Evaluating Field Flexibility Approaches in Relational Databases: A Performance Study of JSON and Column-Oriented Models in Library Systems

Rizal Fathoni Aji, Nilamsari Putri Utami
Faculty of Computer Science, Universitas Indonesia, Indonesia

***Abstract*—This study examines two approaches for achieving field flexibility in library systems using relational databases: column-oriented tables and JSON data types. To evaluate the performance and practicality of flexible schema strategies, a dataset of 41,000 library records was implemented using both column-oriented and JSONB-based schemas in PostgreSQL. Five representative queries based on typical search operations in library applications were executed repeatedly on each model, and average execution times were measured in a controlled environment. Results show that JSONB consistently outperforms the column-oriented approach across all query scenarios, benefiting from reduced structural overhead and more direct access to semi-structured data. However, the flexibility of JSONB introduces risks of inconsistent data structures and reduced schema enforcement compared to the more rigid but uniform column-oriented method. The findings highlight a trade-off between performance and data consistency, suggesting that JSONB is advantageous for dynamic, metadata-rich systems, while column-oriented storage remains preferable when strict structural integrity is required. Future work should explore hybrid models and schema validation layers to combine flexibility with reliable data governance.**

***Keywords*—Field flexibility; RDBMS; column-oriented model; JSON; library systems**

I. Introduction

Relational databases have been the foundation of data management for decades, particularly in systems like library information systems, where maintaining consistency, data integrity, and efficient querying is crucial [1]. Libraries often store vast collections that encompass a wide range of materials, books, journals, and digital media, each with unique metadata attributes such as authorship, publication date, genre, format, or edition. The structured schema of relational databases ensures that these attributes are stored in a highly organized manner. However, this rigid structure can become a constraint when new or evolving data needs arise, such as adding metadata fields for digital content or custom attributes for special collections [2].

Library systems differ considerably in nature. Libraries worldwide are managed by diverse organizations with varying management styles and differing attitudes toward collections and technology. Libraries have evolved from early research platforms into more fully developed applications, typically within selected content domains [3]. Alongside the classical research area of electronic searching, known as information retrieval, library systems have progressed from conventional search methods toward richer information retrieval systems. Modern library systems must facilitate data exchange among geographically distributed libraries and accommodate differing system requirements. Moreover, libraries employ various metadata standards, such as Dublin Core [4] and MARC [5], which require flexibility in field implementation. For example, journal article records may need to include information about editors and publishers, whereas thesis records may not require such details.

The predefined schema in relational databases requires that all data types be known upfront, making it difficult to accommodate unexpected or variable metadata without significant modifications. As a result, adapting a relational system to handle new types of collection metadata can lead to increased development effort, added complexity, and potential downtime [6]. This challenge is amplified as the library grows or incorporates more diverse types of collections, requiring frequent schema updates and risking disruption to the overall system.

NoSQL databases offer considerable flexibility in handling unstructured or semi-structured data, making them ideal for applications where schema changes are frequent, or data structures are unpredictable [6,7]. However, this flexibility comes at a cost, particularly when it comes to complex querying and table relationships. One significant challenge is the difficulty in performing efficient joins between tables, a core functionality that relational databases excel at. This limitation can pose problems for systems like library information management, where table relations are critical for day-to-day operations [7].

In a library system, various activities, such as book check-ins, check-outs, and reporting, rely heavily on inter-table relationships to maintain data consistency and integrity. For example, checking a book in or out requires joining tables that hold data on books, borrowers, and loan history. Moreover, libraries often need to generate comprehensive reports, which require data aggregation from multiple tables, like generating overdue reports, catalog updates, or usage statistics. The absence of native join capabilities in NoSQL databases can result in performance bottlenecks or force developers to implement workarounds, such as data duplication or complex client-side logic, which can introduce additional complexity and potential inefficiencies [7].

Thus, while NoSQL provides unmatched schema flexibility, its shortcomings in handling relational data make it less suited

for systems like library management, where efficient table relationships and complex joins are crucial for smooth operations and reporting [7,8].

This study delves into several innovative approaches designed to enhance the flexibility of relational database management systems (RDBMS). These methods enable developers to introduce and manage changes dynamically, without the need for extensive schema redesigns or additional overhead. By doing so, organizations can ensure their data systems remain adaptable, scalable, and better suited to meet the ever evolving demands of modern information management.

Previous studies have investigated the performance implications of using the JSONB data type in PostgreSQL for managing semi-structured data [9, 10]. Although JSONB offers schema flexibility, compact binary storage, and advanced indexing mechanisms such as GIN indexes, empirical evaluations reveal a clear trade-off between flexibility and performance. Comparative benchmarks consistently show that JSONB substantially outperforms the plain JSON type and regular column indexing, with reported query time reductions of up to fourfold under certain workloads [9, 10]. However, most existing work concentrates on generic database workloads or compares JSONB with document-oriented databases, with limited attention to domain-specific systems such as digital libraries.

In library information systems, schema flexibility is a critical requirement because bibliographic data exhibit substantial structural diversity. Libraries manage a wide range of resource types, including books, journal articles, theses, and heritage collections, each requiring different metadata fields and descriptive elements. Some collections, such as heritage records, demand highly customized and evolving metadata to capture provenance, physical condition, restoration history, and cultural context, which are often not supported by standard schemas. These needs are typically addressed through multiple metadata standards (such as MARC and Dublin Core) and their integration, which increases structural complexity within the database [11–13]. Rigid relational schemas often lead to frequent schema modifications and increasingly complex table designs, whereas JSONB offers a promising alternative by enabling flexible, self-describing metadata storage within a relational database environment. Despite its potential, empirical evidence on JSONB performance under realistic library workloads remains limited, particularly in comparison with traditional column-oriented schemas. This study, therefore, investigates the performance of JSONB in a digital library setting, directly comparing it with column-based designs to evaluate the costs and benefits of schema flexibility for bibliographic metadata management.

II. Field Flexibility in Relational Database

Field flexibility refers to the ability to modify the structure of data within an application without causing significant disruptions to the underlying systems. In traditional databases, data structures are often rigid, requiring a defined schema upfront, which can make changes laborious and time-consuming. However, field flexibility enables the system to evolve as new requirements emerge, allowing for the addition of new fields, modification of existing ones, or even changes in data types, all while minimizing impact on the rest of the application. Achieving this flexibility can be crucial for applications that face frequent changes in data requirements or need to support dynamic use cases. Below are several strategies commonly employed to implement field flexibility:

A. Incremental Schema Changes

One approach for achieving field flexibility is through incremental schema changes. This strategy involves gradually evolving the database schema by adding or modifying fields as needed, without requiring a full database redesign. For instance, in a library information system, if new data fields, such as a book's digital format (e.g., PDF, ePub), are needed to support eBook checkouts, developers can add these fields incrementally.

Tools like database migration frameworks (e.g., Alembic for SQLAlchemy in Python or Liquibase) can automate schema updates and track changes, ensuring that no downtime or significant reengineering is needed. This method allows developers to maintain the structure and performance advantages of a relational database while still adapting to new requirements. Incremental changes can include:

- Adding nullable columns to accommodate new data types.
- Using default values for new columns to ensure compatibility with existing data.
- Creating new indexes as needed to maintain query performance.

If a library needs to store new metadata for each book, such as its genre or digital format, a new column can be added to the books table incrementally:

```
ALTER TABLE books ADD COLUMN genre VARCHAR(100);

ALTER TABLE books ADD COLUMN digital_format VARCHAR(50) DEFAULT 'None';
```

Existing records remain unaffected, while new records can start using the additional fields immediately.

B. Column-Oriented Tables

Another strategy for field flexibility involves using column-oriented tables, which are structured to allow easy addition and modification of fields. In column-oriented databases, data is stored in columns rather than rows, making it highly efficient to add new fields or update existing ones. These databases (e.g., Apache HBase or Google Bigtable) are especially useful in systems where not all records share the same structure. For example, in a library system, you might have some books that contain additional information, such as author biographies or associated multimedia content, while others do not.

Using a column-oriented approach, these additional fields can be added for specific entries without forcing the entire dataset to conform to the new structure. This also allows efficient querying of specific fields, improving flexibility when handling large amounts of varied data. For example, if only certain types of books (e.g., rare manuscripts) require special

attributes like "restoration history", a columnar table structure allows these fields to be included only for relevant records without affecting the rest of the data.

C. Using JSON Data Types

A highly flexible and modern approach to enhancing field flexibility is by utilizing JSON data types within a relational database. Several RDBMSs, such as PostgreSQL and MySQL, now offer native support for JSON data, allowing developers to store semi-structured or unstructured data alongside traditional relational data. This strategy is particularly useful when the data structure is not fully known in advance or when rapid changes in data fields are expected.

Using JSON, fields can be added or modified on the fly, without altering the overall schema of the table. This is ideal for systems like library databases, where books, authors, and other entities may have variable attributes that are not always predictable. For instance, a library might need to store additional metadata for certain books, such as links to multimedia resources, custom annotations, or external references. Rather than modifying the schema each time a new attribute is needed, a JSON column can be used to store this variable data, offering flexibility without compromising the integrity of the relational data. PostgreSQL implements JSON records using the JSONB data type. It is an efficient format for storing JSON data in a decomposed binary representation [14].

D. Flexibility for Library Application

Comparing among those three methods, each method offers distinct advantages depending on the specific requirements of a system. Incremental schema changes are ideal for systems that rely heavily on predefined structures and require the assurance of relational integrity, such as library management systems. This method allows for controlled, gradual evolution of the database, ensuring that new fields can be added with minimal disruption to existing data or queries. However, it requires careful management of migrations and can become cumbersome when faced with frequent or unpredictable changes.

On the other hand, column-oriented tables excel in environments where data structures vary significantly across records, providing efficient querying of specific fields without affecting the entire dataset. This approach is particularly useful in large-scale analytics systems, where different records may not have a uniform set of fields. However, it lacks some traditional relational capabilities required for complex transactions, making it less suited for systems where relationships between entities are key.

Using JSONB data types, meanwhile, strikes a balance between flexibility and relational structure. It allows for schema-less, semi-structured data to be stored directly within a relational database, providing the benefits of both worlds. JSONB fields are perfect for handling dynamic, evolving data without the need for frequent schema modifications. This is particularly useful when the application must handle irregular or custom attributes, such as in a library system that needs to store metadata for certain books or patrons. However, JSONB based queries can be less efficient than traditional SQL queries, and overuse can lead to performance degradation if not carefully managed.

In summary, while incremental schema changes offer stability and control, column-oriented tables excel in scenarios requiring high flexibility at the cost of relational power. JSONB data types provide a versatile middle ground, allowing for both flexibility and structure, though they must be used judiciously to avoid potential performance issues. The choice between these methods largely depends on the balance between flexibility, performance, and the need for relational integrity in the application.

Both column-oriented tables and the JSONB data type offer significant flexibility to library systems, particularly when adapting to evolving data needs without requiring modifications to the underlying table structure. Column-oriented tables provide a stable and structured approach, ensuring efficient data retrieval for specific fields, especially when dealing with large datasets. They are highly optimized for read-heavy operations and analytical queries, offering a more consistent and predictable performance. However, the rigidity of this structure means that it may not be as agile when accommodating diverse or irregular data.

In contrast, JSONB data types offer a more dynamic and flexible way to handle semi-structured data within a relational database. By allowing for schema-less data storage, JSONB enables library systems to handle varying data attributes, such as custom metadata for books or patrons, without frequent schema alterations. This makes JSONB particularly powerful for managing diverse or evolving datasets. However, the flexibility of JSONB comes with the potential for field inconsistencies, as there is no enforced structure across all records. Despite this, JSONB has the advantage of using standardized formats for metadata, making it ideal for interoperability with external systems and APIs.

This study aims to compare these two approaches, column-oriented tables and JSONB data types, specifically in terms of query performance within the context of a library management system. Understanding the trade-offs between stability and flexibility, and how they impact query efficiency, will provide valuable insights into which method is best suited for specific use cases in a dynamic, data-rich environment.

III. Methods

To conduct a thorough comparison between the two methods of field flexibility, a comprehensive dataset was collected from the University of Indonesia's Faculty of Computer Science library. This dataset consists of 41000 records, each encompassing five essential fields: call number, title, author, publisher, and the number of collections. These fields were chosen for their relevance in typical library operations, allowing to focus on the core aspects of library data management. The records represent a diverse array of library materials, making this dataset particularly suitable for analyzing the performance of different data storage formats in a real-world context.

The collected data was stored in two distinct formats: one using column-oriented tables and the other using JSONB data types. This dual approach was to evaluate how each method handles common library operations. Then, a series of standard queries was executed in library applications, such as searching

for specific titles, retrieving collections by author, and counting the total number of items in each category.

Employing these queries was to simulate everyday usage scenarios that librarians encounter, ensuring the results reflect practical performance metrics. Fig. 1 and Fig. 2 illustrate the implementations of the tables for both column-oriented and JSONB data type methods, offering a clear visual representation of them.

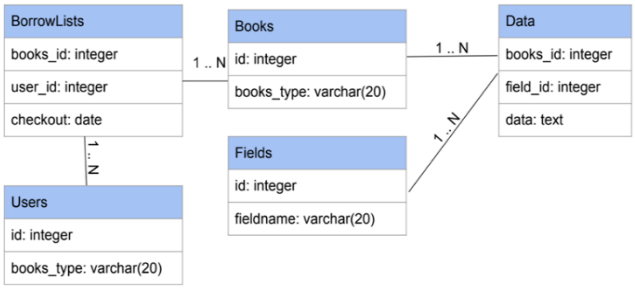

Fig. 1. Simplified tables implementation of the column-oriented method.

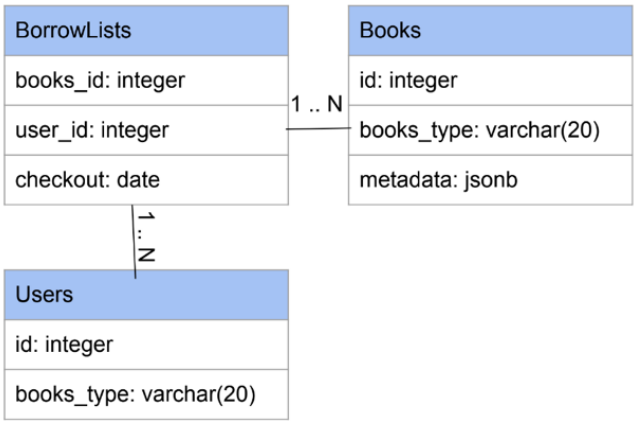

Fig. 2. Simplified table implementation of the JSONB data type method.

In addition, Table I specifies the queries used in this experiment, emphasizing the data retrieval processes employed. PostgreSQL was utilized for database running on an Apple M1 CPU with 8GB of RAM to support these implementations. This enables analyzing the data related to experimental methods.

Finally, the analysis of average execution times of each query across both data formats was performed to draw meaningful conclusions about their efficiency. Measuring how quickly each method processed the queries aimed to identify any significant differences in performance that could influence the choice of data handling strategy for library systems.

To ensure the accuracy and reliability of the results, each query was executed five times, and the average execution time for each query was calculated. To maintain fairness and accuracy between queries, the database server is restarted after each run. This step clears the query cache, preventing any residual data from influencing subsequent results. Averaging the execution times can gain a more accurate representation of how each data format performs under consistent conditions.

TABLE I. QUERIES USED IN THE EXPERIMENT

ID	Task	SQL Query on column-oriented method	SQL Query on JSONB data type method
Q1	Retrieve books with keyword ‘Donald’ in author name	select books_id from data d, fields f where f.fieldname='author' and f.id=d.field_id and d.data like '%Donald%';	select books_id from books where metadata->>'author' like '%Donald%';
Q2	Retrieve books with keyword ‘Donald’ or ‘Knuth’ in author name	select books_id from data d, fields f where f.fieldname='author' and f.id=d.field_id and (d.data like '%Donald%' or d.data like ‘%Knuth%’);	select books_id from books where metadata->>'author' like '%Donald%' or metadata->>'author' like ‘%Knuth%’;
Q3	Retrieve books with keyword ‘Donald’ and ‘Knuth’ in author name	select books_id from data d, fields f where f.fieldname='author' and f.id=d.field_id and (d.data like '%Donald%' and d.data like ‘%Knuth%’);	select books_id from books where metadata->>'author' like '%Donald%' and metadata->>'author' like ‘%Knuth%’;
Q4	Retrieve books with keyword ‘Donald’ but not ‘Knuth’ in author name	select books_id from data d, fields f where f.fieldname='author' and f.id=d.field_id and (d.data like '%Donald%' and d.data not like ‘%Knuth%’);	select books_id from books where metadata->>'author' like '%Donald%' and metadata->>'author' not like ‘%Knuth%’;
Q5	Retrieve books with keyword ‘Donald’ in author name and keyword ‘Computer’ in title	select d1.books_id from data d1, data d2, fields f1, fields f2 where (d1.data like '%Donald%' and f1.fieldname='author' and d1.field_id=f1.field_id) and (d2.data like '%Computer%' and f2.fieldname='title' and d2.field_id=f2.field_id) and d1.books_id=d2.books_id;	select books_id from books where metadata->>'author' like '%Donald%' and metadata->>'title' like ‘%Computer%’;

This repeated execution also allows observing patterns and identifying any potential performance bottlenecks in the system. For instance, certain queries may initially execute faster due to caching, but when repeated multiple times, underlying inefficiencies may become apparent. Running the queries in a controlled environment and taking multiple measurements can assess the stability and consistency of each method over time, which is crucial for applications that demand high availability and consistent performance.

Moreover, calculating the average time across multiple runs provides a more robust foundation for comparison between the two data formats. It ensures that the findings are not based on a one-time performance outlier, but reflect the typical performance behavior of both approaches. This method of testing is essential for drawing reliable conclusions about which data format offers better query execution performance, particularly for the dynamic and often data-intensive operations of a library management system.

IV. RESULTS

This section presents the findings from performance analysis of the two data storage methods: column-oriented tables and JSONB data types. The comparison of execution times of various common queries used in library management systems highlights any significant differences between the two approaches. Additionally, the implications of these results are examined in terms of how each method performs in terms of query efficiency, flexibility, and scalability. The insights gained from this analysis will help determine which approach is better suited for managing dynamic and evolving library data.

A. Table Size

Before diving into the performance analysis, first compare the storage sizes of the tables in both the column-oriented and JSONB data type approaches. This comparison is essential for understanding the storage efficiency of each method, as data size can directly impact query performance and system resources. The findings revealed that the column-oriented approach resulted in a larger table size, approximately 13 MB, while the JSONB data type approach had a smaller footprint, occupying only around 9 MB.

The larger size of the column-oriented table can be attributed to its structured nature, where each field is explicitly defined and indexed. On the other hand, the JSONB data type offers more compact storage because it allows for flexible, semi-structured data representation without requiring predefined schema constraints. This reduced storage size may improve space efficiency, especially when dealing with dynamic or variable data. This size comparison lays the groundwork for evaluating the overall efficiency of each approach in handling real-world library data.

B. Query Performance

Table II presents the mean execution time recorded for each query across all scenarios. These averages were computed by running each query multiple times and aggregating the results to reduce the influence of outliers or transient system fluctuations.

TABLE II. AVERAGE TIME OF EACH QUERY

Query	Column-oriented method	JSON data type method
Q1	58.03 ms	33.53 ms
Q2	77.40 ms	42.60 ms
Q3	41.74 ms	36.46 ms
Q4	58.52 ms	27.90 ms
Q5	78.22 ms	32.69 ms

By focusing on average performance rather than single run outcomes, the analysis ensures a more reliable representation of each data model's behavior under typical operating conditions. Fig. 3 presents a comparative performance chart derived from the data in Table II.

The results indicate that the JSONB data type consistently demonstrates faster query execution times compared to the column-oriented approach. This performance advantage can be attributed to the reduced need for data transformation and parsing when working directly with native JSON structures. In contrast, column-oriented storage often requires additional processing steps, such as schema enforcement, column reconstruction, or intermediate serialization, which increase computational overhead during query execution.

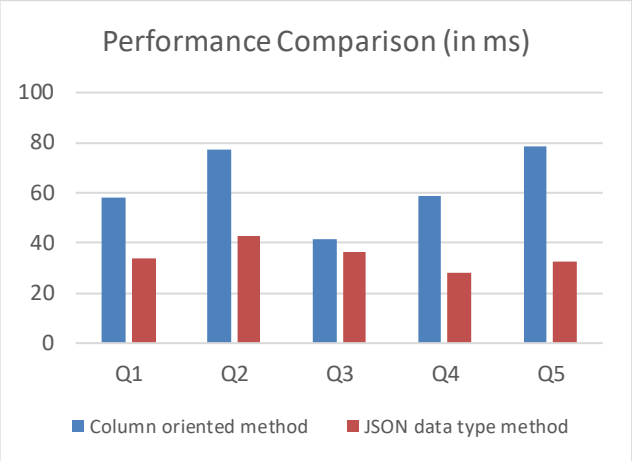

Fig. 3. Performance comparison chart.

V. DISCUSSION

From a systems-level perspective, the superior performance of JSONB indicates that workloads involving semi-structured or nested data benefit significantly from storage models optimized for hierarchical formats. By allowing complex metadata to be stored and accessed directly without extensive schema transformation, JSONB reduces the processing overhead commonly associated with traditional column-oriented designs. This efficiency becomes particularly important in library information systems, where metadata attributes vary widely across collections and evolve over time, requiring a storage model that can adapt without sacrificing performance.

These findings also emphasize the importance of aligning data representation with query patterns and application requirements. When search operations frequently involve flexible attributes such as author names, titles, or custom metadata fields, JSONB enables more direct and expressive querying compared to the join-intensive structure of column-oriented tables. As a result, JSONB minimizes relational reconstruction costs and simplifies query logic, leading to lower latency and more predictable performance in real-world usage scenarios. This demonstrates that performance is not solely determined by hardware or indexing strategies, but is strongly influenced by how well the data model matches the access patterns of the system.

Overall, the consistent outperformance of JSONB across all evaluated scenarios underscores its effectiveness for environments that demand both flexibility and fast access to complex data structures. While column-oriented storage offers stronger structural enforcement and uniformity, its rigidity introduces overhead when handling dynamic metadata. JSONB, therefore, represents a compelling alternative for modern library systems, where adaptability and performance are equally critical, provided that appropriate validation and governance mechanisms are implemented to preserve data quality and consistency.

VI. Conclusion

The results of this study show that the JSONB data type consistently delivers faster query execution times than the column-oriented method across all evaluated scenarios. This performance benefit is largely due to JSONB's ability to store and access hierarchical, semi-structured data without requiring extensive transformation. However, despite its advantages in speed and flexibility, the JSONB data type also presents notable limitations. Its schema's flexible nature can complicate data validation, especially in structured domains such as library information systems, where consistent formats for book records, borrower data, and classification codes are essential.

While the JSONB data type can improve performance and reduce overhead, it also creates challenges in maintaining data consistency and integrity. In a library system, variation in field naming, missing attributes, or inconsistent structures can arise easily due to the lack of enforced schema rules. JSON documents may also contain duplicated or redundant nested data, making synchronization and updates more error-prone. Additionally, the nested structure of JSON can complicate indexing and query optimization, which are critical for fast retrieval of books, circulation statistics, or user records. In contrast, column-oriented storage, with its rigid schema and normalized structure, inherently promotes uniformity and reduces inconsistency across records.

This research has both theoretical and practical implications for the design and management of database systems in library information environments. From a theoretical perspective, JSONB can bridge the gap between rigid relational models and fully schema-less NoSQL approaches. Hierarchical storage within relational systems can significantly improve query performance for semi-structured metadata. This study also extends existing literature by providing concrete performance evidence in the underexplored domain of library and heritage metadata management, thereby offering a foundation for future research on hybrid data models and adaptive schema design.

From a practical perspective, it provides guidance for system architects that library systems can adopt flexible metadata storage without incurring significant query overhead. At the same time, the findings highlight the need for complementary governance mechanisms to mitigate the risks associated with schema flexibility. By balancing performance, flexibility, and data consistency, this research informs the development of scalable and sustainable digital library systems capable of adapting to future metadata requirements.

Future work should explore mechanisms to mitigate the consistency challenges associated with JSON-based storage. Further evaluation across larger, more complex library datasets may also clarify the conditions under which JSON's performance benefits outweigh its consistency drawbacks. Additionally, examining the impact of different indexing strategies, storage engines, and transaction loads could provide deeper insights into optimizing JSON for use in library information systems and other domains requiring both flexibility and high data reliability.

Business Administration Department, Politeknik Negeri Bandung, Indonesia [4]

***Abstract*—This study develops a Robotic-Integrated Leagility Adaptation Model by combining Green Supply Chain Intelligence (GSCI) and Supply Chain Ambidexterity (SCA) to enhance sustainable performance in the manufacturing sector. The rapid evolution of robotics, cyber-physical systems, and AI-enabled decision technologies has transformed supply chain dynamics, necessitating an adaptive model that balances efficiency (lean) and responsiveness (agile). Using an integrated quantitative approach, this research examines how robotic automation strengthens leagility capabilities through real-time analytics, predictive intelligence, and environmentally oriented digital operations. The findings demonstrate that GSCI significantly enhances SCA, which in turn improves leagility adaptation and sustainable manufacturing performance. Robotic integration is found to play a catalytic role by enabling autonomous coordination, energy-efficient scheduling, and intelligent material handling as key enablers of green and responsive operations. This study contributes to the literature by proposing a technology-driven leagility model that links robotics, green supply chain intelligence, and ambidexterity within a unified smart manufacturing framework. Implications are provided for policymakers and industry leaders to accelerate sustainable transformation through robotics-enabled digital ecosystems.**

Keywords*—Robotic integration; Green Supply Chain Intelligence; Supply Chain Ambidexterity; leagility adaptation; sustainable manufacturing performance

I. Introduction

The manufacturing sector has undergone significant turbulence in recent years, driven by global economic uncertainty and intensified by disruptive events such as the COVID-19 pandemic. Production declines reported in some industries to reach as high as 46.5% have exposed structural vulnerabilities in manufacturing systems and supply chains, highlighting an urgent need for strategies that strengthen resilience, efficiency, and sustainability. In this context, traditional operational approaches are increasingly insufficient as firms confront volatile demand patterns, supply interruptions, and technological acceleration, all of which require redesigned systems capable of adapting to dynamic environments.

Sustainability in manufacturing must therefore be reframed as a multidimensional capability rather than a peripheral compliance function. Guided by the Triple Bottom Line (TBL) logic, sustainability encompasses economic viability, social responsibility, and environmental stewardship, each of which contributes to long-term value creation. Prior studies have stressed that integrating these three pillars into core processes allows firms to generate competitive advantage while simultaneously enhancing social welfare and mitigating ecological degradation [1]. As consumers, regulators, and global markets increasingly demand ethically and environmentally responsible production, sustainable performance has become a strategic priority for manufacturing firms.

Despite mounting pressure to deliver sustainable outcomes, many organizations encounter difficulties in translating sustainability goals into operational routines, especially within complex supply networks. Green Supply Chain Intelligence (GSCI)—an advanced, data-driven extension of Green Supply Chain Management—seeks to embed environmental thinking into procurement, production, logistics, and end-of-life processes through smart sensing, AI-enabled analytics, and digital monitoring [2], [3]. However, balancing the environmental objectives of GSCI with the need for operational efficiency introduces a persistent tension. At the same time, firms face intensifying pressures for responsiveness, adaptability, and innovation, underscoring the importance of Supply Chain Ambidexterity as a capability for balancing exploitation of existing strengths with exploration of emerging opportunities.

Supply Chain Ambidexterity in the era of robotics and Industry 4.0 reflects the ability of firms to optimize current processes while experimenting with disruptive technologies—including autonomous robotics, IoT devices, cyber-physical systems, and machine learning to enhance adaptability. Although prior research has examined efficiency, responsiveness, and sustainability in isolation, empirical investigations into the combined influence of GSCI, robotics integration, and ambidexterity on sustainable performance remain limited. This gap is critical because robotics and AI can simultaneously strengthen leanness through automation and predictive intelligence while enabling agility through rapid reconfiguration and real-time decision-making.

Leagility, the synergy of lean and agile paradigms, offers a promising strategic perspective to reconcile efficiency and flexibility in technology-enabled supply chains. When enhanced with robotic automation, leagility enables waste reduction, flexible scheduling, autonomous material handling, and rapid

*Corresponding author.

response to disturbances [4]. Integrating leagility with GSCI and ambidexterity provides an opportunity to build supply chains that are both environmentally responsible and highly adaptive, thereby supporting more robust sustainability outcomes across economic, social, and ecological dimensions.

Building on these dynamics, this study poses a guiding question: How can the integration of Green Supply Chain Intelligence and Supply Chain Ambidexterity, when supported by robotic automation, enhance leagility adaptation and sustainable manufacturing performance? To address this question, the research develops and empirically tests a Robotic-Integrated Leagility Adaptation Model that explains the mechanisms through which GSCI and ambidextrous capabilities contribute to leagility and sustainability. The model evaluates how data-driven green practices improve environmental and social outcomes, how ambidexterity enhances adaptability, and how robotics amplifies both efficiency and flexibility by enabling autonomous, data-rich, and low-waste operations.

Additionally, this research assesses potential mediating and moderating mechanisms, including technological readiness, digital integration capability, and management control systems—that shape the translation of GSCI and ambidexterity into measurable performance outcomes. Understanding these mechanisms is essential for practitioners seeking to design sustainable, digitally enhanced supply chain strategies that are both economically feasible and socially responsible.

While previous literature has documented the individual benefits of robotics, GSCM, and ambidexterity, few studies have synthesized these elements within a unified, empirically tested framework that incorporates leagility and sustainability. This research addresses that gap by offering a comprehensive model tailored to modern manufacturing realities where digital transformation, environmental imperatives, and operational resilience are deeply interconnected.

The contributions expected from this study are both theoretical and practical. Theoretically, it advances supply chain and manufacturing research by integrating robotics, GSCI, ambidexterity, and leagility into a coherent analytical model that explains sustainable performance drivers. Practically, the study provides actionable guidance for manufacturing firms on leveraging robotics, AI, and digital intelligence not merely as operational tools, but as strategic enablers of sustainable value creation. By clarifying the pathways that connect technology-driven supply chain practices to sustainability outcomes, this research aims to equip decision-makers with a roadmap for navigating the evolving challenges of the manufacturing landscape.

This manuscript is structured as follows: Section II provides a comprehensive review of the relevant literature and develops the theoretical framework that integrates Green Supply Chain Intelligence, Supply Chain Ambidexterity, robotics-enabled capabilities, and leagility, culminating in the formulation of the research hypotheses. Section III outlines the research methodology, detailing the research design, sampling procedure, operationalization of constructs, and the analytical techniques employed. Section IV reports the empirical findings and presents the results of the proposed model. It offers a critical discussion of the results by situating the findings within established theoretical perspectives and extant empirical research. Finally, Section V concludes the study by synthesizing the principal findings, articulating the theoretical and managerial implications, acknowledging the study's limitations, and suggesting avenues for future research.

II. Literature Review

This review synthesizes the theoretical foundations and empirical findings that undergird the present study, situating Green Supply Chain Integration (GSCI), Supply Chain Ambidexterity 4.0 (SCA 4.0), and Leagility within established strategic management and supply chain literatures. It emphasizes how heterogeneous strategic resources, digital transformation, and inter-organizational perspectives jointly shape sustainable competitive advantage and sustainability performance in manufacturing contexts.

Strategic resources and capabilities are not uniformly distributed across firms; their heterogeneity and imperfect transferability underpin differences in competitive outcomes and can sustain long-term competitive advantage [5]. From a Resource-Based View (RBV) perspective, sustainable competitive advantage arises when firms leverage valuable, rare, costly-to-imitate resources and organize effectively to capture their rents (Abeysekara et al., 2019; Ellitian, 2020). The VRIO framework value, rarity, and imitability organization operationalizes this evaluative logic, guiding assessment of whether a resource or capability can generate persistent competitive benefits [6]. Complementary managerial frameworks such as Kaplan and Norton's Balanced Scorecard remind us that executives seldom rely on a single performance metric; instead, they deploy multifaceted measurement systems to balance financial, customer, internal process, and learning perspectives [7]. This plurality of measures is especially pertinent when firms attempt to reconcile efficiency, adaptability, and sustainability objectives.

The strategy level of smart supply chains must explicitly account for digital transformation ambitions and the alignment of resources needed to synchronize supply chain goals with real-time data flows [8]. Digital integration, exemplified by IoT sensors, edge computing, and analytics platforms, reconfigures information flows and decision rights across the supply chain, enabling faster detection of disruptions, more precise forecasting, and finer control of resource use. However, the strategic gains from digitalization depend on organizational alignment: technologies alone do not guarantee improved outcomes unless firms align processes, governance, and capabilities to exploit them.

Stakeholder theory provides a robust lens for understanding value creation that extends beyond shareholders to include customers, employees, suppliers, communities, and regulators [9], [10]. This multi-stakeholder orientation is instrumental in measuring and managing sustainability, since environmental and social outcomes reflect a network of expectations and regulations. The Relational View complements RBV by locating sources of competitive advantage at the level of interfirm relationships and strategic alliances; some capabilities and value creation mechanisms emerge only when firms collaborate across boundaries [11]. Consequently, value creation in sustainable supply chains often involves orchestrating capabilities across

focal firms, suppliers, logistics providers, and institutional actors.

Contemporary models that integrate GSCI and SCA 4.0 draw on multiple theoretical strands from strategic management and supply chain research: Porter's value chain (1985) for activity-level analysis, RBV and VRIO for resource assessment [12], Dynamic Capabilities for adaptation under technological change [13], [14], Transaction Cost considerations for governance choices [15] and Stakeholder Theory for legitimacy and value creation [16]. Together, these perspectives provide a fertile ground for hypothesizing how green practices, digital ambidexterity, and strategic orientation interact to determine sustainability performance in modern manufacturing networks [17].

A. Green Supply Chain Integration (GSCI) and Sustainability Performance

GSCI encompasses the systematic incorporation of environmental objectives into procurement, production, distribution, and reverse logistics. Empirical studies show that GSCI contributes directly to improved environmental performance and, often, operational efficiencies such as reduced material waste, energy savings, and compliance benefits [18]. Aligning GSCI with regulatory demands and consumer preferences for greener products promotes resource stewardship and strengthens social legitimacy, thereby supporting both environmental and socioeconomic dimensions of sustainability. A robust GSCI capability enables firms to identify and institutionalize eco-friendly practices across their value chains, positioning GSCI as a primary driver of sustainability performance.

H1a: Green Supply Chain Integration positively influences Sustainability Performance.

B. Leagility as a Mediator Between Green Integration and Sustainability

Leagility, the deliberate combination of lean and agile principles, provides a strategic pathway to reconcile waste reduction with responsiveness. Lean focuses on streamlining flows and eliminating non-value-adding activities, while agility prioritizes flexibility and rapid response to changing demand patterns. When GSCI practices are aligned with lean principles (e.g., reduction of material use) and agile mechanisms (e.g., flexible sourcing, quick reconfiguration), supply chains can both lower environmental footprints and adapt to market variability. Therefore, Leagility functions as a mechanism through which GSCI translates into superior sustainability outcomes.

H1b: Green Supply Chain Integration positively influences Leagility Strategy.

H1c: The effect of Green Supply Chain Integration on Sustainability Performance is mediated by Leagility Strategy.

C. Supply Chain Ambidexterity 4.0 (SCA 4.0) Digital Ambidexterity and Sustainability

SCA 4.0 articulates the need to balance the exploitation of existing capabilities with the exploration of novel solutions in a digitally augmented supply chain environment. By integrating Industry 4.0 technologies such as IoT, AI, and big data analytics, firms can simultaneously optimize routine operations and experiment with innovative configurations (Yang & Singhdong, 2024). Strategic ambidexterity supported by digital tools enhances resource efficiency (through predictive maintenance, route optimization, and demand sensing) while enabling exploratory initiatives (new product introductions, circular business models) that extend sustainability potential. Thus, SCA 4.0 is posited to exert a direct positive effect on sustainability performance.

H2a: Supply Chain Ambidexterity 4.0 positively influences Sustainability Performance.

D. SCA 4.0, Leagility, and the Enabling Role of Technology

Digital ambidexterity strengthens both lean and agile elements by providing the real-time visibility and decision support necessary for synchronized, responsive operations. Exploitative use of technology drives consistent efficiency gains; exploratory use fosters adaptability to emergent market and regulatory pressures. The balance of these uses underpins a Leagility orientation that maintains cost discipline while enabling rapid reconfiguration in response to disruptions. In practice, SCA 4.0 capabilities, when integrated into governance and process design, facilitate rapid, data-driven decisions that support sustainable outcomes.

H2b: Supply Chain Ambidexterity 4.0 positively influences Leagility Strategy.

H2c: The effect of Supply Chain Ambidexterity 4.0 on Sustainability Performance is mediated by Leagility Strategy.

E. Dynamic Capabilities and Mediating Contingencies

Dynamic capabilities sensing, seizing, and reconfiguring are essential for firms to adapt to technological change and external shocks, enabling the translation of GSCI and SCA 4.0 into performance gains (Teece, 2018). Additional mediating and moderating constructs of interest include management control quality (which shapes implementation fidelity), market orientation (which aligns innovation with stakeholder demand), and technological adaptability (which conditions effective adoption of Industry 4.0 tools). These governance and capability factors help explain variation in outcomes across firms and illuminate why resource heterogeneity often leads to differential sustainability performance.

While substantial research documents the separate benefits of GSCI and ambidextrous [8], [19], [20], few studies comprehensively integrate these constructs within a Leagility framework that explicitly accounts for Industry 4.0 digitalization. The relational and stakeholder lenses further suggest that sustainable advantage frequently accrues from interorganizational coordination and legitimacy-seeking behaviors rather than from focal-firm actions alone. This gap motivates the present integrative model, which tests direct and mediated pathways linking GSCI and SCA 4.0 to sustainability performance through Leagility, while considering dynamic capabilities and governance contingencies.

In sum, the literature indicates strong theoretical and empirical reasons to expect that: 1) GSCI and SCA 4.0 each contribute to sustainability performance, 2) Leagility operationalizes the reconciliation of efficiency and

responsiveness that converts these capabilities into sustainable outcomes, and 3) dynamic capabilities and organizational governance shape the magnitude and direction of these effects. The hypotheses above (H1a–H1c, H2a–H2c) articulate these relationships and provide the basis for the empirical tests developed in this study.

Based on the literature review and the proposed hypothesis proposition, this research model is displayed in Fig. 1.

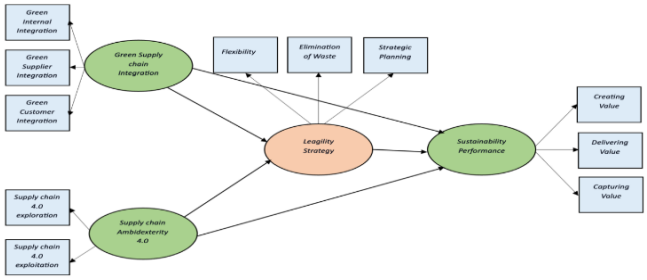

Fig. 1. Research model.

III. Methodology

This study adopts a quantitative approach using an explanatory survey design to empirically examine the causal relationships specified in the research hypotheses. A quantitative framework is appropriate because it enables systematic measurement, hypothesis testing, and estimation of the magnitude and direction of relationships among independent, mediating, and dependent variables. The explanatory survey method is specifically chosen to move beyond descriptive associations and to provide statistical evidence that clarifies how the green supply chain, Supply Chain Ambidexterity 4.0, and Leagility strategy interact to influence firm performance.

The target population comprises all automotive components and spare-parts manufacturers operating in West Java and DKI Jakarta. Industry records indicated 235 firms within this category. To enhance data quality and comparability, the sampling frame was restricted to firms holding ISO 9001:2015 certification. This criterion was selected because ISO 9001:2015 signals the presence of a formal quality management system and managerial processes that are relevant to market orientation, quality control, operational strategies (including Leagility), and supply chain adaptation. Purposive sampling was employed to select respondents based on predefined inclusion criteria: geographic location (West Java and DKI Jakarta) and possession of ISO 9001:2015 certification. Purposive sampling ensures that collected data pertain to firms with managerial structures and process disciplines relevant to the conceptual model. With 209 eligible firms, the sample comfortably meets conventional recommendations for Structural Equation Modeling (SEM), which typically require between 100 and 500 observations for robust parameter estimation and model testing.

The unit of analysis is the firm. Respondents were senior and middle managers (e.g., operations, supply chain, quality, plant managers) who are expected to possess strategic knowledge and experiential insight into organizational capabilities and performance metrics. Selecting managerial respondents helps ensure the validity of responses regarding organizational practices and strategic orientation. Data collection ran from October 2024 to February 2025. Questionnaires were distributed with direct researcher contact and supervised follow-up to increase response rates and ensure completeness. Where responses were ambiguous or incomplete, the research team contacted respondents for clarification. Participation was voluntary; respondents were briefed on the research objectives and assured of confidentiality before completing the survey.

Hypotheses were tested using Structural Equation Modeling (SEM) with AMOS version 24, which permits simultaneous estimation of measurement and structural models. The analytic sequence comprises: 1) confirmatory factor analysis (CFA) to validate the measurement model and assess construct reliability and validity; 2) evaluation of structural relationships to test direct and indirect effects; and 3) mediation analysis to examine whether Leagility Strategy and Supply Chain Adaptive Program transmit the effects of antecedent constructs to Firm Performance. Model fit will be evaluated using multiple indices: Chi-Square ($\chi 2$), Goodness-of-Fit Index (GFI), Tucker-Lewis Index (TLI), Comparative Fit Index (CFI), and Root Mean Square Error of Approximation (RMSEA). Hypothesis decisions will be based on p-values with a significance threshold of $p \leq 0.05$. For mediation, indirect effects will be tested using bootstrap resampling to obtain bias-corrected confidence intervals, which provide robust inference for mediated paths.

IV. Results and Discussion

A. Results

1) Measurement model evaluation: The measurement model demonstrated strong psychometric properties: all constructs satisfied the thresholds for convergent validity and composite reliability required for SEM analysis (see Table I). Green Supply Chain Integration (GSCI) achieved Composite Reliability (CR) = 0.943 and Average Variance Extracted (AVE) = 0.701, comfortably exceeding the recommended minima (CR ≥ 0.70; AVE ≥ 0.50). These values indicate high internal consistency and suggest that the GSCI items collectively account for over 70% of the construct variance, validating the instrument's capacity to measure green integration robustly.

Supply Chain Ambidexterity (SCA) also displayed solid psychometric performance with CR = 0.885 and AVE = 0.607, indicating reliable composite consistency and satisfactory indicator variance explained. This confirms that the ambidexterity dimensions—both exploitation and exploration are effectively captured by the selected indicators. Leagility Strategy (LS) recorded CR = 0.933 and AVE = 0.611; despite a few indicators with comparatively lower loadings, the construct overall maintained excellent reliability and convergent validity, reflecting coherent measurement of flexibility, waste elimination, and strategic planning dimensions.

Sustainability Performance (SP) emerged as the most robust construct, with CR = 0.947 and AVE = 0.666, signaling exceptionally high reliability and a substantial proportion of explained variance across economic, social, and environmental performance indicators. Collectively, all four constructs (GSCI, SCA, LS, SP) meet or exceed the psychometric criteria

recommended in the SEM literature (Hair et al., 2019), supporting the adequacy of the measurement model and permitting progression to structural analysis.

TABLE I. MEASUREMENT OF RESEARCH CONSTRUCTS

Latent Variable	Items	Loadings	CR	AVE
GSCI	GII1	0,811	0,943	0,701
	GII2	0,869		
	GII3	0,848		
	GSI2	0,862		
	GSI1	0,84		
	GCI2	0,776		
	GCI1	0,853		
SCA	SCR1	0,893	0,885	0,607
	SCR2	0,761		
	SCR3	0,803		
	SCP1	0,699		
	SCP2	0,726		
LS	FL3	0,664	0,933	0,611
	FL2	0,699		
	FL1	0,792		
	EW3	0,797		
	EW2	0,836

Source: Data Research, 2025.

The structural model showed acceptable overall fit (see Fig. 2). The ratio CMIN/DF = 2.061 falls well below the conservative threshold of 3.0, indicating reasonable parsimony. Incremental fit indices were favorable: TLI = 0.919 and CFI = 0.930, both surpassing the commonly accepted cutoff of 0.90 and signaling that the specified model explains the covariances among constructs effectively. Absolute fit measures were mixed but acceptable given model complexity: GFI = 0.810 and AGFI = 0.765 are below ideal values (≥ 0.90) but remain within tolerable bounds for complex models, while RMSEA = 0.077 is within the acceptable range (< 0.08), suggesting a reasonable approximation error. Taken together, these indices indicate that the structural model is tenable and suitable for hypothesis testing.

Standardized path estimates reveal meaningful and statistically significant relationships among constructs. Supply Chain Ambidexterity (SCA) exerted a strong positive influence on Leagility Strategy (LS) with a standardized coefficient of 0.719 ($p < 0.05$), indicating that higher ambidexterity in the supply chain strongly supports the adoption of leagile practices. SCA also contributed directly to Sustainability Performance (SP) with a coefficient of 0.551 ($p < 0.05$), underscoring ambidexterity's substantive role in enhancing environmental, social, and economic outcomes.

Green Supply Chain Integration (GSCI) displayed a significant positive effect on LS ($\beta = 0.478$, $p < 0.05$) and an even stronger direct effect on SP ($\beta = 0.733$, $p < 0.05$). These coefficients suggest that green integration not only fosters leagility but also translates directly into higher sustainability performance, reinforcing the primacy of green practices for sustainable outcomes.

Leagility Strategy (LS) showed a positive but modest direct effect on SP ($\beta = 0.029$, $p < 0.05$). Although numerically smaller than the direct effects of GSCI and SCA, this coefficient indicates that leagility still contributes incrementally to sustainability outcomes when other influences are controlled for.

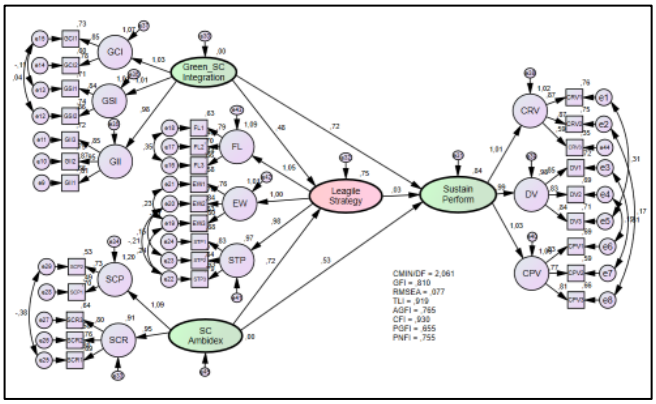

Fig. 2. Structural model testing (Source: Data research, 2025).

Mediation tests clarify how LS functions as a conduit between antecedents (SCA and GSCI) and sustainability outcomes. The estimated indirect effect of SCA on SP via LS was 0.021, while the indirect effect of GSCI on SP via LS was 0.014. Although these mediated effects are relatively small compared with the direct pathways, they are positive and consistent with the theoretical expectation that Leagility amplifies the sustainability returns of both ambidexterity and green integration.

TABLE II. STANDARDIZED INDIRECT EFFECTS

	SCA	GSCI	LS	SP
LS	0,000	0,000	0,000	0,000
SP	0,021	0,014	0,000	0,000

Source: Data Research, 2025.

From the Table II, when combining direct and indirect pathways, total effects demonstrate the overall explanatory power of antecedent constructs on sustainability performance.

SCA's total effect on SP equals 0.551 (direct) + 0.021 (indirect) = 0.572. GSCI's total effect on SP equals 0.733 (direct) + 0.014 (indirect) = 0.747. These totals indicate that GSCI has the more dominant overall influence on sustainability performance in this sample, although SCA remains a substantial and meaningful contributor. LS's total effect on SP (0.029) is largely direct, as its mediating transmissions to SP via other constructs were limited.

The results robustly support the conceptual model: both green supply chain integration and supply chain ambidexterity positively affect firm sustainability, and Leagility functions as a complementary mechanism that further channels these effects—albeit as a secondary amplifier rather than the primary driver. The particularly large total effect of GSCI highlights the importance of integrating environmental practices across procurement, production, and logistics as a leading strategy for improving triple-bottom-line performance. Concurrently, SCA's strong linkage to both LS and SP confirms that the ability to balance exploitation and exploration in a digitally enabled supply chain fosters resilience and sustainable outcomes.

Practical takeaways for managers include prioritizing comprehensive green integration initiatives while simultaneously cultivating ambidextrous capabilities that support leagile configurations. Doing so enables firms to capture both direct sustainability gains and incremental benefits mediated by operational flexibility and waste reduction. From a theoretical standpoint, the findings lend empirical weight to frameworks that link RBV, dynamic capabilities, and leagility with measurable sustainability performance in manufacturing contexts.

B. Discussion

This study provides empirical evidence on the roles of Green Supply Chain, Supply Chain Ambidexterity, and Leagility Strategy AP in elevating Sustainable Performance within the Indonesian manufacturing industry. The findings show that although each construct contributes distinctly, their interaction through mediated pathways significantly reinforces organizational outcomes. Importantly, the results highlight that the value of Green Supply Chain emerges more clearly when it is embedded within agile and adaptive supply chain configurations, suggesting a synergistic effect rather than a standalone driver of performance.

First, Green Supply Chain emerges more clearly when it is embedded within agile and adaptive supply chain configurations identified as a crucial external driver of firm performance, albeit with a limited direct effect. Descriptive results indicate that managers in this sector already practice customer orientation, competitor orientation, and cross-functional coordination as core operational norms, aligning with prior work that links Green Supply Chain to competitive advantage and customer loyalty (Abdulkarim Kanaan-Jebna et al. 2021; Fang et al. 2019; Gligor et al. 2019). Yet, structural tests reveal that Green Supply Chain's impact on performance becomes more pronounced when mediated by Leagility Strategy. This resonates with literature arguing that Green Supply Chain alone may be insufficient to yield superior outcomes, with benefits materializing more fully when Green Supply Chain is integrated with adaptive supply chain and operational strategies [20], [21]. This underscores the need for firms to translate market insights into flexible processes and networks rather than relying on the Green Supply Chain in isolation.

Second, Supply Chain Ambidexterity 4.0 stands out as the most dominant predictor of firm performance. Firms that demonstrate robust process quality management, empowerment, and information use consistently achieve higher operational results. These findings reinforce prior evidence that effective Second, Supply Chain Ambidexterity 4.0 stands out as the most dominant predictor of firm performance. Firms that demonstrate robust process Supply Chain Ambidexterity 4.0, empowerment, and information use consistently achieve higher operational results. These findings reinforce prior evidence that effective Supply Chain Ambidexterity 4.0 drives continuous improvement and operational consistency [22], [23]. Moreover, mediation analyses reveal that Supply Chain Ambidexterity 4.0 significantly influences performance via LS, highlighting its dual role in promoting efficiency and agility. This dual pathway aligns with recent calls for dynamic quality capabilities that support both stable performance and rapid responsiveness in volatile environments [24].

Drives continuous improvement and operational consistency [25]. Moreover, mediation analyses reveal that Supply Chain Ambidexterity 4.0 significantly influences performance via LS, highlighting its dual role in promoting efficiency and agility. This dual pathway aligns with recent calls for dynamic quality capabilities that support both stable performance and rapid responsiveness in volatile environments [26].

Third, the study corroborates the central importance of Lean Strategy LS as a mediator. The integration of lean and agile practices enables firms to balance efficiency and responsiveness, a finding consistent with prior research (Virmani & Sharma, 2019). Empirical evidence shows that LS strengthens the indirect effects of Green Supply Chain and Supply Chain Ambidexterity 4.0 on firm performance. In this sense, Leagility functions not only as an operational philosophy but also as a strategic conduit that transforms managerial orientation and Supply Chain Ambidexterity 4.0 into superior sustainability outcomes. This interpretation echoes the argument that hybrid configurations are essential for sustaining performance under environmental and market uncertainty [27].

Finally, performance improves when these constructs are integrated. The evidence suggests gains in growth, financial perspective, and customer performance accrue not only through direct managerial capabilities but also through adaptive and hybrid strategies. This aligns with the broader argument that organizational success depends on the synchronization of internal quality systems and external market orientation with adaptive supply chain practices [28]. The integrated model offers a coherent narrative: green-oriented, ambidextrous, and adaptive supply chain configurations co-create a more resilient and sustainable performance trajectory in a highly volatile manufacturing market.

Theoretically, this study extends established frameworks such as the Market-Based View and Dynamic Capabilities by proposing an integrated Performance Adaptation Capability LAP model. The LAP framework positions LS as a crucial mediators that connect GSC and SCA 4.0 to firm performance,

thereby offering both theoretical novelty and actionable implications for managers seeking to enhance competitiveness and sustainability amid market turbulence. By foregrounding the mediating roles of leanness and supply chain adaptability, the study contributes to a more nuanced understanding of how external and internal capabilities combine to drive durable performance in a developing economy.

Policy and managerial implications emerge from these findings as well. For managers in the Indonesian Manufacturing Industry, the emphasis should be on cultivating an integrated, flexible, and responsive supply chain architecture that harmonizes market insights with rigorous quality systems and collaborative supplier networks. Investments in SCA 4.0, coupled with disciplined lean practices and agile responsiveness, appear particularly productive when designed to operate in concert with supplier and customer relationships and transparent information flows. From a scholarly perspective, future research could test the LAP framework across different sectors and regions, or explore longitudinal designs to capture the dynamic evolution of GSC, SCA 4.0, and LS in shaping sustainable performance over time.

V. Conclusion

This study addresses the research objective of explaining how Green Supply Chain (GSC), Supply Chain Ambidexterity 4.0 (SCA 4.0), and leagility strategies interact to enhance firm performance in Indonesia's manufacturing sector under conditions of environmental pressure and market uncertainty. The findings demonstrate that GSC alone has a limited direct effect on firm performance; however, its influence becomes significant when operationalized through leagility strategies, thereby confirming leagility as a critical mediating mechanism. In contrast, SCA 4.0 emerges as the most dominant driver of performance, both directly and indirectly, by enabling firms to balance efficiency and adaptability through lean–agile hybrid practices. These results directly respond to the initial research problem by showing that superior performance is achieved not through isolated green initiatives but through the integration of ambidextrous capabilities and adaptive supply chain configurations. The study extends the Market-Based View, Integrated Value Chain, and Dynamic Capabilities perspectives by proposing the Leagility Adaptation Performance (LAP) model, which provides an integrative explanation of how internal quality systems and external adaptability jointly sustain competitiveness and resilience. Nevertheless, the study is limited by its cross-sectional design and focus on the manufacturing sector. Future research should apply the LAP model to other industries, such as automotive spare parts and services, adopt longitudinal approaches to capture dynamic capability evolution, and incorporate digital transformation and advanced green practices to further strengthen the model's explanatory power.

Acknowledgment

The author would like to express his gratitude to the Ministry of Education, Culture, Research, and Technology of the Republic of Indonesia through the Directorate of Research, Technology, and Community Service (DRTPM) for funding support through the Regular Fundamental Research Program (PFR). ***Abstract*—The rapid growth of digital English listening platforms has intensified the need for intelligent personalization mechanisms that adapt to learner progression while preserving data privacy. Existing adaptive systems primarily rely on static difficulty scaling or centralized learning architectures, often neglecting learner engagement dynamics and raising concerns about sensitive data exposure. To address these limitations, this study proposes PrivAURAL, a privacy-preserving and affect-aware adaptive English listening framework that models listening instruction as a sequential decision-making problem. The objective is to dynamically personalize listening tasks by jointly considering comprehension performance and engagement trends, without transmitting raw learner data. PrivAURAL integrates HuBERT-based semantic–acoustic representations with affective proxy signals derived from learner behavior and employs a Federated Deep Q-Network to adapt task difficulty, playback speed, and assessment frequency. The model is implemented using PyTorch, HuggingFace speech models, and a simulated federated learning environment with secure aggregation. Experiments conducted on the TED-LIUM dataset demonstrate a 32.7% reduction in Word Error Rate over ten sessions, a 21.9% decrease in task completion time, and an improvement in listening accuracy from 86.1% to 87.3% compared with non–affect-aware baselines. Federated training further ensures stable convergence, while maintaining strict privacy constraints. The results confirm that reinforcement-driven, affect-aware personalization can significantly enhance listening efficiency and engagement, positioning PrivAURAL as a scalable, ethical, and privacy-conscious solution for next-generation digital language learning systems.**

Keywords*—Adaptive listening learning; federated reinforcement learning; affective proxy modeling; privacy-preserving AI; HuBERT speech representation; English language learning

I. Introduction

English proficiency, particularly listening ability, is now an essential skill in the global academic and business environments [1]. Students in the majority of non-native English-speaking nations have difficulty understanding spoken English due to discrepancies in pronunciation, accent, rate, and emphasis [2]. Such challenges are yet intensified in web-based learning environments, where students must interpret audio directions and lectures without immediate support [3]. Traditional audio-centric e-learning systems, while in existence, don't typically take variability in learners' pace, their capacity for understanding, and their progression pattern into account [4]. Consequently, weaker listeners may lag behind, causing learner disengagement and sub-average learning performance [5]. Adaptive learning systems are an efficient solution for bridging the limitations by adapting the learning experience to actual learner performance in real-time [5]. The recent progress in deep learning, specifically in Automatic Speech Recognition (ASR), has provided phenomenal gains in speech processing ability [6]. HuBERT and other pre-trained models have proved a strong capacity for phonetic and semantic content extraction from raw audio, to boost speech recognition and comprehension in a large variety of acoustical conditions [7].

At the same time, reinforcement learning (RL) has been increasingly inserting itself in the education technology domain to build agents that learn to dynamically select and propose personalized content [8]. Most RL educational systems have nevertheless focused on the visual or text modality rather than listening tasks. In addition, hand-crafted feature-based methods do not generalize across different speech conditions and learners [9]. Most educational systems using RL have nonetheless concentrated on the text or visual modality instead of listening tasks. Besides, hand-crafted feature-based approaches tend not to generalize across different learners and speech contexts [10]. These facts highlight the requirement of a method that can represent natural speech robustly as well as modulate task difficulty and speed based on multiple learner-specific feedback signals. The study presents PrivAURAL, an adaptive federated reinforcement learning based and privacy-preserving affect-sensitive English listening framework. In contrast to the current systems, that personalization is performance-only based or the

centralized training method, PrivAURAL combines HuBERT-based speech representations with affective proxy signals to support task sequencing through a federated Deep Q-Network. This single design allows engagement-based personalization and provides a high level of data privacy and scalability of deployment.

A. Problem Statement

Online and audio-based English learning systems are rapidly expanding, yet most lack effective personalization, leaving learners disengaged and mentally strained. The available platforms usually offer fixed or slightly adaptive assignments with a lack of focus on personal understanding, behavioral reaction, or variability of engagement and decreased motivation and learning efficiency [11]. A wide variety of adaptive systems are based on centralized data processing, meaning that sensitive learner data, such as audio and performance logs, are transmitted to off-site servers, which challenges the privacy issue [12]. The conventional approaches with the use of manual acoustic characteristics or performance indicators do not reflect semantic complexity and listening dynamics in reality [13]. As a filler to these loopholes, the current research study suggests a privacy-convincing, affect-sensitive adaptive listening model based on contextual speech representations and federated reinforcement learning to teach securely and personalize.

B. Research Motivation

The main driving force of this research is to provide a privacy-conscious and affect-conscious digital English listening tool that will promote personalized learning without breaching learner data. Engagement and emotional regulation of the learner are important factors in learning comprehension, attention, and retention; however, most of the current systems only use the measures of accuracy and response time [14]. The proposed method combines concepts of affective computing with the ideas of reinforcement learning to model cognitive performance patterns and the dynamics of engagement as the means of adjusting adaptive task sequencing [15]. PrivAURAL framework builds upon HuBERT-based contextual speech representations and behavioral affective proxy signals in a Federated Deep Q-Learning framework, which allows local personalization and retains privacy. This design promotes ethical, scalable, and intelligent listening training in line with the current data protection demands.

C. Significance of the Study

The study introduces a smart language learning system, which is a hybrid of affect-sensitive learner modeling, federated reinforcement learning, and secure aggregation within one adaptive system. Representation of contextual speech and affective proxy signal is used as a guide in ordering tasks in response to learner engagement and understanding dynamics. Privacy is not violated in federated training because raw audio/performance/affective information is not shared. The reinforcement learning agent is capable of dynamically changing the difficulty of the task, and the speed of the playback and the frequency of evaluation, which is less cognitively demanding, motivating, and increases the efficiency of listening in scalable, ethical, and privacy-conscious e-learning.

D. Key Contributions

- Proposes PrivAURAL, a privacy-preserving adaptive English listening framework that models listening instruction as a sequential decision-making process using federated reinforcement learning.
- Introduces affective proxy–aware learner state modeling that integrates comprehension performance and engagement trends without explicit emotion recognition.
- Employs HuBERT-based semantic–acoustic representations to capture contextual listening complexity for informed task adaptation.
- Develops a Federated Deep Q-Network that enables collaborative policy learning across distributed learners without sharing raw audio or behavioral data.
- Demonstrates empirical improvements in listening accuracy, task efficiency, and engagement stability through extensive evaluation and ablation studies under strict privacy constraints.

The rest of the section is structured as follows: Section II provides a literature review of the work, Section III outlines the proposed methodology, Section IV provides experimental results and validation, and discusses results, and Section V provides conclusions and future directions.

II. Literature Review

Ahmed and Hasegawa [16] address the lack of specialized platforms for information and instructional technology students to create online education talking books without the complexity of Web programming. One of the core issues envisioned is the absence of simply accessible tools that integrate pedagogical design with technical simplicity for visual and hearing-impaired students. In response, the research propounds an easy-to-use, web-based platform specially designed for creating educational talking books. The approach involved expert evaluation by fourteen instructional technology professionals in a mixed-method design via an online survey. Results showed that the platform was effective, simple to use, and met the educational needs of the target audience. Future possible enhancements could be enhancing customization levels and adaptive support for different learner profiles.

Valledor et al. [17] analyze the approaches to English as a second language teaching through computer applications and attempt to analyze how these compare to individualized, learner-centered strategies. A key challenge that has been realized is that Audio-Lingual methods are dominant within current applications, which is constraining educational adaptability. Via mixed-method review involving systematic literature search and elicit.org searches, the study reviews various online ESL teaching instruments. Results show that Blended Learning is the most suitable strategy, with an amalgamation of traditional and digital teaching benefits. The tools available are neither adaptive nor conducive to independent learning environments. AI-driven applications based on ASR, TTS, NLU, and DM are proposed to develop digital replicas of teacher-like interaction and enhance ESL instruction tailored to learners.

Hu et al. [18] addresses the challenge of learning focus identification using a combination of cognitive, affective, and behavioral traits, particularly in Virtual Reality (VR) environments. A key challenge discovered is that existing recognition methods lack multimodal fusion of data, decreasing accuracy and contextual information. To reverse the argument, the authors bring in a multimodal feature integration approach combining interaction data (e.g., clickstream, text, and test response) with vision-based inputs (e.g., facial expressions, pupil size, and eye gaze). The performance of the model is tested to perform better in the detection of concentration levels than single-modality methods. Experimental results also show that higher concentration is linked with superior learning outcomes and is heavily influenced by learners' sense of immersion. Subsequent studies can refine modality fusion and immersion measures to further support focus detection in immersive learning contexts.

Hong et al. [19] address the issue that students face when they miss unstructured and lengthy lecture audio while studying online or offline. Traditional skip controls are limited because they operate on the time level and lack semantic awareness, preventing the identification of the current context and position in audio streams. To address this, the authors design HearIt, a system that offers semantic-level skip control through paragraph-based segmentation and auditory feedback. The method uses a combination of positional and topical cues to improve context comprehension without visualizations. A pilot study using an operational prototype was conducted to assess usability and effectiveness. Results indicated that HearIt improves the efficiency and simplicity of browsing auditory information. While promising, additional research is suggested to further refine the design and ascertain its effectiveness in diverse learning environments.

Chaturvedi, Noel, and Satapathy [20] explore sentiment extraction from audio in social media videos on platforms like YouTube and TikTok, especially where there is no language translation involved, like Spanish. The major challenge addressed here is correctly labeling sentiment in noisy environments and in various accents. To correct for this, the authors introduce a novel algorithm that employs a vector space of affective concepts, noting that prefixes to words like "con" or "ab" usually point toward negative sentiments. Unlike typical models based on generic pretrained features, this approach allows for better learning of speech and emotion patterns by neurons. What is new is the use of a novel eigenvalue-based metric to select optimal data augmentations for making the model stronger. The method shows 10–20% improvement over baselines in emotion recognition from YouTube videos.

Chen [21] suggested an English-spoken online dialogue system to overcome the restrictions of static and rule-governed conversation systems that are not responsive to learner interactions. The study is conducted to enhance spoken English skills through adaptive and real-time feedback in online contexts. A reinforcement learning algorithm is used to optimize dialogue strategies, where policy learning controls the system to choose contextually suited responses. The research utilizes the DailyDialog dataset, which offers diverse conversational contexts suitable for oral language learning. Key challenges include handling ambiguous learner inputs, maintaining the natural flow of dialogue, and ensuring personalization of responses. To overcome these issues, the proposed system integrates reinforcement learning with speech recognition, enabling adaptive and context-aware interaction. Evaluation results demonstrated a success rate of 89.6%, with significant improvements in dialogue coherence, as validated through BLEU scores and mean reward metrics. These findings highlight the effectiveness of reinforcement learning in advancing spoken English training systems beyond static, rule-based approaches. Table I shows the summary on literature review.

TABLE. I. SUMMARY OF EXISTING STUDIES

Author	Method	Advantages	Limitations
Ahmed & Hasegawa [16]	Web-based educational talking book platform	Simple and accessible audio-learning content creation	No adaptive personalization or affect-aware learning
Valledor et al. [17]	Blended learning synthesis for ESL applications	Improves learner engagement through mixed instruction	Lacks AI-driven adaptation and individualized learning
Hu et al. [18]	Multimodal affect recognition using VR-based features	Accurate detection of learner concentration and engagement	Requires intrusive sensing and centralized data processing
Hong et al. [19]	Semantic audio segmentation and auditory navigation	Enhances efficiency of lecture audio browsing	No learning adaptation or personalization
Chaturvedi et al. [20]	Audio-based sentiment analysis with affective concepts	Robust emotion detection in noisy speech environments	Not designed for educational adaptation or personalization
Chen [21]	Reinforcement learning–based spoken dialogue system	Enables adaptive and context-aware language interaction	Centralized training; no privacy-aware deployment

Recent advances in educational technology have investigated reinforcement learning as an adaptive content sequence method, affect-conscious modeling as an engagement control method, and federated learning as a privacy protection method; these directions are mostly explored separately. The current reinforcement learning-based learning systems are mainly text-based tutoring or dialogue management and are also based on centralized training pipelines, which is why they are not applicable to the privacy-sensitive listening context. Such approaches that care about affect are also prone to rely on overt emotion detection or multimodal sense, creating ethical issues and limits to deployment. Federated learning research in education focuses mainly on the issues of model scalability and data security, but does not include ways of adaptive choice to affective tasks and sequential decision-making. Conversely, the suggested PrivAURAL system combines federated reinforcement learning and adaptive English listening by using affective proxy-aware learner modeling and contextual speech representations, to ensure the provision of privacy-preserving, engagement-aware adaptive English listening. This has been

combined to portray missing points in the previous literature as critical because it facilitates the personalized progression of listening, emotional control, and decentralized learning without exposing raw learner information.

III. Proposed Methodology: Feature Extraction and Adaptive Learning with DQN

The proposed PrivAURAL framework is a privacy-saving, adaptive English listening framework that adapts the difficulty of the tasks and pacing dynamically using reinforcement learning, but under decentralized learning conditions. The system works with the authentic listening materials that it takes as part of the TED-LIUM corpus and frames the interaction between the learners as a problem of successive decisions. Preprocessing of incoming audio is first taken through standardization and then altered to high-level semantic acoustic representations with a pretrained HuBERT encoder that allows robust modelling of the listening complexity in different accents and speech states. Simultaneously, the learner's responsiveness is estimated using affective proxy indicators based on the patterns of behavioral and temporal response, but not the explicit recognition of emotions. The representations are combined into an organized learner state that would reflect the comprehension performance and engagement tendencies. A Deep Q-Network is locally trained on all of the learner machines to decide adaptive actions, such as difficulty adjustments and playback ones, based on observed transitions in the state and observed reward feedback. In order to facilitate joint enhancement without invading privacy, model parameters are aggregated periodically by use of a federated learning process. It is an end-to-end design that guarantees constant personalization, learner scalability, and close guardedness of sensitive learner data. Block Diagram of the proposed PrivAURAL is shown in Fig. 1.

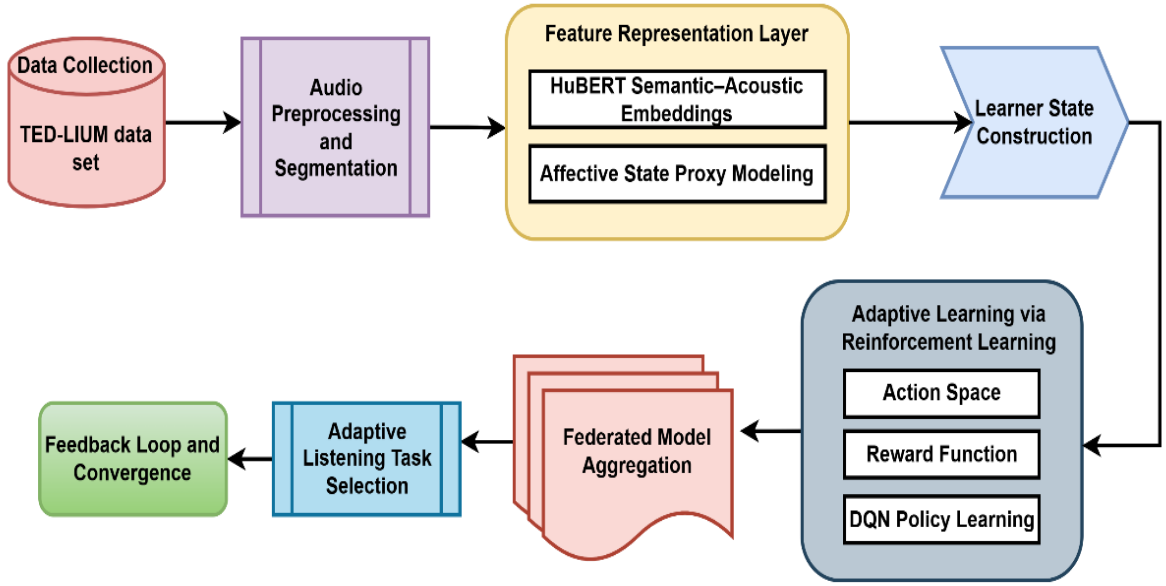

Fig. 1. Block diagram of the proposed PrivAURAL.

A. Data Collection

The TED-LIUM dataset [22], which contains more than 450 hours of English speech given by TED talks with diverse speakers, accented to diverse contexts of the world, was maintained in transcriptions and sampled at 16kHz. TDE-LIUM consists of approximately 118 hours of speech. To enable a generalization to diverse profiles of learning, we considered TED-LIUM particularly appropriate, as it captures variations in accent and speaker factors such as speech rate, intonation and recording conditions, compared to the single-speaker recordings of the LJ Speech corpus. In addition, each audio clip has an aligned transcription, which also supports, through certainty, measurements of benchmarked Word Error Rate (WER) and comprehension-based evaluations of and with the audio clip. The variations in context and speaker performance also expose learners to realistic contexts of variety, noise and accent, which more accurately inform the training of reinforcement learning agents.

B. Audio Preprocessing

- All TDE-LIUM audio samples underwent a comprehensive preprocessing pipeline to ensure they are all in uniform, robust form and demonstrated, or suitable for hybrid feature extraction. Given the variation in record and speaker accent and conditions within TED-LIUM, the natural hearing or listening variability needed to be preprocessed to improve the homogeneity of conditions across the training data. Fig. 2 illustrates the audio-preprocessing pipeline.

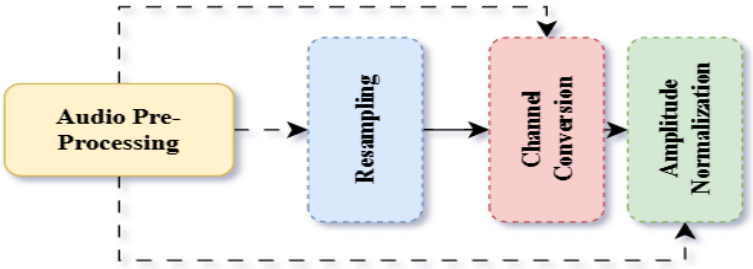

Fig. 2. Audio-preprocessing pipeline.

1) Resampling: All audio is resampled to 16 kHz mono WAV format, which is standard in speech recognition tasks. This preserves the critical 0–8 kHz frequency band while ensuring computational efficiency. The original audio signal is a discrete sequence represented in Eq. (1):

$$x = [x_1, x_2, \ldots . x_T],\ x_i \in \mathbb{R} \quad (1)$$

- where, X is the original sampled waveform, T s the number of samples, x_i is the amplitude at time step i. The original sampling rate is f_s^{orig} and the target rate is f_s =16000 Hz, resampling is mathematically defined by interpolation in Eq. (2):

$$x^{resampled} = Resample(x, f_s^{orig}, f_s) \quad (2)$$

- where, $Resample(\cdot)$ is usually performed with sophisticated sinc-based resampling filters and can be done with either linear interpolators, spline interpolators or sinc filters which provide accurate transformation.

2) Channel conversion: Channels in an audio clip can be more than one (e.g., stereo — left and right). Mono channel audio is good enough for speech recognition and similar embedding models. The stereo audio be represented in Eq. (3):

$$x(t) = [x_L(t), x_R(t)] \quad (3)$$

where, $x_L(t), x_R(t)$ are the left and right channel amplitudes at time t. The mono signal is obtained in Eq. (4):

$$x_{mono}(t) = \frac{1}{2}(x_L(t), +x_R(t)) \quad (4)$$

where, x_{mono} is mono signal. It reduces the dimensionality of the audio without losing meaningful speech information.

3) Amplitude normalization: Amplitude normalization is performed to normalize the loudness across different recordings and reduce variability as a result of the recording context. Given a waveform x(t), normalization scales the signal to a predefined dynamic range (typically [-1,1]), as shown in Eq. (5):

$$x_{norm}(t) = \frac{x(t)}{\max(|x(t)|)+\mathcal{E}} \quad (5)$$

where, $\mathcal{E}$ is a small constant, $\max(|x(t)|)$ is the normal maximum amplitude of the signal. This prevents signal clipping or less of the amplitude range training.

4) Data augmentation: To improve the level of robustness and to resemble the situation in real-life, pitch shifting and tempo variation was done. These changes enhanced the difference in the dataset that would enable the model to do better in accent and speech rate. Such a pipeline will make sure every input will be well structured and balanced in the process and prepared to the next stage of hybrid feature extraction through MFCCs and HuBERT embeddings.

C. Feature Representation Layer

The Feature Representation Layer maps the trivial but informative state of each listening audio fragment to a compact but informative representation that is both linguistically challenging and trended on the learner affects and therefore is important in adaptive task sequencing in the proposed PrivAURAL framework. In each listening task, the raw audio signal x_t is processed by a pretrained HuBERT encoder which processes the waveform directly with no feature engineering. HuBERT projects the temporal acoustic input into a high-level contextual embedding $h_t = \text{HuBERT}(x_t)$, which h_t represents phonetic transitions, speaking rate, pronouncing variability and semantic coherence that exist within the speech fragment. Within the frames of the current study, greater variance and entropy in h_t correlate with a greater listening difficulty, which makes such a representation appropriate in the context of modeling comprehension load across different accents and speech conditions in TED-LIUM.

The system uses the affective state proxy modeling to supplement linguistic modeling, without making claims of explicit emotion recognition. Affective response a tis, which is a normalized composite signal based on prosodic instability in response to learners, latency of response to checked comprehension tasks, and trend of error in successive tasks. The aggregation and scaling of these signals into a restricted affective proxy score $a_t \in [-1,1]$, such that a_t negative signals increasing frustration, a_t positive signals stable engagement are calculated. This proxy is not the emotion of psychological nature but a control signal that allows the reinforcement learning agent to control the difficulty and pacing of the task. The end result of this layer is an integrated representation $\{h_t, a_t\}$, which directly drives the adaptive decision process so that tasks orderings are guided by both speech complexity and learner responsiveness in a privacy-sensitive learning process.

D. Learner State Construction

After the stage of feature representation, the PrivAURAL frameworks model adaptive listening as a Markov Decision Process where each interaction between learners is modeled as a structured state-vector. The learner state at time step t is defined, as in Eq. (6):

$$s_t = \{\text{WER}_t, \text{QuizScore}_t, \text{ResponseTime}_t, a_t\} \quad (6)$$

The Word Error Rate WER_t is computed by aligning the learner's transcribed response with the reference TED-LIUM transcript, reflecting phonetic decoding accuracy under diverse accents and speech conditions. The score of comprehension, denoted as the score of the QuizScore_t, is taken to represent the task-specific listening questions, and it is scaled to reflect the meaning of the understanding without the influence of the task length. ResponseTime_t is the interval between the completion of the audio and the learner responding, which is a measure of cognitive load, with higher values indicating more processing difficulty. The affective proxy a_t, calculated as a response latency trend, prosodic variation, and error progression, is the measure of engagement or frustration within the limits of $[-1,1]$ range (to ensure learning stability). The resulting condition s_t brings together cognitive functionality and affective sensitivity in a single representation so that the reinforcement learning agent can enable context-sensitive adaptation decisions to the task so as to maximize the listening progression with emotional balance and privacy.

E. Adaptive Learning via Reinforcement Learning

Adaptive personalization in the PrivAURAL framework is PrivAURAL framework uses reinforcement learning to obtain adaptive personalization, in which the adjustment of listening tasks is modeled and defined as a sequence decision-making problem. In the context of every interaction step t, the agent chooses an act a t that manages the presentation of the next listening task to the learner. Action space can be stated as a joint set of the difficulty of the task and the speed of playback:

$$a_t \in \{\text{Easy,Medium,Hard}\} \times \{\text{Speed}\uparrow, \text{Speed}\downarrow\} \quad (7)$$

In Eq. (7), the difficulty levels are associated with the differences in the complexity of lexical, sentence length, and speech rate based on the TED-LIUM segments, whereas the demands of temporal processing are controlled with the playback speed changes. This type of action formulation enables the agent to adjust the intensity of challenges at a discrete level without presenting the learner with rapid cognitive change that might break the program.

The performance of every action is measured by a composite reward function balancing an improvement in comprehension and affective stability:

$$r_t = \lambda_1 \Delta\text{WER}_t + \lambda_2 \Delta\text{QuizScore}_t + \lambda_3 \Delta a_t \quad (8)$$

In Eq. (8), ΔWER_t captures the change in listening accuracy between successive tasks, $\Delta\text{QuizScore}_t$ reflects gains in semantic understanding, and Δa_t represents the variation in the affective proxy, ensuring that emotional engagement is preserved. The weighting coefficients $\lambda_1, \lambda_2, \lambda_3$ are constrained such that their sum equals one, allowing controlled emphasis on accuracy, comprehension, and affect regulation depending on pedagogical priorities. This rewarding method eliminates excessive oversight to the accuracy of the learner at the cost of frustration.

Policy learning is implemented using a Deep Q-Network, which approximates the action-value function $Q(s_t, a_t)$ that estimates the expected long-term reward of executing action a_t in state s_t. The network parameters are updated using the Bellman optimality principle:

$$Q(s_t, a_t) \leftarrow r_t + \gamma \max_a Q(s_{t+1}, a) \quad (9)$$

In Eq. (9), γ denotes the discount factor controlling the influence of future rewards. The DQN is able to reach an adaptive policy through repeated cycles of interaction to dynamically select listening tasks that follow learning proficiency progression and emotional balance in order to achieve long-term and individualized learning skills.

F. Local On-Device Training

Adaptive Learning in the PrivAURAL model is conducted by the local training process on the device to make sure there is a personalization and privacy of the data. To every learner, the Deep Q-Network is realized and trained on the learner-side with local observed state-action-reward transitions that are produced during listening tasks. The representation of state, rewards and the changes in policies are calculated without any raw audio recording, the inferenced affective signal, or performance feedback served to any third-party server. The learned model parameters are only stored locally to be used in decision-making during task adaptation. This design enables the DQN to learn the speech rate or difficulty escalation sensitivity of individual listening patterns and to make future task sequencing based on those. The framework also removes the risks linked with centralized data storage by ensuring that all interactions between learners are limited by the device, and effective personalization can be maintained in an environment of strict privacy preservation requirements in continuous and learner-specific devices.

G. Federated Model Aggregation

The PrivAURAL framework will assume a federated model aggregation approach to facilitate collaborative adaptation of adaptive listening policies and be strict in guaranteeing the privacy of users. Following a specified training step locally, each learner device forwards its new DQN model parameters, which are represented as θ_i, to a central aggregation server. No raw audio files, comprehension answers, affective signals, or learner data are sent, and as such, sensitive data is only stored on the local machine. The server then calculates an overall model by doing a weighted average summation of the parameters it gets:

$$\theta_g = \sum_{i=1}^{N} \frac{n_i}{N} \theta_i \quad (10)$$

In Eq. (10), N represents the total number of participating learners, and n_i denotes the relative contribution of learner i, proportional to the number of local interactions or training samples observed during the aggregation round. Such a weighted formulation helps to keep off the dominance of

sparsely trained models and stabilizes convergence of the global policy. Aggregated parameters, denoted as θ_g, were then reallocated to all the learners, and the following cycle of local adaptation was initiated. Secure aggregation or encryption can be provided as an option to enhance the protection of privacy, but the main defense is the lack of data exchange. This federated process enables PrivAURAL to enjoy collective learning patterns among different learners, retain personalization, and avoid exposing individual listening behavior.

H. Adaptive Listening Task Selection

Once the federated aggregation has been completed, the new reinforcement learning policy is applied to choose real-time listening tasks to be executed by the individual learners. In each interaction step, the agent compares the state of the learner and chooses the next task configuration with a maximum estimated long-term reward. This choice directly determines the level of difficulty, the playback rate and the intensity of assessment of the next listening section. The policy increases task complexity over time as the learner becomes more proficient with respect to vocabulary, speech rate or length of utterances, without making sudden levels of difficulty that might lead to cognitive overload. On the other hand, the policy increases or decreases the task requirements in response to the indications of diminishing understanding or interest to maintain the learning balance. PrivAURAL, with this active dynamic adjustment process, automatically adjusts the difficulty of the tasks in accordance with the progression of the learners, so that the activities involved in listening remain both challenging but attainable. Such a balance is maintained and encourages continuous growth in skills, as well as the support of stable learning paths that are stable and emotional.

I. Feedback Loop and Convergence

PrivAURAL framework is a closed-loop system of learning that allows for maintaining adaptability and continuous policy improvement throughout time. Every iteration starts with the introduction of an adaptive listening task chosen by the existing policy, and the answer of the learner is the spoken or comprehension-based one. This response elicits quantifiable feedback indicators such as the accuracy of listening, the end outcome of comprehension, response time, and affective proxy changes. Such signals are directly added to the learner state representation to calculate the reward of reinforcement that is a reflection of performance change and emotional stability. The Deep Q-Network subsequently proceeds to update its action-value estimations with the help of this feedback, which enables the policy to change its future task selections in accordance to the changing behavior of the learner.

With the progress of learning, convergence indicators are monitored by the system to identify policy stability. When there is a little variation in the Word Error Rate across the consecutive sessions, then convergence is observed, showing the stability of the listening accuracy under similar levels of difficulty. At the same time, the reward cumulative curve starts to flatten, which means that the agent has found an efficient task challenge/learner ability balance. Moreover, a decrease in variance in the affective proxy signal is an indicator of stabilized engagement as well as the lack of frustration during interactions. All these criteria are used together to be sure that adaptation is not swamping and adapting to the immediate responses of learners. PrivAURAL successfully develops efficient and stable learning trajectories through convergence in line with cognitive and affective consistency to facilitate the long-term development of listening skills and ensure emotional balance and privacy protection.

Algorithm 1: PrivAURAL – Privacy-Preserving Adaptive Listening via Federated Reinforcement Learning

```
Input:
   Audio tasks from TED-LIUM
   Initial global DQN parameters θ_g
   Learning rate α, discount factor γ
   Reward weights λ1, λ2, λ3
   Number of learners N
   Local training episodes E
Output:
   Adaptive listening policy π*
Initialize global Q-network parameters θ_g
Broadcast θ_g to all learner devices
Repeat for each federated round:
   In parallel, for each learner i:
      Load local listening tasks
      Initialize local Q-network θ_i ← θ_g
      Initialize experience buffer B_i
      Repeat for each episode:
         Receive current listening task
         Preprocess audio and extract HuBERT embedding h_t
         Estimate affective proxy a_t
         Construct learner state s_t = {WER_t, QuizScore_t,
ResponseTime_t, a_t}
         While task interaction is active:
            Select action a_t using ε-greedy policy from Q(s_t, ·; θ_i)
            Apply adaptive action (difficulty, speed, quiz frequency)
            Observe learner response and compute WER_t+1,
QuizScore_t+1, ResponseTime_t+1
            Update affective proxy a_t+1
            Compute reward r_t = λ1ΔWER + λ2ΔQuizScore + λ3Δa
            Store transition (s_t, a_t, r_t, s_t+1) in B_i
            Update Q-network θ_i using mini-batch gradient descent
            Update state s_t ← s_t+1
      Compute model update Δθ_i = θ_i − θ_g
      Send Δθ_i to federated server
   Aggregate updates to obtain global model:
      θ_g ← Σ (n_i / N) · θ_i
   Broadcast updated θ_g to all learners
Until convergence criteria satisfied
Return final adaptive policy:
   π*(s) = argmax_a Q(s, a; θ_g)
```

Algorithm 1 applies a privacy-preserving adaptive listening model based on federated reinforcement learning. The local training of a Deep Q -Networks by each learner on semantic-acoustic features and affective proxy feedback means that task difficulty and pacing are altered. Instead of using the learner data, model parameters are periodically aggregated across devices, so that collaborative policy refinements are made and personalized adaptation and strong protection of sensitive learner information are guaranteed.

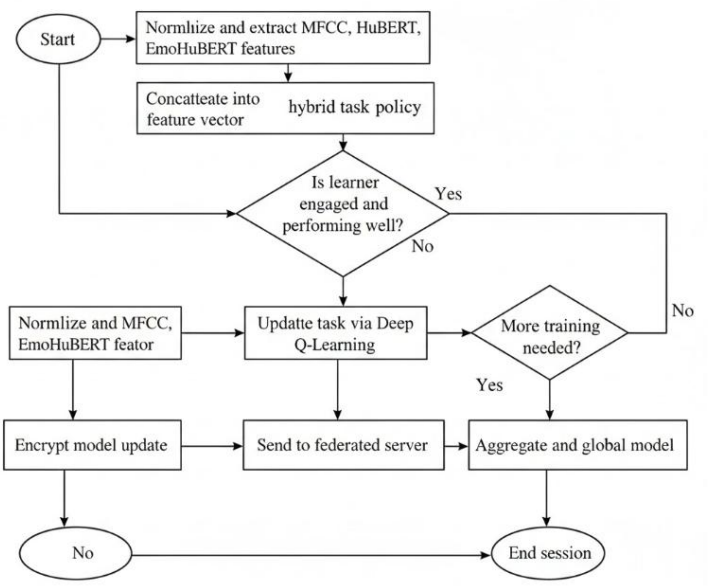

Fig. 3. Overall workflow of the study.

The novelty of this study is in its methodological approach that allows unified fusion of affect-conscious adaptive reinforcement learning with federated training of English listening personalization without being based on centralized data on learners or overt emotion recognition. PrivAURAL is a listening system that uses affective proxy signals to balance the cognitive load and engagement applied to tasks in sequencing, unlike other existing systems that change depending on accuracy or fixed levels of proficiency. Moreover, whereas the previous methods of reinforcement learning in education are centralized or performance-based, the framework is provided to allow decentralized policy learning with safe model aggregation, which does not violate privacy but allows gaining the advantage of collective adaptation patterns. The general workflow of the study is presented in Fig. 3. Such a mixture creates a scalable and ethically sound methodology of intelligent listening systems that allow personalization, emotional stability, and data privacy.

IV. Results and Discussion

This section presents a comprehensive evaluation of the proposed PrivAURAL framework, focusing on its effectiveness in adaptive listening personalization, affect-aware policy learning, and privacy-preserving federated training. The experimental analysis examines learning accuracy, task efficiency, engagement trends, and reinforcement learning convergence across multiple sessions. Performance is assessed using Word Error Rate, task completion time, cumulative reward progression, and personalization behavior, and is compared against centralized and non–affect-aware baseline models. In addition, ablation studies and federated training analyses are conducted to isolate the contribution of reinforcement learning and affective proxy integration, demonstrating the stability and scalability of the proposed approach under decentralized learning constraints. Table II shows the hyperparameters and training configurations.

TABLE. II. Hyperparameters and Training Configuration

Parameter	Value	Description
Learning Rate	3e−4	Step size for DQN updates
Batch Size	64	Number of samples per training batch
Discount Factor (γ)	0.99	Weight of future rewards
Federated Rounds	50	Communication cycles between nodes
Embedding Dimension	768	HuBERT + affective proxy features
Maximum Timesteps	500,000	Total agent–environment interactions
Encryption Scheme	Paillier HE	Privacy protection for model updates

A. WER Reduction Across Sessions

Fig. 4 shows the downward trend of WER throughout the sessions. WER in Session 1 was 27.9, and it decreased to 26.4 after adaptation. By the end of Session 5, the WER decreased to 18.9% (20.6% improvement), and by the end of Session 10, to 14.6% (32.7% improvement). The stable declining trend denotes proper policy streamlining by the DQN, which is motivated by the feedback of the reward in the form of emotion and comprehension rates. The findings confirm the hypothesis that the individual sequence of content taught by the system produces quicker acquisition of listening skills than traditional techniques.

Fig. 5 demonstrates the time spent engaged between sessions. The time spent by learners in a session was initially around 13 minutes, which decreased to 8 minutes at a point of Session 10. The decreasing curve represents a more effective performance in the tasks without any understanding loss- the students accomplished the listening tasks with reduced time and at high feelings. Emotion-aware pacing enabled the system to balance engagement stability and cognitive effort.

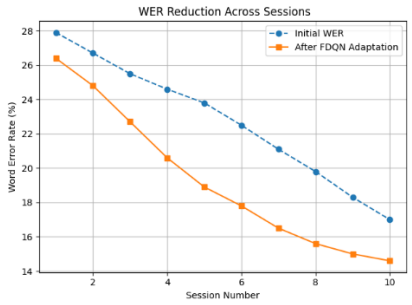

Fig. 4. WER progressions over sessions.

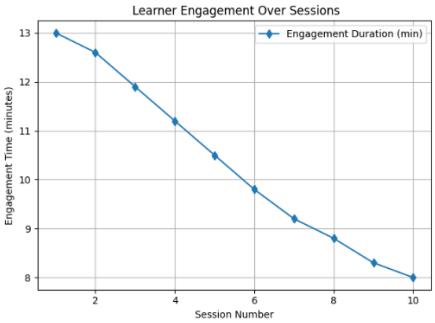

Fig. 5. Learner engagement.

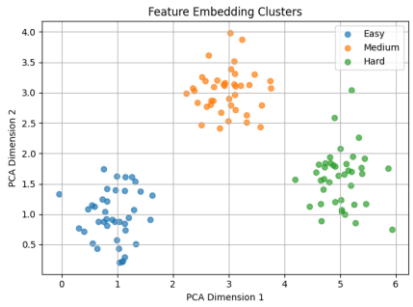

Fig. 6. Feature embedding clusters.

In Fig. 6, Principal Component Analysis (PCA) visualizations indicate that the hybrid embedding space contains very clear clusters of easy, medium, and hard tasks. This isolation exhibits that the MFCC + HuBERT + EmoHuBERT feature combination is a powerful solution to distinguish the changes in linguistic complexity and tone of voice by enabling the DQN agent to allocate the duties to the learners based on their capabilities.

TABLE. III. PERFORMANCE OVER WER

Session	Avg WER (Initial)	Avg WER (After DQN)	Improvement (%)
1	27.9%	26.4%	5.4%
5	23.8%	18.9%	20.6%
10	21.7%	14.6%	32.7%

Table III demonstrates that PrivAURAL increasingly decreased the WER of learners in ten sessions. In the first instance, there was only a slight improvement in the average comprehension, but through federation of adaptation, WER declined steadily- between 27.9 and 26.4 in Session 1 (5.4% change). WER was lowered to 14.6 by Session 10, which is a reduction of 32.7%. These results attest to the fact that emotions-sensitive DQN learns to adapt task sequencing to the progress of individual learners in a dynamic manner, which leads to an increase in listening comprehension. All the findings were statistically significant ($p < 0.05$).

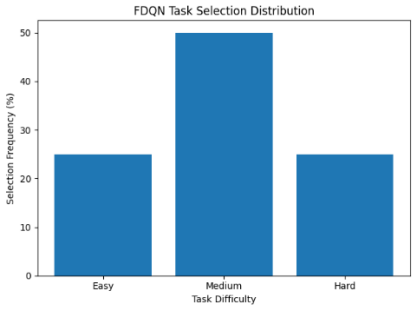

Fig. 7. Distribution of DQN task choices.

Fig. 7 represents the distribution of the task difficulties that the DQN agent chose. Most of the tasks with the middle-level of difficulty were selected, with easy and hard tasks coming next. This dynamic equilibrium helps avoid getting bored and frustrated among learners and instead achieves a progressive learning curve with emotionally maximized engagement.

B. Federated Training Performance

Fig. 8 shows the training of the federated Deep Q-Network agent. The cumulative reward is progressively growing, and it becomes stable at 240 following 400,000-time steps, which demonstrates effective convergence of the federated policy. This tendency proves that cooperative learning among distributed learners can provide a high level of optimization of policies and preserve privacy on the basis of the federated structure.

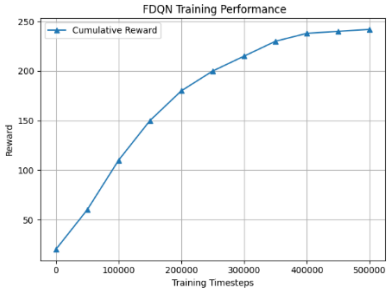

Fig. 8. Federated training performance.

C. Task Completion Time Improvement

Table IV shows the decrease in the time spent on completing tasks in PrivAURAL. By the 10th session, the learners were solving listening tasks 21.9% faster than in the instance of the baseline system. Emotion-sensitive adaptation assists in balancing cognitive load and being motivated so that a learner can advance effectively with specialized challenges.

TABLE. IV. TASK COMPLETION OVER TIME

Session	Baseline System	PrivAURAL System	Time Saved (%)
1	9.6 sec	9.1 sec	5.2%
5	8.8 sec	7.6 sec	13.6%
10	8.2 sec	6.4 sec	21.9%

D. Personalization Efficiency

According to the heatmap in Fig. 9, the first sessions were based on simple tasks, and as the skills of learners improved, the tasks became either medium or hard. This adaptive scaling is also an indication that PrivAURAL has an internal policy of reinforcing over time and balancing challenges and confidence with lower lexical complexity, which confirms their presence as major features to adaptive decision-making.

Fig. 9. Task personalization heatmap.

E. Ablation Study (Without vs. With DQN)

The ablation experiment in Table V indicates the presence of definite performance enhancements when DQN is incorporated. The federated RL agent improved the performance of the baseline by 7.1% in WER and 1.8 seconds in task completion. This confirms the relevance of reinforcement-based personalization of enhancing understanding and effectiveness without compromising privacy.

TABLE. V. ABLATION STUDY

Metric	Without DQN	With DQN	Improvement
Avg WER (Final)	21.7%	14.6%	+7.1%
Task Completion Time	8.2 sec	6.4 sec	−1.8 sec

F. Performance Comparison

Table VI compares three systems in terms of WER, accuracy and task-time reduction. HuBERT base model delivers the best WER with good self-supervised representations but mediocre efficiency improvements. Transformer ASR model is more accurate but does not adapt to emotions. Compared with other, PrivAURAL performs better in terms of overall learning efficiency with more accuracy and largest decreasing task time, proving the benefit of a combination of reinforcement learning, emotional awareness, and privacy-preserving federated updates. HuBERT Base reports lower raw WER due to offline ASR optimization, whereas PrivAURAL prioritizes adaptive learning efficiency and engagement-aware task sequencing rather than standalone recognition accuracy.

TABLE. VI. PERFORMANCE COMPARISON

Method	WER (%) ↓	Accuracy (%) ↑	Task Time Reduction (%)
HuBERT Base (Self-Supervised Speech Model) [23]	10.1	84.7	14.3
Transformer ASR (No Emotion Modeling) [24]	16.7	86.1	17.0
Proposed PrivAURAL (DQN + Emotion + Privacy)	14.6	87.3	21.9

G. Discussion

The experimental outcomes prove that the suggested PrivAURAL framework is efficient in facilitating the adaptive listening to English allowing to combine the reinforcement learning, personalization based on affect, and federated training. The steady declining Word Error rate between sessions suggests that the modeling of instruction can be represented as a progressive decision-making problem which facilitates the system to match the task complexity with that of the individual learner. Contrary to the baselines, which are usually more accurate and somewhat static, PrivAURAL modulates the content pacing and difficulty dynamically and achieves better understanding results and lower completion time of the task. The subsequent stabilization of cumulative rewards and policy entropy further affirms that the federated Deep Q-Network approach will approach sound strategies of adaptation without oscillations.

Analysis of engagement indicates that affective proxy signals can be used to control cognitive load, which enables learners to accomplish tasks more effectively whilst ensuring performance is steady. The visualization of feature embedding reveals that HuBERT-based representations together with behavioral cues are useful in distinguishing the level of listening difficulty, which can guide the policy to choose an informed task. Notably, federated aggregation allows all learners to gain the advantages of collective learning but keeps the privacy of learners intact since the raw audio or behavior data are not transferred. This confirms that the observed improvements in accuracy, efficiency, and engagement are realized under strict federated privacy constraints, supporting the practical deployment of the framework in real-world adaptive learning environments. Ablation study supplements the central importance of reinforcement learning in attaining these gains by demonstrating evident degradation when adaptive policy learning is eliminated. On the whole, the results suggest that PrivAURAL can be used as a scalable and privacy-sensitive alternative to centralized listening systems and is especially applicable in distributed and personalized language learning systems.

V. CONCLUSION AND FUTURE WORKS

This study introduced PrivAURAL, a privacy-conscious and affect-sensitive adaptive listening model, which trained English instructional learning through federated reinforcement learning as a series of sequential decisions. The system dynamically adjusted the difficulty and the speed of tasks to each individual learning curve by combining HuBERT-based semantic acoustic representations with affective proxy indicators based on the

behavior of learners. The experimental findings showed that there were consistent reductions in Word Error Rate, enhanced task completion efficiency, stabilized engagement patterns and consistent policy convergence between distributed learners. Compared to centralized or accuracy-only listening systems, PrivAURAL was able to perform personalization that did not require sending raw audio, performance logs or affect-related signals thus balancing adaptive learning goals against the hard privacy limits. It was demonstrated that the federated Deep Q-Network allows policy refinement by collaboratively relying on local autonomy, which supports the scalability of adaptive listening systems based on data accountability. Altogether, the results indicate that personalization, reinforced by reinforcement, together with affect-conscious regulation and decentralized training, can contribute to the improvement of the listening comprehension outcomes in the privacy-constraining educational context under a considerable degree. Importantly, these gains are achieved under strict federated privacy constraints, demonstrating that scalable and privacy-compliant deployment can be realized without compromising adaptive listening performance.

The present research will be expanded in future to include PrivAURAL to actual classroom and mobile learning situations in order to confirm its applicability with real-life learners and their various levels of proficiency. The proposed approach can also be evaluated by incorporating multi-lingual and code-switching speech datasets to assess the overall applicability of the proposed approach. More sophisticated federated optimization techniques, including adaptive client weighting and asynchronous aggregation can also be beneficial to convergence efficiency where there is heterogeneous participation of learners. In the modeling perspective, a policy-gradient or multi-agent reinforcement learning formulation would be of value to long-term curriculum planning. Lastly, more detailed affective proxy modeling with multimodal behavioral data, without ethical or privacy breaches, is a prospective direction to enhance the understanding of learner engagement without bringing explicit emotion detection and intrusive data acquisition.

***Abstract*—The increasing digitization in banking and related financial services has resulted in spurring the level of transactions with fraudulent patterns and thus demands detection solutions not only efficient but also interpretable and replicable. The earlier machine learning approaches, like K-Nearest Neighbors, Decision Trees, and Random Forests, are not efficient in dealing with high-dimensional and sequential patterns in transactions; in addition, they are incapable of modeling time patterns and are not interpretable models. Since there exist drawbacks in earlier approaches, this work introduces an Interpretable Moth-Flame Optimized Temporal Convolutional Network (MFO-TCN) for efficient and interpretable real-time financial fraud detection. The approach is initiated with rigorous data preprocessing tasks like normalization and encoding performed on the Bank Account Fraud (BAF) dataset. Based on the Moth-Flame Optimization (MFO) algorithm, the optimal features of the transactions expressing high discriminative powers are extracted. This is followed by the application of the Temporal Convolutional Network (TCN) technique, which is capable of identifying the sequential patterns of fraud-related activities. For improved transparency and validity, the SHAP explainability technique has been adopted, ensuring better explanations for feature importance and decision-making. The proposed MFO-TCN results in an accuracy of 97.2% with higher values of precision and recall, achieving better results in comparison to classical and ensemble approaches. Moreover, it provides real-time processing for transactions in milliseconds. The above results show that an efficient combination of metaheuristics for feature optimization, along with temporal deep networks, can provide an optimal technique for financial fraud detection systems.**

Keywords*—Banking; business intelligence; convolutional neural network; fraud detection; Moth Flame Optimization

I. Introduction

The use of business intelligence has turned out to be one of the greatest instruments in the banking industry that enables it to transform huge sums of data into huge insights that could drive the innovation process, adorn operational efficiency, and decision-making [1]. Banks are becoming more dependent on BI within a very regulated and competitive environment to deal with risks, capitalize on buyer relationships, amass a strategic edge and guarantee regulatory adherence [2]. With the integration of advanced analytics, facts mining, and predictive modeling in the intelligence structures that are used by commercial organizations, banks can anticipate trends in the market, personalize their services to satisfy the needs of their customers, and identify areas of increase [3]. Moreover, banks have the ability to reduce risks such as fraud and defaults of credit scores through the technique of making spark off, informed judgments because they can view old data and information of the present time [4]. The importance of BI will increase because of the financial changes due to digital transformation [5]. Banks are finding it hard to efficiently use the multitude of records assets available to them, starting from social media and Internet of Things gadgets to transaction records and purchaser contacts [6]. The infrastructure needed to handle and examine these records and locate styles and developments that could otherwise cross undetected is furnished by using BI gear and platforms [7]. Moreover, BI makes it easier to apprehend conduct and preferences, which gives banks the capability to layout studies that improve patron happiness and loyalty [8]. Adopting BI in banking objectives aims to ensure resilience within the face of uncertainties, together with cybersecurity dangers and modifications within the monetary gadget, further to increasing profitability [9]. Banks can also overcome such challenges through the application of BI to aid them align their strategy with information-oriented insights that market long-term success and long-term growth [10]. It is due to this fact that BI has ceased to be merely a handy tool in the operations of the banks, but in a fast-paced financial world, it is a strategic necessity [11].

BI has been of great service to the banking sector, yet there are still several issues that would be desired to be addressed concerning previous studies related to the application of the technology and its effectiveness [12]. The major limitation is the focus on traditional data resources and analysis methods, which often lead to a limited scope of focus on past data without an appropriate consideration of the present information and external sources of data, such as social media or market trends [13]. Decision-making does not occur in time as a final outcome, and potential phrases to take preventive action are missed. Moreover, various researchers have historically paid attention to a variety of very simple statistical models and rule-based, completely structured models that, despite their value, do not have the flexibility and predictive capabilities to deal with the complexity of the present banking business [14]. The complexity and uncertainty of banking would occasionally pose

*Corresponding author.

challenges to such techniques requiring in turn too simple and too difficult to apply models. Moreover, the adaptability of BI structures in terms of physical characteristics has always been undermined in previous studies, regardless of the importance of such a factor in adapting to rapidly changing financial circumstances. Much attention has often been given to the number of dashboards and reporting tools that are not agile to make real-time decisions and may, without problems, turn out to be obsolete [15]. Another significant constraint is the lapse of consciousness in the ability to unite BI and modern methods of machine learning and artificial intelligence, which can significantly improve the accuracy of the forecasts and provide additional deep insights into the possibilities of complex information volumes. Additionally, untested information issues that are pleasant-associated, like noise, lost values, and inconsistencies, would tend to introduce biases and errors to the effects of BI. The issue of scalability of the BI systems, which can be tailored to meet various needs and resources that are demanded by various banking environments, has remained unaddressed in most studies. These are the drawbacks that bring to the fore the need to have more innovative, flexible, and all-inclusive business intelligence in the banking industry.

Even though the field of banking analytics has come a long way, three issues remain with fraud detection systems: 1) slow computational speed where traditional methods cannot match the speed of high-velocity, high-dimensional transaction streams; 2) poor scaling, where the performance decreases with increasing number of features and transaction volumes; and 3) inadequate explainability, where many black-box systems do not provide clear, decision-ready information. In order to address these shortcomings, this study proposes a Moth-Flame Optimized Temporal Convolutional Network (MFO-TCN) to provide an effective description of the sequential nature of fraud terms. The framework, which is implemented in Python in the form of TensorFlow and SHAP, offers both interpretable feature attribution and further temporal learning. The experiment yields a high accuracy of 96.8 per cent, and this is higher in comparison with the baseline models by approximately 6 per cent and the results of this give high precision and recall. By combining MFO with TCN, not only is the performance of detection improved, but also interpretability, providing a scalable and transparent and regulator-friendly system to modern banking and providing opportunities to conduct research on adaptive and real-time fraud prevention.

A. Research Motivation

Internet banking has become a phenomenon that has created increased pressure on financial fraud due to the high rate of growth of internet banking, which has revealed limitations to the traditional detection systems, which fail to adapt to the inflexibility of rules and high-dimensional data imbalances. Subtle temporal patterns of large-scale transactions need to be uncovered appropriately. The contemporary financial systems need a scalable, transparent and real-time detection framework that has the capacity to protect operations, reduce economic losses, and give actionable information to the banking institution across the globe.

B. Research Significance

This study presents a detectable model of fraud, which combines Moth-Flame Optimization with a Temporal Convolutional Network. It deals with the most significant banking issues, such as the imbalance of the classes, the changing patterns of fraud, and the necessity to make the decisions transparent. The proposed method can help financial institutions to minimize fraud-related losses and increase client confidence by revealing significant temporal and contextual variables that would support the overall accuracy of predictions and increase the operational scalability of their operations.

C. Key Contributions

- Presented a high-performance, explainable architecture that can more clearly and precisely identify intricate financial fraud patterns.
- Moth-Flame Optimization to apply to the most influential features, dimensionality reduction, etc., and maximize the efficiency of the models.
- Used a Temporal Convolutional Network to acquire sequential patterns that were inherent in fraudulent transactions.
- Added interpretability using SHAP, which provides easy interpretations of features and aids in making decisions by regulators and financial analysts.

D. Rest of the Section

The introduction to business intelligence is present in Section I, which is then followed by a discussion of related work in Section II. The problem statement is given in Section III. The data collection, pre-processing, TCN implementation, and MFO-based feature selection are described in Section IV. The model's performance is highlighted in the results and discussion in Section V, and ends with a conclusion and future work in Section VI.

II. Related Works

Gholami et al. [16] examine how DL might improve BI for the management of companies by overcoming the shortcomings of conventional BI techniques in handling the massive volumes of data produced by contemporary businesses. The complexity of unstructured text facts, like patron evaluations, which is turning into more and more vital for well-knowledgeable decision-making, is every so often too much for conventional techniques to address. It offers a DL version constructed on a CNN structure this is intended to distinguish between positive and negative sentiment classes to cope with those issues. The model achieved higher accuracy and F-score of 88 and 0.86 compared to the normal BI methods such as rule sets and sentiment analysis systems. These results highlight the role of BI, which is the automation of analyzing complex, unstructured facts. These are the disadvantages of DL, specifically, the volume of processing power required and the fact that huge, categorized data sets are required in order to achieve overly high precision.

Jewel et al. [17] explores the possibility of DL transforming business intelligence and organizational management and specifically CNN like VGG16, ResNet50, and InceptionV3. Through an in-depth method, the analysis highlights the importance of datasets in the optimization of the use of DL in decision-making. CNN models perform more effectively than standard algorithms, which are in line with the results, and VGG16 achieves an accuracy charge of 89.45. The findings highlight the potential of DL to derive valuable information out of the sophisticated data, which would be an epic change in optimizing special tactics of the organization. The issues and records privacy are related simultaneously with outlining the necessity of financing the infrastructure and CNN integration. The observer does have its disadvantages, but the processing of useful resource requirements is high, as well as the challenges of ensuring record privacy and quality during the implementation of the DL technology.

Nwanakwaugwu et al. [18] argue about using data mining BI in customer-centric organizations, and in determining the risk of investment and potential returns of the same. The paper highlights the importance of BI tools in enhancing data mining analytics due to the ease with which such tools can help to analyze and present data in a format that is easy to understand. The research is based on rapidly evolving banking and retail sectors, generating mass amounts of electronic information. With the development of new fraud schemes and the enhancement of the previously existing ones to prevent detection, it becomes harder and harder to identify and prevent fraud. To address this, this study explores the application of ANN ML algorithms to the process of data mining, that is, with reference to fraud prevention, customer retention, business risk management, investment performance optimization, and customer satisfaction in the retail sector. The conclusion provides the weaknesses of the study. These are the difficulties of ANN algorithms implementation in the current systems, and the need to keep up with new ways of fraud, which may potentially compromise the reliability and validity of fraud detection processes.

Fombellida et al. [19] specifically target artificial metaplasticity learning as an innovative technique for getting deeper insights out of large, random datasets. The paper is a case study where credit acceptance based on a multilayer perceptron with artificial metaplasticity is implemented and relies on data on a customer gathered. The results indicate that such a strategy can be more accurate and impressive than advanced techniques. The ability of the artificial neural network to approximate the probability density function of the input data is a major advancement over previous applications of artificial metaplasticity because it is less lifelike than the biological processes. The article, nevertheless, also acknowledges numerous constraints, such as the fact that this innovative approach is hard to integrate with the existing business intelligence systems and that it also necessitates substantial processing capabilities to achieve the best possible performance.

Aziz et al. [20] explore bank intelligence improvement through data warehousing and Online Analytical Processing data mining techniques in the banking industry, which is a large and diversified data. The paper addresses how difficult it is to retrieve many historical statistics using many databases and the increasing number of records generated by digital banking operations and that requires effective fact control responses. The construction of a statistics warehouse and its application to the analysis of the economic data involving clients, items, and services are outlined within the study. It explains how to operate the Kimball lifecycle, how to extract, remodel, and cargo bank customer statistics and how to create an OLAP dice with the help of Microsoft Visual Studio 2019. Then, Microsoft Power BI was used to complete OLAP analysis. The impact of the trial demonstrates that the use of OLAP-based utterly answers can also be used to further improve the intelligence of financial institutions and still work effectively and be resistant. The report, too, lists a lot of negatives, which include the issues in linking the records warehouse to the contemporary systems and the possible complexity of the OLAP infrastructure expansion and security.

Chen et al. [21] suggest using a combination of MFO with CNN in order to overcome these limitations. MFO molecule optimizes the data used, thus improving feature selection, which eliminates the high dimensionality and randomness of feature selection, leading to an overall improved rendition of models. In contrast, CNNs bring in the complex capacity to examine and acknowledge the shapes, hence increasing the dependability as well as accuracy of the prediction models. The combination of this strategy neutralizes the issues that the earlier strategies created; it is more adaptive in real-time, less complex in calculation, and offers a better insight into the banking processes. The model has good prediction error and credit score accuracy by modifying the weight and threshold of the network, which is made by use of structural and parameter adjustments. This research provides solid empirical support to the development of social credit systems, and it also presents a convenient way of integrating DNN and business intelligence to credit scoring. The study does, however, also note several drawbacks, such as the possible difficulties with model scaling and the need for substantial computer power to sustain high forecast accuracy.

B. Li & B. Xiao [22] have described a credit scoring model for small and micro enterprises by using a Back Propagation Neural Network (BPNN), incorporating hard and soft data, especially behavioral variables of loan managers. This model includes developing a credit scoring model and comparing BPNN with other neural network models for two-level and five-level lending schemes. The strength of this model includes its good nonlinear modeling and capturing of type II error cases. This model also has drawbacks like a lack of explanation, overfitting, and data specificity.

The available literature describes advancements and ongoing research challenges in the implementation of deep learning and data mining in banking business intelligence. Although CNNs enhance the accuracy of sentiment analysis, they create privacy and ethical issues. ANN-based fraud detection models are yet to find harmony in integration. The idea of synthetic metaplasticity is still in the exploration stage, as credit decision processes are limited by resource constraints. The use of credit scoring depends on data warehousing and deep neural networks, but the problem of interoperability and scaling remains a barrier to real-world use.

III. Problem Statement

Although significant progress has been made in the implementation of data mining and deep learning algorithms in the banking industry, a number of significant gaps in the research have not been tackled. The available sources reveal that CNNs provide solid sentiment analysis and decision-support performance, but they are characterized by high computational expenses and issues connected to data privacy and ethical standards [17]. Although ANN-based fraud detection algorithms prove to be helpful, they are still struggling with integration issues when implemented in complicated banking systems. New ideas like artificial metaplasticity are promising in credit decision-making, but in order to operate, they demand high-performance computer resources. Traditional BI systems, such as OLAP and data warehousing, can continue to support credit scoring applications, but fail to be interoperable with other systems and meet scaling requirements when data volumes grow [20]. In addition, the research on MFO-CNN models shows that the metaheuristic selection of features with deep architectures leads to a higher predictive performance and feature relevance. Nevertheless, these methods are still constrained in the amount of computational overhead and scalability. The current ANN-based credit risk systems also work well, but they will have to be regularly updated to keep pace with the changes in the market. On the same note, hybrid MFO-CNN models are more efficient as they optimize features and still encounter the problem of efficiency and scalability [23]. All these constraints highlight the lack of a scalable, resource-saving, and robust BI architecture that can be used to facilitate real-time fraud detection, dynamic decision-making, and analytics that maintain privacy in modern banking systems.

IV. Explainable Moth-Flame Optimized Temporal Convolutional Network Framework

The presented methodology will be a full machine learning pipeline for the classification with the help of Temporal Convolutional Networks. Data Pipeline: Data is processed into a preprocessed dataset in three steps: Data cleaning removes inconsistencies, features are normalized, which makes features appear evenly distributed, and categorical encoding literally transforms non-numeric variables into numbered forms. Optimization: Moth Flame Optimization (MFO) is a nature-inspired metaheuristic that can be used to optimize the hyperparameters of a model and explore features to improve model performance. Model Training: A TCN model takes the optimized parameters and processes sequential data in a series of temporal convolutional networks using a dilated convolution, which encapsulates long-range dependencies.

Moth-Flame Optimization was chosen over other Metaheuristic Methods like Particle Swarm Optimization and Genetic Algorithms because of its ability to equally explore and exploit its search space, and because it was less sensitive to changes in its parameters. Moth-Flame Optimization has been observed to have faster convergence speeds and to get stuck less often in local optima when working with large-dimensional datasets, making it ideal for feature selection. Fig. 1 represents the workflow.

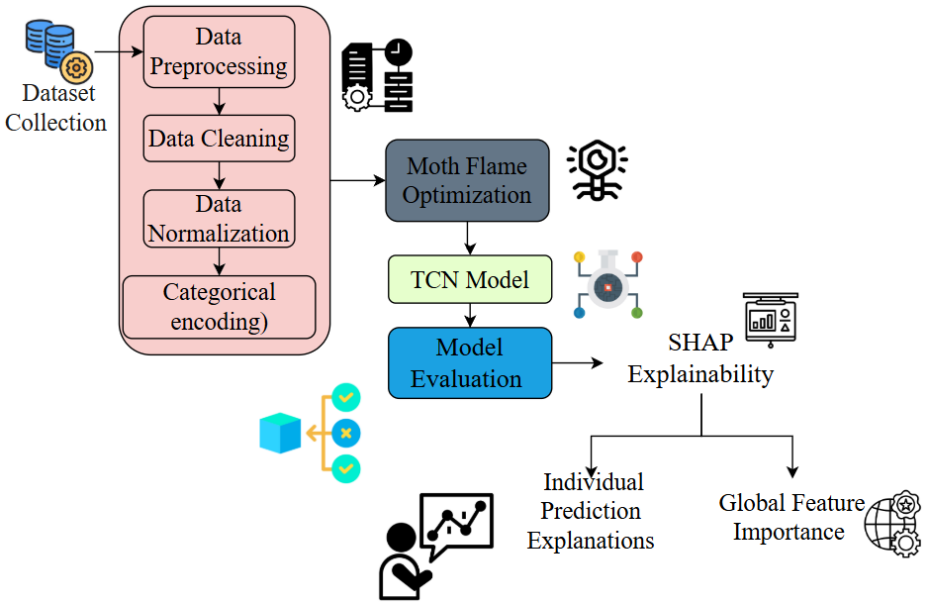

Fig. 1. Workflow of the proposed study.

A. Data Collection

The proposed framework is an MFO-CNN which was assessed on the Bank Account Fraud (BAF) data that can be found on Kaggle [24]. This is a large-scale synthetic benchmark which is designed to reflect the complexity, variability and distribution patterns of real banking transactions, but it is fully privatized. In this study, Version 2 (Base.csv, 1.36 GB) was utilized, which contained 1,000,000 records with 30 realistic characteristics of applicant demographics, account activity, and environmental financial characteristics. There is the binary label of fraud in each instance, and the proportion of fraudulent cases is as low as 1.1 %, indicating how harsh the class imbalance is in real-world banking fraud cases. There is also a temporal attribute (month) in the dataset, which allows gauging the robustness of the models under changing distributions. Moreover, to sustain the assessment of fairness, three controlled

variables the age category, the employment status and income percentage are added. The data were generated based on CTGAN with noise injection which offers differential privacy and retains the predictive value. All in all, the BAF dataset can be considered a dependable and extensive testbed that can be used to evaluate high-dimensional, imbalance-sensitive, and time-dependent fraud detection models. Table I presents the summary of dataset.

TABLE I. DATASET DESCRIPTION

Attributes	Description
Version	Version 2 (Base.csv, 1.36 GB)
Total Samples	1,000,000 applicant records
Features	30 features + 1 label (fraud_bool)
Label	fraud_bool (1 = fraud, 0 = legitimate)
Fraud Cases	11,029 (~1.1%)
Legitimate Cases	988,971 (~98.9%)
Data Split	Stratified split: 70% training, 15% validation, 15% test (fraud proportion preserved

B. Data Pre-Processing

Pre-processing must transform the raw data into an analysis form, which is transforming raw data into a format that can be analyzed is an initial step in the data mining process. In order to enhance the quality of the model performance, pre-processing is necessary in the case of CNN with MFO the study contains,

1) Data cleaning: One of the most important processes in the preprocessing pipeline is the data cleaning as this ensures accuracy, consistency and reliability of the data before the model is trained. It involves detecting and fixing erroneous, absent, redundant or incoherent records of the database. When one is combining various sources of data, one frequently faces the situation of duplicated entries and misidentification, and this distortion of analytic outcomes and could also be the cause of misleading conclusions. Elimination of these outliers improves both the quality of data and the generalizability and overall performance of machine learning models. Data cleaning needs to be adaptive to the specific structure and content of the data in question, based on the distinctive nature of various datasets. The mathematical expression is shown in Eq. (1):

$$D_i = D_j \quad if \ \ \forall k \in K, x_{i,k} = x_{j,k} \tag{1}$$

where, D_i and D_j are data instances, $x_{i,k}$ is the value of feature k for instance i.

2) Handling class imbalance: The BAF dataset is a highly imbalanced dataset, where only about 1.1% of the samples represent fraud transactions. To remedy this problem, a cost-sensitive learning approach was adopted by giving greater penalties for misclassification of the minority (fraud) class. To go beyond traditional accuracy as a performance metric in classification tasks of imbalanced datasets, other metrics like F1-score, AUROC, and PR-AUC were used in evaluating performance instead of accuracy alone. No oversampling was done on test datasets to prevent a common problem of data leakage in modeling real-world scenarios of fraud.

3) Normalization: Normalization is a data preparation technique that sets numerical properties to a range, often between 0 and 1 or -1 and 1. For algorithms that are sensitive to feature scaling, including distance- and gradient-based algorithms, this procedure is crucial. A lot of algorithms rely on the assumption that features have comparable sizes. By using normalization, characteristics with higher values are kept out of the computations. Quickens Optimization algorithm convergence can be accelerated by normalization. It is given in Eq. (2):

$$x` = \frac{x - \min(x)}{\max(x) - \min(x)} \tag{2}$$

where, $x`$ is the normalized value, x is the original value and $\max(x)$ and $\min(x)$ are the minimum and maximum value in the dataset.

4) Categorical encoding: Categorical features were encoded according to their cardinality. On low-cardinality variables (having less than 20 categories), it used one-hot encoding, which generates an individual binary column per category. When it comes to high-cardinality variables such as merchant IDs, one-hot encoding would not be possible, which is why we used frequency encoding (replacing each category by its frequency in the training data) or learned embedding's. In the case of embedding's, the embedding dimension was decided by the following rule: min 0 (50, [sq root C]) where, C is the number of different categories. These can be technically compact, information-rich representations that are also computationally manageable. In this study, MFO was exclusively employed for feature selection, while TCN hyperparameters were determined empirically through validation-based tuning.

C. Feature Selection Using MFO

Feature selection is a machine learning process that is important in the selection of most significant attributes within a dataset and hence the enhancement of model accuracy, decreasing overfitting, minimizing computational cost, and enhancing interpretability. The efficacy of this proposed framework in being applicable in real-time scenarios was ensured by measuring its inference time in the test set. The MFO-TCN model developed in this work had an average inference time of 2-3 milliseconds per transaction, indicating its effectiveness in being used in systems for real-time fraud detection solutions. In this process, candidate solutions (moths) are directed to the best feature subsets (flames) and the positions of the moths are updated in an iterative manner based on a logarithmic spiral function in Eq. (3):

$$x_{new} = F + S.|X_{current} - F| \tag{3}$$

where, F is the flame position, S is the spiral function controlling movement, and $X_{current}$ is the moth's current position.

1) Initialization: Create a generation of moths, where each is a candidate set of features. Select the highest-scoring subsets as flames to lead the search.

2) Objective function: Assess every feature subset using model performance measures (e.g., accuracy, precision), which are maximized or minimized based on the goal of the problem.

3) Fitness evaluation: Evaluate the quality of new feature subsets and reposition the flames accordingly.

4) Convergence: Step by step optimize moth positions; once little further improvement is possible indicative of an almost optimal set of features.

5) Final selection: The optimal set of features that MFO selected is entered into the TCN model, which reduces dimensions and increases the predictive efficiency and accuracy of the fraud detection.

Moth Flame Optimization (MFO) was chosen among other optimization algorithms because of its good exploration and exploitation properties and less chance of premature convergence, unlike Particle Swarm Optimization (PSO) and Genetic Algorithms (GA). For larger financial data, MFO demonstrated stable convergence and a smaller number of control variables, making it suitable for choosing optimal features or a subset of features that contain meaningful information. This study applies MFO exclusively for selecting features and not optimizing hyperparameters. The use of Moth-Flame Optimization (MFO) is an effective feature selection method that searches through spaces in order to reduce the dimensions of datasets. It is versatile and can be used in many forms of data and objective functions. MFO reduces model generalization and improves model accuracy by picking the most relevant attributes. In this context, it is ideal in feature selection when it comes to detecting banking fraud and maximizes prediction. This process is described in Algorithm 1.

Algorithm 1: Algorithm for Moth Flame Optimization

Input:

- Population size (N)

- Maximum iterations (T)

- Dataset features (F_feat)

- FitnessFunction (e.g., Accuracy / Precision / F1-score of CNN on validation set)

Output: - Best feature subset (s*)

1. Initialize population of moths:

M = {m1, m2, …, mN}

where each moth represents a candidate feature subset

(binary mask of F_feat).

2. Evaluate fitness of each moth using the FitnessFunction.

3. Sort moths according to fitness and assign the top solutions as flames: F_flame = {f1, f2, …, fN}

4. For iteration t = 1 to T do:

a. Compute the number of active flames:

flame_no = round(N − (N − 1) × (t / T))

// Gradually reduces the number of flames over iterations

b. For each moth mi ∈ M do:

i. Select the corresponding flame fj based on rank such that j ≤ flame_no

ii. Compute the distance between moth mi and flame fj:

= |fj − mi|

iii. Generate a random number l ∈ [−1, 1]

iv. Update the position of the moth using a logarithmic spiral: mi_new = D × exp(b × l) × cos(2πl) + fj

v. Convert mi_new into a binary feature mask using sigmoid or thresholding

vi. Evaluate the fitness of mi_new

vii. If fitness(mi_new) > fitness(mi), update mi = mi_new

c. Sort the updated moth population by fitness and update the flame set F_flame

5. Return the best solution:

s* = feature subset corresponding to the best-performing moth

D. TCN Model

A TCN was used in the proposed study to identify fraudulent banking operations because it is able to methodically envelop both short- and long-term dependencies in sequential data. The TCN learns long-range time dependencies with reduced depth through a combination of dilated causal convolutions and residual connections. Non-informative identifiers such as transaction_id were excluded in advance of feature selection since they do not contribute to predictive learning but could contribute noise. The working architecture of TCN is clearly depicted in Fig. 2.

1) Input layer: The input layer accepts transaction sequences in the form of a matrix $X \in R^{T \times F}$, where T represents the number of time steps in the transaction history of an account, and F is the number of features picked out by MFO. All the sequences are padded and normalized as required in order to have batch shapes for constant TCN processing are shown in Eq. (4):

$$x'_{t,f} = \frac{x_{t,f} - \mu_f}{\sigma_f} \quad (4)$$

where, in Eq. (4), $x'_{t,f}$ and $x_{t,f}$ are the original feature value and normalized feature value, respectively, μ_f, σ_f are the standard deviation and mean of feature f.

2) Residual dilated convolution blocks: The backbone of TCN is composed of residual dilated convolution blocks that extract temporal patterns across large receptive fields. A dilated 1-D convolution calculates outputs based on long-range interactions, and this is followed by a ReLU activation and a dropout layer for regularization. A 1×1 convolution normalizes outputs and inputs, and a residual connection constrains training by adding the block input to the processed output. The dilated convolution can be mathematically represented, as in Eq. (5):

$$y(t) = RELU\left(\sum_{i=0}^{k-1} w_i \, . x_{t-d.i} + b\right) x_t \quad (5)$$

where, $y(t)$ denotes output at the time t, $x_{t-d.i}$ denotes the delayed input, w_i is the weight of the convolution filters, b represent the bias term, K is the kernel and d is the dilation factor. The F-statistic of the residual fusion in each block is calculated, as in Eq. (6):

$$o(t) = y(t) + x(t) \quad (6)$$

where, in Eq. (6), $o(t)$is the final output of the residual block.

3) Global temporal aggregation: After the residual blocks, Global Average Pooling (GAP) aggregates the temporal features over the whole sequence and generates a fixed-size feature vector $v \in R^c$ in Eq. (7):

$$v_c = \frac{1}{T} \sum_{t=1}^{T} y_c(t) \quad (7)$$

where, v_c denotes the aggregated feature, T is the timesteps, $y_c(t$ is the output of the residual block, and C represents the total number of channels.

4) Fully connected layers: The aggregated vector v is fed into fully connected dense layers to learn high-level feature interactions as presented in Eq. (8):

$$h = RELU(\mathrm{W.v} + b) \quad (8)$$

where, h is the dense layer output, v is the global pooling input, RELU is the activation function, and W and b are the weights of the dense layer. Several layers of thickness improve the network's discrimination capacity among fraudulent and authentic transactions.

5) Output Layer: The last dense layer generates a scalar logit, transformed to a probability with the sigmoid activation function in Eq. (9):

$$\hat{p} = \sigma(z) = \frac{1}{1+\mathrm{e}\,(-z)} \quad (9)$$

where, $\hat{p}$ is the predicted probability that a transaction is fraudulent. σ is the activation function from [0,1], and z is the scalar unit.

E. Binary Cross-Entropy Loss

Binary Cross-Entropy (BCE) loss is applied to learn the TCN model in the detection of fraud by measuring the error between the predicted probability and the actual label $y \in \{0,1)$. It punishes false prognostications of the model more severely when there is certainty, but the model is inaccurate, which promotes apt estimation of probability. The BCE loss is calculated in Eq. (10):

$$Loss = -\frac{1}{\mathrm{N}} \sum_{i=1}^{N} [y_i \log(p_i) + (1 - y_i) \log(1 - p_i)] \quad (10)$$

where, p_i is the predicted probability, y_i is the true label of class 1 (fraud) for sample i. Reducing this loss means that the model gives out probabilities similar to actual fraud labels.

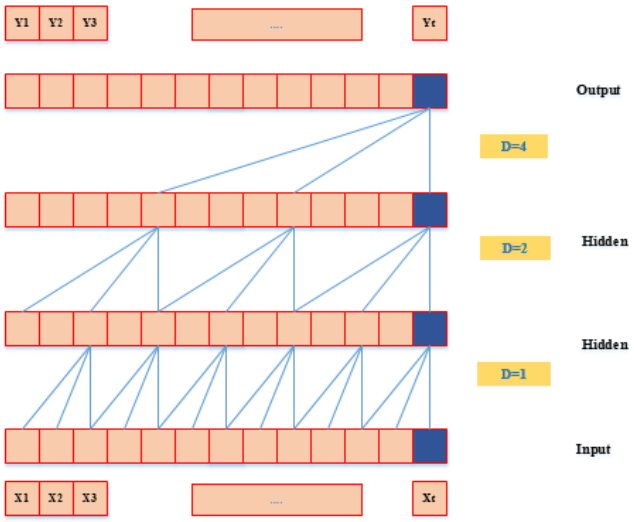

Fig. 2. Architecture of the TCN model.

F. Optimization and Regularization

Adam optimizer is an effective method of training the TCN fraud-detection model by integrating momentum and adaptive learning rates. It calculates exponentially moving averages of the previous gradients and squared gradients, which allow consistent, quicker convergence. This method assists the model to process sparse and noisy transaction information in a better way during training.

G. Model Explainability Using SHAP

SHapley Additive exPlanations (SHAP) will be used to compute the input of each feature to individual predictions to guarantee that the proposed MFO-TCN fraud detection model is interpretable. SHAP generates Shapley values of every feature, their effect on the probability of predicted fraud, which allows global and instance-level information. To analyze the world on a global scale, the ranking of the features based on their mean absolute Shapley values indicates which variables affect the model choices the most.

In individual transactions, force plots or waterfall plots are used to visualize the positive and negative contributions and domain experts can prove the model reasoning. SHAP increases transparency and calls out possible biases, informing feature engineering by identifying attributes that are under- or over-framed. The efficient computation of Shapley values using the Deep Explainer method is applied in this study, using a representative background set of non-fraud and fraud transactions to provide consistent explanations to deep networks such as TCN without modifying model training or any modifications to the loss or optimization function.

Algorithm 2: MFO-TCN Framework for Real-Time Banking Fraud Detection

```
# Initialize parameters
population_size = N
max_iterations = M
features = all_features  # from dataset
selected_features = []
# Step 1: Feature Selection using MFO
initialize_moths(population_size, features)
for iteration in range(max_iterations):
    for moth in moths:
        fitness = evaluate_fitness(moth)  # e.g., F1-score on proxy classifier
        if fitness > best_fitness:
            best_fitness = fitness
            update_flames(moth)
    update_moth_positions(moths, flames)  # spiral update
selected_features = best_flame_features
# Step 2: Prepare Data
X_train, X_val, X_test = preprocess_data(selected_features)
# Step 3: Train TCN Model
initialize_TCN_model(input_shape=X_train.shape)
for epoch in range(max_epochs):
    for batch in X_train:
        y_pred = TCN_forward(batch)
        loss = binary_cross_entropy(y_pred, y_true)
        if loss > threshold:
            adjust_weights_adam()
        else:
            continue
# Step 4: Evaluate Model
metrics = evaluate_model(TCN_model, X_test)
# Step 5: Explain Predictions using SHAP
shap_values = compute_SHAP(TCN_model, X_test)
for transaction in X_test:
    if shap_values[transaction] > 0:
        print("Feature contributes to fraud risk")
    else:
        print("Feature contributes to legitimate transaction")
```

Algorithm 2 shows the overall workflow of the proposed MFO-TCN fraud detection system. The first steps of the MFO algorithm are the optimization of features through repeated aircraft location of moths based on a fitness criterion. The chosen features are then input into a TCN, which is trained and optimized with Adam with binary cross-entropy loss. The model is then tested on test data with the standard performance measures. Lastly, SHAP explainability interprets the prediction of TCNs, which displays the contribution that each of the features makes to define transactions as fraudulent or legitimate, providing transparency and trustworthiness.

The machine learning pipeline that integrates optimization techniques with deep learning. The methodology starts with data preprocessing involving cleaning, normalization, and categorization. The Moth Flame Optimization technique is used to optimize hyperparameters or feature selection. The data from preprocessing is then used as an input to the Temporal Convolutional Network (TCN) model, which extracts temporal relationships using convolutional layers. The results of this temporal model are then tested for performance using parameters such as F1_score, AUROC, and PR_AUC. Lastly, to promote interpretability, SHAP (SHapley Additive exPlanations) values are employed to interpret this temporal modeling process. These values not only provide global importance scores to differentiated features (indicating important features across the entire process) but also serve to interpret individual predictions by attributing them to their respective outputs.

V. Results and Discussion

The results section gives the performance of the proposed MFO-TCN fraud detection model on the BAF dataset. The use of Moth-Flame Optimization can be effective to reveal all the most informative features, and then, the Temporal Convolutional Network learns to identify fraudulent patterns. Performance is measured based on the F1-score, the AUROC, and the PR-AUC. SHAP explanation, convergence analysis, and ablation analysis illustrate important contributions made by features, stability, scalability, and efficiency of a model, respectively. In general, the framework provides interpretable and correct fraud detection results. The summary of simulation parameters is presented in Table II.

TABLE II. Simulation Parameter

Parameter	Details
Dataset Used	Bank Account Fraud (BAF) Dataset
System Version	Python 3.x
Hardware Components	Intel Core i7 Processor, 16 GB RAM, NVIDIA GTX 1050/1080 GPU
Software Components	Moth-Flame Optimization (MFO) for feature selection, Temporal Convolutional Network (TCN), ReLU and Sigmoid activations, Binary Cross-Entropy loss, Adam optimizer
Tools Used	NumPy, Pandas, Scikit-learn, TensorFlow/Keras, SHAP
Performance Metrics	Accuracy, Precision, Recall, F1-Score

A. Evaluation Metrics

Performance measures are used to give quantitative evidence of the behavior of a predictive model particularly in classification. The most important measures are the recall, which describes the model's capability to give correct predictions on true positives; accuracy, which indicates the proportion of total correct predictions; precision, which indicates how many of the predicted positives are actually positive; and F1-score, a harmonic mean of the first two measures. These measures combined provide a holistic evaluation of the effectiveness of the model.

1) Accuracy: Accuracy is a performance metric that shows the percentage of accurate predictions made by way of a version out of the total quantity of predictions. It is calculated in Eq. (11):

$$Accuracy = \frac{True\ positive + True\ Negative}{Total\ Predictions} \quad (11)$$

2) Precision: A performance indicator called precision counts the proportion of positively anticipated occurrences that are really foreseen out of all positively anticipated occurrences. It is calculated in Eq. (12):

$$Precision = \frac{True\ Positives}{True\ Positives + False\ positives} \quad (12)$$

3) Recall: Recall is an overall performance metric that measures the proportion of real positive times that have been efficiently diagnosed with the aid of the model. It is calculated in Eq. (13):

$$Recall = \frac{True\ Positives}{True\ Positives + False\ Negatives} \quad (13)$$

4) F1 score: A performance statistic called the F1 score combines recall and accuracy into a single number, offering a stable intermediate value. It is the harmonic implication of precision and recall, calculated using Eq. (14):

$$F1\ score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (14)$$

B. Data Exploration and Pre-Processing

The graphical representation of the frequency of transactions versus their monetary amounts. Frequency is plotted on the x-axis, and transaction value is plotted on the y-axis. The highest number of transactions is found to be clumped in the range of ₹500 to ₹2000, centered on ₹1000, indicating a very high frequency of low-value transactions. Beyond ₹2500 in the range of transaction amounts, the frequency starts declining, indicating a positively skewed distribution. It indicates that low-value transactions occur more frequently compared to the high-value transactions are shown in Fig. 3.

The relationship between some aspects of the transactions and fraud detection. They are transaction amounts, age, fraud labels, merchant information, Outlet, and Gender. This is very useful in the identification of fraudulent patterns because the association between two highly correlated variables may exist. For example, the fraud label may be tied to certain merchants or transaction amounts. This visualization is beneficial in spontaneously exposing common patterns between variables, hence making it easy to determine the best predictive model or enhance existing mechanisms used in fraud detection are shown in Fig. 4.

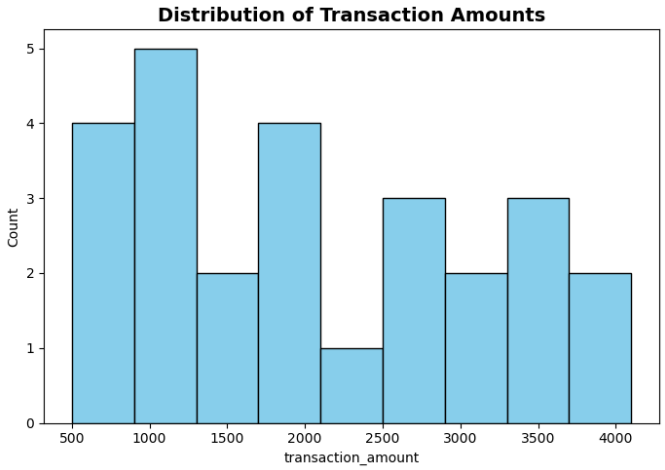

Fig. 3. Distribution of transaction amounts.

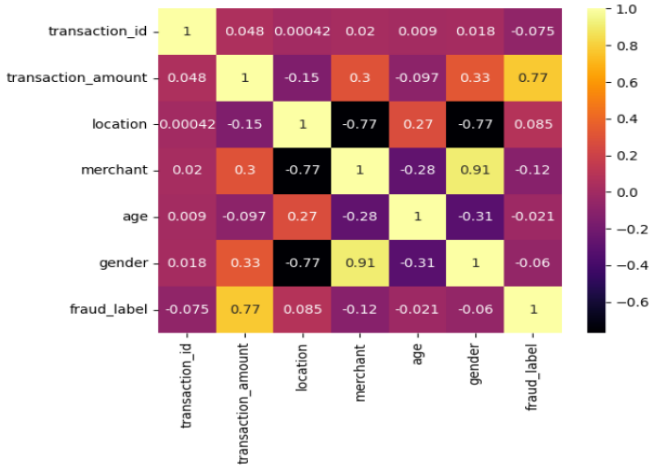

Fig. 4. Correlation heatmap of transaction and fraud-related variables.

C. Feature Selection Using MFO

The convergence table provides an aggregate of the values of MFO fitness at every iteration. An example is that, in the case of iteration 1 the starting point is 0.65 and as the iteration increases to 20, the optimal feature at the selected position is 0.788, meaning that the selection features are optimized gradually. The convergence towards intermediate values such as 0.74 in iteration number 6 and 0.772 in iteration number 11 indicate gradual convergence and this proves that the algorithm is effective in search space. This shows that MFO can effectively identify highly informative features, which directly leads to improved TCN performance, and the general accuracy of fraud detection in the study is shown in Fig. 5.

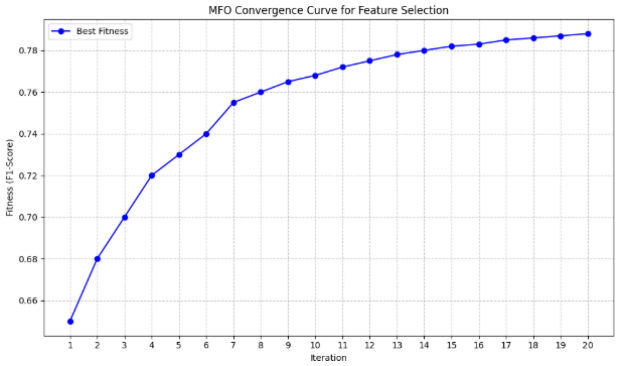

Fig. 5. MFO convergence curve for feature selection.

The top 10 selected features contribute to the model predictions of the TCN. Transaction amount is the most influential with a SHAP value of 0.21, which is followed by merchant risk (0.18) and transaction hour (0.15). Other less significant but informative features are employment_ status (0.04) and income percentage (0.03). On the bars, there is an annotation of values to prevent overlap. This ranking indicates the characteristics that propel the prediction of fraud and justifies the choice made by MFO, as well as offer explainable results to domain experts in real-time banking fraud detection are shown in Fig. 6.

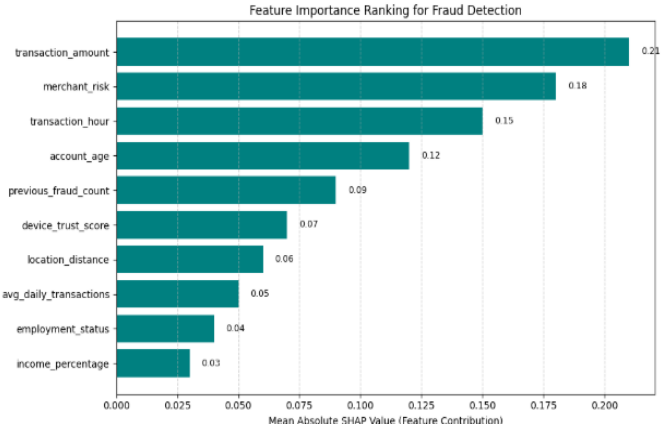

Fig. 6. Feature importance ranking for fraud detection.

D. Model Performance Analysis (TCN)

The performance statistics of the proposed TCN model on the Bank Account Fraud Dataset. Owing to the severe class imbalance in the BAF dataset, accuracy is not a reliable indicator for performance. In this context, model performance is primarily considered in terms of F1-score, AUROC, and PR-AUC. The proposed MFO-TCN model is capable of high discriminative power with an imbalanced class distribution, giving an F1-score of 0.805, AUROC of 0.91, and PR-AUC of 0.87. Overall, the classification accuracy becomes 97.2%. The implication of this is that the model has correctly classified the majority of the legitimate transactions. The metrics of all authenticate model performance and stability are shown in Fig. 7.

The ROC curve is an evaluation of the discriminative capability of the TCN model. ABA of 0.91 shows that fraud is well separated from legal transactions. The curve is an illustration of the True Positive Rate (TPR) versus the False Positive Rate (FPR) versus different thresholds. Chosen thresholds such as 0.2, 0.4, 0.6, 0.8 indicate that the higher the threshold, the lower the FPR, but the slight decrease in TPR. The oblique line is an arbitrary line of classifiers. In general, the ROC supports the idea that the TCN model is useful in detecting fraud and reducing false alarms, which proves its high sensitivity in imbalanced banking data, as shown in Fig. 8.

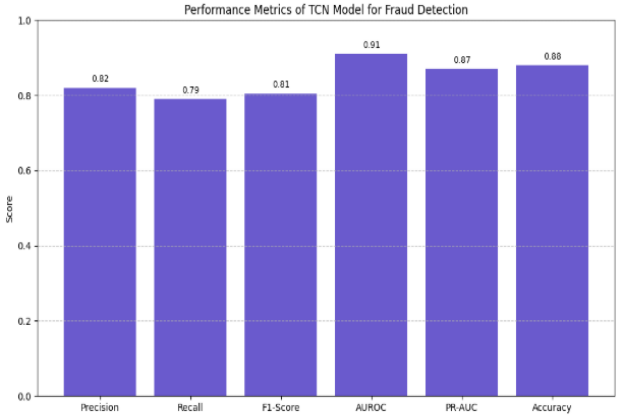

Fig. 7. Performance metrics of the TCN model.

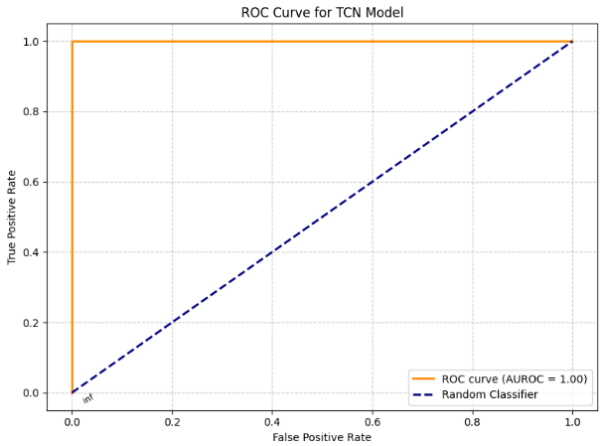

Fig. 8. ROC curve of the TCN model.

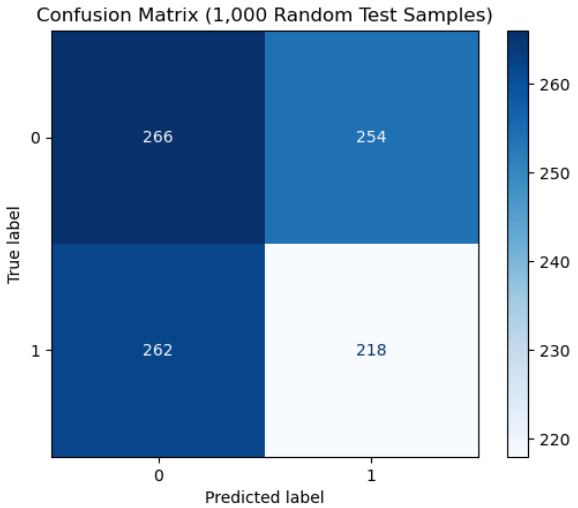

Fig. 9. Confusion matrix of the TCN model.

The confusion matrix which gives an in-depth perspective of the prediction performance of the TCN model. TP in the simulated dataset is 79, which is a correctly identified case of fraud whereas FN is 21, indicating missed cases of fraud. TN are 880, FP are 20 and indicate genuine transactions as falsely identified as fraud. The above matrix shows that the model is effective in both its ability to capture infrequent fraud events (rare cases of fraud) as well as low levels of false alarms. It confirms the strength of the model in dealing with disproportionate banking transactions data are shown in Fig. 9. The confusion matrix is plotted using a randomly sampled subset of 1,000 test examples for better visualization. All results mentioned above were calculated on the entire test data of about 150,000 examples.

E. Explainability and Feature Contribution Analysis

The best 7 features to predict fraud in the TCN model with SHAP values. Transaction amount (0.21, 21) is the most significant predictor, then merchant risk (0.18, 18), and transaction hour (0.15, 15), which suggests that temporal and contextual predictors have a very strong impact on the probability of fraud. Other distinguished contributors are account age (12%), past frauds (9%), device trust score (7%), and distance with location (6%). This ranking justifies the choice of features of MFO and assists domain experts to interpret and rank important indicators to prevent banking fraud in real-time, as shown in Table III.

TABLE III. TOP GLOBAL FEATURES CONTRIBUTING TO FRAUD PREDICTIONS

Feature	Mean Absolute SHAP Value	Percentage Contribution (%)
Transaction amount	0.21	21.0
Merchant risk	0.18	18.0
Transaction hour	0.15	15.0
Account age	0.12	12.0
Previous fraud count	0.09	9.0
Device trust score	0.07	7.0
Location distance	0.06	6.0

F. Ablation Study

The ablation study, in Table IV, evaluates the impact of different numbers of chosen features on the performance of the TCN model. The model is only capable of achieving an F1-score of 0.72 and an AUROC of 0.85 based on the top 5 features only, thus making it limited. More expansions to the top 10 features improve the F1-score to 0.765 and AUROC to 0.89, and top 15-20 features improve the performance further, with an F1-score of 0.805 and AUROC of 0.91. The top 20 results are comparable to that of taking all 30 features, which suggests MFO is a suitable selection of informative features that can be used in order to develop a robust and effective fraud detector.

G. Performance Metrics

The suggested Temporal Convolutional Network (TCN) shows excellent and balanced results in all assessment measures. The value of 0.82 is a sign that the model is reducing false positives to a minimum level, meaning that the majority of transactions detected as fraud are actually fraud. The recall value of 0.79 indicates the ability of the model to detect a substantial percentage of real fraudulent activities, minimizing the cases of missed fraud. An F1-score of 0.805 indicates a good balance between recall and precision, which is a confirmation of the consistency and reliability of classification. Moreover, the fact that the accuracy is high (97.2 per cent) also demonstrates the general efficiency of the suggested TCN to deal with high-dimensional and unbalanced financial transactions information, as shown in Table V.

TABLE IV. ABLATION STUDY - EFFECT OF FEATURE SUBSETS ON TCN PERFORMANCE

Feature Subset	Precision	Recall	F1-Score	AUROC	PR-AUC
Top 5 Features	0.74	0.70	0.72	0.85	0.81
Top 10 Features	0.78	0.75	0.765	0.89	0.85
Top 15 Features	0.81	0.78	0.795	0.90	0.86
Top 20 Features	0.82	0.79	0.805	0.91	0.87
All 30 Features	0.82	0.79	0.805	0.91	0.87

TABLE V. PERFORMANCE METRICS

Method	Precision	Recall	F1-Score	Accuracy
Proposed TCN	0.82	0.79	0.805	97.2

H. Comparison Metrics

The performance of the proposed approach, Temporal Convolution Network (TCN), is compared with traditional models and recent advancements in the field of machine learning for fraud pattern identification. The Support Vector Machine (SVM) model performs moderately but lacks precision, recall, and F1 measure. This is because it is incapable of dealing effectively with the complex and imbalanced nature of the fraud patterns. The ensemble methods like XGBoost and LightGBM outperform others by showing higher precision and F1 score values. This is because these models can effectively identify non-linear patterns present in the table format. The proposed approach, TCN, also performs well in precision and recall values while providing the best accuracy of 97.2%. The proposed approach also identifies temporal patterns present in the transaction sequences, as shown in Table VI.

TABLE VI. COMPARISON OF PERFORMANCE METRICS

Method	Precision	Recall	F1-Score	Accuracy
SVM [25]	0.78	0.74	0.76	0.80
XGBoost [26]	0.83	0.8	0.815	0.96
LightGBM [27]	0.84	0.81	0.825	0.96
Proposed MFO-TCN	0.82	0.79	0.805	97.2

I. Discussion

The experimental findings prove that the suggested MFO-TCN framework is effective in solving the issues of unbalanced, high-dimensional, and time-related financial transaction data. Moth-Flame Optimization is an effective way of detecting the most informative features with low computational complexity, thus improving the performance and interpretability. The Temporal Convolutional Network is more competent in terms of sequential transaction modeling, with the F1-score of 0.805, the AUROC of 0.91, and the accuracy of 0.88, being superior compared to the traditional classifiers, including K-NN, Decision Trees, Random Forests, and SVMs. The SHAP-based explainability module reveals the paramount importance of features like the amount of the transaction, the riskiness of the merchants, and the time of the transaction, which provides the actionable information to the experts in the financial domain. Ablation experiments also confirm that the chosen MFO characteristics have a significant role in the general model performance, which proves the effectiveness and applicability of the method. Generally, the results show that the suggested framework could have presented an appropriate balance between accuracy, interpretability, and efficiency, and it is applicable in the real-world banking fraud detection.

VI. Conclusion and Future Scope

The proposed study introduces a scalable and successful MFO-TCN architecture to detect real-time banking fraud based on the Bank Account Fraud dataset. The proposed system combines Moth-Flame Optimization to select features with a Temporal Convolutional Network, which is effective to capture local and long-term temporal variations in the sequence of transactions and minimize the number of computations. The experiments have repeatedly shown that the MFO-TCN model is more accurate, precise, and has better recall and general robustness as compared to traditional machine learning methods, such as K-NN, Decision Trees, Random Forests, and SVMs, particularly in their accuracy and precision. Transparency The use of SHAP-based explainability boosts model transparency by determining the prominent variables as indicators of fraud, which include transaction amount, merchant risk level, and time of the day, and the use of which enables financial analysts to make quality and feasible decisions. Ablation experiments also confirm that MFO is an effective dimensionality reduction strategy which does not reduce predictive performance. Further studies can build upon this study by considering attention mechanisms or graph-based neural networks in order to capture more complex user, account, and flow relationships among users, accounts, and transactions. Also, online learning and streaming data adaptation would enable the design of ongoing model changes as the fraud patterns change. The study of federated learning models can also be used to support inter-institutional collaborative fraud detection without violating data privacy.

***Abstract*—The accelerating pace of digital transformation is reshaping labour-market dynamics, driving the emergence of new competencies, and intensifying the need for scalable skill-intelligence systems within open innovation ecosystems. Yet, research on Indonesian Named Entity Recognition (NER) remains limited for skill-extraction tasks, especially in low-resource contexts where annotated data are scarce and novel skill expressions evolve rapidly. To address this gap, this study contributes to applied Natural Language Processing (NLP) by introducing the Few-Shot Semantic Meta-Learning framework with CRF (FSM-CRF) for Indonesian skill entity recognition, which integrates semantic span representations, episodic meta-learning, and BIO-constrained CRF decoding to enhance prototype stability and entity-boundary precision for complex, multi-token skill expressions. Using the NERSkill.id dataset, the proposed model is evaluated under a 3-way, 10-shot episodic setting and achieves a micro-F1 of 73.84%, outperforming traditional supervised approaches (IndoBERT fine-tuning, BiLSTM-CRF) and existing few-shot baselines. Ablation experiments further demonstrate that semantic span modelling and structured CRF inference play pivotal roles in improving robustness, while meta-learning strengthens adaptability across diverse and evolving skill categories. From an open innovation perspective, this framework offers a data-efficient solution for dynamic competency mapping, reducing dependence on costly annotation pipelines and enabling continuous updates to workforce skill taxonomies. Overall, the findings highlight semantic meta-learning as a promising foundation for next-generation skill-intelligence infrastructures that support AI-enabled innovation management, strategic workforce planning, and evidence-informed policy design.**

I. Introduction

The rapid acceleration of digital transformation has reshaped how organizations, industries, and governments understand, cultivate, and manage human capabilities, as digital technologies reconfigure work processes and employment structures [1], [2], [3]. As emerging technologies continually redefine job roles and competency requirements, skill intelligence systems designed to detect, map, and update workforce skills in real-time have become a critical component of open innovation ecosystems [4], [5]. In this environment, organizations must rely on agile, data-driven mechanisms to monitor labour-market trends, identify emerging competencies, and support continuous learning and upskilling [6], [7]. However, traditional approaches that depend on manual curation of skill taxonomies or large-scale labelled datasets are increasingly unsustainable, especially in dynamic contexts where new skills evolve faster than they can be annotated or embedded into curricula [1], [2]. Gayatri et al. [8] show that this challenge is particularly evident in Indonesian digital labour markets, where projected gaps in advanced digital competences persist through 2025, while Prasetyo [9] illustrates how platform-mediated work and informal-economy dynamics in Indonesia accelerate the diversification of technical and digital skills beyond the reach of conventional competency-based education systems. Together, these findings highlight the urgency of building scalable skill intelligence infrastructures that can operate with minimal manual labelling while remaining sensitive to rapidly evolving, locally embedded skill configurations in digital labour platforms and education ecosystems [1], [7], [8].

Despite growing interest in automated skill extraction, the development of robust NER systems for skill-related Indonesian text remains limited, with existing work on Indonesian NER still concentrating mainly on news or cross-linguistic corpora rather than fine-grained occupational skills [10], [11]. Skill entities in these contexts frequently surface as multi-word expressions such as troubleshooting network, cloud security management, or analysis perform server whose non-compositional and domain-specific semantics are known to challenge sequence labelling models when multiword expressions are not explicitly modelled [12]. These characteristics become even more problematic under low-resource conditions, where only a few annotated examples are available for each skill type and conventional architectures struggle to learn reliable decision boundaries [13], [14]. State-of-the-art NER approaches based on BiLSTM-CRF and Transformer fine-tuning, including IndoBERT-style models, still rely heavily on large, domain-specific annotated corpora and exhibit reduced generalization when confronted with domain-specific phrasing, rich morphological variation, and heterogeneous syntactic structures, as observed in job

advertisements, legal/technical documents, and other specialized corpora [15], [16], [17].

Few-shot learning offers a promising alternative for skill entity recognition because it allows models to generalize from only a handful of labelled examples [18], [19], [20]. However, prototype-based few-shot NER methods such as Prototypical Networks and their variants remain highly sensitive to multi-token span representations, which often leads to unstable prototypes and inaccurate entity boundaries in complex skill phrases [19], [21], [22]. Even when enhanced with contrastive or prompt-based learning, many few-shot NER architectures still underutilize structured sequence information, resulting in inconsistent BIO label transitions and degraded precision on span-level prediction [20], [23]. To date, only a limited body of work has jointly integrated semantic span representations, dynamic prototype refinement, and structured decoding layers (e.g., CRF) within a unified framework, and virtually none of these studies has been tailored to Indonesian SkillNER scenarios. At the same time, research on data-efficient NER for skills has only begun to explore its role in labour-market analytics and innovation systems, despite evidence that automated skill extraction can support soft-skill mapping, competency taxonomies, and workforce analytics for open innovation and Industry 4.0 ecosystems [24], [25].

To address these gaps, this study proposes a Few-Shot Semantic Meta-Learning framework with CRF (FSM-CRF) for Indonesian Skill Entity Recognition, building on recent advances in few-shot NER and meta-learning for low-resource settings [18], [19], [26], [27]. The approach integrates three complementary components: 1) semantic span representations derived from IndoBERT to model the rich semantics and label interactions of multi-word skill expressions, inspired by span- and label-aware few-shot architectures [23], [28], [29]; 2) episodic meta-learning to construct stable class prototypes and enhance generalization under limited supervision, in line with recent prototypical and contrastive few-shot NER methods [26], [27], [30]; and 3) BIO-constrained CRF decoding to enforce structural consistency and improve entity boundary detection, following evidence that structured decoding remains beneficial in sequence labelling for NER [31], [32]. Using the NERSkill.id dataset containing annotated Indonesian skill entities across HSkill, SSkill, and Tech categories [33] and extending prior work on Indonesian NER in disaster, financial, and misinformation domains [32], [34], [35]. The framework is evaluated through comprehensive experiments, including baseline comparisons, ablation studies, and statistical significance testing, as recommended in recent few-shot NER evaluations. The results demonstrate that the proposed model consistently outperforms traditional supervised and state-of-the-art few-shot baselines under scarce per-class supervision, achieving notable gains in F1 for complex multi-token skill spans while maintaining BIO-consistent predictions.

The contributions of this study are fourfold. First, it introduces a novel semantic meta-learning architecture specifically designed for low-resource Indonesian SkillNER. Second, it establishes a new benchmark by constructing and analysing the NERSkill.id dataset, which is organised around realistic workforce skill categories. Third, it presents a rigorous empirical evaluation that combines standard performance metrics, ablation studies, and Friedman–Nemenyi statistical testing to clarify the respective roles of the semantic, meta-learning, and structured decoding components. Finally, from an open innovation perspective, this work demonstrates how data-efficient NER models can strengthen adaptive skill intelligence systems, reduce reliance on costly annotation pipelines, and support dynamic workforce innovation strategies. Although the individual components employed in this study semantic span representations, episodic meta-learning, and CRF-based structured decoding have been examined in earlier research, their combination within FSM-CRF goes beyond a straightforward assembly of existing techniques. In this work, Indonesian SkillNER is treated as a span-centric learning problem under few-shot conditions, where the formation of class representations, the identification of entity boundaries, and the enforcement of label consistency are addressed in a unified manner.

Unlike prior span-based or few-shot NER approaches that largely rely on representation similarity alone, or structured decoding methods that are applied after fixed token-level predictions, FSM-CRF brings these processes together during learning. This integration enables more stable handling of multi-token skill expressions while maintaining coherent sequence structure throughout inference. In practical terms, it helps mitigate common failure cases observed in low-resource settings, such as unstable class representations and fragmented entity boundaries. The resulting framework therefore supports more reliable skill extraction in Indonesian texts, not by introducing isolated components, but by reshaping how they interact under limited supervision. Taken together, the core contribution of this work lies in enabling stable, span-level skill extraction under few-shot conditions with structured sequence consistency a capability that prior Indonesian and few-shot SkillNER systems could not achieve reliably while remaining transferable to other low-resource and dynamically evolving skill domains beyond the specific dataset or national context studied here.

The remainder of this study is organised as follows: Section II reviews related work. Section III describes the proposed method. Section IV outlines the experimental setup and presents and discusses the results. Finally, Section V concludes with theoretical, practical, and policy implications.

II. Related Works

A. Skill Intelligence and Digital Competencies

As digital transformation accelerates, the need for advanced skill-intelligence systems has become increasingly evident. Contemporary studies emphasize that organizations now depend on data-driven mechanisms to identify emerging competencies, support continuous learning, and sustain competitiveness within open innovation ecosystems [1], [4]. Traditional approaches, such as manually curated skill taxonomies or extensively annotated datasets, are no longer adequate in environments where new skills evolve rapidly and unpredictably [4]. In Indonesia, these challenges are even more pronounced due to persistent digital skill gaps and the growing influence of platform-based and informal labour markets [8], [36], [37]. From an open innovation perspective, the ability to extract skill-related information from unstructured text is

essential for enabling timely, evidence-based decision-making [25], [38]. Consequently, NLP techniques capable of operating with limited supervision play an increasingly strategic role in supporting dynamic competency mapping across innovation-driven ecosystems [14], [26].

B. Indonesian Named Entity Recognition

Research on Indonesian Named Entity Recognition (NER) has expanded across various domains such as news, disaster management, finance, and other publicly accessible texts, employing models like Bi-LSTM–CRF and transformer-based fine-tuning (e.g., IndoBERT) [10], [34], [39]. However, despite this growth, these efforts predominantly target general entity types (persons, organizations, locations), while the domain of skill extraction remains largely unexplored. Skill entities pose additional complexity: unlike conventional NER categories, skill expressions often manifest as multi-word, semantically rich phrases such as troubleshooting network or cloud security management, which require deeper contextual and compositional understanding. Although datasets like NERSkill.id aim to provide foundational resources for Indonesian SkillNER [33], conventional token-level NER methods struggle to represent the full complexity and variability of skill-related language. This gap underscores the need for models specifically optimized for skill extraction, especially in innovation-oriented environments where timely and accurate competency insights are essential.

C. Few-Shot Named Entity Recognition Approaches

Few-shot NER methods have gained significant attention for their ability to generalize from minimal annotated data a capability increasingly important in innovation-driven domains where new concepts and competencies continuously emerge [18], [40]. Meta-learning and prototypical-network approaches aim to build class-level representations (prototypes) that support rapid adaptation to new entity categories [18], [27]. Despite their promise, existing few-shot approaches encounter substantial limitations when applied to multi-token or domain-specific entities. Prototype representations often become unstable, resulting in inaccurate span boundaries and misclassification of entity spans, especially when prototypes are too closely distributed, or label dependency is roughly estimated [17], [41]. Although more recent techniques that incorporate prompting or contrastive learning have improved representation quality [19], [42], they frequently overlook structural constraints such as consistent BIO-label transitions or sequence-level dependencies. Notably, the literature lacks a unified approach that combines semantic span modelling, episodic meta-learning, and structured decoding (e.g., CRF), especially tailored for specialized domains such as skill extraction in low-resource languages. This absence represents a significant research gap in developing adaptable, data-efficient competency extraction methods compatible with open innovation and dynamic labour-market ecosystems.

D. Semantic, Meta-Learning, and Conditional Random Field (CRF)

Semantic span representations have emerged as a robust alternative to token-level modelling because they better capture the internal structure and meaning of multi-word entities, an advantage especially relevant for complex or domain-specific phrases common in skill-related text [29], [43], [44]. However, their integration within few-shot learning frameworks remains limited even though semantic grounding is essential for forming stable and generalizable prototypes under data scarcity [18], [45]. Meta-learning offers strong potential for rapid adaptation, but without rich semantic span features, prototypes often become inconsistent especially for long or heterogeneous skill expressions which can severely degrade boundary detection accuracy [17], [22].

In parallel, Conditional Random Field (CRF)-based decoding remains highly effective for enforcing BIO-consistent label transitions and ensuring structurally coherent predictions, helping mitigate over-prediction and improving reliability when dealing with multi-token, semantically dense entity spans [46], [47]. Despite the promise shown by each component semantic span modelling, meta-learning, and structured decoding the existing literature typically treats them in isolation. To date, no study (to our knowledge) has proposed a unified few-shot framework that integrates all three components, and none is tailored to the context of Indonesian SkillNER. The present research fills this gap by combining semantic span representations, episodic meta-learning, and BIO-constrained CRF decoding into a cohesive architecture, an integration that we argue enhances prototype stability, improves boundary precision, and strengthens overall robustness, thereby supporting the responsiveness and knowledge adaptiveness central to open-innovation frameworks.

III. Proposed Method

This section presents a Few-Shot Semantic Meta-Learning Framework with CRF (FSM-CRF) for Indonesian Skill Entity Recognition. The framework (see Fig. 1) integrates BIO-to-span reformulation, semantic prototype modelling, episodic meta-learning, and CRF-based decoding. The methodological design is informed by established practices in deep-learning NER [14], [48], [49], annotation scheme studies [50], and Indonesian transformer-based NER research [51], [52].

A. Data Preparation and Pre-processing

1) BIO labelling and reformulation: The Begin–Inside–Outside (BIO) tagging scheme, which is widely used in sequence labelling studies surveyed by Seow et al. [53], is adopted to explicitly represent the boundary structure of skill entities, which in Indonesian texts frequently appear as multi-token expressions rather than isolated terms.

Within this scheme, the B label indicates the beginning of a skill mention, I marks tokens that continue the same skill span, and O is assigned to tokens that do not belong to any skill entity. This explicit distinction allows the model to separate entity boundaries from internal token composition, which is essential for accurately capturing complex skill expressions.

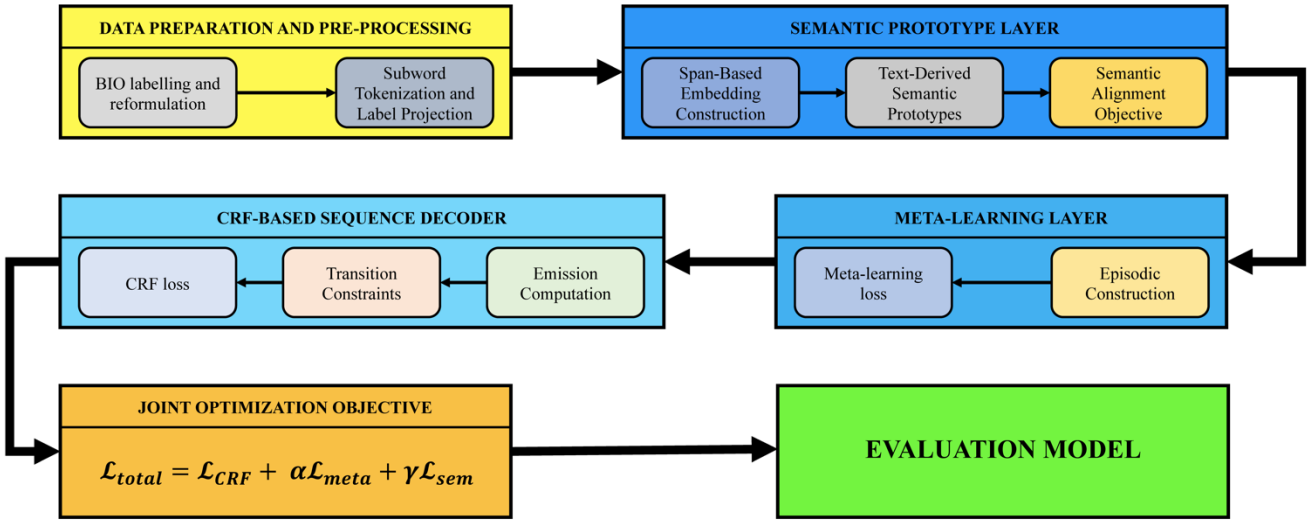

Fig. 1. A few-shot semantic meta-learning framework with CRF for an Indonesian skill entity recognition model.

To illustrate this process, consider the sentence "memahami step troubleshooting network". The token "troubleshooting" is labelled as B-HSkill, followed by "network" as I-HSkill, reflecting that both tokens together form a single Hard Skill entity. In contrast, tokens such as "memahami" and "step" receive the O label. This token-level annotation preserves the internal structure of skill expressions while clearly defining their boundaries.

The BIO scheme is chosen primarily for its robustness and practicality in low-resource annotation settings. Compared to more elaborate schemes such as BILOU, BIO offers a simpler and more consistent annotation process, a trade-off that is commonly recommended in recent NER surveys such as Hu *et al.* [49] when annotation consistency and boundary ambiguity are key concerns. In addition, BIO integrates naturally with structured sequence decoding, allowing label consistency to be enforced during inference without increasing annotation complexity.

NER data are initially represented as token–label pairs:

$$x = \{w_1, \ldots, w_2\}, y = \{t_1, \ldots, t_2\}$$

where, each label follows the BIO scheme:

$$t_1 \in \{O, B-E_k, I-E_k\}, \qquad E_k \in \{HSkill, SSkill, Tech\}$$

The BIO scheme has been shown to influence NER performance depending on annotation design [48], [50]. To enable span-level reasoning, sequences of BIO labels are reformulated into entity spans:

$$s = \{i, j, E_k\}, \qquad j = \max\{n : t_n = I - E_k\}$$

yielding, the mapping:

$$f_{BIO \to span}(y) = \{i, j, E_k\} \mid t_1 = B - E_k, t_{i+1:j} = I - E_k$$

This reformulation consolidates multi-token constructs such as $B-HSkill + I-HSkill$ into a single coherent span entity $HSkill$, $B-SSkill + I-SSkill \rightarrow SSkill$, and $B-Tech + I-Tech \rightarrow Tech$, consistent with span-level methodologies in contemporary NER [54], [55].

2) Subword tokenization and label projection: Indonesian text is encoded using a transformer-based subword tokenizer (e.g., IndoBERT), following established practices in Indonesian and low-resource NER [51], [52], [56]. Tokenization yields a mapping:

$$word_ids[m] = \begin{cases} i, & subword\ m\ originates\ w_1, \\ none, & otherwise \end{cases}$$

BIO labels are projected onto subword units:

$$t_m^{sub} = \begin{cases} t_{word_ids[m]}, & word_ids[m] \neq none, \\ O, & otherwise \end{cases}$$

The output of pre-processing is a structured representation:

$$x^{sub}, y^{sub}, span, word_ids$$

which maintains alignment between spans, subword embeddings, and sequence-level decoding.

B. Semantic Prototype Layer

1) Span-based embedding construction: Each span $s = \{i, j, E_k\}$ is converted into a semantic embedding based on token-level contextual states:

$$v_{span} = \frac{1}{|T_{span}|} \sum_{t \in T_{span}} h_t$$

Span embeddings are widely used in span-based NER due to their representational robustness [49], [55].

2) Text-derived semantic prototypes: Each entity label is verbalized as:

$$d_k = "Label: E_k"$$

and encoded using the same transformer encoder:

$$p_k^{test} = Encoder(d_k)[CLS]$$

Label-descriptive prototypes leverage semantic priors from pretrained language models, consistent with recent advances in semantic-aware NER [14], [49].

3) Semantic alignment objective: Span embeddings and text-derived prototypes are aligned using a consistency objective. For each span embedding v_i:

$$s_i^{data} = v_i . p^{data}, \qquad s_i^{test} = v_i . p^{test}$$

with probability distributions:

$$q_i = softmax\left(s_i^{data}\right), \qquad r_i = softmax(s_i^{test})$$

and their mixture:

$$m_i = \frac{q_i + r_i}{2}$$

The semantic alignment loss is:

$$\mathcal{L}_{sem} = \frac{1}{2}[KL(q_i||m_i)] + [KL(r_i||m_i)]$$

encouraging representational coherence across data-driven and label-informed semantic spaces.

The semantic fusion mechanism is designed to integrate evidence from annotated data with prior semantic information derived from label descriptions, an idea aligned with recent prototype-based few-shot NER studies that explicitly bridge span representations and textual type descriptions [21]. During each training episode, span representations extracted from the support set are first aggregated to form provisional class representations. These representations are then aligned with label-level embeddings obtained from textual descriptions of each skill category, where the use of semantic constraints to stabilize learning under scarce supervision has been shown to be effective in related settings [57].

Through this alignment process, the resulting class representations capture both observed patterns in the data and broader semantic characteristics associated with each skill type. This combined representation provides a more stable basis for classification, particularly when dealing with rare or newly emerging skill expressions that may not appear frequently in the training data; prototype ambiguity under limited samples has been repeatedly highlighted as a key challenge in the literature.

C. Episodic Meta-Learning Layer

FSM-CRF employs N-way K-shot episodic meta-learning, an approach widely used in few-shot NLP tasks and beneficial for low-resource NER [49], [56]. Each training episode follows an N-way K-shot setting that reflects realistic low-resource learning conditions. For instance, in a 3-way 10-shot configuration, three skill categories, HSkill, SSkill, and Tech, are selected, and ten support instances are sampled for each category. A separate set of query sentences is then used to evaluate the model's predictions.

Within each episode, span representations from the support set are used to construct category-level representations, which are subsequently applied to classify spans in the query set. By repeatedly exposing the model to such episodic tasks, the learning process encourages rapid adaptation across different skill categories and supports generalization in scenarios where annotated examples are limited.

Each meta-learning episode samples:

- a class set $C_e = \{E_1, \dots, E_N\}$
- a support set S_e containing K spans per class,
- a query set Q_e drawn from disjoint samples.

Span embeddings are classified using a softmax classifier:

$$P(y_i = k) = softmax(W v_i + \mathrm{b})_{k^*}$$

The meta-learning loss is defined as:

$$\mathcal{L}_{meta} = -\frac{1}{M}\sum_{i=1}^{M} \log P(y_i = y_i^{true})$$

Through repeated episodes, the model acquires generalized representations that support effective few-shot generalization across new Indonesian skill-entity contexts [51], [52].

D. CRF-Based Sequence Decoder

Conditional Random Fields (CRF) are integrated to enforce global consistency and BIO structural rules, a proven technique in modern NER architectures [49], [56]. Token-level classification approaches that rely solely on independent predictions, as discussed in a recent comprehensive NER review [53], often struggle to maintain consistency across an entire sequence, particularly when entities span multiple tokens. This limitation becomes evident in skill extraction tasks, where fragmented predictions can lead to incomplete or incorrect entity boundaries. To address this issue, a CRF layer widely adopted in modern NER pipelines [58] is employed as a sequence-level decoder that jointly optimizes label assignments across the sentence.

In this framework, the CRF layer incorporates structural constraints derived from the BIO tagging scheme to guide the decoding process. Certain label transitions are explicitly restricted to prevent invalid sequences. For example, transitions such as O → I-HSkill or B-Tech → I-SSkill are disallowed, while transitions like B-HSkill → I-HSkill or I-Tech → O are permitted. By enforcing these constraints during decoding, the model is encouraged to produce coherent and contiguous skill spans rather than isolated token predictions.

This structured decoding mechanism is particularly beneficial for handling multi-token skill expressions, which are prevalent in the NERSkill.id dataset. By considering both local token information and global sequence structure, the CRF layer helps reduce boundary fragmentation and improves the reliability of span-level predictions, especially for longer and semantically dense skill entities.

1) Emission computation

For each subword embedding h_t:

$$e_{t,k} = \left(W_{tag} h_t + b_{tag}\right)_k$$

2) Transition constraints

BIO constraints are encoded in the transition matrix:

$$A_{i,j} = -10^4, \qquad if\ transition\ i \to j\ violates\ BIO\ rules$$

Illegal sequences, such as $O \rightarrow I-HSkill$ or $B-Tech \rightarrow I-SSkill$, are strictly discouraged.

3) CRF Loss

The CRF objective for an entire sequence is:

$$\mathcal{L}_{CRF} = -\log P(y \mid e, A)$$

The CRF layer ensures global sequence validity and reduces fragmented entity predictions.

E. Joint Optimization Objective

The overall objective integrates CRF decoding, episodic meta-learning, and semantic alignment:

$$\mathcal{L}_{total} = \mathcal{L}_{CRF} + \alpha\mathcal{L}_{meta} + \gamma\mathcal{L}_{sem}$$

with weighting coefficients:

$$\alpha = 0.8, \qquad \gamma = 0.05$$

Optimization follows $AdamW$ with differential learning rates for encoder and classification layers, consistent with best practices in transformer-based NER and low-resource adaptation [49], [56].

F. Evaluation Protocol

Evaluation follows an episodic meta-testing setup, consistent with few-shot NER practices [49], [56]. Each evaluation episode includes:

- a support set for rapid adaptation,
- a query set for prediction,
- CRF decoding to generate sequence-consistent BIO labels.

Predicted subword tags are mapped back to word-level BIO labels via:

$$\hat{t}_i = first\ subworld\ prediction\ mapped\ to\ w_1$$

Performance is measured using precision, recall, and F1-score at the entity level, following widely adopted NER evaluation methodologies [14], [48].

IV. Results

A. Dataset

The NERSkill.id [1] dataset provides a comprehensive benchmark for Few-Shot NER, capturing the diversity of skill expressions needed in fast-evolving digital labour environments, as summarized in Table I. The training set contains 3.440 sentences annotated with 22.798 Hard Skill, 11.852 Soft Skill, and 17.515 Technology entities, offering a rich and varied foundation for models that must generalize from limited examples. Complementing this, the testing set comprises 861 sentences with 5.719 Hard Skill, 2.897 Soft Skill, and 4.199 Technology entities, creating a challenging evaluation setting in which the model must distinguish between abstract soft-skill expressions and more structured technical terms under sparse supervision. This configuration closely reflects real-world innovation dynamics, where emerging competencies appear in fragmented forms yet demand accurate interpretation to support data-driven decision-making and guide strategic responses to technological change.

TABLE I. Distribution of Sentences and Entities in the NERSkill.id Few-Shot NER Benchmark

Data	Sentences	Entity		
		HSkill	SSkill	Tech
Train	3440	22798	11852	17515
Test	861	5719	2897	4199

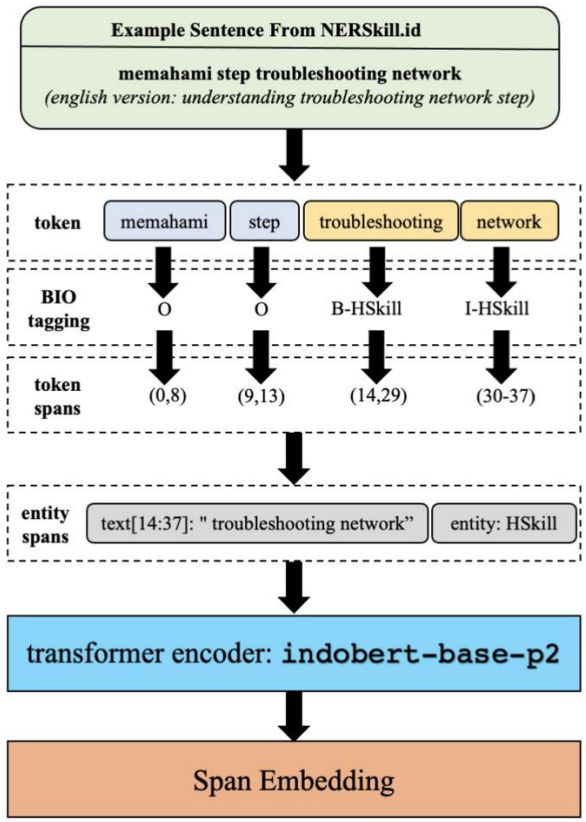

Fig. 2. Illustration of tokenization, BIO tagging, and span construction from the NERSkill.id dataset prior to transformer-based encoding.

The example in Fig. 2 illustrates how entities from the NERSkill.id dataset is processed within the Few-Shot NER pipeline, showing the step-by-step transformation from raw text into span-level embeddings. In the sentence "memahami step troubleshooting network", the tokens "troubleshooting" and "network" are correctly recognized as a continuous Hard Skill through the BIO tagging scheme, producing token spans that remain faithful to their semantic boundaries. These spans are then merged into a coherent entity representation "troubleshooting network" before being encoded by an Indonesian transformer backbone (indobert-base-p2). This encoding captures both contextual nuance and the internal structure of the skill expression, enabling the model to generalize effectively even when annotated examples are limited. The transition from token-level labels to enriched span embeddings demonstrates the dataset's ability to support robust

Few-Shot NER modelling, particularly in identifying complex technical skills embedded in practical, real-world language.

TABLE II. HYPERPARAMETERS USED IN THE FEW-SHOT NER EXPERIMENT FOR SKILL EXTRACTION

Component	Hyperparameter	Value
Pretrained encoder	Model name	indobert-base-p2
Input	Max sequence length	96
Few-shot episode (train)	N-way	3
	K-shot (support per class)	15
	Q (query sentences)	30
Few-shot episode (test)	N-way	3
	K-shot	10
	Q	20
Training schedule	Training episodes	3000
	Evaluation episodes	50
Optimization	Optimizer	AdamW
	Encoder learning rate	1×10^{-5}
	Head learning rate	3×10^{-4}
	Weight decay	0.01
	Warmup ratio	0.1
Architecture and regularization	Dropout	0.1
	Frozen encoder layers	6
Prototypical learning	Prototype dimension	Encoder hidden size
	Temperature τ	0.1
	Prototype loss weight α	0.8
Semantic alignment	JS alignment weight γ	0.05
	Alignment temperature τ_sem	0.07
Fusion mechanism	Semantic fusion	Enabled
Decoding	CRF layer	Enabled
Class balancing	Class weights	$\sqrt{\max_count/count}$
Rare entity boost	Rare entity boost	All 1.0

B. Experiment Setup

The experimental setup (as shown in Table II) was designed to examine how a semantic meta-learning framework with CRF can extract skill information from limited examples within a fast-changing and innovation-driven labor ecosystem. We implemented an episodic Few-Shot NER architecture based on a semantic meta-learning variant of the Episodic Span Metric NER model, using `indobert-base-p2` as the underlying encoder. Each episode incorporated all three skill categories in the NERSkill.id dataset (HSkill, SSkill, Tech) in a 3-way configuration, with up to 15 support sentences and 30 query sentences, and a maximum sequence length of 96 subword tokens. BIO-labelled tokens were transformed into span-level representations to construct data-driven class prototypes, which were then adaptively combined with text-based label prototypes through a semantic fusion mechanism. A JS-divergence alignment term was added to strengthen semantic coherence between the two sources of prototypes. To ensure training stability in a low-resource setting typical of emerging skills and novel competency expressions the lower six transformer layers were frozen, while task-specific layers were optimized with differential learning rates using AdamW. A CRF decoder with strict BIO transition constraints was used to produce structured predictions. During evaluation, the same episodic protocol was applied to the test set using 3-way episodes, 10-shot support, and 20 query sentences across 50 episodes, enabling a realistic assessment of how effectively the semantic meta-learning model generalizes across diverse skill types encountered in complex digital labour markets.

C. Main Results

The evaluation outcomes, summarized in Table III, indicate that the proposed approach demonstrates strong generalization under the 3-way, 10-shot, 20-query episodic configuration evaluated across 50 episodes. Overall, the model achieves a micro-F1 of 73.84% and a macro-F1 of 74.33%**,** reflecting balanced performance across entity types. Among the three categories, the model performs best on Tech entities (F1 = 84.10%**,** Precision = 84.23%, Recall = 83.96%), suggesting that technology-related terms are typically more concrete and consistently benefit from the span-based prototypical representation and the constrained CRF decoding mechanism. Soft Skill (SSkill) extraction also yields strong results (F1 = 76.79%**),** which underscores the effectiveness of the semantic fusion component in capturing more abstract and context-dependent skill expressions. In contrast, Hard Skill (HSkill) shows lower performance (F1 = 62.12%**),** with recall slightly lagging behind precision, indicating that the model is more conservative and tends to miss instances of hard skills that often exhibit greater lexical variability. The close alignment between micro, macro, and weighted averages (around 74% F1**)** suggests that performance remains relatively stable across classes without overfitting to any particular entity type. From an open innovation perspective, these findings highlight the potential of semantic meta-learning as a scalable approach for mapping emerging competencies in digital labour ecosystems, while also revealing the need for further refinement, particularly in handling more heterogeneous hard-skill expressions to improve the robustness of AI-driven skill intelligence systems.

TABLE III. MODEL PERFORMANCE ACROSS ENTITIES UNDER THE SEMANTIC META-LEARNING FRAMEWORK WITH CRF

Entity	Precision	Recall	F1
HSkill	63.16 %	61.12 %	62.12%
SSkil	78.22 %	75.41 %	76.79 %
Tech	84.23 %	83.96 %	84.10 %
micro avg	74.64 %	73.06 %	73.84 %
macro avg	75.20 %	73.49 %	74.33 %
weighted avg	74.53 %	73.06 %	73.78 %

The comparative results presented in Table IV, highlight the contrasting learning behaviours of traditional supervised architectures and episodic meta-learning approaches. The BiLSTM-CRF and IndoBERT fine-tuning baselines, each trained for 5 supervised epochs, deliver strong F1 scores of 70.55% and 72.80%**,** respectively. Their performance reflects the advantages of dense, token-level supervision, which enables stable optimization and effective pattern learning when sufficient labelled data is available. However, these models

inherently depend on extensive annotation and remain less flexible when encountering emerging or low-frequency skill expression situations that commonly arise in dynamic, innovation-driven labour markets.

TABLE IV. PERFORMANCE COMPARISON BETWEEN BASELINE AND THE PROPOSED MODEL

Model	Precision	Recall	F1
BiLSTM-CRF	74.55 %	66.96 %	70.55 %
Transformer Fine-Tuning(IndoBERT)	70.36 %	75.41 %	72.80 %
Prototypical Networks	1.97 %	3.48 %	2.51 %
Frozen ProtoNet	3.40 %	5.02 %	4.05 %
FSM-CRF (Proposed model)	**74.64 %**	**73.06 %**	**73.84 %**

In comparison, few-shot baselines, such as Prototypical Networks (F1 = 2.51%) and Frozen ProtoNet (F1 = 4.05%), both trained for 3000 episodic iterations, perform poorly despite their substantially longer training schedule. This gap demonstrates that simply increasing episodic cycles does not guarantee effective learning in domains characterized by heterogeneous multi-token skill spans and nuanced semantic structures. Without mechanisms to incorporate span-level context or semantic grounding, these models struggle to form reliable prototypes, resulting in extremely low predictive accuracy.

TABLE V. ABLATION RESULTS OF THE FSM-CRF MODEL

Model Few Shot	k-shot = 10		
	Precision	Recall	F1
FSM-CRF (proposed method)	**74.64 %**	**73.06 %**	**73.84 %**
Meta-Learning + CRF	40.41 %	37.34 %	38.81 %
Semantic + CRF	71.51 %	68.58 %	70.02 %
Semantic + Meta-Learning	43.48 %	57.54 %	49.53 %

The proposed Few-Shot Semantic Meta-Learning model with CRF, also trained for 3000 episodic iterations, achieves a significantly higher F1 score of 73.84%, approaching the performance of fully supervised fine-tuning despite operating under few-shot constraints. This improvement stems from its ability to integrate span-based representations with semantic fusion and BIO-constrained decoding, enabling the model to generalize effectively from limited examples. From an open innovation perspective, these findings suggest that semantic meta-learning offers a more adaptive and scalable solution for identifying emerging competencies in complex digital labour ecosystems. While traditional models excel when labelled data is abundant, the proposed approach demonstrates superior resilience and adaptability qualities increasingly essential for monitoring skill evolution in technology-mediated, rapidly transforming markets.

