Finally, in accordance with [21], the WHO-5 General Well-Being Index was translated and validated into the Collao variant of Quechua with 186 speakers from Puno, using translation, back-translation, focus groups, and expert evaluation. The results showed high relevance, good internal consistency ($\alpha = 0.88$), and an adequate unidimensional model. The WHO-5 is a reliable tool for measuring subjective well-being in Quechua-speaking communities, useful for primary care and future research.

In this section, the theories and conceptual framework related to the topic were developed and evaluated, based on the relationship between the independent variable and the dependent variable.

Digital image processing emerged in the 20th century thanks to advances in computing and optics. Initially, it was used in military and aerospace applications, but later it was applied in medicine, education, and entertainment [22]. With improvements in sensors, displays, and graphics engines such as Unity, virtual reality has moved beyond being just an experimental technology to become an accessible tool. This is especially important in education, where it enables more engaging and meaningful learning, particularly in cultural and language subjects.

III. METHODOLOGY

The research was applied in nature with a quantitative approach and a single-group pre-experimental design, evaluating the effect of an immersive educational application developed in Unity for learning Quechua. Thirty young people between the ages of 12 and 22 participated, selected through non-probabilistic convenience sampling and evaluated with a pre-test and post-test.

A. Case Development

The Mobile-D methodology, suitable for agile mobile projects, was used to develop the application. During the exploration phase, the scope of the project was identified, aimed at creating an immersive virtual reality educational application for basic Quechua language learning. Development was carried out in Unity, complemented by free software tools, while data management and storage were implemented using Firebase (Firestore), allowing for automatic recording of user progress and interactions.

The application was developed in Unity as the main engine, using C# for internal logic and virtual reality packages compatible with mobile devices. Communication with the database was implemented using Firebase, employing Firestore for cloud storage and Firebase Authentication for secure user management. The architecture followed a client-server model, where the mobile application acts as a client handling local processing of the immersive experience, while the Firebase server manages the recording of progress, results, and usage metrics. This integration allowed for real-time data storage, synchronization of user progress, and ensured stable operation during virtual reality interaction. See Table I.

TABLE I. FUNCTIONAL REQUIREMENTS

Code	Module	Functional Requirement
RF01	Login	The application will allow users to log in.
RF02	Registration	Users will be able to register with their basic information.
RF03	Main Menu	It will display the application options upon logging in.
RF04	Lessons	Allows access to mini-games or educational activities in Quechua.
RF05	Tracking	The system will save the user's progress (e.g., levels completed)
RF06	Results	Displays the results of each lesson or educational game.
RF07	Logout	The user can log out from the menu.

Once the functional requirements have been established, the non-functional requirements that guarantee the stability and reliability of the application are described. within the application. See Table II.

TABLE II. NON-FUNCTIONAL REQUIREMENTS

Code	Category	Non-Functional Requirement
RNF01	Performance	Activities must run without noticeable delays to maintain immersion.
RNF02	Usability	The application must be intuitive, even for users with no previous VR experience.
RNF03	Compatibility	The app must work on Android devices with support for virtual reality headsets.
RNF04	Accessibility	Texts must be legible and controls accessible from VR.
RNF05	Security	Personal data must be stored securely using Firebase Authentication.

The aim was to create a virtual reality application that offers an interactive and engaging experience, helping users to learn the basics of Quechua in a dynamic and educational way. See Fig. 1.

Fig. 1. Architecture, Client-Server.

During the development of the application, the phases defined by the selected methodology were followed. In the Exploration stage, the stakeholders and the scope of the project were identified. Then, in Initialization, the base architecture and necessary resources were configured. The Production phase consisted of building the system modules, prioritizing the immersive virtual reality experience. Subsequently, in Stabilization, the developed functionalities were integrated and adjusted. Finally, in the Testing phase, unit and integration evaluations were performed, verifying the correct functioning of the application and the adequate recording of user performance. See Table III.

TABLE III. METHODOLOGY PHASES

PHASE	ITERACIÓN	DESCRIPCIÓN
Exploration	Iteration 0	Study of stakeholders, project scope, and necessary requirements.
Initializa tion	Iteration 1	Configuration of the project, architecture, and resources to be used.
Production	Iteration 2	Declaration and development of each module.
Stabilization	Iteration 3	Integration of functions and recommendations for optimal operation of the mobile application.
Testing	Iteration 4	Unit and integration testing of the application, in software and real time.

During Phase 3: Production, the main components of the application were progressively built, prioritizing the immersive virtual reality experience and the inclusion of interactive elements. At this stage, the essential modules of the system were developed: user authentication, navigation through a main menu, immersive learning of Quechua in VR, and educational mini-games controlled by eye movement. In addition, a basic feedback module was incorporated to indicate correct and incorrect answers, along with a progress tracking module responsible for storing key data on user performance. These modules work together to provide a consistent and functional learning experience.

A general verification was performed to ensure that the internal modules of the application function correctly, both at the hardware and software levels. For testing, a device with 16 GB of RAM, Wi-Fi or mobile data connection, integrated gyroscope, and mobile phone-compatible virtual reality headsets was used. See Fig. 2.

