 44 distinct features—35 for network metrics and 8 for patient vital signs. The dataset includes man-in-the-middle attacks, such as spoofing and data injection, and data confidentiality and integrity violations. Researchers are using WUSTL-EHMS-2020 to develop and evaluate IDSs specifically designed for IoMT environments, leveraging ML techniques to analyze the complex interaction between network activity and medical data [35].

The dataset is typically divided into training, validation, and test sets for model development and evaluation. Common split ratios include 70% for training, 15% for validation, and 15% for testing, or 80% for training and 20% for testing, to ensure fair evaluation and good generalization performance.

TABLE II. IOMT DATASETS

Ref.	Dataset	Field	Year	Total Features	Target attack
[28]	UNSW-NB15	Cybersecurity, Network ID	2015	49	DoS, Fuzzers, Backdoor, Exploits, Generic, Reconnaissance, Shellcode, Worms
[29]	ToN-IoT	IoT network traffic.	2020	44	DDoS, Mirai, Keylogging, Scanning, DoS, Backdoor, Ransomware, Injection, XSS, Password attack, MITM
[30]	IoT-23	IoT network traffic.	2020	47	DDoS, DoS, Brute Force, Port Scan, MITM, Malware, Backdoor, Worm, Credential Stuffing, Botnet attacks
[31]	CICIDS2017	Network traffic data from various real-world scenarios	2017	80	DDoS, Brute Force, DoS, Port Scan, Heartbleed, Botnet, Web Attack, SSH, Infiltration, etc.
[32]	CICIoMT-2024	Network traffic data from IoMT devices	2024	44	DDoS, DoS, Spoofing, Recon, MQTT
[33]	The SEN-MQTTSET	Network traffic data from IoT devices using MQTT protocol	2021	120	DoS, Subscriber Attack, Broker Attack
[34]	NF-ToN-IoT v1, v2, v3	Network traffic data from IoT devices	2021-2025	8, 43, 53	Backdoor, DoS, DDoS, Injection, Scanning, XSS
[35]	WUSTL-EHMS-2020	IoMT network	2020	44	MITM attacks: Spoofing, Data Injection

V. EXPLAINABLE AI (XAI) ALGORITHMS

XAI refers to a group of methods and techniques designed to enhance the transparency, interpretability, and trustworthiness of AI models. Traditional AI models, especially DL and complex ML models, often function as "black boxes", making it difficult to understand how they arrive at specific decisions. XAI algorithms aim to bridge this gap by providing insights into model predictions, ensuring accountability, and facilitating human-AI collaboration. XAI algorithms can be broadly classified into two types:

A. Model-Specific XAI Algorithms

These methods are built into specific models and provide intrinsic interpretability.

- DTs: A hierarchical structure that allows for straightforward interpretation by mapping decision paths.
- LR: Provides direct interpretability through feature coefficients that indicate the impact of each variable.
- Rule-Based Models: Generate human-readable rules that explain decision-making, such as in fuzzy logic systems.

B. Post-Hoc XAI Algorithms

These techniques analyze and interpret complex, pre-trained models without altering their structure.

- Shapley Additive Explanations (SHAP): Founded on cooperative game theory, SHAP allocates a significant score to every feature, indicating its contribution to the prediction made by the model.
- Local Interpretable Model-agnostic Explanations (LIME): Creates local approximations of a black-box model by training simple surrogate models in the vicinity of single predictions.
- Gradient-weighted Class Activation Mapping (Grad-CAM): Used for DL to reveal the regions of an image that supported a model's decision.
- Counterfactual Explanations: Explain decisions by identifying minimal changes in input that would lead to a different output, providing actionable insights [36]. These are all XAI techniques, as shown in Table III:

TABLE III. COMPARISON OF XAI TECHNIQUES

Technique	Description	Strengths	Weakness	Use Cases
DT	A hierarchical structure where decisions are made based on feature values.	Transparent, easy to visualize, interpretable.	Prone to overfitting, less powerful for complex tasks.	Customer segmentation, medical diagnosis, credit scoring.
LR	Predicts outputs based on a weighted sum of input features.	Simple, easy to interpret, direct feature influence.	Limited to linear relationships, sensitive to outliers.	Price prediction, demand forecasting, stock market prediction.
Rule-Based Models	Make decisions based on predefined or learned rules.	Transparent, easy to implement, interpretable.	Can become overly complex, less powerful for complex patterns.	Expert systems, diagnostic systems, regulatory compliance.
SHAP	Assigns an important score to each feature based on game theory (Shapley values).	Theoretically grounded, consistent across models.	Computationally expensive, slow for large models.	Feature importance analysis, model interpretation, ML.
LIME	Approximates complex models with simpler interpretable models around individual predictions.	Model-agnostics provides local explanations.	Local explanations may not generalize, computationally expensive.	Image classification, text classification, fraud detection.
Grad-CAM	Visualizes which parts of an image influenced the model's decision.	Provides intuitive visualizations, works well with CNNs.	Limited to CNNs, hard to interpret for complex models.	Image classification, object detection, medical imaging.
Counterfactual Explanations	Explain a decision by identifying minimal changes in input to alter the output.	Actionable, easy to understand, intuitive.	May not be meaningful in complex models, computationally intensive.	Decision support, recommender systems, financial services.

VI. FEATURE SELECTION TECHNIQUES IN ID

Feature selection is a necessary process in developing IDSs to reach dimensionality reduction, better accuracy, and better computational efficiency. By selecting the most informative features from network traffic data, IDS can gain a higher classification accuracy while, in the meantime, decreasing the number of false positives and negatives. A few optimization algorithms in feature selection, specifically bio-inspired ones such as GA, PSO, GWO, and ABC, play an important role in this process. GA ensures solution diversity through crossover and mutation, but it can be computationally expensive.

PSO is efficient and simple, but may suffer from early convergence. GWO effectively balances exploration and exploitation, making it suitable for high-dimensional IDS datasets. ABC offers flexibility and robustness but may converge slowly than other algorithms. Despite their limitations, these methods continue to evolve, addressing weaknesses and improving feature selection performance, ultimately enhancing IDS effectiveness. The selection of an appropriate feature selection technique relies on factors like dataset size, feature complexity, and the desired balance between computational cost and classification performance. Proper feature selection can significantly enhance IDS effectiveness by improving detection rates while reducing processing overhead [37].

VII. PRACTICAL DEPLOYMENT: CONSIDERATIONS AND LIMITATIONS

Practical deployment of IoT and IoMT intrusion detection systems also reveals important evaluation limitations commonly observed in existing studies. In particular, several datasets rely on labeling mechanisms derived from device identifiers, such as source MAC addresses. When MAC-related or identity-derived attributes are simultaneously included in the feature space, learning models may unintentionally capture device identity rather than genuine attack behavior, leading to label–feature leakage and overly optimistic performance results. To mitigate this risk, robust experimental practices explicitly exclude direct device identifiers (e.g., raw MAC addresses, organizationally unique identifiers, or vendor-specific prefixes) from the feature set and enforce device-level data partitioning, ensuring that traffic generated by the same device does not appear across training and testing splits. Clear documentation of feature

inclusion/exclusion decisions and data-splitting strategies is therefore essential for realistic, generalizable, and reproducible IoMT IDS evaluations.

VIII. Conclusion

The review shows that combining ML and XAI represents a promising direction in designing IDSs for IoMT environments. ML techniques enable accurate detection of complex threats, while XAI helps interpret these decisions and support trustworthy responses in sensitive medical contexts. However, challenges remain regarding scalability, real-time data handling, and privacy protection. The study recommends further studies to develop more efficient hybrid models, increase the adoption of XAI to ensure transparency, and establish standardized testing frameworks suitable for IoMT systems. Additionally, existing evaluations may suffer from label–feature leakage when device identifiers such as MAC addresses are used for labeling while also being included in the feature space. To ensure realistic and generalizable results, future studies should exclude direct device identifiers and apply device-level data partitioning between training and testing sets.

Institute of Visual Informatics, Universiti Kebangsaan Malaysia, Malaysia[3]

***Abstract*—Ensuring the integrity of outsourced data in cloud storage remains a critical challenge, especially when existing auditing schemes rely on centralized third-party auditors (TPAs), which introduce single points of failure, privacy leakage risks, and a lack of economic fairness. Current blockchain-based approaches improve transparency but still fail to simultaneously achieve privacy-preserving verification and fair payment between data owners and cloud service providers (CSPs). To address this gap, this study proposes a blockchain-based integrity verification scheme that supports decentralized, privacy-preserving, and economically fair audits for encrypted cloud data. The proposed scheme integrates homomorphic linear authenticators (HLA) and multi-party computation (MPC) to verify data integrity without revealing plaintext, while smart contracts are used to enforce automatic payment or penalty based on audit results, ensuring fairness and accountability. A prototype implementation confirms the practicality of the system. Experimental results show that the audit latency is reduced by up to 35 per cent and smart contract gas consumption by approximately 30 per cent compared to existing schemes, while maintaining low computation and communication overhead. Security analysis demonstrates that the scheme provides data integrity, privacy protection, fairness, and resistance to replay and collusion attacks. Overall, this work offers a practical and scalable solution for secure cloud storage auditing.**

***Keywords*—Cloud storage; blockchain; integrity verification; smart contract; privacy-preserving audit; fair payment**

I. Introduction

Cloud storage has become an essential component of modern data management infrastructures [1]. However, outsourcing data to third-party cloud service providers (CSPs) raises critical concerns regarding data integrity, confidentiality, and user trust [2]. Since users no longer possess physical control over their data, they require reliable mechanisms to ensure that outsourced files remain intact and unmodified. Traditional auditing schemes rely on trusted third-party auditors (TPAs), but these centralized architectures suffer from inherent weaknesses such as single points of failure, implicit trust assumptions, potential collusion, and limited transparency [3].

Blockchain technology provides a decentralized and tamper-resistant alternative for cloud auditing, replacing TPAs with distributed consensus and verifiable smart contract execution [4], [5]. Although several blockchain-based integrity verification schemes have been proposed, most of them still exhibit one or more of the following limitations:

- They focus on transparency but fail to protect data privacy during audits.
- They do not support fair economic compensation between users and CSPs in cases of data loss or fraud.
- They provide incomplete support for dynamic data operations or require additional trust in off-chain verifiers [6].

Therefore, an important research gap remains: existing approaches do not offer a unified framework that simultaneously achieves decentralized verification, privacy preservation, and fair payment in cloud storage environments.

To address this gap, this study proposes a blockchain-based integrity verification scheme that integrates privacy-preserving audit and economic fairness into a single framework. Homomorphic Linear Authenticators (HLA) and Multi-Party Computation (MPC) are combined to enable verification of encrypted data without revealing its content. In addition, smart contracts are employed to enforce an automatic fair payment mechanism that compensates CSPs only when data integrity is successfully proven, while also providing dispute resolution in case of corruption or data loss.

The main contributions of this work are summarized as follows:

- We design a fully decentralized cloud data integrity verification framework that removes reliance on TPAs and guarantees audit correctness while preserving data privacy.
- We develop a smart contract–based fair payment protocol that enforces automatic rewards or penalties based on audit outcomes, ensuring economic accountability between users and CSPs.

- We implement the prototype and conduct comprehensive security analysis and experimental evaluation. Results demonstrate that the proposed scheme achieves low audit latency, reduced communication overhead, and feasible gas consumption in practical cloud environments.