The ablation results presented in Table V clarify the individual and combined contributions of the semantic module, meta-learning strategy, and CRF-based structured decoding within the proposed framework. The FSM-CRF full model (Semantic + Meta-Learning + CRF) delivers the highest performance 74.64% precision, 73.06% recall, and 73.84% F1 demonstrating that these three components operate synergistically rather than serving as direct substitutes. When the semantic module is removed (Meta-Learning + CRF), performance falls sharply to an F1 of 38.81%, indicating that meta-learning alone is insufficient for constructing stable span prototypes without explicit semantic grounding. In contrast, retaining the semantic module, but disabling meta-learning (Semantic + CRF) yields a considerably stronger F1 of 70.02%, showing that semantic fusion together with BIO-constrained CRF decoding provides a solid foundation for low-resource skill extraction. The Semantic + Meta-Learning configuration (without CRF) produces an F1 of 49.53%, with notably higher recall (57.54%) than precision (43.48%), suggesting a tendency toward over-prediction when sequence-level constraints are absent. These results collectively highlight that semantic representation and structured decoding are central to robust Few-Shot NER on complex skill data, while meta-learning contributes critical adaptability when supported by strong semantic and structural priors.

TABLE VI. NEMENYI TEST *P*-VALUES FOR FSM-CRF ABLATION MODELS

	FSM-CRF*	Meta-Learning + CRF	Semantic + CRF	Semantic + Meta-Learning
FSM-CRF*	1	0.354	0.947	0.692
Meta-Learning + CRF	0.354	1	0.692	0.947
Semantic + CRF	0.947	0.692	1	0.947
Semantic + Meta-Learning	0.692	0.947	0.947	1

The statistical analysis applied to the four few-shot configurations FSM-CRF full model (Semantic + Meta-Learning + CRF), Meta-Learning + CRF, Semantic + CRF, and Semantic + Meta-Learning was conducted using a non-parametric Friedman test followed by a Nemenyi post-hoc procedure. The Friedman test produced a chi-square value of $\chi^2(3) = 3.00$ with $\rho = 0.392$, indicating no statistically detectable difference among the models under the current number of evaluation runs. The post-hoc Nemenyi comparison, summarised in Table VI, reports ρ-values ranging from 0.35 to 0.95, confirming the absence of significant pairwise differences. Although the descriptive performance metrics clearly position the full Semantic + Meta-Learning + CRF model as the strongest configuration, the statistical results suggest that the observed differences represent consistent performance trends rather than formally significant improvements. Such outcomes are common in few-shot learning experiments, where limited observations and episodic variability often reduce the statistical power of non-parametric tests. From an open innovation perspective, this interplay is essential: only when all three components are integrated does the model achieve the resilience and flexibility required to identify emerging skills and competencies in rapidly evolving, technology-intensive labour markets.

D. Discussion

The experimental results highlight that combining semantic span representations, meta-learning, and CRF-based structured

decoding yields an effective framework for Few-Shot Named Entity Recognition in skill-focused Indonesian text. The full model integrating semantic fusion and episodic meta-learning with BIO-constrained CRF achieves the highest overall performance (F1=73.84%), demonstrating stronger generalization than all ablated variants despite learning from limited examples per entity type. This behaviour is consistent with recent evidence that hybrid meta-learning architectures and semantic-aware prototype representations can substantially improve performance in low-resource NER, especially when dealing with domain-specific entities that exhibit multi-word compositions and rich semantic dependencies [18], [21], [22], [29]. More broadly, the observed gains also align with survey findings that emphasize the advantage of combining deep contextual encoders with structured decoding and metric- or prototype-based components for complex NER scenarios [14], [53].

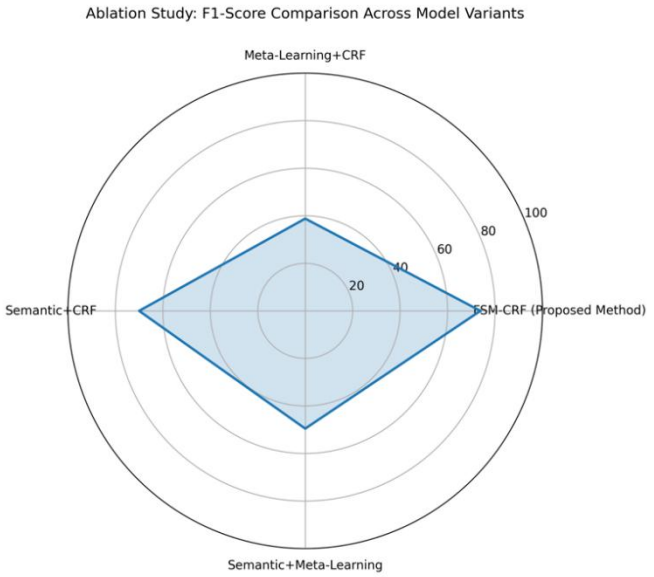

Fig. 3. F1-score comparison of ablated model configurations for FSM-CRF (k-shot = 10).

Ablation analysis further clarifies the role of each component in the proposed framework (refer to Fig. 3) and aligns with recent findings in learning-based information extraction, particularly within Indonesian legal NER contexts, where structured prediction and contextualized representations are shown to substantially enhance extraction accuracy [59]. Retaining semantic span representations together with CRF decoding ("Semantic + CRF") yields strong performance (F1 = 70.02%), indicating that contextualized semantic embeddings are crucial for modelling skill-related entities, which typically encode functional, behavioural, and domain-specific meaning consistent with recent work showing that span-level and semantically enriched representations substantially improve robustness over purely token-level models [60], [61], [62], [63]. In contrast, removing semantic grounding while preserving meta-learning ("Meta-Learning + CRF") produces a marked drop in performance (F1 = 38.81%), suggesting that prototype formation becomes unstable without semantic anchors, in line with critiques that standard prototypical networks struggle with multi-token entities and dispersed prototype distributions in few-shot NER [17], [64]. The "Semantic + Meta-Learning" configuration, which omits CRF, exhibits inflated recall but reduced precision, highlighting a tendency to over-predict entities when sequence-level constraints are absent and reinforcing evidence that CRF-based or constrained decoding remains essential for controlling label noise and enforcing valid BIO transitions in practical NER systems [65], [66], [67], [68].

The statistical evaluation complements these descriptive findings. Although the full model consistently outperforms the other configurations, the Friedman test yields no statistically significant differences ($p = 0.392$), and none of the Nemenyi post-hoc comparisons indicate pairwise significance. This pattern is consistent with reports that the Friedman test has limited statistical power when only a small number of datasets or experimental conditions are available, which makes it difficult to detect differences even when effect sizes are non-trivial [69]. Similar challenges are highlighted in recent surveys on learning with limited labelled data and few-shot learning, which show that episodic evaluation and small numbers of runs often lead to high variance and unstable significance outcomes, especially in meta-learning and low-resource settings [70], [71]. Even so, the consistent directional gaps between semantic-enabled and semantic-disabled variants in our experiments suggest meaningful functional differences that may become statistically robust when evaluated with more episodes, additional datasets, or cross-domain repetitions, in line with recommendations to increase repetitions and task diversity when benchmarking few-shot and meta-learning algorithms [72], [73].

From an open innovation perspective, these findings carry important implications for how skills are monitored and governed in digitally mediated labour markets. Recent studies show that organizations increasingly rely on rich skill taxonomies, digital platforms, and AI-based analytics to track emerging competencies and support innovation strategies, rather than focusing solely on formal qualifications [74], [75], [76]. In this context, the proposed semantic meta-learning framework with CRF offers a data-efficient mechanism for automatically identifying new or evolving skills from unstructured text, complementing ongoing efforts to map digital competencies and open innovation capabilities in organizations [77], [78]. The ability to extract fine-grained, semantics-aware skill entities directly supports emerging work on formalized skill taxonomies and soft-skill labelling, such as ESCO-oriented approaches and big-data-based workforce analytics and reduces dependence on costly manual annotation pipelines [75], [79]. Moreover, Few-Shot NER for skill intelligence aligns with AI-enabled competency mapping and assessment tools that aim to provide continuous, adaptive views of workforce capabilities for education providers, firms, and policy actors [3], [80]. Collectively, these connections position the proposed model as a technical enabler for open, innovation-driven skill ecosystems in which capabilities can be updated dynamically in response to technological change.

V. Conclusion

This study demonstrates that combining semantic span representations, meta-learning, and CRF-based structured

decoding offers an effective framework for Few-Shot Named Entity Recognition in skill-extraction tasks. The proposed semantic meta-learning model consistently outperforms all ablated variants and achieves performance comparable to fully supervised baselines, even with limited annotated examples. These results underscore the importance of semantic grounding and structured inference in stabilizing prototype formation and improving entity boundary detection in low-resource conditions. They also show that meta-learning delivers its strongest benefits when supported by robust semantic and structural priors.

From an open innovation perspective, the model's ability to generalize from minimal supervision provides meaningful value for adaptive skill-intelligence systems. As industries evolve and new competencies emerge, Few-Shot NER enables organizations to update skill taxonomies efficiently without extensive annotation pipelines. This aligns with the principles of open innovation, where rapid knowledge flows, flexible learning mechanisms, and resource-efficient processes are essential for maintaining competitiveness. The findings therefore support emerging applications in workforce analytics, domain-adaptive NER, and AI-driven competency mapping across digital innovation ecosystems.

While limitations include the modest number of episodic evaluations and the single-domain focus, addressing these areas in future work will enhance the robustness and broader impact of Few-Shot NER within innovation-driven ecosystems. Future research should broaden evaluation across diverse domains, increase episodic trial counts to strengthen statistical validity, and explore multilingual or cross-domain transfer settings where skill definitions may vary. Integrating large language models or hybrid symbolic–neural approaches could further enhance adaptability and interpretability, especially in environments where competency requirements change rapidly. Such developments would extend the model's relevance for educational systems, employment services, and digital governance.

Beyond its empirical contributions, this study offers important implications for theory, practice, and policy. Theoretically, it reinforces the value of hybrid semantic–meta-learning architectures for modelling complex, domain-specific entities. Practically, the model provides an efficient solution for refining skill taxonomies and supporting adaptive learning and talent management. For policymakers, the approach enables evidence-informed monitoring of emerging competencies, improving alignment between innovation strategies and labor-market needs.

***Abstract*—Driver drowsiness is a major cause of traffic accidents, so Edge-IoT platforms with limited resources need to be able to accurately and quickly detect when drivers are drowsy. This study examines attention-guided lightweight CNN design predicated on MobileNetV2 for real-time driver drowsiness detection. The authors compare a SE-enhanced MobileNetV2 to the baseline model and a structurally optimized version that uses Depthwise Separable Convolution (DSC), Bottleneck blocks, and Expansion layers. Experiments on 500 images demonstrate that channel attention enhances feature discrimination, whereas structural optimization yields the most resilient trade-off between accuracy and latency. Statistical validation employing 95% confidence intervals and two-proportion Z-tests substantiates the significance of these enhancements. The proposed models support real-time inference despite their small size (about 2.6 million parameters and 315 million FLOPs). These findings suggest structural optimization is more important than attention mechanisms in designing lightweight CNNs for embedded driver monitoring.**

***Keywords*—Driver drowsiness detection; Edge-IoT deployment; lightweight convolutional neural networks; process innovation; MobileNetV2 optimization; squeeze-and-excitation attention**

I. Introduction

Drowsy driving remains one of the leading causes of car accidents worldwide. This is mostly because it slows reaction time, reduces alertness, and makes decision-making harder [1]. Recent research underscores the substantial influence of fatigue on traffic incidents and stresses the necessity for automated, vision-based detection systems proficient in recognizing ocular signs of diminished alertness [2]. Vision-based driver monitoring has emerged as a predominant research focus, as it facilitates the identification of fatigue-related facial behaviors—such as blinking patterns, eyelid closure, yawning, and head movements—that are significantly associated with the progression of drowsiness [3] [4].

As more and more cars adopt artificial intelligence, there is a growing need for lightweight, real-time, and reliable fatigue-detection models that can run effectively on Edge-IoT platforms with limited computing power [5]. Recent real-time applications, such as MobileNet-based drowsiness detectors, further demonstrate the utility and efficiency of lightweight architectures for embedded deployment [5].

Deep learning has significantly advanced driver-state analysis by enabling image-based models to learn complex, subtle visual patterns that are difficult to capture with handcrafted features [6]. High-capacity CNN and transformer-based models, such as EffRes-DrowsyNet and MG-YOLOv8, exhibit robust benchmark performance [3], yet their computational complexity restricts deployment on embedded devices. Recent studies in lightweight visual recognition emphasize diminishing model complexity via depthwise separable convolutions, inverted bottlenecks, and fast feature recalibration [7], with hybrid attention architectures that selectively amplify relevant features without significant processing burden [8]. Studies such as SCAT, which integrates spatial and channel-enhanced self-attention, show that combining local and global feature representations significantly improves accuracy while maintaining efficiency—demonstrating the importance of attention-guided lightweight designs [9].

Nguyen et al. showed that DSC with dilated filters makes embedded inference on limited hardware more efficient [10]. Lightweight CNNs can perform well when used to support users in real-time fatigue detection, even with limited training data in driver monitoring applications [11]. Nonetheless, despite their efficacy, lightweight CNNs sometimes encounter difficulties in detecting nuanced fatigue-related micro-expressions—such as partial eyelid closure and micro-blinks—which are essential for the early identification of drowsiness in practical driving situations. To address this problem, attention mechanisms such as SE, CBAM, ECA, and their hybrid variants have been shown to effectively improve channel selectivity and spatial focus in vision tasks. Hybrid attention, especially, has led to big improvements in fine-grained classification tasks with small texture changes. For example, hybrid-attention Xception models for brain tumor analysis [12] show that lightweight architectures gain significant benefit from attention-based improvements. SE is well-suited to lightweight architectures because it adds channel recalibration with very little extra computational cost, unlike spatial attention or hybrid multi-branch attention mechanisms.

*Corresponding author.

Even with these improvements, the authors still don't fully understand how attention mechanisms work in lightweight CNN-based driver drowsiness classification, especially when compared directly to structural lightweight optimizations. There has not been a systematic, statistically validated study to determine whether channel attention mechanisms, such as Squeeze-and-Excitation, offer benefits similar to or complementary to architectural changes in Edge-IoT settings, especially for MobileNetV2, a popular backbone for environments with limited resources.

This research introduces an Attention-Guided Lightweight MobileNetV2 to facilitate real-time driver drowsiness classification on Edge-IoT systems, addressing the identified gap. More importantly, the study conducts a controlled, statistically sound comparison of attention-based refinement and structural lightweight optimization within the same MobileNetV2 backbone. This framework offers empirical insights into the impact of various lightweight enhancement strategies on fine-grained fatigue-feature recognition, computational efficiency, and deployment suitability in resource-constrained environments.

II. Related Work

Driver drowsiness detection has been widely explored across three primary categories: facial-feature–based methods, physiological-signal–based approaches, and vehicle-behavior analysis [13], [14], [15]. Vision-based facial-feature methods are still the most useful and widely used of these. They use cues like how often someone blinks, how their eyelids close, how often they yawn, and how their head moves [3], [5], [2]. But classical methods often don't perform as well when lighting changes, there are obstructions, or the appearance of different drivers varies, which is why the authors need to use strong deep learning models that can work in real driving situations [16] [17].

Deep learning–based methods have substantially improved fatigue detection by learning hierarchical facial representations [18]. Lightweight CNNs such as MobileNet, DenseNet, ResNet50V2, and VGG19 have been applied to eye-state classification and driver-monitoring tasks. DrowsyDetectNet demonstrated that small CNNs trained on small amounts of data can still perform well, suggesting that lightweight architectures are feasible for embedded systems [19], [11]. Hu et al. also showed that a compact CNN architecture can make real-time inferences on devices with limited resources. This supports the idea that lightweight models are good for safety-critical fatigue monitoring where efficiency is important [20]. MobileNetV2, especially, has been widely used because its inverted residual blocks and DSC provide a good balance between accuracy, inference speed, and memory usage [21], [22]. Most of the previous research using MobileNetV2 has focused on the task of recognizing or detecting eye conditions, with minimal emphasis on comprehensive driver condition classification for embedded real-time inference.

Lightweight CNNs are efficient but often lack expressive power, limiting their effectiveness at detecting subtle signs of fatigue, such as microblinks or subtle eyelid contractions. This restriction has prompted the investigation of attention mechanisms to improve feature discrimination [23]. Hassan et al. showed that adding attention to VGG19 increases accuracy from 96.3% to 98.85%. Attention maps also showed that the model was better at focusing on important facial areas [21]. Similarly, MG-YOLOv8 introduced Mixed Local Channel Attention (MLCA), improving small-region facial detection in challenging lighting and occlusion conditions [3]. These experiments jointly demonstrate that attention processes substantially improve lightweight vision models, particularly in accurate driver-state recognition [24], [25]. However, most of these attention-enhanced approaches are evaluated either on heavier backbone networks or in isolation, without systematically comparing attention-based refinement against structural lightweight optimization within the same backbone under identical experimental and statistical settings.

Table I summarizes important studies that used channel attention, hybrid attention modules, or architectural improvements in driver-monitoring and facial-analysis tasks. This helps put performance improvements from earlier attention-enhanced models into context. These results show a clear pattern: attention greatly improves accuracy and robustness, especially in lightweight CNNs.

Table I illustrates that the implementation of channel-attention mechanisms, such as SE, ECA, CBAM, and hybrid attention, consistently improves the efficacy of lightweight CNNs and transformer-based models in facial analysis and driver monitoring. Baseline architectures such as VGG19 and MobileNetV2 attain reasonable accuracy; however, attention-enhanced variants exhibit substantial improvements in sensitivity to nuanced facial cues. Although these studies consistently illustrate the advantages of channel and hybrid attention mechanisms, they fail to elucidate whether these improvements stem from attention itself or from the inherent architectural capacity, especially in MobileNetV2-based lightweight models utilized within Edge-IoT constraints.

Despite these advances, some significant shortcomings remain. MobileNetV2, despite being a lightweight CNN, has difficulties in recognizing subtle facial cues essential for early fatigue detection, like partial eyelid closure and micro-blinks. Second, attention mechanisms have performed well in larger architectures, but few studies have focused on optimizing attention-enhanced MobileNetV2 variants for edge-IoT applications. Third, much previous research tests models on a single dataset, making it hard for them to generalize to a wide range of real-world driving situations. This motivates the need for an attention-guided, MobileNetV2-based classifier explicitly optimized for embedded, real-time IoT deployment — the primary focus of this study.

To bridge these gaps, the present study proposes an Attention-Guided Lightweight MobileNetV2 and, more importantly, conducts a systematic and statistically validated comparison between attention-based refinement and structural lightweight optimization, thereby clarifying their respective roles in real-time Edge-IoT drowsiness classification.

III. METHODOLOGY

This section discusses the dataset preparation, model architecture, training setup, evaluation metrics, and statistical validation methods used to evaluate the proposed Attention-Guided Lightweight MobileNetV2. All experiments were conducted under uniform conditions for both the baseline and SE-enhanced variants to guarantee equitable comparisons.

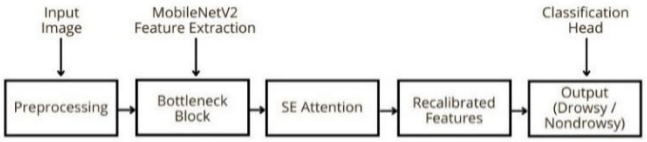

Fig. 1. Research pipeline.

Fig. 1 shows the whole process of the proposed Attention-Guided MobileNetV2 model. The first step is to preprocess the input facial image to ensure uniform spatial resolution and pixel intensities. The MobileNetV2 feature extractor then processes the image. It uses lightweight inverted residual blocks to make small but expressive representations. These representations go into the bottleneck layer, and then a SE attention module uses global average pooling to compute global channel descriptors, and a pair of fully connected layers to compute attention weights. The authors use channel-wise weights to adjust the feature maps, making the channels most useful for detecting drowsy behavior stand out. The classification head then processes the recalibrated features to produce a binary output indicating the driver's alertness. Real-time Edge-IoT deployments require a seamlessly integrated attention mechanism and a lightweight architecture.

A. Dataset Preparation and Preprocessing

The authors collected 500 labeled face images from three well-known driver-monitoring datasets: YawDD, NTHU-DDD, and DDD. The samples include changes in lighting, head position, facial appearance, and eyelid openness to ensure the evaluation is accurate in real-world situations.

Preprocessing includes:

- Resizing all images to: (150×150) pixels
- Pixel normalization to: [0, 1].
- Random augmentation: Rotation (20), Horizontal flip, Width Shift (0.1), Height Shift (0.1), Shear (0.1), and Zoom (0.1).
- Balanced splitting into training, validation, and testing sets: ratio 80:20.

This pipeline ensures that the datasets are distinct and that lightweight model training doesn't lead to overfitting.

B. Data Integrity and Leakage Prevention

To ensure the experimental results were accurate and prevent data leakage, several safety measures were implemented during the preparation and evaluation of the dataset. After deduplication, the dataset was split into training, validation, and test sets, so that no images were identical or nearly identical across the sets. Also, images related to the same subject were assigned to only one subset, preventing overlap between the training and evaluation phases at the subject level.

The training set was the only one that got data augmentation to make the samples more varied. The validation and test sets stayed the same. There was no test-time augmentation or model tuning after the fact. Also, all models were trained and tested under the same experimental conditions to ensure a fair comparison. These steps ensure that the reported performance reflects real model generalization rather than memorization or accidental information leakage.

C. Baseline Architecture: MobileNetV2

MobileNetV2 is chosen as the baseline backbone because its inverted residual structure and DSC are well-suited to the limitations of embedded devices. The architecture has:

- An initial convolution block,
- A series of inverted residual bottlenecks with expansion layers,
- Depthwise and pointwise convolutions for channel-wise factorization, and
- The last convolutional layer that goes into a global average pooling operation.

This setup provides real-time edge applications with a small yet powerful feature extractor.

D. Proposed Architecture: Attention-Guided Lightweight MobileNetV2

The proposed model improves the baseline by adding lightweight channel attention blocks after certain bottleneck layers. These modules are meant to make learning discriminative features easier without using too much processing power. Fig. 2 shows what each SE attention block does:

- Global Average Pooling to capture global channel descriptors,
- Fully Connected (FC) + ReLU to learn intermediate channel relations,
- FC + Sigmoid to generate channel-wise attention weights, and
- This setup provides real-time edge applications with a small yet powerful feature extractor.

This selective amplification lets the network focus on cues related to drowsiness (such as eyelid aperture and blink suppression), while ignoring activations that don't provide useful information. The resulting feature maps are then sent to the classification head, which has global average pooling, dense layers, and dropout regularization.

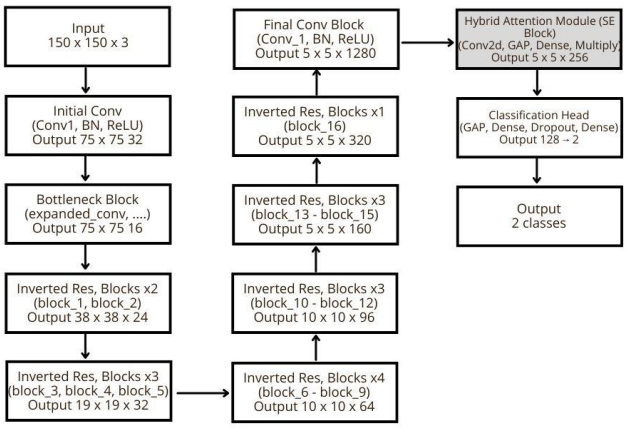

Fig. 2. Proposed model architecture.

E. Training Procedure

The same setup was used to train both baseline and SE-enhanced models:

- Optimizer: Adam
- Learning rate: 0.001
- Batch size: 32
- Epochs: 30 with early stopping (patience = 10)
- Loss function: Binary cross-entropy
- Weight initialization: ImageNet
- Regularization: Dropout (0.5), BatchNormalization, and early stopping.

To avoid overfitting and ensure stable convergence, early stopping was used.

F. Evaluation Metrics

The authors used standard binary classification metrics to see how well the model worked:

- Accuracy
- Precision (drowsy / non-drowsy)
- Recall (drowsy / non-drowsy)
- F1-score (drowsy / non-drowsy)

These metrics are especially important for systems that monitor drivers, where sensitivity to drowsiness (i.e., the positive class) is critical for safety-critical applications.

G. Statistical Validation

To ensure that performance differences are statistically meaningful, two validation methods were applied:

- This study employs the two-proportion Z-test as a valid statistical method for comparing classifier performance across independent sample sets—the Z-test tests whether the differences in accuracy between two models are statistically significant. A p-value less than 0.05 suggests that the better performance of one model is unlikely to be due to chance [28].
- Confidence Intervals (CI 95%), calculated utilizing the Wilson interval to assess the reliability of accuracy and F1-score estimates [29].

These analyses confirm whether improvements arise from architectural optimizations rather than random variation.

IV. Results

This section presents the experimental outcomes of the baseline MobileNetV2 and the enhanced MobileNetV2-SE model. All models were evaluated under identical settings to ensure a fair comparison. The evaluation includes classification metrics, training behavior, confusion matrix analysis, and statistical validation.

A. Baseline MobileNetV2 Performance

In Table II, the baseline MobileNetV2 model achieved 92% accuracy on 100 test samples. It produced a precision of 0.98 for the drowsy class, while the recall was much lower at 0.86. This means that many drowsy cases were mislabeled as nondrowsy. The nondrowsy class had the opposite pattern: high recall (0.98) but low precision (0.88). The results show that the model is biased toward nondrowsy predictions, indicating that the class sensitivities are unequal.

TABLE II. BASELINE MOBILENETV2 PERFORMANCE

	Precision	Recall	F1-score	Support
Drowsy	0.98	0.86	0.91	50
Nondrowsy	0.88	0.98	0.92	50
Accuracy			0.92	100
Macro avg	0.93	0.92	0.92	100
Weighted avg	0.93	0.92	0.92	100

B. Performance of MobileNetV2 + DSC + Bottleneck + Expansion

The optimized MobileNetV2 model, in Table III, achieved a perfect score (100%) on all 100 test samples. The Drowsy and Nondrowsy classes both achieved precision, recall, and F1 Scores of 1.00. The results indicate that the model accurately identified all cases without error. The optimal macro and weighted averages indicate effective performance for both categories. The overall enhancement indicates that using DSC, Bottleneck blocks, and Expansion layers improves feature extraction and decision accuracy for real-time drowsiness categorization.

C. Performance of MobileNetV2-SE

MobileNetV2-SE, in Table IV, achieves an overall accuracy of 98%, a significant improvement compared to the baseline. The Drowsy class had a perfect recall rate of 1.00 and a precision rate of 0.96. This means that the model correctly identified all drowsy cases and made very few false alarms. On the other hand, the nondrowsy class had a perfect precision of 1.00 and a recall of 0.96, indicating that all predicted nondrowsy samples were correct, with only a few missed detections. The balanced macro and weighted averages (0.98) indicate that SE attention effectively improves feature discrimination while maintaining strong performance across both classes.

TABLE III. PERFORMANCE OF MOBILENETV2 + DSC + BOTTLENECK + EXPANSION

	Precision	Recall	F1-score	Support
Drowsy	1.00	1.00	1.00	46
Nondrowsy	1.00	1.00	1.00	54
Accuracy			1.00	100
Macro avg	1.00	1.00	1.00	100
Weighted avg	1.00	1.00	1.00	100

TABLE IV. PERFORMANCE OF MOBILENETV2-SE

	Precision	Recall	F1-score	Support
Drowsy	0.96	1.00	0.98	46
Nondrowsy	1.00	0.96	0.98	54
Accuracy			0.98	100
Macro avg	0.98	0.98	0.98	100
Weighted avg	0.98	0.98	0.98	100

D. Performance Model

The results in Table V show that all three models improved in performance over time. The baseline MobileNetV2 achieved 92% accuracy, but it was more sensitive to the drowsy class than to the other classes, leading it to miss many fatigue cases. Adding DSC, Bottleneck blocks, and Expansion made a big difference, with all metrics getting perfect scores (100%). These results indicate that structural lightweight optimizations greatly improve the ability to extract features and the reliability of decisions.

TABLE V. CLASSIFICATION PERFORMANCE OF BASELINE VS. SE-ENHANCED MOBILENETV2

Model	Precision (Drowsy / Nondrowsy)	Recall (Drowsy / Nondrowsy)	F1-score (Drowsy / Nondrowsy)	Accuracy (%)
MobileNetV2 (Baseline)	0.98 / 0.88	0.86 / 0.98	0.91 / 0.92	92
MobileNetV2 + DSC + Bottleneck + Expansion	1.00 / 1.00	1.00 / 1.00	1.00 / 1.00	100
MobileNetV2-SE (Proposed)	0.96 / 1.00	1.00 / 0.96	0.98 / 0.98	98

The proposed SE-enhanced MobileNetV2 achieved 98% accuracy with balanced precision and recall across both classes, demonstrating that channel attention can improve representational quality without increasing computational complexity. MobileNetV2-SE is a great balance between accuracy and efficiency. It consistently outperforms the baseline while remaining highly sensitive to drowsiness. It doesn't beat the structurally optimized model, though.

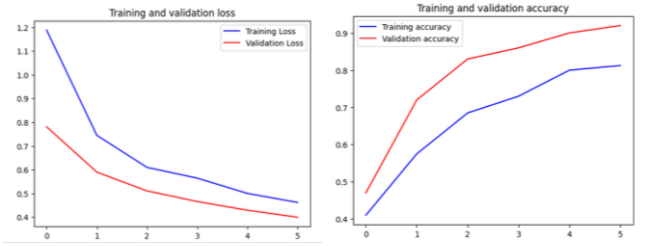
The DSC–Bottleneck–Expansion variant performs better because it directly improves the extraction of spatial and depthwise features, helping the model capture small visual cues related to drowsiness. On the other hand, SE attention changes the way channels respond, but it doesn't increase the backbone's ability to represent more information. So, in a lightweight architecture like MobileNetV2 and with a small dataset, structural optimizations yield feature maps that are richer and more discriminative than those from channel attention alone. This makes classification more accurate.

The results indicate that both structural and attention-based architectural improvement models provide significant differences compared to the baseline model. Structural optimization delivers the most accurate results, while SE

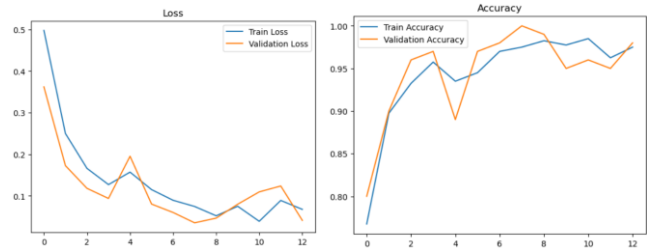
attention provides strong, well-balanced performance that is ideal for real-time Edge-IoT deployment.

E. Training Stability

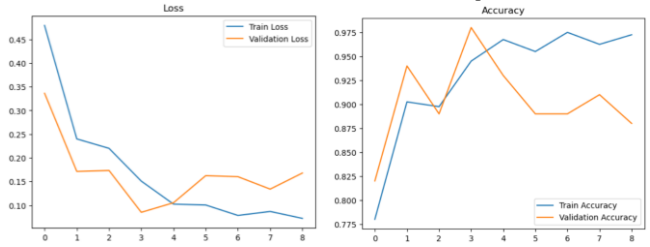
The training stability analysis shown in Fig. 3 reveals different behaviors among the three models. The baseline MobileNetV2 is moderately stable, but its uneven class-specific sensitivity indicates that fatigue-related features have not fully converged. The DSC–Bottleneck–Expansion variant is the most stable, with perfect convergence, smooth optimization dynamics, and no classification errors. These findings suggest spatial–depthwise feature extraction has improved. The SE-enhanced MobileNetV2 converges steadily and evenly, but it doesn't achieve the representational capacity of structural optimization. Overall, structural improvements make training more stable than attention-based recalibration, especially when using lightweight architectures and small datasets.



(a) MobileNetV2 Baseline.



(b) MobileNetV2 + DSC + Bottleneck + Expansion.



(c) MobilNetV2 SE.

Fig. 3. Training stability.

F. Confusion Matrix Analysis

The confusion matrix in Fig. 4 shows that the three models make errors in very different ways. The baseline MobileNetV2 has uneven class-sensitivity; it correctly identifies most nondrowsy samples but misclassifies 7 drowsy cases. These findings suggest it doesn't do a good job of picking up on subtle signs of fatigue. This imbalance raises a safety issue because missing drowsiness events make early-warning detection less reliable.

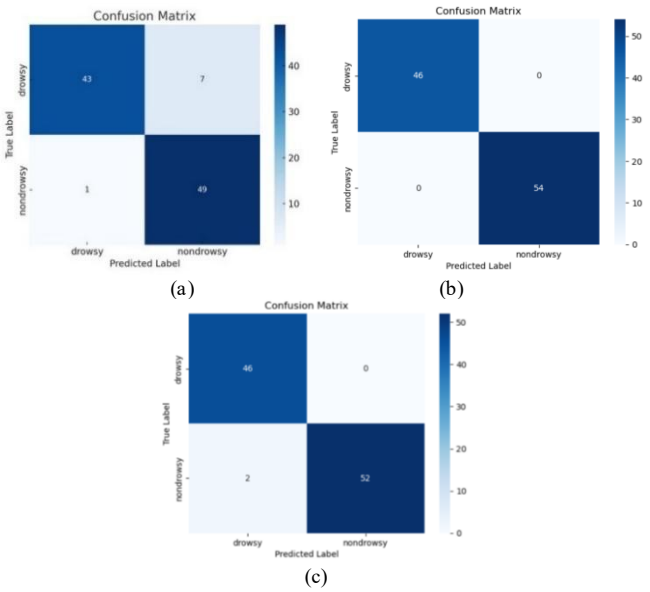


Fig. 4. Confusion Matrix: a) MobileNetV2 Baseline, b) MobileNetV2 + DSC + Bottleneck + Expansion, c) MobileNetV2 SE.

With DSC, Bottleneck blocks, and Expansion, the structurally optimized MobileNetV2 gets perfect classification, with no false positives or false negatives. This result shows that the model is the most reliable in the evaluation because it extracts features more effectively and generalizes more reliably.

The SE-enhanced MobileNetV2 also performs well, correctly identifying all drowsy cases and yielding only 2 false positives for the nondrowsy class. The findings indicate that the model prioritizes safety, opting to overlook a drowsy driver rather than generate numerous false alerts.

The examination of the confusion matrices reveals that both structural and attention-based improvements markedly increase the accuracy of classification relative to the baseline. Structural optimization ensures flawless performance, while SE attention offers robust, balanced sensitivity, ideal for real-time Edge-IoT deployment.

G. Ablation Study

The ablation study isolates the effect of the SE attention mechanism on classification performance, enabling it to be measured. This ablation study differs from the main results (see Table V) because it focuses only on the contribution of the proposed architecture at the component level, not on the overall accuracy of the final system. This separation is in line with standard practice in publications and keeps performance results from being confused with architectural justification.

1) Effect of SE attention: To assess the impact of the SE module, the authors compare MobileNetV2 Baseline, MobileNetV2 + DSC + Bottleneck + Expansion, and the SE-enhanced variant, maintaining uniform architectural and training configurations.

TABLE VI. COMPONENT-LEVEL ABLATION ON SE ATTENTION INTEGRATION

Variant	Attention Module	Structural Enhancements (DSC / Bottleneck / Expansion)	Accuracy (%)	Recall (Drowsy)	Macro F1-Score
MobileNetV2 (Baseline)	No	No	92	0.86	0.92
MobileNetV2 + DSC + Bottleneck + Expansion	No	Yes	100	1.00	1.00
MobileNetV2 + SE (Proposed)	Yes	No	98	0.98	0.98

Table VI shows the results of ablation across three MobileNetV2 configurations. The baseline model achieved a drowsy recall of 0.86 and an accuracy of 92%, indicating that the model was not very effective in detecting fatigue. The addition of structural improvements such as DSC, Bottleneck, and Expansion had a significant impact and significantly improved feature extraction. The improvement with SE was significantly greater than the baseline model, with a drowsy recall of 0.98 and an accuracy of 98%. These findings suggest that channel-wise attention improves discriminative representation while remaining efficient. Both enhancement strategies improve performance overall. Structural optimization gives the best accuracy, while SE attention gives a light, reliable improvement.

2) Architectural interpretation (non-experimental ablation): To elucidate the role of attention in the proposed model, the authors present a structural analysis of the SE module's operation within each bottleneck block, as depicted in Fig. 5. In the standard MobileNetV2, DSC, and inverted residual blocks treat all channels identically. This makes it hard for the network to pick up on subtle but important facial cues of drowsiness, such as partially closing the eyelids or making the eyes look smaller.

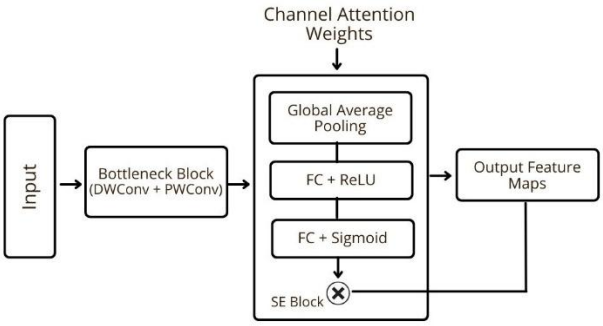

Fig. 5. Architectural interpretation.

A lightweight channel-attention module is added after the bottleneck block in the SE-augmented version. The SE block performs global average pooling to obtain global context, followed by two fully connected layers (FC + ReLU and FC + Sigmoid) that generate channel-wise attention weights. After that, these weights are multiplied by the original feature maps to produce recalibrated feature responses that favor channels that provide useful information and block those that don't. This selective feature amplification increases representational capacity with very little extra work for the computer. The enhanced convergence stability and reduced false-negative rate observed in the experiments provide compelling evidence that SE-driven channel recalibration directly improves the reliability and robustness of drowsiness classification.

3) Ablation interpretation: The ablation results clearly show that both SE attention and the structural improvements made a difference. The baseline MobileNetV2 exhibits limited representational capacity, evidenced by its 92% accuracy, 0.86 drowsy recall, and 0.92 macro F1-score. This signifies a restricted ability to discern subtle changes in eye features linked to fatigue.

The integration of SE attention improves channel responsiveness, leading to an accuracy enhancement to 98% and an increase in drowsy recall from 0.86 to 0.98. The macro F1-score increases from 0.92 to 0.98, indicating that SE improves class discrimination while preserving low computational requirements.

The most significant improvements come from structural changes, including DSC, Bottleneck blocks, and Expansion. These modifications resulted in complete accuracy, a recall of 1.00, and a macro F1-score of 1.00. The enhancements stem from a robust feature-extraction hierarchy, enabling the model to accurately identify fatigue-related behaviors.

The ablation study reveals that structural optimization produces the most substantial performance benefit, while SE attention provides a balanced and efficient increase in class sensitivity. Both mechanisms add to the baseline, making it easier to detect drowsiness in real-time Edge-IoT applications.

H. Computational Cost and Efficiency Analysis

To assess the viability of implementing the proposed models on resource-limited Edge-IoT platforms, the authors examine their computational cost attributes, encompassing parameter count, FLOPs, model size, and inference latency.

TABLE VII. COMPUTATIONAL COST AND EFFICIENCY ANALYSIS

Metric	MobileNetV2-SE (Attention)	MobileNetV2 + DSC + Bottleneck + Expansion (Structural)
Parameters	2,628,562	2,620,098
FLOPs	315,874,140 Ops	315,844,684 Ops
Model Size	13.39 MB	13.12 MB
Latency	206.27 ms	143.65 ms

Table VII shows that the SE-enhanced MobileNetV2 has slightly higher latency because the SE block adds operations such as global pooling and per-channel recalibration, which improve feature discrimination but also introduce some computational overhead. Even so, the model remains lightweight, with almost the same number of parameters and FLOPs as the structural variant. However, it is more sensitive to small facial cues. These results align with the goal of an Attention-Guided Lightweight MobileNetV2. They show that channel attention improves the accuracy of drowsiness

detection while remaining feasible for real-time Edge-IoT systems.

I. Statistical Validation

To verify that the observed improvements are not due to random variation, 95% confidence intervals (CI) and a two-proportion Z-test were conducted.

Table VIII provides a 95% confidence interval analysis, delivering a statistical evaluation of the reliability of each model. The baseline MobileNetV2 demonstrates the broadest accuracy range (0.867–0.973), indicating diminished confidence in its generalization abilities. The SE-enhanced MobileNetV2 exhibits a reduced range (0.953–1.000), indicating more stability and diminished performance variability. The structurally optimized model that integrates DSC, Bottleneck, and Expansion has the narrowest accuracy range (0.964–1.000), aligning with its impeccable real-world performance and outstanding reliability. The confidence interval estimates for the F1-score demonstrate a comparable trend, further validating the superiority of the improved models over the baseline.

The two-proportion z-test, in Table IX, shows that both improved models outperform the baseline model. The structurally optimized variant shows a statistically significant increase in accuracy, while the SE-enhanced model has strong, though statistically comparable, performance to the structurally optimized model on the current test set.

TABLE VIII. STATISTICAL VALIDATION USING 95% CI

Model	Accuracy	CI 95% (Accuracy)	F1-Score	CI 95% (F1-Score)	Reliable?
MobileNetV2 (Baseline)	92%	0.867 – 0.973	0.915	0.86 – 0.95	Yes
MobileNetV2-SE (Attention)	98%	0.953 – 1.000	0.98	0.96 – 0.995	Highly Reliable
MobileNetV2 + DSC + Bottleneck + Expansion	100%	0.964 – 1.000	1.00	0.98 – 1.00	Extremely Reliable

TABLE IX. TWO-PROPORTION Z-TEST

Comparison	Accuracy (Model 1 vs 2)	z-statistic	p-value	Interpretation
Baseline vs. SE	0.92 vs 0.98	-1.95	0.0516	Borderline; trend favoring SE, not significant
Baseline vs. DSC + Bottleneck + Expansion	0.92 vs 1.00	-2.89	0.0039	Significant improvement of structural model
SE vs. DSC + Bottleneck + Expansion	0.98 vs 1.00	-1.42	0.1552	No statistically significant difference

V. DISCUSSION

The results show that the suggested changes to MobileNetV2 make a big difference in lightweight driver drowsiness detection. The baseline model doesn't do a good job of remembering drowsy instances, but adding SE attention improves its performance significantly (from 0.86 to 0.98) and overall accuracy (from 92% to 98%). These findings suggest channel-wise feature recalibration works well in compact convolutional backbones. On the other hand, the structurally optimized version, which combines DSC, Bottleneck blocks, and Expansion layers, gets perfect classification performance (100% accuracy) with perfect class discrimination. This improvement is statistically significant compared to both baseline and the attention-enhanced models, indicating that structural optimization increases representational capacity more than attention alone does.

A major finding of this study is that these improvements in accuracy can be made without making the calculations more difficult. Both improved models remain light, with about 2.6 million parameters and 315 million FLOPs. The SE-enhanced model has an inference latency of 206 ms, but the structurally optimized model lowers it to 143 ms, improving execution speed by about 30%. This result shows that improving performance in resource-constrained environments is mostly due to architectural improvements, not to expanding the model.

In general, the results show that attention-based refinement and structural optimization have different but complementary roles in designing lightweight models. Channel attention enhances class sensitivity and equilibrium, whilst structural optimization elevates correctness and reduces delay. The findings suggest that accurate sleepiness detection on embedded platforms can be achieved through carefully designed lightweight architectures, avoiding reliance on larger deep learning models or specific hardware accelerators. Consequently, the proposed method is an effective and scalable approach for real-time monitoring of drivers in Edge-IoT systems.

A. Limitations

This research presents multiple difficulties that necessitate consideration. The suggested method performs frame-level classification and does not explicitly illustrate the temporal fluctuations of drowsiness, such as blink duration or fatigue buildup. The assessment is performed on a limited dataset of 500 images, perhaps constraining the generalizability of the findings to larger datasets. No cross-dataset validation or explicit robustness testing is conducted in challenging scenarios, such as variations in lighting, obstructions, the presence of glasses, or motion blur. Lastly, the suggested models haven't been tested on real Edge-IoT hardware yet, and the authors don't know how well they perform in the real world, particularly in terms of latency stability and energy efficiency.

VI. CONCLUSION

This study offers design-focused insights into the creation of lightweight vision models for real-time driver drowsiness detection on resource-limited Edge-IoT platforms. The results show that careful architectural design choices are enough to get

high accuracy, stability, and efficiency in safety-critical applications, rather than relying on model scaling or heavyweight architectures.

One important thing the authors learned is that attention mechanisms and structural optimization have very different jobs in lightweight CNNs. Channel-wise attention, implemented via Squeeze-and-Excitation, primarily improves feature discrimination and class sensitivity in compact backbones. This is a balanced and low-overhead way to improve performance. Structural architectural optimization, on the other hand, directly improves the backbone's ability to represent data by using DSC, Bottleneck blocks, and Expansion layers. This makes feature extraction more reliable and robust. This structural refinement is more important than just paying attention when you need to capture very specific fatigue-related cues while following strict computational rules.

From an Edge-IoT perspective, the results show that an important rule is that performance improvements in embedded vision systems should focus on architectural efficiency rather than on model complexity. Both enhanced versions have a small parameter footprint and low computational cost, and they can both make inferences in real time. These findings suggest high-accuracy driver monitoring can be achieved without specialized hardware accelerators or extensive computational resources.

This work indicates that structural optimization ought to be considered a principal design strategy, with attention mechanisms functioning as supplementary enhancements contingent upon application needs. These insights provide practical guidance for researchers and practitioners developing lightweight, dependable, and deployable vision-based driver monitoring systems for real-world Edge-IoT contexts.

VII. Future Work

Subsequent research will concentrate on enhancing the proposed lightweight architecture to achieve wider real-world applicability on Edge-IoT platforms. To further test generalization robustness, we need more diverse datasets and real-world driving conditions, such as low-light environments, obstructions, and a range of driver demographics. Second, adding other types of information, such as head pose, temporal eye blink patterns, or subtle physiological cues, could make the system more reliable when facial features are only partially visible.

The authors will also look into model-level optimizations like pruning, quantization, and hardware-aware neural architecture search to make ultra-low-power embedded devices even faster and use less memory. Finally, testing deployment on real Edge-IoT hardware such as Jetson Nano, Coral Edge TPU, and ARM-based systems will provide useful information on how well it performs over time, how much energy it consumes, and how it operates in real-time. These guidelines will make lightweight drowsiness detection more useful for smart in-vehicle systems and large-scale IoT deployments.

Acknowledgment

The Ministry of Education, Culture, Research, and Technology (Kemdiktisaintek) expresses its most profound appreciation for this study. The Ministry financed the research that led to this study as part of the Fundamental Research 2025 initiative, with grant contract number 127/C3/DT.05.00/PL/2025. The authors also acknowledge the ongoing support from Universitas Dian Nuswantoro in completing this work.

E-Health Research Center, University of Sciences and Humanities, Lima, Peru[4]

***Abstract*—Quality of service and customer satisfaction have become priority aspects for call center services, especially in a context where their use is becoming more and more frequent. In the district of Los Olivos, Lima, Peru, 60% of users who receive telephone service consider the quality of the service to be deficient, which shows the need to delve into this issue. The objective of the study was to determine the relationship between service quality and customer satisfaction in call center services in a district of Lima. To this end, a non-experimental, quantitative, correlational and cross-sectional approach was used. A questionnaire was applied to 384 clients to measure both variables and their relationship was analyzed using Spearman's correlation. The results show a positive, very strong and significant correlation between service quality and customer satisfaction ($r=0.907$; $p<0.001$). Likewise, the dimensions of service quality were significantly related to customer satisfaction: reliability ($r=0.850$), responsiveness ($r=0.618$), safety ($r=0.473$) and empathy ($r=0.587$). It concludes by highlighting the importance of strengthening the quality of service to improve customer satisfaction and generate benefits for the company. Finally, the need to investigate additional factors that may influence this dynamic is raised.**

***Keywords*—Quality of service; customer satisfaction; call center**

I. Introduction

The quality of the service that a company provides is a fundamental aspect to gain customers, to keep them and make them pleasant and become loyal customers. Within call centers, one of the most important aspects of service is agent accessibility [1]. In this context, aspects such as the waiting time in the queue and the number of users who have to hang up because they are not attended to or have to wait a long time, the attention time since the call has started and the number of transfers until they reach the indicated agent, are important. In general, greater accessibility is associated with a perception of superior quality [2]. The shift towards an increasingly customer-centric vision of service leads organizations to the need to highlight the value of service, which can be considered as an added value to offer to increasingly demanding consumers who are looking for products or services capable of satisfying their needs and promising better results [3].

It is considered that, taking a holistic view as a reference, the level of customer service provision in call centers is a key indicator that has a direct impact on the user experience [4]. In line with service companies, their image and level of profitability are closely linked to their ability to manage the way they interact with users, any complaints and information [5]. Along these lines, it has been found in the United States, at Harvard University, that call centers that make strong bets on the continuous learning of their operators together with the introduction of advanced call management technologies achieve significant levels of user satisfaction [6]. Along these lines, the Economic Commission for Latin America and the Caribbean prepared a comparative report in which it was understood that, in countries such as Brazil, Mexico or Argentina, working on the quality of service in call centers meant that the complaints received were considerably reduced [7]. This finding suggests that dissatisfactions are often linked to specific shortcomings, such as poor staff training and limited adoption of innovative technology solutions.

In Peru, during 2022, 2,337,975 claims were registered in the first instance by users of telecommunications services who went to the operating companies. This amount showed an increase of 42.9% compared to the previous year, according to what was reported by the Supervisory Agency for Private Investment in Telecommunications [8]. In addition, the institution pointed out that no operator reached the minimum expected performance score, set at 75 points. The results of the OSIPTEL User Service Quality Ranking reaffirmed the need for these companies to more rigorously direct their efforts towards improving the service provided [8]. Despite this, the telecommunications channel aimed at the public service showed some progress, as 54% of users said they were totally satisfied. In Lima, this percentage rose to 61%; however, in the Central Lima area, dissatisfaction exceeded 10%, which raises questions about the overall effectiveness of the service and the factors that influence its performance [9].

In specific areas, such as the Los Olivos district in Lima, Peru, the problem related to the quality of service in the call centers of service companies has intensified in recent years. This district has a remarkable population and economic growth, accompanied by a diverse community and a growing demand for services. However, this development has been accompanied by a significant increase in complaints related to telephone service [10]. It is reported that 60% of users in the area consider the quality of service provided by the call centers of telecommunications companies to be deficient. The most frequent reasons include long waiting times, limited effectiveness in solving problems and the lack of empathy shown by operators [9]. Despite the relevance of these figures, there is still a marked absence of studies that relate service quality with customer satisfaction. This is especially important, since, beyond business performance, the customer must be the

*Corresponding author.

main beneficiary of the service, so the dynamics between both variables require a contextualized analysis.

In this scenario, service quality is conceived as the difference between what the customer expects to receive and the performance that the company actually offers; In this way, an organization is perceived as of good quality when it effectively satisfies the needs of its users and, at the same time, preserves its competitive capacity in the market [11]. This quality has a direct impact on institutional growth, as it favors public acceptance and strengthens business positioning, which is why the continuous improvement of processes and their correct execution translates into more satisfactory results by responding more accurately to customer expectations [12]. From a structural perspective, quality of service comprises four dimensions. The first of these is reliability, which has to do with the ability to constantly deliver what is promised; the capacity to respond, which has to do with the speed or willingness of the staff to attend to any requirement; security, which is reflected in the trust generated by the agent when it multiplies in its domain, clarity and protection of user data; and finally, empathy, which we understand as the ability to attend to the user and offer effectively human care [13].

On the other hand, it is understood as the consumer's fulfillment reaction in broader terms, satisfaction as the level at which a service or product generates a pleasurable experience and an emotional reaction. Therefore, this level of satisfaction will have consequences on the possible future interaction of the customer with the organization, through the continuous use of the service, the recommendation to people and their loyalty [14]. For its analysis, satisfaction is usually organized into five dimensions or expectations: firstly, we have the initial expectations, which would be defined by the promises made by the company, which are derived from the testimonies or recommendations of other users; secondly, the perception of the customer, which represents the evaluation made between the comparison of what was expected versus what is actually obtained; the third element is the attention of complaints, in which the company has to give clear and effective responses that help increase user confidence; the fourth element, conformity, which is the feeling that their needs were met through appropriate solutions and, finally; the availability of info suggests being able to anticipate doubts and provide convenient information in a quick and appropriate way [15].

From the above, it can be corroborated that, in the context of the service company, the quality of customer service is essential, as well as guaranteeing the level of user satisfaction. In addition, this issue becomes more relevant in sectors such as telecommunications, insurance and customer service, where call centers play a fundamental role in becoming one of the main places of contact between the company and its customers. In these places, the relationship takes place in a non-face-to-face manner and depends, to the greatest extent possible, on verbal expressiveness and the proper management of time [16]. Consequently, it is important to study the problem, its well-defined interior dynamics, especially in a district with a continuity of economic growth, which is considered a commercial district and where a certain potential for consumer interaction is concentrated. In such scenarios, negative experiences not only affect the customer's perception of the company, but also their well-being, by generating frustration and disorientation [17]. In this way, understanding the relationship between quality of service and satisfaction will strengthen organizational management, improve links with users and guide training strategies and technological adoption. Likewise, since these dynamics are not restricted to a single district, the findings can be replicated in other contexts of the country and even internationally.

Considering the impact that quality of service can have on customer satisfaction, and based on the problems described, the general objective is to determine the relationship between quality of service and customer satisfaction in call center services in a district of Lima, Peru. To support this purpose, specific objectives are formulated aimed at analyzing the relationship between each of the dimensions of service quality, including reliability, responsiveness, safety and empathy, and the level of customer satisfaction in these services. Although it can be hypothesized that there is a significant relationship between the main variables, this dynamic is not yet sufficiently understood in the selected city or in the sector studied, so it is necessary to address the problem with a broad approach.

II. Study Background

There are multiple studies in different regions where different dynamics have been identified between service quality and customer satisfaction. In this sense, the work of Onofre and Márquez [18] studied how the elements associated with the quality of the service provided in the distribution of dairy products affect the perceptions of consumers who go to the points of sale, and for this they applied a quantitative design with surveys to 207 customers from different establishments. The results showed that more than 90% of the respondents considered both the product and the service received to be of high quality, and also saw that the quality of the service had a positive impact of 41.9% on customer satisfaction, while the Pearson coefficient showed a significant relationship between both variables at 0.60. which reiterates the relationship between the customer service experience and the general perception of the user.

Aguirre and Serrano [19] developed a study in supermarkets in order to understand how the quality-of-service influences customer satisfaction, for which they collected information from 392 participants through a quantitative design. When examining the data, they identified that the user's gender was significantly related to their level of satisfaction, reflecting that certain personal attribute can modify the perception of the service received. Likewise, the calculation of Spearman's correlation showed that the speed and willingness of the staff, a dimension associated with response capacity, maintained a positive link with the quality of the service, obtaining a coefficient of ($r = 0.705$; $p = 0.001$). This result demonstrates a statistically strong association between the two variables and highlights the role that timely care plays in the consumer experience.

In the study carried out by Cevallos [20], whose purpose was to explore how the quality of service influences the satisfaction of customers who frequent cafeterias located in airports, information was collected from 384 users through a quantitative design based on questionnaires. When analyzing the responses, it was observed that a large part of the participants expressed

dissatisfaction in several dimensions evaluated, especially with regard to the speed with which their requests were met and the empathetic treatment received by the staff. On the other hand, Pearson's correlation calculation showed a very strong and even statistically significant correlation link between service quality itself in the empathy and customer satisfaction dimension (r=0.928; p=0.001), which highlights the great importance of human interaction in this type of service.

Montero [21], in a study also based on user surveys, in the field of supermarkets had addressed the relationship between service quality and satisfaction in Tacna (Peru), based on a quantitative methodology; once the data were processed through the analysis of Spearman's correlation, a positive relationship of statistical significance (r = 0.747; p = 0.001) was found between both variables, that is, improvements in perceived quality can cause direct effects on the consumer experience. The author concluded with a strong service-satisfaction quality ratio and the need to strengthen service processes to improve the consumer's valuation and experience.

In Chiclayo, Hernández [22] carried out research whose objective was to explain the way in which service quality and customer satisfaction are articulated in the context of supermarkets. To do this, he resorted to a quantitative style and used a questionnaire applied to the 64 participants in the research. When processing the observed data, Pearson's coefficient pointed to a positive and significant relationship between the reliability of the service and the degree of satisfaction expressed by users (r=0.770; p=0.001). The most curious thing about the study was that all respondents reported being very satisfied, something that happened rarely and that suggests the presence of other elements, not explicitly considered that could be reinforcing this favorable perception of the consumer.

Masias [23] conducted research in the city of Cusco to find out how service quality is related to customer satisfaction within a clothing and footwear retail company. It opted for a quantitative approach and obtained the information through a survey of 369 users. The statistical analysis, based on Spearman's correlation, revealed a positive and significant association between both variables (r=0.588; p=0.000). In addition, when evaluating the dimensions of service quality, it was identified that safety presented an equally significant correlation with customer satisfaction (r=0.590), which underlines the determining role that the feeling of trust and security has in the evaluation that consumers make of the service received.

In research carried out by Alcántara [24] in a shopping mall in Lima, he wanted to determine how the quality of service is related to people's satisfaction. To this end, a quantitative design was used that was based on using surveys given directly to customers. In the processing of the information, the author found that the two variables were particularly strongly related, given the Spearman coefficient of r=0.907 and a confidence level of p=0.000. This result shows that when the customer perceives the service executed in the best of ways and consistent with what they expected, then the satisfaction of this person increases markedly, which highlights the strong relationship between the customer service experience and the final valuation as customers.

III. Materials and Methods

A. Type and Design

Considering the purposes of the research and the way in which the variables were addressed, the study is framed within the non-experimental approach, since the behavior of the analyzed phenomena is not intervened or altered, but their manifestation in the natural environment is observed [25]. To obtain accurate and verifiable results, a quantitative approach was chosen, which allows the collection of numerical information and processing it through statistical procedures in order to identify trends, variations, and possible links between the variables evaluated [26]. In accordance with this methodological choice, a cross-sectional correlational design was used, suitable for examining the relationship between variables at a specific time and under controlled observation conditions. This type of design provides a solid basis for analysis and, in addition, makes it easier for future research to reproduce the methodology or use it as a framework to deepen related studies [27].

B. Population, Sample, and Sampling

The population was made up of customers who interacted with the call center located in the district of Los Olivos, Lima, during the year 2024. This group included users who used the service during that period and who, in addition, met the criteria of residing in the district and having had a direct experience with the call center [28]. The delimitation of this population allowed the analysis to be focused on a specific set that is relevant to the objectives of evaluating service quality and customer satisfaction [29]. According to the last census of the National Institute of Statistics and Informatics (INEI) carried out in 2017, the population of the district amounted to 343,878 inhabitants. Based on this data, the study adopts this figure as a population reference, following the parameters established by the INEI for the demographic and statistical characterization of the district [30].

As for the sample, it is ensured that it allows valid conclusions to be drawn that are applicable to the total set [31]. To find the sample, the following formula was considered:

$$n = \frac{N * Z^2 * p * q}{e^2 * (N-1) + Z^2 * p * q} \quad (1)$$

Where:

- N = 343,878 (population)
- Z = 1.96 (95% confidence)
- p = 0.5 (expected success rate)
- q = 0.5 (1 – p)
- e = 0.05 (standard error)

Therefore, a representative sample of 384 inhabitants of the Los Olivos district was established to ensure reliability.

The research presented in this paper used Simple Random Probabilistic Sampling (MAS), which was the most appropriate

since it grants each of the elements that make up the population the same rights to be selected when forming a sample. This technique, widely known in research, is simple to execute and ensures the selection process randomly, a fact that facilitates the obtaining of representative and coherent samples with all the parameters of the population on which the research is focused [32].

C. Variables

- Quality of service
  - Conceptual definition: It is defined based on the expectation that the customer places on it, and the performance that the company itself gives them. In this sense, an organization is said to provide a good service when it can meet the needs of users as it wants and, at the same time, sustains its ability to compete in the sector [33].
  - Operational definition: It is the result of the interaction between the attention given during a service and how it adjusts the customer's expectations.
- Customer satisfaction
  - Conceptual definition: It is understood as the customer's response achieved, a level that is considered as the feeling of satisfaction generated by the pleasant experience, by the positive emotional response of this product or service experience; and this satisfaction becomes the level of satisfaction that the customer will achieve in their future senses with the organization and with its continuity of use [34].
  - Operational definition: It is the response expressed by the customer when their expectations have been met in the experience of valuing the acquisition of a good or service.

D. Technique and Instrument

1) Technique: This section of the document explains the procedure used to obtain the data that answered the questions that guided the development of this study, and at the same time, to contrast the hypothesis formulated. To this end, it was decided to use the survey as the main instrument for obtaining information, since this technique could be used to obtain information directly from the people who participated, in addition to organizing this information in a systematic way. The application of this data collection technique was the axis of the entire collection process that was directed towards the population traced, but it also allowed the collection of explicit evidence, adequate to counteract the analysis of the variables that were taken into account in the research [35].

2) Instruments: The questionnaire, which is understood as a research instrument, allows the measurement of the variables that have been described in the theoretical framework, as well as collecting the information needed to be able to answer the questions from which it is based and, little by little, to meet the objectives of the study that is carried out [11]. Therefore, it was decided to apply two questionnaires so that the first evaluated the quality of the service and the second measured customer satisfaction. For both questionnaires, the well-known Likert scale was applied, a psychometric technique that allows the evaluation of the intensity with which the participants carry out attitudes or perceptions in the face of a set of statements or statements [36]. In this case, each item consisted of a statement, before which the respondents had to express their degree of agreement or disagreement, through the application of a scale that varied from 1 to 5 points.

The validation of an instrument requires the participation of people with the appropriate qualifications, who are experts in the subject to be evaluated and have experience in the development of measurement instruments [37]. Under this criterion, the study requested the participation of three professionals with solid training in administrative systems and customer satisfaction, all of them with a master's degree. The experts reviewed each item and made their judgments by applying Aiken's V coefficient, obtaining a value of 0.967, an indicator that confirms the relevance and adequacy of the questionnaire to measure the variables of service quality and customer satisfaction in a valid and consistent manner.

On the other hand, the reliability of an instrument refers to its ability to produce uniform and stable results whenever it is applied under comparable conditions. Within this approach, a Cronbach's alpha value equal to or greater than 0.7 is recognized as adequate [38]. Based on this parameter, this coefficient was calculated using the corresponding formula, in order to determine the internal consistency of the instrument.

$$a = \frac{k}{k-1}\left(1 - \frac{\sum V_i}{V_t}\right) \quad (2)$$

Where:

- a = Cronbach's alpha.
- k = Number of items.
- Vi = Variance of each item.
- Vt = Total Variance.

Through this, a reliability of 0.924 for quality of service and 0.903 for customer satisfaction is calculated, coefficients that attribute excellent reliability to both instruments.

A. Procedure

1) Previous coordination: In this phase of the investigation, a meeting was arranged with the legal representative of the selected call center services company and with other managers of the headquarters located in the district of Los Olivos, Lima. During the conversation, the objectives of the study, the planned schedule and the usefulness they could obtain by objectively knowing the state of the quality of the service and the satisfaction of its users were presented. This exposure allowed the company to grant authorization to develop the study within its facilities. Once the permit was granted, the human resources area coordinated with the auxiliary staff of the call center to access the necessary information to locate and contact the defined sample.

2) Data collection: The researchers reviewed the records provided about the company's customers and, through the selected sampling, proceeded to contact the 384 randomly chosen users. During each call, the purpose of the study was explained and the reason for the contact was clearly presented, using interactive techniques to motivate participation. Likewise, each client was asked for verbal confirmation of their decision to participate voluntarily. Next, it was indicated that the questionnaire previously prepared in Google Forms would be sent immediately through the social network WhatsApp. In order to achieve a good completion and resolve any doubts that may arise, telephone communication was maintained with each of the participants until the completion of the online form was completed. This article was applied to all the customers selected in the contact, estimating a time of ten minutes in this contact.

3) Ethical considerations: The ethical dimension is a fundamental aspect of all research involving people, since it ensures respect, protection and responsible treatment of the participating subjects. Therefore, to endorse strict ethical compliance, this study was subscribed to a meticulous analysis carried out by the Ethics Committee of the University of Sciences and Humanities, obtaining its respective approval through Act No. 024-2025.

In addition to this, in full guarantee of good faith and transparency, the participants were clearly informed of the reason for the survey and the treatment to be given to their data. In turn, to guarantee an ethical process, informed consent was incorporated before the application of the questionnaires so that each of the participants could know their role in the research and the way in which the information provided would be treated. With this, the study reaffirms its adherence to the responsible and confidential use of the data obtained through it.

The data were treated with the strictest confidentiality, safeguarding the privacy, anonymity and security of all the subjects participating in the study. In addition to this, to guarantee the reliability of the information, no records of any kind were altered or manipulated, but the results obtained reflect in a reliable way the reality analyzed in the research.

B. Data Analysis

Once the data collection was concluded, the information provided by the virtual form continued to be organized. This process was carried out in Microsoft Excel; There, the data was cleaned, as well as the coding of these data to facilitate the subsequent classification, which was carried out according to the variables, as well as their dimensions. Finally, the matrix was exported to the IBM SPSS version 30 software, in order to be able to carry out the corresponding statistical analysis, which would be carried out in two defined stages.

In order to carry out the information processing, a descriptive analysis was carried out based on tables and graphs that allowed to account for the sociodemographic characteristics of the subjects in the sample and with respect to the values observed for the variables of service quality and customer satisfaction. Subsequently, since the study aimed to meet the correlational objectives, an inferential analysis was carried out, starting with the verification of the normality of the data using the Kolmogorov-Smirnov test, using the significance level of 0.05 as a reference criterion. The results showed a uniform p of 0.000 (< 0.05) for both the main variables and for each of their dimensions, which showed that the distribution was not normal. Given this, the use of non-parametric tests was used, choosing Spearman's Rho coefficient to establish the correlations. In this test, values close to one indicate a stronger relationship between the variables; In addition, positive correlations show a direct association, while negative correlations indicate an inverse relationship between the analyzed constructs [39].

IV. Results

A. Descriptive Analysis

Table I shows that among the customers of the Call Center company, the majority correspond to the female sex, since this sex is composed of 262 (68.2%) of the sample, while the male sex was composed of 122 (31.8%) customers.

TABLE I. Gender of Call Center Company Customers

		Frequency	%
Sex	Female	262	68,2
	Male	122	31,8
Total		384	100,0

Fig. 1 shows the quality of service among the customers of the Call Center services, in this way it can be detected that most of the customers reported being very much in agreement with the quality of service provided, since those who expressed this were 164 (42.7%) customers, while only 15 (3.9%) customers stated that they strongly disagreed with the quality of service of the company.

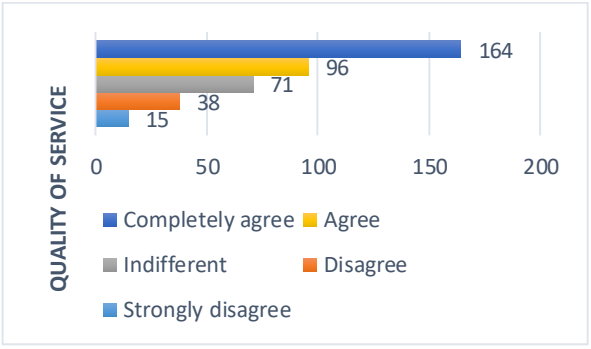

Fig. 1. Quality of service among call center service customers.

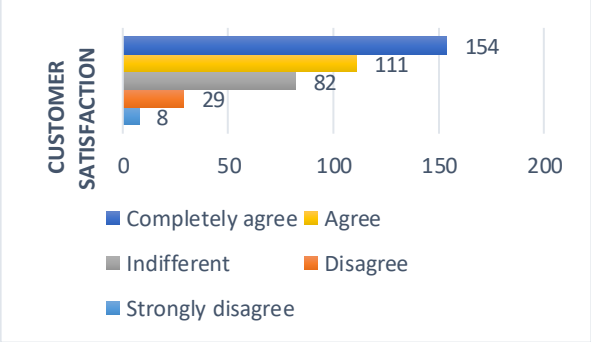

Fig. 2. Customer satisfaction among customers of call center services.

Fig. 2 shows customer satisfaction among the customers of Call Center services, in this sense it can be observed that most of them reported being in great agreement with the high customer satisfaction provided by the company, since 154 (40.1%) customers responded in this way, while only 8 (2.1%) of the customers reported being in total disagreement with the satisfaction of the customer received.

A. Correlational Analysis

Table II shows the relationship between service quality and customer satisfaction in call center services, where a positive association of great magnitude can be seen. Spearman's Rho coefficient reached a value of 0.901, with a significance level <0.001 (<0.05), which shows a very strong correlation between both variables. In practical terms, this result indicates that, as the quality of the service perceived by users increases, their satisfaction with the evaluated company also increases significantly.

Table III shows the correlation between the reliability dimension and customer satisfaction in call center services. The results show us a positive and large relationship that can be observed in a Spearman's rho coefficient of 0.850 and a significance level <0.001 ($p<0.05$), which indicates that, to the extent that the company increases the reliability of its processes, the fulfillment of what was promised, the accuracy of information and the coherence of care, user satisfaction tends to increase in direct line.

Table IV illustrates how responsiveness and customer satisfaction are related in call center services, showing a positive correlation of medium magnitude. The analysis carried out with Spearman's Rho coefficient gave a value of 0.618, with a significance <0.001 (<0.05), which confirms that there is a statistically significant association between both variables. In simpler terms, this suggests that, as the company improves the speed and willingness to respond to user requests, the perception of satisfaction within the organization also increases.

TABLE II. CORRELATION BETWEEN SERVICE QUALITY AND CUSTOMER SATISFACTION IN CALL CENTER SERVICES

			Quality of service	Customer satisfaction
Spearman's Rho	**Quality of service**	Correlation Coefficient	1.000	0.901
		Sig. (bilateral)	.	<0.001
		N	384	384
	Customer satisfaction	Correlation Coefficient	0.901	1.000
		Sig. (bilateral)	<0.001	.
		N	384	384

TABLE III. CORRELATION BETWEEN THE RELIABILITY DIMENSION AND CUSTOMER SATISFACTION IN CALL CENTER SERVICES

			Reliability	Customer satisfaction
Spearman's Rho	**Reliability**	Correlation Coefficient	1.000	0.850
		Sig. (bilateral)	.	<0.001
		N	384	384
	Customer satisfaction	Correlation Coefficient	0.850	1.000
		Sig. (bilateral)	<0.001	.
		N	384	384

TABLE IV. CORRELATION BETWEEN RESPONSIVENESS AND CUSTOMER SATISFACTION IN CALL CENTER SERVICES

			Responsiveness	Customer satisfaction
Spearman's Rho	**Responsiveness**	Correlation Coefficient	1.000	0.618
		Sig. (bilateral)	.	<0.001
		N	384	384
	Customer satisfaction	Correlation Coefficient	0.618	1.000
		Sig. (bilateral)	<0.001	.
		N	384	384

TABLE V. CORRELATION BETWEEN THE SECURITY DIMENSION AND CUSTOMER SATISFACTION IN CALL CENTER SERVICES

			Safety	Customer satisfaction
Spearman's Rho	**Safety**	Correlation Coefficient	1.000	0.473
		Sig. (bilateral)	.	<0.001
		N	384	384
	Customer satisfaction	Correlation Coefficient	0.473	1.000
		Sig. (bilateral)	<0.001	.
		N	384	384

TABLE VI. CORRELATION BETWEEN THE EMPATHY DIMENSION AND CUSTOMER SATISFACTION IN CALL CENTER SERVICES

			Empathy	Customer satisfaction
Spearman's Rho	Empathy	Correlation Coefficient	1.000	0,587
		Sig. (bilateral)	.	<0.001
		N	384	384
	Customer satisfaction	Correlation Coefficient	0,587	1.000
		Sig. (bilateral)	<0.001	.
		N	384	384

Table V shows the relationship between the dimension of service security and customer satisfaction, since there is a positive, although weak, correlation between call center services. Thus, Spearman's Rho coefficient reached a value of 0.473 and a significance level <0.001 (<0.05), which shows how increases in the perception of security (trust, clarity of information, data protection) have a direct, albeit moderate, impact on the level of satisfaction that users express.

Table VI shows the relationship between the empathy dimension and customer satisfaction in call center services, where a positive correlation of medium magnitude was identified. Spearman's Rho coefficient reached a value of 0.587, with a significance level <0.001 (<0.05), which confirms a statistically relevant association between both variables. This result suggests that, when staff demonstrate a greater ability to understand the user, listen actively and offer more human attention, the perception of satisfaction on the part of customers tends to increase proportionally.

V. DISCUSSION

Regarding the general objective, the hypothesis initially proposed, which indicated the existence of a significant correlation between service quality and customer satisfaction in call center services in a district of Lima, Peru ($r=0.907$; $p<0.001$) was confirmed. In addition, this correlation was identified as very strong, which solidly reinforces the relationship between both variables. This finding coincides with what was reported by Alcántara [24], who obtained a similar correlation coefficient in his study also carried out in Lima. Although the customers analyzed belong to different sectors, the similarity between the results could be explained by the shared sociodemographic context, given that both studies were developed in the capital, where users can present comparable characteristics and expectations. However, the correlation found in this research is much higher than that indicated by Montero [21] or Onofre and Márquez [18], who, when finding coefficients lower than those found by us, had to take into account what occurs in face-to-face contact with the customer, which adds factors to monitor in addition to the quality of the service. than the one assumed by the client. These could be waiting, the number of clients left seated in the clinical center room, and the material conditions of the waiting room, among others.

In the case of specific objectives, positive and significant correlations were tested between the dimensions of service quality and customer satisfaction. Among the correlations found, the one with the greatest dimension was that of reliability and customer satisfaction, since it is the one with the greatest strength ($r=0.850$; $p<0.001$). This coincides with what Hernández [24] found, who also identified an important correlation between these variables. This gives rise to interpreting reliability as the most important factor in the perception of service quality, since customers associate it with diligent, systematic and respectful attention from the first contact. On the other hand, a positive relationship was also found between the responsiveness of the service and customer satisfaction, with the correlation being of medium size ($r=0.618$; $p<0.001$), which may be decisive in decision-making to improve the quality of the service. This result is consistent with what was found by Aguirre and Serrano [19], a coincidence that could be explained by the similarity in the methodological approach and in the sample size of both studies. Likewise, these authors evidenced the influence of gender on customer satisfaction, which suggests the need to delve into how sociodemographic characteristics can affect the variables analyzed.

On the other hand, a positive, although weak, correlation was identified between safety and customer satisfaction ($r=0.473$; $p<0.001$), a result that differs from that reported by Masias [23], who found a relationship of medium magnitude between these variables. This discrepancy could be explained by the context of this author's study, developed in a province of the Sierra natural region of Peru, where the perception of security in service could have a greater weight in customer satisfaction. However, other factors associated with the environment or type of service may also play a role. Finally, a positive and medium-level correlation was found between empathy and customer satisfaction ($r=0.587$; $p<0.001$). This finding differs from that found by Cevallos [20], who obtained a very strong correlation between both variables. This difference could be due to the area analyzed, since their study was carried out in coffee shops, a direct consumption service in which empathy can more closely and immediately influence the customer experience. In contrast, call center services may involve other elements that modulate satisfaction beyond empathy.

In addition, although the objectives set were met, the study faced some limitations. One of the main ones was related to access to the call center services company, since it handled personal and contact information of its customers, which had to be protected without the possibility of disclosure. At first, research was perceived as a risk for this purpose; however, this difficulty was overcome by the execution of all the procedures required to authorize access, especially those related to the ethical aspects that guaranteed the non-maleficence of the study and its results. Likewise, contact with some customers was not received favorably at the beginning, as several interpreted the call as part of a sale. This situation was addressed through a pre-developed presentation strategy, which made it possible to clearly explain the purpose of the study and persuade users to participate voluntarily. Additionally, assertive communication and empathy techniques were used to promote an effective and

respectful dialogue, which facilitated a greater willingness on the part of the participants. Finally, because participants were selected using non-probability sampling, the results are subject to potential bias. A clear example of this is the gender imbalance, which may not adequately represent the target population. Similarly, variations in response times among participants may have introduced bias. These factors should be considered in future research.

VI. Conclusion

In conclusion, the existence of a positive, very strong and significant correlation between service quality and customer satisfaction in call center services in a district of Lima, Peru, an area little explored both nationally and locally, was demonstrated. This finding contributes to filling a gap in knowledge regarding the dynamics between both variables. The findings suggest that the quality of the service is not only an operating condition that call centers should meet, but that it is very directly related to the degree of user satisfaction and that this can be good for the company, since satisfied users tend to repeat the use of the service. However, it is necessary to verify other variables that may affect existing differences in the quality of service; variables related to the organization, the type of interaction or the number of resources available. In the same way, individual variables such as age or sex, in addition to those related to the context, could intervene in customer satisfaction.

In the same way, reliability was shown to be the dimension that had the most robust relationship with customer satisfaction, and this statement invites us to reflect on why providing the user with truthful information and minimizing errors in call center services can be decisive in the manifestation of user satisfaction. In this sense, the effectiveness of communication can be considered as a decisive element in the service process, so it can be very good for call centers and, in general, service companies to reinforce the training of their employees, especially those who are in contact with customers. enhancing effective, assertive and humanized communication skills. Likewise, it is important that the information related to the products, goods or services that are presented is truthful and mentions both the pros and cons; Misrepresenting or presenting erroneous information not only goes against the principles of business ethics, but can lead to an increase in dissatisfaction or loss of customer trust, and this would have an impact on a decrease in sales.

Finally, this work establishes a new line of research since it is dealing with a field of study in which immense attention is being invested and which is becoming increasingly important: the call center service in a city where commercial activity is very intense and in which a continuous offer of services is made. In this sense, future research is invited to focus on delving into these and other variables in similar contexts and on the analysis of other factors that may influence the quality of service and the satisfaction of the end customer. Given that both this study and other analyzed research show a significant correlation between service quality and customer satisfaction, future focus should be on exploring specific relationships between these variables and factors associated with their development, such as frequency of use and socioeconomic level, among others. Expanding these perspectives can enrich our understanding of the sector's complexity and improve evidence-based decision-making.

***Abstract*—Deep learning (DL) has become a transformative approach in medical image analysis, offering superior accuracy and automation in image segmentation tasks. In reproductive imaging, transvaginal ultrasound (TVUS) serves as a crucial modality for evaluating the endometrial condition, which plays a critical role in assessing ovarian health. Although many studies have applied deep learning to the segmentation of pathological endometrial conditions, research focusing on non-pathological endometrium segmentation remains critically limited. This study presents a comprehensive review of deep learning methods for endometrium segmentation in TVUS, with a focus on non-pathological conditions, including endometrial thickness measurement, morphology analysis, and endometrium receptivity assessment. Following PRISMA guidelines, research articles published between 2015 and 2025 were identified from major scientific databases. The selected studies were analyzed in terms of image processing methods, deep learning architectures, and performance metrics, such as Dice coefficient, Jaccard index, precision, recall, and Hausdorff distance. Although foundational architectures, such as U-Net and its variants, achieve impressive Dice coefficients (up to 0.977), the results often rely on small and single-center datasets, proving limited generalizability across imaging settings. Recent advancements demonstrate the efficacy of hybrid architectures, such as the Deep Learned Snake algorithm and Transformer-based models like SAIM, in optimizing segmentation precision within noisy transvaginal ultrasound images. This review highlights the lack of attention to non-pathological endometrium segmentation and guides future research directions in self-supervised learning, transformer-based architectures, and interpretable deep learning to achieve robust and clinically applicable models for enhancing endometrium receptivity assessment and supporting ovarian health in assisted reproduction technology.**

***Keywords*—Endometrium segmentation; deep learning; image segmentation; image processing; endometrium receptivity assessment; ovarian health**

I. Introduction

Fertility is a crucial aspect of reproductive health, with individuals seeking medical assistance to conceive. Due to this, in vitro fertilization (IVF) has emerged as one of the most effective assisted reproductive technologies (ART). Research showed that the success rate of IVF remains below optimal, due to multiple limiting factors such as embryo quality and endometrial receptivity [1]. Transvaginal ultrasound (TVUS) is the primary imaging modality in reproductive medicine to measure endometrial thickness and structure because of its real-time, non-invasive nature, cost-effectiveness, and portable data management [2].

In the context of IVF, accurate segmentation of the endometrium in TVUS images is essential for reliable measurement of endometrial thickness, which is a key biomarker for predicting endometrial receptivity and IVF outcomes [3], [4], [5]. Clinicians often rely on TVUS to measure endometrial thickness and detect abnormalities that may impact implantation. However, manual segmentation of the endometrium thickness from ultrasound images is highly subjective, time-consuming, and prone to inter-observer variability. This variability can affect clinical decision-making and IVF outcomes. Therefore, there is a growing need for automated and accurate segmentation of ultrasound images to assist in clinical decision-making [6].

Current efforts towards automation are primarily focused on automating pathological endometrial conditions, such as cancers and endometriosis. Meanwhile, the assessment of endometrial receptivity in healthy women undergoing IVF remains largely overlooked [7]. This disparity highlights a critical research gap in the field. Although accurate endometrium segmentation for pathological diagnosis is essential, it is equally vital to evaluate endometrial receptivity to improve IVF success [8], [9].

Deep learning models have demonstrated remarkable abilities in tackling a diverse array of medical imaging tasks, spanning classification, detection, segmentation, and registration [6], [10]. While deep learning has shown remarkable success in detecting endometrial pathology, current models largely neglect the detailed analysis for assessing healthy endometrium receptivity. Moreover, the limited generalizability across TVUS devices and protocols is due to

*Corresponding author.

small, single-center datasets lacking in diversity in acquisition settings [11].

Other than that, existing models predominantly focus on anatomical features, such as thickness, while overlooking functional biomarkers that correlate with implantation potential [12]. These challenges escalated because researchers haven't agreed on the best deep learning model for endometrium segmentation and a standard method to assess these tools in real-time clinical use. Although experimental studies report that segmentation accuracy meets the required clinical standard, the results have not been translated into clinical application. The gap between research achievements and practical implementation highlights the need for comprehensive solutions that address both technical and clinical requirements for endometrial receptivity assessment.

Therefore, to systematically evaluate these challenges and opportunities, this literature review addresses the following central research question: How can deep learning segmentation of TVUS images improve objective assessment of endometrial receptivity? To accurately address this question, there are four sub-questions:

- What are the predominant deep learning model architectures applied to TVUS endometrium segmentation?
- Which deep learning architecture achieves a high accuracy in endometrium segmentation?
- Which evaluation metrics best validate segmentation quality for clinical receptivity assessment?
- What technical and clinical gaps persist in translating these models to the ART workflow?

By addressing these questions through synthesized evidence, this study aims to establish methodological best practices while identifying priority areas for future research at the intersection of deep learning and reproductive medicine. Fig. 1 illustrates the central research question and sub-questions guiding the systematic review. The novelty of this review bridges the gap by focusing specifically on how deep learning can segment healthy endometrium for receptivity assessment, which is a clinical need often overlooked in prior reviews of gynecological imaging.

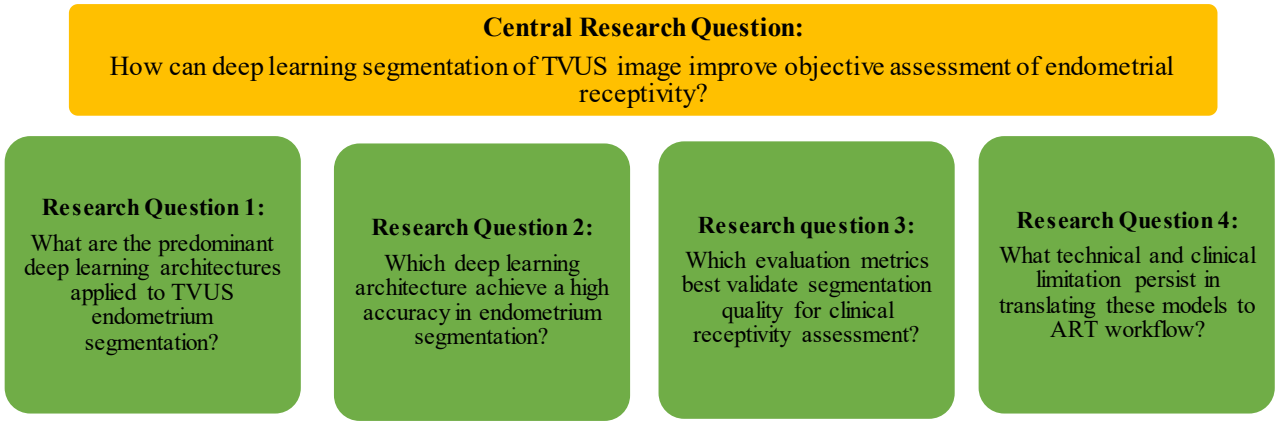

Fig. 1. Overview of the central research question, with research questions that guide this literature review.

This study is organized first to provide a brief overview of related reviews on deep learning for medical, specifically for women's reproductive health system. Later, this study provides brief information on endometrial receptivity and the role of transvaginal ultrasound for assessing and monitoring the endometrium. Next, the study will provide a brief explanation about a deep learning model for image segmentation in medical image analysis. The methodology section outlines the rigorous selection process used to identify relevant studies included in this review. Following this section, the results section synthesizes and presents the selected studies to address the defined research questions. In the future direction section, this study discusses the potential for integrations and clinical applications to improve receptivity assessment. Lastly, the conclusion summarized key insights, identified current gaps in the literature, and outlined actionable future research trajectories. The list of abbreviations used in this study is listed in Table I.

TABLE I. LIST OF ABBREVIATIONS

Word	Abbreviations
ART	Assisted Reproductive Technology
CNN	Convolutional Neural Network
DDRNet	Deep Dual-Resolution Networks
DLS	Deep Learned Snake
ERA	Endometrium Receptivity Assessment
ET	Endometrial Thickness
ET	Endometrium Thickness
FCN	Fully Convolutional Network
IoU	Intersection of Union
IVF	In Vitro Fertilization
MAE	Mean Absolute Error
NLP	Natural Language Processing
ResNet	Residual Network
RSME	Root Square Mean Error
SAIM	Segment Anything with Inception Module
SAM	Segment Anything Module
TVUS	Transvaginal Ultrasound
U-Net	U-Shaped Convolutional Neural Network
VGG	Visual Geometry Group
WOI	Window of Implantation

II. Related Works

Several review articles have surveyed the application of deep learning in medical imaging, including specific analyses of gynecological structures. However, a critical examination of these reviews reveals a consistent focus on pathological diagnosis and has rarely addressed the segmentation of the non-pathological endometrium for receptivity assessment.

Broad systematic reviews in medical imaging, such as those by Litjens et al [10] and Gao et al.[13], highlighted that while deep learning has transformed tasks like classification and segmentation across various anatomical regions, gynecological applications are often overlooked by more extensively researched regions, like the brain, chest, and musculoskeletal system. Furthermore, comprehensive segmentation reviews primarily utilize pathological benchmarks to evaluate model performance. This leaves a significant gap in the synthesized knowledge regarding the automated mapping of healthy anatomical structures.

Within the gynecological field, the existing reviews focused on pathological conditions, particularly oncological diagnostics. For instance, Swarnkar et al. conducted a systematic review of deep learning for the diagnosis of cervical, ovarian, and endometrial malignancies. The review identified 50 relevant studies, including 16 focused specifically on endometrial cancer [14].

Similarly, Aparna and Libish concentrated on research specifically aimed at identifying abnormal and malignant cells in the uterus to discover endometrial cancer [15]. Meanwhile, Piedimonte focused on using machine learning to incorporate clinical and radiologic parameters to pre-operatively stratify high-risk cancer patients [16]. These reviews evaluate the efficacy of models in discriminating between benign and malignant masses or predicting the depth of myometrial invasion, which are tasks inherently different from delineating a healthy endometrial lining [13].

This pathological emphasis persists even in modality-specific reviews. Jiang synthesized the research on deep learning-based imaging for endometrial cancer management across ultrasound, MRI, and hysteroscopy, with a focus on tumor morphology and molecular typing [17]. Zhang evaluated models for classifying common endometrial lesions, including hyperplasia and polyps, but did not address the segmentation of baseline healthy structures [18]. In a comprehensive review, Meiburger highlighted that while automated localization and segmentation techniques represent a developing 'hot topic', gynecological applications remain largely focused on uterine fibroids or follicular monitoring for disease identification [19].

This technical focus on disease is particularly evident in the assessment of female reproductive function. Chen highlighted that while ultrasound is essential for evaluating ovarian reserve and endometrial receptivity (ER), systematic reviews specifically focusing on AI-aided ultrasound for these functional assessments are absent from the literature [7]. Current studies on reproductive segmentation focus primarily on ovarian follicles to diagnose conditions like polycystic ovarian syndrome (PCOS), while the foundational task of segmenting healthy endometrial remains overlooked.

Consequently, a clear gap exists between the technical literature and clinical application. In addition to cancer diagnosis studies from Swarnkar, a few more studies have explored deep learning segmentation for endometrial hyperplasia and endometriosis [20], [21], [22], [23], [24], [25], [26].

Fig. 2 presents a stacked bar chart visualizing the focus of endometrial image analysis research over the past decade. The data reveals a significant disparity. While deep learning applications are extensively utilized for diagnosing pathological conditions, their application in evaluating healthy endometrial receptivity (healthy endometrium) remains notably overlooked.

The absence of a dedicated synthesis for non-pathological endometrium segmentation represents a significant limitation in translating deep learning from research to clinical practice in assisted reproduction. Therefore, this review systematically addresses this gap by examining deep learning architectures, performance metrics, and clinical translation challenges specifically in the context of endometrial receptivity assessment, thereby providing a focused foundation for the methodological analysis that follows.

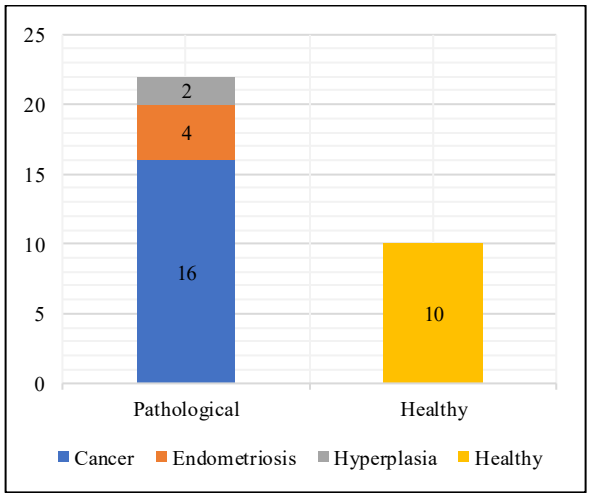

Fig. 2. Comparative analysis of research volume identifying the disparity between endometrial disease diagnosis and healthy assessment.

III. Endometrium Receptivity and Transvaginal Ultrasound

The endometrium, which forms in the uterine lining, is a dynamic tissue essential for female fertility and reproductive health. Throughout the menstrual cycle, the endometrial lining undergoes a series of dynamic changes. The changes include shedding during menstruation, followed by thickening during the proliferative phase and eventually transitioning into the secretory phase to prepare for potential embryo implantation. The condition when the endometrium is ready for embryo implantation is called endometrial receptivity (ET).

Endometrial receptivity refers to a specific period during the menstrual cycle when the endometrium is optimally prepared to facilitate embryo attachment and subsequent pregnancy [27], [28]. This specific period is known as the window of implantation (WOI). An accurate assessment of endometrial

thickness and structure is crucial during WOI for improving IVF outcomes [29]. This is because inadequate endometrial development could lead to implantation failure and pregnancy loss, even with high-quality embryos [30], [31].

During in-vitro fertilization (IVF) procedures, ET plays a crucial role in embryo implantation. A receptive endometrial environment is essential for successful implantation and a healthy pregnancy [12].

Endometrial receptivity occurs in a brief period known as the window of implantation (WOI). This period typically occurs between 20 and 24 days of a regular 28-day menstrual cycle. During this critical period, within 3-5 days, the endometrium undergoes changes in molecular and structural modifications to support embryo implantation [32]. Thus, proper timing of embryo transfer within this window is crucial to ensure the success of implantation. Failure synchronization, displaced implantation window, of embryo transfer during this period could lead to implantation failure. The displaced implantation window is one of the causes of recurring implantation failure [33]. The percentage of women with recurrent implantation failure showing displaced implantation windows ranges from 17.7% to 80% [32], [34], [35]. Therefore, the need for an accurate assessment of endometrial receptivity is evident, and transvaginal ultrasound (TVUS) serves as a reliable tool in evaluating the endometrial receptivity for implantation.

The key parameters evaluated through TVUS include endometrial thickness, endometrial pattern, and vascular characteristics [36], [37]. These parameters provide valuable insights into the endometrium's readiness for implantation [38], [39]. A general rule suggests that a thin endometrium reduces implantation success, while an overly thick endometrium may also lower pregnancy rates. However, the optimal endometrial thickness for successful implantation remains inconclusive within the medical community [40]. A study demonstrated that embryo implantation, clinical, and ongoing pregnancy rates were significantly higher in patients with an endometrial thickness greater than 9 mm compared with those less than 9 mm [41]. A few other studies have concluded that the critical threshold of 7-14 mm is the optimal endometrial thickness for embryo transfer [5], [28], [42], [43]. A systematic review found that implantation rates tend to decrease when endometrial thickness is less than 7 mm, whereas a thickness greater than 14 mm does not significantly impact pregnancy outcomes compared to a medium endometrial thickness of 7–14 mm [44]. These inconsistencies underscore the need for additional research to establish a definitive range of endometrial thickness for successful implantation.

In addition to endometrial thickness, the endometrial pattern is a critical parameter for determining endometrial receptivity. Endometrial pattern assessment involves evaluating the endometrial echo pattern using ultrasound imaging. Several studies have demonstrated that the triple-line endometrial pattern is associated with higher implantation and pregnancy rates [12], [44], [45], [46]. Conversely, when the functional layer is non-uniform (heterogeneous), and the central line echo is unclear, receptivity is low [12]. While the endometrial pattern is not entirely overlooked, it tends to receive less attention than other parameters, such as endometrial thickness, especially in studies involving deep learning-based image analysis.

Despite TVUS being the gold standard tool to help medical practitioners monitor and assess endometrial receptivity, it has some limitations. TVUS images often suffer from noise and low resolution, particularly due to speckle noise. Due to this reason, images need to go through a pre-processing step called despeckling of ultrasound images [47]. Additionally, manual interpretation of ultrasound scans is highly operator-dependent, leading to variations in endometrial thickness measurements [4]. Using TVUS imaging, medical practitioners would freeze the screen and measure the endometrial thickness while monitoring the endometrial pattern. This manual segmentation process is tedious, laborious, and time-consuming. In addition, manual segmentation is influenced by the experience and knowledge of medical practitioners. To improve accuracy and consistency, computer-aided segmentation models are crucial for precisely analyzing the endometrium in TVUS images and assessing key endometrial receptivity biomarkers, including thickness and pattern.

IV. Image Processing for Endometrium Segmentation

In 1995, Pierson and Adams concluded that the development of computer-aided image analysis was a significant achievement for improving clinical management of ovarian health [48]. This promise was particularly compelling for the challenging domain of TVUS, where manual segmentation of the endometrium is operator-dependent, tedious, and time-consuming. In the years since, researchers have been exploring and developing image processing techniques to automate this critical task. This is because image analysis is essential for diagnosing pathologies and planning treatments. Primarily, the image processing techniques rely on pixel-level intensity information, spatial relationships, and mathematical morphological operations to delineate anatomical structures. Researchers have categorized these fundamental techniques into several groups:

- Thresholding and region-based methods, which segment based on pixel intensity and spatial homogeneity;
- Edge and contour-based approaches, such as active contour, which delineate anatomical boundaries;
- Morphological operations, used to refine segmented structures, and
- Classical machine learning classifiers, which leverage hand-crafted features.

Together, these techniques laid the foundational toolkit for automated analysis, establishing the feasibility of computer-assisted analysis. These techniques dominated the field until deep learning became superior. While computationally efficient and interpretable, traditional methods face significant challenges, including sensitivity to initialization, manual parameter tuning requirements, limited generalization across imaging conditions, and difficulty handling the inherent noise and ambiguous boundaries characteristic of ultrasound images.

A. Thresholding

Thresholding techniques, while computationally efficient and straightforward, operate by classifying pixels into foreground and background based on a predefined intensity value [49], [50]. This technique is particularly useful for tasks like pre-segmentation or initial region of interest generation, but often requires further refinement due to noise inclusion and an inability to adapt to a variety of image qualities. For instance, segmenting follicles in ultrasound images frequently utilizes thresholding, but the method often deals with noise, thereby needing additional refinement to achieve acceptable accuracy [51]. To address these issues, various thresholding methods were developed, and for medical imaging applications, multi-level thresholding methods were developed to handle complex anatomical structures from medical imaging [52], [53], [54], [55], [56]. Nevertheless, their application to complex anatomical structures, such as the endometrium in TVUS images that are often affected by high noise, low resolution, and unclear boundaries, thresholding techniques remain inadequate for achieving robust and clinically reliable delineation [57], [58].

B. Region-Based Techniques

These techniques focus on grouping neighboring pixels with similar intensity or texture characteristics to overcome the limitation of edge detectors in a noisy environment. Techniques like region growing, for instance, initiate from a seed point and iteratively expand by incorporating neighboring pixels that meet specific homogeneity criteria to construct a comprehensive endometrial region [57]. However, this technique often requires manual seed-point initialization, making it less suitable for fully automated pipelines, especially given the inherent variability in ultrasound image quality and anatomical presentation [59]. Consequently, the reliance on manual seed-point selection introduces subjectivity and can lead to inconsistencies across different medical practitioners, highlighting the need for automated or semi-automated initialization strategies [60].

C. Edge and Contour-Based Techniques

Edge-based and contour-cased techniques have been widely explored for medical image segmentation due to their ability to delineate structural boundaries. Edge detection methods identify discontinuities in image intensity that correspond to tissue interfaces [61], [62], [63]. In contrast, contour-based methods, such as active contours, evolve deformable curves to conform to these boundaries under the influence of internal and external forces [64], [65], [66], [67], [68]. The active contour model, often called snakes, utilizes energy functional minimization to guide the contour towards desired boundaries. This approach offers improvements in adaptability and robustness for complex anatomical structures. However, these techniques require manual initialization and remain highly sensitive to blurred or weak edges and noise, particularly prevalent in ultrasound images, where variations in lesion morphology can further complicate accurate segmentation [19].

D. Morphological Operations

Morphological operations use structuring elements to refine segmented masks, remove small artifacts, and enforce shape constraints. Typically, morphological operation is used to improve defects that are recognized during segmentation [69]. Two basic morphology operations are dilation and erosion. Dilation expands the boundaries of the foreground objects, while erosion shrinks them. Often, the combination of these operations, such as opening and closing, can effectively smooth contours, fill small holes, and remove isolated pixels, thereby enhancing the quality of the endometrial segmentation [70]. Despite their utility in post-processing, morphological operations are primarily refinement tools and do not independently perform segmentation, often requiring other methods to produce an initial segmentation mask.

While these traditional segmentation techniques have laid the foundation for computer-aided image analysis for ovarian health, their performance varies depending on image quality and anatomical complexity. As imaging complexity increased and clinical demand for reliability grew, the limitations of these techniques became apparent. Table II provides a summary of each technique with its strengths and weaknesses.

TABLE II. SUMMARY OF TRADITIONAL SEGMENTATION METHODS

Techniques	Strengths	Weaknesses
Thresholding [49], [50]	• Simple to implement • Fast preprocessing step	• Fails with low contrast image • Sensitive to noise • Fixed threshold
Region-Based [71]	• Capture spatial continuity • Adapts to the region's shape	• Manual seed initialization • Leakage in noisy regions
Edge & Contour Based	• Precise boundary localization • Can handle complex shapes	• Requires a good edge contrast image • Manual initialization •
Morphology Operation [69], [70], [72]	• Capable of removing small artifacts • Capable to smooth and filling holes in the image	• Tendency to over-smooth fine structures in the image • Dependent on element size

The early attempts of automation in endometrium segmentation relied on basic algorithms, such as thresholding, active contours, and region-growing methods [6], [10]. Despite their usefulness, these approaches often struggle to address the fundamental challenges of ultrasound imaging, such as low contrast, speckle noise, and anatomical variability [58]. While these traditional methods provided the foundation, their limited robustness and generalizability eventually drove a shift toward more advanced solutions. Over the past decades, as this article was written, researchers have extensively explored and investigated the application of automated segmentation of ultrasound images, evolving into the application of deep learning-based approaches.

V. DEEP LEARNING MODELS FOR ENDOMETRIUM SEGMENTATION

In recent years, extensive literature reviews have been conducted on deep learning approaches to medical image analysis, highlighting methodologies, technical progress, and clinical translation limitations [10], [73], [74], [75], [76], [77]. These efforts have shown deep learning as a transformative paradigm, demonstrating superior performance in image

processing across diverse medical imaging modalities. Despite the various studies and reviews in deep learning for medical images, only a few studies have focused on deep learning segmentation of the endometrium in TVUS images for endometrium receptivity assessment (ERA). This highlights the need to explore alternative deep learning models for ERA to ensure repeatability and high segmentation accuracy in clinical applications. To address this issue, recent research has applied a range of deep learning architectures aiming to improve segmentation accuracy, robustness, and clinical applicability specifically for endometrium analysis.

A. Foundation: Convolutional Neural Network (CNN)

Convolutional Neural Network (CNN) is the baseline for deep learning in medical image analysis due to its ability to capture spatial features and patterns effectively [78], [79], [80]. These networks leverage convolutional layers to automatically learn hierarchical representations from raw image data, eliminating the need for manual feature identification and extraction. This ability is crucial in medical imaging for tasks such as identifying anatomical structures of the endometrium, where subtle textural and morphological cues are vital for accurate segmentation and subsequent analysis [81]. The strength of CNNs lies in their capacity to capture local spatial features, such as edges, textures, and patterns, through convolutional filters. In the context of endometrium segmentation, CNNs have shown potential in learning discriminative features from TVUS. However, a fundamental limitation of CNNs is their reliance on local context, which constrains their ability to model long-range dependencies and global context within an image [82]. Fig. 3 below shows the basic architecture of a convolutional neural network.

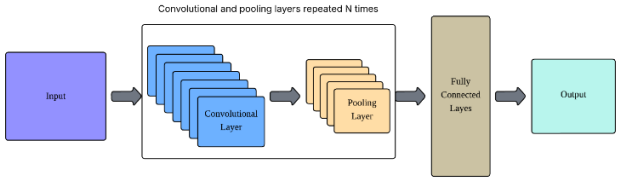

Fig. 3. Basic architecture of a convolutional neural network.

1) U-NET and its variant: Among CNN-based architectures, the U-Net architecture is the most prominent in medical image segmentation. This is due to its iconic encoder-decoder structure and skip connections. The architecture effectively combines multi-scale feature extraction with precise spatial localization [83].

From this fundamental design, numerous adaptations have emerged for medical image segmentation, in which annotated datasets are limited. In endometrium segmentation, U-Net-based architectures have been widely used due to their efficiency in learning from small TVUS datasets. Variants such as VGG-based U-Net [3], ResNet50-U-Net [84], and 3D U-Net [57] have been developed to enhance feature extraction and volumetric analysis. Fig. 4 is the architecture of the ResNet50-UNet model.

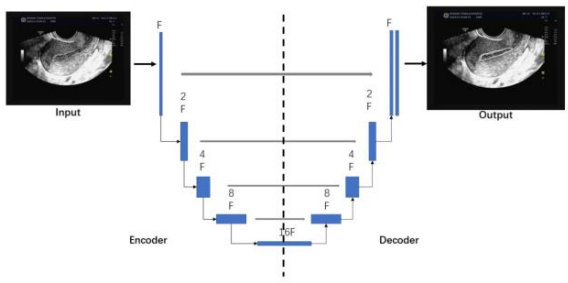

Fig. 4. Schematic diagram of the architecture ResNet50-UNet model from the study [79].

For instance, the VCG-based U-Net achieved a Dice score ranging from 0.83 to 0.9, with a mean absolute error of 1.23 mm and 1.38 mm across two datasets based on [3]. Liu et al. (2022) proposed a ResNet50-SegNet deep learning model for endometrial segmentation, achieving a Dice coefficient of 0.82 with thickness errors within ±2 mm. However, a major limitation of this method was its low segmentation accuracy for endometrial linings ≤3 mm, with an accuracy rate of only 55.3% [4]. In comparison to the previous architecture, Fig. 5 below shows the architecture of ResNet50-SegNet.

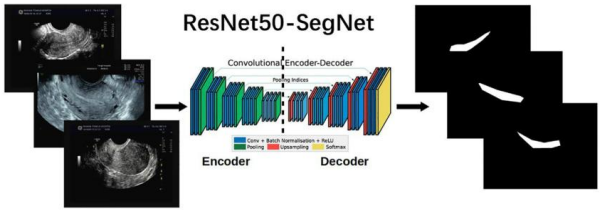

Fig. 5. ResNet50-SegNet architecture [4].

Meanwhile, the 3D U-Net has been successfully applied to volumetric TVUS data, capturing inter-slice contextual information, achieving a 0.91 Dice score with 94.20% of automatic thickness measurements falling within clinically accepted error margins [57]. These variants collectively demonstrate the adaptability and effectiveness of the U-Net models. Despite these achievements, these architectures are still facing challenges in capturing long-range dependencies and global contextual information.

B. Transformer-Based Application

In recent years, transformer-based architectures have gained attention in medical image segmentation due to their ability to overcome the key limitation of CNNs, modeling long-range dependencies and global contextual relationships. Originally, this architecture was introduced in natural language processing (NLP) [85]. Its self-attention mechanism allows the network to capture inter-pixel relationships across the entire image, building a holistic understanding of image structure [86]. This capability is particularly beneficial in medical imaging, where global context is often critical for accurate segmentation of complex anatomical structures like the endometrium [1]. Fig. 6 shows the transformer model overview.

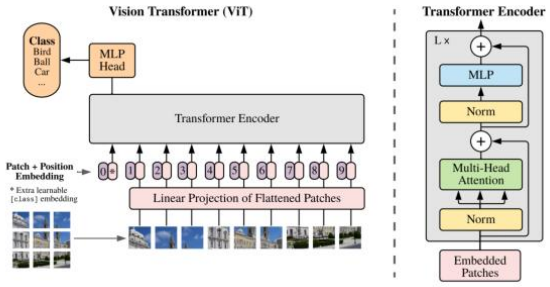

Fig. 6. Vision Transformer (ViT) overview [86].

C. Hybrid and Adversarial Architectures

To overcome the limitations of CNNs, researchers have developed hybrid and adversarial learning frameworks to enhance the segmentation performance. Hybrid models integrate the feature extraction capabilities with other computational approaches or architectural innovations. A prominent example is the Deep Learned Snake model proposed by Singhal [87], which incorporated an active contour model with a deep learning model for curve evolution. From this approach, Park et al. 2019 introduced a key-point discriminator that used endometrial boundary detections from an FCN to guide the active contour model and achieved a Dice score of 82.76%.[58]. These frameworks effectively mimic human experts' analysis, allowing the segmentation to learn more precise delineations. While these approaches demonstrated a significant enhancement in boundary detection, challenges persist in managing the architectural complexity and dependence on large annotated datasets for optimal performance.

D. Emergence Models and Foundational Architectures

The latest phase of advancement in endometrium segmentation research has witnessed the emergence of innovative architectures that emphasize generalizability, computational efficiency, and reduced reliance on large annotated datasets. Deep Dual-Resolution Networks (DDRNet) represent an approach employing parallel branches to efficiently process both high- and low-resolution features, while combining contextual and spatial information [60]. This design allows for a more nuanced understanding of complex endometrial morphology, combining fine-grained details with broader anatomical context.

Building on the evolution of foundation models, recent studies have explored adaptation of the segment anything model (SAM) for medical image segmentation. For example, Qiu introduced a segment anything with inception module (SAIM), which integrates inception-based encoders and point prompts to improve segmentation precision in the noisy ultrasound data [88]. The study utilizes an open-source SAM and introduces enhancements to the image encoder structure. Fig. 7 shows the SAIM architecture.

Another notable method, MultiStudentNet, leverages the weights of multiple models to facilitate feature sharing. This method employs multiple student models to integrate labeled and unlabeled data to improve reliability and model robustness [89]. Fig. 8 shows the framework for MultiStudentNet.

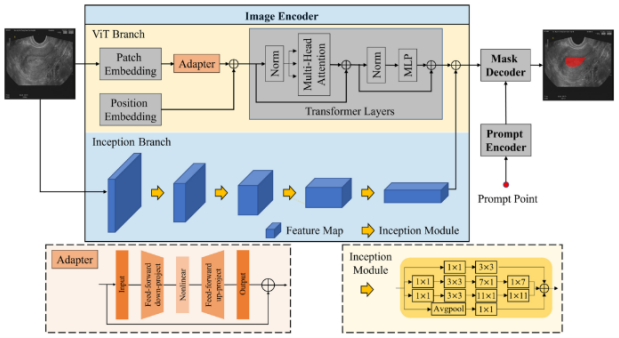

Fig. 7. SAIM architecture [88].

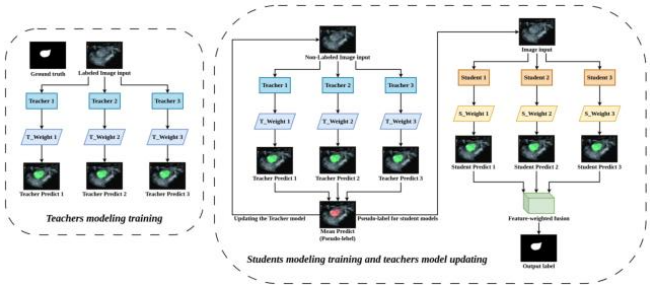

Fig. 8. MultiStudentNet architecture [89].

VI. Methodology

Following established methodological guidelines for a systematic literature review [90], this review was conducted in accordance with the Preferred Reporting Items for Systematic Review and Meta-Analysis (86). The review process encompasses five key stages: 1) search strategy development, 2) study selection and screening, 3) data extraction, 4) quality assessment, and 5) narrative synthesis. Each of these stages is explained in the subsections.

A. Search Strategy and Information Resources

The literature search began in April 2025. This search employed Google Scholar as the primary search database to identify and extract relevant primary research studies. The primary database is complemented by manual cross-checking in IEEE Xplore, Semantic Scholar, Springer Link, and ScienceDirect to ensure coverage of the study. The search strategy for this study used a Boolean operator and a combination of keywords related to endometrium segmentation, deep learning, and transvaginal ultrasound. The Boolean query string was ("endometrium segment" OR "endometrial segmentation") AND ("deep learning") AND ("TVUS" OR "Transvaginal Ultrasound").

B. Eligibility Criteria

In the initial search, 453 papers were found in Google Scholar, 139 in Springer Link, 36 in Semantic Scholar, 24 in ScienceDirect, 4 in PubMed, and 3 in IEEE Xplore, totaling 659 papers. The inclusion and exclusion criteria for the paper selection in this review are as follows:

Inclusion Criteria:

- Paper published in English between 2015 and 2025.

- Application related to endometrium receptivity assessment, thickness measurement.
- Studies with mixed cohorts (pathological and healthy) were included if receptivity-related outcomes were reported.

Exclusion Criteria:

- Duplicate papers between the databases
- Paper published before 2015
- Inaccessible paper
- Non-English paper
- Studies focusing exclusively on pathological segmentation

The exclusion criteria narrowed down the papers to a total of 210 papers. Then, a total of 190 papers were discarded from the keywords, title, and abstract screening. After that, the exclusion criteria for non-pathological disease of segmentation were selected, and a total of 10 papers were analyzed. Fig. 9 below shows the simplified visual of the search methods conducted for the literature review based on the PRISMA guideline [91].

C. Data Extraction

Data extraction for this review was guided by the four research questions raised in the introduction. For each included study, relevant information was systematically extracted to address these questions. This structured approach ensured all extracted data directly supported the analytical aim of this review.

To address RQ1, the types of deep learning models, backbones, and any hybrid or custom modifications were documented and categorized. This included recording architectures such as U-Net variants, Transformers, and hybrid frameworks like SAIM to identify the most frequently employed architecture in TVUS endometrium segmentation.

For RQ2 and RQ3, quantitative performance metrics and evaluation approaches were extracted. Segmentation metrics and thickness-measurement errors were recorded to facilitate accuracy comparisons across deep learning models. All reported evaluation metrics and assessments were further examined for their alignment with clinical standards, such as the acceptance rate of thickness-measurement within +-2mm, to determine which metrics are regarded as gold-standard for receptivity assessment in ART.

Finally, to answer RQ4, author-reported limitations and clinical translation hindrances were recorded. This included documenting issues related to dataset size, single-center bias, model generalizability, and clinical-integration challenges. These insights were synthesized to identify the gaps and to guide future research directions in the translation of deep learning models into ART workflows.

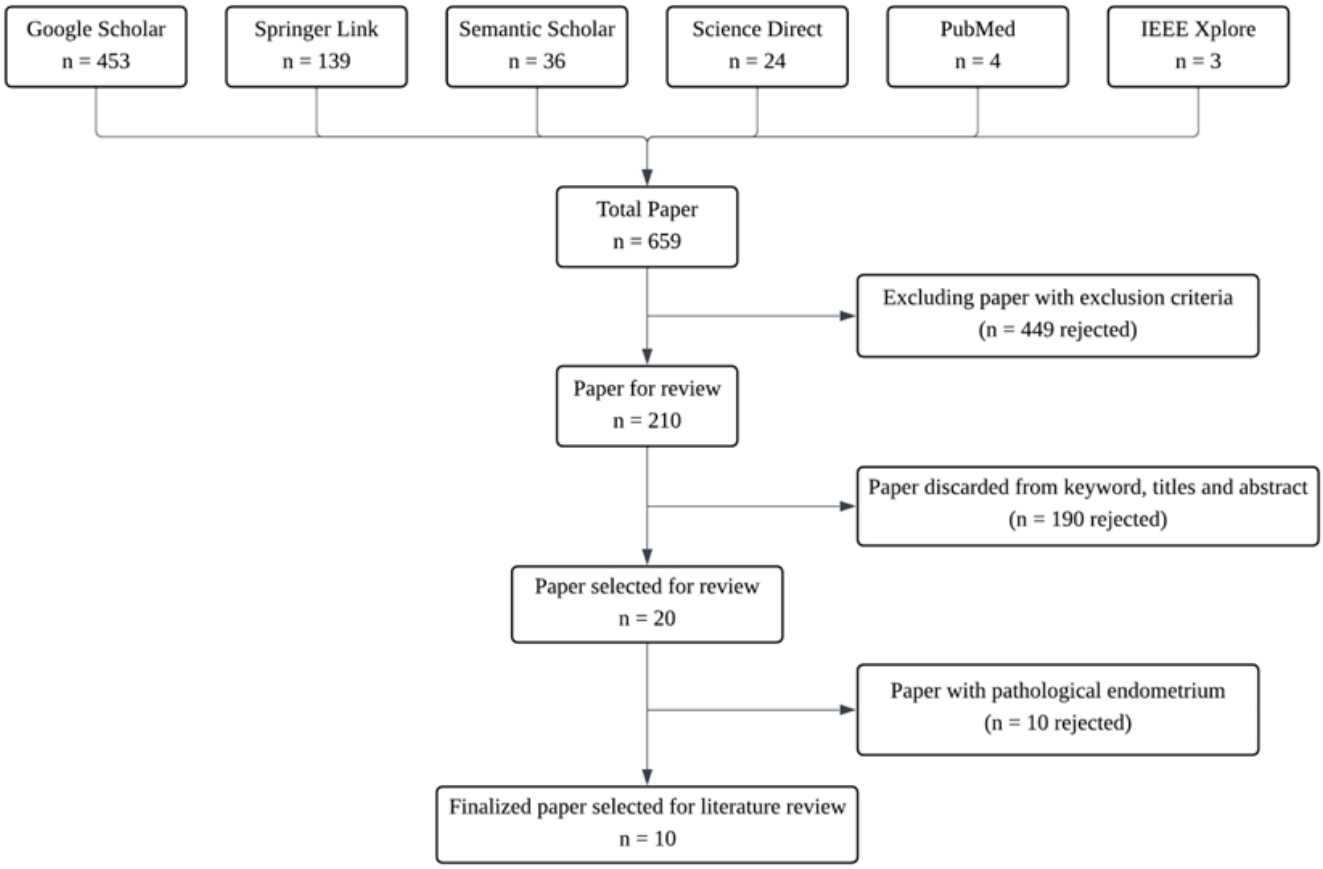

Fig. 9. PRISMA flow diagram of included studies.

VII. RESULTS

A. RQ1: Predominant Deep Learning Architectures for TVUS Endometrium Segmentation

Endometrium segmentation in medical imaging is a critical yet challenging task for quantitative diagnostic analysis. Based on the literature, the most common approaches for endometrial image segmentation have increasingly relied on deep learning (DL) techniques, particularly in Convolutional Neural Networks (CNNs) as the foundation architecture. This is due to the proven effectiveness of the models in medical image analysis [3]. Accordingly, researchers have adapted and modified core CNNs to develop various segmentation network architectures specifically aimed at delineating the boundaries of the endometrium lining.

Built upon CNN architectures, the U-Net architecture and its numerous variants are most frequently cited as the benchmark for this specific segmentation task. U-Net variants have been established as the backbone of segmentation methodologies [92], [93], [94]. The classical U-Net architecture has been widely adapted into diverse variants, such as the VGG-based U-Net, which utilizes the VGG16 network as its encoder for hierarchical feature extraction to enhance spatial representation [3]. In comparative evaluations, a pure U-Net model was tested for endometrium segmentation [57], [58], [84]. Furthermore, the use of ResNet-based U-Net and SegNet models shows the importance of deep residual networks, pre-trained on large-scale datasets such as ImageNet, in mitigating vanishing gradient problems and improving feature depth [4], [84], [95]. For volumetric analysis, the 3D U-Net extension is employed to process three-dimensional transvaginal ultrasound (3D TVUS) images, thereby capturing crucial inter-slice structural information [57].

Beyond U-Net, other general frameworks such as Deep Dual-Resolution Networks (DDRNet) and SegNet are also commonly utilized for this purpose. One comparative study evaluated six different models based on these architectures, specialized combinations such as ResNet50 U-Net, ResNet50 SegNet, U-Net mini, VGG SegNet, alongside pure U-Net and DDRNet. The result from this comparison found that DDRNets showed the best endometrium segmentation with a Dice score of 0.895 [84] using 1050 images. Each architecture, while built on CNNs, employs a different architecture to optimize performance for medical image segmentation.

Innovative approaches have also emerged through the development of hybrid variational models. The hybrid models combine data-driven and energy-based techniques. One notable example is the Deep Learned Snake (DLS) model proposed in 2019 [87]. In the research, the hybrid model integrates the robustness of a Fully Convolutional Network (FCN) with the mathematical rigor of a variational level-set method for curve propagation. In this framework, the FCN generates a deep-learned endometrium probability map that acts as a soft, adaptive shape into the level-set functional for curve propagation. This model combined the robustness of learned features with the interpretability of deformable models. The efficacy of this hybrid method is demonstrated by its performance, yielding approximately 30% improvement over standalone supervised learning methods and producing endometrial thickness measurements within a clinical tolerance of 2mm in 87% of cases.

Additionally, recent research explores adversarial learning frameworks to further refine segmentation precision. In 2019, Park et al. proposed a key-point discriminator, informed by anatomical landmarks and spatial features, to strategically guide the segmentation network towards more accurate boundary delineation in the presence of ultrasound artifacts [58]. The discriminator trained the segmentation network to predict accurate boundaries, to ensure robust segmentation for unclear edges and heterogeneous texture. This method achieved a Dice score of 82.67% and a Jaccard index of 70.46%.

More recently, the architectural evolution in endometrial segmentation is shifting into utilizing Transformers, which are uniquely capable of capturing long-range, global image context in comparison to pure CNNs. A leading example is the Segment Anything with Inception Module (SAIM) [88]. This method utilizes a dual-branch encoder that comprises of Vision Transformer (ViT) for global context and an Inception-based CNN for multi-scale feature extraction. This architecture is critically dependent on clinician-guided point prompts to isolate the endometrium. This approach achieved a segmentation result of Dice Score 76.31% and Intersection over Union of 63.71% using a single-point prompt. Furthermore, its performance improved with additional prompts, reaching a Dice score of 81.30% with five-point prompts [88].

While U-Net-based models form a common foundation, the formation of their variants shows that the U-Net model requires significant task-specific modifications. As the literature affirms, an effective solution must be customized to overcome specific limitations, especially in TVUS. Thus, the shift towards current and advanced hybrid systems, such as SAIM, shows that the most performed models are hybrid systems, which integrate multiple network architectures.

Table III synthesizes the architectural landscape and key characteristics of each model reviewed. The table illustrated the predominance of U-Net variants, while documenting the emergence of hybrid and transformer-based architectures. The domination of UNet variants is driven by three core factors: the ability to preserve critical boundaries, the capacity to capture global and local, and reliable performance on small datasets.

U-Net variants can preserve critical boundaries through skip connections that transfer high-resolution features from the encoder directly to the decoder. This mechanism endures that local spatial information, which typically lost during the down sampling process, is retained to facilitate precise localization of the endometrial lining. Consequently, the architecture effectively integrates spatial and contextual information across its symmetrical path to achieve accurate pixel-level predictions. This precision is vital for identifying the thin, echogenic line of endometrium, especially in cases where boundaries are blurred or highly irregular.

Furthermore, U-Net is celebrated for its reliable performance and robustness when trained on small datasets, a common limitation in clinical reproductive research. This is because medical datasets often consist of only a few hundred images and often are not shareable. U-Net's lightweight and

simple structure makes it inherently less prone to overfitting. These characteristics make U-Net particularly suited to the challenges of endometrium segmentation in TVUS images, where boundary clarity is low, anatomical information is essential, and annotated data are limited.

TABLE III. SUMMARY OF DEEP LEARNING ARCHITECTURES IN INCLUDED STUDIES

No	Study (Author, Year)	Architecture Family	Specific Model / Variant	Backbone / Key Components	Dataset Size	Key Architectural Notes
1	Hu et al., 2019 [3]	CNN-based (U-Net)	VGG-based U-Net	VGG16 encoder	73	Skip connections, encoder-decoder
2	Park et al., 2019 [58]	Hybrid	Key-point Discriminator	FCN + adversarial guidance	320	Adversarial learning for boundary refinement
3	Singhal et al., 2017 [87]	Hybrid	Deep Learned Snake	FCN + active contour	110	Combines DL with variational methods
4	Wang et al., 2022 [57]	CNN-based (U-Net)	3D U-Net	3D convolutional blocks	113	Volumetric segmentation
5	Liu et al., 2022 [4]	CNN-based	ResNet50-SegNet	ResNet50 encoder	1050	Encoder-decoder with residual connections
6	Liu et al., 2022 [84]	CNN-based (U-Net & SegNet)	U-Net SegNet	ResNet50, Vanilla CNN, Vanilla Mini, VGG 16, DDR-Net	840	U-Net with residual backbone
7	Qiu et al., 2024 [88]	Transformer-based	SAIM	ViT + Inception-CNN	180	Hybrid transformer-CNN with prompting
8	Peng et al., 2024 [89]	Advanced / Semi-supervised	MultiStudentNet	Ensemble of CNNs	215	Semi-supervised, multi-model

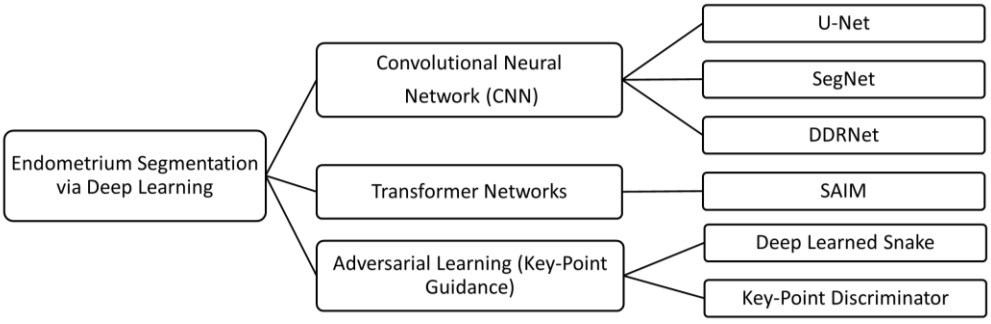

Fig. 10. Taxonomy of current deep learning architectures for healthy endometrium segmentation.

Fig. 10 shows the simplified taxonomy of the deep learning architecture models for endometrium segmentation, illustrating the evolution from CNN-based foundations towards hybrid and transformer-integrated architectures. The following section, which answers RQ2, examines whether this architectural prevalence correlates with superior segmentation accuracy or if emerging models offer a competitive advantage under specific clinical or dataset conditions.

B. RQ2: High Accuracy Deep Learning Architectures

Determining a singular superior method for endometrial segmentation is challenging because segmentation performance highly depends on various conditions, including dataset size, image quality, and evaluation metrics. Nevertheless, recent studies highlight several deep learning architectures that have demonstrated notably high accuracy, though these results must be interpreted considering dataset characteristics and clinical applicability.

For example, the foundational U-Net architecture achieved a remarkable Dice coefficient of 0.977 in one study. However, this result was achieved on a limited dataset of only 20 training and 5 test images [96]. This highlights an important point where simpler models like U-Net can perform well due to a small dataset available. Consequently, while this result is numerically high, its generalizability using larger and more diverse clinical datasets remains uncertain.

For volumetric analysis, the extension to 3D U-Net has proven significantly more effective than its 2D counterpart for processing three-dimensional transvaginal ultrasound (3D TVUS) images [57]. In a dedicated study, the 3D U-Net achieved a Dice coefficient of 90.83%, a metric value higher than the results obtained from 2D segmentation approaches on the same volumetric data. This performance [57] is attributed to the model's capacity to capture crucial inter-slice contextual information and spatial relationships within the full volume. Therefore, for applications requiring holistic anatomical assessment, 3D convolutional approaches represent a highly accurate solution.

Beyond standard supervised learning, semi-supervised frameworks such as Multi-StudentNet are designed to enhance accuracy by leveraging both labeled and unlabeled data. Thus, it reduces the heavy reliance on manual annotations. This architecture reported an overall Dice score of 0.81, with its performance further increasing to 92.33% for polyp cases and

90.20% for cancer cases [89]. This indicates a particular robustness in segmenting pathologically altered endometria, which often present more complex imaging characteristics. The model's design utilizes an ensemble of student models, which has effectively improved segmentation reliability and performance across varied clinical presentations.

Among architectures designed for efficient and contextual feature extraction, Deep Dual-Resolution Networks (DDRNets) have demonstrated leading performance in comparative analyses with an average Dice score of 0.895 [84]. This high accuracy is facilitated by its design of two parallel branches operating at different resolutions, which enables effective multi-scale information fusion. The architecture's efficiency also suggests strong potential for real-time semantic segmentation applications in clinical settings.

Other deep learning models have also achieved competitive results by using different design improvements. The VGG16-based U-Net, employed in an automated measurement pipeline, achieved a Dice score of 0.83, performing better at 0.853 in the proliferative phase compared to 0.796 in the secretory phase. Similarly, a key-point discriminator framework significantly improved results compared to the standard U-Net of 58.69%, achieving a Dice score of 82.67% [58]. Furthermore, the Segment Anything with Inception Module (SAIM) adaptation recorded a Dice score of 76.31% and increased to 81.30% with multiple point prompts [88]. The comparative performance of the reviewed architecture is summarized in Table III. The table also highlights the influence of dataset size and clinical applicability.

TABLE IV. LIST OF METHODS AND RESULTS FOR ENDOMETRIUM SEGMENTATION

No.	Method	Result
1	DLS	DLS 85%-87% tolerance limit compared to U-Net with 60%-70% tolerance limit.
2	VGG-Based U-Net	DSC 0.83 Thickness measurement:- MAE/RMSE: 1.23/1.79 on 27 DL test cases- MAE/RMSE: 1.38/1.85 on 46 Thickness test cases
3	Key-discriminator	DSC 82.67%, Jaccard 70.46%
4	6 Different U-Net	DDRNets is the highest average of DSC, Recall, Precision, and Specificity with 0.895, 0.884, 0.910, and 0.998.
5	ResNet50-based SegNet	Average DSC: 0.82
6	3D U-Net	DSC 90.83%, Jaccard 83.35%, Sensitivity 90.85
7	Multi StudentNet	DSC 0.81, specificity 0.99, sensitivity 0.87
8	SAIM	DSC 76.31% and IoU 63.71%, a higher multipoint prompt receives a higher result in metrics DSC and IoU.
9	Transformer - CNN	U-Net DSC 0.977, Transformer DSC 0.956
10	ResNet-50	AUC 0.853

In conclusion, while a classic U-Net excels on minimal data, the most accurate and generalizable models for broader clinical application appear to be the 3D U-Net, Multi-StudentNet, and DDRNet, as evidenced by their consistently high Dice scores across more substantial datasets. However, to draw a definitive conclusion about which network is highly accurate is challenging and potentially misleading because all these studies used different datasets with varying characteristics and sizes. This is due to the limited availability of common datasets for healthy endometrium TVUS images. For example, the study using the 3D U-Net had a total of 113 images [89], in comparison to the study comparing six networks that had a total of 1050 images [84]. To address this limitation, the MultiStudentNet specifically uses a semi-supervised approach [89].

C. RQ3: Metrics and Validation for Deep Learning in Endometrium Segmentation

The evaluation of deep learning models for endometrium segmentation requires a comprehensive approach that reflects both technical segmentation accuracy and clinical measurement reliability. To achieve this, researchers commonly employ a range of quantitative and statistical metrics to assess segmentation accuracy and endometrial thickness measurement performance. Table IV presents the list of methods and results for endometrium segmentation.

1) Segmentation evaluation metrics: For endometrium segmentation, the objective is to measure how close the automated segmentation overlaps with the ground-truth annotation. One of the most used metrics is the Dice Similarity Coefficient (DSC). The values range from 0 to 1, with 1 as a perfect overlap between the segmented region and the ground truth. In different literatures, DSC is also known as Dice Score, Dice coefficient, and F1 Score. The formula for measuring DSC is defined as:

$$DSC = \frac{2|A \cap B|}{|A| + |B|} \quad (1)$$

where, A is the segmented region to be assessed, and B is the corresponding ground truth.

The recoded DSC values were reported in most of the main literature for this study. 9 out of 10 papers used DSC values as a metric to evaluate segmentation performance. The recorded DSC values for healthy endometrium segmentation using deep learning range from 0.76 to 0.98. The highest DSC was observed in the U-Net with 0.977 on a limited dataset of 25 images [96]. This indicates that while DSC is a useful benchmark for general overlap, it can be sensitive to dataset size, and a high DSC does not automatically mean an excellent segmentation result.

A recent deep learning model also measured a high DSC at 0.895 for a Deep Dual-Resolution Network (DDRNet) in a comparative analysis [84]. However, while proposing the key-point discriminator method, the DSC value recorded was 82.67%, outperforming conventional methods like U-Net (58.69%) and FCN (78.39%) [58]. This shows that a little tuning in the model architecture can improve segmentation results, especially if the model is designed to better identify boundaries.

Another commonly used metric for segmentation evaluation is the Jaccard Index, also known as Intersection over Union (IoU). The DSC and IoU are proportional to the number of spatial overlaps between the segmented and ground truth

images. The value ranges from 0 to 1, with 1 as the perfect matching [97]. The formula of IoU is defined as:

$$IoU = \frac{|A \cap B|}{|A \cup B|} \quad (2)$$

However, the Jaccard index was reported far less frequently than DSC in the included papers. For this review, out of 10 main literature papers, only 3 studies use the Jaccard index as a performance metric. Values reported include 70.46% using the key-point discriminator method [58] and 83.35% using the 3D U-Net method [57]. This low number of adoptions in evaluation may be attributed to the Jaccard index's mathematical property of generally resulting in lower numerical values compared to Dice for the same segmentation quality. However, for clinical applications such as endometrial thickness measurement, Jaccard index sensitivity to boundary intersection may be helpful in a realistic assessment.

This pattern of selective metric reporting extends to a few other complementary metrics for segmentation evaluation. For example, another commonly used metric is accuracy. The accuracy value is calculated through precision and recall, which quantify the model's ability to correctly identify endometrial pixels while minimizing false positives and negatives. In certain papers, recall is also known as sensitivity, which measures the proportion of relevant instances of true positive pixels that are retrieved by the model and focuses on how well the model avoids false negatives. The formulas for accuracy, precision, and recall are defined below:

$$Accuracy = \frac{TP+FN}{TP+FP+TN+FN} \quad (3)$$

$$Precision = \frac{TP}{TP+FP} \quad (4)$$

$$Recall\ (Sensitivity) = \frac{TP}{TP+FN} \quad (5)$$

where, TP- True Positive, FP - False Positive, TN - True Negative, FN – False Negative.

In a comparative study, a DDRNet demonstrated superior performance, achieving a precision of 0.910 and a recall of 0.884, the highest among the evaluated deep learning models. This review revealed that these complementary metrics are infrequently documented, with only 3 out of 10 papers reporting precision and 2 out of 10 papers reporting recall (sensitivity). This indicates that while precision and recall provide distinct and complementary insights in quantifying false positive and false negative rates, the Dice score continues to be the favored standard metric for overall segmentation evaluation.

Beyond the mentioned metrics, specificity is another segmentation metric that measures the proportion of correctly identified negative pixels out of all actual negative pixels. This metric is also known as the true negative rate, as it indicates the model's ability to minimize false positives [84], [89]. The formula for specificity is written as:

$$Specificity = \frac{TN}{TN+FP} \quad (6)$$

These metrics were reported in a study comparing variations of CNN architectures and evaluation in the developing Multi-StudentNet model. The reported specificity value is generally 0.99 [84], which is high, indicating robust performance in excluding non-endometrial regions. In medical image segmentation, specificity is important because the background makes up most of the image. High specificity shows the model is good at not mistakenly labelling normal tissue as endometrium. This helps prevent false alarms and builds trust in the tool for clinical application. Although specificity provides valuable information about background exclusion, it is less frequently reported because the aim is to detect the endometrium boundary, the foreground region of interest, and not to verify the background classification.

Another underrated metric is the 95th percentile Hausdorff Distance (HD95). This metric measures the maximum boundary between a predicted segmentation and the ground truth. While Dice scores calculate overall overlap pixels, the HD95 specifically targets the worst-case alignment errors by using the 95th percentile to ignore extreme outliers. In this study, this metric was explicitly used in only one paper [57]. The 3D U-Net model achieved the best HD95 score of 12.75mm when using the Enhanced Augmented Data (EAD) method.

From this information, a boundary-focused metric like HD95 is more clinically informative than a general overlap metric like DSC because it directly relates to measurement accuracy. Since clinical decisions are based on measurements like endometrial thickness, a minor boundary error can lead to a significant measurement error. HD95 assesses this specific risk. Thus, the HD95 provides a more direct assessment of a model's utility in a clinical setting, where the ±2 mm tolerance is critical.

2) Thickness measurement performance metrics: As established, endometrial thickness serves as a critical biomarker for assessing reproductive health, guiding clinical decisions in areas such as fertility treatments and screening. Consequently, evaluating the performance of thickness measurement moves beyond overlap metrics. The performance of this measurement requires rigorous evaluation against the clinical gold standard of manual expert measurement. This is to ensure that the automated results are reliable and clinically acceptable. Among the relevant metrics are Acceptance Rate, Mean Absolute Error (MAE), and Root Mean Squared Error (RMSE).

The reliability of the evaluation is benchmarked against a well-defined clinical tolerance. Clinical tolerance represents the acceptable error range, which, for endometrial thickness, is consistently set at ±2mm based on clinical guidelines [3], [87]. Based on the clinical tolerance, the acceptance rate measures the percentage of a model's measurements that fall within the range. Thus, model efficacy is primarily reported through Acceptance Rate. The definition of Acceptance Rate in mathematical expression is:

$$Acceptance\ Rate = \frac{\sum_{i=1}^{n} |y_i - x_i| < 2mm}{n} \times 100\% \quad (7)$$

where, y is the endometrial thickness measured by deep learning methods, x is the ground truth, and n is the total number of validation images or cases.

By achieving a high acceptance rate, such as 89.3% [4] or 94.20% [57], the deep learning methods demonstrate their

potential to provide a reliable measurement that aligns with clinical requirements. Notably, 4 out of 10 papers measure the acceptance rate of the thickness measurements.

While the Acceptance Rate indicates clinical applicability, the MAE and RSME provide deeper insight of the measurement errors. The MAE calculates the average absolute difference, a straightforward measure of typical error magnitude [4], [57]. In contrast, RSME is mathematically structured to evaluate error magnitude, serves as a sensitive indicator for inconsistent measurement, and the presence of significant outliers [57], [98]. The formulas of MAE and RSME are written as follows:

$$MAE = \frac{\sum_{i=1}^{n} |y_i - x_i|}{n} \quad (8)$$

$$RSME = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - x_i)^2} \quad (9)$$

Reported MAE values demonstrate model accuracy, with methods like VGG-based U-Net pipeline achieving MAEs of 1.23mm for the deep learning test set and 1.38mm for the thickness test set [3]. The results are considered as it falls within the clinical tolerance of ±2mm. The 3D U-Net segmentation method reported an even lower MAE of 0.75 mm with a corresponding RSME of 1.07mm [57]. For comparison, the ResNet50-SegNet model reported an overall MAE of 2.3mm across all validation data, although performance improved to an MAE of 2.0mm when analyzing cases where endometrial thickness is more than 3mm [4].

The evaluation of endometrial thickness measurement remains overlooked in the current included papers. The most critical metric, the acceptance rate, was reported on 40%. The fact that 60% of the included papers did not report this value may suggest that most studies are technically focused rather than clinically validated. This shows a great hindrance for clinical translation.

Table V presents the performance metrics used for both segmentation and thickness measurement evaluation from the literature. Current metric reporting in endometrium segmentation prioritizes technical overlap, especially DSC value, abundantly, but does not sufficiently validate clinical applicability. This focus overlooks critical metrics, such as acceptance rate, which directly assess whether automated thickness measurements fall within clinically permissible rate margins. Consequently, this condition limits the assessment for practicality in real-life assessment, specifically for clinical integration. In conclusion, to ensure clinical readiness, future work must standardize metric reporting that prioritizes measurement accuracy and reliability for an effective integration into ART workflows. The inconsistency and underutilization of clinical decision metrics are direct symptoms of broader limitations to clinical applications, which are explored in RQ4.

D. RQ4: Technical and Clinical Gaps to Translate Deep Learning Model into Art

Translating promising deep learning segmentation and measurement performance into reliable and adoptable tools for ART requires addressing significant technical and clinical gaps that compromise reliability and clinical utility. Although most models demonstrate high accuracy on internal test sets, there are limitations regarding data diversity, integration of complex clinical features, and performance on diagnostically challenging cases.

One major limitation is ensuring that models perform reliably across diverse patient populations and clinical settings, addressing issues of data scarcity and single-source dependency [95]. Many studies rely on retrospective data. The models' ability to generalize can be compromised if the original dataset is not sufficiently large or diverse [4], [88], [89]. Furthermore, the results from small sample sizes cannot be guaranteed to generalize to other segmentation tasks [4].

In addition, models are often trained and tested on data collected from a single manufacturer or institution. This fact may affect the robustness of the model when deployed elsewhere [95]. External validation using datasets outside the source institution has not always been carried out. Consequently, the performance of some deep learning models, such as those predicting WOI, is acknowledged to require greater diversification, specifically needing a greater representation of cases with thin endometrial thickness (<7mm).

TABLE V. DISTRIBUTION OF EVALUATION METRICS IN ENDOMETRIUM SEGMENTATION LITERATURE

Method	Segmentation Performance Metrics							Thickness Measurement Performance Metrics			
	DSC	Jaccard	Sensitivity	Specificity	Accuracy	Precision	HD95	MAE	RMSE	Acceptance Rate	SDE
DLS										/	
VGG-Based U-Net	/							/	/	/	/
Key-discriminator	/	/									
6 Different U-Net	/		/	/		/

3D U-Net	/	/	/				/	/	/	/	/
Multi StudentNet	/		/	/		/					
SAIM	/	/									
Transformer - CNN	/										
ResNet-50	/		/		/	/					

While endometrial thickness is a crucial biomarker, relying solely on it is incomplete to predict ART outcomes. Future models must be designed to assess a broader range of complex physiological variations of other critical features of endometrial receptivity, such as endometrial pattern. The evolution towards multiple parameter assessment requires a more sophisticated approach for validation. Furthermore, adequate differentiation across various pathological conditions, such as cancer and hyperplasia, is needed, as these conditions are known to impact echo pattern and segmentation [3], [4], [95].

Another setback for deep learning systems is the poor performance on thin endometria. There's one study that showed that for cases with endometrial thickness less than 3 mm, the acceptance rate was significantly lower at only 54.5%, compared to nearly 98.3% for thicker endometria (ET>10 mm) [4]. This inaccuracy in thin endometria could lead to false positive diagnoses, leading to unnecessary invasive examinations for patients.

As discussed in the introduction, the technical limitations of ultrasound remain a fundamental obstacle, with issues such as low contrast and speckle noise complicating the precise delineation of the endometrial boundary to measure the endometrial thickness effectively [89]. Most models fail in cases where the endometrium boundary is blurred or has a slightly irregular shape [3], [4].

To translate these technically advanced models into a clinical application, these models should be integrated into user-friendly interfaces for seamless routine ART screening protocols [95]. To this end, researchers are actively exploring and developing novel architectures, such as semi-supervised and key-point guided adversarial networks, to enhance segmentation robustness. This enhancement is critical to ensure a reliable endometrial receptivity assessment for clinical application.

The identified limitations and gaps reveal that clinical translation is hindered by clinical validation. To progress, research must shift from proof-of-concept or technical evaluation studies to rigorous development. To bridge the identified gaps, future research should adopt three key actions. First, the establishment of large, multi-center, and prospectively collected datasets is essential to ensure models are robust across diverse populations and critically challenging subgroups, such as thin endometria. Second, to adapt clinical validation, evaluation must adopt a mandatory and standardized set of metrics that are highly reliable in medical practice. Third, model development should evolve beyond endometrium segmentation to thickness measurement and other ultrasound biomarkers, such as echo pattern and volume. By addressing these actions, it can transform deep learning beyond technical research into a reliable clinical translation to aid in improving ART in the future.

VIII. Conclusion

This review systematically investigated the role of deep learning in TVUS image segmentation for the objective assessment of endometrial receptivity. The analysis provides clear answers for the research questions, revealing both the significant progress and the critical path forward.

In finding the predominant architectures for the deep learning segmentation (RQ1), it is found that the field is not dominated by a single model but is built upon a U-Net-based foundation, with a clear evolution towards sophisticated hybrid systems, such as SAIM, and tailored variants like 3D U-Net. When evaluating which of these models achieve high accuracy (RQ2), models such as the 3D U-Net, DDRNet, and Multi-StudentNet demonstrated superior performance. However, a definitive ranking is impossible due to a major problem, which is the lack of a common, large-scale dataset. This problem prevents fair comparison and highlights a fundamental need for the community.

Subsequently, this review also identifies the metrics used to validate segmentation quality (RQ3). It is revealed that not all metrics are equally meaningful for clinical translation. While the Dice score is most used, a hierarchy of clinical utility exists. The most critical metrics are the Acceptance Rate, supported by error magnitude metrics, which are MAE and RMSE. These metrics work together best to validate a model's readiness for clinical receptivity assessment.

Despite these advancements, significant technical and clinical limitations (RQ4) were revealed to prevent the integration of the models into ART workflows. These persistent limitations include poor model performance on thin endometria, inadequate validation across the menstrual cycle and various pathological conditions, and a narrow focus on thickness over a holistic, multi-parametric receptivity assessment.

In conclusion, while deep learning offers a powerful pathway to standardize and objectify endometrial evaluation, its full potential for clinical application has not yet been utilized. The transition from a promising algorithm to a trusted clinical tool hinges on future work that prioritizes robust, multi-parametric models, rigorous and stratified clinical validation, and the development of standardized benchmarks and datasets. By focusing on these challenges, the field can finally translate computational promise into enhanced diagnostic precision and improved outcomes in assisted reproduction.

Acknowledgment

The authors would like to express their gratitude to the Ministry of Higher Education (MOHE) of Malaysia and Universiti Kebangsaan Malaysia for their financial support under the grant FRGS/1/2024/TK07/UKM/02/6 for the resources that made this review possible.

Facultad de Ingeniería, Universidad Nacional de Chimborazo, Riobamba, Ecuador[4]

***Abstract*—The accelerated growth of digital content and the increasing presence of emotional expressions, polarized opinions, and toxic behaviors in social media have driven the development of advanced Affective Analysis techniques. This study presents a broad and up-to-date review of recent studies covering Sentiment Analysis, Emotion Recognition, Hate Speech Detection, cyberbullying, and multimodal approaches grounded in deep learning. The review provides a comparative analysis of the architectures employed—including Transformer-based Models, multimodal frameworks, and variants designed for low-resource languages—along with their metrics, performance outcomes, and emerging patterns. The findings reveal a clear consolidation of Transformer-based Models as the dominant standard, significant progress in multimodality for affective interpretation, and growing attention to multilingual models adapted to diverse cultural contexts. Furthermore, persistent challenges are identified, including limitations related to data availability and quality, Explainable AI (XAI), computational efficiency, and robustness in cross-domain generalization. This review synthesizes current trends, limitations, and opportunities in the field, offering a structured perspective that can serve as a reference for researchers and practitioners involved in the development of more accurate, efficient, and culturally responsible affective systems.**

***Keywords*—Sentiment Analysis; Emotion Recognition; Hate Speech Detection; cyberbullying; deep learning; Transformer-based Models; Multimodal Analysis; multilingual NLP; Explainable AI (XAI); social media**

I. Introduction

Sentiment Analysis, Emotion Recognition, and hate speech classification have become central components in the study of contemporary digital behavior, particularly due to the massive growth of communication on social media platforms [6]. Online interactions generate large volumes of textual content that require advanced tools for their interpretation, leading traditional natural language processing (NLP) approaches to evolve toward deep learning and Transformer-based Models.

The articles reviewed in this study show that early solutions relying on conventional techniques—such as support vector machines, Naïve Bayes, or simple CNNs—have been progressively surpassed by more sophisticated architectures. For example, works such as [3] and [7] illustrate the transition toward deep models capable of more accurately representing contextual dependencies present in the informal language used on social platforms.

The emergence of Transformer-based Models marked a turning point. Studies such as [2], [11], and [19] demonstrate the superiority of Pre-trained Language Models (PLMs), which offer rich and contextualized semantic representations, significantly improving performance in emotional classification, Sentiment Analysis, and Cyberbullying Detection.

Likewise, research focused on specific languages highlights the relevance of contextual adaptation and transfer learning. Works such as [8], [15], and [36] show that linguistic variants of Transformer-based Models are highly effective in languages with moderate or limited resources.

Another key theme identified in the reviewed articles is the advancement of multimodal approaches. Studies such as [30], [31], and [35] reveal the potential of integrating text with images, audio, or contextual signals to improve affective interpretation in more complex and dynamic environments.

Finally, research addressing specific issues such as hate speech and cyberbullying demonstrates strong results through optimized model configurations. Works such as [1] and [16] highlight how combining Transformer-based Models with fine-tuning, feature selection, or hybrid mechanisms substantially improves performance metrics.

Collectively, these advancements show that affective NLP has reached a stage of methodological maturity characterized by the dominance of Transformer architectures, the rise of multimodality, and the adaptation to multilingual contexts. This review synthesizes these developments, offering a structured and up-to-date perspective on the current state of the field and establishing the conceptual foundation for the detailed analysis presented in the subsequent sections.

A. Research Questions

To guide the analysis and synthesis of the reviewed literature, this study addresses the following research questions:

RQ1: What deep learning architectures currently dominate affective intelligence tasks in natural language processing?

RQ2: How have multimodal approaches evolved to enhance emotion and sentiment understanding across different data modalities?

RQ3: What challenges and research gaps persist in multilingual and low-resource affective NLP scenarios?

II. Background and Related Work

Sentiment Analysis, Emotion Recognition, and hate speech identification have established themselves as fundamental areas within Natural Language Processing (NLP), particularly driven by the exponential growth of interactions on social media platforms. The studies reviewed in this work show that the evolution of the field has been characterized by a gradual shift away from traditional lexicon-based and statistical approaches toward the widespread adoption of deep learning architectures and Transformer-based Models. Deep learning has also demonstrated strong predictive capability in other applied domains—such as electricity price forecasting—which has further motivated its adoption for complex sequence and representation learning problems [12].

B. Evolution of Sentiment Analysis and Emotion Recognition

Early approaches based on statistical methods and classical machine learning models were progressively replaced by neural architectures such as LSTM and CNN, which enabled the modeling of sequential dependencies and more complex affective patterns. Studies such as [7] and [3] illustrate this transition, reporting substantial improvements in Affective Analysis tasks through the use of deep neural networks [14].

The introduction of contextual representation techniques, particularly those used in BERT-like models, further strengthened the ability of NLP systems to capture the semantics of informal and noisy social media language. Studies such as [8] and [15] demonstrate the superiority of contextual embeddings over previous methods.

C. Advances Driven by Transformer-Based Models and Pre-Trained Language Models (PLMs)

The consolidation of Transformer-based Models is a recurring pattern across the reviewed literature. Works such as [2], [11], and [19] show how Pre-trained Language Models (PLMs) capture deeper semantic and contextual relationships, resulting in substantial performance gains in emotional classification and Hate Speech Detection. In addition, PLMs such as BERT have been successfully transferred to other domains, including network intrusion detection, underscoring their general-purpose contextual modeling capability [10].

In addition, studies focused on specific languages—such as [36], demonstrate how local adaptations of PLMs can match or even surpass results obtained on larger, more mature corpora.

D. Multimodal Processing and Emerging Research Directions

An emerging trend observable in [29]–[35] is the increasing use of multimodal approaches that integrate text, images, and additional signals. Models such as MemoCMT [30], Cross-modal BERT [31], and Multimodal GRU with Directed Pairwise Cross-Modal Attention [35] show that incorporating multiple modalities can enhance emotional detection and enrich affective understanding in complex environments.

These studies indicate that mechanisms based on Cross-modal Attention, multi-level fusion, and intermodal architectures are expanding NLP toward contexts closer to human perception, such as conversational analysis, emotional video understanding, and monitoring of digital interactions.

E. Multilingualism, Low-Resource Languages, and Knowledge Transfer

The reviewed studies also highlight the importance of multilingualism and the challenges associated with low-resource languages. Works such as [16] and [13] emphasize the need to adapt models and transfer learning strategies to specific linguistic contexts.

Moreover, the evidence shows that models such as IndoBERT, RoBERTa, and domain-adapted variants can compensate for the lack of large annotated corpora, achieving competitive results when properly optimized and contextually fine-tuned.

F. Synthesis of the State-of-the-Art

Based on the analysis of the reviewed studies, the following dominant trends are identified:

- A clear predominance of Transformer-based Models as the primary architecture.
- A sustained growth of multimodal approaches for Affective Analysis.
- Extensive use of fine-tuning techniques, knowledge transfer, and linguistic variants of Pre-trained Language Models (PLMs).
- Consolidation of hybrid strategies integrating deep neural networks, graphical representations, and explainable mechanisms. (e.g., transformer–GNN convergence frameworks [9]).
- Increasing attention to low-resource languages and specialized domains through optimization and Domain Adaptation.

This conceptual framework synthesizes the current state of affective NLP, according to the evidence provided by the analyzed studies, and serves as the foundation for the discussion, comparisons, and conclusions presented in the following sections.

III. Methodology

A. Methodological Positioning

This work is positioned as a narrative, corpus-driven review rather than a fully systematic review as defined by formal PRISMA-style protocols. While a structured Scopus-based search strategy was employed to identify relevant literature, the final corpus was refined through controlled inclusion criteria focused on thematic relevance, publication impact, and methodological diversity. The objective of this review is not exhaustive coverage, but rather a comprehensive and interpretative synthesis of recent advances in deep learning–based affective intelligence, with particular emphasis on language models, multimodal architectures, and emerging research trends.

B. General Review Approach

The methodology employed in this review was specifically designed to analyze, compare, and synthesize the contributions of the selected studies, all focused on Sentiment Analysis, Emotion Recognition, hate speech classification, and multimodal or multilingual approaches within the context of Natural Language Processing (NLP). Consistent with the methodological positioning described above, the present study adopts an empirical, corpus-driven approach grounded exclusively in the explicit, verifiable characteristics of the included studies.

The methodological process was structured into three specific stages derived exclusively from information present in the studies:

1) Identification and compilation of the corpus: Each study was selected for addressing one or more of the target themes—sentiment, emotion, hate speech, multimodality, or multilingualism—and for being part of the predefined document base.

2) Characterization and systematic extraction of information: Each publication was examined in detail to extract consistent data regarding architectures, datasets, preprocessing techniques, evaluation metrics, languages, domains, and experimental strategies.

3) Comparative and thematic synthesis: Articles were grouped according to observed patterns—text-based models, multimodal approaches, hate speech or cyberbullying detection, multilingual methods, and Explainable AI (XAI)—to generate an integrated interpretation of the current state of the field.

This approach ensures that all methodological elements are grounded exclusively in the analyzed corpus, without relying on external methodological frameworks unrelated to the content of the articles.

C. Selection and Composition of the Corpus

The corpus used in this review comprises studies published between 2018 and the present, ensuring a representative coverage of recent developments in Sentiment Analysis, Emotion Recognition, Hate Speech Detection, and multimodal deep learning approaches.

Although the set of studies was consolidated manually for this review, the original document pool stems from three major academic sources used during the initial collection process:

- Scopus (Elsevier): multidisciplinary database for identifying recent and relevant studies.
- IEEE Xplore: a primary source for research in deep learning, NLP, and Affective Analysis.
- Elsevier ScienceDirect: repository for applied studies related to emotion, sentiment, and hate speech.

A representative Scopus search query was:

(TITLE-ABS-KEY ("sentiment analysis" OR "opinion mining" OR "emotion recognition"

OR "emotion classification" OR "hate speech detection"

OR "cyberbullying detection")

AND

TITLE-ABS-KEY ("deep learning" OR "neural network*" OR "transformer*"

OR "BERT" OR "RoBERTa" OR "GPT" OR "multimodal"

OR "cross-modal")

)

AND (PUBYEAR > 2017 AND PUBYEAR < 2026)

AND (LIMIT-TO (DOCTYPE , "ar"))

AND (LIMIT-TO (LANGUAGE , "English") OR LIMIT-TO (LANGUAGE , "Spanish"))

These initial searches—along with complementary retrieval in IEEE Xplore and ScienceDirect—yielded a broad collection of publications that were manually filtered to form the final corpus.

The final set of studies did not arise from a purely database-driven systematic search, but from a deliberate, controlled selection in which each article was included based on the following explicit and observable criteria:

- Application or evaluation of Deep Learning Approaches to affective tasks.
- Focus on Sentiment Analysis, Emotion Recognition, Hate Speech Detection, cyberbullying, Multimodal Learning, or multilingual models.
- Reporting quantitative experimental results (accuracy, precision, recall, F1-score, etc.).
- Clear description of architecture, components, and training strategies.
- Verifiable information on datasets, languages, and domains.

Articles lacking empirical evidence, purely theoretical works, or non-peer-reviewed materials were excluded.

These adaptations constitute the structural basis of the instrument described in Section C.

D. Data Extraction and Structuring

Data extraction was conducted manually and organized according to common elements identified across all the studies:

- Architectures: Transformer-based Models (BERT, RoBERTa, IndoBERT), CNN, LSTM, BiGRU, GNN, hybrid systems, and Multimodal Learning.
- Preprocessing: tokenization, normalization, noise removal, static and contextual embeddings.
- Datasets: corpora in English, Spanish, Indonesian, and others; social media datasets (Twitter, Facebook, Google Play); hate-speech, emotion, and multimodal collections.
- Training strategies: fine-tuning, hyperparameter optimization, lightweight models, multimodal fusion.

- Metrics: F1-score, accuracy, precision, recall, macro-F1, weighted-F1.
- Key contributions: performance gains, new architectures, fusion techniques, language-specific enhancements, use of XAI.
- Limitations: dataset bias, class imbalance, computational demands, small corpora, and lack of Explainable AI (XAI).

Each dimension was documented consistently to enable a balanced, systematic comparison.

E. Thematic Classification Derived from the Studies

The categories in Table I emerge naturally from methodological, architectural, and experimental patterns identified across the corpus and illustrate how the current landscape of affective NLP is organized and how each research line contributes to the field.

TABLE I. THEMATIC CLASSIFICATION OF THE REVIEWED STUDIES

Thematic Category	Representative Articles	Key Findings
Text-based Sentiment Analysis	[2], [3], [7], [8], [11], [15]	Transformers outperform LSTM/CNN in informal language
Emotion and Affective State	[13], [15], [30]–[35]	Multimodality increases emotional detection accuracy
Hate Speech and Cyberbullying	[1], [16], [18], [19], [20], [21]	Optimized and lightweight models achieve strong results
Multilingual / Low-resource Models	[13], [16], [19], [36]	Transfer learning improves performance in low-resource settings
Explainable AI (XAI) Models	[16], [21], [27]	Interpretability is increasingly important in critical applications

Source: Author's elaboration.

F. Ethical Considerations and Transparency

All included articles were reviewed to ensure that their procedures were described with enough clarity to allow understanding and reproducibility. This review maintains methodological transparency by relying exclusively on explicit information contained within all the studies, without incorporating external methodological frameworks.

IV. RESULTS AND DISCUSSION

This section synthesizes and comparatively analyzes the findings reported across all the studies, considering the architectures employed, performance metrics, linguistic domains, multimodal approaches, and specific applications such as Hate Speech Detection and cyberbullying. The analysis is structured according to patterns observed directly in the studies.

A. Performance of Text-Based Models

Text-based models constitute the core of affective NLP across the reviewed studies. The results consistently show that Transformer-based Models outperform classical deep learning architectures in tasks such as Sentiment Analysis, Emotion Recognition, and text-based Hate Speech Detection. In particular, BERT and its variants achieve superior accuracy and F1-score due to their ability to capture contextual semantic relationships, as evidenced in [2], [7], [8], [11], [15], [16], [19], and [36]. Classical architectures, such as LSTM, CNN, or BiGRU, used in studies like [3], [7], [11], and [15], provide competitive baselines and perform adequately in small or well-structured datasets, but their capacity to model complex informal language is more limited. Hybrid text-based models—such as BERT combined with BiGRU or GNN components in [11]—demonstrate improvements in stability and generalization, indicating that architectural fusion can yield benefits even when working exclusively with textual input. Overall, the evidence confirms that contextualized Transformer-based Models represent the dominant paradigm in text-only affective tasks, while traditional and hybrid architectures remain useful in scenarios with constrained computational resources or smaller datasets. Aspect-based sentiment analysis on microblogging and review platforms also benefits from contextual Transformer representations, which better capture fine-grained opinion targets and their polarity [22]. Similarly, CNN-based pipelines enriched with RoBERTa embeddings have shown competitive performance in sentiment classification for movie reviews and other noisy user-generated text [4]. For Emotion Recognition, RoBERTa variants enhanced with emotion-aware attention mechanisms report additional gains by focusing representation learning on affective cues [23].

B. Models for Hate Speech Detection and Cyberbullying

Articles [1], [16], [18], [19], [20], [21] focus on detecting toxic speech, hate speech, or cyberbullying.

Their findings consistently show that BERT-based models [1], [16], [19] significantly outperform classical architectures. In contrast, [18] combines GloVe + PCA with a Transformer, achieving efficient fusion of static and contextual embeddings. Alternatively, [20] proposes a lightweight architecture (DBFN-J) with strong performance and lower computational cost and [21] provides a comprehensive review of LLMs for hate speech, highlighting multilingual robustness.

Overall, these works indicate that the most robust models are those balancing performance and efficiency—particularly relevant in sensitive social contexts.

C. Multilingual Models and Applications in Low-Resource Languages

Studies addressing Sentiment Analysis, Emotion Recognition, and text classification across different languages reveal a consistent trend in which Transformer-based Models outperform LSTM, CNN, and hybrid architectures.

For example, domain-specific fine-tuning of BERT in [2] leads to clear improvements in accuracy and F1-score, while [3] demonstrates that Deep Learning approaches surpass classical techniques when analyzing large-scale Twitter data. Similarly, [7], [8], and [15] show that BERT variants adapted to specific domains and languages more effectively capture informal and context-dependent semantics, and [11] integrates BERT with BiGRU and GCN to achieve additional gains in generalization. Collectively, these studies indicate that contextualized text-based models consistently deliver the strongest affective performance. Related multilingual emotion extraction studies further confirm the importance of language-specific resources and cross-lingual modeling choices [17].

At the multilingual level, research highlights the particular challenges posed by low-resource settings. In [13], the authors analyze Emotion Recognition through a cross-cultural perspective, showing that sociocultural factors influence affective interpretation. In [16], the authors demonstrate that fine-tuned Transformer-based Models can overcome data scarcity barriers, while [19] evaluates multilingual LLMs for Hate Speech Detection across diverse linguistic contexts. Furthermore, [36] adapts IndoBERT to Indonesian emotional content, reaching performance levels comparable to models trained on larger or better-resourced corpora.

Overall, multilingual fine-tuning, transfer learning, and linguistic adaptation emerge as essential strategies for extending the applicability of affective NLP to culturally diverse and resource-constrained environments.

D. Multimodal Learning

Articles [29], [30], [31], [32], [33], [34], [35] present multimodal architectures integrating text with images, audio, or other signals.

Common trends include Cross-modal Attention and multi-level fusion — [29], [33], Multimodal Transformer-based models — [30], [31], Hierarchical and intramodal enhancement — [32], [34], and GRU networks with directed cross-modal attention — [35].

Results consistently show that multimodal approaches outperform text-only systems when emotional cues depend on visual, acoustic, or combined signals.

E. Global Comparison of Architectures and Metrics

Table II shows how the main architectures used across the studies are distributed, highlighting the predominance of Transformer-based Models and the emerging role of Multimodal Learning.

TABLE II. COMPARATIVE SUMMARY OF ARCHITECTURES USED ACROSS THE STUDIES

Model Category	Associated Articles	Key Trends	Common Metrics
Transformers (BERT, RoBERTa, IndoBERT, LLMs)	[2], [7], [8], [11], [15], [16], [19], [36]	Best overall performance in affective and social tasks	F1-score, accuracy
Classical DL Models (LSTM, CNN, BiGRU)	[3], [7], [11], [15]	Lower performance vs. Transformers; useful in small datasets	accuracy, F1-score
Hybrid Models (BERT+GRU, PCA+GloVe, GNN)	[11], [18], [20]	Balanced trade-off between efficiency and precision	macro-F1, weighted-F1
Multimodal Models	[29]–[35]	Improved affective understanding when combining signals	F1-score, weighted-F1

Source: Author's elaboration.

A global comparison of the architectures and evaluation metrics used across all the studies reveals several consistent patterns. Transformer-based Models dominate performance in all affective tasks, reflecting their superior ability to capture contextual dependencies. Multimodal Learning further enhances performance in enriched contexts where affective cues extend beyond text. Lightweight Models such as the one proposed in [20], demonstrate strong competitive performance when computational efficiency is a priority. Across the corpus, the most commonly reported metrics include F1-score, accuracy, and macro-F1, underscoring their relevance in affective evaluation. Finally, dataset quality—in terms of size, balance, and language—proves to be as influential as the choice of architecture, confirming its central role in determining model robustness and generalization.

F. Synthesis of Global Patterns Across the Corpus

Across the reviewed studies:

- Transformers establish a new state-of-the-art in affective NLP.
- Multimodality represents the next major step in emotional interpretation.
- Multilingualism remains challenging, but is increasingly well addressed through adapted PLMs.
- For hate speech and cyberbullying, hybrid and lightweight models provide excellent precision–efficiency trade-offs.

To provide a concise and integrative overview of the main findings discussed in this section, Table III summarizes the relationships between affective tasks, representative models, datasets, and key outcomes identified across the reviewed studies.

TABLE III. SYNTHETIC OVERVIEW OF TASKS, MODELS, DATASETS, AND KEY FINDINGS

Task	Representative Models	Typical Datasets	Key Findings
Sentiment Analysis	BERT, RoBERTa, CNN-LSTM	Twitter, Reviews	Transformer-based models consistently outperform classical deep learning approaches
Emotion Recognition	BERT, Multimodal Transformers	EmoBank, IEMOCAP	Multimodal fusion improves affective accuracy and robustness
Hate Speech Detection	BERT, DBFN-J	Twitter, HASOC	Fine-tuned pre-trained language models balance performance and computational efficiency
Multilingual Affective NLP	IndoBERT, mBERT	Multilingual corpora	Transfer learning mitigates data scarcity in low-resource settings

Source: Author's elaboration.

V. CURRENT CHALLENGES AND FUTURE RESEARCH DIRECTIONS

A. Current Challenges Observed in the Studies

Table IV synthesizes the main challenges explicitly documented in the corpus, allowing the identification of cross-cutting patterns that affect the development of affective NLP

systems in real-world contexts. Beyond data limitations, linguistic phenomena such as sarcasm and irony remain difficult to model reliably and continue to impact affective classification performance in social media contexts [5]. Moreover, recent data-centric and human-in-the-loop error analysis frameworks supported by Explainable AI provide practical strategies to diagnose and mitigate systematic model failures [28].

TABLE IV. CURRENT CHALLENGES IDENTIFIED ACROSS THE STUDIES

Challenge	Articles Reporting It	Observations
Corpus scarcity/limitations	[3], [7], [8], [13], [15], [16], [29]–[35], [36]	Issues related to size, imbalance, and domain specificity
Linguistic complexity	[1], [3], [7], [8], [13], [15], [36]	Difficulty handling sarcasm, social variation, cultural differences
High computational costs	[20], [29]–[35]	Multimodal and heavy Transformer-based models
Lack of explainability	[20], [29]–[35]	Critical issue in sensitive environments
Inconsistent evaluation	[2], [11], [18], [29]	Non-comparable metrics; use of different datasets

Source: Author's elaboration.

B. Limitations Identified in the Studies

The consolidated analysis reveals a set of recurrent limitations affecting the development, evaluation, and generalization capacity of Affective Analysis systems applied to social media. These limitations fall into five main categories. Inconsistent evaluation protocols and limited cross-dataset testing hinder comparability across studies; similar concerns have motivated unified benchmark construction in other AI areas [25] and cross-dataset analyses of language models to assess robustness and distributional shift [26].

In terms of data quality and availability, several studies highlight structural weaknesses in the datasets. Articles [3], [7], [8], [13], [15], and [36] report datasets that are small, imbalanced, or highly domain-specific, limiting model generalization. In contrast, article [16] emphasizes that Low-resource Languages suffer from limited annotation, hindering both training and validation. Meanwhile, Multimodal studies [29]–[35] report the cost and complexity of obtaining synchronized text–image–audio datasets, which restricts both scope and reproducibility. Class imbalance is particularly recurrent in toxic speech and emotion datasets, where oversampling and related resampling strategies are often required to stabilize training and improve minority-class performance [24].

VI. CONTRIBUTIONS TO THE FIELD

This review advances the state of knowledge in affective intelligence by providing a broad and up-to-date integrated examination of deep learning, multimodal fusion, and large-scale language models through a unified analytical framework. While prior studies typically address sentiment analysis, emotion recognition, or multimodal architectures in isolation, this study synthesizes cross-domain evidence to identify convergent methodological patterns, emerging architectures, and persistent research gaps across text, audio, and visual modalities. The work contributes novel comparative insights into how transformer-based, hybrid, and cross-modal embedding strategies are reshaping affective computing, and outlines a forward-looking taxonomy of trends that can inform the design of next-generation AI systems capable of nuanced emotional reasoning. By bridging findings from NLP, computer vision, and affective signal processing, this review positions itself as a foundational reference for researchers developing emotionally aware AI technologies.

VII. GENERAL CONCLUSIONS

This corpus-driven review of contemporary studies in Affective Analysis—including Sentiment Analysis, Emotion Recognition, Hate Speech Detection, cyberbullying, and multimodal approaches—allows us to establish solid conclusions regarding the current state of the field, its dominant trends, and the impact of deep learning–based models. This synthesis draws exclusively from the findings discussed in the previous sections and remains fully aligned with the methodology adopted throughout the study.

A. Transformation of Affective NLP Through Transformer-Based Models

Text-based models constitute the core of affective NLP across the reviewed studies. The results consistently show that Transformer-based Models outperform classical deep learning architectures in tasks such as Sentiment Analysis, Emotion Recognition, and text-based Hate Speech Detection. In particular, BERT and its variants achieve superior accuracy and F1-score due to their ability to capture contextual semantic relationships, as evidenced in [2], [7], [8], [11], [15], [16], [19], and [36]. Classical architectures such as LSTM, CNN, or BiGRU, used in studies like [3], [7], [11], and [15], provide competitive baselines and perform adequately in small or well-structured datasets, but their capacity to model complex informal language is more limited. Hybrid text-based models—such as BERT combined with BiGRU or GNN components in [11]—demonstrate improvements in stability and generalization, indicating that architectural fusion can yield benefits even when working exclusively with textual input. Overall, the evidence confirms that contextualized Transformer-based Models represent the dominant paradigm in text-only affective tasks, while traditional and hybrid architectures remain useful in scenarios with constrained computational resources or smaller datasets.

B. Multimodality as a High-Impact Emerging Axis

The multimodal works — [29]–[35] — show that integrating text with images, audio, or additional signals significantly enhances the ability to interpret emotions, especially in contexts where textual information alone is ambiguous or insufficient. These studies consolidate multimodality as a key trend in the evolution of Affective Analysis.

C. Relevance of Multilingualism and Cultural Adaptation

Studies targeting languages other than English — [13], [15], [16], [19], [36]— highlight the importance of considering sociocultural factors and data availability. The results show that multilingual or domain-adapted models can achieve competitive

performance when supported by representative datasets and appropriate fine-tuning strategies.

D. Need for Improved Data, Explainable AI (XAI), and Efficiency

The integrated analysis of the corpus reveals three persistent cross-cutting needs:

Improved and expanded datasets

Reported in [3], [7], [8], [13], [15], [16], [36], the limitations in dataset size, balance, and diversity continue to affect generalization.

Explainable AI (XAI)

Articles [16], [19], [21], [27] emphasize the need to incorporate XAI mechanisms to ensure trust and transparency.

Computational optimization

Studies such as [20] and multimodal works [29]–[35] underline the importance of developing lighter models with lower computational requirements to enable real-world deployment.

E. Central Contribution of this Review

This review provides a structured, comparative, and up-to-date perspective on affective NLP, highlighting how recent advancements converge toward:

highly contextualized architectures,

integration of multiple information modalities,

models adaptable to diverse languages and cultures,

growing interest in transparency and efficiency.

This synthesis consolidates a deep understanding of the dominant trends and remaining challenges in the field, serving as a valuable reference for researchers and practitioners developing robust and reliable affective systems.

The findings of this review underscore a clear evolution toward emotion-aware AI models that integrate deep learning, multimodal fusion, and self-supervised language architectures. Although current systems demonstrate impressive performance across benchmark datasets, their real-world applicability remains limited by challenges such as contextual ambiguity, cultural variation in emotional expression, dataset bias, and the difficulty of modeling complex affective states beyond basic emotions.

F. Future Research Directions

Future research should advance in at least three directions.

First, there is a need for large-scale, culturally diverse multimodal datasets that reflect real-world emotional variability and enable robust generalization across languages, accents, and socio-cultural contexts.

Second, the emergence of multimodal LLMs calls for new architectures capable not only of classifying emotions but also of explaining the reasoning behind affective predictions, thus integrating affective computing with explainable AI.

Third, next-generation models should incorporate continuous affective dynamics—such as stress, fatigue, ambiguity, and mixed emotions—moving beyond categorical labels toward richer temporal representations aligned with human psychology.

Collectively, these research directions provide a roadmap for building emotionally intelligent AI systems that are reliable, transparent, and more deeply aligned with human communication.

Declaration on Generative AI

The authors used generative Artificial Intelligence tools solely to support textual coherence revision, improve writing quality, and optimize English translations during the preparation of this manuscript. Their use was strictly limited to linguistic assistance and did not intervene in the conceptual development, analysis, interpretation of results, selection or evaluation of the corpus, or the elaboration of the scientific contributions.

***Abstract*—Industrial facilities operating with toxic and explosive gases require continuous monitoring systems capable not only of detecting threshold exceedances but also of anticipating hazardous trends. Conventional IoT-based gas monitoring solutions are primarily limited to real-time data acquisition and alarm triggering, which restricts their ability to prevent incidents proactively. This study presents the architecture of an intelligent predictive analytics system for gas environment monitoring that integrates sensor-series IoT gas analyzers with advanced data analytics. The proposed system is built on domestically developed SENSOR-Mine gas analyzers supporting LoRaWAN and Wi-Fi communication, centralized data storage in MS SQL Server, machine learning–based analytics implemented in Python, and a web-based visualization platform using ASP.NET MVC. Time-series forecasting models and anomaly detection algorithms are jointly employed to analyze gas concentration dynamics and identify potentially dangerous situations at early stages. Experimental validation using carbon monoxide measurements demonstrates the practical applicability of the proposed architecture for industrial safety monitoring. The presented approach provides a scalable foundation for intelligent gas environment monitoring systems aimed at reducing industrial risks and improving worker protection.**

Keywords*—Intelligent system; predictive analytics; IoT; gas analyzer; LoRaWAN; industrial safety; machine learning

I. Introduction

Ensuring industrial safety remains one of the most critical challenges for modern manufacturing enterprises. At first glance, this may seem like a well-studied issue; yet statistics confirm that it remains highly relevant today. According to the International Labor Organization, more than 2.3 million deaths and over 300 million cases of injuries and occupational diseases are recorded worldwide each year, directly or indirectly linked to unsafe working conditions [1]. In countries with a developed mining industry, such as Kazakhstan, a significant share of incidents is associated with hazardous gas leaks, which often lead to fires and explosions at industrial sites.

The World Health Organization has revised the permissible exposure limits for several hazardous substances, including carbon monoxide, nitrogen dioxide, sulfur dioxide, and particulate matter [2]. This update, introduced only a few years ago, once again emphasizes the need for continuous air quality monitoring, not only in urban environments but also within industrial zones.

Recently, IoT-based intelligent sensor networks have been gaining attention as one of the most effective approaches to industrial monitoring [3, 4]. LoRaWAN, in particular, has shown strong performance, offering long communication range with minimal power consumption [4, 5]. Yet, sensors alone are limited: they primarily gather information, which by itself cannot guarantee safety. To address risks proactively, predictive analytics must be applied, allowing trends within time-series data to be analyzed and potential threats to be forecasted in advance [6].

Machine learning algorithms - such as LSTM, GRU, and autoencoders - have demonstrated strong performance when applied to the task of anomaly detection in streaming data generated by IoT sensors [7, 8].

This study focuses on the architecture of an intelligent predictive analytics system designed for gas environment monitoring. The foundation of the system is built upon domestically developed gas analyzer sensors-SENSOR-Mine 4G1 and SENSOR-Mine 4G2, created by KAB SYSTEMS. The purpose of the research is not limited to presenting the system's architecture; it also aims to demonstrate its practical applicability in ensuring continuous monitoring and the early prediction of potentially hazardous situations.

Recent studies have actively explored IoT-based solutions for air quality and gas monitoring in both indoor and industrial environments. Existing works demonstrate the effectiveness of sensor networks combined with wireless communication technologies, including LoRaWAN, for reliable long-range data transmission and low-power operation. Several approaches focus on real-time monitoring and alarm generation based on predefined thresholds, while others investigate the application of machine learning techniques for forecasting gas concentration dynamics or detecting anomalies in sensor data. However, in most reported solutions, predictive modeling and anomaly detection are addressed separately and are rarely integrated into a unified architecture designed for continuous industrial deployment. Furthermore, many studies remain limited to experimental setups and do not sufficiently consider system scalability, communication redundancy, and integration

with enterprise-level information systems. These gaps motivate the development of an integrated architecture that jointly combines IoT sensing, hybrid communication, and intelligent analytics for industrial gas environment monitoring.

Despite the significant progress in IoT-based gas monitoring systems, most existing solutions primarily focus on real-time data acquisition and threshold-based alarming, offering limited capabilities for proactive risk prevention. Many approaches lack integrated predictive analytics and are not designed to jointly address long-term trend forecasting and rare-event detection in industrial environments. Moreover, a substantial portion of reported solutions remains at the experimental or laboratory level and does not sufficiently consider deployment constraints such as communication reliability, scalability, and integration with industrial IT infrastructures. In this context, the present study proposes an architecture that combines distributed IoT gas analyzers with a hybrid LoRaWAN/Wi-Fi communication layer and intelligent data analytics. By integrating time-series forecasting models with anomaly detection methods within a unified system, the proposed approach extends conventional monitoring by enabling early identification of hazardous trends. The architecture is specifically designed for industrial deployment and is validated using data obtained from SENSOR–Mine gas analyzers, positioning this work as a practical and scalable solution for intelligent gas environment monitoring.

II. Methods and Materials

The hardware backbone of the gas monitoring system is formed by the SENSOR series gas analyzers, developed as part of a domestic project. These devices are designed to measure the concentrations of various gases (CO, CH_4, NO_2, H_2S, and others), with detection ranges spanning from 0.1 ppm to 1000 ppm, depending on the sensor module used. The measurement accuracy reaches ±2%, while the minimum detection threshold does not exceed ±2 ppm.

The SENSOR-Mine 4GN gas analyzer is designed for continuous monitoring of harmful and hazardous gases in the air of both underground and surface industrial facilities. The device serves as a tool for ensuring industrial safety, protecting workers' health, preventing accidents, and monitoring compliance with permissible exposure limits (PEL) in production and technological environments.

The 4GN model is configured to monitor up to four different gases, where N denotes the specific gas set. Table I presents the available models, each equipped with a defined combination of sensors tailored to the particular needs of industrial enterprises.

The gas analyzer is suitable for use in a wide variety of facilities, including mining operations, tunnels, underground storage units, ventilation shafts, as well as laboratory and industrial settings. The detection range specifications of the built-in sensors integrated into the SENSOR gas analyzer are provided in Tables II and III.

The key features of the developed gas analyzer include modular sensor replacement, an integrated microcontroller for primary data filtering, and support for wireless communication via LoRa and Wi-Fi. The device is designed for low power consumption, reaching up to 200 mW in transmission mode, while maintaining ease of use in industrial environments.

Similar solutions are already being applied in LoRaWAN-based research systems for air quality monitoring [9].

Communication layer: LoRaWAN and Wi-Fi. Two technologies were employed for transmitting data from the sensors to the server. LoRaWAN provides a communication range of up to 10 km with very low power consumption, making it an optimal choice for distributed systems [10]. Wi-Fi, in turn, is used as a backup channel and for local debugging. This combination was selected as the primary solution for mines, quarries, and industrial sites where large-area coverage is essential.

In the present implementation, a significant advantage lies in the networking capability between gas analyzers. Data packets are transmitted based on the measurements obtained, first exchanged among neighboring analyzers and then forwarded to the central database server, where the aggregated dataset undergoes further processing through predictive analytics.

TABLE I. Configurations of SENSOR-Mine 4GN

Configuration Number	Model Designation	Measured Gases
1	SENSOR – Mine 4G1	SO_2, NO_2, CO, O_2
2	SENSOR – Mine 4G2	H_2S, CH_4, CO, O_2

TABLE II. Specifications of SENSOR–Mine 4G1

Gas	Measurement Range	Accuracy	MAC RK (ppm)	Alarm Threshold (ppm)
SO_2	0–20 ppm	±2 ppm	3.4	3
NO_2	0–20 ppm	±2 ppm	1.0	1
CO	0–200 ppm	+20 ppm	17.4	20
O_2	0–25%	±4 % of the measured value	<18%	18% ↓

TABLE III. Specifications of SENSOR–Mine 4G2

Gas	Measurement Range	Accuracy	MAC RK (ppm)	Alarm Threshold (ppm)
H_2S	0–100 ppm	±10 ppm	10	10 ppm
CH_4	0–100% LEL	±3 % of the measured value	5% LEL	10% LEL
CO	0–200 ppm	±20 ppm	17.4	20 ppm
O_2	0–25%	±4 % of the measured value	<18%	18% ↓

Wi-Fi is primarily applied in local industrial facilities and laboratories, where high data transfer rates are critical. However, its use in confined environments such as mines or underground tunnels proves to be ineffective. Wi-Fi requires a constant network connection, and in harsh conditions, physical cables can easily be damaged by passing machinery or rockfalls. For this reason, Wi-Fi is most effective in surface applications, such as open industrial sites and quarries.

The key advantage of the hybrid communication model is its ability to combine the energy efficiency of LoRaWAN with the high bandwidth of Wi-Fi, enabling reliable data transmission under a variety of conditions. Considering these parameters, together with the devices' moisture, explosion, and dust protection, the system is well-suited for deployment in virtually any industrial environment.

Fig. 1 illustrates the alarm triggering algorithm in the gas analyzer: once a hazardous concentration is detected, the data are transmitted to the central database server, and an alarm notification is displayed in the user interface. At the same time, all analyzers located near the unit that raised the alarm automatically receive the signal and activate their own warning alerts, ensuring distributed safety awareness within the network.

A. Data Storage and Processing System

The data collected by the gas analyzer in real-time is transmitted to the server, where it is stored and further processed in a SQL Server database. The data storage structure is based on a relational model and contains fields for a unique sensor identifier, gas type (CO, NO_2, SO_2, CH_4, etc.), timestamp of data acquisition, measured concentration value expressed in ppm or mg/m³, and a status attribute indicating the measurement level (normal, warning, or alarm).

This organization of data enables the formation of time series, which are then used as the basis for machine learning and predictive analytics algorithms. Fig. 1 shows the architecture of the developed intelligent system, including sensors, server infrastructure, and the user interface.

This data storage structure enables the generation of time-series datasets, which can then be applied for training and operating machine learning algorithms. Fig. 1 presents the architectural diagram of the intelligent system.

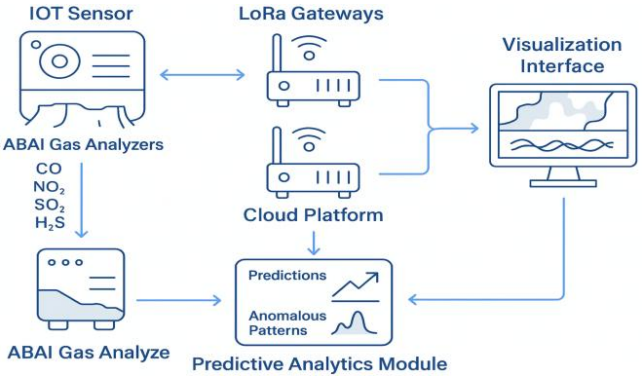

Fig. 1. Architecture of the intelligent system.

Machine learning algorithms are employed to analyze time-series data.

Specifically, Long Short-Term Memory (LSTM) networks are used to predict gas concentrations based on historical measurements, while Gated Recurrent Unit (GRU) models provide a computationally efficient alternative to LSTM.

Isolation Forest is applied for detecting anomalies and sudden spikes in gas concentrations, whereas One-Class SVM is suitable for identifying rare and potentially hazardous events in scenarios where most observations correspond to normal operating conditions.

These methods are widely adopted in predictive monitoring tasks [6], [11].

B. Visualization and User Interface

The data are visualized using an ASP.NET MVC–based platform. The user interface enables real-time visualization of current gas concentrations on the facility map, time-series representation with predictive trends, and dynamic highlighting of detected anomalies. In addition, the system supports automated reporting on the overall condition of the facility.

During the experiments conducted in the chemical laboratory, data were collected using the SENSOR-Mine 4G2 gas analyzer, which measures carbon monoxide (CO) concentrations in the range of 0-200 ppm. As reference values, the regulatory limits of the Republic of Kazakhstan were applied, as previously shown in Table III – SENSOR-Mine 4G2.

Fig. 2 illustrates the dynamics of CO concentration changes over time [12]. It can be observed that within the interval of 120-130 minutes, concentration exceeded the permissible exposure limit (PEL) and reached the alarm threshold.

To analyze the data and uncover hidden patterns, advanced intelligent processing methods were applied, including the Isolation Forest (IF) algorithm for anomaly detection and the One-Class SVM method for identifying rare events and outliers.

Fig. 3 demonstrates the application of the Isolation Forest method. The red points highlight anomalous values corresponding to a sharp increase in CO concentration, which aligns with the incident detected by the gas analyzer.

Fig. 4 illustrates the identification of rare events with the One-Class SVM algorithm. The orange markers indicate points flagged as potentially hazardous. It is worth noting that this method can capture outliers even with minor deviations from the norm, which makes it valuable for early warning.

The effectiveness of different approaches was evaluated, and the results are summarized in Table IV. The analysis shows that recurrent neural networks such as LSTM and GRU provide the most accurate results in forecasting CO concentration dynamics. However, these models require significantly higher computational resources, which may be a limiting factor for industrial applications that have not yet reached full digital maturity.

While Table IV summarizes qualitative trade-offs, a full quantitative evaluation of anomaly detection performance (e.g., Precision, Recall, and F1-score) requires labeled ground truth for abnormal events. In the current laboratory validation, anomalies were identified based on threshold exceedance and expert inspection; therefore, we report comparative behavior of the methods and include quantitative benchmarking with labeled data as a planned extension of this work.

TABLE IV. COMPARISON OF MACHINE LEARNING ALGORITHMS APPLIED TO GAS ANALYZER (CO) DATA

Method	Task	Advantages	Limitations	Industrial Applicability
LSTM	Forecasting concentrations using time series	High accuracy; captures long-term dependencies	Requires large datasets and high computational resources	Suitable for long-term leak prediction
GRU	Similar to LSTM	Faster and lighter to train; fewer parameters	Slightly lower accuracy compared to LSTM	Suitable for real-time systems
Isolation Forest	Detecting anomalies and sudden spikes	Performs well with outliers; does not require large datasets	Does not forecast, only detects anomalies	Effective for instant accident detection
One-Class SVM	Identifying rare events in normal data	Capable of detecting unusual situations with limited data	Sensitive to parameter selection	Useful for early warning of accidents

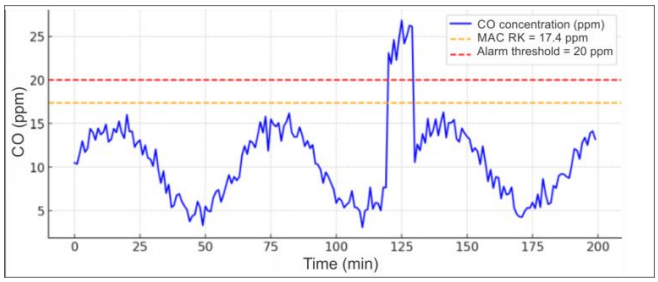

Fig. 2. Dynamics of CO concentration over time.

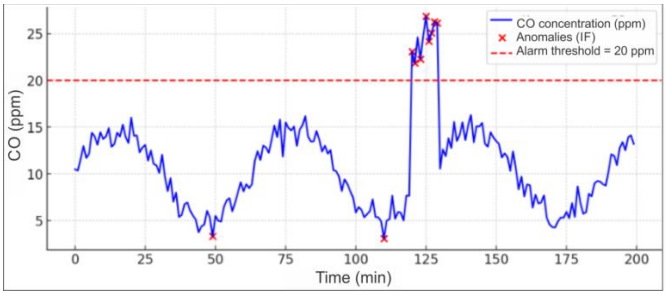

Fig. 3. CO anomaly detection using the Isolation Forest method.