Fig. 2. Screenshot – test scene.

In terms of the software environment, the application was evaluated on devices running Android operating system version 5.0 or higher with 4G network connectivity, ensuring adequate performance and a stable immersive experience for the user.

IV. RESULTS

Two questionnaires were used to measure these indicators: the pre-test, administered before using the mobile application, and the post-test, administered after using it. In the case of progress in interactive activities, this was recorded directly by the application, allowing for an objective assessment of the participants' progress.

A. Testing of Specific Hypothesis 1

An immersive educational application based on Unity An immersive educational application based on Unity improves vocabulary recognition in the Quechua language. Table IV shows the results of this indicator, obtained from the questionnaire administered before (pre-test) and after (post-test) use of the application. The questionnaire included questions on the identification and comprehension of Quechua words, recording the answers as correct or incorrect (1 = correct, 0 = incorrect), with the aim of measuring progress in vocabulary recognition. See Table IV.

In this part, the Shapiro–Wilk normality test was applied to the vocabulary recognition scores, obtaining a significance value of 0.014 for the pretest and 0.135 for the posttest. In the initial assessment, the significance was less than 0.05, indicating that the data did not follow a normal distribution. In contrast, in

the subsequent assessment, the value was greater than 0.05, suggesting an approximation to normality.

TABLE IV. NORMALITY TEST FOR VOCABULARY RECOGNITION

	Shapiro-Wilk		
	Statistic	df	Sig.
PRE_TEST	.909	30	.014
POS_TEST	.946	30	.135

Given that normality is not met in both measurements, the nonparametric Wilcoxon test is applied to compare the results obtained in the pretest and posttest. See Table V.

TABLE V. WILCOXON SIGN RANKS - VOCABULARY RECOGNITION

		N	Average rank	Sum of ranks
PUNTAJE_POS -	Negative ranks	2 ^a	2.50	5.00
PUNTAJE_PRE	Positive ranks	22 ^b	13.41	295.00
	Tie	6 ^c		
	Total	30		

a. PUNTAJE_POS < PUNTAJE_PRE

b. PUNTAJE_POS > PUNTAJE_PRE

c. PUNTAJE_POS = PUNTAJE_PRE

The ranks obtained using the Wilcoxon test are presented. There are 22 positive ranks with an average rank of 13.41 and a sum of ranks of 295.00. Likewise, there are 2 negative ranks with an average rank of 2.50 and a total sum of ranks of 5.00. Finally, N ties are recorded, which shows a general improvement in vocabulary recognition after using the educational application.

Table VI presents the test statistics.

TABLE VI. TEST STATISTICS – WILCOXON TEST FOR VOCABULARY RECOGNITION

Test statistics ^a	
	PUNTAJE_POS - PUNTAJE_PRE
Z	-4.149 ^b
Sig. asin. (bilateral)	<.001

a. Wilcoxon signed-rank test

b. Based on negative ranks.

Finally, there was an increase in average vocabulary recognition scores after using the Unity-based immersive educational application. This shows a positive impact on Quechua language learning, demonstrating that participants achieved better word identification and comprehension after the intervention.

B. Testing Specific Hypothesis 2

An immersive educational application based on Unity increases progress in interactive activities in the Quechua language. Below are the descriptive results related to the indicator of progress in interactive activities, which reflects the level of advancement of participants within the application and the relationship with the dimensions of vocabulary retention and error rate. See Table VII.

The group with high progress (levels 8 to 10) obtained an average score of 15.58, while the group with low or medium progress (levels 1 to 7) achieved an average of 13.17. This difference reflects a positive trend: participants who advanced more levels within the interactive environment achieved better results in vocabulary retention. See Table VIII.

TABLE VII. AVERAGES (MEAN) BY LEVEL – VOCABULARY RECOGNITION

Group Level	Media	N	Desv. Deviation
1.00	13.17	6	3.488
2.00	15.58	24	3.322
Total	15.10	30	3.438

TABLE VIII. AVERAGES (MEAN) BY LEVEL – ERROR RATE

Group Level	Media	N	Desv. Deviation
1.00	34.1667	6	17.44037
2.00	22.0833	24	16.61041
Total	24.5000	30	17.18811

On the other hand, participants in group 1 (levels 1–7) had an average error rate of 34.17%, while those in group 2 (levels 8–10) had a lower average error rate of 22.08%. This indicates that the higher the level achieved, the lower the percentage of errors.

C. Testing Specific Hypothesis 3

An immersive educational application based on Unity reduces the error rate in the use of the Quechua language. Descriptive statistics related to the participants' error rate are presented. To this end, the column showing the percentage of errors obtained in the pre-test and post-test, measured before and after using the educational application, was used. See Table IX.

TABLE IX. ERROR RATE NORMALITY TEST

	Shapiro-Wilk		
	Statistic	gl	Sig.
PRE_TEST	.909	30	.014
POS_TEST	.946	30	.135

The Shapiro-Wilk normality test was applied to the error rate scores. For the pretest, the statistic was 0.909 with a significance value of 0.014, indicating that the data are not normally distributed. For the posttest, the statistic was 0.946 with a significance value of 0.135, suggesting that the data are normally distributed.