The rest of the study is organized as follows: Section II reviews related work. Section III introduces the system architecture and threat model. Section IV presents the proposed scheme in detail. Section V provides security analysis. Section VI discusses performance evaluation and experimental results. Finally, Section VII concludes the study and outlines future research directions.

II. Related Work

Ensuring the integrity of outsourced data has long been a fundamental challenge in cloud storage systems. Early cryptographic solutions such as Provable Data Possession (PDP) and Proof of Retrievability (PoR) enabled users or trusted third-party auditors (TPAs) to verify data correctness without downloading the entire file [7]. However, these methods rely heavily on centralized auditors, which introduces risks of single-point failure, collusion, and trust assumption issues [8].

To mitigate reliance on TPAs, blockchain-based integrity verification schemes have gained increasing attention. Zhang et al. combined blockchain with lattice-based cryptography to achieve public auditing and improved transparency, but their scheme lacks support for efficient computation and dynamic data updates, which limits real-world applicability [9]. Zhou et al. proposed a blockchain-enabled data monitoring scheme; however, it provides limited analysis of computational costs and does not address economic fairness between cloud service providers (CSPs) and users [10].

Recent works have explored the integration of homomorphic authenticators and advanced cryptographic techniques to enhance verifiability. Sankar et al. introduced a lattice-based multi-cloud auditing model, which offers theoretical security but lacks practical deployment evaluation [11]. Xie et al. proposed a T-Merkle hash tree to support dynamic data operations; nevertheless, their design does not incorporate fair payment or dispute resolution mechanisms [12]. Liu and Huang presented privacy-preserving and blockless verification schemes, but challenges remain in achieving decentralized enforcement and secure economic incentives [13], [14].

Another research direction focuses on blockchain-based economic mechanisms for cloud data services. While these methods record audit outcomes on-chain, most do not leverage smart contracts for automatic enforcement or compensation. For example, He et al. improved communication efficiency but failed to establish a clear arbitration mechanism for disputes [15]. Li et al. incorporated zero-knowledge proof-based privacy, yet did not support on-chain payment settlement or dynamic file updates [16].

Wang et al. developed a smart contract-driven integrity auditing scheme for multi-cloud and multi-replica environments, optimizing tag generation to reduce overhead [17]. However, their system assumes a trusted key generation center (KGC) and primarily focuses on multi-CSP coordination rather than privacy preservation and fair exchange in a single-cloud scenario.

In summary, existing blockchain-based auditing schemes still face the following limitations:

- Reliance on centralized authorities such as TPAs or KGCs.
- Absence of fair payment mechanisms to guarantee accountability between users and CSPs.
- Incomplete support for encrypted data verification while preserving privacy.

To overcome these challenges, this study proposes a decentralized, privacy-preserving integrity verification scheme that integrates homomorphic authenticators, multi-party computation (MPC), and smart contracts to achieve secure auditing, automated dispute resolution, and fair compensation.

III. Scheme Framework

A. Scheme Model

The proposed scheme consists of three primary entities, as illustrated in Fig. 1.

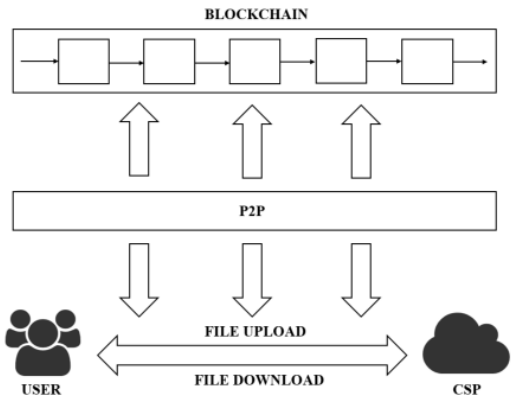

Fig. 1. Scheme model.

1) Data owner (DO): A user who outsources encrypted data to the cloud and later requests integrity verification. The DO is responsible for generating encryption keys, computing homomorphic tags, and initiating audit requests.

2) Cloud service provider (CSP): A storage service provider that maintains outsourced data on behalf of the DO. The CSP responds to audit challenges by generating proofs of data possession.

3) Blockchain network: A decentralized ledger that hosts smart contracts. It facilitates audit challenge distribution, proof aggregation, verification, and fair payment based on audit results. The blockchain is assumed to be transparent, tamper-resistant, and always available.

The system is designed to operate without relying on any third-party auditor or centralized key generation authority. All integrity audits, payment mechanisms, and verification processes are executed through smart contracts deployed on the

blockchain. Data remains encrypted throughout the process using AES-GCM, while integrity verification is performed using homomorphic linear authenticators (HLA).

B. Threat Model

We consider both internal and external adversaries.

- Malicious CSP: The primary threat arises from a dishonest CSP, who may:
  - Delete or alter outsourced data to reduce storage overhead.
  - Forge integrity proofs to pass audits without storing actual data.
  - Reject fair payment conditions or evade penalties following a failed audit.
- External Attacker: An outsider may attempt to:
  - Intercept or tamper with communication between DO and CSP.
  - Replay previous audit responses to bypass verification.
  - Eavesdrop on blockchain transactions to infer private information.
- Collusion Risk: The CSP may attempt to collude with external entities to manipulate audit results or payment transactions. However, smart contracts on the blockchain act as impartial executors, preventing such collusion.

We assume that the blockchain platform is secure, the consensus mechanism is reliable, and all cryptographic primitives (e.g., AES-GCM, Keccak-256, HLA) are resilient against known attacks. All communication channels are assumed to be protected by standard TLS protocols.

C. Security Targets

The proposed scheme aims to achieve the following security objectives:

1) Data integrity: CSPs should be unable to modify or delete data without detection. Audit verification must fail if the data is tampered with.

2) Privacy preservation: The CSP cannot learn the content of the data during upload, verification, or audit, as all data remains encrypted and audit is performed via MPC and HLA.

3) Audit correctness: If the CSP stores data correctly and follows the audit protocol honestly, the verification will succeed with high probability.

4) Fair payment: The smart contract ensures that CSPs are compensated only when audits are successful and penalized when they fail to produce valid proofs.

5) Collusion resistance: Neither the CSP nor any external party can manipulate or falsify audit results due to the tamper-proof nature of the blockchain and the transparency of smart contract execution.

6) Replay resistance: Each audit challenge is randomly generated and time-bound, preventing the reuse of old responses.

IV. Scheme Realization

This section outlines the proposed scheme's implementation process, which is divided into five main phases. It begins by introducing the notations and initialization settings that establish the theoretical foundation of the scheme. Following this foundational setup, the focus shifts to a detailed examination of the three critical parts: file upload, file download, and file update.

A. Notations

The symbols used throughout the scheme are defined in Table I.

TABLE I. Notations

Notation	*Definition*
F	File
C	Ciphertext
B_i	i-th data block
S_j	j-th share in MPC
P_j	j-th party in MPC
M	MPC protocol
R	Merkle Hash Tree Root Node
n	Number of data blocks
ID	Identifier
σ	Homomorphic tag
Pay_{stor}	Storage service fees
Pay_{comp}	Compensation costs

B. Initial Setting

The proposed scheme leverages several core cryptographic components and concepts:

1) Cyclic groups and bilinear mapping: Let G and G_T be two cyclic groups of the same prime order p, with g as the generator of group G. A bilinear mapping is defined as, $e: G \times G \rightarrow G_T$. These form the foundation for constructing the cryptographic scheme.

2) User and file identity: Each user U is identified by an ID_U and a corresponding Ethereum account EA_U. Files are identified by an ID_F. The Cloud Service Provider (CSP) is also identified by an ID_{CSP} and has a corresponding Ethereum Account EA_{CSP}.

3) Encryption keys and signatures: User U randomly generates an RSA key pair (spk, ssk) for digital signature purposes. Additionally, user U selects an element u from G, with a private key $ssk = x \in Z_p$, and calculates the public key $y = g^x$.

4) Multi-Party Computation (MPC): To enhance the security and trustworthiness of the integrity verification process, MPC is employed. In MPC, the data is divided into multiple shares S_j, which are distributed among different parties P_j. These parties collaboratively perform computations

under the MPC protocol without disclosing their individual inputs.

5) Economic model: Upon successful storage of user data, users are required to pay the CSP storage fees Pay_{stor}. If user data is lost or damaged, the CSP must provide compensation to the user, denoted as Pay_{comp}.

These cryptographic elements and concepts provide the necessary theoretical and technical foundation for the proposed blockchain-based cloud data integrity verification scheme, ensuring data security and transaction fairness.

C. File Upload

There are a total of six steps for file upload, as shown in Fig. 2.

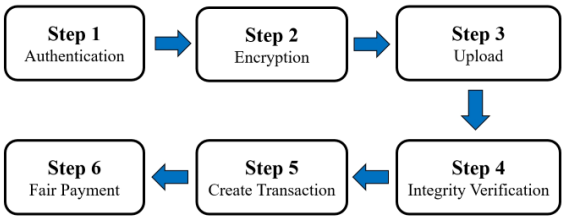

Fig. 2. Steps of file upload.

1) Step-1: Authentication: Before uploading file F, the CSP must verify the user's identity. The user U uses a digital certificate issued by a trusted Certificate Authority (CA) to verify their identity. Specifically, user U first hashes their identity as $h\ (ID_U)$ and then signs this hash using their private key to create the signature $Sig_{ssk}\ (h\ (ID_U))$. The user U sends this signature along with their digital certificate to the CSP. Upon receiving the signature and the certificate, the CSP uses the CA's public key to validate the digital certificate, ensuring its authenticity. Then, CSP uses the public key spk from the certificate to verify the signature . If the verification is successful, the user is authenticated and can proceed to the step-2.

2) Step-2: Encryption: User U generates a signature for file F using the private key ssk.

$$Sig_F = ID_F \parallel Sig_{ssk}(ID_F) \tag{1}$$

Sig_F can be used as an identifier for file F. Subsequently, user U divides the file F into n data blocks, $F = \{B_i\}(1 \le i \le n)$. For the i-th data block B_i, user U uses PBKDF2 algorithm to calculate the convergence key and uses AES-GCM algorithm to calculate the ciphertext.

Generate a unique salt value P_i for each data block B_i.

$$K_{B_i} = PBKDF2(B_i, P_i, iterations, dklen) \tag{2}$$

Encrypt the data block using the derived key K_{B_i}.

$$C_{B_i} = AES\text{–}GCM(K_{B_i}, B_i) \tag{3}$$

User U calculates file tags, using Keccak-256 hash function.

$$T_F = Keccak - 256(C_{B_i}) \tag{4}$$

User U uses data block ciphertext $\{C_{B_i}\}$ to construct a Merkle hash tree and calculate its root points.

$$R_C = MerkleTree(\{C_{B_i}\}) \tag{5}$$

User U calculates file signature.

$$\delta = H(R_C)^{x\ mod\ p} \tag{6}$$

User U calculates homomorphic signature.

$$W_i = ID_F \parallel i \tag{7}$$

$$\sigma_i = (H(W_i \times u^{C_{Bi}}))^{x\ mod\ q} \tag{8}$$

3) Step-3: Upload: User U sends the file label T_F to CSP, and CSP performs repeatability detection. If the file label T_F already exists on the cloud server, it indicates duplication. In this case, CSP and the user execute a proof of ownership agreement to prove that the user indeed owns the file F, and the user does not need to upload the file F again. If the file label T_F is not stored on the cloud server, it indicates that the file F is not duplicated, and user U will send $(Sig_F, \{C_{B_i}\}, \{\sigma_i\})$ to CSP.