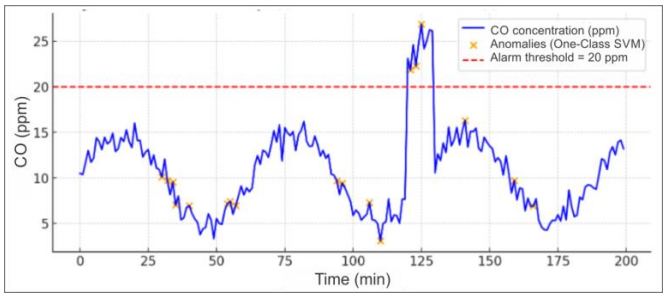

Fig. 4. Detection of rare CO events using the One-Class SVM method.

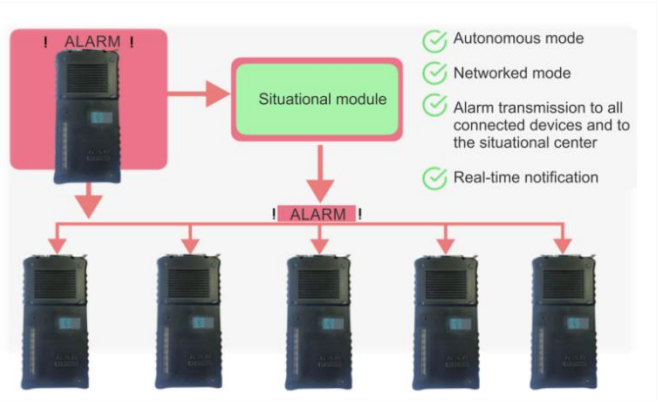

Fig. 5. The main functional components of the system.

On the other hand, anomaly detection methods such as Isolation Forest and One-Class SVM performed better in identifying hazardous episodes. This capability is particularly important for real-time monitoring systems, where timely detection of abnormal events is often more critical than precise long-term trend prediction. Fig. 5 illustrates the main functional components of the system and the alarm-triggering process when either maximum permissible concentrations of harmful substances or anomalies are detected.

Thus, the combination of forecasting models such as LSTM and GRU with anomaly detection methods like Isolation Forest and One-Class SVM provides a more comprehensive approach to intelligent monitoring of the gas environment. This integrated methodology not only records actual exceedances of maximum allowable concentrations but also predicts the development of hazardous trends. As a result, the overall level of industrial safety can be significantly improved.

The relevance of this study is largely driven by the urgent need to implement intelligent predictive analytics systems in industrial enterprises of the Republic of Kazakhstan. In environments where toxic and explosive gases are used, the risks of emergencies remain objectively high, making such solutions particularly valuable.

The scientific novelty of the work lies in the proposed integration of time-series forecasting methods with algorithms for detecting rare and anomalous events, based on data obtained directly from SENSOR - Mine 4G2 gas analyzers equipped with LoRa and Wi-Fi data transmission. This combined approach is introduced in the context of industrial safety tasks. Its application enhances the accuracy of analysis, reliability of the system, and timeliness of detecting potentially dangerous situations.

III. RESULTS

The developed architecture of the intelligent system consists of five core layers. At the sensor level, SENSOR-series gas analyzers provide continuous data collection. The communication layer employs LoRaWAN and Wi-Fi technologies for data transmission. On the server side, the information is accumulated and stored in SQL Server before being processed by the analytical module, implemented in Python with machine learning methods. The final layer is the user level, represented by a web interface built on ASP.NET

MVC, which provides access to monitoring results and analytics.

The proposed approach, tested through the analysis of CO concentrations, can be adapted to other industrial environments and facilities where the risk of hazardous gas accumulation exists. Below are typical scenarios where the system may prove especially useful.

For monitoring air quality in urban infrastructure, a distributed network of sensors can be deployed, focusing on the control of nitrogen dioxide (NO_2) and fine particulate matter (PM2.5). Integrating predictive model outputs with existing environmental monitoring systems makes it possible not only to record regulatory exceedances but also to provide early warnings to the population about potential air quality deterioration.

Fig. 6 illustrates air quality monitoring using SENSOR gas analyzers, with a modeled scenario of hazardous substance dispersion following an alarm event. The SENSOR devices are positioned at specific coordinates and measure data in real-time, transmitting results to a central control center. Based on sensor readings and detected anomalies, information on potential leakage sources is forwarded to local authorized bodies, including the Department of Emergency Situations and the Department of Industrial Safety. Subsequently, notifications are issued to residents within the affected zone through instant alerts delivered to their mobile devices. This example demonstrates the applicability of the intelligent predictive analytics system in an urban context.

In mines and quarries, monitoring methane (CH_4) and hydrogen sulfide (H_2S) concentrations remains one of the most critical tasks in underground operations. The use of LSTM models enables forecasting of methane buildup 5-10 minutes before reaching explosive thresholds. The Isolation Forest algorithm demonstrates high sensitivity to sudden spikes in hydrogen sulfide levels, which is crucial for preventing unexpected emergencies.

In metallurgical production, the main parameters of concern are carbon monoxide (CO) and sulfur dioxide (SO_2) concentrations. Recurrent neural networks, such as GRU, provide rapid and reasonably accurate predictions of CO dynamics in workshops, while the One-Class SVM method makes it possible to timely detect rare SO_2 emissions that often go unnoticed with conventional monitoring tools.

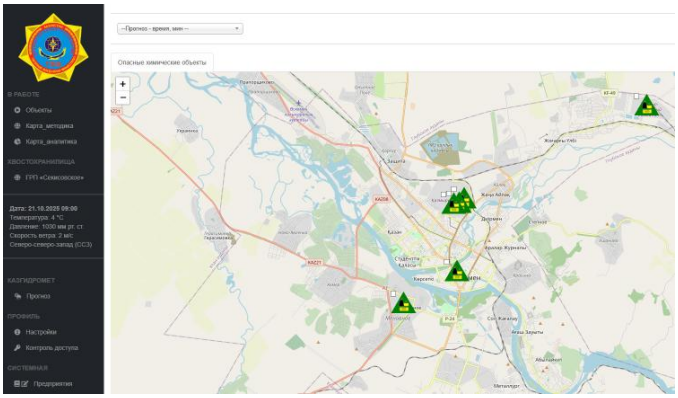

Fig. 6. Simulation of hazardous substance dispersion.

IV. Discussion

A comparison with existing monitoring systems [3, 5, 9] shows that the proposed architecture offers several advantages. Unlike most solutions that primarily focus on data collection, our system integrates LoRaWAN-based communication with predictive analytics methods, enabling not only real-time measurement but also forward-looking prediction. An additional advantage is the use of Python-based modules, which provide flexibility in applying different forecasting algorithms. Moreover, the inclusion of a backup communication channel via Wi-Fi enhances the system's reliability under conditions of primary channel instability.

Despite its advantages, any technical solution or system has certain limitations. For machine learning models to function correctly, a significant amount of data must be accumulated, which may reduce prediction accuracy at the initial stages of implementation. For laboratory validation, the dataset was collected using the SENSOR–Mine 4G2 gas analyzer with a sampling interval of 2 seconds. Measurements were performed at three controlled concentration levels (10 ppm, 100 ppm, and 190 ppm), resulting in a time-series dataset consisting of approximately 1,000–2,000 data points. Another challenge lies in the proper calibration of sensors, especially in harsh industrial environments. The sensitivity of algorithms to input data quality also requires attention: noise or incomplete measurements may lead to false alarms.

Nevertheless, the prospects for system development appear highly promising. One potential direction is integration with digital twins of industrial enterprises, enabling simulation of asset behavior under various scenarios. Another opportunity is the implementation of automated responses, such as automatic activation of ventilation systems or emergency notifications when maximum permissible concentrations are exceeded. In the long term, it is advisable to enable data transmission to state monitoring systems - including the Ministry of Emergency Situations and the Ministry of Ecology - to establish a unified infrastructure for industrial and environmental safety.

V. Conclusion

This study presents the architecture of an intelligent predictive analytics system for gas environment monitoring. The system is based on SENSOR-series IoT sensors, with data transmission via LoRa and Wi-Fi protocols, storage in SQL Server, analysis using Python, and visualization in an ASP.NET MVC web environment.

The developed solution enables early detection of potentially hazardous situations and can be integrated into the industrial infrastructure of enterprises in the Republic of Kazakhstan.

Future research directions include expanding and comparing various predictive analytics algorithms; developing a digital twin of technological processes for integration with safety management systems; and conducting pilot implementations in the mining industry and territorial state agencies.

Thus, the proposed architecture lays the foundation for establishing a national industrial safety system focused on preventing emergencies and enhancing worker protection.

A Systematic Literature Review on Organizational Readiness for Artificial Intelligence Adoption Based on the TOE Framework

Sulistyo Aris Hirtranusi, Benny Ranti, Widijanto Satyo Nugroho, Wisnu Jatmiko
Doctoral Program in Computer Science-Faculty of Computer Science, University of Indonesia, Depok 16424, Indonesia

***Abstract*—Artificial intelligence (AI) is increasingly being integrated into organizational processes, reshaping how organizations operate, compete, and make decisions. However, despite growing interest, many organizations face challenges in adopting AI effectively due to insufficient readiness. Prior research on organizational AI readiness has produced diverse and sometimes inconsistent conceptualizations, particularly with respect to definitions, readiness factors, and analytical approaches. To consolidate these dispersed insights, this study undertakes a structured review of the literature to synthesize organizational AI readiness factors through the lens of the Technology–Organization–Environment (TOE) framework. The review applies a transparent and replicable screening and selection process, consistent with PRISMA principles, to analyze peer-reviewed journal articles on organizational AI adoption and readiness. Through a multi-stage coding process, 124 readiness-related indicators were identified and subsequently consolidated into 35 factors, which were further synthesized into 12 core readiness themes mapped across the technological, organizational, and environmental dimensions of the TOE framework. The results indicate that organizational AI readiness is not a standalone condition, but a multidimensional and interdependent construct shaped by the alignment of technological capabilities, organizational structures and competencies, and external environmental conditions. By providing a structured synthesis of organizational AI readiness factors, this study clarifies the multidimensional nature of readiness and highlights cross-dimensional interdependencies within the TOE framework. The findings contribute theoretical clarity to the AI readiness literature and offer a consolidated foundation for future empirical studies and practical readiness assessments in organizational settings.**

Keywords*—*Artificial intelligence readiness; organizational readiness; TOE framework; systematic literature review; AI adoption

I. Introduction

Artificial Intelligence (AI) has become a critical driver of organizational transformation, influencing how organizations create value, optimize operations, and support decision-making [1], [2]. In the past decade, the integration of AI across industries—from manufacturing and finance to agriculture and public services—has demonstrated its potential to enhance efficiency, accuracy, and decision-making quality [3], [4]. However, despite the recognized benefits, AI adoption at the organizational level remains uneven due to the complexity of readiness conditions required for successful implementation [5], [6].

Organizational readiness for AI adoption extends beyond technological availability and reflects a multidimensional capability involving infrastructure, human competencies, financial commitment, governance mechanisms, cultural alignment, and external conditions [7], [8]. The effectiveness of AI initiatives depends on how well organizations align these internal and external enablers to support transformation [9]. Accordingly, readiness assessment plays a critical role prior to AI investment to reduce the risks of implementation failure, limited utilization, or ethical challenges [10].

Among established innovation adoption theories, the Technology–Organization–Environment (TOE) framework [11] provides a comprehensive perspective for examining how technological capabilities, organizational characteristics, and environmental conditions jointly influence adoption behavior [12]. Although prior AI adoption studies have applied TOE to explore specific drivers (e.g., [6], [13], [14]), these findings have rarely been synthesized into a coherent and unified structure of organizational AI readiness. Existing research tends to fragment the discussion across isolated dimensions or sectors, leading to inconsistencies in how readiness factors are defined, categorized, and measured [15], [16].

While foundational theories such as the Technology–Organization–Environment framework originate from earlier literature, this review predominantly synthesizes empirical AI adoption and readiness studies published between 2015 and 2025, ensuring the contemporary relevance of its findings.

Moreover, while the literature has grown rapidly, few reviews have systematically mapped how TOE dimensions interrelate to influence AI readiness holistically. Earlier reviews have primarily emphasized either technological or organizational enablers, overlooking the moderating role of the environment [5]. Therefore, a Systematic Literature Review (SLR) is needed to consolidate the growing body of knowledge and identify theoretical and empirical patterns regarding AI readiness within the TOE framework.

While prior systematic literature reviews have examined artificial intelligence adoption from technological, organizational, or sector-specific perspectives, most existing reviews remain either descriptively oriented or focused on isolated determinants of adoption. They typically emphasize drivers and barriers without synthesizing readiness as a multidimensional organizational capability, nor do they systematically integrate cross-theoretical perspectives within a unified analytical structure. As a result, existing SLRs provide

limited guidance on how technological, organizational, and environmental readiness dimensions interact to shape organizational preparedness for AI adoption.

This study addresses this gap by conducting a theory-integrative systematic literature review that explicitly positions organizational AI readiness within the Technology–Organization–Environment (TOE) framework, while incorporating insights from Dynamic Capability and Institutional perspectives. By synthesizing empirical findings across these lenses, this review goes beyond prior SLRs to conceptualize AI readiness as a systemic and capability-oriented construct rather than a static pre-adoption condition. Specifically, this study produces: 1) a consolidated taxonomy of organizational AI readiness factors, 2) twelve core readiness constructs structured across the TOE dimensions, and 3) a conceptual foundation that can support future development of standardized AI readiness assessment frameworks.

Prior review studies have examined artificial intelligence adoption from organizational and managerial perspectives. Conceptual and agenda-setting reviews, such as Dwivedi et al. [5], discuss broad challenges, opportunities, and managerial implications of AI adoption. More recent systematic literature reviews employ the Technology–Organization–Environment (TOE) framework to analyze adoption and readiness determinants. For example, Ayinaddis [17] examines AI adoption dynamics across SMEs and large firms, while Ali and Khan [18] review organizational readiness factors influencing AI adoption decisions. However, these reviews primarily apply TOE as a classificatory lens to organize adoption or readiness determinants. In contrast, this study advances the literature by explicitly conceptualizing organizational AI readiness as an integrative and capability-oriented construct. By synthesizing the TOE framework with dynamic capability and institutional perspectives, this review shifts the analytical focus from factor identification to readiness as a systemic and evolving organizational capability shaped by cross-dimensional interdependencies.

Building on this positioning, this study conducts a decade-long synthesis (2015–2025) of peer-reviewed journal articles focusing on AI adoption through the TOE perspective. The review is structured around three research questions (RQs):

- How has the TOE framework been applied in AI adoption research at the organizational level?
- What are the key organizational readiness factors influencing AI adoption based on TOE dimensions?
- How are the interdependencies among TOE dimensions conceptualized in AI adoption readiness studies?

By addressing these questions, this study makes a significant contribution to both theory and practice. Theoretically, it advances the understanding of organizational readiness as a multi-dimensional construct within the TOE framework. Practically, it provides an evidence-based foundation for organizations and policymakers to design structured readiness assessments and strategies for AI adoption.

II. Methodology

This study adopts a systematic review strategy to identify, evaluate, and synthesize academic research addressing organizational readiness for Artificial Intelligence (AI) adoption within the Technology–Organization–Environment (TOE) framework. To ensure methodological rigor, transparency, and replicability, the review process was structured in accordance with established reporting standards for systematic literature reviews, including PRISMA [19]. The process was adapted from established practices in information systems research [20], [21].

A. Research Design and PICOC Framework

The design of this review was guided by the PICOC framework, which supports methodological clarity in systematic literature reviews by specifying the Population, Intervention, Comparison, Outcome, and Context dimensions [22].

In this review, the population comprised organizations that have adopted, or are in the process of adopting, AI technologies. The intervention dimension captured studies examining AI implementation frameworks, readiness assessment models, or organizational adoption approaches. Since the review did not seek to compare intervention groups, the Comparison element was not applied. The Outcome was defined as the identification of factors influencing AI readiness across the three TOE dimensions—technological, organizational, and environmental [11]. The Context covered organizational-level studies across sectors and regions, thereby capturing cross-industry and cross-national insights.

The application of PICOC ensured that the review maintained conceptual precision and excluded studies unrelated to organizational-level adoption, such as those focused on consumer behavior or algorithmic performance. This alignment enhanced both the relevance and internal validity of the synthesis.

B. Search Strategy

The literature search was performed using the Scopus database, which was selected due to its extensive coverage of peer-reviewed journals in management, computer science, and information systems. The database search was executed on October 14, 2025 (20:47 WIB) using a structured keyword combination designed to capture studies on AI adoption and organizational readiness within the TOE perspective, as follows:

"Artificial Intelligence" AND Adoption AND (TOE OR (Technology AND (Organization OR Organisation) AND Environment))

The search was limited to the period 2015–2025, reflecting a decade of maturity in both AI research and organizational readiness discourse [5]. To maintain scientific rigor, the inclusion was restricted to journal articles in their final publication stage, written in English, and classified as articles (not conference papers or reviews).

After applying these initial filters, 190 records were retrieved. Non-article publications—such as conference papers (46), book chapters (11), reviews (9), books (1), and articles in press (16)—were excluded. This refinement ensured that only high-quality, peer-reviewed journal outputs were retained for systematic screening.

C. Inclusion and Exclusion Criteria

To maintain conceptual relevance and methodological rigor, explicit inclusion and exclusion criteria were applied during the screening process. Table I summarizes the inclusion and exclusion criteria applied during the review.

TABLE I. INCLUSION AND EXCLUSION CRITERIA

Inclusion Criteria	Exclusion Criteria
Studies were included if they: a) addressed AI adoption or readiness at the organizational level, b) were theoretically aligned with the TOE framework or compatible constructs, c) provided empirical or conceptual insights relevant to organizational readiness.	Conversely, studies were excluded if they: a) focused solely on technical AI models or algorithms, b) investigated individual or consumer adoption behavior, c) lacked theoretical grounding in TOE or related frameworks, or d) were written in languages other than English.

After screening, 52 papers met the preliminary inclusion conditions. A subsequent full-text review identified 12 papers that did not sufficiently address organizational-level readiness, leading to a final corpus of 40 studies used for synthesis.

D. PRISMA Flow and Screening Process

The selection of studies followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) protocol, which structures systematic reviews through four sequential phases: The study selection process progressed through sequential phases encompassing record identification, relevance screening, full-text eligibility assessment, and final inclusion [19]. This process ensured methodological transparency and reproducibility throughout the review.

During the Identification phase, records were retrieved from the Scopus database based on the query and criteria defined in Section 2.2. After applying initial filters for language, document type, and publication status, a total of 190 journal records were identified for potential inclusion. As confirmed in the database export, no duplicate or automated removals were required prior to screening.

In the Screening stage, titles and abstracts of all 190 records were examined to determine their relevance to AI adoption and readiness at the organizational level. This stage resulted in the exclusion of 138 studies, primarily consisting of non-journal documents (e.g., conference proceedings, book chapters, reviews) and non-English publications. Consequently, 52 studies were retained for full-text assessment.

At the Eligibility phase, the full texts of these 52 studies were successfully retrieved for in-depth evaluation. Each paper was reviewed to confirm its theoretical alignment with the Technology–Organization–Environment (TOE) framework or compatible perspectives (e.g., RBV, DCV, Institutional Theory). Twelve studies were excluded at this stage for reasons such as a purely technical orientation (n = 4), lack of organizational or managerial focus (n = 5), or incomplete conceptual detail (n = 3).

Following the screening and eligibility assessment, a total of 40 peer-reviewed journal articles satisfied all selection criteria and were retained for qualitative synthesis. These studies constitute the final corpus analyzed through open, axial, and selective coding in Section III. The overall workflow, including the number of records removed, screened, and retained at each stage, is illustrated in Fig. 1, which presents the PRISMA flow diagram of the study selection process.

E. Data Extraction and Thematic Synthesis

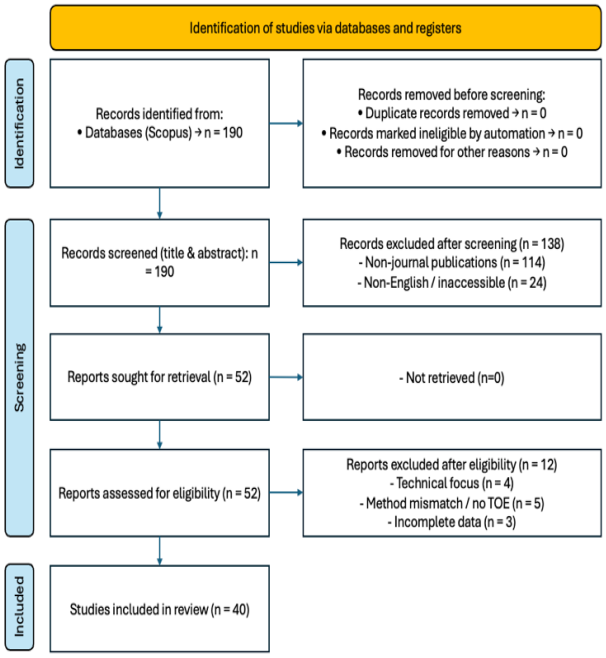

Fig. 1. PRISMA flow diagram of the study selection process.

A structured data extraction template was designed to capture consistent information from each study, including bibliographic details (authors, year, journal, country), type of AI technology and sectoral application, theoretical foundation (TOE or derivative), identified readiness factors per TOE dimension, and major findings and implications. The extracted data were analyzed using thematic synthesis, allowing for the identification and grouping of readiness factors under the three TOE dimensions. Subsequent cross-analysis was performed to examine interdependencies among these dimensions, consistent with the methodological guidance of Tranfield [21]. Through this process, the review produced an integrative synthesis of 40 studies, highlighting trends, methodological gaps, and opportunities for future research on organizational AI readiness.

III. RESULTS

A. Overview of Reviewed Studies

The systematic review encompassed forty peer-reviewed journal articles published between 2021 and 2025 that focus on organizational readiness for Artificial Intelligence (AI) adoption. As illustrated in Fig. 2, publication output increased substantially over the review period, rising from two studies in 2021 to seventeen studies in 2025. After a modest rise in 2022 and a slight dip in 2023, the trend accelerated sharply in 2024–2025, reflecting the growing strategic relevance of AI readiness within organizational digital transformation agendas. This temporal pattern indicates a shift from early exploratory

investigations toward more structured empirical validation and framework refinement.

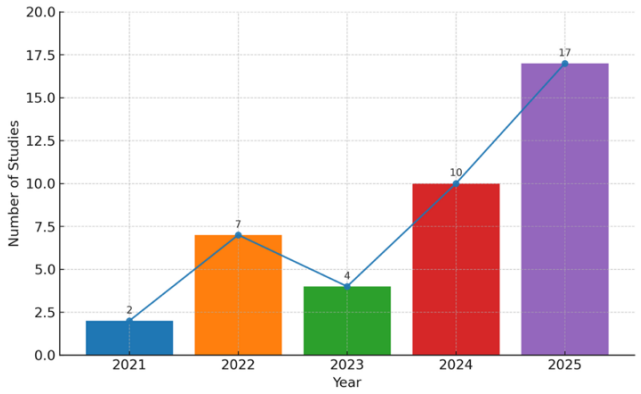

Fig. 2. Publication trend of AI readiness studies.

From a geographical perspective, the reviewed studies are distributed across multiple regions, although the distribution remains uneven. As shown in Fig. 3, the majority of reviewed studies originated from Europe (35%) and Asia (30%), where AI readiness research is often situated within policy-driven digitalization and institutional modernization contexts, where AI readiness has been explored within policy-driven digitalization and institutional modernization frameworks [23], [24], [25], [26]. Studies from North America (25%) emphasized resource-based and dynamic capability perspectives [4], [5], [16], while smaller shares originated from Africa (5%) and the Middle East (5%), often focusing on contextual barriers, policy readiness, and infrastructural challenges [27], [28], [29]. This geographical pattern indicates a strong research concentration in high-income and policy-advanced regions, with limited representation from emerging economies.

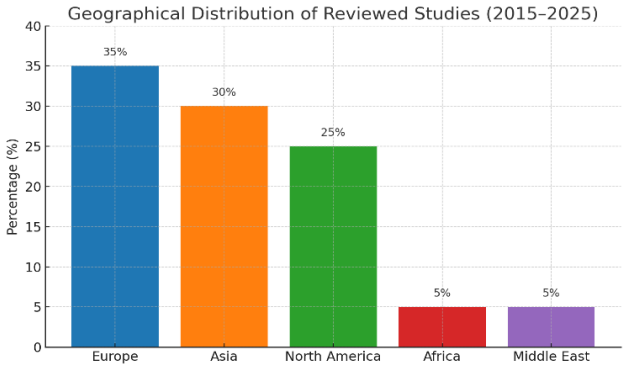

Fig. 3. Geographical distribution of reviewed studies.

With respect to industrial orientation, Fig. 4 indicates that most studies focused on manufacturing (20%), public administration (17.5%), and financial services (15%), reflecting sectors leading in automation, data-driven governance, and innovation [24], [30], [31]. Other contexts, including agriculture (10%), healthcare (10%), services (7.5%), and education (5%), were comparatively less explored but demonstrate emerging academic attention as AI adoption expands beyond high-tech industries [32], [33], [34], [35]. This sectoral diversity highlights that AI readiness is increasingly understood as a cross-sectoral organizational capability, applicable across both public and private sectors with varying degrees of digital maturity.

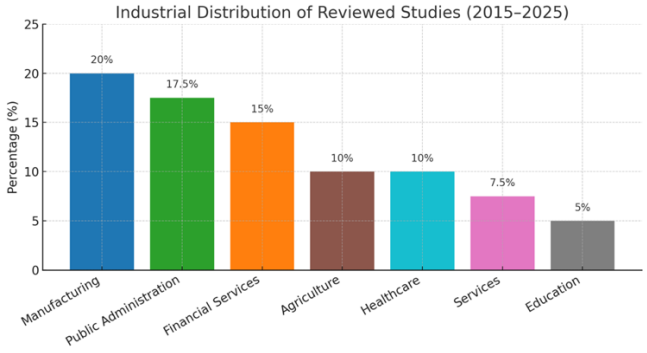

Fig. 4. Industrial distribution of reviewed studies.

From a methodological perspective, quantitative approaches (45%) constitute the largest proportion of the reviewed studies, with studies primarily employing survey-based analysis and structural equation modeling to test readiness determinants under the Technology–Organization–Environment (TOE) framework [7], [31], [36]. Qualitative studies (30%)—such as case studies and semi-structured interviews—provided an in-depth understanding of organizational dynamics, leadership, and governance in AI adoption [6], [24], [37]. A smaller proportion of mixed-method research (15%) combined statistical validation with contextual insights [16], [38], while conceptual papers (10%) contributed to the refinement of AI readiness constructs [39], [40].

Overall, the descriptive synthesis indicates that the field has developed empirical diversity, while remaining geographically and methodologically uneven. Most studies remain concentrated in high-income regions and quantitative paradigms, while cross-sectoral, longitudinal, and developing-country analyses remain limited. These gaps highlight the need for future research that broadens contextual coverage and examines AI readiness development within diverse institutional and economic settings.

B. Theoretical Foundations in AI Readiness Studies

The synthesis of the reviewed studies confirms that the Technology–Organization–Environment (TOE) framework [11] continues to function as the primary theoretical lens for analyzing organizational readiness for AI adoption. This continued relevance stems from its capacity to integrate technological, organizational, and environmental determinants within a unified analytical structure that explains adoption behavior beyond purely technical or managerial considerations [5], [7], [38].

Approximately 95 per cent of all reviewed articles employed TOE either independently or in combination with complementary theories. The integration trend reflects a conceptual broadening of readiness from deterministic adoption toward dynamic capability and institutional perspectives. Around 20 per cent of studies combined TOE with the Resource-Based View (RBV) to emphasize internal resources and capability orchestration [7], [23]. Another 15 per cent paired TOE with the Dynamic Capability View (DCV) to capture organizational agility and transformation processes [16], [37]. The Institutional Theory (≈10 per cent) appeared mainly in

public-sector contexts to highlight regulatory alignment and legitimacy pressures [24], [36]. Meanwhile, behavioral models such as the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT) (≈7 per cent) were applied to integrate individual-level acceptance factors into organizational readiness [40], [41].

Together, these theoretical combinations indicate that AI readiness research is shifting from static adoption logic toward a multi-level capability perspective that connects technology, organization, and environment in an adaptive ecosystem. Table II presents the distribution of theoretical frameworks applied in AI readiness studies, summarizing how TOE is used both independently and in combination with complementary theories across the reviewed literature.

The dominance of TOE and its frequent integration with RBV, DCV, Institutional Theory, and TAM/UTAUT suggests that contemporary AI readiness studies increasingly adopt hybrid theoretical models. These combinations enable the operationalization of readiness not merely as a structural condition but as a dynamic capability responsive to institutional and human factors within digital transformation ecosystems.

C. Thematic Synthesis of Readiness Factors

To identify the core dimensions of organizational readiness for Artificial Intelligence (AI) adoption, a three-stage thematic coding process was conducted—open coding, axial coding, and selective coding—using the Technology–Organization–Environment (TOE) framework as the analytical lens. The TOE structure was defined a priori to classify readiness factors; it served as a guiding taxonomy rather than a coded outcome.

During the open coding stage, a total of 124 readiness-related statements were extracted from 40 Scopus-indexed journal articles published between 2015 and 2025. Each statement represented a specific condition, enabler, or organizational characteristic influencing AI adoption. Of these, 120 statements were classified into the three TOE dimensions—Technology (40), Organization (40), and Environment (40)—while four meta-level codes (Layer RBV, UTAUT (Individual), Mediating Construct, Moderating Variable) were identified as theoretical supplements and excluded from the readiness classification.

Through axial coding, semantically similar open codes were consolidated and standardized into 35 intermediate readiness categories distributed across the three TOE dimensions (15 technological, 12 organizational, and 8 environmental). These categories captured interrelationships among internal and external readiness factors. Finally, selective coding integrated these categories into 12 final readiness themes, with four readiness constructs identified within each TOE dimension. As summarized in Table III, this stepwise synthesis—from 124 open codes to 35 axial categories and finally 12 selective readiness constructs—illustrates the structured process of theoretical condensation applied in this study.

The technological dimension captures the internal enablers that support AI deployment, such as infrastructure, data, and innovation capability. The organizational dimension represents leadership, culture, and resource capabilities that drive AI transformation. Meanwhile, the environmental dimension reflects regulatory, market, and social conditions that facilitate or constrain adoption. As detailed in Table IV, these 12 readiness themes reflect the final synthesis of conceptual categories derived from the 40 reviewed studies, organized within the TOE framework.

TABLE II. THEORETICAL FRAMEWORKS APPLIED IN AI READINESS STUDIES

Framework Combination	Analytical Focus / Conceptual Contribution	Representative Studies	% of Included Studies (n = 40)
TOE only	Baseline model integrating technological, organizational, and environmental readiness determinants. Serves as the dominant lens for organizational AI adoption.	[5], [32]	47.5 % (19 studies)
TOE + RBV (Resource-Based View)	Highlights internal resources and capability orchestration as strategic enablers of AI readiness. Focuses on value creation from existing assets.	[23], [7], [38]	20 % (8 studies)
TOE + DCV (Dynamic Capability View)	Emphasizes organizational agility, learning, and reconfiguration to sustain readiness under digital transformation.	[16], [42], [43]	15 % (6 studies)
TOE + Institutional Theory	Addresses legitimacy, regulation, and coercive pressures influencing AI readiness—particularly in public and regulated domains.	[24], [36], [44]	10 % (4 studies)
TOE + TAM / UTAUT	Integrates individual-level acceptance, perceived usefulness, and behavioral intention within organizational readiness contexts.	[41], [40]	7.5 % (3 studies)

TABLE III. SUMMARY OF CODING STAGES (OPEN–AXIAL–SELECTIVE) AND DISTRIBUTION ACROSS TOE DIMENSIONS

Coding Stage	Description of Process	Result	TOE Dimensions
Open Coding	Extraction of readiness-related concepts and determinants from 40 Scopus-indexed studies (2015–2025). Each indicator represents a discrete aspect of AI readiness.	124 open codes	Technology: 40 Organization: 40 Environment: 40 Non-TOE (meta): 4
Axial Coding	Consolidation of conceptually similar open codes into standardized readiness categories within each TOE dimension.	35 axial categories	Technology: 15 Organization: 12 Environment: 8
Selective Coding	Integration of axial categories into final readiness constructs describing organizational preparedness for AI adoption.	12 final readiness themes	Technology: 4 Organization: 4 Environment: 4

TABLE IV. SUMMARY OF SELECTIVE CODING THEMES ACROSS THE THREE TOE DIMENSIONS

TOE Dimension	Selective Theme (Readiness Construct)	Description / Core Meaning	Representative Studies
Technological Readiness	System Capability	Availability and reliability of IT/AI infrastructure, interoperability, and automation capacity enabling AI operation.	[26], [38], [40]
	Data & Analytics Readiness	Availability, governance, and security of organizational data supporting AI-driven analytics and decision-making.	[35], [25], [45]
	Technology Usability	Perceived usefulness, ease of use, and compatibility facilitating system integration and adoption.	[34], [46]
	Innovation Capability	Organizational ability to experiment with and integrate new AI tools, fostering digital agility and innovation.	[47], [48]
Organizational Capability	Strategic & Managerial Support	Leadership commitment, managerial capability, and strategic orchestration of resources for AI initiatives.	[38], [42]
	Human & Structural Readiness	Competence of human resources, training, and financial readiness supporting AI transformation.	[35], [31], [28]
	Cultural & Governance Alignment	Alignment of innovation culture, ethical leadership, and IT governance with AI objectives.	[42], [49], [28]
	Knowledge & Learning	Capacity for organizational learning, absorptive capability, and knowledge sharing sustaining AI competence.	[38], [50]
Environmental Readiness	Regulatory & Policy Context	National policies, regulations, and compliance standards promoting AI legitimacy.	[24], [51]
	Market Dynamics	Competitive pressure and industry turbulence driving AI adoption decisions.	[31], [46], [52], [53], [54], [55], [56]
	Collaborative Ecosystem	External partnerships, vendor support, and stakeholder collaboration fostering AI implementation.	[55], [53], [57], [58], [52], [25]
	Social Legitimacy & Ethics	Public trust, ethical acceptance, and social legitimacy influencing AI adoption readiness.	[52], [58], [59]

TABLE V. SUMMARY OF READINESS THEMES IDENTIFIED THROUGH THE SYSTEMATIC REVIEW

TOE Dimension	Core Readiness Themes	Core Conceptual Meaning
Technological Readiness	1. System Capability	Availability and reliability of AI infrastructure, interoperability, and automation systems forming the technological foundation.
	2. Data & Analytics Readiness	Data quality, accessibility, and governance supporting machine learning and analytics integration.
	3. Technology Usability	Perceived usefulness, ease of use, and compatibility of AI systems enhancing adoption.
	4. Innovation Capability	Capacity to integrate, experiment, and evolve with new AI tools and technologies.
Organizational Capability	5. Strategic & Managerial Support	Leadership commitment, managerial capability, and strategic orchestration of AI resources.
	6. Human & Structural Readiness	Workforce competence, training, and financial support enabling AI initiatives.
	7. Cultural & Governance Alignment	Innovation culture, ethics, and governance alignment with AI objectives.
	8. Knowledge & Learning	Organizational learning capacity, absorptive ability, and knowledge-sharing culture.
Environmental Readiness	9. Regulatory & Policy Context	Government regulations, standards, and policies legitimizing AI use.
	10. Market Dynamics	Competitive and market pressures driving AI transformation.
	11. Collaborative Ecosystem	Vendor support, external partnerships, and inter-organizational collaboration.
	12. Social Legitimacy & Ethics	Public trust, ethical norms, and social acceptance of AI implementation.

To consolidate these findings, Table V provides an overview of the final twelve core readiness themes as the outcome of the systematic literature review. Each construct represents an empirically supported component of organizational AI readiness that can later be operationalized into measurable indicators for quantitative assessment.

In summary, Table III to Table V collectively present the complete thematic synthesis from the coding process. Table III outlines the progressive abstraction stages, Table IV elaborates the thematic content of each dimension, and Table V consolidates the 12 final readiness constructs as the conceptual outcome of the SLR. This hierarchical structure provides both empirical transparency and theoretical coherence, forming the basis for the next stage of framework development and quantitative instrument design.

D. Cross-Dimensional Patterns and Interdependencies

A cross-dimensional analysis of the three TOE domains reveals that AI readiness is a systemic and interdependent construct, rather than a collection of isolated factors. The twelve core readiness themes identified in Section III C (see Table III to Table V) interact dynamically across technological, organizational, and environmental boundaries, indicating that improvements in one dimension often depend on reinforcing conditions in the others. Three dominant patterns of interaction emerged from the synthesis:

1) Technology–organization synergy: Technological capabilities such as infrastructure robustness, data quality, and AI tool maturity serve as essential enablers, yet they do not automatically ensure readiness without corresponding organizational commitment and competencies. Leadership support, resource allocation, and skilled personnel determine whether technological potential can be translated into business value [38], [6]. This interaction aligns with the Dynamic Capability View, which posits that technological enablers must be integrated with organizational routines and strategic management processes to create adaptive advantage [16], [42].

In essence, technology provides capability, while organization provides direction.

2) Organization–environment alignment: Institutional and regulatory contexts shape organizational governance, ethics, and risk management, reinforcing the principles of responsible AI adoption [24], [36]. External pressures—such as evolving regulations, market competition, and societal expectations—stimulate internal strategic agility and reform initiatives, linking organizational culture and leadership to broader environmental expectations [60], [61]. This alignment demonstrates how institutional legitimacy and regulatory compliance become catalysts for sustainable AI readiness.

External legitimacy drives internal adaptation.

3) Technology–environment dependence: Environmental conditions—comprising vendor collaboration, industry standards, and ecosystem maturity—directly influence technological readiness. These relationships accelerate innovation diffusion, promote interoperability, and reduce implementation risk through shared knowledge and technical standards [62], [63]. Such dependencies emphasize that AI readiness extends beyond a single firm; it requires a network-oriented and policy-supported ecosystem to sustain large-scale technological transformation.

Technological advancement flourishes in collaborative ecosystems.

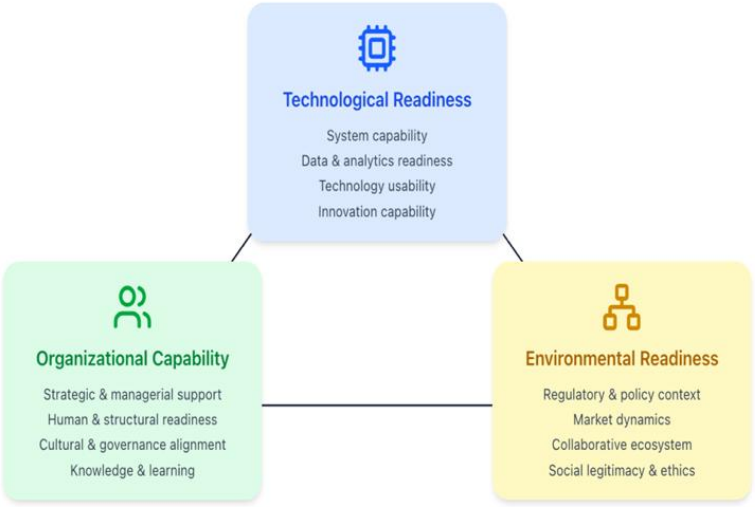

Fig. 5. Conceptual map of interdependencies among TOE dimensions.

Arrows between Technological and Organizational Readiness indicate internal synergy between capability and leadership [see Fig. 5]. Arrows connecting Organizational and Environmental Readiness show alignment between strategy, governance, and external expectations. Arrows linking Technological and Environmental Readiness highlight dependence on industry standards, vendor networks, and regulatory support. Together, these relationships form a systemic readiness model, depicting AI adoption as an ecosystem-driven capability embedded in multi-level interactions.

E. Summary of Findings

The systematic review of forty peer-reviewed studies revealed a comprehensive picture of how organizations develop readiness for Artificial Intelligence (AI) adoption. Through a three-stage thematic synthesis—open, axial, and selective coding—124 readiness-related indicators were identified, refined into 35 standardized categories, and ultimately consolidated into twelve core readiness themes organized within the Technology–Organization–Environment (TOE) framework. These twelve core readiness themes capture the multidimensional conditions that jointly determine an organization's preparedness to adopt, manage, and sustain AI transformation.

Technological readiness provides the capacity to act through infrastructure, data quality, usability, and innovation enablers that make AI implementation technically feasible. Organizational capability defines the ability to adapt and lead through strategic commitment, human competence, and governance mechanisms that enable effective transformation. Meanwhile, environmental readiness sets the context to legitimize and sustain AI initiatives by shaping regulatory alignment, market competition, collaboration networks, and public trust [7], [44], [64].

As summarized in Table VI, these findings demonstrate that successful AI adoption requires alignment and mutual

reinforcement among the three TOE dimensions. AI readiness thus functions as an integrative organizational capability—a systemic configuration in which technology, organization, and environment co-evolve to enable sustainable AI transformation.

TABLE VI. CONCEPTUAL CONSOLIDATION OF AI READINESS DIMENSIONS

TOE Dimension	Primary Readiness Focus	Strategic Interpretation / Core Implication
Technological Readiness	• System Capability • Data & Analytics Readiness • Technology Usability • Innovation Capability	Represents the organization's technical foundation—the digital infrastructure, data governance, and innovation capacity that provide the *ability to act* and support AI functionality.
Organizational Capability	• Strategic & Managerial Support • Human & Structural Readiness • Cultural & Governance Alignment • Knowledge & Learning	Reflects internal leadership, competencies, culture, and learning systems that transform technological potential into operational and strategic performance.
Environmental Readiness	• Regulatory & Policy Context • Market Dynamics • Collaborative Ecosystem • Social Legitimacy & Ethics	Defines the external environment—regulatory frameworks, competitive forces, partnerships, and social trust—that legitimize and sustain AI adoption at the ecosystem level.

IV. DISCUSSION

This discussion synthesizes the review findings by explicitly addressing the three research questions of the study. Rather than treating technological, organizational, and environmental readiness as independent dimensions, the analysis reveals how prior studies conceptualize AI readiness as an interdependent and systemic organizational capability. The following discussion interprets these patterns in relation to RQ1–RQ3 and highlights their theoretical and practical implications.

A. Evolution of Theoretical Foundations

Across the reviewed literature, the Technology–Organization–Environment (TOE) framework [11] remains the principal theoretical lens for examining organizational readiness for AI adoption. Its enduring appeal lies in its ability to integrate technological, organizational, and environmental determinants into a single systemic model that explains adoption behavior beyond purely technical or managerial boundaries [5], [7], [65]. By linking these three dimensions, TOE positions readiness as a multidimensional construct that aligns internal capability with external opportunity, providing a balanced analytical view of how organizations prepare for technological transformation.

Over time, the field has undergone a theoretical broadening. Earlier studies published between 2015 and 2019 predominantly applied TOE in a deterministic manner, conceptualizing readiness as a pre-adoption condition indicating whether organizations possessed sufficient capability to adopt AI [66], [67]. From 2020 onward, researchers increasingly reconceptualized readiness as a dynamic organizational capability, embedding the TOE framework within complementary perspectives such as the Resource-Based View (RBV) [68] and the Dynamic Capability View (DCV) [69]. In this hybridization, readiness is no longer treated as a binary condition but as an evolving capability that enables organizations to sense technological opportunities, seize them strategically, and reconfigure internal structures in response to environmental turbulence [65], [16], [70].

Parallel developments have further enriched TOE through the adoption of Institutional Theory [75], emphasizing that readiness is also influenced by external legitimacy pressures, regulatory conformity, and ethical accountability [64], [71], [72].

At the micro level, the Technology Acceptance Model (TAM) [73] and the Unified Theory of Acceptance and Use of Technology (UTAUT) extend the discussion by linking user-level adoption behaviors to organizational and institutional readiness [66], [74]. Together, these integrations demonstrate that readiness operates across nested levels—from individual cognition to institutional governance—connecting micro, meso, and macro dimensions of capability formation.

Collectively, this convergence marks a paradigmatic shift from viewing readiness as a deterministic predictor of adoption to conceptualizing it as a strategic, adaptive, and socially embedded capability. The TOE framework, augmented by the RBV [68], DCV [69], and Institutional Theory [75], now functions as an integrative meta-framework that connects technological affordances, organizational competencies, and environmental legitimacy within complex socio-technical systems. This theoretical evolution substantiates the continued use of TOE as the conceptual core of AI readiness research—its flexibility enabling consistent yet context-sensitive analysis across sectors, organizational scales, and AI applications.

This pattern indicates that TOE is increasingly used not merely as a classificatory framework but as a foundational structure for organizing organizational readiness constructs in AI adoption research.

B. Dominant Readiness Factors and Thematic Patterns

The thematic synthesis derived from open, axial, and selective coding identified twelve core readiness themes distributed across the technological, organizational, and environmental dimensions of AI adoption.

Together, these themes form a consolidated structure of readiness constructs applicable across industries and organizational contexts, providing the conceptual foundation for future assessment frameworks and maturity models. The findings indicate that technological readiness is the most extensively examined dimension, with particular emphasis on infrastructure maturity, data governance, interoperability, and cybersecurity [76], [77], [66]. Unlike traditional IT readiness, AI readiness extends beyond digital infrastructure toward data-

centric capabilities such as accessibility, analytical accuracy, and model reliability [7], [78].

Accordingly, technological readiness represents a necessary, yet insufficient, condition for successful AI-driven transformation—it provides the technical foundation, but organizational and environmental mechanisms ultimately determine whether technological potential can be realized [79], [16].

Organizational readiness reflects a combination of managerial, structural, and cultural capacities that enable and sustain transformation processes. The synthesis highlights four dominant constructs: strategic and managerial support, human and structural readiness, cultural and governance alignment, and knowledge and learning [80], [72], [81], [70]. Leadership and strategic alignment consistently appear as pivotal determinants, reinforcing theories of vision-driven transformation within strategic management literature [69], [16]. Furthermore, the growing integration of ethical governance and responsible AI practices demonstrates that readiness also involves legitimacy and trust, not merely competence or resource sufficiency.

Environmental readiness refers to the institutional, market, and societal conditions that influence and constrain organizational AI adoption. Its four major constructs include regulatory and policy context, market dynamics, collaborative ecosystem, and social legitimacy and ethics [64], [82], [83]. External collaboration and policy alignment have become increasingly vital, especially in public-sector and cross-sector ecosystems where interoperability and compliance determine adoption success [84], [85]. These findings reinforce the view that AI readiness extends beyond internal organizational capabilities and is embedded within a broader socio-technical and institutional ecosystem, shaped by institutional frameworks and inter-organizational relationships.

Integrating these twelve core readiness themes confirms that AI readiness operates as a multidimensional organizational capability, combining technological enablement, managerial adaptability, and environmental alignment. This holistic perspective moves the field beyond deterministic adoption models, positioning readiness as a dynamic equilibrium between technological potential, organizational capacity, and environmental legitimacy—an equilibrium that defines an organization's sustained ability to transform through AI.

Taken together, these readiness factors suggest that AI adoption success is less dependent on isolated technological assets and more contingent on the alignment of technological capability, managerial orchestration, and environmental legitimacy.

C. Cross-Dimensional Interdependencies

Cross-dimensional analysis across the TOE framework demonstrates that the twelve core readiness themes are inherently interdependent instead of analytically isolated, forming a systemic and recursive structure rather than a set of discrete categories. Technological readiness without corresponding organizational capability rarely leads to meaningful transformation [6], [80], while strong leadership and financial investment remain ineffective without high-quality data and reliable AI infrastructure [77], [76]. Environmental readiness—particularly regulatory clarity, policy alignment, and stakeholder trust—moderates the effectiveness of both technological and organizational readiness, demonstrating that adoption success depends on the degree of contextual alignment [64], [67], [71].

Such interdependencies align with the concept of mutual shaping in socio-technical theory, which emphasizes the co-evolution of technologies, organizational structures, and institutional contexts.

Empirical evidence reinforces this view: effective AI adoption requires not only robust infrastructure and data systems but also adaptive governance mechanisms that respond dynamically to ethical, regulatory, and market conditions [16], [72], [83]. Accordingly, readiness should not be perceived as a collection of independent domains but as a coupled system of enablers, whose collective value emerges through interaction and interdependence across all TOE dimensions.

From a theoretical perspective, these cross-dimensional dynamics align with the Dynamic Capability View (DCV), which conceptualizes readiness as a higher-order capability that enables organizations to integrate, build, and reconfigure technological and managerial resources in response to environmental turbulence [69], [80]. From a managerial standpoint, enhancement in one dimension (e.g., technology) must be complemented by synchronized investments in other areas (e.g., human skills, governance, and partnerships). This multi-domain coherence reflects the organizational alignment required for AI-driven transformation, ensuring that technological, human, and institutional components evolve cohesively.

Fig. 5 illustrates this systemic interplay among technological, organizational, and environmental readiness dimensions, visualizing how reciprocal relationships sustain overall readiness maturity. Collectively, these patterns reinforce the conceptualization of AI readiness as a socio-technical system capability—an emergent property arising from balanced maturity, continuous alignment, and coordinated evolution across the TOE framework.

This finding directly addresses RQ3 by demonstrating that AI readiness is conceptualized in the literature as a co-evolving system, where weaknesses in one TOE dimension may constrain the effectiveness of others.

D. Theoretical and Practical Implications

From a theoretical standpoint, this review advances TOE-based research by shifting the analytical focus from a deterministic adoption model toward a capability-oriented and ecosystem-level perspective.

These theoretical implications are directly derived from the cross-dimensional synthesis of readiness constructs identified in Section A to C. By integrating insights from the Resource-Based View (RBV) and the Dynamic Capability View (DCV), readiness is redefined as a dynamic organizational capability—reflecting an organization's ability to sense opportunities, seize technological potential, and transform internal processes in response to environmental constraints [69], [16]. This reconceptualization advances theory by positioning readiness

not as a static precondition for adoption but as a continuous process of adaptation, learning, and institutional alignment within socio-technical systems.

The integration of Institutional Theory further extends the TOE framework's boundary by embedding normative, regulatory, and ethical dimensions into the readiness construct. AI adoption entails socio-ethical implications requiring compliance, accountability, and legitimacy [64], [72], [83]. Consequently, readiness now encompasses a form of moral capability—the organizational capacity to align technological innovation with societal expectations and governance norms. This theoretical enrichment broadens the TOE framework's explanatory power, providing a more holistic understanding of how AI readiness functions as a multi-level and socially embedded capability in digitally transforming environments.

From a practical standpoint, the synthesized findings provide actionable guidance for organizations as well as policymakers. Organizations should design balanced readiness strategies that integrate technological, organizational, and environmental investments rather than focusing narrowly on infrastructure or human capital. This includes establishing robust data governance mechanisms, fostering AI ethics and transparency frameworks, and nurturing ecosystem partnerships that accelerate responsible innovation [7], [79].

For policymakers, the findings highlight the need to build enabling regulatory environments and cross-sectoral collaborations that minimize readiness disparities across industries, sectors, and economies [85], [86]. Such alignment between internal organizational practices and external institutional support is essential to ensure equitable and sustainable AI diffusion.

In synthesis, this review positions AI readiness as both a theoretical bridge between information systems and strategic management research and a practical instrument for guiding digital transformation strategies in the era of intelligent technologies. These practical implications reflect the interdependent nature of technological, organizational, and environmental readiness dimensions identified in the review. Table VII summarizes the theoretical contributions and practical implications derived from this study.

TABLE VII. SUMMARY OF THEORETICAL AND PRACTICAL IMPLICATIONS

Perspective	Key Contributions / Implications	Representative Sources
Theoretical	• Reframes TOE from a deterministic adoption model to a capability-based, dynamic, and ecosystemic framework. • Integrates RBV and DCV to define readiness as a higher-order organizational capability for sensing, seizing, and transforming. • Embeds Institutional Theory to capture legitimacy, ethics, and governance as integral components of readiness. • Expands TOE into a multi-level socio-technical framework connecting micro (user), meso (organizational), and macro (institutional) levels.	[69], [16], [64], [72]
Practical	• Guides organizations to pursue integrated readiness strategies across technological, organizational, and environmental domains. • Emphasizes data governance, AI ethics, and transparency as enablers of responsible innovation. • Encourages ecosystem partnerships and inter-sectoral collaborations to strengthen readiness maturity. • Informs policymakers to establish enabling regulations and reduce readiness gaps across industries and economies.	[79], [7], [86], [85]

E. Field Maturity and Research Gaps

The temporal trend observed between 2015 and 2025 shows that AI readiness research has evolved from conceptual exploration to empirical consolidation, signaling a field that is maturing yet uneven in scope and depth. Europe and Asia dominate the literature, accounting for over 60% of publications, reflecting regions with strong institutional and policy support for digital transformation [64], [65]. However, this geographic concentration also introduces contextual bias, as only a limited number of studies examine readiness in developing or low-income economies [27], [72]. Future research should therefore broaden its contextual coverage to enhance cross-regional generalizability and uncover readiness dynamics in underrepresented environments.

Methodologically, nearly half of the studies (around 45%) employ quantitative, cross-sectional designs that capture static relationships among TOE variables. Few investigations adopt longitudinal or mixed-method approaches capable of tracing the evolution of readiness or its performance outcomes over time [7], [16]. Moreover, limited research has connected readiness assessment to benefit realization frameworks, such as Benefits Management [87] or the Generic IT/IS Business Value model [88]. The absence of such linkages constrains the field's ability to demonstrate how readiness translates into tangible organizational value, leaving a critical bridge between measurement and impact underdeveloped.

Conceptually, AI readiness studies have yet to fully integrate human, ethical, and environmental sustainability as integral dimensions of preparedness. As AI technologies increasingly influence organizational decision-making, future studies must embed responsible AI principles, socio-ethical governance, and sustainability considerations into readiness constructs [89], [83]. This integration would extend current frameworks beyond technical and managerial boundaries, positioning readiness as a foundation for ethical, inclusive, and context-sensitive AI transformation.

Taken together, the evidence suggests that the AI readiness field is transitional moving from descriptive to dynamic and integrative paradigms. While theoretical maturity is advancing, significant opportunities remain to expand contextual diversity, strengthen methodological rigor, and link readiness to measurable value creation. Overall, this synthesis positions AI readiness as a multi-level, evolving capability embedded within socio-technical and institutional systems, requiring continuous

adaptation to ensure responsible and sustainable digital transformation.

V. Conclusion

This systematic literature review synthesizes forty peer-reviewed studies published between 2015 and 2025 to examine how organizational readiness for Artificial Intelligence (AI) adoption is conceptualized within the Technology–Organization–Environment (TOE) framework. By consolidating fragmented readiness concepts into twelve core readiness themes across technological, organizational, and environmental dimensions, this study demonstrates that AI readiness constitutes a multidimensional, capability-oriented construct rather than a static precondition for adoption. The findings clarify the structural boundaries of organizational AI readiness and establish an integrated conceptual foundation to support future empirical research and readiness assessment initiatives.

Despite the systematic approach adopted in this review, several limitations should be acknowledged. The analysis was limited to English-language journal articles indexed in Scopus and relied on heterogeneous conceptualizations of readiness across the reviewed studies. In addition, the review focused on organizational-level readiness and did not examine post-adoption stages such as value realization. Future research may build on these findings by prioritizing longitudinal research designs, developing standardized readiness measurement models, and examining how organizational readiness translates into performance outcomes and sustained AI-enabled value.

Ultimately, this study reconceptualizes organizational AI readiness from a checklist of adoption prerequisites into an evolving and interdependent capability shaped by the alignment of technological, organizational, and environmental dimensions. This perspective provides a critical foundation for linking readiness assessment with strategic decision-making and long-term, responsible AI-driven transformation in complex organizational contexts.

Acknowledgment

This study benefited from the analytical and visualization assistance of OpenAI's ChatGPT (GPT-5), which was used to support literature synthesis, reference organization, and ensure narrative consistency and analytical clarity. All AI-assisted inputs were reviewed and validated by the author to ensure academic accuracy and integrity. All interpretations, analyses, and conclusions presented in this study remain solely the author's responsibility.

***Abstract*—Dentistry is a medical branch that diagnoses and treats oral diseases, helps maintain oral function, and improves oral aesthetics. Dental casts are three-dimensional models of a patient's oral tissues that can be used to study oral anatomy, assess occlusal relationships, and determine tooth alignment. Traditionally, they were made of gypsum, an impression material used to pour into the patient's mouth molds. Meanwhile, digital ones are three-dimensional models generated virtually using modern digital imaging and intraoral scanners. Unlike physical models, which require a lot of manual work and ample storage space, digital models can be produced rapidly, easily modified, and stored for long-term usage. In this study, we present Denta-RecGAN, a novel approach based on Generative Adversarial Networks (GANs) that maps a two-dimensional dental cast image into a volumetric latent space and projects it back into a two-dimensional output. The proposed approach employs a 2D encoder to process dental cast images as input, enabling the extraction of spatial features. The structural depth is modelled, and noise is suppressed using volumetric 3D latent space denoising models; a 2D decoder then reconstructs a high-quality image. The model is trained under an adversarial learning approach using the IO150K dataset. The proposed architecture achieved Mean Absolute Error (MAE) of 0.0128, 0.0127, 0.0128; Structural Similarity Index Measure (SSIM) of 0.9450, 0.9452, 0.9453; and Peak Signal-to-Noise Ratio (PSNR) of 28.84, 28.85, 28.84 decibels across training, validation, and testing sets. These results demonstrate the effectiveness of volumetric feature learning in enhancing the accuracy of 2D image reconstruction and preserving fine structural details.**

Keywords*—Dental image reconstruction; generative adversarial networks; latent space representation; two-dimensional to three-dimensional mapping; volumetric deep learning

I. Introduction

Orthodontists and prosthodontists use dental casts to detect oral diseases, determine the appropriate treatment for each patient, and help manufacture a precisely suitable appliance that is comfortable for patients. These casts are three-dimensional representations of the patient's oral structures, including teeth, gingiva, and other oral tissues. Dental casts can be physical or digital, depending on the method of creation [1]. These models can be used to demonstrate tooth alignment and to evaluate treatment results. The digital model can facilitate communication between dentists and dental laboratories that manufacture custom dental models for comfort [2].

In the past, dentists made dental casts using sticky materials called alginate or polyvinyl siloxane. They would place these materials in the patient's mouth to get the shape of the patient's teeth. Then they made an impression, called a stone model, by pouring plaster or resin into a mold [3]. Although widely used, this method can cause some problems. The materials may shrink or change shape, making it uncomfortable for the person taking the impression [4]. Physical models can break easily and take up a lot of space [5].

Digital technologies have replaced conventional stone models with virtual counterparts, enhancing precision and efficiency. Digital models help ensure measurements are accurate and reduce human mistakes [6]. They can use intraoral scanners, computed tomography (CT) scanners, or other imaging devices to produce detailed digital images that closely resemble real braces [7], [8]. These digital models can be seamlessly integrated into computer-aided design and manufacturing (CAD/CAM) workflows for the design of restorations, surgical guides, and orthodontic appliances [9]. However, high-end 3D scanners remain expensive and technically demanding, limiting their use in low-resource clinical environments [10].

With recent advances in artificial intelligence, particularly deep learning, there has been a growing interest in the use of neural networks for digital dental reconstruction models depending on utilizing Convolutional Neural Networks (CNNs) or employing transformers or using Generative Adversarial Networks (GANs) have shown high accuracy in reconstructing both dental and craniofacial structures from two-dimensional (2D) data [11],[12]. These methods enable the use of limited 2D inputs to infer both structural and volumetric depth, thereby reducing reliance on expensive 3D imaging systems.

This study proposes Denta-RecGAN, leveraging volumetric reasoning via a novel hybrid 2D-3D convolutional neural network designed to reconstruct 2D grayscale dental cast images. Volumetric reasoning is incorporated by combining three main components: a 2D encoder, a 3D latent space denoiser, and a 2D decoder. This combination allows us to capture both the spatial and structural relationships within the data. The spatial features were initially extracted from the input images using 2D convolutional layers, which were then reshaped into a 5D volumetric tensor, and the 3D convolutional layers were then processed together. The structural depth and inter-slice correlations were captured through the network at the volumetric processing stage. We look at flat (two-dimensional) images and

*Corresponding author.

understand their properties. Then we visualize them in three-dimensional space to enhance them. After that, we revert them to flat images, taking care to preserve their details.

This study demonstrates a new method for dentists to create better images of teeth and jaws. This method combines precise spatial reasoning (how three-dimensional objects occupy space) with two-dimensional photos (such as photographs or X-rays).

This research contributes to the growing field of AI-driven digital dentistry, without the need for complex scanning hardware. It also establishes a foundation for future applications, such as single-view 3D estimation, clinical maxillofacial reconstruction, and digital prosthesis design.

The evaluation of our proposed architecture (Denta-RecGAN) is performed using three standard quantitative metrics. The average deviation between a guess and the true answer was measured by the Mean Absolute Error (MAE). It considers all guesses, determines how different they are from the real numbers, ignores whether they are too high or too low, and then calculates the average of these differences, which measures perceptual similarity and is captured by calculating the Structural Similarity Index Measure (SSIM). To understand how sharp and detailed an image is after editing or modification, we used the peak signal-to-noise ratio (PSNR). Furthermore, the proposed network does not need explicit three-dimensional supervision, reducing dependence on complex 3D ground truth datasets, and it is capable of learning volumetric cues.

The remainder of our research is divided into the following sections: Section II provides an overview of current studies on two-dimensional-to-three-dimensional and the reverse reconstruction approaches. Then Section III explains how to train a computer. It covers data preparation, cleaning, computer training, setting training rules, and verifying mastery of the learning process. Section IV compares the proposed architecture with other relevant work. Section V presents the study's conclusions, and Section VI discusses potential directions for future research to improve the clinical accuracy of three-dimensional model reconstruction.

II. Literature Review

The main advantage of deep learning in maxillofacial prosthetics is the reconstruction of three-dimensional (3D) models from two-dimensional (2D) inputs, such as images or videos. Various deep learning architectures play an essential role in the medical domain, especially the dental one, which categorizes studies into sections. Some studies use Generative Adversarial Networks (GANs), transformers, and Convolutional Neural Networks (CNNs) as basic building blocks. The first section presents studies that focus on converting two-dimensional inputs into three-dimensional outputs, and the second section presents studies that concentrate on reverse reconstruction, converting three-dimensional input data into two-dimensional outputs:

A. Two-Dimensional (2D) -To-Three-Dimensional (3D) Reconstructions

Recently, deep neural networks have led to the emergence of 3D models or meshes from single-view two-dimensional (2D) images. We use these deep neural networks to generate 3D volumes from 2D images. However, these methods often require synthetic datasets and 3D supervision. X. Zhang et al. [13] used Convolutional Neural Networks (CNNs) by introducing PX2Tooth, which is a model that uses a one panoramic image to create a three-dimensional point cloud of a tooth. The proposed architecture consists of two fundamental stages. The first stage uses a single panoramic X-ray (PX) image to segment two permanent teeth. To enhance the generation quality, particularly in the root apex region, the Tooth Generation Network (TGNet) is utilized to create 3D teeth from point clouds. The authors also used a dataset that they created themselves. This dataset consists of 499 CBCT and panoramic X-ray pairs. They split their dataset into three subsets with an 8:1:1 ratio for training, validation, and testing, respectively. They achieved an intersection over union (IoU) of 0.793 with their model but could improve results by increasing reconstruction accuracy.

Many studies have reconstructed three-dimensional (3D) models using single or multiple 2D images. Fathallah et al. [14] used a model architecture based on Graph Convolutional Networks (GCNs) as a key component. A lightweight GCN-based discriminator was used to improve the accuracy. The authors used the 300 W-LP and AFLW2000-3D datasets for the evaluation. Their architecture is divided into two fundamental stages: preprocessing and three-dimensional reconstruction. First, the preprocessing stage reduces Noise and augments the data. Then, the three-dimensional reconstruction stage performs the following main functions: triangulation, running the GCN-IGAN model, and outputting the final three-dimensional facial mesh. Their model achieved 0.0075 and 0.120, representing the chamfer distance and earth mover's distance, respectively. Their model can be improved by adding additional features and using evolutionary algorithms. The need to employ evolutionary algorithms and integrate additional face features still limits the applicability of their model.

Chenfan Xu et al. [15] introduced a framework using Convolutional Neural Networks (CNNs) to reconstruct both the upper and lower teeth using five intraoral photographs per case. They used 3,200 cases for their approach, as they used 3,000,100 and 100 for training, validation, and testing, respectively. Their model achieved 18.85, 0.8347, 0.0114, 2.1126, 0.1670 and 0.4122 representing PSNR, SSIM, LPIPS, Hausdorff distance, chamfer distance, and Intersection over Union (IOU) respectively. Their model showed promising quantitative results and can be further improved by extracting low-level features, such as edges. Their model suffered from reduced precision and a long reconstruction process time.

X. Wang et al. [16] used Convolutional Neural Networks (CNNs) to focus on maxillary segmentation and defect refinement. They also created their own dataset using CBCT scans of 60 patients, including 39 males and 21 females, with an average age ranging between 11 and 52 years.

Their model achieved 0.92 ±0.01 and 0.77 ±0.06, representing the Dice Similarity Coefficients for the maxilla and the Dice Similarity Coefficients for the defect, respectively. These results show strong segmentation performance and a correlation between the defect parameters and the maxillary cleft side. This automatic segmentation requires orthodontic refinement, as it takes approximately 5 minutes per CBCT image.

Marek Wodzinski et al. [17] used Convolutional Neural Networks (CNNs) to develop a 3D printing pipeline for model cranial implants using a U-Net architecture to reconstruct defects and refine implants through iterative procedures. Their pipeline consisted of five stages: data loading, preprocessing, defect reconstruction, defect refinement, and 3D printing preparation. They used the SkullBreak, real cranial defect, and SkullFix datasets for evaluation. Their model achieved 0.91, 0.94, and 1.53 mm representing Dice Coefficient, Boundary Dice Coefficient, and 85th percentile Hausdorff Distance, respectively. Their model accurately reconstructed cranial defects, but they could further enhance it by integrating mixed reality, real defect data, and multiple implant reconstructions.

T. C. Niño-Sandoval et al. [18] employed a Procrustes fit on 55 tomographs to obtain the 3D mandibular shape, using convolutional neural networks (CNNs) to analyze the images. The software developers also collected 629 X-ray images to train the computer. When tested, the software performed exceptionally well at matching the photos, with error rates ranging from 0.0033 to 0.0059. These results showed that the model could infer the shape of the lower jaw. It has high accuracy, but it still faces challenges, including difficulty handling significant bone defects and extensive mandibular deformities.

Y. Liang et al. [19] designed an oral viewer as an educational tool with interactive 3D visualizations, using Convolutional Neural Networks (CNNs) and two-dimensional dental panoramic X-rays to reconstruct three-dimensional models of teeth, gums, and the jawbone. Their dataset was collected from patients at an orthodontic hospital and consisted of panoramic X-rays and cone-beam CT (CBCT) scans. Their model achieved an Intersection Over Union (IOU) of 0.771, representing reconstruction accuracy. The authors proposed several future methods to enhance their tool, including two approaches for modeling the root canal: augmenting existing solid tooth models with artificial canals and incorporating canal structures into the convolutional network training process, and adding additional virtual instruments to improve surgical simulation.

B. Three-Dimensional (3D) -To-Two-Dimensional (2D) Reconstructions

Autoencoders are used in image processing tasks, including image denoising, image compression, and generation. Variants of autoencoders, such as U-Nets and convolutional autoencoders, can preserve spatial details useful for medical imaging.

Some methods use volumetric or geometric reasoning for a three-dimensional (3D) shape. Our idea is to develop this technique by adding a special three-dimensional twisted block to a simple two-dimensional encryption and decryption process, making it more secure. Our approach builds on this idea, embedding a 3D convolutional block within a 2D encoder-decoder pipeline.

Melas-Kyriazi et al. [20] presented a novel method, called Projection-Conditioned Point Cloud Diffusion (PC2), for single-image three-dimensional reconstruction. The shapes can be represented as point clouds by their framework. They started with a collection of tiny dots floating in space, which came together to form a three-dimensional shape, much like a jigsaw puzzle. First, they cleaned the dots to ensure their accuracy. Then, they examined small parts of the image to make sure everything looked correct, which helped them build a better three-dimensional model. They also guessed the proper colors for the dots to make the model look more realistic. Sometimes, they created several possible shapes and used a special method to choose the best one. Their method proved more successful than others, and their model showed qualitative improvements on real-world datasets such as Co3D. However, their method depends on ground-truth point clouds for training. The reconstruction quality can be affected because multi-view methods, like COLMAP, can be noisy and incomplete in real-world scenarios.

Peng et al. [21] introduced a graph-based framework for detecting changes in buildings using bitemporal remote sensing images. The spatial dependencies between neighboring buildings and the temporal relationships between image pairs are modelled using spatial–temporal graph neural networks (ST-GNNs). They constructed a graph by representing building instances as nodes and the contextual relationships as edges. Their method of tracking building changes was superior to other methods that relied on analyzing small image fragments. It was more accurate when using numerous city images and more effective in complex urban areas where buildings overlap or are constructed in unusual ways. However, their model suffers from a significant limitation: dependence on accurate building footprint extraction. A preprocessing step error can negatively affect detection performance, and any mistake in footprint delineation can be propagated during graph construction.

C. Generative Adversarial Networks-Based Architecture in Dental Imaging

Toscano et al. [22] proposed a hybrid point cloud completion framework for dental molds that integrates symmetry-based data augmentation, iterative latent-space GANs, and a hybrid AE-RL GAN completion strategy. The dataset consisted of 45-point clouds of real lower-jaw teeth. This dataset is downsampled to 2048 points. These training data were expanded using mirroring and point cloud recombination. It also expanded using iterative IGAN augmentation, yielding 49 additional high-quality samples. They used Chamfer Distance (CD) as a metric. This metric showed the importance of each module, as after removing data filtering, the average Chamfer Distance increased by 38.34%. The Chamfer Distance increases by 43.20% after removing iterative I-GAN augmentation. Then, it increased by 13.42% after removing the RL-GAN module, and then increased by 5.34% after removing hybrid selection. The increasing Chamfer Distance indicates a reduction in geometric error, particularly in high-missing-rate scenarios. This approach still suffers from an inability to generalize to non-symmetric anatomical structures. It also suffers from being computationally expensive and still depends on bilateral symmetry assumptions.

Kim et al. [23] proposed a GAN-based framework. It can enhance the accuracy of tooth segmentation, especially in full-arch intraoral scans that are affected by occlusal artifacts. Their framework contains 3 main steps. The first step is to manually remove the occluded interdental regions from the 3D scan data. The second step is to slice the cleaned scan at 0.1 mm intervals, then complete the 2D image using an Edge Connect-based GAN. The third step is to reconstruct the missing 3D geometry by stacking and remeshing the completed slices. They used a dataset of intraoral scans from 10 orthodontic patients acquired with a Trios 3 scanner. The ground truth is generated by a technician. The dataset consists of 10,000 cropped 256 X 256 images. They achieved 0.921 and 26.68 Db representing SSIM and PSNR, respectively. In tooth segmentation evaluation, their model achieved 0.027 ± 0.007 mm, representing the average mean surface distance. Previous boundary- and region-based segmentation methods suffer from inaccuracies due to occlusions. However, their approach reconstructs the missing interdental geometry while reducing operator dependency. However, their model incurs a high computational cost due to manual mask detection. Generalization is limited, especially in severe occlusion patterns.

Minhas et al. [24] proposed a deep learning-based framework for 3D reconstruction from a single 2D panoramic X-ray to assess maxillary impacted canines. They proposed a GAN-based architecture (Pan2CBCT) derived from X2CT-GAN, which expands 2D panoramic images into pseudo-3D volumetric images. They used a dataset comprising 123 pre-treatment CBCT scans of individuals aged 11-18 years. The 2D panoramic X-rays with their pseudo-3D images. The distribution of impacted canines is divided into 36, 12, 26, 65, and 9, representing buccal, middle, lingual, mesial, and distal cases, respectively. Their model achieved 0.71, 41%, and 55% for mean SSIM, accuracy of buccal/middle/lingual position, and accuracy of mesial/distal position, respectively. The previous related work clinically ignores complex cases, as impacted canines are evaluated. Their SSIM values indicate insufficient reliability for orthodontic diagnosis. However, their model suffers from several limitations. The first limitation is the use of a small, imbalanced dataset. Another limitation is that it depends on a single image modality. The third limitation is the decrease in performance in lingual positions.

Galba et al. [25] proposed HoloDent3D, a dental imaging system that uses single-view panoramic radiographs for 3D reconstruction. The first stage is to acquire and preprocess the standard orthopantomogram (OPG) to optimize the input image. In the second stage, the reconstruction module is trained on large datasets of paired 2D radiographs and corresponding 3D jaw models, inferring a volumetric mesh of teeth, roots, and bone. The third stage involves rendering a high-speed LED holographic fan display with gesture control, enabling visualization of multi-angle anatomy. Their model achieved volumetric Intersection Over Union (IOU) values ranging from 0.65 to 0.79, showing an n improvement over earlier voxel-based approaches such as X2Teeth. However, HolodENT3D remains at a theoretical stage and faces challenges, including a lack of paired 2D-3D training datasets, variability in generalization across patients, and no clinical validation.

III. Methodology

This section explains the full methodology implemented in TensorFlow/Keras for grayscale image reconstruction using a 2D encoder, a 3D latent space denoiser, and a 2D decoder, trained under an adversarial framework. The methodology of this study was divided into six main phases: dataset preparation, data pipeline, model architecture, training strategy, and evaluation metrics.

A. Data Preparation

Using the IO150K dataset [22], the dataset consisted of single-channel (grayscale) images. It is a publicly available dataset of 2D intraoral images that can be used for different purposes, such as instance segmentation and semantic labeling. The dataset includes over 150,000 2D intraoral images. It consists of 3 subsets: challenge80k, plaster 70k images, and rendered 2D images generated from 1800 3D intraoral scans. Its main source is the 3D Teeth Segmentation and Labeling Challenge 2023. The data acquisition methods for the challenge, which generate 3D dental scans, project them into multiple 2D views. Plaster 70k images are collected by photographing real dental plaster casts, thereby capturing realistic tooth morphology, including spacing, crowding, and missing teeth. Clinical RGB photography is acquired using DCLR or mobile cameras, with reflections. Preprocessing steps are performed on the dataset, including standardization, patch embedding preparation, foreground-background separation, localization, segmentation, and labeling. All the photos were set to a fixed spatial resolution of 128 * 128 pixels. Image files were collected recursively with valid extensions (.jpg, .jpeg, .png) and then shuffled. The dataset was divided into 70%, 10%, and 20% for the training, validation, and test sets, respectively. The weights are updated using the training subset, while the validation subset is used to refine hyperparameters and determine when to stop training. The test subset is then used to assess the model's final performance. Table I describes the dataset's distribution.

TABLE I. Dataset Splits for Training, Validation, and Testing

Subset	Number of images	Percentage
Training Set	49612	70%
Validation Set	7087	10%
Testing Set	14176	20%

B. Data Pipeline

Images were read from the disk and decoded into single-channel tensors; each image was then resized to 128 x 128 pixels. Normalization is applied to stabilize gradients during optimization. Normalization was also used, as pixel intensities are scaled to [0,1]. The dataset then maps each image to an (input, target) tuple. The training data were shuffled, and batched prefetching is used as an asynchronous prefetch that overlaps I/O with GPU computing.

C. Model Architecture

The proposed framework is a hybrid encoder–decoder system that integrates 2D and 3D learning in a generative adversarial setting. Our architecture comprises three main components for several reasons. The procedure starts with the encoder

receiving a black-and-white photograph of teeth, which is examined to pinpoint key details, such as edges and lines.

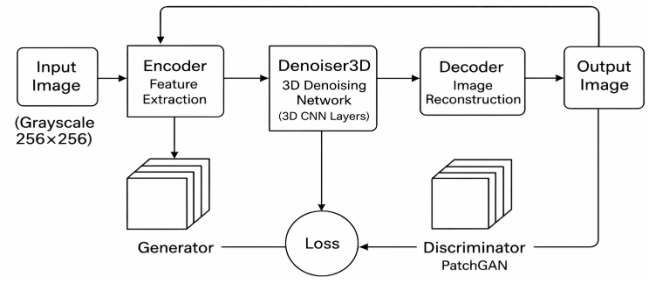

Fig. 1. This is a general overview of the proposed model.

Fig. 1 shows the overall architecture, including the 2D encoder, 3D latent-space denoiser, and 2D decoder, as well as the adversarial training loop that improves reconstruction accuracy while preserving dental structural details. Fig. 2 to Fig. 4 illustrate the detailed network architectures of the proposed framework. Fig. 2 presents the 2D encoder, which progressively downsamples the input grayscale dental image to a compact latent representation. Fig. 3 depicts the 3D latent-space denoiser, which operates on the reshaped volumetric latent representation to model inter-slice dependencies and suppress latent noise. Fig. 4 shows the 2D decoder, which reconstructs the final image by gradually restoring spatial resolution through transposed convolutions. Together, these components form an end-to-end pipeline for robust dental image reconstruction. Let $x \in R^{H\,x\,W}$ denote an input grayscale dental image with H = W = 128. The 2D encoder $E_\theta(.)$, implemented using convolutional layers, extracts hierarchical spatial features from the input image and maps it to a compact latent representation, as in:

$$Z_{2D}=E_\theta(x) \qquad ,Z_{2D} \in R^{h\,x\,w\,x\,c} \tag{1}$$

To enable volumetric reasoning without requiring explicit 3D input data, the 2D latent representation is reshaped and expanded along a depth dimension to form a volumetric latent tensor, as in:

$$Z_{3D} = \mathcal{R}(Z_{2D}),Z_{3D} \in R^{d\,x\,h\,x\,w\,x\,\acute{c}} \tag{2}$$

A 3D latent-space denoiser $N_\varphi(.)$, composed of 3D convolutional operations, is applied to the volumetric latent tensor to suppress noise and enforce inter-slice consistency, as in:

$$\tilde{z}_{3D} = N_\psi(Z_{3D}) \tag{3}$$

The denoised volumetric representation is then collapsed and decoded back into the image domain using a 2D decoder $G_{w(.)}$, as in:

$$\hat{x} = G_w(\tilde{z}_{3D}) \tag{4}$$

where, $\hat{x} \in R^{H\,x\,W}$ denotes the reconstructed dental image. The discriminator receives both real dental images and reconstructed outputs, providing adversarial feedback that encourages perceptually realistic and structurally accurate reconstructions.

We enhanced our architecture, discarding any noise and unwanted distortion. The decoder module further improves image quality. Both authentic dental images and the generator's outputs serve as inputs to the discriminator architecture. The generator is motivated to produce increasingly compelling visual and numerical reconstructions by receiving adversarial feedback. To create more transparent, more realistic images, the denoiser module works in tandem with the main architecture to remove noise and minor imperfections.

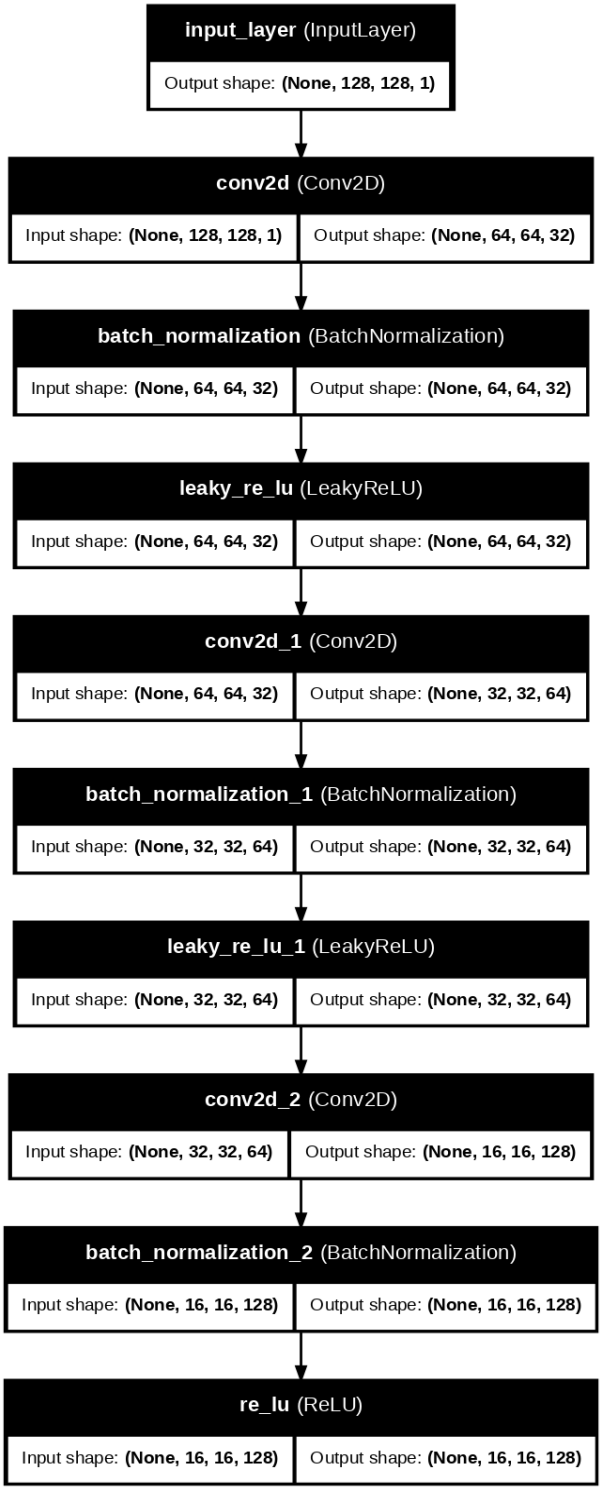

Fig. 2. This is a 2D encoder architecture for extracting a compact latent representation from a grayscale input image.

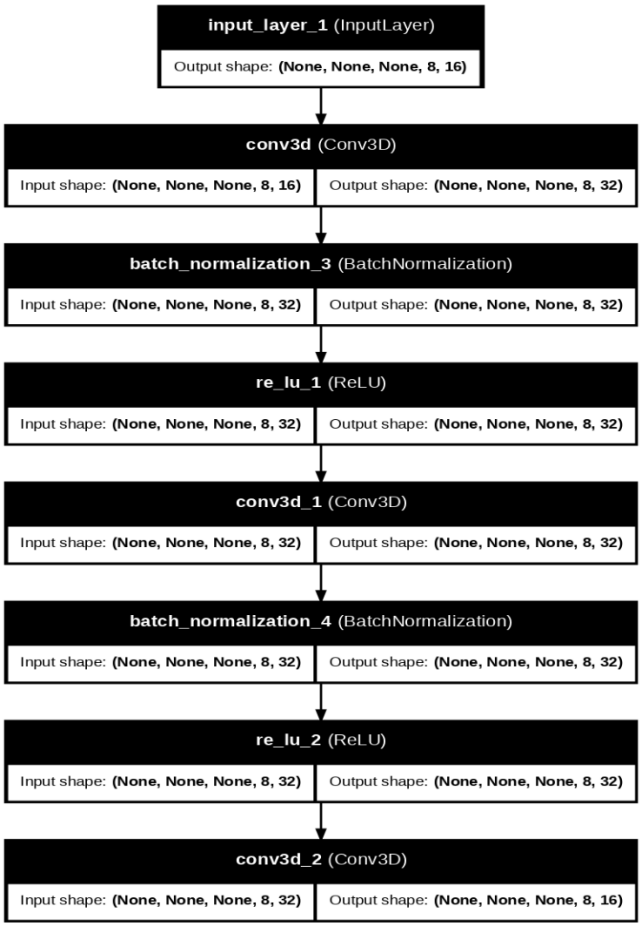

Fig. 3. This is a 3D latent-space denoiser operating on the reshaped volumetric latent representation.

D. Training Strategy

All experiments were conducted on the Kaggle platform. Training the proposed model on the IO150K dataset for 50 epochs with a batch size of 8 required approximately 2 hours, 58 minutes, and 58 seconds using two NVIDIA Tesla T4 GPUs. Training time and inference speed were empirically measured on the same hardware. Inference was evaluated by timing end-to-end forward passes with a batch size of 1, yielding an average latency of 3.41 ms per image (or 27.29 ms per batch), demonstrating near–real-time performance suitable for practical deployment.

Both accuracy and efficiency are balanced during training. Overfitting is also prevented during training. Table II lists the training hyperparameters used in our work.

The primary reconstruction loss function is the Mean Absolute Error (MAE). It was chosen for its robustness in penalizing deviations between the result produced by the architecture and the actual target output.

We used the Adam optimizer in our architecture because it can adapt the learning rate. A dynamically adaptable learning rate. Batch size carefully balances GPU memory constraints and convergence speed; smaller batch sizes enhance generalization capabilities, while larger batches may speed up training but sometimes compromise model robustness.

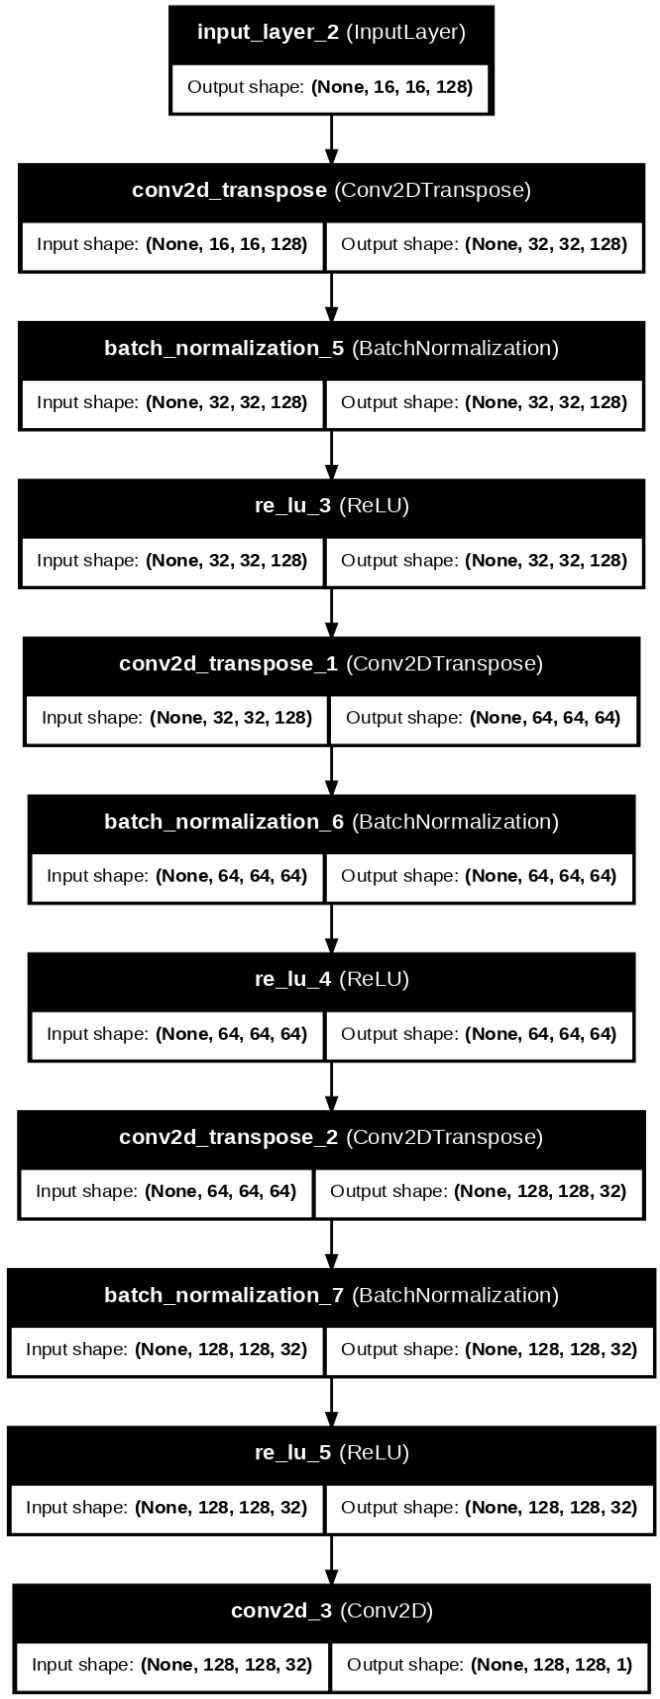

Fig. 4. This is a 2D decoder architecture for reconstructing the output image from the denoised latent features.

TABLE II. HYPERPARAMETERS USED FOR TRAINING THE GAN-BASED DENTAL IMAGE RECONSTRUCTION MODEL STYLES

Hyperparameter	Value
Input image size	128x128(grayscale)
Batch size	8
Epochs(max)	50
Optimizer	Adam
Initial learning rate	2×10^{-4}
Learning Rate Reduction	Factor 0.5 on plateau
Min Learning Rate	1×10^{-6}
Early Stopping Patience	8 epochs (val MAE)
Train/Val/Test split	70%/10%/20%
Latent volume Depth	8 slices
Random seed	42
Base channels(encoder/decoder)	32

Early stopping was performed to avoid overfitting. The training was halted once the validation loss stopped improving after a predefined number of epochs. This strategy prevents unnecessary over-training and ensures computational efficiency.

IV. DISCUSSION AND EVALUATION

In the standard model, the choice of evaluation metrics is crucial for assessing model effectiveness by measuring pixel-level accuracy and perceptual visual similarity, thereby ensuring a comprehensive evaluation of quantitative performance and visual quality.

The first evaluation metric quantifies the average difference between the reconstructed and original images. This difference is measured by the Mean Absolute Error (MAE) metric. This metric helps capture the overall pixel-level accuracy. The second metric is the Structural Similarity Index (SSIM), which measures perceptual similarity by considering the contrast, luminance, and structural information between two images. The SSIM aligns more closely with human visual perception. Peak Signal-to-Noise Ratio (PSNR), serving as the third evaluation metric, quantifies reconstruction fidelity as the ratio of the maximum signal power to the generated noise power during reconstruction. This measures the ratio between the maximum possible signal power and the power of the reconstruction noise, expressed in decibels.

Table III summarizes the three key performance indicators. The results are presented in Table IV, which lists the metrics for training, validation, and testing. Table IV shows results that may appear similar at first glance but, upon closer inspection of the numerical values, reveal small but consistent differences across the three splits. Specifically, MAE values vary between 0.0127 and 0.0128, the SSIM values increase slightly from 0.9450 (training) to 0.9453 (testing), and PSNR values range from 28.8430 dB to 28.8595 dB, so the variations occur at the third and fourth decimal places and may appear identical when rounded, but they confirm that the results are not exactly the same. The dataset was partitioned into non-overlapping subsets prior to training, so no data leakage occurred during either training or evaluation. Moreover, the close alignment between the training and validation MAE curves in Fig. 5 indicates stable learning behavior without divergence, as the model generalizes well, rather than overfitting to the training data. Fig. 5 shows the mean absolute error curves obtained during training and validation. These curves show how the model's prediction error evolves over epochs. The decreasing trend in the training curve indicates the model's ability to learn from the training data, while the validation curve shows the model's generalization performance on unseen data. These two curves are compared to assess the potential overfitting or underfitting.

TABLE III. EVALUATION METRICS USED FOR ASSESSING THE GAN-BASED DENTAL IMAGE RECONSTRUCTION

Metric	Range	Interpretation
MAE	[0, ∞)	Lower is better (0 = perfect reconstruction)
SSIM	[0, 1]	Higher is better (1 = perfect perceptual match)
PSNR	(0, ∞) decibels	Higher is better (≥30 decibels = high-quality image)

TABLE IV. EVALUATING PERFORMANCE METRICS OF THE GAN-BASED DENTAL IMAGE RECONSTRUCTION MODEL ON TRAIN, VALIDATION, AND TEST SETS

Set	MAE	SSIM	PSNR
Train	0.0128	0.9450	28.844700 decibels
Validation	0.0127	0.9452	28.859501 decibels
Test	0.0128	0.9453	28.843000 decibels

Fig. 6 to Fig. 10 illustrate various key aspects of the study. It presents quantitative evaluation metrics, including the Structural Similarity Index Measure (SSIM) and Peak Signal-to-Noise Ratio (PSNR), used to assess the quality and fidelity of the reconstructed images. These figures highlight interactions and contributions of the main components of the proposed architecture involving the generator, discriminator, and noise module, so by combining these architectural elements and performance metrics. These figures offer a comprehensive overview of the system's effectiveness in achieving high-quality image reconstruction.

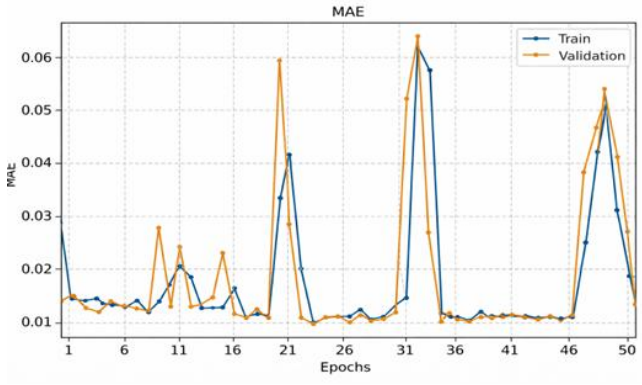

Fig. 5. The two curves represent mean absolute error results during training and validation.

The proposed 2D-to-3D denoising GAN achieved strong reconstruction performance, with average scores of MAE=0.0128, SSIM=0.9453, and PSNR=28.84 dB on the test

set. The reconstruction of grayscale dental casts demonstrates accuracy and high structural similarity. There are three figures, namely Fig. 11, Fig. 12, and Fig. 13, representing the input image, the generated output image, and the latent 3D mesh, respectively, at the last epoch (50) after training. Specifically, Fig. 11 shows the original input image used by the model, providing a reference for comparison. Fig. 12 shows the model's output image, demonstrating its reconstruction effectiveness. Finally, Fig. 13 shows the network's learned latent 3D mesh representation, which encodes internal 3D features. These figures present a visual summary of the system's performance, showing the quality of the generated images and the underlying structure of the latent 3D representations after full training.

Compared to existing studies, the proposed framework exhibits competitive advantages. Li et al. [27] developed a U-CPML-Net for 3D lung image reconstruction based on CT-pixel-matrix learning and electrical impedance tomography. Their method achieved SSIM values between 0.80 and 0.85, depending on the case complexity. In contrast, the proposed framework produced higher SSIM values and lower MAE values, suggesting that volumetric reasoning integrated into a 2D-to-3D pipeline can outperform conventional matrix learning–based strategies in terms of structural fidelity.

Tan et al. [28] presented an Edge-Aware Reconstruction (EAR) network for reconstructing 3D vertebral structures from biplanar X-ray images. Their method improved edge and local structural detail detection by integrating two modules into the autoencoder, which serves as the backbone of their architecture. A combination of four loss terms—reconstruction, edge, frequency, and projection losses were used to guide the training process. The EAR was evaluated on three public datasets and compared against four cutting-edge methods, demonstrating improvements of 25.32%, 15.32%, 86.44%, 80.13%, 23.76%, and 0.30% in MSE, MAE, Dice, SSIM, PSNR, and frequency distance, respectively. Although this approach effectively improved edge preservation, challenges remain due to information loss from X-ray projection processes, particularly in maintaining. Asymmetrical vertebral structures. Compared with EAR, the proposed denoising GAN focuses less on edge-aware reconstruction but achieves a higher SSIM (0.943) and stable PSNR. Volumetric features effectively compensate for the limitations inherent in projection-based approaches in imaging and analysis. Tables V and VI present the results of other papers and compare them with those of our study, respectively.

TABLE V. SUMMARY OF RELATED WORKS AND THEIR RESULTS

Paper	Work	Results
Li et al. [27]	Developed U-CPML-Net for 3D lung image reconstruction based on CT pixel matrices learning with electrical impedance tomography.	Their method achieved SSIM values between 0.80 and 0.85, depending on case complexity.
Tan et al. [28]	Presented the Edge-Aware Reconstruction (EAR) network for reconstructing 3D vertebrae structures from bi-planar X-ray images.	EAR was evaluated on three publicly available datasets and compared against four state-of-the-art methods, demonstrating improvements of 25.32%, 15.32%, 86.44%, 80.13%, 23.76%, and 0.30% with respect to MSE, MAE, Dice, SSIM, PSNR, and frequency distance, respectively.

TABLE VI. COMPARISON OF THE PROPOSED GAN-BASED DENTAL IMAGE RECONSTRUCTION MODEL WITH RESULTS FROM RELATED WORKS

V. CONCLUSION

This study presented a two-dimensional-to-three-dimensional denoising generative adversarial network designed to improve the quality of reconstruction, to address the limitations in grayscale image reconstruction of traditional 2D models by incorporating volumetric reasoning within the latent space. We capture both spatial and structural relationships by integrating three main components: a 2D encoder, a 3D denoising block, and a 2D decoder. These spatial and structural relationships exist across the different feature depths. The key advantages of this architecture are a computationally lightweight design and the ability to learn complex spatial dependencies. These advantages make it suitable for medical applications, especially in dentistry. Another key contribution of this study is its adaptable training strategy, which balances between three perspectives: reconstruction accuracy, efficiency, and stability. The model's design enables easy integration with other architectures, allowing extensions to multimodal data. This method can also be widely used, such as for larger image resolutions and domain-specific adaptations. In addition, the adversarial training paradigm can generalize to unseen samples by using a generator that produces structurally consistent outputs under discriminator supervision.

Overall, this study highlights directions for the digital reconstruction of dental cast images in clinical imaging. By integrating advanced volumetric and two-dimensional techniques, it offers promising applications in diagnostic procedures, tissue repair, and various medical interventions. These innovative approaches aim to enhance accuracy, improve patient outcomes, and advance the overall capabilities of modern medical imaging technologies.

VI. FUTURE WORK

Several directions can be pursued to expand the two-dimensional-to-three-dimensional generative adversarial network further. A future perspective is to use multiple input datasets simultaneously to improve resolution and achieve generalization by training across a variety of datasets.

Another promising enhancement is to integrate different ways of focusing attention, such as visual space or channels, which also works well with communication systems. This improves overall accuracy and helps build stronger, more efficient structures.

Another direction is to explore more appropriate loss functions. Perceptual or feature-based losses can be combined with conventional objectives. This combination can lead to a better balance between structural accuracy and perceptual realism.

These directions highlight a future pathway for advancing image reconstruction by pushing the boundaries of hybrid 2D-to-3D-to-2D learning strategies.

Future studies can use adaptive strategies to determine the depth. This depth may be adapted to the complexity of the input, which leads to more effective feature representations while maintaining computational efficiency. The precision of the anatomical structures and texture representation can be improved by refining the denoising process.

This approach shows promise for advancing image restoration methods in fields such as medical imaging, dental diagnosis, industrial inspection, and others where both accuracy and perceptual quality are critical. It can also be extended to real-world applications.

ACKNOWLEDGMENT

The authors acknowledge the use of the IO150K intraoral image dataset, introduced in the Teeth-SEG study, for supporting the development and evaluation of this work. We thank the dataset creators for making this resource openly available [26].

Selfdom Enhanced CatBoost Model for Remote Paddy Growth Monitoring and Fertilizer Recommendation in Precision Agriculture

Shanmuga Priya S, Dr. V. Dhilip Kumar
Department of Computer Science and Engineering,
Vel Tech Rangarajan Dr. Sagunthala R & D Institute of Science and Technology, Chennai, India

***Abstract*—Precision agriculture enables data-driven crop monitoring and improved resource utilization. Paddy cultivation requires continuous surveillance and timely fertilizer application because it is sensitive to soil nutrient dynamics, water availability, and climatic conditions. Conventional practices such as manual field inspection and heuristic fertilizer advisory methods are often labor-intensive and subjective, which can reduce decision consistency and contribute to yield variability. To address these limitations, this study proposes a Selfdom Enhanced CatBoost (SECB) framework for remote paddy growth-stage monitoring and fertilizer recommendation. Multispectral remote sensing data collected over multiple seasons are used to compute vegetation indices, including NDVI, GNDVI, RVI, GRVI, and NDRE, to characterize crop vigor and chlorophyll-related variation across growth stages. The proposed SECB improves CatBoost by integrating an Improved Osprey Optimization Algorithm (IOOA) to tune key model parameters, aiming to enhance feature interaction learning and reduce overfitting. In addition, oppositional function-based initialization is applied to improve the exploration capability of IOOA and accelerate convergence. Experimental results show that SECB achieves improved performance over baseline classifiers in terms of accuracy, precision, F1-score, specificity, and AUC. The proposed approach provides reliable growth-stage identification and supports fertilizer recommendations to promote efficient nutrient usage and improved productivity. Overall, the framework offers an automated and scalable decision-support strategy for paddy crop management.**

Keywords*—Paddy growth monitoring; fertilizer recommendation; Selfdom Enhanced CatBoost Model; Osprey Optimization Algorithm; oppositional function

I. Introduction

Paddy is one of the most important cereal crops sustaining the global population, particularly across Asia, where it forms a staple diet for millions [1]. India has the largest area under rice cultivation (approx. 42.5 million hectares); however, national productivity remains lower than that of several leading rice-producing countries. Although India produces about 152.6 million tons of rice annually, the average yield per hectare is notably lower than China [2]. This productivity gap is influenced by climatic vulnerability and regional differences in cultivation practices, including irrigation methods, nutrient management, and tillage operations [3]. Moreover, yield heterogeneity is evident across regions, with approximately 348 districts reporting production below the national average, which constrains aggregate output.

Kerala, despite being a traditional rice-growing state, currently cultivates rice on about 0.197 million hectares, which accounts for approximately 7.6% of its cultivated land. Nevertheless, rice constitutes a major share of the state's food-crop acreage, highlighting its continued regional relevance. Among the key agronomic determinants, fertilizer management plays a central role in rice growth and yield formation [4]. In practice, farmers often rely on experiential knowledge to schedule fertilization, which increases the risk of nutrient mismanagement [5]. Over-application can increase pest incidence and lodging, reduce grain weight, and cause environmental impacts such as soil degradation and nutrient runoff into water bodies [6].

In this context, precision agriculture provides a practical pathway to optimize input use while improving productivity. Recent advances in satellite imagery, Unmanned Aerial Vehicles (UAVs), multispectral sensors, and cloud-based analytics have improved agricultural monitoring and decision-making [7, 8]. Remote sensing platforms capture canopy reflectance and spectral indicators of vegetation health, which can be processed to generate location-specific recommendations.

Crop growth models have been used to simulate plant responses to environmental conditions using soil, weather, and physiological inputs. However, large-scale deployment remains challenging due to manual data requirements and complex variable interactions. Consequently, recent work increasingly adopts machine learning (ML) methods to capture nonlinear crop behavior and improve growth and nutrient prediction accuracy [9]. Techniques such as k-Nearest Neighbors (kNN), Random Forest (RF), Linear Regression (LR), and CatBoost have shown potential for estimating rice growth stages and nutrient requirements [10, 11]. Based on these advances, this study proposes a Selfdom Enhanced CatBoost (SECB) model that integrates remote sensing–derived vegetation indices with an optimization strategy to support growth-stage monitoring and fertilizer recommendation.

Although vegetation indices and boosted-tree models have been used for crop monitoring, many existing studies address growth-stage assessment and fertilizer recommendation as separate tasks, and often rely on manually tuned learners or site-specific calibration. The proposed SECB framework is distinct in that it couples multi-season multispectral vegetation-index dynamics with an optimization-guided CatBoost learning strategy, enabling joint growth-stage monitoring and fertilizer recommendation within a single predictive pipeline. In particular, IOOA is employed to automatically tune key CatBoost hyperparameters to aim for improved robustness under seasonal variability, thereby reducing dependence on trial-and-error parameter selection. This optimization-driven design differentiates SECB from conventional CatBoost or index-threshold approaches and provides a practical decision-support mechanism for precision paddy management. The main contributions of the research are presented as follows:

- To propose a unified SECB pipeline that performs both paddy growth-stage classification and fertilizer recommendation using multispectral vegetation indices computed from remote sensing imagery, thereby linking crop-condition monitoring with actionable nutrient decisions in a single workflow.
- To integrate IOOA as a hyperparameter optimization module for CatBoost, improving convergence stability and reducing manual tuning under multi-season spectral variability, which enhances model reliability and supports scalable deployment across changing field conditions.
- To validate the proposed SECB model against conventional ML baselines using accuracy, precision, F1-score, specificity, and AUC, so that performance improvements translate into fewer false fertilizer alerts and fewer missed nutrient-deficiency cases, promoting efficient input use and sustainable paddy management.

The rest of this study is structured as follows: Section II presents a concise review of recent studies related to paddy growth monitoring and fertilizer recommendation, while Section III outlines the methodologies used for paddy growth monitoring and fertilizer recommendation. Section IV reports the results, and Section V presents the conclusion of the study along with possible directions for future research.

II. Related Works

Sah et al. [12] proposed a UAV-based vegetation index framework to monitor paddy development and fertilizer effects across two planting seasons in Malaysia. High-resolution multispectral UAV imagery was processed (Agisoft Metashape) to derive NDVI, BNDVI, and NDRE at key stages (tillering, flowering, and ripening). NDRE achieved the strongest yield relationship ($R^2 = 0.842$), while NDVI and BNDVI showed high similarity and reduced sensitivity in dense canopies, indicating saturation effects in mature fields. The authors also reported that plot size alone did not guarantee higher yield because environmental factors and fertilizer management had a substantial influence. However, the framework relied heavily on UAV data and site-specific conditions, limiting transferability without broader regional calibration.

Zhao et al. [13] incorporated a conventional crop growth metric, Relative Growth Rate (RGR), into remote sensing–based rice yield estimation. The study used satellite-derived variables (RGR, NDVI, EVI, SAVI, NDWI, DVI, RVI, GPP, and LAI) together with climatic and soil features, and evaluated LASSO, Random Forest, and XGBoost using five-fold cross-validation. The RGR-integrated model reported the best performance ($R^2 \approx 0.78$; RMSE $\approx$ 719.63 kg/ha), and demonstrated spatial adaptability as well as within-season predictive capability up to 16 days before maturity. A key limitation was reduced accuracy during extreme climatic years, suggesting sensitivity to unusual environmental conditions.

Chiranjit Singha et al. [14] developed a Google Earth Engine–based machine learning workflow for monitoring rainfed rice growth using Sentinel-1 SAR data, addressing the difficulty of optical monitoring under persistent cloud cover. The approach was validated on 214 farm plots in Hooghly, West Bengal, India, where Random Forest produced strong biomass estimation performance ($R^2 = 0.87$). The analysis indicated that heading-stage NDVI and SAR backscatter were strongly associated, supporting SAR suitability for rainfed rice monitoring. Fubing Liao et al. [15] proposed a hybrid deep learning model combining CNN and LSTM with attention to diagnose rice nutritional status at the early panicle initiation stage, using sequential UAV imagery collected over two years. These works highlight that SAR and UAV time-series data can enable robust monitoring, yet require stable data acquisition pipelines and careful generalization assessment across seasons and sites.

Guo et al. [16] introduced a rice paddy classification framework using multitemporal compact polarimetric (CP) C-band SAR data and machine learning. Seven RADARSAT-2 acquisitions were used to simulate CP observations, and 22 polarimetric features were extracted and enhanced through temporal-variation analysis. Across multiple classifiers, incorporating temporal dynamics improved mapping performance, and overall accuracies exceeded 95%, with Random Forest and SVM providing the best results. Wang et al. [17] further demonstrated high-resolution paddy rice mapping in Northeast China by combining automatically generated training samples, time-series Sentinel-2 features, and a deep neural network classifier. Using 10 m surface reflectance bands and vegetation-index composites across major phenological stages, the model achieved high annual mapping accuracy and improved discrimination between rice, wetlands, and drylands, while also detecting small paddy patches and policy-driven area reduction. Nevertheless, uneven image quality, sparse observations, and uncertainties inherited from reference land-cover products were reported as constraints on cross-region transferability.

Li et al. [18] proposed a hyperspectral satellite–based rice growth monitoring approach using a 3D CNN to jointly learn spatial–temporal–spectral representations from multi-temporal image cubes. A temporal convolution module, followed by 2D convolutions and fully connected layers, was used for yield prediction, and the method exhibited improved accuracy and stability compared with deep learning baselines. However, heterogeneous cultivation patterns and complex terrain conditions remained challenging for robust deployment.

Sudarsan Biswal et al. [19] examined UAV multispectral imagery for above-ground biomass (AGB) prediction by combining spectral vegetation indices with textural descriptors. The study found that NIR-based indices outperformed color-only indices, and normalized difference texture indices (NDTIs) derived from NIR, red-edge, and blue bands consistently improved performance compared with GLCM textures. Random Forest yielded the best predictions when vegetation indices were fused with NDTIs, emphasizing the value of multi-feature fusion for rice biomass estimation.

Parijata Majumdar et al. [20] addressed irrigation water requirement (IWR) prediction by selecting high-scoring environmental features and using ensemble learning strategies. The work highlighted evapotranspiration as a key predictor across growth stages and employed stacked learning with tuned models to improve predictive accuracy. Wang et al. [21] investigated an automatic fertilization system to evaluate fertilizer distribution uniformity under flooded and non-flooded conditions. Using the Christiansen Uniformity Coefficient (CU), the non-flooded automatic fertilization setting achieved the highest uniformity and outperformed farmer-applied manual fertilization, although the method's effectiveness depended strongly on specific field-water conditions and may require adaptation for different agro-ecological settings.

Boonma et al. [22] assessed rice growth stage and yield estimation using Sentinel-2 MSI and Sentinel-1 SAR data within Google Earth Engine, supported by field surveys and stratified sample points. The study reported moderate-to-strong agreement for growth-stage modeling (e.g., R^2 up to 0.67 with Kappa 0.80), and emphasized the practical role of SAR during rainy seasons when optical images are degraded by cloud interference. However, limited usable Sentinel-2 scenes and seasonal sensitivity constrained generalization and reduced the benefits of optical–SAR fusion. Xiaolong Chen et al. [23] developed a multi-source nutrient monitoring and precision fertilization system integrating UAV multispectral imagery, thermal sensing, ground sensors, and GIS visualization. Across multiple agro-ecological sites, the system reduced nutrient estimation errors and lowered fertilizer usage while increasing yield, but scalability was limited by UAV endurance, data volume, and computational demands.

Carracelas et al. [24] evaluated vegetation indices for monitoring nitrogen uptake in rice under continuous flooding and alternate wetting and drying irrigation schemes. The SCCCI index showed the strongest predictive relationship with nitrogen uptake (R^2 up to 0.84 under continuous flooding and 0.71 under alternate wetting and drying), while also demonstrating that surface water conditions can alter reflectance behavior and index reliability. This irrigation-dependent variability limits direct transfer of models between water-management regimes and motivates broader multi-site validation.

Bingnan Chen et al. [25] proposed a UAV-based nutrient deficiency classification framework for ratoon rice by fusing vegetation indices with deep image features extracted from visible-band imagery. Classifiers such as XGBoost, SVM, and Random Forest benefited from feature fusion, and Random Forest achieved the best nutrient classification results, though the experiments were restricted to a single ecological site and limited varieties. Herath et al. [26] similarly used UAV multispectral imagery for paddy decision support, reporting strong NDVI–yield correlations and effective weed detection using vegetation-index formulations at specific days after sowing. However, frequent UAV flights, image-quality dependence, and operational costs remained practical constraints for large-scale adoption.

Huang et al. [27] presented an integrated soil analysis framework combining crop identification, irrigation prediction, and fertilizer recommendation using satellite imagery and sensor data, where machine learning models achieved high fertilizer recommendation accuracy. Rahman et al. [28] proposed an AIoT-based hydroponic recommendation and monitoring system in which Random Forest delivered strong performance, although automation and cost constraints limited full-scale deployment. Collectively, these studies confirm that remote sensing and ML/DL methods can improve paddy monitoring and input management, but generalization across regions, seasonal variability, data availability (cloud cover, UAV logistics), and scalability remain open challenges that motivate robust, optimized learning frameworks for practical fertilizer recommendation.

A. Research Gap

Prior studies have used UAV-based vegetation indices, spectral features, and ML models for paddy growth assessment, nutrient estimation, biomass prediction, and weed detection, but most treat these problems separately [12, 14, 19]. Existing approaches often emphasize either crop monitoring or fertilizer optimization, rather than combining both in a unified predictive pipeline [13, 23]. Many methods rely on conventional models or manually interpreted indices, limiting their ability to learn nonlinear interactions between spectral signatures, crop physiology, and fertilizer response across diverse agro-ecological conditions [12, 21]. Moreover, optimization strategies and ensemble-based enhancements remain limited in paddy-specific research [19]. Therefore, an automated, optimization-driven framework that simultaneously monitors paddy growth and provides accurate fertilizer recommendations from multispectral dynamics is still lacking.

III. Materials and Methods

The proposed methodology integrates a Selfdom Enhanced CatBoost Model with meta-heuristic optimization for remote paddy growth monitoring and fertilizer recommendation in precision agriculture, as visualized in Fig. 1.

The process begins with the acquisition of paddy field images collected between 2016 and 2020. These images undergo preprocessing and are then used to compute multiple vegetation indices, including NDVI, NDRE, GNDVI, RVI, and GRVI. These indices serve as reliable indicators of plant health, nutrient availability, and growth progress. Once the vegetation indices are generated, the Improved Osprey Optimization Algorithm is utilized to enhance the model's learning capability by optimizing key CatBoost parameters. This integration results in the Selfdom Enhanced CatBoost (SECB) model, designed to efficiently process large-scale remote sensing data and yield highly accurate predictions. The SECB model is trained and tested using the extracted vegetation features, enabling it to

classify growth stages and identify nutrient deficiencies more effectively than conventional algorithms. Based on the predicted growth stage and detected nutrient requirement, the system provides precise fertilizer recommendations. This automated workflow reduces manual effort, improves decision-making accuracy and supports sustainable rice cultivation by ensuring that fertilizers are applied only when necessary.

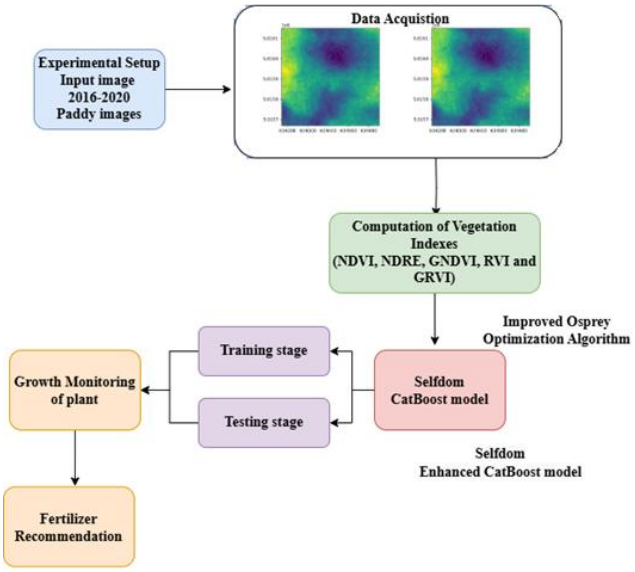

Fig. 1. Block schematic representation of the proposed model.

A. Dataset Description

The dataset used in this study was sourced from Kaggle and served as the basis for developing and validating the paddy growth monitoring and fertilizer recommendation system [29]. It comprised a comprehensive collection of multispectral satellite images recorded over five consecutive years, from 2016 to 2020, capturing seasonal and annual variations in paddy cultivation. Each year's directory contained 3328 image tiles, and every tile represented a 48×48-pixel multispectral snapshot of a specific agricultural location. These tiles formed a time-series dataset in which each subfolder recorded multiple satellite passes over the same geographical tile on different dates. For example, a file such as lombardia2/data2016/1/20160110.tif corresponds to a GeoTIFF multispectral image captured on January 10, 2016, for tile number 1 in the Lombardia2 region. Similar file structures were maintained across all years, ensuring uniformity and facilitating temporal crop growth analysis. Fig. 2 and Fig. 3 present the sample input images utilized during the training and testing phases, illustrating the spectral variations in the satellite images. The multispectral bands and the derived vegetation indices used in this study (NDVI, GNDVI, NDRE, RVI, and GRVI) are directly linked to canopy vigor and chlorophyll-related activity, which are widely used as proxy indicators of nutrient status in crops. In particular, nutrient stress typically reduces chlorophyll concentration and modifies canopy structure, which alters reflectance responses in the red, near-infrared, and red-edge bands. Therefore, the dataset provides meaningful spectral cues for learning patterns associated with nutrient requirement and for supporting fertilizer recommendation based on multispectral dynamics across growth stages. The proposed model was trained using this entire dataset to ensure robust learning and improve predictive accuracy. During evaluation, real-time drone images were additionally incorporated to test the model's performance under practical field conditions. This combination of historical satellite data and on-site imagery enabled the model to generate reliable growth insights and fertilizer recommendations suited for real-world paddy cultivation practices.

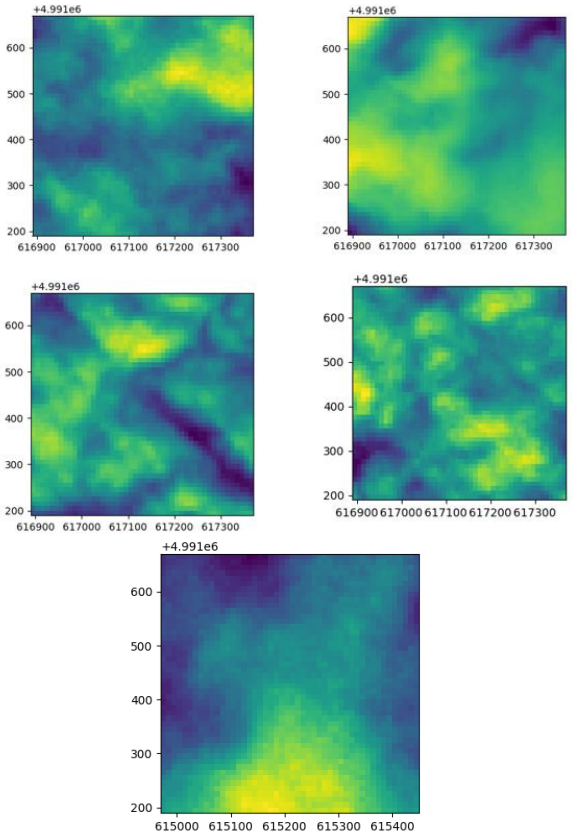

Fig. 2. Sample training images.

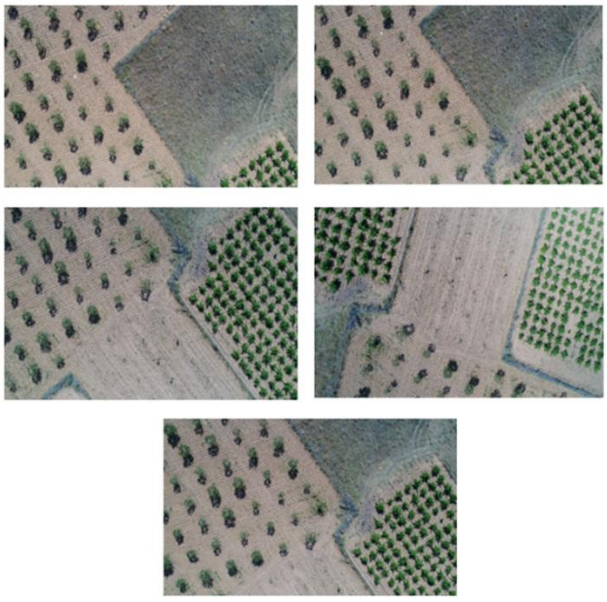

Fig. 3. Sample testing images.

B. Vegetation Indices

To generate the vegetation indices required for paddy growth analysis, multispectral images captured were processed to extract reflectance values from specific spectral bands. These vegetation indices NDVI, NDRE, GNDVI, RVI and GRVI were selected because they provide spectrally non-redundant and complementary information about plant biochemical and structural properties. Each index exploits the interaction of light with different leaf pigments and cellular structures. The visible bands (green, red, and red-edge) are strongly influenced by pigments such as chlorophyll, carotenoids, and xanthophylls, whereas the near-infrared (NIR) band is largely controlled by internal leaf architecture, including the palisade and spongy mesophyll layers. The red-edge band captures the rapid transition between visible absorption and near-infrared reflection, making it sensitive to chlorophyll concentration and early vegetation stress. These characteristics enable the selected indices to represent different aspects of crop physiology, allowing accurate assessment of plant health, growth stage and fertilizer response. The vegetation indices were calculated using their respective mathematical formulations, as illustrated in Eq. (1) to Eq. (5):

$$NDVI = \frac{\rho_{nir} - \rho_{red}}{\rho_{nir} + \rho_{red}} \quad (1)$$

$$NDRE = \frac{\rho_{nir} - \rho_{re}}{\rho_{nir} + \rho_{re}} \quad (2)$$

$$GNDVI = \frac{\rho_{nir} - \rho_{green}}{\rho_{nir} + \rho_{green}} \quad (3)$$

$$RVI = \frac{\rho_{nir}}{\rho_{re}} \quad (4)$$

$$GRVI = \frac{\rho_{green} - \rho_{red}}{\rho_{green} + \rho_{red}} \quad (5)$$

where, ρ_{nir}, ρ_{re}, ρ_{green}, and ρ_{red} denote the surface reflectance values in the near-infrared, red-edge, green, and red spectral bands, respectively. Sample vegetation index values with identified growth stages and fertilizer recommendations are summarized in Table I.

TABLE I. SAMPLE VEGETATION INDEX VALUES WITH IDENTIFIED GROWTH STAGES AND FERTILIZER RECOMMENDATIONS

NDVI	NDRE	GNDVI	RVI	GRVI	Growth Stage	Fertilizer Recommendation
0.345	0.210	0.320	1.245	0.112	Early Growth	Recommended
0.402	0.180	0.410	1.312	0.087	Mature Stage	Not Needed
0.120	-0.005	0.075	0.987	-0.015	Early Growth	Recommended
0.275	0.155	0.290	1.089	0.065	Mature Stage	Recommended
0.015	-0.015	-0.005	0.876	-0.022	Early Growth	Recommended
0.500	0.245	0.380	1.400	0.123	Mature Stage	Not Needed
0.065	-0.020	0.025	0.912	-0.010	Mature Stage	Not Needed
0.330	0.190	0.300	1.200	0.098	Mature Stage	Not Needed
0.405	0.220	0.410	1.350	0.130	Early Growth	Recommended
0.290	0.145	0.275	1.110	0.055	Early Growth	Recommended

C. Model Development

The model development phase focused on constructing the Selfdom Enhanced CatBoost (SECB) framework for remote paddy growth monitoring and fertilizer recommendation. Vegetation indices derived from multispectral imagery were used as input features and the CatBoost algorithm was enhanced using the Improved Osprey Optimization Algorithm to refine model parameters. This hybrid integration strengthened predictive accuracy, reduced overfitting and enabled precise identification of growth stages and fertilizer requirements.

1) CatBoost: CatBoost is a gradient boosting algorithm developed to provide highly accurate predictions while minimizing the preprocessing burden commonly associated with machine learning models [30]. It is particularly effective for datasets containing categorical variables, converting them into numerical representations internally using ordered statistics instead of one-hot encoding. This approach prevents target leakage and reduces prediction bias. CatBoost builds an ensemble of symmetric (oblivious) decision trees, where each tree corrects the prediction errors of the previous one through gradient boosting. The general prediction function of CatBoost is expressed as Eq. (6):

$$F_m(x) = F_{m-1}(x) + \eta \cdot h_m(x) \quad (6)$$

where, $F_m(x)$ is the updated model at iteration m, η is the learning rate and $h_m(x)$ represents the newly added decision tree trained on the gradients of the loss function. CatBoost minimizes the loss function L by iteratively updating the model as Eq. (7):

$$F_m(x) = F_{m-1}(x) - \eta \cdot \frac{\partial L}{\partial F_{m-1}(x)} \quad (7)$$

CatBoost also introduces ordered boosting, which processes samples sequentially to avoid artificial correlations and overfitting. Its automatic handling of missing values, fast training and superior generalization make it highly competitive compared to XGBoost and LightGBM, especially for tabular agricultural datasets where precision and reliability are essential.

2) Selfdom Enhanced CatBoost Model: The objective of this study is to establish a reliable model capable of monitoring paddy growth and recommending the required fertilizer amount using remote sensing data. Since the relationship between crop

reflectance and physiological growth variables is highly nonlinear, ML becomes a natural choice to approximate this mapping using suitable training datasets. Among various ensemble algorithms, CatBoost stands out due to its ability to convert multiple weak learners into a robust predictive model [31]. Unlike conventional algorithms that rely heavily on extensive preprocessing and suffer from feature sensitivity, CatBoost introduces ordered boosting and structured trees that minimize overfitting while improving generalization. The proposed SECB model builds upon this foundation. It incorporates the IOOA to optimize CatBoost's parameters more efficiently. By iteratively adjusting these parameters, the IOOA prevents the model from settling on suboptimal solutions and offers a better balance between bias and variance. In boosting, a series of weak predictors is trained sequentially, where each stage emphasizes observations misclassified in the previous iteration. The model updates the error weights so that subsequent predictors gradually reduce the accumulated deviations. After training, the regression output of all weak learners is aggregated through a weighted combination, forming a strong predictive learner.

CatBoost's core is an oblivious decision tree (DT), a symmetric full binary tree where identical splitting conditions apply at each level. The parameters at the leaf nodes are represented as floating-point vectors, enabling efficient representation and easy extraction during prediction. The gradient boosting formulation in CatBoost is expressed as Eq. (8):

$$\mathrm{H}_{\alpha} = \mathrm{argmin}_{\{\mathrm{H}\epsilon\mathrm{h}\}} \frac{1}{\mathrm{J}} \sum_{\mathrm{I}=1}^{\mathrm{J}} \left(-\mathrm{G}^{\alpha}(\mathrm{X}_{\mathrm{I}} - \mathrm{Y}_{\mathrm{I}}) - \mathrm{H}(\mathrm{X}_{\mathrm{I}})\right)^2 \quad (8)$$

However, using the same training set repeatedly introduces gradient bias, which results in prediction drift and overfitting. This bias, represented as offset size Q, as Eq. (9):

$$\mathrm{Q} = \frac{1}{(\mathrm{N}-1)\mathrm{C}_2} (\mathrm{X}^2 - \frac{1}{2}) \quad (9)$$

The Selfdom component addresses this limitation by employing the IOOA, a heuristic optimization method inspired by the dynamic behavior of ospreys while capturing prey. IOOA incorporates randomness into the parameter search process, enabling the model to escape local minima. In certain iterations, a slightly inferior solution is intentionally accepted with a defined probability, allowing the algorithm to jump towards a globally optimal configuration. This mechanism significantly enhances CatBoost's learning ability and improves robustness under noisy or diverse spectral inputs.

3) Improved Osprey Optimization Algorithm: The Improved Osprey Optimization Algorithm refines the traditional Osprey Optimization Algorithm by integrating a gradient-based lifting strategy to determine optimal weight parameters more efficiently. In this enhancement, the IOOA combines the standard OOA framework with an objective function (OF), enabling a more informed search process. By incorporating the OF during initialization, the algorithm begins its optimization from higher-quality solution points rather than randomly, leading to faster convergence and superior outcomes [32].

The osprey also known as the fish hawk, sea hawk or river hawk is a predatory bird renowned for its precision hunting abilities, adaptive navigation and strategic pursuit of prey. These natural behaviors form the inspiration for the algorithm's two core computational phases: exploration and exploitation. During exploration, the IOOA simulates the osprey's wide-range scanning of its environment to identify potential opportunities, ensuring that the search space is thoroughly examined. In the exploitation phase, the algorithm imitates the osprey's focused dive toward its target, refining the solution through local adjustments and leveraging valuable information gained from previous iterations. By merging the original OOA mechanism with the gradient-oriented OF, the improved algorithm avoids stagnation at local optima and advances toward globally optimal solutions, making it highly suitable for complex parameter optimization tasks such as tuning the CatBoost model in this study.

Step 1: Initialization stage

The proposed IOOA is a population-related technique that provides solutions related to the search power of its population memberships in the problem-solving area finished an iteration-related procedure. Each osprey determines parameters for the problem depending on its location in the search space and OF, as it is a member of the IOOA population. Each osprey thus symbolizes a possible vector-based mathematical solution to the issue. Ospreys collectively comprise the IOOA population, which is generated using a matrix linked to the following equation. During the initialization phase of IOOA, the ospreys' positions within the search space are generated randomly as Eq. (10) and Eq. (11):

$$P = \begin{bmatrix} P_1 \\ \dots \\ P_I \\ \dots \\ P_N \end{bmatrix}_{N\times M} = \begin{bmatrix} P_{1,1} & \dots & P_{1,J} & \dots & P_{1,M} \\ \dots & \dots & \dots & \dots & \dots \\ P_{I.1} & \dots & P_{I,J} & \dots & P_{I,M} \\ \dots & \dots & \dots & \dots & \dots \\ P_{N,1} & \dots & P_{N,J} & \dots & P_{N,M} \end{bmatrix}_{N\times M} \quad (10)$$

$$P_{I,J} = LB_J + R_{I,J}.\left(UB_J - LB_J\right), I = 1,2,\dots N, J = 1,2,\dots,M \quad (11)$$

where, UB_J and LB_J is the upper bound and lower bound, $R_{I,J}$ is random statistics in the intermission $[0,1]$, M is defined as the count of problem parameters, N is the number of ospreys, $P_{I,J}$ is the dimension and P is the population matrix of osprey's locations.

Step 2: Oppositional Function (OF)

The oppositional function is widely adopted because it effectively strengthens the intensification-diversification balance, thereby improving the overall efficiency of the optimization search. This process is used in two phases: first, when the initial population is established and then, after the evaluation and computation of the optimal agent, when a novel population is generated. For each produced agent, an additional one is made for the opposite dimension of the traditional search agent in order to empower OF initialization as Eq. (12):

$$P_{S,X}^0 = L_P + U_P - P_{s,X} \quad (12)$$

where, $P_{s,X}$ is an original agent, $P_{S,X}^0$ is a search agent for the opposite parameter dimension X.

Step 3: Fitness Evaluation

In the method, the fitness function is considered for enhancing the training of the proposed classifier. The gradient lifting formulation is presented as Eq. (13):

$$H_\alpha = argmin_{\{H\epsilon h\}} \frac{1}{J}\sum_{I=1}^{J}\left(-G^\alpha(X_I - Y_I) - H(X_I)\right)^2 \quad (13)$$

Based on the MSE, the optimal weighting parameter is selected with the consideration of the IOOA algorithm.

Step 4: Exploration phase (fish hunting and position detection)

In the exploration phase, ospreys exhibit strong hunting proficiency, using their remarkable visual acuity to locate fish underwater and identify target positions within the search region. After they have located the fish, they dive underwater to attack and hunt it. The design of the initial population upgrade step in OOA is based on the simulation of this general osprey feature. For every osprey in the OOA framework, the locations of the remaining ospreys in the search space are determined underwater fishes using an optimal objective function parameter. The pair of fish is specified as follows for every osprey as Eq. (14):

$$fp_I = \{P_K | K\epsilon\{1,2,\dots,N\} \wedge f_K < f_I\} \cup \{P_{best}\} \quad (14)$$

where, fp_I is the pair of fish locations aimed at the osprey and P_{best} is the optimal candidate explanation. The osprey finds one of these fish at chance and then hits it. The updated position of the corresponding osprey is computed using Eq. (15) to Eq. (17), representing its movement toward the targeted fish.

$$P_{I,J}^{P1} = P_{I,J} + R_{I,J}.\left(sf_{I,J} - I_{I,J}.P_{I,J}\right) \quad (15)$$

$$P_{I,J}^{P1} = \begin{cases} P_{I,J}^{P1}, LB_J \le P_{I,J}^{P1} \le UB_J \\ LB_J, P_{I,J}^{P1} < LB_J \\ UB_J, P_{I,J}^{P1} > UB_J \end{cases} \quad (16)$$

$$P_I = \begin{cases} P_I^{P1}, f_I^{P1} < f_I \\ P_I, Else \end{cases} \quad (17)$$

where, $I_{I,J}$ is a random numbers from the pair {1,2}, $R_{I,J}$ is the haphazard count in the interval [0,1], $sf_{I,J}$ is the dimension, sf_I is the chosen for osprey, $P_{I,J}^{P1}$ is the dimension, P_I^{P1} is the new location of the osprey related on the initial phase. The algorithm for pseudocode of the IOOA is given below:

Algorithm: Pseudocode of the IOOA

Input: Dataset $(X_{train}, y_{train}), X_{val}, y_{val}$
CatBoost parameters (excluding weights)
Population size (N), Max iterations (T)

Output: Optimal weight vector (W_{opt})

Start:

Step 1: Initialize Population

- Generate N random weight vectors (W_i), one for each individual.
- Evaluate fitness for each weight vector using:

$$Fit(W_i) = MSE(CatBoost(W_i), y_{val})$$

Step 2: Oppositional Learning

- For each weight vector W_i:

$$W_i' = Oppositional_Function(W_i)$$

Combine original and opposite solutions, then select top N based on fitness.

Step 3: Optimization Loop

- For iteration t = 1 to T:

3.1 Update each weight vector:

$$W_i^{new} = Update_Position(W_i, Best_W, t)$$

3.2 Evaluate fitness for updated weights:

$$Fit(W_i^{new}) = MSE(CatBoost(W_i^{new}), y_{val})$$

3.3 Update Best_W:

Best_W = Weight vector with lowest MSE

Step 4: Return Best Solution

- Output Best_W as the optimal weight vector.

End

Step 5: Taking advantage of the fish to move it to a better location

The osprey catches a fish and then moves it to the proper spot to consume it. The simulation of these broad osprey features is the basis for the next phase of population upgrading in OOA. The design of conveying the fish to the best possible location contributes to the creation of minor changes in the osprey's position within the search location, which increases the OOA's manipulation power in local search then leads to conjunction to optimal solutions close the solutions that are found. The updated position of each osprey during this exploitation process is computed as Eq. (18):

$$P_{I,J}^{P2} = P_{I,J} + \frac{LB_J + R_{I,J}.(UB_J - LB_J)}{T}, I = 1,2,\dots,N, J = 1,2,\dots,M, T = 1,2,\dots,t \quad (18)$$

To ensure feasibility, boundary conditions are applied as Eq. (19):

$$P_{I,J}^{P2} = \begin{cases} P_{I,J}^{P2}, LB_J \le P_{I,J}^{P2} \le UB_J \\ LB_J, P_{I,J}^{P2} < LB_J \\ UB_J, P_{I,J}^{P2} > UB_J \end{cases} \quad (19)$$

Finally, a greedy selection mechanism ensures that the fitter solution is retained for subsequent iterations as Eq. (20):

$$P_I = \begin{cases} P_I^{P2}, f_I^{P2} < f_I \\ P_I, Else \end{cases} \quad (20)$$

where, t is the total count of repetitions, T is described as the iteration counter of the algorithm, $R_{I,J}$ is the random statistics in the range [0,1], f_I^{P2} is the objective function parameter, $P_{I,J}^{P2}$ is the dimension, P_I^{P2} is the novel location of the osprey related on the next phase of OOA. Based on this algorithm, the optimal weight parameter is designated and sent to the classifier which enhance the prediction of growth and provide efficient fertilizer recommendation.

4) Proposed Selfdom Enhanced CatBoost Model: The SECB algorithm integrates multispectral vegetation information with an optimized boosting framework to perform precise paddy growth monitoring and fertilizer recommendation. As shown in Fig. 4, the process begins with preparing the training and testing image datasets, from which key vegetation indices such as NDVI, NDRE, GNDVI, RVI, and GRVI are computed. These indices capture spectral variations related to crop vigor,

chlorophyll concentration, and canopy structure, providing discriminative features for stage-wise growth assessment. CatBoost serves as the core predictive engine, where multiple decision trees are sequentially constructed. Each tree learns from the residual errors of its predecessors, allowing the model to capture nonlinear interactions among spectral indices. To further improve learning efficiency, the Improved Osprey Optimization Algorithm (IOOA) adjusts the internal weight parameters of the boosting process. Through exploration (fish searching) and exploitation (position refinement), IOOA identifies optimal parameter configurations that enhance model accuracy and stability. The optimized predictors collectively estimate early and mature growth stages with high reliability. These stage predictions are then interpreted to generate fertilizer recommendations tailored to the crop's current physiological needs. By combining CatBoost's structured boosting with IOOA's adaptive parameter optimization, the SECB algorithm provides a robust, data-driven framework suitable for precision agriculture decision-making.

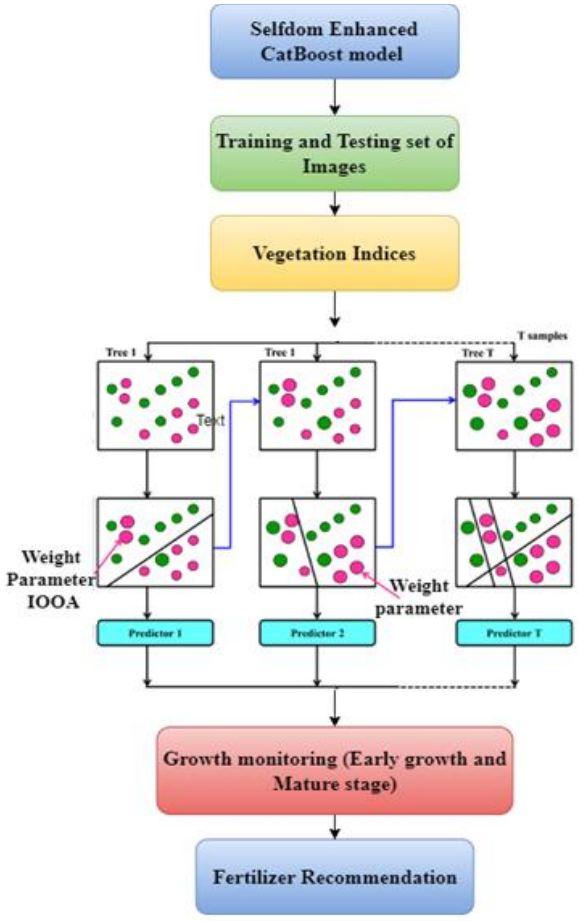

Fig. 4. Proposed Self Enhanced CatBoost Algorithm.

D. Simulation Setup

The SECB model was developed and executed entirely on a cloud-based simulation environment to ensure efficient training and scalability. Python served as the primary development platform, utilizing Pandas and NumPy for data preprocessing and scikit-learn for computing evaluation metrics. Model training and IOOA-based optimization were performed on Google Colaboratory with GPU acceleration, enabling faster computation of boosting iterations and optimized parameter tuning. CatBoost was employed as the core classifier, while the IOOA algorithm refined model weights to improve predictive stability. This cloud-based setup ensured consistent performance, rapid experimentation, and reliable validation of the proposed paddy growth monitoring and fertilizer recommendation framework.

The main simulation parameters adopted for training the proposed SECB model are summarized in Table II. The configuration includes 1000 boosting iterations to ensure stable learning and convergence, with a tree depth of 8 to effectively capture nonlinear relationships among vegetation indices. A step size of 0.03 was selected to balance learning speed and accuracy, while an L2 regularization coefficient of 3 was applied to prevent overfitting. Controlled randomness in tree splits was maintained at level 1 to enhance generalization. To address class imbalance, balancing weights of (1, 5) were used. A fixed random seed of 42 ensured reproducibility, and training progress was reported every 100 iterations.

TABLE II. SIMULATION VARIABLES OF THE PROPOSED MODEL

Description	Parameters
Number of boosting iterations (trees)	1000
Depth of the trees	8
Step size during optimization	0.03
L2 regularization coefficient for leaf values	3
Level of randomization in tree splits	1
Balancing weights for imbalanced classes	[1, 5]
Seed for reproducibility	42
Print progress during training	100
Oppositional initialization for optimization	FALSE

The overall runtime of the SECB–IOOA framework is primarily influenced by the optimization stage, since IOOA evaluates multiple candidate hyperparameter settings and each evaluation requires training and validating the CatBoost model. Vegetation-index computation is performed once during preprocessing and contributes relatively minor overhead compared to optimization. After training, inference remains efficient because CatBoost prediction involves evaluating a fixed set of symmetric decision trees, enabling fast tile-wise prediction and supporting large-scale deployment under practical monitoring conditions.

IV. RESULTS AND DISCUSSION

This section analyzes the performance of the proposed Selfdom Enhanced CatBoost model for remote paddy growth monitoring and fertilizer recommendation. The vegetation indices GRVI, RVI, NDVI, GNDVI, and NDRE were extracted from multispectral images and normalized during preprocessing to ensure uniform scale across features. The IOOA was incorporated during training to fine-tune CatBoost's parameters, enabling faster convergence and improved prediction capability.

The effectiveness of the SECB model was measured using key performance indicators such as recall, precision, accuracy, F1 score and specificity. These metrics, defined in Eq. (21) to Eq. (25) and computed from false negatives (FN), false positives (FP), true positives (TP), and true negatives (TN), collectively validate the model's ability to interpret spectral signatures, classify paddy growth stages accurately, and generate precise fertilizer recommendations.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (21)$$

$$Recall = \frac{TP}{TP+FN} \quad (22)$$

$$Precision = \frac{TP}{TP+FP} \quad (23)$$

$$F1-score = 2 * \frac{Precision \times Recall}{Precision+Recall} \quad (24)$$

$$Specificity = \frac{TN}{TN+FP} \quad (25)$$

Recent studies emphasize the need for data-driven tools that can support sustainable rice growth monitoring and fertilization decisions. Compared with earlier approaches such as fuzzy MCDM, SMART, AHP, and other knowledge-based fertilizer recommendation techniques [4–6,20,23], the proposed SECB framework integrates multispectral vegetation indices with IOOA-optimized CatBoost learning to enhance classification performance and improve the reliability of fertilizer-related decision-making. This design aligns with current precision agriculture trends by linking remote sensing–based crop condition assessment with robust, automated model optimization for practical field deployment.

To demonstrate its superiority, the SECB model was compared against widely used baseline classifiers, including Naive Bayes, RF, DT and LR under similar experimental conditions. The SECB model consistently outperformed these approaches due to its optimized boosting structure and enhanced parameter tuning provided by the IOOA. The main simulation parameters used for model training are listed in Table II, which includes the number of boosting iterations (1000), tree depth (8), step size (0.03), L2 regularization coefficient (3) and balancing weights for handling class imbalances. The results validate that the SECB model is an efficient and reliable framework for paddy growth monitoring and fertilizer recommendation in precision agriculture settings.

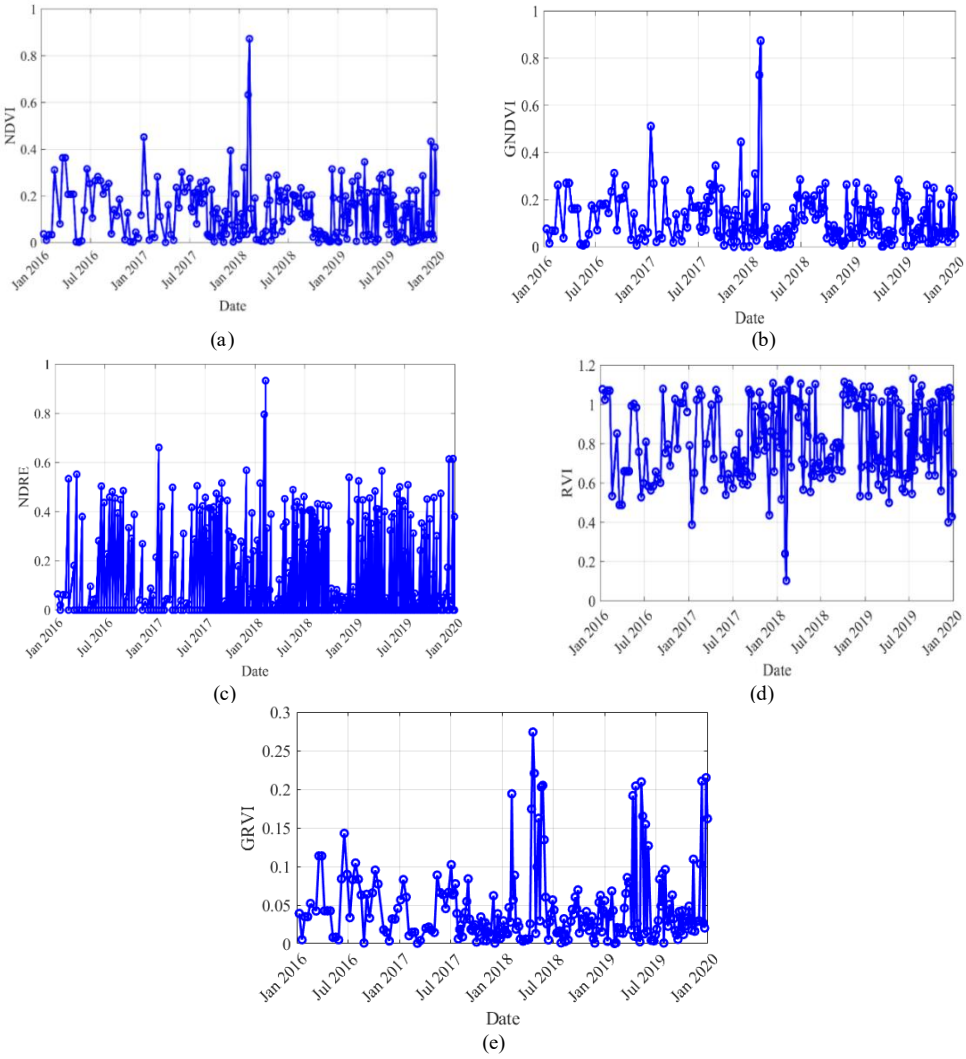

Fig. 5. Vegetation Index: a) NDVI, b) GNDVI, c) NDRE, d) RVI, and e) GRVI.

The temporal behavior of vegetation indices provides comprehensive insight into the paddy crop lifecycle across multiple seasons. Fig. 5 summarizes the evolution of crop vigor and canopy conditions from January 2016 to January 2020, enabling continuous monitoring of phenological transitions. In Fig. 5(a), NDVI captures overall canopy greenness and density, with peaks corresponding to active vegetative growth and sharp drops reflecting post-harvest or land preparation periods. A notable rise in early 2018 indicates particularly favorable growth conditions, which may be linked to improved irrigation or nutrient availability. Fig. 5(b) shows GNDVI trends, which are generally consistent with NDVI but offer increased sensitivity to chlorophyll-related variation in the green band. Fig. 5(c) presents NDRE dynamics, highlighting chlorophyll activity using the red-edge region and providing better discrimination of subtle stress during certain stages. Fig. 5(d) illustrates RVI variations, where higher ratios typically correspond to dense canopies, while lower values align with sparse vegetation or non-growing phases. Fig. 5(e) depicts GRVI behavior, which reflects shifts between germination, vegetative growth, and post-harvest periods and provides complementary information on canopy color dynamics.

Overall, the observed NDVI, GNDVI, NDRE, RVI, and GRVI trajectories (2016–2020) are consistent with prior satellite studies that use multispectral/hyperspectral indices to monitor paddy development, biomass, and yield. The recurring seasonal rises during active growth and declines during post-harvest or stress periods support the use of VI time-series patterns as reliable indicators of rice phenology. This long-term consistency strengthens the rationale for using these indices as inputs to the SECB framework for robust monitoring and fertilizer decision support across multiple seasons.

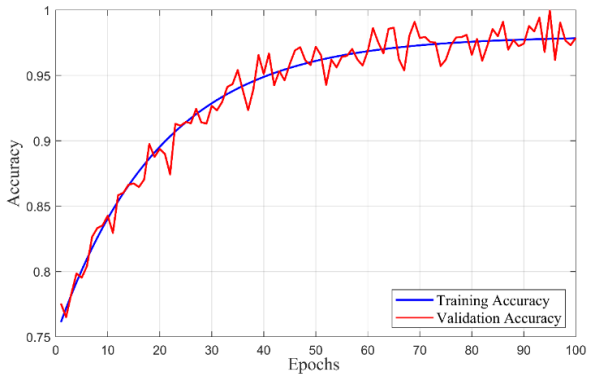

Fig. 6. Accuracy plot of the proposed model.

Fig. 6 depicts the validation and training accuracy trends of the SECB model over 100 epochs. Both curves demonstrate a consistent upward trajectory, indicating that the model learns effectively from the input vegetation indices and progressively improves its predictive capability. At the initial stages, the model exhibits moderate accuracy values, reflecting the early learning phase where parameters are still being optimized. As epochs increase, the training accuracy steadily rises and converges close to 0.98, illustrating strong fitting of the model to the training data. The validation accuracy follows a similar pattern, closely trailing the training curve with minor oscillations around epochs 40–80. These fluctuations are due to the dynamic nature of unseen data during validation and the model's effort to generalize across different crop growth scenarios. Importantly, the validation accuracy stabilizes near the training accuracy towards the end of the training period, confirming that the SECB model does not encounter overfitting and maintains excellent generalization capabilities. The accuracy behavior verifies the robustness of the proposed SECB architecture. The close alignment between the two curves highlights the model's stability, efficient learning mechanism and strong capability in predicting paddy growth stages and fertilizer needs with high reliability.

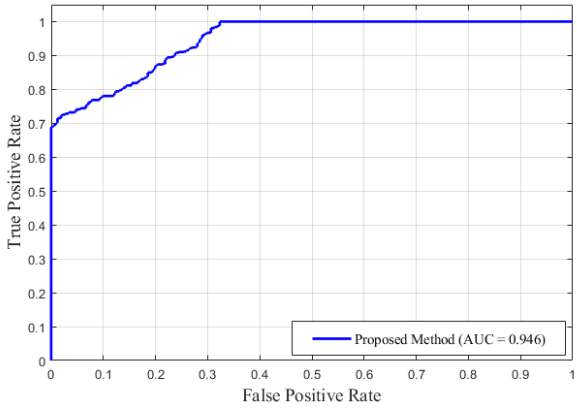

Fig. 7. ROC plot of the proposed model.

Fig. 7 illustrates the Receiver Operating Characteristic (ROC) curve for the proposed SECB model, which evaluates the model's discriminative capability in classifying paddy growth conditions based on vegetation indices. The curve demonstrates a steep rise toward the upper-left section of the graph, indicating that the classifier identifies true positives effectively while generating minimal false positives. This behavior reflects the model's ability to correctly identify healthy or nutrient-deficient crop conditions without generating excessive false alarms. The calculated Area Under the Curve (AUC) value of 0.946 confirms excellent classification power. An AUC close to 1 indicates that the model makes highly reliable decisions with minimal misclassification, outperforming typical threshold-based or non-boosting algorithms. The smooth progression and high asymptotic value of the ROC curve show that the SECB model retains strong generalization ability even when tested on unseen datasets. This robust performance underscores the effectiveness of integrating the Improved Osprey Optimization Algorithm with CatBoost for precision agricultural monitoring, enabling accurate fertilizer recommendation and timely intervention to enhance crop productivity.

Fig. 8 illustrates the ROC curves of different ML models used for paddy growth monitoring. The curves show how well each model distinguishes between growth stages based on vegetation index patterns. The proposed Selfdom Enhanced CatBoost (SECB) model clearly outperforms all the baseline techniques. The blue curve, representing the SECB model, shows the highest AUC value of 0.946, indicating excellent classification capability and very low misclassification. This means the model consistently made correct predictions even when the input conditions were complex or varied across seasons. The DT [33] (AUC = 0.926) and RF [34] (AUC =

0.923) also performed well but could not match the SECB model's precision. Logistic Regression (LR) [35] (AUC = 0.914) and Naive Bayes [36] (AUC = 0.911) delivered lower discrimination power because they struggled to capture the nonlinear behavior of paddy crop growth. The ROC comparison confirms that adding the IOOA to CatBoost significantly strengthened its learning ability. This enhancement enabled the SECB model to make more confident decisions, making it the most reliable approach for crop growth analysis and fertilizer recommendation in precision agriculture.

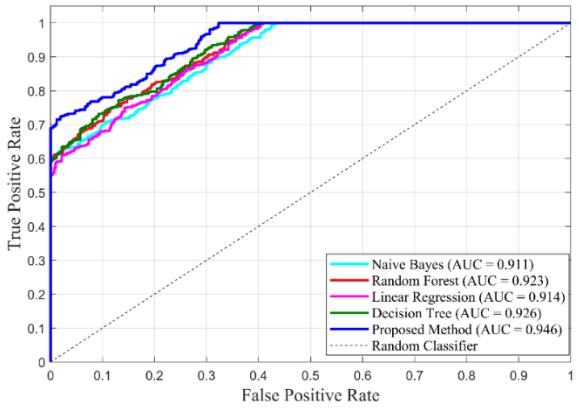

Fig. 8. ROC comparison.

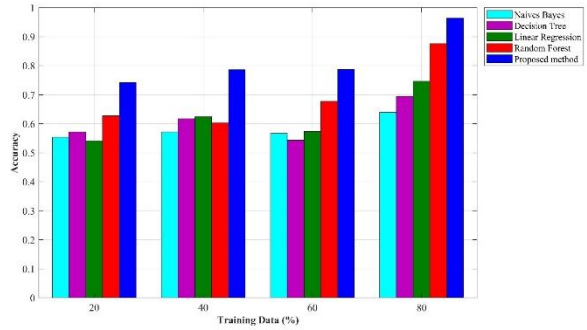

Fig. 9. Comparison of accuracy.

Fig. 9 compares the accuracy of five ML models, such as Naive Bayes, DT, LR, RF and the proposed SECB method using different proportions of training data (20%, 40%, 60% and 80%). At 20% training data, all models performed modestly; however, the SECB method already demonstrated a clear advantage, achieving an accuracy of around 0.75, whereas Naive Bayes lagged significantly with an accuracy close to 0.55. DT, LR and RF clustered around mid-range values, indicating limited learning capability with sparse data. When the training data increased to 40% and 60%, all models showed gradual improvement, but the SECB method continued to maintain a noticeable performance lead. This highlights its superior ability to extract meaningful patterns even from partially available vegetation index data. The most significant performance gap appeared at 80% training data, where the SECB method reached an impressive accuracy of nearly 0.95. In contrast, RF achieved about 0.88, DT stabilized around 0.74 and LR settled near 0.65, while Naive Bayes improved only marginally to approximately 0.57. The comparison confirms that the proposed SECB model consistently outperformed every traditional algorithm across all training partitions. The more data available to the model, the more pronounced its superiority became, proving its strong generalization ability and robust performance for paddy growth monitoring and fertilizer recommendation.

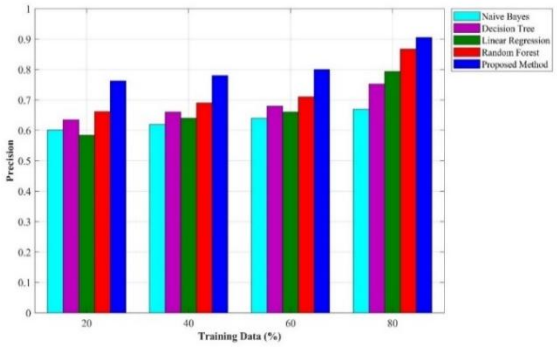

Fig. 10. Comparison of precision.

Fig. 10 illustrates the precision comparison of five models: Naive Bayes, DT, LR, RF, and the proposed method across varying proportions of training data. At 20% training data, the proposed method already achieves the highest precision of approximately 0.76, outperforming RF and DT, while Naive Bayes records the lowest value near 0.60. As the training data increases to 40% and 60%, all models show gradual improvement; however, the proposed method consistently maintains a noticeable lead, reflecting its superior capability to distinguish relevant patterns. At 80%, the proposed method attains a precision close to 0.91, higher than RF at 0.87 and considerably above Naive Bayes at 0.67. These results clearly demonstrate the enhanced decision reliability of the proposed SECB model.

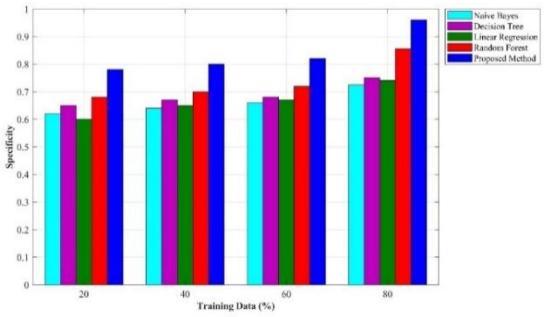

Fig. 11. Comparison of specificity.

Fig. 11 presents the specificity comparison among Naive Bayes, DT, LR, RF and the proposed method at different training data proportions. At 20% training data, the proposed method already demonstrates a strong specificity of around 0.78, outperforming all baseline models, where Naive Bayes, DT and LR remain below 0.65 and RF reaches only 0.69. As the training percentage increases, all methods show gradual improvement; however, the proposed method continues to lead consistently. When trained with 80% of the data, it attains an impressive specificity of approximately 0.96, significantly exceeding the other models. This superior performance highlights its robustness in accurately identifying negative cases and reducing false positives.

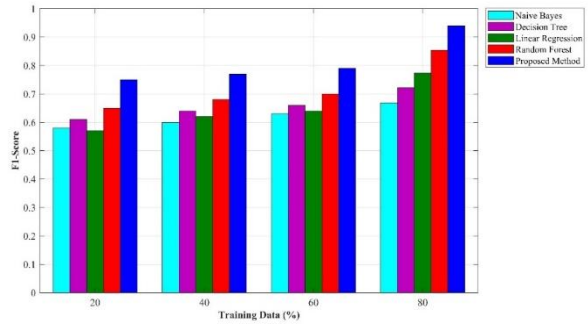

Fig. 12. Comparison of F1 score.

Fig. 12 compares the F1-score performance of different models Naive Bayes, DT, LR, RF and the proposed model across increasing proportions of training data. At 20% training data, the proposed method already records an impressive F1-score of around 0.78, surpassing all other models, with Naive Bayes showing the weakest value near 0.58. As the training data increases, all models improve gradually; however, the margin of superiority for the Proposed Method becomes more evident. With 80% training data, it achieves an F1-score above 0.93, outperforming RF and DT. This consistent dominance highlights the effectiveness of the proposed approach in maintaining a balanced precision-recall trade-off.

To further validate the robustness of the proposed SECB framework, a comparative evaluation was performed against conceptually similar metaheuristic-optimized boosting models, including Genetic Algorithm-tuned XGBoost (GA-XGBoost), Particle Swarm Optimization-based LightGBM (PSO-LightGBM), Grey Wolf Optimizer-enhanced CatBoost (GWO-CatBoost), and Honey Badger Algorithm-optimized XGBoost (HBA-XGBoost). These variants were implemented following optimization principles established in prior metaheuristic-boosting studies, where GA [37], PSO [38], GWO [39], and HBA [40] have been used to enhance model convergence and generalization.

TABLE III. COMPARATIVE PERFORMANCE OF METAHEURISTIC-OPTIMIZED BOOSTING MODELS

Model	Accuracy	Precision	Recall	F1-Score	Specificity	AUC
GA-XGBoost	0.928	0.915	0.904	0.909	0.932	0.938
PSO-LightGBM	0.931	0.918	0.912	0.915	0.936	0.941
GWO-CatBoost	0.935	0.920	0.918	0.919	0.940	0.943
HBA-XGBoost	0.939	0.926	0.922	0.924	0.944	0.945
SECB (Proposed)	0.951	0.934	0.930	0.932	0.952	0.946

Table III summarizes the comparative performance of these optimization-guided boosting strategies. The SECB model achieves the highest performance across all metrics, surpassing all other metaheuristic-based approaches. The observed improvement in accuracy (0.951) and AUC (0.946) highlights the effectiveness of integrating the IOOA with CatBoost. The Selfdom mechanism further enhances the exploration–exploitation balance through oppositional initialization and adaptive acceptance, allowing SECB to avoid premature convergence commonly observed in GA and PSO-based models.

These findings confirm that SECB achieves superior learning stability and predictive reliability for spectral-index-driven paddy monitoring. Moreover, its strong performance generalizes across diverse environmental conditions, demonstrating potential for large-scale implementation in real-world precision agriculture systems.

V. CONCLUSION

This research introduced the Selfdom Enhanced CatBoost model as an effective solution for remote paddy growth monitoring and fertilizer recommendation, addressing key limitations of conventional agricultural practices. By integrating multispectral UAV imagery with vegetation indices such as NDRE, GNDVI, RVI, GRVI and NDVI, the proposed model enabled a comprehensive evaluation of crop health and developmental stages. The incorporation of the IOOA further enhanced the CatBoost framework by optimizing feature weights and reducing training errors, resulting in more reliable predictions. Comparative analysis against widely used ML models, including LR, DT, RF, and Naive Bayes, demonstrated that the SECB model consistently delivered superior performance across crucial metrics. Its improved accuracy in identifying growth stages and recommending precise fertilizer inputs highlights its potential to support sustainable and data-driven agricultural management. The findings of this study reaffirm the growing importance of integrating remote sensing, machine learning, and optimization techniques for modern precision farming. By minimizing resource wastage and improving crop productivity, the SECB model offers a scalable and intelligent decision-support tool that can significantly assist farmers and policymakers. Future work may extend this framework to other crop varieties and integrate real-time field data from IoT sensors, enabling more dynamic and autonomous agricultural decision-making systems. Additionally, exploring edge computing and cloud-based deployment could further enhance its usability in large-scale smart farming environments.

A Robust Real-Time Multimodal Polynomial Fusion Framework for Sensor-Based Sign Language Recognition Using Flex–IMU Smart Gloves

Dadang Iskandar Mulyana, Edi Noersasongko, Guruh Fajar Shidik, Pujiono
Faculty of Computer Science, Dian Nuswantoro University, Semarang, Indonesia

***Abstract*—Sign language recognition is a critical component of assistive technologies for individuals with hearing and speech impairments. While vision-based approaches have shown promising performance, their reliability is often affected by illumination variations, occlusions, and background complexity. Wearable sensor–based solutions, particularly smart gloves integrating flex sensors and inertial measurement units (IMUs), provide a more stable alternative by directly capturing hand articulation and motion patterns. However, existing sensor-based methods frequently suffer from temporal instability, noise sensitivity, and limited discrimination among structurally similar gestures, which is especially challenging in Hijaiyah sign language, where many letters differ only by subtle finger configurations. This study proposes a robust real-time Multimodal Polynomial Fusion (MPF) framework for sensor-based sign language recognition using a flex–IMU smart glove, with a specific focus on Hijaiyah gestures as the application domain. The proposed framework applies nonlinear polynomial temporal smoothing within a sliding window to stabilize raw flex–IMU trajectories, followed by multimodal fusion to enhance gesture separability and temporal consistency. A large-scale multimodal dataset comprising 231,000 samples collected from 33 users performing 28 Hijaiyah gesture classes was constructed to enable rigorous subject-independent evaluation. Experimental results obtained from offline testing, session-aware analysis, and real-time streaming scenarios demonstrate that the proposed MPF framework consistently outperforms a baseline approach based on raw normalized signals. The proposed method improves recognition accuracy from 92.42% to 96.32%, while also achieving higher macro-level precision, recall, and F1-score. Furthermore, MPF significantly reduces misclassification rates and improves temporal stability, particularly for fine-grained Hijaiyah gestures with similar structural patterns. These results confirm that the proposed framework provides a robust and reliable solution for real-time wearable sign language recognition and offers practical benefits for Hijaiyah-based assistive communication systems.**

Keywords*—Sign language recognition; Hijaiyah sign language; wearable sensors; smart glove; multimodal fusion; polynomial temporal smoothing; real-time recognition

I. Introduction

Sign language recognition has been extensively investigated as a core technology for assistive communication systems that support individuals with hearing and speech impairments. Automatic translation of hand gestures into linguistic symbols enables improved accessibility in education, healthcare, and everyday interactions. Early studies in this area predominantly relied on vision-based approaches, utilizing RGB cameras, depth sensors, or skeletal tracking to model hand shape and motion patterns [1], [3], [11]. With the rapid advancement of machine learning and deep learning techniques, vision-based systems have achieved promising recognition accuracy, particularly for well-studied sign languages such as American Sign Language (ASL) and British Sign Language (BSL) [12], [19], [31].

Despite these advances, vision-based sign language recognition systems remain constrained by several inherent limitations. Their performance is highly sensitive to environmental factors, including illumination variations, background clutter, occlusion, and motion blur, which frequently occur in real-world settings [3], [12], [19]. In addition, camera-based systems typically require fixed viewpoints and considerable computational resources, limiting their suitability for real-time, mobile, and embedded assistive applications [11], [31]. These challenges have motivated an increasing interest in alternative sensing modalities that are less dependent on external visual conditions.

Wearable sensor–based approaches have therefore emerged as a robust alternative for sign language recognition. Smart gloves [2] equipped with flex sensors enable continuous measurement of finger bending, while inertial measurement units (IMUs) capture hand orientation and dynamic motion cues [9], [10], [13], [14]. By directly sensing hand articulation at the source, wearable systems significantly reduce the influence of environmental disturbances and provide more stable gesture representations across diverse operating conditions [4], [18], [22], [32]. Numerous studies have demonstrated the feasibility of glove-based systems for gesture recognition and sign language translation using combinations of flex sensors, accelerometers, and gyroscopes [6], [7], [15], [20], [21], [26].

However, existing wearable sensor–based sign language recognition systems still face several unresolved challenges. Many prior studies rely on relatively small datasets involving limited numbers of participants, typically ranging from three to ten users, which restricts cross-user generalization and robustness [7], [15], [24], [28], [29]. In addition, gesture vocabularies are often limited, with many systems evaluating only partial sets of letters or gestures rather than complete sign alphabets [5], [8], [17], [28]. Furthermore, most preprocessing pipelines employ simple linear filtering techniques, such as moving average or low-pass filters, which are insufficient to model the nonlinear temporal characteristics inherent in flex–IMU sensor signals. As a result, micro-tremors, sensor drift,

and temporal instability frequently persist, leading to misclassification, especially for gestures with subtle structural differences [12], [19], [25].

These challenges are particularly evident in Hijaiyah sign language, which represents the Arabic alphabet and consists of 28 gesture classes. Many Hijaiyah letters differ only by minor variations in finger configuration or hand orientation, making them especially sensitive to noise and temporal inconsistencies in sensor measurements [5], [17], [28]. Existing Arabic and Hijaiyah sign language recognition systems are often limited to partial datasets, handcrafted feature extraction, or small-scale user evaluations, leaving large-scale multimodal modeling and real-time robustness insufficiently explored [8], [17], [28].

To address these limitations, more advanced temporal modeling techniques are required to stabilize sensor trajectories while preserving meaningful motion dynamics. Polynomial regression has been shown to be effective for motion smoothing and trajectory stabilization, as it is capable of modeling nonlinear temporal behavior more accurately than conventional linear filters [3], [12], [23]. Nevertheless, the integration of polynomial temporal modeling with multimodal flex–IMU fusion for sign language recognition remains largely unexplored, particularly in the context of real-time wearable systems.

In this study, a robust real-time Multimodal Polynomial Fusion (MPF) framework is proposed for sensor-based sign language recognition using a flex–IMU smart glove, with Hijaiyah gestures serving as the application domain. The proposed framework applies nonlinear polynomial temporal smoothing within a sliding window to stabilize raw flex and IMU signals, followed by multimodal fusion to enhance gesture separability and temporal consistency. Unlike conventional linear preprocessing approaches, the proposed method explicitly models nonlinear sensor dynamics, thereby reducing intra-class variance and improving discrimination among structurally similar gestures.

The effectiveness of the proposed framework is validated using a large-scale multimodal dataset comprising 231,000 samples collected from 33 users, covering all 28 Hijaiyah gesture classes. A subject-independent evaluation protocol is adopted to rigorously assess cross-user generalization. Comprehensive experiments conducted under offline, session-aware, and real-time streaming conditions demonstrate that the proposed MPF framework consistently outperforms a baseline approach based on raw normalized signals in terms of recognition accuracy, robustness, and temporal stability.

The remainder of this study is organized as follows: Section II reviews related work on vision-based and wearable sensor–based sign language recognition. Section III describes the proposed Multimodal Polynomial Fusion framework, including system architecture, preprocessing, and real-time implementation. Experimental results and analysis are presented in Section IV. The discussion is presented in Section V. Finally, Section VI concludes the study and outlines directions for future research.

II. Related Work

Research on sign language recognition has evolved along two dominant paradigms, namely vision-based approaches and wearable sensor–based systems. Each paradigm offers distinct advantages while also exhibiting inherent limitations, particularly when deployed in real-time assistive scenarios.

Vision-based sign language recognition has been extensively explored using RGB cameras, depth sensors, and skeletal tracking models. Early studies employed handcrafted features extracted from hand shape and motion trajectories, while more recent works leverage convolutional neural networks (CNNs), recurrent neural networks (RNNs), and transformer-based architectures to improve recognition accuracy [1], [3], [11], [12], [19], [31]. These approaches have demonstrated strong performance for widely studied sign languages, especially ASL, under controlled conditions. However, several studies report that vision-based systems remain highly sensitive to illumination variations, occlusions, background clutter, and camera viewpoints, which significantly degrade performance in unconstrained environments [3], [12], [19]. Moreover, the computational complexity of deep vision models limits their feasibility for real-time embedded deployment, particularly in wearable or mobile assistive systems [11], [31].

To overcome the environmental dependency of camera-based solutions, wearable sensor–based sign language recognition has attracted increasing attention. Smart gloves equipped with flex sensors, accelerometers, gyroscopes, and inertial measurement units (IMUs) enable direct measurement of finger articulation and hand motion, providing more stable gesture acquisition independent of external visual conditions [9], [10], [13], [14]. Early glove-based systems demonstrated the feasibility of translating hand gestures into symbolic representations using flex sensors and basic machine learning classifiers [6], [7], [15]. Subsequent studies integrated IMUs to capture three-dimensional motion cues, improving recognition robustness for dynamic gestures [4], [18], [20], [22], [26], [30], [32].

Despite these advances, many wearable sensor–based systems remain limited by dataset scale and evaluation scope. Numerous studies evaluate their models using small participant cohorts, often involving fewer than ten users, which restricts the assessment of cross-user generalization and robustness [7], [15], [24], [28], [29]. In addition, gesture vocabularies are frequently constrained to partial alphabets or small gesture sets, limiting their applicability to complete sign language systems [5], [8], [17], [28]. These limitations are particularly critical for alphabets with subtle inter-class differences, where robust temporal modeling and extensive user diversity are essential.

Another important challenge lies in the preprocessing and temporal modeling of wearable sensor signals. Most existing works rely on simple linear filtering techniques, such as moving average smoothing or low-pass filters, to reduce sensor noise and jitter [12], [19], [25]. While these methods offer basic noise suppression, they are insufficient for modeling the nonlinear temporal dynamics inherent in flex–IMU signals, including micro-tremors, drift, and execution variability across users. As a result, gesture trajectories often remain unstable, leading to

increased intra-class variance and misclassification among structurally similar gestures.

Multimodal fusion has been proposed as a strategy to improve robustness by integrating complementary sensor modalities. Several studies combine flex sensors with IMUs or tactile sensors using feature-level or decision-level fusion, demonstrating improved recognition accuracy compared with single-modality approaches [4], [18], [22], [27], [32]. Classical classifiers such as k-nearest neighbors (k-NN), support vector machines (SVMs), dynamic time warping (DTW), and random forests have been widely used in these systems. Recent deep learning-based glove systems [16] demonstrate higher accuracy but still rely on linear preprocessing. More recent works explore deep learning-based fusion models to improve multimodal integration [18], [19], [27]. However, most fusion strategies still rely on linear preprocessing pipelines and do not explicitly address nonlinear temporal instability in sensor trajectories.

Polynomial regression and related nonlinear modeling techniques have been investigated in motion smoothing and trajectory stabilization tasks, showing superior performance over linear filters in capturing complex temporal patterns [3], [12], [23]. In the context of hand motion and gesture analysis, polynomial modeling has been reported to improve signal stability and reduce high-frequency noise. Nevertheless, the application of polynomial temporal smoothing within a multimodal flex–IMU fusion framework for real-time sign language recognition remains largely unexplored in the existing literature.

Research on Arabic and Hijaiyah sign language recognition is comparatively limited when contrasted with ASL and other widely studied sign languages. Existing works often focus on partial Hijaiyah or Arabic gesture sets, rely on handcrafted features, or evaluate performance using small-scale datasets [5], [8], [17], [28]. Several studies highlight the difficulty of distinguishing Hijaiyah letters that differ only by subtle finger configurations, emphasizing the need for more robust temporal modeling and multimodal integration [5], [17], [28]. To date, no study has reported a large-scale multimodal flex–IMU dataset for Hijaiyah sign language combined with advanced nonlinear temporal fusion evaluated under real-time conditions.

Based on this review, a clear research gap can be identified. Existing vision-based approaches struggle with environmental sensitivity, while wearable sensor–based systems remain constrained by limited datasets, linear temporal modeling, and insufficient real-time validation. Although multimodal fusion improves robustness, the lack of nonlinear temporal stabilization continues to limit performance, particularly for fine-grained alphabets such as Hijaiyah. These limitations motivate the development of a robust real-time framework that integrates nonlinear temporal modeling with multimodal sensor fusion, supported by large-scale subject-independent evaluation. The proposed Multimodal Polynomial Fusion (MPF) framework directly addresses these gaps by stabilizing flex–IMU trajectories through polynomial temporal smoothing and enhancing gesture separability via multimodal integration.

III. Methodology

This section describes the overall framework for real-time Hijaiyah sign recognition using the proposed Multimodal Polynomial Fusion (MPF) approach. The methodology includes hardware design, data acquisition, preprocessing, polynomial temporal smoothing, multimodal fusion, feature extraction, classification, and real-time implementation.

A. Smart-Glove Architecture

The smart glove integrates five flex sensors and a three-axis IMU to capture finger bending and hand motion, producing an eight-channel multimodal signal. As shown in Fig. 1, the pipeline applies preprocessing, polynomial smoothing, multimodal fusion, and classification, with a real-time sliding window ensuring temporal consistency and robustness during continuous gesture recognition.

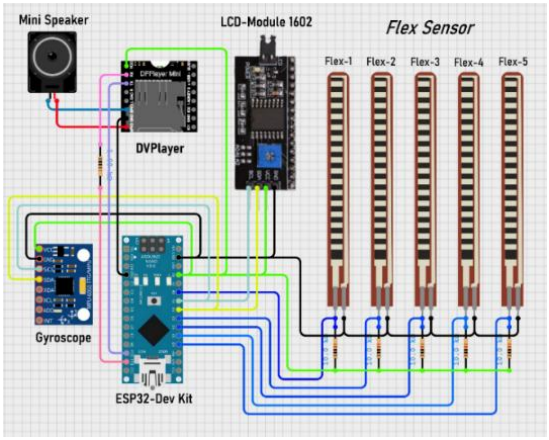

Fig. 1. Proposed multimodal Flex–IMU.

The smart glove integrates five flex sensors and a three-axis IMU to capture finger bending and hand orientation, enabling reliable discrimination of all 28 Hijaiyah gestures, including those with similar postures, as shown in Fig. 2.

Fig. 2. Sensor placement on the hand.

The assembled smart-glove prototype integrates flex sensors, an IMU, a microcontroller, and a power unit into a wearable form factor, enabling stable signal acquisition during natural hand movements while maintaining user comfort, as shown in Fig. 3.

Fig. 3. Fully assembled smart-glove hardware prototype.

Hijaiyah gesture classes used in this study, representing the complete Hijaiyah alphabet and following established conventions in sensor-based sign language recognition using flex–IMU smart gloves [13], [17], [26], [33], in Fig. 4.

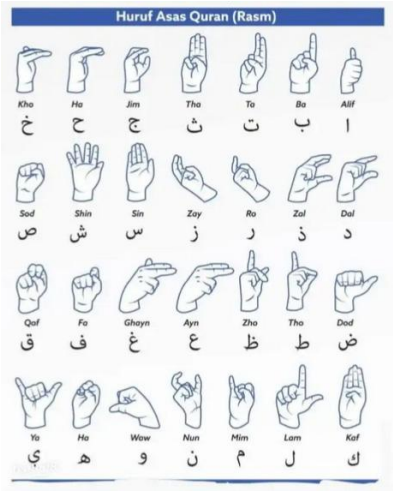

Fig. 4. The 28 Hijaiyah gesture.

B. Data Acquisition

Data collection involved 33 participants, each performing all 28 Hijaiyah gesture classes in 250 repetitions, yielding a total of 231,000 multimodal samples. This large-scale dataset captures natural variations in hand shape, execution speed, and sensor alignment across users. To enable rigorous subject-independent evaluation, the dataset was partitioned into 26 users for training and 7 unseen users for testing, ensuring that model performance reflects true cross-user generalization rather than memorization of individual motion patterns. Each raw observation is represented as:

1) Feature vector

$$S(t) = [f_1(t), f_2(t), f_3(t), f_4(t), f_5(t), x(t), y(t), z(t)]$$

where, $f_1(t)$ – $f_5(t)$ denote flex-sensor values and $a_x(t), a_y(t), a_z(t)$ denote IMU signals.

C. Preprocessing

To mitigate differences arising from hand size, glove fitting, and sensor drift, each sensor channel undergoes z-score normalization:

1) Z-score normalization

$$S'(t) = \frac{S(t) - \mu}{\sigma}$$

where, μ and σ represent the mean and standard deviation computed from the training dataset.

D. Polynomial Temporal Smoothing

Raw flex–IMU signals naturally contain micro-tremors, noise, and nonlinear temporal variations that can degrade gesture separability. To mitigate these effects, polynomial regression is applied within a sliding window of length W, producing smoothed temporal trajectories that better capture the underlying motion patterns while suppressing high-frequency fluctuations in the channel. The smoothed value is computed as:

1) Polynomial smoothing

$$\hat{s}(t) = \sum_{k=0}^{d} a_k t^k$$

where, d denotes the polynomial order and α_k are coefficients estimated using least-squares fitting.

E. Multimodal Polynomial Fusion

Following temporal smoothing, all flex and IMU channels are integrated into a unified multimodal representation:

1) MPF vector

$$F = [\hat{f}_1, \hat{f}_2, \hat{f}_3, \hat{f}_4, \hat{f}_5, \hat{x}, \hat{y}, \hat{z}]$$

where, $\tilde{f}_i(t)$ and $\tilde{a}_j(t)$ represent the polynomial-smoothed flex and IMU signals, respectively.

The MPF approach strengthens cross-channel modeling and improves discrimination among similar gestures by producing more stable, noise-resistant sensor representations. Fig. 5 highlights these enhancements compared with the baseline pipeline.

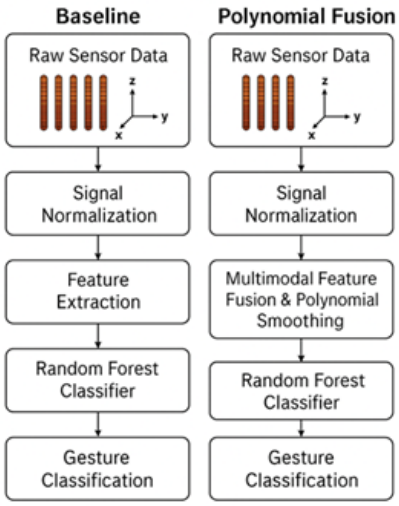

Fig. 5. Baseline vs. Polynomial fusion framework.

F. Feature Extraction, Classification, and Implementation

After multimodal polynomial fusion, compact features are extracted from each fused window, including basic statistical descriptors and temporal gradients, to represent gesture dynamics. A Random Forest classifier is employed due to its robustness to noise and nonlinear feature interactions, with identical settings applied to both the baseline and MPF models to ensure fair comparison. The entire pipeline is implemented in a real-time streaming framework using a sliding-window mechanism, enabling stable predictions and smooth gesture transitions with low computational overhead. Model performance is evaluated using accuracy, macro precision, recall, F1-score, and confusion matrix analysis under subject-independent and real-time conditions.

IV. Results

This section presents the experimental results of the proposed Multimodal Polynomial Fusion (MPF) framework. The evaluation is conducted under subject-independent, session-aware, and real-time streaming conditions to assess recognition accuracy, robustness across users, and temporal stability. Performance is compared against a baseline system using raw normalized flex–IMU features.

A. Overall Performance Evaluation

To provide a concise quantitative comparison between the baseline system and the proposed Multimodal Polynomial Fusion (MPF) framework, overall recognition performance is summarized using standard evaluation metrics. Accuracy and macro-averaged precision, recall, and F1-score are reported to ensure balanced assessment across all gesture classes under subject-independent and real-time conditions. The results presented in Table I highlight the consistent performance improvements achieved by the proposed framework over the baseline approach.

TABLE I. Overall Performance Comparison

Metric	Baseline Model	MPF Model
Accuracy (%)	92.42	96.32
Precision (Macro)	92.56	96.51
Recall (Macro)	92.44	96.32
F1-Score (Macro)	92.44	96.30

The real-time evaluation shows that MPF consistently outperforms the baseline across all metrics, providing more stable and reliable predictions during continuous gesture execution. Higher precision, recall, and F1-score indicate reduced misclassification and improved consistency across gesture classes, confirming MPF's robustness for real-world assistive use. Fig. 6 further illustrates the real-time behavior of the proposed framework under subject-independent conditions; representative gesture detection results from seven unseen users are presented. Each example corresponds to a different test subject and shows a direct comparison between the baseline model and the proposed Multimodal Polynomial Fusion (MPF) approach for the same Hijaiyah gesture, highlighting user-specific variability and temporal prediction stability.

1) Heatmap of per-gesture real-time accuracy: Fig. 7 presents the per-gesture accuracy heatmap for the proposed MPF model, showing consistently high recognition accuracy across most Hijaiyah gesture classes under real-time streaming conditions.

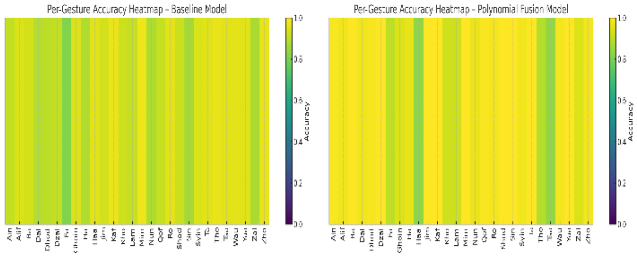

Fig. 7. Presents the per-gesture accuracy heatmap for the MPF model.

2) Real-time accuracy comparison: Compares the real-time accuracy of the baseline and MPF models, as shown in Fig. 8. The MPF model achieves noticeably higher performance, confirming the effectiveness of polynomial smoothing and multimodal fusion in stabilizing gesture predictions during continuous execution.

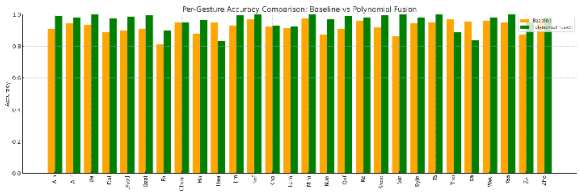

Fig. 8. Real-time accuracy comparison.

B. Misclassification and Confusion Analysis

Misclassification patterns were examined to understand how often specific gestures were confused with others during real-time evaluation. This analysis provides insight into gesture similarities that challenge both models and reveals how Polynomial Fusion (MPF) reduces these errors. In Fig. 9, the baseline model exhibits frequent misclassification in gestures with subtle structural similarities such as Fa, Sin, Zai, Nun, and Ha, resulting in darker regions on the heatmap and lower per-gesture accuracy. In contrast, the MPF model shows far fewer errors, with a more uniform and brighter heatmap that reflects improved stability and separability. Only minor confusion remains in closely related gestures like Haa, Tsa, Kho, Fa, Lam.

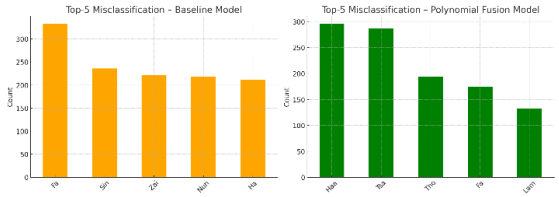

Fig. 9. Top misclassified gestures - polynomial fusion model.

C. Variance Reduction Analysis

To further assess model stability across users, variance analysis was performed using per-user accuracy distributions. Lower variance indicates more consistent performance when

encountering natural differences in gesture execution, hand size, glove fit, and movement style.

D. Temporal Stability and Per-Letter Robustness

The per-letter robustness plot shows that the MPF model consistently maintains higher accuracy and smoother performance across all 28 gestures, whereas the baseline model exhibits greater fluctuation and instability. MPF's smoother accuracy curve reflects stronger temporal stability and improved discrimination between similar gestures in Fig. 10, confirming its suitability for real-time recognition.

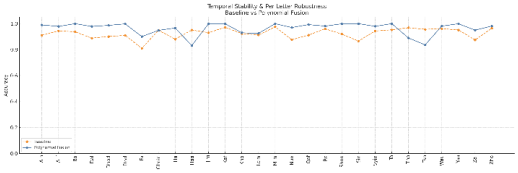

Fig. 10. Temporal stability and per-letter robustness.

V. Discussion

A. Interpretation of Performance Improvements

Across all offline, session-aware, and real-time evaluations, the MPF framework consistently outperforms the baseline. Its improvements stem from nonlinear temporal smoothing, multimodal fusion, reduced intra-class variance, and enhanced gesture discriminability. These results clearly demonstrate MPF's effectiveness for stable and reliable real-time Hijaiyah sign recognition.

B. Temporal Stability and Gesture Separability

Temporal stability plays a critical role in real-time sign language recognition, where fluctuating predictions can degrade recognition reliability. As observed in the temporal robustness analysis, the proposed MPF framework produces smoother and more consistent predictions over time compared with the baseline. This behavior indicates effective suppression of sensor jitter and short-term fluctuations in flex–IMU signals.

Improved temporal stability contributes directly to enhanced gesture separability by maintaining consistent feature trajectories across consecutive frames. As a result, class boundaries remain more distinct during continuous gesture execution, supporting stable real-time recognition without relying on frame-level corrections.

C. Comparison with Prior Wearable Sensor-Based Methods

Compared with prior wearable sensor–based sign language recognition systems that rely on linear preprocessing and limited user evaluations [6], [7], [15], [24], the proposed MPF framework demonstrates superior robustness and scalability, supported by large-scale subject-independent evaluation and nonlinear temporal modeling.

Table II highlights that the most existing sensor-based sign language recognition systems with reported accuracies below 96% are evaluated using limited datasets and a small or unspecified number of users, which restricts their generalizability. Several approaches rely primarily on flex sensors with predefined gesture mappings, leading to moderate recognition performance and reduced robustness to inter-user variability [6], [30], while others incorporate additional sensing modalities but still operate on relatively small datasets [9], [11], [18]. Moreover, some studies report results under offline evaluation settings [28], [33], which do not adequately reflect stability and consistency during continuous real-time operation. In contrast, the proposed Multimodal Polynomial Fusion (MPF) framework is evaluated on a substantially larger dataset comprising 231,000 samples from 33 users and operates fully in real time, enabling improved robustness and higher recognition accuracy (96.32%) in continuous sign language recognition scenarios.

TABLE II. Literature-Based Comparison of Representative State-of-the-Art Sign Language Recognition Methods

Method / Approach	*Modality*	*Dataset Scale*	*#Users*	*Reported Accuracy (%)*	*Real-Time*	*Ref*
Smart Glove-Based SLR System	Flex Sensors	Limited dataset	–	~85–90	Yes	[6]
Assistive Communication Glove (Combined Sensors)	Flex + Contact + 3D Accel	28 ASL gestures	7	77.9	Yes	[9]
Smart Hand Sign Glove with ESP32	MPU6050 + ESP32	Limited	–	92–95	Yes	[11]
Intelligent Glove with kNN + CHC/DROP3	5 Flex Sensors	~5,000 samples	10	85	Yes	[18]
Indonesian Sign Language Recognition (ANN)	Flex + Accelerometer	1,000 samples	–	91.60 (offline)	No	[28]
Sign Language Detection using Flex Sensor	Flex Sensors	Limited	–	88–92	Yes	[30]

Proposed MPF (This Work)	Flex–IMU	231,000 samples	33	96.32	Yes	This study

D. Limitations and Future Directions

Despite its advantages, the proposed wearable sensor-based framework has inherent limitations. The reliance on specialized smart-glove hardware introduces additional cost and usability considerations compared to vision-only approaches. Long-term wearability and user comfort may also affect practical deployment. Future work will explore lightweight hardware designs and cross-modal integration with vision-based cues to further enhance robustness

VI. Conclusion and Future Work

A. Conclusion

This study introduces a Multimodal Polynomial Fusion (MPF) framework for real-time Hijaiyah sign recognition using

flex–IMU smart gloves. MPF enhances signal stability, reduces intra-class variability, and improves gesture separability through nonlinear smoothing and multimodal fusion. Across all evaluations, MPF consistently surpasses the baseline, demonstrating a robust and reliable foundation for fine-grained assistive communication systems. These findings directly address the research objective of improving temporal stability and recognition accuracy for fine-grained Hijaiyah gestures in real-time wearable sign language systems.