4) Step-4: Integrity verification: To enhance the security and privacy of the integrity verification process, user U can act as an auditor and engage in an integrity verification protocol with the Cloud Service Provider (CSP), leveraging Multi-Party Computation (MPC) as follows:

User U retrieves the file identifier $Sig_F = ID_F \parallel Sig_{ssk}(ID_F)$ from the cloud server.

Using the public key spk to verify the correctness of the signature $Sig_{ssk}(ID_F)$.

If the verification fails, the user will output a result of false. If the verification is successful, the user can recover the file identification ID_F.

Initialization: User U selects a subset $I = \{S_1, S_2, S_3, \ldots, S_{c-1}, S_c\} \subset [1, n]$ containing c elements. This subset is used as the seed value set $\{S_i\}$ to initiate M.

Sharing Data for MPC: User U divides the data into shares S_j for the selected indices I. These shares are distributed among different parties P_j involved in M.

Engaging the MPC Protocol: The parties $\{P_j\}$ collaboratively execute M to securely compute random numbers. The protocol ensures that none of the parties, including the CSP, can learn the individual shares or the final random numbers until the computation is complete.

Secure Computation: M employs a pseudo-random function, denoted as $f: \{0,1\}^* \to [1, n]$, to securely compute the random numbers. The function takes as input the shares $\{S_j\}$, the current block identifier B_{id} and the current timestamp T_s.

Output Generation: As a result of the secure computation, M outputs two sets of random numbers: $\{r_i\}$ and $\{z_i\}$. These numbers are generated in such a manner that they are

unpredictable to outside observers, ensuring the integrity of the computation process.

Challenge Formation: User U forms a challenge $chal = \{(r_i, z_i)\}$ using the random numbers generated by M. This challenge is then sent to the CSP to verify the integrity of cloud data.

CSP calculates the proof information μ and L using the received challenge, where:

$$\mu = \sum_{i \in I} z_i C_{B_i} \quad (9)$$

$$L = \prod_{i \in I} \sigma_{z_i}^{r_i} \quad (10)$$

CSP sends (μ, L) as proof to user U.

User U checks the correctness of the following equation to check the integrity of cloud data:

$$\Gamma_1 : e(L, g) = e((\prod_{i \in I} H(W_i)^{z_i} \cdot u^{\mu}), y) \quad (11)$$

This step utilizes MPC to ensure that the computation of μ and L is done without revealing the actual values of $\{C_{B_i}\}$ and $\{\sigma_{Z_i}\}$ to any single party, enhancing the privacy of the data.

By incorporating MPC into the integrity verification process, this approach not only maintains the confidentiality of the data during the verification but also enhances the security and trustworthiness of the cloud storage system. The use of MPC allows multiple parties to compute the verification without revealing their inputs, thereby providing a more secure and privacy-preserving verification process. Fig. 3 illustrates the process of step-4.

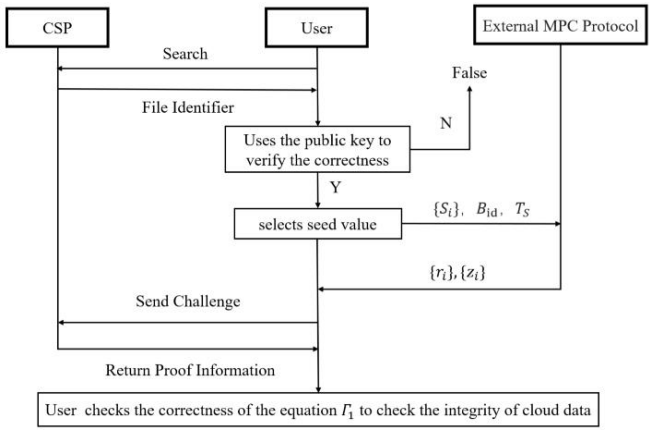

Fig. 3. Step-4 integrity verification.

5) Step-5: Create transaction: User U can generate effective file tamper proof records by integrating auxiliary information from file F into a transaction in the blockchain. This allows other users to have a clear understanding of the storage service quality provided by CSP and helps them choose the most suitable storage service. The details are as follows. User U calculate:

$$Data = H(ID_U) \parallel H(ID_F) \parallel flag \cdot Pay \parallel \delta \parallel Aug_F \quad (12)$$

where, $flag \cdot Pay > 0$ indicates that user U pays storage service fees to CSP, $flag \cdot Pay < 0$ indicates that CSP pays compensation fees to user U, and Aug_F represents additional information for file F.

As shown in Fig. 4, the user submits Smart Contract 1 to generate a transaction TX, where the transaction TX parameter is $From = EA_U$,$T_o = EA_{CSP}$ and $Data = H(ID_U) \parallel H(ID_F) \parallel flag \cdot Pay \parallel \delta \parallel Aug_F$.

Smart Contract 1

Input: $ID_U; ID_{CSP}; Data$
Output: TX
1: Compute EA_U;
2: Compute EA_{CSP};
3: $From = EA_U$;
4: $T_o = EA_{CSP}$;
5: $Value = Gas$;
6: TX= $From||T_o||Value||Data$;

Fig. 4. Smart contract 1.

After receiving the output result of Smart Contract 1, User U uses the private key ssk to generate signature information $Signature = Sig_{ssk}(\text{TX})$, and submits the transaction $\text{TX} = From \parallel T_o \parallel Value \parallel Data \parallel Signature$ to the blockchain.

6) Step-6: Fair payment: After data is uploaded to the cloud server, users need to pay for the storage services provided by CSP. As shown in Fig. 5, user U can submit Smart Contract 2 to the blockchain, where Smart Contract 2 will be automatically activated and executed. If the formula Γ_1 is established, it means that the data block $\{B_{ij}\}$ has been fully stored on the cloud server, and at this time, user U needs to pay the corresponding storage service fee to CSP. Otherwise, if the equation Γ_1 is not valid, it indicates that the data block $\{B_{ij}\}$ has been damaged or lost, and CSP needs to take corresponding responsibility and provide certain compensation for the damage or loss of the data. The mechanism of fair payment is shown in Fig. 6.

Smart Contract 2

Input: $ID_U; ID_{CSP}; Pay_{stor}; Pay_{comp}$
Output: $flag$
1: Compute EA_U;
2: Compute EA_{CSP};
3: **If** (Γ_1) **then**
4: $Pay = Pay_{stor}$;
5: $flag = 1$;
6: **Else**
7: $Pay = -Pay_{stor}$;
8: $flag = -1$;
9: **Return** $flag$

Fig. 5. Smart contract 2.

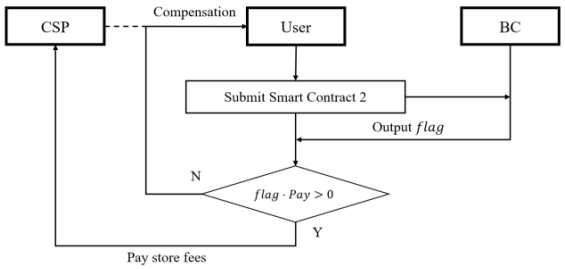

Fig. 6. Step-6 fair payment.

D. File Download

The user first submits a download request to the CSP and retrieves all encrypted data blocks. To verify the consistency of the data and restore the original file F, the process is as follows:

The encrypted data blocks are used as leaf nodes to construct a Merkle hash tree, from which the root node R_C is derived.

An external Multi-Party Computation (MPC) protocol is executed to verify the consistency of the data blocks. This step ensures a secure verification process without revealing any actual data to individual parties, while confirming that the blocks have not been tampered with.

The user then parses the transaction TX from the blockchain to extract the file identifier and associated verification metadata.

Verify the correctness of equation $\Gamma_2: e(\delta, g) = e(H(R_C), y)$. If the equation Γ_2 holds true, it confirms the integrity and authenticity of the data blocks.

The decryption keys K_{B_i} are securely distributed among multiple parties using the MPC protocol. This ensures that no single party has access to the complete decryption key, enhancing the security of the decryption process.

With the securely distributed keys, decrypt each data block using the AES-GCM algorithm:

$$B_i = AES\text{–}GCM\text{–}decrypt\left(K_{B_i}, C_{B_i}\right) \tag{13}$$

Reassemble the original file $F = \{B_i\}$ from the decrypted data blocks B_i.

Fig. 7 shows the complete file download process.

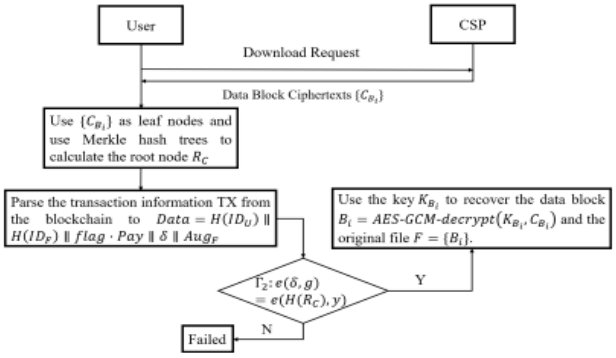

Fig. 7. File download.

E. File Update

When a data block B_i in file F needs to be updated to a new version, the process incorporates MPC to enhance privacy and security.

User U first encrypts the updated data block using the PBKDF2 key derivation function and the AES-GCM encryption algorithm to encrypt the updated data block B_i' to obtain the ciphertext C_i', and recalculates the homomorphic signature $\sigma_i' = (H(W_i) \cdot u^{C'_{B_i}})^x$. Subsequently, user U will send an update request (i, C_i', σ_i') to CSP. CSP replaces the ciphertext block C_i in file F with the new block C_i' and send $\{\varpi_i\}$ to user U, where ϖ_i represents the information of the sibling nodes associated with the path from $H(C_i')$ to the root node.

User U first calculates the value R_C of the root node based on $\{\varpi_i\}$ and $H(C_i)$, and then continues to verify whether the condition $\Gamma_2: e(\delta, g) = e(H(R_C)^x, g)$ holds. If it is true, it indicates that the position updated by the server is correct, that is, the ciphertext block C_i' is the updated block of ciphertext block C_i.

User U recalculates the value R_C' of the root node based on $\{\varpi_i\}$ and $H(B_i')$, and signs it $\delta' = H(R_C')^x$. Then, U recalculates the $Data = H(ID_U) \parallel H(ID_F) \parallel flag \cdot Pay \parallel \delta' \parallel Aug_F$, and finally integrates the $Data$ information into a blockchain transaction on the blockchain. The insertion and deletion operations of data blocks can refer to the data block update operations mentioned above.

V. Security Analysis

This section evaluates the proposed scheme against the adversarial threats defined in Section III and demonstrates how the system satisfies its key security objectives.

A. Data Integrity and Unforgetability

Theorem 1: If the user does indeed download the original uploaded data, then the user will be able to successfully pass data consistency verification, with the process further secured by MPC.

Proof: In this scheme, when users download encrypted data $\{CB_i\}$ from the CSP, it is necessary to verify the consistency of their data in order to recover the correct original plaintext F. To achieve this goal, users can utilize a Merkle hash tree to compute the root node R, where the root node R is determined by all data block ciphertexts $\{CB_i\}$ as leaf nodes. If any part of this information is altered, the value of R will also change accordingly. Users can verify the correctness of the following equation to detect data consistency.

If equation $\Gamma_2: e(\delta, g)$ holds true, it indicates that the downloaded ciphertext information $\{CB_i\}$ corresponds to the originally uploaded data. Subsequently, the user can recover the original file through convergence keys. Otherwise, if equation Γ2 does not hold true, it signifies that during the downloading process, the ciphertext of data blocks $\{CB_i\}$ has been corrupted.

B. Privacy Preservation

Theorem 1: This scheme can ensure the privacy protection of user data, and adversary X cannot obtain any useful information about user data during the integrity verification process.

Proof: The parameters $\{r, z, \mu, \delta, \sigma\}$ involved in this scheme do not expose any information about the user-uploaded data blocks B_i. In particular, there is a security vulnerability in the integrity verification scheme based on HLA, where in the integrity verification process, adversary X would utilize the generation of aggregate signature $\mu' = \sum_{i \in I} z_i C_{B_i}$, by repeatedly selecting indices (i, z_i) to obtain specific linear combinations. Finally, by solving linear equations, adversary X could extract user information contained in the aggregate signature.

C. Fair Payment Guarantee

The smart contract logic enforces incentive compatibility between the DO and CSP. Both parties deposit tokens before an audit round. The contract releases:

- Payment to the CSP if the audit passes.
- Refund or penalty compensation to the DO if the audit fails.

This design ensures that CSPs cannot receive rewards without proving data possession, and DOs cannot cheat without valid evidence. All transactions and outcomes are verifiable and immutable on the blockchain ledger, providing accountability without external arbitration.

D. Resistance to Replay and Collusion

Each audit challenge is freshly generated via secure on-chain randomness (e.g., Keccak-based hash or block nonce). Since the challenge indices and weights are unpredictable, a CSP cannot reuse previous responses (replay resistance).

In addition, the smart contract acts as an impartial, decentralized entity. Any attempt by DO and CSP to collude would be visible on-chain. Moreover, data tags and Merkle roots are bound to each user and file instance, making it infeasible to reuse or share tags across users (collusion resistance).

E. Soundness and Completeness of Verification

The verification algorithm satisfies:

- Completeness: If the CSP honestly stores all data and follows the protocol, verification always passes.
- Soundness: If any challenged block is corrupted or missing, the aggregated tag will not satisfy the bilinear verification equation, and the audit will fail with overwhelming probability.

Under the random oracle model, the probability of passing an audit without the correct data is negligible.

VI. Evaluation and Results

In this section, we evaluate the performance of our proposed scheme in terms of computational overhead, communication cost, and scalability. We also compare it against existing schemes to demonstrate its efficiency and practicality.

A. Experimental Setup

All experiments were conducted on a machine with an Intel Core i7-11700 CPU, 16 GB RAM, running Ubuntu 22.04. The implementation was developed in Python and Solidity. The blockchain environment is a local Ethereum testnet using Ganache, and smart contracts were deployed using the Truffle scheme.

We use the following cryptographic primitives:

- AES-GCM (128-bit) for symmetric encryption.
- Keccak-256 for hashing and challenge randomness.
- HLA over elliptic curve groups (BLS12-381).
- PBKDF2 for key derivation from file ID.

We evaluate performance on files ranging from 10 MB to 1 GB, and measure:

- Tag generation time
- Audit-proof generation and verification time
- Encryption time
- MPC overhead (optional component)
- Gas cost of smart contract interactions

B. Tag Generation and Upload Performance

As shown in Fig. 8, the tag generation time grows linearly with the file size. For a 100 MB file, the average tag generation takes 1.2 seconds, which is significantly lower than Zhou et al. and Sankar, both of which exceed 2.5 seconds under similar settings [10][11].

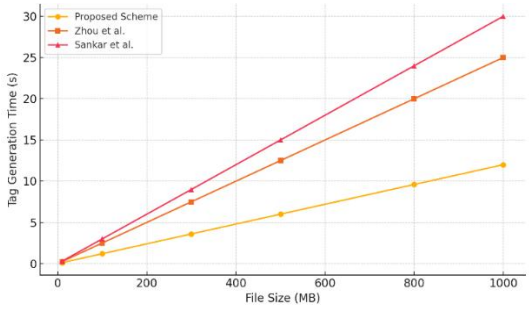

Fig. 8. Tag generation time vs. File size.

The AES-GCM encryption adds a fixed overhead of approximately 0.9 seconds per 100 MB, which remains acceptable in practice. Combined upload time remains under 2.5 seconds per 100 MB.

C. Audit Efficiency

Fig. 9 presents the time taken by the CSP to compute the audit proof and the time taken by the smart contract to verify it. Even for files of 500 MB, the audit process completes within 200 ms. The aggregated tag greatly reduces computational effort compared to verifying each block individually.

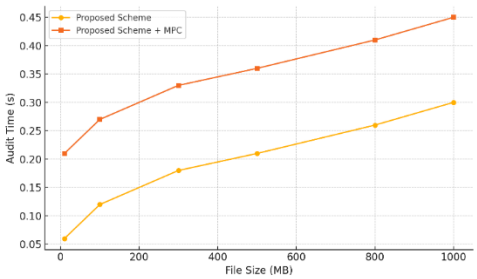

Fig. 9. Audit time vs. File size.

With MPC enabled, verification time increases modestly due to interaction rounds, reaching 420 ms for a 500 MB file. However, this added cost ensures privacy without revealing μ.

D. Data Update Overhead

Fig. 10 shows the cost of a single block update (modify/insert/delete). Tag recomputation and Merkle tree adjustment combined take less than 80 ms per block. On-chain update verification (including Merkle path) adds ~15,000 gas (~$0.03 equivalent on Ethereum).

This demonstrates that dynamic updates are practical and lightweight.

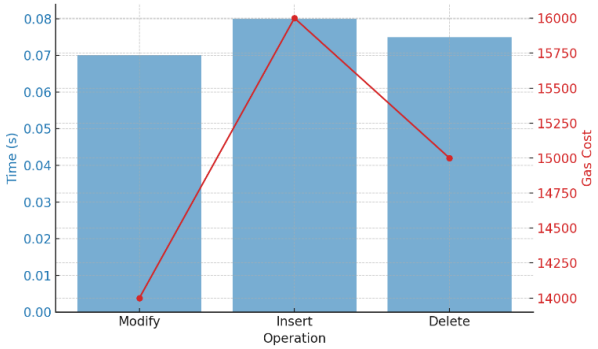

Fig. 10. Update overhead per operation.

E. Smart Contract Gas Cost

Fig. 11 shows the estimated gas consumption of core smart contract functions. Contract 1 handles audit-related operations, while Contract 2 governs fair payment and dispute resolution. Deployment is the most gas-intensive, followed by storage-heavy and payment functions.

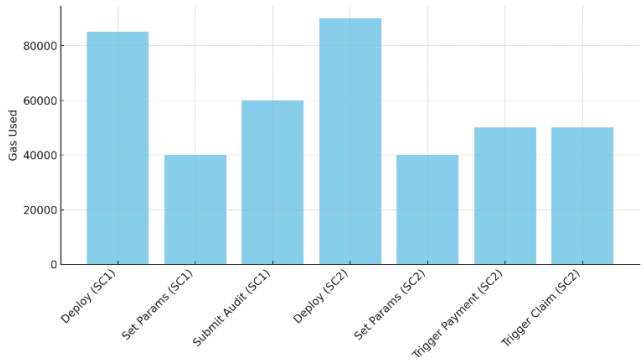

Fig. 11. Smart contract gas consumption.

The core smart contract functions involved in each audit namely, submitting audit evidence and triggering payment consume approximately 90,000 to 100,000 gas in total, which demonstrates the practical feasibility and scalability of the proposed scheme.

F. Comparison with Existing Schemes

Fig. 12 compares our scheme with Zhou et al. and Liu in terms of audit latency and update overhead [10][13]. This scheme consistently outperforms baselines due to:

- Tag aggregation via HLA (vs. per-block tag checking).
- No third-party verifier involvement.
- On-chain automation via smart contracts.

For 1 GB files, our scheme achieves 35 to 50 per cent reduction in audit time and 30 per cent lower update cost.

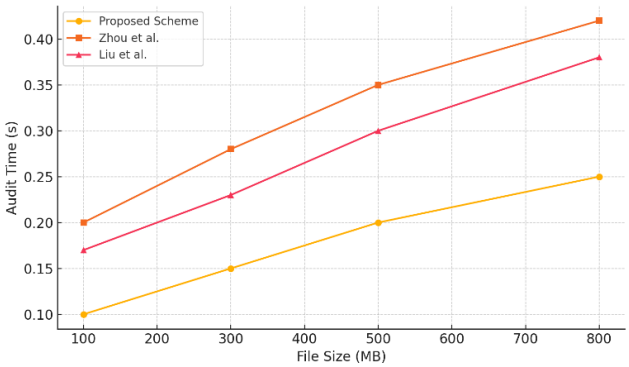

Fig. 12. Comparison with existing schemes.

VII. Conclusion

This study proposes a blockchain-based integrity verification scheme for encrypted cloud data that achieves decentralized auditing, privacy preservation, and fair economic incentives. By integrating Homomorphic Linear Authenticators (HLA), Multi-Party Computation (MPC), and smart contracts, the scheme eliminates reliance on third-party auditors and ensures automatic and transparent dispute resolution and payment settlement between data owners and cloud service providers. The system supports dynamic data operations and enables encrypted data verification without exposing plaintext information. Security analysis confirms that the scheme achieves data integrity, confidentiality, fairness, and resistance to replay and collusion attacks. Experimental results further demonstrate that the proposed protocol achieves low audit latency, acceptable computation and communication overhead, and practical gas consumption.

Despite its advantages, the proposed scheme has several limitations. First, the use of MPC introduces additional communication overhead, which may affect performance in large-scale or resource-constrained environments. Second, the prototype is designed for a single-cloud setting and does not fully consider multi-cloud interoperability or cross-chain audit synchronization. Third, the cost of deploying smart contracts and executing transactions on public blockchains may increase under high network congestion or volatile gas prices.

Future research will focus on three directions:

- Optimizing the MPC protocol and reducing on-chain interaction costs through lightweight cryptographic primitives or zero-knowledge proofs;
- Extending the framework to support multi-cloud and cross-provider integrity verification, enabling collaboration and redundancy among distributed storage services;
- Migrating the scheme to Layer-2 or permissioned blockchain platforms to reduce gas consumption and enhance scalability.