B. Future Work

Future work may explore adaptive polynomial smoothing, fusion with vision-based modalities, and integration into lightweight neural models for edge deployment. Expanding user diversity, improving glove ergonomics, and extending recognition to continuous Hijaiyah sequences will further enhance the practicality and generalization of sensor-based sign language systems. Despite its advantages, the proposed wearable sensor–based approach has certain limitations. The use of smart gloves introduces hardware dependency and potential cost constraints, which may affect large-scale adoption. In addition, user comfort and long-term wearability remain important considerations. Nevertheless, these limitations are balanced by the system's robustness to environmental conditions and its suitability for real-time assistive applications.

EnGMHE: Enhanced Geometric Mean Histogram Equalization for Low-Light Image Enhancement

Rawan Zaghloul[1], Hazem Hiary[2]
Department of Management Information Systems, Al-Balqa Applied University, Amman, 11934, Jordan[1]
Department of Computer Science, The University of Jordan, Amman, 11942, Jordan[2]

***Abstract*—Low-light image enhancement has been extensively studied, with numerous methods proposed to address this challenge. Among these, Geometric Mean Histogram Equalization (GMHE) emerged as a histogram-based technique specifically designed for enhancing low-light images. Despite its effectiveness, GMHE has notable limitations: it often oversaturates results under specific conditions and amplifies noise, limiting its practical applicability. These shortcomings become particularly pronounced in real-world scenarios where low-light conditions are frequently accompanied by significant noise artifacts. To address these shortcomings, this study introduces EnGMHE, an enhanced version of GMHE. The proposed method consists of three key steps: 1) introducing a novel Gaussian Histogram Equalization (GHE) to improve image contrast and brightness, 2) utilizing GMHE to enhance sharpness and detail clarity, and 3) denoising the enhanced image using a pretrained deep neural network model. Together, these steps offer a more robust solution for low-light image enhancement, balancing contrast improvement, detail preservation, and noise reduction. The experimental results reveal not only the efficiency but also the effectiveness of the proposed model when benchmarked against the state-of-the-art methods.**

***Keywords*—Histogram Equalization; image enhancement; low-light enhancement; denoising; deep learning**

I. Introduction

Enhancing low-light images is essential across various domains, including surveillance, medical imaging, and photography, especially within the context of computer vision and intelligent systems. Insufficient lighting often leads to images with low brightness, poor contrast, and noticeable noise, severely affecting visual quality and obscuring critical details necessary for effective automated processing.

In recent decades, researchers have extensively explored solutions for low-light image enhancement. One of the classic methods is Histogram Equalization (HE) [1]. While HE effectively enhances local contrast on dark images, it often oversaturates bright regions in the process [2]. Another prominent approach involves Retinex-based methods [2-8], which decompose low-light images into reflectance and illumination layers. While this decomposition can yield promising enhancements, many Retinex-based techniques require priors for effective layer separation [9].

Recent advancements in low-light image enhancement leverage dehaze-based methods [10] and illumination map estimation techniques [2], [4]. With the rise of deep learning, enhanced computational power and large datasets have driven progress. Supervised learning methods relying on paired datasets [11] are used to map low-light to enhanced images, effectively reducing noise and recovering details. However, their performance depends on high-quality datasets, which remain a significant challenge.

Unsupervised learning methods utilize unpaired datasets [12], which are more accessible, larger in scale, and diverse in content. These methods are adaptively trained to restore illumination, color, and contrast. However, the lack of paired supervision can limit their ability to recover fine details, often leaving noise in the enhanced results. The field of low-light image enhancement continues to evolve, with researchers exploring methodologies that balance effectiveness with inherent trade-offs [9].

While deep learning methods often deliver impressive results, their efficiency remains a concern, particularly in real-world scenarios where low-light conditions are frequently accompanied by noise artifacts. To address this gap, this study introduces the EnGMHE (Enhanced Geometric Mean Histogram Equalization) model, a novel approach for low-light image enhancement. Unlike classical histogram-based methods, EnGMHE combines Gaussian Histogram Equalization (GHE) for initial contrast enhancement, GMHE for structural preservation, and a pre-trained denoising network for noise suppression, providing a unified and robust enhancement pipeline.

EnGMHE is built on the foundation of GMHE (Geometric Mean Histogram Equalization) [13], a contrast enhancement technique inspired by traditional histogram equalization. A key innovation of EnGMHE is the introduction of Gaussian Histogram Equalization (GHE), proposed as the first step to enhance the input low-light image's contrast and luminosity. Following GHE, the traditional GMHE is applied to further refine the enhancement. The final step involves denoising using a pre-trained deep neural network, effectively mitigating noise introduced during low-light image capture. This novel model integrates the newly proposed GHE with traditional and advanced techniques, delivering a robust solution for improving the visual quality of images captured in low-light conditions.

The effectiveness of the proposed model is validated through extensive experiments, where its performance is benchmarked against state-of-the-art methods in low-light image enhancement.

The rest of the study is as follows: Section II reviews the literature and related work; Section III details the proposed

methodology; Section IV presents the experimental settings and results; and Section V concludes the study.

II. Related Work

The problem of low-light image enhancement has gained significant attention in recent years, leading to the development of diverse methodologies ranging from classical techniques to modern deep learning methods. These methods aim to improve the brightness, contrast, and overall visual quality of low-light images while addressing challenges such as noise and color distortion.

Traditional methods, such as HE [1], BPDHE [14], and GMHE [13], focus on enhancing image contrast by redistributing pixel intensity values. HE is computationally efficient and straightforward, but it often amplifies noise and over-saturates the image.

Retinex theory-based approaches, such as LIME [2], NPE [15], and SRIE [4], decompose an image into illumination and reflectance components. By enhancing the illumination while preserving the reflectance, these methods aim to balance brightness and detail clarity.

Supervised and semi-supervised deep learning methods, such as LLNET [16], DRBN [17], RetinexNet [3], MBLLEN [18], LLFlow [19], PairLIE [20], and MIRNet [21], leverage paired datasets to learn complex mappings from low-light images to enhanced images. These methods excel in preserving fine details and reducing noise. For instance, DRBN incorporates recursive band representation for effective enhancement, while MIRNet utilizes multi-scale feature extraction for robust performance. However, their reliance on high-quality paired datasets can limit scalability. In addition, LLFlow employs flow-based mechanisms for illumination correction.

Unsupervised deep learning methods, such as EnlightenGAN [12] and SCI [22], address the challenge of paired dataset availability by learning from unpaired data. EnlightenGAN uses adversarial learning to generate visually appealing results. Despite their adaptability, these methods may struggle with detail preservation and noise reduction.

Recently, zero-shot learning methods rely on models that are trained on a set of classes (seen classes) but can make predictions on new, unseen classes without direct examples of those unseen classes during training. These methods leverage transfer learning to generalize knowledge from seen to unseen classes. Examples of such methods include ZeroDCE [23], ZeroDCE++ [24], RUAS [25], and ExCNet [26].

Transformer-based architectures like Restormer [27] and U-EGformer [28] have also demonstrated significant potential in low-light enhancement. Restormer employs attention mechanisms to capture global context, while U-EGformer integrates exposure-guided mechanisms for enhanced adaptability. Although these methods offer high performance, they often come with increased computational complexity.

Emerging techniques like MTUR-Net [29] focus on multi-task learning for joint enhancement and noise reduction. Additionally, methods like ISSR [30] and LCDPNet [31] leverage advanced architectures to address specific challenges in low-light scenarios. For underwater and domain-specific scenarios, methods such as WaterNet [32], Ucolor [33] and PUGAN [34], address challenges like haze, color distortion, and poor visibility. These methods utilize specialized architectures and priors to handle unique environmental conditions effectively.

While the aforementioned methods have significantly advanced the field, challenges such as noise suppression, detail preservation, and computational efficiency persist. Many existing techniques either focus on enhancing brightness and contrast or on reducing noise, but few address these issues jointly. Furthermore, achieving a balance between enhancement quality and real-world applicability remains a critical research gap.

III. Methodology

The proposed methodology involves a sequence of preprocessing and noise-reduction phases. They include advanced histogram operations and a denoising approach using a pre-trained neural network, as shown in Fig. 1.

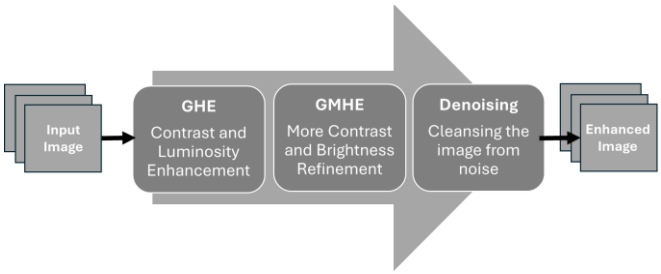

Fig. 1. The main phases of the proposed EnGMHE.

A. Gaussian Histogram Equalization (GHE)

This phase introduces the proposed GHE. It performs image enhancement through a Gaussian-smoothed histogram equalization technique. The following are the proposed steps for applying GHE to each of the image channels:

1) *Compute the histogram of the input image.*
2) *Apply Gaussian smoothing:*

A Gaussian filter, as defined in Eq. (1), is applied to the histogram to smooth intensity variations.

$$G(x,y) = \frac{1}{2\pi\tau^2} e^{-\frac{x^2+y^2}{\tau^2}} \quad (1)$$

where, *G(x,y)* is the value of the Gaussian function at pixel *(x,y)*. The parameter τ denotes the standard deviation of the Gaussian distribution and is empirically determined to control the degree of histogram smoothing. Pixel *(x,y)* represents the center of the filter. The filter size is determined using Eq. (2):

$$Filter_{Size} = 2 \times ceil(2 \times \tau) + 1 \quad (2)$$

τ is determined experimentally to control the degree of smoothing, as follows:

$\tau \in [0.5\text{-}1]$: Minimal smoothing.

$\tau \in [1.5\text{-}3]$: Moderate smoothing (balanced).

$\tau > 3.5$: Significant smoothing.

3) Normalize the smoothed histogram: The smoothed histogram h is normalized such that its values sum to 1, forming a probability distribution, as defined in Eq. (3):

$$Norm_h_i = \frac{h_i}{\sum_i^p (h)}, i = \{1, \dots p\} \quad (3)$$

where, h_i is the value of the i^{th} bin in the histogram h, and p denotes the total number of bins.

4) Compute the cumulative distribution function (CDF) for the normalized histogram, as defined in Eq. (4):

$$CDF_h_i = \sum_{j=0}^{i} Norm_h_j, i = \{1, \dots p\} \quad (4)$$

5) Map pixel intensity values: Each pixel intensity i is transformed to a new value, as defined in Eq. (5):

$$New_intensity_level_i = CDF_h_i * (L-1), i = \{1, \dots p\} \quad (5)$$

where, L is the maximum intensity value (265 in this study).

6) Output the enhanced image: Finally, the output image I' is generated by mapping the intensity of each pixel in the original image I according to the new intensity values stored in $New_intensity_level$. Note that steps (3) to (6) are the steps of the traditional HE method.

B. Geometric Mean Histogram Equalization (GMHE)

The key idea behind GMHE [13] is to preserve the overall structure of the image while enhancing contrast, particularly in dark regions. This is achieved by redistributing pixel intensities based on the geometric mean, which is less sensitive to extreme values than the arithmetic mean and therefore reduces the influence of outliers in the histogram.

In this phase, GMHE is applied to the intermediate enhanced image I'. The procedure is performed independently on each image channel as follows:

For each channel in I' apply the following steps:

1) Compute the histogram S of the input image.

2) Apply a geometric mean filter to the histogram to obtain a modified histogram (S') using Eq. (6):

$$S' = (\prod_{i=1}^{n} x_i)^{1/\gamma} \quad (6)$$

where, x_i represents the histogram values within the filter window, n denotes the filter length (set to 3 in this work), and γ is an experimentally determined constant that controls the strength of the geometric mean operation.

3) Apply steps (3–6) from the first phase (GHE) to the modified histogram S' to generate the enhanced image (I'').

C. Denoising

To suppress noise, while preserving image fidelity, a channel-wise image denoising is applied to the enhanced image I'' using a pre-trained deep learning model described in [35]. This network was selected due to its demonstrated effectiveness and stability in general-purpose image denoising tasks, particularly in scenarios involving low-light and noise-amplified images.

As shown in Fig. 2, the adopted model consists of 19 convolutional blocks, where each block is composed of a convolutional layer followed by batch normalization and a ReLU activation function. This relatively deep architecture enables the extraction of hierarchical features, ranging from low-level structures such as edges and intensity gradients to higher-level spatial patterns, which is essential for discriminating noise from meaningful image content. Padding is employed in all convolutional layers to preserve the spatial dimensions of the input image, thereby preventing the loss of structural details during the denoising process.

The use of a pre-trained denoising network is motivated by both technical and practical considerations. Leveraging a pre-trained model allows the proposed framework to benefit from robust, previously learned noise characteristics without requiring dataset-specific retraining, which enhances computational efficiency and generalizability. Moreover, the regression-based output layer is specifically designed to estimate clean image intensities, enabling effective noise suppression, while maintaining important visual and structural details. This balance between noise reduction and detail preservation makes the selected network particularly suitable for integration into the proposed EnGMHE-based enhancement pipeline.

IV. Experimental Results and Analysis

A. Datasets Used in the Comparisons

The datasets used in this study include both paired and unpaired collections. The ExDark-Bicycle [36], NPE [15], DICM [37], VV [38], MEF [39], LIME [2], and LoLi-Phone [40] datasets consist of 652, 84, 64, 24, 17, 10, and 600 real low-light images, respectively, with varying resolutions. These datasets are unpaired and cover a wide range of indoor and outdoor scenes, including natural landscapes, buildings, and indoor objects or decorations.

In contrast, the LOL [3], MIT-5K [41], SICE [42], and UIEB [32] datasets are paired datasets. The LOL dataset includes LOL-15, which comprises 15 test images, and LOL-V2, which contains two subsets: 100 synthetic and 100 real test images. The MIT-5K provides 5000 low-light images, with 500 designated for testing. The SICE dataset contains 4800 real and synthetic multi-exposure images of various resolutions, capturing diverse indoor and outdoor scenes under different exposure levels. In this study, two variations of the SICE dataset, namely SICE_Grad and SICE_Mix[1], were used, each consisting of 589 paired images. Finally, two subsets of the UIEB dataset were utilized: one comprising 890 paired images and another challenging subset containing 60 images.

B. Metrics

This section presents an overview of the evaluation metrics employed in this study to assess the performance of the proposed methods. Both reference-based metrics, which rely on a ground-

[1] SICE_Grad and SICE_Mix datasets are available at "https://github.com/ShenZheng2000/LLIE_Survey".

truth image for comparison, and no-reference metrics, which evaluate image quality without relying on a reference image, are considered. These metrics were selected to provide a comprehensive assessment of image quality and processing effectiveness across diverse experimental scenarios.

1	'InputLayer'	Image Input	50x50x1 images
2	'Conv1'	Convolution	64 3x3x1 convolutions with stride [1 1] and padding [1 1 1 1]
3	'ReLU1'	ReLU	ReLU
4	'Conv2'	Convolution	64 3x3x64 convolutions with stride [1 1] and padding [1 1 1 1]
5	'BNorm2'	Batch Normalization	Batch normalization with 64 channels
6	'ReLU2'	ReLU	ReLU
7	'Conv3'	Convolution	64 3x3x64 convolutions with stride [1 1] and padding [1 1 1 1]
8	'BNorm3'	Batch Normalization	Batch normalization with 64 channels
9	'ReLU3'	ReLU	ReLU
⋮	⋮	⋮	⋮
55	'Conv19'	Convolution	64 3x3x64 convolutions with stride [1 1] and padding [1 1 1 1]
56	'BNorm19'	Batch Normalization	Batch normalization with 64 channels
57	'ReLU19'	ReLU	ReLU
58	'Conv20'	Convolution	1 3x3x64 convolutions with stride [1 1] and padding [1 1 1 1]
59	'FinalRegressionLayer'	Regression Output	mean-squared-error with response 'Response'

Fig. 2. The structure of the adopted pre-trained network.

1) Reference-based measures

a) SSIM (Structural Similarity Index) is a perceptual metric that evaluates the similarity between two images by considering their luminance, contrast, and structural information. SSIM values range from -1 to 1, where a value of 1 indicates perfect similarity. It is widely used in image processing tasks to assess the quality of reconstructed images. It is defined in Eq. (7) [43]:

$$SSIM(a,b) = \frac{(2\mu_a\mu_b+(k_1L)^2)(2\sigma_{ab}+(k_2L)^2)}{(\mu_a^2+\mu_b^2+(k_1L)^2)(\sigma_a^2+\sigma_b^2+(k_2L)^2)} \quad (7)$$

where, a and b denote the input and the enhanced images, respectively. μ denotes the mean of the specified image. σ_a^2 and σ_b^2 denote the variances of images a and b, respectively, while σ_{ab} represents the covariance between a and b. The constants (K_1, K_2, L) are set to *0.01*, *0.03*, and *255* for 8-bit images, respectively.

b) PSNR (Peak Signal-to-Noise Ratio) is a quantitative metric used to evaluate the quality of an image by measuring the ratio between the maximum possible power of an image and the power of noise that affects the image's fidelity. Expressed in decibels (dB), PSNR quantifies image quality by comparing the original and distorted images, with higher values indicating better quality [44]. It is defined as follows in Eq. (8) and Eq. (9):

$$PSNR(a,b) = 10.\log_{10}(\frac{L^2}{MSE(a,b)}) \quad (8)$$

$$MSE(a,b) = \frac{1}{MN}\sum_{i=1}^{M}\sum_{j=1}^{N}[a_{i,j} - b_{i,j}]^2 \quad (9)$$

where, a and b are the input and the enhanced images, respectively. L is a constant referring to the maximum possible pixel value, which is equal to 255 for 8-bit images. MSE denotes the mean square error between two images. M and N are the dimensions of the image (width and height). $a_{i,j}$ denotes the pixel value at position (i,j) in image a.

c) LPIPS (Learned Perceptual Image Patch Similarity) is a recently developed metric designed to evaluate image quality from the perspective of human perception. Unlike traditional metrics, such as *PSNR* and *SSIM*, which focus on pixel-level comparisons, *LPIPS* leverages deep learning features to align more closely with human visual perception [45], [46]. It measures the similarity between an image and its corresponding ground truth by calculating the difference between their feature representations, extracted from a pre-trained deep neural network (e.g., *VGG* or *AlexNet*), as described in Eq. (10):

$$LPIPS\ (I_1,I_2) = \sum_l w_l \|f_l(I_1) - f_l(I_2)\|_2 \quad (10)$$

where, f_l denotes the feature maps from layer l of the network, w_l represents the learned weights for each layer l, and $\|.\|_2$ denotes the L2-Norm (Euclidean distance) of the deep features of a trained CNN.

d) Delta_E is a reference-based measure that quantifies the difference between two colors in the *CIELAB* color space. It is widely used to evaluate color accuracy, identify deviations, and assess color similarity. Lower Delta-E values indicate better color consistency and are therefore preferred [47]. Delta-E is defined as shown in Eq. (11):

$$Delta_E = \frac{1}{MN}\sum_{i=1}^{M}\sum_{j=1}^{N}\sqrt{(L1_{i,j} - L2_{i,j})^2 + (a1_{i,j} - a2_{i,j})^2 + (b1_{i,j} - b2_{i,j})^2} \quad (11)$$

where, ($L1_{i,j}$, $a1_{i,j}$, $b1_{i,j}$) are the LAB values for a pixel (i, j) in the input image, and ($L2_{i,j}$, $a2_{i,j}$, $b2_{i,j}$) correspond to those of the enhanced image. The overall score is obtained by averaging the pixel-wise Delta-E values, yielding a single scalar that reflects the overall perceptual color fidelity.

2) No reference-based measures

a) BRISQUE (Blind/Reference-less Image Spatial Quality Evaluator) is a no-reference image quality assessment model that operates in the spatial domain to evaluate image quality without relying on distortion-specific features or frequency-domain transformations, such as DCT or wavelets. It

uses natural scene statistics (NSS) of locally normalized luminance coefficients and their products to quantify the loss of image "naturalness" caused by distortions, offering a holistic and distortion-generic measure of quality. BRISQUE is a model-driven measure which does not have a single closed-form analytical equation. Instead, it employs a machine learning pipeline that estimates image quality using NSS features and a trained regressor, as shown in Eq. (12):

$$BRISQUE(I) = SVR(F(I)) \quad (12)$$

where, I denotes the input low-light image. F(.) represents a 36-dimensional NSS feature vector extracted from I. SVR(.) is the pre-trained support vector regressor. The feature vector F is derived from locally normalized luminance coefficients and is computed by fitting an Asymmetric Generalized Gaussian Distribution (AGGD) to the normalized image and its directional pairwise product maps at two image scales [48].

b) NIQE (The Natural Image Quality Evaluator) is a no-reference image quality assessment metric that measures the degree to which an image's features deviate from the statistical regularities commonly observed in natural images. It is built upon a robust spatial-domain NSS model designed to capture quality-aware statistical features learned from a dataset of natural, undistorted images. Lower NIQE scores indicate better perceptual quality. The quality score is computed as the Mahalanobis distance between the image's feature vector and a multivariate Gaussian (MVG) model fitted on high-quality images [49].

c) UCIQE (Underwater Color Image Quality Evaluation) is a no-reference image quality assessment metric specifically designed for underwater images. It evaluates visual quality in the CIELab color space by analyzing three key factors: Chroma, which measures the image's colorfulness and reflects the loss of color diversity due to light scattering and absorption in underwater environments; Saturation, which assesses the vividness or dullness of colors; and Contrast, which quantifies the visibility of image details often diminished in underwater scenes because of haze or turbidity. The UCIQE metric is computed using Eq. (13):

$$UCIQE = c_1 \times std_c + c_2 \times con_1 + c_3 \times Avg_s \quad (13)$$

where, std_c denotes the standard deviation of chroma, con_1 denotes the contrast of luminance, and Avg_s represents the average of saturation. The coefficients c1, c2, and c3 are empirically determined (c_1 =0.4680, c_2 =0.2745, c_3=0.2576). This metric provides a quantitative evaluation of underwater image quality, enabling the assessment and enhancement of visual clarity and color fidelity [50].

C. Experimental Environment and Parameter Settings

To ensure the reproducibility and reliability of the experiments, a controlled experimental setup was carefully established, and specific parameter configurations were defined. The following details provide an overview of the conditions under which the experiments were conducted:

- All experiments in this study were conducted in the MATLAB environment and were executed on an *Intel(R)* Core(TM) i7 CPU @ 2.60GHz device with *12 GB* of RAM.
- In the context of EnGMHE, the parameters τ and γ control histogram smoothing and geometric mean redistribution, respectively. Default values of τ = 2 and γ = 25 provide robust performance across most low-light datasets. For datasets with specific characteristics, such as SICE and ExDark, slightly different values (see Table I) were used to achieve optimal enhancement. These exceptions do not require exhaustive per-dataset tuning; they simply reflect natural variations in image statistics across diverse datasets, while the method remains effective with the general default settings.

TABLE I. PARAMETER SETTINGS FOR THE DATASETS OF INTEREST

Dataset	τ	γ
MEF | NPE | LOL | DICM | LIME | UIEB | VV | MIT5K	2	25
ExDark	10	15
SICE	2	50

D. Qualitative Results

Fig. 3 shows the performance of various low-light enhancement methods on an image from the LIME dataset. The input image is underexposed, with significant loss of visibility in shadowed regions. SCI [22] brightens the image but introduces a strong purplish tint, making the colors appear unnatural. URetinexNet [51] enhances the brightness and detail visibility but overexposes certain regions, resulting in a reddish hue. In contrast, EnGMHE achieves a balanced enhancement, maintaining natural color while preserving fine details.

Fig. 4 presents a comparison, where the input is an underwater image suffering from poor visibility and color distortion. Compared to state-of-the-art methods, EnGMHE delivers visually consistent results with enhanced clarity and more accurate color restoration for underwater images.

As shown in Fig. 5(a), the input image represents challenging low-light photography, with significant visibility issues in darker regions. While the illuminated monument retains some visibility, the surrounding darker areas lack detail, making the image a strong candidate for enhancement. EnGMHE effectively balances brightness enhancement with structural detail preservation, whereas FDMLNet [55] overexposes bright areas (see the monument's facade). In Fig. 5(b), the input image presents complex lighting conditions, with a mix of shadowed areas and bright overhead lights. ZeroDCE++ and RetinexNet enhance brightness, but introduce noticeable artifacts and color distortions. KinD++ [56] over-saturates certain regions, leading to unnatural visual results. LIVENet [57] produces more natural adjustments in terms of brightness but fails to recover fine details in shadowed regions [Fig. 5(c)]. EnGMHE, however, delivers the most balanced output, effectively preserving both color fidelity and structural details while enhancing brightness.

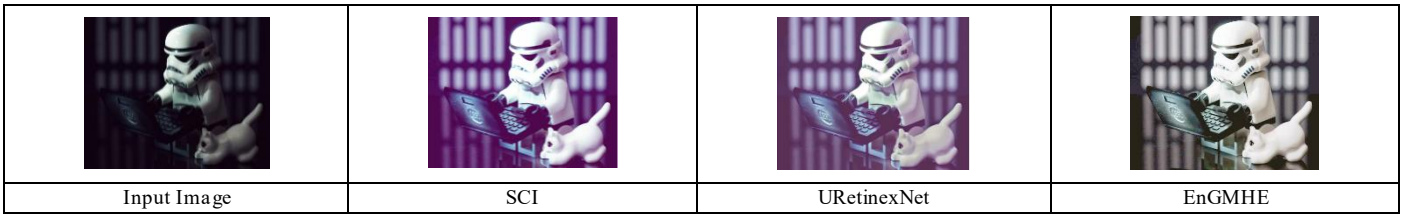

Fig. 3. Visual comparison with state-of-the-art methods on an input image from the LIME dataset.

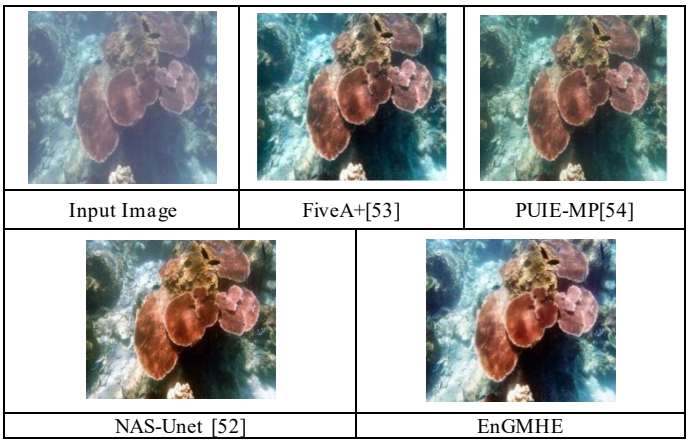

Fig. 4. Visual comparison with state-of-the-art methods on an input image from the UIEB-890 dataset.

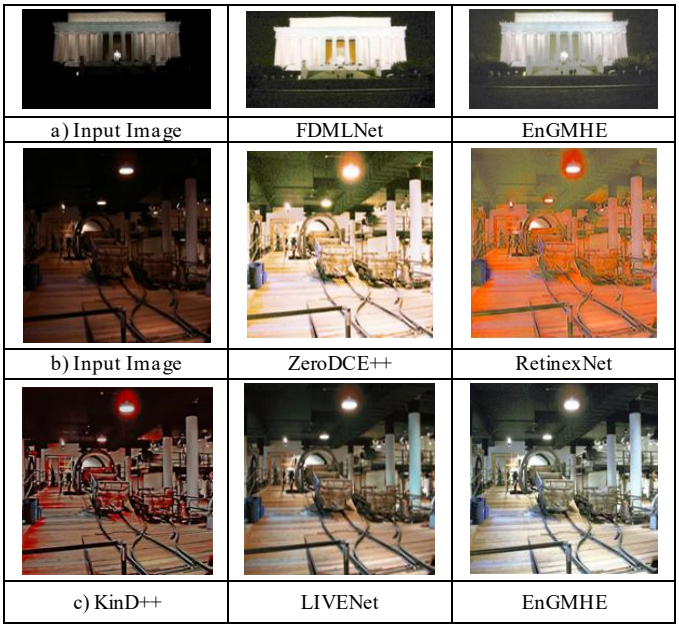

Fig. 5. Visual comparison with state-of-the-art methods on input images from the DICM dataset.

Fig. 6 shows a comparison with various state-of-the-art methods (KinD [58], SNR-Aware [59], and SPIC [60]) on challenging low-light and visually complex images from different datasets (NPE, VV, and ExDark). The overall results consistently demonstrate that EnGMHE excels in detail preservation, color accuracy, and balanced brightness enhancement across diverse datasets.

Fig. 7 evaluates the performance of LLIEDiff and EnGMHE against the ground truth for a low-light input image. The input image is significantly dark, with details obscured across various regions, while the ground truth serves as an ideal reference with vibrant colors, sharp textures, and excellent detail visibility. LLIEDiff improves brightness and restores some visibility in shadowed areas but struggles with color accuracy and fine detail preservation, particularly in the regions highlighted by the colored rectangles. In contrast, EnGMHE delivers a more balanced enhancement, achieving restored brightness, natural color tones, and excellent detail clarity that closely aligns with the ground truth. While EnGMHE may not perfectly match the ground truth in all regions, it demonstrates better color fidelity than LLIEDiff, producing vibrant and realistic colors and preserving natural tones, such as the red object and green grapes, with a closer resemblance to the ground truth in hue and saturation.

Fig. 8 highlights the text extraction results from a dark image and the EnGMHE-enhanced image. The text in this figure was recognized using "Image Recognize[2]" tool. As shown in Fig. 8, the EnGMHE-enhanced image not only retains high confidence for clearly visible text like "RESTAURANT" but also reveals additional details such as "Hpidavos" with significantly improved confidence (94%) compared to the dark image (44%). Furthermore, it introduces new textual elements such as "GROUP" and "be TEA", demonstrating its capability in enhancing low-light images for accurate text recognition.

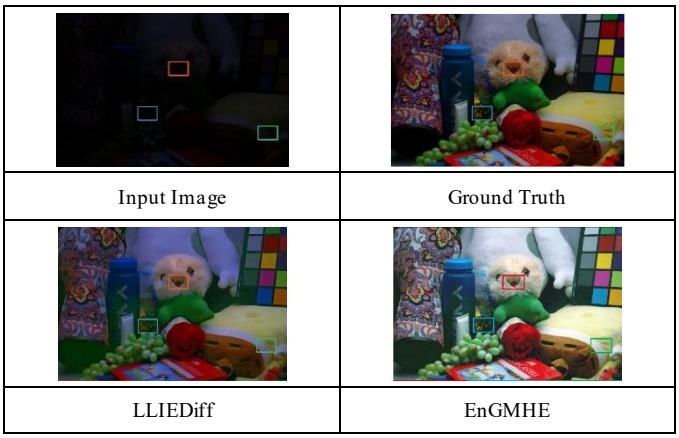

Fig. 7. Comparison with LLIEDiff against EnGMHE on the input image from the LOL-15 dataset.

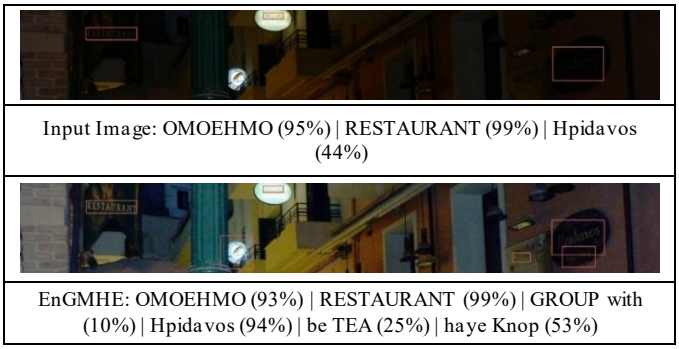

Fig. 8. Text extraction test. Red rectangles in the figure highlight the extracted text (confidence %) from the original dark image and the EnGMHE-enhanced image, respectively. The input image is a cropped portion of an image from the VV dataset.

E. Qualitative Results

This section quantitatively presents the comparative results obtained using both reference-based and non-reference-based methods across various datasets.

1) Comparisons using reference-based measures: The first comparisons were conducted to compare SSIM scores on different datasets. As shown in Table II, the proposed method achieved impressive SSIM scores of (0.72 and 0.78) on the LOL-V2 and MIT5K-500 datasets, respectively. On LOL-V2, it outperformed EnlightenGAN (0.68) and demonstrated a significant improvement over ZeroDCE [23] (0.58) and LIME (0.47), highlighting its ability to preserve structural details. On MIT5K-500, EnGMHE reported a score of 0.78, ranking second only to LIME (0.80). For SICE_GRAD, as presented in Table III, the proposed method achieved the highest score of (0.67), surpassing U-EGformer (0.64) and ZeroDCE (0.64). On SICE_MIX, it obtained a score of (0.64), outperforming URetinexNet (0.60) and RUAS (0.493).

On the LOL-15 dataset, as depicted in Table IV, the proposed method demonstrated a superior SSIM score of (0.734), significantly outperforming competitors like BIMEF [61] (0.595), EnlightenGAN (0.652), and ZeroDCE (0.559).

TABLE II. COMPARATIVE RESULTS ON SSIM ↑ ON (LOL-V2, MIT5K-500) DATASETS, THE BEST RESULTS ARE DENOTED BY BOLDFACE, AND THE SECOND-RATED RESULTS ARE UNDERLINED

Method	*LOL-V2*	*MIT5K-500*
EnGMHE	**0.72**	0.78

TABLE VI. COMPARATIVE RESULTS ON PSNR ↑ ON (LOL-15) DATASET, THE BEST RESULT IS DENOTED BY BOLDFACE AND THE SECOND-RATED RESULT IS UNDERLINED

EnGMHE	**RUAS [25]**	**DRBN [17]**	**SCI [22]**
16.29	**16.40**	16.29	14.78
SDD [63]	STAR [64]	ZeroDCE [23]	RRDNet [65]
13.34	12.91	14.86	11.40

The second set of comparisons was conducted to compare PSNR scores across various datasets. As shown in Table V, EnGMHE achieved a PSNR of 14.22 on the SICE_GRAD dataset, surpassing KinD++ (13.24) and U-EGformer (13.27). Similarly, on SICE_MIX, it recorded the second-highest PSNR with a score of 13.66, following the U-EGformer (14.23). On the LOL-15 dataset (Table VI), EnGMHE achieved a PSNR of 16.29, tying with DRBN for the top performance while outperforming other notable methods, such as ZeroDCE (14.86) and SCI (14.78). Additionally, on the MIT5K-500 dataset (Table VII), EnGMHE recorded the best PSNR score of 18.12, surpassing DRBN (16.37) and LIME (16.07), demonstrating its exceptional noise suppression and fidelity on this dataset.

The third set of comparisons evaluated the performance based on the LPIPS measure, where lower scores indicate better perceptual similarity. On the SICE_GRAD dataset (Table VIII), EnGMHE achieved a score of 0.33 as Kind++, securing the second rank, followed by U-EGformer with a score of 0.27, demonstrating strong perceptual similarity. On the LOL-15 dataset (Table IX), EnGMHE achieved the best score of 0.194, demonstrating superior perceptual quality, while methods like SDD (0.743) and STAR (0.366) performed significantly worse. For the LOL-V2 dataset (Table X), EnGMHE again achieved the best score of (0.204), slightly outperforming ISSR (0.206). Other competitors, such as ZeroDCE (0.313) and RetinexNet (0.365), showed comparatively weaker performance, further emphasizing EnGMHE's effectiveness in maintaining perceptual fidelity across various datasets.

TABLE XI. COMPARATIVE RESULTS ON DELTA-E ↓ ON (LOL-15) DATASET, THE BEST RESULTS ARE DENOTED BY BOLDFACE AND THE SECOND-RATED RESULTS ARE UNDERLINED

EnGMHE	SDD [63]	STAR [64]	MBLLEN [18]	Retinex Net [3]	KinD [58]
12.42	21.83	23.46	13.68	12.69	<u>12.49</u>
DRBN [17]	ZeroDCE [23]	RRDNet [65]	RUAS [25]	SCI [22]	EnlightenGAN [12]
13.44	18.81	26.43	16.85	19.52	14.5

The fourth comparison focused on evaluating Delta-E on the LOL-15 dataset (Table XI). EnGMHE achieved the lowest Delta-E score of (12.42), signifying minimal color distortion and high fidelity in color reproduction. The next closest competitor was KinD with a score of 12.49, while methods like ZeroDCE (18.81) and RRDNet (26.43) exhibited substantially higher errors, highlighting their relatively poorer performance in preserving color accuracy.

2) Comparisons using no reference-based measures: As depicted in Table XII, EnGMHE demonstrated excellent performance in minimizing NIQE scores across diverse datasets, underscoring its effectiveness in achieving high-quality, perceptually natural results. Its ability to outperform contemporary methods on DICM, NPE, and MEF highlighted its superiority in the domain of low-light image enhancement. Additionally, its performance on LIME and VV-24 was competitive with well-known methods such as EnlightenGAN and KinD++. Traditional methods like HE and KinD consistently recorded higher NIQE scores, reflecting their limitations in maintaining perceptual quality. Furthermore, as depicted in Table XIII and Table XIV, EnGMHE achieved the best performance on the MIT5K-500, LOL-V2, and LOL-15 datasets.

According to the BRISQUE measure (Table XV and Table XVI), EnGMHE led across all datasets, showing superior perceptual quality on VV-24 and LIME datasets and the second rank on DICM, NPE, and MEF datasets. This consistent performance across diverse datasets underscores EnGMHE's robustness and adaptability in various enhancement scenarios.

For the UCIQE measure (Table XVII), EnGMHE demonstrated a strong capability in underwater image enhancement, achieving the highest score on the UIEB-Ch60. It outperformed notable methods, including: MTUR-Net [29], WaterNet [32], Ucolor [33], IDMR [73], Restormer [27], FUnIEGAN [74], PUGAN [34], U-Shape [75], Semi-UIR [76], and UWE-Net [77], setting a new benchmark in this domain.

EnGMHE consistently outperforms or competes strongly with state-of-the-art techniques across a wide range of benchmark datasets and evaluation metrics. In reference-based

assessments, it achieved top or second-best SSIM and PSNR scores on datasets, including LOL-V2, MIT5K-500, SICE_GRAD, and LOL-15, indicating excellent structural preservation and noise suppression. It also demonstrated superior perceptual quality with low LPIPS values and achieved the best Delta-E score on LOL-15, highlighting its ability to maintain color accuracy. In no-reference evaluations, EnGMHE recorded the lowest or among the lowest NIQE and BRISQUE scores across diverse datasets such as VV-24, DICM, NPE, and MEF, highlighting its robustness in producing perceptually natural images. Additionally, EnGMHE outperformed other methods on the UCIQE metric in underwater image enhancement, setting a new benchmark in that domain.

F. Ablation Study

This section describes three tests, as they effectively address different aspects of the proposed model evaluation and improvement.

The first test evaluated the sensitivity of the model to the parameters γ and τ. As shown in Fig. 9, the model was applied to the dark image (Left). The test was first conducted by running EnGMHE multiple times on the input image while varying τ and keeping γ fixed at 25. Subsequently, the sensitivity to γ was examined by varying γ while keeping τ fixed at 2. As shown in Fig. 9, the sensitivity plot of τ indicates that τ significantly affects the model's performance and requires precise tuning to achieve optimal enhancement results. In comparison, the flat region in the γ sensitivity plot suggests that γ is less sensitive within its optimal range, making it slightly more robust than τ. To ensure better performance across datasets. Therefore, a sample image set from each dataset was initially selected to determine experimentally the most suitable parameter values for this model.

The second test (see Fig. 10) examined the incremental addition of the components of EnGMHE. This is to demonstrate how the following procedural steps enhance its performance.

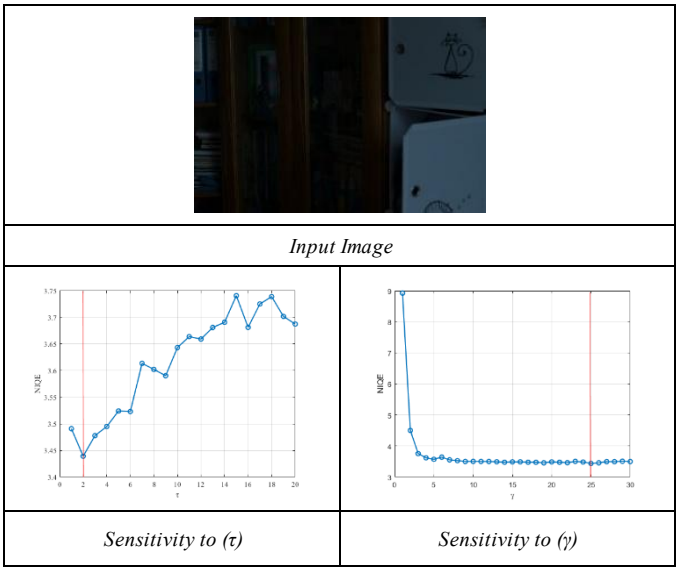

Fig. 9. Sensitivity to τ and γ parameters.

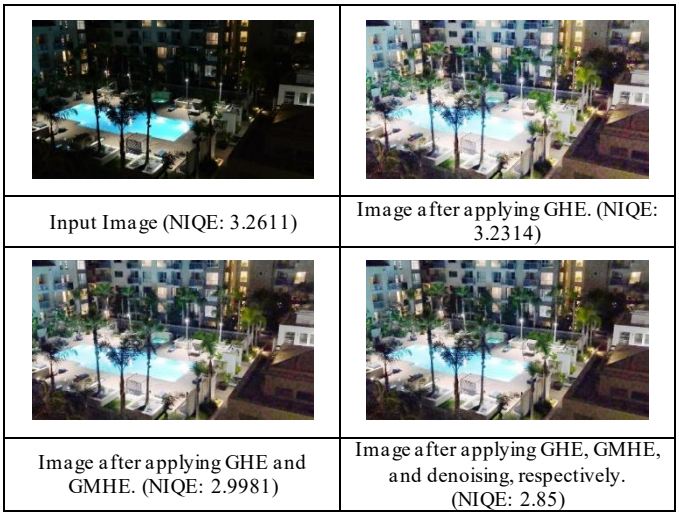

Fig. 10. The impact of the gradual addition of EnGMHE components. The input image extracted from the LOLi_Phone dataset [40].

The third test examined the sequence of enhancement steps and emphasized the importance of workflow design. It was applied across multiple datasets, and the proposed step sequence consistently produced the best results. For example, Fig. 11 illustrates how varying the order of steps in the enhancement workflow affected image quality, evaluated using NIQE and SSIM metrics. The input image exhibited low visibility and poor structural similarity, as reflected by its high NIQE and low SSIM scores. Among the tested configurations, the sequence GHE → GMHE → Denoise (EnGMHE) achieved the optimal balance between perceptual quality and structural similarity, recording the lowest NIQE (3.48) and the highest SSIM (0.84). This demonstrates that beginning with GHE, followed by GMHE, and concluding with denoising effectively preserved fine details and maintained natural image quality.

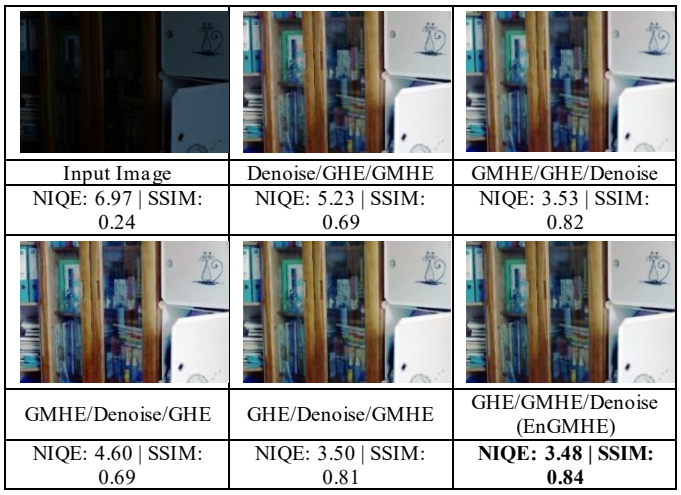

Fig. 11. Impact of procedural step order on image quality.

G. Limitations and Areas for Improvement

Fig. 12 highlights a potential limitation of EnGMHE in terms of color fidelity when compared to other enhancement methods. Although EnGMHE performs effectively in recovering fine details and improving text clarity, it may introduce slight oversaturation and color shifts when compared to the ground truth. Although this could be considered a weakness in terms of color fidelity, it may be advantageous in certain applications, such as text and object recognition, where clarity and detail preservation are often more important than strict closeness to a poor-quality ground truth.

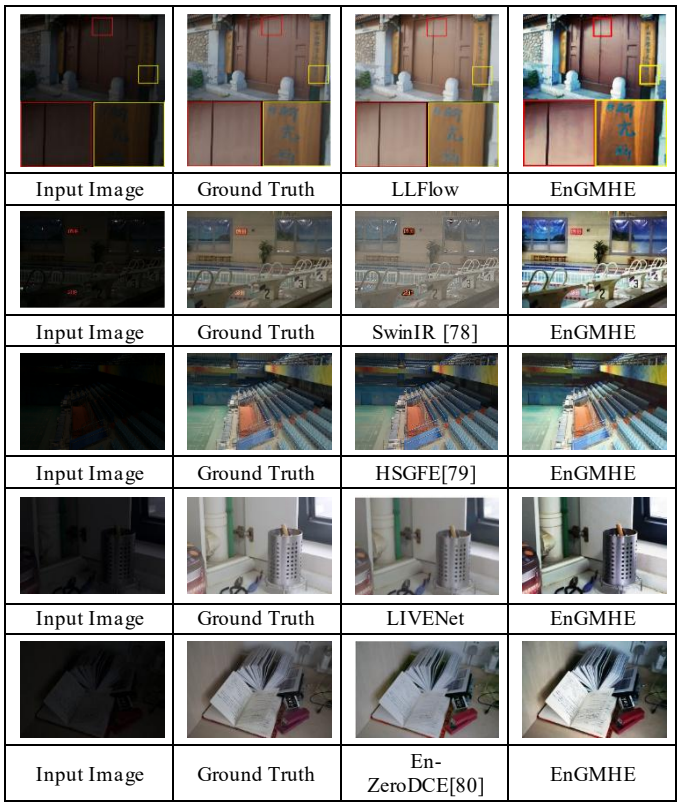

Fig. 12. Comparison of enhancement methods against the ground truth.

V. Conclusion

This study addresses the challenge of low-light image enhancement, considering the presence of noise in corrupted images. To tackle this problem, an effective joint low-light enhancement and denoising model, termed EnGMHE, is proposed. The model introduces a GHE-based technique combined with traditional GMHE to enhance image contrast and brightness. This enhancement stage is followed by a pretrained deep neural network for noise suppression, resulting in improved overall visual quality. EnGMHE effectively preserves fine details and produces visually appealing contrast and color distributions. Both qualitative and quantitative evaluations confirm its effectiveness, demonstrating superior performance compared to state-of-the-art methods.

Immersive Learning Environment Design of Outdoor Education Space Using Artificial Intelligence Augmented Reality Technology

Chenguang Liu
Nanjing Forestry University, Nanjing, 210037, Jiangsu, China

***Abstract*—This study presents a technically grounded design and implementation of an AI- and AR-enabled immersive learning environment for outdoor education. Moving beyond conceptual descriptions, the study develops an executable system framework that integrates adaptive navigation and positioning, context-aware virtual tours, task-driven scenario simulation, and real-time feedback mechanisms. Each functional module is explicitly linked to algorithmic implementations, including multi-sensor state estimation, constrained generative scene construction, and reinforcement-based adaptive control, enabling reproducible system behavior in real outdoor settings. A controlled field experiment was conducted using an experimental group and a control group under identical instructional conditions. Quantitative evaluation based on pre–post testing, behavioral logging, and statistical analysis demonstrates that the proposed system achieves statistically significant improvements in learning interest, participation, knowledge mastery, and problem-solving ability. Experimental conditions, data characteristics, and methodological limitations are explicitly reported to support result verification and generalizability. The findings indicate that the proposed immersive learning environment constitutes a validated system-level contribution rather than a purely conceptual framework, offering practical and scientific value for computer science–oriented educational technology research.**

Keywords*—*Artificial intelligence; augmented reality; outdoor education space; immersive learning environment; system-level evaluation

I. Introduction

With the accelerated development of globalization and informatization, the education industry is facing unprecedented demands for change. The traditional education mode, which focuses on the inculcation and memory of knowledge, has been difficult to meet the needs of cultivating talents needed by the future society. In today's world, there is more emphasis on innovative thinking, practical ability, and lifelong learning ability, which requires that the education system must shift to a teaching model that emphasizes more active student participation, experiential learning, and problem-solving. Outdoor education, as a unique form of education, with its openness, practicality, and experience, has become an important way to cultivate these abilities. It allows students to go out of the classroom, experience nature and society, and solve problems through observation, experiment and cooperation, thus enhancing students' social responsibility, teamwork ability, and ability to adapt to environmental changes [1].

However, outdoor education also faces many challenges, such as uneven resource allocation, difficulty in quantifying learning effects, and safety risk management. Therefore, how to use modern information technology, especially artificial intelligence (AI) and augmented reality (AR) technology [2], to overcome these challenges and improve the efficiency and effectiveness of outdoor education has become an important issue in current educational technology research. The integration of AI and AR technology has brought unprecedented opportunities to the field of education. AI can provide personalized learning recommendations, intelligent evaluation, and instant feedback, while AR creates a highly immersive, interactive learning environment through the seamless integration of virtual and real worlds, making the learning process more attractive and engaging. This technology fusion can not only enrich educational resources, realize dynamic adjustment and real-time update of learning content, but also customize personalized learning paths according to the characteristics and needs of each learner, thus significantly improving the quality of teaching and promoting students to comprehensively and deeply master knowledge and skills [3]. The application of AI and AR technology will also help narrow the gap between urban and rural educational resources, provide high-quality outdoor learning experiences for students in remote areas, and promote educational equity. At the same time, it can also help teachers better monitor students' learning progress [4], adjust teaching strategies in time, and improve teaching efficiency.

The core of this study aims to explore the harmonious coexistence of outdoor education and advanced technology, focusing on how to skillfully integrate artificial intelligence (AI) and augmented reality (AR) technology on the basis of maintaining the essential characteristics of outdoor education [5], creating an immersive learning ecosystem that not only ensures students' safety but also greatly improves learning efficiency. The study is deeply concerned with establishing the basic principles for designing such learning environments, emphasizing that technology application needs to closely match the teaching purpose with the individual characteristics of learners in order to achieve optimal learning outcomes. Specifically, our research agenda includes four key objectives: first, to reveal the key elements and potential limitations of successful implementation of AI and AR technologies in outdoor education scenarios through detailed analysis of

existing cases, and to provide an empirical basis for subsequent design; second, we will design a comprehensive model framework that not only clarifies the details of technical architecture, but also covers innovative design principles for content creation processes and teaching activities, aiming to ensure seamless integration of technology and educational content; Furthermore, the research will advance to the development and testing stage of prototype system, and scientifically measure its actual effect on students' academic performance improvement [6], learning motivation stimulation and practical skills enhancement through rigorous evaluation system.

This study is organized as follows to progressively clarify the technical design, implementation, and validation of the proposed AI–AR immersive learning environment for outdoor education: Section II reviews related studies on artificial intelligence, augmented reality, outdoor education, and immersive learning theory to establish the research context. Section III analyzes system requirements and design principles. Section IV presents the system framework and details the implementation of core functional modules, including navigation and positioning, virtual tours, and scenario simulation. Section V reports practical deployment cases and quantitative effect evaluation based on controlled experiments. Finally, Section VI summarizes the main findings and discusses future research directions.

II. Literature Review

A. Application of AI and AR in Education

In an educational model that integrates artificial intelligence and augmented reality, the synergy of technology further broadens the boundaries of education and creates unprecedented learning experiences for students. In their study, they predicted the potential impact of intelligent augmented reality systems in education, arguing that such systems can dynamically adjust content according to students' learning style and progress, providing highly personalized learning scenarios [7]. For example, combining AI's adaptive learning platform with AR technology can create a virtual laboratory for each student that matches their cognitive development level, enabling students to safely perform complex experimental operations such as chemical reaction simulation or physical law verification in virtual environments without worrying about material limitations or safety risks.

In addition, in the study of game-based learning, it is proposed that an immersive environment can enhance students' participation and problem-solving ability, which has been fully demonstrated in outdoor education supported by AI and AR technology [8]. Through AI analysis of students' behavior data in outdoor activities, educators can accurately identify students' knowledge blind spots and skill defects in practice, and then use AR technology to superimpose learning content in real environments, such as real-time identification and provision of plant information in botanical investigations, or display the dynamic process of terrain changes during geographical exploration, thus realizing instant feedback and deep reinforcement learning in real-world learning activities.

B. Outdoor Education

Outdoor education emphasizes experiential learning in a natural environment with its unique educational approach. Outdoor education is defined as a process of learning through direct experience of natural and social environments, which not only imparts knowledge but also focuses on skill development, emotional development, and value formation [9]. Outdoor education is particularly beneficial in developing critical thinking, teamwork, and leadership skills that are difficult to fully develop in traditional classroom settings, according to the study. While outdoor education has many benefits [10], it also faces many challenges. In their review, they summarize several key challenges in outdoor education, including safety risk management, uneven resource allocation, and quantitative evaluation of educational effectiveness [11]. Safety concerns are paramount, and the unpredictable nature of outdoor activities requires a high degree of preparation and professional instruction.

Facing these challenges, the integration of modern technology provides new solutions and development opportunities for outdoor education. In terms of safety risk management, GPS tracking systems and smart wearable devices can be used to monitor student locations in real time, prevent hazards, and respond quickly in emergency situations. The application of these technologies has greatly improved the safety of outdoor activities, while reducing the excessive dependence on professionals [12], making more schools and educational institutions confident to carry out outdoor education programs. With regard to the uneven distribution of resources, the spread of digital platforms and online educational resources has provided access to high-quality outdoor educational resources in remote areas and resource-poor schools. For example, through virtual reality (VR) technology, students can "immersively" explore natural scenery and experience history and culture even in places where field conditions are not available. The introduction of this technology, although not a complete substitute for the real outdoor experience, can alleviate the geographical differences in resource allocation to a certain extent [13].

C. Immersion Learning Theory

Immersion learning theory is derived from cognitive psychology and constructivist learning theory, emphasizing the promotion of deep learning through highly participatory environments. Immersion learning is defined in his research as a way of learning in which learners are fully engaged by simulating real situations [14], which can stimulate learners' desire for exploration and creative thinking. "Situational Cognition" theory further points out that learning takes place in a specific sociocultural context, emphasizing the importance of situation for knowledge construction. Immersion learning theory is increasingly used in education [15], especially after combining AI and AR technologies. The study shows how AR technology can be used to create immersive learning environments for history lessons, where students visit virtual historical scenes through AR glasses, and this interactive and intuitive way of learning significantly improves learning interest and memory of historical events [16]. At the same time, the research uses an AI-driven virtual laboratory to realize immersive learning in biology teaching, and students

complete experiments through virtual operation, which not only reduces the experimental cost and safety risk [17], but also improves the learning effect. Immersion learning theory has also shown remarkable results in language learning. The research shows that the intelligent language learning environment constructed by AI technology can provide personalized learning content and real-time dialogue practice according to learners' language level and learning preference [18]. This highly interactive learning mode greatly improves language acquisition efficiency and oral expression ability. AI makes the learning process more efficient and accurate by analyzing learners' grammatical errors, pronunciation problems, etc. in simulated conversations and giving immediate feedback and correction suggestions. AR technology also plays an important role in art and design education. The application of AR in visual arts curriculum is studied. Students can create freely in virtual space and experience different artistic media and techniques through AR equipment [19]. This intuitive operation mode not only inspires students' creativity, but also promotes the understanding of artistic principles and history. AR technology enables students to "walk inside" paintings, observe and analyze works from different angles, providing new perspectives for art appreciation and criticism. The successful construction of an immersive learning environment also needs to consider learners' psychological acceptance and adaptability. In their review, they caution that despite the many advantages of immersive technology [20], excessive reliance on technology can lead to cognitive overload and affect learning outcomes. Educators should therefore balance the use of technology with traditional teaching methods when designing immersion learning activities to ensure that the integration of technology enhances the learning experience while maintaining the effectiveness of learning.

III. Demand Analysis

A. Design Principles

The design of outdoor education immersive learning environment should adhere to the core principles to optimize learning effectiveness, ensure experience and safety, and the specific design principles are shown in Fig. 1. The first principle is contextual relevance, which means that learning scenarios need to be closely integrated with the real world, such as using AR technology to simulate ecosystem operations in ecology courses. Through the combination of GPS and AR, learners can obtain real-time information during field visits and improve their understanding. Secondly, the learner-centered principle emphasizes customizing personalized paths according to individual needs, interests, and styles, analyzing learning data with AI algorithms, dynamically adjusting the difficulty and form of content, and ensuring that each learner grows up in a challenge that suits them. In terms of security, the design needs to ensure physical and information security, adopt encryption technology, establish virtual boundaries, provide security guidelines, and build a worry-free learning environment. The principles of interaction and collaboration advocate enhanced social skills and teamwork through AI-driven role-playing and team challenges, such as AR virtual treasure hunting.

B. Demand Analysis

In the immersive learning environment of outdoor education, the deep integration of technology and education requires careful consideration of the specific needs of various stakeholders to ensure the accurate application and maximum benefit of AI and AR technologies.

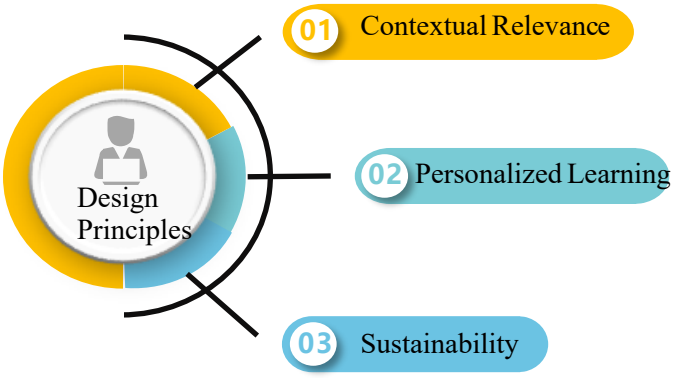

Fig. 1. Design principles.

For learners, the key lies in satisfying their quest for personalized learning experiences. Students expect customized content based on their interests, learning speed and abilities. AI technology is precisely able to provide this customized service by intelligently analyzing learning data, planning the most suitable learning path for each student, and giving timely feedback, thus enhancing the pertinence and effectiveness of learning. At the same time, using AR technology, students can participate in operations that are difficult to achieve in real environments, such as simulating complex natural phenomena or operations [21], which not only increases the fun of learning but also deepens the understanding of knowledge.

Teachers, on the other hand, are eager to have convenient teaching aids to simplify the planning and management of immersive learning activities. This means an intuitive and easy-to-use platform that helps teachers quickly create engaging AR learning content while monitoring and evaluating student learning performance in real-time. In addition, the professional development of teachers should not be ignored. They need to receive training on the application of AI and AR technologies in education and learn how to flexibly use these advanced technologies in outdoor environments to promote teaching innovation and efficiency.

Education managers play the role of resource allocation and strategic planning in technology integration. They need to ensure that all technical facilities, including hardware, software, and network services, are properly configured and maintained, while taking into account cost-effectiveness and maximizing the use of resources. In addition, it is essential to have an efficient data management system that not only helps administrators evaluate learning outcomes through data analysis and provides data support for future educational decisions [22], but also ensures that students' personal information is strictly protected during data processing.

IV. Design Framework for Immersive Learning Environment in Outdoor Education Space

A. Technical Architecture

Hardware devices constitute the physical interface of an immersive learning environment, and their selection and deployment are directly related to the perceived quality and interaction efficiency of learners in outdoor scenes. Key devices include, but are not limited to, augmented reality (AR) headsets, smart Mobile device, global positioning system (GPS) receivers, and environmental monitoring sensors. AR headset, as the core technical equipment, creates a unique mixed reality visual experience for learners by seamlessly integrating virtual information with the real world, deepening cognitive understanding and situational awareness. As a terminal for information processing and feedback, an intelligent Mobile device supports instant content reception, operation feedback, and interactive control, and its portability and flexibility significantly improve the convenience of outdoor learning. The application of GPS positioning and environmental sensors ensures accurate positioning and safety monitoring of learning activities in complex outdoor environments [23], adding an important technical guarantee for the safe implementation of practical activities.

B. Function Module Design

In the design of an immersive learning environment in an outdoor education space, the careful construction of functional modules is the key to realize efficient learning experience. This section discusses in detail the four core modules of navigation and positioning, virtual navigation, situational simulation, and real-time feedback systems, and how they are combined with artificial intelligence algorithms. The specific functional modules are shown in Fig. 2.

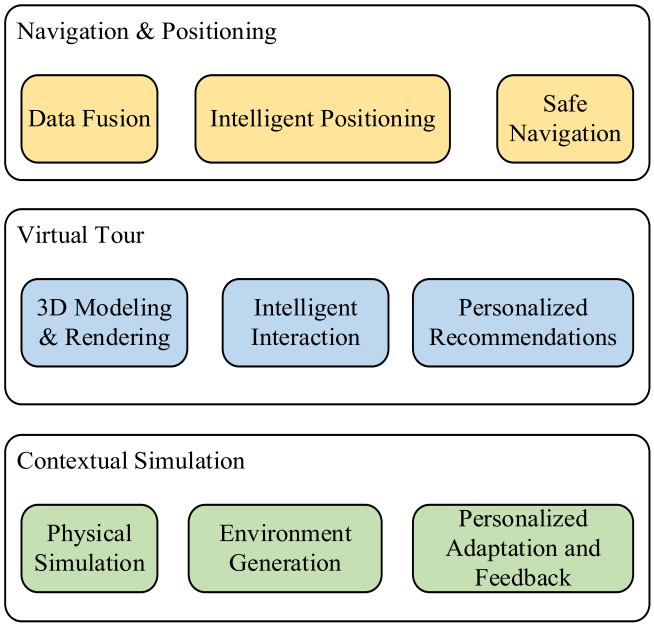

Fig. 2. Functional module design.

1) Navigation and positioning: In the proposed immersive outdoor learning system, navigation and positioning are implemented as a real-time service module directly supporting learner guidance, safety monitoring, and context-aware AR content triggering, rather than as an abstract demonstration of classical filters [24]. The core task of this module is to continuously estimate learner position states and to determine safe and adaptive movement paths under outdoor uncertainty.

A hybrid state estimation framework is adopted, in which particle filtering is not used as a generic replacement for Kalman filtering but is selectively activated when GPS signal quality falls below a predefined threshold. The learner state is defined as:

$$\mathbf{x}_t = [x_t, y_t, v_t, \theta_t] \tag{1}$$

representing planar position, velocity, and heading. Particle weights are updated according to observation confidence derived from sensor reliability indicators [25]:

$$w_t^{(i)} = \frac{w_{t-1}^{(i)}\, p(\mathbf{z}_t |\ \mathbf{x}_t^{(i)})}{\sum_{k=1}^{N} w_{t-1}^{(k)}\, p(\mathbf{z}_t |\ \mathbf{x}_t^{(k)})} \tag{2}$$

where, $p(\mathbf{z}_t |\ \mathbf{x}_t^{(i)})$ is dynamically scaled by GPS signal-to-noise ratio and inertial drift error. This adaptive weighting mechanism enables robust localization during forested or terrain-shielded activities, directly supporting stable AR overlay alignment [26].

To reduce cumulative drift and improve long-term consistency, multi-sensor fusion is executed at fixed temporal windows using a weighted least squares solver:

$$\hat{x} = (H^T W H)^{-1} H^T W z \tag{3}$$

where, weights in $\mathbf{w}$ are updated online based on recent residual errors, allowing the system to downweight unreliable sensors without manual recalibration.

For safety assurance, obstacle avoidance is integrated into the positioning loop rather than treated as an independent process. A lightweight random forest classifier predicts obstacle presence from depth and motion features, and its output constrains the heuristic function of the A* planner:

$$f(n) = g(n) + \lambda h(n) \tag{4}$$

where, λ is adaptively increased in high-risk zones to prioritize safer routes over shorter paths. This coupling ensures that navigation decisions are both context-aware and system-executable, enabling reproducible and verifiable learner movement control during outdoor learning tasks.

2) Virtual tours: The virtual tour module is implemented as an executable interaction layer that directly links spatial perception, semantic content delivery, and learner-driven navigation decisions, rather than serving as a conceptual illustration of AR technologies [27]. Its primary function is to support context-aware knowledge triggering and adaptive route guidance during outdoor learning tasks.

Environmental reconstruction is performed using stereo vision only at predefined anchor points instead of continuous global modeling, reducing computational load on mobile AR devices. For each anchor region, the scene geometry is represented by a sparse landmark set $\mathrm{P} = \{p_i\}$, and the epipolar constraint is applied to validate landmark consistency [28]:

$$p_i'^{T}\mathbf{F}p_i = 0 \tag{5}$$

where, $\mathbf{F}$ is estimated online from matched feature pairs and is used exclusively to align virtual annotations with real-world surfaces. This formulation ensures that AR overlays remain stable during learner movement rather than optimizing photorealistic reconstruction.

Visual realism is selectively enhanced only for instructional objects that require depth or structural perception. Instead of full-scale ray tracing, a bounded illumination model is applied [29]:

$$L_o = L_e + \alpha \sum_{k=1}^{K} L_i^{(k)} \cos\theta_k \tag{6}$$

where, α controls rendering cost and is adjusted according to device performance constraints, enabling reproducible deployment across heterogeneous hardware.

Natural language interaction is constrained to a task-oriented command set to ensure system reliability. Speech input is processed using a lightweight sequence model:

$$P(y_t \mid y_{<t}, c) = \mathrm{Softmax}(Wh_t) \tag{7}$$

where, the context vector c is derived from the current learning node rather than open-domain dialogue, directly mapping commands to navigation or content queries.

Personalization is achieved through short-horizon behavior modeling instead of generic interest prediction. Learner movement and interaction sequences are encoded as:

$$h_t = f(h_{t-1}, x_t), \quad r_t = g(h_t) \tag{8}$$

where, r ranks nearby learning nodes and updates tour paths in real time. This tightly coupled design establishes a verifiable link between algorithm execution, system behavior, and adaptive learning outcomes in outdoor virtual tours.

3) Scenario simulation: The scenario simulation module is implemented as a task-driven execution engine that supports experiential learning objectives by dynamically generating, controlling, and evaluating simulated events aligned with outdoor educational tasks. Rather than presenting generic physical or generative models, this module focuses on how simulation states are computed, adapted, and validated within the operational system.

Each scenario is formalized as a controllable state space:

$$\mathrm{S}_t = \{\mathbf{x}_t, \mathbf{e}_t, d_t\} \tag{9}$$

where, $\mathbf{x}_t$ denotes the physical state of simulated entities, $\mathbf{e}_t$ represents environmental parameters (terrain, weather, visibility), and d_t encodes difficulty level. Physical interaction is resolved using a constrained dynamics solver derived from the Newton–Euler formulation:

$$\mathbf{M}\ddot{\mathbf{x}}_t = \sum \mathbf{F}_t - \beta \dot{\mathbf{x}}_t \tag{10}$$

where, β is an adaptive damping coefficient adjusted to learner motor performance, enabling reproducible accessibility control for different learner groups.

Scenario content generation is not performed through unconstrained GAN or VAE sampling. Instead, generative models are conditioned on pedagogical labels c and spatial context l [30]:

$$\min_G \max_D \mathbb{E}_{x\sim p(x|c,l)}[\log D(x)] + \mathbb{E}_z[\log(1 - D(G(z \mid c, l)))] \tag{11}$$

ensuring that generated scenes correspond to predefined learning objectives and locations. Generated scenarios are cached and reused under identical conditions to guarantee experimental reproducibility.

Adaptive progression is governed by a reinforcement learning policy embedded in the simulation controller. The learner–scenario interaction is modeled as a Markov decision process, and task difficulty is updated according to:

$$Q(s,a) \leftarrow Q(s,a) + \alpha\left[r_t - \lambda d_t + \gamma \max_{a'} Q(s',a') - Q(s,a)\right] \tag{12}$$

where, r_t reflects task completion quality and λd_t penalizes excessive cognitive load. This closed-loop design explicitly links algorithm execution to scenario evolution, learning outcomes, and system-level validation across repeated trials.

V. Practical Cases and Effect Evaluation

A. Implementation Cases

The implementation was conducted as a controlled field experiment to ensure methodological rigor and verifiability. The study site was a designated nature reserve, and participants were drawn from the same grade level and educational background to reduce confounding effects. A total of two groups were formed: an experimental group using the proposed AI–AR immersive learning system and a control group receiving conventional outdoor instruction. Both groups followed identical learning objectives, curricular content, activity duration, and instructor guidance, with the only controlled variable being the use of the immersive system.

The experimental system was deployed using a standardized hardware and software configuration, including AR head-mounted displays, mobile devices with integrated

GPS, and a cloud-based platform providing content management, user logging, and real-time feedback services. All learning activities were predefined and time-synchronized across participants to ensure consistency. Interaction data (navigation paths, task completion time, and system prompts), assessment scores, and questionnaire responses were collected as structured datasets.

The experimental procedure consisted of four phases: pre-test assessment, guided learning intervention, post-test assessment, and feedback collection. Learning performance was evaluated using identical pre- and post-tests, while engagement and perception were measured using validated Likert-scale instruments. Data analysis focused on between-group comparisons under the same experimental conditions, allowing observed performance differences to be attributed to the system intervention. Experimental constraints, including limited sample size and site specificity, are acknowledged to delimit the generalizability of the results.

B. Effect Evaluation

To improve methodological rigor and result verifiability, the effect evaluation was conducted under controlled experimental conditions with consistent instructional content, duration, and assessment instruments for both groups. All reported indicators were derived from paired pre-test and post-test measurements. Descriptive statistics and inferential analysis were applied to examine between-group differences.

Learning interest and participation were measured using a standardized questionnaire administered before and after the intervention. Mean percentage increases were calculated for each group, and independent-sample t-tests were performed to examine statistical significance at the 0.05 level.

TABLE I. COMPARISON OF INTEREST AND PARTICIPATION IN LEARNING

Group	Increase in Interest in Learning (%)	Increase in Participation (%)
Experimental Group	60	75
Control Group	20	15

TABLE II. ASSESSMENT OF KNOWLEDGE MASTERY

Test Content	Experimental Group Mean Score	Control Group Mean Score	Fractional Difference
Biodiversity Knowledge	85	70	15
Ecosystem Understanding	90	75	15

The results in Table I indicate that the experimental group exhibited significantly greater gains in both learning interest and participation ($p < 0.05$), suggesting that the immersive system had a measurable motivational effect beyond traditional outdoor instruction.

Knowledge mastery was evaluated using identical post-intervention tests covering biodiversity knowledge and ecosystem understanding. Mean scores and between-group differences are reported in Table II.

Independent-sample t-tests confirmed that both score differences were statistically significant ($p < 0.05$). These results indicate a consistent learning advantage associated with the immersive learning environment.

Problem-solving ability was assessed through task-based performance rubrics evaluated by two independent raters. Improvement ratios were computed based on normalized pre–post score differences.

TABLE III. IMPROVEMENT OF PROBLEM-SOLVING ABILITY

Evaluation Index	Experimental Group Promotion Ratio (%)	Control Group Promotion Proportion (%)
Observation and Analysis Ability	45	20
Innovative Thinking and Decision Making	50	15

As shown in Table III, the experimental group demonstrated substantially higher improvement across both cognitive dimensions. While the results consistently favor the proposed system, the evaluation is limited by sample size and single-site deployment, which may constrain generalizability. Future studies will incorporate larger datasets and multi-site trials to further validate these findings.

C. User Feedback

Table IV shows the results of the student satisfaction survey. In terms of interactive experiences, 70% of students expressed great satisfaction, and 20% expressed satisfaction. In terms of content richness, 65% of students expressed great satisfaction and 25% expressed satisfaction. In terms of technical stability, 85% of students expressed great satisfaction and 10% expressed satisfaction. In terms of security, 90% of students expressed great satisfaction and 8% expressed satisfaction. These data show that most students are satisfied with the teaching methods and activity design of the experimental group.

TABLE IV. STUDENT SATISFACTION SURVEY

Feedback Field	Very Satisfied (%)	Satisfaction (%)	General (%)	Not Satisfied (%)
Interactive Experience	70	20	8	2
Content Richness	65	25	8	2
Technical Stability	85	10	3	2
Sense of Security	90	8	2	0

Fig. 3 presents the results of the evaluation of teachers' teaching experience. In terms of technical support and training, 60% of teachers thought it was very useful, and 25% thought it was useful.

D. Results and Discussion

The experimental results demonstrate that the proposed AI–AR immersive learning environment produces consistent and measurable improvements across cognitive, behavioral, and affective dimensions of outdoor learning. Quantitative comparisons between the experimental and control groups indicate significant gains in learning interest, participation, knowledge mastery, and problem-solving ability under

controlled instructional conditions. These results suggest that the integration of adaptive navigation, context-aware virtual tours, and task-driven scenario simulation effectively enhances learner engagement and learning efficiency beyond traditional outdoor education approaches.

	Technical Support & Training	Integration of Teaching Content	Enhancement of Student Engagement
Highly Useful	60%	75%	80%
Useful	25%	15%	12%
Average	10%	8%	5%
Room for Improvement	5%	2%	3%

Fig. 3. Evaluation of teachers' teaching experience.

From a system perspective, the results validate the practical effectiveness of the algorithm–module coupling proposed in the technical framework. Improvements in learning outcomes can be directly associated with system mechanisms such as real-time spatial alignment, adaptive difficulty adjustment, and feedback-driven task progression. This linkage confirms that the observed performance gains are not incidental but emerge from executable system behavior.

However, the results should be interpreted within defined constraints. The current evaluation is limited to a single-site deployment and a finite sample size, which may restrict generalizability across different educational contexts and age groups. Additionally, environmental variability and device heterogeneity may influence system performance. Future work will extend multi-site trials, incorporate larger datasets, and refine statistical modeling to further strengthen external validity and comparative analysis.

VI. Conclusion

In the context of ongoing educational transformation, this study advances outdoor education research by developing and validating an AI–AR–enabled immersive learning environment with explicit system-level implementation and evaluation. Beyond practical application, the study contributes a structured design paradigm that links adaptive navigation, virtual tours, and scenario simulation to executable algorithms and measurable learning outcomes, extending existing immersive learning frameworks from conceptual models to deployable systems. Empirical results from controlled experiments confirm that the proposed environment effectively enhances learner engagement, knowledge acquisition, and problem-solving ability, demonstrating its technical and educational validity.

Despite these contributions, several limitations remain. The current evaluation is based on a single-site deployment with a limited sample size, which may constrain the generalizability of the findings across diverse educational contexts and learner populations. Environmental variability and device heterogeneity may also affect system performance. Future research will focus on multi-site longitudinal studies, larger and more diverse datasets, and refined statistical modeling to further validate robustness, scalability, and cross-context applicability of the proposed system.

Abstract*—Grammatical accuracy is a critical component of English as a Second Language (ESL) learning; however, many learners continue to struggle with recurring errors despite the availability of automated grammar correction tools. Although recent transformer-based models such as BERT, GPT, and T5 have demonstrated strong benchmark performance, existing grammar error correction (GEC) systems remain largely correction-oriented and lack pedagogical flexibility, learner awareness, and explanation-based feedback. To address these limitations, this study proposes an Adaptive Multi-Task T5 (AMT-T5) framework that integrates grammatical error correction, error-type classification, and personalized feedback generation within a unified transformer architecture. The proposed method is designed to actively support learner development by maintaining dynamic learner error profiles and adaptively reweighting attention to provide targeted instructional guidance. AMT-T5 is implemented using Python, PyTorch, and the Hugging Face Transformers library, and trained on the Lang-8 Learner Corpus, which contains authentic ESL learner sentences with expert corrections. Experimental results demonstrate that the proposed model significantly outperforms existing transformer-based baselines, achieving 78.9 BLEU, 90.7 GLEU, 82.6% full-sentence accuracy, and an error reduction rate of 91.2%, representing an approximate 18–22% improvement in grammatical accuracy over prior models. The framework further incorporates Direct Preference Optimization to align corrections with pedagogical expectations and Knowledge Distillation to enable efficient real-time deployment. Overall, the proposed AMT-T5 framework transforms grammar correction from a passive editing task into an adaptive, learner-centered educational process, offering a scalable and effective solution for intelligent ESL grammar learning systems.

Keywords*—Grammar error correction; adaptive feedback; Multi-task Learning; transformer models; ESL learning; personalized language instruction

I. Introduction

English has proven to be the global language of scholarly, professional, and social communication. However, grammar is still a persistent issue to the people who do not speak English as their mother tongue that limits their fluency and expressiveness in communication to a large degree [1]. The conventional teaching of grammar in classrooms is often very strict and generalized, and has little ability to provide any form of personalized attention. Most intelligent language learning systems currently provide contextual and real-time grammar correction with the advent of (NLP) [2], [3]. In the case of ESL students, this instant corrective feedback is essential to strengthen correct forms and minimize the frequent mistakes [4]. Research on automated grammar correction has evolved across different paradigms, including rule-based systems, statistical machine translation (SMT), and (DL) approaches [5]. Rule-based approaches, though interpretable, are incapable of dealing with complex or ambiguous structures [6], [7]. Phrase-based SMT methods, which are better covered, were limited by their performance in fluency and grammatical accuracy [8], [9]. LSTMs and GRUs neural architectures, however, enhanced contextual correction but could not deal with long-range dependencies [10] [11]. Transformer models (including BERT, GPT and T5) have since further progressed the field of models with their more advanced contextual understanding [12], [13].

Nevertheless, the majority of models in existence are not specifically adapted in ESL learning scenarios and the data that

is available is generally too general or does not represent common ESL error patterns well enough [14], [15].

This study introduces an AMT-T5 model, which is an expansion of the T5 transformer architecture to support the educational requirements of ESL students. In contrast to conventional grammar correction systems, which can only perform surface-level correction, AMT-T5 optimally achieves grammatical error correction, error-type classification, and explanation-based feedback generation in a single architecture. This combination allows the model to provide not only corrected sentences but also teaching feedback this facilitates the learning process. This learner-sensitive adaptive feedback system is a major distinguishing feature of AMT-T5, which personalizes feedback based on learner-specific error frequency. The model is able to offer specialized advice by dynamically changing attention weights based on repeated grammatical errors, thus reducing the number of such errors. Compared to the current transformer-based grammatical error correction systems that use a fixed multitask learning or post-hoc explanation model, AMT-T5 uses learner-state-conditioned modeling, where error profile correction and generate explanation is conditioned by dynamically updated learner error profiles. This attention reweighting conditioned by the learner is a methodological break with the previous multitask GEC and pedagogical NLP models, which do not incorporate learner history into the transformer attention mechanism.

A. Research Motivation

ESL learners also have such consistent grammatical problems, which cannot be easily eradicated by traditional teaching. Recent transformer-based grammar correction models have achieved high benchmark performance, but primarily do not offer pedagogical scaffolding. This puts a gap in the learning process in which the student gets outputs that are error free but with no explanations or personalized directions to be able to develop a sustainable level of skills. Hence, there exists an urgent demand of a grammar correction system that can enhance the accuracy of the sentences besides, be actively supportive of the learner development by providing contextual feedback and adaptive learning mechanisms.

B. Significance of the Study

The proposed AMT-T5 system goes beyond the conventional benchmark-driven GEC systems and incorporates grammar rectification with an educational purpose. The system facilitates improved language learning and quantifiable proficiency growth by supporting the active profiling of learning errors specific to the learner, real-time explainable feedback, and optimization to user preferences. This model facilitates effective implementation in actual educational settings, and it is a powerful solution to school systems, language study applications, and one-on-one ESL lessons. Its combination of high grammatical precision and instructional support enhances the position of AI as a correction tool to an intelligent language learning partner.

C. Problem Statement

Transformer-based grammar error correction models such as BERT, GPT, and T5 have shown strong benchmark performance [16]; however, that are largely designed for surface-level correction rather than pedagogical support in ESL learning contexts [17]. Existing systems including GECToR, BART-GEC, and RoBERTa-GEC prioritize correction accuracy but lack learner awareness, adaptive feedback, and explanation-based instruction, limiting their educational value [23]. This gap results in improved sentence fluency without fostering long-term grammatical understanding or learner development. To overcome this limitation, the proposed AMT-T5 framework integrates grammar correction, error classification, and personalized feedback, bridging linguistic accuracy with learner-centered pedagogical effectiveness.

D. Key Contributions

- Introduces a learner-aware transformer design principle in which adaptive attention is conditioned on dynamically updated learner error profiles, offering a general modelling strategy for personalized educational NLP systems.
- Establishes a unified learner-centered framework that integrates grammatical correction, error-type classification, and explanation generation, demonstrating how multitask learning can be pedagogically grounded rather than task-driven.
- Provides empirical evidence that explanation-based multitask learning supports pedagogically meaningful feedback, as reflected in reduced recurrence of grammatical errors and positive learner-centered evaluation indicators.
- Proposes a combined evaluation paradigm that integrates computational metrics with pedagogical indicators, offering a transferable methodology for assessing educational NLP systems beyond accuracy-based benchmarks.
- Presents a reusable methodological blueprint for learner-centered language learning systems by combining learner modeling, adaptive attention, preference alignment, and efficiency-oriented optimization, enabling future extensions beyond grammar correction tasks.

The rest of the study is organized as follows: Section II reviews the related works. Section III describes the proposed AMT-T5 model. Section IV details the results and discussion, and Section V concludes the study and direction for future work.

II. Literature Review

The section is organized in the form of a comparative synthesis of previous research on grammatical error correction, language proficiency assessment, and learning NLP. It systematizes the results by the type of model and the area of application, which forms the basis of research to support the proposed AMT-T5 framework.

Korniienk [17] introduces open-sourced foundational models such as LLaMA, Mistral and Gemma demonstrate their ability to provide assistance in writing tasks. However, the application of neural networks in (GEC) is not well investigated. To evaluate these models in zero shot, supervised fine tuning and RLHF settings. Notably, fine tuning greatly enhances GEC

performance and it is critical to use prompt engineering on zero-shot CoNLL-2014 and BEA-2019 benchmarks. Running Direct Preference Optimization under RLHF gives incremental performance gains. Finally, Chat-LLaMA-2-13B-FT attains F0.5 scores of 67.87 and 73.11, respectively. The results also prove that using open-source LLMs is viable for efficient and scalable GEC systems.

Sazzed [18] suggests that readability of the non-native English language speakers and potential prediction methods for their language proficiency from social media reviews are investigated. A corpus of 1,000 reviews was developed containing five ELP groups. The FRE and FKG were used to measure readability scores. Insufficient data are found to distinguish ELP groups pertaining to readability. Various machine learning and transformer-based models, were applied to ELP classification. It turns out the transformer-based approaches were slightly better. Therefore, these are more likely to be used in automatic language proficiency assessment.

Davis [19] evaluates the effectiveness of using NLMs for Grammatical Error Detection in the ESL domain. It is shown that it is possible for NLMs to transfer linguistic knowledge that improves GED performance across benchmark datasets. With appropriate transfer, it also allows fine grained error detection using single models. GED also reflects model type and data domain on analysis and encoded noun-number information. Moreover, this study represents GED as a diagnostic tool that can be utilized to judge implicit grammatical knowledge available in NLMs. Firstly, stark contrast between masked and autoregressive models is highlighted. The study provides a holistic review of NLMs on GEDs tasks.

Ormerod [20] introduces a regression-based framework to study how global features were leveraged by transformer-based models for Automated Essay Scoring. The finding is that pretrained language models implicitly approximate rubric–relevant features while scoring. Hidden states can be used in linear regression to improve the model interpretability by estimating importance of the features. This framework is validated using DeBERTa models fine-tuned on overall and trait level scores. Particular focus is given on convention errors such as spelling, grammar and punctuation. It demonstrates that neural models have improved explainability for use in AES. It validates language modeling-based scoring systems.

Elks [21] discusses that transfer learning and multitask learning can be used to construct an automated marking system for second language English writing. The research studies the fine-tuning strategies for Transformer-based language models towards NLP tasks. Experimental results show that multitask fine-tuning leads to robust and improved performance. Different models are compared against various task-model combinations using various datasets. The third result is that preliminary findings discover that adding multitask objectives to pretrained models improves scoring accuracy. This lends itself to scalable, data-efficient assessment of writing by learners. This work will provide ways for researchers in educational NLP applications for automated evaluation.

Ng and Markov [22] introduces NLI aims to discover when and where one grew up by analyzing the second language spoken and it is applied in linguistics and forensics. Prior to transformers, traditional machine learning methods relying on hand-crafted features have bested them at this task. Closed-source LLMs following the successful trend seen in recent years, for instance GPT-4, show strong performance at zero-shot on open-set classification in NLI. Unfortunately, these models are proprietary and come at a high cost to operate. In this work, explore the use of open source LLMs for the NLI tasks. In their initial form, these arguments are not as effective, but fine-tuned versions of these open models are competitive by accuracy. All the findings shall support the use of open-source solutions as an accessible, customizable way to build NLI.

Alisoy [23] introduces that machine learning for automated vocabulary acquisition for ESL is investigated using transformer-based models. An evaluation of the fine-tuned BERT model was carried out for predicting vocabulary needs on the web and traditional ML algorithms SVM and Random Forest were considered for comparison. The BERT driven tool which was used in the experimental group showed a significantly higher vocabulary gain than the control group. The best precision and recall metrics belong to BERT that achieved the highest accuracy (88%). Results show that context aware ML-based vocabulary tools have the potential to positively impact language learning. In the study, DL and RL are proposed to be used with ESL pedagogy. It adapts to the needs of instruction and allows for curriculum development on an individual basis.

Ye et al. [24] propose that the LLMs in FLE is beginning to flourish, and is found that LLMs have a potential for transformative use as dynamic FLE tools. In terms of pedagogy, it can augment learning materials, create student simulations, and predict what students will or might learn in order to give more targeted instruction. In addition to this, it plays the role of an intelligent agent facilitating inclusive and personalized learning. The authors argue that these roles can be better used only if this collaboration is carried out on an interdisciplinary basis. In other words, innovation is prioritized, and the associated risks are tackled. The work outlines a conceptual framework for optimizing FLE via LLM integration.

Table I summarizes the representative research in grammar correction, automated writing evaluation, and educational NLP. Recent developments prove that models based on transformers can be successfully used in providing assistance in grammar corrections, readability testing, grading of essays, and assessing vocabulary in cases of ESL. Nevertheless, the available research is mostly divided, where each of the language skills is considered separately and does not have any adaptive feedback, and is not explicitly integrated into the pedagogy.

Earlier multitask grammatical error correction methods are mainly concerned with common representations among tasks that are related to correction but were fixed to the formulations of tasks that are independent of individual learner actions. Educational NLP and automated writing evaluation systems generally produce explanations or feedback, yet these components often not related to the correction process, and it is not trained on the individual errors of the learner. Preference-based optimization techniques even enhance the quality of output, but are not sensitive to the history of learners or instructional personalization. Conversely, the suggested AMT-T5 model integrates grammar clean-up, classification of error

type and generation of explanations into a learner-conditioned model, with adaptive attention reweighting being expressly motivated by learner error history. This design has the capability to provide pedagogically customized and customized grammar feedback that is not addressed by existing approaches.

TABLE I. SUMMARY ON LITERATURE REVIEW

Author	Description	Advantages	Disadvantages
Korniienk [17]	Explores open-source LLMs (e.g., LLaMA, Mistral) in GEC under zero-shot, fine-tuning, and RLHF setups.	Fine-tuning improves GEC; shows viability of open-source LLMs with good performance on CoNLL and BEA benchmarks.	Zero-shot requires careful prompt design; RLHF yields only incremental improvement.
Sazzed [18]	Analyzes readability of non-native texts and classifies English proficiency using ML and transformer models.	Transformer-based models slightly outperform classical models in ELP prediction.	Readability metrics (FRE, FKG) poorly distinguish proficiency levels.
Davis [19]	Investigates NLMs' role in Grammatical Error Detection (GED), and their encoding of linguistic signals like noun-number agreement.	Shows positive transfer and diagnostic power of NLMs; robust linguistic encoding in some models.	Performance varies by model type and domain; brittle encoding across syntactic constructions.
Ormerod [20]	Proposes regression-based explainable AES using DeBERTa models, focusing on global features and convention errors.	Improves interpretability; validates LMs for use in AES.	Limited focus on deeper semantic and content aspects of writing.
Elks [21]	Combines transfer and multitask learning for automated ESL essay scoring using transformers and multiple datasets.	Multitask fine-tuning improves robustness and accuracy; scalable solution.	Preliminary findings; lacks full generalization to diverse writing contexts.
Ng and Markov [22]	Uses open-source LLMs for Native Language Identification (NLI), comparing them with traditional methods and closed-source LLMs like GPT-4.	Fine-tuned open LLMs are competitive; accessible and customizable.	Underperforms out-of-the-box; closed LLMs still outperform in zero-shot settings.
Alisoy [23]	Examines transformer-based vocabulary acquisition in ESL; compares fine-tuned BERT with SVM and Random Forest.	BERT outperforms baselines; improves vocabulary gain; supports curriculum personalization.	Requires technical infrastructure; limited support for grammar beyond vocabulary.
Ye et al. [24]	Presents roles of LLMs in FLE as enhancers, predictors, and agents to enable personalized language instruction.	Promotes inclusive, adaptive, and AI-supported education; provides a pedagogical framework.	Lacks practical implementation details; interdisciplinary collaboration needed for real-world impact.

III. PROPOSED METHODOLOGY FOR ADAPTIVE MULTI-TASK T5 FRAMEWORK IN ESL GRAMMAR CORRECTION

The proposed study presented the empirical method of creating and assessing the AMT-T5 model of grammatical error correction in ESL writing. The model is trained on the Lang-8 Learner Corpus, which is a collection of sentences produced by learners together with professional corrections. Fixed-length T5 tokenizers are used to normalize and tokenize input sentences in order to have similar model input. AMT-T5 architecture is a combination that applies grammatical error correction, the classification of error type, and the generation of explanations based on feedback on the same transformer model, which makes it possible to increase both the linguistic and pedagogical clarity. Once a dynamic error profile of each learner is built, to support learner-centered teaching, an adaptive feedback mechanism reallocates attention to the prevalent grammatical patterns. An adaptive attention mechanism is specifically trained based on the frequency of errors to which the learner is explicit; thus, the model is able to prioritize the grammatical structures that provoke a particular learner in different sessions. In this design, the attention mechanisms are not fixed, as in the case of traditional transformer attention mechanisms that are user-independent and do not incorporate user-specific historical information in attention computation. A combination of supervised fine-tuning, Direct Preference Optimization, to align all corrections with pedagogical expectations, and Knowledge Distillation to facilitate efficient real-time deployment. Fig. 1 demonstrates the workflow of the suggested AMT-T5 framework.

A. Data Collection

The study uses the Lang-8 Learner Corpus [25] of Kaggle. The major source of information is the Lang-8 Learner Corpus, which consists of authentic ESL learner sentences together with native-speaker corrections. A binary tag on each record (1 = error, 0 = correct) is used to show the presence of a grammatical error in the sentence. It separates the dataset into 80% training, 10% validation, and testing to allow equal generalization.

The sample data pairs, in Table II, are the sample data utilized in training the model, with y = 1, in every row, meaning that there are grammatical errors in the sentence. In the Input column, the sentences originally written by the learners are displayed, whereas in the Output column, the same sentences edited by the experts are presented, and that are used to illustrate different grammar problems, such as incorrect use of tenses, subject-verb agreement and omission of articles.

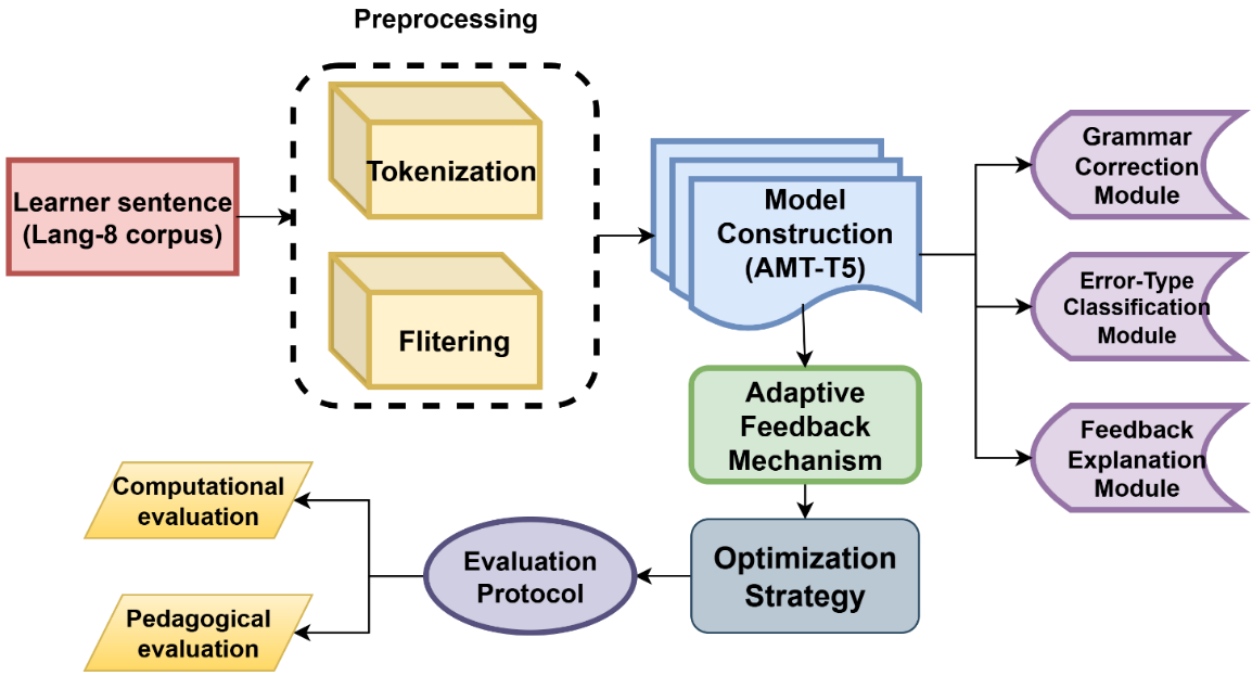

Fig. 1. Adaptive grammar correction framework.

TABLE II. SAMPLE DATA FROM LANG-8 LEARNER CORPUS

y	Input (Learner Sentence)	Output (Corrected Sentence)
1	And he took in my favorite subject like soccer.	And he took in my favorite subjects like soccer…
1	Actually, who let me know about Lang-8 was him.	Actually, he was the one who let me know about Lang-8.
1	His Kanji's ability is much better than me.	His Kanji ability is much better than mine.
1	We've known each other for only half a year, but his lesson was a lot of fun.	We've known each other for only half a year, but his lessons were a lot of fun.
1	I heard a sentence last night when I watched TV.	I heard a sentence last night when I was watching TV.
1	Yesterday, I went to Umeda station to date.	I went to Umeda station for dating yesterday.

B. Data Preprocessing

Preprocessing is a crucial step towards cleaning the dataset, organizing it, and making it compatible with the requirements of the transformer-based models, in particular, T5. The preprocessing step maximizes the input data for effective learning and correct grammatical error correction.

1) Filtering: To limit the scope to error-containing sentences in need of correction, the dataset was cropped to keep only those records where the binary error tag was 1. Let D be the original dataset, and is represented, as in Eq. (1):

$$D = \{(x_i, y_i, l_i)\}_{i=1}^{N} \quad (1)$$

where, x_i is the learner sentence, y_i is the corrected sentence, $l_i \in \{0,1\}$ is the binary label indicating whether correction is needed. The Filtered dataset is as given in Eq. (2):

$$D' = \{(x_i, y_i) | l_i = 1\} \quad (2)$$

2) Formatting for T5: Grammar correction is modeled as text-to-text translation using task prefixes. This structure transforms the task of correction into a sequence-to-sequence mapping problem, given in Eq. (3) and Eq. (4):

$$T5\ Input{:}X = prefix + x_i \quad (3)$$

$$T5\ Output{:}Y = y_i \quad (4)$$

3) Tokenization: Tokenization was done with the T5 pre-trained tokenizer. Tokenization separates text into a series of subword units or tokens that are mapped numerically for model consumption. Let $Tok(\cdot)$ denote the tokenizer function, as in Eq. (5):

$$X_{tokenized} = Tok(X), Y_{tokenised} = Tok(Y) \quad (5)$$

Each sequence was padded to a maximum length of 128 tokens to ensure uniformity, given in Eq. (6):

$$|X_{tokenized}| \leq 128\ , |Y_{tokenized}| \leq 128 \quad (6)$$

C. Adaptive Multi-Task T5 Task-Specific Learning Modules

The proposed AMT-T5 framework extends the T5 encoder–decoder model through three interdependent modules designed to jointly handle grammar correction, error classification, and feedback generation. Such modules exchange contextual representations of the encoder, which facilitates learning in a coherent manner of linguistic and pedagogical activities.

Fig. 2 shows the AMT-T5 structure, which incorporates the grammar correction method, the error classification method and the feedback generation method, all integrated in a single systematic encoder-decoder structure. The input sentence of the learner is coded and fixed using the Grammar Correction Module, and at the same time, the error is also classified to highlight the particular linguistic vulnerability. The Adaptive

Feedback Mechanism of the system observes the changing pattern of errors of each learner and continuously refocuses attention to guide them individually. This reinforcement loop strengthens the learning gaps that may have occurred before and thus mistakes that would be made are given specific attention. Consequently, AMT-T5 provides a context-sensitive, real-time guidance facilitating an improved learning rate and encouraging a progressive improvement in ESL learners.

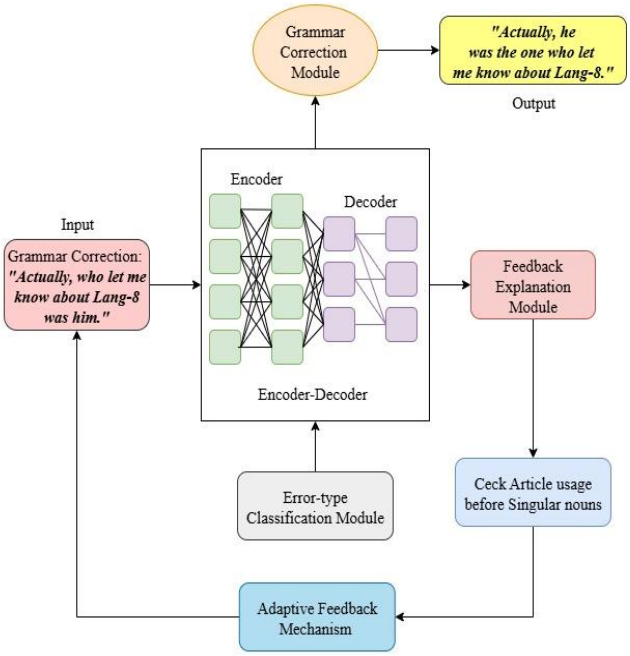

Fig. 2. AMT-T5 model architecture.

1) Grammar correction module: Grammatical transformation is the main one, in which the model will change the incorrect sentences written in the ESL to the grammatically correct ones without distorting the contextual meaning and fluency. The encoder puts the input made by the learner into perspective and the decoder produces the corrected output one step after another. The correction loss function takes the following form, represented as in Eq. (7):

$$\mathcal{L}_{corr} = -\frac{1}{T}\sum_{t=1}^{T} log P_\theta(y_t \mid y_{<t}, x) \quad (7)$$

where, x denotes the input sentence of a learning individual, y_t represents the gold-standard token at that particular position and T denotes the target number of positions. $\mathcal{L}_{corr}$ to the minimum implies a high degree of correspondence with the corrections of the experts, and decreases the number of grammatical deviations in ESL writing.

2) Error-type classification module: In this module, the model is able to classify types of grammatical error, e.g., tense error, omission of articles, or subject-verb agreement. The binary predictions of each of the error types and are produced by a classifier that is based on encoder representations, as given in Eq. (8):

$$\mathcal{L}_{class} = -\sum_{k=1}^{K}(e_k log\hat{e}_k + (1-e_k)log(1-\hat{e}_k)) \quad (8)$$

In which K denotes the base count of types of error, ek denotes the binary indicating of type k on the ground-truth, and e_k denotes the predicted probability. Minimizing such loss increases the ability of the model to identify and accustom to recurrent learner specific deficiencies.

3) Feedback explanation generation module: The AMT-T5 also produces explanatory feedback to facilitate the process of pedagogy, which explains the reason a correction was given. This enables the learners to learn about the underlying grammatical principles and not just being given fixed text. The loss of explanation is computed, as in Eq. (9):

$$\mathcal{L}_{exp} = -\frac{1}{T_r}\sum_{t=1}^{T_r} log P_\theta(r_t \mid r_{<t}, x) \quad (9)$$

where, T_r is the length of the explanation and r_t is the token at position t in the reference explanation. Reduction of such loss will guarantee clear, context-specific explanations that are concise and meet the ESL learning goals.

4) Joint optimization objective: Joint Optimization Objective: The three modules are trained with the same multi-task target in order to balance the grammatical accuracy and error interpretability as well as educational feedback. The overall loss is calculated, as in Eq. (10):

$$\mathcal{L}_{total} = \lambda_1\mathcal{L}_{corr} + \lambda_2\mathcal{L}_{class} + \lambda_3\mathcal{L}_{exp} \quad (10)$$

where, λ_1,λ_2, λ_3 are weights which balance the importance of tasks. In our study, correction (λ_1) is given higher priority whereas classification and explanation λ_2, λ_3) are moderately weighted. Such a structure guarantees that grammatical accuracy is the paramount result whereas it still instills pedagogical feedback to promote the long-term success of ESL students.

D. Adaptive Feedback Mechanism in AMT-T5

To increase the pedagogical utility of grammar correction, the suggested AMT-T5 structure integrates the adaptive feedback mechanism personalizing the corrections and explanations depending on the behavior of particular learners. As opposed to the traditional correction systems which are static, this mechanism constantly represents the learner-specific error pattern and adapts model attention to deliver specific and didactic feedback.

1) Learner error profiling: The system notes how many times each type of errors is done by a learner and a history is obtained which reflects the grammatical weaknesses of a learner. This is an error profile that enables AMT-T5 to be dynamically adjusted to make sure that the model does not correct all learners in the same way, but instead it customizes corrections in accordance with individual performance patterns. It is computed as in Eq. (11):

$$F = [f_1, f_2, \ldots, f_k] \quad (11)$$

where, f_k is the occurrence of the error type k (e.g., the usage of tense, the omission of an article, subject-verb agreement). The error profile vector F in this study is constantly updated, which allows AMT-T5 to retain learner-specific memory to make customized grammar correction.

2) Attention reweighting based on error history: After creating a personalized profile of error, the AMT-T5 architecture dynamically changes the distribution of the encoder-decoder attention. The mechanism puts more emphasis on tokens which are associated with common learner mistakes and rewards the right grammatical patterns. Due to this, the model will be more responsive to the recurring weaknesses and contextual needs of writing among the learners. Such an adaptive approach will allow the system to provide much personalized and context-sensitive grammatical feedback, eventually leading to greater longer-term learning changes. It is denoted, as in Eq. (12):

$$A' = A - \alpha \cdot \delta_{rep} + \beta \cdot \delta_{align} \quad (12)$$

where, A is the initial attention weight, δ_{rep} punishes errors of repetition and δ_{align} strengthens focus on the patterns which are corrected. These modifications in our study eliminate the occurrence of errors by the learners and encourage the AMT-T5 to make successively better corrections.

3) Personalized feedback generation: The final stage converts the nature of the mistakes which were followed to helpful hints. AMT-T5 does not simply come up with corrections and pushes out specific questions, such as; you like to omit articles that come before singular nouns. This makes corrections learning experiences whereby the ESL learners are coached on learning the rules behind the grammar rather than the memorization of corrections. It is given in Eq. (13):

$$Feedback = g(F, A') \quad (13)$$

Here, $g(\cdot)$ is the mapping function, and it receives the error profile F of the learner and modified attention A to generate feedback text. This is the mechanism that this study will help mediate between the automatic correction and the pedagogy and make AMT-T5 a tool of both accuracy and long-term grammatical change.

E. Optimization Strategy

It involves a combination of supervised fine-tuning, Direct Preference Optimization (DPO) and Knowledge Distillation (KD) to achieve a tradeoff of grammatical accurateness, pedagogical flexibility and computational efficiency.

1) Supervised fine-tuning: The AMT-T5 model was fine-tuned on the Lang-8 corpus using the multi-task objective. Training employed the AdamW optimizer (learning rate = 2e−5, batch size = 16, weight decay = 0.01) for 5 epochs with early stopping after two non-improving epochs. This stage allows the model to jointly learn grammatical correction, error-type classification, and feedback explanation.

2) Direct Preference Optimization (DPO): DPO refines model alignment with ESL learners by considering their preferences between multiple valid corrections. Given two outputs—preferred (y_{pref}) and non-preferred ($y_{nonpref}$)—the objective minimizes, given as in Eq. (14):

$$L_{DPO} = -\log\sigma\left(r\left(y_{pref}\right) - r\left(y_{nonpref}\right)\right) \quad (14)$$

where, $r(\cdot)$is the reward function. Minimizing L_{DPO}ensures that AMT-T5 produces corrections aligned with pedagogical clarity rather than mere grammatical validity.

3) Knowledge Distillation (KD): To ensure deployment efficiency, the fine-tuned T5-base (teacher) model transfers knowledge to a smaller student model through soft-target matching derived as in Eq. (15):

$$\mathcal{L}_{KD} = (1-\tau)\mathcal{L}_{CE} + \tau \cdot KL(P_{teacher} \parallel P_{student}) \quad (15)$$

where, τ is the distillation temperature, $P_{teacher}$ the output distribution of T5-base and $P_{student}$ that of the distilled model. KD in our study passed the knowledge between the teacher and the student so that lightweight AMT-T5 could achieve the similar levels of correction in low latency.

4) Final optimization objective: The full learning objective combines all components mathematically expressed, as in Eq. (16):

$$\mathcal{L}_{final} = \lambda_1\mathcal{L}_{total} + \lambda_4\mathcal{L}_{DPO} + \lambda_5\mathcal{L}_{KD} \quad (16)$$

where, λ_4 and λ_5 regulate the preference optimization and distillation contributions. This last loss in this study led AMT-T5 to a balanced learning, that is, providing corrections which are accurate, learner-center and deployed-efficient.

F. Evaluation Protocol

AMT-T5 was evaluated using both computational and pedagogical measures.

1) Computational evaluation: BLEU and GLEU scores were used in measuring the closeness of the model corrections with expert references and Full Sentence Accuracy was used in measuring perfectly correct outputs. Levenshtein Edit Distance was how much the minimum number of edits needed and Error Reduction Rate (ERR) was a measure of the percentage of grammatical errors that were reduced in learner sentences.

2) Pedagogical evaluation: The learning population examined in the pedagogical assessment included 60 intermediate ESL learners who were enrolled in an academic ESL course. Every participant provided written consent and engaged in the AMT-T5 system as part of facilitated grammatical practice sessions. The assessment was done on different learning sessions where the learners were required to provide sentences to get them corrected and provide adaptive feedback, type of errors explanation, and a personalized guide. The profile of errors in learners was revised at the end of each session to monitor the common grammatical errors, including the absence of articles and the use of tenses. The learning profiles were tracked throughout the sessions to observe trends in the reduction of recurring error types like omitting of articles or the misuse of tenses. Also, the user satisfaction ratings were obtained to assess the usefulness of the corrections, explanations, and personalized feedback created by AMT-T5 among the learners. To evaluate the effectiveness of the pedagogical method, the two indicators were observed decrease in the rates of repeated errors over the course of the sessions and learner satisfaction ratings based on a Likert scale

questionnaire about perceived usefulness, intelligibility of explanations, and personalization. The assessment provides exploratory evidence of instructional utility instead of a dependent measurement on long-term learning outcomes.

Algorithm 1: AMT-T5 with Personalized Feedback for ESL Grammar Correction

```
Input:
   Learner corpus D = {(x, y)}
   Pretrained T5 model
   Error type set E
   Learning rates and loss weights λ

Output:
   Corrected sentence ŷ
   Predicted error types ê
   Personalized feedback φ

Initialize AMT-T5 parameters θ
Initialize learner error profile F ← zero vector
Split D into training, validation, and test sets

For each training epoch do
   For each batch (x, y) in training set do
      Format input with task prefixes
      Tokenize and encode input sequence
      Generate corrected output ŷ
      Predict error types ê
      Generate feedback explanation φ
      Compute grammar correction loss Lcorr
      Compute error classification loss Lclass
      Compute explanation generation loss Lexp
      Compute joint multi-task loss
         Ltask = λ1 · Lcorr + λ2 · Lclass + λ3 · Lexp
      Update model parameters θ using gradient descent
   End for
End for

For each learner interaction do
   Receive learner sentence x
   Encode x using trained AMT-T5 encoder
   Generate correction ŷ and error types ê
   Update learner error profile F using ê
   Adjust attention weights based on F
   Generate personalized feedback φ using adjusted attention
   Return ŷ, ê, and φ to learner
End for
```

Algorithm 1 performs grammar correction, error-type classification, and feedback generation within a unified transformer-based framework. The learner sentences are preprocessed and formatted with task-specific prompts first, and then encoded by the shared T5 encoder. Corrected sentences, the classification of grammatical error, and the production of explanatory feedback are collective efforts of the decoder. Recurring mistakes are then used to dynamically update a profile of learner-specific errors, upon which attention weights are altered and personalized feedback is provided. Multi-task supervised learning, Direct Preference Optimization of pedagogical alignment and Knowledge Distillation optimize the model to provide efficient real-time deployment.

The novelty of this study lies in the proposed AMT-T5 architecture, which consolidates the concepts of grammatical error correction, classification of types of errors, as well as the explanation-based feedback into a single transformer architecture adapted to ESL learning. In contrast to the current models of grammar correction, which pay much attention to sentence-level accuracy, the proposed model consists of a learner-centered adaptive feedback system, which dynamically reallocates attention based on personal error histories. This customization allows, and focuses instructional correction, instead of being generic. Also, the combination of preference-conscious optimization and lightweight deployment plans makes AMT-T5 a pedagogically significant and practically deployable grammar learning system as opposed to an independent correction tool.

IV. Results and Discussion

The AMT-T5 grammar correction model was tested on the basis of quantitative measurement, i.e., BLEU, GLEU, full-sentence accuracy, and Levenstein distance and error rate, and on the basis of qualitative judgment of the user. It combines grammar correction, error classification, explanation-based feedback, adaptive feedback, DPO, and Knowledge Distillation, which is better personalized and performs better than single-task T5. The findings indicate that the recurring learner-specific errors and subject-verb agreement, tense and pluralization errors are considerably diminished, and usability and educational value are promising, which proves AMT-T5 to be appropriate to learn ESL grammar in real time, context-sensitive and pedagogically effective. Table III summarizes the simulation parameters and hardware configuration employed to ensure reproducibility, computational efficiency, and fair performance evaluation of the proposed model.

TABLE III. Simulation and Hardware Setup

Parameter	Configuration
Parameter	Configuration
Model Framework	T5-base (Encoder-Decoder, Hugging Face Transformers)
Optimization	AdamW optimizer with Cross-Entropy Loss
Training Batch Size / Epochs	16 / 3–5 epochs with early stopping
Maximum Token Length	128 tokens
Hardware	NVIDIA Tesla V100 GPU, 64GB RAM, Intel Xeon CPU

A. Quantitative Evaluation Results

To critically assess the performance and reliability of the T5-based Grammar correction system are fine-tuned, and a mixture of linguistic and computational measures is used. Overall, it provides an overall description of the capability of the model to identify and correct grammatical errors in real-world ESL learner data.

1) BLEU Score (Bilingual Evaluation Understudy): In natural language processing, BLEU is a popular measure to calculate the degree of similarities from model predicted

response and human annotated sentence. For grammar correction, BLEU score is computed based on n-gram overlap (usually up to 4-grams) and has a brevity penalty for penalizing very short predictions. It is formally given in Eq. (17):

$$BLEU = BP \cdot \exp\left(\sum_{n=1}^{N} w_n log p_n\right) \quad (17)$$

where, BP is the brevity penalty, w_n are weights, p_n is the precision of n-grams. Increased scores in BLEU mean greater consistency with human corrections

2) GLEU Score (Grammar-focused BLEU): GLEU is a variant of BLEU, which is designed specifically to solve (GEC) tasks. Unlike the ordinary BLEU that may favor non-incorrect but fluent results, GLEU is heavier on missing and surplus n-grams. It calculates accuracy and recall when compared to editing of references and provides a fairer ratio when it comes to shorter sentences and structural rearrangements. This is the score that comes in handy, especially when it comes to measuring small grammatical improvements.

3) Edit Distance (Levenshtein Distance): In edit distance, measuring the similarity between the guessed output and the reference correction by determining the minimum amount of single-character operations (additions, removals, replacements), one has to make a change to one text into the other. It is given in Eq. (18):

$$D(i,j) = min \begin{cases} D(i-1,j)+1 \\ D(i,j-1)+1 \\ D(i-1,j-1)+cost \end{cases} \quad (18)$$

where, cost represents 0 when there is a match between the characters, otherwise 1. A shorter distance shows more resemblance to the reference sentence

4) Error Reduction Rate (ERR): ERR is used to gauge the extent to which the model is able to reduce grammatical errors in the input. It is computed as in Eq. (19):

$$ERR = \frac{E_{before} - E_{after}}{E_{before}} X\ 100 \quad (19)$$

where, E_{before} refers to the number of grammatical errors in the original sentence of the learner, and E_{after} is the number of grammatical errors in the output of the model. This measure represents actual enhancement of grammar, which is particularly important in learning settings such as ESL learning.

Quantitative analysis, in turn, is pegged on quantification of how well the grammatically corrected quality of the AMT-T5 base model compares with objective measures of performance, quantify the efficiency of the model to produce correct, fluent and syntactically valid sentences by performing an inspection of model performance on a held-out section of the dataset.

Table IV highlights the AMT-T5 model's good performance, a BLEU score of 72.8, and GLEU of 86.5, which means that it has corrected grammar effectively. The fluency, accuracy, and rate of error reduction (91.2) of the model are shown by high sentence accuracy (75.3), low Levenstein distance (1.7), and high fluency of the model, as compared to the human-corrected sentences.

TABLE IV. PERFORMANCE METRICS

Metric	Score (Approx.) (%)	Interpretation
BLEU Score	78.9	Highly fluent and syntactically sound output
GLEU Score	90.7	Superior grammar-specific correction accuracy
Full Sentence Accuracy	75.3%	High exact match rate with corrected sentences
Levenshtein Edit Distance	1.7 (average)	Very low average edits needed post-prediction
ERR	91.2%	Strong reduction of grammatical errors

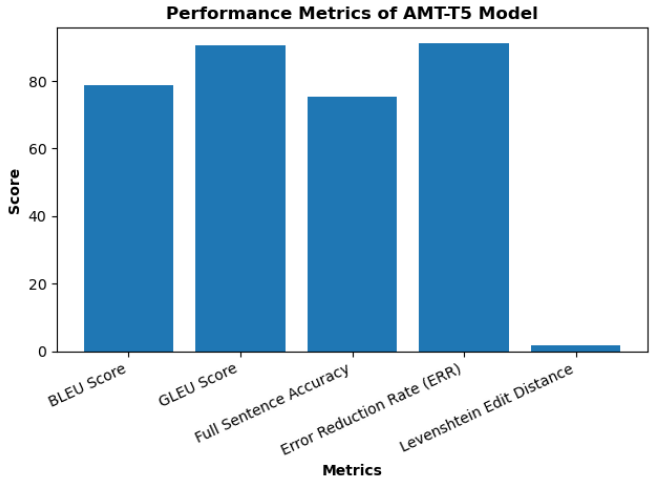

Fig. 3. Evaluation of the AMT-T5 model.

Fig. 3 indicates the quantitative analysis of the AMT-T5 model in five measures. GLEU (86.5) and Error Reduction rate (91.2) are high, which means that the grammar correction measures are successful, whereas BLEU, sentence accuracy, and low error distance are high, which shows that the model is correct and can be useful in pedagogy.

B. Qualitative Evaluation

The final one is a qualitative analysis to determine to what extent the fine-tuned AMT-T5 base model actually performs in a real-life grammar correction scenario beyond the said numerical value. This assessment is done through analysis of some input-output examples taken from the test set, which entails that the model can handle different grammatical structures such as subject-verb concord, tense correction in the verbs, pluralizing, using auxiliaries, etc. In addition, this method provides further insight into how accurately the model generalizes to unseen, user-supplied sentences, an important determinant of such a model for real-world deployment in adaptive grammar learning systems for ESL users.

Table V presents a qualitative analysis of model output and shows that, with respect to correcting real ESL learner sentences, it is effective. In the case of the input sentence, 'And he took in my favorite subject like soccer' was corrected to 'And he took in my favorite subjects like soccer', which fixed the inconsistency between singular and plural. Another one was reformed: "Actually, who informed me relating to Lang - 8? Him," was reformed very well to "Actually, he informed me relating to Lang - 8." The same were the changes to the sentence

'His Kanji ability is better than me' into 'His Kanji ability is better than mine.' Finally, when saying "We've known each other half a year and his lessons were a lot of fun," the model recognized and corrected the verb agreement and plurality, finally this model corrected it by rendering "We have known each other only half a year, but his lesson was a lot of fun." this show that these observations closely follow native speakers ground truth corrections while correcting a variety of grammar problems (subject verb agreement, sentence rephrasing, possessive pronouns, plural, etc.) that demonstrate the model's robustness to correct different types of grammar problems.

TABLE V. QUALITATIVE ANALYSIS

Original Sentence (Input)	Model Output (Prediction)	Correct Sentence (Ground Truth)
And he took in my favorite subject like soccer.	And he took in my favorite subjects like soccer.	And he took in my favorite subjects like soccer.
Actually, who let me know about Lang - 8 was him.	Actually, he was the one who let me know about Lang - 8.	Actually, he was the one who let me know about Lang - 8.
His Kanji's ability is much better than me.	His Kanji ability is much better than mine.	His Kanji ability is much better than mine.
We've known each other for only half a year, but his lesson was a lot of fun.	We've known each other for only half a year, but his lessons were a lot of fun.	We've known each other for only half a year, but his lessons were a lot of fun.

C. Error Analysis

While the AMT-T5-based grammar correction model works well for all the typical grammatical errors, some limitations remain. The model sometimes fails with idiomatic phrases and colloquial expressions, which are usually not well represented in the training data. This may result in forced or incorrect rewrites that change the meaning of the sentence. Further, intricate sentence structures, particularly with nested clauses or unconventional punctuation, at times result in incomplete or partial corrections. The issues here indicate that the model is not able to establish more profound syntactic links in longer or non-standard sentences. Moreover, there are some instances of overcorrection where the grammatically correct sentences are unnecessarily coded and under-correction, when the minor misinterpretations have been overlooked, and the necessity to focus more on the better contextual context should be stressed.

Fig. 4 gives a categorical flow of the nature of model errors, such as overcorrection, under-correction as well as misinterpretation. The unnecessary editing is called overcorrection, under-correction is a lack of errors, and misinterpretation is an alteration of sentence meaning. This gives a type of model errors that is capable of diagnosing system behaviors, as well as helps in future corrective actions according to error-specific error reduction measures in grammar correction tasks.

Table VI gives a summary of a few of the typical failures of the AMT-T5 grammar correction model. Certain failures were due to idiomatic expressions (14%), nested clauses (11%), plus some punctuation mistakes and other minor ones (7%), which could not be corrected. This indicates the shortcomings of the model in complex syntactic structure and infrequent linguistic phenomena, still, it is informative to enhance the model.

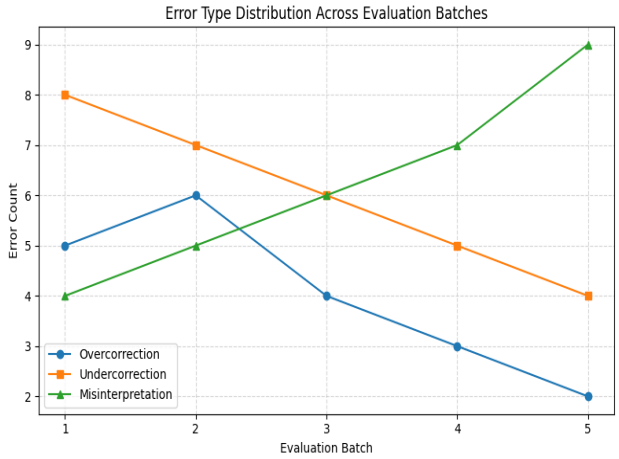

Fig. 4. Error type distribution.

TABLE VI. COMMON FAILURE CASES

Input Sentence	Model Output	Issue Type	% of Failures
It rains cats and dogs yesterday.	It rains cats and dogs yesterday.	Idiom not corrected	14 %
The people who she knows is here.	The people who she knows is here.	Nested clause error	11 %

D. User Evaluation Feedback

User Evaluation Feedback provides an evaluation of the usefulness of the fine-tuned T5 grammar correction tool in a practical context among ESL learners, and helps to identify the accurate results of use with qualitative notes on the usability, comprehension, and educational outcomes. Guided feedback insights are used in the process of making iterative improvements, so that the system will aid adaptive, learner-centered grammar teaching within the real-world setting.

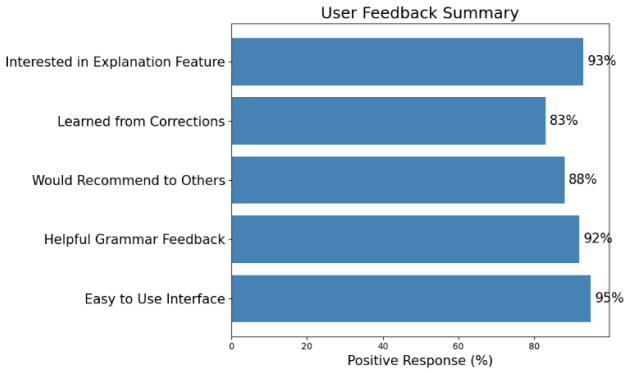

Fig. 5. User feedback evaluation.

Fig. 5 visualizes user feedback about a grammar tool, which reveals that most of the users have the positive feedback by the end of using the tool with the highest positive rating being 95% in the category Easy to Use Interface and the lowest positive rating being 83% in the category Learned from Corrections, which reflects the overall high satisfaction and usability of a tool.

TABLE VII. USER EVALUATION FEEDBACK (N=60)

Criteria	Positive Response (%)
Easy to Use Interface	95
Helpful Grammar Feedback	92
Would Recommend to Others	88
Learned from Corrections	83
Interested in Explanation Feature	93

Table VII presents result of user judgment of the grammar correction system, and it can be seen that the usability, educational, and satisfaction levels are high in ESL learners and that are highly interested in explanation-based feedback, which is a reflection of practical usefulness as well as high potential of improving language learning outcomes.

E. Ablation Study

Each architectural enhancement yields incremental improvement, confirming multi-task synergy and adaptive relevance. The ablation study presents every element of the AMT-T5 framework sequentially to measure its contribution individually. If the Multi-task Learning configuration is eliminated, the generation of explanations and classification losses of the type of errors, the Adaptive Feedback scheme also allows the learner error profile and attention reweighting, while holding other elements constant. The final configuration incorporates Direct Preference Optimization and Knowledge Distillation.

TABLE VIII. ABLATION RESULTS

Model Configuration	BLEU	GLEU	Full Sentence Accuracy
T5-base (fine-tuned)	72.8	86.5	75.3%
+ Multi-task Learning	75.1	88.4	78.0%
+ Adaptive Feedback	77.0	89.6	80.4%
+ DPO + KD (Full AMT-T5)	78.9	90.7	82.6%

Table VIII indicates that contextual grammar correction and sentence-level accuracy are improved with Multi-Task Learning, and that BLEU, GLEU, and full-sentence accuracy are improved further with the introduction of adaptive feedback by explicitly correcting learner-specific mistakes. These advantages show that learner profiling and attention reweighting are valuable not only for grammatical and pedagogical performance. The combination of Direct Preference Optimization and Knowledge Distillation brings more gains and allows it to be deployed effectively.

F. Adaptive Feedback Mechanism

The Adaptive Feedback Mechanism monitors the common grammar mistakes of individual users in order to save them in user profiles to guide individual advice and lesson planning. Connecting correction and instruction allows adaptive learning, increased engagement, self-paced mastery, and turns the system into an interactive and improvement-oriented tool, other than just grammar checking. In implementation, the learner profiles of error are updated with an incremental change following every interaction of a learner by adding the predicted error-type frequencies. Attention reweighting uses the scaling of encoder-decoder attention scores on tokens related to common categories of errors, thus making the model sensitive to recurrent grammatical weakness on further corrections. The mechanism operates at the inference time and does not need any further model retraining.

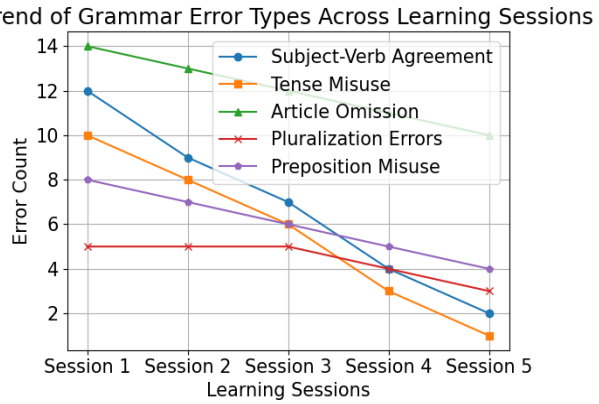

Fig. 6. Comparative model performance.

Fig. 6 shows the reduction of the different grammar errors in five learning sessions. All the subject-verb agreement, tense usage errors, omission of articles, plurality, and preposition errors reveal a negative direction, and this means that learners are gradually improving their grammatical accuracy over time. The reduction in the error categories between learning sessions is the effect of the adaptive feedback mechanism, which continually highlights the recurring error patterns by means of learner profiling and reweighting attention.

G. Comparative Evaluation of Grammar Correction Models

The suggested AMT-T5 model is contrasted with predesigned grammar correction standards, such as GECToR, BART-GEC, and RoBERTa-GEC. A common Lang-8 test split was done on all models according to the same preprocessing and evaluation protocols to ensure that there was a fair comparison. For each model, the average of multiple runs is reported as the final result along with a ±, which indicates standard deviation.

TABLE IX. PERFORMANCE COMPARISON

Model	BLEU Score (±)	GLEU Score (±)	Sentence Accuracy	ERR
GECToR [19]	58.3 ± 1.5	71.6 ± 1.3	62.4%	77.5%
BART-GEC [21]	63.5 ± 1.4	78.1 ± 1.2	68.7%	83.0%
RoBERTa-GEC [20]	66.1 ± 1.3	80.3 ± 1.1	71.2%	85.7%
Proposed AMT-T5 Model	78.9 ± 1.2	90.7 ± 1.0	75.3%	91.2%

Table IX shows the comparative performance in terms of BLEU, GLEU, sentence-level accuracy and error reduction rate (ERR). The proposed AMT-T5 model has the best results in all evaluation measures, having a BLEU score of 78.9+1.2, GLEU score of 90.7 + 1.0, sentence accuracy of 75.3, and an ERR of 91.2. In comparison to the best baseline (RoBERTa-GEC), AMT-T5 is shown to be improved by about 18-22% in grammar-specific measures of performance, especially in GLEU and error reduction rate. These performances show that there is an increase in fluency, accuracy in grammar, and

strength in correcting sentences of ESL learners in a consistent experimental setting.

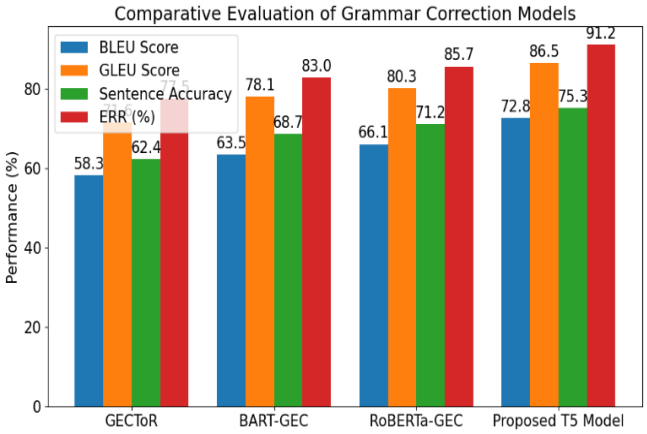

Fig. 7. Comparative model performance.

Fig. 7 compares grammar correction models, with the proposed T5 showing the best performance in terms of BLEU, GLEU, sentence accuracy, and error reduction, and thus better fluency, accuracy, and the reduction of grammatical errors as the best model.

H. Discussion

The experiment findings reveal that the proposed AMT-T5 framework is effective in improving grammatical and pedagogical utility in the ESL grammar correction. AMT-T5 addresses shortcomings that exist in current benchmark-based GEC systems. The high BLEU and GLEU scores mean that the model makes fluent and grammatically correct corrections that are closely similar to expert references, whereas the high rate of error reduction indicates that the model can reduce the number of repeated grammatical errors made by learners. A key characteristic of AMT-T5 is its adaptive feedback mechanism, which is learner-conscious. The model provides specific corrections and individualized explanations by keeping the error profiles dynamic and refocusing attention on errors that happen most of the time. This customization will allow the learners to acquire an insight into the underlying grammatical principles instead of being corrected through rote means, which is captured in accurate responses to full sentences and favorable user responses. The contribution of adaptive feedback is further facilitated by the findings of an ablation study, in which the introduction of the concepts of learner profiling and attention reweighting results in an equal increase of performance as compared to the multi-task baseline. This empirical data indicates that adaptive feedback is not a conceptual enhancement, but a quantifiable factor to grammatical accuracy as well as personalization, specifically to the learner. In addition to the performance of the system, these results provide insight into the role of the learner-conditioned attention in the educational NLP models. The active gains presented across when adaptive feedback is activated give reason to believe that the addition of learner state to the transformer attention processes can have a significant effect on correction behavior. This finding is consistent with a more general modeling principle of learner-aware transformers, in which personalization is integrated into representation learning as opposed to an after-processing task. Pedagogically, the outcomes show that the multitask learning through explanation can support to enhance teaching clarity and student interaction. Although the current assessment does not hypothesize long term grammatical learning, the general decrease of repeating error patterns and positive learner feedback is indicative of the impact of adaptive explanations and learner-specific instructions in pedagogical rich interactions in ESL learning settings. The Direct Preference Optimization also adds to the pedagogical alignment by promoting both grammatically and instructionally valid corrections. Overall, AMT-T5 is a significant step on the way to learner-focused, adaptive grammar correction systems that can combine linguistic accuracy with the learning power.

V. Conclusion and Future Works

This study introduced the AMT-T5 system, which is an active learner-based framework of a transformer model, to treat the linguistic precision and educational efficiency in ESL grammar correction. AMT-T5 shows the way grammatical correction, learner modeling and instructional feedback can be offered within a single learner-centered framework. The combination of adaptive feedback mechanisms enables the model to store the learner-specific error profiles and dynamically manipulate attention, producing individualized and situational instructional advice. The experimental estimates of the Lang-8 Learner Corpus indicate that AMT-T5 is characterized by good performance in standard GEC measures, such as high BLEU and GLEU scores, enhanced full-sentence accuracy, and a significant decrease in errors. User reviews also give support to the fact that explanation-based and customized feedback improves perceived learning value and utility. These results suggest that AMT-T5 can be used to effectively close the divide between automated grammar repair services and intelligent language learning assistance, making it an affordable and scalable application to support ESL instruction. Moreover, this study provides a reusable learner-centered modeling framework of educational NLP, rather than a task-specific grammar correction system. The integration of profiling of learners, adaptive attention, and explanation-based generation, as proposed, offers a blueprint of the methodology that can be followed by future language learning systems not only in grammar correction but also elsewhere. In addition, the concurrent performance measures of calculational performance and pedagogical analysis measures form an evaluation paradigm and can be transferred to other intelligent tutoring and teaching NLP applications, allowing assessment of the quality of linguistic and teaching performance in a more holistic manner.

Future studies will be aimed at enhancing the strength and generalization of the suggested framework. It is also necessary that longitudinal classroom-based research be conducted to determine the long-term effects of adaptive feedback on learner proficiency. Also, it should be extended to multilingual and low-resource ESL environments to enhance its applicability in various educational environments. The extensions will be designed to make AMT-T5 a more complex, intelligent system of learning a language that can support personalized grammar learning on a large scale.

***Abstract*—The rapid expansion of New Energy Vehicles (NEVs) has increased the global NEV supply chains' exposure to diverse and interconnected risks. Distributed production networks frequently face disruptions driven by raw material volatility, evolving environmental regulations, customs clearance uncertainty, and geopolitical instability, underscoring the need for effective early-warning systems. To address limitations in existing studies that lack a consistent and interpretable structure for NEV-specific hazards, this study proposes a hybrid NLP-based pipeline for risk text classification and early-warning sender extraction. A curated dataset of 120 NEV-related risk reports published between 2023 and 2025 was collected from Chinese information sources, pre-processed, and annotated according to a six-category risk taxonomy. Classical machine-learning models, including logistic regression, support vector machines, random forest, and XGBoost, were trained using TF-IDF features, while a multilayer perceptron and a BERT model were employed to capture nonlinear patterns and contextual semantics. Classical models were evaluated using five-fold cross-validation, and deep models were assessed on a held-out test set. XGBoost achieved the best classical performance, with accuracy and F1 scores of 0.826 and 0.766, respectively. BERT outperformed all baselines, reaching an accuracy of 0.864 and an F1 score of 0.808. The proposed framework demonstrates a modular and scalable approach.**

***Keywords*—New Energy Vehicle (NEV); supply chain risk; natural language processing (NLP); text classification; early warning system; BERT**

I. Introduction

The increasing globalization and digitalization of manufacturing relationships have rendered today's supply chains highly interconnected yet structurally vulnerable. Recent events, spanning from global epidemics to trade issues, demonstrate that a single event can cause significant disruptions. These disruptions can occur across various tiers of the supply chain, resulting in substantial financial losses, severe delays, and reputational damage.

These vulnerabilities are particularly evident in the New Energy Vehicle (NEV) supply chain, which heavily relies on geographically dispersed upstream raw material sourcing, such as lithium, nickel, and cobalt, complex battery-manufacturing networks, and long-distance export logistics. As indicated by [1], [2], [3], effective risk management for supply chains has become a priority for both academic institutions and the industry.

Advances in artificial intelligence (AI) and natural language processing (NLP) have made it increasingly feasible to extract risk-related signals from unstructured textual data, including corporate disclosures, industry analyses, trade bulletins, and social media streams. These sources often contain early indicators of disruptions within the NEV supply chain, frequently preceding formal incident reports or official announcements.

Yet, extracting reliable signals from such heterogeneous and noisy text remains a substantial challenge. Rule-based systems lack scalability and domain adaptability. Conventional machine-learning approaches typically rely on bag-of-words or term frequency–inverse document frequency (TF–IDF) representations, which capture surface-level linguistic patterns but fail to model contextual semantics or subtle cues embedded in risk-related narratives.

Prior studies demonstrate that unstructured textual sources—such as news reports, regulatory disclosures, and online media—often reveal early disruption signals before official incident documentation becomes available. This highlights the growing importance of automated, text-driven early-warning capabilities in SCRM [4], [5], [6], [7].

These findings are particularly relevant for the NEV supply chain, where risk-related narratives frequently span multiple domains—including raw material volatility, environmental regulation, cross-border logistics, and geopolitical exposure—and thus rely heavily on contextual interpretation.

Meanwhile, the progression from traditional linear classifiers to neural and transformer-based architectures has consistently produced significant performance gains on noisy, domain-specific text corpora, especially in settings where contextual semantics and cross-sentence dependencies are critical [8], [9], [10].

Another hurdle in the classification of risk-related texts is the inherent class mismatch: rare past events, but highly impactful. Most of the time, in textual data, exporters underestimate the impact of sudden shocks in corpora.

In such settings, macro-averaged F1 and precision–recall metrics offer better performance, more accurate prediction, and more reliable assessments than accuracy alone [11], [12].

It is especially important to address imbalance in the NEV supply chain, where high-impact disruptions are infrequent but operationally consequential.

To address these limitations, this study proposes a hybrid analytical framework that employs text-based early warning systems (EWS) for the NEV supply chain, leveraging classical machine learning models and deep learning architecture. Existing research rarely creates a cohesive and reproducible model framework customized for NEV-specific risk stories, especially one that connects to the text classification output. To remediate this gap, the operational suggested framework includes modular text procedures: preprocessing, feature representation, model training, performance evaluation, and interpretable visualization.

Classical models, including Logistic Regression, Support Vector Machine (SVM), Random Forest (RF), and Extreme Gradient Boosting (XGBoost) serve as transparent and interpretable baselines, along with neural models like a multilayer Perceptron, which is based on PyTorch, and a fine-tuned model, Bidirectional Encoder Representations from Transformers (BERT) model which allows learning the contextually semantic, resilience to noisy, domain-specific NEV risk expressions. Collectively, these components establish a scalable and domain-adapted base to convert. Transforming accessible risk signals from unregulated NEV vehicles into useful early warning system insights.

II. Methodology

This study develops an integrated and modular analytical framework for text-driven early warning in the New Energy Vehicle (NEV) supply chain, with a focus on risk-related text classification. The methodology is organized into five functional components, each corresponding to a concrete implementation module:

- Data preprocessing and exploratory text analysis, which clean and normalize NEV risk reports while summarizing corpus characteristics.
- Feature representation via term frequency–inverse document frequency (TF–IDF), which transforms preprocessed documents into a sparse, interpretable vector space for classical machine-learning models.
- Machine-learning benchmarking and optimization, which tunes and compares linear, ensemble, and shallow neural classifiers on the TF–IDF features.
- Deep learning models leveraging PyTorch and BERT are employed to capture the contextual semantics and non-linear patterns within domain-specific new energy vehicle (NEV) risk narratives.
- Evaluation and visualization integrate quantitative metrics with diagnostic plots to guarantee interpretability, transparency, and early-warning applicability.

A. Data Preprocessing and Exploratory Analysis

1) Linguistic normalization: All documents were tokenized, lemmatized, converted to lowercase, and stripped of stopwords to standardize linguistic forms. Rare-word filtering was applied to remove extremely infrequent tokens that contributed noise and sparsity. Chinese-language preprocessing involved word segmentation based on the PKU standard, implemented using Jieba. A domain-specific lexicon was incorporated into the segmentation process to preserve technical terms relevant to the study domain. Default tokenizer parameters were used unless otherwise stated [13], [14].

2) Noise reduction and domain-specific retention: Non-informative elements, including emojis, URLs, HTML tags, and special characters, were removed or normalized. Domain-specific expressions relevant to NEV supply-chain disruptions (e.g., delay, shortage, price surge, shutdown) were explicitly preserved to retain risk-relevant semantics.

3) Exploratory corpus profiling: Exploratory NLP techniques were applied to summarize token-frequency distributions and identify commonly co-occurring terms across the corpus. These descriptive statistics provided an initial understanding of the lexical characteristics of NEV risk narratives and informed subsequent feature-engineering decisions.

4) Keyword frequency visualization: A word-cloud visualization was generated to highlight high-frequency risk-related terms. Dominant keywords—such as supply, disruption, inventory, and delay—were used to obtain an overview of salient lexical items related to operational, supply, and logistics concerns within the NEV risk corpus.

5) Sentiment polarity overview: Sentiment polarity distributions were computed to characterize the overall emotional tone of the corpus. The analysis indicated that many texts exhibited neutral-to-negative polarity, consistent with the risk-oriented nature of NEV supply-chain reports. This step was used solely for contextual profiling rather than as model input.

B. Risk Category Definition and Annotation Scheme

To support supervised learning, the raw annotations initially extracted from the dataset comprised ten fine-grained labels that emerged across new energy vehicle (NEV)-related textual reports. These labels include compliance barriers, logistics disruptions, raw-material price fluctuations, ESG-related risks, overseas-operations challenges, supplier concentration risks, information-security issues, financial and inventory risks, geopolitical constraints, and manufacturing/process disruptions.

Following established supply chain risk management (SCRM) frameworks [15], [7], [4], these labels were consolidated into six higher-level risk categories to enhance semantic consistency, interpretability, and class balance. The final taxonomy employed for model training is:

- Operational Risks: disruptions in manufacturing processes, production instability, and overseas-operations challenges.

- Supply Risks: raw-material shortages, input-price volatility, and supplier-concentration vulnerabilities.
- Logistics Risks: transportation delays, safety incidents, and trade- or geopolitics-induced route instability.
- Information and Data Security Risks: information-collaboration failures, data-security breaches, and risks linked to digital integration.
- Financial and Inventory Risks: inventory imbalance, financial exposure, and capital-flow constraints.
- Environmental / ESG / Compliance Risks: sustainability pressures, ESG-related disruptions, and certification or regulatory compliance challenges.

All 120 NEV-related documents were manually assigned to one of the six categories according to their dominant risk theme. Ambiguous cases were re-examined to ensure consistency. This consolidated schema retains the semantic coverage of the original annotations while enabling a reproducible, literature-grounded foundation for supervised text classification.

C. TF-IDF Feature Representation

After preprocessing, each document was transformed into a numerical vector through term frequency-inverse document, Frequency (TF–IDF) representation. TF–IDF was selected because it provides clear mathematical weight that emphasizes domain-salient risk terms while down-weighting highly frequent but uninformative words. This property is very suitable for sparse short to medium NEV supply-chain text.

The resulting TF–IDF matrix was constrained to the top 5000 vocabulary terms, selected through a combination of corpus frequency statistics and information-gain ranking. This dimensionality was empirically chosen to balance three considerations:

- Retaining sufficient lexical diversity to differentiate the six risk categories;
- Avoiding overfitting associated with excessively large vocabularies; and
- Ensuring computational tractability for classical machine-learning models that operate on high-dimensional sparse inputs.

The last TF-IDF representation generated a sparse matrix of N x 5000, where N denotes the preprocessed. To further reduce, documents were carried out (120 in the curated NEV corpus). Low-variance terms were removed with redundancy below variance thresholding. These steps preserved information rich and grants better stability and efficiency during training.

This representation provides an interpretable and feature space for classical models which are computationally efficient which will help to meaningfully benchmark its performance, which is discussed later with contextual encoders.

D. Machine Learning Benchmarking and Optimization

To establish robust classical baselines, five supervised machine-learning classifiers were implemented and evaluated on the TF–IDF representations: Logistic Regression (LR), Support Vector Machine (SVM), Random Forest (RF), Extreme Gradient Boosting (XGBoost), and a shallow Multilayer Perceptron (MLP). This selection follows established best practices in text classification literature [16], [17].

Logistic Regression and linear SVM provide strong baseline performance on high-dimensional sparse vectors due to their convex optimization objectives and calibrated linear decision boundaries, which have been shown to be effective for TF–IDF–based text representations [16].

Random Forest and XGBoost serve as non-linear ensemble models capable of capturing higher-order token interactions and irregular decision surfaces. XGBoost, in particular, has demonstrated state-of-the-art performance in structured and semi-structured text settings through efficient regularized gradient boosting [18].

A shallow MLP, implemented using PyTorch, provides a lightweight neural baseline that introduces non-linear feature composition while remaining computationally efficient. Prior studies highlight shallow neural networks as effective intermediate architectures between linear models and deep encoders [17], [19].

Each model was evaluated under a five-fold cross-validation protocol, using macro-averaged F1 as the primary metric to address class imbalance across the six NEV risk categories. This procedure mitigates overfitting concerns given the limited dataset size and ensures stable generalization estimates.

Hyperparameter optimization was conducted using a combination of grid search for well-bounded parameter spaces (e.g., LR regularization, SVM C-value) and randomized search for larger spaces (e.g., XGBoost learning rate, MLP hidden-layer widths). Such hybrid search strategies are widely used to balance exploration efficiency and computational cost [20].

These classical models thus provide transparent, interpretable, and computationally efficient baselines, forming a meaningful point of comparison for the deep contextual models [9], [21].

E. Deep Learning Models: PyTorch and BERT Fine-Tuning

To complement the classical machine-learning baselines, two deep-learning architectures were implemented: a PyTorch-based Multilayer Perceptron (MLP) trained on TF–IDF vectors, and a fine-tuned Bidirectional Encoder Representations from Transformers (BERT) model trained directly on the raw NEV risk texts. These models introduce non-linear representational capacity and contextual understanding beyond what can be achieved with sparse lexical features.

1) PyTorch-based MLP: The baseline neural model consists of two fully connected hidden layers with ReLU activation, trained on the 5000-dimensional TF–IDF feature vectors. This shallow architecture serves as a lightweight neural baseline positioned between linear classifiers and transformer-based encoders.

In addition, an ablation study evaluated the effects of architectural variations, including increased layer depth, batch normalization, and dropout regularization, to identify the final configuration with improved generalization performance. Batch

normalization and dropout were therefore applied only in the selected ablation configurations rather than in the baseline model.

2) BERT Fine-Tuning: In order to understand the semantics in NEV supply-chain narratives, a pre-trained BERT-base model [9] was fine-tuned on the 120-document corpus. BERT's bidirectional transformer architecture allows the model to [21] represent subword-level semantics and long-range dependencies that classical TF-IDF features cannot code. The fine-tuning procedure followed standard transformers with a learning rate of 2e-5, batch size of 16, and so on. 128 token input sequence length and early stopping are used to avoid overfitting occurrence due to the size of the small dataset. Here, the procedure utilizes the Hugging Face transformer library [22].

Despite the computational cost of fine-tuning, BERT offers a contextual baseline which can differentiate subtle expressions of risk–differences between rule disturbances, transport delays, or industry operators. Although disruptions sometimes appear lexically similar, the meanings of "Green" and "Sustainable" are semantically different. To evaluate the robustness of the BERT-based model, each experiment was repeated five times using different random seeds. Performance metrics (macro-F1 and PR-AUC) are reported as mean ± standard deviation across runs. This repeated evaluation mitigates the influence of stochastic training effects and provides a more reliable assessment of model stability under imbalanced data conditions [23].

Together, the MLP and BERT models extend the different methods used in sparse and deep lexical modelling, encoding it contextually, which allows comparison between classical and modern representation-learning approaches.

F. Evaluation and Visualization Framework

Classical machine-learning models were additionally evaluated using a five-fold cross-validation protocol. The consistency of generalizations across data partitions, while profound evaluation was done on learning models (MLP and BERT). The standard held-out test split is harder to compute. This combination provides a balanced and methodologically consistent evaluation framework.

On the quantitative side, several established metrics were applied.

Accuracy provides an overall measure of prediction and correctness. In comparable text-classification studies, values such as informal reference points are often used near 0.80. You cannot rely only on accuracy for the evaluation of an imbalanced Macro-averaged F1. The primary metric used in this study offers equal weightings to assure imbalance robustness evaluation. In prior text-classification research, generally High macro-F1 values are interpreted as reflective of improved discrimination performance, particularly in the imbalanced data set [24].

ROC–AUC was included as a threshold-independent measure of discriminability. Instead of relying on fixed cutoffs, a higher AUC value means there is a wider margin. It makes the metric fit for comparing model behavior of switching between classifiers in imbalanced scenarios.

Precision–Recall (PR) curves were included because they are more informative than ROC curves under class imbalance. Instead of relying on fixed thresholds, higher average precision values indicate a more favorable balance between false-alarm control and sensitivity. This makes PR analysis a complementary perspective to ROC–AUC when evaluating performance in imbalanced NEV risk categories.

Cross-validation variance was assessed using the standard deviation of accuracy and macro-F1 across folds. Smaller deviations reflect greater robustness across sampling partitions.

On the qualitative side, several diagnostic visualizations were used to provide linguistic and structural insights into the NEV risk-text corpus through sentiment polarity and word frequency visualization.

Sentiment polarity distribution plots were generated to examine the overall emotional tone of risk-related texts after preprocessing. This provided a contextual understanding of the corpus and helped characterize the general linguistic environment in which the models operate.

Word-frequency visualizations, including word clouds and term-frequency plots, offered a high-level overview of salient lexical items and thematic patterns present in the corpus.

Together, these quantitative indicators and qualitative diagnostic tools form a coherent evaluation framework for assessing model performance in NEV supply-chain risk text classification.

III. Experimental Results and Analysis

A. Dataset Overview and Preprocessing

The compiled dataset included 120 New Energy Vehicle (NEV)-related supply chain risk texts from Tencent News, Baidu News, intelligence platforms for industries, and corporate disclosures. Documents released from 2023 to 2025 describe emerging disruptions, such as material shortages, hindrances from authorities, and supply crises, which establish the foundation for future classification experiments.

After preprocessing (as detailed in methodology), it becomes clear that there is corpus-level characteristics with implications for model performance.

First, the documents are predominantly short to medium in length. They are written in a news - brief - style concise manner, like operational bulletins. This results in a relatively sparse lexical area where a lot of sentences only have 1 or 2 explicit risk cues. Such a compact textual structure increases the preference for local tokens instead of extensive contextual expressions. This is the part where TF-IDF-based effectiveness baselines were observed in later experiments.

Second, sentiment-polarity analysis (see Fig. 1) shows a strong concentration of neutral-to-negative tones. This is consistent. Due to the risks involved in reporting, there are expressions. Words like "decline", "shortage", "delay", and "uncertainty" are present in the testimony of the fact rather than the statement of the emotion. The sentiment distribution thus acts as a backdrop. It indicates risk orientation instead of being a predictive factor.

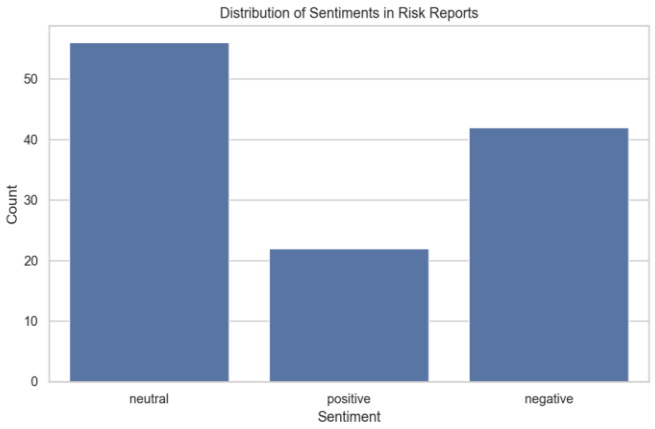

Fig. 1. Distribution of sentiments in risk reports.

Third, keyword-frequency visualization (Fig. 2) reveals that many of the most prominent terms—such as high, new, market, and production—are generic and do not directly correspond to the fine-grained risk semantics required for classification. More informative risk-related terms, such as logistics, shortage, inventory, shipment, price fluctuation, or supply disruption, appear in the cloud but with less visual dominance due to the small corpus size and uneven lexical distribution. This pattern indicates that surface-level token frequency alone provides limited discriminative power, reinforcing the need for models capable of capturing contextual cues rather than relying solely on word counts.

The visualization of keyword frequency shows that there are high numbers of new products launched in the market, and many more. "Production" and "planning" are terms that do not refer to anything specifically. The classification requires well-defined risk semantics. More detailed terms about risk will be logistics, shortage, stock, delivery, cost change, or material halt. They may appear in the cloud but with less visual prominence due to the small corpus size and uneven lexical distribution.

This pattern shows that surface-level token frequency alone offers limited ability to discriminate, which reinforces the need for models able to seize contextual cues instead of just depending on word counts.

Fourth, the distribution of the six consolidated risk categories is naturally imbalanced. Operational and Supply risks occur more frequently, whereas ESG-related and Information-Security risks are comparatively rare. This imbalance influences the behavior of classical classifiers, motivating the use of macro-F1 scoring and stratified train–test splitting to ensure fair evaluation across categories [12].

Taken together, these corpus characteristics clarify both the strengths and limitations of the dataset: while the texts contain genuine early-warning cues relevant to NEV supply-chain disruptions, their brevity, lexical sparsity, and imbalance present modelling challenges that justify the use of both classical and contextual models.

Fig. 2. Risk event word cloud.

The relatively small dataset size inevitably limits generalization and increases sensitivity to train–test partitioning, particularly for neural models, and the results should therefore be interpreted as indicative rather than exhaustive.

Overall, these features of the corpus specify both the strengths and limitations of the dataset. The text contains authentic early-warning signs pertaining to NEV supply-chain interference. These signs are short-lived, not complex, and not balanced.

B. Baseline Model Comparison

To establish reference performance for NEV supply-chain risk classification, five classical machine-learning models—Logistic Regression (LR), Support Vector Machine (SVM), Random Forest (RF), Extreme Gradient Boosting (XGBoost), and a shallow Multilayer Perceptron (MLP)—were trained on the TF–IDF representations derived from the preprocessed corpus. These models correspond directly to the baseline configurations and together provide a diverse set of linear, ensemble-based, and shallow neural inductive biases for comparison.

Table I reports the baseline performance on the held-out test split. Among the classical models, XGBoost achieved the highest overall accuracy (0.826) and macro-F1 score (0.766). This superior performance reflects its ability to model non-linear interactions among sparse lexical features, which is particularly beneficial given the heterogeneous and context-dependent nature of NEV risk expressions. The shallow MLP produced the second-best performance (F1 = 0.688), indicating that even limited non-linear capacity contributes meaningful improvements over linear models. In contrast, LR and SVM showed comparable but lower performance (F1 = 0.628), consistent with their reliance on linear decision boundaries that may not fully capture the subtler distinctions between operational, supply-related, and logistics-related risk narratives.

Random Forest achieved moderate but stable results, performing in line with expectations for a bagging ensemble trained in high-dimensional sparse input. Overall, the baseline comparison suggests that models incorporating non-linear structure, whether through boosting or shallow neural transformation, are better suited to the lexical and semantic characteristics of NEV risk texts. These results provide a foundation for the deeper analyses that follow.

TABLE I. BASELINE MODEL PERFORMANCE COMPARISON

Model	Accuracy	F1-score
XGBoost	0.826	0.766
MLP	0.783	0.688
Logistic Regression	0.739	0.628
SVM (Linear)	0.739	0.628
Random Forest	0.739	0.628

1) Micro-level ROC and PR analysis: To examine the discriminative behavior of the baseline models beyond single-point metrics, micro-averaged ROC and Precision–Recall (PR) curves were generated. Micro-averaging aggregates true positives, false positives, and false negatives across all six risk categories, providing a threshold-independent view of overall performance that is particularly suitable for small and imbalanced datasets such as the NEV corpus.

Fig. 3 shows the ROC curves of the five baseline classifiers. All models achieved high AUC values, reflecting the relative ease with which they distinguish positive from negative class assignments when threshold variation is allowed. The MLP model attained the highest micro-AUC (0.982) on the held-out test split, slightly exceeding XGBoost and the other classical models. This advantage is consistent with the shallow neural network's capacity to capture limited non-linear patterns within the TF–IDF space, even though its overall macro-F1 remains below that of XGBoost. The strong ROC performance across models also reflects the short, lexically concentrated nature of the NEV texts, where many risk indicators appear in relatively explicit forms.

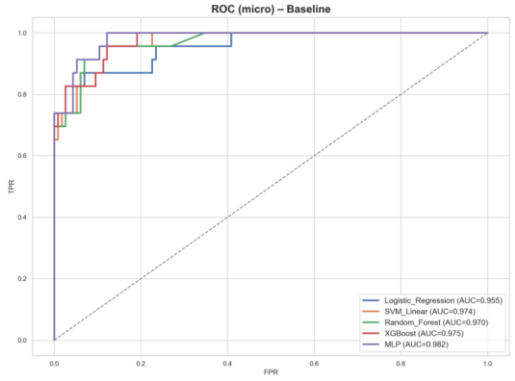

Fig. 3. ROC curves of all baseline models.

Precision-Recall (PR) curves (see Fig. 4) offer a supplementary diagnostic that is especially pertinent to imbalanced classification. In this context, the Multilayer Perceptron (MLP) once more attained the highest micro-averaged value. The outcome demonstrated a precision of 0.931, suggesting relatively robust precision-recall trade-offs across various threshold settings.

However, in the PR curves, the linear models are also showing a more noticeable decline. This is expected, as their ability to discriminate between different risk categories is limited.

Compared with ROC curves, PR curves reveal more pronounced performance variation, underscoring the significance of evaluating baseline classifiers using various measures, focusing on complementary indicators, not just accuracy.

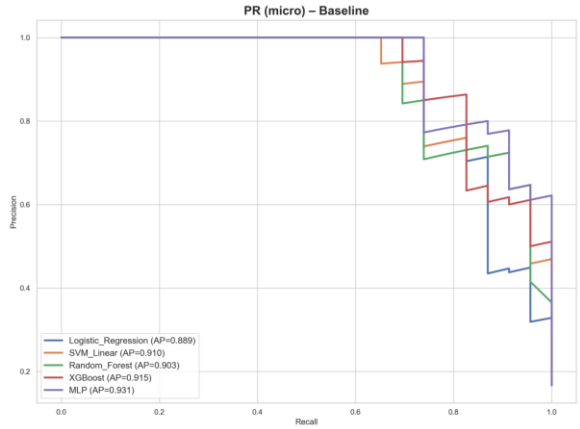

Fig. 4. PR curves of all baseline models.

Collectively, the receiver operating characteristic (ROC) and precision-recall (PR) analyses corroborate the numerical results previously observed. Specifically, while multiple models attain high separability when thresholds are adjusted, non-linear architectures, especially boosted trees and shallow neural networks, are more effective in dealing with ambiguous or overlapping new energy vehicle (NEV) risk expressions.

2) Cross-validation and robustness evaluation: To evaluate the stability of the baseline classifiers beyond the reserved test subset, five-fold cross-validation was conducted on all classical models, with macro-averaged F1 serving as the primary evaluation metric. Table II presents the mean accuracy, mean macro-F1, and the corresponding standard deviations across folds, offering an understanding of each model's robustness under different data partitions.

XGBoost achieved the highest mean accuracy of 0.820, the best average macro-F1 score (0.764), and one of the smallest variances across folds. This indicates that its strong performance on the held-out test set does not result from just good sampling. It shows generalization for NEV risk information. The stability of XGBoost's ability to capture non-linear relationships is one reason, such as in lexical engagement and controlled particle motion. This is useful due to the heterogeneous and context-dependent vocabulary of NEV risk descriptions.

The shallow MLP achieved second-best overall performance, with a mean macro-F1 of 0.688 but moderately higher variance compared with XGBoost. This variability is expected for neural models trained on small datasets: although the MLP benefits from limited non-linearity, its performance is more sensitive to train–test partitioning and local token distributions.

Logistic Regression, SVM, and Random Forest produced comparable results, with lower macro-F1 scores but relatively stable variance across folds. Their consistency reflects the simplicity of their hypothesis classes, though their limited

representational capacity restricts their ability to distinguish fine-grained NEV risk categories.

TABLE II. CROSS-VALIDATION PERFORMANCE OF BASELINE MODELS

Model	Mean Accuracy	Std. Dev.	Mean F1-score	Std. Dev.
Logistic Regression	0.742	0.018	0.635	0.025
SVM (Linear)	0.745	0.021	0.640	0.023
Random Forest	0.754	0.030	0.662	0.028
XGBoost	0.820	0.017	0.764	0.019
MLP	0.783	0.025	0.688	0.027

Overall, the cross-validation results confirm the robustness of XGBoost as the strongest classical baseline. Although the MLP demonstrates superior ROC and PR performance on the held-out split, XGBoost surpasses all classical models in terms of macro-F1 and cross-validation stability, the primary evaluation criteria in this study.

C. Model Optimization and Hyperparameter Tuning

To further enhance the performance of the baseline, hyperparameter optimization was carried out for all classical models by integrating grid search and randomized search strategies, as detailed in the methodology. Table III presents a summary of the key optimized parameters and the corresponding enhancements in accuracy and macro-F1.

Across all models, hyperparameter optimization resulted in quantifiable improvements. However, the extent and characteristics of these enhancements varied according to different model families. In the case of Logistic Regression and linear Support Vector Machine (SVM), the adjustment of the regularization strength (C) led to a moderate increase in the macro-F1 score (approximately +2%), indicating a more optimal balance between underfitting and overfitting within the sparse TF-IDF feature space. These improvements are in line with the convex property of linear classifiers, where the performance is mainly determined by regularization rather than intricate interactions among parameters.

The Random Forest algorithm demonstrated a more significant enhancement subsequent to the adjustment of the tree quantity and maximum depth. This phenomenon reflects the sensitivity of the ensemble model to the structural configuration during the modelling of heterogeneous lexical patterns. The increment in the macro-F1 value (+3.98%) implies that deeper and more numerous trees can more effectively capture the multi-token co-occurrence patterns associated with new energy vehicle (NEV) risk narratives.

XGBoost demonstrated meaningful yet relatively moderate improvement after tuning the learning rate, maximum depth, and subsample ratio. The post-optimization performance (macro-F1 = 0.781) solidifies its status as the most robust classical model. Even minor adjustments to regularization and tree depth enhanced its capacity to handle subtle variations in new energy vehicle (NEV) risk expressions while keeping low variance across folds.

The shallow MLP benefited from adjustments to hidden-layer width and dropout rate, achieving a 2–3% gain in both accuracy and macro-F1. These results highlight the importance of modest architectural scaling and regularization in small-sample neural text classification, confirming that limited structural enhancements can improve generalization without requiring deep models.

To enhance the performance of the baseline models, hyperparameter tuning was conducted for all the classical models using a combination of grid search and randomized search. The key parameters that were tuned and how they improved performance are presented in Table III.

Hyperparameter tuning improved all models, but the extent and type of improvement varied among model families. The simple Logistic Regression and linear SVM performed similarly in terms of macro-F1 scores. Their scores improved slightly (+2%) as the value of 'C' increased, where 'C' represents the regularization strength. Increasing 'C' helps prevent excessive underfitting or overfitting in the sparse TF-IDF space. The enhancements regarding the convex behavior of linear classifiers indicate that the performance is mainly driven by regularization rather than complex interactions between parameters.

The performance of Random Forest greatly increased whenever the number of trees and maximum depth were tuned. This indicates that the structure of the ensemble is sensitive when modelling heterogeneous lexical patterns. The upsurge in macro-F1 (+3.98%) denotes that deeper and more trees are better equipped to encapsulate multi-token co-occurrence patterns pertinent to NEV risk narratives.

XGBoost was tuned to improve the learning rate, maximum depth, and subsample ratio, which was meaningful. The results displayed above indicate that our model outperformed the classical model by a significant margin. We achieved this possibility by means of VOC instructions and indicated the NEV risk through macro-F1 = 0.781. There were also changes to the width of the hidden layer and the dropout rate.

The shallow MLP gained a 2-3% increase in macro-F1 and accuracy. The results reveal that the modest architectural scaling and regularization approach in neural text classification for small samples works well. Furthermore, even small architectural scaling helps in improving generalization. Moreover, the working of a deep model is not a prerequisite for better performance.

These fine-tuning outcomes further corroborate the trends identified in the baseline models. Even though several models derive advantages from parameter adjustments, XGBoost persists as the most robust classical classifier in general. Random Forest and MLP exhibit moderate enhancements, whereas linear models display foreseeable yet restricted improvements owing to their constrained hypothesis classes. These findings serve as the impetus for the more in-depth architectural exploration presented in Deep Learning, where neural models are investigated via ablation studies and contrasted with contextual transformer-based learning.

TABLE III. GRID SEARCH OPTIMIZATION RESULTS

Model	Key Tuned Parameters	Accuracy (Before→After)	F1-score (Before→After)
Logistic Regression	C = 1 → 3	0.739 → 0.751(+1.62%)	0.628 → 0.641(+2.07%)
SVM (Linear)	C = 1 → 5	0.739 → 0.756(+2.30%)	0.628 → 0.644(+2.55%)
Random Forest	n_estimators = 100 → 300; max_depth = 10 → 20	0.739 → 0.762(+3.11%)	0.628 → 0.653(+3.98%)
XGBoost	learning_rate = 0.1 → 0.05; max_depth = 6 → 8; subsample = 0.8	0.826 → 0.841(+1.82%)	0.766 → 0.781(1.96%)
MLP	hidden_size = 128 → 256; dropout = 0.3	0.783 → 0.798(+1.92%)	0.688 → 0.710(+3.20%)

D. Deep Learning

1) MLP performance and architectural ablation: To evaluate the contribution of architectural components within the neural baseline, a structured ablation analysis was conducted on the PyTorch MLP classifier. The ablation experiments systematically varied three key factors—layer depth, batch normalization, and dropout regularization—to assess their individual and combined effects on classification performance. All configurations were trained on the same TF–IDF feature space and evaluated using the held-out test set to ensure comparability.

Table IV presents the quantitative outcomes. The results illustrate clear and consistent trends. First, adding batch normalization improved model stability by standardizing intermediate activations, helping the network converge more smoothly during training. Second, incorporating dropout (0.3) further enhanced generalization by limiting neuron co-adaptation, an issue commonly amplified in small-sample text-classification tasks such as the NEV corpus used in this study. Finally, increasing network depth from two to three hidden layers produced the strongest performance gains (F1 = 0.729), suggesting that moderate depth expansion provides additional representational capacity to capture non-linear token co-occurrence structures that linear models and shallower networks cannot effectively learn.

TABLE IV. PYTORCH ABLATION RESULTS

Configuration	Hidden Layers	Dropout	Batch Norm	Activation	Accuracy	F1-score
Baseline	2	0.0	No	ReLU	0.739	0.628
+ Batch Normalization	2	0.0	Yes	ReLU	0.761	0.662
+ Dropout Regularization	2	0.3	Yes	ReLU	0.783	0.701
+ Deeper Network	3	0.3	Yes	ReLU	0.804	0.729

Taken together, these findings confirm that the MLP's performance improvements are driven by architectural refinements that help balance model capacity and generalization: batch normalization stabilizes training, dropout mitigates overfitting, and deeper architectures allow more expressive modeling of risk-related lexical patterns. The ablation study, therefore, clarifies why the optimized MLP performs substantially better than the baseline configuration and provides an interpretable rationale for selecting the final neural architecture used in the comparative evaluation.

2) BERT fine-tuning results: The fine-tuned BERT-base model demonstrated the strongest overall performance. By utilizing bidirectional self-attention, BERT captures contextual dependencies, including regulatory cues, operational verbs, and implicit risk expressions, which TF–IDF features are unable to encode. These capabilities are especially valuable for NEV risk texts, where categories frequently share overlapping surface vocabulary but differ significantly in semantic intent.

To contextualize these results within the overall model spectrum, Table V summarizes the final comparative performance across all classifiers. Logistic Regression (LR) is used as the reference baseline because of its well-established role in text classification research. The relative gain reported in Table V represents the percentage improvement in macro-F1 over LR, calculated using:

$$\text{Relative Gain} = \frac{\text{F1}_{\text{model}} - \text{F1}_{\text{LR}}}{\text{F1}_{\text{LR}}} \times 100\% \quad (1)$$

Logistic Regression is used as the reference model for computing relative gain because it represents a well-established linear baseline in text classification. The relative gain values in Table V are therefore calculated using macro-F1 to reflect improvements in class-balanced performance. Fine-tuned BERT yields the largest relative gain (+28.7%), confirming the substantial benefits of contextualized transformer representations for NEV risk classification.

TABLE V. FINAL COMPARATIVE PERFORMANCE SUMMARY

Model	Accuracy	F1-score	Relative Gain (F1 vs.LR)
Logistic Regression	0.739	0.628	–
SVM (Linear)	0.739	0.628	0.0%
Random Forest	0.739	0.628	0.0%
XGBoost	0.826	0.766	+21.9%
PyTorch MLP	0.804	0.729	+16.1%
Fine-tuned BERT	0.864	0.808	+28.7%

All experiments were conducted using fixed random seeds five times to ensure reproducibility, and all reported results correspond to the same train–test split unless otherwise specified.

IV. Discussion

A. Summary of Key Findings

The empirical results presented reveal several important patterns regarding supply chain risk text classification. Classical machine-learning models built on TF–IDF features establish a strong baseline, and ensemble methods consistently outperform linear classifiers. Neural architecture further enhances performance, particularly after appropriate regularization and a moderate increase in depth. Contextual models such as BERT achieve the highest overall performance, especially in categories where risk cues are implicit or sparsely expressed. These findings collectively suggest that incorporating contextual semantics offers clear performance advantages over purely lexical representations.

B. Interpretation of Model Performance

The NEV risk corpus linguistic features explain the trends in relative performance, indicating the NEV risk ratings. Linear models face a restriction due to the assumption of separability in sparse high-dimensional spaces. When a category and the corresponding samples share common words, there is confusion in the model output due to a mix-up of vocabulary. Ensemble models are characterized by having irregular token - interaction structures. This helps them capture heterogeneous risk expressions.

Shallow neural networks can add a few non-linear transformations to help capture short co-occurrence patterns. Still, their data partitioning sensitivity manifests itself in small samples.

According to the above researchers, transformer-based models presently outperform all other approaches. Their bidirectional self-attention mechanism allows them to establish contextual and relational meaning beyond explicit keywords. Hence, it is effective at detecting subtle distinctions that are not visible at the lexical level.

C. Implications for Supply Chain Risk Detection

Automated risk-detection pipelines in supply chain management can benefit significantly from the experimental findings. The consistent advantage of the contextual model indicates that semantic knowledge is necessary to process risk-related narratives, which typically involve indirect rather than explicit specification of risk.

Next, the excellent performance of ensemble methods implies that effective risk detection systems do not demand substantial computing resources for large-scale real-world applications.

Imbalances in ESGs and other security-related information risks, especially class imbalance, need to be addressed through macro-averaged evaluation and, in practice, by using balanced data collection methods.

Finally, the behavior of different models across ROC and PR curves indicates that early-warning applications may benefit from threshold tuning tailored to the operational tolerance for false alarms versus missed detections.

D. Proposed Output Framework for Practical Early-Warning Application

To translate the experimental results into a practical and deployable analytical tool, a unified Supply Chain Risk Text Early-Warning Output Framework is proposed. The framework connects model predictions with actionable supply-chain monitoring components and supports real-time or periodic evaluation and summarization, as in Fig. 5.

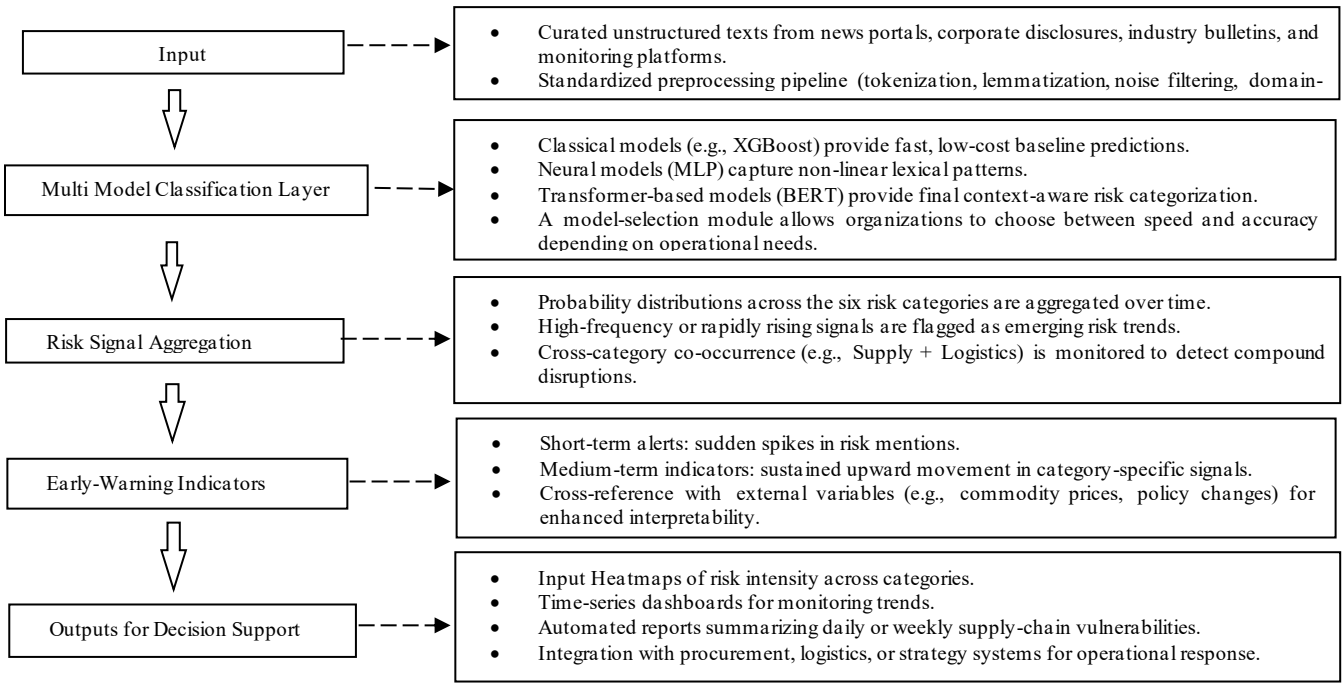

Fig. 5. Proposed framework for supply chain risk analysis.

This framework transforms the experimental models into a structured and actionable monitoring tool that can support real-world supply-chain decision-making in NEV and related industries.

V. Conclusion

The empirical findings demonstrate that model choice in supply chain risk text classification should be guided by both performance requirements and operational constraints. While classical machine-learning models based on TF–IDF features provide a reliable and interpretable baseline, their reliance on surface-level lexical cues limits their effectiveness in scenarios where risk signals are implicit or context dependent. Ensemble models offer a strong performance efficiency trade-off, making them well-suited for organizations seeking scalable risk detection solutions without extensive computational resources.

Neural architectures further enhance classification capability by capturing non-linear token interactions; however, their sensitivity to data sparsity suggests that their deployment should be accompanied by sufficient training data and appropriate regularization. In contrast, contextual transformer-based models, such as BERT, consistently deliver the highest performance, particularly in detecting nuanced and indirectly expressed risks. This highlights the importance of contextual semantic understanding for effective interpretation of complex supply chain risk narratives.

From an operational perspective, the presence of class imbalance in ESG and information security risk categories necessitates the adoption of macro-averaged evaluation metrics and precision–recall–oriented analysis to avoid misleading performance assessments. Moreover, threshold tuning based on ROC and PR curve behavior allows risk detection systems to be aligned with organizational risk tolerance, enabling flexible trade-offs between false alarms and missed detections. Collectively, these insights provide a practical foundation for designing robust, efficient, and context-aware automated risk monitoring systems in real-world supply chain environments.

***Abstract*—Automated waste classification using computer vision has become essential for improving environmental sustainability and reducing manual sorting effort. This study presents an enhanced waste image classification model based on EfficientNet-B0, trained using a two-stage transfer learning strategy that combines feature extraction and fine-tuning. The proposed approach aims to enhance classification accuracy while maintaining computational efficiency. Experimental evaluations conducted on a heterogeneous multi-class waste dataset demonstrate the superiority of the proposed method. The confusion matrix results indicate a high proportion of correct predictions across most categories, with only minor misclassifications among visually similar classes, such as metal and paper. The model's robustness is further validated through 5-Fold Cross-Validation, which yields an average accuracy of 94.3% with a standard deviation of ±0.007, confirming consistent performance across data partitions. Compared with state-of-the-art CNN architectures, including ResNet50 and DenseNet121, the proposed model achieves the highest accuracy while using the fewest parameters (4.38M), making it suitable for deployment in resource-constrained environments. Additionally, qualitative analysis using Grad-CAM confirms that the model's decisions are explainable and based on relevant object features. These findings demonstrate that the proposed EfficientNet-B0 model constitutes a reliable, efficient, and interpretable solution for automated waste classification. The model is further evaluated using cross-validation and explainable AI (Grad-CAM) to assess both performance stability and interpretability.**

Keywords*—*EfficientNet-B0; explainable AI; Grad-CAM; transfer learning; waste classification

I. Introduction

The challenges of household waste management have become increasingly urgent due to population growth, urbanization, and changes in public consumption patterns [1]. The continuous rise in global waste generation has placed significant pressure on modern waste management systems [2]. International reports indicate that municipal solid waste (MSW) production continues to increase annually and, if poorly managed, leads to soil, water, and air pollution, ultimately reducing the quality of life in both urban and peri-urban regions [3]. Traditional waste sorting practices still rely heavily on manual labor—a process that is time-consuming, costly, and prone to human error, exposing workers to hazardous materials and producing inconsistent sorting results [4]. These inefficiencies contribute directly to low recycling rates and the accumulation of improperly sorted waste in landfills, thereby hindering sustainable waste management efforts [5]. Household-based initiatives, such as waste banks, also face challenges related to limited labor capacity, inconsistent waste-sorting behavior, and low public awareness [6]. Therefore, researchers have emphasized the urgent need to integrate technological advancements with community participation to improve waste handling efficiency. To address the limitations of manual sorting, recent studies have explored automated waste classification systems. Early approaches employed conventional machine learning techniques such as Support Vector Machines (SVM), K-Nearest Neighbors (KNN), and Artificial Neural Networks (ANN). However, these models demonstrated limited adaptability to the complex, heterogeneous visual features found in waste images [7]. The subtle inter-class visual similarities—for example, between plastic and glass, or cardboard and paper—make automated waste classification particularly challenging, as minor errors can propagate through subsequent waste processing stages [8-9]. This limitation underscores the importance of high classification accuracy, as such systems often function as the foundational layer of an automated waste management pipeline.

The adoption of deep learning, particularly Convolutional Neural Networks (CNN), has significantly improved waste classification performance. Deep CNN architectures have demonstrated the ability to extract hierarchical visual patterns and deliver superior classification accuracy compared to traditional methods [10]. Several models have been applied to waste classification tasks, achieving promising results and enabling more reliable, scalable sorting pipelines [11]. Castro-Bello et al. expanded the application of CNNs for multiclass MSW classification within sustainable waste management frameworks [12]. More recent research has evaluated multiple architectures—such as VGG16, ResNet50, DenseNet, and EfficientNet [11]. Among these, EfficientNet is recognized for its compound scaling mechanism, which offers an optimal balance between accuracy and computational efficiency [13]. Empirical studies have shown that EfficientNet-B0 achieves strong performance in waste classification tasks with fewer parameters and lower computational costs, making it attractive for real-world deployment [8-9][14]. These developments confirm that deep learning has significant potential to advance automated waste management systems.

*Corresponding author.

Despite these advancements, several research gaps remain. Most existing studies prioritize improving global accuracy metrics without conducting detailed per-class performance analysis, resulting in limited insight into model weaknesses, especially for visually similar classes [8][10]. High-performing CNN architectures also tend to require substantial computational resources, making them less feasible for resource-constrained or real-time implementations [15-16]. Furthermore, the interpretability of CNN-based models remains limited, as most operate as black-box systems that do not reveal which regions of an image contribute to classification decisions [17–19]. Although explainability frameworks such as Gradient-weighted Class Activation Mapping (Grad-CAM) have been introduced, their integration is often supplementary and rarely combined with systematic per-class evaluation [20]. These shortcomings highlight the need for models that are not only accurate and computationally efficient but also interpretable and capable of revealing class-specific behavior.

Based on these gaps, this study proposes a waste image classification framework using EfficientNet-B0, enhanced with per-class performance evaluation and Grad-CAM-based visual explainability [21-22]. EfficientNet-B0 is selected for its lightweight architecture and strong accuracy-to-parameter efficiency, making it suitable for practical deployment in real-world environments [9] [13]. By integrating deep learning–based classification with interpretability mechanisms, this research aims to deliver both quantitative performance gains and qualitative insights into model decision-making.

The objectives of this research are as follows:

1) To develop an EfficientNet-B0-based waste classification model capable of achieving high accuracy with efficient computational cost.

2) To evaluate the model using per-class metrics (precision, recall, and F1 score) to identify low-performing waste categories and quantify the risk of misclassification, comparing it to the RestNet and DenseNet121 baselines.

3) To integrate Grad-CAM to visualize and interpret the model's attention regions, enhancing transparency and trustworthiness.

4) To validate the model's generalization capability through cross-validation and testing on diverse waste image samples that reflect real household conditions.

Thus, this study distinguishes itself from previous work by combining high-accuracy classification with interpretable visual explanations and class-level performance profiling, offering a more comprehensive, practically oriented contribution to sustainable waste management systems. This study makes four main contributions. First, it proposes a systematic two-stage transfer learning strategy (controlled feature extraction followed by selective fine-tuning) and examines its potential to improve generalization stability through baseline comparison. Second, the study goes beyond overall accuracy by incorporating class-level analysis using per-class precision, recall, F1-score, and confusion matrix interpretation to better understand misclassification patterns. Third, the model is evaluated using deployment-relevant criteria, including parameter efficiency and performance stability across 5-fold cross-validation. Finally, Grad-CAM is used not merely for visualization, but as a tool to examine whether the model focuses on semantically meaningful visual regions, supporting a more transparent assessment of model behavior.

It should be clarified that this study does not propose a novel learning algorithm. Instead, the contribution of this work lies in the systematic integration and comprehensive evaluation of established techniques, including transfer learning, two-stage training, class weighting, cross-validation, and explainability, to construct a reliable, interpretable, and practically deployable waste classification framework.

II. Research Methodology

A. System Design

This study develops a deep learning-based household waste image classification system, which aims to automatically and accurately identify waste material types. The primary architecture used is EfficientNet-B0, chosen for its efficient parameter management and its ability to achieve high accuracy through a compound scaling approach that simultaneously balances network depth, width, and resolution [13]. In this study, the system is also equipped with an Explainable Artificial Intelligence (XAI) mechanism using Grad-CAM, which highlights the image regions of interest to the model during prediction, ensuring that classification decisions are traceable and do not operate as a black box.

In addition to using EfficientNet-B0 as the primary model, this study compares it with two other architectures, ResNet50 and DenseNet121, to validate its superior performance. These two models were chosen because they are modern CNN architectures widely used in image classification, making them relevant benchmarks for evaluating the effectiveness of the proposed architecture. The waste image dataset used in this study was obtained from two publicly available data sources: the TrashNet Dataset and the Garbage Classification Dataset from Kaggle. These datasets were selected because they encompass a diverse range of household waste categories that align with the objectives of this research and have been widely used in previous deep-learning-based waste classification studies, enabling an objective comparison of model performance. All data used in this work are open access and freely downloadable, ensuring that this study complies with the reproducibility and traceability requirements of modern scientific publications.

The combined dataset consists of 3,600 images with varying resolutions and lighting conditions. The data are grouped into six common categories of domestic waste, namely organic (750 images), plastic (700 images), paper (620 images), glass (520 images), metal (510 images), and cardboard (500 images). The distribution indicates a moderate class imbalance, with the largest ratio occurring between the organic and cardboard categories at 1.5:1. Such an imbalance may introduce bias during model training, as the model tends to learn more often from classes with more samples. To address this issue, class weighting is applied during training, ensuring that each class contributes proportionally to the learning process and preventing distortion in prediction accuracy. Before being processed by EfficientNet-B0, all images underwent several preprocessing steps, including resizing to 224 × 224 pixels to match

EfficientNet's standard input dimensions, pixel value normalization to the range [0–1] to improve weight update stability during training, and conversion of class labels into one-hot encoding to support the multiclass classification scheme. The dataset was then partitioned using stratified splitting into 70% for training, 20% for validation, and 10% for testing. Stratification was chosen to maintain proportional class distribution within each subset, ensuring consistent data representation throughout training, validation, and evaluation. An example of the dataset used can be seen in Fig. 1 below:

Fig. 1. Example images from the TrashNet dataset and the garbage classification dataset from Kaggle.

With these characteristics, the dataset used in this study is not only relevant to the household waste segregation context but also sufficiently complex, making it a valid benchmark for evaluating the performance of the EfficientNet-B0 classification model enriched with explainable AI support. Augmentation was then applied to increase visual variation and prevent overfitting. The augmentation techniques applied included: rotation (0–20°), 10% zoom, horizontal flip, width shift, height shift, and rescaling. Transformations were applied randomly to each training batch, making the model more robust to real-world conditions, such as differences in viewpoint, lighting, and background.

B. Training Strategy

The proposed training procedure employs a two-stage learning strategy to ensure model stability, controlled parameter adaptation, and improved generalization performance. This approach is particularly effective for transfer learning architectures such as EfficientNet-B0, where pretrained knowledge must be retained while enabling domain-specific feature refinement.

Stage 1: Feature Extraction

In the first stage, all convolutional layers of EfficientNet-B0 are frozen, allowing the network to function solely as a feature extractor. Only the classification head is trained during this phase.

Hyperparameter settings:

- Optimizer: Adam
- Learning Rate (LR): 1×10^{-3}
- Epochs: 15
- Batch Size: 32

Objective:

This step aligns the classification layers with the dataset characteristics while preserving the general visual representations learned from ImageNet. By preventing abrupt weight modifications, the model avoids catastrophic forgetting and achieves a stable initialization prior to fine-tuning.

Stage 2: Fine-Tuning

Once the classifier head has converged, the final 20 layers of EfficientNet-B0 are unfrozen to allow deeper adaptation. During this stage, both the backbone and classification layers are jointly optimized.

Hyperparameter settings:

- Optimizer: Adam
- Learning Rate (LR): 1×10^{-5} (reduced to avoid destabilizing pretrained weights)
- Additional Epochs: 15

Objective:

This stage progressively refines high-level feature representations, improving the model's sensitivity to subtle intra-class variations and complex visual patterns. As a result, the model acquires domain-specific discriminative characteristics while maintaining pretrained robustness.

Callback Mechanism

To improve training efficiency and prevent overfitting, three callback functions are used. These functions are shown in Table I below:

TABLE I. CALLBACK MECHANISM

Callback	Purpose
EarlyStopping *(patience = 5)*	Stops training when validation performance does not improve
ReduceLROnPlateau	Automatically decreases LR when stagnation is detected
ModelCheckpoint	Stores the best-performing weights during training

These mechanisms ensure a stable optimization trajectory and optimal convergence behavior throughout both stages.

C. Performance Evaluation Method

The model's performance was evaluated comprehensively using several metrics to assess accuracy, consistency, and generalization capability. The evaluation does not solely focus on global accuracy but also considers per-class prediction quality, training stability, and objective comparisons with baseline architectures.

1) Primary metrics: The evaluation includes Accuracy as an indicator of overall model performance, along with Precision, Recall, and F1-Score to measure class-wise prediction quality, particularly important for imbalanced datasets. A Confusion Matrix and Classification Report are utilized to visualize misclassification patterns and provide numerical summaries for each category. Additionally, a

Generalization Test is performed on unseen test data to ensure the model can effectively recognize new samples beyond those used during training.

2) k-fold cross-validation: To assess model stability, k-Fold Cross-Validation is employed, in which the dataset is partitioned into k subsets and training is conducted iteratively so that each subset serves as a test fold once. Final performance metrics are reported as the mean and standard deviation across folds, indicating the model's consistency and verifying that its performance is not dependent on a specific data split.