***Abstract*—Non-invasive neural speech interfaces aim to reconstruct intended words from brain activity, offering critical communication options for individuals with severe dysarthria or locked-in syndrome. Among the available recording modalities, electroencephalography (EEG) remains the most accessible and cost-effective choice for long-term brain–computer interface (BCI) applications. Decoding imagined speech from EEG, however, remains difficult because of low signal-to-noise ratio, pronounced inter-subject variability, and the small, heterogeneous corpora that are currently available. This review adopts a narrative methodology to synthesise peer-reviewed studies on EEG-based imagined-speech decoding. Relevant articles were identified through keyword-based searches in major digital libraries and were included if they used non-invasive EEG, explicitly instructed imagined or covert speech, and reported quantitative decoding performance. The selected studies are organised along the processing pipeline, from experimental paradigms and data acquisition to preprocessing, feature extraction, representation learning, and classification. Across this body of work, binary imagined-speech tasks that rely on carefully designed time–frequency features and shallow classifiers often report accuracies above 80 percent, whereas multi-class word or phoneme recognition exhibits a much wider spread of performance and remains highly sensitive to dataset design and evaluation protocol. Recent trends favour convolutional and recurrent neural networks, temporal convolutional networks, and transfer learning strategies, which improve performance on some datasets but do not yet resolve fundamental issues of restricted vocabularies, inconsistent evaluation practices, and limited cross-subject generalisation. The review distils these observations into practical recommendations for dataset construction, model design, and evaluation protocols and outlines research directions aimed at more robust and clinically meaningful EEG-based imagined-speech BCIs.**

***Keywords*—Electroencephalography (EEG); Imagined speech; Brain–Computer Interfaces (BCIs); neural speech decoding; deep learning; transfer learning; time–frequency analysis; evaluation protocols**

I. Introduction

Human–computer interaction is increasingly seeking to bypass impaired neuromuscular pathways by directly reading intent from the brain. Brain–computer interfaces (BCIs) instantiate this vision by translating neural activity into actionable commands, opening communication channels for people with severe dysarthria or locked-in syndrome (e.g., ALS) [1]. Among BCI paradigms, imagined speech, which involves mentally articulating words without overt movement, provides a highly natural control signal that aligns closely with the cognitive actions users intend to perform.

Multiple neuroimaging modalities have been explored for imagined speech, such as electroencephalography (EEG) [2], [3], electrocorticography (ECoG) [4], and magnetoencephalography (MEG) [5]. EEG remains the most practical route for broad deployment due to its non-invasiveness, portability, and millisecond-scale temporal resolution [2], [3]. Yet decoding imagined speech from scalp potentials is intrinsically difficult: signals are low-amplitude and noisy, non-stationary across sessions, and highly variable across subjects; vocabularies are small; and existing corpora are heterogeneous and limited in size [6], [7]. These factors jointly confound generalisation and inflate reported accuracies under convenient but optimistic evaluation splits.

Early pipelines relied on handcrafted representations, band-limited filtering, and artefact suppression techniques (such as notch filtering and Independent Component Analysis, or ICA). This was followed by the extraction of features like Common Spatial Patterns (CSP), Power Spectral Density (PSD), wavelets, Hjorth parameters, and Riemannian mappings, which were then fed into conventional classifiers. Recent advancements have shifted towards deep learning methods for end-to-end representation and sequence modelling. Convolutional Neural Networks (CNNs) are now commonly used to capture spatial-spectral structures, while Bidirectional Long Short-Term Memory networks (BLSTMs) and Transformers are employed to model temporal dynamics. This approach is often supplemented by transfer learning and self- or contrastive pretraining to address challenges such as data scarcity and cross-subject variability [8], [9]. Although there has been encouraging progress, the field still lacks unified protocols for train/test splits (intra- vs. cross-subject), consistent metrics (accuracy/F1 vs. sequence-level WER), and transparent baselines with code releases. These limitations hinder reproducibility and fair comparisons across imagined speech datasets [5].

Several review articles have previously examined speech-related brain–computer interfaces and neural speech decoding from a broad perspective, often spanning both invasive and non-invasive modalities or merging imagined speech with overt, whispered, or attempted speech paradigms. These surveys are valuable for framing the overall landscape,

*Corresponding author.

particularly the neurophysiology of speech production and the evolution of decoding architectures, yet they often treat EEG-based imagined speech as a secondary case within a wider taxonomy of neural speech interfaces [45], [46], [47], [48]. As a result, key methodological details that strongly determine EEG performance, such as trial segmentation conventions, artefact handling, representation choices, and cross-subject evaluation practice, are frequently dispersed across sections rather than consolidated into an end-to-end pipeline view. In contrast, the present review is deliberately scoped to non-invasive EEG-based imagined-speech decoding and is organised along the full processing chain from acquisition and signal conditioning to representation learning and evaluation, with the aim of making both the current state of the art and its unresolved gaps more transparent to readers.

This article adopts a narrative review methodology with a defined scope and explicit selection criteria to improve transparency and replicability. Relevant literature was identified through keyword-based searches in major digital libraries, including IEEE Xplore, PubMed, Scopus, and Google Scholar, using combinations of terms such as “imagined speech”, “covert speech”, “silent speech”, “EEG”, “brain–computer interface”, and “neural speech decoding”. Studies were included if they used non-invasive EEG in human participants, employed explicit imagined or covert speech tasks at the level of phonemes, syllables, words, or short phrases, and reported quantitative decoding results. Studies were excluded if they relied solely on invasive recordings, did not include an imagined-speech component, or were non-empirical papers without original experimental evaluation. Screening was performed in two stages, first by title and abstract to remove clearly irrelevant work, then by full-text inspection to verify modality, task design, and reported outcomes. To reduce selection bias and ensure coverage of influential lines of work, citation chaining was applied to key papers, and the final set was prioritised toward peer-reviewed sources that reported sufficient experimental detail to permit methodological comparison, particularly regarding preprocessing, data splits, and evaluation metrics.

The objectives of this review are to:

- Summarise publicly available imagined-speech EEG datasets, their experimental paradigms, acquisition setups, preprocessing techniques, and data-structuring strategies for deep learning;
- Provide actionable recommendations for designing efficient and generalisable deep-learning architectures tailored to EEG-based imagined-speech decoding; and
- Examine the potential of EEG-driven deep learning for advancing neural speech interpretation and assistive communication technologies.

The remainder of this paper is organised as follows. Section II reviews the foundations of EEG, data acquisition protocols, and preprocessing methods. Section III presents feature engineering and deep learning approaches. Section IV discusses evaluation protocols and metrics. Section V synthesises results and discussion, and Section VI concludes with future research perspectives.

II. EEG Foundations, Data Acquisition, and Preprocessing

A. Electroencephalography (EEG)

Electroencephalography (EEG) is a non-invasive method for measuring brain electrical activity, where electrodes placed on the scalp detect voltage differences generated by brain transmissions, forming signals [10]. EEG systems typically use 14–64 electrodes, producing multidimensional signals, and are favoured for Brain-Computer Interfaces (BCIs) due to their non-invasiveness, simplicity, and high temporal resolution. However, EEG is susceptible to motion artefacts and myoelectric interference, especially during spoken language, posing challenges for Automatic Speech Recognition (ASR) [11]. Despite these challenges, EEG has been effectively used to analyse perceived speech and classify imagined phonics [12].

EEG signals are categorised into five frequency bands: gamma (>35 Hz), beta (12–35 Hz), alpha (8–12 Hz), theta (4–8 Hz), and delta (0.5–4 Hz) [13], each of which corresponds to distinct cognitive states. Gamma waves, for example, are linked to overt and covert speech, showing significant changes in various brain regions [14]. Beta waves are associated with muscle activity and speech generation, while alpha waves are crucial for auditory feedback and speech perception, with lower frequencies during covert speech [3]. Theta waves support phonemic restoration and the processing of coarticulation cues [14], aiding in consonant identification [15]. Lastly, delta waves play a role in intonation, rhythm, and other speech-related processes [16].

B. Data Acquisition

Acquiring high-quality EEG data is pivotal in developing Brain-Computer Interface (BCI) systems for deciphering imagined speech. The process involves recording the brain's electrical activity through electrodes on the scalp. This section outlines the key factors and methodologies for collecting EEG data for imagined speech recognition.

In the study, participants were presented with speech cues (either vowels or words) through visual, auditory, or audiovisual means. When these cues were shown before the imagery of speech, participants memorised them, which helped to differentiate the imagined speech task from reading or listening tasks. Participants engaged in imagined speech while simultaneously performing reading or listening tasks in scenarios where cues were provided concurrently. It is important to note that listening and reading activate different areas of the brain: the temporal lobes are involved in listening, while the occipital lobes are activated during reading. Therefore, the format of the cues and their timing in relation to imagined speech can impact brain activation patterns.

The acquisition protocol of the Arizona State University dataset [17] solely employed visual cues, presented simultaneously with an imagined speech recording. Subjects performed speech imagery at each "beep" until cue cessation (7 x T seconds), using short and long words. Common Spatial Pattern (CSP) was applied to identify active brain areas. Results highlighted activity primarily in the left frontal, middle, and parietal regions, corresponding to the motor cortex and

language areas. The KaraOne dataset [18] employing separate cue presentation aimed at distinguishing pronounced and imagined speech states. Central brain areas showed discriminative features. Without a specified rationale, Coretto et al. [19] employed a distinct protocol utilising audio and visual cues before imagined speech tasks. They used vowels and Spanish words, recording EEG data without spatial analysis. Further investigation is warranted to ascertain brain regions involved in cue processing.

Studies have elicited speech imagery at multiple linguistic levels, including vowels [17], phonemes [18], syllables [20], words [21], [22] and sentences [23] .As summarised in Fig. 1, word classification constitutes the largest share of reported EEG imagined-speech tasks, followed by vowel and phoneme or consonant–vowel targets, with a smaller fraction devoted to phrase-level decoding and symbol-like targets (digits or letters). This distribution is not only a matter of experimental convenience. Coarser targets such as isolated words reduce label ambiguity, shorten annotation pipelines, and often permit simpler evaluation, whereas phoneme-level and phrase-level settings impose stricter demands on temporal alignment, representation capacity, and cross-subject robustness. Consequently, comparisons across papers should be interpreted in light of the underlying task unit, because “high accuracy” in a small closed vocabulary does not imply comparable progress toward open-vocabulary decoding.

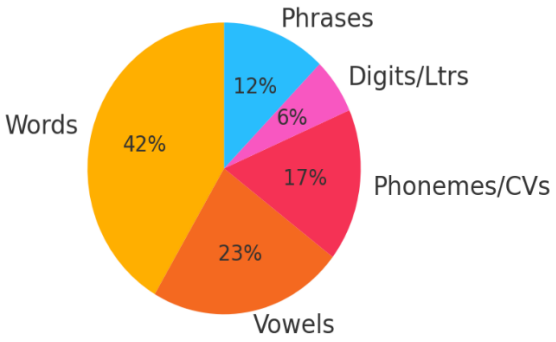

Fig. 1. Speech unit types across studies.

Sub-lexical units, such as vowels, phonemes, and syllables, are often used to focus on early planning and articulatory coding. In contrast, lexical items and binary-response questions (like yes/no) explore message preparation with a greater emphasis on syntactic and semantic complexity. From the literature we reviewed, we identified 28 EEG datasets related to imagined speech: eight are publicly available and twenty are private. Dataset selection is concentrated around a small number of publicly available corpora, which shapes what is routinely benchmarked and what remains underexplored. Fig. 2 shows that Kara One, the Coretto database, and the ASU dataset dominate the empirical evidence base, while other datasets appear only sporadically. This imbalance has practical implications. First, methodological “trends” can become dataset-specific, optimised to a narrow range of paradigms and recording setups. Second, generalisation claims are often constrained by repeated evaluation on the same few corpora, sometimes with inconsistent splitting conventions across studies. For readers, the figure clarifies why cross-dataset conclusions should be framed cautiously, and why broader benchmarking across heterogeneous corpora is essential for credible progress.