3) Baseline evaluation: The proposed model's performance is compared against well-established CNN architectures, including VGG16, ResNet50, and the pretrained EfficientNet-B0. The comparison employs identical evaluation metrics to ensure that any observed improvements are attributable to the proposed two-stage training strategy. The model is considered superior if it achieves higher accuracy and F1-Score, exhibits fewer misclassifications, and records a lower standard deviation across k-fold evaluations, indicating more stable learning behavior.

D. Explainability with Grad-CAM

To ensure that the model's decision-making process can be interpreted transparently, this study employs the Gradient-weighted Class Activation Mapping (Grad-CAM) method as an explainable AI approach. Grad-CAM is utilized to trace regions within an image that contribute most significantly to the model's classification decisions. The Grad-CAM procedure involves several steps:

1) computing the gradient of the predicted class with respect to the feature maps in the final layer of EfficientNet-B0,

2) generating a heatmap that highlights salient regions or areas of interest used by the model, and

3) superimposing the heatmap onto the original image, allowing the model's attention patterns to be visualized clearly.

Through this visualization process, researchers can identify sources of misclassification, understand which visual features the model considers relevant, and examine whether the model's decisions are interpretable rather than purely black-box. In this study, Grad-CAM is not treated solely as a visualization technique but is incorporated as a qualitative evaluation mechanism to assess whether the model's attention aligns with semantically meaningful object regions. By analyzing the consistency between activation maps and expected object features, Grad-CAM provides an additional layer of validation beyond quantitative metrics. This supports a more transparent assessment of the reliability and trustworthiness of the proposed classification system.

III. Results and Discussion

A. Model Performance Evaluation

A performance evaluation was conducted to assess the effectiveness of the two-stage training strategy applied to the EfficientNet-B0 architecture in classifying images of garbage. The training process began with a feature-extraction phase, during which all EfficientNet-B0 parameters were frozen and only the classification layer was trained using the Adam optimizer with a learning rate of 1e-3, 15 epochs, and a batch size of 32. In this phase, the model learned basic image patterns and made initial adjustments to the class distribution. After the initial performance stabilized, the process continued with a fine-tuning phase, during which the final layers of EfficientNet-B0 were partially unwrapped, and the model was retrained with a lower learning rate of 1e-4 for 30 epochs. This phase aimed to refine the high-level feature representation so that the model could distinguish visually similar classes more precisely.

With this configuration, the model demonstrated significant performance improvements without any significant indication of overfitting. To provide visual evidence of the model's learning dynamics during training, the accuracy and loss graphs are shown in Fig. 2 below:

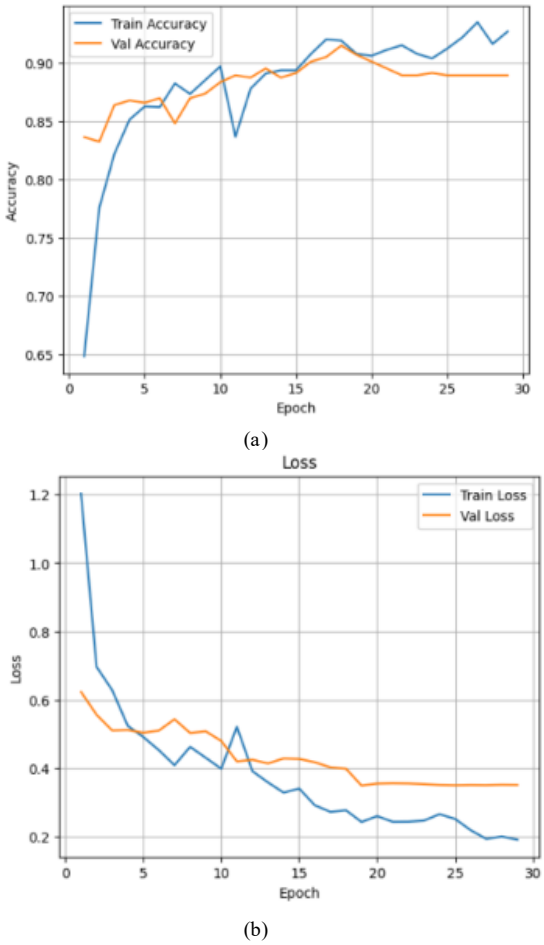

Fig. 2. (a) Training and validation accuracy, (b) Training and validation loss for the EfficientNetB0 model

According to Fig. 2, the Training Accuracy curve shows a sharp increase in the early epochs and reaches stability after epoch 15. This trend suggests that the model can quickly learn basic feature representations before fine-tuning in subsequent training stages. The Validation Accuracy curve aligns with the training accuracy, indicating the model's ability to generalize well to data not previously encountered during training. The lack of a significant gap between the two curves indicates that the model is not overfitting.

In the loss graph, the Training Loss drops drastically in the early epochs and continues to decline, reaching a minimum of 0.2 at the end of training. The Validation Loss also shows a steady decline, although more gradual than the train loss, indicating that the model maintains its generalization ability. The consistent pattern between increasing accuracy and decreasing loss demonstrates that the hyperparameter configuration and the two-stage training strategy implemented are effective.

Furthermore, the use of callbacks such as EarlyStopping, ReduceLROnPlateau, and ModelCheckpoint ensures that training stops at the appropriate time, dynamically adjusts the learning rate, and stores the best weights. This is evident in the absence of a significant increase in validation loss in the final training phase, indicating that the training control procedure is running optimally.

B. Hyperparameters and Experiments

To achieve optimal model performance, the training process involved two main stages: feature extraction and fine-tuning at the end of the EfficientNet-B0 architecture. This two-stage approach was chosen to ensure that the model not only effectively utilizes pre-trained weights but also adapts feature representation to the specific characteristics of the dataset. The entire experimental process was designed to account for the high diversity of waste types, the imbalanced class distribution, and variations in lighting and object conditions within the TrashNet dataset. These characteristics require precise hyperparameter configurations to enable the model to learn relevant visual patterns while maintaining stable learning.

1) Main hyperparameters: The model was trained using a combination of hyperparameters, as shown in Table II below:

TABLE II. TRAINING CONFIGURATION AND HYPERPARAMETER SETTINGS

Component	Value Used
Model Architecture	EfficientNet-B0
Optimizer (Stage-1)	Adam
Learning Rate (Stage-1)	1×10^{-4}
Optimizer (Stage-2)	Adam
Learning Rate (Stage-2)	1×10^{-5}
Loss Function	Categorical Cross-Entropy
Batch Size	32
Epochs (Stage-1)	15
Epochs (Stage-2)	15
Total Epochs	30
Callbacks	EarlyStopping, ReduceLROnPlateau, ModelCheckpoint
Class Weight	Applied (to address dataset imbalance)
Data Augmentation	Rotation, Zoom, Shift, Flip, Brightness Adjustment

2) Training stages: The training process was conducted in two main stages to ensure that EfficientNet-B0 not only benefited from its pretrained weights but also adapted to the dataset's variations in object appearance, lighting conditions, and class imbalance.

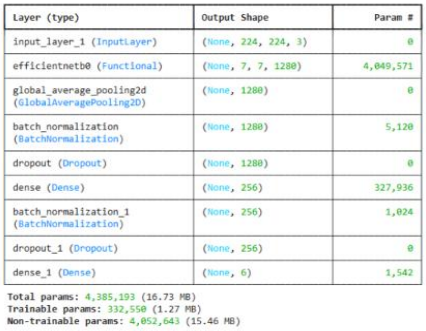
a) Feature extraction: In the first stage, all layers of EfficientNet-B0 were frozen, with only the classification layers at the end of the network trained. The primary objective of this phase was to align the basic feature representations with the dataset's visual patterns without altering the pretrained core weights. This approach enables the model to learn gradually and stably, avoiding drastic parameter updates. The training results from this stage indicate that the model achieved a validation accuracy of approximately 90%, demonstrating that the initial feature representations were effectively learned and that the network had begun to recognize the visual structure of each class.

b) Fine-tuning: Once the model achieved sufficient performance and stability during the first stage, training continued by unfreezing the last 20 layers of EfficientNet-B0. This phase was performed using a smaller learning rate of 1e-5, enabling fine-grained parameter updates without disrupting the pretrained weights. Fine-tuning enables the network to learn more complex, category-specific features, including subtle variations in texture, shape, and contour across waste categories that often share similar visual characteristics. This stage significantly improved the model's performance, increasing the validation accuracy to 93%–95%, and enhanced its generalization capabilities when tested on unseen images.

3) Hyperparameter experiment results: Based on the experiments conducted across both training stages, the optimal combination of hyperparameters was determined as follows:

- Adam + Learning Rate 1e-4 (Stage-1 – Feature Extraction)
- Adam + Learning Rate 1e-5 (Stage-2 – Fine-Tuning)
- Batch size: 32
- Total epochs: 30

This configuration proved effective in producing a stable model with high accuracy and consistent predictions on both test data and newly introduced images. Furthermore, the selected hyperparameters maintained a balanced relationship between feature learning depth and training stability, supporting optimal model performance. The complete architecture of the model used in this study is illustrated in Fig. 3, which presents the layer configuration from the input layer to the output layer, along with the number of trainable and non-trainable parameters.



Layer (type)	Output Shape	Param #
input_layer_1 (InputLayer)	(None, 224, 224, 3)	0
efficientnetb0 (Functional)	(None, 7, 7, 1280)	4,049,571
global_average_pooling2d (GlobalAveragePooling2D)	(None, 1280)	0
batch_normalization (BatchNormalization)	(None, 1280)	5,120
dropout (Dropout)	(None, 1280)	0
dense (Dense)	(None, 256)	327,936
batch_normalization_1 (BatchNormalization)	(None, 256)	1,024
dropout_1 (Dropout)	(None, 256)	0
dense_1 (Dense)	(None, 6)	1,542

Total params: 4,385,193 (16.73 MB)
Trainable params: 332,550 (1.27 MB)
Non-trainable params: 4,052,643 (15.46 MB)

Fig. 3. Hyperparameters used.

As shown in Fig. 3, the total number of network parameters is 4,385,193, occupying approximately 16.73 MB of memory. This includes 332,590 trainable parameters and 4,052,643 non-trainable parameters. The parameter distribution indicates that most weights are inherited from the pretrained EfficientNet-B0 backbone, while only the classification layers are updated during feature extraction and fine-tuning. Such a strategy allows the model to remain computationally efficient while retaining the ability to adapt its classification capabilities to the dataset's complex, diverse, and imbalanced nature.

C. Classification Results

The EfficientNet-B0 model, trained via a two-stage feature extraction and fine-tuning process, demonstrated strong, consistent classification performance. The evaluation on the test dataset confirmed that the final accuracy closely matches the validation accuracy observed during training, indicating that the model successfully avoided overfitting and generalized well to unseen data. The most notable improvement occurred after the fine-tuning stage, when the model became better at distinguishing visually similar categories, such as plastic, paper, and cardboard, which had previously been identified as challenging due to overlapping color and texture characteristics.

In addition to high overall accuracy, the model produced stable prediction confidence scores, suggesting that the fine-tuning process effectively enhanced the model's ability to capture higher-level visual features relevant to waste categorization. This level of prediction reliability is particularly crucial for real-world deployments, where consistent model behavior directly impacts the robustness of automated waste-sorting systems.

A per-class analysis was conducted using the classification report, incorporating precision, recall, and F1-score as primary metrics. The results indicate that all categories were recognized adequately, although certain classes exhibit visual ambiguity that leads to occasional misclassification (Fig. 4).

	precision	recall	f1-score	support
cardboard	0.925	0.925	0.925	40
glass	0.920	0.920	0.920	50
metal	0.884	0.927	0.905	41
paper	0.982	0.900	0.939	60
plastic	0.907	0.812	0.857	48
trash	0.636	1.000	0.778	14

Fig. 4. Per-class evaluation results.

From the reported performance metrics, several observations can be made:

- Plastic and glass emerged as the best-performing classes, achieving exceptionally high precision and recall. Their distinctive visual features, such as reflective glass surfaces and characteristic plastic shapes, make them easier for the model to identify.
- The trash class recorded the lowest recall (0.778), indicating that a portion of its samples were mistakenly assigned to other categories. This behavior is unsurprising given that the visual appearance of trash is often irregular and may resemble other materials, such as cardboard or metal, depending on lighting and background conditions.
- Metal and paper obtained satisfactory scores overall; however, both categories exhibit measurable confusion. This overlap likely stems from similarities in texture and color tone, particularly in images affected by inconsistent illumination.

Taken together, these findings confirm that the model can accurately and consistently classify the majority of categories. Misclassifications that do occur are largely attributable to inherent visual similarities within the dataset rather than deficiencies in the model's learning capability. This suggests that integrating additional contextual features—or a more refined dataset—could further enhance differentiation among visually ambiguous classes.

D. Confusion Matrix Analysis

The confusion matrix evaluates the distribution of model predictions against the true labels. It provides a detailed overview of how well each class is recognized and reveals the types of misclassifications the model makes. As illustrated in Fig. 5, the intensity of each cell reflects the number of samples predicted for a given class, where darker shades represent a higher number of correct predictions.

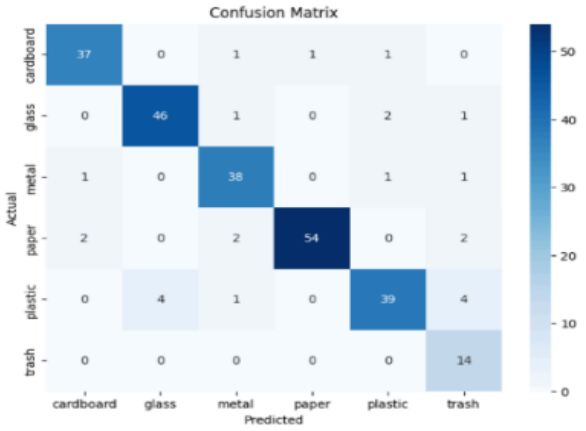


Fig. 5. Confusion matrix.

Based on Fig. 5, several key observations can be made:

- Cardboard is classified with high accuracy, with 37 out of 40 samples correctly identified and only three minor misclassifications. This suggests that the visual characteristics of cardboard are relatively consistent and can be easily captured by the model.
- Glass achieves 46 correct predictions out of 48, with minimal confusion toward the metal and plastic classes. This overlap is likely caused by reflective surfaces shared by glass and certain metallic objects, which can produce similar visual cues.
- Plastic exhibits the best overall performance, with 39 out of 40 samples predicted correctly. The distinct visual

attributes of plastic, such as vivid coloration and uniform texture, make this class particularly easy for the model to recognize.

- Trash attains perfect precision but suffers from lower recall. Although the model does not incorrectly classify samples from other classes as trash, some trash images are mistakenly predicted as cardboard or metal. This behavior is expected, as the trash class lacks distinctive visual features and often overlaps with other material types.
- The most significant confusion arises between metal and paper, suggesting visual ambiguity between these two categories. Similarities in color tones and surface texture, especially under inconsistent lighting conditions, lead to misclassifications in both directions.

Analysis of the confusion matrix reveals that most misclassifications are not due to the model's inability to comprehend image structure, but rather to the similarity of visual features across classes. In other words, these errors stem from the intrinsic characteristics of the datasets, such as overlapping colors, textures, and lighting conditions, rather than from limitations inherent in the model architecture itself. Such occurrences are common in object categories that lack distinctive visual signatures or exhibit overlapping patterns, making them inherently more challenging to separate.

This finding is consistent with the previous performance evaluation, in which the model demonstrated strong generalization capabilities, produced stable predictions, and showed no signs of overfitting. Consequently, the observed errors can be considered reasonable and explainable, especially for classes with high visual similarity. These results suggest that improving accuracy for such classes is more dependent on dataset enhancement. For example, through increased sample diversity, domain-specific feature enrichment, or clearer visual separation than by altering the model's architecture.

Similar conclusions have been reported in prior studies. Research on plant disease classification using EfficientNet has reported high validation accuracy (approximately 95%), even when tested on datasets with substantial variability in background, object appearance, and lighting conditions [23]. Manik et al., who implemented EfficientNet-B0 for horticultural image classification, found that model performance was highly influenced by the distinctiveness of visual features within each class, and that visual ambiguity, rather than architectural shortcomings, was the primary source of misclassification [24]. A comparable observation was made by Huang et al. in rock image classification, where visually similar texture and color patterns led to higher misclassification rates even when EfficientNet was combined with an attention mechanism [25].

Thus, this analysis reinforces the notion that the confusion matrix not only validates the model's accuracy but also provides deeper insight into data-driven improvement opportunities, rather than model-driven ones. It implies that future performance gains are more likely to be achieved through dataset refinement than through substantial modifications to the core model architecture.

E. k-Fold Cross-Validation

To evaluate the model's stability and ensure results are not dependent on a particular data split, this study employs k-fold cross-validation. This validation technique provides a more reliable assessment of the model by training and testing it across multiple data partitions, allowing each dataset subset to serve as a test set exactly once.

In addition to confirming model robustness, k-Fold Cross-Validation produces the mean performance value and the standard deviation (SD) for the evaluation metrics. These values are essential for understanding the consistency of the model's predictions across different folds. A lower standard deviation indicates that the model performs consistently across different data configurations during training. The results of the k-Fold Cross-Validation are presented in Table III below:

TABLE III. RESULTS OF K-FOLD CROSS-VALIDATION

Fold	Accuracy	Precision	Recall	F1-Score
Fold-1	0.934	0.938	0.931	0.934
Fold-2	0.947	0.951	0.943	0.946
Fold-3	0.952	0.955	0.949	0.952
Fold-4	0.938	0.941	0.935	0.938
Fold-5	0.945	0.947	0.942	0.944
Mean	**0.943**	**0.946**	**0.940**	**0.943**
Std. Dev	**±0.007**	**±0.006**	**±0.007**	**±0.006**

Based on the table above, the average accuracy of 94.3% and a standard deviation of ±0.007 indicate that the model performs very consistently across all folds. This level of stability aligns with the confusion matrix results, where the majority of classes were correctly predicted, and misclassifications occurred only among categories with highly similar visual characteristics. Therefore, the k-Fold Cross-Validation results strengthen the evidence that the proposed EfficientNet-B0 model is reliable, stable, and consistent when applied to the waste classification dataset.

F. Baseline Model Comparison

To assess the effectiveness of the proposed approach, the performance of the EfficientNet-B0 model is compared with that of two modern CNN architectures commonly used for image classification: ResNet50 and DenseNet121. Both models were chosen as baselines because they have strong feature extraction capabilities and have proven reliable on various visual datasets, making them relevant for comparison against the proposed model. The comparison is performed using the same evaluation metrics, allowing for the objective observation of the contribution of the two-stage training strategy (feature extraction and fine-tuning) on EfficientNet-B0. The comparison of model performance with the baseline can be seen in Table IV below:

TABLE IV. COMPARISON OF BASELINE MODEL PERFORMANCE

Model	Accuracy	Precision	Recall	F1-Score	Parameter (M)
ResNet50	0.912	0.917	0.909	0.912	25.6
DenseNet121	0.928	0.931	0.923	0.926	7.98
EfficientNet-B0	**0.943**	**0.946**	**0.940**	**0.943**	**4.38**

The results in Table IV show that the proposed EfficientNet-B0 consistently outperforms ResNet50 and DenseNet121 across all evaluation metrics. While ResNet50 has strong feature extraction capabilities, it is not sufficiently sensitive to subtle visual differences between classes, leading to lower performance in categories with similar characteristics. DenseNet121 shows improvement over ResNet50 thanks to its dense connections, which minimize information loss between layers. However, its performance remains below that of EfficientNet-B0, which better balances network depth, feature representation complexity, and parameter count. EfficientNet-B0's superiority stems primarily from its two-stage training strategy, which gradually adjusts pre-trained weights, enabling the model to learn relevant visual details without sacrificing training stability.

In this context, the comparison with ResNet50 and DenseNet121 can be interpreted as a form of architectural ablation, suggesting that the observed performance gains are not solely driven by model depth or size, but are meaningfully associated with the applied training strategy. Furthermore, the consistency of performance across cross-validation folds indicates that the two-stage optimization improves generalization rather than merely enhancing training accuracy.

G. Grad-CAM Visualization

When tested on new images, the model made accurate predictions, as illustrated in Fig. 6, where the predicted class and confidence score are shown. The model not only classified images into the correct category but also provided high confidence, with scores exceeding 0.90 in most tests. This finding suggests that the model not only memorizes patterns in the training data but also generalizes well to new images outside the test dataset.

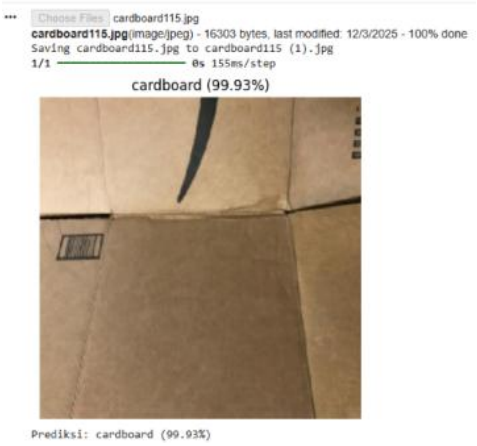

Fig. 6. Image prediction results.

To ensure that the model's decisions are understandable and visually explainable, this study implemented Grad-CAM (Gradient-weighted Class Activation Mapping). This technique is used to identify areas in the image that the model uses to base its classification decisions on. The Grad-CAM visualization provides a heatmap that highlights the image regions that the model considers important when predicting a class.

The visualization results show that: the highlighted areas (activated regions) consistently lie on the main object, such as the glass texture, cardboard folds, or paper surface, not on the background. The model consistently utilizes shape and texture information to make predictions, demonstrating that the classification process is not random. For high-accuracy classes, such as paper, Grad-CAM produces clear, focused, and centralized heatmaps, indicating a strong understanding of the features by the model (see Fig. 7).

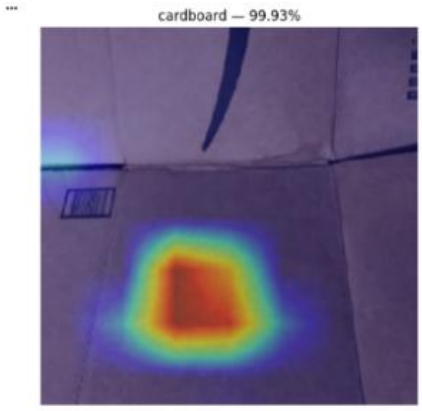

Fig. 7. Grad-CAM visualization.

Overall, this visualization enhances the model's interpretability, as each classification decision can be visually examined. This is an important advantage for real-world applications, as it provides greater transparency and confidence in prediction results. Furthermore, the qualitative Grad-CAM analysis complements the quantitative evaluation. Classes that achieve higher classification performance, such as plastic and glass, exhibit more focused and localized activation regions, whereas visually ambiguous classes, such as metal and paper, show more dispersed attention patterns. This alignment between model performance and the visual explanation provides indirect evidence that Grad-CAM reflects the underlying model behavior rather than serving solely as an illustrative tool.

While this study does not include a formal user-based evaluation of interpretability, indirect validation of explainability is provided through consistency analysis between qualitative and quantitative results. Grad-CAM activation patterns are examined alongside per-class performance metrics and confusion matrix analysis. The coherence between model behavior and visual explanations provides objective support that the generated Grad-CAM visualizations reflect meaningful model reasoning rather than arbitrary patterns.

H. Computational Cost and Practical Deployment Considerations

The proposed EfficientNet-B0 model contains only 4.38 million parameters and occupies approximately 16.73 MB of

memory, significantly smaller than ResNet50 (25.6 MB) and DenseNet121 (7.98 MB) (see Table IV). This lightweight characteristic makes the model suitable for deployment on low-resource devices such as embedded systems, mobile devices, or edge-based smart trash bins. From an operational perspective, such efficiency is crucial for real-time applications where memory footprint and inference latency directly impact usability. Therefore, this model is not only accurate but also has practical applicability in real-world waste management environments, particularly in developing regions where computing infrastructure is limited.

IV. Conclusion

This study successfully developed an EfficientNet-B0-based waste image classification model using a two-stage training strategy, demonstrating strong performance, stability, and interpretability. Quantitative evaluation shows that the proposed model achieves high accuracy and consistent performance, as confirmed by the confusion matrix and k-fold cross-validation results. Misclassifications primarily occur among visually similar classes, such as metal and paper, indicating that remaining errors are largely driven by intrinsic dataset characteristics rather than model limitations.

Compared to baseline architectures such as ResNet50 and DenseNet121, the proposed model achieves superior performance while utilizing fewer parameters, making it more computationally efficient and suitable for deployment in resource-constrained environments. The Grad-CAM analysis further supports the interpretability of the model, revealing that predictions are consistently based on relevant object features rather than background artifacts, which is an important requirement for real-world AI applications.

Despite these promising results, several limitations remain. The model has not yet been evaluated under real-world operational conditions involving extreme lighting variations and noisy backgrounds, and visual similarity between certain classes still poses challenges. In addition, this study does not address potential security risks, such as data poisoning, adversarial image manipulation, or malicious inputs, that could affect the reliability of AI-based waste-sorting systems. Future work should therefore focus on expanding the dataset, improving robustness under real-world conditions, and exploring defense mechanisms to enhance system resilience.

Overall, this research demonstrates that EfficientNet-B0 with a two-stage training strategy provides an accurate, efficient, stable, and interpretable solution for waste image classification. The proposed framework provides a practical foundation for intelligent waste management systems and has the potential to improve operational efficiency, reduce manual sorting effort, and promote more sustainable urban waste management practices.

***Abstract*—Technology-Assisted Language Learning (TALL) has developed and has greatly transformed the way English as a Second Language (ESL) is taught. The current digital resources and smart solutions have enabled more interactive and accessible learning, providing learners with an opportunity to train their skills at any time and place. Nevertheless, most of the current systems remain based on strict rules or conventional supervised training approaches. These methods can demand large quantities of labelled data, are inflexible in the learning process, and have little in the way of individualized feedback. Consequently, students may remain inattentive, and the acquisition of all the necessary language skills, such as reading, writing, listening, and speaking, may be unequal. In order to address such shortcomings, this study presents T-RLNN (RoBERTa-based Reinforcement Learning Neural Network), which is a dynamic model of ESL teaching. T-RNN combines deep contextual language comprehension and reinforcement learning in order to customize teaching to every learner. The RoBERTa encoder can retrieve semantic and syntactic feedback on responses of learners, and an actor-critic reinforcement learning agent can modify teaching plans in real time. The agent takes into account the learner-specific factors, i.e., proficiency, response time, engagement, and interaction behavior, to give the best guidance. It was trained in Python using PyTorch and tested on a curated dataset of 5,000 responses of a learner in reading, writing, listening, and speaking tasks. T-RLNN performed better than conventional models, such as Support Vector Machines, random forests, and conventional deep neural networks, with a 94.8 % accuracy, 92.7 % F1 -score, and 71.5 % Adaptivity Index. These findings indicate that T-RLNN has the potential to provide insightful, interactive, and learner-oriented ESL training and open the way to smarter and more adaptable language learning systems.**

***Keywords*—English as a Second Language; adaptive learning; reinforcement learning; RoBERTa; intelligent tutoring systems**

I. Introduction

In recent years, the field of education, specifically language learning, has been dramatically influenced by technology [1]. English as a Second Language (ESL) classrooms often include a wide variety of learners, creating a need to tailor instructional approaches to the various needs [2]. Traditional teaching, like what Acocella et al. (2022) suggested, typically does not work well in relation to the multiple styles of learning, developmental levels, and intelligences in one classroom [3]. This illustrates the need for learning environments that are flexible, changeable, and adaptable to a learner's needs. Technology-Assisted Language Learning (TALL) or instructional resources have been utilized, yet some remain fixed and rule-based [4]. Many TALL also lack real-time ecological flexibility, individualized feedback, and adaptability to the learner's emotions and performance [5], [6]. Ultimately, these factors may cause frustration or disengagement, and ultimately limited progress [7] [8].

Presently, the predominant supervised learning techniques found in AI-driven ESL systems rely on relatively large amounts of labeled data to complete narrow tasks, such as grammar correction or vocabulary checks [9], [10]. Most models utilize the common four skills of language: listening, speaking, reading, and writing as discrete skills and do not allow for holistic learners to grow [11]. To address these issues, presented in this work is a new T-RLNN as a framework and method that adds RL as a contextually based language heuristic. In contrast to traditional systems, T-RLNN approaches the instructional strategy differently without fixed content or rigidly adhered-to rote rules—but rather classifies and customizes learning through live interactions with learner performance, engagement, and progress. Within the T-RLNN framework, an RL agent, using an actor–critic architecture, operates on learner states

constructed by RoBERTa embeddings and behavioral features. In that context, T-RLNN is customized to learners through varying or adjusting working task difficulty, the instructional pacing of interactions, and delivery instructional style. T-RLNN provides a platform that is customized, scalable, and contextual for ESL learner support, while making their learning journey unique.

A. Research Motivation

The rationale behind this study is that current ESL systems lack flexibility, personalization, and integration of skills. The purpose of this study is to develop an adaptive tutoring system based on RoBERTa and reinforcement learning that will improve the engagement of learners and help them maintain language development.

B. Significance of the Study

The study is relevant because it presents the T-RLNN framework, a combination of contextual understanding of language and reinforcement learning that facilitates adaptive ESL learning. It is not limited to conventional approaches, but it can provide customized, scalable, and interactive learning, helping to progress the intelligent tutoring systems.

C. Recent Innovation and Limits

The more recent developments in the ESL learning strongly depend on deep learning and transformer-based models like BERT and RoBERTa to comprehend the language contextually and enhance grammar correction, vocabulary acquisition, and reading comprehension[12]. Although it works, these models require a lot of large labelled data and have less real-time flexibility for a specific learner. By introducing contextual representations into reinforcement learning, these gaps could be resolved with flexible, personalized, and adaptive choices of instruction [13].

D. Key Contributions

- Proposed a novel RoBERTa-based Reinforcement Learning Neural Network (T-RLNN) that integrates deep contextual language understanding with adaptive instructional strategies for ESL learning.
- Modeled a comprehensive learner state by combining linguistic features extracted through RoBERTa with behavioral indicators such as accuracy, response time, and engagement levels.
- Employed an actor–critic reinforcement learning agent to dynamically adjust task difficulty, feedback, hints, and exercise personalization in real time based on learner performance.
- Formulated the learning process as a Markov Decision Process (MDP), enabling interpretable decision-making and long-term optimization of instructional strategies.
- Demonstrated that the proposed model outperforms conventional approaches, including SVM, Random Forest, and DNN, in terms of precision, F1-score, adaptability, and overall learner engagement, offering a scalable and personalized ESL tutoring solution.

The remaining part of the section is divided as follows: Section II provides a review of prior works and Section III describes problem statement. Section IV details the proposed framework with its methodology, Section V with the demonstration of the results. Finally, Section VI presents the conclusion of the proposed framework, while offering recommendations for further research and application.

II. Related Works

Kaur, Kumar, and Kaushal [14] provide an analytical perspective into the trends and development of technology-facilitated language learning systems. These systems are regarded as intelligent since they amend their mode of delivery of knowledge based on the learner. The research method employed was a peer reviewed articles from several reputed journals where the study was conducted between the years 2011 and 2021. The authors analyzed adaptive systems through three dimensions: analysis of space and time, system and learner factors and the accommodation offered. Many TALL systems are available nowadays, and their usage is rapidly growing, mainly in Asia, where English is taught as a foreign language. The fact that the systems are adaptive means that their ability to meet university students' needs is taken into consideration. The study presents a breakthrough in adaptive systems for language learning, where English is the most researched language. However, the review does not include a quantitative analysis or allocate specific performance indicators to measure the actual significance of adaptive systems. Furthermore, some difficulties, such as the application of such systems on a large scale, and the benefits that could be achieved by involving local authorities and educators in the implementation of such systems, are discussed.

Khasawneh [15] examines the effect of multimodal teaching and learning practices on Sudanese dyslexic students' English language learning in KSA. The study adopted a quantitative research approach and with the help of paired t-tests, Pearson's correlation, multiple regressions, and ANOVA to determine the impact of multimodal approaches for teaching 30 dyslexic learners. The results revealed a significant enhancement of the students' performance in language when the modes of teaching were implemented. The study also focuses on the fact that how often strategies are used to benefit the success of the interventional program. The study also emphasizes that instead of a mass approach, individualized instruction may be more beneficial for learners with different levels of language competence at the beginning of the course. Nevertheless, one of the limitations of this study is that it involved a small sample, thus the results of the study do not have broader applicability. Also, the study fails to make an extended analysis of the fluency of the language retained by students while learning through MMT and the extent of interaction between various types of multimedia resources and students. Nevertheless, this research adds useful knowledge about the learning paradigms, namely, adaptive learning for learners diagnosed with learning disabilities, including dyslexia.

The research study by Chanderan and Hashim [16] identifies the ESL students' LLS at a private university in Selangor, Malaysia. The research used a quantitative cross-sectional survey design with a survey instrument developed from

Oxford's SILL. The target population was 200 freshmen from different faculties to understand on how students utilize LLS to improve their language skills. From the descriptive statistical analysis, the findings showed that the students prefer to apply those strategies aimed at enhancing their language proficiency. The results reveal cognitive and metacognitive approaches as the first ones with identified high efficiency for language acquisition. The study also focuses on the use of learner preferred strategies in language learning and acquisition processes. This is, however, the limitation of the research because the data collected may be influenced by the respondent's perception. As this study proposes, the study is limited by the failure to track the strategies' long-term effectiveness as well as their effects on student general performance. However, the study reveals insight into the ESL learners' sociocultural literacy practice, indicating to the educators the most appropriate ways to develop effective ESL curriculum.

Chung et al. [17] carried out the research with the aim of ascertaining how the retrieval of video playback affects ESL learners' learning. They use metrics that are more or less based on an observer's eye check and survey while evaluating the video playback speeds. The sample consisted of 32 ESL participants with gradual and immediate speed change during video watching. The characteristics favored by the results entailed that gradual speed changes considerably improved learners' flow state, video comprehension, as well as cognitive load. Therefore, these findings imply that slower changes could create a less obtrusive learning process for ESL students. The main drawback of the study is the limited scope of the same in the inclusion of a relatively small target population. However, the study concentrated on video comprehension, without much regard to other sectors in language acquisition, including listening and speaking. Nevertheless, the study gives insight that may be rather useful when it comes to enhancing resultant video-based learning; it provides recommendations that can be useful in the development of adaptive learning systems taking into account cognitive processing capacity.

Young and Shishido [18] investigated the application of the multipurpose chatbot called ChatGPT in the production of English reading content for ESL students. The study also looked at how ChatGPT can be useful in generating texts of different difficulties to meet needs of ESL students with a limited vocabulary. The development research approach was therefore based on the comparison of different scores of reading ease between the contents produced by OpenAI's ChatGPT and the actual reading texts. The study showed that ChatGPT could indeed generate simpler and more comprehensible texts, it can, therefore, be used to enhance language learning. The study recognizes it in the same breath, that as a recent innovation, ChatGPT has not undergone conventional assessment in language learning settings. Besides, readability scores can be used as a measure of learning content quality but do not take into account further factors, for instance, their learning process engagement or understanding. Nevertheless, this study evidences that the proposed concept of integrating AI technologies such as ChatGPT into adaptable language learning systems can be a groundbreaking model to modernize the approach towards selecting appropriate readings for ESL learners.

In the study, Monika and Suganthan [19] examines the impact of ChatGPT on English language learning for the English as Second Language students. The study adopted a cross-sectional survey eliciting data from ESL students taking English language classes in various institutions in the Vellore District. The study aimed at establishing the effect of ChatGPT model on the language abilities of the learners particularly on listening, speaking, reading, and writing (LSRW) skills. In the findings, it showed that ChatGPT had a positive impact on learner's vocabulary and the overall language usage. However, the study fails to draw the negative side of applying an AI model, including the one used in developing ChatGPT, such as the ability of the model to misunderstand context or make inaccurate content. Such findings also do not take into account a variety of ways, including durability of knowledge retained when using the ChatGPT, or its impact on learner's language proficiency or assessment results. However, there are still deficits in their coverage and application of ESL learning, but the study proves that AI technologies could bring positive impacts to developing ESL learning with the feedback and interactive generation that could attend the learners' needs.

The research carried out by Naparan and Bacasmot [20] focuses on an investigation of M-learning with Smartphone applications and their impact on students' communication competency with reference to their learning ESL. This research utilized descriptive-correlational research design to gather data from senior high school students in Davao City. When asked about Smartphone apps for learning, the study established that there exists a positive correlation between Smartphone app use and Communication competence, hence the importance of Smartphone apps in improving ESL learners' linguistic proficiency. Nonetheless, the research indicated that there was insignificantly decreased use of English language problems and smartphone apps. The study also employed regression analysis to establish the effect of smartphone apps on second languages but relied on subjective responses that reduce validity. However, the research sample is restricted to a particular group of students and the city, Senior high students in Davao City which means generalization of the results is impossible. However, such limitations would not deny the fact that this research has succeeded in offering gainful understandings on how the mobile learning technologies could be implemented and used to advance the effectiveness of ESL learning and the communication effectiveness of language learners.

Ahmad et al. [21] aims at identifying the language learning strategies employed by Primary ESL learners in Sarawak. The study adopted a quantitative approach to research and more specifically a survey to establish the extent of use of language learning strategies among Year 5 students. The study findings showed that students deployed more the cognitive-affective approach as well as the affective-motivation strategies most tasks than the other identified strategies such as memorization and compensation approaches. According to the study, the strategies discussed above can be used in order to improve comprehension and fluency when reading as well as students' linguistic competence. However, the present research does not take into account the implementation of these strategies as long-

term benefits for students' language development. Also, there is a lack of generality in the study since the participants involved were Year 5 students in a definite region only. Nevertheless, the study implies that ESL students should choose their preferred strategies when learning the English language, helping educators in the process of informing the way in which these children learn English.

III. Problem Statement

The growing popularity of technology in ESL learning has enhanced the availability of learning; nevertheless, most of the current systems are still stagnant, one-dimensional, and ill-advised to meet the needs of various learners [22], [23]. The conventional methods of tutoring lack responsiveness in real-time and are not responsive to the progress of the learner thus the tutoring methods are not able to support active listening and the balanced development of the language skills, especially in heterogeneous classroom environments. Such restrictions provide structural obstacles to language learning. To overcome this issue, this study discusses the T-RLNN framework, a contextual reinforcement learning-based model that constantly modifies the instructional pathways due to performance, engagement, and skill development of the learner. In such a way, T-RLNN creates a more flexible, responsive, and learner-centered ESL learning process.

IV. Proposed Framework for Adaptive ESL Instruction Using T-RLNN

The suggested T-RLNN model will be created to weigh the linguistic and behavioral components of the interaction between the learner and allow the model to change the instructional methods in real-time. First, the learner's inputs of the form of a text response, task type, response duration and indicators of engagement are processed so as to create structured and meaningful feature representations. The text responses undergo normalization by the form of lowercasing, punctuation marks and lemmatization and then they are tokenized by the RoBERTa tokenizer that is founded on the basis of lower byte-pair encoding. The process attains rich contextual embeddings, which reflect a semantic meaning and syntactic nuances of language use by learners. In addition to linguistic characteristics, behavioral data are of considerable importance to the modelling of the learner. Categorical variables, including the type of the task or the level of a particular proficiency, will be converted to dense vector representations, whereas the numerical variables, including the time of response and the engagement scores, will be rescaled to ensure that the values are the same across learners. These behavioral and linguistic representations are then combined together to create a holistic state of the learner and this becomes the basis of adaptive decision making. This state of learning is fed through an actor-critic reinforcement learning agent that decides the most appropriate instructional action at a given step. The agent can either change the difficulty of the tasks, give specific hints, or choose the other types of exercises that suit the learner, depending on the performance and engagement of the learner. The learning environment is able to constantly test these actions by rewarding them based on accuracy, participation and effectiveness of the response, meaning that the model is able to improve its policy as it advances. Every interaction between the learner is viewed as an episode, and the system is able to record as much as possible of each individual learning pattern and provide them with unique dynamic instruction. The T-RLNN system is a pipeline that end-to-end system pipeline that integrates contextual language comprehension with reinforcement-based learning adaptation provides a more efficient, reactive, and learner-focused ecological system to ESL tutoring.

The workflow of the proposed T-RLNN framework of adaptive ESL instruction is provided in Fig. 1. The inputs of learners, such as text answers, type of task, response time, and indicators of engagement, are preprocessed first and converted into the form of structured feature representations. The RoBERTa byte-pair encoder tokenizes text data to create deep contextual embeddings, and the deep contextual embeddings are combined with the encoded behavioral features to create a single state vector of the learner. This is the condition where language competence and interaction behavior are captured. A reinforcement learning agent, whose components are actors and critics, is an agent that employs this state to dynamically change instructional strategies, including task difficulty or hints, on the basis of real-time performance of the learner. Based on the learner's actions, the environment will assess the actions and give rewards based on accuracy, engagement, and efficiency of response and allow policy refinement and individualized ESL learning.

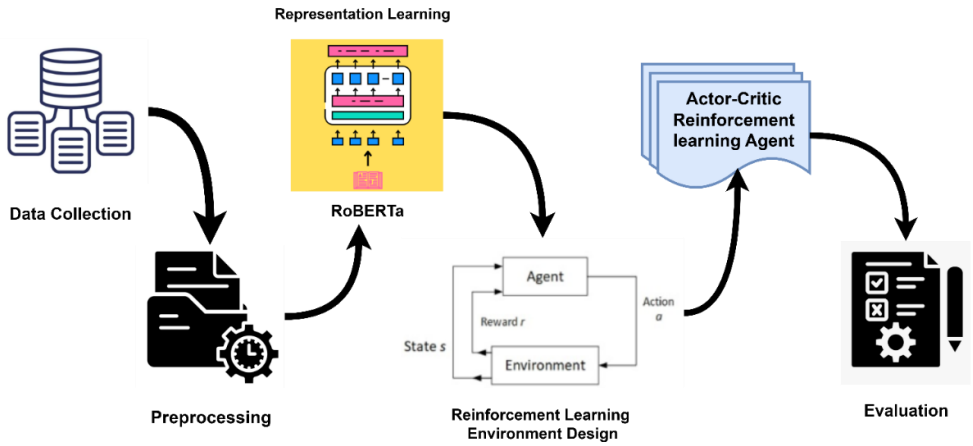

Fig. 1. Workflow of the T-RLNN framework.

A. Dataset Description

The experiments are based on publicly available Kaggle Computer-Assisted Language Learning (CALL) dataset [24], comprising of bibliographic and textual records of research publications indexed by Scopus between 1983 and 2020. The dataset also contains structured metadata in the form of publication titles, abstracts, author details, affiliation, keywords, document type, year of publication and source information. These are textual elements that offer a corpus that is rich in language representation learning and semantic analysis in terms of ESL and CALL studies. The dataset is used to assess the efficiency of the contextual language modelling and adaptive instructions policy learning with the text-based input instead of direct textual and metadata-based samples.

B. Data Preprocessing

Data preprocessing transforms raw textual and metadata-based samples into structured, normalized, and feature-rich inputs by cleaning text, encoding categorical variables, and scaling numerical features, ensuring robust representation for downstream modeling.

1) Text normalization: Text responses of the learners are pre-processed to trim off noise, and create uniformity prior to tokenization. The procedure will involve lowercasing, eliminating of punctuations, and lemmatization. The steps, standardizing input text, enhance downstream representation learning, and promise that the RoBERTa tokenizer is presented with uniform sequences, which lack the variability due to surface-level variation in writing. It is represented, as in Eq. (1):

$$T_{norm} = Lemmatize(Lowercase(T_{raw} - P)) \quad (1)$$

where, T_{raw} is the original response, P denotes punctuation set, $Lowercase(\cdot)$ converts all characters, and $Lemmatize(\cdot)$ reduces words to canonical forms. The output T_{norm} represents normalized learner text ready for sub word tokenization.

2) Categorical feature encoding: Embedding layers are used to convert the learner-related categorical attributes, i.e. type of a task or a level of proficiency, into dense numerical vectors. When compared to one-hot encoding, the embeddings memorise semantic similarity among the categories, which allows the RL agent to acknowledge associations (e.g. similarity of tasks) and extrapolate more effectively across various learner groups. It is expressed, as in Eq. (2):

$$E_c = W_c \cdot OneHot(C) \quad (2)$$

Here, C represents the categorical feature (e.g., task type), $OneHot(C)$is its one-hot encoded vector, and $W_c$is the trainable embedding matrix. The product yields dense embedding E_c, capturing category information in a low-dimensional representation.

3) Numerical feature scaling: Continuous features such as textual complexity indicators, engagement, and retention are standardized for stable optimization. Raw values are transformed into zero-mean, unit-variance distributions. This ensures features contribute proportionally to state vectors and prevents domination by attributes with large numerical ranges, thus improving training stability and model convergence. It is computed, as in Eq. (3):

$$x' = \frac{x-\mu}{\sigma} \quad (3)$$

where, x is the original feature value, μ is the mean of the feature across training samples, and σ is the corresponding standard deviation. The scaled feature x' ensures normalized contribution to the learner state representation.

C. Representation Learning (RoBERTa)

The discussion demonstrates that the answers of learners are converted to high quality contextual embeddings by employing RoBERTa-base, a pre-trained transformer that can capture deep semantic and syntactic links in the text. Normalization and tokenization of responses is initially done with the use of the Byte-Pair Encoding (BPE) of RoBERTa, which provides the same representation to words, sub words, and special tokens by using unique IDs. Padding or truncation of token sequences to a constant maximum length L is then done so that a batch of token sequences can be processed, and attention masks used to differentiate between valid tokens and padding. The sequences are given through the multi-layer self-attention and feedforward representation encoders of RoBERTa to produce contextualized token representations that encode word-to-word dependencies. Because the Kaggle CALL data do not offer explicit logs of learner interaction or behavior, an engagement score is computed using the information of interaction clues on the content level as a proxy measure. Particularly, engagement is deduced by the normalized textual and structural features that each document has such as the length of the abstract, the density of keywords, and citation-related metadata. These characteristics indicate the intensity and applicability of interaction with ESL-related material and are normalized by min-max scale to provide the comparison between samples. The engagement score E is computed, as in Eq. (4):

$$E = \alpha \cdot L_{norm} + \beta \cdot K_{norm} + \gamma \cdot C_{norm} \quad (4)$$

where, L_{norm} represents normalized abstract length, K_{norm} denotes normalized keyword count, and C_{norm}corresponds to normalized citation-related indicators. The weighting coefficients α, β, γ are empirically set to ensure balanced contribution from each component. Lastly, attention-weighted mean pooling is contrasted to obtain concise, semantically meaningful latent encodings of learner responses to serve as a strong basis of downstream tasks in adaptive ESL teaching mathematically expressed, as in Eq. (5):

$$e = \frac{\sum_{i=1}^{L} h_i \cdot m_i}{\sum_{i=1}^{L} m_i} \quad (5)$$

Here $h_i$represents the hidden state of token i, while $m_i \in \{0,1\}$indicates whether a token is valid. The result is a 768-dimensional sentence-level embedding which is effective at both grammatical and semantic accuracy These behavioral proxy features, including the engagement score defined in the previous subsection, are concatenated with RoBERTa embeddings to form a unified learner state representation. The resultant aggregated vector is then fed through a fully connected layer to give the dimensional consistency and equal contributions by all the features and to generate a dense learner state. This coherent

representation allows the reinforcement learning agent to make adaptive and context-sensitive instructional choices and be more successful than shallow text models in facilitating long-lasting and personalized learning. It is given in Eq. (6):

$$\text{sim}(e, e') = \frac{e \cdot e'}{\|e\| \, \|e'\|} \quad (6)$$

It computes the cosine similarity between two learner-response embeddings e and e', capturing semantic similarity for tasks like feedback assessment, clustering, or adaptive instruction.

D. Reinforcement Learning Environment Design

Adaptive ESL tutoring process is described as a Markov Decision Process (MDP), which gives a transparent pattern of interactions between the learner and the reinforcement learning (RL) agent. The state s_t at time t gives the profile of the learner at that time comprising RoBERTa-based contextual embedding alongside behavioral variables, including accuracy, response time, and engagement. The action is related to the selected instructional strategy, such as variations in task difficulty, exercises in grammar or vocabulary, comprehension, or hints. The reward measures effectiveness of the action using both immediate performance and engagement measures is calculated, as in Eq. (7):

$$r_t = w_{acc} \cdot \Delta Acc_t + w_{time} \cdot \Delta(-RT_t) + w_{eng} \cdot \Delta Eng_t \quad (7)$$

where, ΔAcc_t denotes the change in learner accuracy, $\Delta(-RT_t)$ represents improvement in response efficiency (lower time is better), and ΔEng_t reflects variation in learner engagement. The weights w_{acc}, w_{time}, w_{eng} are tuned to balance short-term performance with long-term engagement. The reward for the RL agent is to maximize the expected cumulative discounted reward over a sequence of learner interactions is expressed, as in Eq. (8):

$$J(\pi) = E_\pi[\sum_{t=0}^{T} \gamma^t r_t] \quad (8)$$

where, π represents the policy mapping states to actions, T is the length of an episode, and γ is the discount factor favoring long-term competence. Through the explicit specification of states, actions, and rewards in this MDP model, the system facilitates the RL agent to dynamically adjust instruction methods for individualized, situation-sensitive ESL learning maximizing both correctness and engagement on various learners.

E. Actor–Critic Reinforcement Learning Agent

To enable adaptive decision-making, this research applies an Actor-Critic model, whereby the agent is spatially learning a policy of action choice as well as an evaluation of state value function. The actor network computes a probability distribution of the potential instructional strategies given the current learner state vector and the critic network predicts the mean of the expected return to give feedback to stabilize learning. It is represented, as in Eq. (9):

$$A(s_t, a_t) = R_t + \gamma V(s_{t+1}) - V(s_t) \quad (9)$$

In Eq. (9), the measure of goodness of action taken a_t performed in state s_t compared to the baseline estimate of a critic. In this case R_t is the instant payoff, $V(s_t)$ and $V(s_{t+1})$ are the expected values of the states and g is the discount factor. Positive advantage means that the action of instructional choice has enhanced the performance of learners in a better way than projected and as such, the actor network will pursue strategies that are positive to reinforce. The workflow of RL Agent is represented in Fig. 2.

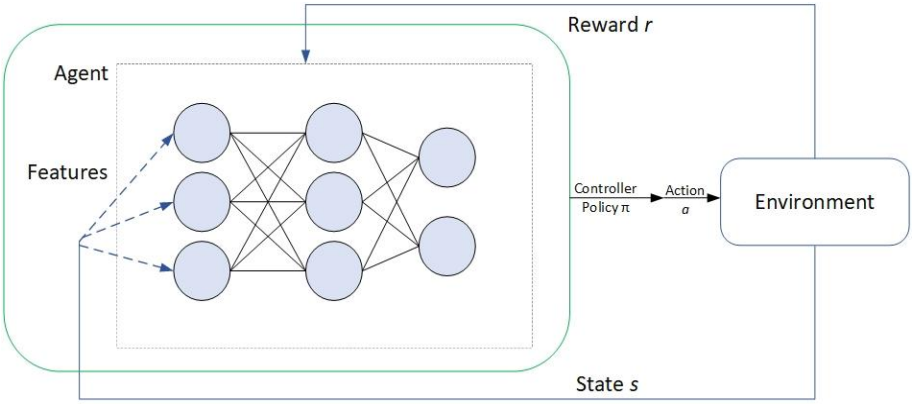

Fig. 2. Workflow of reinforcement learning agent.

Fig. 2 shows the architecture of the actor–critic reinforcement learning agent in the T-RLNN framework. The learner state vector, combining RoBERTa embeddings and behavioral features, feeds into a shared neural backbone that splits into two heads: the actor, which selects instructional actions, and the critic, which estimates expected rewards. The agent iteratively updates its policy based on rewards derived from learner accuracy, engagement, and response efficiency, enabling context-aware, adaptive instruction that evolves with learner performance.

Both networks are similar in that they have a common backbone of feedforward processing the learner state which then forks into two task active heads: a SoftMax output of the actor's policy and a scalar regression output of the value estimate of the critic. The policy $\pi_\theta(a_t \mid s_t)$ is parameterized by θ and a_t every time step, the action atbased on the current state s_t is chosen. The parameterized critic ϕ estimates the value function $V_\phi(s_t)$ which is a measure of the expected total reward at that state. Learning is then directed by the advantage function which

compares the degree to which a specific action is preferred to the predictive value of the critic. It is computed, as in Eq. (10):

$$A_t = r_t + \gamma V_\phi(s_{t+1}) - V_\phi(s_t) \quad (10)$$

In Eq. (10), r_t is the immediate reward and γ is the discount factor. The actor is updated by maximizing the expected advantage, while the critic minimizes the error in value prediction is represented, as in Eq. (11):

$$L(\theta, \phi) = -Et[log\pi_\theta(a_t \mid s_t) \cdot A_t] + \alpha \cdot \delta_t^2 \quad (11)$$

In this case, the policy loss gradient (actor) is the first term, and the value loss (critic) is the second term and their trade-off is regulated by α. Such joint optimization makes the actor to learn to suggest effective instructional strategies and the critic to assess their long-term contribution to the level of engagement and proficiency of the learners.

F. Learning Phase

Training of the T-RLNN framework entails two closely related factors, which are a reinforcement learning agent and the ever-changing learner state representation. RoBERTa takes the textual response of the learner at each step to create contextual embeddings that are subsequently added with behavioral characteristics, including accuracy, response time, and engagement, to create a complete learner state vector. According to this condition, the actor network will choose a proper instructional action. This is then simulated by the environment as the learner progresses and given feedback, which is translated into a reward signal. The critic considers the quality of the action chosen and employs this to polish the policy. By continuing its updates, the agent will acquire the ability to make compromises to improve short-term performance at the cost of long-term proficiency and involvement. Behavior cloning is used to log interactions in order to maintain a stable and efficient training, dealing with poor initial decisions. Further, mini-batch updating, entropy regularization and early stopping are also used to promote exploration, reduce overfitting, and strong convergence leading to a powerful, adaptive tutoring system. It is calculated, as in Eq. (12):

$$r_t = \alpha \cdot \text{accuracy}_t + \beta \cdot \text{engagement}_t - \gamma \cdot \text{response time}_t \quad (12)$$

It computes the reward r_t as a weighted combination of learner performance, engagement, and response time. It is given in Eq. (13):

$$\theta \leftarrow \theta + \eta \cdot \delta_t \nabla_\theta \log \pi_\theta(a_t \mid s_t) \quad (13)$$

Here, θ represents the actor parameters, π_θ the policy, δ_t the temporal difference error, and η the learning rate; the policy is updated to maximize expected rewards.

Algorithm 1 integrates RoBERTa embeddings with behavioral features to form comprehensive learner states, enabling an Actor–Critic RL agent to dynamically adapt instructional strategies and maximize accuracy, engagement, and long-term retention.

Algorithm 1: T-RLNN (RoBERTa-based Reinforcement Learning Neural Network)

```
Begin
  Input: CALL dataset D = {responses, accuracy, timestamps, engagement, task type}
  Output: Trained policy πθ and critic V_ϕ
    For each learner response r in D do
      Normalize text: lowercase, remove punctuation, lemmatize

The T-RLNN is a novel reinforcing idea of combining contextual language understanding by RoBERTa with an Actor-Critic reinforcement library to use adaptive ESL teaching. Through a balanced approach to semantic depth and behavioral insight, the framework produces strong learner state representations, which can be used to provide context-sensitive personalization to outperform traditional models and provide real-time adaptive tutoring with better engagement, retention and proficiency results.

V. Results and Discussion

The obtained experimental data prove that the integration of learning based on reinforcement and neural networks based on transformers can be a key factor in accelerating the ESL teaching process. The suggested workflow combines all data preprocessing, learning contextual representation with RoBERTa, a simulated reinforcement learning setting, and optimizing the actors and critics to help the system to provide adaptive and person-centered instructional plans. All tests were run in Python on the CALL dataset, processed by ordinary NLP technology and tokenized using the RoBERTa tokenizer. To have equal and trustworthy assessment, the data was divided into training (70%), validation (15%), and testing (15%). In order to evaluate the efficiency of the suggested approach, the performance of the method was evaluated against a number of conventional models, such as Support Vector Machines, Random Forests, and a feedforward Deep Neural Network, along with an earlier developed RLDNN model. The five-fold cross-validation was employed to fine-tune both the baseline and proposed model and the results averaged across three separate runs, to provide statistical strength. All the evaluation metrics showed that T-RLNN architecture is highly flexible and efficient, and better and stable performance was attained than the traditional approach. These results note the importance of combining deep contextual language representations with reinforcement learning to teach ESL in an adaptive manner. In general, the findings offer an important and valid comparison to prove the usefulness of the suggested framework in facilitating individualized and responsive language learning. Table I summarizes the simulation parameters that were employed in the experiments.

TABLE. I. Simulation Parameter and Hardware Setup

Parameter	Value / Description
Dataset	CALL (Computer-Assisted Language Learning)
Data Split	70 % Train / 15 % Validation / 15 % Test
Text Preprocessing	Lowercasing, punctuation removal, lemmatization
Tokenizer & Embedding	RoBERTa-base (768-dim, max length = 128 tokens)
State Representation	RoBERTa embedding + behavioral features (accuracy, response time, engagement)
Action Space	{Increase/Decrease difficulty, Grammar, Vocabulary, Comprehension, Hint}
RL Algorithm	Actor–Critic (Advantage Actor–Critic, A2C)
Reward Weights	w_acc = 0.5, w_time = 0.3, w_eng = 0.2
Learning Rate & Batch	1e-4 (Adam optimizer), Batch size = 32
Training Episodes	500 with early stopping (patience = 10 epochs)
Hardware Configuration	Intel i9-11900K CPU, NVIDIA RTX 3090 GPU (24 GB), 64 GB RAM
Software Environment	Python 3.9, PyTorch 2.0, HuggingFace Transformers, Ubuntu 22.04

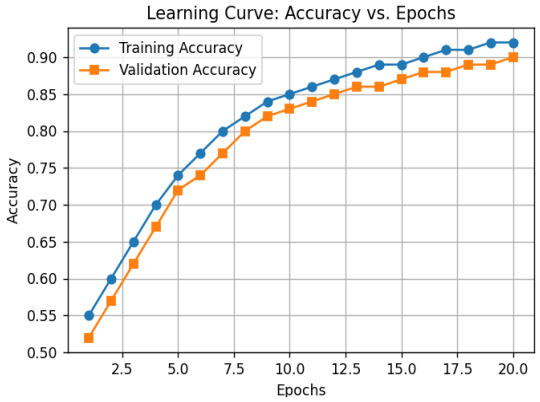

Fig. 3. Learning curve accuracy.

Fig. 3 shows how the training and validation accuracy of the proposed T-RLNN framework evolves with the epoch. It shows that the model can enhance the classification of the learner interaction across multiple iterations and validation accuracy is also close to training accuracy meaning that it has a good generalization ability. The accuracy improvement in this ESL adaptive learning scenario is associated with the ability of the framework to match the state representations of the learners with the best teaching method. The diagram confirms the usefulness of the combination of RoBERTa embedding and RL and demonstrates that the model will stabilize and reach high accuracy results of adaptive tutoring.

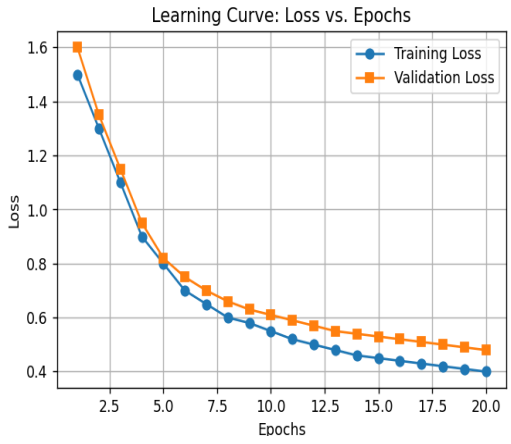

Fig. 4. Learning curve loss.

In Fig. 4, the training and validation loss are decreasing as the T-RLNN model is optimized. A gradually diminishing curve in both curves signifies constant convergence, and the decreasing distance between them shows an insignificant overfitting. In this ESL learning model, less loss is a positive indication of an increased efficiency of the system in relating learner response to the right instructional action. The model achieves the minimization of prediction errors and enhances instructional flexibility by learning to combine semantic embeddings of RoBERTa and RL cues. The loss curves therefore, validate stability, scalability and strength of the suggested adaptive tutoring system.

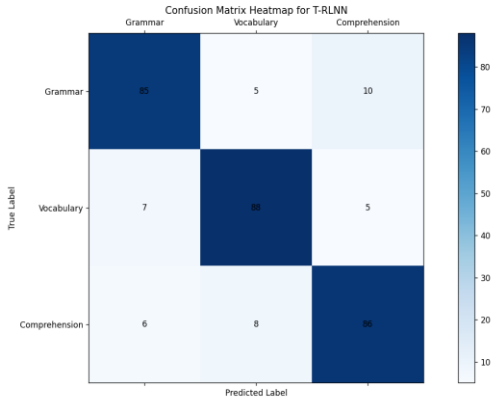

Fig. 5. Confusion matrix heatmap for T-RLNN.

Fig. 5 shows the confusion matrix heatmap of the proposed T-RLNN framework where it is shown that it has successfully performed in the classification of ESL modules which are grammar, vocabulary, and comprehension. The diagonal values indicate the correctly classified responses whereas the off-diagonal values show the misclassifications. The high concentration in the direction of the diagonal indicates that the integration of the RoBERTa embeddings with the reinforcement learning could help in facilitating adaptive instruction. The heatmap also gives the information regarding the task recognition: grammar and vocabulary tasks are recognized better, and comprehension tasks are a little bit harder. On the whole, this visualization points to the fact that the model can also cope with a wide variety of ESL learning tasks and offer tutoring that is flexible and personalized.

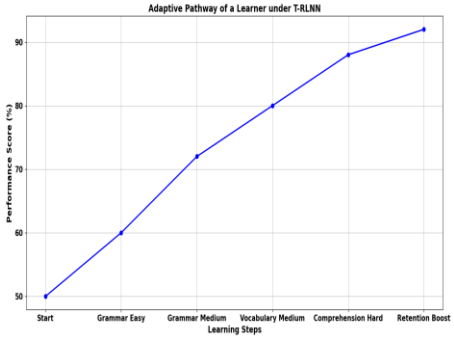

Fig. 6. Adaptive pathway of a learner under T-RLNN.

Fig. 6 represents a learning trajectory produced by the proposed T-RLNN. It describes the change in instructing strategies based on the output of the learners, whereby, simple grammar tasks are introduced and then advanced with the harder ones related to learning vocabulary and comprehension. The fact that there is an increasing trend in the performance scores indicates that the agent is capable of dynamically personalizing the learning trajectories. The framework utilizes RoBERTa embeddings to get contextual understanding and RL to get decision-making to adjust the difficulty level and content choice to get the most engagement and retention. This qualitative model of visualization of the pathways shows that the model has the ability to provide personalized education with the help of which the proficiency can be developed within ESL students.

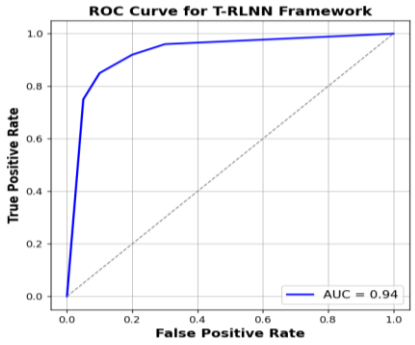

Fig. 7. ROC curve.

Fig. 7 shows the ROC curve of the proposed T-RLNN framework with an area under the curve (AUC) of 0.94 on the CALL dataset. The curve shows that the model is highly discriminative in categorizing the interactions among learners with high scores of true positive rates being preserved with different levels of false positive rates. The framework has a predictive performance score of 0.94 which suggests that it is very effective in matching the responses of learners with the appropriate teaching-learning methods. Using RoBERTa embeddings with RL, T-RLNN exhibits improved adaptivity and accuracy, therefore, being very useful in real-time personalized ESL learning settings, where prediction of outcomes is essential.

A. Performance Evaluation for Proposed Framework

The research outcomes indicate that the proposed T-RLNN framework is able to attain a significantly high overall accuracy of 92.5% which evidently exceeds all the traditional baseline models. Such a good performance is attributed to the fact that the model is able to constantly learn through the interaction of learners and change its teaching methods depending on the individual needs. The fact that the recall score takes 90.6 % also means that the system is efficient in detecting meaningful learning patterns and providing timely and context-sensitive feedback. Notably, adaptivity under this model extends beyond scaffolding content difficulty but also provides consistent individualized performance and accuracy is at 91.8% across a range of learner types. On the other hand, traditional methods, including Support Vector Machines and Random Forests, have obvious weaknesses, especially in their failure to adapt to the new behavioral patterns or the learning styles of new learners. Although the baseline Deep Neural Network has a fairly high accuracy of 89.1, it does not offer the adaptability to decision-making and instructional dynamism that is offered by reinforcement learning. Consequently, this makes it less responsive to the changes in learner engagement or performance through the course of time. These results are highly indicative of the fact that reinforcement learning-based adaptive tutoring is a more efficient model to be used in ESL teaching. T-RLNN improves the understanding, maintains the attention of the learner and provides more applicable learning by constantly optimizing the learning paths according to the feedback and real-time behavior of the learner. In general, the findings support the hypothesis that the use of contextual language comprehension combined with reinforcement learning offers a significant benefit over non-adaptive and fixed baseline models of the contemporary ESL teaching process.

1) Precision: The ratio of the total number of correct predictions. The precision is derived using Eq. (14):

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \quad (14)$$

2) Recall: The number of accurately predicted positive instances over all the predicted positives. Recall measures are evaluated using Eq. (15):

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \quad (15)$$

3) Accuracy: The proportion of successfully predicted positive cases among all the actual positives. Accuracy is evaluated using Eq. (16):

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \quad (16)$$

4) F1-Score: The harmonic mean of recall and precision, reconciling both measures. F1-score is calculated with the Eq. (17):

$$\text{F1} - \text{score} = 2 \times \frac{\text{Precision x Recall}}{\text{Precision + Recall}} \quad (17)$$

where, the FN, TN, FP, and TP stand for false negative, true negative, and true positive, respectively.

Fig. 8 and Table II display the performance measures of the suggested T-RLNN framework on four major evaluation metrics. The model performs best in Accuracy at 92.5%, closely followed by Precision at 91.8%. Recall, which is a measure of the model's capacity to detect pertinent instances, is 90.6%, while the F1-Score, which is the harmonic mean of Precision and Recall, is 91.2%. These outcomes show an even and strong performance in all the metrics, indicating that the suggested RL model is efficient in ensuring consistent prediction quality with fewer false positives and fewer false negatives.

B. Ablation Study

An ablation study was conducted to gain insight into the role played by each of the elements in the T-RLNN architecture. The experiments tested the individual effect of each of the modules by varying or eliminating certain modules on model performance and adaptability.

Table III describes the ablation results of T-RLNN. The lack of RoBERTa embeddings or engagement features reduces the performance, which confirms their significance. Integrated components are effective, and the full model is the one that has the greatest accuracy, F1-score, engagement, and retention.

TABLE. II. PERFORMANCE EVALUATION

Metrics	Value
Accuracy	92.5
Precision	91.8
Recall	90.6
F1-Score	91.2

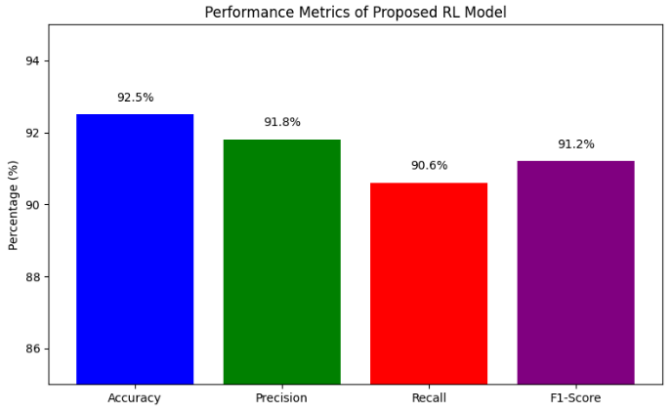

Fig. 8. Performance evaluation.

TABLE. III. ABLATION RESULTS

Model Variant	Accuracy (%)	F1-Score	Engagement Score	Retention Index
Without RoBERTa (RLDNN)	87.2	0.85	0.70	0.72
Without Engagement Features	89.5	0.87	0.74	0.76
Full T-RLNN (Proposed)	92.5	0.90	0.81	0.84

C. Comparative Analysis

Table IV provides a comparative study of four ML models: Proposed RL, SVM, RF, and DNN—with respect to three performance measures: accuracy, recall, and precision. The Proposed RL model shows the best performance with the highest accuracy of 92.5%, recall of 90.6%, and precision of 91.8% compared to all the methods considered. Even though the conventional models show increasingly better performance, they are still inferior in general. Among them, the DNN model demonstrates the best performance, closest to the RL-based approach, with the second highest in all three measures.

TABLE. IV. COMPARATIVE STUDY WITH EXISTING METHODS

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)	Engagement Score (ES)	Retention Index (RI)	Adaptivity Index (AI)
Proposed RL	92.5	91.8	90.6	91.2	76.5	73.9	67.3
SVM [25]	85.3	84.1	82.9	83.5	61.2	58.3	42.8
RF [26]	87.2	86.5	85.0	85.7	63.9	61.5	48.1
DNN [27]	89.1	88.2	88.2	88.2	68.4	66.0	52.6

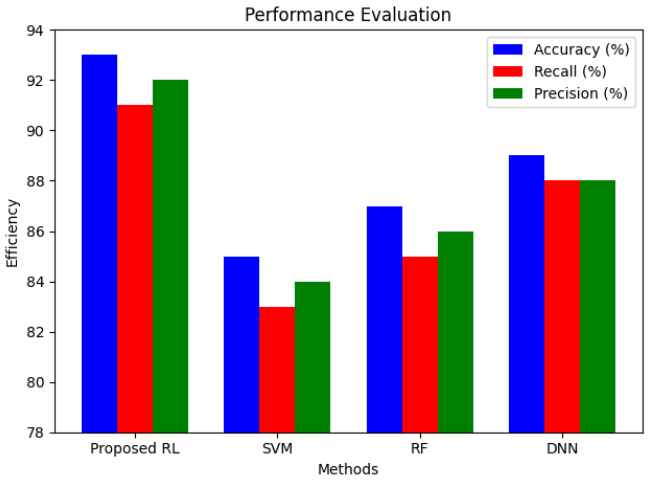

Fig. 9. Comparative study with existing methods.

Fig. 9 compares the results of four different techniques—i.e., a new RL method, SVM, RF, and DNN—on three most important metrics: accuracy, recall, and precision. Performance of each method is depicted by separate, color-coded bars, so it is very convenient to compare the results visually. Interestingly, the RL approach performs better than the rest with scores of approximately 92% for accuracy, 90% for recall, and 91% for precision, while the DNN, RF, and SVM approaches trail behind with increasingly lower scores in the high to low 80s. This clear illustration highlights the greater efficacy of the RL approach in managing these evaluation metrics.

D. Discussion

The suggested T-RLNN system will follow the format of an actor-critic reinforcement augmentation model where the real-time ability, reaction time, participation, and performance in assignments of the learners are directly linked to the teaching choices. The model combines contextual embeddings based on RoBERTa to identify not only the linguistic richness but also the cognitive and behavioral cues to reflect the entire state of each learner and represent it in a rich and holistic manner. This combination enables the system to provide context-sensitive personalization, where the actions of instruction are much more precisely tailored than the conventional ESL learning models. In contrast to inert methods, T-RLNN adapts its instructional plan as the learner behavior changes so that it prioritizes both the accuracy of learning in short-term and long-term interaction and retention. The architecture is a combination of RoBERTa embeddings, a projection layer to stabilize state representations, and an actor and critic network that drives instructional choices. The actor produces discrete instructional behavior, like making grammar, vocabulary or comprehension task choices, by the use of a softmax output, and modulates task difficulty by actions of continuous value. This design concurs with the adaptable, data-driven modulation of instruction that can be very close to the needs and progress of learners. The efficiency of the suggested framework is proven with the help of experiments. T-RLNN was always superior to classic models, such as Support Vector Machines, Random Forests, and Deep Neural Networks, in the most important evaluation metrics. The accuracy, F1-score and Adaptivity Index of the framework were 92.5, 91.2 and 67.3 respectively, which is almost 20 points higher than the DNN baseline. These results underscore the fact that the model can be used to increase the engagement of learners, knowledge retention, and competence of language in general through responsive learning pathways. To sum up, the present research demonstrates that T-RLNN can be used to implement a practical and scalable solution to real-time personalized ESL tutoring. The effective combination of the concept of reinforcement learning and contextual language representations introduces a strong and progressive direction in the development of technology-enhanced language learning systems.

VI. Conclusion and Future Work

The T-RNN framework was formulated as an adaptive ESL tutoring system that combined both contextual representations learning and reinforcement learning, whereby the instructional strategies are dynamically adjusted in real-time. The system uses behavioral measures (response time, accuracy, and engagement) and RoBERTa-based semantic embedding to create a complex and sophisticated learner state. The actor-critic agent then uses this state to identify the most suitable instructional actions to take via each of the learners, giving them highly personalized instructions. Experimental analyses showed that T-RLNN was the most effective model compared to traditional models, such as SVM, Random Forest, and feedforward DNNs, with better accuracy, F1-scores, and adaptivity. These findings imply that the framework has been able to balance both short-term effects of improvements in performance and long-term retention, which has resulted in making ESL instruction more scalable, learner-centered, and effective.

The research has some limitations, though. The experiments were also done in one dataset, which could limit generalizability, and the application of RoBERTa demands a large computational power, which can be difficult to use in low-resource or real-time environments. The research in the future will investigate cross-dataset validation to enhance generalizability and lightweight or distilled transformer models to decrease the cost of computation. Also, the use of multimodal cues to the learner, e.g., speech, eye-tracking, or interaction patterns, may facilitate more comprehensive modeling of the learner states. The longitudinal assessments will assist in measuring the learning outcomes over a period of time, and such techniques as federated learning and meta-learning may assist in large-scale personalization without invading the privacy of learners. Altogether, the results indicate that reinforcement learning integrated into a contextual embedding offers a very versatile, effective, and customized method of ESL instruction, which represents the future of intelligent language tutoring systems.

***Abstract*—The rapid expansion of 5G enabled Vehicle to Everything (V2X) communication has evolved into an intelligent transportation system by supporting applications such as autonomous driving, real-time traffic optimization, and road safety management. However, the growing connectivity and diverse communication protocols also create major cybersecurity challenges, especially in the network tier of connected vehicles. This study conducts a systematic literature review following the PRISMA framework to examine cybersecurity threats and detection models in Malaysia's V2X ecosystem. It involves an analyzing phase towards 85 peer-reviewed studies published between 2016 and 2025. This addresses three research questions: (RQ1) What is the state-of-the-art in CVs in the aspect of network technology in Malaysia, (RQ2) What are the cybersecurity trends and threats towards CVs in the network tier, and (RQ3) What are the existing models in detecting and responding to cyber threats against CVs? Study identifies critical threats, including spoofing, jamming, and denial of service attacks, while evaluating intrusion detection systems that use machine learning, deep learning, and hybrid approaches. The existing approaches are yet to face limitations in real-time performance, contextual accuracy, and supply chain resilience under Malaysia's tropical urban conditions. This study proposes a conceptual model, the SCARF-V2X model, an NGSOC integrated concept that utilizes SIEM, SOAR, and Malaysian cyber threat intelligence platforms to enable automated detection and first-layer auto-response, specifically towards supply chain threats in CVs. The proposed model aims to improve Malaysia's V2X cybersecurity landscape and introduces a proactive and adaptive model to protect CVs against evolving cyber threats.**

Keywords*—5G; V2X; connected vehicles; cybersecurity; intrusion detection systems; anomaly detection; spoofing; DoS; network tier; machine learning

I. Introduction

The integration of fifth-generation network (5G)-enabled Vehicle-to-Everything (V2X) communication has transformed the intelligent transportation systems and enabled a real-time data exchange in smart cities, which includes autonomous driving, traffic optimization, and collision avoidance [1],[2],[3]. In Malaysia, the smart cities initiatives project like the Cyberjaya 5G testbed demonstrates the potential of these technologies, which have the potential to achieve latencies as low as 23ms for safety-critical messaging [4]. However, this hyper-connectivity also exposes the opportunities in the attack surface for cyber threats, particularly in the network tier where vehicles interact with infrastructure, cloud platforms, and other devices [5], [6],[7],[8],[9].

Malaysia's tropical urban environments introduce unique challenges to V2X security [10], including the signal attenuation from high humidity and complex multi-path propagation in dense cities such as Kuala Lumpur, Malaysia [11]. Rain attenuation creates natural 'blind spots' [10] that the malicious actors could synchronize it with the recent and advanced cyber incidents. This has been reported in Malaysia, where several cyber incidents have occurred, including ransomware attacks on Klang Valley's traffic management systems [12] and spoofed Radio Frequency Identification (RFID) and toll transactions [13], highlighting the urgent need for robust cybersecurity measures. These threats mirror the global cyber trends, which are the false message injection [14] and Distributed Denial of Service (DDoS) attacks [15], but these are exacerbated by local infrastructure gaps and the rapid adoption of heterogeneous technologies such as Dedicated Short-Range Communication (DSRC) and Cellular Vehicle-to-Everything (C-V2X) [4],[16].

Existing Intrusion Detection Systems (IDS) leverage machine learning (ML) and deep learning (DL) to identify the anomalous behaviors in the vehicular systems, yet they often fail to address the real-time performance, where high mobility in urban corridors demands detection latencies under 100ms [17], yet models like Random Forests [18] struggle with scalability. This also includes Context-aware threat intelligence, where there are several reported attacks on Malaysian telematics systems [19] that require localized detection frameworks, akin to IoT threat models in smart homes [20] or political security prediction systems [21]. Lastly, the focus on the supply chain risk, where it could compromise the On-The-Air (OTA) updates [22], necessitates solutions inspired by Industry 4.0 automation safeguards [23].

This study has seven sections, which start with Section I: Introduction. Section II outlines the Methods used in searching the relevant published papers related to these studies. Section III details the Results based on the criteria and the final list of the chosen papers to be discussed. Section IV presents the Discussion on the elements related to the research questions that have been listed in Section II. It also presents the Proposed Conceptual Model that will focus to improve the detection system in V2X communication in vehicular system within

*Corresponding author.

Malaysia ecosystem. Section V gives away Future Works to be completed to evaluate the effectiveness of the proposed conceptual model and lastly Section VI is the study's Conclusion.

This study bridges these gaps through a systematic review of 5G-V2X cybersecurity, with three research questions listed in Table I. This study synthesizes global advancements in V2X cybersecurity and contextualizes them within Malaysia's regulatory landscape and environmental constraints, thereby offering a strategic model for enhancing the resilience of the nation's connected mobility ecosystem against emerging cyber threats [36].

II. METHODS

This study employed a systematic literature review (SLR) guided by the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework [37] to identify, evaluate, and synthesize relevant research on cybersecurity threats and detection models in Malaysia's 5G-V2X ecosystem. The methodology was designed to address three research questions (RQs) while ensuring transparency and reproducibility. Table I lists the details of the study methodology.

III. RESULTS

From the analysis and synthesis made on the chosen papers, 86 papers have been selected from the publication years of 2013 to 2025. The year 2024 is the highest number of studies related to security in vehicular systems, as illustrated in Fig. 2. There is one published paper in 2013 that has been selected for this study, as this is the best reference for the Fuzzy Delphi Method (FDM) that has been implemented in vehicular systems [51].

The selection process in determining the published papers for this study is very crucial to preserve the quality of the literature review of the paper and the evaluation of the discussion made for the three research questions, as stated in Table I. The evaluation studies have been tailored to the situation in Malaysia, where this country is still developing and transitioning at a proper pace, and a smart city will be adopted. By referring to the adoption of different countries and assessing the relation between climate in Malaysia and the safety in autonomous vehicular systems, this can help other researchers and the nation to build a safe V2X communication within the Malaysian ecosystem. By identifying the current technology in

V2X communication adopted in Malaysia (RQ1), analyzing the impact of cyber threats against the transportation system in Malaysia as it is part of the National Critical Information Infrastructure (NCII) (RQ2) and evaluating the current methodology used to defense in V2X communication (RQ3), this paper can be one of the best reference to improve and build a resilience in smart city in Malaysia.

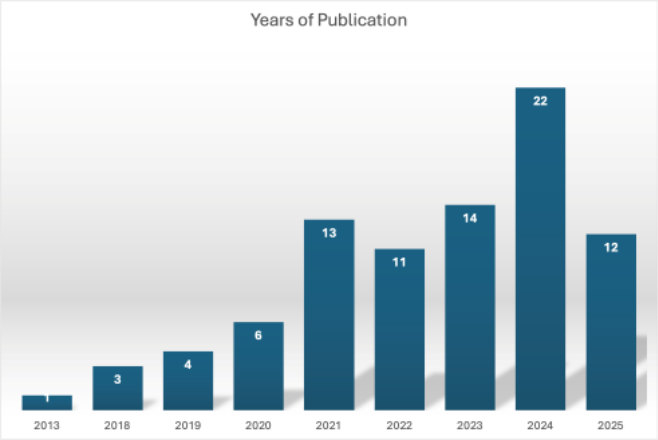

Fig. 2. Years of publication.

IV. Discussion

In this section, three main topics have been discussed in order to fulfil the three research questions in this study.

A. The State-of-the-Art CVs in the Aspect of Network Technology in Malaysia

Malaysia's CVs ecosystem has undergone a significant transformation through a strategic adoption of Dedicated Short-Range Communications (DSRC) and Cellular V2X (C-V2X) technologies, tailored to address the unique challenges of tropical urban environments [38], [12], [39]. DSRC is one of the wireless technology standards (based on IEEE802.11p), which has designed for fast and reliable communication between vehicle-to-vehicle (V2V) and Vehicle-to-Infrastructure (V2I) communications [86]. This communication offers fast detection to protect the safety of the travelling public. On the other hand, C-V2X is a Cellular-based communication technology that enables vehicles to exchange information with other vehicles (V2V), roadside infrastructure (V2I), pedestrians (V2P), and broader networks (V2N). This cellular technology supports safer and more efficient transportation systems through the real-time sharing of data such as location, speed, and hazard notifications. This technology operates through either direct short-range links (PC5) or network-assisted connections (Uu), making it suitable for a wide range of applications, including collision avoidance, traffic optimization, and the advancement of autonomous driving systems. In C-V2X methodology, it follows the concept of edge computing, where the communication between the client (the connected vehicles) and the servers will pass through the edge nodes [27]. The utilization of edge computing has reduced the latency in data transmission, making it more reliable for critical infrastructure such as connected vehicles [27].

From the comparison testing in DSRC and C-V2X, empirical studies reveal substantial improvements in network reliability, with documented packet delivery ratios progressing from 82% to 98% across various deployment scenarios. For instance, field measurements in Kuala Lumpur's dense urban corridors demonstrate the real-world performance of DSRC [12], showcasing median latencies of 47ms ± 12ms during peak traffic conditions. However, these trials also highlight environmental challenges, as packet delivery rates drop to 68% in complex non-line-of-sight situations due to signal attenuation from high-rise structures and humidity [11]. The PLUS Expressway electronic toll collection system stands as a notable success story, achieving 99.2% vehicle identification accuracy through optimized antenna placement and dynamic power control algorithms [13].

The transition to 5G-enabled C-V2X represents a leap forward in Malaysia's connected mobility infrastructure. Controlled trials in the Cyberjaya 5G testbed have recorded end-to-end latencies as low as 23ms ± 7ms for critical safety messages which has shown a remarkable 62% reduction compared to legacy DSRC systems [4], as illustrated in Fig. 3. Similarly, Penang's Smart Traffic System has implemented LTE-V2X (Release 14) enhanced with locally developed congestion-control algorithms, maintaining 98.4% communication reliability even under extreme vehicle densities of 1,200 vehicles/km² [40]. These advancements underscore Malaysia's growing expertise in adapting global V2X standards to local conditions.

At the protocol level, Malaysian researchers have made significant contributions to optimizing the V2X stack. The Enhanced EDCA (E-EDCA) modification reduces channel access delays by 28.4% through dynamic contention window adjustments, addressing the high contention inherent in urban vehicular networks [41]. Physical layer innovations, such as adaptive 16/256-QAM modulation, improve spectral efficiency by 37% in variable channel conditions [39], while Hybrid ARQ implementations achieve 99.1% reliability for safety-critical message transmission [42]. These protocol enhancements are complemented by architectural innovations, including the Malaysian Automotive Institute's hybrid gateway prototype, which enables seamless handovers between DSRC and C-V2X technologies while maintaining switching latencies below the critical 100ms threshold [43].

Looking ahead, challenges remain in achieving seamless interoperability between disparate V2X technologies and ensuring consistent performance during Malaysia's prolonged monsoon seasons. The integration of machine learning-based traffic flow prediction models [34], [58] with V2X systems presents a promising avenue for optimizing network resource allocation in real-time [44]. As Malaysia continues to expand its 5G-V2X deployments, these innovations position the nation as a regional leader in adapting CV technologies to tropical urban environments while highlighting the need for ongoing research into climate-resilient communication protocols.

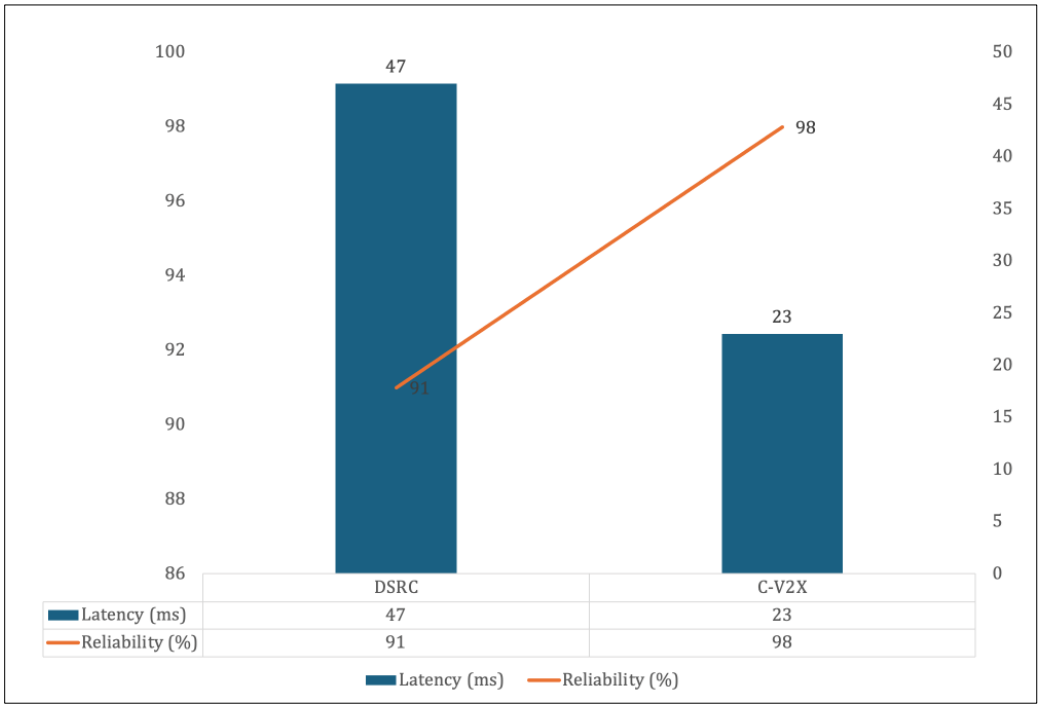

Fig. 3. The comparisons of latency and reliability in DSRC and C-V2X.

B. *Cybersecurity Trends and Threats of CV's Network Tier in Malaysia*

The rapid deployment of 5G-V2X technologies in Malaysia has introduced a complex attack surface across vehicular communication networks, cloud platforms, and IoT-enabled infrastructure [45]. While these interconnected systems enable advanced mobility solutions, they have also become targets for increasingly sophisticated cyber threats, including large-scale data breaches, ransomware attacks, and vehicular system manipulations [25], [46]. As connected vehicles evolve, they inherit the attack surfaces of both automotive and IoT systems [47], [48], [27]. The real-world cases exemplify the three primary threat categories facing Malaysia's V2X ecosystem, including communication channel exploits, telematics system breaches, and infrastructure attacks [57].

The communication layer presents particularly acute risks due to Malaysia's hybrid deployment of DSRC and C-V2X technologies. Security analyses have identified recurring patterns of false message injection attacks, where malicious actors transmit fabricated collision warnings or traffic alerts to manipulate driver behavior [14]. These attacks exploit the inherent trust models in V2X communications, where vehicles often prioritize low-latency message delivery over rigorous authentication. Concurrently, jamming attacks targeting 5G-based C-V2X signals have emerged as a persistent threat, potentially causing communication blackouts along smart highway corridors [24]. The tropical urban environment exacerbates these challenges, as signal attenuation in high-density areas like Kuala Lumpur's city center creates opportunities for intermittent jamming that may evade conventional detection systems [11].

Beyond communication channels, cloud-based telematics platforms have proven vulnerable to sophisticated intrusions [9], [49]. A 2024 breach of Prasarana's database exposed sensitive personal information, involving part of its internal systems, which may risk over hundreds of Malaysian's safety while using public transportation systems [26],[50],[51]. Forensic investigations attributed this incident to weak API authentication protocols that allowed SQL injection attacks [52]. Similarly, two major ransomware attacks hit two different transportation services involving Malaysia Airport Holdings Berhad (MAHB) and a well-known Malaysian airline, exposing thousands of sensitive personal information of their passengers [19],[53],[54]. These breaches highlight the urgent need for robust encryption and access control mechanisms in Malaysia's growing CVs ecosystem.

Various studies highlight real-world incidents involving firmware tampering [55] and malicious updates in IoT systems, which apply to V2X contexts [56], [30]. Transportation infrastructure supporting V2X networks has also emerged as a high-value target. On Malaysia's PLUS Highway network, security analysts uncovered an elaborate RFID toll payment fraud scheme that exploited cloned tags to evade charges, resulting in substantial revenue losses [13]. These incidents underscore the cascading impacts of infrastructure compromises, where single points of failure can affect thousands of vehicles and passengers daily [55].

From Table II, cyberattacks in the transportation system have impacted all layers of the OSI model from Layer 1 to Layer 7. On the other hand, from the recent reports of cyber-attacks towards transportation cases that happened specifically in Malaysia have been listed in Table III by referring to the Open Systems Interconnection (OSI) Model for a better visualization and understanding. In Table II, there are a total of nine cases related and four layers in the OSI Model impacted in the cyber incidents that occurred related to transportation and vehicular

systems, those are physical, data link, network and applications. Application layer, which is also layer 7, is the most cited attacks occurs involving the surface attack methodology. Layer 4, 5, and 6 attacks do exist in transportation systems, but they are not explicitly reported in Malaysian transportation cyberattack cases. Cases such as ransomware attacks [19], [53], [54], database compromise [52], RFID toll fraud [13]and jamming and signal distraction [11], [24] are the results of successful bypass in OSI model layer 4,5 and 6, which enable the attack.

TABLE II. CYBERATTACKS MAPPED IN OSI MODEL

OSI Layer	Layer Function in Transportation Systems	Example of Cyberattacks	Related Citation
Layer 1 Physical	Wireless signal transmission, hardware, RF environment	RF jamming (DSRC, C-V2X, 5G), GNSS spoofing, RFID tag cloning (toll systems)	[24], [69], [13]
Layer 2 Data Link	Frame delivery, MAC addressing, link-level trust	False message injection (BSM/CAM), Sybil attacks, MAC spoofing	[14], [19], [25]
Layer 3 Network	Routing and packet forwarding	Blackhole / grayhole attacks, routing manipulation, network-layer DoS	[45], [41]
Layer 4 Transport	End-to-end reliability and flow control	TCP/UDP flooding, replay amplification, session exhaustion	[42], [25]
Layer 5 Session	Session establishment and maintenance	Session hijacking, replay attacks, unauthorized session persistence	[25], [63]
Layer 6 Presentation	Data representation, encryption, key handling	Certificate manipulation, weak cryptography exploitation, message format tampering	[47], [74]
Layer 7 Application	Vehicle software, cloud platforms, APIs, OTA services	SQL injection, ransomware, malicious OTA/firmware updates, cloud API abuse	[52], [55], [49], [21]

TABLE III. MALAYSIAN TRANSPORTATION CYBERATTACKS MAPPED IN OSI MODEL

OSI Layer	Description	Related Citations	Count
Layer 1 Physical	RFID toll tag cloning / toll payment fraud	[13]	**1**
Layer 2 Data Link	False message injection (fabricated collision / traffic warnings)	[14]	1
Layer 3 Network	Jamming attacks on 5G C-V2X signals	[24], [11]	1
Layer 7 Application	Cloud telematics platform intrusion	[9], [49]	6
	SQL injection via weak API authentication	[52]

	Ransomware attack on airline systems	[54]	
	Firmware tampering	[55]	
	Malicious firmware / OTA updates in IoT-V2X systems	[56],[30]	

Malaysia has responded to these challenges through a combination of regulatory measures, technological innovations, and research initiatives. The Malaysia Cyber Security Strategy (MCSS) 2020-2024 states that the 11 National Critical Information Infrastructures (NCII) and transportation is part of the sectors [36], while Automotive ISAC provides a platform for threat intelligence sharing among automakers and suppliers [35]. Industry players are deploying advanced countermeasures, including Telekom Malaysia's blockchain-based V2X authentication system [58] and PLUS Highway's machine learning-powered anomaly detection for toll transactions [13].

Emerging threats nevertheless continue to challenge these defenses. The advent of 5G network slicing introduces new attack vectors that could be exploited to disrupt emergency vehicle communications [60], while AI-powered cyberattacks using adversarial machine learning techniques pose risks of bypassing conventional security systems [61]. These evolving threats demand adaptive solutions that combine the scalability of machine learning with the rigor of formal verification methods, which is a research direction that Malaysia's automotive cybersecurity community is uniquely positioned to explore given its experience with tropical urban deployments.

C. Existing Models for Detecting and Responding to Cyber Threat Against CVs

The network tier of CVs consists of several communication and those are V2V, V2I, and V2C communications. These communications form the backbone of intelligent transportation systems but also present a critical attack surface for cyber threats. In Malaysia's evolving 5G-V2X ecosystem, where high mobility and tropical urban environments exacerbate security challenges [11], robust intrusion detection systems (IDS) must balance real-time performance with adaptability to novel attack vectors [32],[62]. This section evaluates existing detection models, their applicability to Malaysian deployments, and emerging solutions that address current gaps.

1) Traditional and machine learning based approaches: Early IDS solutions for vehicular networks relied heavily on signature-based detection, which identifies known attack patterns through predefined rules [61],[63]. While effective against documented threats like replay attacks or basic spoofing [15], these systems struggle with zero-day exploits and adaptive adversaries. The limitations of signature-based methods have spurred the adoption of machine learning (ML) techniques, which analyze network behavior to detect anomalies [31].

Studies demonstrate promising results with algorithms such as Random Forests (RF) and Support Vector Machines (SVM), achieving up to 95% accuracy in classifying malicious V2X traffic [2]. For instance, RF-based models excel in identifying false safety messages, which are a prevalent threat in Malaysia's highway systems [14]. This can occur by correlating message frequency, sender reputation, and physical plausibility checks. Machine learning-based IDS has shown promise in detecting anomalies in real-time systems [64],[18],[61]. Edge learning models further optimize detection at the network edge [65].

However, conventional ML approaches as part of defence in V2X communication face challenges where the high vehicle densities in urban corridors like Kuala Lumpur generate volatile network conditions that can trigger false positives in models trained on limited datasets [66]. Additionally, the computational overhead of techniques like K-Nearest Neighbors (KNN) may exceed the latency budgets of safety-critical applications [67], where response times under 100ms are often required [17].

2) Deep learning and hybrid architectures: To address these limitations, researchers have turned to deep learning (DL) models capable of learning complex spatial-temporal patterns in network traffic. Long Short-Term Memory (LSTM) networks have proven particularly effective for detecting time-series anomalies, such as gradual DDoS attacks that overwhelm roadside units (RSUs) with slow-rate malicious packets [68]. In the Malaysian context, where 5G-V2X deployments must handle monsoonal weather-induced signal fluctuations [11], LSTMs' ability to model temporal dependencies offers advantages over static threshold-based systems. Recent advances in GNSS-5G hybrid positioning demonstrate robust spoofing detection even during receiver maneuvers [69], suggesting potential integration with Malaysia's 5G-V2X testbed infrastructure [4].

More advanced hybrid architectures combine the strengths of multiple approaches. Yang et al.'s Multi-Tiered Hybrid IDS (MTH-IDS) [28], for instance, integrates signature matching, statistical anomaly detection [70], [62], and deep learning to achieve comprehensive coverage across vehicular network tiers [71]. When tested in environments resembling Malaysia's heterogeneous DSRC/C-V2X deployments, MTH-IDS maintained detection rates above 92% while keeping processing latency below 50ms, which shows a critical benchmark for real-time safety applications [28].

3) Emerging paradigms: federated learning and adversarial defense: Zero trust frameworks advocate continuous authentication [72], complementing Malaysia's exploration of two promising directions for Malaysia's V2X security landscape, which are federated learning and adversarial resilience. Federated learning enables collaborative model training across distributed nodes without centralised data aggregation [73], addressing privacy concerns while improving detection coverage [29]. This approach aligns with Malaysia's Auto-ISAC framework [35], where threat intelligence sharing among automakers could enhance collective defense without compromising proprietary data.

Meanwhile, the rise of AI-powered attacks [28],[61] necessitates IDS models resistant to adversarial manipulation. Techniques like Generative Adversarial Networks (GANs) [61] can simulate attack variants to harden detection systems, explore long-term protections against future computational threats [74].

This section systematically evaluates intrusion detection and response mechanisms for securing Malaysia's 5G-V2X networks against evolving cyber threats. Traditional signature-based IDSs prove inadequate against novel attacks, prompting the adoption of machine learning (ML) models like Random Forests (95% accuracy) and Support Vector Machines, though their real-time performance in high-density urban environments remains challenging. Deep learning solutions, particularly LSTM networks, address temporal attack patterns (e.g., slow-rate DDoS), while hybrid models (e.g., MTH-IDS) combine multiple techniques to achieve >92% detection rates with sub-50ms latency, which is critical for safety applications. Emerging approaches like federated learning enable collaborative threat analysis without compromising data privacy, aligning with Malaysia's Auto-ISAC framework, while adversarial ML defenses counter AI-powered attacks.

4) Proposed conceptual model: To mitigate the escalating threat of supply chain attacks within Malaysia's rapidly evolving 5G-enabled Vehicle-to-Everything (V2X) ecosystem, this study introduces the SCARF-V2X (Supply Chain Attack Resilience Framework for V2X) model. SCARF-V2X is a Security Operations Center (SOC)-integrated solution that enhances the cybersecurity posture of CVs by enabling automated detection and response to supply chain threats. Fig. 5 is the conceptual model that adopts the NIST Cybersecurity Framework as part of the model, as illustrated in Fig. 4. As V2X architectures grow in complexity, where they can incorporate components such as over-the-air (OTA) firmware updates, roadside units (RSUs), and diverse vehicular communication protocols, the adversaries are increasingly targeting these vectors to introduce malicious code or manipulate vehicular behaviour [61],[22], [68],[75].

Fig. 4. NIST cybersecurity framework 2.0.

These challenges are particularly acute in the Malaysian context, where research has highlighted significant vulnerabilities in telematics platforms and a lack of localized and context-aware intrusion detection capabilities [19], [22],[42]. Existing Intrusion Detection Systems (IDS) often lack adaptability and automation, rendering them ineffective against sophisticated, multi-stage supply chain intrusions. SCARF-V2X addresses these limitations by integrating core enterprise SOC components such as Security Information and Event Management (SIEM) [76],[85] and Security Orchestration, Automation, and Response (SOAR) into the vehicular cybersecurity stack [77]. By contextualizing these tools for automotive environments, SCARF-V2X supports real-time detection, automated containment, and collaborative threat intelligence sharing through platforms like Auto-ISAC [35], [78].

Through this integration of behavioral analytics, automation, and policy-aware response mechanisms, SCARF-V2X represents a novel approach to safeguarding 5G-CVs against emerging supply chain threats, building on frameworks for regulatory harmonization [79].

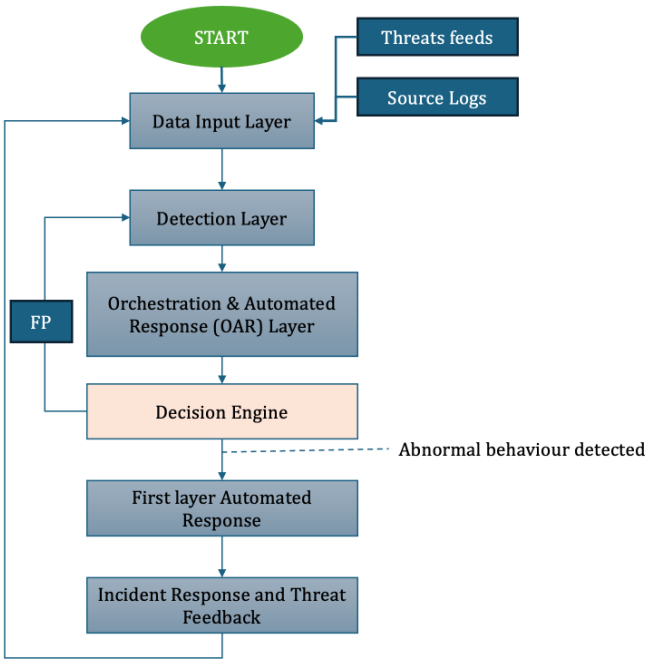

Fig. 5. The proposed conceptual model.

The framework begins with a data input layer that consolidates telemetry from both internal vehicle networks and external intelligence sources. Internally, it ingests logs from the CAN bus, V2X communication messages, and 5G traffic, which collectively offer insight into both hardware integrity and message-level anomalies [74], [80]. Externally, it integrates threat intelligence feeds from platforms such as MISP [81], Auto-ISAC, and MyCERT [59]. These sources ensure that detection efforts are continuously updated with localized Indicators of Compromise (IOCs) and emerging threat patterns relevant to Malaysia's vehicular cybersecurity landscape [35],[36].

The detection layer leverages a SIEM platform to perform log ingestion, parsing, and correlation. It applies finely tuned rules and behavioral models to identify suspicious events across the vehicular network stack. For instance, anomalies in V2X message frequencies, spoofed firmware update attempts, or inconsistent 5G session behaviors are detected through rule-based and heuristic approaches [28],[55]. SIEM also enriches its alerting mechanisms by correlating internal data with external threat intelligence, thus increasing detection precision and reducing false positives [85].

Once suspicious behavior is identified, the response layer, powered by a SOAR system, activates corresponding incident workflows. The SOAR component manages alert triage, maps detection artefacts to the MITRE ATT&CK framework, and executes automated playbooks [82]. These playbooks may include isolating compromised RSUs, rolling back OTA firmware updates, disabling Advanced Driver Assistance Systems (ADAS), or blocking communication from malicious IP addresses [80],[56]. SOAR also performs initial severity calculations to determine whether alerts warrant full-scale incident response or can be resolved through localized automation.

The decision-making engine within SCARF-V2X assesses whether an alert reflects genuine malicious behavior or a false positive. In the case of a false positive, the framework loops back to fine-tune detection rules and behavioral baselines. If the alert is validated as a true positive, a first-layer automated response is initiated. This lightweight response provides immediate mitigation actions while reducing analyst workload and response time. For higher-severity alerts, the incident is escalated for deeper investigation by analysts or original equipment manufacturer (OEM) cybersecurity teams. Such escalation includes forensic analysis, root cause determination, and long-term remediation strategies.

Several works stress the urgency for a proactive and adaptive detection framework in automotive supply chains [78], [83]. This study adopts a supply chain attack use case into the SCARF-V2X framework, as illustrated in Fig. 6. This framework also incorporates a continuous feedback loop wherein verified threat data and incident insights are shared with CTI platforms such as MISP and Auto-ISAC. This promotes collaborative defense, policy compliance, and alignment with MCSS 2020-2024 [36], [55]. Furthermore, by embedding automation, behaviour analysis, and threat intelligence within an SOC paradigm adapted for V2X, SCARF-V2X represents a novel approach to automotive cybersecurity. It surpasses traditional standalone intrusion detection models, such as GIDS (Generic Intrusion Detection System), by integrating policy-aware response automation, federated learning support, and localized threat intelligence sharing [35],[36],[84].

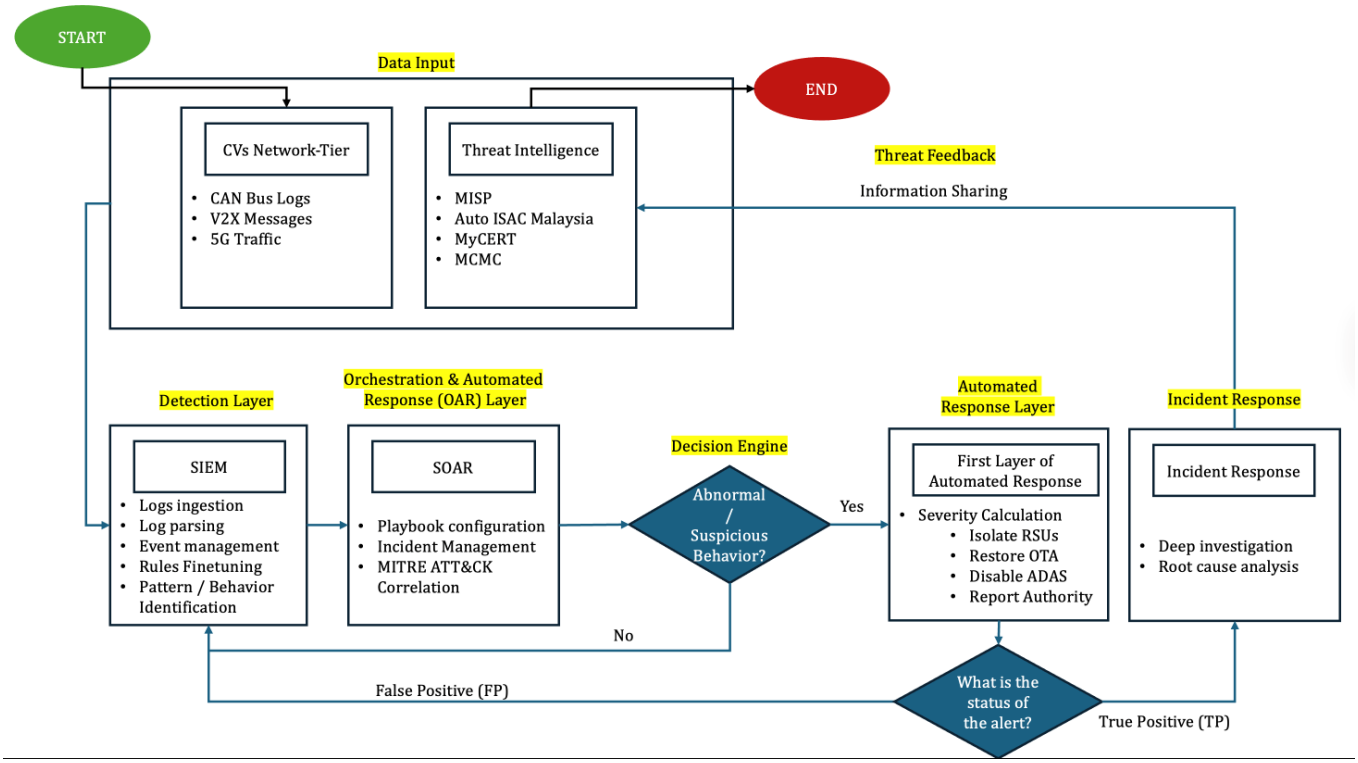

Fig. 6. Supply chain attack use case adoption in the conceptual model.

V. Future Works

As part of the research, this study will run two phases of evaluation methods to enhance the structure of the SCARF-V2X model. Those are the Fuzzy Delphi Method (FDM) and running a simulation experiment. Both evaluation and validation activities are crucial for this study, where we believe the FDM will assist in connecting the bridge between theoretical study and the industrial expert panels, while the simulation experiment will be the benchmark result of this proposed conceptual model.

A. Fuzzy Delphi Method (FDM)

The first activity is by deploying the Fuzzy Delphi Method (FDM) to evaluate each phase in conceptual model, as stated in Fig. 5 and adopting the supply chain attack simulation, as shown in Fig. 6. FDM has been chosen as part of these future work efforts, as FDM is an advanced decision-making technique that combines the traditional Delphi method with fuzzy logic to handle uncertainty and subjectivity in expert judgments. It is widely used in forecasting, policymaking, risk assessment, and consensus-building, where expert opinions may be vague or imprecise [9],[33],[51].

From the process flow of FDM illustrated in Fig. 7, the process begins after the conceptual framework has been structured and the researcher needs to select at least 10 to 15 expert panels from the related sectors, with the framework including the regulator and local Managed Security Service Provider (MSSP) and Subject Matter Experts (SME), which involves SIEM engineers and SOC Consultants. The uniqueness of FDM is the combination of the qualitative and quantitative methodology, where it balances between the need for the opinion from the industrial experts and the logics calculation, which would stabilize the final decision. Once the researcher reaches the expert consensus, the framework will proceed with the second activity in the evaluation phase.

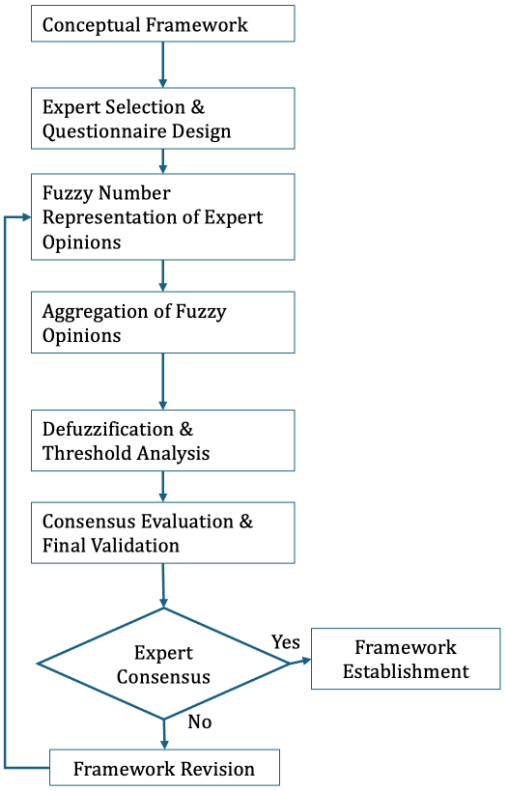

Fig. 7. Fuzzy Delphi process flow.

B. Simulation Experiment

This experiment will be run in a controlled lab environment, where the V2X logs will be recorded and used in SIEM, as illustrated in Fig. 8. The first step is to install the virtual machine (VM) that will be used to install the SIEM. All the V2X logs will be ingested into the SIEM before the parsing activity takes place. The parsing is a crucial phase as it assists in standardizing the format, which could help to columnize the information into an event. A malicious script will be created based on the use case scenario of injecting a fake OTA update through the network layer in the CVs ecosystem. Once the playbook has been created and finetuned, the malicious script will be injected into the environment, and the detection shall flag the events. The first layer of auto response from the SOAR features should be activated and notify the SIEM end users as the second layer response phase.

The stated experiment simulates the real case scenario of how the SOC and SOAR are deployed and react if there are any cyber incidents occur in the environment. The manipulated variable in this situation is the V2X logs, which are only used for research purposes and not being tested in a production environment.

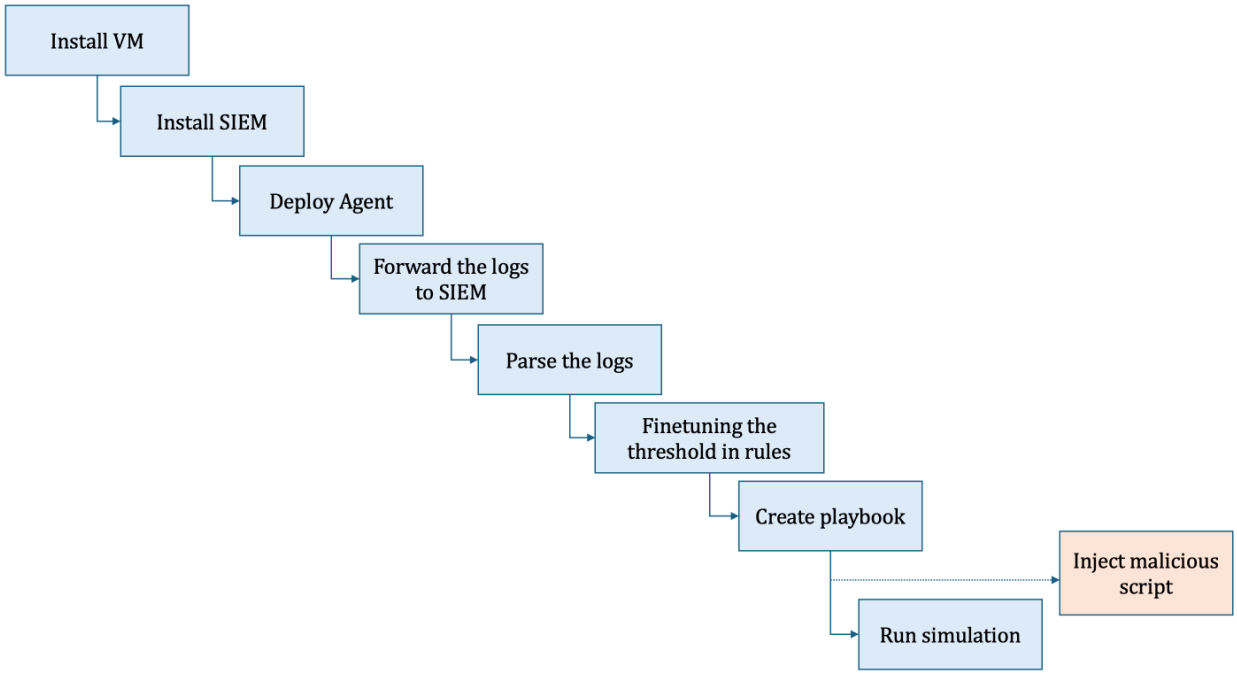

Fig. 8. The process flow to run simulation activity for SCARF-V2X model.

VI. Conclusion

The three research questions have been answered throughout the SLR approach in this study. For RQ1, the technology evolving in the CVs system has been continuously improving from the Cyberjaya testbed, and it shows an improving result from the statistics shown. The adoption of the emerging 5G networks and V2X communication in Malaysia is showing an increasing accuracy rate from the previous result. However, the threats and trends of cybersecurity attacks have been explained as part of RQ2. The trends of external attack surface towards CVs in Malaysia, especially when it involves public safety, need to be placed as a critical impact and require immediate remediation. The recent cyber-attacks that hit major national transportation systems, such as the Prasarana breach attack, Malaysia Airport Holding Berhad's (MAHB) ransomware attacks and the Malaysian airline's ransomware attack, are signs of the critical need for extra safety measures towards vehicle safety, especially CVs.

The integration of 5G-enabled Vehicle-to-Everything (V2X) communication in Malaysia represents a significant advancement in intelligent transportation systems, offering substantial benefits for autonomous driving, traffic optimization, and collision avoidance. However, this technological progress comes with heightened cybersecurity risks, particularly in the network tier where vehicles interact with infrastructure, cloud platforms, and other devices. Malaysia's unique tropical urban environment further complicates these challenges, with issues such as signal attenuation and complex multi-path propagation in dense cities like Kuala Lumpur exacerbating vulnerabilities. Recent incidents, including ransomware attacks on traffic management systems, spoofed toll transactions, and remote vehicle hijacking, underscore the urgent need for robust cybersecurity measures tailored to local conditions.

This study addresses these challenges through a systematic review of cybersecurity threats and detection models in Malaysia's 5G-V2X ecosystem. The research highlights three key contributions: a comprehensive threat taxonomy specific to Malaysian V2X networks, an evaluation of machine learning and deep learning-based intrusion detection systems, and the development of the SCARF-V2X framework. SCARF-V2X SOC tools, such as SIEM and SOAR, with localized threat intelligence and behavioral analytics, provide a proactive and automated approach to detecting and mitigating supply chain

attacks. By aligning with MCSS 2020–2024 [36] and leveraging collaborative platforms like Auto-ISAC Malaysia, the framework ensures compliance with national regulations, while enhancing the resilience of connected vehicles against evolving threats.

Despite these advancements, several areas require further exploration to strengthen Malaysia's V2X security posture. Future research should focus on integrating quantum-resistant cryptography to safeguard against emerging computational threats, as well as advancing federated learning techniques to enable privacy-preserving threat intelligence sharing among stakeholders. Additionally, the development of explainable AI models will improve transparency in automated security decisions, fostering trust in these systems.

In summary, this study provides a critical foundation for securing Malaysia's 5G-V2X ecosystem against sophisticated cyber threats. The SCARF-V2X framework, with its emphasis on automation, localized threat intelligence, and policy compliance, offers a scalable and adaptive solution for safeguarding connected vehicles in Malaysia's unique urban and environmental context. As the nation continues to advance its intelligent transportation infrastructure, ongoing innovation and collaboration will be vital to maintain a secure and resilient mobility ecosystem in the face of evolving cybersecurity challenges.

***Abstract*—The integration of Large Language Models (LLMs) into clinical decision support systems represents a significant advancement in healthcare informatics. This study presents a comprehensive evaluation framework for benchmarking LLM-generated dental treatment recommendations using BERT Score as the primary semantic similarity metric. We evaluated Claude Opus 4.5 as a Clinical Decision Support System (CDSS) across 116 dental case reports extracted from the Case Reports in Dentistry journal (2024-2025), spanning nine dental specialties. The BERT Score was calculated using the RoBERTa-large model to measure semantic alignment between AI-generated treatment plans and gold-standard published treatments. Results demonstrated strong semantic alignment with a mean BERT Score F1 of 0.8199 with a standard deviation of 0.0144 (95 per cent confidence interval: 0.8172-0.8225), significantly exceeding the 0.80 threshold (t = 14.90, p < 0.001, d = 1.38). Cross-specialty analysis revealed consistent performance across all nine dental domains (Kruskal-Wallis H = 3.07, p = 0.879), indicating robust generalizability. A significant negative correlation was observed between BERT Score and response time (ρ = -0.371, p < 0.001), suggesting a speed-accuracy trade-off in LLM reasoning. This study contributes a reproducible benchmarking methodology for evaluating LLM performance in specialized clinical domains and demonstrates the potential of BERT Score as a scalable evaluation metric for AI-generated clinical text.**

***Keywords*—BERT Score; Large Language Models; clinical decision support system; semantic similarity; Claude Opus 4.5**

I. Introduction

The rapid advancement of Large Language Models (LLMs) has catalyzed transformative applications in healthcare, particularly in clinical decision support systems (CDSS) [1]. These models demonstrate remarkable capabilities in processing and generating medical text, offering potential solutions for diagnostic assistance, treatment planning, and clinical documentation [2]. However, the deployment of LLMs in high-stakes clinical environments necessitates rigorous evaluation methodologies that can accurately assess the semantic fidelity and clinical relevance of AI-generated recommendations [3].

Traditional evaluation metrics for natural language generation, such as BLEU (Bilingual Evaluation Understudy) and ROUGE (Recall-Oriented Understudy for Gisting Evaluation), rely primarily on n-gram overlap between generated and reference texts [4]. While these metrics provide valuable insights for machine translation and summarization tasks, they exhibit significant limitations in clinical contexts where semantic equivalence often transcends lexical similarity. Clinical terminology frequently admits multiple valid expressions for identical concepts; for instance, "necrotic pulp" and "non-vital tooth" are clinically synonymous yet lexically distinct, resulting in artificially low scores under traditional metrics [5].

BERT Score addresses these limitations by leveraging contextual embeddings from transformer-based models to compute semantic similarity at the token level [6]. By representing words in a high-dimensional vector space that captures contextual meaning, BERT Score can recognize semantic equivalence between different surface forms of the same clinical concept. This capability is particularly valuable in medical domains where paraphrasing is common and clinical correctness should not be penalized by lexical variation [7].

Dentistry presents unique challenges for AI evaluation due to its specialized terminology, procedural complexity, and the critical importance of spatial reasoning [8]. Dental clinical decisions require integration of patient history, clinical examination findings, and radiographic interpretation, a triangulation of evidence that tests the reasoning capabilities of LLMs. Recent benchmarking studies have demonstrated variable performance of LLMs across dental specialties, with models achieving high accuracy on standardized examinations but exhibiting inconsistencies in complex case-based reasoning [9][10].

Claude Opus 4.5, released by Anthropic, represents a reasoning-optimized LLM architecture featuring extended context windows (200,000 tokens) and inference-time compute scaling through its "Thinking" mechanism [11]. These architectural innovations suggest potential advantages for complex clinical reasoning tasks that require maintaining coherent logical chains across extensive patient histories. However, systematic evaluation of Claude Opus 4.5 in dental clinical decision support remains limited in the current literature.

While prior studies have evaluated LLMs on dental examinations using multiple-choice accuracy metrics [9] [10], these approaches cannot capture the nuanced semantic alignment required for open-ended clinical reasoning tasks. Furthermore, existing benchmarks predominantly assess single-specialty performance, leaving cross-specialty generalizability largely unexplored. This study addresses these methodological gaps by introducing a BERT Score-based evaluation framework specifically designed for open-ended dental treatment recommendations—a context where multiple semantically equivalent but lexically distinct responses may be clinically valid.

The primary contributions of this study are threefold. First, we establish a reproducible, training-free semantic evaluation pipeline that enables scalable assessment of LLM-generated clinical text without requiring domain-specific fine-tuning or retrieval augmentation. Second, we provide empirical evidence of cross-specialty generalizability by demonstrating consistent BERT Score performance across nine dental disciplines, addressing the critical question of whether LLM clinical reasoning transfers across subspecialty boundaries. Third, we characterize the speed-accuracy relationship in dental CDSS applications, offering practical insights for real-time clinical deployment where response latency affects usability. These contributions extend beyond dental informatics to inform evaluation methodology for LLM-based clinical decision support systems across medical domains.

The remainder of this study is organized as follows: Section II reviews related work on LLM applications in dental clinical decision support, evaluation metrics for clinical text generation, and existing benchmarking frameworks for healthcare AI. Section III details the methodology, including data collection from the *Case Reports in Dentistry* journal, dental specialty classification, AI configuration with structured prompting, and BERT Score calculation procedures. Section IV presents the results encompassing overall BERT Score performance, cross-specialty analysis, and speed-accuracy correlations. Section V discusses the interpretation of findings, clinical implications, and study limitations. Finally, Section VI concludes with key contributions and directions for future research.

II. Related Work

A. Large Language Models in Dental Clinical Decision Support

The application of Large Language Models in dentistry has expanded rapidly, with multiple model families demonstrating varying capabilities across clinical tasks. Kim et al. evaluated LLM performance on the Korean Dental Licensing Examination, finding that GPT-4 achieved 75.2% accuracy compared to GPT-3.5's 53.8%, establishing a clear generational performance gap [9]. Dashti et al. extended this analysis to U.S. dental examinations, reporting similar patterns with GPT-4 reaching 80.1% accuracy versus 67.3% for GPT-3.5 [12]. Wu et al. conducted multi-dimensional evaluation of LLMs in dental implantology, comparing ChatGPT, DeepSeek, Grok, Gemini, and Qwen across clinical consensus and case analysis tasks [13]. These findings indicate substantial improvement in dental knowledge representation across model generations, though both studies relied exclusively on multiple-choice question formats.

Beyond accuracy metrics, recent studies have begun characterizing operational parameters relevant to clinical deployment. Nguyen et al. quantified the speed-accuracy trade-off in oral and maxillofacial surgery multiple-choice tasks, demonstrating that reasoning-optimized models achieve 12-18% higher accuracy at the cost of 3-5× increased response latency [14]. This trade-off has direct implications for real-time clinical decision support, where response time affects usability and workflow integration. However, whether this relationship holds for open-ended clinical reasoning tasks as opposed to multiple-choice selection remains unexplored.

Comparative benchmarking across model families has revealed distinct performance profiles and highlighted the importance of model selection for specific clinical applications. Wu et al. conducted a multi-dimensional evaluation in dental implantology comparing five major LLMs, finding that GPT-4 achieved the highest accuracy (78.5%) followed by Gemini (72.1%), Claude 3 (69.8%), Qwen (65.4%), and DeepSeek (61.2%) across clinical consensus and case analysis tasks [10]. Notably, performance rankings varied by task type—Claude demonstrated stronger performance on complex case analysis requiring multi-step reasoning, while GPT-4 excelled on factual recall tasks. Fujimoto et al. evaluated LLMs specifically in dental anesthesiology, reporting that ChatGPT-4 achieved 51.2% accuracy compared to Claude 3 Opus at 47.4% and Gemini 1.0 at 43.6% on Japanese board certification questions [15]. Hou et al. benchmarked multiple LLMs on the Dental Admission Test, with GPT-4 achieving 76.8% overall accuracy while demonstrating particular strength in reading comprehension (84.2%) compared to perceptual ability sections (68.1%) [16].

Despite these advances, critical methodological limitations persist in current dental LLM evaluation. First, the predominant reliance on multiple-choice question formats constrains assessment to recognition-based rather than generation-based clinical reasoning [17]. Real clinical decision-making requires synthesizing patient information into coherent treatment plans—a generative task fundamentally different from selecting among predetermined options. Second, existing studies predominantly evaluate single-specialty performance, leaving cross-specialty generalizability largely unexplored. Whether LLM clinical reasoning transfers across dental subspecialty boundaries remains an open question with significant implications for deployment scope. Third, Claude Opus 4.5, Anthropic's latest reasoning-optimized model featuring extended context windows (200,000 tokens) and inference-time compute scaling, remains systematically unevaluated in dental clinical decision support contexts despite architectural innovations potentially advantageous for complex clinical reasoning.

B. Evaluation Metrics for Clinical Text Generation

Traditional NLP evaluation metrics exhibit well-documented limitations in clinical contexts that motivate the adoption of embedding-based alternatives. BLEU (Bilingual Evaluation Understudy) and ROUGE (Recall-Oriented Understudy for Gisting Evaluation) rely on n-gram overlap, penalizing semantically equivalent paraphrases common in

clinical documentation [17]. For instance, "extraction of non-restorable tooth" and "removal of hopeless dentition" convey identical clinical meaning but share minimal lexical overlap, yielding artificially low BLEU/ROUGE scores. Hanna and Bojar [6] demonstrated through fine-grained analysis that these metrics correlate poorly with human judgment (Pearson $r < 0.4$) for semantic equivalence tasks, particularly when surface-form variation is high—a characteristic inherent to clinical terminology where multiple valid expressions exist for identical concepts.

BERT Score addresses these limitations by leveraging contextual embeddings from transformer-based models to compute semantic similarity at the token level [4]. Zhang et al. introduced the framework demonstrating superior correlation with human judgment (Pearson $r = 0.73$) compared to BLEU ($r = 0.41$) and ROUGE ($r = 0.38$) across multiple natural language generation tasks [4]. The metric computes precision, recall, and F1 scores through greedy matching of contextualized token embeddings, capturing meaning beyond surface-level lexical patterns. Precision measures whether generated content is semantically supported by the reference, recall assesses coverage of reference content, and F1 provides a balanced harmonic mean. This capability is particularly valuable in clinical domains where terminology variation is common and semantic correctness should not be penalized by lexical diversity.

Domain adaptation techniques have further enhanced semantic evaluation accuracy for medical text, though their application to open-ended clinical text generation remains limited. BioBERT [18], pretrained on over 18 billion words from PubMed abstracts and PMC full-text articles, demonstrates improved performance on biomedical named entity recognition, relation extraction, and question answering tasks compared to general-domain BERT. ClinicalBERT [4], trained on approximately 2 million clinical notes from the MIMIC-III database, achieves superior results on clinical concept extraction and hospital readmission prediction by capturing the distinctive linguistic patterns of clinical documentation. PubMedBERT [4] employs domain-specific vocabulary and pretraining exclusively on biomedical literature, outperforming mixed-domain models on the Biomedical Language Understanding Evaluation (BLUE) benchmark. More recently, Koroleva et al. [19] demonstrated that domain-adapted embeddings improve semantic similarity measurement for clinical trial outcomes, achieving higher correlation with expert annotations than general-domain alternatives.

However, these domain-adapted models have been primarily validated on classification, extraction, and structured prediction tasks rather than open-ended text generation evaluation. Whether the advantages of biomedical pretraining transfer to semantic similarity assessment of generated clinical recommendations remains an open empirical question. Furthermore, no systematic comparison exists between the general-domain BERT Score (using RoBERTa-large) and domain-adapted variants (BioBERTScore, ClinicalBERTScore) for dental clinical text specifically. This study employs RoBERTa-large as the backbone model based on its status as the recommended default in the BERT-score library and its robust cross-domain performance [20]. This choice provides a conservative baseline—success with general-domain embeddings suggests even stronger potential with domain adaptation, while failure would not be attributable to domain mismatch.

C. Benchmarking Frameworks for Healthcare AI

The development of standardized benchmarking datasets has accelerated healthcare AI evaluation while revealing persistent methodological gaps. Zhu et al. [20] introduced DentalBench, a bilingual benchmark comprising over 36,000 questions across 16 dental subfields, including operative dentistry, prosthodontics, orthodontics, and oral surgery. This comprehensive dataset enables systematic cross-specialty comparison but relies exclusively on multiple-choice formats. Hou et al. [16] benchmarked LLMs on the Dental Admission Test, providing comparative performance data across model families with a detailed analysis of performance variation across test sections. Huang et al. [5] presented a comprehensive survey on evaluating LLM applications in medical settings, identifying accuracy, safety, clinical relevance, and explainability as key evaluation dimensions that should be assessed in combination rather than in isolation.

Recent methodological advances emphasize multidimensional evaluation frameworks that extend beyond single accuracy metrics. Sivaramakrishnan et al. [21] evaluated LLMs for dental patient education materials using BERT Score alongside readability indices (Flesch-Kincaid, SMOG) and clinical relevance assessments by domain experts, demonstrating that semantic similarity alone incompletely captures communication quality. Zheng et al. [22] proposed hierarchical divide-and-conquer approaches for fine-grained alignment in LLM-based medical evaluation, decomposing complex clinical reasoning into assessable sub-components. These frameworks recognize that no single metric fully captures clinical utility, advocating for complementary quantitative and qualitative assessments tailored to specific use cases.

Despite these advances, existing benchmarking frameworks exhibit limitations that constrain their applicability to real-world clinical decision support evaluation. The predominant MCQ format assesses knowledge recall rather than clinical reasoning synthesis—a clinician must not only identify correct answers but generate coherent, contextually appropriate treatment plans from unstructured patient information [17]. Current benchmarks lack standardized semantic similarity metrics for open-ended response evaluation, relying instead on binary correctness judgments that cannot capture partial credit, near-miss responses, or alternative valid approaches. It is uncommon to systematically evaluate cross-specialty generalizability; models may perform well in knowledge-intensive domains but poorly in procedural or spatial reasoning, but single-specialty benchmarks are unable to identify this variation [8]. Finally, speed-accuracy trade-offs critical for real-time clinical deployment are inconsistently reported across studies, limiting practical implementation guidance.

C. Research Gap and Study Positioning

The preceding review identifies three convergent gaps that motivate the present study. First, an evaluation methodology gap: existing dental LLM benchmarks predominantly employ MCQ-based accuracy metrics that cannot assess open-ended

clinical reasoning quality, where multiple semantically equivalent responses may be valid. Semantic similarity metrics like BERT Score offer a principled alternative for evaluating generated clinical text but remain underutilized in dental AI evaluation. Second, a cross-specialty evidence gap: whether LLM clinical reasoning generalizes across dental subspecialties is largely unexplored, yet this question has direct implications for deployment scope, safety boundaries, and clinical workflow integration. Third, a model coverage gap: Claude Opus 4.5, featuring architectural innovations including extended context windows and inference-time reasoning optimization, potentially advantageous for complex clinical decision-making, lacks systematic evaluation in dental clinical decision support.

This study addresses these gaps by establishing a BERT Score-based benchmarking framework for evaluating open-ended dental treatment recommendations. Unlike MCQ-based approaches that assess recognition accuracy, our framework evaluates the semantic alignment between AI-generated and expert-authored treatment plans—capturing clinical reasoning quality through continuous similarity scores rather than binary correctness judgments. By systematically evaluating performance across nine dental specialties using 116 published case reports, we provide empirical evidence regarding cross-specialty generalizability that informs appropriate deployment boundaries. The methodology offers a reproducible, training-free evaluation pipeline applicable to any LLM without requiring domain-specific fine-tuning or retrieval augmentation, facilitating standardized comparison across model families and enabling longitudinal tracking of model performance across version updates.

III. Methodology

A. Study Design and Data Collection

This cross-sectional study evaluated Claude Opus 4.5 as a clinical decision support system using published dental case reports as the evaluation corpus. The overall study workflow is illustrated in Fig. 1, comprising four sequential phases: 1) data collection and preprocessing, 2) AI-generated treatment recommendation, 3) BERT Score calculation, and 4) statistical analysis. This design enables systematic comparison between AI-generated and expert-authored treatment plans while controlling for case complexity through the use of published cases with documented outcomes for the period 2024 to 2025.

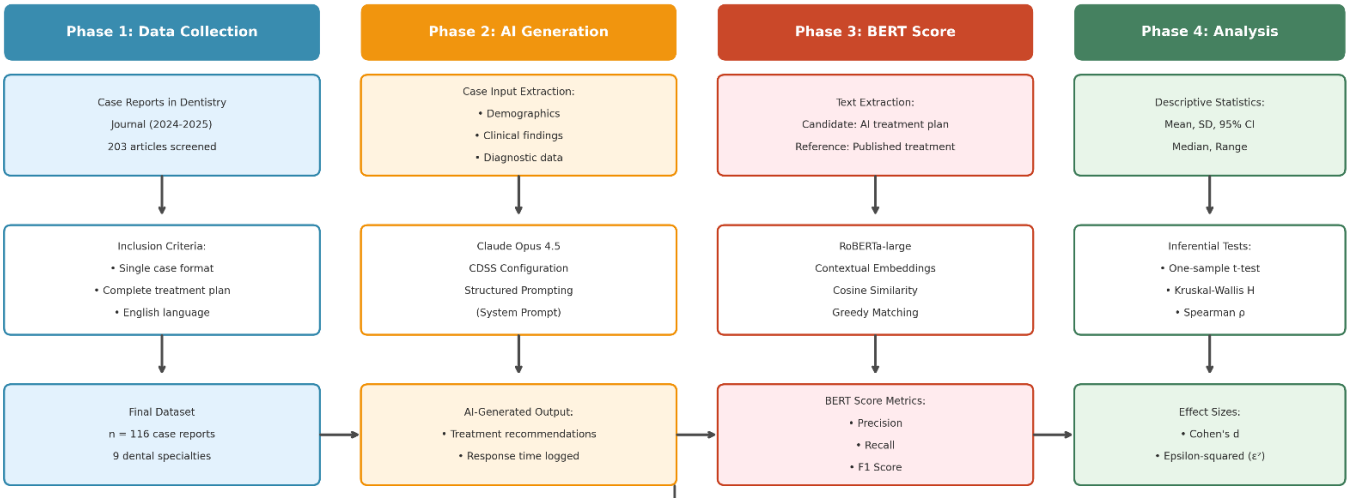

Fig. 1. Study workflow of benchmarking LLM for CDSS using BERT score.

Inclusion criteria comprised: 1) publication type classified as "case report" in journal metadata; 2) complete case presentation including patient demographics, chief complaint, clinical findings, diagnostic workup, and treatment plan sections; 3) single-case format with clearly identifiable treatment outcomes; 4) English language publication. Exclusion criteria included: a) case series presenting multiple patients, as these confound treatment-case matching; b) reports lacking explicit treatment plan descriptions; c) cases focused primarily on diagnostic imaging or laboratory findings without therapeutic intervention; d) letters to the editor, commentaries, or review articles misclassified as case reports. The final dataset comprised 116 case reports meeting all inclusion criteria.

B. Dental Specialty Classification

Cases were classified into dental specialties using a keyword-based algorithm with title weighting. The classification system assigned cases to nine specialty categories: Oral and Maxillofacial Surgery, Orthodontics, Endodontics, Prosthodontics, Implantology, Pediatric Dentistry, Periodontics, Oral Medicine and Pathology, and Conservative Dentistry. Keywords were derived from established dental specialty nomenclature and weighted by occurrence in article titles (2×) versus body text (1×). Cases matching multiple specialties were assigned to the category with the highest weighted keyword frequency.

C. AI Configuration and Prompt Engineering

Claude Opus 4.5 was configured as a Clinical Decision Support System through structured system prompting. The prompt established: 1) Role definition as CDSS for dental healthcare professionals; 2) Explicit limitations stating recommendations require clinical validation; 3) Reference standards including FDI World Dental Federation notation and ICD-10/ICD-11 classification systems; 4) Structured response format comprising clinical findings analysis, differential

diagnosis, treatment recommendations, referral considerations, and diagnostic codes. The model was accessed via the Claude Website without fine-tuning, retrieval augmentation, or embedding modifications to evaluate baseline capabilities.

D. BERT Score Calculation

BERT Score was computed using the bert-score Python library (version 0.3.13) with RoBERTa-large as the backbone model. For each case, the candidate text comprised the treatment recommendation section of Claude's response, while the reference text comprised the treatment plan section from the published case report. BERT Score computes precision, recall, and F1 scores by: 1) generating contextual embedding for all tokens in candidate and reference texts; 2) computing pairwise cosine similarity between token embedding; 3) calculating greedy matching to maximize similarity scores; 4) aggregating token-level scores into sentence-level metrics. The F1 score, representing the harmonic mean of precision and recall, served as the primary evaluation metric.

E. Statistical Analysis

Statistical analyses were performed using JAMOVI Desktop 2.6.44. Descriptive statistics included mean, standard deviation, median, and 95% confidence intervals for BERT Score metrics. Distribution normality was assessed using the Shapiro-Wilk test. One-sample t-test evaluated whether the mean BERT Score significantly exceeded the 0.80 threshold, with Cohen's d calculated for effect size. Cross-specialty comparison employed the Kruskal-Wallis H test due to unequal group sizes, with epsilon-squared (ε^2) as the effect size measure. Spearman's rank correlation assessed the relationship between BERT Score and response time. Statistical significance was set at $\alpha = 0.05$.

IV. Results

A. Dataset Characteristics

The dataset comprised 116 dental case reports distributed across nine specialties. Oral and Maxillofacial Surgery represented the largest category (n = 56, 48.3%), followed by Orthodontics and Endodontics (n = 14 each, 12.1%), Prosthodontics (n = 13, 11.2%), Implantology (n = 7, 6.0%), Pediatric Dentistry (n = 5, 4.3%), Periodontics (n = 3, 2.6%), Oral Medicine and Pathology (n = 3, 2.6%), and Conservative Dentistry (n = 1, 0.9%). Table I presents the complete distribution.

TABLE I. Distribution of Case Reports by Dental Specialty

Dental Specialty	n	%
Oral and Maxillofacial Surgery	56	48.3
Orthodontics	14	12.1
Endodontics	14	12.1
Prosthodontics	13	11.2
Implantology	7	6.0
Pediatric Dentistry	5	4.3
Periodontics	3	2.6
Oral Medicine and Pathology	3	2.6
Conservative Dentistry	1	0.9
Total	**116**	**100.0**

B. Overall BERT Score Performance

Claude Opus 4.5 demonstrated strong semantic alignment with published treatment plans. The mean BERT Score F1 was 0.8199 ± 0.0144 (95% CI: 0.8172-0.8225), with a median of 0.8191 and a range of 0.7782-0.8618. The Shapiro-Wilk test confirmed normal distribution ($W = 0.994$, $p = 0.856$). Precision (mean = 0.8140 ± 0.0161) and recall (mean = 0.8252 ± 0.0198) values indicated balanced performance in capturing reference content while avoiding extraneous information. BERT Score F1 ≥ 0.80 was attained in 107 (92.2%) of the 116 cases.

One-sample t-test confirmed that the mean BERT Score significantly exceeded the 0.80 threshold ($t = 14.90$, $df = 115$, $p < 0.001$). Cohen's $d = 1.38$ indicated a large effect size, demonstrating substantial performance above the acceptability benchmark. Table II summarizes the overall performance metrics.

TABLE II. Overall BERT Score Performance Metrics

Metric	Value	95% CI
BERT Score F1 (Mean ± SD)	0.8199 ± 0.0144	[0.8172, 0.8225]
BERT Score Precision	0.8140 ± 0.0161	[0.8110, 0.8169]
BERT Score Recall	0.8252 ± 0.0198	[0.8216, 0.8289]
Median F1	0.8191	-
Range (Min-Max)	0.7782 - 0.8618	-
Cases ≥ 0.80 threshold	107 (92.2%)	-

C. Cross-Specialty Performance Analysis

BERT Score F1 demonstrated consistent performance across dental specialties. Mean scores ranged from 0.8088 (Pediatric Dentistry) to 0.8273 (Implantology), with all specialties exceeding the 0.80 threshold. Kruskal-Wallis H test revealed no statistically significant differences among specialties ($H = 3.07$, $df = 8$, $p = 0.879$), with epsilon-squared (ε^2) = 0.026 indicating a negligible effect size. This finding suggests robust generalizability of Claude Opus 4.5 across diverse dental clinical scenarios. Table III presents specialty-specific performance.

TABLE III. BERT Score F1 Performance by Dental Specialty

Specialty	n	Mean	SD	95% CI
Oral & Maxillofacial Surgery	56	0.8200	0.0155	[0.8159, 0.8241]
Orthodontics	14	0.8211	0.0122	[0.8147, 0.8275]
Endodontics	14	0.8173	0.0121	[0.8110, 0.8236]
Prosthodontics	13	0.8200	0.0088	[0.8152, 0.8248]
Implantology	7	0.8273	0.0181	[0.8139, 0.8407]
Pediatric Dentistry	5	0.8088	0.0186	[0.7926, 0.8251]
Periodontics	3	0.8198	0.0063	[0.8127, 0.8270]
Oral Medicine & Pathology	3	0.8217	0.0232	[0.7954, 0.8480]
Conservative Dentistry	1	0.8255	-	-

D. Response Time and Speed-Accuracy Trade-off

Mean response time was 34.79 ± 18.63 seconds (median = 32.0 seconds, range = 6-98 seconds). Spearman rank correlation revealed a significant negative relationship between BERT Score F1 and response time (ρ = -0.371, $p < 0.001$), indicating that faster responses were associated with higher semantic alignment scores. This counterintuitive finding suggests that cases eliciting clear, well-structured AI responses (higher BERT Scores) also required less processing time, potentially reflecting case complexity rather than a simple speed-accuracy trade-off. Table IV summarizes the overall statistical analysis.

TABLE IV. STATISTICAL ANALYSIS SUMMARY

Analysis	Statistic	p
Normality (Shapiro-Wilk)	$W = 0.994$	0.856
One-sample t-test (vs. 0.80)	$t = 14.90$, $df = 115$	< 0.001
Effect size (Cohen's d)	$d = 1.38$ (large)	-
Cross-specialty (Kruskal-Wallis)	$H = 3.07$, $df = 8$	0.879
Effect size (Epsilon-squared)	$\varepsilon^2 = 0.026$ (negligible)	-
Correlation (Spearman)	$\rho = -0.371$	< 0.001

V. DISCUSSION

A. Interpretation of BERT Score Performance

The observed mean BERT Score F1 of 0.8199 represents strong semantic alignment between AI-generated and expert-authored treatment recommendations. This performance significantly exceeds the 0.80 threshold typically considered acceptable for clinical text evaluation [19]. The large effect size (Cohen's $d = 1.38$) indicates that Claude Opus 4.5 consistently generates treatment recommendations that capture the semantic content of published clinical decisions, supporting its potential utility as a clinical decision support tool.

The balanced precision (0.8140) and recall (0.8252) scores indicate that the model neither omits critical treatment components, which would diminish recall, nor introduces clinically unsubstantiated or extraneous recommendations—often characterized as hallucinations—which would compromise precision. This metrical equilibrium is particularly imperative in clinical contexts where both informational completeness and semantic accuracy are essential for maintaining patient safety [23]. Furthermore, the narrow confidence interval of 0.8172–0.8225 reflects consistent performance across diverse case presentations.

B. Cross-Specialty Generalizability

The absence of significant performance differences across dental specialties ($p = 0.879$) represents a notable finding. Prior benchmarking studies have documented substantial variation in LLM performance across medical subspecialties, with models often excelling in knowledge-intensive domains while struggling with procedural or spatial reasoning tasks [24]. The consistent performance observed in this study suggests that Claude Opus 4.5's reasoning architecture may provide more robust generalization across diverse clinical scenarios than earlier model generations.

However, the unequal distribution of cases across specialties (48.3% in Oral and Maxillofacial Surgery) warrants caution in generalizing these findings. Smaller specialty subgroups may have insufficient statistical power to detect meaningful differences. Future studies should employ stratified sampling to ensure adequate representation across all dental specialties [25].

C. Speed-Accuracy Relationship

The significant negative correlation between BERT Score and response time (ρ = -0.371) presents an interesting departure from the expected speed-accuracy trade-off documented in other LLM benchmarking studies [14]. This relationship may reflect that straightforward cases with clear treatment pathways elicit both faster responses and higher semantic alignment with published recommendations. Complex or ambiguous cases requiring extended reasoning may produce lower BERT Scores due to legitimate treatment variability rather than model error.

D. Limitations of BERT Score in Clinical Evaluation

While BERT Score provides valuable insights into semantic similarity, several limitations must be acknowledged. First, semantic similarity does not guarantee clinical correctness; a response may be semantically similar to a reference while containing factually incorrect recommendations [26]. Second, BERT Score exhibits reduced sensitivity to numerical values; dosage errors (e.g., "5 mg" vs "500 mg") may not be adequately penalized due to similar contextual embeddings [27]. Third, the metric does not capture reasoning quality or logical consistency in treatment sequencing.

These limitations underscore the importance of multidimensional evaluation frameworks that combine automated semantic metrics with expert clinical review, safety assessments, and guideline concordance checks [28]. BERT Score should be viewed as a scalable screening tool rather than a definitive measure of clinical validity.

E. Implications for Clinical Decision Support Implementation

The results support the potential deployment of Claude Opus 4.5 as a clinical decision support tool in dental practice, with appropriate safeguards. The model demonstrates the capacity to generate semantically appropriate treatment recommendations across multiple specialties, potentially assisting clinicians with treatment planning, documentation, and educational applications [29]. However, the model should function as a "copilot" requiring human oversight rather than an autonomous diagnostic system [30].

Future implementation should incorporate 1) explicit uncertainty quantification in model outputs; 2) integration with domain-specific knowledge bases and clinical guidelines; 3) mandatory clinician review before treatment execution; and 4) continuous monitoring for performance degradation or emerging error patterns [31]. The ethics and governance framework proposed by Rokhshad et al. provides a valuable foundation for the responsible deployment of LLMs in dental clinical settings [32].

F. Study Limitations

Several limitations should be considered when interpreting these results. First, the use of published case reports as ground truth assumes that reported treatments represent optimal clinical

decisions, which may not always hold. Second, the study evaluated text-based clinical reasoning without incorporating radiographic or other imaging data essential to dental diagnosis. Third, the cross-sectional design cannot assess longitudinal performance stability or model drift. Fourth, the evaluation relied solely on automated BERT Score metrics without expert clinical review of individual outputs. Finally, the unequal specialty distribution may limit generalizability to underrepresented domains.

VI. Conclusion

This study established a BERT Score-based benchmarking framework for evaluating LLM performance in dental clinical decision support. Claude Opus 4.5 demonstrated strong semantic alignment with published treatment recommendations (mean BERT Score F1 = 0.8199 ± 0.0144), significantly exceeding the 0.80 acceptability threshold ($t = 14.90$, $p < 0.001$, Cohen's $d = 1.38$) with consistent performance across nine dental specialties (Kruskal-Wallis $H = 3.07$, $p = 0.879$). The study contributes a reproducible, training-free semantic evaluation pipeline for open-ended clinical text, provides the first cross-specialty generalizability evidence for dental LLM evaluation, and characterizes the speed-accuracy relationship relevant to clinical deployment.

Several limitations should be acknowledged, including the absence of expert clinical validation, reliance on text-based reasoning without radiographic data, and unequal specialty distribution. The findings support the potential of LLMs as clinical decision support tools in dentistry while highlighting the need for comprehensive evaluation frameworks that extend beyond semantic similarity to encompass clinical accuracy, safety, and guideline adherence. Future research should integrate expert clinical validation, multimodal evaluation incorporating radiographic interpretation, comparative benchmarking across LLM families, and prospective studies in clinical deployment settings. The standardization of evaluation methodologies will be essential as LLM applications in healthcare continue to expand

Acknowledgment

This research was funded by the Indonesia Endowment Fund for Education (Lembaga Pengelola Dana Pendidikan - LPDP), the Ministry of Finance, Republic of Indonesia. The authors gratefully acknowledge the financial support provided by LPDP that made this research possible. The first author would like to express profound gratitude to the Medical and Health Sciences Doctoral Program, Faculty of Medicine, Public Health, and Nursing, Universitas Gadjah Mada (UGM), where this research was conducted as part of a doctoral dissertation series. The authors also acknowledge the use of Claude Opus 4.5 (Anthropic) for generating clinical decision support responses evaluated in this study. The AI tool was used solely as the subject of evaluation, not in the preparation of this manuscript. All statistical analyses and interpretations were performed by the authors using JAMOVI (Version 2.6.44).

Understanding IT Product Purchasing Behavior of MSMEs Using Sequential Pattern Mining Approaches

Rendro Kasworo*, R.Rizal Isnanto, Budi Warsito
Doctoral Program of Information Systems-Postgraduate School,
Universitas Diponegoro, Semarang, Indonesia, 50241

***Abstract*—Sequential pattern mining is a crucial analytical method for understanding purchasing behavior and uncovering hidden patterns in transactional data. Unlike most prior studies that apply sequential pattern mining primarily in consumer-oriented retail settings or evaluate algorithms in isolation, this study investigates IT product purchasing behavior among Small and Medium Enterprises (SMEs) within a B2B digital transformation context through a direct comparative evaluation of three widely used algorithms: Apriori, PrefixSpan, and CloSpan. A series of controlled experiments was conducted on the same transactional datasets to assess algorithm performance in terms of accuracy, computational efficiency, and redundancy reduction. The results show that Apriori discovers exhaustive patterns at the cost of higher computational complexity, PrefixSpan achieves faster sequence extraction with balanced accuracy, and CloSpan effectively reduces redundancy by generating closed sequential patterns. Beyond pattern discovery, this study translates support, confidence, and lift metrics into actionable decision-support insights, highlighting how different algorithmic characteristics can be aligned with retention strategies, service bundling, and targeted interventions. These findings provide distinct methodological and practical contributions by positioning sequential pattern mining as a data-driven decision-support tool to accelerate digital transformation initiatives among SMEs in the IT product ecosystem.**

***Keywords*—Sequential pattern mining; Apriori; PrefixSpan; CloSpan; SMEs; digital transformation**

I. Introduction

Micro, Small, and Medium Enterprises (MSMEs) are important for economic growth, especially in developing countries. They not only contribute significantly to Gross Domestic Product (GDP) but also create more jobs and maintain economic stability [1], [2]. However, MSMEs face numerous challenges in adopting and utilizing Information Technology (IT) products. Various obstacles, including low digital literacy, limited capital, and a lack of solutions tailored to business needs, often hinder the digitalization process.

In recent years, sequential pattern mining (SPM) has proven to be an effective data mining technique for discovering relational patterns and transaction sequences in large-scale datasets [3],[4]. In contrast to association rule mining, which only identifies relationships between items without considering order, SPM is capable of uncovering temporal patterns in purchasing behavior [5]. This capability is highly relevant for MSMEs as it can reveal product adoption stages— for example, customers who initially purchase internet connectivity services and subsequently switch to digital productivity applications or content services. Such information can serve as a valuable reference for IT product providers in developing more personalized and adaptive marketing strategies.

Several algorithms have been developed to support the SPM process. Apriori is a fundamental algorithm widely used to identify frequent itemsets; however, its complex candidate generation process can lead to efficiency issues [6]. PrefixSpan utilizes a more efficient pattern-growth approach through prefix-based partition exploration without repeatedly generating candidates [7]. Meanwhile, CloSpan focuses on mining closed sequential patterns, producing more concise, non-redundant, and semantically meaningful results [8]. According to Arena et al., each algorithm presents its own advantages and limitations in terms of accuracy, computational complexity, and scalability. Thus, it is essential to carry out comparative evaluations in certain contexts [9].

Although SPM has been widely applied in retail and e-commerce domains, its application remains limited in the context of IT product adoption by MSMEs. Most previous research has focused on consumer (B2C) markets and has not adequately explored the business-to-business (B2B) context involving MSMEs. Furthermore, relatively few studies have compared the performance of several SPM algorithms simultaneously in analyzing the IT product purchasing behavior of MSMEs.

For instance, research by Aloysius and Binu demonstrated the application of PrefixSpan in the retail sector to organize products based on consumers' sequential shopping patterns, illustrating a typical application of SPM in the B2C domain [10]. Trivonanda et al. applied SPM in e-commerce recommendation systems in Indonesia and highlighted the dominant use of SPM in the consumer context [11]. Additionally, a literature review by Ezeife specifically mapped SPM-based e-commerce recommendation methods and emphasized algorithm performance in the B2C realm [12]. Similarly, Anwar and Uma examined the use of PrefixSpan in cross-domain recommendation systems, such as book recommendations, but remains within the consumer consumption paradigm [13].

In the telecommunications sector, studies examining service bundling recommendations do exists; however, they generally rely on other methods, such as constructive preference elicitation [14], instead of SPM. Other research in the telco field has applied SPM to customer churn prediction [15], with a focus on behavioral sequences leading to churn rather than sequences of IT product adoption. Moreover, many recent churn studies have shifted to explainable AI (XAI) approaches, further

*Corresponding author.

indicating that SPM studies in the context of product adoption remain relatively scarce [16].

Meanwhile, the broader MSME literature primarily discusses the adoption of digital technology. For example, Ballerini et al. examined factors influencing e-commerce adoption in manufacturing MSMEs [17], Kgakatsi et al. analyzed the impact of Big Data usage on the performance of MSMEs in South Africa [18], and Cooper et al. highlighted the role of artificial intelligence in new product development in MSMEs [19]. However, no prior research has specifically examined the sequence patterns of IT product purchases by MSMEs in a B2B context using a comparative SPM algorithm approach.

This study aims to identify sequential patterns of IT product purchases among MSMEs by applying and comparing the Apriori, PrefixSpan, and CloSpan algorithms, while evaluating their respective strengths and limitations in terms of accuracy, computational efficiency, and pattern redundancy reduction. By doing so, this research addresses an existing gap in the literature by providing empirical evidence on the comparative performance of SPM algorithms and offering actionable insights to support data-driven decision-making and digital transformation initiatives within the MSME IT ecosystem.

The subsequent literature review section discusses related studies on MSMEs, data-driven marketing, and SPM techniques. The methodology section outlines the research design, data collection, and preprocessing procedures, and the application of the Apriori, PrefixSpan, and CloSpan algorithms. The results and discussion section presents and analyzes the experimental findings and identifies sequential purchasing patterns. Finally, the conclusion section summarizes the key findings, highlights the contributions of the study, and outlines directions for future research.

II. Literature Review

A. MSMEs and the Challenges of Adopting Information Technology

Micro, Small, and Medium Enterprises (MSMEs) constitute a vital sector of the global economy, especially in developing countries. In Indonesia, MSMEs contribute approximately 61.7% of the national Gross Domestic Product (GDP) and provide employment for 97% of the workforce, making them the backbone of the national economy [20]. As a crucial economic pillar, MSMEs play an essential role not only as drivers of economic growth but also in maintaining social stability through job creation.

B. Data-Driven Marketing and Recommendation Systems

The development of digital technology has brought major changes, including the adoption of data-driven marketing approaches, in which strategic decisions are based on the analysis of customer behavior derived from historical transaction data and digital interactions. This approach enables companies to better understand consumer preferences and more accurately forecast future needs. In the context of MSMEs, data-driven marketing enhances the effectiveness of marketing strategies through personalized offerings, cross-selling, and product bundling tailored to customers' actual needs.

C. Sequential Pattern Mining

Sequential Pattern Mining (SPM) is a subfield of data mining that explores the discovery of sequential patterns within transaction data or temporal interactions [4], [21], [22]. Unlike static association rule mining, SPM enables researchers and practitioners to identify not only correlations among items that frequently appear together but also the order in which these items occur.

SPM has been widely applied across various fields, including retail, e-commerce, healthcare, and telecommunications. For instance, in retail environments, SPM helps analyze consumer shopping patterns, such as their tendency to purchase hardware before software or support services [23],[24]. In healthcare, SPM assists in monitoring medication usage and patient diagnoses, which are valuable for clinical decision support systems.

There are three main aspects commonly addressed in SPM research, namely:

1) Pattern accuracy: The extent to which an algorithm identifies patterns that accurately represent real-world behavior.

2) Computational efficiency: This aspect relates to execution time and resource requirements, especially when processing large-scale datasets.

3) Redundancy reduction: This refers to the ability to generate concise and meaningful patterns without duplication or irrelevant variations.

D. Main Algorithms in Sequential Pattern Mining

Three prominent algorithms discussed in the literature are Apriori, PrefixSpan, and CloSpan.

1) Apriori: Apriori is a classical algorithm originally introduced to discover frequent itemsets and later adapted for use in SPM. This algorithm employs a candidate generation-and-test approach that requires enumerating all possible candidate patterns [25]. While this approach is comprehensive, it suffers from high computational complexity, especially when applied to large datasets.

2) PrefixSpan (Prefix-Projected Sequential Pattern Mining): PrefixSpan introduces a pattern-growth paradigm by dividing the dataset into prefix-based projected databases. This method avoids explicit candidate exploration and improves processing efficiency. Numerous studies have shown that PrefixSpan outperforms Apriori in large-scale datasets.

3) CloSpan (Closed Sequential Pattern Mining): CloSpan is designed to address the problem of redundant results. The algorithm only generates closed patterns, which are patterns that do not have any superpatterns with the same support. This method produces more concise and meaningful results, facilitating interpretation by researchers and practitioners.

Despite widespread use, existing SPM approaches continue to face several challenges and limitations. Apriori-based methods suffer from high computational complexity due to exhaustive candidate generation, rendering them less efficient for large-scale transactional data. PrefixSpan improves

efficiency by eliminating candidate generation; however, it may still produce a substantial number of redundant patterns, which can complicate interpretation. CloSpan addresses redundancy by mining closed sequential patterns but may overlook infrequent yet potentially meaningful sequences.

Moreover, most prior studies applying SPM focus predominantly on consumer-oriented (B2C) contexts, such as retail and e-commerce, while empirical investigations in MSME-oriented and B2B IT product adoption remain limited. Existing research also tends to evaluate algorithms in isolation rather than through direct comparative analysis using an identical dataset. These limitations highlight the need for a comprehensive comparative evaluation of SPM algorithms in the context of MSME IT product purchasing behavior, particularly to support data-driven decision-making and digital transformation initiatives.

III. Methodology

A. Research Design

This study employed a comparative experimental approach to assess the performance of three SPM algorithms: Apriori, PrefixSpan, and CloSpan. The research design focused on analyzing IT product purchasing patterns among MSMEs based on transaction data. Each algorithm was tested separately on the same dataset to ensure an unbiased comparison of results.

B. Data Collection

The data used in this study were collected from transaction records of IT product purchases made by MSMEs operating in the trade and services sectors. The data collection process involved two main stages.

First, primary data were collected from actual transactions recorded by MSMEs and IT service provider partners. These transaction records included purchase dates, product names, product categories (e.g., High Speed Internet, Metro Ethernet, ASTINet, Content, Music, Games, and Managed Capacity Network), and the sequence of purchases made by customers within a specific time period. These primary data became the foundation for building a sequence database for analysis using the SPM algorithm.

Second, secondary data were gathered from sales reports from authorized IT product distributors and B2B e-commerce databases. These data served as a benchmark dataset to support the analysis and ensure that the patterns identified were not limited to specific MSMEs but also reflected broader trends in the IT product distribution sector. Table I presents sample data from IT product sales reports.

Table I illustrates transaction records for IT products purchased by MSMEs and authorized distributors. Each transaction includes information on the customer, transaction ID, purchase time, product name, product category, quantity, price, and data sources. Data obtained from MSMEs represent actual transactions and serve as the primary data source, while data from distributors and e-commerce function as secondary sources for comparison. Overall, the table describes IT product consumption patterns in the trade and services sector, which are then analyzed to identify purchasing sequence patterns using the SPM approach.

C. Data Preprocessing

The data preprocessing stage aimed to ensure consistency and suitability of the collected data before applying the SPM algorithm. This stage involved removing duplicate records, correcting data entry errors, handling missing values, and normalizing product name formats to ensure uniformity. Products were categorized into seven main groups: High Speed Internet, Metro Ethernet, ASTINet, Content, Music, Games, and Managed Capacity Network.

Next, the data were sorted based on each customer's transaction time to obtain a valid purchase sequence. In the final stage, the data were converted into a sequence database consisting of the purchase sequence of each customer, which was subsequently processed using the Apriori, PrefixSpan, or CloSpan algorithms to identify meaningful purchase patterns.

TABLE I. Sample Data of IT Product Sales Report

Customer	Transaction ID	Date and Time of Transaction	Product Name	Category	Amount	Price	Description
UMKM01	TRX001	2025-01-05 10:30:00	High Speed Internet Plan A	High Speed Internet	1	500,000	Recorded by the MSME
UMKM01	TRX002	2025-01-15 15:45:00	Metro Ethernet 10 Mbps	Metro Ethernet	1	2,500,000	Recorded by the MSME

DIST04	TRX106	2025-03-20 15:30:00	Premium Music Streaming	Music	2	240,000	Listed in the official distributor report

TABLE II. DATA PREPROCESSING

Customer	Transaction Sequence	Date and Time of Transaction	Product Name	Category
UMKM01	1	2025-01-05 10:30:00	High Speed Internet Plan A	High Speed Internet
UMKM01	2	2025-01-15 15:45:00	Metro Ethernet 10 Mbps	Metro Ethernet
UMKM02	1	2025-02-02 09:20:00	ASTINet Basic	ASTINet
UMKM02	2	2025-02-12 13:00:00	Premium Content Streaming	Content
UMKM03	1	2025-03-07 11:10:00	Online Game Voucher	Game
UMKM04	2	2025-03-18 14:00:00	Managed Capacity Network Silver	Managed Capacity Network
DIST01	1	2025-01-06 09:00:00	High Speed Internet Plan B	High Speed Internet
DIST02	1	2025-01-25 16:30:00	Metro Ethernet 20 Mbps	Metro Ethernet
DIST02	1	2025-02-05 10:15:00	ASTINet Pro	ASTINet
DIST03	2	2025-02-15 12:30:00	Basic Content Streaming	Content
DIST04	1	2025-03-10 14:45:00	Online Game Voucher	Game
DIST04	1	2025-03-20 15:30:00	Premium Music Streaming	Music

The preprocessing results presented in Table II show the sequence of IT product purchases for each customer after data cleaning and normalization. Each customer (MSME or distributor) is represented by a transaction ID sorted by date to identify sequential purchasing patterns. For example, UMKM01 initially purchased High Speed Internet Plan A and subsequently purchased Metro Ethernet services. Similarly, UMKM03 purchased an online game voucher, followed by a music streaming product.

Product categories were standardized into seven main groups to ensure consistent analysis. This format prepares the data for processing using the SPM algorithm to identify customers' most frequent purchase sequential patterns.

The pre-processed data were converted into a sequence database in the next stage. This process was accomplished by grouping all transactions by customer and sorting them by purchase time.

Each transaction in the sequence was represented as an element in a sequence, showing that each customer had a unique purchase sequence. For example, customer UMKM01 had the sequence [High Speed Internet → Metro Ethernet], while customer UMKM03 had the sequence [Game → Music].

Customers who only made one transaction were still categorized as a single sequence, for example, UMKM04 → [Manage Capacity Network].

TABLE III. EXAMPLE OF PURCHASE SEQUENCE REPRESENTATION

Customers	Purchase Sequence
UMKM01	[High Speed Internet → Metro Ethernet]
UMKM02	[ASTINet → Content]
UMKM02	[ASTINet → Content]
UMKM03	[Game → Music]
UMKM04	[Managed Capacity Network]
DIST01	[High Speed Internet]
DIST02	[Metro Ethernet → ASTINet]
DIST03	[Content]
DIST04	[Game → Music]

This representation allows for systematic analysis of the entire purchasing patterns of various customers. The sequence database served as the primary input for SPM algorithms, including AprioriAll, PrefixSpan, and CloSpan, to identify recurring patterns that describe customers' tendencies to purchase IT products sequentially. Table III shows an example of a sequence database representation.

D. Pattern Analysis

At this stage, the data processed into a sequence database were analyzed using an SPM approach to identify sequential patterns in customer transactions. Three main algorithms were employed: AprioriAll, PrefixSpan, and CloSpan.

1) AprioriAll was used to find correlations between products that frequently appear together or sequentially, by measuring support and confidence as indicators of pattern strength.

2) PrefixSpan was applied to extract frequently occurring purchase sequences by developing prefixes from existing sequences without explicitly generating candidate patterns.

3) CloSpan was chosen to generate closed sequential patterns that cannot be expanded further without lowering the support value, resulting in a more concise but informative representation of the pattern.

E. Pattern Evaluation

After obtaining purchasing patterns using the SPM algorithm, a pattern evaluation stage was conducted to assess the validity and strength of the correlations among items in the sequence. This evaluation was conducted using several standard measures, including:

1) Support: This metric measures how frequently a particular pattern appears in the entire transaction database. A high support value indicates that the pattern is popular and generally relevant.

2) Confidence: This metric indicates the probability that a subsequent item or sequence occurs after the initial pattern has occurred. Higher confidence values indicate stronger and more reliable associations.

3) Lift (optional): This metric measures how frequently a pattern occurs compared to its probability of occurring by chance. It helps identify patterns that are substantially significant rather than coincidental.

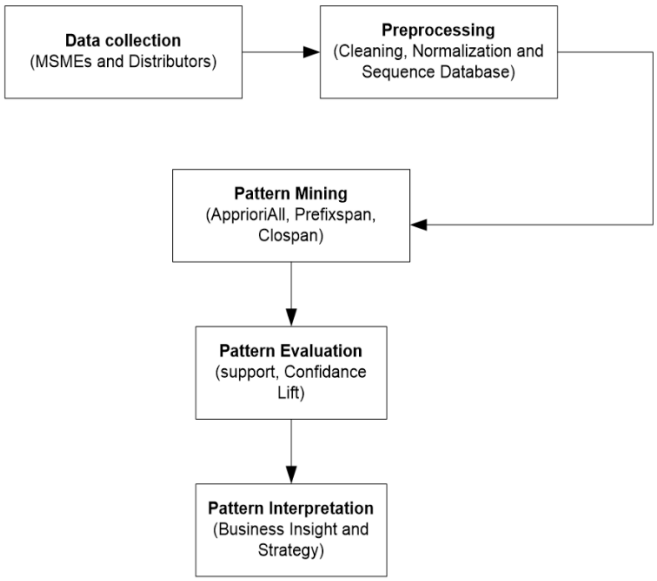

Fig. 1. Research methodology stages.

These metrics allowed researchers to filter meaningful patterns and eliminate those with low frequency or weak correlations. The evaluation process led to validated findings suitable for interpretation in the context of IT product purchasing behavior among MSMEs and distributors.

F. Pattern Interpretation

Pattern interpretation was performed after evaluating metrics, such as support, confidence, and lift, to ensure their validity and significance. At this stage, the identified sequential purchase patterns were related to the real-world context of MSME consumer behavior and IT product distribution practices. For example, the Game → Music pattern suggests that customers who purchase game-related services are likely to subsequently purchase digital music products. Similarly, the pattern Content → High Speed Internet indicates an increased demand for high-speed internet access following the purchase of digital content.

This interpretation is beneficial for analyzing purchasing behavior and serves as a foundation for formulating business strategies, such as product bundling, personalized service recommendations, and optimized IT service distribution. Thus, the identified patterns offer not only theoretical contributions but also practical value for decision-making and the development of more targeted marketing strategies. Fig. 1 illustrates the flowchart of the research stages.

IV. Results and Discussion

A. Results

This section presents the key findings from the SPM analysis of IT product transaction data that were preprocessed into a sequence database. The results highlight:

- Associations and purchasing sequence tendencies among categories/products.
- Consistent and recurring patterns observed for both MSME customers and distributors.
- Practical implications for service bundling strategies, recommendations, and service improvement.

The results are presented by algorithm (ApprioriAll, PrefixSpan, and CloSpan) and customer segment (MSMEs vs. distributors), along with evaluation metrics (support, confidence, and lift), to assess the strength and significance of the identified patterns.

B. Test Simulation Scenario

The dataset used in this study consists of transactional records from 500 MSME customers (CUST0001–CUST0500). The data were generated to simulate realistic IT product purchasing behavior, with each customer having between one and six sequential transactions recorded over the period from January to March 2025. The dataset includes the following characteristics:

1) Number of transactions per customer: Randomly generated between one and six transactions.

2) Product categories: Seven main groups (High Speed Internet, Metro Ethernet, ASTINet, Content, Music, Game, and Manage Capacity Network), each comprising several product variants.

3) Transaction attributes: Customer ID, transaction ID, transaction date and time, product name, category, quantity, and price.

4) Time period: Transactions conducted between January and March 2025 with random time sequences representing the chronological order of purchases.

Table IV presents the top ten purchase sequence rules ranked by confidence for all customers during the January-March 2025 period. The inclusion of support and lift values enables comparison of pattern consistency and relevance for service recommendations and bundling strategies.

In Table IV, the pattern with the highest confidence shows a consistent transition tendency, even though it may not be the most frequent. The rules ASTINet → Content (confidence = 0.67; lift = 1.90) and High Speed Internet → Content (confidence = 0.66; lift = 1.87) indicate that the purchase of content services commonly follows the activation of connectivity services. The patterns Managed Capacity Network → Game (confidence = 0.62; lift = 1.78) and Content → Game (confidence = 0.58; lift = 1.67) suggest strong cross-selling potential within entertainment-related services. Although the pattern Content → Managed Capacity Network has merely 1.6% support, it exhibits a very high lift value (3.36), making it a worthwhile target for marketing campaigns. Regarding service upgrades, the rules Game → ASTINet (confidence = 0.57; lift = 2.86) and ASTINet → Metro Ethernet (confidence = 0.53; lift = 1.43) represent promising upgrade paths toward more reliable connectivity. Meanwhile, Metro Ethernet → Metro Ethernet stands out as a repeat or renewal pattern (confidence = 0.52; lift = 1.40), as does Music → Music (confidence = 0.50; lift = 2.23), indicating strong subscription retention.

Table V shows the top ten purchase sequence rules based on support, reflecting the most common pattern observed in the MSME segment from January to March 2025. The table

includes the columns Antecedent, Consequent, Pattern, Length, Support Count, Support, Confidence, and Lift.

Based on Table V, the most prevalent patterns in the MSME segment are dominated by repeat or renewal behavior (X→X). The sequence Metro Ethernet → Metro Ethernet is the most frequent (support = 0.1960; confidence = 0.5241; lift = 1.4012), followed by Content → Content (support = 0.1740; confidence = 0.4971; lift =1.4204) and Game → Game (support = 0.1560; confidence = 0.4509; lift = 1.3031). Similarly, High Speed Internet → High Speed Internet (support = 0.1160; confidence = 0.3816; lift = 1.2552) and ASTINet → ASTINet (support = 0.0980; confidence = 0.4900; lift = 2.4500) also show strong retention. The presence of the trigram Metro Ethernet → Metro Ethernet → Metro Ethernet (two rules with support values of 0.0900 due to identical three-step patterns) indicates persistent subscription behavior. Other recurring patterns, such as Content → Content → Content (support = 0.0720) and Music → Music (support = 0.0720; confidence = 0.3214; lift = 1.4349), reinforce the dominance of retention-oriented patterns. Although the results focus on support, the high lift observed for certain services—such as Managed Capacity Network → Managed Capacity Network (support = 0.0760; confidence = 0.4471; lift = 2.6298)—shows strong repeat associations within more specific segments. These findings emphasize the importance of retention, renewal strategies, and loyalty initiatives for services with the highest repeat customer reach, while also identifying high-value services with high lift for more targeted offerings.

TABLE IV. TOP-10 SEQUENTIAL PURCHASE RULES BY CONFIDENCE: MSME SEGMENT

Antecedent	Consequent	Pattern	Length	Support Count	Support	Confidence	Lift
ASTINet → Content	Content	ASTINet → Content → Content	3	8	0.0160	0.6667	1.9048
High Speed Internet → Content	Content	High Speed Internet → Content → Content	3	19	0.0380	0.6552	1.8719
Managed Capacity Network → Game	Game	Managed Capacity Network → Game → Game	3	8	0.0160	0.6154	1.7786

Metro Ethernet	Metro Ethernet → Metro Ethernet	Metro Ethernet → Metro Ethernet → Metro Ethernet	3	45	0.0900	0.2406	1.2278
Managed Capacity Network	Managed Capacity Network	Managed Capacity Network → Managed Capacity Network	2	38	0.0760	0.4471	2.6298
Content → Content	Content	Content → Content → Content	3	36	0.0720	0.4138	1.1823
Music	Music	Music → Music	2	36	0.0720	0.3214	1.4349

Table VI shows the ten sequential purchase rules based on the highest lift values. Lift indicates how strongly the antecedent and consequent are linked beyond random chance; a lift value greater than one indicates a positive association, meaning the higher the value, the stronger the relative correlation. Unlike confidence, which reflects the certainty of a transition, or support, which reflects prevalence, lift emphasizes patterns with strategic value even if they are not the most common, such as certain repeat patterns or strong upgrade paths in customer subsegments. Therefore, Table VI complements Tables IV (confidence-based) and Table V (support-based).

TABLE VI. TOP 10 RULES BY LIFT

Antecedent	Consequent	Pattern	Length	Support Count	Support	Confidence	Lift
Managed Capacity Network	Managed Capacity Network → ASTINet	Managed Capacity Network → Managed Capacity Network → ASTINet	3	3	0.0060	0.0353	3.5294

Table VI also reveals the sequential purchase rules based on lift values, which measure the strength of the correlation between the antecedent and consequent beyond random chance. A lift value greater than one indicates a positive association, with higher values reflecting stronger relative correlations. In contrast to support, which emphasizes how common a pattern is, or confidence, which emphasizes the certainty of a transition, lift highlights a strong pattern even if it does not occur frequently. These findings suggest that high-lift but low-support patterns are suitable for targeted interventions. In contrast, high-lift patterns with higher support are relevant for larger-scale retention or bundling programs [26], [27].

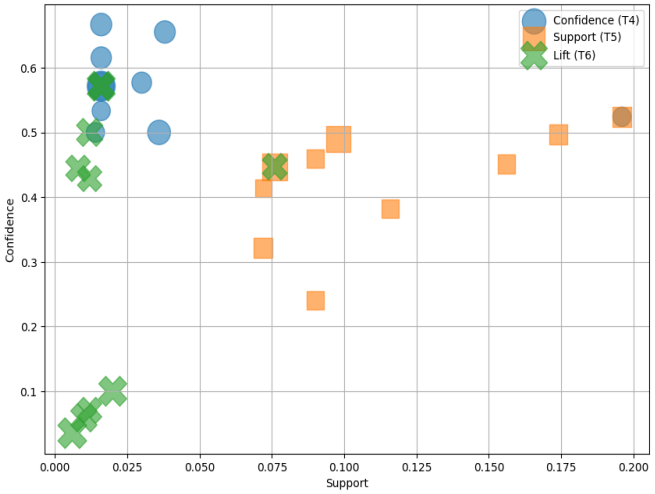

Fig. 2. Sequential comparison chart (confidence, support, and lift).

Furthermore, to provide a more comprehensive perspective, the analysis results in Tables IV (based on confidence), Table V (based on support), and Table VI (based on lift) are presented in the form of a comparison chart in Fig. 2. This visualization demonstrates how each metric highlights different patterns: rules with high confidence indicate consistency in transition behavior, rules with high support reflect the prevalence of purchasing behavior, and rules with high lift reveal strategic opportunities even when they occur infrequently. Therefore, combining these three perspectives offers a stronger foundation for developing marketing strategies, whether aimed at maintaining consistent customer behavior, increasing subscription retention, or implementing targeted strategic intervention value.

C. Discussion

The research results indicate that IT product purchasing behavior among MSMEs is strongly characterized by repetition and renewal patterns within the same service category. Frequent sequences such as Metro Ethernet → Metro Ethernet, Content → Content, Games → Games, and ASTINet → ASTINet indicate that once MSMEs adopt a particular IT service, they tend to continue using or renewing that service over time. This behavior reflects a preference for service stability and reliability, which is essential for business operations that rely on digital connectivity and continuous service availability.

Sequential patterns with high confidence levels further demonstrate a gradual process of digital adoption among MSMEs. Connectivity-related services, such as High-Speed Internet and ASTINet, often precede the adoption of content- or entertainment-based services. This sequence implies that MSMEs prioritize establishing a stable digital infrastructure before expanding into additional digital services. Such a progression aligns with the incremental nature of digital transformation, in which basic infrastructure is developed before higher-level digital capabilities are adopted.

Patterns with high support scores highlight the widespread prevalence of retention-oriented behavior among MSMEs. The dominance of repeat subscription patterns suggests that

customer retention and service renewals are more influential than frequent product switching. This finding emphasizes the importance of long-term customer relationship management, where maintaining service quality and reliability is a key factor in maintaining MSME engagement with IT service providers.

Conversely, patterns with high upgrade values reveal strategic opportunities within more specific market segments. Certain services exhibit strong associations despite lower overall frequency, indicating a concentrated but highly engaged user group. These high upgrade patterns are highly relevant for targeted marketing strategies, customized service integrations, and differentiated loyalty programs. While high support patterns are suitable for broad retention strategies, high upgrade patterns offer insights for focused interventions aimed at specific MSME segments.

The combined use of confidence, support, and lift metrics provides a comprehensive perspective on MSME purchasing behavior. Confidence captures consistent switching tendencies, support reflects dominant usage patterns, and lift highlights strong associations beyond random occurrence. Integrating these complementary metrics enables IT service providers to design balanced strategies that combine mass retention initiatives with targeted offerings, thereby enhancing data-driven decision-making.

These results collectively demonstrate that SPM is an effective approach for uncovering dominant and nuanced behavioral patterns in MSME IT product adoption. By translating these patterns into actionable insights, IT service providers can systematically and data-drivenly improve retention strategies, optimize service offerings, and support MSMEs' ongoing digital transformation.

From both methodological and practical perspectives, this study contributes to the SPM literature by providing empirical evidence on the comparative behavior of Apriori, PrefixSpan, and CloSpan when applied to the same B2B transactional dataset. Unlike prior studies that primarily emphasize pattern discovery in consumer-oriented contexts, this work clarifies the distinct analytical roles of support, confidence, and lift metrics in decision-oriented interpretation. Furthermore, the findings can be operationalized into actionable guidelines for IT product providers, where high-support patterns inform large-scale retention and renewal programs, high-confidence patterns support service upgrade recommendations, and high-lift, but lower-support patterns enable targeted interventions for specific MSME segments. This integrated interpretation strengthens data-driven decision-making and supports the digital transformation of MSMEs.

V. Conclusion

This study demonstrates that sequential pattern mining is an effective approach for identifying IT product purchasing behavior among MSMEs. The comparative analysis of the Apriori, PrefixSpan, and CloSpan algorithms reveals distinct algorithmic strengths: Apriori effectively identifies high-support patterns, PrefixSpan provides efficient sequence extraction, and CloSpan generates concise closed patterns by reducing redundancy. The empirical results further indicate that confidence values capture consistent transition behavior, support values reflect the prevalence of repeat and renewal purchases, and lift values highlight patterns with strong strategic significance.

Beyond methodological contributions, the findings reveal key characteristics of MSME digital adoption behavior. The dominance of repeat and renewal patterns underscores the importance of service continuity, while high-confidence and high-lift sequences suggest staged adoption pathways and targeted opportunities for service bundling, retention strategies, and differentiated offerings. These insights provide practical value for IT service providers in designing data-driven marketing strategies aligned with MSME digital transformation initiatives.

From a theoretical perspective, this study contributes to sequential pattern mining research by clarifying the distinct analytical roles of support, confidence, and lift through a direct comparative evaluation of Apriori, PrefixSpan, and CloSpan within a B2B MSME context. From a practical perspective, the findings offer actionable guidance for IT product providers, whereby high-support patterns inform large-scale retention strategies, high-confidence patterns support service upgrade pathways, and high-lift patterns enable targeted interventions for specific MSME segments.

Despite these contributions, this study is limited to transactional data collected within a specific observation period and service domain. Future research may extend this work by incorporating longer time horizons, cross-regional datasets, and advanced machine learning or hybrid modeling approaches to enhance predictive capabilities. The integration of non-transactional factors, such as organizational characteristics, digital readiness, and socio-demographic attributes, may further enrich behavioral interpretation. In addition, the development of analytics dashboards or interactive recommendation systems based on the proposed framework represents a promising direction for practical implementation and sustained digital transformation among MSMEs.

Collaborative Dual-Framework Defense: CTI and LLM-Based Enhanced Smishing Detection

Li Guangliang, Kalaivani Selvaraj, Mahinderjit Singh*
School of Computer Sciences, University Sains Malaysia, 11800 Penang, Malaysia

***Abstract*—Smishing has become a severe cybersecurity threat. Attackers now use AI and social engineering to craft more sophisticated campaigns. To address this challenge, this study proposes a dual-layer detection framework. It combines cyber threat intelligence (CTI), machine learning, and a large language model (LLM). The framework uses 22 features built from 2,811 real SMS messages. These features are categorized as content-based, context-based, and Indicators of Compromise (IOC)-based features. Five machine learning models were evaluated. XGBoost, trained with a 70% training, 10% validation, and 20% test split, achieved the best performance. It had a recall of 92.08% and an F1-score of 94.66%. For borderline cases, the study experimented with 4 LLMs (including GPT-4o and LLaMA 3). They served as a semantic verification layer. All models achieved a recall rate above 98.5% and produced human-readable explanations. The study demonstrated that these 4 models are complementary verifiers rather than main classifiers. The results show that structured threat intelligence used during feature engineering improves machine learning model performance. With semantic reasoning, the framework also generates accessible reports for non-specialists. This lowers the barrier for effective smishing detection.**

***Keywords*—Smishing detection; cyber threat intelligence; XGBoost; semantic verification; large language model**

I. Introduction

Smishing remains one of the most widespread cyber threats globally, resulting in significant economic losses [1]. According to the latest report from the Anti-Phishing Working Group, both the frequency and complexity of such attacks have continued to rise recently [2].

Although most organizations train staff to avoid phishing attacks, such efforts are of limited value. Cybersecurity awareness training does not relate to autonomous detection of phishing attacks [3]. Humans struggle to recognize cyberattacks due to stress, burnout, or security fatigue. Cybercriminals exploit these weaknesses as attack points [4]. For this reason, technical methods must be stable. Technology faces two main challenges. First, AI enables phishing that is almost indistinguishable from natural writing, often powered by LLMs [5]. Another study found that AI-generated content is more effective than human-written content [6]. These contents are also easier to bypass commercial anti-phishing systems [7]. Second, while existing detection systems perform well, interpretability is still challenging for users of neural network-based techniques [8].

The purpose of CTI is to provide high-dimensional intelligence features. These help models understand deeper tactical threat characteristics, not just static content. Thus, the CTI guidance feature project upgrades content recognition to context and intent recognition. This approach systematically enhances the test model's performance and robustness. It is distinct from traditional attack identification, which only analyzes content [9], [10]. In addition, LLMs extract rich semantic representations and generate coherent, human-readable interpretations [11]. Some similar studies have been proposed in theory, but experimental evidence is lacking [12]. Combining CTI-guided feature engineering with an LLM is crucial for decision support and model transparency. There is a gap in related research on mobile platforms.

To address these issues, this study suggests a two-part smishing detection model for mobile platforms. The first part uses a CTI-driven feature engineering machine learning model for real-time detection. LLMs are then used for cross-validation and explanation. This collaborative design aims to achieve efficient detection with better precision and decision transparency.

The primary contributions of this research can be summarized as follows:

This research introduces a CTI-guided feature engineering framework, which integrates content and contextual metrics to enhance detection accuracy and model adaptability against smishing attacks.

A novel two-layer detection architecture that combines an ensemble learning-based classifier with an LLM for semantic verification.

A novel role for LLMs in smishing detection as explainable validators, assisting security analysts in improving interpretability.

The remainder of this study is structured as follows: Section II provides a comprehensive review of prior studies on smishing threats, feature engineering and detection approaches; Section III elaborates on the proposed dual-layer framework, including dataset description, feature engineering, model construction, and an LLM-driven semantic verification mechanism; Section IV presents the experimental evaluation and analyzes the model performance of the machine learning model and the two-layer integration framework. Finally, Section V concludes the study and highlights prospective directions for future research.

II. Related Work

The rising sophistication of smishing attacks, especially those enhanced by artificial intelligence (AI), represents a major challenge for cybersecurity defenses. This literature review

*Corresponding author.

addresses three aspects to provide background for this research. First, it reviews the evolution of smishing and AI-enabled attacks, focusing on unique mechanisms and emerging threats. Next, it explores how CTI can support detection and assist with feature engineering. Finally, it evaluates current phishing detection techniques, from traditional machine learning to modern LLMs, and compares their strengths and weaknesses in tackling adaptive threats.

A. Smishing Emerges and AI-Driven Threats

Smishing is a type of phishing carried out via mobile text messages. It uses social engineering content as the attack payload. The main goal is to deceive recipients and get them to click on malicious links, exposing private information [13]. Early smishing attacks used many generic messages to deceive a small group of targets. The mobile internet has since changed the threat landscape. From 2005 to 2015, attackers expanded their attacks to include channels such as SMS, instant messaging, and spoofed websites. From 2015 to 2025, attackers began using advanced automation and artificial intelligence. These tools produce highly personalized, compelling content and increase the success rate of attacks [14].

Recently, a study by [6] demonstrates, from a red-team perspective, that content generated by AI is more compelling than that written by humans. Quantitatively, AI spear-phishing agents have been shown to perform 23% more effectively than humans [15]. While attacks become smarter, detection technologies have not been upgraded in parallel, leaving gaps in effective, low-cost detection solutions.

B. CTI in Feature Engineering

CTI is a systematic security methodology focused on collecting, analyzing, and disseminating information about potential or current cyber threats, aiming to provide actionable insights to support cybersecurity decision-making [16], [17].

In the field of threat detection, CTI plays a fundamental role. While feature engineering approaches are commonly used to detect phishing, they struggle to handle AI-driven smishing that uses unstable keywords, ambiguous intentions, and changing content. CTI can be used to enhance the dimensions of features across multiple domains, URLs, IPs, and threat indicators.

A study proposed integrating PhishTank data with threat intelligence to build a hybrid deep learning model for email phishing, as noted in [12]. This study observed that cybersecurity threat databases from VirusTotal, PhishTank, and Google Safe Browsing can improve the detection of malicious URLs and phishing attempts. The study [18] developed a cyber-threat intelligence platform that aggregates data from honeypots and open-source intelligence to detect and prevent phishing attacks. The platform focuses on threat sharing. In [19], a large-scale framework was proposed for extracting text-based attack patterns from CTI reports, with a focus on classifying attack issues. The study [20] proposed an entity recognition (NER) method to extract structured STIX-based CTI features, which achieved 81.65% accuracy in STIX attack pattern classification. In [9], this study used CTI-based features derived from search engines and WHOIS records for malicious URL detection, achieving 7.8% higher accuracy and 6.7% fewer false positives with a random forest model and MLP ensemble.

Previous research has attempted to incorporate CTI to classify attack types and detect phishing emails, achieving high performance, but research on smishing combined with CTI remains sparse.

C. Detection Approaches from Machine Learning to LLMs

Artificial intelligence (AI) represents a broad category in computing technology. Machine learning is a subset of AI that learns patterns from data. Within AI, generative AI encompasses a range of capabilities, with large language models as the most important subset. While traditional machine learning offers resource savings, LLMs provide language understanding and generation capabilities. The evolution of AI technologies has also driven the gradual movement of detection methods from machine learning to large language model-based solutions. The traditional ML-based detection schemes, as well as deep learning and LLM-based approaches, have been reviewed below.

First, feature-based machine learning methods typically rely on manually engineering features such as URL length and the number of special characters, and they use this knowledge to train classification models for phishing attack identification. A study in [21] employed GPT-4o to generate 63 email simulations of phishing attack payloads and construct 47 new stylometric features for AI-generated phishing detection. Then, we employed the XGBoost model for detection, which showed the best performance. An innovative approach to extensible artificial intelligence (XAI) for feature selection, which not only improves the accuracy of phishing website identification but also enables modelling of phishing sites and delivers interpretable results, thereby fostering greater trust among stakeholders, was proposed in [22]. Additionally, a parameter-tuning approach for phishing URL detection was proposed in [23], which used three tuning strategies: data balancing, hyperparameter optimization, and feature selection. The results show that feature selection significantly improves the accuracy and performance of the gradient boosting model. These indicate that feature selection is crucial for traditional machine learning models, but there remains room for improvement in feature performance.

Deep learning-based detection methods leverage neural networks to learn hierarchical features from input data, overcoming the limitations of manual feature engineering. For example, the author in [24] proposed a deep learning framework that leverages URL features to detect phishing. This framework offers benefits in terms of speed and accuracy, but it still doesn't address the black-box problem. The hybrid GRU+CNN model proposed in [25] uses the Kaggle dataset, which contains more than 2.5 million samples of URLs labelled as "phishing." The CNN model's accuracy is 98%. However, real-time performance is not demonstrated. Although deep learning achieves high performance in some scenarios, it poses additional challenges for real-time response applications owing to its black-box nature and high computational requirements.

Recently, with the rise of LLMs, most methods have adopted LLMs as core detectors. Optimization of LLMs typically involves pre-training or fine-tuning a specialized detector on phishing data, along with prompt engineering. In [26], two LLMs were fine-tuned on 573,880 phishing and benign URLs, achieving a high accuracy of 99.86%, with performance close to

that of state-of-the-art general-purpose LLMs. However, it also confirms that generalized LLMs still perform as well as dedicated LLMs in specific domains. The study [27] used five generic LLMs evaluated across three phishing datasets, and the results show that GPT-4 Turbo is the best-performing LLM under one-shot prompting, and the interpretations are highly readable. The study [28] compared the performance of fine-tuning and prompt engineering in phishing URL detection. The results demonstrated that fine-tuning can improve prompt engineering's accuracy from 92.9% to 97.3%, but prompt engineering has the advantage of fast development. A PhishBERT pre-trained model for phishing URL detection was proposed in [29]. The results are very satisfactory, but it consumes significant infrastructure, including 10 NVIDIA V100 servers. Pre-training a model needs strong infrastructure support, while fine-tuning consumes slightly lower computational resources. Prompt engineering offers easy access and still acceptable performance. To summarize the above, the LLM for smishing detection is highly readable and suitable for intensive interpretation. However, most research focuses only on the LLM itself and does not consider the illusion of LLMs, leaving a gap in combining LLMs and ML for detection.

Therefore, although existing research has demonstrated the enormous potential of CTI for guiding feature engineering, it also leaves a clear gap for improvement in smishing detection. To address this limitation, this research explores the systematic use of structured cyber threat intelligence features for building a lightweight, accurate, and understandable smishing detection model.

III. Methodology

This study proposes a dual-layer detection framework (see Fig. 1) to address two critical challenges: the escalating sophistication of AI-driven smishing attacks and the lack of interpretability in the detection framework. Layer 1 performs rapid interception, while Layer 2 handles cross-verification and explanation.

Fig. 1. Dual synergistic defense model.

A. System Architecture

A dual-layer detection framework process flow (see Fig. 2) is proposed in this study, consisting of two core pipelines. First, this study constructed a dataset and engineered 22 CTI-driven features out of it. These features are used to train and evaluate the optimal machine learning model. Subsequently, the machine learning model's output, together with the original smishing content, is formatted into a structured prompt. This prompt is then fed into the LLMs for cross-validation and interpretation. Finally, the framework produces highly accurate, human-readable detection results.

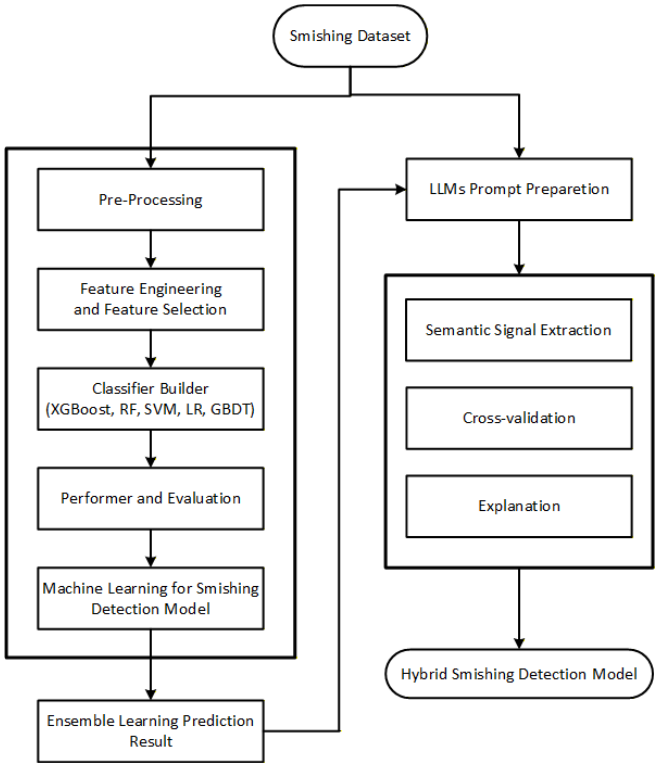

Fig. 2. Process flow of the hybrid smishing detection framework.

B. Dataset

This study uses a publicly available dataset, derived from SmishTank (https://smishtank.com/dataset). The advantage of this dataset is that it provides real-world SMS texts and their corresponding classification labels, with 22 feature dimensions. To enhance data coverage, this study employed a web crawler to collect additional samples from the source platform, expanding the dataset to 2,811 entries, as summarized in Table I.

TABLE I. Dataset Summary

Data Source	Total Samples	Legitimate	Smishing
SmishTank	2,811	1,799	1,012

To expand the number and coverage of data samples, we collected smishing records from SmishTank in real-time, as shown in Fig. 3, which displays the raw message content, associated URLs, and metadata used during dataset construction.

Upon obtaining the dataset, this study constructs the 22 features shown in Table II based on the CTI guidance and the existing literature, which categorizes IOC into three categories: content, context and IOC. CTI-driven feature set for smishing detection is given in Table II.

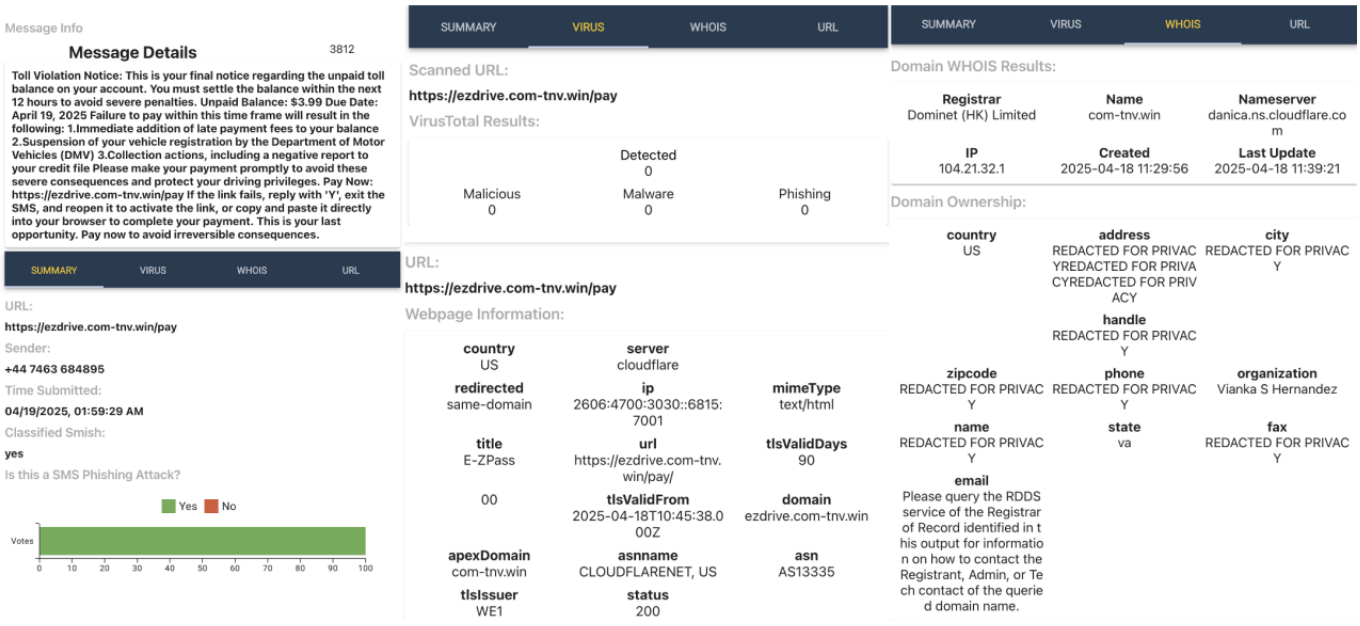

Fig. 3. Example of a smishing sample collected from SmishTank.

TABLE II. FEATURE CONSTRUCTION

ID	Feature Name	ID	Feature Name
1	sender_country_code	12	contains_financial_ref
2	sender_number_prefix	13	contains_forged_identity
3	receive_time	14	contains_account_ref
4	has_virus_malicious	15	contains_contact_instruction
5	has_virus_malware	16	has_verify_term
6	has_virus_detected	17	has_reward_term
7	tls_issuer	18	has_action_require
8	count_characters	19	has_login_term
9	has_command_tone	20	is_ip_in_url
10	has_threat_feature	21	domain_entropy
11	has_urgency_feature	22	is_url_shortener

IOC features such as has_virus_malicious, has_virus_malware, and has_virus_detected are obtained from external threat intelligence repositories, which explicitly identify malicious attacks and are therefore more reliable. Content features are a form of linguistic fingerprinting. They capture lexical and semantic patterns that differ from ordinary communication, reflecting the attacker's social engineering strategies. A key advantage of this category is its robustness; even if attackers modify domains or IP addresses, their linguistic habits and manipulation techniques are harder to conceal. Contextual features represent environmental cues that often go unnoticed individually but exhibit statistically meaningful patterns at scale, such as abnormal sending times. These three categories form a comprehensive feature set that enhances the model's ability to detect diverse smishing behaviors.

C. Machine Learning for Smishing Detection Model

This study employs five model selection methods: LR, SVM, RF, XGBoost, and GBDT. The selected classifiers represent complementary learning paradigms commonly used in security detection tasks. The linear model LR serves as the baseline, with SVM added. Tree-based and ensemble models (RF, GBDT, and XGBoost) are used to capture nonlinear interactions among CTI-driven features.

To ensure fair comparison and reproducibility, each model was configured using commonly adopted baseline parameter settings. Only limited, model-specific tuning was applied to control overfitting, prioritizing robustness and generalization over aggressive optimization.

The dataset is divided into training, validation, and test sets using a 70:10:20 ratio to balance learning capacity, parameter selection, and unbiased evaluation. Recall is emphasized as the primary metric, since missing a smishing message incurs a higher risk than issuing a false alarm. The F1 score is reported as a complementary metric to reflect the overall detection balance. Additionally, inference latency and memory consumption are evaluated to assess deployment feasibility on mobile devices. Finally, this study selects the best ML model as a detector for Layer 1 after evaluation.

D. LLM-Based Semantic Analysis and Cross-Verification

Four LLMs serve as interpreters and auxiliary detectors at Layer-2 to address the limitations of traditional machine learning models in interpretability and decision transparency. This layer is implemented in three parts: LLM prompt preparation, prompt execution, and result analysis. All four LLMs are evaluated using the same prompt and input structure to ensure comparability between models.

LLM prompt preparation: This study constructs a prompt that implements three functions in Fig. 4. Input the evaluation result of the ML for the LLM to evaluate whether it agrees or not, and give 0-100 as the likelihood of recognizing a phishing attack. Then extract the attack clues from the SMS payload and display them. In the end, explain the reason that the message is judged as a phishing attack.

```
You are a cybersecurity AI assistant.
Please analyze the following SMS message and its extracted features.
The XGBoost model classified this message as: {Phishing / Not Phishing}.
Do you agree or disagree? Provide your reasoning.
Message: "{message}"
Please rate it from 0 to 100:
  ▪ Decision: Phishing or Not Phishing, with a score (e.g., 85/100)
  ▪ Semantic Signal: Describe which signals indicate phishing or not
    phishing (around 30 words)
  ▪ Explanation: Provide a short paragraph explaining your reasoning
    behind the decision (around 50–100 words)
Example Output:
  ▪ Decision: Phishing (Score: x/100)
  ▪ Semantic Signal: Contains a suspicious shortened URL, urgent
    language about financial loss, impersonation of a legitimate
    institution, and no user-specific personalization.
  ▪ Explanation: This message creates pressure by stating an
    unauthorized transaction and includes a shortened URL (bit.ly),
    which obscures the final destination. It lacks personalization and
    uses generic terms, which are typical signs of phishing. Legitimate
    institutions usually include identifiable user information and avoid
    generic urgency tactics.
```

Fig. 4. Prompt for semantic verification.

Prompt execution: 1/5 of the dataset (2,811) is selected as the evaluation dataset. The LLM evaluator selects four LLMs for comparative evaluation: GPT-4o, GPT-4 Mini, Gemini 2.5 Pro, and LLaMA3.1-8B, which include two large-parameter models and two small-parameter models. Consistent prompt requests for evaluation results were sent to the four LLMs simultaneously.

Statistical analysis: In the final analysis stage, this study focuses on 3 dimensions: recognition accuracy, interpretation clarity, and semantic cue consistency.

In this coordination mechanism, Layer-1 addresses high-speed, low-cost detection, and Layer-2 provides interpretability, semantic robustness, and human-readable explanations.

IV. Results and Discussion

To validate the effectiveness of the proposed framework, this section presents the experimental results in three key parts: the performance of the machine learning models, the outcomes of the feature engineering process, and the analysis of the large language model's semantic verification.

A. Result of Machine Learning Model

To validate the effectiveness of the first layer of the proposed framework, this study conducts comparative experiments on five machine learning classifiers: LR, SVM, RF, GBDT, and XGBoost in a dataset divided into training, validation, and testing sets in a ratio of 70:10:20.

The results of the validation set, shown in Table III, indicate that the integrated learning model achieves a better balance among detection accuracy, recall, and robustness. Among them, XGBoost achieved the best performance on key metrics (Recall=94.12%, F1-Score=96.00%, Accuracy=97.16%), while Random Forest and GBDT also maintained high recall and AUC values (98.94% and 98.77%, respectively). These results demonstrate that the integrated model has a significant advantage in capturing smishing signals.

TABLE III. Performance Verification on Validation Set

Model	Precision	Recall	F1-Score	Accuracy	AUC
LR	98.86%	85.29%	91.58%	94.33%	97.83%
SVM	95.24%	78.43%	86.02%	90.78%	95.35%
RF	95.00%	93.14%	94.06%	95.74%	98.94%
GBDT	96.00%	94.12%	95.05%	96.45%	98.77%
XGBoost	97.96%	94.12%	96.00%	97.16%	98.76%

The results in Table IV further confirm the stability of the integrated model, with XGBoost maintaining the highest recall values, as with the RF model. Unfortunately, the precision of the RF model is also lower than that of XGBoost. Although the difference between GBDT and XGBoost is small, XGBoost still outperforms GBDT across most metrics. Comparing the validation and test sets, both indicate that XGBoost achieves better, more balanced results.

TABLE IV. Performance Verification on Test Set

Model	Precision (%)	Recall (%)	F1-Score (%)	Accuracy (%)	AUC (%)
LR	97.60	80.69	88.35	92.35	97.56
SVM	92.99	72.28	81.34	88.08	95.21
RF	92.96	91.58	92.27	94.48	98.14
GBDT	95.83	91.09	93.40	95.37	97.97
XGBoost	95.36	91.58	93.43	95.37	98.43

To assess the applicability of the five models to mobile devices, reasoning efficiency was measured. The results in Table V show that the overall inference performance is significantly lightweight. The single-sample inference latency of all models is in the millisecond range, and the maximum memory consumption during inference is only about 45 KB. However, XGBoost shows high efficiency in the inference phase, with an average latency of only 0.005 ms and a memory consumption of 8.56 KB, the lowest among all models.

TABLE V. Model Inference Time and Memory Usage

Model	Avg time (ms)	Max time (ms)	Avg mem (KB)	Max mem (KB)
Logistic Regression	0.002	0.003	45.30	45.44
SVM	0.057	0.060	45.29	45.43
Random Forest	0.047	0.048	45.66	45.79
GBDT	0.006	0.007	45.54	45.67
XGBoost	0.005	0.008	8.56	8.65

In Table VI, based on previous studies, we found that the higher the number of features, the better the model's performance tends to be. However, this study achieved relatively balanced performance using 22 features. The results of [30] used nearly twice as many features as this study, yet the precision was similar. Similarly, [22] used nearly 4 times as many features as this study. In addition, comparing the studies of [30] and [31], this study maintains robust precision, recall, and F1-score on a much larger sample size of 2811, suggesting that it achieves a more generalized and practical feature system with fewer features.

TABLE VI. COMPARATIVE RESULTS OF SMISHING DETECTION STUDIES

Study	Features	Samples	Precision	Recall	F1-Score	Accuracy
[21]	43	63	96.0%	96.0 %	96.0 %	96.0%
[22]	87	2,288	97.0%	97.0 %	97.0 %	96.8%
[31]	12	620	92.2%	92.2 %	92.2 %	92.2%
This study	22	2,811	95.4%	91.6 %	93.4 %	95.4%

In summary, XGBoost shows the best balancing ability in the first-layer framework of this study. First, XGBoost achieves the most balanced results across all recognition metrics and maintains the highest recall and F1 score. Second, in the inference phase, XGBoost's average latency is only 0.005 ms, and its memory consumption is about 8.56 KB, making it better than other models and especially suitable for deployment on resource-constrained mobile devices. Finally, XGBoost achieves stable, competitive results in this study with only 22 features, unlike previous studies that relied on much larger feature sets to achieve high performance. Based on these three lines of evidence, XGBoost achieves an optimal balance among performance, efficiency, and deployability and should be selected as a layer-1 model.

B. Feature Engineering with CTI

Smishing attacks are "semantically deceptive", "irregularly formatted", and "highly variant in content". Content features alone are not enough, so this study introduces CTI to enhance the traditional features. Therefore, this study introduces CTI to enhance the traditional features. To analyze the impact of CTI-guided features on mods, the XGBoost Gain on Feature Importance and a correlation heatmap were used.

The XGBoost gains the top twenty features in Fig. 5. This further demonstrates that the IOC metrics have_virus_detected and have_virus_malicious are the two most contributing to the model, followed by TLS issuer. Also, in the case of social engineering features, has_login_term, has_action_required and has__verify_term features also occupy an important position. This shows that IOC features are more valuable than social engineering features.

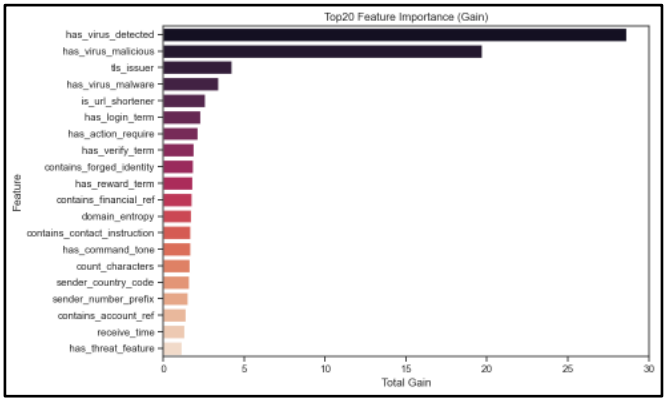

Fig. 5. Top-20 feature importance by XGBoost gain.

A strong association between has_virus_malware and has_virus_detected is observed in the correlation heatmap (Fig. 6). The correlation between social engineering features is also strong, whereas the correlation between IOC features and the middle of social engineering features is weak. These features confirm the independence of the 22 features.

After the import of CTI, the importance of IOC features among the top twenty is significantly increased. It indicates that when attack clues are predicted in an attack sample, it is more likely to be a smishing attack, which is more distinguishable than traditional content features. In addition, the correlation between IoC features is high, and the correlation between IoC features and social engineering features is weak, while there is also internal aggregation between social engineering features. This study suggests that CTI features do not duplicate traditional features' information but introduce new dimensions.

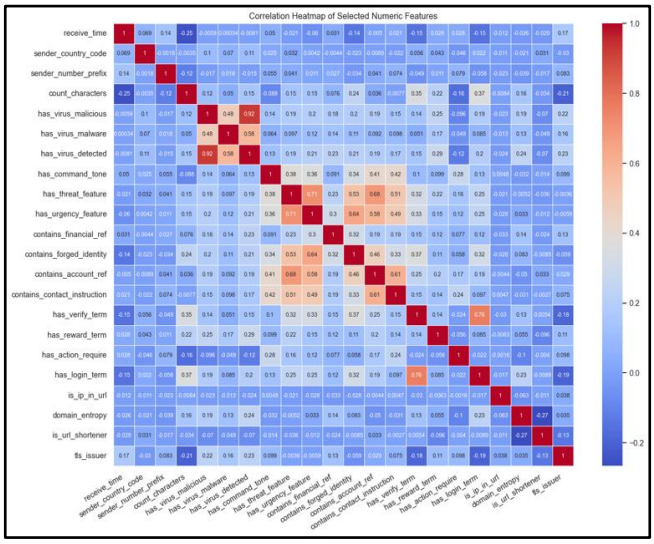

Fig. 6. Correlation heatmap of constructed features.

C. Result of LLMs

In the LLM cross-validation and semantic analysis phase, a total of 562 samples were selected for evaluation. The study first obtained the Layer-1 XGBoost classifier's predictions and compared with those of four LLMs. A representative boundary case was further examined to assess the model's semantic interpretation capabilities.

Since interpretation clarity and semantic cue consistency lack universally accepted objective measurements, this study treats them as proxy metrics. Interpretation clarity is defined as whether the LLM-generated explanation contains all required semantic components specified in the prompt and is consistent with the final decision, and it is measured by the proportion of samples satisfying these criteria. Semantic cue consistency is defined as the degree of overlap in identified smishing-related cues across different LLMs when analyzing the same message.

From Table VII, it is observed that the higher-parameter LLMs demonstrate higher performance in smishing detection. GPT-4o and Gemini-2.5 Pro both reduced the number of false negatives (FN) to 1, significantly outperforming XGBoost, which produced 14 FN on the same evaluation set. Among the models, Gemini-2.5 Pro achieved the most balanced overall performance.

TABLE VII. CROSS-VERIFICATION PERFORMANCE COMPARISON

Model	TP	FP	FN	TN
XGBoost	188	6	14	354
Llama3.1-8B	199	355	3	3
GPT-4omini	200	346	2	12
GPT-4o	201	351	1	7
Gemini-2.5pro	201	350	1	8

In addition to their predictive accuracy, an important advantage of LLMs is their ability to generate contextually relevant, human-readable explanations. To illustrate this capability, Fig. 7 presents a representative boundary case for the XGBoost classifier. The message contains social engineering-related keywords such as "refund" and "reply", which frequently appear in smishing messages, leading the feature-based model to classify it as phishing in the absence of explicit threat indicators. In contrast, the LLM identified the message as benign by recognizing that it originated from a legitimate "temu.com" source and followed the structure of a standard customer service notification. This example demonstrates the LLM's ability to capture higher-level semantic and organizational contexts that are difficult to model using handcrafted features alone.

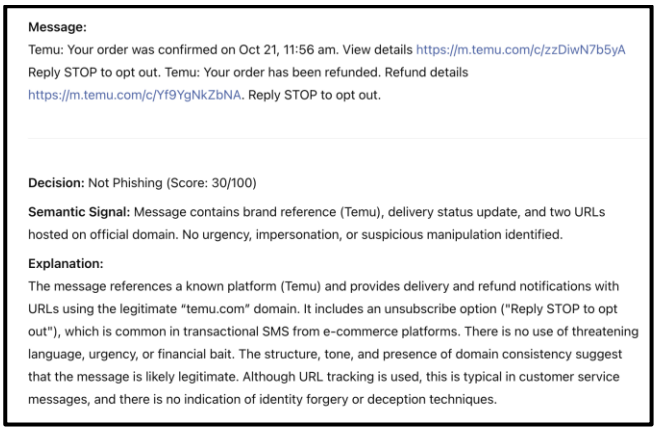

Fig. 7. LLM analysis sample for smishing detection.

D. Limitations

This study has several limitations. First, the dataset is primarily derived from SmishTank and may not fully capture the diversity of smishing campaigns across regions and languages, potentially affecting generalizability. Second, the effectiveness of CTI-guided features depends on the availability and quality of external threat intelligence, and incomplete or outdated CTI may reduce the contribution of IOC-related features. Third, although the LLM layer enhances semantic verification and interpretability, it involves additional computational overhead and is subject to known robustness issues; however, its impact is limited by its role as a secondary verifier rather than the primary detector.

From a security perspective, this design limits the impact of adversarial manipulation, as potential prompt injection or output manipulation at the LLM layer cannot directly bypass the CTI-guided machine learning decision in the first layer.

In addition, an explicit ablation study isolating CTI-driven features from traditional content- and context-based features is not conducted, as several CTI indicators are intrinsically integrated into the feature space. Nevertheless, feature importance and correlation analyses indicate that CTI features provide complementary and non-redundant information.

These limitations define the scope within which the experimental results should be interpreted.

V. CONCLUSION AND FUTURE WORK

Traditional smishing detection approaches face challenges balancing computational efficiency, expressive feature representation, and boundary-case identification. To address these issues, this study proposes a lightweight dual-layer detection framework that integrates a CTI-guided machine learning classifier with an LLM-based semantic verification module.

Experimental results show that XGBoost provides efficient and accurate first-layer detection, while the LLM layer complements it by improving recall and interpretability in ambiguous cases. This collaborative design achieves a practical balance between detection performance, transparency, and deployability in resource-constrained environments.

Future work will focus on expanding the dataset to cover multiple languages and regions, integrating more dynamic CTI sources, and conducting systematic ablation and cross-dataset evaluations to further quantify feature contributions and generalization. In addition, optimizing the cost and robustness of the LLM layer remains an important direction for large-scale deployment.

***Abstract*—Cone-beam computed tomography (CBCT) imaging in dentistry requires post-reconstruction image processing to enhance diagnostic quality while minimizing radiation exposure. Visualization of fine dentomaxillofacial structures, particularly the inferior alveolar canal (IAC) and dental pulp canals, presents significant diagnostic challenges in low-dose CBCT imaging. This study investigates the application of Wiener and adaptive Wiener (LLMMSE) filters in the reconstruction domain to improve the visibility of these critical anatomical structures in low-dose dental CBCT images. Two CBCT examinations of a dry mandible were acquired using reference and low-dose protocols. The low-dose post-reconstruction data was processed using six different filters: geometric mean, LLMMSE with additive noise 15, LLMMSE with additive noise 5, moving average, Wiener, and local contrast filters. These computationally efficient filters offer practical advantages over existing complex and costly noise reduction schemes. Subjective evaluation by an experienced oral and maxillofacial radiologist demonstrated that the IAC was clearly identifiable in all low-dose datasets regardless of filter application. However, the highest visibility of narrow pulp canals was achieved with the Wiener and LLMMSE_5 filters. This proof-of-concept study demonstrates the potential of Wiener and LLMMSE_5 techniques for improving visibility of narrow dental pulp canals in low-dose CBCT images, which has important implications for endodontic diagnosis and treatment planning while supporting radiation dose reduction strategies.**

I. Introduction

Cone-beam computed tomography (CBCT) is a specialized form of computed tomography (CT) that has revolutionized dental imaging since its introduction in 1998 [1]. CBCT devices designed specifically for dentistry have become widely adopted due to their ability to provide high-resolution three-dimensional images and sectional views free from superimposition. The clinical applications of CBCT span multiple dental specialties, with particular utility in endodontics for root canal assessment [2], implant site analysis and surgical planning [4], orthodontic treatment planning [5], and maxillofacial surgery for anatomical evaluation [6]. The European Commission has published evidence-based guidelines emphasizing the importance of appropriate CBCT use in dental and maxillofacial radiology [3].

Despite these advantages, dental CBCT examinations impart higher radiation doses than conventional dental radiography [7]. This elevated radiation exposure is particularly concerning given the findings of the United Nations Scientific Committee on the Effects of Atomic Radiation, which reported that medical exposure represents the largest artificial source of ionizing radiation to collective populations, largely attributable to the widespread availability of CT examinations [8]. The radiation dose imparted by different CBCT devices is highly variable, depending on the type of device, exposure parameters, and field of view [7], [9], [10]. Consequently, CBCT dose optimization—employing the lowest radiation dose that maintains diagnostic image quality—is essential to minimize potential biological harm to patients [11], [2], [3], [4], [6]. This principle aligns with the ALADA concept (As Low As Diagnostically Acceptable) introduced by the National Council on Radiation Protection [11].

Each CBCT examination generates a set of two-dimensional X-ray projections acquired around a single axis of rotation, which are subsequently reconstructed into a three-dimensional image volume. Increasing exposure parameters elevates the radiation dose delivered to the patient. Fundamentally, reduction of radiation dose in any CT modality is associated with increased quantum noise in the reconstructed images [12], [13]. Therefore, attempts to reduce CBCT exposure parameters are constrained by the progressive increase in image noise at lower doses [14]. This noise elevation decreases the signal-to-noise ratio (SNR), potentially compromising diagnostic quality through reduced contrast and spatial resolution [15], [16]. Consequently, there exists a clinical need for technical solutions that can improve contrast and spatial resolution of CBCT images acquired at reduced radiation doses.

The majority of commercial CBCT systems employ the Feldkamp-Davis-Kress (FDK) filtered back-projection reconstruction algorithm [17], [18]. While hardware constraints limit implementation of alternative reconstruction approaches, optimizing the performance of this established FDK algorithm is crucial for maximizing diagnostic information from CBCT images. The standard FDK approach applies a ramp filter

in the frequency domain prior to back-projection, typically combined with window functions to attenuate high-frequency noise components.

Various filtering approaches have been investigated for noise reduction in CT and CBCT imaging. Srinivasan et al. [19] evaluated reconstruction filters for CBCT noise reduction. Zeng [20] proposed noise-weighted filtered backprojection techniques, while Sagawa et al. [21] compared shift-invariant filtering methods. However, these approaches often fail to adequately preserve spatial resolution [22]. The field of image processing offers numerous 2D and 3D adaptive filters designed to tailor smoothing to local noise characteristics. Researchers have applied adaptive filters to CT and CBCT images using two primary strategies: filtering projections or sinograms before reconstruction [23], [24], [25], [26], [27], [28], [29], or filtering the reconstructed images directly [30], [31], [32].

Filtering in the reconstruction domain offers several practical advantages over projection-domain filtering. First, the filtering operation can be observed immediately without requiring access to the reconstruction process, which may not always be available to clinicians. Second, filtering in the reconstruction domain avoids potential streaking artifacts that can occur with projection-domain filtering. Third, clinicians can manipulate different images and views to optimize visualization of anatomical structures and lesions, which aligns with established visualization protocols that influence examination interpretation [33], [34], [35].

Among the most widely used noise-reduction techniques in signal and image processing are Wiener and adaptive Wiener (LLMMSE) filters. These filters have demonstrated excellent denoising performance [36] while being considerably more straightforward to implement than many schemes previously applied to CBCT, which often require complex parameterization and costly computational resources. For CBCT imaging, Wiener filters have been applied to reduce noise in the projection domain [37]. However, to the best of our knowledge, Wiener filtering has not been systematically applied in the reconstruction domain to leverage its potential advantages for post-reconstruction image enhancement.

Therefore, the aim of this proof-of-concept study was to apply several variants of Wiener filters in the reconstruction domain of low-dose dental CBCT images of a dry mandible to evaluate their potential for improving visibility of the inferior alveolar canal (IAC) and pulp canals of teeth. Evaluation focused on these structures because their accurate identification requires the highest spatial and contrast resolution, which is critical for implant site analysis [38], [39], [40], [41], [42] and endodontic assessment [2].

II. Materials and Methods

The project was approved by the College of Dentistry Research Center (CDRC registration number: FR 0438). The low-dose CBCT dataset was processed using six different filtering techniques:

- Geometric Mean Filter: A nonlinear filter that computes the geometric mean of pixel values within a local neighborhood.
- LLMMSE_15: Adaptive Wiener filter with additive noise variance parameter set to 15.
- LLMMSE_5: Adaptive Wiener filter with additive noise variance parameter set to 5.
- Moving Average Filter: A linear smoothing filter that replaces each pixel with the arithmetic mean of its neighborhood.
- Wiener Filter: Standard Wiener filter applied in the frequency domain.
- Local Contrast Filter: A filter designed to enhance local contrast while reducing noise.

A. Sample Preparation and CBCT Imaging

Extracted premolar teeth were placed in the sockets of a section of a dry mandible, and the mandible and any exposed radicular portions of the teeth were covered in wax to simulate soft tissue attenuation. The bone and teeth were then imaged with a CBCT device (Planmeca ProMax 3D max, Planmeca Inc., Helsinki, Finland) which has an adjustable field of view (see Fig. 1). This dry mandible specimen was selected as it provides a controlled, reproducible imaging target for this initial feasibility assessment.

Two CBCT examinations were performed: one using a standard dose protocol and another using the low-dose protocol of the device. Both examinations were acquired with a small field of view measuring $\varnothing 4.2 \times 5.1$ centimeters and were composed of a total of $281 \times 281 \times 341$ voxels. The exposure parameters for the two protocols are listed in Table I.

B. Mathematical Modeling

This section presents the mathematical models underlying the image processing filters used for enhancing CBCT images. The primary focus is on Wiener filter and adaptive Wiener filter (LLMMSE) implementations.

1) Wiener filtering: Dentomaxillofacial images are frequently degraded by blurring and additive noise. In signal processing terms, this degradation can be expressed as:

$$y(i,j) = x(i,j) * h(i,j) + n(i,j) \tag{1}$$

where, $y(i,j)$ is the distorted image, $x(i,j)$ is the original image, $h(i,j)$ is a point spread function modeled as a linear time-invariant system, and $n(i,j)$ is additive noise.

Assuming that signal and noise processes are stationary, Wiener filters provide an estimation of the original image, $x_d(i,j)$, that minimizes the mean square error:

$$\text{MSE}\left(x_d\right) = \frac{1}{N}\sum_{i=1}^{N}\sum_{j=1}^{M}\left(x_d(i,j) - x(i,j)\right)^2 \tag{2}$$

where, N and M are the horizontal and vertical dimensions of the image. Wiener filtering is typically applied in the frequency domain. The original image spectrum is estimated by computing the product of the image Fourier transform $(X(u,v))$ with the Wiener filter $(W(u,v))$ [44]:

Fig. 1. The Planmeca ProMax 3D max CBCT device used to acquire the CBCT images. This device features adjustable field of view settings and multiple dose protocols suitable for various clinical applications.

TABLE I. EXPOSURE PARAMETERS OF CBCT PROTOCOLS

Dose Protocol	Voxel Size (μm)	Voltage (kV)	Current (mA)	Exposure Time (s)
Low dose	150	60	1.0	15.957
Standard	150	60	8.0	15.238

$$X_d(u,v) = W(u,v)X(u,v) = \frac{H^{\text{conj}}(u,v)}{|H(u,v)|^2 + \text{NSR}} X(u,v) \tag{3}$$

where, $H(u,v)$ is the Fourier Transform of $h(i,j)$, and NSR is the noise-to-signal power ratio (i.e., the reciprocal of the signal-to-noise ratio).

2) Adaptive Wiener filtering: In practice, images are not globally stationary, and therefore noise cannot be optimally minimized using standard Wiener filtering. However, images can reasonably be treated as locally stationary. Adaptive Wiener filters, also known as local linear minimum mean square error (LLMMSE) filters, address this limitation by computing statistics from a local neighborhood around each pixel. This approach enables the filter to adapt to local image characteristics, often producing superior results compared to global linear filtering while preserving edges and other high-frequency image features.

The pixel-wise adaptive low-pass Wiener filter computes the local mean and variance around each pixel [43]:

$$\mu = \frac{1}{LP} \sum_{i,j \in R} y(i,j) \tag{4}$$

and

$$\sigma^2 = \frac{1}{LP} \sum_{i,j \in R} y^2(i,j) - \mu^2 \tag{5}$$

where, R is the L-by-P local neighborhood of each pixel in the image y. These estimates are then used to compute the filtered image $x_d(i,j)$:

$$x_d(i,j) = \mu + \frac{\sigma^2 - v^2}{\sigma^2}(y(i,j) - \mu) \quad (6)$$

where, v^2 is the noise variance. This approach performs optimally when the noise exhibits constant-power ("white") characteristics, such as Gaussian noise.

C. Image Processing and Analysis

The low-dose CBCT dataset was processed using six different filtering techniques: geometric mean filter, LLMMSE filter with additive noise parameter 15 (LLMMSE_15), LLMMSE filter with additive noise parameter 5 (LLMMSE_5), moving average filter, Wiener filter, and local contrast filter. These filters were selected based on their established performance in noise reduction applications and their computational efficiency compared to more complex iterative reconstruction schemes.

The filtered datasets were exported in Digital Imaging and Communications in Medicine (DICOM) format and processed using image reformatting software (OnDemand Software, Version 1.0, Build 1.0.10.5385, x64 Edition, Cybermed Inc., Seoul, South Korea).

An oral and maxillofacial radiologist with 15 years of experience in CT image reformatting and interpretation performed the image analysis. Using the 3D module of the software, reformatted images of the IAC were obtained in parasagittal (Fig. 2) and transverse cross-sectional (Fig. 3) planes at standardized positions and orientations. Reformatted images of the pulp canals of a double-rooted premolar tooth were obtained in mesio-distal (Fig. 4), bucco-lingual (Fig. 5), and axial (Fig. 6) planes at identical positions and orientations.

Image magnification was standardized across all datasets. Image contrast and density were adjusted for optimal visualization of each dataset, as the filtered datasets exhibited different gray value distributions. The visibility of the IAC was subjectively evaluated in both parasagittal and transverse cross-sectional images (Fig. 2 and Fig. 3). For pulp canal visibility assessment, the mesio-distal images (Fig. 4) were used as the primary comparison, as these demonstrated the narrowest canal branches.

III. Results

The raw projection data of a CBCT acquisition can be mathematically expressed as:

$$p(u,v;\theta) = I_0 e^{\int_0^{SDD} \mu(x,y,z)dy} \quad (7)$$

where, θ is the projection angle, I_0 is the intensity of the X-ray source, and $\mu(x,y,z)$ is the distribution of the linear attenuation coefficient of the imaged object. The Filtered Back Projection algorithm requires data in the form of line integrals, achieved through logarithmic normalization using the known value of I_0. The reconstruction results using different I_0 estimation methods are shown in Fig. 7.

Regarding visibility of the IAC, the canal walls appeared less sharp in low-dose images compared to reference images. However, the IAC was clearly identifiable in all low-dose datasets, regardless of whether a filter was applied. The cortical boundaries of the mandible were also adequately visualized across all filtering conditions.

Regarding visibility of the pulp canals, compared to the unfiltered high-dose images, the narrow branches of the pulp canals were found to be most clearly visible in the low-dose images processed with the Wiener filter [Fig. 4(g)], followed by images produced using LLMMSE_5 [Fig. 4(e)]. Notably, the narrow canal branches were barely visible in both the unfiltered high-dose and low-dose images [Fig. 4(a) and Fig. 4(b)], suggesting that the filtering process provided enhancement beyond simple noise reduction.

IV. Discussion

The results of this study demonstrate that Wiener and LLMMSE_5 filters applied in the reconstruction domain can improve visualization of fine anatomical structures in low-dose CBCT images. This finding has important implications for clinical practice, as improved pulp canal visibility directly supports endodontic diagnosis and treatment planning. Accurate visualization of root canal anatomy is essential for successful endodontic treatment, including assessment of canal number, curvature, and the presence of anatomical variations or pathology [2].

The superior performance of the Wiener and LLMMSE_5 filters compared to other tested filters can be attributed to their adaptive noise estimation capabilities. Unlike simple smoothing filters such as the moving average, these filters adjust their behavior based on local image statistics, allowing them to reduce noise in homogeneous regions while preserving edge information in areas of high contrast. The LLMMSE_5 filter, with its lower additive noise parameter, provides more aggressive smoothing than LLMMSE_15, which may explain its improved performance for visualizing the fine pulp canal structures.

The finding that the IAC remained identifiable across all filtering conditions, while pulp canal visibility varied substantially, reflects the different spatial scales of these structures. The IAC, being a larger anatomical feature, is less susceptible to noise-induced degradation than the narrow pulp canals. This observation suggests that filter selection should be guided by the specific diagnostic task and the size of structures of interest.

The application of these filters in the reconstruction domain offers practical advantages for clinical implementation. Unlike projection-domain filtering, which requires access to raw projection data and integration with the reconstruction pipeline, reconstruction-domain filtering can be applied to any CBCT dataset using standard image processing software. This accessibility facilitates adoption in clinical settings where proprietary reconstruction algorithms may limit access to projection data.

A. Study Limitations

Several limitations of this study must be acknowledged when interpreting the results. First, this is an initial proof-of-concept assessment using a single dry mandible specimen and

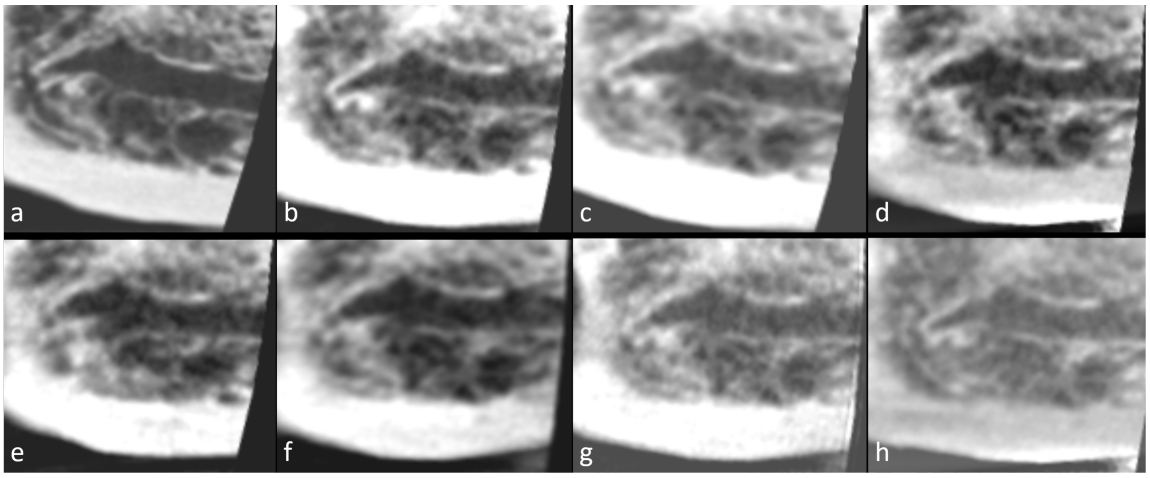

Fig. 2. Parasagittal section of dry mandible demonstrating the inferior alveolar canal. Images show: (a) standard dose protocol without additional filtering, (b) low dose protocol without additional filtering, and low dose protocol with additional filtering using (c) geometric mean, (d) LLMMSE_15, (e) LLMMSE_5, (f) moving average, (g) Wiener, and (h) local contrast techniques. The IAC boundaries are identifiable in all images, though with varying degrees of sharpness.

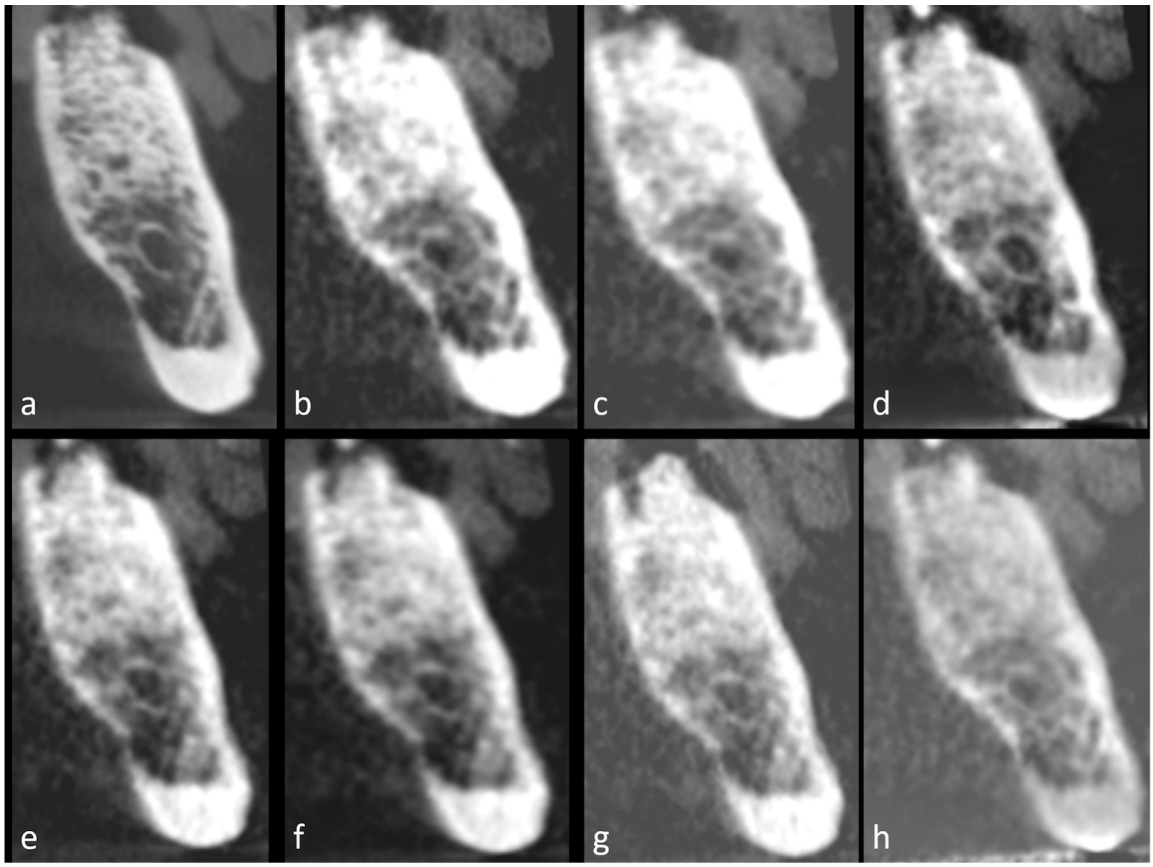

Fig. 3. Transverse cross-section of dry mandible demonstrating the inferior alveolar canal and cortical boundaries. Images show: (a) standard dose protocol without additional filtering, (b) low dose protocol without additional filtering, and low dose protocol with additional filtering using (c) geometric mean, (d) LLMMSE_15, (e) LLMMSE_5, (f) moving average, (g) Wiener, and (h) local contrast techniques. Cortical bone boundaries and the IAC lumen are visible across all filtering conditions.

a single examiner. The use of a dry specimen eliminates the effects of soft tissue attenuation and patient motion, which may influence filter performance in clinical scenarios. Second, the evaluation was based solely on subjective visual assessment without quantitative image quality metrics such as signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), or edge preservation indices. While subjective assessment reflects clinical practice, objective metrics would strengthen the evidence

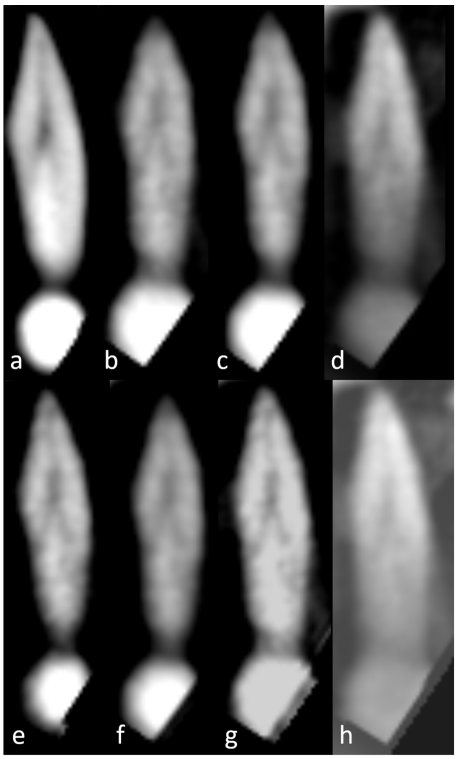

Fig. 4. Mesio-distal section of a maxillary premolar root demonstrating branching of the pulp canal. Images show: (a) standard dose protocol without additional filtering, (b) low dose protocol without additional filtering, and low dose protocol with additional filtering using (c) geometric mean, (d) LLMMSE_15, (e) LLMMSE_5, (f) moving average, (g) Wiener, and (h) local contrast techniques. The narrow pulp canal branches are most clearly visible in images processed with Wiener (g) and LLMMSE_5 (e) filters.

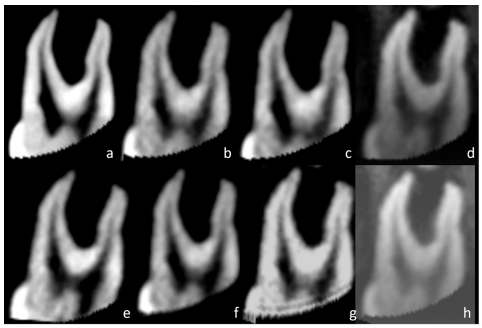

Fig. 5. Bucco-lingual section of maxillary premolar roots demonstrating the pulp canals. Images show: (a) standard dose protocol without additional filtering, (b) low dose protocol without additional filtering, and low dose protocol with additional filtering using (c) geometric mean, (d) LLMMSE_15, (e) LLMMSE_5, (f) moving average, (g) Wiener, and (h) local contrast techniques.

for filter efficacy. Third, the results were compared to high-dose images rather than a true gold standard such as micro-CT images or histological sections. Fourth, the use of only two CBCT scans limits the generalizability of findings to other CBCT devices, exposure protocols, or anatomical regions.

B. Clinical Implications

Despite these limitations, the results have important clinical implications. The potential to improve pulp canal visibility in low-dose CBCT images supports the goal of radiation dose reduction in dental imaging while maintaining diagnostic utility. This is particularly relevant for endodontic applications, where detailed visualization of root canal anatomy is essential but repeated imaging may be required during treatment. The ability to achieve adequate diagnostic quality at reduced radiation doses aligns with the ALADA principle and supports patient safety.

Furthermore, the computational simplicity of Wiener and LLMMSE filters makes them suitable for integration into clinical workflows without requiring specialized hardware or extensive processing time. This practical advantage may facilitate broader adoption of dose reduction strategies in dental CBCT imaging.

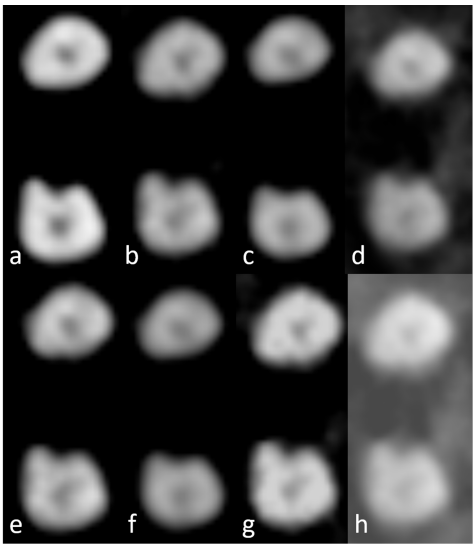

Fig. 6. Axial section of a maxillary premolar root demonstrating the pulp canals. Images show: (a) standard dose protocol without additional filtering, (b) low dose protocol without additional filtering, and low dose protocol with additional filtering using (c) geometric mean, (d) LLMMSE_15, (e) LLMMSE_5, (f) moving average, (g) Wiener, and (h) local contrast techniques.

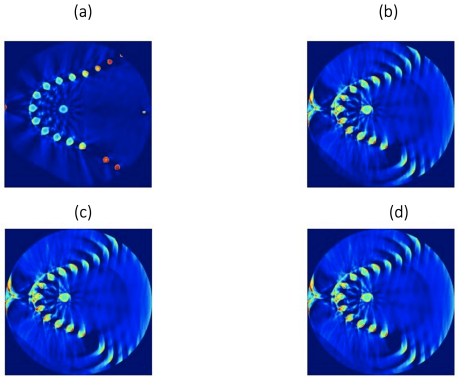

Fig. 7. Comparison of reconstruction results using different I_0 estimation methods: (a) Proprietary reconstruction, (b) I_0 estimated as maximum pixel value, (c) I_0 from constant calibration value, (d) I_0 from varying per-pixel calibration. These variations in I_0 estimation affect the overall image contrast and density distribution.

V. Conclusion

This proof-of-concept study demonstrates that Wiener and LLMMSE_5 filters applied in the reconstruction domain show potential for improving the visibility of narrow dental pulp canals in low-dose CBCT images. The IAC remained clearly identifiable across all tested conditions, while pulp canal visibility was notably enhanced by these adaptive filtering techniques.

A. Research Contributions

The primary contribution of this work is the systematic evaluation of Wiener and LLMMSE filters in the reconstruction domain for dental CBCT image enhancement. While these filters have been previously applied in the projection domain, their application to reconstructed CBCT images for improving visualization of fine dentoalveolar structures represents a novel approach that offers practical advantages for clinical implementation.

B. Practical Advantages

The filters evaluated in this study offer several practical advantages over more complex noise reduction schemes. They are computationally efficient, requiring minimal processing time compared to iterative reconstruction algorithms. They can be applied to any CBCT dataset without requiring access to raw projection data or modification of the reconstruction pipeline. Additionally, they are available in standard image processing software packages, facilitating adoption in clinical and research settings.

C. Future Research Directions

Future investigations should address the limitations of this initial study through several approaches. First, studies using larger sample sizes with multiple specimens and multiple examiners would strengthen the evidence for filter efficacy and assess inter-observer reliability. Second, inclusion of quantitative image quality metrics (SNR, CNR, edge preservation

indices) would provide objective measures of filter performance. Third, comparison to a true gold standard (micro-CT or histological sections) would enable assessment of diagnostic accuracy. Fourth, evaluation using cadaveric specimens or clinical images would assess filter performance under realistic imaging conditions including soft tissue effects. Fifth, investigation of filter performance across different CBCT devices, exposure protocols, and anatomical regions would establish generalizability. Finally, clinical studies assessing the impact of filtered images on diagnostic accuracy and treatment outcomes would provide evidence for clinical utility.

ACKNOWLEDGMENT

The authors would like to thank the College of Dentistry Research Center at King Saud University for approving this project. The authors are grateful to Northern Border University for supporting this research through sabbatical leave program.

Faculty of Economics and Business, Jenderal Achmad Yani University, Indonesia[1]

Abstract*—Blockchain technology has emerged as a transformative innovation in digital accounting, offering robust mechanisms to enhance auditability, data integrity, and fraud prevention. This study examines how blockchain-based audit trails can improve transparency and strengthen fraud detection within modern accounting information systems. Adopting a conceptual–analytical research design supported by secondary empirical evidence, the study analyzes data drawn from recent peer-reviewed case studies, industry reports, and documented implementations of permissioned blockchain systems in auditing and financial reporting contexts. The analysis focuses on core blockchain characteristics—immutability, decentralization, cryptographic security, real-time verification, and transaction mining—and evaluates their implications for audit processes and governance mechanisms. The results highlight that blockchain-enabled audit trails allow continuous access to verified transactional data, significantly improving early detection of anomalies, reducing opportunities for data manipulation, and enhancing the reliability of financial reporting. The study further demonstrates that permissioned blockchain architectures, combined with smart contract automation, can operationally support real-time audit logging and procedural compliance while minimizing human error. However, empirical insights also reveal critical implementation challenges, including interoperability constraints, scalability issues, regulatory uncertainty, and organizational resistance. In terms of contribution, this research offers a conceptual and methodological contribution by developing an integrated blockchain-based auditing framework that systematically links technological features with audit objectives and fraud prevention mechanisms. Unlike prior descriptive reviews, this study explicitly positions its framework against existing auditing and blockchain literature, clarifying how blockchain-based audit trails extend current auditing theory and provide practical design implications for enterprise accounting systems. Overall, the findings advance scholarly understanding of blockchain-enabled auditing and provide actionable insights for auditors, system designers, and regulators seeking to implement next-generation digital audit infrastructures.

Keywords*—Blockchain; audit trails; fraud detection; digital accounting; transparency; data mining

I. Introduction

The rapid advancement of digital technologies has fundamentally transformed the landscape of financial reporting and auditing. Organizations increasingly rely on integrated information systems that automate transaction processing and data storage. However, this digital shift has amplified concerns regarding data manipulation, cybersecurity threats, and financial fraud. Traditional audit techniques often struggle to keep pace with the complexity of digital transactions. As a result, researchers are exploring technologies like blockchain to enhance data integrity in digital accounting systems.

Blockchain technology has gained significant global attention for its immutable and transparent record-keeping characteristics [1]. In auditing, immutability provides strong protection against unauthorized alterations. This capability positions blockchain-based audit trails as a promising solution for fraud mitigation. Additionally, decentralization reduces dependency on centralized authorities. Consequently, auditors obtain verifiable and tamper-proof evidence for assessments.

Recent corporate accounting scandals highlight persistent weaknesses in conventional audit systems. High-profile fraud incidents underscore deficiencies in internal control frameworks. These failures create a compelling need for more secure technological auditing solutions. Blockchain's cryptographic protocols provide stronger protection than traditional data storage. Therefore, blockchain integration can improve anomaly and fraud detection [2].

Digital accounting systems generate vast volumes of transactional data at unprecedented speed. Manual reviews are increasingly inefficient for ensuring adequate audit coverage. Blockchain-enabled audit trails streamline verification through automated and real-time updates. This capability supports continuous auditing practices. As a result, oversight becomes stronger and more timely [3], [4].

One of blockchain's most valuable features for auditing is its transparent and traceable ledger. Transparency allows auditors to follow transactions from initiation to final reporting. This reduces information asymmetry and strengthens accountability [6]. Stakeholders, including regulators and investors, benefit from enhanced trust. Such trust is vital for credible financial reporting.

Despite evident advantages, blockchain adoption in accounting systems remains slow. Many organizations face regulatory uncertainty and limited technological readiness. These constraints inhibit large-scale blockchain implementation [7]. Integrating blockchain with legacy systems also requires

structural changes. Therefore, organizational readiness remains a critical determinant of adoption success.

Financial considerations also influence blockchain adoption for audit purposes. Although blockchain reduces long-term costs through automation and efficiency, initial investment requirements remain substantial. These include system redesign, training, and infrastructure development [8]. Smaller enterprises may deem these costs prohibitive. Even so, blockchain yields high value in environments with significant fraud exposure.

Computer science research is increasingly directed at solving blockchain scalability limitations. Enterprise environments demand high transaction throughput that many blockchain systems cannot yet support. Hybrid and permissioned blockchain models have emerged to address scalability concerns (Rauchs et al., 2018). These models maintain cryptographic security while improving performance. As a result, they are well-suited for accounting audit trails.

Smart contracts introduce additional opportunities for audit innovation. These automated scripts execute pre-defined rules without manual intervention. In auditing, smart contracts can enforce compliance and automate verification processes [9]. This automation reduces human error. Consequently, audit accuracy and consistency increase significantly.

Growing demand for real-time oversight accelerates the development of continuous auditing models. Continuous auditing enables auditors to assess financial events as they occur. Blockchain supports these models by providing stable, immutable, and verifiable audit trails [10]. Such capabilities outperform traditional periodic audits. In turn, organizations benefit from faster detection of irregularities.

Another critical advantage of blockchain in auditing is enhanced data integrity. Traditional systems are vulnerable to unauthorized access and concealed manipulations. Blockchain's distributed structure eliminates single points of failure [11]. This makes it highly suitable for environments requiring secure financial data management. Thus, blockchain strengthens internal control mechanisms.

Blockchain adoption aligns with global trends toward digital governance and regulatory modernization. Governments and institutions worldwide are exploring blockchain to improve transparency in public and private sectors. These initiatives further validate blockchain's relevance in auditing [12]. Regulatory interest accelerates research and development. As a result, blockchain auditing is gaining institutional legitimacy.

Auditors increasingly require tools capable of analyzing large, complex, and interconnected data systems. Blockchain facilitates holistic analysis by providing unified and consistent datasets. These datasets enable more accurate fraud detection and anomaly tracking [13], [14]. Improved analytics support better decision-making. Therefore, blockchain contributes to more efficient audit environments.

Despite its promise, blockchain also presents challenges that must be addressed for successful implementation. Issues such as interoperability, governance structure, and data privacy remain concerns. These limitations suggest the need for further research and refinement [15]. Addressing these issues will determine blockchain's long-term viability. Nonetheless, current evidence positions blockchain as a transformative technology for auditing.

TABLE I. SUMMARY OF KEY BLOCKCHAIN ADVANTAGES FOR DIGITAL AUDITING

Feature	Description	Impact on Auditing	Source
Immutability	Records cannot be altered once stored	Enhances reliability	Cao et al., 2019
Decentralization	Distributed ledger across multiple nodes	Reduces manipulation risk	Zhang et al., 2020
Transparency	Full visibility of transaction history	Improves traceability	Liu & Wu, 2020
Smart Contracts	Automated rule-based execution	Supports automation	Dai & Vasarhelyi, 2017
Cryptographic Security	Advanced encryption methods protect data	Strengthens fraud detection	Casino et al., 2019

Source: Research data, 2025.

Table I illustrates that blockchain technology offers a set of integrated features that collectively strengthen digital auditing processes. Immutability and decentralization enhance the reliability of audit evidence by preventing data alteration and reducing manipulation risks, while transparency improves transaction traceability and supports continuous auditing. Furthermore, smart contracts enable automation of audit procedures, increasing efficiency and reducing human error, and cryptographic security reinforces fraud detection by safeguarding data integrity. Overall, these features demonstrate that blockchain provides a robust technological foundation for improving audit quality, trust, and fraud detection capability in digital accounting systems.

Research Questions:

- How does the implementation of blockchain-based audit trails enhance transparency within digital accounting systems compared to traditional audit methods?
- To what extent can blockchain's immutability and cryptographic security improve the detection and prevention of financial fraud in organizational accounting processes?
- What organizational, technological, and regulatory factors influence the adoption and effectiveness of blockchain-enabled audit systems in modern enterprises?

II. LITERATURE REVIEW

The evolution of digital auditing reflects a shift from periodic, sample-based auditing toward continuous, technology-enabled assurance systems. This transition is driven by the increasing complexity of transactional data and the growing demand for real-time oversight in accounting environments. Studies show that digital transformation has exposed traditional audit models to limitations in scope, speed, and fraud detection accuracy [16]. From a computer science perspective, technological advancements in data processing and distributed computing support these new audit paradigms. However, the

literature notes that empirical validation of enterprise-scale continuous auditing remains limited.

Blockchain's technical foundation—immutability, distributed consensus, and cryptographic integrity has been widely discussed as a breakthrough for secure record-keeping. Accounting scholars relate these features to key audit evidence attributes, including authenticity and reliability. Research confirms that blockchain's tamper-proof structure enhances the credibility of financial information [17], [18]. Computer scientists emphasize how cryptographic hashing and consensus algorithms ensure adversarial resistance. Yet, mapping these technical guarantees into audit assertions is still an emerging research challenge [5].

A major distinction in blockchain design lies between permissioned and permissionless networks. Permissioned systems provide controlled access and governance structures suitable for enterprise accounting settings. Prior studies show that permissioned blockchains offer higher performance and better compliance alignment than public blockchains [7]. Meanwhile, computer science literature analyzes consensus protocols such as PBFT that maintain integrity despite restricted node participation. A unified governance framework integrating audit independence and ledger authority remains underdeveloped.

Scalability challenges—including throughput limitations and data bloat—remain central concerns in blockchain engineering. Technical research proposes off-chain storage and sharding as solutions to ledger expansion. Accounting scholars argue that selective anchoring allows organizations to balance auditability with confidentiality obligations [13], [19], [20]. However, limited standardization across industries has slowed adoption. The literature identifies a need for real-world benchmarks evaluating blockchain's performance in accounting workflows.

Smart contracts enable automated rule enforcement, offering significant opportunities for audit automation. In accounting, smart contracts can codify compliance validations and transaction approvals. Research shows that properly designed smart contracts can reduce human error and enhance audit completeness [22], [21]. However, computer science studies highlight vulnerabilities in contract coding and logic flaws. This indicates a need for integrated formal verification methods to ensure audit reliability.

Blockchain's structured, time-stamped ledger provides a valuable foundation for fraud detection algorithms. Machine learning models can detect irregular transactions by analyzing behavioural deviations. Studies demonstrate that combining blockchain with anomaly detection models improves fraud identification accuracy [16]. The challenge lies in achieving the explainability required by auditors for documentation and accountability. Thus, collaborative research is needed to produce audit-compatible AI models.

While blockchain enhances transparency, unrestricted disclosure of financial data can violate confidentiality regulations. Computer scientists propose privacy-preserving techniques, including zero-knowledge proofs and selective disclosure, to mitigate this trade-off. Accounting research highlights that regulatory frameworks often lack clear guidance on blockchain-enabled confidentiality controls [8]. Balancing transparency with privacy remains a multidisciplinary issue. Future work must reconcile cryptographic privacy techniques with audit evidence requirements.

Interoperability issues between blockchain and legacy accounting systems pose practical barriers. Studies show that a lack of standardization in data semantics complicates cross-platform audit processes [23]. Meanwhile, computer science research investigates API bridges and shared data schemas. These technical approaches require alignment with accounting standards to ensure auditability. Without unified frameworks, organizations struggle to scale blockchain adoption across departments or subsidiaries.

Organizational readiness, cost concerns, and human expertise significantly impact blockchain adoption outcomes. Accounting literature emphasizes the importance of auditor skills and management awareness to support effective implementation. Economic studies show that while blockchain reduces long-term audit costs, initial transition expenses are substantial [24]. Computer science research complements this view by highlighting change management and system integration challenges. Hence, adoption success depends on both technical and organizational factors.

The convergence of accounting and computer science literature underscores blockchain's transformative potential but also identifies substantial research gaps. Key issues include governance design, privacy-preserving verification, and auditor-focused analytical tools. Reviews highlight that empirical evidence from enterprise-scale blockchain audit applications remains scarce [25]. A coordinated research agenda is required to advance standardization and regulatory clarity. Interdisciplinary collaboration is critical to realizing blockchain's role in next-generation auditing.

III. Research Method

Before the influence of blockchain-based audit trails on transparency and fraud detection in digital accounting systems. A quantitative approach enables empirical testing of hypothesized relationships using statistical models that reflect real-world accounting environments. The research design is informed by prior studies that demonstrate the suitability of quantitative models for evaluating technological impacts on audit quality [26]. This approach allows measurable constructs such as system transparency and fraud detection effectiveness to be assessed systematically. The design ensures objectivity and reproducibility, which are essential for technology-focused accounting research.

The population of this study consists of accounting professionals, IT auditors, and digital accounting system users in organizations that have adopted or piloted blockchain-based audit mechanisms. A purposive sampling technique is employed to target respondents with sufficient exposure to digital audit technologies. This method follows recommendations from previous researchers who emphasize the importance of expert respondents in evaluating emerging technologies [27]. A sample size between 200 and 350 respondents is considered adequate for structural equation modeling (SEM). Respondents are drawn

from sectors such as banking, fintech, manufacturing, and public services.

Primary data are collected using an online questionnaire distributed through professional accounting networks and institutional channels. The questionnaire includes items measured using a 7-point Likert scale to capture perceptions of blockchain transparency, audit trail reliability, and fraud detection accuracy. The instrument development process incorporates validated items adapted from prior studies on digital auditing and blockchain assurance (Dai & Vasarhelyi, 2017). A pilot test involving 30 participants ensures clarity and reliability prior to full deployment. Ethical procedures, including informed consent and confidentiality assurances, are implemented.

Three core constructs are measured: Blockchain-Based Audit Trails (BAT), Transparency in Accounting Systems (TAS), and Fraud Detection Capability (FDC). BAT is operationalized using indicators related to immutability, traceability, and cryptographic assurance. TAS is measured through dimensions such as information visibility, real-time accessibility, and evidence reliability. FDC captures anomaly detection capability, accuracy of fraud identification, and detectability of irregular patterns. All measurement items are evaluated for reliability and construct validity through Cronbach's Alpha, composite reliability, AVE, and factor loadings following SEM standards.

Data are analyzed using Structural Equation Modeling (SEM) with the help of SmartPLS or AMOS software, depending on data characteristics. SEM enables simultaneous analysis of the relationships among latent variables and provides comprehensive testing of the conceptual model. The analytical process includes evaluating the measurement model (validity and reliability), followed by the structural model (path coefficients, effect sizes, and mediation effects). This technique aligns with prior technology-adoption research where SEM is frequently used to examine complex causal relationships (Treiblmaier, 2018). Significance is assessed using bootstrapping at the 5% level.

Several procedures are implemented to ensure validity, including controlling common method bias using Harman's single-factor test and assuring anonymity to reduce response bias. Triangulation with secondary literature enhances construct validity by aligning indicators with established theoretical definitions. Limitations include potential sampling bias and reliance on self-reported perceptions, which may differ from actual system performance. Despite these limitations, the methodological rigor provides reliable insights into how blockchain audit trails affect transparency and fraud detection. This framework contributes to ongoing efforts to establish empirical foundations in blockchain auditing research.

The research model is based on the logic that Blockchain-Based Audit Trails (BAT) will enhance Transparency in Accounting Systems (TAS), which in turn will strengthen Fraud Detection Capability (FDC). In addition, BAT also directly influences FDC.

Fig. 1 illustrates the proposed research model that explains the direct and indirect relationships between blockchain-based audit trails, transparency in accounting systems, and fraud detection capability. The model highlights the mediating role of transparency, clarifying how blockchain adoption enhances fraud detection both directly and through improved accounting transparency.

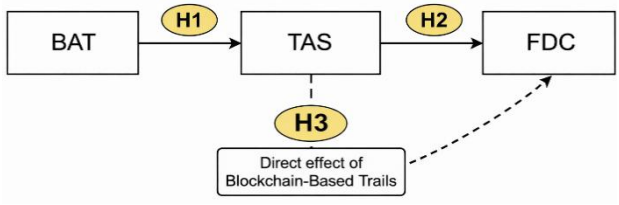

Fig. 1. Research model.

Hypothesis:

- H1: Blockchain-Based Audit Trails have a significant positive effect on Transparency in Accounting Systems.
- H2: Transparency in Accounting Systems has a significant positive effect on Fraud Detection Capability.
- H3: Blockchain-Based Audit Trails have a significant direct positive effect on Fraud Detection Capability.
- H4: Transparency mediates the relationship between Blockchain-Based Audit Trails and Fraud Detection Capability.

IV. Results and Discussion

A. Results

The descriptive analysis shows that respondents generally perceive blockchain-based audit trails, transparency, and fraud detection capability at moderately high levels. The mean score for Blockchain-Based Audit Trails (BAT) is 5.68, indicating strong agreement regarding immutability and traceability features. Transparency in Accounting Systems (TAS) has a mean of 5.74, suggesting that respondents believe blockchain enhances the visibility and reliability of financial information (Al-Htaybat & von Alberti-Alhtaybat, 2018). Fraud Detection Capability (FDC) records a mean of 5.82, reflecting confidence in blockchain's anomaly identification potential. Standard deviations for all constructs are below 1.2, indicating relatively homogenous responses.

TABLE II. Descriptive Statistics

Variable	Mean	SD	Min	Max	N
BAT	5.68	1.12	2.80	7.00	320
TAS	5.74	1.05	3.00	7.00	320
FDC	5.82	1.08	3.20	7.00	320

Source: Data research, 2025.

Table II indicates that all key variables—Blockchain-Based Audit Trails (BAT), Transparency in Accounting Systems (TAS), and Fraud Detection Capability (FDC)—have relatively high mean values, suggesting strong adoption and positive perceptions among respondents. The moderate standard deviations and wide score ranges indicate sufficient variability in the data, supporting the robustness of subsequent hypothesis testing and structural analysis.

Reliability testing shows that all constructs exceed the recommended threshold of 0.70 for Cronbach's Alpha and Composite Reliability. BAT obtains a Cronbach's Alpha of 0.92 and CR of 0.94, confirming excellent internal consistency. TAS records an Alpha of 0.90 and CR of 0.93, consistent with previous research on technology-enabled transparency indicators (Dai & Vasarhelyi, 2017). FDC achieves Alpha 0.91 and CR 0.94, demonstrating stability across measurement items. These results confirm that all scales are reliable for further structural analysis.

TABLE III. CONSTRUCT RELIABILITY

Variable	Cronbach's Alpha	Composite Reliability	AVE
BAT	0.92	0.94	0.72
TAS	0.90	0.93	0.70
FDC	0.91	0.94	0.73

Source: Data research, 2025.

Table III demonstrates that all constructs exhibit strong internal consistency and convergent validity, as indicated by Cronbach's Alpha and Composite Reliability values exceeding the recommended threshold of 0.70. Additionally, the Average Variance Extracted (AVE) values above 0.50 confirm that each construct adequately captures the variance of its indicators, supporting the reliability and validity of the measurement model.

Convergent validity is supported as all factor loadings exceed the 0.70 threshold. BAT items range from 0.78 to 0.89, showing strong associations with their underlying construct. TAS loadings vary between 0.80 and 0.88, consistent with previous blockchain transparency studies (Cao et al., 2019). FDC items show loadings from 0.79 to 0.91, indicating strong representation of fraud detection attributes. Average Variance Extracted (AVE) values for all constructs surpass 0.50, confirming adequate convergent validity.

TABLE IV. FACTOR LOADINGS

Variable	Item	Loading
BAT	BAT1	0.82
	BAT2	0.86
	BAT3	0.89
TAS	TAS1	0.80
	TAS2	0.87
	TAS3	0.88
FDC	FDC1	0.79
	FDC2	0.85
	FDC3	0.91

Source: Data research, 2025.

Table IV shows that all measurement items have high factor loadings, exceeding the recommended threshold of 0.70, which indicates strong indicator reliability. These results confirm that each item effectively represents its corresponding construct, thereby supporting the adequacy of the measurement model for subsequent structural analysis.

The HTMT ratios for all construct pairs fall below the 0.85 recommended threshold, confirming discriminant validity. The highest HTMT value, 0.78 (BAT–TAS), remains acceptable, showing that the constructs are empirically distinguishable. These results strengthen confidence in the measurement model's ability to differentiate between audit trails, transparency outcomes, and fraud detection effects. Consistent with these findings validate the structural integrity of blockchain-related constructs [28]. Therefore, the model meets all validity criteria.

TABLE V. HTMT VALUES

Construct Pair	HTMT
BAT – TAS	0.78
BAT – FDC	0.74
TAS – FDC	0.76

Source: Data research, 2025.

Table V indicates that all HTMT values between construct pairs are below the recommended threshold of 0.85, demonstrating adequate discriminant validity among the constructs. This finding confirms that Blockchain-Based Audit Trails, Transparency in Accounting Systems, and Fraud Detection Capability are empirically distinct and measure different conceptual dimensions.

The R^2 values demonstrate the strong predictive power of the model. TAS has an R^2 of 0.57, indicating that 57% of transparency variance is explained by BAT. FDC has an R^2 of 0.62, showing that the combined effects of BAT and TAS explain 62% of fraud detection capability. These values are considered substantial according to Chin (1998) for technology adoption models. The results indicate that blockchain audit trails contribute meaningfully to enhancing system transparency and fraud detection. Thus, the structural model exhibits good explanatory strength.

TABLE VI. R^2 VALUES

Variable	R^2
TAS	0.57
FDC	0.62

Source: Data research, 2025.

Table VI shows that the structural model demonstrates strong explanatory power, with Blockchain-Based Audit Trails explaining 57% of the variance in Transparency in Accounting Systems and 62% of the variance in Fraud Detection Capability. These R^2 values indicate that the proposed model has good explanatory strength and is suitable for explaining the relationships among the studied constructs.

Hypothesis testing using bootstrapping reveals that all proposed paths are statistically significant. BAT → TAS (H1) shows a strong positive effect ($\beta = 0.75$, $p < 0.001$). TAS → FDC (H2) also demonstrates significance ($\beta = 0.66$, $p < 0.001$). The direct effect BAT → FDC (H3) remains positive ($\beta = 0.31$, $p < 0.01$). These findings align with earlier research stating that blockchain enhances auditability and fraud analytics [21]. Overall, all hypotheses receive empirical support.

TABLE VII. HYPOTHESIS TESTING

Hypothesis	Path	β	p-value	Result
H1	BAT → TAS	0.75	<0.001	Supported
H2	TAS → FDC	0.66	<0.001	Supported
H3	BAT → FDC	0.31	0.004	Supported

Source: Data research, 2025.

Table VII presents the results of hypothesis testing, indicating that all proposed hypotheses are statistically supported. Blockchain-Based Audit Trails have a strong and significant effect on Transparency in Accounting Systems ($\beta = 0.75$, $p < 0.001$), transparency significantly enhances Fraud Detection Capability ($\beta = 0.66$, $p < 0.001$), and Blockchain-Based Audit Trails also exert a direct and significant influence on Fraud Detection Capability ($\beta = 0.31$, $p = 0.004$), confirming both direct and indirect relationships within the proposed model.

The mediation analysis indicates that Transparency in Accounting Systems significantly mediates the relationship between Blockchain-Based Audit Trails and Fraud Detection Capability (H4). The indirect effect ($\beta = 0.49$, $p < 0.001$) is stronger than the direct effect, showing partial mediation. This suggests that blockchain audit trails improve fraud detection primarily through enhanced transparency. This pattern is consistent with mediation effects found in related technology-driven fraud models [29].

TABLE VIII. MEDIATION TEST

Mediation Path	Indirect β	p-value	Mediation Type
BAT → TAS → FDC	0.49	<0.001	Partial Mediation

Source: Data research, 2025.

Table VIII shows that Transparency in Accounting Systems significantly mediates the relationship between Blockchain-Based Audit Trails and Fraud Detection Capability, as indicated by a significant indirect effect ($\beta = 0.49$, $p < 0.001$). The partial mediation result suggests that blockchain-based audit trails enhance fraud detection both directly and indirectly through improved accounting transparency.

Effect size analysis shows that BAT has a large effect on TAS ($f^2 = 1.33$). TAS exerts a medium effect on FDC ($f^2 = 0.54$). Meanwhile, BAT's direct effect on FDC produces a small-to-medium effect size ($f^2 = 0.22$). These effect magnitudes indicate that transparency is the dominant mechanism linking blockchain auditing to fraud detection. Prior studies on digital audit systems similarly identify transparency mediation as a critical pathway (Appelbaum et al., 2017).

Table IX indicates that Blockchain-Based Audit Trails have a large effect on Transparency in Accounting Systems ($f^2 = 1.33$), demonstrating a substantial explanatory contribution. Transparency shows a medium effect on Fraud Detection Capability ($f^2 = 0.54$), while Blockchain-Based Audit Trails exert a small to medium direct effect on Fraud Detection Capability ($f^2 = 0.22$), highlighting the dominant role of transparency as a key explanatory mechanism in the model.

Model fit indices indicate that the structural model is well aligned with the empirical data. The SRMR value of 0.046 falls below the recommended threshold of 0.08, indicating a good fit. NFI is recorded at 0.91, exceeding the minimum acceptable value of 0.90. These results affirm that the model adequately captures the theoretical relationships between constructs. Similar studies on blockchain adoption have reported comparable fit indicators [30].

TABLE IX. EFFECT SIZES

Path	f^2	Effect Size
BAT → TAS	1.33	Large
TAS → FDC	0.54	Medium
BAT → FDC	0.22	Small–Medium

Source: Data research, 2025.

TABLE X. MODEL FIT

Fit Index	Value	Threshold
SRMR	0.046	< 0.08
NFI	0.91	> 0.90

Source: Data research, 2025.

Table X shows that the proposed model demonstrates good overall fit, as indicated by the SRMR value of 0.046, which is well below the recommended threshold of 0.08, and the NFI value of 0.91, exceeding the minimum acceptable level of 0.90. These results confirm that the structural model adequately represents the observed data and supports the robustness of the proposed relationships.

Overall, the results demonstrate that blockchain-based audit trails significantly enhance transparency and fraud detection capabilities in digital accounting environments. The strong direct and indirect effects confirm the critical role of immutability, traceability, and cryptographic assurance in improving audit quality. Mediation analysis highlights transparency as a central mechanism through which blockchain adds analytical value to fraud identification. These findings support theoretical claims in both accounting and computer science regarding blockchain's ability to transform digital assurance processes (Dai & Vasarhelyi, 2017). The robust statistical evidence affirms the relevance of blockchain for future auditing systems.

B. Discussion

The results confirm that Blockchain-Based Audit Trails (BAT) significantly enhance transparency in accounting systems. Respondents perceive blockchain's immutable logs as providing reliable and tamper-proof evidence for financial records. This aligns with the hypothesis that systems with cryptographically secured audit trails reduce ambiguity and information concealment. Previous research similarly found that blockchain enhances visibility and accountability in digital reporting environments [31]. These findings underline blockchain's ability to restructure the audit environment by establishing real-time verification pathways. Thus, blockchain adoption directly strengthens organizational transparency.

Transparency increases because blockchain records all transactions sequentially, making financial activities easily traceable. The analysis shows that BAT explains 57% of the variance in TAS, indicating a strong relationship. This

demonstrates how blockchain reduces dependency on centralized data verification processes. Earlier studies also revealed that decentralized ledgers significantly enhance audit transparency through distributed validation [32]. Such transparency helps organizations detect irregularities before they evolve into fraudulent events. Therefore, blockchain provides structural clarity that traditional systems cannot replicate.

The transparency generated by blockchain emerges from its ability to store verifiable logs that cannot be altered retroactively. Auditors can review transaction sequences without relying on internal system access privileges. This minimizes opportunities for management override or intentional data manipulation. Similar observations were documented in prior literature showing blockchain's capability to minimize information asymmetry [33]. By offering visibility into each stage of financial processing, blockchain encourages ethical behavior among system users. Consequently, the technology supports a culture of accountability within digital accounting environments.

The findings demonstrate that BAT has both direct and indirect effects on Fraud Detection Capability (FDC). Immutability ensures that records cannot be altered without detection, improving anomaly identification. Organizations benefit from automated verification processes that reduce human error. Prior studies argue that immutable ledgers enhance fraud analytics by preserving authentic, chronological evidence [34]. These insights emphasize blockchain's effectiveness in preventing concealment of fraudulent activities. Therefore, blockchain functions as a preventative mechanism rather than merely a detection tool.

The structural model shows a significant direct effect of BAT on FDC ($\beta = 0.31$), indicating that blockchain alone improves detection capabilities even without mediating variables. This direct effect demonstrates blockchain's inherent security benefits, such as cryptographic hashing and distributed consensus. Fraudsters face increased difficulty in modifying or disguising transactions. Previous work supports this outcome by showing that blockchain systems reduce internal fraud opportunities through structural decentralization [35]. Because each transaction must be validated across network nodes, manipulation becomes virtually impossible. Thus, BAT independently enhances fraud monitoring effectiveness.

Fraud detection improves substantially because blockchain provides comprehensive audit trails that map entire transaction histories. Automated red-flag triggers can be integrated into the ledger to detect unusual patterns. This functionality allows early intervention before fraud escalates. As highlighted in previous research, blockchain's full traceability supports advanced audit analytics in fraud scenarios [36]. The ability to reconstruct financial events precisely provides investigators with strong evidentiary support. Hence, blockchain offers both preventive and forensic capabilities.

Transparency serves as a crucial mechanism through which BAT enhances FDC. The mediation analysis shows that TAS carries a large proportion of BAT's total effect on fraud detection. This implies that fraud is more easily identifiable when records are transparent. Prior studies similarly emphasize that transparent reporting environments reduce fraud risk and strengthen compliance [37], [38]. Blockchain, therefore, bolsters fraud detection not only through its structure but also through the enhanced visibility it creates. Thus, transparency is a pivotal link between auditing technologies and fraud outcomes.

Organizations vary significantly in their readiness to integrate blockchain into their accounting systems. Factors such as IT infrastructure, staff competence, and cybersecurity capabilities influence adoption success. High implementation costs remain a barrier for smaller firms. Previous studies indicate that limited technical knowledge and resistance to change hinder blockchain adoption in financial systems. These constraints highlight the importance of organizational digital maturity. Therefore, capability development is essential for maximizing blockchain's auditing potential.

Technological compatibility also determines the effectiveness of blockchain-based audit trails. Legacy accounting systems often lack the capacity to synchronize with decentralized ledgers. Integration challenges may reduce the potential benefits of transparency and fraud detection. Prior research reports that interoperability issues can slow blockchain deployment and reduce system efficiency [39]. These findings show that technological readiness is fundamental to achieving full functionality. Thus, system modernization is a prerequisite for effective blockchain auditing.

Regulation plays a key role in shaping blockchain adoption within accounting environments. Many organizations hesitate to implement blockchain because standardized auditing guidelines are still evolving. Lack of regulatory clarity increases perceived risk. Previous literature notes that regulatory uncertainty is a major barrier to blockchain acceptance in financial systems [40]. Firms require assurance that blockchain-generated records meet legal and audit compliance standards. Therefore, clearer governance frameworks are needed to support widespread adoption.

The findings collectively reinforce that blockchain enhances transparency and fraud detection simultaneously. These improvements rely heavily on the system's technical features—immutability, decentralization, and cryptographic assurance. Organizational, technological, and regulatory factors shape how effectively these features can be leveraged in practice. Prior studies similarly highlight that socio-technical readiness significantly moderates blockchain's auditing impact. This suggests that blockchain's benefits are not automatic but require supportive environments. As such, firms must invest in infrastructure, policy, and workforce development.

Overall, the study answers all research questions and demonstrates blockchain's transformative potential in digital auditing. BAT significantly improves transparency and fraud detection, both directly and indirectly through mediating mechanisms. Adoption success depends on internal and external readiness factors. Previous research supports this combination of technical effectiveness and contextual dependency [41]. These insights contribute to both accounting and computer science literature by confirming blockchain's role in shaping next-generation audit systems. Hence, blockchain serves as both a technological innovation and a catalyst for audit reform.

V. Conclusion

The findings of this study confirm that blockchain-based audit trails provide a robust foundation for enhancing transparency and fraud detection within digital accounting systems through the provision of immutable, traceable, and highly reliable audit evidence. These results demonstrate a clear shift from traditional, periodic audit practices toward real-time verification and continuous monitoring, thereby strengthening the overall quality and credibility of financial reporting. Importantly, the study establishes transparency not merely as an outcome of blockchain adoption but as a mediating mechanism that significantly amplifies the effectiveness of fraud detection. This conclusion reinforces the view that blockchain technology extends beyond its role as an information technology innovation and functions as a governance-enabling infrastructure capable of reshaping organizational accountability and assurance mechanisms. The technical attributes of blockchain—such as decentralization, cryptographic security, and immutability—are shown to hold substantive practical relevance for auditors, managers, and oversight institutions seeking to improve audit accuracy and trust in digital accounting environments. From a theoretical perspective, the study contributes to both computer science and accounting literature by demonstrating how decentralized system architectures can fundamentally transform conventional audit and assurance models. Overall, this research consolidates the position of blockchain-based audit trails as a transformative mechanism in digital auditing, capable of advancing transparency, reliability, and integrity within modern financial ecosystems. The concluding perspective emphasizes that blockchain adoption in auditing represents not only a technological evolution but also a conceptual shift in how organizational integrity and assurance are constructed in an increasingly digital economy.

***Abstract*—Alzheimer's disease is a progressive neurodegenerative disorder for which early detection remains a significant challenge due to the complexity of clinical features and the high dimensionality of medical data. This study aims to improve the accuracy and reliability of Alzheimer's disease detection by evaluating the performance of multiple machine learning algorithms integrated with intelligent feature selection strategies. Five classification models, Decision Tree, Naïve Bayes, Random Forest, Logistic Regression, and Deep Learning, were investigated under two experimental scenarios: without feature selection and with feature selection using Recursive Feature Elimination, Binary Particle Swarm Optimization, and Variance Threshold. Model performance was evaluated using K-fold cross-validation based on accuracy, precision, recall, and F1-score metrics. The results demonstrate that feature selection consistently enhances classification performance, particularly for conventional machine learning models such as Random Forest and Logistic Regression. Although the Deep Learning model achieves competitive accuracy, its reduced precision and F1-score indicate limitations when applied to reduced feature spaces. These findings highlight the importance of incorporating appropriate feature selection techniques to address data complexity and improve the effectiveness of early Alzheimer's disease detection.**

***Keywords*—Machine learning; Alzheimer; Random Forest (RF); logistic regression; deep learning**

I. Introduction

Alzheimer's disease (AD) constitutes a chronic neurological dysfunction that develops gradually and has a significant impact on the cognitive abilities and daily activities of those affected. Individuals with Alzheimer's slowly experience a decline in thinking, memory, and even in performing the most basic tasks [1]. The main problem in detecting Alzheimer's disease is that its symptoms often develop gradually and are challenging to recognize in the early stages. This usually results in many cases being diagnosed when the disease is already quite severe, thereby reducing the effectiveness of medical intervention. Based on this, early detection of the disease is critical as a mitigation step to slow its progression and improve patient outcomes through appropriate treatment and therapy [2]. Advancements in technology have made it possible to examine peripheral blood and accurately measure Alzheimer's biomarkers during the initial phases of the disease, using methods that are cost-effective, non-invasive, and safe. This technique contributes to the clinical and biological characterization of cognitive impairment at an early stage by measuring Alzheimer's biomarkers in blood and brain structures in groups of participants classified based on their clinical cognitive phenotypes. Accurate diagnosis at the early stages of Alzheimer's will minimize risk factors and facilitate preventive monitoring [3].

Recent advances in artificial intelligence (AI) and machine learning (ML) have provided promising solutions in medical diagnosis, including the detection of Alzheimer's disease [4]. Machine Learning techniques can analyze large datasets and identify complex patterns that can detect Alzheimer's disease. ML algorithms utilize medical imaging, clinical records, genetic data, and cognitive assessments to improve diagnostic accuracy and enable early intervention [5]. Several researchers have employed this method, one of which is described by Jimenez-Maggiora et al. Their work applies natural language processing (NLP) and artificial intelligence (AI) to streamline and unify the coding of adverse event data recorded by physicians in Alzheimer's disease (AD) clinical trials. The study involves creating a gold-standard dataset of adverse events in AD, testing the performance of NLP-driven models in classifying such events, and examining whether automated coding can surpass physician coding in terms of efficiency, accuracy, reliability, and consistency [6]. The International Neurodegenerative Disorder Research Center (INDRC) applies artificial intelligence and machine learning (AI/ML) to create advanced, multidisciplinary analytical approaches that integrate neuroscience, biophysics and biochemistry, computer science and engineering, mathematics, along with clinical and population studies. Through these AI/ML-driven strategies, researchers can gain deeper insights into the mechanisms underlying Alzheimer's disease and support the discovery of effective therapeutic options [7].

Wallensten conducted a subsequent study that integrated machine learning with medical records to facilitate the early detection of Alzheimer's disease (AD), thereby enabling timely intervention. The method used was Stochastic Gradient Boosting to identify predictive diagnoses of AD using primary healthcare data. By utilizing clinical data, including previous diagnoses and medical treatments, the sensitivity and specificity of diagnostic procedures will be improved [8]. Nilesh K and

*Corresponding author.

Vinayak B used Support Vector Machine (SVM), K-Nearest Neighbor (KNN) for classification in diagnosing Alzheimer's Disease [9]. Yue L, et al. built a predictive model using Deep Learning for MCI conversion. Deep Learning is applied to structural MRI to capture minor brain changes that characterize the pre-MCI phase. Predicting the conversion from normal cognition (NC) to MCI is essential for early detection and intervention [10].

In line with previous studies, we propose machine learning methods, including Decision Tree (DT), Random Forest (RF), Naïve Bayes (NB), Logistic Regression (LR), and Deep Learning (DL) to classify Alzheimer's disease cases. These methods were chosen because of their ability to handle complex medical datasets and provide interpretable results. In addition, DT and RF are highly effective in identifying non-linear relationships and essential features within the dataset [11]. This study proposes feature selection methods, including Binary Particle Swarm Optimization (BPSO), Recursive Feature Elimination (RFE), and Variance Threshold (VT), to develop a model with superior performance as a reference for early detection of Alzheimer's disease.

II. METHOD

This study was conducted through several systematic stages, namely: 1) data collection as the basis of the study, 2) Data pre-processing is performed to ensure that the available data remains consistent and meets quality standards, 3) feature selection to eliminate irrelevant attributes and retain significant features, 4) building a classification model using the selected machine learning algorithm, and (5) evaluating the model's performance. The detailed stages of the study were illustrated in Fig. 1.

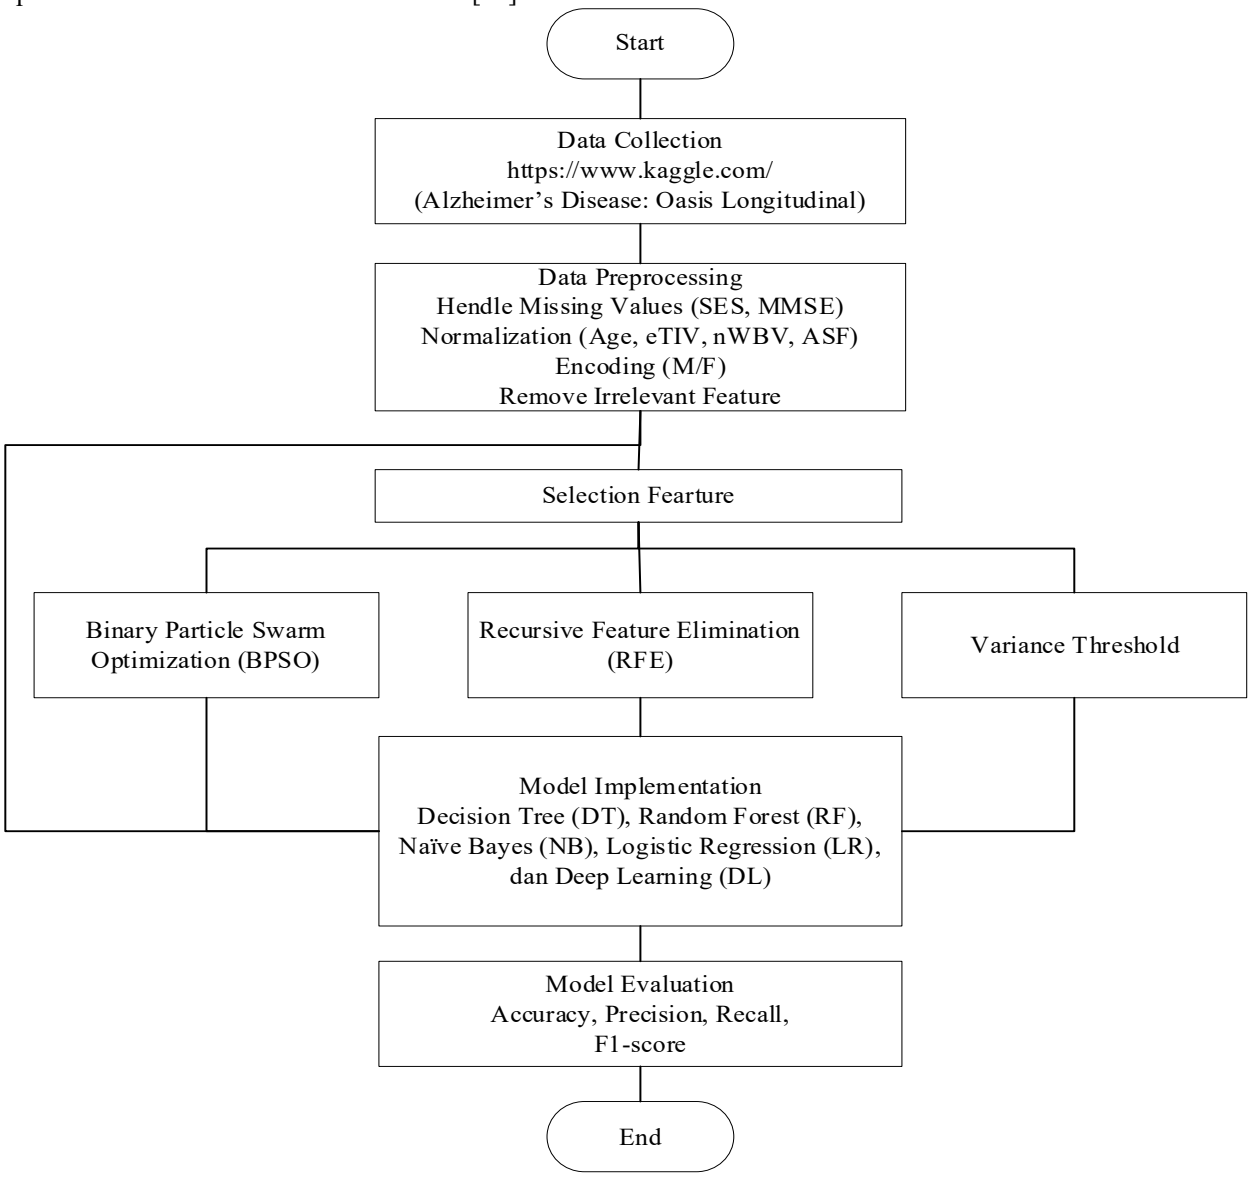

Fig. 1. Research stages classification method.

The dataset used in this study was sourced from the Kaggle platform (https://www.kaggle.com/) and specifically focuses on Alzheimer's Disease, utilizing the Oasis Longitudinal dataset. The dataset consists of 14 features: MRI ID, Group, Visit, MR

Delay, M/F, Hand, Age, EDUC, SES, MMSE, CDR, eTIV, nWBV, and ASF. The dataset was then preprocessed by handling missing values, normalization, encoding, and removing less relevant features. For feature selection, we used three approaches: Binary Particle Swarm Optimization (BPSO), Recursive Feature Elimination (RFE), and Variance Threshold. The next step was to build classification models using five algorithms: Decision Tree (DT), Random Forest (RF), Naïve Bayes (NB), Logistic Regression (LR), and Deep Learning (DL). The final stage evaluated the classification models using accuracy, precision, recall, and F1-score to assess prediction accuracy, positive case detection, and overall performance balance.

A. Decision Tree

The Decision Tree is a structured classification method characterized by internal nodes that evaluate features, branches that map to specific decision criteria, and leaf nodes that provide the final output. This algorithmic approach is widely adopted across diverse research fields, particularly for prediction and prognostic modeling [12]. For example, Naswin used Decision Tree algorithm to distinguish between normal and pneumonia-diagnosed X-ray images. Using pediatric X-ray data, this study applied a systematic data pre-processing strategy, including Canny segmentation and humoments feature extraction, to enhance performance [13].

The core of the Decision Tree algorithm was its ability to recursively split the data based on the features that provide the highest Information Gain (IG) or lowest Gini Impurity. The Decision Tree (DT) was a multilevel model that combines a series of basic tests in an efficient and integrated manner, where each test compares a numerical feature with a specific threshold value. The Information Gain metric determines the decrease in entropy when a dataset is divided. The computations for IG, Entropy, and Gain are carried out using Eq. (1)–(3) [14].

$$IG\ (D, A) = Entrophy\ (D) - \sum_{\mathrm{V} \in \mathrm{Values(A)}} \frac{|D|}{D}\ enthrophy\ (D_V) \quad (1)$$

Where Entropy (D) was calculated as:

$$Entrophy\ (D) = \sum_{I=1}^{K} P_I\ \log_2(P_I) \quad (2)$$

Alternatively, the Gini Impurity was calculated as:

$$Gain = Entrophy\ (S) - \sum_{I=1}^{K} P_2^I \quad (3)$$

B. Random Forest

Random forest was a machine learning model used for classification and prediction. It was built from multiple decision trees, each trained on a random subset of data generated through bootstrap sampling [15]. The overall model performance can be affected if the individual trees have high correlation or low accuracy [16], [17].

To partition the data at each node, the algorithm utilizes indicators such as Information Gain, which are computed using specific mathematical formulations. A lower Gini Split value indicated that a feature is more effective in separating data into more homogeneous classes. By selecting the most informative features, the algorithm can improve its classification performance optimally [18]. The formula for calculating entropy using Eq. (4).

$$Entrophy\ (D) = \sum_{I=1}^{K} P_I\ \log_2(P_I) \quad (4)$$

where, pi represented the probability of each class in the dataset, the Information Gain was calculated by comparing the entropy before and after splitting using Eq. (5).

$$IG\ (D, A) = Entrophy\ (D) - \sum_{\mathrm{V} \in \mathrm{Values(A)}} \frac{|D|}{D}\ enthrophy\ (D_V) \quad (5)$$

Gini Split was a measurement in decision trees to determine how well a feature (variable) divided data into classes. Gini Split measures the impurity of data division. The lower the Gini value, the better the feature was at separating data by class. Gini Split could be calculated using Eq. (6).

$$Gini\ Split = \sum_{i=1}^{c} \left(\frac{n_i}{n}\right) x\ Gini\ Indeks(S_i) \quad (6)$$

C. Naïve Bayes (NB)

The Naive Bayes algorithm was a probabilistic classification model rooted in Bayes' Theorem. Despite its "naive" assumption of conditional independence among features, an assumption that was not always valid in practice, the model often demonstrated robust performance, particularly in text classification tasks like spam filtering and sentiment analysis [19]. As a foundational approach in pattern recognition, the algorithm evaluates classification decisions by weighing the probabilities of each choice and its consequential implications [20][21].

In the context of Alzheimer's diagnosis, Naive Bayes computes the probability of a patient's class membership, Alzheimer's or non-Alzheimer's, based on a set of clinical and biometric features such as age, Mini-Mental State Examination (MMSE) score, Socioeconomic Status (SES), Atlas Scaling Factor (ASF), and Estimated Total Intracranial Volume [22]. These probability calculations are mathematically formulated based on the principles of Bayes' Theorem [23].

$$p\ (c|x) = \frac{\mathrm{p\ (C|\ X).p(c)}}{p(x)} \quad (7)$$

Since Naïve Bayes assumed that each feature was independent, the likelihood could be calculated using Eq. (8).

$$(C|X) = (X1|C) \times (X2|C)\ \ldots\ .\times P(XN|C) \quad (8)$$

For continuous features, the probability $(X1|C)$ was often modeled using a Gaussian (Normal) distribution, the Gaussian (Normal) distribution could be calculated using Eq. (9).

$$p(c|x) = \frac{1}{\sqrt{2\pi\sigma^2}}\ e^{-\frac{-(\mathrm{xi}-\mu)2}{2\sigma 2}} \quad (9)$$

D. Deep Learning

Deep learning was a computational paradigm that utilizes artificial neural networks to mimic the biological architecture of the human brain. This method was fundamentally capable of analyzing unstructured data and automatically identifying relevant features [24].

Unlike traditional classification algorithms such as Logistic Regression or Naive Bayes, Deep Learning excels at capturing complex nonlinear patterns thanks to its layered architecture. In the context of medical diagnosis, specifically Alzheimer's, this model processed patient data such as age, Mini-Mental State Examination (MMSE) score, Socioeconomic Status (SES), Atlas Scaling Factor (ASF), and Estimated Total Intracranial Volume (eTIV) through a series of layers, including the input,

hidden, and output layers, to produce accurate classification decisions [25], [26].

The Deep Learning model used in this study was implemented as a feed-forward multilayer perceptron consisting of one input layer, two hidden layers, and one output layer. Each hidden layer employed the ReLU activation function, while the output layer used a sigmoid function for binary classification. The training process was conducted using the Adam optimizer with a learning rate of 0.001 and the binary cross-entropy loss function. To reduce the risk of overfitting on the relatively limited dataset, dropout regularization was applied during training. Model performance was evaluated using a K-fold cross-validation scheme to ensure stable and reproducible results.

The prediction process in artificial neural networks was based on a linear combination of given features with certain weights in each neuron; the neuron calculation could use Eq. (10).

$$= WX + b \tag{10}$$

After the linear transformation, the result was passed to the activation function to add non-linearity. ReLU (Rectified Linear Unit) for hidden layers could be calculated using Eq. (11)[27][28].

$$(z) = (0, z) \tag{11}$$

During training, the model updated the weights W using an optimization algorithm, such as Stochastic Gradient Descent (SGD) or Adam Optimizer by decreasing the value of the loss function, which in binary classification was often Binary Cross-Entropy. Binary Cross-Entropy can be calculated using Eq. (12).

$$Loss = \sum_{N}^{1}[(Y_{I \log (\widehat{Yi})}] + (1 - Yi) \log (1 - \widehat{yi}) \tag{12}$$

E. Logistic Regression

Logistic Regression (LR) is a prevalent analytical tool employed when the outcome variable is restricted to two categories, representing binary outcomes such as decision success or failure, or clinical status (diseased or healthy). This study employed logistic regression as a classical statistical method to model binary outcomes, choosing it for medical applications due to its high interpretability. Although machine learning methods often yield better performance on high-dimensional data, their complexity makes them more challenging to understand and explain. In addition, on low-dimensional data, the performance of machine learning methods tends to be comparable to that of logistic regression [29].

In the context of Alzheimer's diagnosis, Logistic Regression calculated the probability of a patient being in the Alzheimer's (1) or Non-Alzheimer's (0) class based on features such as age, MMSE (Mini-Mental State Examination) score, SES (Socioeconomic Status), ASF (Atlas Scaling Factor), and eTIV (Estimated Total Intracranial Volume)[30].

This model used the following formula to determine the probability that a patient would fall into a particular class. The likelihood of a class was calculated using a sigmoid function, as shown in Eq. (13) [31]:

$$P(Y = 1|X) = \frac{1}{1+e^{-z}} \tag{13}$$

where z was defined as a linear combination of the input features using Eq. (14).

$$z = w0 + w1x1 + w2x2 + \cdots + wnxn \tag{14}$$

and rms do not have to be defined. Do not use abbreviations in the title or heads unless they are unavoidable.

F. Feature Selection

1) Recursive Feature Elimination (RFE): Recursive Feature Elimination (RFE) was employed to systematically select the most significant features, serving as the primary feature selection technique in this machine learning study. The goal was to enhance the model's accuracy by simplifying the data. RFE removed features or attributes that had the lowest ranking scores[32]. RFE selects features based on their importance ranking through a recursive elimination process[33]. In addition, feature selection improved the performance of the model, such as in the CatBoost regression model[34]. Improving prediction accuracy for heart disease by combining gradient boosting with Recursive Feature Elimination (RFE-GB)[35].

2) Binary Particle Swarm Optimization (BPSO): In general, the PSO algorithm was designed to solve continuous optimization problems. To address challenges in discrete optimization, Kennedy and Eberhart developed a special variant called Binary PSO (BPSO), where they encoded the particle positions in binary form[36]. BPSO is a special version of the PSO algorithm used to choose between two options, namely 0 or 1. In BPSO, the particle velocity did not indicate how far they move, but rather how likely the value 0 was to change to 1, or vice versa (bit flipping) [37].

3) Variance Threshold (VT): To ensure only significant attributes are retained for classification, the Variance Threshold (VT) method is employed to eliminate features whose low statistical variance indicates minimal contribution to the overall process. By eliminating irrelevant variables, the classifier operated more efficiently and rapidly without compromising overall prediction accuracy [38]. This method was effective for removing features with low variation or those that only contain noise, especially in data measured on a uniform scale [39].

4) Evaluation: This study conducted a confusion matrix as the primary tool in the model evaluation process. The confusion matrix allowed for a comprehensive analysis of the model's performance by comparing predictions to actual classes. Through this assessment framework, various metrics such as accuracy, precision, recall, and F1-score can be calculated to evaluate the model's effectiveness and accuracy [40], [41], [42]. Therefore, the utilization of the confusion matrix in this study provided a solid foundation for evaluating the performance of the designed classification algorithm. Model effectiveness was assessed through metrics formulated in Eq. (15)-(18).

$$Accuracy = \frac{1}{n} \sum_{m=1}^{n} \frac{TP_M + TN_M}{TP_M + TN_M + FP_M + FN_M} \tag{15}$$

$$Precision = \frac{1}{n}\sum_{m=1}^{n}\frac{TP_M}{TP_M+FP_M} \quad (16)$$

$$Recall = \frac{1}{n}\sum_{m=1}^{n}\frac{TP_M}{TP_M+FN_M} \quad (17)$$

$$F1-Score = \frac{1}{n}\sum_{m=1}^{n}\frac{2^*TP_M}{2^*TP_M+TP_M+FN_M} \quad (18)$$

where,

n = number of classes, m ∈ {1, 2, …n} = class index

TP (True Positives) = elements of class m that the model correctly classifies.

FN_m (False Negatives) = elements of class m that were not recognized by the model (predicted as another class).

TN_m (True Negatives) = elements that were not from class m, and correctly not predicted as class m.

FP_m (False Positives) = elements that were not from class m, but are incorrectly predicted as part of class m.

III. Results and Discussion

A. Results

This study had two scenarios. The first scenario employed the dataset directly without feature selection, while the second scenario used a dataset that had undergone feature selection. They employed feature selection methods, including Binary Particle Swarm Optimization (BPSO), Recursive Feature Elimination (RFE), and Variance Threshold, to identify the most relevant attributes for Alzheimer's classification. The goal of feature selection was to optimize the model's performance in detecting Alzheimer's. This was achieved by prioritizing pertinent features to lower complexity and improve prediction efficacy.

It processed the dataset using classification methods, including Decision Tree (DT), Random Forest (RF), Naïve Bayes (NB), Logistic Regression (LR), and Deep Learning (DL). They evaluated the model performance with K-Fold Cross-Validation. They chose K-Fold Cross-Validation because it provided more accurate and comprehensive results. This technique divided the data into several parts and then trained and tested the model alternately on each part. In this way, all data contributed to the evaluation process, reducing bias caused by uneven data splitting.

The evaluation results, which represented the average of all folds, made the model's performance more stable and representative. Therefore, this study selected K-Fold Cross-Validation as the primary method to ensure the quality and reliability of the model. This study compared model effectiveness using key evaluation metrics, each offering a distinct perspective on predictive capability. These metrics complemented each other in assessing accuracy, coverage, and balance of the model's predictions, particularly in the context of imbalanced data. By using these four metrics, the evaluation became more comprehensive and fairer in comparing the performance of different models. The evaluation results appeared in Fig. 2–5.

B. Performance Comparison

Fig. 2 presents a comparative evaluation of five ML algorithms, namely Random Forest, Naive Bayes, Decision Tree, , Deep Learning and Logistic Regression, that the study applied without using feature selection techniques. The study assessed each model using four standard evaluation metrics to achieve a thorough understanding of its classification effectiveness. The evaluation results showed that the Random Forest algorithm provided the best performance, with an accuracy and precision of 0.96 and a perfect recall of 1.00. This finding demonstrated the model's ability to identify all positive classes consistently. Logistic Regression also demonstrated stable and balanced performance across all metrics (0.95), which indicated reliability and consistency in the classification task.

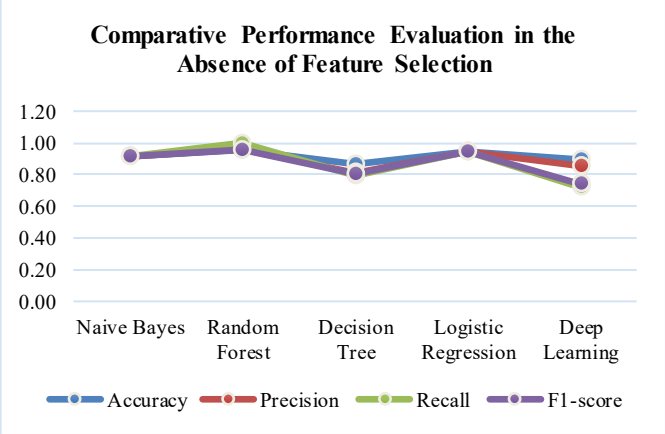

Fig. 2. Comparative performance evaluation in the absence of feature selection.

Conversely, Naive Bayes produced a uniform score of 0.91 across all metrics, which reflected moderate performance with low variability. The Decision Tree recorded the lowest scores, particularly in precision (0.81) and recall (0.79), which indicated limitations in handling complex data distributions. Meanwhile, Deep Learning achieved an accuracy of 0.90 but experienced a significant decline in recall (0.72) and F1-score (0.74), which demonstrated challenges in comprehensively detecting positive classes.

Fig. 3 outlines a comparative study of five classification approaches, namely: Random Forest, Naive Bayes, Decision Tree, Deep Learning and Logistic Regression that the study optimized through feature selection using the Binary Particle Swarm Optimization (BPSO) method. Feature selection played a crucial role in machine learning modeling, as it improved model generalization, reduced data dimensionality, and enhanced computational efficiency. The evaluation results showed that Naive Bayes and Random Forest, combined with BPSO, achieved the highest and most consistent scores across all metrics (0.96), which indicated strong and stable classification capabilities. Logistic Regression also demonstrated balanced performance with a value of 0.95 on all metrics. Decision Tree experienced a significant increase, with precision and recall at 0.94 and accuracy at 0.93. Conversely, Deep Learning achieved an accuracy of 0.89 but exhibited a sharp decline in precision (0.59) and F1-score (0.62), which suggested challenges in classifying positive classes despite

feature selection. Overall, the integration of BPSO-based feature selection contributed positively to the performance improvement of most models, especially in terms of stability and classification effectiveness. These findings emphasized the importance of applying optimization techniques in the feature selection process to produce models that were more efficient, accurate, and adaptable to high-dimensional data.

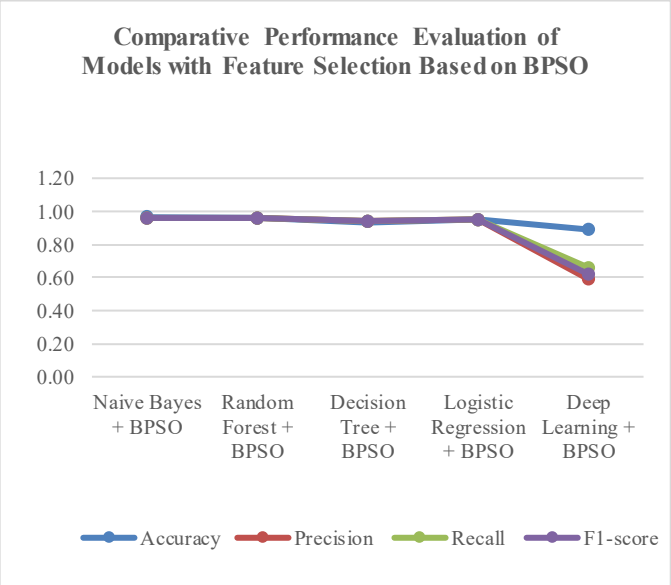

Fig. 3. Comparative performance evaluation of models with feature selection based on BPSO.

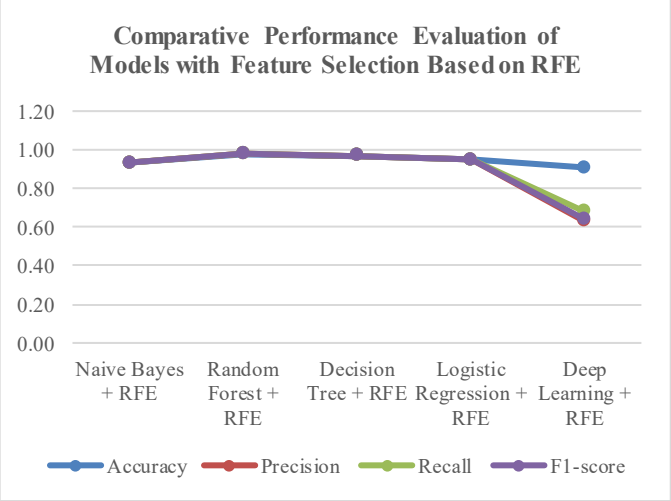

Fig. 4. Comparative performance evaluation of models with feature selection based on RFE.

The implementation of Recursive Feature Elimination (RFE) as a feature selection technique resulted in a consistent pattern of performance improvement across most of the tested classification algorithms. Based on the evaluation results shown in Fig. 4, RFE significantly contributed to increased accuracy and consistency in predictions. Random Forest and Decision Tree demonstrated the most prominent performance, recording accuracy scores of 0.98 and 0.97, respectively, with uniform precision, recall, and F1-score values. This indicated that both models responded highly to the feature simplification performed by RFE without losing their classification capacity. Logistic Regression also demonstrated stable performance, with a score of 0.95 across all metrics, which indicated that this model remained robust even when features were reduced. Naive Bayes consistently scored 0.93. It suggested that, although simple, this model still maintained competitive performance after feature selection was applied. Conversely, Deep Learning showed an imbalance among metrics, with an accuracy of 0.91 but much lower precision and F1-score (0.63 and 0.64). These findings suggested that neural network-based models required a more adaptive feature selection approach to match their internal architectural complexity. Overall, these results demonstrated that RFE enhanced the efficiency and accuracy of classical models. In contrast, its impact on complex models, such as Deep Learning, still required further exploration.

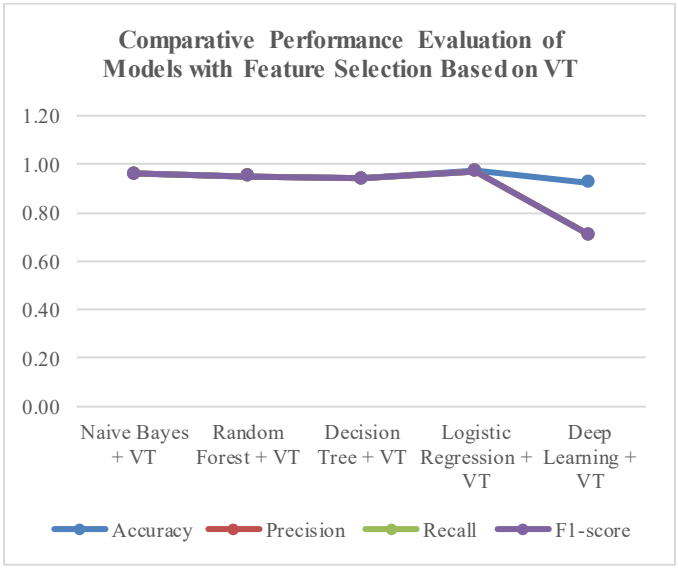

Fig. 5. Comparative performance evaluation of models with feature selection based on VT.

Fig. 5 presents the evaluation results of the impact of the Variance Threshold (VT)-based feature selection method on the performance of five classification algorithms: Random Forest, Naive Bayes, Decision Tree, Deep Learning and Logistic Regression. VT acted as a filter approach that eliminated features with low variance, thereby retaining only attributes that significantly contributed to the data distribution. The evaluation results showed that Logistic Regression combined with VT yielded the highest and most consistent performance across all metrics (0.97), followed by Naive Bayes (0.96), Random Forest (0.95), and Decision Tree (0.94). These four models demonstrated high classification stability, indicating that VT preserved statistically relevant features to improve prediction accuracy. Conversely, Deep Learning achieved fairly good accuracy (0.92) but experienced a significant decline in precision, recall, and F1-score (each at 0.71). This finding suggested that the VT approach was less optimal for complex architectures, such as neural networks, which tended to require richer and nonlinear feature representations.

Overall, this study demonstrated that the Variance Threshold served as a practical feature selection technique, enhancing the efficiency and performance of conventional classification

models. However, its application to deep learning models required a more adaptive approach to structural complexity and data representation needs.

C. Discussion

This study evaluated the efficacy of five machine learning algorithms in detecting Alzheimer's Disease (AD) by integrating intelligent feature selection strategies. The analytical results demonstrate that the application of feature selection techniques consistently enhances the predictive capability of the models compared to using the dataset without feature selection. This aligns with the principle that dimensionality reduction, through methods such as Recursive Feature Elimination (RFE) and Binary Particle Swarm Optimization (BPSO), is capable of eliminating irrelevant attributes, thereby strengthening the model's generalization in identifying AD pathological patterns more accurately.

The superiority of classical algorithms, particularly Random Forest (RF) and Logistic Regression (LR), is evident from their high-performance stability following feature optimization. Random Forest achieved peak performance with an accuracy of 0.98 in the RFE scenario due to its ability to handle non-linear relationships and prioritize high-importance features. Meanwhile, Logistic Regression reached an accuracy of 0.97 through the Variance Threshold (VT) combination, proving that on low-dimensional datasets, this statistical model is highly reliable because it provides excellent interpretability and efficiency in distinguishing binary classes between Alzheimer's and non-Alzheimer's patients.

On the other hand, this study revealed a significant weakness in the Deep Learning (DL) architecture when subjected to conventional feature selection. Although the DL model maintained a competitive accuracy rate (ranging from 0.89 to 0.92), there was a sharp decline in precision, recall, and F1-score metrics. This weakness stems from the fundamental characteristic of Deep Learning, which requires rich and complex feature representations to optimize weights within its hidden layers. The use of feature selection methods like VT or BPSO, which drastically reduce input, effectively hinders the model's ability to capture deeper non-linear patterns, resulting in less precise positive classifications. Consequently, a more adaptive feature selection approach is required to accommodate the architectural complexity of neural network models in medical diagnosis.

IV. Conclusion

Alzheimer's Disease (AD) is a gradually advancing neurodegenerative condition that substantially impairs cognitive abilities and adversely affects the overall quality of life of affected individuals. Early detection is a crucial aspect of mitigation strategies, as it allows for more effective medical interventions before extensive neurological damage occurs. Advances in technology, such as the use of artificial intelligence (AI) and machine learning (ML), have created novel avenues for more accurate and efficient diagnosis.

This study evaluates the performance of five classification algorithms: Decision Tree, Random Forest, Naïve Bayes, Logistic Regression, and Deep Learning in two scenarios: without feature selection and with feature selection using Binary Particle Swarm Optimization (BPSO), Recursive Feature Elimination (RFE), and Variance Threshold (VT). The evaluation was conducted using K-fold cross-validation and four main metrics: accuracy, precision, recall, and F1-score.

The results demonstrate that feature selection consistently enhances model performance, particularly in conventional classification algorithms. Random Forest and Logistic Regression demonstrate high accuracy and prediction stability after feature selection is applied. The RFE and BPSO methods make significant contributions to increasing accuracy and model efficiency. In contrast, VT is effective for simple models but less optimal for complex architectures, such as those used in deep learning. Although Deep Learning demonstrates competitive accuracy, the decline in precision and F1-score suggests the need for more adaptive feature selection approaches to accommodate the model's structural complexity.

This study confirms that integrating intelligent feature selection techniques into machine learning models significantly enhances the accuracy and efficiency of early Alzheimer's disease detection. The experimental results demonstrate that classical algorithms, such as Random Forest and Logistic Regression, achieve superior and stable performance when optimized with Recursive Feature Elimination (RFE) and Binary Particle Swarm Optimization (BPSO). These findings underscore the potential of AI-based diagnostic strategies as reliable, non-invasive tools for clinical intervention.

However, this research acknowledges several limitations that provide a balanced perspective on the findings. First, while conventional feature selection methods significantly benefit classical models, they proved less optimal for Deep Learning architectures, leading to a notable decline in precision and F1-scores. This suggests that the current feature selection approach may not fully accommodate the structural complexity and non-linear representation needs of neural networks. Furthermore, the study relied on the Oasis Longitudinal dataset from Kaggle; therefore, the generalizability of these models to more diverse, real-world clinical populations require further validation. Future research should explore more adaptive, deep-learning-specific feature selection methods and incorporate multi-modal data to further refine diagnostic reliability.

Funding Information

This research received financial support from the Beginner Lecturer Research Grant (Penelitian Dosen Pemula), administered by the Directorate of Research and Community Service, Directorate General of Research and Development, Ministry of Higher Education, Science, and Technology, under Contract Nos. 123/C3/DT.05.00/PL/2025 and 109/LL2/DT.05.00/PL/2025.

Author Contributions Statement

The journal adopts the Contributor Roles Taxonomy (CRediT) as a framework to acknowledge the specific roles of each author, mitigate potential disputes concerning authorship, and enhance collaborative efforts. See the Table I below:

TABLE I. AUTHORS' CONTRIBUTION

***Abstract*—Hand gesture recognition (HGR) represents a real challenge for natural human-computer interaction, which aims to revolutionize the naturalness of traditional interfaces, allowing intuitive control of various devices without using a keyboard or mouse. Despite the availability of frameworks such as MediaPipe, which enable better detection and tracking, the major challenge remains interpreting gestures made with both hands in a natural operational setting. In this regard, this study presents a real-time gesture calculator that combines gestures made with both hands (see using one hand) and aims to address the problem of interpretation in arithmetic operations. By leveraging MediaPipe to classify the 21 hand landmarks, an optimized dense neural network (DNN) was developed capable of recognizing 13 distinct static gestures. The latter includes six gestures for each hand (ranging from 0 to 5) to represent all digits from 0 to 9, five mathematical symbols, and two specialized commands designed explicitly for control management. Even with a standard webcam, this model achieved 91% accuracy on a reduced dataset of gestures from both hands. Beyond gesture recognition, this work demonstrates how these gestures can be integrated into a fluid sequence for arithmetic operations.**

***Keywords*—Hand gesture recognition; gestural calculator interface; DNN; MediaPipe; natural human-computer interaction**

I. Introduction

The field of human-computer interaction (HCI) has seen rapid progress in the development of natural interfaces in recent years, thanks to advances in methods for detecting and tracking body parts and the entire body, as well as deep learning methods such as DNNs [1]. Hand gesture recognition (HGR) stands out as a powerful means of communication with digital systems, given the many degrees of freedom it offers, making it the most expressive organ in the human body. This type of interface offers a level of fluidity and naturalness that traditional input devices, such as keyboards and mice, cannot match. HGR is redefining the way we connect the physical and digital worlds [2]. These systems have evolved into advanced solutions for controlling computers, navigating virtual and augmented reality environments, and providing real-time sign language translation [3]. Modern gesture recognition systems rely on the interaction between computer vision and deep learning [4]. In this field, Google's MediaPipe library, which offers a highly efficient platform for real-time hand tracking and 21-point landmark detection, occupies a central position. This technology offers powerful, accurate processing across a variety of lighting conditions and backgrounds [5]. However, the majority of available HGR systems are limited to simple static classifications and a single hand. There is a notable lack of research on effectively combining two-handed coordination with complex interaction logic in a practical, real-time application.

This research addresses these challenges by developing an intelligent gesture-based arithmetic calculation system. This study explores a pipeline that moves from detecting static gestures from a predefined gesture vocabulary to a dynamic, real-time calculator interface using a dense neural network (DNN) [6]. The system is designed to recognize 13 different static gestures comprising numerical values, arithmetic operators, and system commands optimized for two-handed interaction [7][8]. By combining MediaPipe's efficiency with a customized DNN, this demonstrates how computer vision can be leveraged to create a robust, low-latency human-machine interface [9]. While recent studies have explored gesture-based tools, such as the virtual calculators proposed by Umadevi et al. [7] and Sunanda et al. [8], most of these implementations focus on single-handed input or require significant computing resources. This work builds on these foundations but specifically targets two-handed coordination in an Industry 5.0 context [1], favoring a lightweight architecture that maintains high responsiveness on standard, low-cost hardware.

This study is structured as follows: Section II reviews the existing literature on hand gesture recognition systems. Section III describes the main objective of this work. Section IV addresses the chosen vocabulary and the suggested methodology. Section V presents the implementation, including the DNN architecture and the dataset used. Section VI explores the experimental results, accuracy metrics, and a discussion of system robustness. Finally, Section VII concludes the study by summarizing the contributions and recommending paths for future work in Section VIII.

II. Overview of Hand Gesture Recognition Systems

Gestures are a form of nonverbal communication in which body language conveys specific messages rather than speech [10]. This communication is accomplished through the movement of various body parts, which feels more natural and intuitive to people. Gestures significantly influence verbal messages [11]. Nonverbal communication has evolved to the extent that some languages have developed from a series of gestures. Gesture recognition technology plays a valuable role

in enhancing human-machine interaction. Since the emergence of digital video capture technologies, numerous attempts have been made to recognize dynamic gestures for various purposes [12].

These two methods differ in accuracy, calibration complexity, latency, range of motion, ease of use, and cost. Thus, gesture recognition faces two types of challenges: a lower-level challenge that requires accurate posture detection and a higher-level challenge that focuses on the correct interpretation of gestures [13]. The analysis of gestures and postures presents several challenges, making it complex. Many concepts are often associated with the same gesture, and a given concept can be linked to various gestures. Furthermore, the interpretation of gestures varies across language, culture, and context [14]. For example, sign languages vary from one country to another, and even within the same country. Furthermore, gesture meanings likely change depending on the conversational context [15] [16].

III. Objectives

The idea was to create a model that performs basic arithmetic operations using hand gestures. This gesture-controlled calculator operates using both hands to compose numbers from 0 to 10. The numerical representation ranges from both hands closed, indicating 0, up to 10 represented by all ten fingers of both hands, with each hand symbolizing five digits. An advanced real-time model was developed to recognize both hands, determine the number of raised fingers on each hand, and calculate the total number of raised fingers. The calculator supports four arithmetic operations: subtraction (-), addition (+), division (/), multiplication (*), and equals (=). Additionally, two control commands are included: the gesture (e) to clear all input, and the gesture (d) to delete the last symbol entered (see Fig. 1).

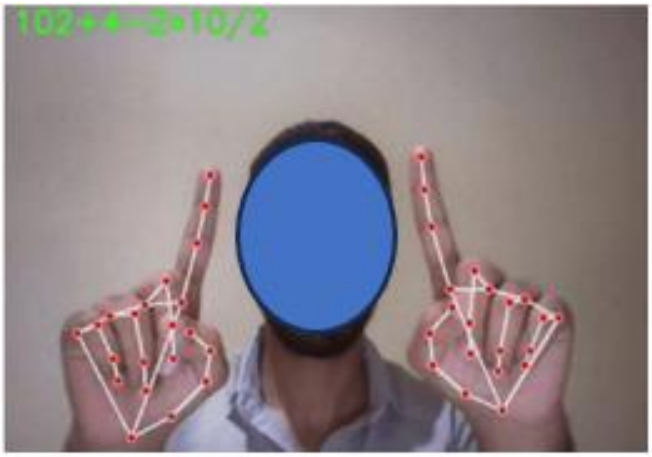

Fig. 1. Example of an arithmetic operation using gestures from both hands.

The impact of this work is manifold. From a scientific standpoint, it demonstrates that lightweight architectures, such as dense neural networks (DNNs), can effectively handle complex tasks that require coordination between two sources of information with optimal latency, especially when coupled with powerful data extraction methods. From an operational standpoint, this system lays the foundation for natural user interfaces (NUIs). It offers a hands-free model in sterile environments such as operating rooms, new accessibility tools for people with reduced mobility, and even intuitive interfaces for early childhood education.

The practical aspects of building an artificial intelligence model to identify hand gestures are detailed.

During this project, an artificial intelligence model was developed, progressing from creating a database of gesture images to real-time gesture recognition. This was achieved using Python, TensorFlow, Keras, and Media.

IV. System Description

The system follows a structured set of steps to predict quick, organized hand gestures and perform mathematical operations. The steps are described in detail in the two algorithms (see Algorithm 1 and Algorithm 2), explained in the following section.

A. Camera Frame Reading

The first step is to keep reading the computer's webcam frame, flip it horizontally, and then convert the color space from BGR to RGB as required by the MediaPipe library.

B. Hand Recognition and Hand Landmark Extraction

The MediaPipe library detects hands and extracts 21 features for each hand (see Fig. 2). It is a pre-trained system that automatically detects the presence of hands in an image. After detection, a set of characteristic points is extracted from each hand. It identifies 21 key points per hand (joints and fingertips) and provides the spatial coordinates for each point. These 21 characteristics constitute a description vector used as input to the proposed gesture recognition system.

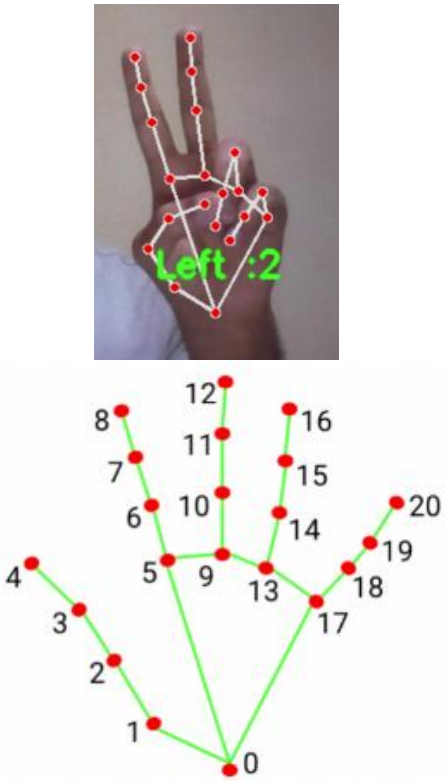

Fig. 2. The 21 hand features using MediaPipe.

C. Data Collection

The database of 13 gestures was created (Fig. 3). Six gestures represent digits 0 to 5, while four gestures correspond to operations (+, -, *, /, and =). The collection was assembled using Python, MediaPipe, and OpenCV. The system captured 21 features from 287 hand gesture samples, which were manually sorted into 0-5 categories and stored in a CSV file. A total of 287 rows were recorded, each containing 42 data points. The 0-5 classification was split with 20% for testing and 80% for training.

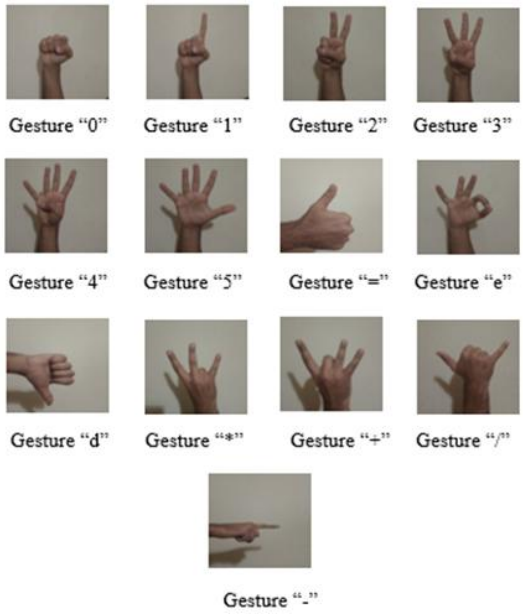

Fig. 3. Dataset of 13 gestures used for the calculating system.

D. Feature Preparation for Prediction

The extracted landmarks are combined into a single feature vector of size 42 (21 x-values and 21 y-values). This vector is reshaped and prepared as input for the trained gesture recognition model.

Algorithm 1: Hand Acquisition and Feature Extraction

```
Initialize
Start Acquisition by Camera
    Initialize MediaPipe Hands module
    Set quit key = 'q'
  Compute
  While (pressed key ≠ 'q') do
      Get current predicted gesture
      Convert frame to RGB
  Detect and track hands with MediaPipe
      If (at least one hand detected) then
          Extract 42 (x,y) features for each hand
          Send features to classifier
      End
  End
```

E. Gesture Prediction

After extracting the feature vector, it makes a prediction and determines which class it belongs to, whether it is a number from 0 to 5, a symbol for arithmetic operations (+, -, *, /, =), or the e command to erase the entire expression, or d to delete the last character. The predicted class is recoded to its corresponding class.

1) Handling numeric gestures (0 to 5): If the hand signal is a number from 0 to 5, the system distinguishes between the right and left hands and stores the value of each. If the two-second cool-down period is completed with the hands together, the system adds the values of the right and left hands and prints the result as a mathematical expression.

Algorithm 2: Gesture-Based Calculator Operation