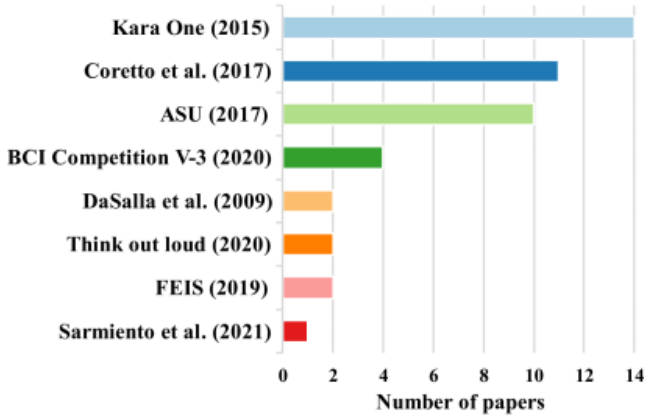

Fig. 2. EEG-based imagined speech public datasets.

In summary, collecting EEG data for imagined speech recognition is a complex process that involves configuring the EEG system, removing artefacts, designing experiments, and taking individual subject considerations into account. Advances in EEG technology and data acquisition methods hold promise for improving brain-computer interface (BCI) systems tailored for imagined speech applications.

C. Preprocessing Techniques

During imagined speech tasks, the raw EEG signals are prone to various artefacts and noise, which can significantly impair subsequent feature extraction and classification stages. Hence, suitable preprocessing methods are crucial for enhancing the signal-to-noise ratio and extracting pertinent information from the EEG data. Nonetheless, effectively cleaning the data without sacrificing important information or features for later analysis or pattern recognition remains challenging. It's crucial to remove noise before downsampling to avoid misinterpreting downsampled values as noise.

In cases where EEG acquisition involves a high sampling rate, such as 1000Hz, downsampling is often employed to balance computational efficiency and data integrity. However, it may lead to the loss of important features. Thus, using the original sample size could facilitate observing discriminative speech recognition features while considering available resources [24].

Standard preprocessing techniques include band-pass filtering, blind source separation (BSS), and subtracting mean values from each channel to remove high-frequency noise and focus on the frequency bands most relevant for speech processes [12]. Notch filters at 60 Hz and band-pass filters with various frequency ranges, such as 0.5-100 Hz [25], 1-50 Hz [26], and 2-40 Hz [27], have been applied to eliminate powerline interference, and the signals were segmented into 5-second epochs with a 0.5-second overlap to capture temporal dynamics. Other preprocessing methods include independent component analysis (ICA) [7], artefact removal [28], sliding window data augmentation [29], and baseline correction [28]. As a result, end-to-end learning methods that require minimal

preprocessing have gained interest in EEG classification. However, directly classifying nearly raw EEG signals remains challenging and requires further investigation [30].

III. Representation Learning and Decoding

In most imagined-speech studies, EEG processing follows a broadly similar structure. After artefact removal and band-limited filtering, continuous recordings are segmented into trials aligned with cue onsets or imagery windows. These trials are re-referenced or normalised, then transformed into representations that emphasise spatial patterns, spectral content, temporal dynamics, or connectivity structure. Handcrafted features compress each trial into a fixed-dimensional vector, which is then passed to a classifier, while deep models often operate directly on multichannel time series or time–frequency maps and learn discriminative features jointly with the decoder. The subsections below describe the main feature-extraction strategies and classification approaches used in this pipeline.

A. Feature Extraction

Feature extraction is a central step in decoding imagined speech from EEG, since it determines how rich but noisy neural activity is converted into stable and discriminative representations for BCI systems. The aim is to retain task-relevant information while suppressing background activity and artefacts. Commonly used transformations include Fourier, wavelet, and Hilbert–Huang decompositions, as well as spatial filtering techniques such as Common Spatial Patterns (CSP) and Principal Component Analysis (PCA). These families of methods, together with their typical application scenarios, can be conveniently summarised in a feature taxonomy table, for example Table I, to provide readers with a compact overview of the design space.

Because EEG is inherently a time-series signal, several studies have relied on time-domain models such as autoregressive (AR) coefficients [31] or borrowed representations from speech processing, such as Mel Frequency Cepstral Coefficients (MFCC) [32]. On the KARAONE dataset, MFCC features achieved higher performance than simple statistical and non-linear descriptors, with reported accuracies of 19.69 percent for MFCC, 15.91 percent for statistical features, and 14.67 percent for non-linear features on an 11-class task, where chance level is 9.09 percent [33]. This pattern is consistent with the intuition that MFCCs capture spectral envelopes and formant-related structure that are more tightly linked to articulatory and phonetic content than raw amplitude statistics. In a related line of work, some authors have treated EEG segments as sequences of local "visual words" and applied Bag of Features (BoF) models, effectively borrowing ideas from text and image representation to capture recurring temporal patterns [34].

Functional and effective connectivity features have received comparatively less attention in imagined-speech decoding, despite their potential to quantify coordinated activity across brain regions. Qureshi et al. [35] employed functional connectivity descriptors, including covariance and the maximum linear cross-correlation coefficient (MaxLCor), and reported 87.90 percent accuracy in a binary imagined-speech classification task. Pawar et al. [36] combined MaxLCor with Discrete Wavelet Transform (DWT) features and obtained 40.64 ± 2.45 percent accuracy. These results suggest that connectivity measures can enhance discrimination, particularly when combined with spectral or time–frequency features, but they have not yet been systematically explored for larger vocabularies or more challenging cross-subject settings.

A further design decision concerns whether features are extracted per channel or jointly across channels. Single-channel analysis is simpler and can highlight localised activity, but simultaneous extraction from multiple channels provides a more realistic view of distributed speech networks. Channel cross-covariance (CCV) matrices are a common way to encode such multichannel structure, since they aggregate relationships between electrodes into a compact form that can be processed by classical or deep models [37]. CCV can be computed in both time and frequency domains and over different window lengths, such as 0.25, 0.5, or 1 second, which allows the representation to trade temporal resolution for robustness [38].

Beyond these families, several works have employed Mel Frequency Cepstral Coefficients (MFCC) [25], Discrete Wavelet Transform (DWT) [21], Wavelet Packet Decomposition (WPD), Short-Time Fourier Transform (STFT) [28], and low-order statistical descriptors [15], [21]. In some cases, investigators have treated the raw microvolt values across channels as a high-dimensional feature vector without additional handcrafted compression [39]. This strategy maximises information content but places a heavier burden on the classifier and typically requires larger datasets or strong regularisation. Overall, the literature reflects a gradual evolution from hand-engineered spectral and spatial markers toward more structured, multichannel representations that are better suited for deep learning.

B. Classification Approaches

Once features have been extracted, the next step is to map each trial to its corresponding imagined-speech category, for example, a word, phoneme, or binary decision. The literature spans a spectrum of classifiers, from shallow machine learning models to deep neural architectures, each motivated by different assumptions about the structure and complexity of EEG data.

Early work relied primarily on traditional machine learning algorithms. Nguyen et al. [40] represented trials as tangent vectors on a Riemannian manifold of covariance matrices and employed a multiclass relevance vector machine to discriminate vowels and short words, achieving accuracies up to 49 percent. This approach leverages the geometry of covariance space to improve robustness but remains limited by linear decision boundaries in the tangent space. Sereshkeh et al. [41] combined autoregressive coefficients and DWT features with a support vector machine (SVM) and achieved 69.3 percent accuracy in online decoding of binary "yes" versus "no" decisions, highlighting the strength of SVMs when feature engineering is carefully tuned to the task. Cooney et al. [33] compared multiple feature sets and found that MFCC features paired with an SVM classifier produced the best performance on an 11-class imagined-speech task, with 22.7

percent accuracy, which exceeds chance but also illustrates the difficulty of multi-class decoding in realistic scenarios.

As datasets and vocabularies grew, many studies shifted toward deep learning to learn representations and decision boundaries jointly. Several efforts have combined Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) to capture spatial and temporal structure, respectively [42]. In some cases, feature vectors, for example channel covariance matrices, are passed through a Deep Autoencoder (DAE) that compresses them into low-dimensional latent codes, which are then used for classification. Siamese networks have been introduced to refine these latent spaces by enforcing that trials with the same label are mapped closer to one another than trials from different classes, which improves discriminability in settings with limited training examples [30]. Using the same Coretto dataset [19], such metric-learning extensions have been reported to outperform baseline architectures without Siamese constraints [27].

To clarify the methodological landscape before comparing individual architectures, Fig. 3 presents the distribution of model families used across the selected studies. The figure is created by categorising each paper according to its primary decoding approach- such as conventional machine learning with handcrafted features, CNN-based models, recurrent or sequence models, and transfer learning or hybrid methods- and then summing these categories throughout the survey. Two key observations emerge: first, deep learning currently dominates recent research, due to its ability to learn task-relevant features directly from noisy, high-dimensional EEG data; second, traditional pipelines remain common in small-data scenarios because their inductive biases and fewer parameters make them easier to train and interpret. This distribution guides the organisation of Section III.B, which compares model families based on the specific problem constraints they address, rather than treating architectures as interchangeable options.

Deep learning architectures explored in this context include pure CNNs, CNN combined with Long Short-Term Memory (LSTM) units, and Deep Autoencoders [7], [28]. Hierarchical designs, in which features are learned at multiple levels using stacked CNN, temporal CNN (TCNN), and DAE modules, have also been proposed [12]. Other classifiers include Random Forests (RF) [15], Support Vector Machines (SVM) [7], K-Nearest Neighbours (KNN), Naive Bayes [39], Deep Belief Networks (DBNs) [43], transfer learning schemes [29], Recurrent Neural Networks (RNNs) [43], Temporal Convolutional Networks (TCNs) [44], bimodal deep neural networks with fusion layers, Transformer-based models, and Capsule Networks. These architectures differ in how they trade off expressiveness, parameter count, and data requirements, but they share the objective of capturing complex, non-linear relationships that cannot be modelled by shallow classifiers.

Reported accuracies span a wide range and depend strongly on task design and dataset characteristics. For binary problems such as distinguishing vowels from consonants (C/V), detecting the presence or absence of nasality (±Nasal), identifying bilabial articulation (±Bilabial), or discriminating specific phonemes like /iy/ and /uw/, accuracies between 69 percent and 89 percent have been reported [26], [45]. Multi-class tasks that target larger phoneme inventories or full words achieve more variable performance, with accuracies reported from around 24.19 percent up to 97.34 percent [12], often under subject-dependent or session-specific splits that may be optimistic. Transfer learning approaches that initialise models from related EEG tasks or from other subjects have also been investigated, with accuracies of 65.65 percent [39] and 95.5 percent [29] reported in particular configurations. These figures demonstrate the potential of advanced classifiers but also underline the difficulty of comparing methods across studies with different protocols.

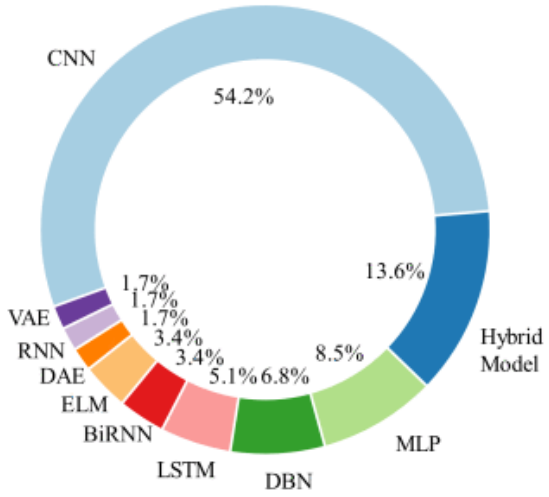

Fig. 3. Distribution of model families used for EEG imagined-speech decoding in our survey.

Despite these advances, several challenges remain for classification in imagined-speech EEG. Inter-subject variability and non-stationarity across sessions make it difficult to design models that generalise reliably beyond the conditions in which they were trained. The limited size of most labelled datasets constrains deep architectures and increases the risk of overfitting, particularly in multi-class problems and when moving toward phrase or sentence-level decoding. Current results therefore, provide important proof-of-concept evidence, but they also point to the need for larger and more diverse datasets, more rigorous cross-subject and cross-session evaluations, and classifier designs that explicitly address variability and uncertainty in real-world settings. These issues are closely linked to the evaluation protocols and metrics discussed in the following section.

IV. Evaluation Protocols and Metrics

The thorough evaluation of imagined-speech decoders relies on three key components: the metric, the validation approach, and the subject segmentation. These factors collectively influence the comparability and reliability of the reported findings across different studies. Reported evaluation practice is dominated by a narrow set of metrics, which partly explains why headline results can be difficult to compare across papers. As summarised in Fig. 4, accuracy is by far the most frequently reported metric, while complementary

measures that reveal class imbalance effects and decision reliability, such as sensitivity, specificity, F-score, and AUC, appear less consistently. Statistical testing and effect-size reporting are rare, despite the known variance induced by subject identity, session effects, and split choice. The practical consequence is that two studies may report similar accuracies while differing substantially in error structure and operational usefulness, particularly in multi-class settings where confusion patterns matter. This motivates the use of a minimal, standard metric set that pairs accuracy with class-sensitive and uncertainty-aware reporting, and it reinforces the need to publish confusion matrices and split protocols alongside aggregate numbers.

In the literature reviewed, accuracy emerges as the most common outcome measure, used in 96.6% of publications, primarily because of its straightforward interpretation for established vocabularies. To assess agreement beyond random chance and reduce issues related to class imbalance, numerous studies also present Cohen's κ (13.6%). Many researchers enhance a single scalar metric with a confusion matrix (27.1%), from which precision/PPV (11.9%), recall/sensitivity/TPR (16.9%), specificity/TNR (2%), and the F-score (15.3%) are calculated. When a classifier's function is based on a continuous decision variable or a threshold score, ROC curves and AUC serve as suitable summaries.

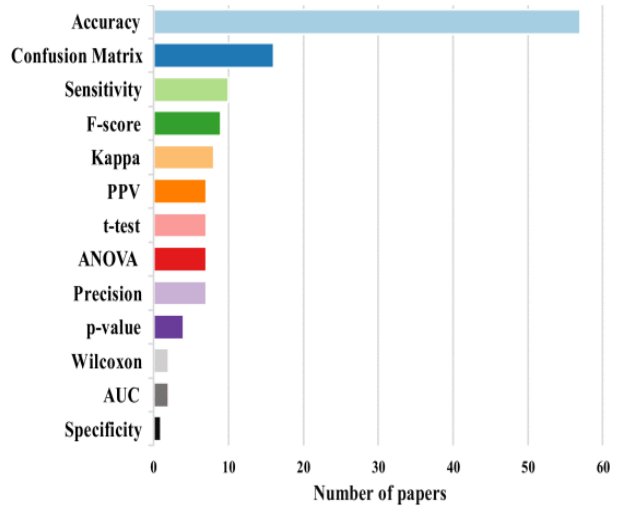

Fig. 4. Frequency of evaluation metrics reported in EEG imagined-speech studies.

Statistical testing is not yet routine in imagined-speech EEG studies, although it is essential for separating genuine methodological gains from variance induced by subject identity and split choice. Across the surveyed papers, roughly one third report inferential evidence, using p-values, t-tests, ANOVA, or non-parametric alternatives such as the Wilcoxon signed-rank test to quantify improvement over baselines. Validation practice is similarly uneven. Hold-out evaluation remains common, but cross-validation is more frequently adopted, and a substantial subset of studies explicitly reserves a validation set for hyperparameter selection, which is particularly important for deep models where tuning decisions can dominate reported performance. These methodological choices interact directly with the most consequential design decision in this literature, namely whether evaluation is subject-dependent or subject-independent. Most studies still follow subject-dependent testing, which typically yields higher scores because the model is assessed on participants represented during training. Consistent with this pattern, stronger results under subject-dependent settings have been reported in [82] and [77]. Subject-independent evaluation is more difficult because inter-subject variability is large and non-stationary, but it is the setting that best reflects practical deployment. For example, although [62] reported that a new deep model improves over conventional baselines, performance across unseen subjects remains weaker than within-subject testing. Against this methodological background, Fig. 5 summarises reported accuracies by target type. Short word sets tend to produce higher central performance than phoneme-level decoding, with vowel classification typically intermediate, a hierarchy that follows expected differences in temporal granularity and class separability. Fig. 5 also includes a sentence-level reference group from high-density ECoG, which provides an upper-bound context given its higher signal fidelity and should not be interpreted as directly comparable to scalp EEG. Overall, the figure reinforces a practical interpretation principle: progress should be judged not only by peak accuracy, but by robustness under stricter splits and by performance retention when moving from simplified targets toward linguistically richer decoding tasks.

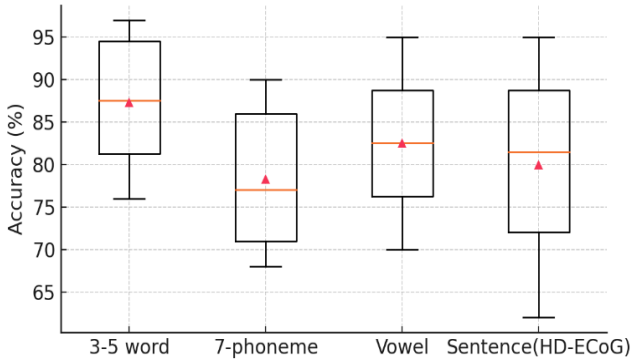

Fig. 5. Reported accuracy ranges per task granularity.

V. Results and Discussion

The surveyed literature shows that EEG-based imagined-speech decoding has moved from proof-of-concept demonstrations to increasingly sophisticated pipelines that combine advanced preprocessing, feature learning, and deep classifiers. Yet, even the strongest reported systems remain some distance from robust, general-purpose communication tools. The gap arises from a combination of signal-level limitations, constrained datasets, substantial inter-subject variability, and heterogeneous evaluation practices that make it difficult to compare methods or to judge their readiness for real-world use.

The corpus of studies considered in this review was drawn from major digital libraries and includes work that focuses on artificial intelligence techniques, feature extraction methods, signal filtering, and data acquisition strategies for speech-related EEG decoding. Most of the selected articles are peer-reviewed journal publications [45], [46], [47], [48], with a

noticeable concentration of contributions from research groups in Korea and India [30], [47], [21], [26]. Foundational work appeared between 2013 and 2016, but the number of publications increased sharply in 2020 and 2021, reflecting a recent shift toward deep learning and transfer learning approaches in this domain.

Table I provides a compact overview of representative studies on EEG-based imagined-speech decoding. It lists, for each work, the task design, preprocessing steps, feature extraction methods, classifiers, and corresponding accuracies. Several patterns emerge. Binary imagined-speech tasks, such as distinguishing a small set of directional commands or phonological contrasts, frequently report accuracies above 80 percent [21], [44], while multi-class settings display wider variation, with values ranging from about 24 percent to above 90 percent depending on vocabulary size, feature choices, and the evaluation protocol [12], [20], [59], [60], [61], [63]. Methods that rely on rich time–frequency representations, including DWT, RADWT, SPWVD, and other time–frequency images coupled with CNN or TCN architectures, account for many of the top-performing models [21], [44], [59]–[61]. Transfer learning, often with ResNet or DenseNet backbones, yields additional gains when labelled data are limited [20], [29], [54].

In comparative terms, EEG-based decoding still trails invasive or high-field modalities in maximum performance. ECoG studies have reported accuracies of 88.3 percent for pairwise imagined-speech classification [49] and 98.8 percent for syllable recognition using spatio-spectral feature clustering [50]. MEG-based systems have achieved phrase classification accuracies around 95 percent [51]. These results illustrate what is possible when spatial resolution and signal-to-noise ratio are high, but they depend on invasive surgery or bulky laboratory hardware. EEG, by contrast, is non-invasive, relatively inexpensive, and portable, which makes it attractive for eventual clinical and home use despite its lower ceiling on accuracy. In practice, current EEG systems are most promising when restricted to modest vocabularies, such as command sets including “up”, “down”, “left”, “right”, “forward”, “backward”, and “select”, which can control screens, mobile devices, or prosthetic devices [52].

To turn this heterogeneous body of work into a coherent roadmap, the remaining discussion is organised into four closely related themes: signal quality and representation, dataset scale and linguistic diversity, individual variability and generalisation, and evaluation protocols and practical deployment. Each theme is framed as an open challenge, then linked to existing studies that partly address it, and finally used to motivate specific directions for future research.

A. Signal Quality and Representation

Low signal-to-noise ratio is an intrinsic limitation of non-invasive EEG. Imagined speech generates weak and spatially diffuse activity that must be recovered in the presence of ocular, muscular, and environmental artefacts. Many of the works in Table I address this by combining classical denoising, such as bandpass and notch filtering, Independent Component Analysis, and Common Average Referencing, with carefully designed features [20], [21], [60], [61]. Time–frequency methods, including DWT, RADWT, SPWVD, and other time–frequency images, further concentrate energy into discriminative bands. When these representations are fed to CNNs, TCNs, or hybrid deep architectures, substantial performance gains are obtained [21], [44], [59]–[61].

These approaches, however, remain tailored to controlled imagery windows and predefined frequency ranges. They are rarely tested in more naturalistic, continuous settings, and their performance may degrade when task timing is variable or when artefact statistics change between sessions. Moreover, most feature pipelines are hand-tuned to particular datasets, which complicates reuse across tasks. One natural extension of the current literature is to replace fixed front-ends with adaptive or learned ones that are trained jointly with the classifier, for example, denoising autoencoders, learnable filterbanks, or self-supervised objectives that encourage separation of neural signal and artefacts. Such work would build directly on the existing time–frequency and connectivity-based representations, but would aim to make them more robust and less dependent on manual feature engineering.

B. Dataset Scale, Vocabulary, and Linguistic Diversity

A second, closely related challenge concerns dataset size and linguistic coverage. Many studies in Table I employ relatively small subject pools and limited vocabularies, often focusing on a handful of vowels, short words, or simple commands [21], [44], [59]–[61], [63]. This is understandable, since imagined-speech experiments are demanding and EEG recording sessions are time-consuming. Nevertheless, small datasets restrict the expressive power that can be used in models, and they make it hard to separate genuine algorithmic improvements from overfitting to narrow tasks. A few works have attempted to move beyond this constraint by combining datasets such as FEIS and KARAONE [20], [29], [59] or by constructing tasks involving subject, verb, and object words [62]. These studies demonstrate that richer vocabularies are technically feasible, but they also highlight the need for more extensive collections of trials if vocabulary size and linguistic variability are to increase.