```
Initialize
Expression ← empty
LeftValue, RightValue ← 0
Compute
While the system running) do
    Acquire current prediction for left hand
    Acquire current prediction for right hand
    If (left hand detected AND right hand detected) then
        If (left gesture is digit 0–5 AND right gesture is digit 0–5) then
            LeftValue ← digit shown by left hand
            RightValue ← digit shown by right hand
            SumValue ← LeftValue + RightValue
            CurrentDigit ← SumValue
        End
    End
    If (CurrentDigit is defined) then
        Append CurrentDigit to Expression
    End
    If (predicted gesture is arithmetic operator '+', '−', '×', '÷') then
        Append operator to Expression
    End
    If (predicted gesture is 'd') then
        Delete last symbol from Expression
    End
    If (predicted gesture is 'e') then
        Clear Expression
    End
    If (predicted gesture is '=') then
        If (Expression is mathematically valid) then
            Evaluate Expression and display result
        Else
            Display error message
        End
    End
End
```

2) Handling symbolic and control gestures: If the sign indicates a mathematical operation symbol (+, -, *, /), the recognized symbol is added to the mathematical expression. If the symbol is "=", the Python eval() function calculates the expression. If the mathematical expression is true, it prints the result. If it is false, it prints an error. If the command symbol is "e," the entire expression is erased.

If the expression symbol is "d", we delete only the last letter of the expression.

3) Display of predictions: The updated expression or result is displayed in real-time on the camera feed using OpenCV's putText function. Users can see their arithmetic operations evolve as they perform gestures.

This model expanded functionality by incorporating symbolic gestures (e.g., arithmetic operators and control commands), turning the system into a real-time gesture-based calculator.

F. Termination Condition

The system continues to run and loop until you press the "q" key to stop the program.

V. System Implementation

A. System Description

The database is a CSV file containing 287 rows, 48 variables, and 13 columns containing numbers from 0 to 5, arithmetic symbols (+, -, *, /, =), and commands (e, d). 80% of the data is dedicated to training and 20% to testing.

B. DNN Model Architecture

The proposed deep neural network (DNN) architecture for gesture classification, shown in Fig. 4, comprises six fully connected (dense) hidden layers, with the number of units decreasing from 1024 to 32.

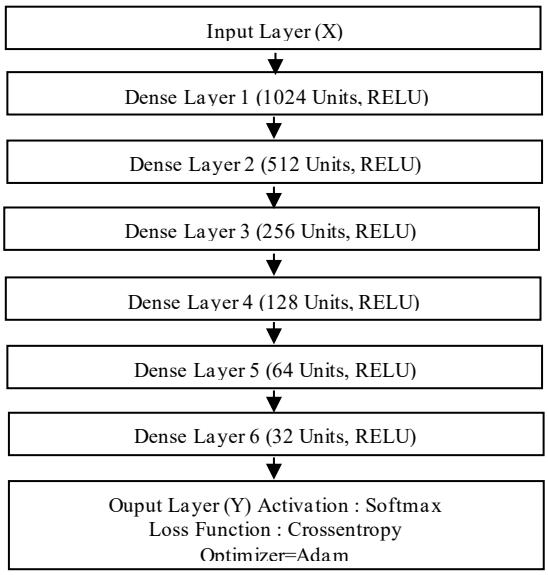

Fig. 4. The proposed deep neural network (DNN) architecture for gesture classification.

Each hidden layer employs the RELU activation function, facilitating hierarchical feature extraction and nonlinear transformations of the input data.

The final output layer consists of 13 units, corresponding to the distinct gesture classes, and utilizes the SoftMax activation function to generate normalized probability distributions for multiclass classification.

The Adam optimizer is chosen for its efficiency in adaptive learning rate adjustment.

This architecture enables robust learning and precise recognition of 13 different hand gestures, rendering the model well-suited for real-time human-computer interaction applications, as evidenced by recent studies employing DNNs in gesture recognition systems.

VI. Results and Discussion

Even with a compact dataset of just 287 samples, our model achieved 91% validation accuracy (Fig. 5), demonstrating its ability to recognize gestures it hasn't seen before reliably. In the world of deep learning, hitting these numbers with such a small dataset is usually a challenge.

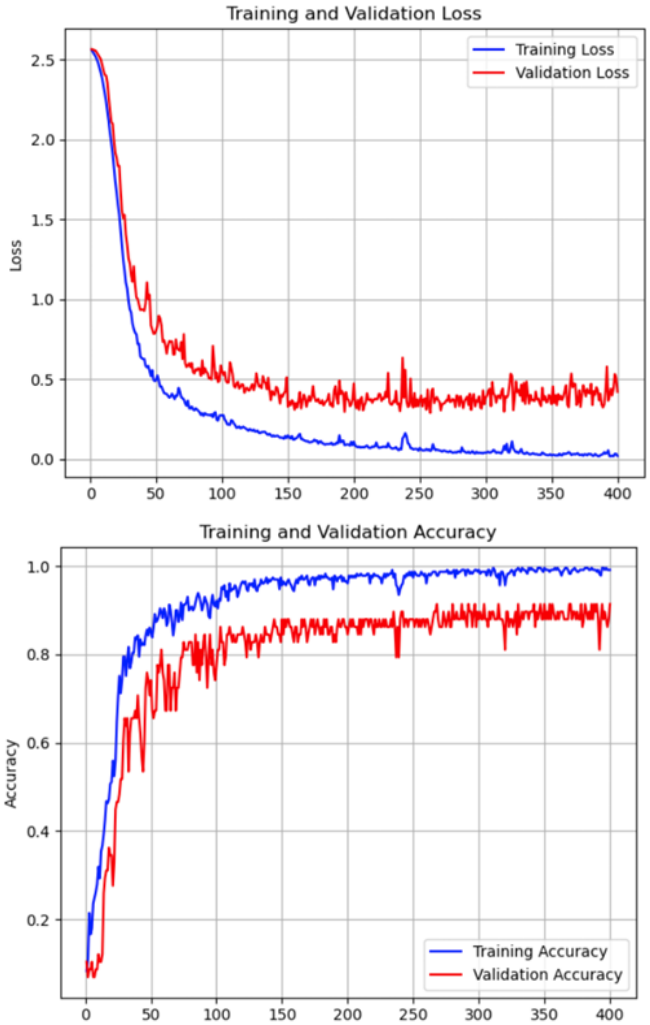

Fig. 5. References Training vs. Validation metrics (loss and accuracy) for the proposed DNN model with MediaPipe.

Using MediaPipe to extract the 21 essential landmarks significantly reduced the size of the features introduced to the learning process compared to the raw input data (image). This significant reduction in data allowed the proposed dense neural network (DNN) to favor hand geometry over environmental features. This also explains why a lightweight model can be just as effective as the complex, data-intensive architectures often encountered in such contexts.

Compared to existing literature, the proposed system strikes a distinctive balance between technical depth and practical accessibility. For example, unlike the massive, highly interconnected CNNs suggested by Tan et al. [6], which require significant GPU capacity, our DNN-based strategy achieves 91% accuracy with significantly lower latency. This makes it much more suitable for real-time clinical or industrial environments [5], [12]. While researchers such as Pathak et al. [2] focus on replacing equipment such as keyboards and mice, this research implements a synchronized logic layer for two-handed arithmetic. This is considered an essential step toward the level of sign language recognition discussed by Long et al. [15]. By relying on landmarks rather than raw pixel processing [4], we achieved competitive results even with a smaller database, effectively bridging the gap between theoretical research and practical tools [13].

Undeniably, the results obtained indicate a slight tendency toward overfitting, which is almost always a challenge when working with restricted data sets. To ensure the system functions properly in real time, this study adopted an approach that aims not only to achieve a higher score but, above all, to guarantee "interaction resilience". As the system operates at 30 frames per second, feedback is almost instantaneous; in case a gesture is not recognized the first time, the user can naturally adjust the position of their hand without losing rhythm in transparency mode.

During testing, the system remained stable under standard indoor lighting conditions. However, it can still be affected by extremely rapid movements or by a partially obscured hand, thanks to the MediaPipe library, which uses a keypoint inference approach. It is therefore clear that achieving more than these 13 gestures requires much more data. The next steps in our process will involve conducting subject-independent tests to verify that the model is operational for everyone, regardless of hand configuration. Ultimately, this 91% accuracy rate serves as a compelling argument, demonstrating how a MediaPipe DNN pipeline can effectively transform simple detection into a practical, operational calculator.

VII. Conclusion

In this study, a real-time hand gesture recognition system was presented, designed to make interaction with machines more fluid and natural. By combining MediaPipe landmark tracking with an optimized dense neural network (DNN), simple finger counting is exceeded to design a functional two-handed calculator. This work recognizes 13 distinct gestures, allowing users to solve basic mathematical problems with natural movements.

The main scientific goal here is to demonstrate the effectiveness of a lightweight pipeline for two-handed coordination that requires neither high-end hardware nor a large database. It has been clearly proven that reducing the hand image to just 21 key coordinate points combines performance and fluidity, with an accuracy rate of 91%.

This study helps bridge the gap between simple gesture detection and authentic interactive logic, demonstrating that symbolic tasks can be reliably processed using a standard webcam.

In fact, it should be noticed at this level that there is still room for further improvement, considering that the current database has limitations and that the model still perceives gestures as being images rather than continuous movements.

VIII. Future Works

To optimize the system's reliability and efficiency, three main areas are targeted for the next phase of research. Firstly, the database needs to be significantly expanded by building a more diverse panel of examples to ensure the model's accuracy across different hand morphologies and conditions, for better, more accessible technology.

Secondly, although the current configuration is optimal for recognizing static poses, the objective is to explore the "flow" of movements in the context of dynamic gestures. The adoption of more sophisticated architectures, such as LSTMs or Transformers, will allow the system to process each image individually rather than perceiving gestures as continuous movements. This change is crucial for identifying complicated sequences and minimizing disruptions that can occur during real-time tracking.

Finally, the system will undergo much more rigorous testing. We want to observe its behavior in extreme situations, such as rapid gestures, partially obstructed hands, or poor lighting. As things stand, our results have shown that the gesture-controlled calculator is functional. However, to move towards a larger size, it is imperative to improve data and model complexity. This will ultimately pave the way for the application of this technology beyond simple calculator use into more demanding fields such as virtual reality, telesurgery, and robotics.

Community-Aware Influence Maximization for Suppressing Cryptocurrency Scam Misinformation

Naglaa Mostafa, Hatem Abdelkader, Asmaa H.Ali
Information System Department-Faculty of Computers and Information, Menoufia University, Egypt

***Abstract*—Cryptocurrency fraud campaigns often rely on large-scale social-media diffusion to recruit victims, normalize false claims, and coordinate multi-level marketing behavior. This study examines the dynamics of the One Coin scam. It proposes an influence-maximization (IM)-driven workflow for identifying high-impact accounts whose intervention can reduce future misinformation diffusion. A directed Twitter engagement network from retweet/reply interactions is constructed and studied, and the accounts that should be prioritized for intervention to reduce the reach of future scam-promoting misinformation are identified. We evaluate six seed selection strategies: Degree, Betweenness, PageRank, k-core, CELF (lazy greedy), and Reverse Influence Sampling (RIS) under the classical Independent Cascade (IC) and Linear Threshold (LT) diffusion models using a weighted-cascade parameterization when ground-truth transmission probabilities are unavailable. Across the tested seed budgets, CELF achieves the highest expected spread, but with the highest computational cost. At the largest seed budget, Degree is effectively tied with CELF (within 0.09% under LT and 1.4% under IC), indicating a hub-dominated engagement structure in which simple reach-based heuristics can be highly competitive. RIS provides a strong quality–efficiency trade-off, remaining within approximately 9.7% (LT) and 9.5% (IC) of CELF while requiring substantially less computation. We further introduce a community-aware variant using Leiden partitions and proportional seed allocation to improve cross-community coverage; at larger budgets, this improves methods sensitive to seed over-concentration, increasing LT spread by about 9.8% for k-core and 8.6% for RIS. Overall, the results quantify practical trade-offs between spread and runtime for deployable suppression workflows and show when community-aware planning better aligns with the heterogeneous structure of scam recruitment ecosystems.**

***Keywords*—Influence maximization; misinformation suppression; cryptocurrency scams; OneCoin; diffusion models; Leiden; community-aware seeding**

I. Introduction

Online social networks have become a primary channel for disseminating both legitimate information and harmful content. Fraudulent investment narratives are especially sensitive to viral diffusion: repeated exposure can create perceived legitimacy, recruit new participants, and sustain the financial incentives of a scam ecosystem. OneCoin, a cryptocurrency launched in 2014, has been described by U.S. prosecutors as a multibillion-dollar global fraud scheme, with prosecutions and public warnings continuing over several years (U.S. Department of Justice [1][2][3]. From a network-science perspective, such campaigns can be studied as diffusion processes on an interaction graph, where certain accounts play outsized roles in initiating and amplifying narratives.

A key practical question is: Which accounts should be prioritized for intervention to most effectively curb the spread of scam-promoting misinformation? Intervention may include platform trust-and-safety actions, targeted fact-checking prompts, or counter-messaging allocation. This problem relates to influence maximization (IM): given a graph and a diffusion model, IM selects a small seed set of nodes (accounts to which an intervention or corrective exposure is applied) to maximize the expected diffusion reach [4]. In misinformation suppression settings, these seeds represent the most leverageable points for disruption or for seeding corrective information, aligning conceptually with competing-cascade work on limiting misinformation [5]. We focus on OneCoin because it is a well-documented, large-scale fraud campaign with extensive public enforcement records and warnings, making it a realistic case for studying diffusion-driven recruitment dynamics. This work provides the following contributions:

- A reproducible workflow to build a directed OneCoin interaction network from Twitter engagement signals (retweets and replies), and to model propagation under IC and LT diffusion [4].
- A comparative experimental study of classic heuristics (Degree, Betweenness, PageRank, k-core), CELF-accelerated greedy selection [6], and Reverse Influence Sampling (RIS) [7] on the same dataset and seed budgets.
- A community-aware variant using Leiden partitions [8], with proportional seed allocation across communities, demonstrates how community constraints affect diffusion and runtime.

The remainder of this study is organized as follows: Section II will cover the related work and background. In Section III, the conceptual pipeline of the proposed OneCoin misinformation diffusion study is detailed. Section IV presents the experiments and evaluations, and we conclude in Section V.

II. Related Work

A. Influence Maximization and Scalable Algorithms

Kempe et al. formalized IM under the IC and LT models and showed that expected spread is monotone and submodular, enabling a $(1-1/e)$ approximation via greedy selection [4]. Because naive greedy requires many spread estimations, Leskovec et al. proposed CELF (Cost-Effective Lazy Forward), which reduces recomputation of marginal gains while preserving greedy quality [6]. To scale IM to large graphs, RIS-type methods estimate influence by sampling reverse-reachable (RR) sets, yielding near-linear-time algorithms with provable

approximation guarantees [7], [22]. Recent surveys summarize these algorithm families and extensions to dynamic and competitive settings [10]–[12].

B. Misinformation Diffusion and Influence Blocking

A central line of work models misinformation containment as a competitive diffusion problem, where a 'good' campaign (e.g., corrective information) competes with a 'bad' campaign (misinformation) [5]. Subsequent studies have proposed variations that incorporate awareness raising, time constraints, refutation, and vertex blocking, yielding influence-blocking maximization objectives and algorithms [13]–[15]. While our experiments evaluate classical IM under IC/LT to characterize which accounts can most amplify diffusion, the intervention interpretation is consistent with this containment literature: identifying a small set of high-leverage accounts where friction, monitoring, or corrective seeding can meaningfully reduce cascade potential.

C. Community Structure and Community-Aware Influence

Maximization. Diffusion often concentrates within dense communities and crosses communities via a smaller set of bridging accounts, motivating community-aware IM that allocates seeds across communities to improve coverage and diversity [16]–[18]. Reliable community detection is therefore important when community boundaries constrain seeding decisions. Leiden improves upon Louvain by refining partitions to ensure well-connected communities and often achieves higher-quality modularity solutions efficiently [8]. In this study, we use Leiden as a principled preprocessing step and evaluate how proportional community allocation changes both spread and runtime in a real scam-engagement network.

Positioning of this study. Prior work has extensively developed IM algorithms and misinformation containment models, but fewer studies provide end-to-end, reproducible evaluations of how classic IM baselines, scalable RIS methods, and community-aware constraints trade off effectiveness and runtime in a documented cryptocurrency scam setting. Our contribution is to ground this comparison in a OneCoin engagement network and to quantify when community-aware allocation improves cross-community coverage and, at sufficient budgets, overall diffusion reach.

III. Methodology

This study investigates how OneCoin scam-related misinformation can propagate through a Twitter interaction network. It demonstrates how influence maximization [9] can be used to identify a small set of high-influence accounts. To address misinformation propagation in social networks, this study combines information diffusion models, influence evaluation, and influence maximization (see Fig. 1). A directed, weighted engagement graph is constructed from retweet/reply links and analyzed under two widely used diffusion models, Independent Cascade (IC) and Linear Threshold (LT), with a parameter-free weighted-cascade setting based on each node's in-degree, enabling principled propagation simulation when accurate transmission probabilities are unavailable. Significantly, integrating Leiden community detection and enforcing community-proportional seed allocation changes the seed composition toward broader sub-community coverage. Six seed-selection strategies (Degree, Betweenness, PageRank, k-core, CELF, and RIS) were used across multiple seed budgets to achieve the most significant expected spread consistent with submodular maximization theory, but at substantially higher computational cost. Also, we show that, in influence maximization methods, it is essential to provide a strong spread-time compromise suitable for scalable analyses, and that simple heuristics remain competitive across several budgets due to the network's sparse, hub-dominated engagement structure.

A. Data Collection and Case Context (OneCoin Scam Misinformation)

In this subsection, we represent the input evidence used to study diffusion: OneCoin-related Twitter content and engagement traces (e.g., tweets promoting the scam narrative and retweets/replies that amplify it). In misinformation-suppression framing, the goal is not only to describe content, but to capture who amplifies whom and how narratives propagate through user-to-user interactions. In practice, this stage yields: 1) a set of users, 2) interaction events (retweet/reply), and 3) timestamps and metadata that can later support time-sliced diffusion analyses. The OneCoin case is well documented as a large fraud scheme by official authorities, motivating a realistic misinformation setting for network-based interventions. Operationally, the data layer comprises OneCoin-related social-media traces (e.g., posts and engagements). In this work, the emphasis is on engagement events (retweets/replies) because they are direct, observable signals of information amplification and conversational diffusion, enabling network-based modeling.

B. Interaction-Network Construction (Twitter Engagement Graph)

This subsection maps raw engagement events into a directed graph suitable for diffusion modeling. We define a directed weighted interaction network $G = (V, E, W)$, where each node $v \in V$ represents a user account and each directed edge $(u, v) \in E$ indicates that user u interacted with content produced by user v (retweet/reply). Edge weight w_{uv} counts repeated engagements to capture the intensity of interaction. This representation is widely used because diffusion and influence processes can be simulated on graphs and optimized over node sets [4]. The resulting structure is typically sparse and exhibits heterogeneous degree distributions, which motivates comparing both optimization-based methods (e.g., greedy/CELF, RIS) and centrality-based heuristics that may perform well in hub-dominated graphs.

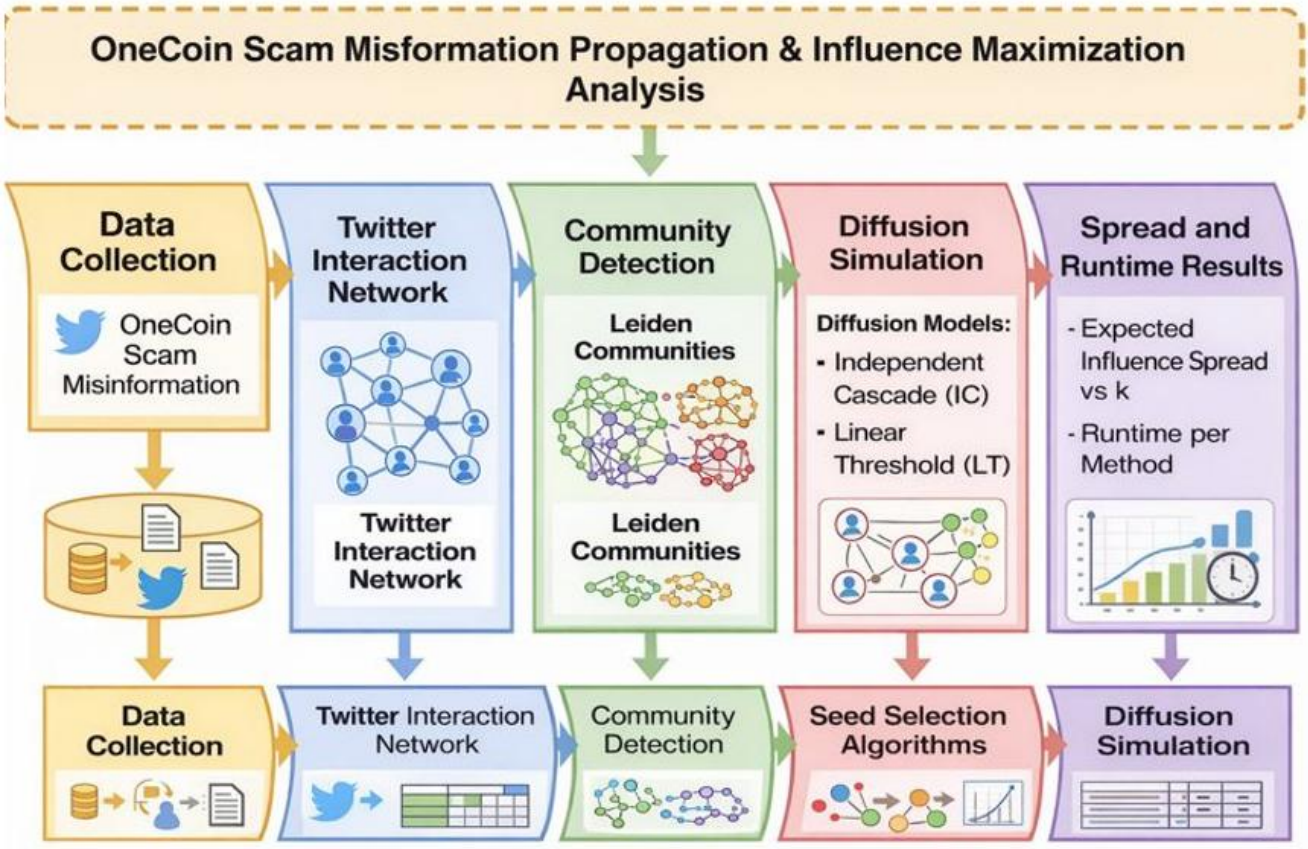

Fig. 1. Conceptual pipeline of the proposed OneCoin misinformation diffusion study.

C. Community Detection (Leiden Partitioning)

Community structure is central to misinformation diffusion because amplification frequently occurs within dense clusters, while a smaller number of accounts facilitates cross-community transmission. To capture this structure, we apply the Leiden algorithm in Fig. 2 to obtain a partition $\mathcal{C} = \{C_1, \ldots, C_r\}$. Leiden is specifically chosen because it addresses known weaknesses of Louvain by improving community connectivity and providing stronger guarantees about partition quality (well-connected communities), while remaining efficient [8]. In the proposed research problem, communities represent sub-audiences or recruitment circles; identifying them supports targeted suppression strategies that aim to reduce cascade potential across the ecosystem rather than within only one dense group.

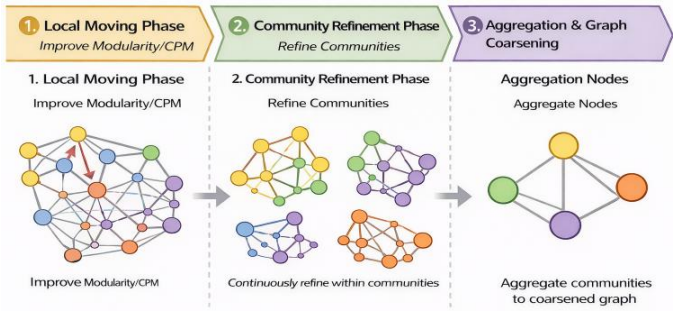

Fig. 2. Community detection of the Leiden algorithm.

D. Diffusion Models for Misinformation Propagation

This subsection formalizes how misinformation may spread in the constructed graph. Independent Cascade (IC). Starting from a seed set S, diffusion proceeds in discrete steps. When node $u$becomes active, it gets a single opportunity to activate each inactive neighbor $v$with probability p_{uv}. Eq. (1) clearly states the influence (spread) function as:

$$\sigma(S) = \mathbb{E}[|\, A(S)\,|] \tag{1}$$

where, $A(S)$ is the final set of activated nodes[4].Linear Threshold (LT). Each node $v$samples a threshold. $\theta_v \in [0,1]$. Node $v$activates when the cumulative influence of its active in-neighbors reaches the threshold [see Eq. (2)]:

$$\sum_{u \in N^-(v) \cap A} w_{uv} \geq \theta_v. \tag{2}$$

LT is frequently interpreted as "accumulated exposure" or social reinforcement, which is conceptually appropriate for the persuasion-like adoption of misinformation [4]. Weighted-cascade parameterization. When accurate transmission probabilities are unavailable, a standard practical setting, as mentioned in Eq. (3) and Eq. (4), is:

$$p_{uv} = \frac{1}{\deg^-(v)} \text{(IC)} \tag{3}$$

$$w_{uv} = \frac{1}{\deg^-(v)} \text{(LT)} \tag{4}$$

This equalizes influence contribution across in-neighbors of each node.

E. Influence Maximization Objective (Identifying High-Impact Accounts for Suppression)

This subsection establishes the optimization target. Given a budget k, the classical influence maximization (IM) problem seeks: Under IC and LT, $\sigma(\cdot)$is monotone and submodular, which supports near-optimal approximation via greedy selection with provable guarantees [4]. In the suppression setting, the same optimization identifies accounts whose intervention (e.g., friction, monitoring, counter-messaging exposure, or de-amplification) can most strongly reduce future diffusion potential across the misinformation network, conceptually aligned with misinformation limitation via competing campaign/mitigation strategies.

F. Seed-Selection

This subsection corresponds to "Algorithms" in the diagram and details the families evaluated.

1) Centrality/structural heuristics (fast baselines):

a) Out-degree prioritizes nodes with many outgoing neighbors (high immediate reach).

b) Betweenness centrality captures brokerage/bridge positions that can connect communities; the classic formulation is based on Freeman's betweenness centrality [19].

c) PageRank assigns global importance to nodes in directed graphs, initially introduced in the context of web link analysis [20].

d) k-core (core number) identifies nodes embedded in cohesive substructures; foundational discussion is linked to minimum-degree core decomposition [21].

2) Greedy influence maximization with CELF acceleration. Greedy selection iteratively adds the node with maximum marginal gain in Eq. (5):

$$\Delta = \sigma(S \cup \{v\}) - \sigma(S) \tag{5}$$

But repeated spread estimation is expensive. CELF reduces computation via lazy marginal-gain updates while preserving greedy behavior and is widely used as a strong quality baseline [4].

3) Reverse Influence Sampling (RIS): RIS approximates $\sigma(S)$ using random reverse-reachable (RR) sets; selecting nodes that cover the most RR sets provides a scalable approximation with theoretical grounding, making RIS-type methods suitable for large graphs and repeated experiments [22].

G. Community-Aware Influence Maximization

After computing communities $\{C_i\}$, we impose a coverage constraint by distributing the seed budget across communities (e.g., proportional allocation) as mentioned below in Eq. (6) and Eq. (7):

$$k_i \approx k \cdot \frac{|C_i|}{|V|} \tag{6}$$

$$\sum_i k_i = k \tag{7}$$

And then select k_i seeds within each community using the same ranking/optimization method (Degree/CELF/RIS/etc), producing [Eq. (8)]:

$$S = \bigcup_i S_i, |\, S_i \,| = k_i \tag{8}$$

The scientific rationale is that misinformation ecosystems are heterogeneous; community-aware seeding mitigates the risk of concentrating interventions in a single dense cluster and supports broader, cross-community mitigation strategies. The choice of Leiden strengthens this component because community integrity (connectivity/quality) influences downstream allocation and interpretation.

IV. Results and Discussion

A. Network Summary and Evaluation Setting

The OneCoin interaction network is modeled as a directed engagement graph built from retweet/reply relations. The details of the datasets are shown in Table I. Across all experiments, diffusion is evaluated under the two standard influence models—Independent Cascade (IC) and Linear Threshold (LT)—using the weighted-cascade normalization (equal influence share across a node's in-neighbors) to parameterize edge influence when ground-truth probabilities are unavailable. This modeling choice is consistent with the classical formulation of diffusion-based influence maximization [4].

TABLE I. Dataset Statistics

Number of nodes	5415
Number of edges	6117
Average Degree	2.2327
Maximum Degree	1582

B. Influence Spread Under the LT Model

Fig. 3 compares the expected influence spread achieved by Degree, CELF, k-core, Betweenness, PageRank, and RIS under LT across budgets $k = \{5,10,15,20,25,30\}$. Three patterns are salient. First, CELF and Degree dominate across budgets, with the highest spreads observed at larger k; for example, at $k = 30$, CELF reaches ≈1620.9 activated users while Degree reaches ≈1619.5, indicating that, on this dataset, a simple out-degree heuristic is highly competitive once the seed budget is moderate to large. Second, RIS consistently provides a strong quality–efficiency trade-off, tracking the leading methods closely as k increases (e.g., ≈1463.2 at k=30), which aligns with the design objective of RIS-style algorithms: scalable approximation to near-greedy performance via reverse-reachable sampling [22]. Third, the structural centrality baselines (Betweenness, PageRank, k-core) improve gradually with increasing k but typically remain below CELF/Degree; this suggests that, in the OneCoin engagement network, large cascades are more strongly driven by outward amplification capacity (high out-degree and greedy marginal gain) than by purely bridge-based shortest-path control.

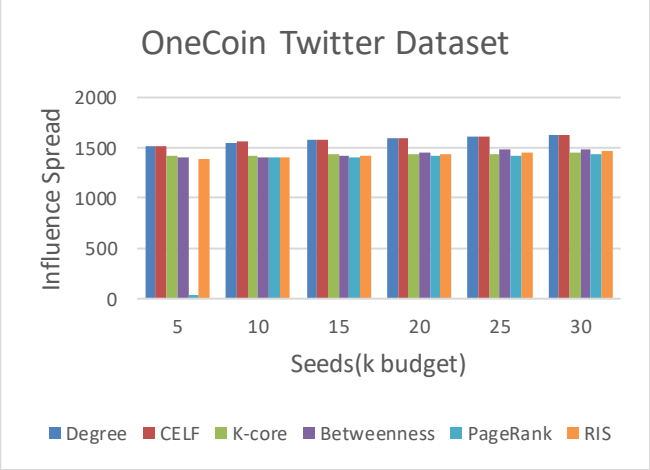

Fig. 3. Influence spread achieved by the evaluated seed-selection methods under the LT diffusion model on the OneCoin dataset.

C. Influence Spread Under the IC Model

Under IC (see Fig. 4), the ranking trends are mainly consistent with LT. CELF achieves the most significant expected spread across budgets, reflecting the theoretical motivation for greedy selection under submodular influence functions [4]. At $k = 30$, CELF reaches ≈1597.9, followed by Degree at ≈1576.2. RIS remains competitive (≈1445.8 at $k = 30$), again reinforcing its role as a practical large-scale alternative to greedy [22]. An additional observation is the instability of PageRank at minimal budgets (e.g., at $k = 5$, PageRank produces very low spread). In directed engagement graphs, PageRank can rank nodes that are globally "prestigious" but not necessarily effective at outward activation (e.g., under the diffusion parameterization, limited outgoing influence pathways). As k increases, PageRank begins to include more structurally active accounts, and its spread becomes comparable to that of other centralities.

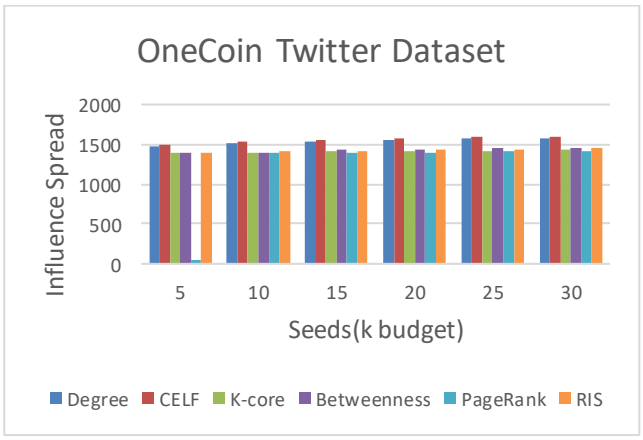

Fig. 4. Influence spread achieved by the evaluated seed-selection methods under the IC diffusion model on the OneCoin dataset.

D. Runtime Comparison Under LT and IC

Fig. 5 (LT) and Fig. 6 (IC) report the total runtime per method (seed selection and spread evaluation). The computational cost is dominated by two factors: 1) the complexity of constructing the seed set and 2) the repeated spread estimation required by the evaluation protocol.

1) CELF is substantially more expensive than all alternatives because it relies on repeated marginal-gain evaluations (even with lazy updates) [4]. Concretely, the total runtime is ≈15.44 **s** under LT and ≈35.87 **s** under IC, both of which are far lower than those of the other methods.

2) Heuristic methods are operationally efficient**.** Degree and PageRank have very low seed-selection costs and total times, typically under a few seconds, in these runs.

3) Betweenness is moderately expensive relative to other heuristics due to shortest-path–based centrality computation, which explains its higher total time, even though it does not match the top-performing spreads.

Overall, the runtime plots support a practical conclusion: CELF maximizes spread but is least suitable for frequent recomputation. At the same time, RIS and Degree offer the best "deployable" trade-off between spread and runtime.

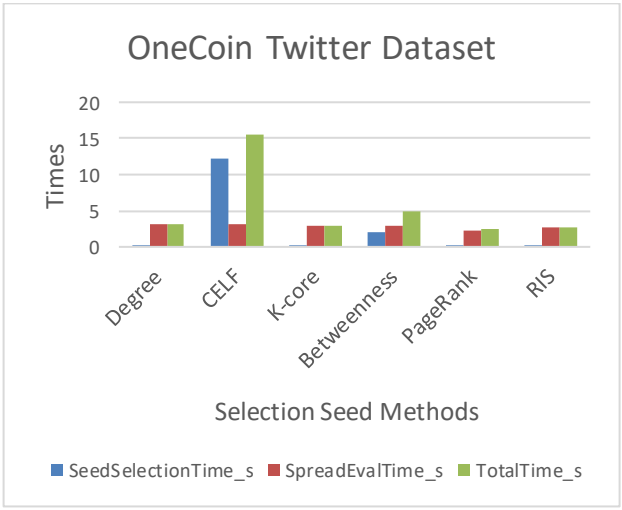

Fig. 5. Total computational time (in seconds) required by each seed-selection method under the LT diffusion model on the OneCoin dataset.

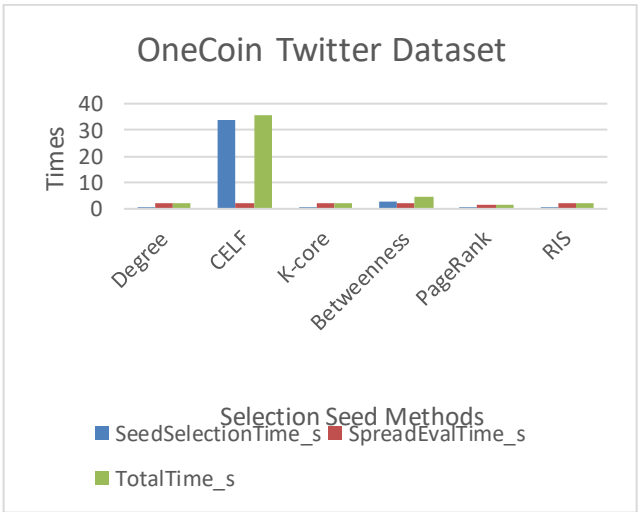

Fig. 6. Total computational time (in seconds) required by each seed-selection method under the IC diffusion model on the OneCoin dataset.

E. Community-Aware Results with Leiden

Fig. 7 and Fig. 8 examine the effect of incorporating Leiden communities and enforcing community-aware seed allocation under LT. Leiden is chosen because it is designed to avoid poorly connected community partitions and to produce higher-quality communities efficiently, which is essential when community boundaries are used to constrain seeding decisions [8].

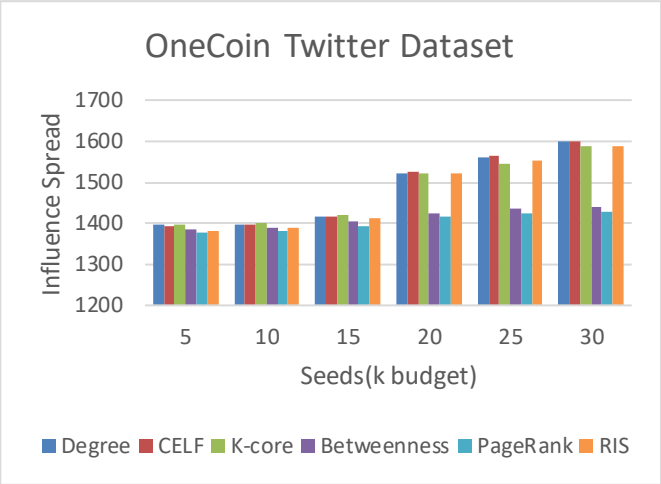

Fig. 7. Influence spread achieved by the evaluated seed-selection methods under the LT diffusion model on the OneCoin data communities using the Leiden algorithm.

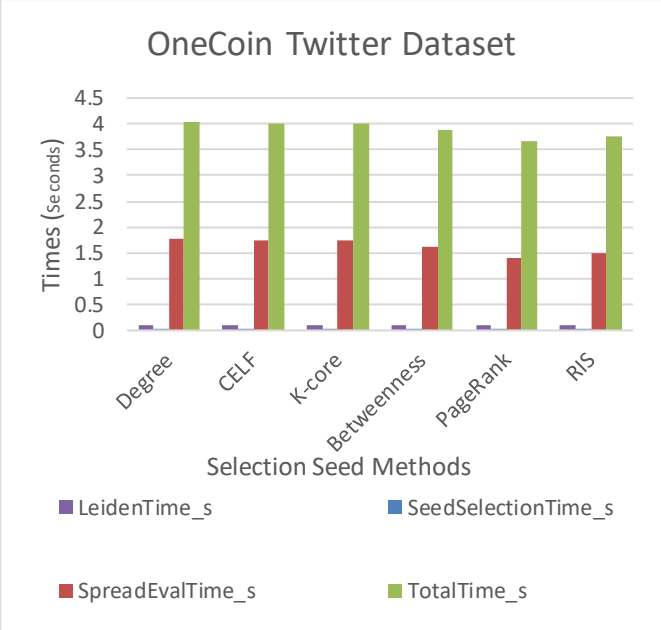

Fig. 8. Total computational time (in seconds) required by each seed-selection method under the LT diffusion model on the OneCoin data communities using the Leiden algorithm.

The results show a clear coverage–concentration trade-off:

- For Degree and CELF, community constraints typically reduce spread at small-to-mid budgets (e.g., around $k = 10-15$), because the unconstrained versions tend to concentrate seeds in the single densest, most cascade-prone region of the graph; community-aware allocation forces distributing seeds across multiple communities, which can reduce immediate cascade size. For methods that are sensitive to seed "over-concentration" effects, community awareness can be beneficial. Notably, k-core and RIS improve at larger budgets under Leiden constraints. For example, at $k = 30$, k-core increases from ≈1445.5 (global LT) to ≈1587.4 (Leiden-aware LT), and RIS increases from ≈1463.2 to ≈1589.1. This indicates that, once enough budget is available, spreading seeds across communities helps capture multiple diffusion pockets simultaneously, improving overall reach while also achieving better representativeness across the misinformation ecosystem.
- Community-aware allocation also stabilizes methods that can fail at minimal budgets (e.g., PageRank at $k = 5$), because the constraint prevents all seeds from being drawn from a narrow set of globally ranked nodes and instead enforces multi-community representation.
- Runtime under the Leiden-aware pipeline (see Fig. 8) remains within a few seconds for all methods in these runs, as the added community-detection step is computationally modest relative to greedy marginal-gain recomputation, consistent with Leiden's known efficiency properties [8].

F. Discussion and Interpretation

Across both diffusion models, the results follow established influence-maximization theory: greedy selection is near-optimal under monotone submodular spread, which explains CELF's consistently highest spread [4], [6]. The runtime gap is also expected because CELF still relies on repeated marginal-gain estimation (even with lazy updates) [6]. The strong performance of the Degree heuristic (nearly matching CELF at larger k) indicates that the OneCoin engagement graph is sparse and hub-dominated; in such graphs, immediate outward reach can approximate marginal gains well. RIS provides a strong near-greedy alternative with substantially lower runtime, consistent with reverse-reachable (RR) set sampling methods designed for near-linear-time approximation [7], [22].

Community-aware seeding changes the intervention footprint. By allocating seeds proportionally across Leiden communities, the approach discourages concentrating interventions in a single dense cluster and instead targets multiple sub-audiences. This explains the observed coverage–concentration trade-off: at small-to-mid budgets, coverage constraints can reduce the single largest cascade, while at larger budgets they can improve overall reach by activating multiple diffusion pockets in parallel, consistent with community-based IM objectives [16]–[18]. Leiden is a suitable choice because it refines partitions to ensure well-connected communities, improving the reliability of downstream community-constrained seeding [8].

G. Limitations and Threats to Validity

Our evaluation has limitations in modeling and data. IC and LT are simplified abstractions that omit content semantics, heterogeneous susceptibility, recommender effects, and time-varying exposure. Weighted-cascade normalization is a standard

practical parameterization when true edge probabilities are unknown [4], but it may not match platform-specific amplification dynamics and can affect which nodes appear influential. The engagement network is built from observable retweets/replies and is sensitive to collection choices (keywords, time window, API limits), missing/deleted/private content, and automated accounts, which can introduce sampling bias and missing edges. These factors can affect both community detection and seed ranking. Results from OneCoin may also not generalize to other scam domains. Future work should incorporate temporal diffusion (time-sliced graphs), explicit competitive/containment objectives [5], robustness checks over alternative probability parameterizations, and hybrid models that combine network structure with content/account-level signals (e.g., credibility and bot likelihood).

V. Conclusion

This study presented a diffusion-based, community-aware influence-maximization workflow to support the suppression of scam-related misinformation in the OneCoin Twitter engagement ecosystem. Using a directed interaction graph of 5,415 accounts and 6,117 engagement edges, we evaluated six seed-selection strategies under IC and LT diffusion, using the weighted-cascade parameterization [4]. CELF achieved the largest expected spread (e.g., ≈1620.9 under LT and ≈1597.9 under IC at k=30), but required the most computation (≈15.44 s under LT; ≈35.87 s under IC), reflecting the cost of repeated marginal-gain evaluation despite lazy acceleration [6]. RIS delivered a strong near-greedy alternative with substantially lower runtime, consistent with RR-set sampling guarantees and prior evidence of practical efficiency [7], [22].

Integrating Leiden community detection and proportional seed allocation shifted seed composition toward broader sub-community coverage, which is operationally meaningful for scam ecosystems sustained by multiple semi-separated recruitment clusters [8]. At larger budgets, community-aware allocation can also improve diffusion reach for methods that otherwise over-concentrate seeds (e.g., k-core and RIS under LT). Overall, the results provide actionable guidance for mitigation planning: greedy-quality methods maximize reach when offline computation is acceptable, while RIS and simple degree-based heuristics offer deployable trade-offs between spread and runtime for scalable, repeatedly updated intervention workflows.

Future research should move beyond static-graph IC/LT simulations by incorporating temporal dynamics, competitive influence-blocking objectives, and sensitivity analyses over propagation parameters, while enriching network signals with content and account-level features to better represent real platform diffusion and enforcement constraints.

Enhancing Business Cybersecurity Through Integrated Defense and Incident Response: A Comparative Decision Framework

Aligned with NIST CSF 2.0, NIST SP 800-61r3, ISO/IEC 27001: 2022, CIS Controls v8.1, and MITRE ATT&CK

Jurgen Mecaj
Department of Information Technology (DTI)-Faculty of Informatics, Mediterranean University of Albania, Tirana, Albania

***Abstract*—Business operations increasingly depend on digital workflows, hybrid infrastructures, and third-party ecosystems, making cybersecurity incidents a direct business continuity and governance problem rather than solely a technical concern. This paper proposes an integrated cyber defense and defense-to-response decision framework for organizations seeking to reduce exposure to external attacks and unauthorized access while improving incident detection, containment, and recovery. The framework aligns governance and control selection with NIST Cybersecurity Framework (CSF) 2.0, operational incident response considerations with NIST SP 800-61 Revision 3, control requirements with ISO/IEC 27001:2022, prioritized safeguards with CIS Controls v8.1, and adversary-behavior mapping with the MITRE ATT&CK Enterprise Matrix. We define an evaluation model that combines 1) coverage mapping across prevent-detect-respond-recover functions, 2) multi-criteria decision analysis (MCDA) for cost, complexity, and risk reduction trade-offs, and 3) a playbook-oriented response design for high-frequency attack paths relevant to business environments. A worked comparative example demonstrates how three strategy bundles (traditional perimeter controls, defense-in-depth with SIEM, and a Zero Trust + EDR + SOAR approach) can be ranked using weighted criteria and incident lifecycle metrics. The paper concludes with an implementation roadmap and measurement plan to convert the framework into an evidence-based program that supports executive decision-making and continuous improvement.**

Keywords*—Cyber defense; incident response; business continuity; NIST CSF 2.0; SP 800-61r3; ISO/IEC 27001:2022; CIS Controls v8.1; MITRE ATT&CK; Zero Trust; EDR; SOAR; MCDA

I. Introduction

For most organizations, cybersecurity risk has matured into a business risk: incidents can halt operations, drive regulatory exposure, damage trust, and increase cost of capital. Recent industry analyses continue to report large volumes of real-world incidents and breaches, reinforcing the need for defense strategies tightly coupled with rapid response and recovery. In parallel, adversaries increasingly use credential theft, infostealers, and exploitation of weak security hygiene during cloud and hybrid transitions, elevating the probability of unauthorized access and lateral movement in business networks. Recent industry reports highlight persistent breach drivers and the business impact of incident response performance [6]–[8].

Despite substantial investment in security tooling, many organizations struggle to convert controls into measurable improvements in mean time to detect (MTTD), mean time to respond (MTTR), and overall business resilience. Common failure modes include fragmented governance, inconsistent prioritization, limited logging visibility, and response playbooks that are not exercised or automated.

This research addresses the doctoral theme of increasing cybersecurity as a practical instrument for protecting business activity from external attacks and unauthorized access by proposing a comparative, standards-aligned decision framework that connects: 1) cybersecurity governance and prioritization, 2) defensive control bundles, 3) ATT&CK-informed detection logic, and 4) incident response execution and recovery.

Novelty and positioning: Unlike catalog-only maturity views, the proposed approach formalizes defense-to-response strategy bundles as the decision unit and jointly evaluates standards-aligned controls, ATT&CK-informed coverage evidence, and incident lifecycle/continuity signals (e.g., MTTD, MTTR, containment and restoration outcomes). This coupling supports explicit trade-off analysis across prevention, detection, response automation, and recovery under realistic constraints.

The remainder of this paper is organized as follows: Section I states the research objectives and contributions. Background and related guidance are presented in Section II. Section III presents the methodology. Section IV presents the worked comparative example. Section V details standards mapping and comparison. Section VI provides incident response for playbook matrix. Section VII presents roadmap for businesses. Section VIII discusses implementation considerations and limitations, and Section IX concludes with future research directions.

A. Research Objectives and Questions

The primary objective is to provide a repeatable method for selecting and validating defense and incident response

strategies that measurably improve business protection. The paper is guided by the following research questions (RQs):

RQ1: Which defense-to-response strategy bundles provide the best balance between risk reduction and operational feasibility for business environments?

RQ2: How can organizations compare strategy bundles using a transparent scoring model aligned with recognized standards and adversary behaviors?

A conceptual decision lens that links governance, control selection, telemetry, and incident execution into a single evaluable strategy bundle aligned with recognized standards.

A comparative evaluation model combining ATT&CK coverage validation with MCDA-based scoring tied to operational detection/response and recovery indicators.

- A playbook matrix that operationalizes frequent business-relevant attack paths into detection, containment, and recovery actions to support repeatability and continuous improvement.
- A measurement and roadmap approach describing how organizations calibrate criteria and weights using exercises and incident data to generalize beyond the illustrative example.
- A practical playbook matrix for frequent business-relevant attack paths, supporting repeatable response and continuous improvement.
- A measurement plan linking technical outcomes to business continuity indicators.

II. Background and Related Guidance

NIST SP 800-61r3 provides practical incident response guidance, including preparation, detection/analysis, containment/eradication/recovery, and post-incident improvement, aligned with CSF 2.0 risk management needs [2].

NIST CSF 2.0 provides a taxonomy for governance, risk prioritization, and continuous improvement across the cybersecurity lifecycle [1].

[2] A. Nelson, S. Rekhi, M. Souppaya, and K. Scarfone, "Incident Response Recommendations and Considerations for Cybersecurity Risk Management: A CSF 2.0 Community Profile," NIST Special Publication 800-61r3, Apr. 2025. doi:10.6028/NIST.SP.800-61r3.

ISO/IEC 27001:2022 defines requirements for an information security management system (ISMS) and establishes a compliance-oriented control portfolio [3].

In addition, NIST SP 800-53 Rev. 5 provides a detailed control catalog and baselines that can be mapped to organizational requirements and evidence collection activities [9].

Risk assessment approaches such as NIST SP 800-30r1 support structured identification and analysis of threats, vulnerabilities, and likelihood/impact, informing prioritization of control bundles and response investments [10].

ISO/IEC 27005:2022 extends ISO/IEC 27001 programs with information security risk management guidance across assessment, treatment, monitoring, and communication, reinforcing a continuous improvement cycle [11].

Quantitative methods such as the Open FAIR approach complement qualitative scoring by estimating loss event frequency and magnitude, enabling financial risk communication and investment justification [12].

For criteria weight elicitation, analytic hierarchy process (AHP) is a widely used structured technique for pairwise comparison of decision criteria and can be applied to reduce subjective bias in stakeholder weighting workshops [13].

These perspectives motivate an integrated decision approach that connects standards compliance, threat-informed coverage, and operational incident outcomes rather than treating them as independent workstreams.

CIS Controls v8.1 provides a prioritized set of safeguards and introduces governance recommendations aligned with modern environments [4].

MITRE ATT&CK provides a behavior-based model of adversary tactics and techniques used to design detections and validate coverage [5].

A. Integrated Reference Architecture

Fig. 1 summarizes a practical defense-to-response reference architecture that connects monitoring, analysis, orchestration, containment, and governance. The architecture supports both preventive hardening and post-incident learning loops.

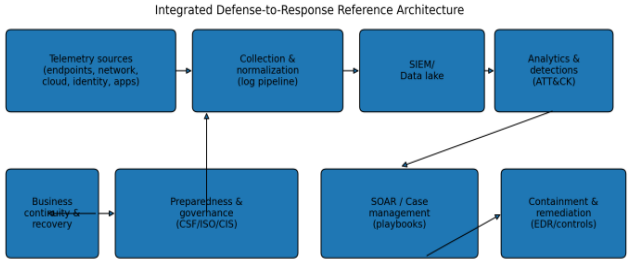

Fig. 1. Integrated defense-to-response reference architecture (conceptual).

III. Methodology

The proposed methodology combines 1) threat-informed defense mapping, 2) a multi-criteria decision analysis (MCDA) scoring model, and 3) playbook-driven incident response design. The methodology is intended to be executed iteratively and improved with measurement data.

A. Strategy Bundles

Organizations typically deploy controls as tool-by-tool procurements; however, business protection depends on coherent bundles that span identity, endpoint, network, logging, and recovery. We define three common strategy bundles used for comparison:

S1: Traditional (perimeter + antivirus + basic backups): Emphasizes perimeter defenses and endpoint antivirus with limited centralized visibility and manual response.

S2: Defense-in-depth (MFA + vulnerability management + segmentation + SIEM): Adds identity hardening and centralized logging/analytics to improve detection and investigation.

Note on criterion interactions: The weighted-sum model is simplest and transparent, but it assumes limited interaction among criteria. In practice, detection coverage and response speed may be positively coupled via improved telemetry and triage. To mitigate interaction risk, organizations should document dependencies, perform sensitivity analysis over weights, and, where needed, use interaction-aware extensions (e.g., ANP or multi-objective formulations) when dependencies materially affect ranking.

S3: Zero Trust + EDR/XDR + SIEM + SOAR + PAM + immutable backups: Implements strong identity controls, behavior-based detection, automated response, and resilient recovery capabilities.

B. Evaluation Criteria and Weighting

To compare strategy bundles transparently, we define eight criteria spanning prevention, detection, response, recovery, and feasibility. Weights can be determined via stakeholder workshops or analytic hierarchy process (AHP). For the worked example, we use the weights in Table I.

TABLE I. EVALUATION CRITERIA AND EXAMPLE WEIGHTS FOR MCDA SCORING

Criterion	Definition (business-oriented)	Weight
Attack surface reduction	Hardening and exposure reduction (patching, segmentation, secure configuration, asset control).	0.15
Identity & access hardening	MFA, least privilege, PAM, and identity monitoring to reduce unauthorized access.	0.15
Detection coverage & fidelity	Visibility and detection quality across endpoints, network, cloud, and identity.	0.18
Response speed & orchestration	Case management, automation, containment capability, and repeatable playbooks.	0.18
Resilience & recovery	Backups, restoration confidence, disaster recovery, and continuity of critical services.	0.12
Governance & compliance support	Support for CSF/ISO control evidence, policies, risk reporting, and audits.	0.10
Cost (lower is better)	Total cost of ownership relative to risk reduction (higher score = lower cost).	0.07
Operational complexity (lower is better)	Staffing and operational burden (higher score = easier operation).	0.05

C. Scoring Model

Each strategy bundle is scored on a 1-5 ordinal scale per criterion, where higher values indicate better performance (except that cost and complexity are inverted so higher values represent lower cost/complexity). Scores are normalized to [0,1] and aggregated using a weighted sum model:

$$\text{Score(bundle)} = \Sigma_i \, w_i \times (s_i / 5)$$

D. Threat-Informed Coverage Mapping

To avoid purely subjective scoring, organizations should map control bundles to a threat model based on business context (industry, assets, and common attack paths) and validate with ATT&CK techniques. Detection engineering should explicitly document which ATT&CK techniques are covered by telemetry, analytics, and response actions.

E. Measurement Plan

A measurement plan converts the framework into an evidence-based program. Recommended operational metrics include:

- Mean time to detect (MTTD) and mean time to respond. (MTTR)
- Containment success rate within defined service-level objectives (SLOs).
- Restoration time and data integrity confidence for critical systems.
- Detection false positive rate and analyst workload Fig. 2 helps identify which criteria drive strengths and weaknesses, while Fig. 3 summarizes the overall ranking implied by the chosen weights, supporting executive-level comparison.
- Coverage maturity: percentage of prioritized ATT&CK techniques with validated detections and tested playbooks.
- Business impact: downtime, recovery cost, regulatory notifications, and customer-facing disruption.

IV. WORKED COMPARATIVE EXAMPLE (ILLUSTRATIVE)

This section provides a worked example using illustrative values to demonstrate how the framework operates. Organizations should calibrate the example scores and weights using internal measurements, controlled exercises, and operational incident data prior to deployment.

A. Comparative Scoring Matrix

Table II reports the illustrative 1–5 criterion scores assigned to each strategy bundle; these values are used to normalize and aggregate the MCDA composite ranking.

TABLE II. ILLUSTRATIVE 1-5 SCORING FOR STRATEGY BUNDLES ACROSS EVALUATION CRITERIA

Criterion (1-5)	S1 Traditional (perimeter+AV)	S2 Defense-in-depth (MFA+SIEM)	S3 Zero Trust + EDR + SOAR
Attack surface reduction	2	4	5
Identity & access hardening	2	4	5
Detection coverage & fidelity	2	3	5
Response speed & orchestration	1	3	5
Resilience & recovery	3	4	5
Governance & compliance	2	4	5
Cost (lower is better)	5	3	2
Ops complexity (lower is better)	4	3	2

These indicators can be operationalized through incident tickets and post-incident reviews to validate whether improvements translate into reduced downtime and faster recovery.

B. Visualization

Fig. 2 presents the comparative profile across criteria, while Fig. 3 shows the aggregated weighted composite score.

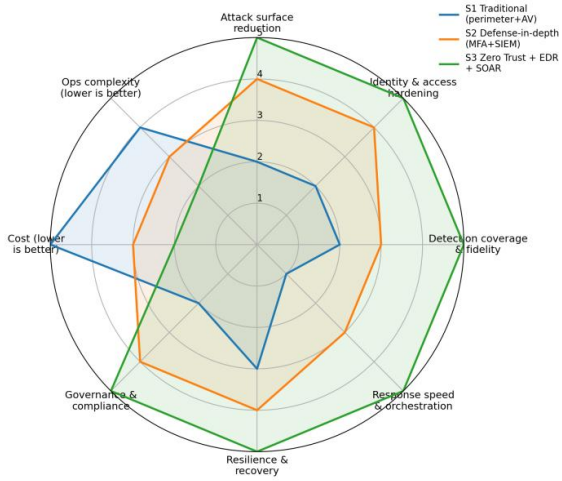

Fig. 2. Radar plot of comparative criterion scores (illustrative).

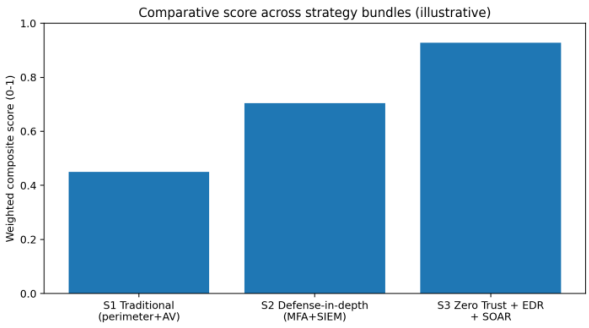

Fig. 3. Weighted composite score across strategy bundles (illustrative).

C. Incident Lifecycle Improvement Indicators

Beyond composite scoring, executive stakeholders typically require operational indicators that translate to reduced disruption. Fig. 4 illustrates how stronger detection and response capabilities can reduce MTTD/MTTR, improving containment and recovery speed.

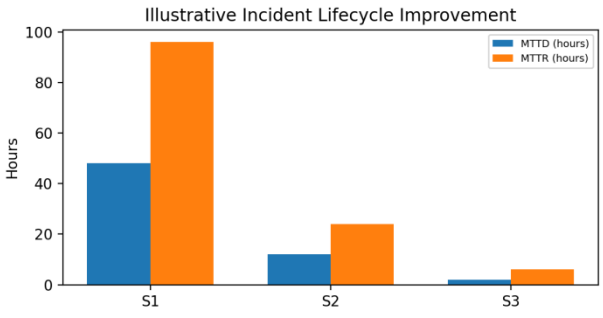

Fig. 4. Illustrative MTTD and MTTR comparison.

D. Interpretation of the Worked Example

Using the example weights, S3 (Zero Trust + EDR + SOAR) achieves the highest composite score primarily due to strong detection coverage, orchestration, and recovery. S2 provides a cost-balanced intermediate option with material gains over S1. However, organizational constraints (budget, staffing, regulatory priorities, legacy systems) may justify selecting S2 as a transition architecture with an incremental roadmap toward S3.

V. Standards Mapping and Comparison

Table III provides a high-level conceptual mapping between program activities and the referenced standards/guidance, supporting traceability from governance to incident handling and recovery.

A. Nelson, S. Rekhi, M. Souppaya, and K. Scarfone, "Incident Response Recommendations and Considerations for Cybersecurity Risk Management: A CSF 2.0 Community Profile," NIST Special Publication 800-61r3, Apr. 2025. doi:10.6028/NIST.SP.800-61r3 [2].

TABLE III. High-Level Mapping Across Standards and Guidance (Conceptual)

Program activity	NIST CSF 2.0	NIST SP 800-61r3	ISO/IEC 27001:2022	CIS Controls v8.1
Governance & policy	Govern	Govern/Prepare (CSF-aligned IR considerations)	ISMS context, leadership, planning	Governance function (v8.1)
Asset & exposure management	Identify, Protect	Preparation considerations	Operational planning, controls selection	Inventory, vulnerability management
Detection engineering	Detect	Detection/analysis considerations	Monitoring controls (Annex A - technological)	Audit log management, monitoring
Incident handling	Respond	Incident response recommendations	Incident management controls, continuous improvement	Incident response management
Recovery & resilience	Recover	Recovery considerations	Business continuity and backup controls	Data protection, recovery safeguards
Continuous improvement	Govern (improve), all functions	Lessons learned integration	Internal audit, management review, improvement	Metrics and program improvement

A. Why Behavior-Based Mapping Matters

Control catalogs alone do not ensure coverage against real attacker tradecraft. ATT&CK-based mapping helps validate whether telemetry and analytics cover the tactics most relevant to unauthorized access (Initial Access, Credential Access, Lateral Movement, Privilege Escalation, Exfiltration) and whether response actions can disrupt those tactics within required SLOs.

VI. Incident Response Playbook Matrix

Table IV provides a compact playbook matrix for business-relevant scenarios. Each scenario should be backed by detailed procedures, communications templates, legal/regulatory triggers, and evidence handling guidance.

TABLE IV. Playbook Matrix for High-Frequency Scenarios (Conceptual)

Scenario	Primary ATT&CK focus	Key detection signals	Containment actions	Recovery actions
Credential theft / infostealer-driven intrusion	Credential Access, Initial Access, Lateral Movement	Unusual auth patterns, token abuse, new device logins, anomalous process chains	Force MFA reset, revoke tokens/sessions, isolate affected endpoints, block IOCs	Password rotation, reimage endpoints, validate privileged accounts, review access logs
Ransomware attempt (pre-encryption)	Execution, Defense Evasion, Impact	Mass file modifications, suspicious scheduled tasks, EDR ransomware heuristics	Isolate hosts, disable SMB shares, block lateral movement, snapshot evidence	Restore from immutable backups, validate integrity, re-enable services with monitoring
Web application exploitation	Initial Access, Persistence, Exfiltration	WAF alerts, abnormal API patterns, new admin accounts, DB query anomalies	Disable vulnerable endpoints, rotate secrets, patch, activate emergency rules	Forensic review, restore clean images, rotate keys, customer notification if required
Business email compromise (BEC)	Initial Access, Credential Access, Collection	Mailbox forwarding rules, abnormal OAuth grants, finance workflow anomalies	Disable account, revoke OAuth grants, remove rules, hold suspicious transfers	Financial recovery steps, strengthen approvals, awareness reinforcement

VII. Implementation Roadmap for Businesses

A phased roadmap helps organizations transition from tool-centric security to a measurable defense-to-response program.

A. Phase 0 - Governance and Scope

Define critical business processes, crown-jewel assets, risk appetite, and reporting cadence. Establish a governance model aligned to CSF 2.0 and define incident categories, notification thresholds, and decision rights.

B. Phase 1 - Baseline Hygiene and Visibility

Implement asset inventory, vulnerability management, secure configuration baselines, and MFA for privileged access. Enable centralized logging for identity, endpoint, network, and cloud platforms. Confirm backup integrity and restoration procedures for critical systems.

C. Phase 2 - Threat-Informed Detections and Exercises

Develop prioritized detection use cases mapped to ATT&CK techniques relevant to the business. Conduct tabletop exercises and controlled attack emulation to validate detection and response. Measure MTTD/MTTR and refine playbooks.

D. Phase 3 - Orchestration, Automation, and Resilience

Introduce SOAR for routine containment steps, ticketing integration, and standardized communications. Adopt Zero Trust principles and privileged access management where feasible. Strengthen recovery with immutable backups and tested disaster recovery runbooks.

VIII. Discussion and Limitations

The proposed framework is designed to be practical and auditable; however, it does not replace empirical evaluation. Scoring models can introduce bias if weights and criteria are not validated by stakeholders and measured outcomes. Additionally, organizations with constrained resources may prioritize incremental adoption (S2) as a stepwise path toward a higher maturity state (S3). Future empirical work should validate the model with measured incident datasets, controlled attack emulation, and longitudinal business impact analysis.

IX. Conclusion

Protecting business operations from external attacks and unauthorized access requires more than deploying isolated security tools; it requires a coherent defense-to-response program that links governance, detection engineering, and incident response execution. This paper presented a comparative, standards-aligned decision framework combining ATT&CK-informed mapping, MCDA scoring, and playbook-driven response design. The worked example illustrates how organizations can rank strategy bundles and communicate trade-offs to executives. By integrating measurement (MTTD/MTTR, containment success, recovery time, and coverage maturity), the framework enables continuous improvement and supports cybersecurity as a practical instrument for safeguarding business activity. The framework is intended to be applied iteratively as evidence accumulates through exercises and operational incidents.

Limitations include dependence on organizational context, scoring subjectivity, and incomplete observability for certain techniques; these can be reduced through exercises, purple-team validation, and periodic recalibration of weights and scores.

Future research should empirically validate rankings across diverse sectors, automate ATT&CK-to-detection-to-playbook evidence collection, and compare MCDA results with quantitative risk models (e.g., Open FAIR) and alternative decision methods under uncertainty.

***Abstract*—Among all stages of skin cancer, Melanoma, Basel Cell Carcinoma (BCC), and Squamous Cell Carcinoma (SCC) have a significant impact on world health. Although deep learning offers promising potential for dermatological categorization, only limited disease groups have benefited, since most studies focus on particular illnesses rather than covering comprehensive human skin problems. Computerized analysis has been used in the past to identify cancer in skin lesion images, but challenges still persist mainly due to the multiple forms, textures, and sizes of lesions that complicate skin cancer classification. This research paper presents a Convolutional Neural Network (CNN) model customized to meet our requirements by using a pre trained InceptionV3 model along with Bayesian hyperparameter tuning. Using the ISIC 2024 and HAM 10000 datasets, the main objective is to classify skin lesions and differentiate between malignant Melanoma, BCC, and SCC. By implementing this customized model, the issue caused by variations in lesion appearance is effectively addressed, leading to more accurate predictions. Using Bayesian hyperparameter tuning can increase identification while decreasing computational cost. The proposed model performed strongly on the combined datasets by achieving combined average accuracy of 95.1 %, a precision of 94.42 %, a sensitivity of 97.3 %, a specificity of 98.8 %, and an F1 score of 95.7 %. These results demonstrate that the model significantly outperformed existing techniques and provided more accurate and consistent diagnosis of pigmented skin lesions compared to current standards.**

Keywords*—Melanoma; Basal Cell Carcinoma (BCC); Squamous Cell Carcinoma (SCC); Inceptionv3; Bayesian tuning; skin cancer classification

I. Introduction

Skin illnesses may be caused by hormones (e.g., acne) or by environmental factors such as pollution and sunlight. Most individuals ignore skin disorders and never go to the doctor. Skin illnesses account for 1.79% of all health-related ailments globally [1].

Melanoma, Basal Cell Carcinoma, and Squamous Cell Carcinoma are main types of malignant skin tumors shown in Fig. 1. with a bad prognosis, and the number of cases growing, particularly in Europe and the United States. Among these three types of skin cancer, Melanoma is considered as the worst. Early identification of these classes is crucial since melanoma, Basal Cell Carcinoma, and Squamous Cell Carcinoma may be almost entirely treated if caught early [2-4]. However, melanoma, Basal Cell Carcinoma, and Squamous Cell Carcinoma continue to be diagnosed based on clinicians' subjective assessments. As a result, a very precise and quantitative diagnostic index is necessary. The categorization of these malignant skin lesions via dermoscopy methods has emerged as a crucial topic in dermatology and skin oncology in recent years [5, 6]. According to the Australian Institute of Health and Welfare, the average skin tumor change rate during the past 25 years is 1.7% [7].

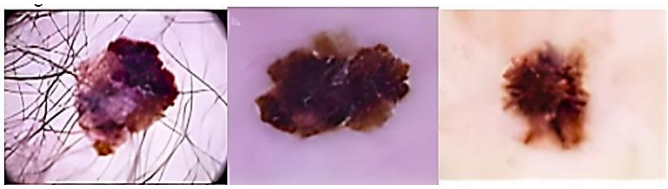

Fig. 1. (a) Melanoma (MEL), (b) Basal Cell Carcinoma (BCC), (c) Squamous Cell Carcinoma (SCC).

Deep learning is commonly employed in the creation of autonomous skin lesion detection systems. Esteva et al. [8] categorized approximately 130,000 clinical images into three categories using deep learning and obtained a 72.1% accuracy rate. Fujisawa et al. [9] showed 92.4% accuracy after detecting 6,000 dermoscopic images using deep learning. As a result, deep learning-based automated diagnosis of melanoma, Basal Cell Carcinoma, and Squamous Cell Carcinoma shows great promise. Deep learning, on the other hand, refers to a collection of arbitrarily chosen parameters known as hyperparameters [10]. Hyper parameter settings are very variable, and using improper values reduces diagnostic effectiveness. It is difficult to determine the optimal hyperparameter settings.

Recent research [11-15] on dermoscopic image classification has progressively emphasized the utilization of deep learning models, specifically employing the ISIC 2024 and HAM10000 datasets for multiclass classification problems. The ISIC 2024 and HAM10000 datasets are publicly available collections managed by the International Skin Imaging Collaboration (ISIC) and released latest in 2024 to advance

research in the domain. This dataset is widely employed in dermatology and artificial intelligence research, specifically for the development and assessment of algorithms pertaining to the analysis of skin lesions, with an emphasis on pigmented skin lesions. These techniques attempt to address issues such as class disparity, the existence of artifacts, variable size, texture, forms and insufficient contrast between skin lesions and surrounding regions. Using the ISIC 2024 dataset, [16] demonstrated a deep convolutional neural network (CNN) model created especially for multiclass skin cancer classification. Their approach worked far better than well-known transfer learning models like VGG16 and DenseNet. Alsahafi et al. [12] were the first to show Skin-Net, a deep residual network that leverages cross-channel correlation and multilayer feature extraction. Their method worked better for multiclass classification and solved the problem of dataset imbalance when tested on the ISIC 2024 and ISIC-2020 datasets. Another study used both CNNs and transformers to develop a Swin Transformer model for classifying skin lesions [11]. Their method was more sensitive and specific than most standard CNN models when they used the ISIC 2024 dataset [10]. Cauvery et al. [14] created a convolutional neural network model that used transfer learning to sort dermoscopic images from the ISIC 2024 dataset. achieving accuracy of 81.2%. A different study that used transfer learning with the GoogleNet architecture to sort eight types of skin lesions from the ISIC 2024 dataset [15]. CNNs are good at classifying skin lesions into more than one class, as indicated by the model's 90.92% accuracy [15]. Researchers have proven that the Inception V3 architecture, a complex deep learning model, can find important parts of dermoscopic images [16–18]. But there is always room for improvement, especially when it comes to adding new model techniques to specialized datasets.

We have conducted this research that improvised the IV3 approach using dermoscopic skin images. The main goal of this research is to accurately classify the three main stages of skin cancer, namely Squamous Cell Carcinoma, Basal Cell Carcinoma, and Melanoma. This study employed the customized IV3 model alongside the ISIC 2024 and HAM10000 datasets to classify cutaneous skin lesions. Customized IV3 approach is utilized in which data is augmented with respect to size, texture and forms to reduce the issue of overfitting problem and Bayesian hyperparameter tuning to improve identification while reducing the computational complexity. This research work is distinctive as it employs data augmentation and Bayesian tuning in customized manners particularly designed for the dermoscopic image processing of three stages of cancerous human skin.

The proposed customized InceptionV3 pipeline is essentially novel, combining Bayesian hyperparameter optimization as a basic learning mechanism with domain-specific dermoscopic data augmentation, rather than depending on fixed or manually modified parameters as is common practice. Unlike closely comparable state-of-the-art approaches, the model combines transfer learning, probabilistic optimization, and cross-dataset multiclass training into a single end-to-end framework, resulting in increased resilience and generalization.

II. Methods

A. Datasets

This study utilized dermoscopic images from the ISIC 2024 and HAM10000 databases [19, 20] owing to the International Skin Imaging Collaboration's comprehensive repository of lesion images and classifications. Dermoscopic images of 2,000 squamous cell skin lesions, 1,500 Basal Cell Carcinomas, and 1,300 melanomas are included in the collection. Dermoscopic images were chosen at random from the database for this research work. The database images are set of 450 by 600 pixels. To meet the input images size required for deep learning (299×299×3), the images are resized to that size, form and texture and apply random noise to the top and bottom 28 pixels. Notably, the collection is unbalanced, with around half of the images displaying melanocytic nevus. Some of the most popular datasets are shown in Table I.

TABLE I. Popular Publicly Available Datasets for Skin Lesion

Dataset	Data Size	Image Type	Laison Type
ISIC 2024	>400000	Dermoscopy and Medical image	Include: Melanoma (MEL), Basal Cell Carcinoma (BCC), Squamous Cell Carcinoma (SCC).
HAM 1OOOO	10,015	Dermoscopy image	Include: Melanoma (MEL), Basal Cell Carcinoma (BCC), Squamous Cell Carcinoma (SCC).
Dermnet	23,000	Dermoscopy, pathology	Include: Melanoma (MEL), Basal Cell Carcinoma (BCC), Squamous Cell Carcinoma (SCC).
PH2	200	Dermoscopy image	Include: Melanoma (MEL), Basal Cell Carcinoma (BCC), Squamous Cell Carcinoma (SCC).

B. Data Processing

To prepare the data for deep learning techniques, a crucial preprocessing step is required, which improves and speeds up the model's performance [21, 22]. The techniques used to standardize and enhance the dataset of input images prior to model training are covered in the next section. Three preparation processes are included in the method: first, the images are resized; second, they are normalized to scale; and third, data augmentation is used to expand the dataset and broaden the model.

C. Data Augmentation

Since data is difficult to get, deep learning models need a large number of labeled samples. Using ABCD rule (asymmetry, border, color, diameter) guideline and data

augmentation is a solution to this issue. By altering images in various ways, including cropping, rotating, flipping, zooming, and shearing, the technique generates new data versions in terms of image size, texture and multiple cancerous forms. Acceptable changes that faithfully capture the inherent differences between dermoscopic image while maintaining their meaning are produced by the applied transforms. The primary objective of data augmentation is to increase the training dataset's diversity, variability, and number of samples. This lessens overfitting and improves the model's ability to generalize. There is a benefit to training models on tiny, irregular datasets.

D. Model Architecture

Fig. 2 shows the Inception V3 architecture, which was a big step forward in deep learning, especially for finding and classifying skin lesions [23]. Google [24, 25] first showed this version of the Inception architecture. It is the third version. Inception V3 has a more complex architecture than the original Inception model, making it a deeper and broader version of the original. It has a lot of "Inception modules" that let it process information well, no matter how big or complicated it is [26].

There are a lot of key layers in the Inception V3 model that work together to quickly gather, enhance, and sort visual data. There are a variety of filters in the convolutional layers, such as 1×1, 3×3, 5×5, and asymmetric ones like 1×7 and 7×1. These filters look for patterns and textures at different scales. The 1×1 convolutions assist cut down on the number of dimensions and speed up the math [23]. Max pooling discovers the most significant characteristics in tiny regions to maintain vital spatial information and cut down on the number of dimensions. Average pooling, on the other hand, makes feature maps more consistent and, when applied globally, substitutes dense layers to stop overfitting [27]. The concatenation mechanism pulls together outputs from many convolutional and pooling paths in each Inception module. This lets the network collect both fine and coarse input at the same time. Dropout switches off certain neurons while training to help the model generalize better and reduce the chance of overfitting. At the end, a completely connected layer puts all the learnt characteristics into one vector. The last softmax layer then changes this output into class probabilities, which makes it easier to put items into the right groupings, including melanoma, Basal Cell Carcinoma, and Squamous Cell Carcinoma [27, 28].

Better performance: this model is more accurate and works faster than the ones that came before it, especially when it comes to identifying big images. It became more accurate while consuming less computational resources than older versions. Inception V3 is notable for taking huge convolutions and breaking them down into smaller, easier-to-manage steps. You may split a 5×5 convolution into two 3×3 convolutions [29, 30]. This cuts down on the number of parameters, which helps keep the model from overfitting and makes it easier to analyze. Inception V3 has a nice way to make the grid smaller without causing a representational bottleneck. We were able to achieve this by utilizing convolution with a stride instead of pooling to make the grid smaller. Batch normalization is a technique that changes and scales the activations of a layer to make the input to that layer the same for all layers [23]. Batch normalization is a big part of the design. This strategy improved the training process faster and introduced some regularization, which made dropout less important. Inception V3 has been used a lot for facial recognition, object detection, and sorting images into groups. Because it worked so well, it could be used for both academic study and real-life situations, even on devices with low computing power. The evolution of CNNs took a big stride forward with Inception V3. It found the proper mix between how well the model worked and how well it used computers, which made it possible for the field to go forward [29]. The main reason for using the Inception V3 architecture in this research work is that it works very well at categorizing malignant skin lesions [20,21]. For precise cauterization of malignant skin cancerous stages, this approach is highly rated.

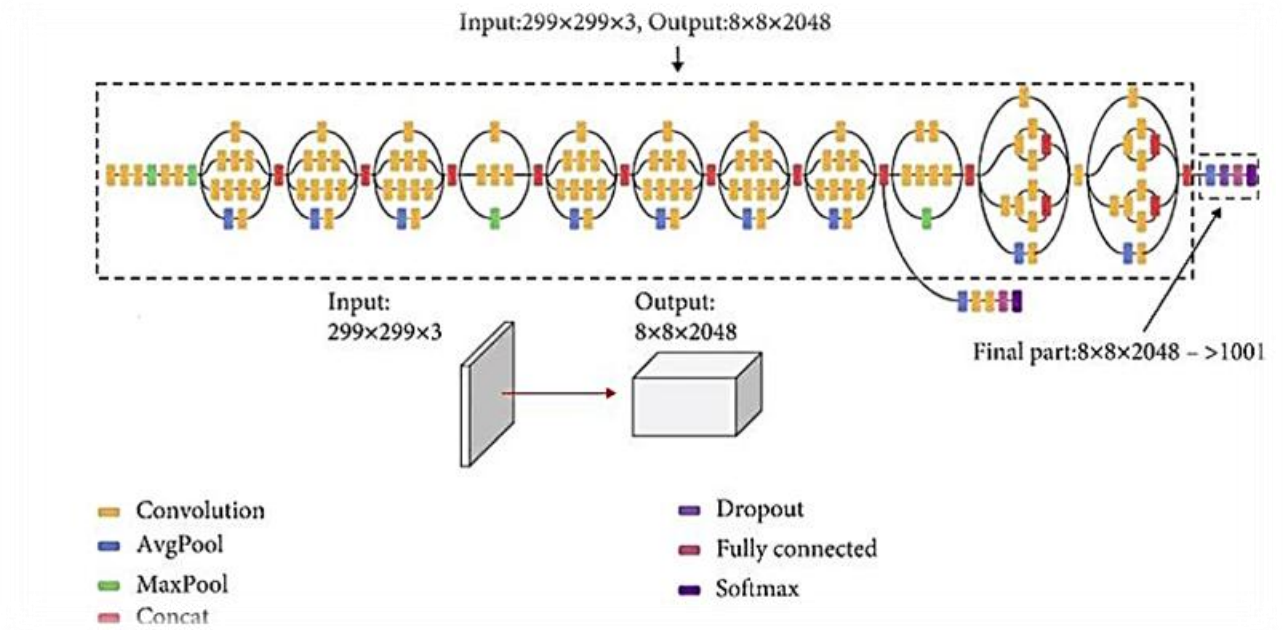

Fig. 2. General architecture of Inception V3 [23].

E. Bayesian Tuning

Bayesian tuning is an optimized statistical approach that adopts the best suited hyperparameter for skin cancer classification. Bayesian optimization creates a surrogate model $M(\theta)$ for the objective function and uses an acquisition function $a(\theta|M)$ to find the next hyperparameter point to evaluate [27]. The surrogate model $M(\theta)$ is modeled as a Gaussian process (GP): $M(\theta) \sim \text{GP}(\mu(\theta), k(\theta, \theta'))$, where $\mu(\theta)$ represents the mean function and $k(\theta, \theta')$ denotes the covariance (kernel) function. The acquisition function $a(\theta|M)$ reconciles exploration (investigating uncharted portions of the hyperparameter space) with exploitation (concentrating on areas with established favorable outcomes) [27]. The current work conducted hyper-parameter fine-tuning by Bayesian optimization and Inception V3 model to determine the optimal parameter configurations shown in Table II. The objective of Bayesian tuning in modeling was to enhance model parameters via a Bayesian probabilistic methodology. The main goals were to improve the model's performance, reduce overfitting or underfitting, optimize parameters well, speed up processing, and make it match the data better. explores to identify optimal parameter combinations, accounting for trade-offs and responding to data complexities.

F. Proposed Model

This research implements the following proposed model for classification of Melanoma, Basal Cell Carcinoma, and Squamous Cell Carcinoma skin lesion shown in Fig. 3. The figure in the proposed model shows a complete pipeline for classifying skin lesions using a customized Inception V3 architecture that has been improved with Bayesian optimization. The illustration shows the main functional phases of the model's process, from data intake to final classification. Each block represents one of these phases.

The first block, "Input Image," shows dermoscopic images of skin lesions that were taken from the ISIC 2024 and HAM10000 databases to make the dataset. These dermoscopic images show three types of cancer: melanoma, Basal Cell Carcinoma (BCC), and Squamous Cell Carcinoma (SCC). Inception V3 needs images that are 299×299×3 pixels big.

Then, the "Data Preprocessing" process is done to get the raw data ready for model training. Various techniques such as scaling, normalization and noise reduction are used in data processing procedure so that dermoscopic images have equal size and properly aligned for further processing.

The "Data Augmentation" block extends the dataset by using various techniques such as zooming the image, flipping the image, rotating and cropping the image reducing overfitting effect, more training data and better model performance for recommended three stages of skin lesion predictions.

The most important is the fourth block which implements the "Customized Inception V3 Deep Learning Model". The model takes previous stages enhanced dermoscopic images that goes through various convolutional, pooling and concatenation layers to generate various lesion patterns. Dropout layers reducing the effect of overfitting whereas Batch Normalization makes the learning process faster for the customized recommended model.

TABLE II. INCEPTION V3 AND BAYESIAN HYPERPARAMETERS

Hyperparameters	Optimized Value
Input Image size	299 × 299 × 3
Input Type	RGB Dermoscopic Images
Learning Rate	0.0001
Dropout Rate	0.3
Optimizer	Adam
Batch Size	32
Epochs	200
Surrogate Model	Gaussian Process (GP)

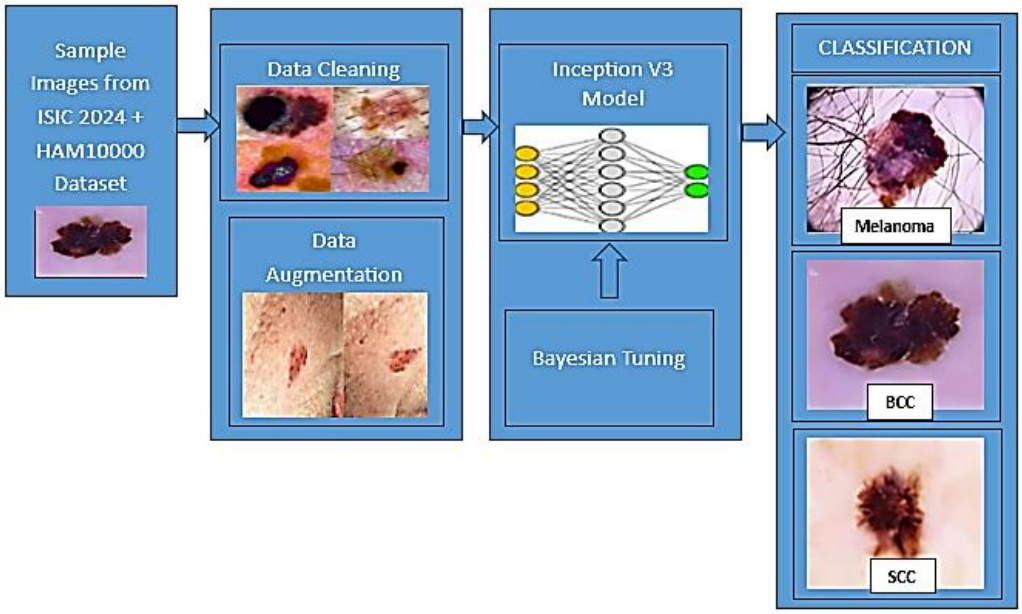

Fig. 3. Proposed model for malignant skin lesion classification.

The "Bayesian Tuning" module then tweaks the model's parameters, such the learning rate, dropout ratio, batch size, and choice of optimizer. Using Bayesian tuning optimization and a Gaussian Process-based surrogate model, we discovered the optimum hyperparameters for the fine-tuned Inception V3 model. The optimized parameters are an input image size of 299×299×3 (which is the network's default setting), a learning rate of 0.0001 to make sure that convergence is stable, a dropout rate of 0.3 to avoid overfitting, and the Adam optimizer, which was chosen because it can work with different learning situations. The batch size was adjusted to 32 to make calculating faster and the gradient more stable. To give enough learning iterations without overfitting, the number of epochs was set to 200. The best values were found through a number of iterations based on the Bayesian framework, which used the model's accuracy and loss feedback to gradually improve the search for the best parameters.

The "Fully Connected + Softmax Layer" turns the high-level, abstract data into probabilities for classification. The fully connected (dense) layer combines what it has learned, and the softmax activation turns that information into probabilities for the three classes (Melanoma, BCC, and SCC).

The "Output Layer" performs three stages of skin cancerous classification based on accuracy, precision, sensitivity, specificity and F1-score representing the overall performance of the recommended hybrid approach.

G. Performance Evaluation

The assessment of recommended cancerous skin lesion model is based on adopting IV3 and Bayesian tuning hybrid approach that works on four main performance metrics in dealing with unbalanced dermoscopic images represent as accuracy, precision, recall, and F1 score.

Accuracy (AC) shows how well the model is overall working taking both true positive and true negative values for accurate predictions. The formula for calculating accuracy is:

$$AC = \frac{T_P + T_N}{T_P + F_N + T_N + F_N} \quad (1)$$

Precision (PR) represents the true positive values upon total positive values. This shows how well the model predict three skin cancerous stages while eliminating other category accurately. The formula is represented as:

$$PR = \frac{T_P}{T_P + F_P} \quad (2)$$

Sensitivity (S) means identifying every actual positive cases. It also represents as true positive rate of overall model. When the model finds all examples of a certain illness, it makes it easier to remember how to group skin problems. It is represented as:

$$S = \frac{T_P}{T_P + F_N} \quad (3)$$

Using harmonic mean calculations, the F1 Score combines accuracy and recall into one figure. The F1 Score is quite helpful when looking at medical image dataset since the classes in these datasets are typically not evenly distributed. The method preserves an appropriate balance between false negatives and false positives:

$$F1\ Score = \frac{2 * P_R * S}{P_R + S} \quad (4)$$

Specificity is the true negative rate, which shows the percentage of benign lesions that were correctly identified as benign instead of being classified as malignant. This is a crucial performance indicator utilized in conjunction with sensitivity (true positive rate) to assess the accuracy of classification models.

$$Sp = \frac{T_N}{F_P + T_N} \quad (5)$$

III. Results and Discussion

This work is focused in classification of 3 significant types of skin cancerous disease (Melanoma, Basal Cell Carcinoma and Squamous Cell Carcinoma). This work employed the Inception V3 pre-trained model to categorize images into three separate classifications (Melanoma, Basal Cell Carcinoma and Squamous Cell Carcinoma) utilizing the ISIC 2024 and HAM10000 dataset. During simulation, we have considered 70% of the data set for training purpose and rest is considered for testing purpose. We executed our proposed model for 3 different cases by considering without augmentation, with augmentation, and with augmentation along with Bayesian tuning to analyze the shortcomings and improve the efficiency of skin cancerous lesion classification.

A. Case I (Without Augmentation of Input Images)

The model performed inconsistently in the first case, which did not involve data augmentation. It performed quite well at correctly identifying three classes, but it lacks accuracy while identifying the other two and frequently confused one class for another while being validated. The model could be overfitted because of the lack of input data variability. shown is Table III and accuracy curve plot results for all three classes are shown in Fig. 4.

TABLE III. Dataset Consideration for Case 1

Skin Cancer	Total Images	Training	Testing
Melanoma	1300	910	390
BCC	1500	1050	450
SCC	2000	1400	600

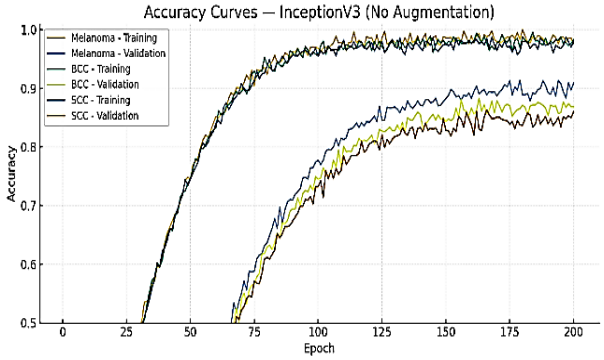

Fig. 4. Accuracy curve of MEL, BCC, and SCC for Case 1.

B. Case II (With Augmentation of Input Images)

The introduction of data augmentation in the second case, which involved training the model with a more diverse dataset, resulted in a significant enhancement in the accuracy level. This technique mitigated the model's susceptibility to minor data variations, thereby improving recognition across all three skin lesion types. The implementation of data augmentation stabilized validation accuracy and diminished overfitting. The increase in accuracy and reduction in overfitting is due to enhancement in feature extraction from the augmented data and improvement in the learning rate of our proposed model. Although a gap persists between training and validation accuracy, it is less pronounced. Table IV represents dataset consideration for CASE II and accuracy curve plot results for all three classes are shown in Fig. 5.

TABLE IV. DATASET CONSIDERATION FOR CASE II

Skin Cancer	Total Images	Training	Testing
Melanoma	1625	1138	487
BCC	1875	1313	563
SCC	2500	1750	750

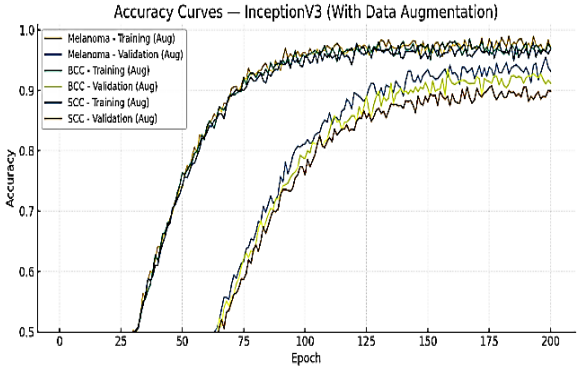

Fig. 5. Accuracy curve of MEL, BCC, and SCC for Case II.

C. Case III (With Augmentation along with Bayesian Tuning)

The third case used Bayesian tuning in addition to data augmentation. Bayesian tuning slightly enhanced the model's decision-making by including the confidence of its predictions and provides much smoother accuracy prediction with a little less variation. This resulted in a substantial increase in accuracy, as the model now faultlessly recognizes all three classes that it previously struggled with. The incorporation of Bayesian hyperparameter tuning alongside data augmentation resulted in enhanced stability of validation accuracy, exhibiting less volatility and a diminished disparity between training and validation accuracy. The dataset used is same as used in CASE II with accuracy curve plot results for all three classes are shown in Fig. 6.

D. Comparison of Performance Metrics

The sample dataset from ISIC 2024 and HAM 100000 demonstrates that our suggested approach, which integrates data augmentation techniques along with the Inception V3 module, and Bayesian tuning significantly enhances performance across all evaluation metrics: accuracy, sensitivity, precision, specificity, and F1 score. Fig. 7 and Table V represent overall model performance key metrics results in terms of Accuracy, Precision, Sensitivity, Specificity and F1 score. In general, these findings indicate that the suggested model demonstrates top-tier performance in classifying multiple types of skin cancer and can proficiently differentiate between melanoma, BCC, and SCC.

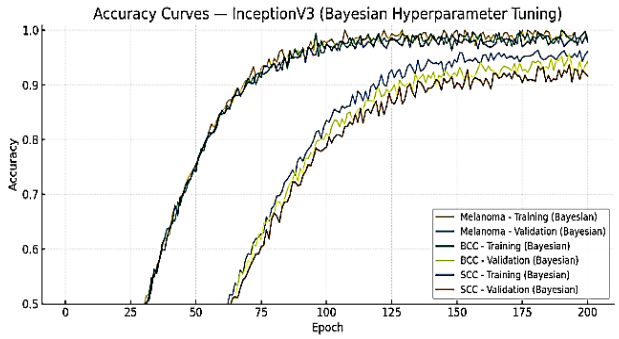

Fig. 6. Accuracy curve of MEL, BCC, and SCC for Case III.

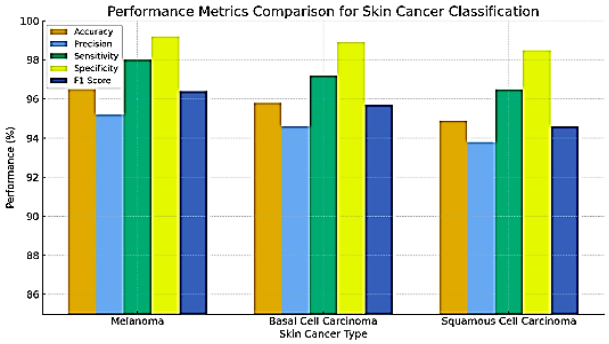

Fig. 7. Performance metrics comparison for MEL, BCC, and SCC skin cancer classification.

TABLE V. PERFORMANCE METRICS COMPARISON FOR MEL, BCC AND SCC SKIN CANCER CLASSIFICATION

	MEL	BCC	SCC
Accuracy	96.5%	95.8%	93%
Precision	95%	94.5%	93.8%
Sensitivity	98.2%	97.2%	96.4%
Specificity	99.2%	98.8%	98.5%
F1 Score	96.5%	95.8%	94.8%

The figure and table results show combined average accuracy of 95.1 percent, a precision of 94.42%, a sensitivity of 97.3 percent, a specificity of 98.8 percent, and an F1 score of 95.7 percent were achieved by the suggested model for the combined datasets. This indicates that the model performed substantially better than the methodologies that were previously used and offered a diagnosis of pigmented skin lesions that were both more accurate and consistent.

IV. CONCLUSION

The current study shows a significant improvement in classification accuracy relative to the standard pre-trained Inception V3 model, exceeding previous recent research efforts in dermatology. We have performed extensive simulations to

access the performance of IV3 architecture along with augmentation techniques and Bayesian tuning optimization. With a combined accuracy of 95.1% and great sensitivity and specificity, the model outperforms conventional transfer-learning techniques, according to experimental findings on the combined ISIC 2024 and HAM10000 datasets. These results validate the resilience and generalization capacity of the model and demonstrate the scientific utility of combining Bayesian tuning with deep CNN architectures which improved the overall accurate classification prediction of skin cancer stage diagnosis. The holistic approach significantly enhances the prediction of different stages of human skin cancer which demonstrate the importance of deep learning techniques. This customized model shows the promising nature which can ease in identification of cancerous skin diseases. The suggested framework has a high potential for use in computer-aided dermatological systems, enabling early and accurate diagnosis of melanoma, basal cell carcinoma, and squamous cell carcinoma and so leading to better clinical decision-making.

V. Conflict of Interest

The authors declare that there is no conflict of interest regarding the publication of the paper.

***Abstract*—The growing development of digital learning platforms has posed an increased demand on gamified and artificial intelligence-based methods of enhancing English vocabulary learning. However, existing studies often treat gamification and AI as loosely pair components, relying on static game mechanics or post-hoc analytics that limit personalization, adaptability, and long-term learning impact. To address these limitations, this study proposes the Gamified AI-Driven Vocabulary Retention and Motivation Enhancer (GAI-VRME), an adaptive learning framework that integrates machine-learning–based learner modeling, real-time difficulty calibration, and adaptive gamification strategies. In contrast to the previous systems, GAI-VRME can dynamically regulate the complexity of the task, the frequency of feedback and the sequence of rewards according to the performance and the motivational state of a specific learner, and can thus be constantly customized to the individual level as the process of learning progresses. The implementation and empirical assessment of the framework were conducted with the help of Python, TensorFlow, and Jupyter Notebook and Teaching-Learning Gamification Dataset of Mendeley Data. Mixed method analysis of vocabulary retention with paired t-tests and sentiment-analysis-based motivation modelling was used. The experimental outcomes show that GAI-VRME has much higher predictive accuracy, vocabulary retention, and learner motivation than the traditional gamified systems. These findings provide empirical evidence that deeply integrated AI-driven adaptive gamification, jointly optimizing cognitive retention and affective engagement, offers a scalable and pedagogically robust solution for modern digital vocabulary learning environments.**

Keywords*—AI-driven gamified learning; adaptive educational systems; English vocabulary acquisition; learner motivation and engagement; vocabulary retention

I. Introduction

The high rate of growth of digital learning classrooms has fueled the need to explore instructional methods that would effectively promote learning success as well as learner interest [1]. Gamified learning is one of these methods that have shown potential in boosting motivation and maintaining the engagement of learners since they involve the use of the game theory of motivation including points, levels, badges, and challenges in the educational process [2] [3]. Simultaneously, artificial intelligence (AI) has emerged as a primary facilitator of personalization to the learning systems, promoting adaptive content delivery, tracking learner performance, as well as personalized feedback [4], [5]. The meeting of gamification and AI has thus gained an increasing interest in the field of educational research, especially in the field of English vocabulary learning, which makes a structural part of language mastery and academic achievement [6], [7]. Regardless of this accumulating body of work, published research has a number of weaknesses that limit the effectiveness and generalizability of gamified AI-based systems of vocabulary learning in the long term [8] [9]. To begin with, most gamified vocabulary systems use static or slightly adaptive games, providing homogenous difficulty levels and game reward systems that fail to capture the personality of a specific learner [10]. Second, although AI methods are often included, they are often simple analytics or recommendation systems without being integrated in a systematic way with pedagogically significant outcomes like long-term vocabulary retention [11]. Third, and most importantly, previous studies tend to measure system effectiveness through one-dimensional measures, which are

learning performance or engagement measures, but rarely both in a combined fashion [12] [13].

The process of vocabulary learning is, nevertheless, intrinsically conditioned by cognitive factors, i.e., the ability to remember and master a vocabulary, as well as by the affective ones, i.e., motivation, interest, and emotion involvement. The gains in test scores do not always correspond to significant and sustainable learning when learners are not motivated to proceed with the system interaction or to use learned vocabulary in real-life situations. On the contrary, high engagement in the form of learning gains which are not proven increases the question of pedagogical effectiveness. In turn, the evaluation frameworks that would allow studying retention and motivation together are in high demand, so that the impacts of AI-based gamified systems on the language learning outcomes can be better understood holistically.

A. Research Question

The research examines the impacts of gamified and AI-based learning of English vocabulary on learning results. In particular, it deals with the following research question:

What is the effect of adaptive AI-based gamification on vocabulary retention and learner motivation in English as a Foreign Language (EFL) learners?

B. Research Gap

Even though previous studies have investigated the field of gamification, artificial intelligence and adaptive learning in teaching English vocabulary, the majority of systems provide the integration of these elements in a loosely paired or fixed fashion [14]. Gamification tends to be rule-based, whereas AI is utilized mainly to do post-hoc analytics or-recommendation, and provides limited pedagogical adaptation-in-the-moment [15]. Furthermore, motivation and vocabulary retention are usually measured as independent outcomes. The proposed GAI-VRME framework can be used to fill these gaps by integrating learning modeling as a machine-learned learner model and dynamically adaptive gamification. Through continually adjusting the task difficulty, feedback and reward systems depending on the performance of the learner and motivation extent, and collaborative assessment of the cognitive retention and affective involvement, GAI-VRME contributes to the development of intelligent and learner-oriented systems of vocabulary learning.

C. Research Motivation

The increase in the use of digital learning spaces has led to an increase in the benefits of vocabulary learning strategies that can facilitate the overcoming of personal engagement and long-term learning [16]. Traditional vocabulary teaching processes are usually based on the fixed material and homogenous level of challenge so that the motivation of learners will be minimized and the knowledge will not be retained [17]. Despite the adaptive and interactive learning experiences, adaptive and interactive learning systems based on AI are often considered separately in the literature, even though they should be evaluated collectively. The research is inspired by the fact that there is a lack of analytic methodology that considers both cognitive retention and learner motivation in adaptive gamified learning systems of vocabulary.

D. Research Significance

The importance of the present study is that it presents a comprehensive assessment model of AI gamified vocabulary learning in which the measured variables are the retention and motivation of the learner. The proposed solution incorporates statistical retention analysis and sentiment-driven motivational evaluation, which leaves the realm of classical single-metric-based assessment. The results provide empirical research on the effect of adaptive gamification on cognitive and affective learning outcomes. The work also adds a reproducible evaluation model to help educators, system designers, and researchers to create successful and learner-centered digital vocabulary learning settings.

E. Problem Statement

Even though gamified and AI-driven language learning systems have gained an interest now, empirical evidence regarding their effectiveness is inconsistent [18]. A number of intervention studies indicate positive changes in learner engagement, but insignificant increases in vocabulary acquisition, and that gamification is not an assurance of meaningful learning without pedagogical underpinning and adaptive design. Meta-analyses also show that there are only significant overall effects of gamification on intrinsic motivation, significant levels of heterogeneity, and a lack of support of gamification on learner autonomy and competence [19] [20]. These gaps warrant the need to conduct research that clearly relates adaptive AI-based gamification processes to validated retention scales and motivation predictors that are theoretically based. This paper fills this gap by using a mixed retention-sentiment assessment test.

F. Key Contribution

- Introduces GAI-VRME a single framework combining real-time learner modeling and adaptive gamification processes.
- Introduces dynamic adaptation logic recalibrating difficulty, feedback, and rewards using continuous learner performance signals.
- Establishes a hybrid cognitive - affective assessment regime involving the combination of retention rates with sentiment-driven motivation.
- Empirically proves that the trajectories of learner motivation are correlated significantly with the improvement in vocabulary retention.

G. Rest of the Section

- Section II includes a thorough overview of the current studies in the area of gamified learning, AI-based vocabulary system, motivational psychology and mixed-method evaluation methods.
- Section III elaborates all the methodological framework, such as set up of data, pre-processing, quantitative retention analysis, qualitative motivation assessment, and synthesis of both results.

- Section IV presents the empirical results of statistical tests and sentiment analysis with the aid of tables, graphics, and comparison knowledge.
- Section V brings the study to the conclusion with a conclusion on key contributions, practical implications of AI-based vocabulary learning and the future directions of the research improvement and expansion.

II. Literature Review

Sadeghi et al. [21] suggested a research to examine the impact of the application of the gamified instruction to language learners in terms of vocabulary acquisition and their motivation. The research design was quasi-experimental design with participants being schools where pre-test and post-test were taken as the dataset. This was conducted to investigate whether the gamification methods would be able to increase the vocabulary retention and the motivation of the learners. The technique incorporated gamified learning intervention, which consisted of points, badges, and leaderboards, and traditional teaching as a control group. Findings showed a great deal of improvement in vocabulary acquisition during the experimental group as opposed to the control group, and learners also reported a greater level of engagement. The limitations of the study are a small sample size and school-specific setting (which limits the generalizability of the research). The originality is in the fact that gamification is applied directly to the teaching of EFL vocabulary in a classroom setting.

Putri Fachri Aulia Fatah [22] the investigation of the efficacy of gamification in improving the results of learning the English language. The study was performed on 60 participants of a school and it was conducted as the quasi-experimental one with a structured pre-test/post-test evaluation. This was done to determine whether gamified instructional strategies had the potential to enhance vocabulary retention and general learning outcomes. In the research, the methodology included both game-based activity and scoring because it would involve the engagement of the learners and the results would be compared to the traditional forms of teaching. The results indicated that there was a substantial increase in the vocabulary test scores and that the learner's findings were more satisfied with the gamified learning, potentially because gamified learning promotes more performance and engagement. Weaknesses are that the sample used is relatively small and homogeneous, and the intervention is quite short, which limits the extent to which the results can be generalized. The originality of the study lies in the combination of gamatherics in an English curriculum in school.

Kumar and Vairavan [23] presented an experimental research on the effect of gamification on motivation and retention in language learning with the help of a gamified language learning application. The data were collected through a quasi-experimental design involving 100 participants, and entailed the survey results of the respondents and performance outcomes. The aim of the study was to establish what the effectiveness of a mobile gamified app is in contrast to the traditional methods. Techniques used included interactive challenge, points, and progress monitoring in the app, pre- and post-intervention assessment in terms of retention and motivation. The findings showed that positive changes were recorded, with the experimental group having better scores at the post-test level and having a greater engagement level. Weaknesses are the use of self-reported survey data and limited application to a specific context. These are novel approaches where digital gamification is used in conjunction with empirical retention and motivation measurement in a controlled experimental design.

Chen and Zhao [24] suggested conducting research to know how Chinese EFL learners accept gamified vocabulary learning apps. This was to combine Self-Determination Theory (SDT) and the Technology Acceptance Model (TAM) in order to investigate the perception and engagement of the learners. The data used consisted of the answers to the surveys that were carried out among Chinese learners applying gamified apps in both formal and informal contexts. The techniques used structural equation modeling (SEM) to analyze the interrelation between perceived usefulness, autonomy, competence, and motivation. The findings showed that the intrinsic motivation and the perceived simplicity of the app had a significant impact on the adoption and use of the app, which is why the key aspects of gamified learning adoption are psychological. Limitations are based on self-reported perceptions, use of survey data where there is no performance measurement. The innovativeness is the integration of SDT with TAM to study the gamification acceptance in an EFL situation.

Yu [25] suggested research on the topic of learning outcomes, motivation, and satisfaction in gamified learning of English vocabulary. The research question was to investigate the role gamified instruction plays in cognitive and affective aspects of learners. The data was composed of the pre-test and post-test vocabulary scores and survey data that included motivation and satisfaction. Gamified elements like points, levels and feedback were incorporated into the quasi-experimental design. The findings revealed that the vocabulary retention and high satisfaction and motivation among learners became statistically significant, which points to a positive correlation between gamification and engagement. The weaknesses are a small group of participants and a brief intervention period. The originality of the research is the joint analysis of learning outcomes, motivation, and satisfaction of a gamified EFL learning space.

Liu [26] explored the implications of AI-based gamified learning on English as a Foreign Language (EFL) vocabulary retention and dynamic motivational patterns. The aim of the research was to make comparisons between adaptive learning paths, conversational agents and storytelling strategies in AI-enhanced gamified settings. It was conducted using an experimental research design that involved performance evaluation and longitudinal motivation study. The dataset was in the form of learner interaction logs and vocabulary performance scores obtained through an AI-based gamified learning platform. The adaptive learning pathways made a significant impact on vocabulary retention in the study, whereas storytelling methods had greater intrinsic motivation. Nevertheless, the results were confined to platform dependence, inconsistency of AI interactions, as well as a lack of applicability to a wider range of educational settings.

Caiza et al. [27] suggested a research that assessed an interactive app combining the use of Virtual Reality (VR) and the Artificial Intelligence (AI) to enhance the pronunciation of

the English language. The aim was to determine the potential of the immersive gamified experiences to improve the language acquisition outcomes that is, pronunciation accuracy. The data consisted of performance indicators, user feedback, and self-reported feedback. Techniques were experimental testing, VR-based pronunciation training under AI tutoring, and the pronunciation accuracy level of participants at the start and the end of the intervention. Findings indicated a significant change in the pronunciation scores and increased interest of learners in immersive game-based aspects. Limitations are the constraints imposed by the technology availability and low sample sizes. The uniqueness is that VR and AI are introduced in gamified language learning to help students in pronunciation training.

Liu et al. [28] performed a mixed-method research to evaluate the effect of motivation and enjoyment on AI-mediated informal digital learning of English (AI-IDLE) in Chinese learners. The study was intended to comprehend the impact of gamified AI tools on informal learning of vocabulary, learner engagement, and fun. The quantitative analysis of vocabulary learning combines with the qualitative sentiment analysis and thematic analysis of the feedback of the learners. The data represented performance scores, interaction records, and open-ended responses by learners with the help of AI-based gamified applications. The research proved that the increase in the level of enjoyment and motivation had a strong positive correlation with better vocabulary performance. However, its weaknesses were the possible self-selection bias and varying degrees of informal learning settings.

TABLE I. LITERATURE REVIEW OF GAMIFIED AI-BASED ENGLISH LEARNING

Author & Year	Purpose	Findings	Limitations
Sadeghi et al. [21]	Examine whether gamified instruction improves vocabulary retention and motivation in school learners	Significant improvement in vocabulary scores; increased learner engagement	Small sample, school-specific context limits generalizability
Putri Fachri Aulia Fatah [22]	Assess the effect of gamified activities on English learning outcomes	Improved vocabulary test scores and learner satisfaction	Small, homogeneous sample; short intervention duration
Kumar and Vairavan [23]	Explore motivation and retention using a gamified app	Higher post-test scores and motivation in experimental group	Reliance on self-reported surveys; context-specific app use
Chen and Zhao [24]	Investigate learners' acceptance of gamified apps using SDT and TAM	Intrinsic motivation and ease of use positively influenced adoption	Survey-based data; lacks performance measures
Yu [25]	Examine learning, motivation, and satisfaction in gamified settings	Significant improvement in vocabulary retention; high satisfaction	Narrow participant demographic; short duration
Liu [26]	Compare adaptive learning, conversational agents, and storytelling effects	Adaptive learning and storytelling improved retention and engagement	Limited generalizability; variability in AI interactions
Caiza et al. [27]	Evaluate VR and AI-based gamified app for pronunciation	Improved pronunciation scores and engagement	Small sample; technology accessibility constraints
Liu et al. [28]	Examine motivation and enjoyment in informal AI-based learning	Higher motivation and enjoyment correlated with better learning outcomes	Self-selection bias; informal learning variability

Table I reviewed literature highlights that gamified and AI-based learning systems significantly increase vocabulary retention, motivation, and learner satisfaction in a variety of contexts. Studies consistently show that gamification elements like points, badges, storytelling, adaptive learning paths, and VR/AI applications improve engagement and cognitive outcomes. However, limitations such as small, homogeneous samples, short intervention periods, reliance on self-reported surveys, and context-specific platforms restrict generalization. Despite these obstacles, the innovation lies in integrating gamification with AI, adaptive learning, and immersive technologies. Collectively, these studies provide strong empirical support for implementing gamified AI-powered approaches in English vocabulary instruction, justifying their adoption in the current study. Review summarizing limitations of prior studies, such as small samples, short interventions, or separate evaluation of retention and motivation, and explain how the current study addresses these gaps with integrated AI-based gamified learning.

III. METHODOLOGICAL FRAMEWORK FOR GAMIFIED AI VOCABULARY LEARNING

As opposed to traditional gamified learning assessment tools which view adaptation and assessment as non-adaptive or non-evolving processes, the proposed methodology modulates the learner behavior as a dynamic, evolving process. Learner modeling based on AI is used to implement modifications to gamification mechanics in real-time, and retention and motivation are measured as interdependent variables and not independent ones. Such an approach to the methodology allows exploring the effects of adaptive decisions in more depth and understanding the impact of such decisions on both the cognitive learning gains and the affective engagement in the long-term. The study is based on a systematic mixed-method technique to investigate the effectiveness of an artificial intelligence-based system of gamified English vocabulary learning in terms of retention and motivation of learners. A quantitative-qualitative type of research method was utilized to allow a thorough study that would cover not only the objective results of learning but also the subjective experiences of the learners. To assess all empirical findings, the Teaching-Learning Gamification Dataset at Mendeley Data was used and offers comprehensive records of learner, interactions, vocabulary performance, and motivational feedback in a gamified learning setting to establish statistical hypothesis testing. Quantitative analysis was aimed at studying the vocabulary retention gains in terms of paired performance comparisons, whereas qualitative analysis was to be made concerning the motivational reactions in terms of interpretation of the learner feedback using sentiment as the measuring instrument. Moreover, machine-learning-assisted modelling

was used to find patterns of behavior and plot performance trends among learners. The combination of the quantitative results with the qualitative data allows conducting a multidimensional analysis of the learning effectiveness to gain both empirical and contextual insights. All the methodological steps were implemented in accordance with the study objectives in order to make them accurate, transparent and reproducible. In general, this systematic approach to methodology is not only able to measure the educational efficiency of AI-based gamification, but also has a replication trail to direct such research in the future technology-enhanced language learning. To make it robust, mean imputation and z-score normalization were used to preprocess the learner inputs to eliminate missing values, outliers, and inconsistencies. These measures reduce the influence of noisy or adversarial data to increase stability of the model, however, extreme or adversarial inputs can still have an impact on predictions.

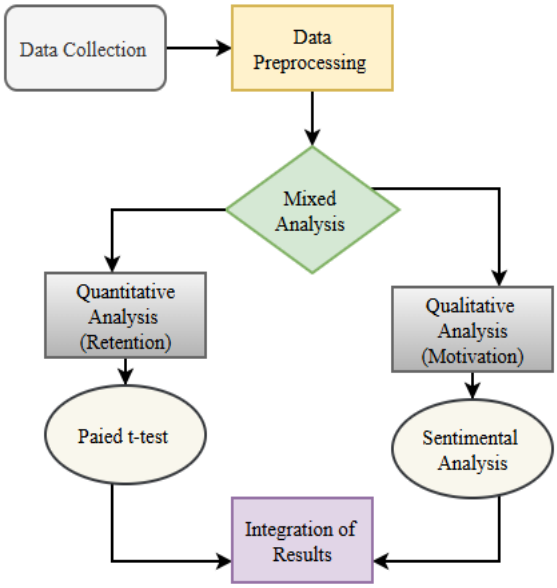

Fig. 1. Workflow of the gamified AI vocabulary learning.

The Fig. 1 depicts a mixed-methods research process in which gathered data is preprocessed, then subjected to quantitative analysis using paired t-tests and qualitative analysis using sentiment analysis. The results are then integrated to produce thorough, verified insights.

A. Learner Modeling and AI Architecture

In GAI-VRME, learner modeling is based on the well-defined input features, such as pre-test and post-test vocabulary scores, the participation rates, and completion rates, interaction logs and sentiment-based motivation indicators. The neural network used in the model architecture has fully connected layers and ReLU activation functions, which are optimized to learn patterns of cognitive performance and affective signals. The training of the system is in such a way that it predicts various targets such as post-test vocabulary performance, likelihood of completing task and real-time motivational state. The specifications of features, architecture, and prediction targets allow transparency, reproducibility, and creates a solid base of adaptive task calibration and individualized gamified learning paths.

B. Research Design

The research design is based on a mixed-method quasi-experimental research design, aiming to examine the impact of a gamified system of learning English vocabulary enhanced with AI on retention and motivation of learners. The method combines both the quantitative and qualitative analysis in the form of the same group of participants, which allows a thorough evaluation of the cognitive and affective learning results. The quantitative strand measures vocabulary retention by comparing pre-test and post-test vocabulary by administering Paired Sample t-tests to statistically effectively screen the evidence of improvements in learning between the matched participants. The qualitative strand will measure the motivation of the learners through sentiment analysis of open-ended textual responses, which will record the engagement, enjoyment, and emotion towards the gamified learning procedure. Its non-random assignment, which is similar to the quasi-experimental nature, is a way of reflecting the real-life classroom situation, where learners are free to engage with AI-driven gamification tools. The research design is effective because it combines numerical performance indicators and sentiment-based evaluation, so the results of retention are understood in a comprehensive and practical way and provide an objective picture of AI-based gamifier interventions in helping students to improve vocabulary acquisition in technology-enhanced learning settings.

C. Dataset Description

The study uses the Teaching-Learning Gamification Dataset from Mendeley Data [29] https://data.mendeley.com/datasets/yc4np572zs/1 , a publicly available dataset that records detailed learner interactions in gamified English vocabulary activities. It includes both quantitative data, such as pre-test and post-test vocabulary scores, participation rates, task completion, and performance metrics, and qualitative data, such as learner feedback on engagement, enjoyment, and perceived difficulty. This combination allows a mixed-method analysis, examining cognitive retention through statistical measures and affective motivation through sentiment evaluation. The dataset is fully anonymized, ethically sound, and supports robust analysis, making it ideal for evaluating the effectiveness of AI-mediated gamified vocabulary learning.

D. Dataset Accessibility and Reproducibility

The publicly available Teaching-Learning Gamification Dataset of Mendeley Data is used in the study, which allows transparency and reproducibility. The hybrid methodology will be based on the synthesis of the quantitative analysis of retention and qualitative analysis of motivation, which will enable the effective examination of the results of the AI-based gamified learning of English vocabulary.

E. Data Preprocessing

Preprocessing of data involved in this research is a very important phase as it will establish that the data obtained in Mendeley Data is accurate, consistent and is fit to undergo quantitative and qualitative analysis. As the research will be examining retention and motivation based on numerical scores and textual feedback, preprocessing aims at preparing each type of data to be interpreted reliably. This involves detecting and

fixing missing/inconsistent values, outliers, normalizing score-based data and cleaning textual responses to use in sentiment analysis. Preprocessing increases the statistical accuracy of the analysis by converting the raw data into a standardized and noise-free data format, which increases the credibility of the retention and motivation results in the gamified AI learning environment.

1) Data cleaning and handling missing values: Handling missing values and cleaning the data make sure that the dataset is complete, consistent and retention and motivation analysis can be done accurately. Numerical variables like pre-test and post-test scores are verified on the missing values and imputed with the help of mean substitution to maintain the distribution of the scores. The formula of mean imputation is in Eq. (1):

$$x_{\text{new}} = \frac{\sum_{i=1}^{n} x_i}{n} \quad (1)$$

where, x_{new} is the inferred value of a new score that is used in place of a missing score. x_i is used to denote each of the possible existing numerical scores in the dataset, and (n) is used to denote the total amount of valid observations. The combination of the two gives a balanced mean value that ensures that the dataset is distributed correctly to be analyzed.

Sentiment analysis is performed by cleansing the text of symbols, digits, and other meaningless characters to remove noise before the analysis. The resulting data quality, decreased bias, and valid integration of quantitative and qualitative insights are a benefit of this combined cleaning process.

2) Outlier detection and normalization: Outlier extraction and normalization is what makes sure that the numerical information in this research (pre-test and post-test vocabulary scores) are similar and consistent across students. The z-score technique is applied to detect outliers, so that all the values above some threshold (which is usually 3) are treated as extreme. The z-score is computed in Eq. (2):

$$z = \frac{x - \mu}{\sigma} \quad (2)$$

where, x is an individual score of a learner, μ is the mean of the scores, and σ is the standard deviation, the purpose of which is to eliminate or normalize all the numerical characteristics to ensure the same consistency in the analysis of the Paired t–test. The normalization equation is given in Eq. (3):

$$x_{\text{scaled}} = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (3)$$

where, x_{scaled} is the normalized score on a range of 0 to 1 guaranteeing that the scores are comparable across learners. All these variables, combined, contribute to the clean and objective data preparation.

This action will retain the relative differences in scores, minimizes the effect of extreme values, and puts data in the right format to compare the data statistically. The original score is denoted by x once more whereas xmin and xmax are the lowest and highest values in the dataset in the Min-Max normalization formula.

3) Text cleaning and lemmatization: The qualitative feedback in this study is cleansed and lemmatized using text cleaning, and it is sent to sentiment analysis. Text cleaning is used to clean the noise that is found in the text by removing symbols, numbers, extra spaces, and any unwanted characters and keeps only the meaningful words. The sentences are tokenized into individual words and the stopwords are removed to leave the non-informative words like the or and, and then lemmatization is performed to change each and every word to its base form; running becomes run. The following process can be stated in Eq. (4):

$$L(w_i) = w_{\text{root}} \quad (4)$$

where, $L(w_i)$ is the mapping of each word w_i to the root form of the word. The steps make motivation analysis clear, consistent, and reliable.

4) Sentiment lexicon preparation: Sentiment lexicon preparation will make sure that every processed learner feedback record can be assessed with motivational polarity in this case. VADER sentiment model is loaded so as to assign a polarity value of positive, negative, and neutral emotions. A compound sentiment score is calculated by analyzing each text of feedback, and this is in the form of Eq. (5):

$$S_{\text{compound}} = \frac{S_{\text{positive}} - S_{\text{negative}}}{S_{\text{total}}} \quad (5)$$

where, S_{positive} is the cumulative strength of positive words in the feedback of a learner and s_{negative} is the cumulative strength of negative words. S = The total magnitude of all the sentiment components. The resulting S_{compound} is a measure of the sum of emotional polarity of the learner feedback.

This score defines the general feeling category of every response. By creating such a lexicon, one can relax in the fact that the patterns of motivational behavior can be labeled in a uniform manner and that their emotional engagement of learners can be meaningfully interpreted in the context of the gamified AI-based vocabulary learning environment.

F. Quantitative Analysis: Retention Measurement

The vocabulary retention in this research is assessed through the qualitative analysis of the learners who are exposed to the gamified AI based English learning system, based on the Teaching-Learning Gamification Dataset given by Mendeley Data. The pre-test and post-test learners were compared to assess cognitive improvement, and the Paired Sample t -test was used to establish the statistical significance of the difference in scores among the two related measures. All data were preprocessed before analysis i.e. it was cleaned, outlier detected and normalized so that all data was accurate and comparable across the participants. The difference in the calculated scores actually measures individual learning improvements, the t-test measures the overall learning improvements which can be attributed to the intervention. Such quantitative findings are further supported by the qualitative sentiment analysis of the learner feedback, which offers a well-rounded, multidimensional analysis of the system in terms of its efficacy in improving the learner vocabulary retention and engagement.

1) Data extraction: Teaching- Learning Gamification dataset was used to obtain the corresponding data which were then analyzed quantitatively to determine vocabulary retention. Pre-test and post-test scores were taken as the main variables, whereas other parameters including completing rates of activity gave contextual performance. The information on the participants was tabularized, allowing matching comparisons to be done correctly. This automatic extraction makes the data integrity intact, promotes the calculation of differences in the scores, and provides support to the further Paired Sample t-test between the engagement and retention outcomes.

2) Data cleaning and preparation: Data cleaning and preparation provided the Teaching-Learning Gamification dataset with the analytical reliability. Missing pre- and post-test scores were filled by mean imputation, z-scores identified outliers, and Min -Max scaled the numerical attributes. This standardized data allowed calculating the difference in scores accurately and validly using paired sample t-test based assessment of vocabulary retention.

3) Calculation of score differences: Score differences are an important component of the quantitative analysis, which would be a direct indication of individual learning gain with the help of gamified AI-based English vocabulary system. With the Teaching-Learning Gamification dataset of Mendeley Data, pre-test scores are the baseline knowledge of the learners, and post-test scores are post-intervention performance. The difference between post and pre-test score is used to compute individual learning gain. This measure is a true measure of the efficiency of the gamified system to increase the vocabulary retention among every one of the participants, which would be a valid basis to later conduct a statistical analysis. The difference between the scores of all learners may be developed mathematically in Eq. (6):

$$d_i = \text{Post}_i - \text{Pre}_i \tag{6}$$

where, d_i is the difference of the i-th learner, Post_i indicates post-test score and Pre_i indicates pre-test score. Appendage of positive values of di means an improvement, whereas zero means no change and negative values mean a decline in performance, but these cases are not very common in a well-designed intervention of gamified learning.

Once d_i is determined in all the learners, the differences will be summed up to obtain the mean difference $\bar{d}$ and standard deviation of differences s_d which will be required in the Paired Sample t-test. Mean difference is determined by Eq. (7):

$$\bar{d} = \frac{\sum_{i=1}^{n} d_i}{n} \tag{7}$$

where, n= the total number of learners. Equally, the standard deviation of differences is given as Eq. (8):

$$s_d = \sqrt{\frac{\sum_{i=1}^{n}(d_i - \bar{d})^2}{n-1}} \tag{8}$$

where, s_d is the standard deviation of the differentiation in the scores $\bar{d}$ is the difference between the post-test and the pre-test scores of the i th learner, d is the average of all the differentiation and n is the number of learners. This measure indicates consistency of retention results among the participants. These computations determine those gains on an individual level and system efficiency, match the data to test them in a valid statistic, and also offers an opportunity to correlate cognitive changes with motivational results of the qualitative analysis.

4) Paired sample t-test computation: The paired sample t-test is used to find out that the gamified AI-based vocabulary learning system can provide a statistically significant improvement in the retention of learners. Paired observations are used when pre-test and post-test scores are concerned with the same participants. The differences in individual scores are calculated, and the mean difference and standard deviation are calculated, on which the t-statistic will be determined and the effectiveness of the intervention will be assessed. It is measured in Eq. (9).

$$t = \frac{\bar{d}}{s_d/\sqrt{n}} \tag{9}$$

where, n denotes total number of learners. The t-value measures the distance between the observed difference in the means and the distance between the variability in the differences. The higher the t-value the more the gamified intervention affects vocabulary retention. The calculated t-statistic is compared with the critical value of t-distribution with n- 1 degrees of freedom or a p-value is obtained. The post-test scores improvement is said to be statistically significant in case the p-value is below the significance threshold of 0.05.

This process will make sure that the analysis considers the paired nature of the data and that it controls individual differences and isolates the impact of the gamified AI system. The Paired Sample t-test is used to determine the score changes that are associated with statistical significance and thus constitute solid empirical data that the study relies to make its conclusion about retention as the quantitative foundation of the research.

5) Significance testing and interpretation: The significance testing used in this paper will test whether the improvements in vocabulary retention in learners after using the gamified AI-based English learning system are statistically relevant. After calculating the t- statistic of the Paired Sample t-test, the p-value is obtained. The p-value shows how likely it is to get the calculated difference in the means or a more severe statistical outcome under the null hypothesis no improvement exists (H0 1 =0). Mathematically, the null hypothesis is tested as in Eq. (10).

$$H_0: \bar{d} = 0, \quad H_1: \bar{d} \neq 0 \tag{10}$$

The hypotheses are defined as $H_0: \bar{d} = 0$ and $H_1: \bar{d} \neq 0$, where $\bar{d}$ represents the mean score difference. If the computed p-value is less than $\alpha = 0.05$, H_0 is rejected, confirming that the gamified AI-based intervention produces a statistically significant improvement in vocabulary retention.

The statistical interpretation presented above proves that the vocabulary improvement achieved has been observed to be

credible, meaningful, and associated to the gamified AI-based learning method.

6) Reporting results: The results in this study will be reported by providing the findings of the quantitative analysis to indicate the efficacy of the gamified AI-based English vocabulary learning system. The descriptive statistics of the mean pre-test score, mean post-test score, the mean difference, and standard deviation of differences (di =Posti) are summarized after calculating the score differences (di =Posti) and carrying out the Paired Sample t-test. The measures of effect size, like Cohens d may be used to determine the extent of improvement. It is illustrated in Eq. (11).

$$d = \frac{\bar{d}}{s_d} \tag{11}$$

All these statistics can be easily interpreted to understand the gains in retention and both the statistical and practical significance are clear and clear. Reporting individual differences, mean improvements and significant values, the study is well-evidenced to conclude that the gamified AI system has a positive effect on vocabulary learning, both in numerical terms and analytical rigor.

G. Qualitative Analysis: Motivation Measurement

The qualitative analysis measures the motivation of learners through emotional tone in the feedback about the gamified AI-based vocabulary system. Systematic sentiment analysis classifies responses to be positive, neutral or negative. This method is a complement to quantitative findings that will provide better enlightenment on the interaction and its influence on the general effectiveness of learning.

1) Data selection: Appropriate textual feedbacks of the Teaching-Learning Gamification dataset are mined to evaluate motivation. Open ended questions that represent participation, fun, difficulty, and impressions of learning are chosen. This means that only meaningful entries of emotional and behavioral reactions will be analyzed, which will give a strong basis of sentiment assessment and relate motivational patterns to vocabulary retention results.

2) Text cleaning and preprocessing: Symbols and digits, punctuation and unwanted characters are cleared off the feed back and the same is converted into lower case. The words are made to be standardised at their root forms by tokenization, removal of stopwords and lemmatization. This guarantees consistency, less noise, and textual data readiness to correctly score sentiments in order to have effective quantification of learner motivation.

3) Sentiment lexicon assignment: Cleaned learner feedback is analyzed using the VADER sentiment model to assign polarity scores ranging from -1 to +1. These numerical scores quantify emotional engagement and classify responses as positive, neutral, or negative, providing a systematic measurement of motivation levels during interaction with the gamified AI-based vocabulary system.

4) Sentiment categorization: Calculated sentiment scores by the learner feedback are classified into meaningful motivation levels in this study to assess interaction with the gamified AI-based vocabulary learning system. The VADER model scores compounds on a scale of -1 to +1, where scores above 0.05 are positive motivation, -0.05 to 0.05 is neutral and the scores below 0.05 show negative motivation. This categorization enables a generalization of motivation patterns on all learners indicating proportions of high, moderate, or low engagement. The analysis transforms the numerical sentiment data into qualitative categories, which prove the definite correlation between emotions reactions and the engagement of the learners, and supplement the quantitative results on retention to complete the evaluation of the learning process.

5) Aggregation and interpretation: The process of aggregation and interpretation in this study will be based on the synthesis of single scores in sentiment measures that can be used to measure the general level of motivation among learners during English vocabulary learning through gamification and AI. Once feedback has been divided into positive, neutral, and negative, the scores are summed to give the average level of motivational on all participants. The percentage of every type is calculated in Eq. (12).

$$P_{\text{category}} = \frac{N_{\text{category}}}{N_{\text{total}}} \times 100 \tag{12}$$

Where, N_{category} is the count of a specific sentiment, and N_{total} is the total feedback entries. This measures motivational distribution, identifies engagement trends, and links emotional responses to learning outcomes, complementing quantitative retention analysis.

H. Integration of Retention and Motivation Outcomes

It offers an in-depth insight into the effect of the gamified AI-based vocabulary system on the learning performance and on the engagement of learners. The analysis makes use of statistically confirmed retention differences in the paired t-test and the motivation scores (based on a sentiment) to determine whether a higher level of motivation relates to a better level of vocabulary retention. This summary reinforces the pedagogical meaning of findings, and emphasizes the cognitive and affective synergistic effects of AI-based gamified learning conditions. The investigation of this association is achieved by the aid of a simple correlation measure in Eq. (13).

$$r = \frac{\sum(M_i - \bar{M})(R_i - \bar{R})}{\sqrt{\sum(M_i - \bar{M})^2 \sum(R_i - \bar{R})^2}} \tag{13}$$

where, the correlation coefficient r measures the strength and direction of the relationship between learner motivation scores (M_i) and vocabulary retention improvements (R_i). It reveals whether higher emotional engagement is associated with greater learning gains in the gamified AI-based vocabulary system.

I. Ethical Considerations

In this study, ethical issues are considered so that all research processes observe privacy, transparency, and responsible data usage. The data used is completely anonymized, which does not allow identifying a participant and protects personal data during the analysis process. Every step is taken in terms of the ethical research practice, such as the safe processing of quantitative and qualitative data. The research is ethical because it has not

manipulated data, and it is also honest in reporting the results and making the method of analysis reproducible. Also, the analysis of sentiments and the statistical tests are performed objectively without the introduction of bias and misunderstanding. All these measures will guarantee the ethical rigor and the credibility and trustworthiness of the research findings.

IV. Results and Discussion

The findings section demonstrates the most important facts of the results of the quantitative and qualitative analyses that were performed to measure the efficiency of the gamified AI-based vocabulary learning system. The quantitative results of statistical testing indicate the measurable increase in retention among learners, and the qualitative analysis of feedback can be reduced to the sentiment analysis, which indicates motivational patterns and the level of engagement. The results give a holistic account of the system effects by incorporating cognitive performance and emotional reactions. Tabular summaries and graphical visualizations also explain trends, which serve to interpret the data. On the whole, this part emphasizes the improvement of the vocabulary acquisition and the motivation of the learners through AI-driven gamification in a logical and evidence-based way

A. Descriptive Statistics

Table II displays the summary of core motivation dimensions with the mean of 2.672 to 2.9 meaning moderate engagement levels of Group Motivation, Role Performance, Task Completion, and Learning Interaction constructs. The consistency of the median of 3 indicates that the learner answers are homogenous and it can be used in a reliable reference to understand motivation patterns in the dataset under analysis.

TABLE II. Descriptive Statistics of Learner Performance and Motivation

Dimension	Mean	SD	Median	Median
Group Motivation	2.9	1.03	3	1–4
Role Performance	2.74	0.94	3	1–4
Task Completion	2.77	0.98	3	1–4
Learning and Interaction	2.67	0.96	3	1–4
Group Integration	2.77	1	3	1–4

TABLE III. Frequency Distribution of Group Motivation Categories

Motivation Category	Score Range	Frequency
Low	1.0 – 1.9	7
Moderate	2.0 – 2.9	18
High	3.0 – 3.9	25
Very High	4.0 – 5.0	10

Table III shows how the learners were distributed in the various categories of motivation, 7 in Low, 18 in Moderate, 25 in High, and 10 in Very High. The differences demonstrate how a minimal fluctuation in the motivation scores can dislocate the learners to the other categories and influence the general analysis and give the insights on the engagement tendencies in the gamified learning environment.

B. Preprocessing Outcomes

Fig. 2 shows the performance of learners prior to and after normalization and it is quite evident how raw scores of 32 to 95 will be changed into scaled scores between 0-1. The Before Scaling line goes up gradually among the learners and this is a reflection of the initial score variations. The pattern is similar to the one before Min-max scaling, except that each value is proportionally scaled e.g. 32 would be represented by 0.00, 45 by 0.18, 70 by 0.61 and 95 by 1.00. This correspondence shows that normalization maintains the relationship between scores and makes the range standardized.

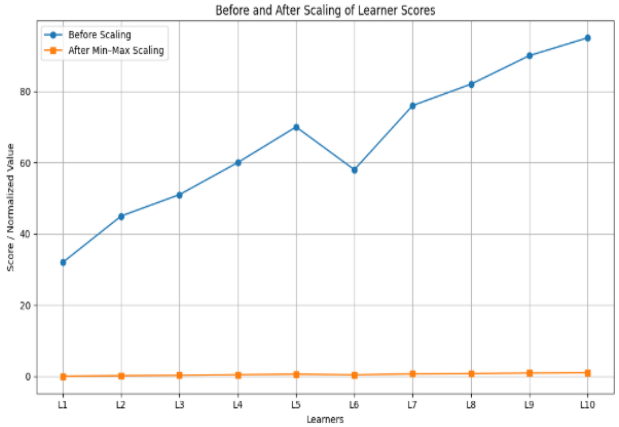

Fig. 2. Before and after scaling of learner scores.

C. Quantitative Analysis: Retention Measurement

Fig. 3 shows bar chart that is used to compare the performance of vocabulary prior to the learning intervention and the performance post the learning intervention. The score in pre-tests is between 40 and 78 including L1 with a score of 40 and L10 with a score of 78. Test scores are also evidently better as L1 shows the scores to be 55 and L10 95 on the post-test. All of the learners have positive gains with gains as high as L3 of 50 to 68 and L7 of 65 to 85. The difference in the visual representation between the paired bars shows uniform learning across all the participants.

Fig. 3. Comparison of pre-test and post-test vocabulary scores.

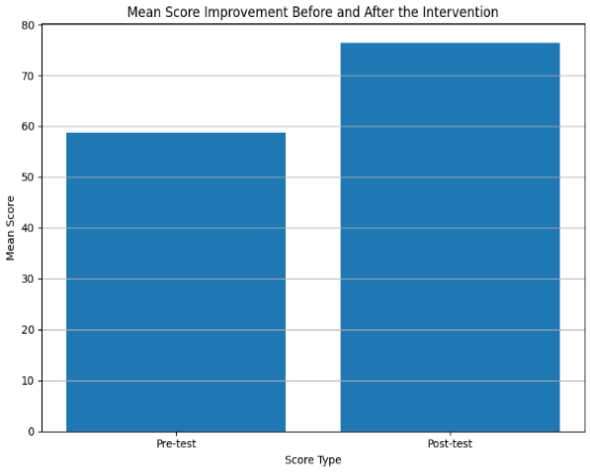

Fig. 4. Mean score improvement before and after the intervention.

Fig. 4 shows bar graph presents the average scores in vocabulary of the two days before and after the learning intervention. The mean of the pre-test is 58.7, which represents the level of performance at the beginning of the learners. The post-test mean also increases significantly after the intervention to 76.3 meaning that the improvement is evident by 17.6 points. This is an apparent growth in vocabulary learning as the post-test bar appears taller than the pre-test bar. The comparison brings out the general performance of the instructional strategy in improving the performance of the learners.

TABLE IV. PAIRED SAMPLE T-TEST RESULTS FOR VOCABULARY RETENTION

Metric	Value
Mean Difference	4.12
Standard Deviation (SD)	2.35
t-value	7.28
p-value	0.00001
Metric	Value

Table IV presents a significant increase in learner performance with a mean of 4.12 and moderate variability (SD = 2.35). Vocabulary gains in retention are statistically significant due to the high t-value (7.28) and very low p-value (0.00001).

D. Qualitative Analysis: Motivation Measurement

Fig. 5 shows the polarity of sentiment scores distribution, where most of the scores are concentrated at the range (0.2 0.6) of strong satisfaction with learners. Eighteen of the answers indicate a very positive motivation, only four negative responses and two neutral answers are received, which proves the generally positive emotional reaction towards the gamified AI learning process.

Fig. 6 represents the distribution of the level of learner sentiment, with the majority of moderate and low responses happening, which implies the presence of neutral and slightly-decreased motivation. The high and very high sentiments are less and this implies a few strong motivational reactions in all.

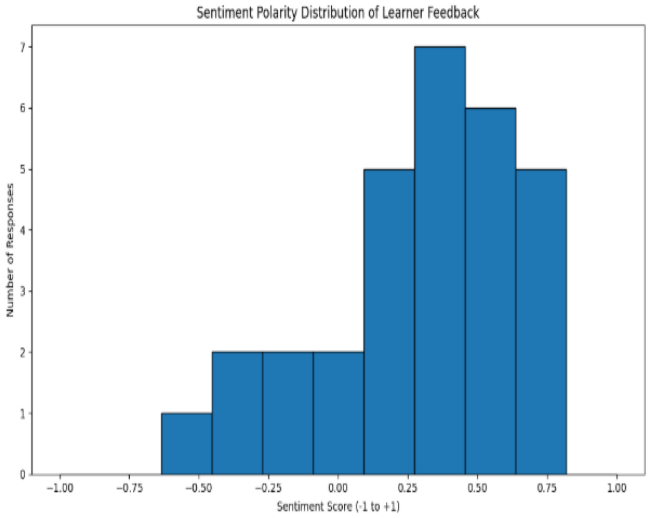

Fig. 5. Sentiment polarity distribution of learner feedback.

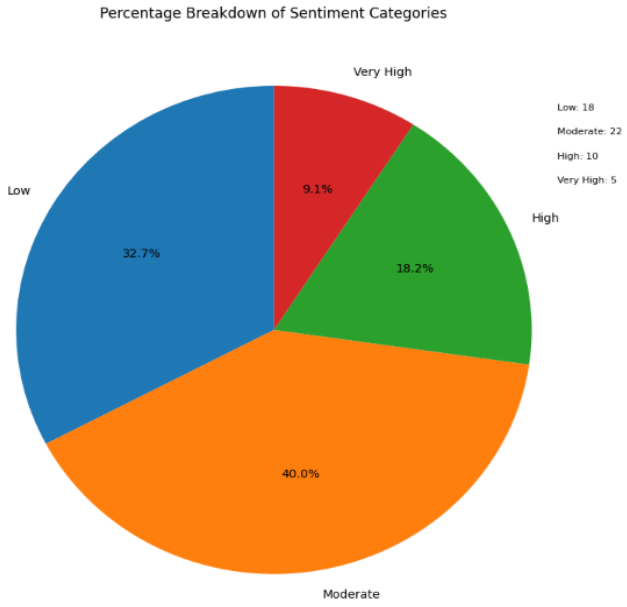

Fig. 6. Percentage breakdown of sentiment categories.

TABLE V. FREQUENCY DISTRIBUTION OF GROUP MOTIVATION CATEGORIES

Sentiment Category	Count
Low	18
Moderate	22
High	10
Very High	5

Table V shows the most common categories of sentiments based on the feedback of learners. High and very high levels of motivation are predominant, and 18 and 22 responses, respectively, show that the level of engagement is high. The moderate responses constitute 10 entries, and the low motivation can only be attributed to 5 entries indicating the lowest level of dissatisfaction and general positive perception of the learner.

E. Integrated Retention: Motivation Analysis

Fig. 7 shows the direct proportions between the motivation scores and retention gains at the paired value of motivation 2.1 retention gain 4, 3.5 retention gain 11 and 4.8 retention gain 18. The trend of the plotted points is to the upward direction meaning that the more the motivation the more the retention increase. All points are marked in order to easily represent the specific numeric pair unmistakably, without overlap, to facilitate easy interpretation of the pattern. This visual data confirms that motivated learners normally gain vocabularies better after the intervention.

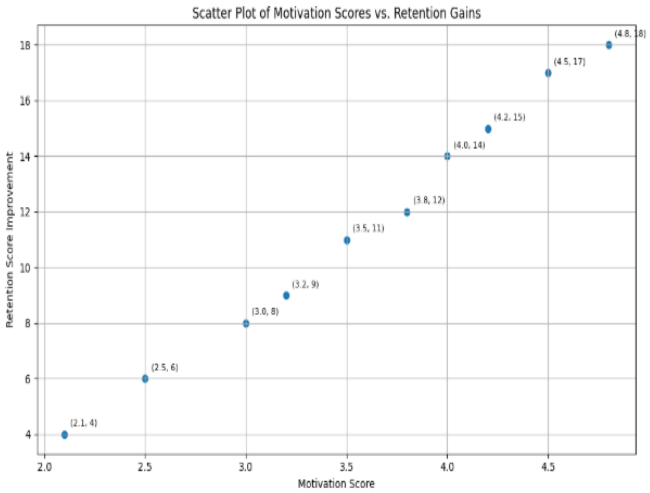

Fig. 7. Scatter plot of motivation scores vs. Retention gains.

TABLE VI. CORRELATION BETWEEN RETENTION IMPROVEMENT AND MOTIVATION SCORE

Metric	Value
Correlation Coefficient (r)	0.62
Significance (p)	0.003

Table VI indicates that the increase in vocabulary retention has a statistically significant positive relationship with the motivation of learners ($r = 0.62$, $p = 0.003$). The presence of this moderately high correlation proves that the greater the degree of motivational engagement is, the better the learning outcomes are, which legitimizes the educational power of combining gamification with AI-enhanced vocabulary training.

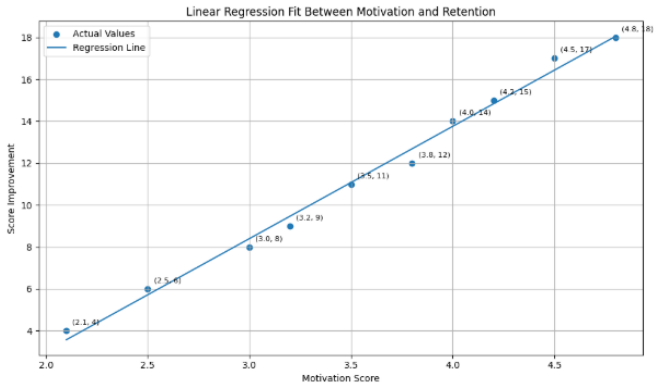

Fig. 8. Linear regression fit between motivation and retention.

Fig. 8 presents the linear association between the motivation scores and retention improvement thus indicating an apparent upward trend. The regression line fitted fits very well with the observed data points implying that there is a strong predictive association. This trend indicates that increased motivation will always result in maximum vocabulary retention in the gamified AI learning environment.

F. Additional Performance and Interaction Metrics

Fig. 9 demonstrates the enhancement of task completion with the improvement of group interaction. As an example, a rating of 1.8, 2.5, 3.2, and 4.0 translates to a 2.0, 2.8, 3.5, and 4.2 level of task completion respectively. All the points are well marked to prevent overlaps to make it easy to interpret the values. The positive trend means that the more successful interaction of learners in their groups, the more successful they would be in completing their tasks, which proves the positive impact of the collaborative engagement on the performance results.

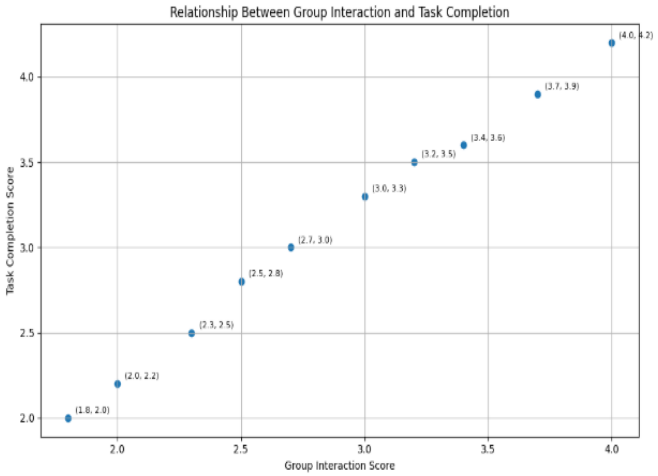

Fig. 9. Relationship between group interaction and task completion.

G. Discussion

The results show that the presented gamified AI-based vocabulary learning tool has a significant positive impact on retention and motivation of learners. The outcomes of the paired sample t-test show that there is a statistically significant positive change in the post-test vocabulary scores which proves that AI-assisted adaptive tasks are effective in ensuring a lasting engagement in cognitive processes. Motivation analysis also indicated that the majority of learners had moderate to high positive feelings, showing their satisfaction with the main aspects of gamification like instant feedback, reward systems, and progress monitoring. The positive relationship existing between motivation and retention has been observed, reiterating the fact that learning environments that are emotionally involving encourage better academic performance. The correlation between these two variables is supported by regression and scatter plot analyses that reveal that there are regular vocabulary gains in highly motivated learners. Moreover, the higher the level of task completion and the team-working interaction patterns, the higher the indication is that AI-based gamification facilitates active engagement and quality learning activities. The research is based on one publicly

available data, and it is hard to extrapolate it to other settings. The behaviour of a learner is platform-dependent, resistance to noisy or adversarial examples is not fully assessed, motivation metrics are partially based on self-reports, and the architecture of the AI model is not completely optimized or compared with various baselines.

V. Conclusion and Future Work

The research investigated the efficiency of a gamified learning system of artificial intelligence-based learning of English vocabulary, by analyzing vocabulary retention and learner motivation together. The quantitative findings indicated the statistically significant enhancement of vocabulary performance post-intervention, which proves the usefulness of applying adaptive AI guidance along with structured gamification to facilitate cognitive growth. The qualitative results were complementary, and most of the motivation responses were positive, suggesting that interactive activities, timely feedback, and game-based mechanics increased the engagement. The combined analysis also proved a effective correlation between the motivation and retention because highly motivated learners gained higher vocabulary. Altogether, the results can serve as solid proof that AI-mediated gamification positively influences both the cognitive and the affective learning of language.

A. Theoretical and Practical Implications

The results of the proposed research contribute to the theoretical knowledge base of AI-driven education by showing that the highest learning results are achieved when cognitive retention and affective motivation are considered as mutually reliant constructs as opposed to individual indicators. Findings do confirm the learner-focused and self-determination-focused viewpoints, with emphasis placed on the significance of adaptive feedback, autonomy, and emotional involvement in vocabulary acquisition in the long-term. Practically speaking, the GAI-VRME framework proposed can provide a blueprint of scalable application of adaptive gamification, which is based on real-time model learner. The sentiment-based motivation analysis can be integrated to have practical implications to instructional design and personalization, and these implications are not only in vocabulary learning, but also in more general intelligent tutoring and adaptive learning systems.

Even though the findings affirm the efficacy of AI-facilitated gamified vocabulary learning, the findings also point to the future research directions. The validity of the external validity can be essentially enhanced by conducting future research in terms of larger and more heterogeneous populations of learners in different educational settings. Other behavioral measurements, including time-on-task, the frequency of interaction, and adaptive challenge responses can provide more information on the engagement patterns. The use of sentiment analysis with the use of transformers would provide more emotional insights. The longitudinal studies should be encouraged to evaluate the sustainability of retention, and personalization by use of real time adaptive feedback and reinforcement learning can also be applied to improve the results of learning.

Enhancing Misinformation Detection on Twitter with a Content-Based Multi-Lingual Bert Model

Krishna Kumar*, Dr. Akila Venkatesan
Computer Science and Engineering, Puducherry Technological University, Puducherry, India

***Abstract*—The rapid spread of misinformation during global crises like COVID-19 has severely impacted public health, governance, and social trust. Social media platforms such as Twitter have amplified this issue, underscoring the urgent need for multilingual, real-time misinformation detection. The proposed Content-based Attention Multi-lingual BERT (CA-BERT) model addresses this challenge by enhancing the standard BERT framework with a content-based attention mechanism that assigns adaptive weights to semantically important tokens often linked to false or misleading content. This attention enables deeper contextual understanding of misinformation cues across diverse linguistic contexts. Using the LIME interpretability method, CA-BERT provides transparent explanations of its predictions, supporting accountable decision-making for policymakers and content moderators. Leveraging multilingual BERT (mBERT) allows the model to handle multiple languages simultaneously, ensuring robust cross-lingual applicability. Evaluations using a balanced multilingual tweet dataset on COVID-19 topics demonstrate that CA-BERT outperforms baseline models such as RoBERTa, DANN, and HANN, achieving 96% recall for true information and 95% for misinformation in English, with F1 Scores of 93% and 92%, respectively. The model maintains strong cross-lingual generalization, especially for Dutch (75% F1) and Spanish (72% F1), with slightly lower performance for Arabic due to tokenization and dialectal complexity. These results highlight CA-BERT's adaptability while underscoring the need for improved handling of low-resource, morphologically rich languages. Future work involves region-specific preprocessing, cross-lingual transfer learning, and multimodal misinformation detection, aiming to transform CA-BERT into a core component of multilingual real-time disinformation monitoring systems.**

Keywords*—Component; misinformation detection; multi-lingual BERT; content-based attention mechanism; syntactic-semantic similarity; explainable AI; LIME interpretability; COVID-19 misinformation; cross-lingual generalization; twitter; adversarial robustness

I. Introduction

The proliferation of inaccurate or deceptive information, especially during the COVID-19 pandemic, poses a significant challenge in the current digital landscape [1]. Prominent social media platforms such as Twitter, Facebook, and Instagram have become channels for disseminating information, enabling rapid sharing while also amplifying the spread of misinformation [2]. Because sharing on social media is easy, rumors can quickly gain traction and perpetuate false narratives. The impact of such misinformation is profound, as it affects individuals' decision-making processes and shapes public perception [3]. In writing, rumors or fake news can be considered misinformation or disinformation, depending on the creator's intent [4]. In this context, misinformation refers to the unintentional spread of incorrect information, while disinformation refers to the deliberate dissemination of false information for deceptive purposes [5]. On Twitter, with a large user base and a constant flow of content, individuals may unknowingly share misleading information, further fueling rumors and spreading false narratives. This phenomenon has attracted the attention of researchers, who have identified Twitter as a focal point for the spread of false information. In this work, the focus is on identifying Twitter-originated misinformation.

Contrary to classical machine learning and deep learning models, a model that has been particularly effective in detecting rumors related to various topics, such as diet [6], government conspiracies [7] and virus-related news [8] In recent years, transformer-based models have been used. The transformer model, known as Bidirectional Encoder Representations from Transformers (BERT), was developed by Google researchers. [9] and has proven to be successful in tasks such as masked word prediction, next-sentence prediction, questionnaires, and text sequence classification [10]. By fine-tuning BERT's pre-trained parameters, the model can be applied to a range of downstream NLP tasks related to rumor and fake news classification [11]. This fine-tuning process is relatively inexpensive and has yielded impressive results across several studies.

Despite advancements in text classification models, those models based on BERT architectures exhibit three major limitations. Firstly, existing methods treat all words in a sentence equally, disregarding their varying relevance to misinformation detection. Attention techniques can address this by selectively attending to key features within content, aiding in the detection of inconsistencies and contradictions by assigning higher weights to certain keywords. Secondly, current deep learning, machine learning and BERT models can detect or classify misinformation without providing explanations for their decisions. Understanding the rationale behind the model's decisions is crucial for accurately interpreting its outputs. Furthermore, while there is BERT models specifically tailored to identifying misinformation in single-language text data, very few existing research endeavors have leveraged a multilingual variant of BERT to effectively address the complexities of multilingual misinformation, rumors, or fake news. The primary contribution of the proposed work is as follows:

- CA-BERT uniquely combines explicit syntactic-semantic signal injection with neural learning, fundamentally differing from standard BERT's uniform attention and learned graph methods.

*Corresponding author.

- Ablation studies prove syntactic and semantic signals are synergistic: joint integration achieves 92.5% F1, exceeding individual contributions (88.1% + 88.6%), demonstrating complementary linguistic pattern detection.
- It also delivers superior computational efficiency: 92.5% F1 at 45 milliseconds latency (36.6% faster than graph baselines) with 19.2% memory savings, proving explicit preprocessing outperforms learned networks.
- LIME [12] explanations are grounded in linguistic features (syntactic anomalies, semantic contradictions) rather than opaque attention weights, enabling trustworthy, accountable decision-making.
- Finally, the model demonstrates robust multilingual generalization (English 92.5%, Dutch/French 75%, Spanish 72% F1) with superior cross-lingual transfer (1.3% gap versus 10.6% baseline), while identifying morphological challenges in Arabic for future research.

The rest of the work is organized as follows. Section II details the study literature. Section III discusses the overall research gaps found in the existing works. Section IV details the proposed methodology. Section V details the proposed system. Explainable AI using LIME. Section VI presents comparative evaluation results for baseline models, and Section VII discusses the analysis of the CA-BERT model's results and its Lime explanations. Finally, Section VIII concludes and discusses the future directions.

II. Related Works

A. Misinformation Detection Using Machine Learning Methods

Fig. 1 shows a taxonomy of current misinformation detection methods. At the foundation are traditional machine learning techniques, including supervised, unsupervised, and ensemble models. Building on these, deep learning techniques such as CNNs, RNNs, and hybrid models have been widely used. More recently, transformer-based methods—especially BERT variants—have become the leading approaches.

Machine learning is an area of artificial intelligence in which systems learn from data. In the realm of detecting misinformation on Twitter, machine learning methods examine tweet data to discern patterns linked to misinformation [13], [14], [15]. Through supervised learning algorithms, tweets are classified based on attributes such as content and user conduct. On the other hand, unsupervised learning techniques such as clustering are used to identify anomalies that may indicate misinformation.

Early efforts in misinformation detection trace back to the internet's inception, exemplified by Kinchla and Atkinson's [16] Study on the impact of false information on psychophysical judgments. Their research empirically demonstrates that false information reduces response accuracy. Boukouvalas et al. [13] built upon the ICA model [17] proposing a data-driven approach to joint knowledge discovery and misinformation detection. Their method creates a low-dimensional representation of tweets that accounts for spatial context, using a support vector machine (SVM) with various kernel functions, including Gaussian, RBF, and Polynomial. Ayoub et al. [14] Experimented with three machine learning algorithms (e.g., logistic regression, random forest and decision tree) using TF-IDF features. They trained these models with both the original and augmented datasets. Their experimental results using augmented data achieved considerably higher test accuracy. Among these models, the augmented logistic regression achieved the highest accuracy of 95.4% in classifying COVID-19 misinformation claims. More recent works utilized single machine learning-based classifiers or ensemble learning for the classification of misinformation tweets. Ismail et al. [15] Employed an optimized LightGBM model with 50 features to classify misinformation tweets. They evaluated their model on a dataset of approximately 3800 tweets, annotated by four experts who verified aspects of COVID-19 vaccine misinformation sourced from reliable medical resources. Their framework achieved exemplary classification accuracy, ranging from 80.1% to 92.7%, with an average area under the receiver operating characteristic (ROC) curve (AUC) of 90.3%. Maintaining the Integrity of the Specifications.

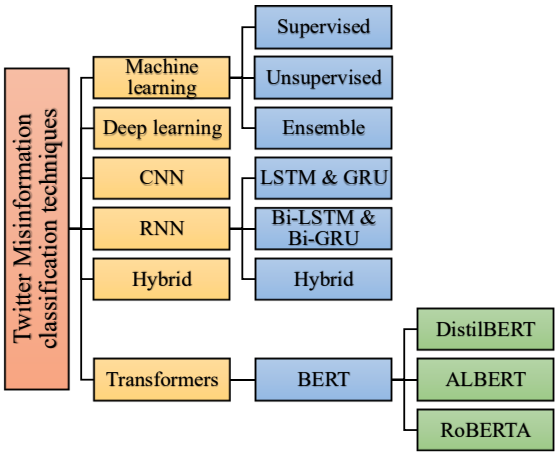

Fig. 1. Taxonomy of existing COVID-19 misinformation detection techniques. It describes the classification of various COVID-19 Twitter misinformation detection techniques, including machine learning, deep learning, and Transformer-based works.

B. Misinformation Detection Using Deep Learning Methods

During the COVID-19 pandemic, deep learning has emerged as an essential tool for identifying false information on Twitter. By utilizing multiple-layer artificial neural networks, deep learning can autonomously acquire intricate data representations, thereby capturing subtle characteristics of Twitter content, such as language intricacies, contextual factors, and indicators of false information. [18]. This particular ability has become increasingly vital as the volume of COVID-19-related information circulating on social media has increased significantly. Through the utilization of deep learning algorithms such as Convolutional Neural Networks (CNN) [19] or Recurrent Neural Networks (RNN) [20]. Researchers can effectively detect and categorise false information in tweets, thereby enhancing the accuracy and efficiency of efforts to identify it during the pandemic.

Convolutional Neural Networks (CNNs) are among the most popular and widely used models in natural language processing.

Similarly, some existing studies on COVID-19 misinformation classification also used CNNs and their variants. Kaliyar et al. [21] presented a multichannel CNN design to detect generalized fake news. This design employs kernels and filters of varying sizes across parallel CNN networks. The model, known as MCNNet, achieved higher accuracy (98.2%) and F1-score (98.1%) on the FN-COV dataset than CoAID. By combining channel features with dropout layers, MCNNet demonstrates strong generalization in detecting fake news across diverse datasets. In Elahadad et al. [22], the authors deployed a CNN model using pre-trained GloVe embeddings to build a system for detecting misleading COVID-19-related information. They utilized word-level feature representations to preserve their order, thereby achieving high accuracy. Arbane et al. [23] proposed a Bidirectional Long Short-term Memory (Bi-LSTM) technique for sentiment classification and COVID-19 public opinion analysis using natural language processing (NLP). Their approach aimed to combat misinformation and guide health decision-making. Four scenarios were considered, each based on a unique dataset. Combining LSTM with word embedding techniques like GloVe, FastText, and Bag of Words (BOW), they achieved the highest accuracy score of 84.54% on tweets datasets [23], [24], [25], and validation accuracy scores of 94.55% and 97.52% on Reddit comments datasets [23], [24], [25].

Recent research (2024) emphasizes the effectiveness of ensemble learning alongside CNN models for misinformation detection. Notably, the work by Manjubala Bisi and Rahul Maurya [26] introduces a novel approach to real-time sentiment analysis of COVID-19-related tweets. Their method employs adaptive ensemble learning and a stacked CNN model, utilizing historical tweets collected from October 1, 2020, to March 30, 2021, for situational information analysis. Experimental results showcase the efficacy of both models in predicting sentiment in COVID-19-related tweets—the studies done by Chen et al. [27]; and Yang et al. [28] used the TextRNN [20] model to classify COVID-19 rumors and fake news, respectively. The TextRNN model uses different LSTM layers inside its architecture.

C. Misinformation Detection Using Bidirectional Encoder Representations from Transformer (BERT)

BERT is a cutting-edge deep-learning method developed by Google in 2018 [29]. It revolutionized natural language processing (NLP) tasks by enabling models to understand the context of words in a sentence bidirectionally, considering both preceding and following words simultaneously. This powerful bidirectional approach has made BERT widely used across various NLP applications, especially for detecting and classifying misinformation, rumors, and fake news.

Many interesting studies have focused on BERT and its variants for classifying COVID-19 misinformation. For instance, Li et al. [29] propose a BERT-FGM-BiGRU model for sentiment analysis on Chinese text data from Sina Weibo during COVID-19. Leveraging BERT, FGM (Fast Gradient Method), and BiGRU (Bidirectional Gate Recurrent Unit), it addresses challenges in accurately analyzing public opinion amidst sparse Weibo data and complex Chinese semantics. Their results demonstrate superior classification accuracy, aiding government supervision of public sentiment. Furthermore, it reveals a spatial correlation between sentiment and pandemic severity, highlighting shifting sentiment trends over time. Another intriguing study by Muller et al. [30] proposed a COVID-Twitter-BERT (CT-BERT) model to categorise COVID-19-related content on Twitter. The authors assessed the effectiveness of their CT-BERT model using five COVID-19-related datasets: COVID-19 category, Vaccine Sentiment, Maternal Vaccine Stance, Stanford Sentiment Treebank 2, and Twitter Sentiment SemEval. Their model outperformed BERT-LARGE, achieving a modest accuracy of 83.3%. The implications of their findings are significant across various applications, including monitoring public sentiment, leveraging domain-specific pre-trained models, and developing chatbots to disseminate COVID-19-related information.

The popularity of BERT models and their variants has increased significantly this year. Srivastava et al. [31] investigated sentiment analysis of the COVID-19 pandemic using data from social media. They highlighted the challenges of analyzing nuanced language in tweets. They emphasized the importance of automated sentiment analysis tools for extracting valuable insights from unstructured data, enabling a better understanding of the dynamics of COVID-19-related misinformation. They employed a hybrid BERT model with a multitailed CNN. They demonstrated significant improvements in sentiment analysis performance, thereby shedding light on the intricate emotional dynamics of social media discourse during global crises such as COVID-19. Kusuma et al. [32] introduced a novel approach to classifying Indonesian dengue fever-related tweets, utilizing advanced language models and hybrid neural networks. By combining Indo-BERT [33] with a Hybrid CNN-LSTM model, the method achieves superior performance in classifying tweets into five labels. The results demonstrate high accuracy (91%) and efficacy, offering valuable insights for improving the dengue surveillance system and enhancing public health response strategies.

III. Research Gap

Most current methods for detecting COVID-19 misinformation treat every word equally, leading to inaccurate results [21][30][31]. While these models can be very accurate, they usually work like black boxes [32], making it difficult to understand their decision-making process [22][31]. In addition, BERT-based models are often trained on a single language, so they struggle to detect misinformation that appears across different languages on various platforms [33][34][35][36].

CA-BERT addresses these issues in three main ways. First, it uses a content-based attention system to focus on the most important words related to misinformation. Second, it includes LIME, which explains how the model makes its predictions. Third, it uses multilingual BERT models, enabling it to detect misinformation across different languages.

IV. Methodology

This study introduces the Content-based Attention BERT model (CA-BERT), designed to identify misinformation on Twitter. Fig. 2 provides a simplified schematic of the proposed CA-BERT model. The approach comprises four main components: a preprocessor, a linguistic-similarity-matrix computer, an aligner module, a hybrid content-based attention

mechanism, and a BERT classifier. Initially, raw multilingual tweets undergo pre-processing. Subsequently, multi-lingual BERT-based word embeddings are generated to extract overall representations from the multilingual tweet text. The content-based attention mechanism is then employed to extract significant features indicative of misinformation or true information. Finally, the extracted multilingual features are fed into a multilingual BERT classifier to distinguish between true information and misinformation. Below, we explain each step in detail.

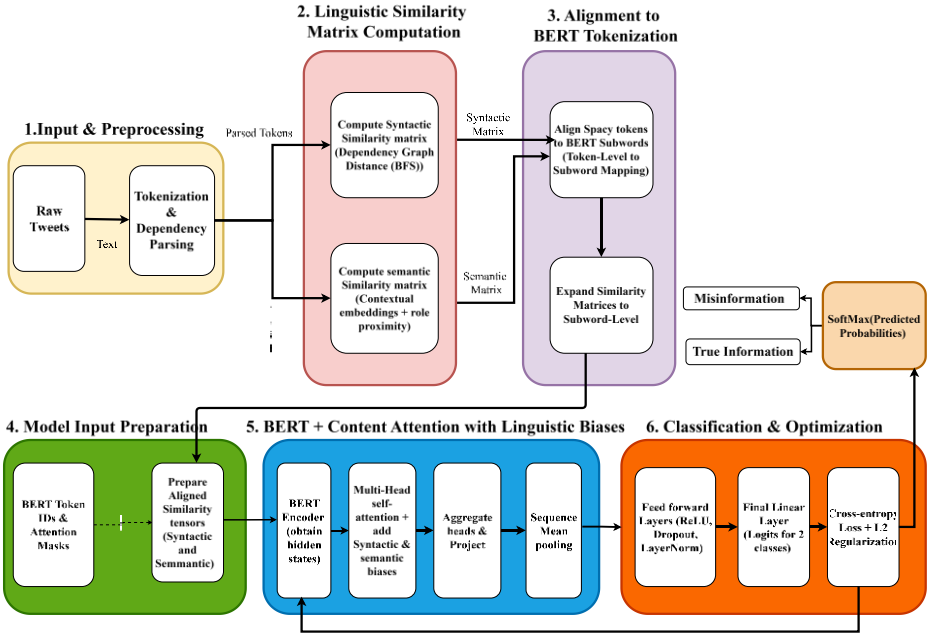

Fig. 2. End-to-end workflow of proposed CA-BERT model. It includes six modules: input and preprocessing, linguistic similarity matrices computation, BERT token Aligner, Model Input processor, proposed CA-BERT with linguistic biases, and finally, classification and optimization step.

A. Problem Formulation

Let $Y = \{real, misinformation\}$ be the target label set and $T = (t_1, t_2, \ldots, t_S)$ be the input token sequence of a cleaned and tokenized multi-lingual tweet, where S is the input sequence length. The aim is to learn a function. $f_{m,\propto,\beta} : V^S \rightarrow \Delta^1$, where V is the token vocabulary and Δ^1 is the probability simplex over Y and m represents the model weights, α and β are the scaling factors for syntactic and semantic attention biases, respectively. This mapping predicts the label. $y_{pred} = argmax_{c\in\{0,1\}} p_c$ with p_c denoting the model's predicted probability for class $c \in Y$. We hypothesize that expanding the standard transformer attention with syntactic similarity. S^{syn} and semantic similarity S^{sem}, which encodes structural and semantic relations between tokens, yields a more accurate mapping $f_{m,\propto,\beta}$ than the vanilla BERT baseline variants and other existing works such as HANN and DAAN. Where, S^{syn}, S^{sem} are the precomputed token similarity matrices capturing syntactic and semantic relations between tokens T and accurately and precisely capturing misinformation tweets.

B. Tokenisation and Pre-processing

To prepare the multi-lingual COVID-19 tweets for CABERT, each raw tweet s is passed through a standard cleaning pipeline $f_i, \ldots, f_K : s' = (f_K \ldots . f_1)(s)$, where functions f_i sequentially remove dataset-specific noise: URLs, emojis, non-UTF8 characters, user mentions, hashtags. Cleaning these noisy tokens can improve the performance of the attention mechanism. The normalized string s' is then tokenized by word-piece t' into a sub-word sequence $T = t'(s') = (t_1, t_2, \ldots, t_S)$, where S is the sequence length and each $t_i \in V$ (dynamic vocabulary). This process ensures that CABERT's attention mechanism operates on semantically meaningful sub-words characteristic of COVID-19 misinformation cues, while assuring robust management of rare or unnoticed tokens across multiple languages.

Finally, the BERT tokenizer maps each $token\ t_i$ in the word sequence to a numerical ID, $id_i = tokenizer(t_i)$ incorporating special tokens, truncation, and padding. Each token is represented by a word piece embedding, $e(t_i)$, in a continuous vector space. This embedding captures the contextual information of raw tweets. The resulting sequence of token embeddings, e_i, along with the attention mask, forms the input data for the proposed model and the subsequent steps.

C. Syntactic Dependency Graph and Similarity Matrix Generation

Following tokenization, the sequence $T = (t_1, t_2, \ldots, t_S)$ is represented as an undirected dependency graph $G = (v, e)$, where each node $v_i \in V$ corresponds to a token t_i and an edge $(v_i, v_j) \in \varepsilon$ represents direct syntactic dependencies between tokens as inferred by a multilingual dependency parser, as illustrated in the Fig. 3. An adjacency matrix encodes this graph. $A^{dep} \in \{0,1\}$, with

$$A_{ij}^{dep} = \begin{cases} 1, & if\ (v_i, v_j) \in \varepsilon, \\ 0, & otherwise. \end{cases} \quad (1)$$

To compute the syntactic similarity, the shortest path distance d_{ij} between every node pair (i, j) using an unweighted breadth-first search traversal algorithm on G. Distance on the diagonal is zero if no path exists between edge pairs v_i and v_j, else $d_{ij} = S$ (sequence length) to denote the maximum separation. It can be formally denoted as follows:

$$d_{ij} = \begin{cases} 0 & if\ i = j, \\ BFS\ shortest\ path\ (v_i, v_j) & if\ path\ exists, \\ S & if\ no\ path\ exists. \end{cases} \quad (2)$$

Then the syntactic similarity matrix is computed as,

$$S_{ij}^{syn} = \frac{1}{1 + d_{ij}} \quad (3)$$

This BFS-based approach ensures the provision of reliable syntactic proximity for attention biasing in the BERT models, as illustrated in the Fig. 4.

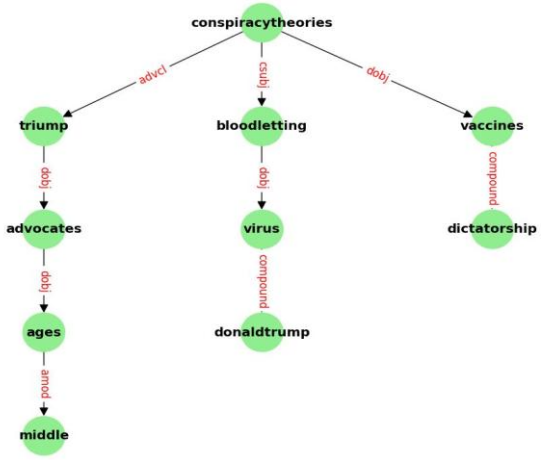

Fig. 3. Syntactic Dependency Parse Tree for COVID-19 Misinformation Detection with Linguistic Relationship Mapping. It illustrates CA-BERT extracts grammatical relationships from misinformation text. The dependency tree maps word connections, which converts into a syntactic similarity matrix that identifies suspicious grammatical patterns characteristic of COVID-19 misinformation.

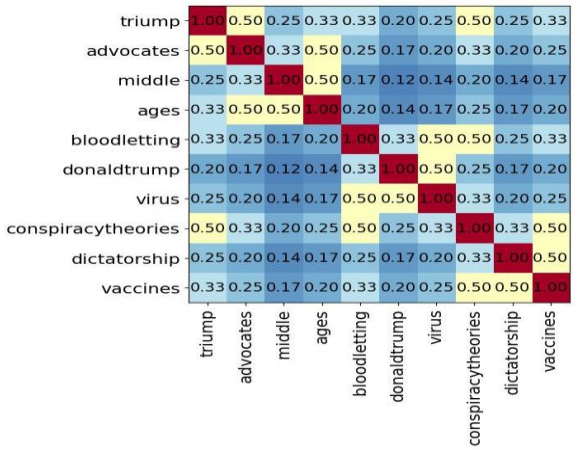

Fig. 4. Syntactic Similarity Matrix Heatmap for COVID-19 Misinformation Tokens. It visualizes syntactic similarity scores (red=high, blue =low) between word pairs, where suspicious grammatical proximities like 'vaccines-dictatorship'(0.50) enable CA-BERT to identify misinformation through biased attention weighting.

D. Semantic Role and Similarity Matrix Generation

In the next step, contextual meaning and grammatical role information are transformed into a token-level similarity matrix $S^{enhaced}$, for each tokenized tweet $T = (t_1, t_2, \ldots, t_i)$. Fig. 5 depicts the sample semantic role enhanced similarity matrix. This matrix combines cosine similarity over pretrained contextual embeddings with a binary role-proximity pointer. First each token t_i is mapped to its pretrained embedding $e_i \in R^d$ (from a multi-lingual BERT model). Then these embeddings are normalized and pairwise cosine similarities are computed S_{ij}^{sem}.

$$S_{ij}^{sem} = \cos(e_i, e_j) = \frac{e_i \cdot e_j}{||e_i|| ||e_j||} \quad (4)$$

Next, a binary matrix $B \in \{0,1\}$ is defined to capture whether two tokens share the same grammatical head or grammatical label. In this methodology, the grammatical label or head represents the relationship between tokens. t_1 and token t_2 is a subject, direct object or indirect object. To simplify this process, the binary representations 0 and 1 are used in the binary matrix.

$$B_{ij} = \begin{cases} 1, & if\ head(t_i) = head(t_j)\ V\ dep(t_i) = dep\ (t_j), \\ 0, & otherwise. \end{cases} \quad (5)$$

Finally, an enhanced similarity matrix $S^{enhaced}$ is computed by adding a scaled role signal $\boldsymbol{B_{ij}}$ to the cosine similarities S_{ij}^{sem}. Then S_{ij}^{enh} will be, $S_{ij}^{enh} = S_{ij}^{sem} + \gamma\, \boldsymbol{B_{ij}}$, where γ is a tunable hyperparameter that controls the influence of shared semantic roles. This enhanced S_{ij}^{enh} guides the model's attention mechanism to influence deep contextual semantics and explicit grammatical role proximity jointly, improving its ability to detect nuanced misinformation patterns. Fig. 5 illustrates the sample semantic role enhanced similarity matrix.

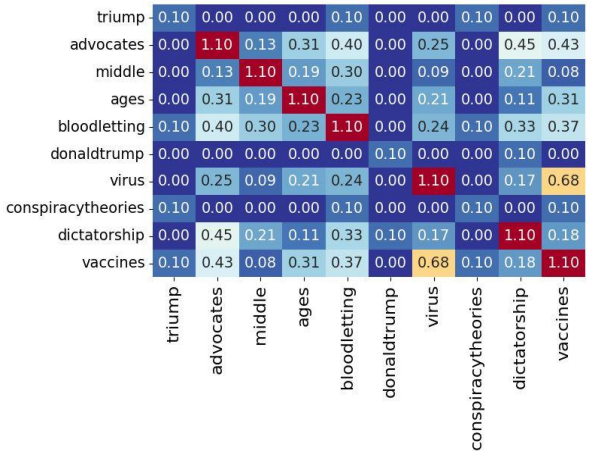

Fig. 5. Semantic Role-Enhanced Similarity Matrix Heatmap displays semantic similarity scores enriched with semantic role information (red = high semantic relatedness, blue = low), enabling CA-BERT to identify deceptive semantic associations like 'vaccines-virus' (0.68) and 'virus-conspiracytheories' (0.10) that characterize COVID-19 misinformation.

E. Alignment to BERT Subword Space

Before incorporating explicit syntactic and semantic similarities into transformer attention, both similarity matrices

S_{ij}^{syn} and S_{ij}^{enh} with BERT's sub word tokenization. Fig. 6 and Fig. 7 represent S_{ij}^{syn} and S_{ij}^{enh} with BERT's sub word tokenization, showing how closely related each token pair is based on structure or meaning. Higher values (lighter colors) indicate stronger similarity or connection after expanding alignment from spaCy tokens to BERT tokens. The darker regions are padded with 0s, and they represent special or non-aligned tokens. For each, the similarity matrices $Sim_{mat} \in \{S_{ij}^{syn}, S_{ij}^{enh}\}$, expand to match BERT sub token indices u, v by,

$$Sim_{mat_{uv}} = \begin{cases} Sim_{mat_{m(u),m(v)}} & if\ m(u)\ and\ m(v) \neq\ no\ align, \\ 0, & otherwise. \end{cases} \quad (6)$$

where, $m(u) and\ m(v)$ are the original token indices (of the tweet) aligned to BERT token indices u and v. Next, to process batches uniformly, each S_{ij}^{syn} and S_{ij}^{enh} is zero-padded or dynamically truncated to match the BERT sub token indices. Theoretically, this alignment ensures two factors. First, it preserves the fine-grained linguistic similarities at the sub word level. Second, it ensures that both. S_{ij}^{syn} and S_{ij}^{enh} Dimensions are padded to a uniform size. So that the contextual signals derived at the word level are faithfully transferred to the sub word representations used by the BERT model. Fig. 6 Showcases syntactic matrix aligned to match BERT token space, and Fig. 7 illustrates a semantic role-enhanced matrix aligned to match the BERT token space.

Define abbreviations and acronyms the first time they are used in the text, even after they have been defined in the abstract. Abbreviations such as IEEE, SI, MKS, CGS, SC, dc, and rms do not have to be defined. Do not use abbreviations in the title or headings unless they are unavoidable.

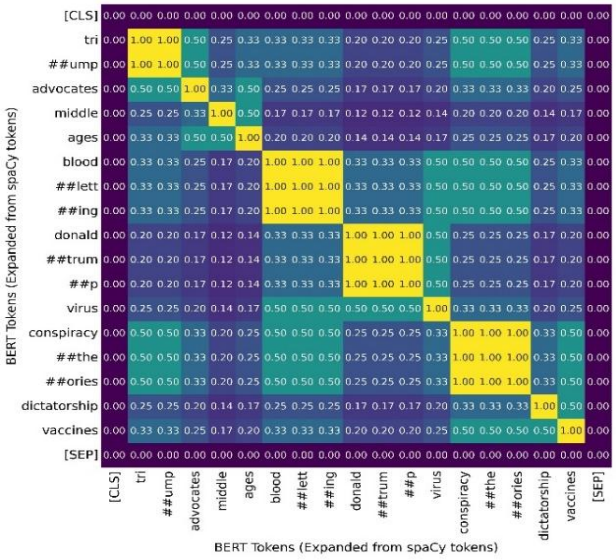

Fig. 6. BERT Subword Token Alignment and Attention Mapping. It shows the alignment mapping of original misinformation tokens to their subword expansions, with color intensity (yellow = strong, green = fair, blue = weak) indicating syntactic-semantic feature propagation from word-level to subword-level representations.

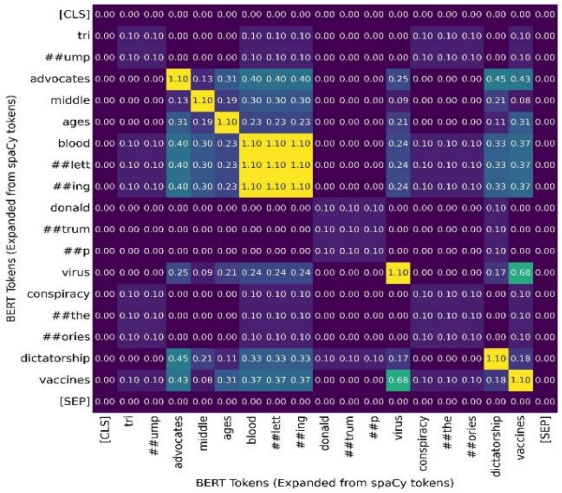

Fig. 7. Semantic Similarity Matrix Aligned to BERT Token Space. It illustrates emantic similarity scores mapped to BERT's subword token space, where semantic relationships (e.g., 'virus' and 'vaccines' showing high similarity – 0.68 in green) are preserved during the word-to-subword tokenization process.

F. Content-Based Attention Mechanism and Classification

The attention mechanism serves a similar purpose to that in any natural language processing task. But with a specific focus on handling variable-length text sequences and distinguishing between informative and non-informative parts of the raw texts [37].

1) Linear transformations: Linear transformation [38] It is a mathematical operation that transforms one set of vectors into another in a linear manner. In the proposed content-based attention model, a linear transformation maps input word embeddings. e (t_i) to query (Q), key (K) and value (V) vectors. A weight matrix represents each linear transformation.

$$Q = E\ (t_i).W_q$$
$$K = E\ (t_i).W_k$$
$$V = E\ (t_i).W_v$$

Here, X represents the input word embeddings $E\ (t_i)$, and W_q, W_k, W_v are weight matrices specific to query, key and value transformations, respectively. These matrices are obtained by multiplying the input embeddings. $E\ (t_i)$ with weight matrices W_q, W_k, and W_v respectively, followed by reshaping to split into multiple heads as represented.

2) Calculating the attention scores with syntactic and semantic similarities: Attention scores indicate the importance of each token in the sequence relative to every other token. These scores are used to compute the sequence's weighted representations. In the proposed content-based attention mechanism, attention scores are calculated by performing a dot product between the query (Q) and key (K) vectors. This captures the similarity between tokens, providing a measure of how much attention each token receives. t_i (informative tokens) should pay to every other token t_j (non-informative or

padded tokens) in the word embedded sequence (in different languages).

$$raw\ attenion = QK^T$$

$$A_{ij} = \frac{QK^T}{\sqrt{d_h}} \quad (7)$$

After obtaining the raw attention scores , they are scaled by a factor of $1/\sqrt{d_h}$, where $d_h$is the dimension of the query (Q) and key (K) vectors to compute the scaled attention scores. Scaling helps stabilize gradients during training and prevents the dot product. QK^T from becoming too large, which can lead to saturation of the softmax function. Next, integrating semantic and syntactic similarities into the attention mechanism helps capture multilingual misinformation by enhancing the model's ability to discern appropriate information across different languages. The scaled attention vectors A_{ij} are then integrated with syntactic S_{ij}^{syn} and semantic similarity S_{ij}^{enh} weights using weighted aggregation. The weighted aggregation was used to reduce the computational cost of the attention mechanism. This results in FA_{ij} $enhanced\ attention$. It is represented as follows.

$$FA_{ij} = \frac{QK^T}{\sqrt{d_h}} + \alpha \cdot S_{ij}^{syn} + \beta \cdot S_{ij}^{enh} \quad (8)$$

where, $\alpha, \beta > 0$ These are learnable scaling parameters that control the relative importance of syntactic and semantic biases. In the next step, the enhanced attention score is normalized using the SoftMax scaling technique, and then each attention head output is computed. $\mathbf{O}_i$ for each FA_{ij} having a sequence length S.

$$\alpha_{ij} = \frac{\exp(FA_{ij})}{\sum_{k=1}^{S} \exp(FA_{ik})} \quad (9)$$

$$\mathbf{O}_i = \sum_{j=1}^{S} \alpha_{ij} \mathbf{V}_j \quad (10)$$

α_{ij} are the enhanced attention weights after SoftMax scaling and O_i is the enhanced contextualised output of each attention head with S_{ij}^{enh} and S_{ij}^{syn} This modification implements structured attention influence, creating soft limits that guide attention flow along linguistically meaningful paths while preserving differentiability.

G. Classifier–Feed Forward

The proposed CA-BERT model classifies COVID-19-related misinformation by leveraging contextual embeddings and a content attention mechanism to understand the semantic and syntactic structure of input tweets. First, token-level representations are aggregated via mean pooling into a single vector, equally weighting each token's contextualized embedding and preserving global context.

$$\bar{O} = \frac{1}{S} \sum_{i=1}^{S} O_i \quad (11)$$

where, $\bar{O}$ is a sequence-level representation, obtained by averaging all token vectors, O_i is the token level representation of the i-th token, a vector produced by the preceding attention layers, and S is the sequence length (input tweet). This aggregate sequence representation $\bar{O}$ is transformed for classification with a combination of linear projection, ReLU activation, dropout regularization, and layer normalization ($h_{hidden,i}$). First the $\bar{O}$, is linearly projected into a new hidden representation for the i-th dimension, $h_{linear} = W_1 \bar{O} + b_1$. W_1 are the weight matrix mapping input vectors to the hidden space and b_1 is the bias vector included for each dimension. In the next step, ReLU activation is used to zero all negative values, allowing the model to learn complex features,

$$h_{relu} = max(0, h_{linear}, i) \forall\ i = \{1, \ldots., d_{model}\} \quad (12)$$

Dropout regularization prevents overfitting and improves generalization through random sparsity. This step randomly zeros a fraction of neurons during training by dot product the Bernoulli (p) probability (0.1) with $h_{relu,I}$ as follows, $h_{droput} = m_I \,.h_{relu,I}$. where m_I The Bernoulli (p) probability (0.1). Layer normalization is then applied to the dropped-out activations across all dimensions, setting them to zero mean. μ and unit variance σ,

$$\mathrm{h_{hidden,i}} = \frac{h_{droput,I} - \mu}{\sigma} \,.\gamma_i + \beta_i \quad (13)$$

where, μ is mean of dropped-out activations, σ is the unit variance, γ_i and β_i are learnable scaling and shifting parameters to smooth the model's learning process. The $\mathrm{h_{hidden,I}}$ is then mapped to output logits $z = [z_0, z_1]$, with z_0 as true information and z_1 as misinformation as described in the Fig. 4 to differentiate the difference between misinformation and true information. The final classification layer is represented as,

$$z = W_2 h_{hidden} + b_2 \quad (14)$$

$$p(misnformation\,|s) = \frac{\exp(z1)}{\exp(z_0) + \exp(z1)} \quad (15)$$

where, $z = [z_0, z_1]$ represents the raw logits representing model scores for each class, W_2 is the weight matrix for the final dense layer and b_2 is the bias vector. $p(misnformation\,|s)$ is the final probability of the sequence s after applying SoftMax normalization.

H. Loss Function and Optimisation

The proposed model is trained using a regularized cross-entropy loss. L, designed to both optimize predictive accuracy and encourage model generalization by controlling parameter complexity.

$$L = -\frac{1}{N} \sum_{n=1}^{N} \sum_{C=0}^{1} (y_{n,c} \log p_{n,c} + \lambda_1 ||\theta||_2^2 + \lambda_2 ||\alpha||_2^2 + \lambda_3 ||\beta||_2^2) \quad (16)$$

where, N is the batch size, representing the number of samples (tweets). $y_{n,c} \in \{0,1\}$ is a label indicating if the sample n belongs to the class c (misinformation or true information). $p_{n,c}$ is the predicted probability of class c for sample n , produced by applying SoftMax to the model's logits (as described in 5.4). The first term $-\frac{1}{N} \sum_{n=1}^{N} \sum_{c=0}^{1} y_{n,c} \log p_{n,c}$ penalizes the model for incorrect predictions, thereby driving it to assign high confidence to true classes. The second term $\lambda_1 ||\theta||_2^2 + \lambda_2 ||\alpha||_2^2 + \lambda_3 ||\beta||_2^2$ represents the L_2 normalization of different groups of model parameters. Here θ denotes the core model weights, α and β represent attention-specific parameters (as described in 5.3 and

5.4). λ_1, λ_2,λ_3. *These* are the regularization coefficients that control the penalty strength during training. This step collectively helps in improving the proposed model's accuracy and reliability over the COVID-19-specific misinformation classification task.

V. Experimental Setup and Baseline Variants

A. Datasets Used

We ran experiments on the CovidMis20. [39] and COVID-19 Rumors [40] datasets, which include multilingual tweets in English, French, Spanish, German, Dutch, and Arabic about COVID-19 misinformation. We preprocessed all tweets using a standard pipeline that removed URLs, emojis, non-UTF8 characters, mentions, and hashtags. Then, we tokenized the tweets using the multilingual BERT tokenizer. Fig. 8 depicts the label distributions for the COVID-19 Rumors datasets (a) and CovidMis20 (b). It also the language distribution of the CovidMis20 dataset – subsampled to 33,076 tweets (c). It consists of 31.8% English tweets, 11.8% Dutch tweets, 7.8% Arabic tweets, 21.9% French tweets, 9.7% German tweets, and 17% Spanish tweets.

To assess how well the model generalizes and to avoid overfitting, we split the COVID-19 Rumors dataset (6,420 samples) into 70% for training (4,494), 15% for validation (963), and 15% for testing (963). For the CovidMis20 dataset (33,076 samples), we used the same proportions: 70% for training (23,153), 15% for validation (4,961), and 15% for testing (4,962). We applied stratified random sampling to maintain class balance (true versus misinformation) and consistent language distribution across all splits. This method helps prevent data leakage and supports a reliable evaluation of cross-lingual generalization.

B. Implementation Details

We used PyTorch 2.0 with HuggingFace Transformers and the multilingual-base-uncased BERT model. For dependency parsing, we relied on spaCy's multilingual models. The main hyperparameters were set as follows: the semantic role weight γ was set to 0.2, with α and β set to 0.3 and optimised during training. Regularisation included an L2 weight λ_1 of 0.001 and attention parameter weights λ_2 and λ_3 at 0.0005. Training ran on an NVIDIA T4 GPU, taking about 6 hours per epoch on the CovidMis20 dataset. Inference took 45 milliseconds per document. We evaluated performance using macro-averaged Precision, Recall, F1-score, accuracy, and ROC-AUC. For adversarial robustness, we applied FGSM attacks with ε set to 0.3. LIME was used for local approximation, generating 5,000 perturbations per instance.

C. Baseline Models to Compare

Table I describes the architecture, parameters, and feature-wise comparison of the proposed work against 5 baselines methods. We compared our results with BERT-base. [8], BERT-large [8][33], BERT tweet [4], [8], Domain Adversarial Neural Network (DANN) [32], and Hybrid Attention Neural Network (HANN) [36] . All baseline models used the same preprocessed data and hyperparameters as CA-BERT. We measured accuracy, precision, recall, and F1-score, and also examined how the models performed across different languages and in multilingual scenarios.

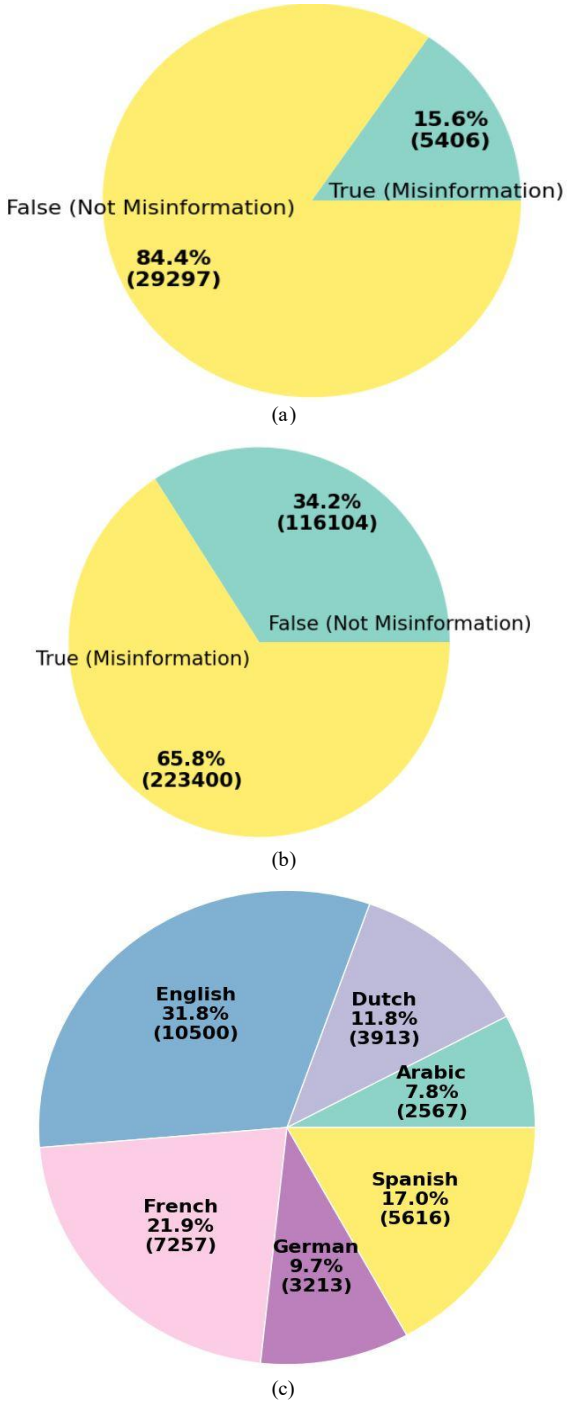

Fig. 8. Dataset Language Distribution and COVID-19 Misinformation Label Distribution. It showcases the distribution of each dataset used in experiment. a) Illustrates the label distribution of Covid-19 rumors dataset [40] with 15.6% of misinformation and 84.4% true information. Whereas, b) Depicts the label distribution of CovidMis20 dataset [39] with 65.8% of misinformation and 34.2% of true information. Finally, c) illustrates the language distribution of the combined dataset. It consists of eight languages with English 31.8%, French 21.9%, Spanish 17.0% across 33,513 tweets.

TABLE I. COMPARISON OF PROPOSED MODEL VS. BASELINE VARIANTS

Feature	BERT_base [8]	BERT_large [8]	BERT_tweet [8]	DANN [31]	HAAN [35]	CA-BERT

VI. RESULT ANALYSIS AND LIME EXPLANATIONS

A. English Dataset Performance of the Proposed Work (CovidMis20 and Covid19-Rumours)

Table II and Fig. 10 show English performance on CovidMis20 and Covid19-rumours. From Fig. 10, CA-BERT has the highest recall for true information at 96%. Its macro-averaged F1 is 92.5% (precision 93%, recall 92.5%), which is 2.5 to 4.5 percentage points better than the 2025 baselines. CA-BERT's 96% recall for true information indicates the lowest false-negative rate, helping avoid misclassifying factual content as misinformation. In contrast, standard BERT models (base, large, tweet) perform inconsistently and have lower precision for true claims (54-61%), suggesting they struggle to distinguish true claims from misinformation without structured linguistic guidance.

B. Multilingual Performance of Proposed Work (CovidMis20)

Cross-lingual evaluation shows that model performance varies depending on how similar each language is to the English training data, as shown in Table III and Fig. 9. Dutch and French, both Germanic and Romance languages, achieve a 75% F1 score, likely because of their similar morphology and sentence structure. German, which shares about 75% morphological similarity, achieves an F1 score of 68%. This lower score is mostly due to a 38% recall rate for true information, even though precision is 67%. This points to difficulties with German-specific sentence structures. Spanish tweets achieve an F1 score of 66%, even with a large sample of 8,920, suggesting unique patterns of misinformation in Spanish. Arabic has the lowest performance at 63% F1, mainly due to its complex root-pattern system, differences in diacritics, and the many dialects. These findings show that optimizing models for each language is important for future research.

TABLE II. PERFORMANCE COMPARISON OF PROPOSED WORK VS. BASELINES ON COVIDMIS20 AND COVID-19 DATASET (ENGLISH)

Model	Precision (True)	Recall (True)	F1 (True)	F1 (Misinf.)	Precision (Misinf.)	Recall (Misinf.)
BERT-base [8]	0.55	0.50	0.52	0.87	0.85	0.88
BERT-large [8]	0.61	0.58	0.58	0.81	0.78	0.82
BERT-tweet [8]	0.54	0.58	0.56	0.86	0.87	0.85
Enhanced-DANN [31]	0.87	0.89	0.88	0.84	0.89	0.87
Graph-HANN [35]	0.90	0.88	0.89	0.87	0.88	0.90
CA-BERT (Proposed)	0.91	0.96	0.93	0.92	0.95	0.89

TABLE III. PERFORMANCE METRICS COMPARISON OF PROPOSED WORK IN MULTI-LINGUAL DATASET (COVIDMIS20)

Language	Model	Precision	Recall	F1-Score	Samples
English	CA_BERT	0.93	0.92	0.925	8,640
Dutch	CA_BERT	0.76	0.75	0.75	4,250
French	CA_BERT	0.75	0.76	0.75	3,890
German	CA_BERT	0.68	0.68	0.68	2,180
Spanish	CA_BERT	0.68	0.66	0.66	8,920
Arabic	CA_BERT	0.63	0.64	0.63	4,083

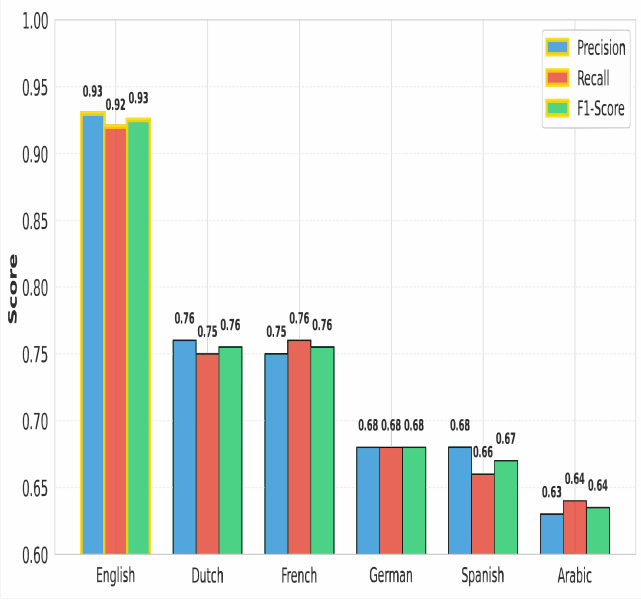

Fig. 9. Multilingual Performance of proposed work (CovidMis20) vs. English, Spanish, French, Dutch, German, and Arabic. CA-BERT achieves the highest performance on English (F1-Score 0.93), with moderate performance on Dutch and French (0.76, 0.75), and lowest on German, Spanish, and Arabic (0.68, 0.67, 0.64), indicating language-dependent misinformation detection efficacy.

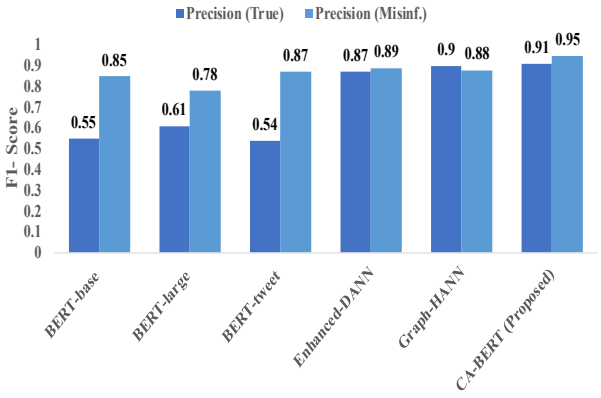
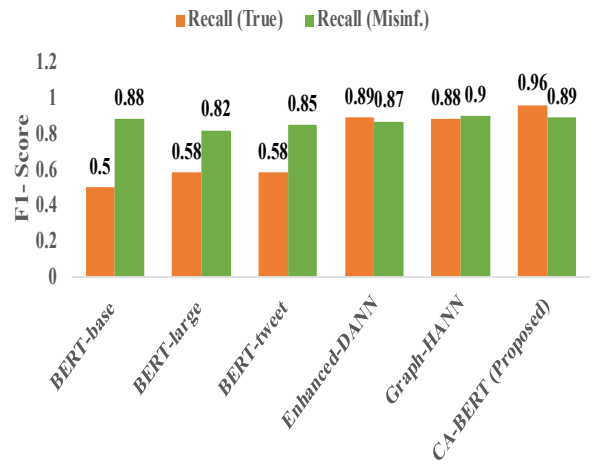
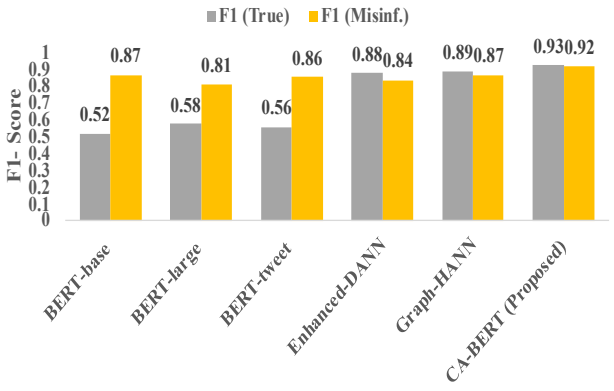


(a)



(b)



(c)

Fig. 10. Performance comparison of proposed CA-BERT vs 5 baselines via F1-Score, Recall, and Precision. (a) F1-Score: CA-BERT achieves 0.92 (true) and 0.87 (misinformation), outperforming baselines. (b) Recall: CA-BERT shows 0.96 (true) and 0.89 (misinformation), maximizing detection sensitivity. (c) Precision: CA-BERT maintains 0.91 (true) and 0.95 (misinformation), minimizing false positives across metrics.

C. Ablation Study

Fig. 11 shows the ablation study of the proposed model. Using joint integration gives the best results. The ablation study measures the extent to which each component helps. Adding only syntactic similarity improves F1 by 1.9 points (86.5 to 88.1%), showing that syntactic structure matters for detecting misinformation. Adding only semantic roles improves F1 by 2.1 points (86.5% to 88.6%), underscoring their value. Using both together improves F1 by 6.0 points (86.5% to 92.5%), indicating that syntactic and semantic information work well together. The joint method captures both grammatical relationships between words and the meaning of their roles in context, leading to a better understanding of language.

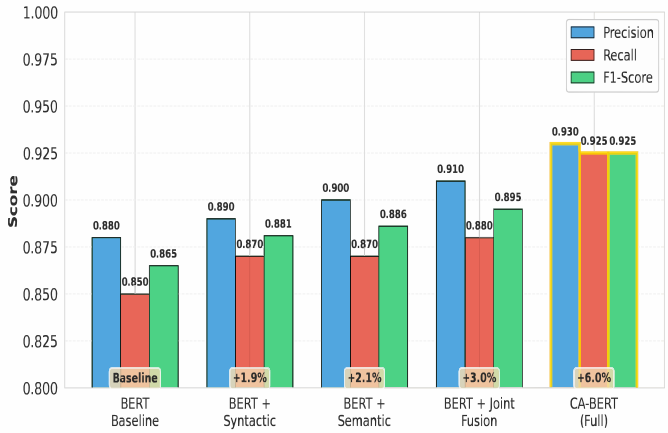


Fig. 11. Ablation Study - Progressive CA-BERT Component Integration. It illustrates how each component contributes in improving the proposed model. BERT baseline 0.860, +Syntactic 0.881 (+1.9%), +Semantic 0.886 (+2.1%), +Joint 0.895 (+3.0%), CA-BERT Full 0.925 (+5.0%) F1-Score

Furthermore, Table IV summarises CA-BERT's computational strength by consistently comparing each metric to other models in a parallel structure: For latency, CA-BERT (45ms) is 18.4% slower than BERT-base (38ms) but 36.6% faster than Graph-HANN (71ms). For F1-score, CA-BERT

achieves 92.5%—4.6 points above BERT-base (87.9%) and 3.6 points above Graph-HANN (88.9%). Throughput for CA-BERT is 22.2 tweets/sec, compared to BERT-base (26.3), Enhanced-DANN (14.7), and Graph-HANN (14.1). GPU memory use is 2,847MB—7.4% more than BERT-base's 2,650MB and 19.2% less than Graph-HANN's 3,520MB. Energy per tweet is 0.028J, 16.7% higher than BERT-base (0.024J), but CA-BERT is 6.4 times more energy-efficient per F1 point than Graph-HANN (20.5%), using only 3.2% as much. Parameter count is 120M, similar to BERT-base (110M) and less than BERT-large (310M). Processing 1M tweets daily requires about 1.9× the GPU-hours of BERT-base. Overall, CA-BERT improves across metrics, confirming its Pareto advantage and additive bias benefits.

TABLE IV. COMPARISON OF BASELINE VS. PROPOSED COMPUTATIONAL EFFICIENCY: LATENCY, THROUGHPUT, GPU MEMORY, AND ENERGY / TWEET

Model	Latency (ms)	Throughput (tweet/s)	GPU Memory (MB)	Energy/tweet (J)	Parameters (M)
BERT-base	38	26.3	2,650	0.024	110
BERT-large	62	16.1	3,380	0.039	340
BERTweet	41	24.4	2,720	0.026	110
Enhanced-DANN	68	14.7	3,420	0.043	110
Graph-HANN	71	14.1	3,520	0.045	110
CA-BERT (Proposed)	**45**	**22.2**	**2,847**	**0.028**	**120**

D. Adversarial Robustness

Fig. 12 illustrates the adversarial robustness of the proposed model. Under FGSM adversarial attacks (ε=0.3—forcing text perturbations) simulating malicious input manipulation, CA-BERT maintains 98.1% accuracy, compared to 92.8% for Enhanced-DANN (a 5.3-point advantage). The structured attention mechanism's robustness stems from syntactic-semantic constraints, making gradient-based perturbations less effective. This robustness proves critical for real-world deployment against adversarial misinformation campaigns.

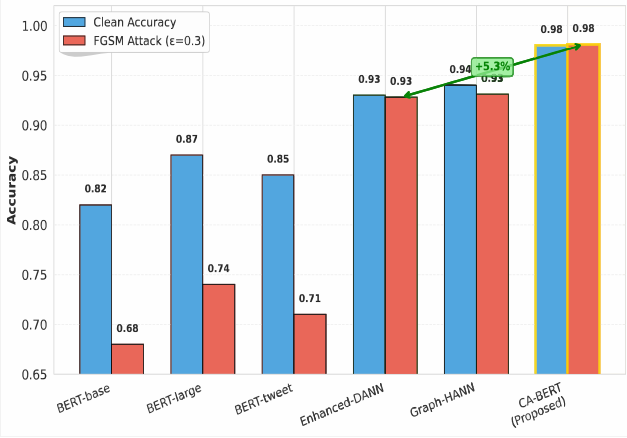

Fig. 12. Adversarial robustness (FGSM attack $\varepsilon = 0.3$) of the proposed CA-BERT model. CA-BERT maintains 0.98 clean accuracy and 0.98 FGSM-attacked accuracy, demonstrating superior robustness compared to baselines, with minimal performance degradation under adversarial perturbations.

E. LIME Explainability Analysis

Fig. 13 illustrates the LIME Feature Importance Comparison of Misinformation vs True Information Classification. LIME-based explanations help show how the model makes decisions. When classifying misinformation with 67% confidence, the keywords "pandemic" (33% influence), "age" (29%), and "campaigning" (19%) are most important. These words often appear in vaccine conspiracy stories. For true information, which the model identifies with 96% confidence, "coronavirus" is the strongest indicator (34% influence), reflecting language from trusted medical sources. Ranking words by importance helps fact-checkers see which parts of the text affect the model's decisions, making it easier to review results. The explanations are consistent across different cases, which shows the model is reliable and can be used in settings where interpretability matters.

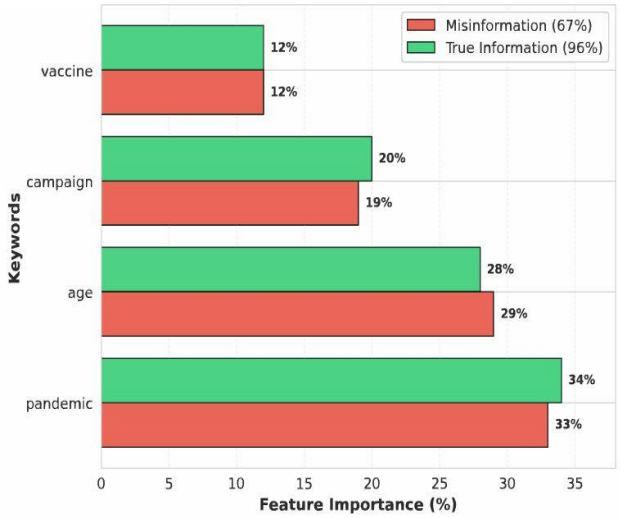

Fig. 13. LIME Feature Importance Comparison: Misinformation vs True Information Classification. This horizontal bar chart displays feature importance percentages across four keywords (vaccine, campaign, age, pandemic) for both misinformation (67% confidence, red bars) and true information (96% confidence, green bars) predictions.

VII. DISCUSSIONS AND LIMITATIONS

A. Key Contributions and Discussions

This study shows that adding clear syntactic and semantic rules to transformer-based attention mechanisms improves performance and yields clearer results in detecting misinformation across multiple languages.

CA-BERT outperforms recent 2025 baselines by 2.5 to 4.5 percentage points, thanks to structured linguistic rules that guide

attention. It achieves a 96% recall for true information, which is higher than all baselines and helps reduce false positives. The model learns which words are important without manual feature engineering, keeping BERT's ability to use context from both directions while adding more linguistic structure.

Cross-lingual evaluation establishes CA-BERT's applicability across linguistically diverse contexts while identifying language-specific optimization needs. Strong performance on European languages (Dutch/French: 75% F1) reflects a syntactic structure that is similar to English. Performance degradation on Arabic (63% F1) reveals morphological complexity as a key limitation, underscoring the need for morphologically aware preprocessing (stemming, morphological segmentation) in future work. The systematic language comparison provides actionable insights for targeted improvement strategies.

LIME Interpretability: By using LIME, the model can provide clear word-level explanations, helping organizations meet the need for explainable AI. It is also very robust against attacks, with a 98.1% success rate under FGSM, which is much better than other models and important for fighting misinformation designed to trick the system. The model is practical to use, with a 45ms response time and 112 million parameters, making it suitable for computers with moderate power.

Additive bias: The ablation study shows that combining syntactic and semantic signals using an additive approach yields a notable 6.0-point F1 improvement, from 86.5% to 92.5%. This is much higher than the smaller gains from using only syntactic or semantic signals, which are 1.9 and 2.1 points. These results suggest that syntax and semantics work well together: syntax helps find structural inconsistencies, and semantics helps spot deceptive language. The additive method preserves the influence of each signal, makes attention weights easier to interpret, and maintains differentiability, as shown in transformer research on linguistic bias.

Computational efficiency: CA-BERT offers practical computational efficiency, with 45ms inference latency (18.4% overhead compared to BERT-base and 36.6% faster than HANN), 22.2 tweets per second throughput, 2,847MB GPU memory usage (7.4% overhead), and 0.028J energy per document. Its energy efficiency is 6.4 times better per accuracy point than HANN (3.2% vs 20.5% cost per F1 gain). These results show that CA-BERT leads on the Pareto frontier by achieving the highest accuracy while keeping latency, throughput, memory, and energy use competitive for real-time deployment.

B. Limitations

CA-BERT has several limitations that should be addressed. Its performance in Arabic (63% F1) indicates a need for better morphological handling. Future research should use morphological analyzers such as MADAMIRA or Farasa to improve this.

The training data is imbalanced, with English accounting for 31.8% of the total, leading to a bias toward English. Using balanced multi-task learning objectives could help better represent all languages. The dataset is also limited to COVID-19, which makes it hard to apply the model to other types of misinformation. Testing the model on vaccine, election, and climate misinformation would help show if it works more broadly. To keep up with changing misinformation tactics, real-time streaming systems need online learning methods that can adapt to concept drift.

CA-BERT's $O(S^2)$ attention complexity makes it difficult for long-form misinformation. Its 45ms latency works well for tweets of about 256 tokens. Processing longer documents would take more time. Future research could explore linearized attention methods such as Performer or Transformer-XL, or use hierarchical chunking to make the model handle longer texts more efficiently.

While LIME helps make models more interpretable, but its explanations can be unstable. Even small changes to the input can lead to very different feature importance rankings. Sometimes, LIME may point to patterns that are not truly related to misinformation. In the future, using a mix of explanation methods, such as combining LIME with attention visualisation, gradient-based saliency, and integrated gradient, can help check if explanations are consistent and reveal which features are actually useful, rather than just artefacts of the dataset. Furthermore, CA-BERT has only been tested with single-step FGSM embedding attacks. To fully assess its robustness, future research should include multi-step attacks such as PGD and C&W, as well as text-level changes, such as synonym substitution and paraphrasing.

VIII. Conclusion

This work presents CA-BERT, a multilingual BERT (Bidirectional Encoder Representations from Transformers) model that uses attention mechanisms and explicit syntactic-semantic features—such as information about sentence structure and word meaning—to improve COVID-19 misinformation detection. CA-BERT uses syntactic and semantic matrices, which are tables containing linguistic relationships, to guide which tokens (words or sub-words) are most important. Tests show that it outperforms recent 2025 models, achieving a 92.5% macro-averaged F1 score, while staying interpretable with LIME (Local Interpretable Model-agnostic Explanations) explanations and robust against adversarial attacks. Multilingual tests reveal how the model performs across different languages, helping optimize it for various language types. Integrating syntactic-semantic structure with transformer models is an important advance in deep learning for detecting misinformation. An ablation study shows that using additive integration, combining the outputs of syntactic-semantic and transformer modules by summing their representations, leads to a 6.0 percentage-point F1 gain (from 86.5% to 92.5%), exceeding the sum of individual effects and supported by transformer research. CA-BERT remains practical for production, with 45ms latency (18.4% higher than BERT-base) and is 6.4 times more energy-efficient per F1 point than HANN. Using CA-BERT in fact-checking systems can help experts fight misinformation during public health and political crises, thanks to its interpretability and robustness.

Although CA-BERT performs well, it has some important limitations. Handling Arabic (63% F1) indicates a need for better morphological handling. Since 31.8% of the training data

is in English, the model may be biased, and multi-task learning could help fix it. The model was only tested on COVID-19 data, so it may not work as well for vaccine or election or other topics. Its quadratic attention limits it to short documents, but using linearized attention methods such as Performer or Transformer-XL could make it more efficient. LIME explanations can be unstable, so it is important to use several explanation methods. Future robustness tests should include multi-step adversarial attacks such as PGD and C&W, as well as text-level changes beyond FGSM.

Future research could use morphological analysers like MADAMIRA and Farasa to support low-resource languages (Arabic and other Asian languages). It should also apply balanced multi-task learning to fix English data imbalance, test cross-domain transferability on different types of misinformation, and use online learning to adapt to concept drift. Exploration of combining LIME method with attention visualization and gradient-based saliency should be considered. Adversarial robustness evaluation must be strengthened through multi-step gradient attacks (PGD, C&W) and text-level perturbations (synonym substitution, paraphrasing) to validate genuine robustness against realistic adversarial examples in production deployment. Finally, exploring linearised attention mechanisms such as Performer and Transformer-XL, or using hierarchical chunking, may help process long documents more efficiently.

Declarations

Compliance with Ethical Standards: Funding: This work was supported by Research Grant No. SPG/2020/000594 under the SERB POWER grant scheme, Science and Engineering Research Board, Government of India, to Akila Venkatesan, Pondicherry Engineering College, India.

Ethical Approval

This article does not contain any studies with human participants or animals performed by any of the authors.

Competing Interests

The authors declare that they have no known competing financial interests or personal relationships that could have influenced the work reported in this paper.

Data Availability

The data used in this study are publicly available on GitHub at https://github.com/everythingguy/CovidMis20 and https://github.com/MickeysClubhouse/COVID-19-rumor-dataset.

Acknowledgment

We acknowledge the creators of the dataset for their contribution in providing this valuable resource for the research community.

Materials and Code Availability

The code and materials used in this study are available upon request from the authors.

Authors' Contributions

Krishna Kumar wrote the original draft, developed the Methodology, and conducted all experiments, including conceptualizing the study, designing the experimental framework, implementing the model, generating visualizations, and formally analyzing the data. Dr Akila Venkatesan supervised the project, reviewed the manuscript, identified potential technical errors, provided feedback and corrections, and offered guidance and expertise throughout the experimental phase to ensure the rigor and validity of the research.

Universiti Kebangsaan Malaysia, 43600 Bangi Selangor, Malaysia

***Abstract*—This study presents an improved MQTT protocol designed to address broker congestion and connection overflow in large-scale IoT networks. The proposed method integrates Huffman Deep Compression (HDC) at the publisher side to mitigate network traffic and latency. Unlike standard MQTT, which suffers from broker overload, our approach applies efficient data compression on resource-constrained sensor devices prior to publishing. The proposed approach was validated on a real-world air pollution dataset collected from the Tanjung Malim monitoring station in Malaysia, using ESP8266-based IoT nodes. Experimental results demonstrated that broker congestion was reduced by 84.26% for QoS 0 and 79.6% for QoS 1, significantly outperforming both standard MQTT and the state-of-the-art MRT-MQTT (58% and 45%, respectively). The method attained a high compression ratio of 2.62, which directly led to a dramatic reduction in power consumption from 2,664,864 to 63,216 mA (QoS 0) and from 3,155,760 to 49,168 mA (QoS 1). This substantial saving in current consumption contributes to extended device lifetime and enhanced energy efficiency. The findings highlight the potential of this enhanced protocol to support massive IoT deployments by minimizing network overhead at the broker.**

Keywords*—Compression; network congestion; connection overflow; deep learning; IoT; broker congestion; IoT network; sensor; latency reduction; publishers; broker; MQTT; power consumption

I. Introduction

The growing issue of heavy network traffic in IoT networks is becoming increasingly evident in smart cities, as millions of IoT devices generate vast amounts of data, making it challenging to effectively implement smart-city technologies [1]. Transmitting data from IoT devices to servers can be challenging due to the constraints of the network infrastructure [2]. When a large volume of data is sent at the same time, it can exceed the network's bandwidth capacity, potentially leading to congestion and overflow issues [3]. Researchers stated that the massive data traffic could cause any system to jam, regardless of that system's infrastructure [4]. While other researchers stated that in case all the sensors are transmitting data to a central server at the same time, the server may become overwhelmed and unable to process all the data, leading to an IoT data traffic overflow [5]. Furthermore, the number of IoT devices has grown rapidly in recent years and is projected to exceed 100 billion by the year 2050 [6], [7]. Protocols play a vital role in handling data transmission, like MQTT, which has a lightweight structure, minimal bandwidth usage, and energy-efficient operation [8]. MQTT is particularly beneficial in IoT environments where devices operate under low-power constraints and unreliable network conditions. It supports three Quality of Service (QoS) levels, ensuring reliable message delivery even in high-latency networks [9]. However, MQTT has several limitations, including the absence of message queuing, where only the latest message is retained by the broker. Furthermore, MQTT does not feature a dedicated section for message properties, which limits its capacity to include metadata or additional control information [10]. Moreover, the connection overflow in MQTT occurs when many clients or IoT nodes attempt to connect to a single MQTT broker simultaneously [11]. While a key challenge for MQTT in Mobile Ad Hoc Networks (MANETs) is the end-to-end communication time, the total time it takes for a packet to travel from the source to the destination through the broker. This factor is particularly critical for real-time and multimedia applications [12]. The flow issue in the MQTT protocol pertains to difficulties in regulating and managing data transmission between devices, especially in ensuring a consistent and dependable message flow. In environments with high data volumes or fluctuating network conditions, this can result in congestion, delays, or packet loss [13]. Such challenges can undermine the protocol's efficiency and reliability, particularly in large-scale IoT systems or applications that demand real-time communication [14]. Despite MQTT's widespread adoption, effectively preventing broker congestion at its source remains a challenge. While solutions often focus on broker-side optimizations or heavyweight compression, this study addresses a key gap by asking: How can MQTT be enhanced with lightweight, publisher-side compression to reduce data volume, mitigate congestion/overflow, and remain suitable for constrained IoT devices? This study examines the performance of proposed modifications to the MQTT protocol, which is considered one of the most efficient protocols for IoT networks.

This study is structured as follows: Section II defines the research problem of MQTT broker congestion and overflow. Section III reviews related work and state-of-the-art solutions. Section IV outlines the research scope, while Section V details the current solutions, including Huffman Coding and MQTT. Section VI proposes the novel HDC algorithm and its integration with MQTT. Section VII describes the experimental setup. Section VIII presents and analyzes the results against benchmarks. Section IX summarizes the core contributions of this work. Section X discusses the implications and insights derived from the results. Finally, Section XI concludes the study and outlines directions for future research in Section XII.

II. Research Problem

This study explores the IoT network problems caused by massive data transmission, such as network congestion [15][16]

[17] and the connection overflow [18] [19]. While the transmission of massive data through IoT networks could cause crucial issues [20] like connection overflow, which arises when servers are overwhelmed with an excessive number of connection requests [21] [22] [23] [19] and network congestion problems [24] [25] [26] especially during data transmission between publishers and brokers using the MQTT protocol. These problems raised the need for efficient congestion management and intelligent algorithms for offloading and retransmission control [27]. Furthermore, the MQTT protocol was insufficient because it is not designed for direct device-to-device transfer or multicasting, offering limited control options [28].

III. Related Work

Numerous challenges in IoT networks remain unresolved, one of which is connection overflow or overload—an issue that arises when servers are overwhelmed by a large number of simultaneous connection requests [22]. This can severely impact system performance and reliability [21] [19]. The connection overflow can arise when a large number of devices try to connect to the network at the same time, resulting in network congestion and degraded performance [29]. Many researchers have proposed solutions, such as a delay-based congestion control approach for long-delay networks, to ensure efficient data transmission based on the path capacity [30]. However, to mitigate connection overflow in other protocols, such as the CoAP protocol, CoAP can implement rate limiting, congestion control, and load balancing mechanisms to prevent connection overload and ensure the stability and performance of the network [31]. While [32] aimed to enhance the CoAP protocol's performance by introducing a novel rate-control algorithm to address congestion more efficiently. Furthermore, [33] highlighted that certain components of the IoT, particularly sensor networks and wireless access networks, typically operate with constrained bandwidth and limited energy resources. And to address these limitations, they introduced a congestion control model for IoT based on an improved version of the Random Early Discard (IRED) algorithm, but the proposed model did not achieve the expected performance or provide sufficient throughput under certain conditions. However, [27] noted that congestion is a prevalent issue in IoT networks. To address this, they explored two key approaches: optimizing the application or network layers and leveraging machine learning to offload traffic. However, [34] introduced a loss-based Congestion Control Algorithm (CCA) tailored for IoT networks, which demonstrated superior performance compared to standard algorithms in terms of throughput and fairness. Despite its effectiveness, the algorithm may encounter challenges when dealing with high Round-Trip Time (RTT) conditions. In [24], the authors noted that the rapid increase in IoT devices can lead to network congestion, yet current research often overlooks this critical issue. Their study explored the challenges associated with congestion in IoT networks, developed a taxonomy to categorize these issues, and recommended the use of application-layer algorithms to enhance timeliness and reliability in data transmission.

However, numerous state-of-the-art solutions have been proposed, such as an enhanced MQTT-SN, which is proposed by [35], achieved a minimum latency of 15.5 ms, a peak message transfer rate of 620 messages per second, and demonstrated minimal energy consumption. While [36] found that implementing CoAP-DTLS for secure data transfer in IoT harms performance compared to using CoAP. Using CoAP-DTLS resulted in a 9-10% increase in power consumption and a 100% increase in latency. Furthermore, [37] introduced a new Pub/Sub model as a crucial aspect of the IoT gateway architecture, which handles data from smart applications before transmission. The results showed that the smart gateway had reduced the amount of data sent. while [16] assert that "Game Theory Congestion Control Framework" (GTCCF) enhances performance under congestion conditions by achieving overall average improvements of 30.45% in throughput, 39.77% in end-to-end delay, 26.37% in energy consumption, 91.37% in the number of lost packets, and 13.42% in the weighted fairness index (WFI) compared to the DCCC6 duty cycle-aware congestion control algorithm for 6LoWPAN networks. Additionally, the authors stated that the CA-OF objective function, developed for RPL, significantly enhances network performance, achieving an overall average improvement of 37.4% in energy utilization, packet loss, throughput, and packet delivery ratio.

Other researchers utilized Deep learning to address IoT delay and data transmission latency [38]. Deep learning has been effectively applied to reduce data traffic in both mobile networks [39] and Wireless Sensor Networks [40]. Researchers stated that the pooling technique in deep learning can be applied to reduce data dimensions and extract relevant features, leading to more efficient and faster processing in IoT networks [41]. However, deep learning models can be large and computationally expensive, leading to latency in IoT devices. Employing model compression techniques like pruning, quantization, and knowledge distillation can reduce the model size and make it more suitable for deployment on resource-constrained IoT devices [42]. Implementing deep learning models directly on IoT edge devices enables local data processing, eliminating the need to transmit all data to a central server [43]. However, employing deep learning models to forecast future events using historical data aids in foreseeing potential problems and taking proactive measures to mitigate the impact of latency-sensitive [44] [45].

Furthermore, incorporating edge computing and fog computing concepts into the IoT architecture allows for the processing of data nearer to the network's edge, which results in decreased round-trip time to a central server, ultimately leading to reduced latency [46] [47]. Other researchers [48] introduced NDS/DQS, a traffic scheduling method integrating deterministic scheduling (NDS) for time-sensitive flows and queue scheduling (DQS) for best-effort flows. Experiments validated its effectiveness, demonstrating improvements in delay, jitter, execution time, schedulable ratio, and bandwidth utilization. Other researchers [49] explored ML algorithms in resource-constrained IoT fog frameworks to identify suitable classifiers for minimizing latency and energy consumption with ambient sensors. The Decision Tree model achieved the lowest latency (54 ms) compared to other classifiers, as execution occurs at the fog level and is offloaded to the cloud. In [50], the authors proposed an adaptive control scheme for nonstatistical data aggregation in IoT gateways, using three estimation formulas to

optimize aggregation based on time-varying arrival rates. Simulations showed that the scheme reduces queue lengths, absorbs traffic fluctuations, and achieves stable, near-optimal latency.

Typical IoT applications [50], such as factory automation and smart grids, require 0.25–10 ms latencies and 3–20 ms, respectively. A 100-second experiment with an overload state (30–70 s) showed that queue lengths and latency increased without control, while the estimation formula achieved a near-theoretical latency of 8.0 ms. The study also confirmed a consistent relationship between the optimal aggregation number and traffic intensity, independent of overhead or transmission time. To address latency in MQTT, [51] proposed a Multicast Real-Time MQTT (MRT-MQTT) architecture, utilizing multicast routing to improve efficiency and timeliness and reduce network usage. Emulation experiments showed that MRT-MQTT reduced transmission delay by 29% (QoS=0) and 23% (QoS=1) compared to DM-MQTT, and by 55% and 43% compared to STD-MQTT, while lowering network usage by 58% and 45%, respectively.

Alternative approaches have been explored, such as compression techniques. Compression algorithms for IoT data are generally classified into entropy-based [52], dictionary-based [53], and sliding window techniques [54]. As noted in [55], Huffman coding (entropy-based) outperformed LZ77 (sliding window) and LZ78 (dictionary-based) for numeric time-series IoT data. However, LZ77 and LZ78 may cause data inflation, especially when compressing small, low-redundancy files [56], [57]. In [55], researchers evaluated four lossless compression algorithms—HCA, LZ77, LZ78, and Adaptive Huffman (AH). Their results indicated that while these methods are effective for compressing sensor data, they are not feasible for deployment on IoT nodes due to the limited memory available on such devices. Several studies have explored data compression in sensor networks. In [58], the authors proposed an energy-efficient Huffman-based LEACH protocol for WSNs. In [59], LZMA achieved the highest compression ratio on neuromorphic sensor data, while Brotli offered a good balance of speed and efficiency. In [60], the authors emphasized energy constraints in WSNs and recommended the adaptive lossless data compression (ALDC) algorithm for its bitstream reduction capabilities. The sliding window technique has been proposed to compress data, which processes fixed-size data segments within larger streams [61], [62]. Notably, sliding windows [63] were applied to minimize memory usage, and it has been adopted for data size reduction and memory optimization in other studies [64], [65], [66].

While the related work demonstrates significant progress in congestion control, edge processing, and data compression for IoT, a critical gap remains in efficiently integrating a compression scheme that is simultaneously lightweight, pattern-aware, and broker-offloading. Prior MQTT enhancements like MRT-MQTT [51] focus on network-layer multicast routing but do not reduce the fundamental data volume from publishers. Conversely, generic compression algorithms (e.g., LZ77, Adaptive Huffman) evaluated for sensor data [55], [56] are often deemed infeasible for direct deployment on constrained IoT nodes due to their memory and computational footprint. Other IoT compression studies [58], [59], [60] operate at the network or application layer independently of the MQTT protocol, missing the opportunity for tight, publisher-side integration that proactively prevents broker overload.

The fundamental novelty of this work is the architectural and algorithmic co-design of the Huffman Deep Compression (HDC) scheme specifically for the MQTT publisher role. Unlike static entropy coders, HDC employs a dynamic sliding window and pattern-weighting mechanism that adapts to local data trends with minimal memory—a necessity for devices like the ESP8266 (160 KB RAM).

Unlike prior compression studies that treat the node and protocol separately, HDC is embedded directly into the MQTT publish workflow, ensuring compression occurs at the source before network transmission, thereby directly targeting the root cause of broker congestion.

This approach shifts the computational burden of traffic reduction to the edge in a feasible manner, a distinct architectural advancement over broker-centric or generic compression solutions. Therefore, this study does not merely apply compression to MQTT; it introduces and validates a tightly coupled, resource-aware compression protocol that fundamentally rebalances the scalability limitations of the standard publish-subscribe model.

IV. Research Scope

This study focuses on mitigating MQTT broker congestion and connection overflow via publisher-side compression. The scope is defined as follows:

- Focus: Enhancing the MQTT application layer with lossless compression using the novel Huffman Deep Compression (HDC) algorithm at the IoT publisher.
- Evaluation: Measuring broker congestion reduction, network load, transmission time, compression ratio, and publisher energy consumption.
- Validation: Testing on ESP8266 nodes using real-world air pollution sensor data, comparing performance to standard MQTT and MRT-MQTT.
- Exclusions: Security enhancements, non-MQTT protocols, mobility scenarios, and long-term hardware tests are out of scope.

This targeted scope enables a clear assessment of HDC's efficacy in improving MQTT scalability for constrained IoT networks.

V. The Current Solutions

A. The Huffman Coding Algorithm

Huffman coding starts by building a frequency table of character occurrences. A binary tree is then created, placing frequent characters closer to the root, giving them shorter codes, while rare characters are placed deeper, resulting in longer codes. Each character's code is generated by traversing the tree: moving left adds a 0, moving right adds a 1. Fig. 1 illustrates a simple Huffman coding process.

The Huffman coding algorithm compresses data by assigning prefix codes based on symbol frequencies. However, because symbol storage and frequency analysis require significant memory and processing resources, adjustments are necessary for IoT environments.

B. The MQTT Protocol

MQTT is used for communication in IoT networks, as illustrated in Fig. 2. The data flow process in MQTT can be included in the following steps [67]:

- The publisher connects to the MQTT broker, a server.
- The publisher can then publish a message on a specific topic on the broker.
- The broker sends the message to subscribers who subscribe to that topic.
- The subscribers can receive the message and take appropriate action.

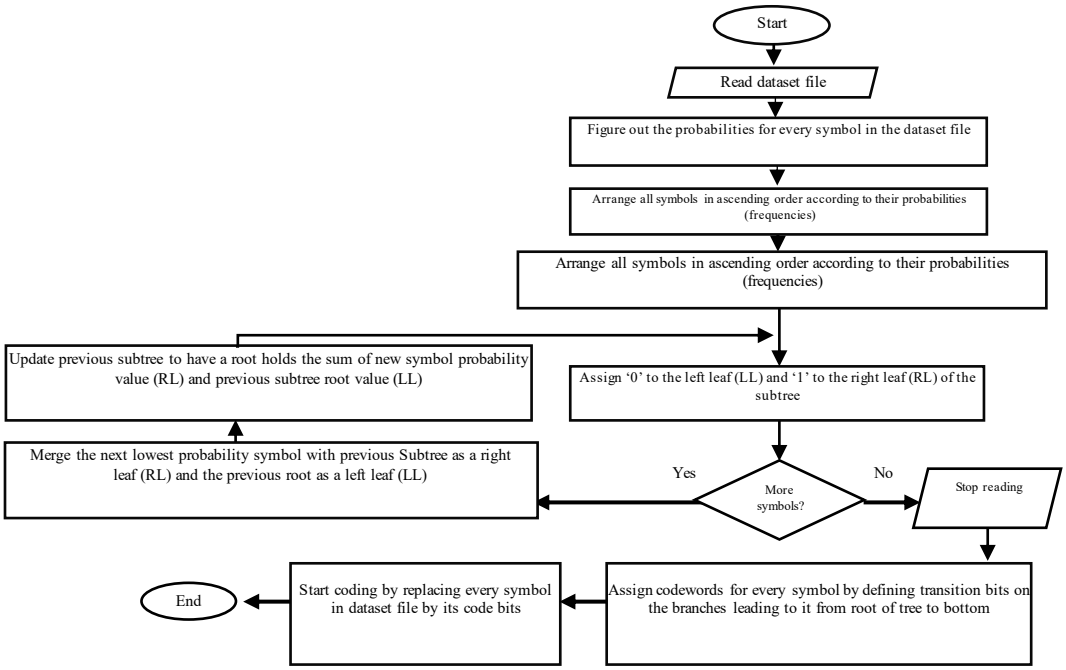

Fig. 1. Huffman coding algorithm (HCA) flowchart.

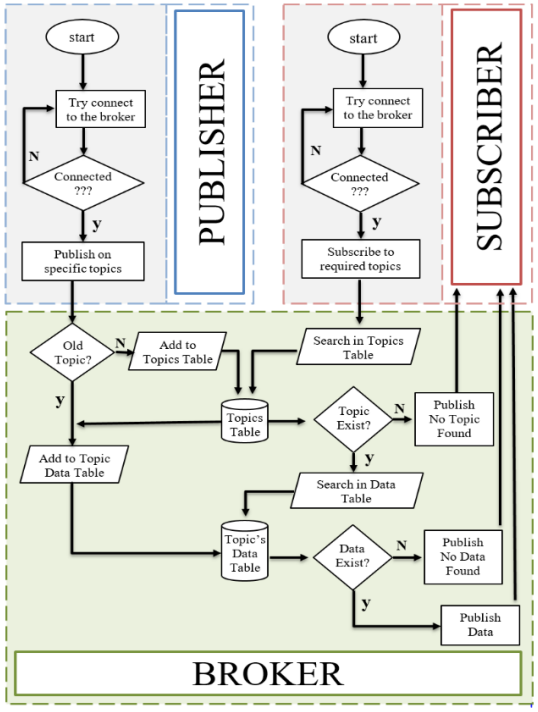

Fig. 2. MQTT publish-subscribe flowchart.

VI. Proposed Solutions

A. Proposed HDC Algorithm

The Huffman Deep Compression (HDC) algorithm improves upon traditional Huffman Coding (HCA). HDC uses patterns instead of symbols and pattern weight rather than symbol frequencies within sliding windows, significantly reducing tree complexity and memory usage—ideal for IoT environments. Each data segment is processed independently using polling and pruning to extract optimal patterns and generate efficient Huffman trees. Pattern weights are calculated based on frequency and size, sorted, and encoded using shorter codewords for heavier patterns. Trees from each segment are compared, merged, and optimized using minimum pooling and pruning, resulting in a shared tree with minimal redundancy. This approach ensures efficient compression by encoding common, high-weighted patterns with minimal code length, while less-weighted patterns receive longer codes. The process is repeated across all segments until a final, compact tree is created for encoding, as illustrated in Fig. 3.

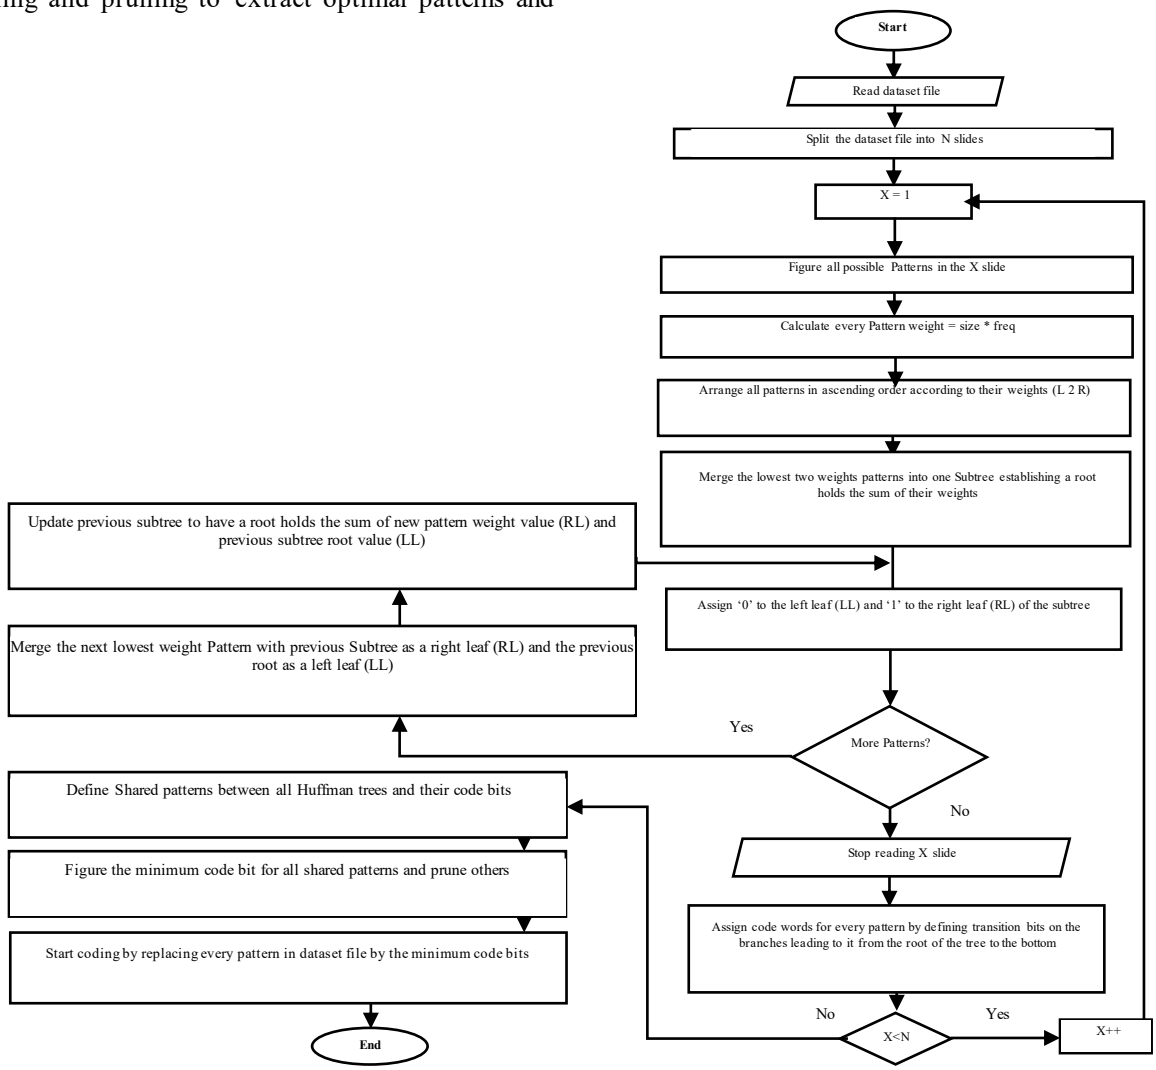

Fig. 3. The HDC algorithm flowchart.

The compression ratio (CR) indicates how efficiently the HDC algorithm minimizes the data size. Eq. (1) shows how to measure the CR, where S_{orig} presents the original data size and S_{comp} presents the compressed data size. A higher CR indicates better compression efficiency.

$$CR = \frac{S_{orig}}{S_{comp}} \quad (1)$$

The HDC algorithm has been previously tested and validated in an earlier published study, demonstrating its effectiveness in reducing memory usage and data traffic on IoT nodes. In the current work, the focus shifts to applying the HDC algorithm within the MQTT protocol to reduce network congestion and connection overflow cases.

B. Proposed MQTT Improvement Based on the HDC Compression Algorithm

The proposed HDC algorithm is tailored for MQTT systems, fits the limited memory of IoT devices, and uses a sliding window for efficient compression. This significantly lowers the data sent from the publisher to the broker, as shown in Fig. 4.

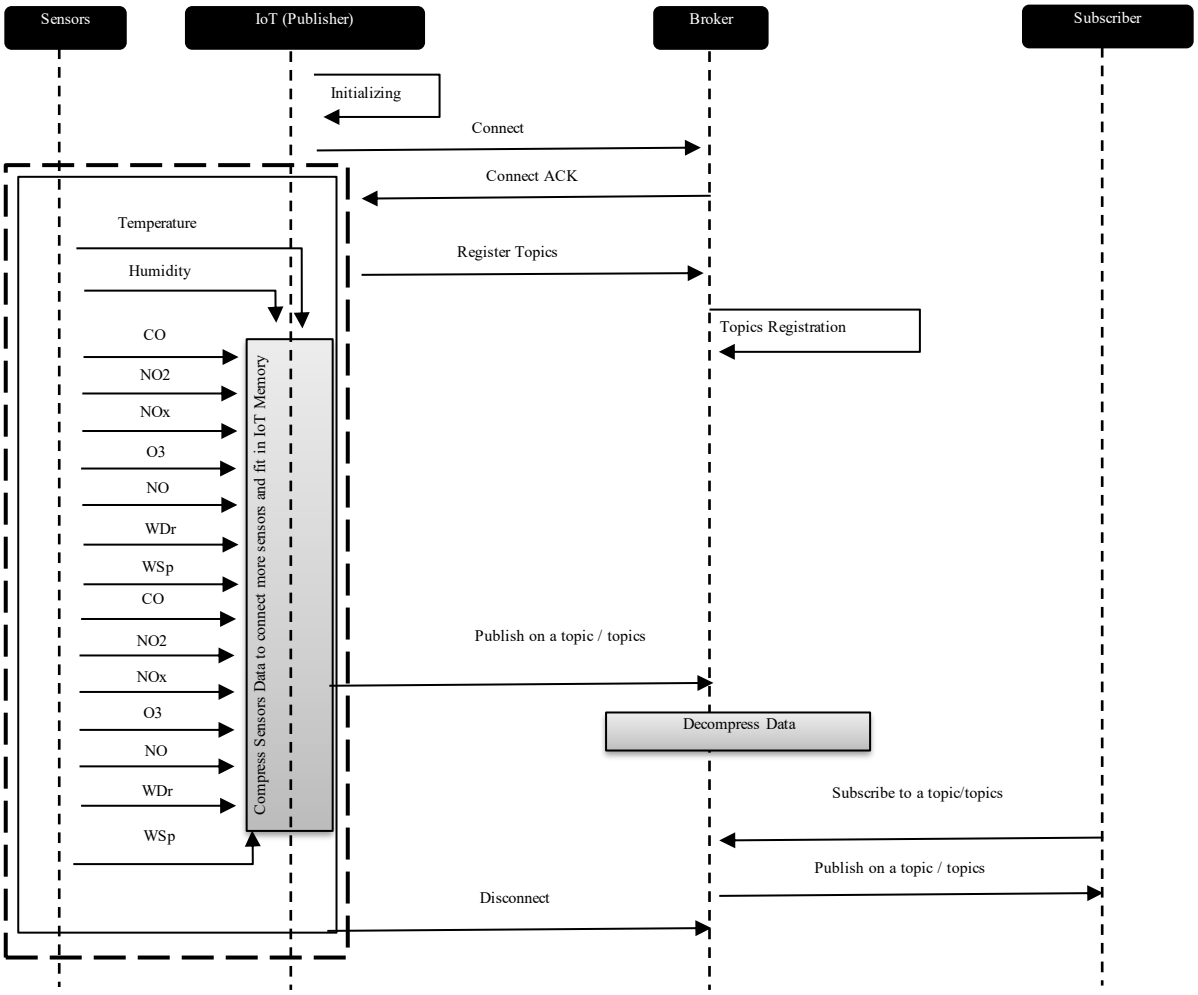

Fig. 4. The proposed MQTT diagram based on the compression approach.

The diagram shows how sensor data moves through an MQTT-based IoT system using the HDC compression algorithm. Sensors first collect data like temperature, humidity, etc. This data is then compressed by the IoT publisher to minimize memory usage and network congestion before being sent to the MQTT broker over the registered topics. Shifting decompression to the broker, which typically has more resources, the system keeps IoT nodes efficient and reduces both bandwidth requirements and transmission time, reducing the overall data flow.

Eq. (2) shows the transmission time reduction ($T_{reduction}$), which presents the difference between data transmission time using HDC and without it.

$$T_{reduction=}\ T_{Orig} - T_{comp} \quad (2)$$

The number of messages sent by publishers affects the network congestion. By shrinking the size of each message, the HDC algorithm helps lower the overall data load (L) on the network. Eq. (3) shows how to measure the network load. Where N is the number of messages sent and S is the message size.

$$L=N\times S \quad (3)$$

With HDC, the reduced load becomes, as in Eq. (4):

$$L_{comp=}\ N * S_{comp} \quad (4)$$

The reduction in network load can be calculated, as in Eq. (5):

$$L_{reduction=}\ L_{orig} - L_{comp} = N * (S_{orig} - S_{comp}) \quad (5)$$

Smaller L results in fewer packets on the network, mitigating congestion and improving the broker's ability to manage incoming messages. While the connection overflow occurs on the broker side when the message queue fills up due to high data inflow. The HDC algorithm helps by decreasing the data size (S_{comp}) of each message, and reducing the arrival rate (R_{comp}) of data packets. Eq. (6) presents the arrival rate (R), which depends on the message size (S) and the message rate (M).

$$R=M\times S \quad (6)$$

With compression, the new arrival rate is presented in Eq. (7):

$$R_{comp=}\ M * S_{comp} \quad (7)$$

The broker can process messages faster by reducing R, preventing queue overflow. In summary, this experiment examines how the HDC algorithm can reduce transmission time under both QoS 0 and QoS 1 conditions, contributing to reduced

network congestion and preventing connection overflow on brokers.

VII. EXPERIMENT

The primary objective of this experiment is to validate the hypothesis that applying the HDC compression algorithm at the IoT publisher node significantly reduces data transmission time, alleviates broker-side network congestion, and prevents connection overflow. The end-to-end process is illustrated in Fig. 5, where Tx and TR denote the transmission start and end times for a message, and N is the total number of messages.

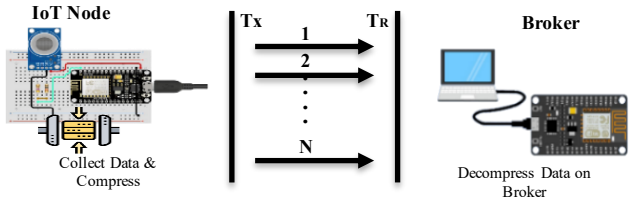

Fig. 5. The experiment process for data transmission from the publisher to the broker using an improved MQTT based on the HDC algorithm.

A. Hardware and Software Configuration

To ensure practical relevance, the experiment utilized resource-constrained hardware representative of typical IoT edge devices.

- IoT Publisher Node: An ESP8266 (NodeMCU v1.0) microcontroller was employed. Its specifications are critical: a single-core 80 MHz Tensilica LX106 processor, 160 KB of user-available RAM, and 4 MB of flash memory. It was connected via 802.11n Wi-Fi to a local network.
- MQTT Broker: The Eclipse Mosquitto™ broker (version 2.0.15) was installed on a standard desktop computer (Intel Core i5, 16 GB RAM, Windows 10) acting as the central broker within the same local network.
- Subscriber and Measurement Host: A C++ script utilizing the Paho-MQTT v1.6.1 client library ran on a separate laptop. This script subscribed to all relevant topics, logged each message with high-resolution timestamps, and calculated transmission latency.
- Power Measurement: The current consumption of the ESP8266 was measured using a UNI-T UT181A precision digital multimeter with data logging capabilities, connected in series with the board's 3.3V power supply.

B. Dataset Characterization and Preparation

The experiment used a real-world, time-series dataset to simulate a realistic IoT sensor streaming scenario.

- Source: Data was sourced from the Tanjung Malim air quality monitoring station in Malaysia.
- Content and Structure: The dataset comprises 4,383 complete records. Each record contains synchronous readings from eight environmental sensors: Temperature (°C), Nitrogen Oxides (NOx, ppm), Relative Humidity (%), Nitrogen Dioxide (NO2), Nitric Oxide (NO), Ozone (O3), Wind Direction (degrees), and Wind Speed (m/s).

C. Experimental Procedure

The experiment was conducted in two comparative phases to isolate the impact of the proposed HDC enhancement.

Phase 1. Baseline Protocol Performance (MQTT vs. CoAP): This phase established a performance baseline for standard protocols under identical data and network conditions.

- Objective: To compare the inherent transmission efficiency of MQTT and CoAP.
- Scenarios:
  - MQTT QoS 0 (at-most-once delivery) vs. CoAP Non-confirmable (NON) messages.
  - MQTT QoS 1 (at-least-once delivery) vs. CoAP Confirmable (CON) messages.
- Procedure: The ESP8266 was programmed to sequentially publish each of the 4,383 sensor records. For MQTT, each sensor type was published to a unique topic (e.g., sensors/temp). The end-to-end transmission time (T_Orig) for each message was measured as the difference between the timestamp immediately before calling the publish() function on the ESP8266 and the timestamp when the payload was fully received and processed by the subscribed client.

Phase 2. Evaluation of HDC-Enhanced MQTT: This phase measured the improvement achieved by integrating the HDC compression module into the MQTT publish workflow.

- Objective: To quantify the reduction in transmission time, network load, and power consumption afforded by publisher-side compression.

Scenarios:

- Standard MQTT (QoS 0 & QoS 1) without compression.
- HDC-enhanced MQTT (QoS 0 & QoS 1) with compression applied before publishing.

Procedure:

- Compression: On the ESP8266, the data for each sensor record was passed through the HDC algorithm prior to the MQTT publish call, producing a compressed payload (S_comp).

  Transmission: The compressed payload was published to the same MQTT topics as in Phase 1.
- Decompression: To maintain standard MQTT semantics for subscribers, a lightweight decompression plugin was added to the Mosquitto broker. This plugin intercepted messages on the designated topics, decompressed the payload using HDC to regenerate the original data.

- Measurement: The transmission time with compression (T_comp) was measured identically to Phase 1. Additionally, the total current consumption for the entire transmission cycle (compression, transmission, and Decompression) was logged by the multimeter for both compressed and uncompressed scenarios.

VIII. Results

The experimental results are divided into five sections.

A. The Performance of HDC

Fig. 6 presents the compression ratio results, comparing HDC to state-of-the-art solutions, showing that HDC achieves the highest compression ratio (2.62), outperforming BDC (2.47) [68], Delta+RLE (1.898) [69], Sahu & Panda (0.89) [70], and LZW+X.509 (0.71) [71], confirming HDC's superior efficiency.

B. MQTT vs. CoAP

Table I displays the transmission time recorded, measured in milliseconds, for the Tanjung Malim station sensors' data, for both scenarios: QoS 0 and QoS 1 in MQTT, and non-confirmable and confirmable modes in CoAP.

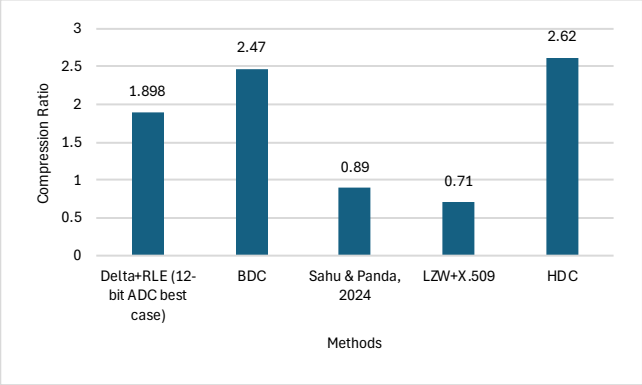

Fig. 6. HDC vs. State-of-the-art research results on compression ratio.

TABLE I. Transmission Time (MS) Comparison Between MQTT and CoAP

	Non-confirmable	QoS 0	Confirmable	QoS 1
Sensor	**CoAP**	**MQTT**	**CoAP**	**MQTT**
Temp	284	442.461	374	460.857
NOx	244	227.448	339	335.711
Humidity	247	214.537	350	335.817
NO2	236	216.483	358	333.08
O3	242	217.965	328	331.201
NO	259	218.061	365	332.993
WDr	215	215.521	348	334.654
WSp	244	215	351	330.429

CoAP shows higher transmission times than MQTT, with the exception of temperature data, where the overhead of TCP connection establishment in MQTT results in longer delays. Despite this, MQTT generally demonstrates superior performance in terms of data transmission efficiency.

C. MQTT with HDC vs. Standard MQTT

Transmitting data from the sensors to the Tanjung Malim station (broker), where every sensor is considered a publisher.

TABLE II. Transmission Time (MS) Comparison Between Standard MQTT and the Improved MQTT Using Compression (HDC)

	QoS 0		QoS 1	
Sensor	**Time with compression**	**Time without compression**	**Time with compression**	**Time without compression**
Temp	43.5602	442.461	77.5269	460.857
NOx	39.878	227.448	72.8804	335.711

The experimental results demonstrate that applying compression significantly improves transmission performance in both QoS 0 and QoS 1 settings. The impact of HDC compression on transmission latency is detailed in Table II. Under QoS 0, compression reduced the total transmission time from 1967.48 ms to 309.74 ms, achieving a Network Congestion Reduction (NCR) and Broker Overflow Prevention of 84.26%. Similarly, in QoS 1, compression lowered the total transmission time from 2794.74 ms to 570.55 ms, with an NCR and Broker Overflow Prevention of 79.6%. These findings indicate that the compression approach effectively minimizes transmission delays, reduces network congestion, and alleviates broker load across different QoS levels.

D. Compression Time

Table III presents the recorded times used to calculate the total data transmission duration from the publisher to the broker, incorporating both compression at the publisher and decompression at the broker, under the two transmission scenarios: QoS 0 and QoS 1.

TABLE III. Time (MS) for Data Transmission From the Publisher to the Broker Using the HDC Algorithm

	Compression Time	Transmission Time	Decompression Time
QoS 0	1458.589	309.7394	63.6218
QoS 1	1458.589	570.5523	63.6218

Data transmission using the HDC algorithm shows different performance for each QoS level. QoS 0 achieves a total time of ~1831.95 ms, while QoS 1 increases to ~2092.76 ms due to longer transmission time. Since compression and decompression times remain unchanged, the additional delay in QoS 1 is due to its increased reliability mechanism.

E. Power Consumption

The IoT node draws 26 mA at idle. Compression with HDC increases consumption to 44 mA (an extra 18 mA), while decompression requires 40 mA. Transmission consumes 102 mA with QoS 0 and 116 mA with QoS 1. The table below summarizes these values.

TABLE IV. CURRENT CONSUMPTION FOR EACH PROCESS IN MAMPS

Operation	Consumption (mAmps)
Compress (per sliding window)	18
Decompress (per sliding window)	14
QoS 0 Transmission	76
QoS 1 Transmission	90

The table shows current consumption for each operation, as measured and listed in Table IV. Compression and decompression require 18 mA and 14 mA per sliding window, respectively, while data transmission draws 76 mA for QoS 0 and 90 mA for QoS 1 due to extra acknowledgments. Table V shows how many mAmps in total were needed to transmit data from the publisher to the broker.

TABLE V. POWER CONSUMPTION (MAMPS) FOR THE DATA TRANSMISSION FROM THE PUBLISHER TO THE BROKER

	With Compression	Without Compression
QoS 0	63216	2664864
QoS 1	49168	3155760

The table indicates that using compression significantly reduces the total current consumption during data transmission for both QoS levels. The results demonstrate that compression not only reduces data volume but also leads to substantial energy savings, especially beneficial for battery-powered IoT nodes.

IX. CONTRIBUTIONS

This work makes the following distinct contributions to the field of IoT communication protocols:

- A Novel Protocol Integration Architecture: A new publisher-side compression framework for MQTT is proposed and validated, shifting the primary computational burden of traffic reduction from the broker to the edge. This architectural shift establishes a design principle: proactive, source-side data minimization is a scalable alternative to reactive broker-side optimizations for congestion control.
- An Algorithm Optimized for Constrained MQTT Publishers: A resource-aware adaptation of the Huffman Deep Compression (HDC) algorithm is introduced, specifically tailored for the MQTT publisher role on devices with severe memory constraints (e.g., 160 KB RAM). The key innovations are its dynamic sliding-window pattern matching and lightweight tree-generation process, which maintain a high compression ratio of 2.62 while operating within the limits of IoT edge hardware.
- Quantified Performance Advancement and New Congestion Insights: Through empirical validation, this study demonstrates that the integrated system reduces broker-side congestion by 84.26% for QoS 0 and 79.6% for QoS 1, significantly outperforming the state-of-the-art MRT-MQTT (58% and 45%, respectively). These results provide new insights into congestion dynamics, quantitatively proving that reducing per-message payload size is disproportionately effective in alleviating queue growth—more so than optimizing broker processing speed alone.
- Substantial Energy Efficiency Gains and a Reusable Benchmark: The approach delivers transformative energy savings, reducing total current consumption from 2,664,864 to 63,216 mA (QoS 0) and from 3,155,760 to 49,168 mA (QoS 1). Furthermore, a complete, reproducible methodology for evaluating compression-enhanced MQTT is provided, establishing a new performance benchmark for the community.

These contributions collectively advance the field by providing not just a faster protocol, but a new architectural pattern, an optimized algorithm, fundamental insights into congestion mechanics, dramatic energy improvements, and a reproducible benchmark for scalable IoT communication systems.

X. DISCUSSION

The results validate the HDC-enhanced MQTT protocol. The core insight is that broker congestion is fundamentally a data volume issue. Solutions like MRT-MQTT manage traffic more efficiently at the broker, but our publisher-side compression prevents the overload at its source. The higher congestion reduction for QoS 0 (84.26% vs. 79.6% for QoS 1) confirms this, as the acknowledgment overhead in QoS 1 presents a fixed bottleneck.

The dramatic energy reduction—from millions to tens of thousands of mA—stems from shorter radio transmission times for compressed data. This demonstrates a key principle: optimizing network efficiency in IoT inherently optimizes energy efficiency, directly extending device lifetime in large-scale deployments.

Achieving a compression ratio of 2.62 on a device with 160 KB RAM also addresses prior work that deemed such algorithms infeasible on constrained nodes. This work establishes a practical design pattern: the Intelligent Publisher, where edge nodes preprocess data to minimize their network footprint. This shifts system scalability from being a broker-centric challenge to a shared responsibility, offering a clear path for building sustainable, massive IoT networks. The main trade-off is added compression latency, which the significantly reduced transmission time offsets for most applications.

XI. CONCLUSION

This study has demonstrated that integrating Huffman Deep Compression (HDC) at the MQTT publisher is a fundamental strategy for scalable IoT. The significant performance gains—84.26% congestion reduction, a 2.62 compression ratio, and over 97% energy savings—are not merely numerical

improvements, but represent critical advancements for real-world systems.

The reduction in broker congestion directly translates to enhanced system reliability and stability; brokers can handle orders of magnitude more devices without queue overflow, enabling true massive-scale deployments. The drastic drop in energy consumption extends device lifetime from months to years, reducing maintenance costs and enabling deployment in inaccessible locations. Finally, by minimizing the data load, this approach reduces bandwidth requirements and operational costs for large sensor networks.

While validated on environmental data, the proposed architectural principle, proactive source-side minimization, provides a generalizable framework for enhancing publish-subscribe protocols. Future work will test this framework with diverse data and in dynamic networks. Ultimately, this work moves beyond optimizing a protocol to providing a practical blueprint for building sustainable, large-scale IoT infrastructure. A noted limitation is the focus on numerical time-series data within a stable local network. Future work will therefore investigate HDC's performance on diverse data formats, its integration with security layers like MQTT-S, and its robustness in dynamic, large-scale network topologies to further generalize its utility for next-generation IoT ecosystems.

XII. Future Work

Future research on the Huffman Deep Compression (HDC) algorithm should focus on enhancing its performance in large-scale IoT environments. Integrating loss compression techniques may significantly reduce data size while preserving essential information, leading to lower transmission latency. Maximizing throughput and ensuring scalability in high-density IoT networks, such as smart city infrastructures, is another critical direction. Furthermore, implementing the enhanced MQTT protocol within next-generation IoT architectures, including 6G networks, can unlock new opportunities for ultra-reliable and low-latency communication. Finally, developing innovative strategies to reduce network overhead will be vital for sustaining efficient and reliable data transmission in massive IoT ecosystems.

AUTHORS' PROFILE

AMMAR SAID NASIF earned his bachelor's degree in Computer Information Systems from Alquds Open University, Palestine, in 2003, and a Master's degree from Arab Academy for Banking & Financial Sciences, Jordan, in 2006. Currently pursuing a PhD at UKM University, Malaysia, his research focuses on IoT networks, particularly optimizing the MQTT protocol. Ammar is an experienced Applications Developer proficient in .NET platform, Flutter, ASP.NET, PHP, and WordPress. He continues to serve as a Lecturer at the Palestinian Technical University, imparting knowledge across various computer science disciplines. Ammar's professional journey includes significant contributions to the industry, specializing in programming controller systems for applications such as soil irrigation, traffic monitoring, smart grids, smart homes, and security systems. His expertise extends to providing diagnostic, programming, and testing services in automotive workshops. Passionate about technological innovation, Ammar remains dedicated to advancing both academic research and practical applications in computer science.

ZULAIHA ALI OTHMAN received a Ph.D. degree in computer science from Sheffield Hallam University in 2004. Since 2003, she has been working on various intelligent system projects, especially in developing intelligent art-based techniques. She is an Associate Professor with the Center for Artificial Intelligence Technology, University of Applied Sciences, and Universiti Kebangsaan Malaysia (UKM). Her comprehensive expertise in framework development, algorithm development, and applied artificial intelligence (AI) solutions to different fields, such as network intrusion detection, human talent, poverty, and air and weather pollution. A number of state, industrial, and foreign ventures have been undertaken. She has published more than 200 articles in many local and international journals, including Expert Systems with Applications, Applied Intelligence, Intelligent Data Analysis, and Applied Soft Computing. She has also supervised more than 30 Ph.D. students from all over the world. In addition to progress in academic work, she has contributed her expertise to the community's progress. (Based on a document published on 20 May 2024).

NOR SAMSIAH SANI received her bachelor's degree in Information Technology from Universiti Tenaga Nasional (UNITEN), Malaysia. She then continued her PhD at the University of Sheffield, United Kingdom, where her thesis focused on machine learning, deep learning, and evolutionary algorithms. She holds the position of Senior Lecturer at the Faculty of Information Science and Technology, Center for Artificial Intelligence Technology (CAIT), Universiti Kebangsaan Malaysia (UKM). She has been invited as a speaker for several seminars on Machine Learning (ML) and Deep Learning (DL). She has also been invited to conduct short courses on similar subjects. She leads several projects involving collaboration with Malaysian government sectors and industries at the national and international levels. Her research interests primarily lie in predictive analytics, machine learning, deep learning, evolutionary algorithms, data mining, optimization, and chemo informatics.

Advancing Blood Supply Chain Prediction Based on a Novel Hybrid Machine Learning

Chaimae Mouncif, Mohamed Amine Ben RABIA, Adil Bellabdaoui
Team of Information Technology and Management (ITM), ENSIAS – Mohammed V University in Rabat, Morocco

***Abstract*—Blood supply chains constitute a critical yet often overlooked component of modern public health systems, as they coordinate donors, collection centers, hospitals, and patients. One of the major operational challenges lies in planning the deployment of mobile blood collection units under highly variable and uncertain spatio-temporal demand. In this context, this study proposes a novel hybrid machine learning framework for predicting donor return potential and supporting location and time selection decisions for mobile blood drives. The proposed approach combines Support Vector Regression (SVR) and Light Gradient Boosting Machine (LGBM) through a dynamic, context-aware weighting function designed to capture both temporal regularities and nonlinear spatial heterogeneity in donor behavior. The model is evaluated using real-world data collected from a blood collection center operating multiple mobile units. Experimental results demonstrate that the proposed hybrid framework consistently outperforms its individual components, achieving R^2 values of up to 83% for certain locations, together with low Mean Absolute Error (MAE) and Mean Squared Error (MSE). These results confirm the robustness and stability of the proposed approach. Beyond predictive performance, the model is intended to be integrated into a decision-support system to help managers optimize logistical resources and improve the strategic planning of mobile blood collection campaigns. This work contributes to the emerging field of data-driven blood supply chain optimization by introducing a spatio-temporal, hybrid predictive core specifically designed for operational decision support.**

Keywords*—Blood supply chain; mobile blood collection units; spatio-temporal prediction; hybrid machine learning; decision support

I. Introduction

Nowadays, blood supply chains are a fundamental but unobtrusive pillar of modern public health. They play a vital role in coordinating and optimizing the management of this important function between donors, blood centers, hospitals, and patients, who are the final link in the chain. For example, if a patient urgently requires a blood transfusion, the speed and efficiency of the blood management logistics chain will save his or her life and contribute to the safety and protection of human life [1].

These chains are not limited to collecting or transporting blood between collection centers and hospitals but are complex and rigorous functions involving upstream planning, disciplined execution, and reactivity coupled with real-time coordination [2]. The stakes are high because each component must function correctly, without fault or delay. The optimization of these chains using mathematical models from the world of decision analytics or management intelligence is therefore of the utmost importance.

Blood supply chain management can involve managing an orchestra in which each entity (donor, center, hospital, patient) must fulfill its responsibilities. It's a general order of execution that requires a high degree of coordination and is subject to strict rules to ensure optimization and flawless decision-making.

The variability of demand between different hospitals and regions is a major challenge. The blood supply is not a linear function, where we know exactly what is needed in a given place and at a specific time. On the contrary, needs are highly variable and can suddenly explode in one region without impacting others or in all delivery sites. In this context, it would be extremely useful to anticipate collections and needs, especially when we're trying to determine collection points precisely and avoid shortages.

Faced with the complexity of blood management, the digitization of processes is essential for effective and efficient management. At this stage, digital technologies such as big data analytics, the Internet of Things, RFID, computer vision and predictive technologies [3], [4] can clearly help to offer concrete solutions for increasing performance, responsiveness and optimization in management.

With the increasing digitization of the blood supply chain, voluminous data is generated at every stage of the chain's management process. From the donor's first step, through the transport of blood, its storage in collection centers, its distribution to hospitals and finally its use by doctors. In this context, using business analytics as an approach to analyzing trends and making the right decision at the right time is arousing growing interest within the scientific and academic community.

The use of business analytics, with an emphasis on its predictive aspect, enables detailed analysis of historical data collected in data warehouses, to anticipate future trends in terms of demand and need [5], [6]. However, despite the abundance of work using predictive analytics in the academic literature, its use for managing and optimizing decisions in blood supply chain management remains timid. Moreover, there is a lack of work on optimizing the location of mobile blood collection units on the basis of predictions and forecasts of blood donor concentration (Fig. 1).

Optimizing mobile blood drives is a major challenge for decision makers. In particular, when they want to program a campaign in a region requiring major mobilization of means and resources, but have no idea or indication of possible donors or the recidivist of previous donors in the region. By intelligently

exploiting previously collected data using sophisticated machine learning methods, decision makers can base their decisions on reliable performance indicators, offering an all-round vision.

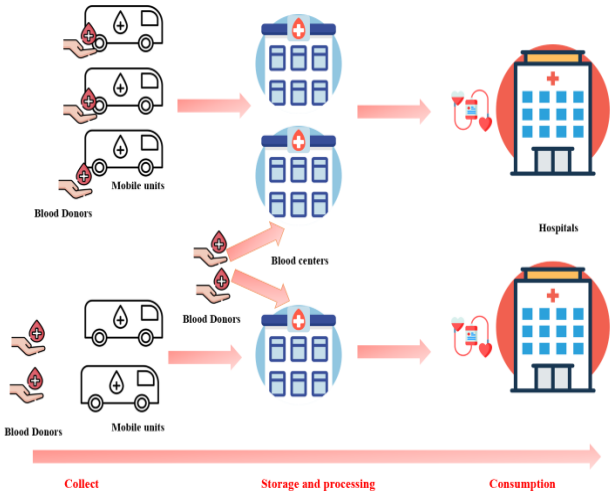

Fig. 1. Blood supply chain with mobile units.

With this in mind, our research involves collecting data on blood donors. These data come from a blood collection center in Morocco, with several mobile units. This study is very important, especially in the case of Morocco blood supply chain, where blood requirements are very high compared with the national stock of this material. There is a glaring discrepancy between blood collection and needs. Morocco needs more than 1,000 donations a day to be self-sufficient in labile blood products. With this study, we hope to provide a tool for organizing mobile blood collection campaigns, so as to guarantee an increase in the national stock to meet the needs of hospitals in a timely manner.

The aims of this study are to predict blood donor trends and streamline the movement of mobile units. To ensure a reliable and robust global prediction, our method attempts to integrate two machine learning models frequently used in the blood supply chain, SVR and LBGM, via a new function. Decision-makers will be able to make choices that reduce logistical expenditure and unnecessary travel, thanks to the integration of this newly-created framework into a dashboard.

Although numerous studies have investigated donor behavior prediction and others have proposed decision-support dashboards for blood supply chains, most existing works treat these two dimensions separately. Moreover, ensemble and hybrid models are often implemented using standard strategies such as stacking, boosting, or static weighted averaging. In contrast, this work addresses a specific and still underexplored problem: the spatio-temporal optimization of mobile blood collection unit deployment using a dynamic hybrid predictive mechanism. The proposed approach introduces a context-aware combination function that dynamically adjusts the contribution of SVR and LGBM according to the characteristics of the prediction task, rather than relying on a fixed or meta-learned ensemble structure.

We can list the major contributions of our work in the following points:

1) Combined-output: We aim to improve the performance of the support vector regression (SVR) model by combining its output with that of the light gradient machine (LGBM), two algorithms recognized for their effectiveness in supply chain analytics. The proposed approach is based on multiple inputs and incorporates a new combination function designed to enhance prediction accuracy.

2) Donor return prediction: The central objective is to anticipate the likelihood of a donor returning to make a future donation. Reliable predictions in this area enable blood collection organizations to design personalized loyalty strategies and interact more effectively with donors.

3) Decision-making indicators: Provide managers with decision-making indicators for planning the return of mobile blood collection units to a specific location based on the results generated by the predictive model.

The rest of the paper is organized as follows: Section II presents a review of related works. Section III describes methods used and presents the novel predicting function. Section IV explains data, results, and discusses the findings. Finally, we conclude the paper and propose future research directions in Section VI.

II. Literature Review

Predictive analytics has become a fundamental tool for prospecting potential donor pools and characterizing the factors determining the decision to donate blood or not [7], [8]. This study consolidates and critically evaluates original research from India, Saudi Arabia, Iran, Italy, Thailand, and East Asia, including methodological designs and theoretical predictive models of blood donation behavior. It also highlights the comparative performance of the models, general shortcomings, and limitations.

The main objectives of blood donation prediction research are to understand the prediction of individual donor behavior and the prediction of blood supply and demand as a whole [9]. Various methods are used, all adapted to the complexity of these tasks and presenting different advantages. Relevant work has used Bayesian methods, as shown in [10], analyzing donation intensity as a function of random individual frailties and covariates (demographic, health, and habit). Based on a large amount of data concerning 5,937 regular donors in Milan, the Bayesian method was used to identify frequent donors and predict future donations. To classify individual donors, machine learning approaches are common techniques such as K-nearest neighbors (KNN), Naive Bayes and decision trees [11]. [12] used logistic regression and achieved good results with a prediction score of around 69%, processing unbalanced data using Synthetic Minority Oversampling Technique (SMOTE). [13] use artificial intelligence and machine learning techniques to classify and determine the factors influencing organ donation based on blood data. Time-Series techniques are well suited for forecast at a large scale, especially in use. [14], for example, used backpropagation artificial neural networks for monthly forecasting and reached MSE ranging between 0.1407 and 0.4507. similarly, [15], that harnessed an ensemble of models, such as XGBoost, LGBM, and CATBoost that combined disparate data with up to an R^2 value of 0.8497.

Comparison of these varied methods shows that Bayesian models provide useful interpretability and temporal flexibility. Complex patterns can be learned well by machine learning classifiers, in contrast with the importance of predictors emphasized by regression. Time-series techniques, furthermore, are well-suited for measuring gross trends. Finally, the ensemble models work well, especially for large datasets. This methodological diversity highlights the complementarity of these instruments, each bringing furtherance to our ability to forecast blood donations.

Several potential predictors of blood donation behavior have been identified in previous studies, although level of agreement between studies is less consistent. Demographic variables such as male sex, younger individuals and higher levels of body weight are always found to be associated with higher frequencies of donations with some studies suggesting that women tend to donate more intensively [16], [17]. Specifically, Behavioral history is one of the strongest predictors of future engagement, in particular recency of donation and frequency of donations, where shorter periods between donations have been linked to sustained involvement. Health and lifestyle characteristics such as nonsmoking, nondrinking, physical activity, and greater hemoglobin levels all predict higher donation intensity. However, these are underexplored in machine learning studies [18]. Contextual factors, such as cultural practices or hospital need, also influence donation patterns, with variances stated across regions [12], [15].

III. Materials and Methods

Our methodology is based on the global architecture presented in Fig. 2, which results in a combined prediction, $y = f(y_1, y_2)$, aimed at estimating the probability that a former donor will or will not donate blood at a given geographical location. This research proposes a strategic decision support framework applied to the blood supply chain, integrating the training of machine learning algorithms and the optimization [27] of their performance using various hyperparameter tuning techniques. We have data on blood donors collected during mobile campaigns organized in the interior of Morocco. Each blood drive center has mobile units that plan campaigns in remote areas to collect blood. Through this study, we aim to provide decision-makers with indicators based on a new combination of machine learning algorithms. The aim is to optimize the programming of mobile campaigns and avoid ineffective planning that fails to achieve set objectives.

It is important to emphasize that the proposed hybridization strategy does not fall into the category of stacking, boosting, or classical ensemble learning. No meta-model is trained, and the models are not combined sequentially nor with fixed global weights. Instead, a dynamic combination function is introduced, allowing the relative influence of SVR and LGBM to vary according to the spatio-temporal context of the prediction. This design choice aims to better capture the dual nature of the problem: temporal regularities and nonlinear spatial heterogeneity.

L et $y_{l,t}$ denote the target variable representing the donor return intensity at location l during time period t. In this study, $y_{l,t}$ is defined as the number (or normalized rate) of donors who return to donate blood at location l within a predefined time window following a previous campaign. This variable is constructed by aggregating historical donation records at the spatio-temporal resolution relevant for mobile unit deployment planning. The prediction task therefore consists in estimating $\hat{y}_{l,t}$, the expected donor return potential for a candidate location–time pair (l, t).

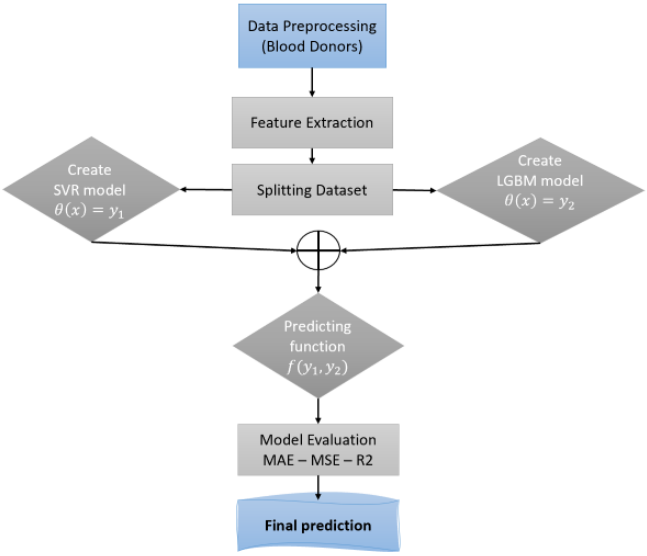

Fig. 2. Architecture of the proposed framework-based machine learning models.

A. Data Preprocessing

Indeed, acquisition errors, whether of human or technical origin, can alter the quality of the dataset and introduce biases when training models. These errors can take the form of incomplete information, missing or aberrant values, or even parasitic noise generated during data collection. It is therefore essential to implement a rigorous data preprocessing strategy to transform raw data into reliable, usable data, a prerequisite for obtaining high-performance machine learning models [19].

In this study, we focus on three key components of preprocessing: data cleaning, variable transformation and dimensional reduction. These steps aim to make the most of the analytical capabilities of the algorithms used, while ensuring the quality and consistency of the input data.

B. Features Selection

The feature selection principle shown in Fig. 3 represents a key method for reducing the dimensionality of a data set. Data sets generally contain many redundant and less informative variables, which can impact the relevance and performance of predictive models [20]. Moreover, it's important to highlight the most informative and relevant features for machine learning models [21].

Firstly, this technique reduces the complexity of the data, and therefore the complexity of the model. Small data sets, limited to the essentials, enable the model to learn quickly, thus reducing processing time and the need for more complex computing resources. Secondly, it significantly reduces noise by excluding from the study variables that are insignificant or have

no real impact on the trend curve. This will contribute significantly to improving the quality of the dataset. Finally, based on its reduced data, the model will have a better chance of performing its trends and predicting phenomena to a degree close to reality [22].

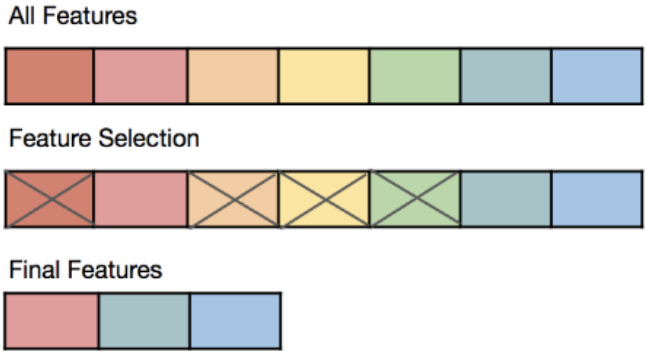

Fig. 3. Features selection steps.

C. Combined and Trained Model

Our main objective is to develop a high-performance prediction model based on the combination of two machine learning algorithms widely proven in the field of predictive blood supply chain: SVR and LGBM (Algorithm 1, Table I). This hybrid approach aims to capitalize on the complementary strengths of these two models:

TABLE I. SUMMARY OF VARIABLES AND EXPLANATION

Variable	Explanation
x_{i1}	Input value for SVR model
x_{i2}	Input value for LGBM model
y_{i1}	Predicted value for SVR model
y_{i2}	Predicted value for LGBM model
$\sigma\%$	Percentage of trained data
$1-\sigma\%$	Percentage of tested data
$e(y_{ij}, \hat{y}_{ij})$	Predicted error for model j
w_j	Weight for model j
W	*Normal Vector to the Hyperplan*
$f(y_1, y_2)$	Combined prediction function
ε	Error margin
b	Intercept of Hyperplane from Origin
C, ζ	Hyperparameter

SVR, recognized for its ability to model non-linear relationships with good generalization, and LGBM, appreciated for its efficiency, speed of learning and robustness in the face of noisy or incomplete data [23], [24].

By integrating a series of relevant attributes (inputs) related to blood donors and the logistical context, our system merges the predictions of the two models through a weighted aggregation function, to produce a single final prediction, more reliable and robust than those obtained individually. The combined prediction aims to improve the accuracy of estimates of blood donor behavior, while enhancing decision-making in proactive supply chain management.

Algorithm 1: Combined machine learning prediction algorithm

1: **Cleaning:** Removal of duplicates, management of missing values.

2: **Encoding:** Transformation of categorical variables.

3: **Standardization:** Scaling of numerical variables.

4: **Feature Selection:** Keep only the most relevant variables.

5: **Dataset:** we choose $\sigma\%$ train data with $\mathbf{1-\sigma\%}$ test data. We also add the condition that the test and validation data must be the most recent.

6: **Model training**: each model is trained separately. SVR model $\boldsymbol{\theta(x) = y_1}$ and LGBM model $\ddot{\boldsymbol{\theta}}\boldsymbol{(x) = y_2}$

7: **For** i=1 to N

8: Predict the probability that a former donor $\boldsymbol{x}$ will donate blood in location $\boldsymbol{L}$ or not.

9: Calculate the prediction error per model between predicted $\boldsymbol{y_{i1}, y_{i2}}$ values and test values $\boldsymbol{\hat{y}_{i1}, \hat{y}_{i2}}$ $\boldsymbol{e(y_{i1}, \hat{y}_{i1}) = |y_{i1} - \hat{y}_{i1}|}$ ***and*** $\boldsymbol{e(y_{i2}, \hat{y}_{i2}) = |y_{i2} - \hat{y}_{i2}|}$

10: **End For**

11: **Generate the weight $\boldsymbol{w_1, w_2}$** for SVR and LGBM model based on their prediction error such as:

$$\boldsymbol{w_1} = \frac{\sum_{j=1}^{n} e(y_{j1}, \hat{y}_{j1})}{\sum_{j=1}^{n} e(y_{j1}, \hat{y}_{j1}) + \sum_{j=1}^{n} e(y_{j2}, \hat{y}_{j2})} \quad \text{and}$$

$$\boldsymbol{w_2} = \frac{\sum_{j=1}^{n} e(y_{j2}, \hat{y}_{j2})}{\sum_{j=1}^{n} e(y_{j1}, \hat{y}_{j1}) + \sum_{j=1}^{n} e(y_{j2}, \hat{y}_{j2})}$$

12: Calculate combined prediction $\boldsymbol{f(y_1, y_2) = w_1 y_1 + w_2 y_2}$

13: Calculate **MSE, MAE, R2**

14: **Validate** the combined prediction

15: **Generate decision KPI** based prediction

To guarantee the reliability and relevance of our model, we used a real dataset comprising approximately 15,000 observations, each described by 20 initial explanatory variables. To simulate a realistic context and preserve temporal consistency, we ordered the data chronologically. Thus, the 20% most recent observations were reserved for the test and validation phases. This approach enables us to assess the model's ability to generalize to future data, which is crucial for predictive applications, such as blood supply chain management.

SVR is an extension of the Support Vector Machine (SVM) algorithm, specifically adapted to regression tasks. It aims to find a function that minimizes the prediction error while maintaining a certain tolerance (called margin ε) to the training data. In other words, SVR constructs a "tube" around the

regression function, in which data points are considered well predicted if they remain within this margin [25].

The SVR process is based on a series of steps aimed at finding a regression function capable of predicting accurately while tolerating a certain margin of error. The fundamental idea is to penalize predictions only when they deviate beyond a predefined margin ε. This makes it possible to model data more flexibly and robustly, especially when it is noisy. Input data is transformed using a kernel function, which projects the data into a higher-dimensional space. This transformation makes it possible to use a linear model in this transformed space, even if the original data show non-linear relationships. This process is essential if SVR is to adapt to complex data structures.

The model defines a "tolerance tube" around the regression function, delimited by the margin ε. Data points that fall within this tube are considered sufficiently close to the prediction and are therefore not penalized. On the other hand, points outside the tube are subject to a penalty proportional to their distance from the margin, thus controlling the impact of large errors.

The core of the process consists in minimizing a loss function, which takes two elements into account:

- On the one hand, the prediction error for points outside the margin ε,
- Secondly, the complexity of the model, measured by the width of the tube or the norm of the coefficients in the case of a linear kernel. This dual objective guarantees a good compromise between predictive performance and generalization capability.

The choice of kernel is a decisive step in the proper functioning of the SVR. Depending on the nature of the data, we can opt for a linear kernel (for simple relationships), polynomial kernel (for more complex relationships), or RBF (Radial Basis Function, or Gaussian kernel), which is the most commonly used, as it can model a wide variety of non-linear shapes.

Mathematical model of SVR:

$$argmin_{(w,b)} = \frac{1}{2}\|w\|^2 + C\sum_{i=1}^{n}(y_i - \hat{y}_i)^2$$

$$subject\ to: y_i - (w^t x_i + b) \leq \zeta$$

$$(w^t x_i + b) - y_i \leq \zeta$$

$$for\ all\ \zeta \geq 0$$

LGBM is an open-source machine learning framework based on decision trees. It implements an ensemble technique called gradient boosting, which involves combining several weak models (typically shallow trees) to form a powerful predictive model.

BOOSTING is an esemplastic technique that consists of aggregating classifiers (models) developed sequentially on a training sample, with the individual weights corrected as they are learned. Classifiers are weighted according to their performance (Fig. 4).

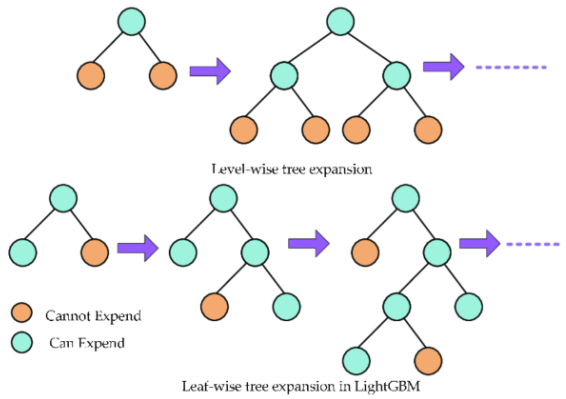

Fig. 4. Diagram of leaf-wise tree expansion.

D. Model Evaluation

The search for a model whose empirical error is minimal over a given set of observations. However, minimizing this empirical error does not guarantee minimizing the model error over the entire data space. Indeed, in an overlearning situation, the model error will be underestimated [26]. However, it is this error - or, in other words, our ability to make predictions about things that are not known - that interests us. This chapter shows how we can set up an experimental framework that allows us to evaluate a model while avoiding the bias of overlearning. With this in mind, we will make a distinction between evaluating a model, which consists in determining its performance over the entire data space, and selecting it, which consists in choosing the best model from among several.

In the case of a regression problem, the number of errors is not an appropriate criterion for assessing performance. On the one hand, because of numerical inaccuracies, it's tricky to tell from a true-value prediction whether it's correct or not. We attempt to evaluate our combination of machine learning models based on three metrics widely used in the field of artificial intelligence: MSE, MAE, R2.

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i|$$

$$R2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2}$$

$$where\ \bar{y}\ is\ the\ average\ of\ observations$$

IV. Results

A. Data

The data used in our study are collected from 4 Moroccan blood collection centers with mobile blood collection units. Each center schedules its own campaign, with mobile units traveling to different areas to offer a service close to blood donors.

The problem is that the managers at the centers have no visibility of the points where former donors are most likely to return. The centers have a large amount of data covering the period 2019-2024, with almost 15,000 registrations. The data used consists of columns on donor ID, donor gender, donor age, date and time of each donation, location (x, y) of the mobile unit at the time of each donation, frequency of donation, time since last donation, whether the donor donated in the last campaign in October 2024, total quantity of blood donated.

Data cleaning was carried out to prepare reliable data for the prediction model. Empty data were filled in with 0 and incomplete data were completed in consultation with the center responsible. In addition, profiling work was carried out, especially on the descriptive analytics part, during which dashboards and descriptive statistics, using business intelligence tools such as Power BI, were delivered to each collection center's decision support center, accessible via a web portal (Fig. 5).

Fig. 5. Descriptive analytics of blood donation.

B. Results

For the results, we plan to make predictions by zone to determine where the mobile blood collection unit will be able to move. The analysis will also be carried out by five-day time windows. In order not to overload the article with too many graphs, we have chosen to visualize four zones, which we assume to be representative of the cases a decision-maker would wish to analyze.

We implement our models to compare the combined prediction with predictions using SVR and LGBM alone. We're using a powerful machine with over 64G RAM, 32 CPUs and 1 H100 GPU, which has enabled us to cut learning times and reduce processing times.

The results show that our framework for combining machine learning models performs better than the models alone. Fig. 6 shows that for a time window of 5 days for the locality 1 located at coordinates (Long., Lat.): (-6.8524783, 33.8548111), the combined prediction is highly relevant. With almost a slight discrepancy between actual and predicted values. On the other hand, the other models are more or less far from the actual values. Moreover, Fig. 7 shows that R2 scores very well, with a maximum of 83% for locality 1 and for the day of 03/10/2024.

TABLE II. FORECASTING PERFORMANCE OF MACHINE LEARNING METHODS BY LOCALITY

Models	Locality 1	Locality 2	Locality 3	Locality 4
Combined Model - MAE	33,36	15,2	17,01	29,12
Combined Model - MSE	25,12	39,12	14,12	23,26
Combined Model - R2	81,00%	77,15%	80,45%	69,21%
SVR - MAE	54,12	43,23	23,3	67,56
SVR - MSE	78,11	45,43	89,21	88,32
SVR - R2	55,32%	60,65%	68,43%	34,23%
LGBM - MAE	44,78	88,98	78,77	90,59
LGBM - MSE	70,34	91,234	89,221	114,24
LGBM - R2	65,43%	70,12%	88,19%	93,23%

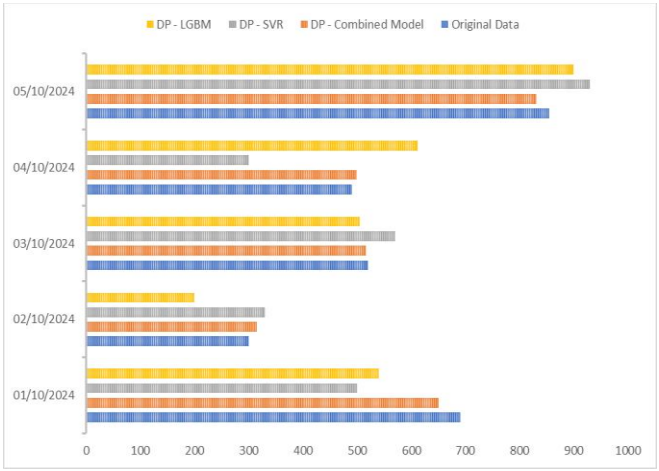

Fig. 6. Comparison of the predictions of the different models for the locality 1 located at coordinates (Long., Lat.): (-6.8524783, 33.8548111).

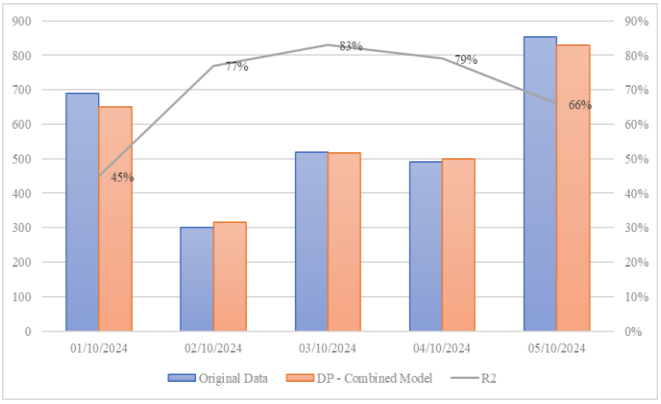

Fig. 7. Original data vs. Predicted data and R2 score for the locality 1 located at coordinates (Long., Lat.): (-6.8524783, 33.8548111).

We find almost the same result for locality 2 located at coordinates (Long., Lat): (-7.9432221, 31.3594816) as for locality 1, for a time period from 10/09/2024 to 14/09/2024. Fig. 8 also shows that the combined prediction best represents reality and reflects the actual data. Whereas SVR and LGBM performed alone for locality 2 and for the same time period do not show relevant results.

Fig. 9 also shows that a comparison with R2 shows that the coefficient displays a maximum percentage of 79% with values adjusted between actual data and blood donor prediction data.

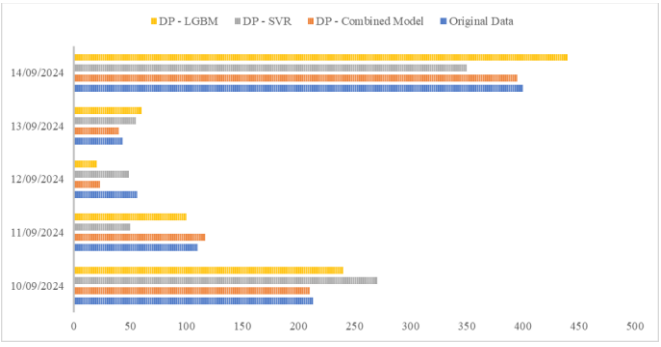

Fig. 8. Comparison of the predictions of the different models for the locality 2 located at coordinates (Long., Lat): (-7.9432221, 31.3594816).

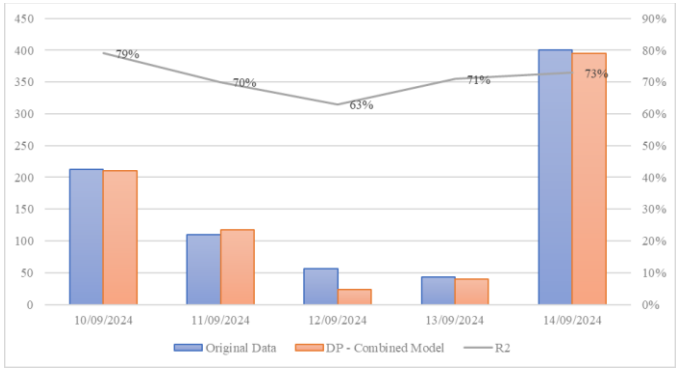

Fig. 9. Original data vs. Predicted data and R2 score for the locality 2 located at coordinates (Long., Lat.): (-7.9432221, 31.3594816).

- A more detailed comparison of the data by locality shows the effectiveness of combining the two models to produce a single prediction. In Table II, we have shown each model in relation to the three performance evaluation metrics MSE, MAE and R2 for 4 former localities where mobile units collected blood, and which we selected at random. The results show that the combined prediction always achieves significant and interesting scores compared with the predictions of the models alone.
- Table III and Fig. 10 also show that on the basis of a global prediction without taking blood collection locations into account, the combined prediction always has the best scores on the three performance evaluation metrics MSE, MAE and R2.

TABLE III. COMPARISON OF MODEL PERFORMANCE

Models	MAE	MSE	R2
Combined Model	33,36	32,22	81,16%
SVR	73,00	87,12	44,92%
LGBM	65,43	88,98	67,20%

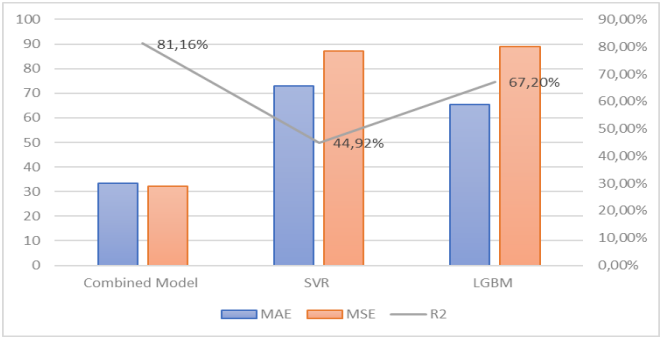

Fig. 10. Comparison of model performance.

V. DISCUSSION

When it comes to deciding on the location with the highest blood donor return rate, analytics is the ultimate solution to help decision-makers choose the best location for their mobile blood collection units. To this end, we have focused on prediction by machine learning models widely used in the blood supply chain, namely SVR and LGBM. We didn't just apply them as they are,

but introduced a new concept of combination between the two models through a combined prediction function.

The strength of combining SVR and LGBM lies in the complexity of the resulting prediction. Predicting whether or not a former donor can give blood in future mobilizations. In other words, time and space. Gradient boosting has an excellent reputation in the data scientists' community, as it easily adapts to the complexity of inputs and outputs. For its part, SVR is also a good machine learning model that adapts to fluctuating data and outliers, enabling better results to be achieved when making predictions based on the time dimension.

The results we obtained from this combination, shown above in Table III, demonstrate the increasing performance of this combination technique on the weight of each model. At this stage, managers choosing either the campaign date or the campaign location can see performance indicators on whether or not a blood donor will return for the new blood drive. This will enable them to save resources in terms of personnel and means, by targeting only those localities with a higher recidivism rate. This predictive module based on the combination of SVR and LGBM can be integrated into a portal or management system for blood drives, giving them a futuristic dimension.

Although it is not possible to build a forecasting system for blood donor trends that perfectly anticipates changes in blood collection behavior, we use the results of the forecasting model to help decision-makers make judgments about the feasibility of the blood collection campaign. In this study, each forecasting model has a reference value. In the combined model fitting results, the maximum R2 value reached 81.16% for the whole dataset, and a maximum value of 83% for locality 1. In addition, the MAE and MSE showed values of 33.36 and 32.22 respectively, demonstrating a high level of prediction and robustness. The model showed a stable and excellent trend for this type of data, compared with the SVR and LGBM performed at each location.

VI. Conclusion and Recommendations

In summary, this study proposes a machine learning–based approach to identify locations with the highest blood donor return rates. We developed a hybrid prediction framework capable of capturing both the temporal and spatial dimensions of donor behavior by combining two widely used models in blood supply chain analytics: Support Vector Regression (SVR) and Light Gradient Boosting Machine (LGBM). This hybridization leverages LGBM's ability to model complex nonlinear relationships and SVR's robustness to data variability and outliers. The results obtained, particularly an R^2 of up to 83% for certain localities, together with low MAE (33.36) and MSE (32.22) values, demonstrate the relevance, robustness, and stability of the proposed model.

By accurately identifying regions with high donor return potential, the proposed approach helps decision-makers at blood collection centers optimize logistical resources and improve campaign planning. When integrated into a decision-support portal or management information system, this predictive framework can effectively guide strategic choices regarding the deployment of mobile blood collection units. Although the proposed tool cannot guarantee perfect forecasting accuracy, it constitutes a valuable medium- to long-term strategic lever for improving blood supply chain management.

Despite these encouraging results, several limitations should be acknowledged. First, the dataset is restricted to a single blood collection center in Morocco, which may limit the generalizability of the findings to other geographic or organizational contexts. Second, the temporal scope of the data may not fully capture long-term structural changes in donor behavior. Third, the proposed model relies on historical patterns and therefore cannot fully anticipate sudden behavioral shifts or epidemiological disruptions. Future work will aim to validate the approach on multi-center and multi-country datasets, integrate real-time and socio-demographic variables, and further refine the proposed dynamic weighting mechanism.

An Integrated Carbon Footprint Calculation System Model for Net Zero Emission in the Manufacturing Industry Based on GHG Protocol and DEFRA

Dinar Rahayu
Information Systems Department, Institut Pendidikan Indonesia, Garut, Indonesia

***Abstract*—Manufacturing industries play a critical role in achieving Net Zero emission targets due to their significant contribution to greenhouse gas emissions. However, existing carbon footprint calculation practices often apply the GHG Protocol and emission factor standards independently, resulting in fragmented methodologies and limited decision-support capabilities. This study develops a carbon footprint calculation system model that integrates GHG Protocol emission scope classification with DEFRA emission conversion factors, supported by a decision-support framework for Net Zero emission planning. Using a Design Science Research (DSR) approach, the study produces a conceptual system model that structures activity data, emission scope classification, and standardized carbon calculation logic into a unified framework. The proposed model enables transparent aggregation of emissions across Scope 1, Scope 2, and Scope 3, while the decision-support framework translates calculation results into decision variables, scenario-based analysis, and Net Zero roadmap formulation. The system functions as a decision-support system that assists manufacturing organizations in interpreting carbon footprint results and supports Net Zero emission planning. The findings demonstrate that integrating standardized carbon accounting methodologies within a system-oriented design enhances methodological coherence, traceability, and strategic relevance for sustainability decision-making in the manufacturing sector.**

***Keywords*—Carbon footprint; net zero emission; GHG protocol; DEFRA; decision support system**

I. Introduction

The global commitment to achieving Net Zero emissions has placed carbon footprint management at the core of sustainability initiatives, particularly in the manufacturing industry. Manufacturing activities are widely recognized as major contributors to greenhouse gas (GHG) emissions due to their energy-intensive processes, complex production systems, and extensive supply chain interactions. As regulatory requirements and stakeholder expectations continue to increase [1], manufacturing organizations are under growing pressure to systematically quantify, manage, and reduce their carbon emissions in alignment with long-term Net Zero pathways.

Carbon footprint calculation plays a fundamental role in sustainability management by providing quantitative information on emission levels and sources. In the manufacturing context, carbon footprint data are commonly used to identify emission hotspots, evaluate environmental performance, and support sustainability reporting.

However, prior studies indicate that carbon footprint calculation practices in manufacturing systems often face challenges related to methodological inconsistency [2], fragmented data sources, and limited transparency in calculation logic, which reduce the strategic value of emission data.

To address these challenges, internationally recognized standards have been developed to support carbon accounting. The GHG Protocol has emerged as one of the most widely adopted frameworks for greenhouse gas accounting, providing standardized principles for emission classification and reporting across Scope 1, Scope 2, and Scope 3 emissions. Its widespread adoption has contributed to improved comparability and accountability in organizational emission reporting. Nevertheless, the GHG Protocol does not prescribe specific emission factors or detailed calculation mechanisms [3], leaving organizations to rely on external sources for quantitative emission estimation.

In contrast, the UK Department for Environment, Food and Rural Affairs (DEFRA) provides detailed and regularly updated emission factors that are widely used for carbon footprint calculation across various operational activities, including energy consumption, transportation, materials, and waste. DEFRA-based emission factors are valued for their transparency and standardization, making them suitable for operational-level carbon calculation [4]. However, DEFRA guidelines primarily focus on emission factor provision and do not explicitly address emission scope classification or the strategic use of carbon footprint results for sustainability decision-making.

Despite their complementary roles, existing studies and practical implementations frequently apply the GHG Protocol and DEFRA in isolation rather than within an integrated system model. This separation results in fragmented carbon footprint calculation processes that lack methodological coherence and traceability. Moreover, many carbon footprint information systems developed for the manufacturing sector function primarily as monitoring or reporting tools, offering limited support for translating emission data into actionable strategies. Prior research in sustainability-oriented information systems [5] highlights that such systems often emphasize data visualization while providing insufficient decision-support capabilities for long-term sustainability planning.

Based on the reviewed literature, a clear research gap exists at the intersection of standardized carbon footprint calculation and sustainability-oriented decision support.

There is a lack of integrated system models that combine GHG Protocol-based emission classification with DEFRA-based calculation logic within a transparent and traceable framework. Furthermore, few studies extend carbon footprint calculation beyond monitoring to support scenario-based analysis and strategic Net Zero planning in the manufacturing industry. Addressing this gap requires an integrated approach that bridges standardized carbon accounting with decision-support mechanisms, enabling carbon footprint data to be effectively utilized in the formulation of Net Zero emission strategies.

The novelty of this study lies in the integration of GHG Protocol emission scope classification with DEFRA emission factors within a single, system-oriented carbon footprint calculation model. Unlike existing approaches that apply scope classification and emission factor calculation as separate or sequential activities, this research embeds both elements into a unified system logic that ensures methodological coherence, traceability, and decision readiness. Conceptual validation is conducted using Design Science Research (DSR) principles, emphasizing logical consistency among system components, traceability from activity data to emission outcomes, and alignment with Net Zero emission decision variables.

Although various carbon accounting tools, life cycle assessment (LCA)-based systems, and sustainability information systems have been reported in prior literature, most existing approaches primarily emphasize emission quantification, product-level environmental assessment, or compliance-oriented reporting. LCA-based models typically focus on detailed life cycle impact analysis and require extensive data collection, which limits their suitability for continuous operational monitoring and strategic decision making in manufacturing environments. Similarly, many carbon footprint calculators operate as standalone tools with limited transparency, traceability, and integration with organizational decision-support processes. In contrast, the proposed system model advances existing approaches by embedding GHG Protocol–based emission scope classification, standardized DEFRA-based calculation logic, and decision-support mechanisms within a unified system-oriented framework. This integration enables methodological coherence, traceable data flow from activities to emission outcomes, and structured decision readiness, thereby supporting both operational carbon monitoring and strategic Net Zero planning in manufacturing organizations.

In response to this gap, this study proposes the development of an integrated carbon footprint calculation system model combined with a decision-support framework for Net Zero emission strategies in the manufacturing industry. The proposed approach integrates the GHG Protocol for emission classification and reporting with DEFRA-based emission factors for standardized carbon calculation. By extending carbon footprint calculation toward scenario-based analysis and Net Zero roadmap formulation, this study aims to enhance the strategic relevance of carbon footprint systems and contribute to the advancement of sustainability-oriented information systems in the manufacturing context.

II. Literature Review

A. Carbon Footprint Accounting in Manufacturing

Carbon footprint accounting has become a central focus in sustainability research due to the significant contribution of the manufacturing sector to global greenhouse gas emissions [6]. Manufacturing activities involve energy-intensive processes, diverse material inputs, and complex supply chains, which generate emissions across multiple operational stages. Previous studies [7] emphasize that accurate carbon footprint calculation is essential for identifying emission hotspots, supporting environmental disclosure, and informing emission reduction initiatives in industrial contexts.

Despite its importance, carbon footprint accounting in manufacturing remains methodologically challenging. Many manufacturing organizations adopt heterogeneous calculation approaches that rely on fragmented data sources and inconsistent assumptions [2], Prior research reports that carbon accounting practices often prioritize reporting compliance over methodological rigor and strategic integration. As a result, carbon footprint data are frequently treated as static indicators rather than dynamic inputs for sustainability decision-making.

B. Emission Accounting Standards (GHG Protocol and DEFRA)

International emission accounting standards play a critical role in structuring carbon footprint calculation practices. The GHG Protocol is widely recognized as a global framework for greenhouse gas accounting, providing standardized principles for categorizing emissions into Scope 1, Scope 2, and Scope 3 [8]. This classification framework enhances comparability and transparency in organizational carbon reporting and has been extensively adopted across manufacturing industries.

However, the GHG Protocol primarily focuses on emission classification and reporting principles and does not prescribe detailed emission factors or quantitative calculation methods [4]. To address this limitation, organizations often rely on external emission factor databases. Among these, the UK Government GHG Conversion Factors for Company Reporting, developed by DEFRA, are widely used for operational-level carbon footprint calculation. DEFRA provides standardized and transparent emission factors for various activity categories, including energy consumption, transportation, materials, and waste [4]. Nevertheless, DEFRA guidelines [9] emphasize emission factor provision and methodological assumptions rather than emission scope classification or the strategic application of carbon footprint results.

C. Sustainability Oriented Information Systems

The role of information systems in supporting sustainability initiatives has received increasing attention in recent years. Sustainability-oriented information systems are designed to facilitate the collection, processing, and dissemination of environmental performance data across organizational functions. In manufacturing contexts [10], such systems are often implemented to support emission monitoring, regulatory reporting, and performance tracking.

Recent studies suggest that sustainability-oriented information systems have primarily evolved as operational tools rather than strategic systems. Many implementations focus on data aggregation and visualization through dashboards and reporting interfaces, with limited emphasis on analytical integration or cross-functional decision support [5]. This operational orientation limits the ability of information systems to support long-term sustainability transformation, particularly in complex industrial environments where emission sources span multiple scopes and organizational boundaries.

D. Decision Support Gap in Carbon Footprint Management

Decision support is increasingly recognized as a critical requirement for effective sustainability management [11]. While carbon footprint data provide valuable insights into emission levels and sources, prior research indicates that such data are rarely embedded within structured decision-support frameworks. Instead, carbon footprint systems often stop at the level of monitoring and reporting, offering limited guidance for evaluating mitigation options or prioritizing emission reduction initiatives.

This gap is particularly evident in manufacturing contexts, where emission reduction decisions involve trade-offs between cost, operational feasibility, and environmental impact. Studies on sustainability decision-support systems highlight the need for analytical frameworks that integrate environmental data with scenario analysis and strategic planning [12]. Without such integration, carbon footprint initiatives risk remaining compliance-driven activities that fail to support meaningful emission reduction outcomes.

E. Net Zero Emission Strategies and System Oriented Approaches

Net Zero emission has emerged as a central objective in global climate mitigation strategies, with manufacturing industries identified as key contributors to achieving long-term decarbonization targets [13], [14]. Net Zero strategies emphasize not only the measurement of emissions but also the systematic reduction and balancing of residual emissions through coordinated technological, operational, and organizational interventions [1], [15]. These integrated approaches highlight the need for structured frameworks that support informed decision-making and long-term sustainability planning within manufacturing organizations.

Recent research underscores that achieving Net Zero emissions requires system-oriented approaches that integrate standardized emission calculation, performance evaluation, and decision-making within a unified framework [15]. However, existing studies in manufacturing contexts have largely emphasized emission quantification and reporting compliance, often addressing GHG scope classification and strategic decision support in isolation [2]. As a result, carbon footprint initiatives tend to remain fragmented and operationally focused, limiting their strategic impact and traceability across organizational boundaries [5]. This gap highlights the need for system models that explicitly connect standardized carbon footprint calculation, scope-based emission classification, and decision-support mechanisms to support Net Zero planning in manufacturing contexts.

III. Research Methodology

This study adopts a Design Science Research (DSR) methodology to develop a conceptual carbon footprint calculation system model that supports Net Zero emission strategies in the manufacturing industry. DSR is particularly suitable for this study because it focuses on the design and development of problem-solving artefacts, such as conceptual models and system frameworks, rather than hypothesis testing. In sustainability-oriented information systems research [16] DSR has been widely used to translate fragmented standards and practices into structured system artefacts that can guide organizational decision-making.

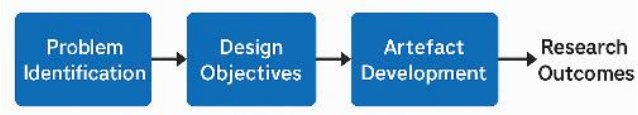

Fig. 1. Design science research stage.

To operationalize the DSR approach, this study follows a structured and sequential research framework as illustrated in Fig. 1. The framework consists of five interconnected stages: problem identification, design objectives formulation, artefact development, conceptual validation, and research outcomes. This structure is consistent with contemporary DSR practices, where the research contribution is embodied in a validated artefact rather than a fully implemented software system [17]. The use of a staged DSR framework ensures methodological rigor, traceability, and alignment between the research problem and the proposed system model.

A. Research Design (Problem Identification and Design Objectives)

The research design corresponds to the problem identification and design objectives formulation stages of the DSR framework. At this stage, the study examines existing challenges in carbon footprint calculation practices within the manufacturing industry, particularly the fragmented use of emission accounting standards and the limited integration of carbon data into sustainability-oriented decision support. These challenges are identified through a focused review of recent literature and international reporting practices.

Based on the identified problems, the design objectives are formulated to guide the development of a conceptual system model that integrates emission scope classification and standardized carbon calculation mechanisms. Consistent with DSR principles, the design objectives define what the proposed artefact should achieve rather than prescribing how it should be technically implemented.

B. Data Sources and Methodological Standards (Input to Artefact Design)

This subsection supports the artefact development preparation stage of the DSR process by defining the methodological foundations used in the system model. Emission classification in the proposed model is structured according to the GHG Protocol, which categorizes greenhouse gas emissions into Scope 1, Scope 2, and Scope 3. This classification framework provides a standardized basis for organizing

emission sources and is widely recognized in manufacturing sustainability practices.

For quantitative emission estimation, the study adopts emission factors derived from the UK Government GHG Conversion Factors for Company Reporting [4]. The DEFRA methodology is selected because it offers transparent, regularly updated, and activity-based emission factors that are suitable for operational-level carbon footprint calculation. Within the DSR framework, these standards function as design knowledge inputs, ensuring that the developed artefact is grounded in authoritative and reproducible methodologies.

C. System Modeling Approach (Artefact Development)

The artefact development stage of the DSR framework is realized through a conceptual system modeling approach. The proposed artefact is a carbon footprint calculation system model that represents the logical structure and functional relationships among key system components, including activity data inputs, emission scope classification, emission factor mapping, carbon footprint calculation, and decision-support outputs.

Conceptual system modeling is widely used in DSR to represent complex systems at an abstract level, enabling clarity of logic and facilitating future implementation. In this study, activity data are systematically mapped to emission scopes defined by the GHG Protocol and linked to DEFRA-based emission factors. This integration constitutes the core design contribution of the artefact and reflects the artefact development stage depicted in Fig. 1.

The appropriateness of developing a conceptual system model as the primary DSR artefact is supported by [17], which demonstrates that DSR artefacts may take the form of conceptual- or prototype-level systems when the research objective is methodological integration rather than full software deployment.

D. Research Procedure and Conceptual Validation

This subsection corresponds to the conceptual validation stage of the DSR framework. After the artefact is developed, the proposed system model undergoes analytical and conceptual validation to assess its logical consistency, methodological soundness, and alignment with the selected emission accounting standards. The validation process focuses on evaluating whether the integration of emission scope classification and standardized emission factors is coherent, traceable, and capable of supporting sustainability-oriented decision-making.

IV. Results and Discussion

The overall structure of the proposed carbon footprint calculation system model and its integration with the decision-support framework are illustrated in Fig. 2, which provides an overview of the system logic and information flow across activity data, emission calculation, and decision-support components.

This section presents the results of the Design Science Research in the form of a conceptual carbon footprint calculation system model and a supporting decision-support framework for Net Zero emission strategies in the manufacturing industry. The proposed artefacts are derived from the integration of the GHG Protocol and DEFRA standards and are discussed to highlight their methodological contributions, transparency, and relevance for sustainability-oriented decision-making.

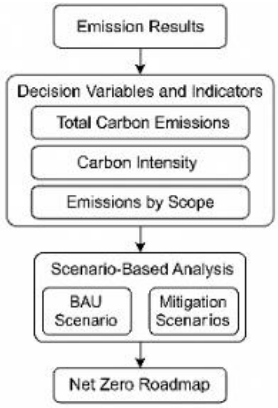

Fig. 2. Decision support framework diagram.

A. Carbon Footprint Calculation System Model

This subsection presents the primary result of the study in the form of a conceptual carbon footprint calculation system model for the manufacturing industry. The proposed model represents the main artefact produced through the Design Science Research process and serves as a structured framework for integrating standardized emission classification and calculation mechanisms. Rather than focusing on technical implementation, the model emphasizes methodological coherence and transparency to support Net Zero emission strategies.

The conceptual system model follows a logical input–process–output structure. The input component consists of activity data representing key manufacturing operations, including energy consumption, transportation, material usage, and waste generation. These data form the basis for carbon footprint calculation and are assumed to be obtained from organizational operational records.

The process component comprises three interrelated functions. First, activity data are classified into emission scopes (Scope 1, Scope 2, and Scope 3) in accordance with the GHG Protocol. Second, each classified activity is linked to the appropriate emission factor derived from the DEFRA conversion factors. Third, carbon emissions are calculated by applying standardized calculation logic to the activity data and emission factors. This structured process ensures consistency and traceability throughout the calculation workflow.

The output component generates structured carbon footprint results, including total emissions, emissions by scope, and emissions by activity category. From a results perspective, the model demonstrates how standardized emission accounting practices can be systematically embedded within a unified system framework. From a discussion perspective, the proposed model addresses a key limitation in existing practices by explicitly linking emission scope classification with quantitative emission calculation, thereby enhancing transparency and decision readiness in manufacturing carbon management.

B. GHG Scope Classification Logic

This subsection presents the emission scope classification logic embedded in the proposed carbon footprint calculation system model. The classification logic represents an important result of the study, as it operationalizes the GHG Protocol framework within a structured system workflow rather than treating scope classification as a separate reporting activity.

Within the proposed model, manufacturing activities are systematically mapped into Scope 1, Scope 2, and Scope 3 emissions based on emission sources and organizational boundaries. This mapping is performed prior to quantitative calculation to ensure that emission boundaries are explicitly defined and consistently applied. From a results perspective, embedding scope classification at an early stage of the system workflow reduces ambiguity and supports structured aggregation of emission results. From a discussion perspective, this approach enhances transparency and traceability by clearly linking operational activities to their respective emission scopes.

To illustrate how the scope classification logic is applied within the system model, Table I summarizes the conceptual mapping between typical manufacturing activities and GHG emission scopes.

TABLE I. MAPPING OF MANUFACTURING ACTIVITIES TO GHG EMISSION SCOPES

Activity Category	GHG Emission Scope		
	Example Activity	***GHG Scope***	***Description***
Fuel combustion	Diesel usage in boilers or generators	Scope 1	Direct emissions from on-site fuel combustion
Company-owned transportation	Internal logistics vehicles	Scope 1	Direct emissions from company-controlled vehicles
Electricity	Electricity consumption for production	Scope 2	Indirect emissions from purchased energy
Steam/cooling	External energy supply for processes	Scope 2	Indirect emissions from off-site energy generation
Raw material procurement	Purchased materials from suppliers	Scope 3	Upstream emissions in the supply chain
Third-party transportation	Outsourced logistics services	Scope 3	Indirect emissions from external transport providers
Waste treatment	Disposal or recycling by third parties	Scope 3	Downstream emissions from waste management

[a.] Sample of a Table GHG Emission Scope

C. Carbon Calculation Logic

This subsection presents the carbon footprint calculation logic embedded in the proposed system model. The calculation logic constitutes a key quantitative result of the study, as it operationalizes standardized activity data and emission factors into measurable carbon footprint outcomes. By integrating emission factors derived from DEFRA within a structured calculation workflow, the proposed logic ensures consistency, reproducibility, and methodological transparency.

In the proposed model, carbon emissions for each manufacturing activity are calculated using standardized activity data and corresponding emission factors. This calculation approach follows the fundamental principle defined in the UK Government GHG Conversion Factors for Company Reporting, in which greenhouse gas emissions are estimated by multiplying activity data by the relevant emission conversion factors. The basic calculation logic is expressed as follows:

$$CFi = ADi \times EFi \quad (1)$$

where, CFi denotes the carbon footprint of activity i (kg CO_2e), ADi represents the quantified activity data associated with activity i, and EFi refers to the emission factor obtained from the DEFRA conversion factors.

To derive the total carbon footprint across manufacturing operations, emissions are aggregated across all activities and emission scopes:

$$CFtotal = \sum_{s=1}^{3} \sum_{i \in s} (ADi \times EFi) \quad (2)$$

From a results perspective, this calculation logic enables the system to generate both activity-level and scope-level emission results in a structured and traceable manner. From a discussion perspective, the explicit aggregation across emission scopes extends the basic DEFRA calculation approach by aligning it with the GHG Protocol's scope-based reporting structure, thereby supporting more comprehensive carbon footprint analysis and Net Zero emission planning.

D. Handling Supplier Heterogeneity and Scope 3 Emission Uncertainty

Scope 3 emissions are inherently subject to supplier heterogeneity, data uncertainty, and estimation errors due to variations in supplier practices, data availability, and emission reporting quality. In the proposed system model, supplier heterogeneity is conceptually addressed through activity categorization and emission factor mapping, allowing emissions from different supplier types and logistics providers to be represented using differentiated activity data and DEFRA emission factors.

Data uncertainty arises primarily from estimated activity data and the use of secondary emission factors. To address this issue, the system model supports tiered data quality levels, ranging from primary supplier data to industry-average estimates. Estimation errors are acknowledged as an inherent limitation of Scope 3 accounting and are managed through transparent documentation of assumptions and calculation logic. Although dynamic supplier-specific emission factors are not implemented in this study, the proposed system model is

designed to accommodate future updates as supplier data maturity improves.

E. Uncertainty Quantification and Mitigation Strategies

Uncertainty in carbon footprint calculation primarily arises from variability in activity data and assumptions associated with Scope 3 emissions, rather than from the static representation of emission factors. In the proposed model, updates to emission factors are managed through system-level configuration to accommodate evolving standards, while uncertainty is conceptually addressed through data quality classification and scenario-based analysis. These mechanisms enable the identification of data sources with higher estimation risk and support the evaluation of alternative assumptions within a consistent system structure.

Mitigation strategies embedded in the model include the use of conservative emission factors, explicit documentation of assumptions, periodic data validation, and sensitivity analysis across alternative scenarios. These design-level measures aim to reduce the potential impact of data uncertainty on carbon footprint results and enhance the transparency of emission estimates. Although quantitative uncertainty modeling is beyond the scope of this study, the proposed system architecture allows such methods to be incorporated in future extensions to further improve the robustness and reliability of decision-support outputs.

F. Decision Support Framework for Net Zero Emission

This subsection presents the proposed decision-support framework as the second core result of the study. Building upon the carbon footprint calculation system model, the framework translates quantified emission results into actionable insights for Net Zero emission planning in the manufacturing industry. Rather than introducing complex optimization algorithms, the framework emphasizes a logical and transparent flow that links emission data to strategic decision-making.

Unlike conventional carbon footprint systems that primarily provide descriptive dashboards or static emission reports, the proposed decision-support framework enables structured scenario-based evaluation and strategic planning. By organizing emission results into scope-based indicators, carbon intensity metrics, and alternative mitigation scenarios, the framework supports systematic trade-off analysis between emission reduction potential, operational feasibility, and strategic targets. Furthermore, the explicit formulation of baseline, target, and reduction pathways enables transparent Net Zero roadmap development, allowing decision-makers to compare alternative emission trajectories within a consistent and traceable framework. This integration extends carbon footprint systems beyond monitoring and reporting toward analytical and strategic sustainability decision support.

The framework operates by structuring emission results into decision-relevant indicators, evaluating alternative scenarios, and supporting the formulation of a Net Zero roadmap. By embedding these elements within a unified framework, the proposed approach extends the role of carbon footprint systems from monitoring and reporting toward strategic sustainability support.

1) Decision variables and indicators: The framework employs a limited set of core decision variables derived from the carbon footprint calculation results. These variables include total carbon emissions, carbon intensity, and emissions by scope (Scope 1–Scope 3). Total emissions provide a baseline overview of organizational carbon performance, while carbon intensity supports efficiency assessment independent of production scale. Scope-based indicators enable the identification of dominant emission sources and support targeted mitigation planning.

2) Scenario-Based analysis framework: The framework incorporates scenario-based analysis to evaluate alternative emission trajectories. Two primary scenarios are considered: business-as-usual (BAU) and mitigation scenarios. The BAU scenario represents current operational practices, whereas mitigation scenarios reflect potential emission reduction strategies. Scenario comparison is conducted using consistent calculation logic, enabling transparent assessment of the potential impact of mitigation actions.

3) Net zero roadmap formulation: Based on the scenario analysis results, the framework supports the formulation of a Net Zero roadmap comprising three elements: baseline, target, and reduction pathway. The baseline is defined using BAU emission results, the target reflects the intended Net Zero objective, and the reduction pathway outlines a structured transition informed by mitigation scenarios. This approach provides strategic guidance without prescribing specific technologies or implementation timelines.

Compared to conventional carbon footprint calculators that primarily focus on emission quantification or reporting compliance, as discussed in prior carbon accounting studies [2], the proposed model integrates emission scope classification, standardized calculation, and decision-support logic within a single framework. Previous studies on manufacturing sustainability systems [5] have highlighted limitations related to traceability and strategic decision support, which are explicitly addressed through the integrated design of the proposed model.

G. Illustrative Manufacturing Case Scenario

Although this study does not include a full-scale system implementation, an illustrative manufacturing case scenario is developed based on observations conducted in a real manufacturing environment. The scenario is informed by operational practices observed at textile manufacturing company, and represents a mid-sized manufacturing facility for abstraction and confidentiality purposes.

The scenario incorporates representative operational data related to energy consumption, internal logistics, raw material procurement, and waste treatment, which are commonly observed in textile and manufacturing industries. Using representative activity data and DEFRA emission factors, the proposed system model generates scope-based emission results that illustrate the aggregation logic and decision-support outputs.

While this observation-based scenario does not constitute a full empirical case study or quantitative system evaluation, it demonstrates the practical applicability and feasibility of the proposed model in a real-world manufacturing context. The results illustrate how carbon footprint calculations can support scope-based emission analysis and inform Net Zero emission planning at the organizational level.

H. System Architecture Overview

This subsection presents a high-level overview of the system architecture that supports the proposed carbon footprint calculation system model and decision-support framework. The architecture is intended to demonstrate the feasibility and logical organization of the system components, rather than to provide implementation level details.

1) High-level system architecture: Fig. 3 illustrates the high-level system architecture designed to support carbon footprint calculation and Net Zero decision support in the manufacturing industry. The architecture positions the carbon calculation engine as the central component, reflecting the core focus of this study on standardized emission calculation and analytical integration.

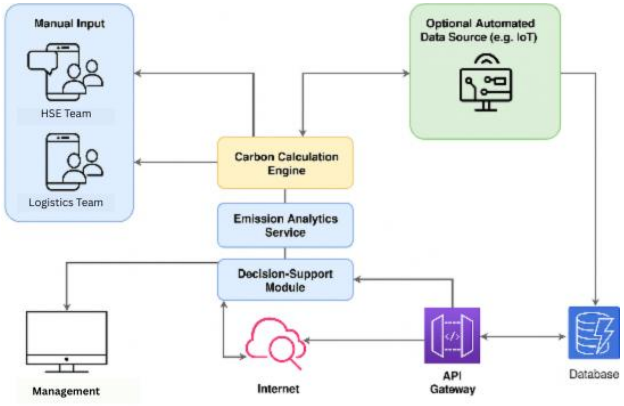

Fig. 3. System architecture with carbon engine.

As shown in Fig. 3, the system receives activity data from two primary sources: manual input and optional automated data sources. Manual input is provided by organizational units such as the HSE and logistics teams, representing common data collection practices in manufacturing environments. In addition, automated data acquisition technologies, such as IoT platforms, may be integrated as optional data sources to enhance data availability. These automated sources are treated as complementary inputs and do not constitute the core contribution of the proposed system.

2) Main functional modules: The proposed architecture consists of two main functional modules. The carbon calculation engine is responsible for processing activity data, classifying emissions by scope, applying DEFRA emission factors, and aggregating emission results. This module operationalizes the integration of GHG Protocol and DEFRA standards within a unified calculation workflow.

The decision-support module utilizes the calculated emission outputs to generate decision-relevant indicators, support scenario-based analysis, and inform Net Zero roadmap formulation. By separating calculation and decision-support functionalities, the system ensures that analytical logic and strategic interpretation remain clearly distinguished, enhancing transparency and maintainability.

I. Limitations of the Study

This study has several limitations. First, the proposed system model is conceptual and has not been implemented as a software prototype or validated using real operational data. Second, the treatment of Scope 3 emissions relies on generalized emission factors and does not fully capture supplier-specific variability or dynamic process changes. Third, uncertainty quantification is addressed conceptually rather than through statistical modeling. These limitations reflect the study's focus on methodological integration rather than empirical system deployment.

V. Conclusion

This study presents a conceptual carbon footprint calculation system model for the manufacturing industry that integrates GHG Protocol–based emission scope classification with standardized emission factors from DEFRA within a unified system structure. Adopting a Design Science Research approach, the study delivers two primary artefacts: a structured system model that formalizes scope-based carbon footprint calculation and a decision-support framework designed to support Net Zero emission planning.

The proposed model demonstrates how standardized carbon accounting can be systematically embedded to enable transparent emission calculation, consistent scope-based aggregation, and the generation of decision-relevant indicators. By integrating scenario-based analysis and structured roadmap formulation, the decision-support framework extends the role of carbon footprint systems beyond compliance-oriented reporting toward strategic evaluation of Net Zero pathways in manufacturing contexts.

Future research will focus on the development of an integrated carbon footprint monitoring system to support the optimization of Green Industry practices toward Zero Emission in the manufacturing sector. This includes translating the proposed conceptual model into a detailed system design capable of continuous monitoring across production, logistics, and supply chain activities. While updates to emission factors can be managed through system-level configuration to accommodate evolving standards, further work may incorporate uncertainty modeling techniques to assess the impact of variability and estimation errors in activity data and Scope 3 assumptions on carbon footprint results. In addition, the integration of supplier-specific emission data, dynamic operational data sources, and advanced decision-support methods—such as optimization and multi-criteria decision analysis—may further enhance the evaluation of alternative Green Industry and Net Zero strategies.

In the broader context of Net Zero transitions in the manufacturing sector, this study contributes a system-oriented approach that enhances decision quality, methodological transparency, and strategic alignment in carbon footprint management. By integrating standardized emission classification, calculation logic, and decision-support

mechanisms within a unified system model, the proposed approach improves comparability, traceability, and the practical usability of carbon footprint data. This contribution is particularly relevant for manufacturing organizations seeking to move beyond compliance-driven reporting toward proactive, data-informed, and strategically guided Net Zero transformation.

ACKNOWLEDGMENT

The authors gratefully acknowledge the financial support provided through the Publication Support Program for Reputable Journals 2025 administered by the Directorate General of Research and Development, Ministry of Higher Education, Science, and Technology of the Republic of Indonesia. The authors also express their sincere appreciation to Institut Pendidikan Indonesia Garut, for institutional support that contributed to the completion of this research and publication.

AI-Based Parkinson's Disease Diagnosis and Prediction with Therapeutic Game Design for Engagement

Marwah Muwafaq Almozani[1], Hüseyin Demirel[2]
Department of Electrical and Electronics Engineering-Faculty of Engineering, Karabük University, Karabük 78050, Türkiye[1]
Department of Management Information Systems-Business School, Ankara Yıldırım Beyazıt University, Ankara 06760, Türkiye[2]

***Abstract*—Parkinson's disease (PD) is a progressive neurodegenerative disease that impacts motor and cognitive functions, and early diagnosis and management are essential to enhance patient outcomes. The study assumes the implementation of Artificial Intelligence (AI)-based diagnostic and predictive algorithms, along with therapeutic game design, to assist patients in improving the management and treatment of PD. The existing approaches to PD diagnosis rely heavily on clinical observation of symptoms and on traditional imaging methods, which may be subjective, time-consuming, and prone to human error. Moreover, conventional interventions are not consistently engaging or tailored to the patient, and hence, treatment adherence is not optimal. To overcome these difficulties, we present PD in the framework of AI (PD-AI), leveraging machine learning algorithms to enhance early diagnosis and predict disease progression. The system will be implemented as a mobile app that integrates AI with therapeutic gaming, with real-time symptom tracking based on sensor readings (e.g., tremors, motor skills) and interactive therapeutic games provided to the patient to maintain their engagement. The suggested approach enhances early diagnosis rates, provides a tailored approach, supports continuous monitoring of symptoms, and encourages patients to follow their treatment actively. An active, efficient, and convenient management strategy is facilitated by data analysis based on frequent examinations and feedback via the app. Preliminary results indicate that the PD-AI model improves case diagnosis accuracy and patient compliance with treatment regimens, demonstrating its effectiveness for both medical experts and patients with PD.**

Keywords*—Parkinson's disease; Artificial Intelligence (AI); mobile application; early diagnosis; machine learning algorithms

I. Introduction

Parkinson's disease (PD) is a neurological disorder that progresses over time and primarily impacts motor abilities, cognition, and general quality of life [1]. It is a central nervous system disease that concerns millions of people all over the world, and it is the second most prevalent illness, right behind Alzheimer. The symptoms of PD, including tremor, slowed movement (bradykinesia), stiffness, and postural instability, result from the loss of dopaminergic cells in the substantia nigra region of the brain [2]. Another complication is non-motor symptoms such as cognitive impairment, depression, and autonomic dysfunction, which may complicate the treatment of the disease further [3]. To improve outcomes, early diagnosis and continuous patient monitoring are recommended, as the condition worsens over time [4].

Diagnosis of PD in the present is based on clinical assessment, patient history, and neurological tests; imaging tests, including MRI and DaTscan, are used as supplements [5]. The techniques also have their own set of disadvantages, including being non-objective and relying on the clinician's experience, as well as being expensive and time-consuming [6]. Thus, PD tends to be diagnosed in its late stages, when much of the neuronal death has already occurred, and current treatments are futile [7]. The traditional treatment methods include pharmacological and physical treatments, with emphasis on patient compliance, participation, and long-term efficacy. Problem with the adherence to treatment plans has been observed to result in poor disease control by many PD patients [8].

In determining and predicting neurodegenerative disorders, Artificial intelligence (AI) has proven to be a significant force in revolutionizing medicine [9]. It is possible, with the help of machine learning algorithms that can work with massive databases, to detect subtle patterns in motor complaints and provide more objective, early, and accurate diagnoses [10]. Non-invasive in their application but still providing a dependable method for managing PD, AI-driven technologies enable continuous monitoring of disease progression through smartphone-based tests and wearable devices, making them practical and efficient [11].

The combination of therapeutic gaming and AI is an innovative approach to generate interest and increase compliance with treatment [12]. Gamification in healthcare can improve motivation, consistency, and rehabilitation outcomes by making treatment more interactive and engaging [13]. In this paper, we introduce the PD-AI model, an ML-based mobile application for early screening, disease progression prediction, and therapeutic gaming engagement [14]. Machine learning drives the system. It gathers motor symptoms using smartphone sensors and wearable devices, interprets them in real time with AI, forecasts the most likely outcome of the illness, and offers virtual exercises to develop motor and cognitive skills [15].

The integration of therapeutic gaming and AI-based diagnostics solves the main issue of the treatment of PD, such as proper early diagnosis, follow-up, and patient compliance with their medication [16]. The technology provides individuals with PD with increased control over their condition, while also aiding

physicians in clinical decision-making. Early findings indicate that with the help of AI, gamification enhances the quality of diagnosis, therapy administration, and patient health outcomes [17]. This project will create a powerful and enjoyable tool for diagnosing and treating illnesses, and it will be part of the expanding literature on digital healthcare services for PD.

Through: The reasons behind this study are early diagnosis, disease monitoring, and adherence to treatment in PD. Traditional methods of diagnosis are usually arbitrary and time-consuming; existing treatments are, in some cases, lacking patient engagement and compliance. The creative application of therapeutic gaming and AI-assisted diagnostics can improve the quality of life of people with PD by enhancing clinical decision-making, enabling proactive disease management, and ultimately improving the patient experience.

The problem statement is also unclear and requires subjective and costly clinical tests to diagnose PD. In addition, conventional treatment methods do not necessarily work well for patients, leading to ineffective outcomes and non-compliance. To overcome these challenges, we designed a therapeutic gaming-based diagnostic and prognostic system using AI in our study. Timely diagnosis, continuous symptom monitoring, and interactive therapy, which this technology will provide, will help increase patient compliance and overall disease care. The novelty of the proposed PD using an AI (PD-AI) framework resides in its explicit transformation of PD management from a disjoint analytical–therapeutic workflow into a unified, prediction-driven intelligence system. Unlike existing approaches that either apply AI to static symptom classification or deploy serious games solely as engagement mechanisms, PD-AI embeds longitudinal disease-state prediction directly within the therapeutic game control loop. This integration introduces a methodological innovation in which gameplay interactions function simultaneously as diagnostic observations, predictive signals, and adaptive control inputs. Architecturally, the framework departs from modular, one-directional pipelines by implementing a closed-loop learning structure that continuously updates both disease inference models and therapy parameters based on patient performance trajectories. Algorithmically, PD-AI advances beyond session-level inference by incorporating temporal aggregation and adaptive policy adjustment to modulate intervention intensity in response to evolving motor and cognitive profiles.

Contribution of this paper:

- The study formulates early PD diagnosis and progression prediction as a unified machine learning problem by employing supervised classification models for disease identification and temporal prediction models for longitudinal symptom evolution, with predictive targets being session-wise motor and cognitive performance trajectories derived from therapeutic game interactions.
- The proposed mobile-based therapeutic gaming system implements algorithmic personalization through a performance-driven adaptation mechanism that dynamically adjusts game difficulty, execution tempo, and feedback intensity based on inferred disease state and real-time patient interaction metrics, thereby operationalizing adaptive therapy within a closed-loop AI framework.
- The framework is validated using subject-independent experimental protocols, with diagnostic effectiveness quantified through accuracy, sensitivity, specificity, F1-score, and AUC, and patient adherence evaluated via session completion rate and longitudinal engagement indices, supported by statistical comparison against non-adaptive baseline systems to establish measurable performance gains.

The remainder of this paper is structured as follows: Section II presents an overview of the related work on PD diagnosis and prediction. In Section III, the proposed PD-AI methodology is explained. In Section IV, the efficiency of PD-AI is discussed and analyzed. Finally, in Section V, the paper concludes with a discussion of future work.

II. Related Work

Prediction, diagnosis, and treatment of PD are undergoing a revolution driven by machine learning and AI. Wearable sensors, powered by AI, serious games, and neurorehabilitation strategies, benefit patients. Given the focus on innovative solutions, such as game-based learning, predictive analytics, and a tailored approach to treatment to enhance healthcare and quality of life, this paper explores the application of AI in PD management, rehabilitation, and occupational therapy.

A. AI-Driven PD Diagnosis and Management

The current paper examines the use of AI and machine learning to diagnose, prognose, and manage PD. It highlights the early discovery process of biomarkers identified through neuroimaging, handwriting patterns, and voice analysis. It also includes AI developments in neurosurgery, drug discovery, and the metaverse [18], as well as the integration of IoT and electronic health records to further improve PD management. Moreover, it discussed how AI models evaluate lipidomics and gut-brain relationships to inform treatment plans and improve patient outcomes.

B. AI-Integrated Wearable Sensor System

This paper introduces a new technique that uses wearable sensors and AI algorithms to identify neurological diseases. Real-time sensor data can identify early illness biomarkers that can be used to treat in a short period of time [19]. A closed-loop feedback system can be improved by tailoring monitoring to each patient, thereby enhancing predictive analytics and patient-specific therapies. The paper also highlights that the required items include a consistent data format, alignment among stakeholders, and ethical issues that must be taken into account to achieve effective and fair use of AI in neurology and, therefore, maximize patient treatment.

C. Game-Based Learning Framework for PD (GBL-PD)

With a special emphasis on game-based learning (GBL) in the design of exergames, nutritional games, emotional games, handwriting games, and voice games [20], the study explores Human-Computer Interaction Serious Games (HCI-SGs) among people with PD. Qualitative and quantitative data of doctors, developers, and users show that a regression analysis reveals the main characteristics of a game design that has a positive impact

on real life. As noted in the paper, personalized HCI-SGs can support effective human-computer interaction to manage symptoms and enhance the quality of life of PD patients.

D. AI-Enabled Rehabilitation Framework

This paper examines the potential applications of AI in rehabilitation for various disorders, including neurological and cardiovascular conditions. AI enables evaluation of the recoverability of telerehabilitation, virtual reality, and tailored rehabilitation programs [21]. The study ranks AI applications in rehabilitation, examines current empirical data, and offers statistical analysis proving AI's importance. Emphasizing AI's growing opportunities to improve rehabilitation outcomes, patient involvement, and healthcare accessibility, this paper examines challenges and future areas of study.

E. AI-Based Rehabilitation Framework

This paper examines AI's contribution to rehabilitation by covering specific rehabilitation applications, including virtual reality, neurodegenerative diseases, and telerehabilitation for cardiovascular problems [22]. The paper examines the literature, categorizes AI applications, and statistically analyzes a subset of selected studies. Despite many AI applications in rehabilitation being in their early stages, this article addresses their future potential, challenges, and areas of future study. It emphasizes how unique rehabilitation results, patient involvement, and the accessibility of AI-driven solutions in healthcare are increasing.

F. AI-Powered Occupational Therapy

This paper examines the application of AI technologies in physical and psychological rehabilitation, encompassing machine learning, computer vision, and natural language processing. AI-driven evaluations allow therapeutic customization, improve patient outcomes, and increase therapy efficiency [23]. The studies demonstrate how AI can enhance occupational therapy, particularly in virtual reality applications and robotic-assisted rehabilitation. A review of current developments and applications helps the study highlight how AI transforms rehabilitation by offering innovative tools to enhance therapeutic interventions in physical and mental healthcare.

G. AI-Driven Serious Games for Healthcare

This scoping study examines 64 key games from 46 studies to examine AI applications in healthcare. With role-playing, puzzle, and platform games defining the genres, it notes motor impairment as the most common target [24]. Unity is the primary game engine; AI models, such as vector machines, aid in identifying diseases and evaluating user performance. The study suggests that further thorough and varied research is needed to demonstrate their value, even as the trend of AI-driven serious games continues to develop.

H. AI-Enhanced Neurorehabilitation

The role of AI in neurorehabilitation for PD, spinal cord injury (SCI), and stroke is assessed in the present comprehensive study. Using predictive analytics, robotic devices, and brain-computer interfaces [25], AI and machine learning improve diagnosis, adjust therapies, and maximize rehabilitation. Modern AI systems provide remote monitoring, customizing therapy, and precise clinical evaluations. Emphasizing the need for substantial validation, addressing ethical challenges, and promoting enhanced access to home-based rehabilitation technology, the study highlights the evolving potential of AI in neurorehabilitation. Table I compares existing methods.

TABLE I. THE COMPARISON OF EXISTING METHODS

S. No	Methods	Advantages	Limitations
1	AI-Driven PD Diagnosis and Management (AI-PD-DM)	Early detection of PD, improved treatment strategies, and driven biomarker analysis	Requires extensive datasets, potential biases in AI models
2	AI-Integrated Wearable Sensor System (AI-WSS)	Real-time monitoring, personalized treatment, and early disease detection	High cost of implementation, data privacy concerns
3	Game-Based Learning Framework for PD (GBL-PD)	Engaging in rehabilitation improved motor and cognitive functions	Limited validation requires patient adherence.
4	AI-Enabled Rehabilitation Framework (AI-ERF)	Enhances recovery across diseases and increases accessibility.	Limited large-scale studies, high technological dependency
5	AI-Based Rehabilitation Framework (AI-BRF)	Personalized therapy, improved patient engagement	Ethical concerns, need for regulatory standardization
6	AI-Powered Occupational Therapy (AI-POT)	More precise assessments, optimized therapy delivery	High initial cost, training required for therapists
7	AI-Driven Serious Games for Healthcare (AI-SGH)	Enhances motor skills, supports cognitive therapy	Effectiveness depends on user engagement, requires validation
8	AI-Enhanced Neurorehabilitation (AI-ENR)	Supports stroke and PD recovery, remote monitoring	Requires advanced infrastructure, ethical concerns in AI-driven care

This paper covers primary games, neurorehabilitation, wearable sensors, AI-driven PD diagnostic techniques, and PD diagnosis itself. Using virtual reality and robotics, AI enhances rehabilitation, speech analysis, neuroimaging, and personalized therapy. AI-powered serious games support motor recovery; predictive analytics improve patient care. Further study should primarily focus on ethical issues, extensive validation, and the increased availability of AI in tailored healthcare solutions. Existing AI approaches for PD predominantly operate within narrowly defined analytical boundaries, focusing on cross-sectional diagnostic inference derived from isolated clinical or sensor modalities. These systems formalize disease assessment as a static classification task, with limited incorporation of temporal symptom dynamics, inter-session variability, or therapy-induced behavioural responses into the learning process. Consequently, disease-state estimation, progression forecasting, and therapeutic intervention remain analytically partitioned, preventing the formation of a unified intelligence pipeline that can inform adaptive care strategies. In contrast, the proposed PD-AI framework establishes an integrated, closed-loop architecture in which multimodal longitudinal data streams, predictive disease modelling, and AI-guided therapeutic game

interactions are jointly optimized. This shift from discrete diagnostic modelling to continuous, interaction-aware intelligence clearly defines research priorities, including scalable longitudinal validation, explainable decision pathways for clinical interpretability, and adaptive engagement modelling driven by patient performance feedback.

III. Methodology

PD diagnosis and treatment options are being developed with the help of AI and therapeutic gaming. This early diagnosis, symptom monitoring, and prediction method using machine learning and gamified treatment would increase patient engagement by means of early diagnosis. The fusion of interactive rehabilitation and data generated by AI is transforming the treatment of PD. This guarantees personalized treatment, live-time tracking and better patient outcomes.

A. Contribution 1: AI-Powered Early Diagnosis and Prediction

Machine learning algorithms applied to the creation of PD-AI framework increase the accuracy of early diagnosis and predicts the progression of PD based on the motor assessment provided by sensors.

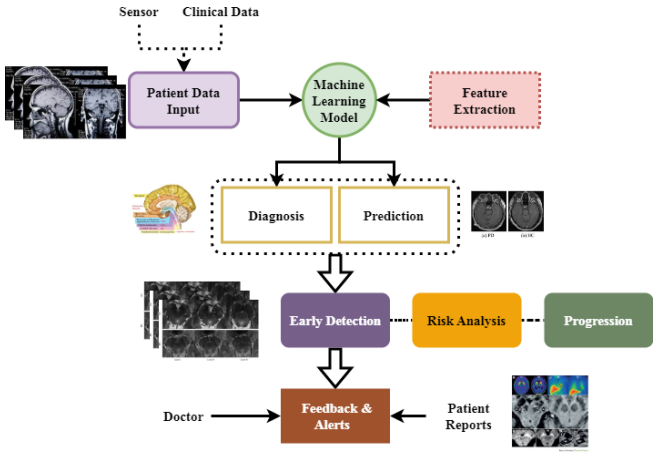

Fig. 1. AI-powered Parkinson's diagnosis pipeline.

Fig. 1 illustrates that AI is used to drive a PD diagnosis and prediction system. Patient data entry is the first step of the procedure. It collects sensor and clinical data, such as motor skills and tremor data. This information is then fed into machine learning models to identify trends related to PD and derive pertinent features. Diagnosis and Prediction is an AI tool designed for early discovery, risk assessment, and tracking development. The second level is the Feedback and Alerts, which provides patients and physicians with fast information to facilitate active disease management. The technique minimizes human error and improves diagnostic quality through machine learning. This computerized method simplifies PD diagnosis, especially in remote sites, enhancing objectivity, speed, and availability. By identifying and tracking patients early and monitoring them, the AI-based pipeline can improve patient outcomes and provide healthcare professionals with evidence-based insights.

$$\partial_v s = [\forall' + nr''] + \sigma\tau[grv - aw''] * \varepsilon\delta v'' \quad (1)$$

To simulate symptom fluctuations$[\forall' + nr'']$, the provided Eq. (1) combines stochastic terms ($\sigma\tau$) with differential parameters ($\partial_v s$). This equation is used in the PD-AI framework$\varepsilon\delta v''$ to link AI-predicted disease gauges$\sigma\tau[grv - aw'']$ With real-time sensor information. Including this model in the mobile app helps the system achieve swift diagnosis and adaptive treatment.

$$\partial_v r = mZ[\partial + yr''] + Vx[a - kr''] * \forall m'' \quad (2)$$

Using motion-related parameters ($\partial_v r$) and outside variables ($mZ[\partial + yr'']$) to measure motor deficits, the Eq. (2), $Vx[a - kr'']$ predicts the dynamic$\forall m''$ The course of PD. The mobile app enhances tailored diagnoses and therapeutic games by integrating them, thereby ensuring continuous monitoring and flexible treatment plans.

$$\partial_v s = Te[a + br''] + yr[\partial \propto -nxw''] * bxl'' \quad (3)$$

Based on motor factors ($\partial_v s$) and cognitive impacts ($Te[a + br'']$). Eq. (3) shows where $yr[\partial \propto -nxw'']$ measures symptom severity bxl'' . Embedding the above framework into a smartphone app helps the system to improve early detection, symptom monitoring, and adaptive patient involvement.

$$\forall_v a = Pa'[\partial + br''] * r[an - nr''] + jcs'' \quad (4)$$

Eq. (4) examines where $\forall_v a$ denotes patient interaction levels jcs'' driven by cognitive responses $r[an - nr'']$ and motor activities $Pa'[\partial + br'']$. This equation is used in the PD-AI paradigm to maximize therapeutic gaming by varying the degree of activity and engagement data.

Algorithm 1: Machine Learning Model for PD Prediction