Language and phoneme variability adds another layer of complexity that has not yet been fully explored. Most experiments are carried out in a single language, with phoneme sets chosen for convenience or for strong acoustic–articulatory contrasts. FEIS and KARAONE provide broader phonetic inventories and are valuable in this respect [20], [59], [60], but there is little systematic work on how language-specific phonology or prosody influences EEG decodability. Future datasets that are designed from the outset to be multi-lingual and multi-phonemic, with shared vocabularies and standardised splits, would enable these questions to be addressed. They would also provide a more solid foundation for the transfer learning strategies already investigated in [20], [29], [54], which rely on diverse data to learn generalisable representations.

C. Individual Variability and Generalisation

Inter-subject and inter-session variability remains one of the most significant barriers to robust imagined-speech decoding. Anatomical differences, variations in electrode placement, and individual cognitive strategies all contribute to

changes in the recorded signal. Many of the highest accuracies in Table I come from subject-dependent or mixed-trial evaluations, where training and test sets share data from the same individuals and recording sessions [44], [59]–[61], [63]. In such settings, complex models can learn idiosyncratic patterns and achieve strong performance, but this success does not guarantee generalisation to new users or days.

TABLE I. SUMMARY OF REPRESENTATIVE STUDIES ON EEG-BASED IMAGINED SPEECH DECODING

Ref.	Task	Preprocessing Method	Feature Extraction	Classification Method	Accuracy
[21]	Muti-class and binary classification of “left,” “right,” “up,” and “down.”	ICA	DWT	- Kernel ELM - Statistical features	Multi-class: 49% Binary: 85%
[54]	Classification of five vowels and six words	Transfer learning	CNN		24%
[55]	addition of new classes to a pre-trained classifier with few trials.	instantaneous frequency and spectral entropy	Deep metric learning framework		-6-class accuracy of 45.00 ± 3.13%. - 5-class accuracy of 48.10 ± 3.68%
[29]	Vowels, Short and long words	- Sliding window data augmentation - Band-pass filtering	MPC MSC	Transfer learning with ResNet50 pre-trained	- 79.7% (min) for vowels - 95.5% (max) for short-long words
[44]	Vowels and words	FastICA	DWT	TCN and CNN	96.49%
[56]	words "rock", "paper", "scissors", and rest state	Classical signal processing	GSP/GL	SVM	50.10%
[57]	long words, short words, vowels	Operational Architectonics	network metrics	Naive Bayes	-62.55% (long words), 66.44% (long vs short), 53.47% (short words), 48.13% (vowels)
[58]	kinesthetic imagery of the “left hand” and “right hand.” . visualise (“split” and “fall in”), imagine the pronunciations (“go” and “stop”),	multiscale convolutional transformer	t-SNE	multiscale convolutional transformer	- 0.62 on the private EEG dataset. - 0.70 on BCI competition IV 2a dataset. - 0.72 on the Arizona State University dataset.
[59]	Vowels, Short and long words classification	SPWVD	TFR images	CNN	- Long words: 94.82% - Short-long words: 94.26% - Short words: 94.68% - Vowels: 84.50%
[60]	Vowels, Short and long words classification	Butterworth bandpass filter, Notch filter, Common average referencing	RADWT/PSO	SVM, KNN, Random Forest, Rotation Forest, Bagging, AdaBoos	87.26% 89.23%, 95.5%, and 92.16% for long words, short–long words, short words, and vowels, respectively.
[61]	Vowels, Short and long words classification	Butterworth bandpass filter, Notch filter, Common average referencing	SPWVD	CNN	Binary: 79.82% to 82.04% Multiclass: 49.93% to 51.44%
[62]	The words included “I” and “partner” as subject words, “move,” “have,” and “drink” as verb words, and “box,” “cup,” and “phone” as object words	Downsampling from 1000 to 500 Hz, Band-pass filtering (30-125 Hz), and Embedding of spectrograms	CNNs and ground truth (mel-spectrogram), (GRU)-based regression	Structural Similarity Index Measure (SSIM)	Subject words 79.2%, Verb words 82.5%, Object words 81.1%
[3]	Four words: UP, DOWN , LEFT, right	Bandpass filtering (10-100 Hz)	WST	LSTM model with L2 regularisation	92.50%
[20]	FEIS : /i/, /u:/, /æ/, /ɔ:/, /m/, /n/, /ŋ/, /f/, /s/, /ʃ/, /v/, /z/, /ʒ/, /p/, /t/, /k/ .KaraOne : /iy/, /uw/, /piy/, /tiy/, /diy/, /m/, /n/,pat, pot, knew, and gnaw	ICA and bandpass filtering	DWT	Deep transfer learning (DenseNet, ResNet)	- KaraOne: 82.35% - FEIS: 89.01%
[63]	/iy/, /uw/, /piy/, /tiy/, /diy/, /m/, /n/,pat, pot, knew, and gnaw	filter up to 1 kHz bandpass	EM-CSP	Ensemble stacking learning	97.34%
[21]	Multi-class and binary classification of “left,” “right,” “up,” and “down.”	ICA	DWT	- Kernel ELM - Statistical features	Multi-class: 49% Binary: 85%

ANN = artificial neural network (NN), AR = autoregression, CNN = convolutional NN, CSP = common spatial pattern, DAE = Deep Autoencoder, DNN = deep NN, DT = decision tree, DTCWT = Double-Tree Complex Wavelet Transform (WT), DTF = direct transfer function, DWT = Discrete WT, ELM = extreme learning, FFT = Fast Fourier Transform (FT), HMM = hidden Markov model, kNN = k-nearest neighbour, LDA = linear discriminant analysis, LSTM = long short-term memory, MaxLCor = Maximum Linear Cross-correlation Coefficient, MFCC = Mel Frequency Cepstral Coefficients, NB = naïve Bayes, PDC = partial directed coherence, RF = random forest, RMS = root mean square, RNN = recurrent NN, t-SNE= t–stochastic neighbor embedding, CAR=Common Average Reference, RVM = relevance vector machine (VM), STFT = Short Time FT, SVM = support VM, TL = transfer learning.

Several studies have started to reduce this gap. Transfer learning approaches initialise models on one dataset or group of subjects and then fine-tune them on a smaller target set. For example, [29] uses ResNet-based transfer with sliding-window augmentation, and [20] explores knowledge transfer between FEIS and KARAONE, reporting accuracies above 80 percent for some configurations. Metric-learning strategies, such as Siamese networks and deep metric learning frameworks [30],

[55], encourage models to place trials with the same label closer together in latent space and trials with different labels further apart. These methods help to reduce subject-specific variability and have outperformed simpler baselines on the same data [27], [30].

Even so, most of these works still require subject-specific fine-tuning and have not yet been evaluated on large, independent cohorts. A promising direction is the development of architectures and training regimes that explicitly disentangle subject and task factors, for instance, through adversarial domain adaptation, subject embedding layers, or factorised latent spaces. The existing transfer and metric-learning literature provides concrete starting points, but more ambitious cross-subject and cross-session benchmarks will be needed to identify which strategies lead to genuine gains in generalisation rather than to improvements confined to a single dataset.

D. Evaluation Protocols and Practical Deployment

The way performance is measured is as important as the models themselves. Evaluation protocols in the imagined-speech literature vary widely. Many studies employ subject-dependent or random cross-validation schemes that mix trials from the same recording session in training and test sets. This practice often yields optimistic estimates of accuracy, because nuisance factors such as noise statistics and electrode placement are shared across splits. Only a subset of studies explicitly report cross-subject or cross-session results, and for widely used datasets such as KARAONE, FEIS, or the Arizona State University corpus, there is still no consensus on standard training and test partitions [3], [20], [58], [59], [63].

Some authors have already taken steps toward more transparent evaluation. For example, [21] distinguishes between binary and multi-class performance on directional commands, [59] and [60] report separate accuracies for vowels, short words, and long words, and [62] analyses subject, verb, and object categories separately. These distinctions make it easier to understand how a model behaves under different task demands. However, further progress will likely require community-wide agreement on recommended protocols, such as fixed cross-subject splits, reporting of both accuracy and F1-score, and the introduction of sequence-level metrics, such as word error rate, when moving toward continuous decoding.

Practical deployment also raises questions that are only beginning to be addressed. Online or real-time experiments remain rare, although [41] demonstrates that binary “yes/no” decisions can be decoded in an online setting with reasonable accuracy. Most of the work summarised in Table I is still offline. Bringing systems into real-time use will require efficient preprocessing, models that can run with limited hardware, and calibration procedures that minimise user burden. The command-based applications discussed in [52] suggest that small-vocabulary control may already be within reach, provided that stability over time and across sessions can be established.

E. Synthesis

Taken together, the available evidence suggests a field that is technically vibrant but structurally constrained. Time–frequency and connectivity features coupled with CNNs, RNNs, and transfer learning have demonstrated that imagined-speech decoding from EEG is feasible and that accuracies can be high on carefully controlled tasks [20], [21], [44], [59]–[63]. At the same time, low signal-to-noise ratio, limited and linguistically narrow datasets, strong individual variability, and heterogeneous evaluation protocols restrict the generalisability of these findings. The four themes discussed above are tightly interconnected. Better representations depend on richer and more diverse data. Robust generalisation relies on both sophisticated modelling and realistic cross-subject evaluations. Practical deployment in turn depends on all three: signal quality, data and model scale, and credible performance estimates.

If future work can align efforts along these lines, for example, by constructing larger multi-site datasets, adopting shared benchmark protocols, and exploiting representation learning techniques that explicitly tackle subject and session variability, EEG-based imagined-speech interfaces may evolve from laboratory prototypes into reliable communication tools for individuals with severe motor and speech impairments [53]. In that sense, the current literature should be viewed not only as a catalogue of methods and accuracies, but also as a foundation on which a more standardised and clinically relevant generation of imagined-speech BCIs can be built.

VI. Conclusion

EEG-based imagined-speech decoding is a promising yet challenging area in non-invasive brain-computer interface research. Despite significant progress in recent years, the field is still limited by low signal-to-noise ratios, high variability among subjects, and a lack of large, standardised datasets. This review consolidates the various methodologies employed throughout the decoding process, covering EEG acquisition, preprocessing, feature extraction, and deep learning-based representation learning, to offer a comprehensive overview of the current state of the art. The synthesis of existing literature indicates a clear shift from traditional handcrafted signal-processing techniques to data-driven deep learning architectures. These new methods can learn spatial, spectral, and temporal representations concurrently. However, methodological inconsistencies—especially regarding dataset selection, evaluation protocols, and performance metrics—persist and hinder reproducibility and direct comparisons between studies. To accelerate advancements in this field, future research should focus on establishing unified benchmark datasets and cross-subject evaluation frameworks. Additionally, incorporating multimodal signals, as well as contrastive and self-supervised learning strategies, and domain adaptation techniques may enhance the generalizability of the models. Furthermore, interdisciplinary collaboration between neuroscientists, linguists, and machine learning researchers is vital to ensure that the models developed are physiologically interpretable and ethically sound. Ultimately, the combination of EEG and deep learning in imagined-speech decoding has the potential to transform assistive communication technologies. Achieving this goal will necessitate not only innovative algorithms but also rigorous experimental standardisation and open, collaborative research practices that promote transparency, reproducibility, and equitable progress across the field.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to Multimedia University and Universiti Teknikal Malaysia Melaka (UTeM) for their valuable support in this research.