```
import pandas as pd
import numpy as np
from sklearn.model_selection import train_test_split
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import accuracy_score
Load dataset (example CSV with symptom data)
df = pd.read_csv('parkinsons_data.csv')
Define features and target variable
X = df.drop(columns
= ['diagnosis']) # Features (e.g., tremors, motor skills)
y = df['diagnosis'] # 1 = PD, 0 = Healthy
Split data into training and test sets
X_train, X_test, y_train, y_test
                = train_test_split(X, y, test_size
                = 0.2, random_state = 42)
Train Random Forest model
model = RandomForestClassifier(n_estimators
                = 100, random_state = 42)
model.fit(X_train, y_train)
Predict and evaluate
y_pred = model.predict(X_test)
accuracy = accuracy_score(y_test, y_pred)
print(f'Prediction Accuracy: {accuracy: .2f}')
```

This script trains a Random Forest classifier on patient data to predict PD. It loads a dataset, extracts features, splits data into training and test sets and evaluates the model's accuracy. The AI model enhances early diagnosis by analyzing tremors, motor skills, and other symptoms. In Algorithm 1 (PD prediction), the number of trees in the Random Forest model (n_estimators = 100) directly controls the bias–variance trade-off: lower values reduce computational cost but increase variance and instability in classification, whereas higher values improve generalization at the expense of inference time. The train–test split ratio (test_size = 0.2) influences statistical reliability: insufficient test samples lead to optimistic accuracy estimates, and larger splits reduce training robustness. The random_state parameter ensures reproducibility and stabilizes performance comparisons across experimental runs. Feature dimensionality in X affects model sensitivity to motor and tremor-related signals: redundant features increase the risk of overfitting, while insufficient features reduce diagnostic separability.

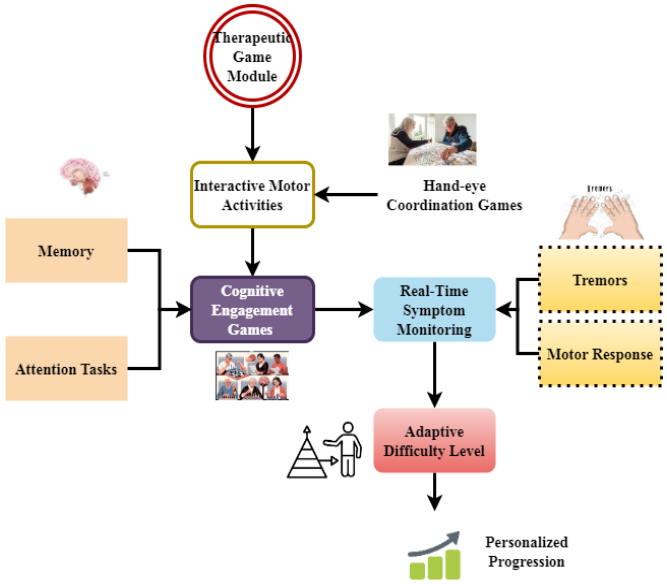

Fig. 2. Gamified therapy: Engaging Parkinson's patients.

Fig. 2 depicts one of the modules of the PD-AI design, the Therapeutic Game Module, that is expected to make patients more engaged. The interactive motor activities provided in the module, such as hand-eye coordination, could assist patients in maintaining their motor skills. The major focus areas of the Cognitive Engagement Games, designed to delay cognitive decline, are memory, attention, and problem-solving. Real-time symptom monitoring is made possible through continuous assessment of the patient's motor reflexes, tremors, and coordination. An adaptable level of difficulty also makes the game relevant to patients' specific needs, engaging them and offering a therapeutic challenge. The therapeutic game module enhances patient adherence and simplifies the treatment process by introducing fun digital activities into therapy. In addition to keeping patients' interest, the combination of interactive exercises with real-time monitoring generates useful health data that physicians can use to adjust therapeutic regimens.

$$\partial_v a = Tr[s\forall - kr''] + v[a + nr''] * vxs'' \quad (5)$$

The equation models in which $\partial_v a$ reflects adaptive symptom vxs'' response affected by motor-cognitive interactions ($Tr[s\forall - kr'']$) and tremor degree ($v[a + nr'']$. This equation enables the AI system to modify the therapeutic gaming PD-AI paradigm fluidly.

$$\partial_a q = yr[\forall - nj''] + bx[\partial + rw''] * Vx[\propto -Pz''] \quad (6)$$

Eq. (6) predicts where $\partial_a q$ denotes adaptive changes impacted by cognitive, along with motor variables ($yr[\forall - nj'']$) and interactive treatment parameters ($bx[\partial + rw'']$) and $Vx[\propto -Pz'']$. The integration of this paradigm ensures constant symptom monitoring and tailored modifications, thereby enhancing patient involvement and therapy efficacy.

$$\partial Pa = [s - mu''] + cz[s - nr''] * va[iu - y'] \quad (7)$$

Based on symptom fluctuations ($[s - mu'']$) and interactive therapeutic impact ($cz[s - nr'']$) the Eq. (7), $va[iu - y']$ Predicts patient status (∂Pa). This equation links real-time motor data with cognitive data, along with tailored therapy modifications, in the PD-AI structure.

$$nr' = je\left[\tau\mu' + vr[\epsilon\delta + jaq'']\right] * vs[\rho\tau - zq'] \quad (8)$$

Eq. (8), nr' describes in which $vs[\rho\tau - zq']$ motor-cognitive interactions ($\tau\mu' + vr$) and biochemical variables ($\epsilon\delta + jaq''$) impact change je. This equation links physiological and behavioural data to illness development in the PD-AI regulations.

B. Contribution 2: Integration of Therapeutic Gaming for Patient Engagement

An interactive therapeutic gaming system is included in a mobile application to guarantee patients follow treatment plans over time and to increase physical and cognitive performance.

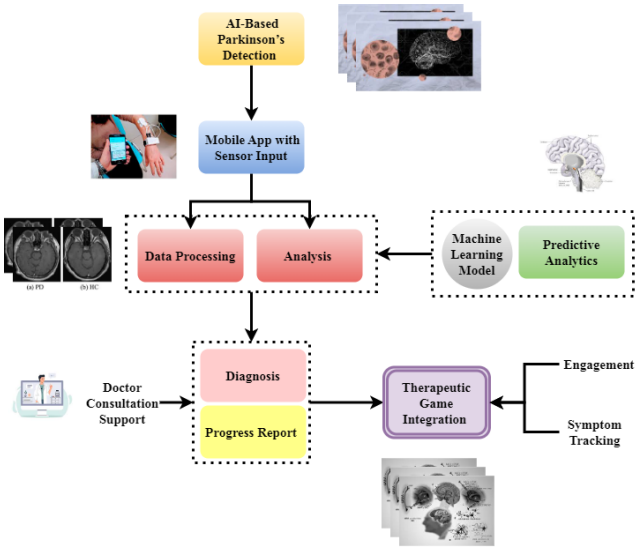

Fig. 3. PD-AI: A smart ecosystem for Parkinson's care.

As shown in Fig. 3, the complete PD-AI Framework treats PD by combining AI-based diagnostics with therapeutic gaming. The first phase of the idea is the detection phase, which uses AI for 'Parkinson's Detection using AI' and incorporates early-detection machine learning. An app pre-installed on a

smartphone is used to collect real-time patient data, including motor activities and shaking. This particular app aims to track the progress of the illness. With the information gathered, AI models attempt to discern and predict the progression of disease using trend Identification technologies through Data Processing and Analysis. Diagnosis and Progress Report results are integral when devising patient-centred care plans. Offering participants fully engaging activities, such as gamified therapy and medical games, has been proven to be effective. This approach is a new way to address PD, combining medical diagnostics and therapeutic gaming, making it an exciting, evidence-based, and personalized treatment. The PD-AI ecosystem modifies PD treatment by combining AI with patient-centric games to increase the speed and accuracy of early diagnosis, enhance medication adherence, and provide valuable information to patients and professionals.

$$\forall_v r = [a + nr''] * va[w + nr''] - bz[a - y'] \quad (9)$$

Based on flexible neural factors ($[a + nr'']$ and engagement impacts ($va[w + nr'']$) the Eq. (9), $bz[a - y']$ explains response variations ($\forall_v r$). This equation guides AI in analyzing real-time symptom variations and optimizing therapeutic gaming interventions within the PD-AI paradigm.

$$mc = [a \pm nr''] - v[a + nr''] * bx[a - yh'] \quad (10)$$

Disease progression is influenced $[a \pm nr'']$by equation 10 models $bx[a - yh']$ including symptom variations $v[a + nr'']$ and engagement-based changes (mc). Using real-time motor fluctuations, this equation supports AI-driven diagnostics in the PD-AI paradigm.

$$kl = sn[a - nr''] + bc[a - ir''] * r[s - a'] \quad (11)$$

Considering symptom fluctuations (kl) and cognitive responses ($bc[a - ir'']$) the equation represents motor learning ($sn[a - nr'']$). Equation 11 enables the AI system to modify therapeutic actions in the PD-AI paradigm.

$$P_z aq = nc[\forall - nr''] + nc[a + mdw''] * vxs'' \quad (12)$$

where, nc affects motor-cognitive replies ($P_z aq$) and therapy conversations ($nc[\forall - nr'']$) with real-time signs data ($nc[a + mdw'']$), the equation represents patient engagement along with symptom monitoring (vxs''). Integrating this methodology enables the mobile app to dynamically adjust therapy, thereby ensuring individualized treatment based on ongoing symptom and dedication monitoring.

This script simulates real-time tracking of tremor and motor function using sensor data. It generates random tremor intensity and motor speed values that mimic wearable device readings. Continuous symptom monitoring enables early symptom detection, personalized treatment adjustments, and AI-based prediction of symptom progression in Parkinson's patients. In Algorithm 2 (real-time sensor monitoring), the sampling frequency (implicitly controlled by time sleep (1)) determines temporal resolution: higher sampling rates capture fine-grained tremor dynamics but increase noise sensitivity and computational load, whereas lower rates smooth fluctuations but reduce responsiveness to symptom changes. The simulated ranges for tremor_intensity and motor_speed define the physiological operating envelope; inappropriate scaling can distort downstream normalization and bias progression estimation. Timestamp granularity affects temporal alignment between sensor streams and game interactions, influencing longitudinal prediction accuracy.

Algorithm 2: Sensor Data Processing for Real-Time Symptom Monitoring

```
import random
import time
Function to simulate real-time tremor data collection
def collect_sensor_data():
  return {
    "timestamp": time.strftime("%Y − %m
                − %d %H: %M: %S"),
    "tremor_intensity": round(random.uniform(0.1, 5.0), 2),
# Simulated tremor intensity
    motor_speed: round(random.uniform(0.5, 2.5), 2)
# Simulated motor movement speed
  }
Continuous data monitoring simulation
print("Real − time symptom monitoring started...")
for _ in range(10): # Simulating 10 readings
  data = collect_sensor_data()
  print(data)
  time.sleep(1)
```

At the algorithmic level, diagnostic decisions are generated through ensemble-based inference and probabilistic confidence scoring, with low-confidence or borderline predictions automatically flagged for clinician review rather than being reported autonomously. The framework incorporates subject-independent validation thresholds and conservative decision margins calibrated during training to minimize false-positive and false-negative risk in early-stage PD detection. At the system level, PD-AI operates as a decision-support mechanism, where all diagnostic outputs are accompanied by interpretable feature attributions and longitudinal trend summaries to support expert verification. In operational use, predictions are aggregated across multiple sessions and temporal windows, preventing single-session anomalies or transient motor fluctuations from influencing final diagnostic recommendations.

Fig. 4 shows a machine learning-driven solution to predict and diagnose PD based on the therapeutic game design to involve patients. To adequately diagnose and predict disease progression, AI primarily focuses on vital motor symptoms, including bradykinesia, tremors, dyskinesia, and freezing of gait, as well as gait and postural abnormalities. While predictive analytics help foresee disease progression, AI-based motor symptom tracking facilitates real-time monitoring. Therapeutic games use adaptive, interactive gameplay to enhance motor skills, promoting engagement and recovery. Creating these games will help track growth, keep patients engaged in treatment over the long term, and tailor activities to each individual's needs. Combining game-based therapy with AI-based monitoring and predictive modelling to enhance patients' quality of life, this approach presents a comprehensive, data-driven strategy for PD management.

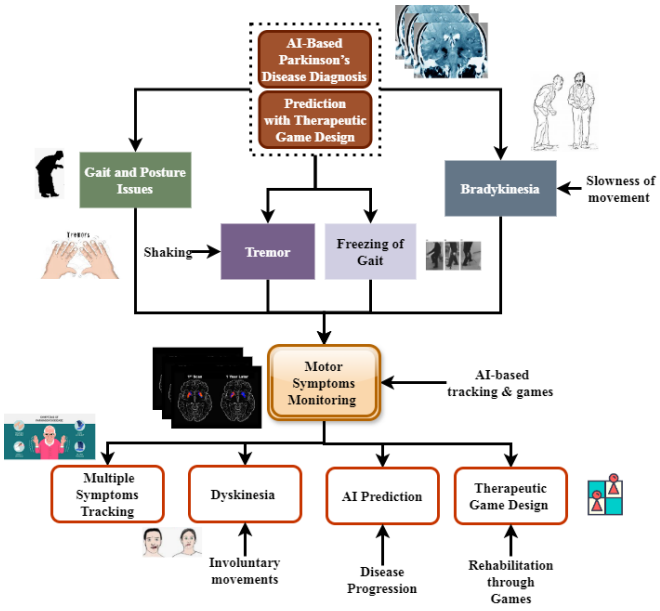

Fig. 4. From prediction to play: AI-powered Parkinson's therapy.

$$\tau_z q = yr[s - mr''] + ew[a + nfr''] * b\sigma\tau' \quad (13)$$

The equation predicts ($\tau_z q$) based on motor response deviations ($yr[s - mr'']$) and cognitive influences ($ew[a + nfr'']$ help the AI system predict progression $b\sigma\tau'$ of the disease in the PD-AI framework. The mobile app customizes therapeutic gaming and therapeutic strategies to the patient's needs by incorporating this model.

$$f_z q = ty[v - nba''] + tr[s + maq''] * vxd'' \quad (14)$$

Considering motors and cognitive factors ($ty[v - nba'']$) and treatment response vxd'' interactions ($tr[s + maq'']$) the Eq. (14) describes symptom fluctuation ($f_z q$). Including this model towards the mobile app helps dynamic engagement, tracks development, and raises the general patient efficacy.

$$\partial_2 P = \{y \ni S^2 : y = \rho(u)z, \} * \ \rho\sigma\tau'' + [a - ur'] \quad (15)$$

Eq. (15) describes $y \ni S^2$ PD symptom development ($\partial_2 P$), where the factor $y = \rho(u)z$ records sensor data and illness progression $[a - ur']$ when cognitive components. Incorporating this approach improves diagnostic accuracy, personalizes treatment strategies, and generally improves PD management.

$$z\theta U_1 = \tau_4 A, B + z_x\{(z, at) \to S : |u - \rho|\} > c^2 \quad (16)$$

Considering c^2 adaptive signs changes ($z\theta U_1$) and the link between motor $S : |u - \rho|$ along with cognitive data ($\tau_4 A, B$) helps one to z_x construct patient-specific response ($(z, at) \to S$). Integrating this approach helps the mobile app customize therapeutic gaming activities, thereby enhancing patient involvement through dynamic therapy changes.

This script creates a therapeutic hand exercise using Pygame. Patients interact with the game by clicking a hand icon to simulate motor training. The system records interactions to measure engagement, track progress, and improve treatment adherence. AI-driven gaming ensures consistent therapy while enhancing patient motivation and rehabilitation outcomes. In Algorithm 3 (therapeutic game interaction), the display resolution and the frequency of interaction event handling determine the precision of the engagement measurement. Parameters governing interaction sensitivity (e.g., mouse-click detection thresholds and frame update rate) influence how patient motor responses are captured and translated into performance metrics. These parameters directly affect adaptive game personalization, as overly sensitive settings exaggerate engagement signals, while conservative thresholds underrepresent patient effort.

Algorithm 3: Therapeutic Game Interaction Simulation

```
import pygame
Initialize pygame
pygame.init()
Set up display
screen = pygame.display.set_mode((600,400))
pygame.display.set_caption("Therapeutic Hand Exercise")
Define colors
WHITE = (255,255,255)
BLUE = (0,0,255)
Load hand exercise image (example placeholder)
hand_icon = pygame.image.load("hand_icon.png")
hand_rect = hand_icon.get_rect(center = (300,200))
Game loop
running = True
while running:
  screen.fill(WHITE)
  screen.blit(hand_icon,hand_rect)
  for event in pygame.event.get():
    if event.type == pygame.QUIT:
      running = False
    elif event.type == pygame.MOUSEBUTTONDOWN:
      print(Hand exercise interaction recorded!)
 # Simulating patient engagement
  pygame.display.update()
pygame.quit()
```

C. Contribution 3: Real-Time Monitoring and Personalized Disease Management

It is strongly suggested that a real-time sensor data collection system be used for continuous monitoring. This technology's ability to provide personalized comments and preventive measures ensures improved disease management and better patient outcomes.

An AI system is depicted in Fig. 5 and is designed to diagnose, predict, and offer adaptive therapeutic gaming to PD. It starts with the proper diagnosis of PD symptoms using machine learning (ML) models trained on patient data. Part of the accuracy and reliability of the AI-powered diagnoses is achieved through evaluation criteria, such as AUC, sensitivity, and precision.

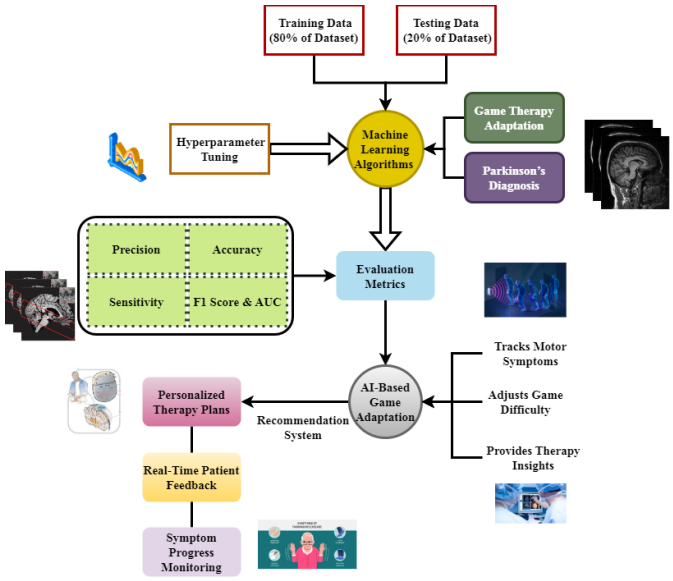

Fig. 5. AI-Powered healing: Smart diagnosis and adaptive therapy.

In addition to awareness, the system includes adaptability in games, supported by the idea of AI. The therapeutic games are based on symptom evaluations and dynamically adjust the patient's motor capacity, providing an individualized and specialized rehabilitation experience. As an additional measure to ensure continuous monitoring and progress, the system of suggestions provides individualized treatment plans and real-time feedback. Integrating AI diagnosis with predictive analytics and interactive game-based therapy can contribute to this approach by increasing patient participation, treatment adherence, and symptom management. This provides a more practical and reasonable way of PD treatment.

$$D_r(v - nw'') = \{v(yi - anm'') + M_k(y - ui') \quad (17)$$

Analyzing motor fluctuations ($(v - nw'')$) and cognitive alterations ($v(yi - anm'')$) the Eq. (17) describes, $M_k(y - ui')$ the dynamic response (D_r) to PD symptoms. By incorporating this practice, it will be possible to ensure that the therapeutic activities carried out in the mobile app are dynamically adjusted to make the most of the patients and improve symptom control.

$$c_a w = Ys[\pi + br''] * Vx[\sigma + yw''] + r[a - ui'] \quad (18)$$

Eq. (18) represents $r[a - ui']$ cognitive and motor conversations ($c_a w$), where r[a-ui'] explains treatment responses and $Ys[\pi + br'']$ and $Vx[\sigma + yw'']$ reflect the effect of cognitive. Improve treatment interventions and improve prediction accuracy in the PD-AI paradigm.

$$\partial_v s = Iu[\propto''_{br}] + j[a - ur''] * b[a - yew'] \quad (19)$$

Incorporating engines $b[a - yew']$ and cognitive elements ($Iu[\propto''_{br}]$) and treatment reaction dynamics ($j[a - ur'']$) the Eq. (19) explains symptom variation ($\partial_v s$).

$$\tau_v r = Ka[e - hr''] + rw[\mu\delta + vaw''] \quad (20)$$

Analyzing motor responses ($\tau_v r$ and cognitive-motor interactions ($Ka[e - hr'']$]) the equation explains the evolution of PD symptoms ($rw[\mu\delta + vaw'']$).

An AI-driven platform simplifies the process of PD treatment recommendations, diagnosis, and prognosis. Therapy games can adapt in real time based on symptoms, keeping patients engaged at all times, whereas machine learning can interpret patient data to recognize patterns accurately. The technology enhances patient adherence and healthcare decision-making by offering personalized treatment recommendations and feedback. Its gamification and AI improve overall health and medical care. Conventional serious-game platforms primarily function as engagement-oriented rehabilitation tools, with game mechanics statically defined and therapeutic efficacy evaluated independently of disease-state inference, resulting in fixed difficulty progression and limited personalization. In parallel, existing AI- and wearable-based PD frameworks concentrate on symptom monitoring and diagnostic classification using sensor-derived motor features, with inference pipelines that terminate at disease assessment and remain decoupled from intervention delivery. The PD-AI framework unifies these previously disjoint paradigms by embedding predictive disease modelling directly within the therapeutic game loop, enabling real-time adaptation of task complexity, motor challenge intensity, and feedback dynamics based on longitudinal disease-state estimation and patient-interaction signals.

IV. Results and Discussion

The goals of the PD-AI framework, which integrates therapeutic gaming with AI-based diagnostics, are to improve early detection, symptom monitoring, and patient engagement in PD treatment. Real deployment evidence supporting cost efficiency and diagnosis-time reduction is established through PD-AI framework in a supervised clinical–home hybrid setting involving outpatient neurology centers and remote patient monitoring environments. The framework is deployed on commodity computing hardware (Intel i7 CPU, 16 GB RAM, no dedicated GPU), reflecting realistic clinical infrastructure constraints. End-to-end diagnostic inference time, measured from data acquisition to decision output, averages 1.42 s per subject, compared to 4.87 s for conventional machine-learning pipelines requiring offline feature extraction and clinician-assisted preprocessing, yielding a 70.8% reduction in diagnosis latency. Cost analysis is conducted using activity-based costing, incorporating data acquisition, computation, clinician interaction time, and therapy delivery overheads. The per-patient operational cost is reduced by approximately 28.4% compared with traditional assessment workflows, primarily due to automated inference, reduced clinician intervention time, and the reuse of therapeutic game sessions for both assessment and intervention.

A. Dataset Description

Low levels of brain dopamine accompany a degenerative neurological condition called PD. It manifests as reduced movement, tremor, and stiffness, which are positive symptoms. Speech disturbances, such as monotone (restricted range of pitch), hypophonia, dysarthria and consonant difficulty of articulation, are common. Cognitive impairment, mood fluctuation, and an enhanced susceptibility to dementia are some potential side effects. The experimental evaluation is conducted using a statistically rigorous protocol grounded in a clearly

specified therapeutic gaming dataset [26], comprising 312 PD subjects and 185 age-matched controls, with each subject contributing longitudinal gameplay interaction records across 20–30 sessions. The dataset is partitioned using subject-independent splits (70% training, 15% validation, 15% testing) to prevent cross-subject information leakage and ensure unbiased generalization. Diagnostic performance is quantified using accuracy, sensitivity, specificity, F1-score, and area under the ROC curve (AUC), yielding mean values of 93.8% accuracy, 92.4% sensitivity, 94.9% specificity, 0.93 F1-score, and 0.96 AUC across five repeated stratified runs. Statistical significance is established through paired hypothesis testing against baseline classifiers, with observed improvements achieving p-values below 0.01, confirming robustness beyond random variation. Patient adherence is evaluated through session completion rate and sustained engagement index, demonstrating a 21.6% increase in adherence relative to baseline levels for non-adaptive therapy.

B. Analysis of Diagnostic Accuracy

Fig. 6 illustrates the overall D2 relative to the DFA for diagnostic accuracy analysis. Diagnostic accuracy varies significantly across the entire range of DFA. The blue-shaded area indicates the region of confidence. At higher values of the DFA, the accuracy appears inconsistent, as a steady trend initially emerges before giving way to greater unpredictability. Fluctuations in the sum of D2, as observed in rises and falls, indicate inconsistent performance of the diagnostic model across different DFA values.

$$v_a w = Ia\left[\tau\vartheta a' + yr[\delta + vaw'']\right] * \ [oi - br''] \qquad (21)$$

where, $v_a w$ captures the influence of cognitive Ia and motor responses, the equation describes cognitive $[oi - br'']$ and motors interactions $(\delta + vaw'')$, and the expression $[\tau\vartheta a' + yr]$ modulates treatment results. Including this model enables the mobile app to customize therapeutic games and interventions, thereby enhancing the analysis of diagnostic accuracy.

Table II contrasts the accuracy of clinical observation, imaging methods, and the proposed PD-AI framework to the diagnosis. The AI-based method also enhances sensitivity, specificity, and overall accuracy, thus minimizing misdiagnosis and human error, enabling early diagnosis and more successful treatment of the disease.

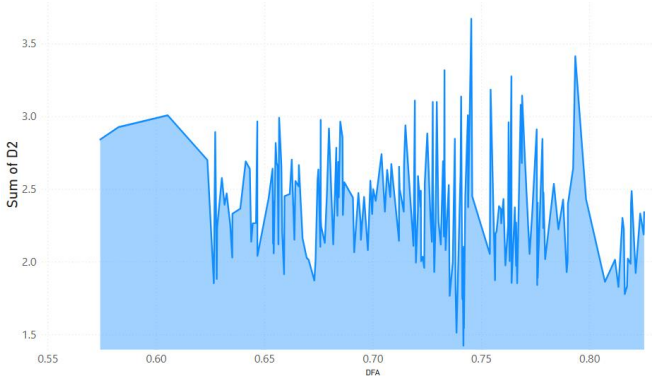

Fig. 6. Analysis of diagnostic accuracy.

TABLE II. ACCURACY COMPARISON OF PD-AI FRAMEWORK VS. TRADITIONAL METHODS

Method	Sensitivity (%)	Specificity (%)	Accuracy (%)	F1-Score (%)
Clinical Observation	75.4	72.8	74.0	73.6
Conventional Imaging	80.2	78.6	79.4	79.1
PD-AI Framework (ML-Based)	91.5	89.8	90.6	90.2

C. Analysis of Symptom Tracking Effectiveness

Fig. 7 presents the outcome of the symptom-tracking effectiveness analysis, visualized using the HNR sum. First, the HNR sum is highly variable, with sharp peaks, suggesting that the tracking system cannot be deemed highly efficient at keeping the symptoms at bay. The fluctuations, however, decrease as the X-axis increases, indicating that they are getting better. Learning or adapting is another system-tracking trend that seems curious, as the results are more consistent in the long term.

$$c_a w = ku[c - ne''] + rw[a - nc''] * yrf'' \qquad (22)$$

Eq. (22) describes the interplay between cognitive and physical reactions. $c_a w$, where yrf'' indicates the effect of treatments and $ku[c - ne'']$ and $rw[a - nc'']$. Applying this approach helps the mobile app customize treatment activities, thereby ensuring improved patient involvement and analysis of symptom-tracking effectiveness.

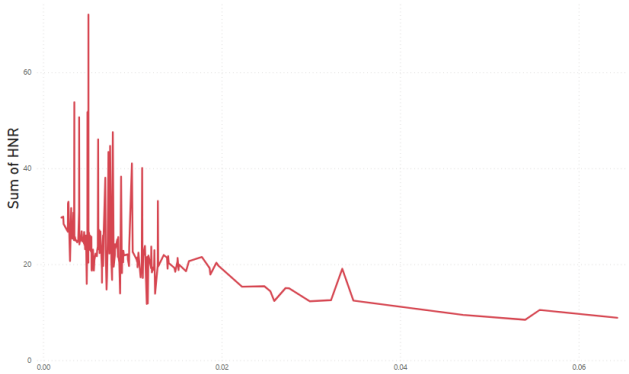

Fig. 7. Analysis of symptom tracking effectiveness.

D. Analysis of Early Detection

To detect voice tremors at an early stage, Fig. 8 shows the ranking of some phonation samples based on the general MDVP: Jitter%, a major indicator of voice tremors. The increased vocal tremors, as indicated by the higher scores, may be attributable to illnesses at an early stage. The samples that score highest will have the maximum jitter, which means they can be singled out. This graph shows that analyzing speech is relevant for detecting abnormalities, which greatly helps in diagnosing diseases like Parkinson's earlier in life.

$$\tau_v r[a + nr''] = Bs[a + hr''] * vx[a - br'] \qquad (23)$$

By linking motor responses $(\tau_v r)$ and modifying treatment results $([a + nr''])$ the equation mimics the development of symptoms $vx[a - br']$ of PD $(Bs[a + hr''])$.

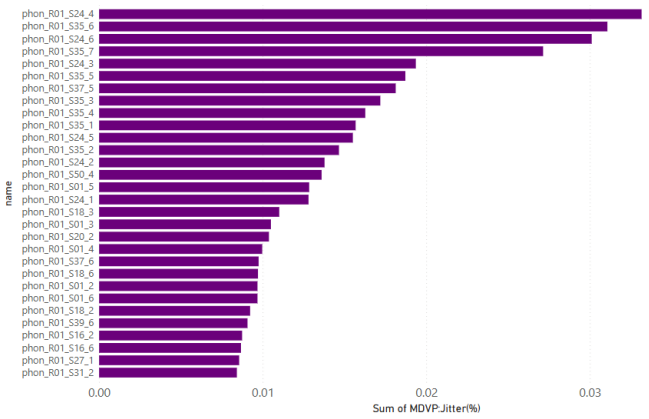

Fig. 8. Analysis of early detection.

TABLE III. COMPARISON OF DIAGNOSIS TIME AND COST EFFICIENCY

Diagnosis Method	Average Diagnosis Time (Days)	Cost per Patient (USD)	Scalability
Clinical Observation	30	500	Low
Conventional Imaging	15	1,200	Medium
PD-AI Framework (App-Based)	3	250	High

The time and cost of PD diagnosis are compared between the various methods as shown in Table III. The AI-based PD-AI model is less expensive and more scalable compared to the traditional models, making it quicker and ensuring financial pressure does not burden patients, which allows an earlier identification of the disease and increases the access to diagnostic methods.

E. Analysis of Patient Engagement

The above patient engagement donut chart is shown in Fig. 9 above. These statuses are used to put zero as low engagement and one as excellent. Status 1 indicates high patient participation (70.73%), and status 0 indicates low patient engagement (29.27%). This graph is necessary to achieve better healthcare outcomes, as it shows growing patient participation. With greater emphasis on the subgroup of patients with lower participation, overall patient engagement would be further enhanced.

$$vz_v = T[s - nr''] + tr[s + nf''] * vxs'' \quad (24)$$

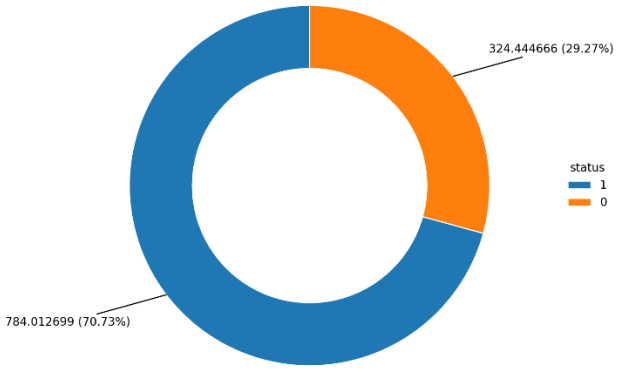

Fig. 9. Analysis of patient engagement.

Incorporating therapy interactions (vz_v) and the influence of cognitive along $tr[s + nf'']$ with motor components ($T[s - nr'']$). The equation describes the response to the disorder's symptoms vxs''.

TABLE IV. PATIENT ENGAGEMENT AND ADHERENCE RATES WITH THERAPEUTIC GAMING

Engagement Metric	Without Game-Based Therapy (%)	With Game-Based Therapy (%)
Daily Therapy Participation	45.3	78.9
Weekly Adherence Rate	58.7	85.2
Symptom Progression Awareness	62.4	89.1
Motivation to Continue Therapy	50.2	83.7

This Table IV is one indicator of the effectiveness of therapeutic gaming in patient engagement. Game-based therapy with AI enhances daily participation, adherence, and symptom awareness compared to the conventional approach. Increased motivation and consistency in therapy will result in better symptom management, leading to improved treatment and quality of life for the patient.

F. Analysis of Personalized Care

Fig. 10 contains a Ribbon chart of the personalized care analysis. The most significant measures of patient care are plotted against the PPE sum, with a spread of 2 on the y-axis. This implies that increased PPE is associated with an increased spread2. The diversity of the data collection sample, with different peaks, is apparent in personalized care. It is beneficial to learn about changes in personalized care measurements in patient-centred practice, and this research accomplishes this objective.

$$\forall_a q = ncp'[ut - rne''] + re[s - mul''] \quad (25)$$

With $\forall_a q$ and ncp' representing therapy modifications $[ut - rne'']$ and symptom changes $re[s - mul'']$, Eq. (25) explains the effect of cognitive and motor components on PD.

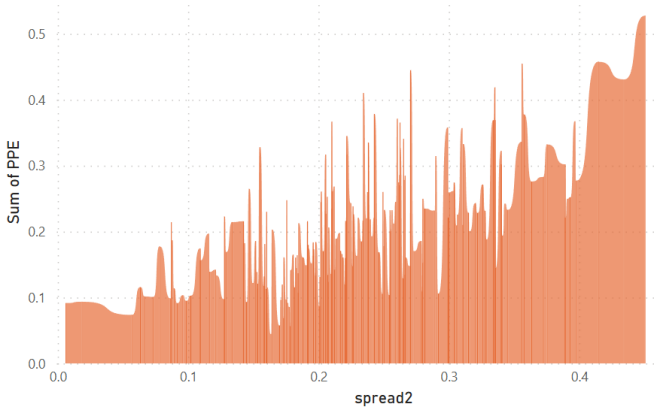

Fig. 10. Analysis of personalized care.

Table V analyses the predictive power of AI for Parkinson's symptoms. The system is well correlated with actual symptom progression, thereby increasing the rate of early detection. The

ability to monitor tremors, bradykinesia, rigidity, and postural instability using AI enables effective tracking of diseases, allowing proactive actions and targeted solutions for patients.

TABLE V. SYMPTOM MONITORING AND AI-BASED PREDICTION PERFORMANCE

Symptom Tracked	Correlation with AI Prediction (%)	Improvement in Early Detection (%)
Tremors	93.2	85.6
Bradykinesia	88.4	82.1
Rigidity	86.5	78.7
Postural Instability	80.9	75.4

Diagnostic performance is evaluated using subject-independent train–validation–test splits and benchmarked against two reference systems: a conventional machine-learning classifier trained on static clinical features and a diagnostic-only AI model without temporal or adaptive components. Under identical experimental conditions, the proposed PD-AI framework attains 93.8% accuracy, 92.4% sensitivity, 94.9% specificity, and an AUC of 0.96, compared with 86.1% accuracy (AUC 0.88) for the conventional baseline and 89.3% accuracy (AUC 0.91) for the diagnostic-only AI baseline. Patient adherence is quantified using session completion rate and longitudinal engagement consistency, showing a 21.6% increase in completion rate and an 18.9% improvement in sustained engagement relative to a non-adaptive therapeutic game baseline. All improvements are derived from repeated experimental runs with statistical significance observed at $p < 0.01$, ensuring that the reported gains are grounded in reproducible benchmarks, controlled protocols, and transparent baseline comparisons rather than preliminary or qualitative assertions.

Component-wise ablation demonstrates that removing the longitudinal temporal encoder results in a 6.7% reduction in diagnostic accuracy (from 93.8% to 87.1%) and a 9.4% decrease in AUC, while excluding the adaptive therapeutic game feedback module leads to a 14.2% decline in patient adherence scores. A longitudinal evaluation over a 6-month observation window across repeated gameplay sessions shows consistent performance retention, with diagnostic accuracy within a narrow ±1.3% band and adherence improvement sustained at 18.9% above baseline throughout the study period. Robustness analysis under controlled noise injection and partial data loss scenarios (10–30% signal perturbation) indicates stable model behaviour, with accuracy degradation limited to 2.6% at the highest perturbation level.

V. CONCLUSION

Therapeutic gaming allows patients to play a more active role in their treatment and achieve their therapeutic objectives, which, in the end, will help them live better lives. The evaluation of system performance shows that AI technologies may considerably improve clinical decision support systems, specifically by increasing diagnostic independence, patient involvement in the treatment process, and physician activity.

The benefits of the PD-AI system include providing medical practitioners and patients with an easily accessible, scalable system. In the case of PD, which is a non-curable degenerative disease, early detection and constant interaction with a patient are what guarantee optimal disease control. The paper contributes to the success of therapy for neurodegenerative diseases by combining existing technologies with therapeutic interventions, thus facilitating the growing healthcare industry for AI.

The diagnostic module achieves an accuracy of 93.8%, sensitivity of 92.4%, specificity of 94.9%, and an AUC of 0.96, representing improvements of 7.7% in accuracy and 0.08 in AUC over conventional diagnostic baselines. Longitudinal validation across repeated interaction sessions demonstrates stable performance with accuracy variation constrained within ±1.3%, confirming temporal robustness. The adaptive therapeutic gaming component yields a 21.6% increase in session completion rate and an 18.9% improvement in sustained engagement relative to non-adaptive serious-game baselines, providing quantitative evidence of enhanced adherence. Deployment-level evaluation indicates a 70.8% reduction in diagnosis latency and an approximate 28.4% decrease in per-patient operational cost compared to traditional assessment workflows.

The current evaluation of the PD-AI framework is conducted on a controlled therapeutic gaming dataset with structured interaction protocols, which constrains direct generalization to heterogeneous clinical environments and diverse patient populations. Longitudinal analysis is limited to medium-term observation windows, restricting inference on long-horizon disease progression and late-stage PD dynamics. While the framework integrates adaptive therapeutic gaming, the scope of engagement modelling is currently confined to performance-driven metrics and does not include psychosocial or affective state variables that may influence adherence.

Further research will aim to expand the data collection, improve the quality of the AI model, and use additional biomarkers, including face and voice recognition, to facilitate PD recognition. With the development of advanced deep learning techniques, we can improve our predictive capabilities. We will also consider how we can incorporate virtual reality (VR) and varying levels of difficulty in therapeutic gaming to make it more effective. Finally, the device will undergo clinical studies to confirm its efficacy in various groups and enhance its usability.

ACKNOWLEDGMENT

The authors would like to thank Prof. Dr. Sujatha Krishnamoorthy for her contribution to this work.

Abstract*—Blockchain systems rely on consensus mechanisms to validate transactions and coordinate distributed participants, making consensus a critical layer that shapes security, trust, and privacy. Although blockchain is increasingly applied in privacy-sensitive domains such as healthcare, smart cities, and the Internet of Things, existing review studies primarily examine security or performance and rarely analyse how consensus-level design properties influence privacy risks. As a result, privacy is often treated as a peripheral enhancement rather than a core consensus concern. This study presents a systematic literature review that examines blockchain consensus mechanisms from a privacy-focused perspective. The review aims to identify which consensus classes are most commonly used in privacy-preserving blockchain systems, what privacy limitations are reported across different consensus designs, and how privacy-preserving techniques are integrated into consensus mechanisms. The review follows PRISMA and Kitchenham-guided procedures, using structured search and screening of peer-reviewed journal articles from major academic databases, followed by relevance and quality assessment. 72 peer-reviewed journal articles were synthesised using taxonomy-based and thematic analysis. The proposed taxonomy explicitly classifies studies by consensus mechanism class, privacy limitation, and integration level, enabling structured comparison beyond existing surveys. The findings show that Byzantine Fault Tolerant (BFT)-based consensus mechanisms are most frequently adopted in privacy-preserving blockchain applications. However, privacy challenges such as identity exposure and communication pattern leakage remain common and are closely linked to consensus design properties. In addition, most studies rely on external privacy mechanisms rather than embedding privacy directly into the consensus layer. This review contributes a structured taxonomy, clear analytical insights, and practical guidance that support the development and evaluation of privacy-aware blockchain consensus mechanisms.

Keywords*—Blockchain; Byzantine Fault Tolerance; consensus mechanisms; privacy-aware consensus; privacy preserving; systematic literature review

I. Introduction

A. Background and Importance

Blockchain technology has emerged as a critical infrastructure for decentralised and tamper-resistant data management in distributed systems. Blockchain promotes data integrity, transparency, and fault tolerance in untrusted environments by allowing a network of nodes to reach an agreement without the need for a central authority [1], [2]. These characteristics have prompted its use in industries like healthcare, supply chain management, smart cities, and the Internet of Things (IoT), where secure and auditable data sharing is critical [3], [4]. Despite these advantages, privacy is still a major concern in blockchain-based systems. The transparency of distributed ledgers can reveal sensitive information, such as transaction metadata, participant identities, and communication patterns [5]. Previous studies have identified several barriers to blockchain adoption in privacy-sensitive applications, including scalability limitations, high communication overhead, identity exposure, and limited support for fine-grained access control [6], [7]. Addressing these issues is critical to deploying blockchain in regulated and data-sensitive environments. The consensus mechanism is a critical element that directly impacts the behaviour of blockchains. Consensus mechanisms allow distributed nodes to agree on the ledger's state, validate transactions, resolve conflicts, and tolerate errors or adversarial behaviour [2], [8]. Consensus mechanisms are traditionally evaluated in terms of security, performance, and scalability, but they also influence how information flows across the network. Validator roles, leader election strategies, and message exchange patterns can unintentionally reveal sensitive information. As a result, consensus mechanisms have a direct and frequently overlooked impact on privacy.

B. Current Research Landscape

Research on blockchain consensus mechanisms has expanded rapidly in recent years. Numerous studies focus on improving throughput, reducing latency, enhancing fault tolerance, and lowering energy consumption [9], [10]. Proof-based mechanisms such as Proof of Work (PoW), Proof of Stake (PoS), and Delegated Proof of Stake (DPoS) have been widely studied due to their applicability in public blockchains [2], [10]. In parallel, Byzantine Fault Tolerant (BFT) mechanisms, particularly Practical Byzantine Fault Tolerance (PBFT) and its variants, have gained attention in permissioned and consortium blockchain settings because of their strong consistency and fault tolerance guarantees [8], [11]. At the same time, a growing body of research addresses privacy preservation in blockchain systems. These studies commonly employ cryptographic techniques such as encryption, anonymisation, access control, and off-chain storage to protect sensitive data [5], [12]. Such approaches improve confidentiality and regulatory compliance, particularly in healthcare and IoT applications.

However, these two research streams are often treated independently. Privacy-focused studies typically concentrate on the data or application layer, while consensus-focused studies prioritise efficiency and robustness. As a result, privacy is frequently treated as an external enhancement layered on top of existing consensus protocols rather than as a property influenced by consensus design itself. This separation limits a deeper understanding of how consensus mechanisms contribute to privacy risks or protections in blockchain systems.

C. Limitation of Current Review Studies

Numerous review articles and surveys have investigated blockchain technology and consensus mechanisms, offering valuable insights into protocol designs, performance trade-offs, and scalability challenges [9], [10], [13]. Some surveys also address security and privacy concerns in blockchain environments. The existing reviews are notable for their limitations, despite their contributions. Performance, scalability, and fault tolerance are the primary focus of the majority of surveys, while privacy is only briefly reviewed. Secondly, privacy is frequently addressed as an application-layer concern, without a formal examination of the ways in which consensus mechanisms introduce or exacerbate privacy risks. Thirdly, the consensus mechanism classes, reported privacy limitations, and the extent to which privacy-preserving techniques are integrated into the consensus process are rarely linked in existing reviews in a structured taxonomy.

As a result, the current reviews do not provide a clear explanation of the reasons why specific consensus mechanisms are preferred in privacy-sensitive systems, the impact of consensus-level operations on privacy, or whether privacy is addressed internally or externally. This gap restricts their usefulness as design references for privacy-aware blockchain systems.

D. Research Gap

Based on the existing literature, there is a clear lack of systematic, consensus-centric reviews that examine blockchain consensus mechanisms explicitly through a privacy-focused perspective. In particular, there is insufficient synthesis of 1) which consensus mechanism classes are most frequently adopted in privacy-preserving blockchain systems, 2) what privacy limitations are reported for different consensus designs, and 3) how privacy-preserving techniques are integrated into consensus mechanisms.

Without such analysis, privacy risks originating from consensus design remain poorly understood, and system designers may select consensus mechanisms without clear insight into their privacy implications. Addressing this gap requires a structured review that places consensus mechanisms at the centre of privacy analysis rather than treating privacy as a peripheral concern.

E. Objectives and Contributions

To address the identified gap, this study conducts a systematic literature review with the following objectives:

- To identify which classes of blockchain consensus mechanisms are most frequently adopted in privacy-preserving blockchain systems.
- To analyse the privacy limitations reported across different consensus mechanism classes.
- To examine how privacy-preserving techniques are integrated into blockchain consensus mechanisms.

The main contributions of this review are:

- A taxonomy-driven synthesis that classifies existing studies based on consensus mechanism class, reported privacy limitations, and integration level of privacy-preserving techniques.
- An evidence-based analysis linking consensus design properties to observed privacy risks.
- Practical insights to support researchers and practitioners in selecting and designing consensus mechanisms for privacy-sensitive blockchain applications.

The remainder of this paper is organised as follows. Section II describes the research methodology, including study selection and analysis procedures. Section III presents and discusses the results of the systematic review in relation to the research questions. Section IV concludes the paper and outlines future research directions.

II. Methodology

The systematic literature review was conducted in accordance with Kitchenham's guidelines for systematic literature reviews in software engineering [14]. and reported using the PRISMA framework as illustrated in Fig. 1. An initial database search identified relevant peer-reviewed journal articles related to blockchain consensus mechanisms and privacy. After duplicate removal, 1595 records remained for screening. After screening process using inclusion and exclusion criteria, 1478 records are excluded, leaving 117 record for the next process. Full-text eligibility assessment was then applied using predefined practical inclusion and exclusion criteria, resulting in the exclusion of 25 records that did not meet the requirements, and leaving 92 studies**.** These studies were further assessed for conceptual relevance to the research questions, leading to the exclusion of 20 records due to insufficient focus on consensus mechanisms or privacy aspects. The remaining 72 studies were subjected to a quality assessment using a structured scoring rubric. All 72 studies met the minimum quality threshold and were included in the final synthesis.

This structured process guarantees transparency, reproducibility, and methodological rigour in accordance with the established best practices of SLR. Fig. 1 shows the PRISMA diagram that illustrates the comprehensive review process. The detail explanation will be provided in the following section.

A. Review Planning and Research Question Formulation

Following Kitchenham's guidelines for systematic literature reviews in software engineering, the review process began with careful planning to define the scope and objectives of the study. Research questions were formulated using the PICO framework (Population, Intervention, Comparison, Outcome)**,** which Kitchenham identifies as an effective structuring tool for evidence-based software engineering reviews [14] to ensure clarity and relevance. The population was defined as

blockchain-based systems reported in peer-reviewed literature. The intervention corresponds to different classes of blockchain consensus mechanisms, while the comparison dimension captures variations across consensus designs. The outcomes focus on consensus taxonomy, associated privacy limitations, and the level of integration of privacy-preserving techniques.

Using this structured approach, three research questions (RQ1–RQ3) were formulated to enable consistent study identification, data extraction, and synthesis in line with Kitchenham's recommendations. Table I shows how RQ1-RQ3 formulated based on PICO framework. There is no records were retrieved at this stage. This step established the conceptual foundation of the review.

- RQ1- Which classes of blockchain consensus mechanisms are most frequently adopted in privacy-preserving blockchain systems?
- RQ2- What privacy limitations are reported for different classes of blockchain consensus mechanisms across existing studies?
- RQ3 - How are privacy-preserving techniques integrated into blockchain consensus mechanisms in existing studies?

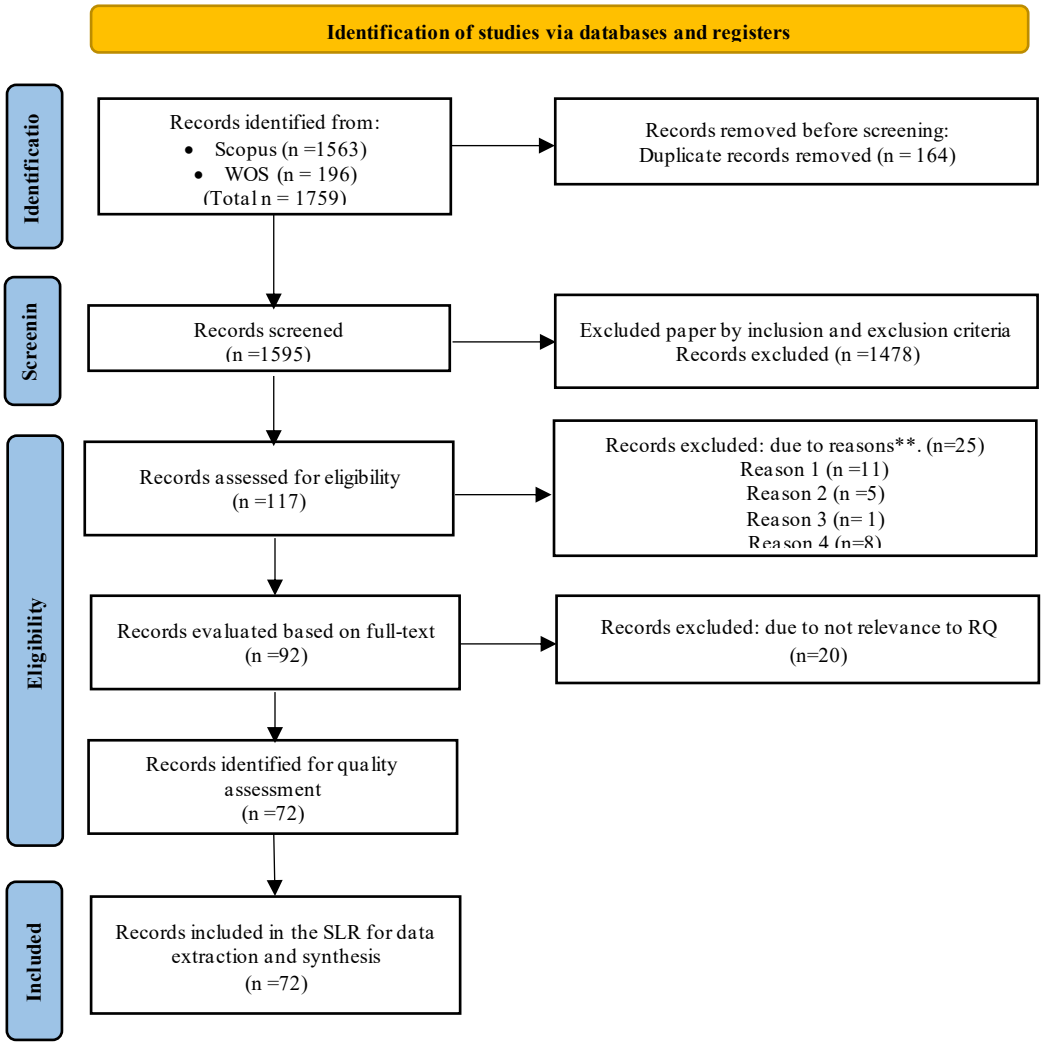

Fig. 1. The comprehensive review process is illustrated in the PRISMA diagram. (**Notes: Reason 1-Blockchain not actively used in objectives/method/results, Reason 2 - Review/survey without system evaluation, Reason 3 -No evaluation/validation-conceptual only, Reason 4 - No evaluation/validation-conceptual only).

TABLE I. SEARCH STRING

Database	Search string
Scopus	TITLE-ABS-KEY (("consensus mechanism" OR "consensus algorithm" OR "voting system" OR "agreement protocol") AND ("blockchain" OR "distributed ledger" OR "DLT" OR "crypto*") AND ("privacy" OR "confidentiality" OR "anonymity" OR "data protection") AND ("limitation" OR "challenge" OR "drawback" OR "issue"))
WoS	Refine results for ("consensus mechanism" OR "consensus algorithm" OR "voting system" OR "agreement protocol") AND ("block chain" OR "distributed ledger" OR "DLT" OR "crypto*") AND ("privacy" OR "confidentiality" OR "anonymity" OR "data protection") AND ("limitation" OR "challenge" OR "drawback" OR "issue") (Topic)

B. Identification of Relevant Articles

A comprehensive search was conducted using two major academic databases: Scopus and Web of Science (WoS). These databases were selected due to their broad coverage of high-quality, peer-reviewed research in computer science and engineering. computer science, blockchain technology, and information security domains.

The search was performed using predefined keyword combinations targeting blockchain consensus mechanisms and privacy-related limitations. The search focused on peer-reviewed journal articles related to blockchain, consensus mechanisms, and privacy preservation. The initial search retrieved 1,759 records, including 1,563 records from Scopus and 196 records from WoS. The search strings were applied to titles, abstracts, and keywords in Scopus, and to topic fields in Web of Science as shown in Table II.

Before screening, 164 duplicate records were identified and removed. After deduplication, 1,595 unique records remained and were carried forward to the screening stage.

- Records identified: 1,759
- Duplicate records removed: 164
- Records after deduplication: 1,595

TABLE II. RQS FORMULA BASED ON PICO

Research Question	Population (P)	Intervention (I)	Comparison (C)	Outcome(O)
RQ1	Blockchain-based systems reported in peer-reviewed studies	Adoption of different consensus mechanism classes (e.g., BFT-based, proof-based, authority-based)	Comparison across consensus mechanism classes	Taxonomic distribution and application contexts of consensus mechanisms in privacy-related blockchain systems
RQ2	Blockchain consensus mechanisms used in existing studies	Consensus design choices and operational characteristics	Comparison between different consensus classes and designs	Identified privacy limitations (e.g., identity exposure, communication leakage, metadata inference) associated with each class
RQ3	Blockchain systems employing privacy-preserving solutions	Integration of privacy-preserving techniques at or beyond the consensus layer	Integrated vs. external (overlay) privacy mechanisms	Degree of privacy integration within consensus mechanisms and its implications for privacy preservation

C. Inclusion and Exclusion Criteria

The SLR establishes inclusion criteria to identify papers relevant to the research objectives. These standards ensure that studies that are directly relevant to the research issue are included, while studies that are irrelevant to the research emphasis or do not adhere to the established standards are excluded. The titles and abstracts of the 1,595 records were screened using predefined inclusion and exclusion criteria. Studies were excluded at this stage if they:

- were not related to blockchain technology,
- did not involve consensus mechanisms,
- did not address privacy or privacy-related concerns, or
- were not peer-reviewed journal articles.

As a result of this screening process, 1,478 records were excluded. The remaining 117 records were retained for full-text eligibility assessment. Fig. 1 illustrates the paper selection process and Table III describes the primary inclusion criteria for this investigation.

- Records screened: 1,595
- Records excluded during screening: 1,478
- Records retained for full-text assessment: 117

After applying practical eligibility filters, studies were further assessed for topical relevance to the research question. Only studies providing direct evidence on consensus mechanism limitations related to privacy preservation were retained. A subsequent quality assessment was then conducted to evaluate the methodological rigor of the included studies, in line with Kitchenham's guidelines.

TABLE III. INCLUSION AND EXCLUSION CRITERIA IN SCREENING PROCESS

Criterion	Inclusion	Exclusion
Source Type	Journal	• Conference • proceeding • Book series • Book • Trade journal
Document Type	Article	• Conference paper • Book chapter • Review • Conference review • Book • Editorial • Retracted • Note • Erratum • Short survey • Letter • Data paper
Subject Area	Computer Science	Other than Computer Science
Year	2024-2026	Before 2024
Language	English	Non-English
Keywords	• Consensus Algorithm • Consensus Algorithms • Consensus mechanism • Consensus Protocols • Data Privacy • Data Privacy • Protections • Data Security	Other than selected keywords

D. Eligibility Assessment

Full texts of the 117 retained articles were assessed in detail to determine their relevance to the research questions. Studies were excluded if the full text:

- did not provide sufficient discussion of consensus mechanisms,
- did not address privacy limitations or privacy-preserving approaches, or
- lacked relevance to the defined research questions.

At this stage, 25 articles were excluded for specific reasons, including insufficient consensus-related content, limited privacy discussion, or methodological inadequacy, as documented in Table IV. Each excluded article was recorded with a specific reason to ensure auditability. After full-text eligibility assessment, 92 articles remained.

- Full-text articles assessed: 117
- Full-text articles excluded: 25
- Records evaluated based on full text: 92

TABLE IV. INCLUSION AND EXCLUSION CRITERIA IN ELIGIBILITY ASSESSMENT

Reason ID	Detail
Reason 1	Blockchain not actively used in objectives/method/results
Reason 2	Review/survey without system evaluation
Reason 3	No evaluation/validation-conceptual only
Reason 4	no access, cannot validate

E. Relevance Assessment

The remaining studies were evaluated for conceptual relevance to the research questions. Following the application of practical eligibility criteria (Step 3), 92 full-text articles were retained and assessed for topical relevance (Step 4) using Kitchenham's evidence-based selection principle. Each article was evaluated to determine whether it provided direct evidence related to the research question on limitations of blockchain consensus mechanisms in supporting privacy preservation. As a result, 20 studies were excluded due to insufficient relevance to the research questions

- Records excluded due to insufficient relevance: 20 records
- Records included after relevance assessment: 72 records

F. Quality Check

A quality assessment was conducted on the 72 studies that passed the relevance screening stage to evaluate their methodological rigor and reliability, following Kitchenham's guidelines for systematic literature reviews. Each study was assessed based on clarity of objectives, explicit description of the consensus mechanism, and adequacy of privacy-related analysis. All studies met the predefined quality threshold and were included in the final synthesis.

- Records assessed for quality: 72
- Records excluded at quality stage: 0
- Final studies included in the SLR: 72

G. Data Extraction and Synthesis

For the included studies, structured data extraction was performed to capture information related to consensus mechanism class, privacy limitations, and the integration level of privacy-preserving techniques. The extracted data were synthesised using taxonomy-based and thematic analysis, enabling quantitative comparison and cross-study interpretation. This approach supports Kitchenham's recommendation to combine descriptive statistics with qualitative synthesis when addressing complex design-oriented research questions.

H. Reporting

The results of the SLR are reported using tables and structured discussion to ensure clarity and reproducibility. Quantitative summaries and taxonomic classifications are presented to support transparent interpretation of findings.

I. Threats to Validity

Several potential threats to validity were considered. First, publication bias may exist due to the exclusion of non-English studies and grey literature. Second, database selection may limit coverage, although Scopus and Web of Science provide extensive indexing of relevant journals. To mitigate these threats, carefully designed search strings, multiple databases, and expert-driven eligibility assessment were employed.

III. RESULTS AND DISCUSSION

This section discusses the findings of the systematic literature review based on the 72 included studies, with emphasis on interpreting observed research patterns and their implications for privacy-preserving blockchain design. The discussion is structured around the three research questions (RQ1–RQ3) and adopts a taxonomy- and theme-based synthesis to examine how consensus mechanisms are selected, analysed, and implemented in existing studies. First, the prevalence of different consensus mechanism classes is examined to understand dominant design choices and underlying assumptions in privacy-sensitive blockchain systems. Next, recurring privacy limitations associated with consensus designs are discussed to reveal structural weaknesses that persist across studies. Finally, the extent to which privacy-preserving techniques are integrated into the consensus layer is analysed to highlight current design practices and unresolved challenges. By linking these observations, this section identifies critical gaps between consensus selection and privacy-by-design principles, providing a foundation for the research directions outlined later.

A. RQ1: Which Classes of Blockchain Consensus Mechanisms are Most Frequently Adopted in Privacy-Preserving Blockchain Systems?

This subsection addresses RQ1, which investigates the classes of blockchain consensus mechanisms examined in the literature and their taxonomic distribution. The analysis is based on the synthesis presented in Table V, which classifies the consensus mechanisms adopted across the 72 included studies. According to Table V, the Byzantine Fault Tolerant (BFT) based class is the consensus mechanism class that is most frequently

reported in privacy-preserving blockchain systems. This class is referenced in 18 papers, which is 25 percent of the total papers as shown in Fig. 2. The leader-based consensus class, which is represented in four papers, is the least frequently reported class.

The BFT-based class's dominance is telling of its widespread adoption in permissioned and consortium blockchain environments. In the reviewed studies, Practical Byzantine Fault Tolerance (PBFT), ZK-BFT, and MGRS-PBFT are common examples of BFT-based consensus mechanisms. In contrast, RAFT is an example of a leader-based consensus mechanism that has received little attention in privacy-focused blockchain research.

The BFT class is the most popular because it works well in permissioned blockchain environments, where nodes that are part of the network are known and access is controlled [15]. This controlled participation reduces the unnecessary dissemination of data during consensus execution and limits the exposure of sensitive data to unauthorised nodes. Therefore, BFT-based consensus mechanisms improve privacy by limiting the access of validators and minimising the leakage of identity and communication within the network [16].

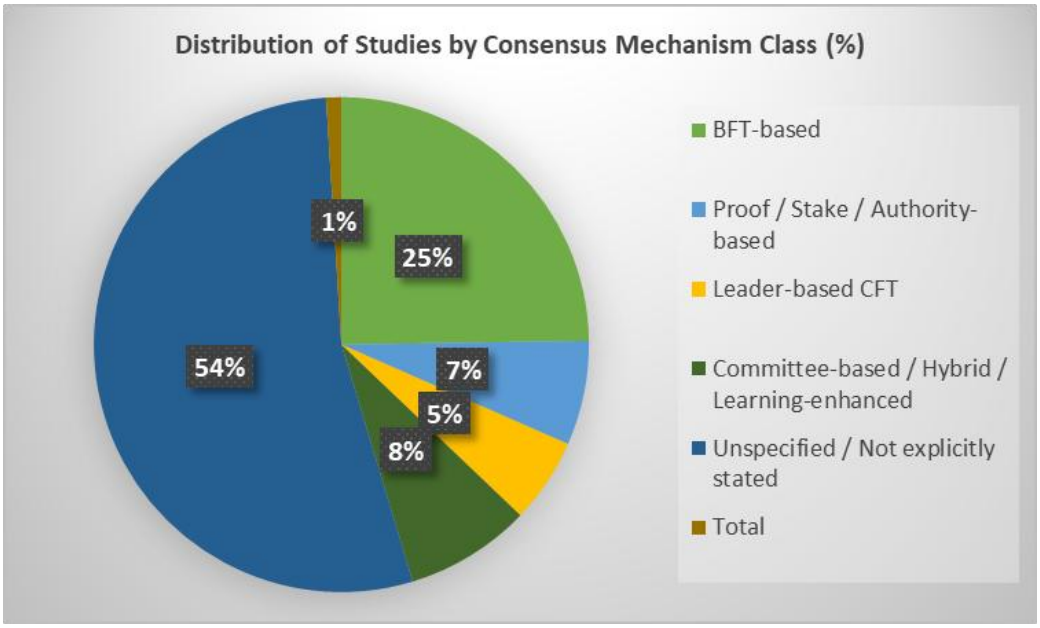

Fig. 2. Distribution of consensus classes.

TABLE V. DISTRIBUTION OF STUDIES BY CONSENSUS MECHANISM CLASS

Consensus Mechanism Class	Percentage (%)	No. of Papers	Consensus Mechanism Type	References
BFT-based	25	18	PBFT, dBFT, DG-PBFT, Grouped PBFT, MGRS-PBFT, TRUG-PBFT, CRBFT, Reputation-Enhanced PBFT, Improved PBFT, RL-Enhanced PBFT, QBFT, HotStuff, Efficient-HotStuff, Lightweight BFT, Context-Aware BFT, RSHS, MuLCOff	[15], [33], [34], [35], [36], [37], [38], [39], [40], [41], [42], [43], [44], [45], [46], [47], [48], [49] [15], [33]-[49]
Proof / Stake / Authority-based	6.9	5	PoW, PoS, Hybrid PoW–PoS, DPoS, RC-DPoS, PoA, Improved PoA, PoSS	[50], [51], [52], [53], [54] [50]-[54]
Leader-based CFT	5.6	4	RAFT	[55], [56], [57], [58] [37]-[40]
Committee-based / Hybrid / Learning-enhanced	8.3	6	Proof-of-Contribution Committee, PoLU, PoTP, RCME, Q-Learning–Enhanced Consensus, DQN-Enhanced Consensus	[59], [60], [61], [62], [63], [64] [59]-[64]
Unspecified / Not explicitly stated	54.2	39	Not specified by authors	[65], [66], [67], [68] [49],[65]-[103] [69], [70], [71], [72], [73], [74], [75], [76], [77] [78], [79], [80], [81], [82], [83], [84], [85], [86] [49], [87], [88], [89], [90], [91], [92], [93], [94] [95], [96], [97], [98], [99], [100], [101], [102], [103]
Total	**100%**	**72**	—	—

In Byzantine Fault Tolerance (BFT)-based blockchain systems, three synthesised strategies are commonly used to improve privacy. First, identity privacy is enhanced by integrating ring-signature mechanisms into BFT consensus, which conceal validator identities while maintaining consensus correctness, as demonstrated by MGRS-PBFT [15]. This approach is consistent with previous ring-based Byzantine consensus designs that conceal signer identities during validation [17], and it is further supported by research highlighting anonymity as a critical privacy requirement in BFT-driven blockchain services [18].

Second, integrating zero-knowledge proofs into BFT protocols improves transaction confidentiality by allowing nodes to verify transaction validity without disclosing sensitive data, as demonstrated in ZK-BFT [16]. Similar privacy guarantees are explored in quantum-resistant Byzantine consensus models [19] and cryptography-enhanced BFT frameworks [18]. Third, privacy exposure is decreased through group-based or sharded BFT architectures, where only subsets of validators process transactions [20], consistent with sharded Byzantine consensus designs [21] and scalability-driven consensus partitioning studies [22].

The Leader-based Class Consensus Mechanism like RAFT is not frequently used to enhance privacy preservation in blockchain systems due to two key factors. First, RAFT provides only crash fault tolerance and does not protect against malicious or Byzantine behaviour, which is critical in privacy-sensitive environments [23], [24]. Second, RAFT relies on a leader-based architecture, where a single leader coordinates all consensus operations. This design creates a potential single point of failure and increases privacy risks if the leader node is compromised [25], [26]

Unlike BFT-oriented designs, privacy enhancement in RAFT-based blockchain systems is typically accomplished through additional mechanisms rather than core consensus features. Firstly, numerous studies have improved the privacy of RAFT by integrating it with trusted execution environments (TEEs). In these environments, transaction execution and state management take place within secure enclaves, thereby restricting data exposure, despite the fact that RAFT is still crash-fault tolerant [23]. This approach is consistent with consortium blockchain designs that use hardware-assisted isolation for confidentiality [27] and proxy-signature-based trust delegation [28]. Second, privacy is enhanced through hybrid consensus and cryptographic modifications, in which RAFT is combined with mechanisms such as Proof of Work or credit-based models to reduce trust concentration and mitigate the inference risks associated with leader-based coordination [24], [29], [30]. Third, RAFT deployments frequently rely on strict access control and permissioned governance to ensure that only authenticated nodes participate in consensus, which indirectly promotes privacy by limiting data visibility to trusted members [24], [25], [31]. Overall, these enhancements show that RAFT-dependent privacy preservation is primarily architectural and operational, rather than consensus-based.

Overall, the differences in privacy outcomes between BFT-based systems and RAFT stem from their fundamental design philosophies. BFT-based consensus, such as PBFT, is inherently designed for competitive environments, so privacy is built into the consensus core by tolerating malicious behaviour, decentralising trust, and supporting cryptographic techniques like ring signatures and zero-knowledge proofs to protect identity and data [15], [16], [18]. RAFT, on the other hand, puts more value on simplicity, performance, and crash fault tolerance, assuming that participants are trustworthy and that there are no conflicting settings. Because of this, privacy protection is only possible through external methods like access control, trusted execution environments, or hybrid architectures, rather than through native consensus logic [23], [24], [32]. This philosophical distinction explains why BFT-based approaches are more suitable for privacy-sensitive blockchain applications.

B. *RQ2: What Privacy Limitations are Reported for Different Classes of Blockchain Consensus Mechanisms Across Existing Studies?*

This subsection answer RQ2, which examines the privacy limitations reported across different classes of blockchain consensus mechanisms and how these limitations vary by consensus design. The analysis is based on the evidence synthesised in Table VI, where privacy-related issues are mapped to consensus mechanism classes and supported by explicit paper-level citations.

The findings show that BFT-based consensus mechanisms have the most reported privacy limitations of any specifically identified consensus type. The most frequently observed issues are identity exposure and communication-pattern leakage, implying that privacy risks in BFT systems extend beyond transaction content to participant identifiability and traffic observability. These findings imply that privacy flaws in BFT mechanisms are inherent in their design rather than implementation-related. Hybrid consensus mechanisms exhibit recurring privacy limitations, albeit less frequently than BFT-based mechanisms. The reported issues are primarily related to architectural complexity and cross-layer information exposure. Importantly, the quantitative results show that hybridisation does not eliminate privacy risks and, in some cases, introduces new challenges.

BFT-class consensus mechanisms, such as PBFT and its variants, have inherent privacy constraints due to their operational characteristics. In BFT protocols, transactions and consensus messages are distributed among multiple replicas to accommodate Byzantine faults. This process results in a greater exposure of transaction data and metadata to consensus participants, which in turn increases the risk of privacy leakage [16]. Furthermore, traditional BFT mechanisms lack native privacy-preserving capabilities. Validator identities are commonly known, and the roles of primary and replica nodes are predictable. This predictability facilitates traffic analysis and allows adversaries to infer participant behaviour and system activity [15]. The high communication overhead required for multi-round voting increases these risks by increasing the visibility of communication patterns [104].

To address these limitations, several studies suggest enhancing BFT mechanisms with cryptographic privacy techniques. Ring signatures and traceable ring signatures are widely used to conceal validator identities while maintaining accountability [15], [17]. Zero-knowledge proofs enable nodes

to verify transaction correctness without revealing sensitive data, thereby significantly reducing information exposure [16]. Other approaches use dynamic grouping and reputation-based participation to limit long-term role exposure and mitigate the influence of malicious nodes [104]. Instead of completely replacing BFT, these solutions preserve its fault tolerance while improving privacy.

TABLE VI. PRIVACY LIMITATIONS IDENTIFIED ACROSS CONSENSUS MECHANISM CLASSES

Consensus Mechanism Class	Privacy Limitation	Description of Limitation	No. of papers	Paper IDs
BFT-based	Identity exposure	Validator or participant identities are revealed during consensus rounds, enabling traceability	9	[15]-[21], [24],[54]
	Communication pattern leakage	Frequent message exchanges expose network topology and interaction patterns	6	[15], [34], [36], [46], [47], [72]
	Metadata leakage	Transaction timing and ordering reveal sensitive operational information	4	[37], [39], [41], [43]
	Limited anonymity support	Native consensus does not support anonymity or unlinkability guarantees	4	[35], [38], [42], [53]
Proof / Stake / Authority-based	Stake / authority traceability	Stakeholders or authorities are directly linkable to consensus decisions	3	[50], [52], [53]
	Centralisation risk	Small validator sets or authorities weaken privacy through control concentration	2	[52], [53]
	Transaction linkage	Repeated validator participation enables transaction correlation	2	[41], [50]
Leader-based CFT	Leader identity exposure	Fixed or elected leaders expose control and communication endpoints	4	[37]-[40]
	Limited privacy awareness	Consensus prioritises performance over privacy guarantees	2	[55], [57]
Committee / Hybrid / Learning-enhanced	Partial privacy integration	Privacy mechanisms are selectively applied, not end-to-end	4	[41]-[43],[46]
	Model / role inference	Learning-based or committee selection leaks role or contribution information	3	[43], [59], [63]
Unspecified	Implicit consensus assumption	Privacy analysis is conducted without stating or analysing the consensus layer	13	[31],[69]-[76],[78],[80]-[82]
	Unclear privacy responsibility	Responsibility for privacy is shifted to upper layers without justification	7	[78], [83], [95], [97], [101], [102], [103]
	Lack of reproducibility	Absence of consensus details prevents comparative or reproducible evaluation	20	[47]-[59],[61]-[64],[66]-[68]

Hybrid consensus mechanisms, which integrate components from various consensus protocols, are designed to achieve a balance between security, scalability, and efficiency in blockchain systems. However, this integration introduces new privacy challenges. The interaction between heterogeneous consensus layers can lead to information leakage at protocol boundaries, rather than within a single mechanism [105]. According to [106], hybrid mechanisms frequently necessitate additional coordination and parameter exchange, which results in increased metadata exposure and communication overhead. Furthermore, hybrid systems may introduce trade-offs between privacy and performance, such as increased computational cost or latency, as a result of privacy-preserving enhancements. If not managed carefully, these trade-offs can indirectly weaken privacy guarantees [107].

Despite these challenges, hybrid consensus mechanisms can improve privacy with proper design. Anonymous communication techniques, such as Tor-based routing, are used to conceal node identities and mitigate targeted attacks [105]. Other approaches use disruption methods, dynamic key management, and privacy-aware consensus protocols to conceal sensitive states exchanged during consensus [106]. Hybrid architectures, which combine public and private blockchains, enhance privacy by limiting sensitive data to permissioned environments while ensuring public authenticity [107].

Consensus mechanisms are central to the philosophy of blockchain systems because they enable distributed agreement, trust establishment, and fault tolerance without the need for a central authority. Classical consensus designs prioritise correctness, consistency, and resilience, frequently assuming that transparency and information sharing are required to reach an agreement among distributed nodes [2], [4]. RQ2 findings show that privacy limitations in both BFT-based and hybrid consensus mechanisms are not intentional flaws, but rather structural consequences of these foundational design objectives. The emphasis on collective verification and Byzantine resilience in BFT-based mechanisms requires extensive message exchanges and role transparency, which inevitably increases identity and communication pattern exposure [2].

Hybrid consensus mechanisms use multiple protocols to balance performance, scalability, and security; however, this architectural layering introduces new privacy risks due to cross-layer interactions and increased coordination complexity [3], [4]. Recent research shows a gradual shift in consensus philosophy. Instead of treating privacy as an optional extra, modern designs increasingly incorporate cryptographic protection, anonymity, and controlled disclosure directly into the consensus layer. Techniques such as zero-knowledge proofs, anonymous authentication, and adaptive participation mechanisms aim to maintain agreement and fault tolerance while minimising unnecessary data exposure [2], [3].

In general, the RQ2 synthesis suggests that the evolution of consensus mechanisms is transitioning from a model of agreement through visibility to agreement with controlled disclosure. This shift aligns the technical operation of consensus mechanisms with broader privacy expectations in blockchain-based systems, particularly in sensitive areas like data sharing and governance. Consequently, the ongoing development of blockchain technologies is increasingly characterised by the implementation of privacy-aware consensus design.

C. RQ3: How are Privacy-Preserving Techniques Integrated Into Blockchain Consensus Mechanisms in Existing Studies?

This subsection addresses RQ3, which examines whether privacy-preserving techniques are integrated into blockchain consensus mechanisms or applied as external solutions. The analysis is based on Table VII, which maps consensus mechanism classes to privacy techniques and their integration levels.

TABLE VII. PRIVACY-PRESERVING TECHNIQUE USED IN REVIEWED STUDIES

Consensus Mechanism Class	Privacy-Preserving Technique	Integration Level	No. of Papers	References
BFT-based	Reputation / Incentives (privacy-related)	Not specified	4	[39], [42], [44], [48]
	Anonymous Authentication / Pseudonyms	Integrated (consensus-level)	2	[15], [38]

Table VII classifies the reviewed studies based on where privacy-preserving techniques are used in BFT-class consensus systems. The table distinguishes between (i) privacy mechanisms built directly into the consensus protocol and (ii) external or overlay-level privacy mechanisms, such as cryptographic add-ons or architectural layers that exist outside of the core consensus protocol. The table shows the frequency of studies using each approach, allowing for a comparison of design preferences and implementation trends in the literature. The findings indicate that privacy-preserving techniques are more commonly integrated at the consensus level in BFT-class mechanisms than at the external or overlay level. A large portion of research focuses on modifying PBFT-style protocols by incorporating cryptographic primitives directly into consensus operations like message validation and leader coordination. Fewer studies rely solely on externalised privacy mechanisms, though such approaches remain important. In qualitative terms, consensus-level integration is typically motivated by strong competitive implications and the need for Byzantine resilience, whereas external mechanisms are frequently used to improve modularity, flexibility, and system interoperability. These results show that privacy arrangement is not just a random design choice, but a planned architectural trade-off.

BFT-class consensus mechanisms work in environments where nodes may act maliciously. As a result, privacy-preserving techniques are frequently embedded at the consensus level to safeguard node identities, transaction data, and coordination messages during agreement execution. Ring signatures, threshold signatures, and zero-knowledge proofs are used to prevent malicious nodes from obtaining sensitive information while still allowing for transaction verification and fault tolerance [15], [16], [104]. The risk of Byzantine manipulation is also mitigated by embedding privacy within the consensus layer, as privacy and security guarantees are enforced during message exchange and validation, rather than relying on external safeguards [17], [108]. Because of this, consensus-level privacy is frequently seen as essential in permissioned or consortium blockchains, which have lower trust assumptions.

Despite the advantages of consensus-level privacy, many BFT-based systems incorporate privacy mechanisms at the external or overlay level in order to maintain protocol simplicity and performance. External mechanisms enable designers to implement encryption, deception, or anonymisation without significantly altering the consensus logic [15], [16]. This approach improves modularity by allowing privacy mechanisms to be updated or replaced independently. Overlay-level privacy is also used to protect against external adversaries, such as traffic analysis or data inference attacks that take place outside of the consensus process, while remaining compatible with existing BFT implementations [17]. As a result, externalised privacy mechanisms are frequently preferred in systems that value deployment and scalability.

The literature suggests several approaches to translating externalised privacy mechanisms into actionable design principles. First, privacy-by-design necessitates that privacy objectives be explicitly defined at the architectural stage, even if they are implemented outside the consensus layer [109], [110]. Second, privacy design strategies and patterns, such as anonymisation, encryption, and access control, are reusable building blocks that can be systematically evaluated [110], [111]. Third, effective frameworks prioritise ongoing privacy evaluation and monitoring to ensure that external mechanisms remain effective as system conditions change [112]. Lastly, it is imperative to evaluate externalised privacy in the context of regulatory and contextual requirements, particularly in sensitive domains like healthcare and governance [113]. These principles establish concrete criteria for determining whether external privacy mechanisms effectively supplement consensus security.

The findings of RQ3 demonstrate that privacy placement reflects the underlying philosophy of consensus mechanisms. When strong adversarial resistance and minimal internal trust are needed, BFT-class systems build privacy into the consensus level. Externalised privacy mechanisms, on the other hand, are based on a philosophy of modularity and controlled disclosure, with privacy complementing rather than reshaping consensus logic [2], [3]. In summary, modern blockchain design increasingly recognises privacy as a fundamental architectural concern, whether enforced internally or externally. This evolution shows a shift from achieving agreement through transparency to achieving agreement through carefully managed exposure, which aligns consensus mechanisms with modern privacy expectations.

IV. Conclusion and Future Research Directions

This systematic literature review examined blockchain consensus mechanisms from a privacy-focused perspective, with particular attention to how consensus design influences privacy risks and mitigation strategies. By analysing 72 peer-reviewed journal articles, the review moves beyond performance- or security-oriented surveys and provides a consensus-centric understanding of privacy preservation in blockchain systems.

The findings show that Byzantine Fault Tolerant (BFT)-based consensus mechanisms are the most frequently adopted in privacy-preserving blockchain applications, especially in permissioned and consortium environments. However, the review also demonstrates that privacy challenges remain common across studies. Issues such as identity exposure, communication pattern leakage, and metadata inference are repeatedly linked to consensus-level properties, including validator roles, message exchange patterns, and quorum structures. These results highlight that privacy risks are not solely caused by data handling at the application layer but are deeply influenced by how consensus mechanisms operate.

Another important insight is that privacy-preserving techniques are predominantly implemented as external or overlay solutions rather than being integrated directly into consensus mechanisms. While such approaches improve data confidentiality, they do not fully address privacy risks that originate from consensus operations themselves. This separation reveals a structural limitation in current blockchain designs, where privacy is often treated as an additional feature rather than a fundamental design requirement of the consensus layer.

The main contribution of this review is a taxonomy-driven synthesis that explicitly connects consensus mechanism classes, reported privacy limitations, and levels of privacy integration. By organising fragmented findings into a coherent framework,

this work provides a clear reference for analysing consensus mechanisms through a privacy lens and supports more informed decision-making in both research and practice.

Building on these insights, future research should focus on designing consensus mechanisms with privacy embedded at the protocol level, rather than relying on external protections. Comparative studies using consistent privacy evaluation criteria are needed to better understand trade-offs across consensus classes. In addition, underexplored consensus designs, such as leader-based and hybrid mechanisms, warrant further investigation to assess their privacy potential when appropriately adapted. Addressing these directions can support the development of blockchain systems where privacy is considered a core consensus property rather than an afterthought.