Since at least one of the samples does not meet the normality requirement, the Wilcoxon test is performed to compare the data obtained in both measurements. See Table X.

Here are the ranks obtained using the Wilcoxon test for the error rate. There are 22 negative ranks, with an average rank of 13.41 and a sum of ranks of 295.00, indicating that most participants reduced their error rate after using the application. In addition, there are 2 positive ranks, with an average rank of 2.50 and a sum of ranks of 5.00, and 6 ties. These results show an overall decrease in the error rate in Quechua with the use of the educational application. See Table XI.

TABLE X. WILCOXON SIGN RANKS – ERROR RATE

		N	Average rank	Sum of ranks
PUNTAJE_POS -	Negative ranks	22 ^a	13.41	295.00
PUNTAJE_PRE	Positive ranks	2 ^b	2.50	5.00
	Tie	6 ^c		
	Total	30		

a. PUNTAJE_POS < PUNTAJE_PRE

b. PUNTAJE_POS > PUNTAJE_PRE

c. PUNTAJE_POS = PUNTAJE_PRE

TABLE XI. TEST STATISTICS – WILCOXON TEST FOR ERROR RATE.

Test statistics ^a	
	PUNTAJE_POS PUNTAJE_PRE
Z	-4.149 ^b
Sig. a sin. (bilateral)	<.001

a. Wilcoxon signed-rank test

b. Based on negative ranks.

The Wilcoxon test shows a significant decrease in the error rate after using the application, $Z = -4.149$, $p < 0.001$. This indicates that most participants improved in their use of the Quechua language.

V. DISCUSSION

This section presents the results obtained from the specific and general objectives set out in the research, comparing them with the theoretical background and previous studies analyzed in the theoretical framework. This process seeks to interpret the findings, understand their relationship with the proposed hypotheses, and with the pedagogical approach to learning the Quechua language through virtual reality. In addition, this analysis in this report may contribute to future research in the area of technology in the teaching of indigenous languages, strengthening the connection between educational innovation, cultural preservation, and the quality of learning.

Vocabulary recognition is one of the first stages in language learning, as it involves identifying and understanding words within a communicative context [23]. According to Orellana-García et al. (2020), the ability to recognize words visually or auditorily facilitates progressive language acquisition. In this sense, virtual reality offers an environment conducive to reinforcing this skill, allowing students to relate the terms they have learned to specific objects and situations, thereby promoting retention [24]. Unity, as a development engine, contributes to the design of these interactive immersive environments that stimulate visual and auditory memory [25]. According to the results obtained, the Wilcoxon test showed statistically significant differences between the pretest and posttest in vocabulary recognition ($p < 0.001$). Participants demonstrated a notable increase in the number of words correctly identified after using the application.

In addition, the positive ranges (22) compared to only 2 negative ones reflect a clear trend toward overall improvement in learning. This confirms that the immersive application had a positive impact on the assimilation of Quechua vocabulary. These findings are in line with Yuditseva (2024) [15], who

demonstrated that immersive environments reduce communicative anxiety and increase linguistic confidence, improving vocabulary retention. Similarly, Franco et al. (2025) [16] showed that virtual reality optimizes word-image association and enhances verbal ability. Likewise, Conrad, Kablitz, and Schumann (2024) [18] pointed out that immersive virtual environments increase declarative and procedural learning through active interaction. The results suggest that the use of the immersive educational application in Unity generated a meaningful experience for participants, facilitating vocabulary recognition through interaction with cultural and visual elements specific to the Quechua language. Immersion, combined with the gamification of the environment, maintained user motivation and promoted autonomous learning. As a result, the application not only strengthened the understanding of basic words but also increased interest in the language and its cultural context.

The error rate in language learning is associated with accuracy in the comprehension and production of words or phrases within a communicative context [26]. Según Krashen (1982), los errores son parte del proceso. According to Krashen (1982), errors are part of the natural process of language acquisition, but their reduction reflects progress in the internalization of knowledge. In immersive environments, immediate feedback and the possibility of repeating actions allow students to correct errors autonomously, reinforcing procedural memory. In this sense, virtual reality is considered an effective tool for improving accuracy in language learning as it integrates visual, auditory, and kinesthetic practice [24]. The results obtained in the pretest and posttest analysis showed a statistically significant decrease in the error rate ($p < 0.001$). Most participants reduced their errors in identifying or pronouncing Quechua vocabulary, reflecting an improvement in learning accuracy. This progress indicates that constant use of the application not only reinforced knowledge but also automated correct responses to stimuli in the virtual environment. These results coincide with Conrad, Kablitz, and Schumann [17], who demonstrated that immersive environments increase declarative and procedural learning by encouraging direct interaction with content. Similarly, Alizadeh [18] argues that virtual experiences allow for more effective communicative practice, strengthening self-efficacy and reducing errors in the use of a second language. Along the same lines, Fombona et al. [20] highlight that multisensory stimulation in virtual reality generates greater retention and accuracy in language learning. The significant reduction in errors observed in this study can be attributed to the design of the application, which combines visual and auditory elements with immediate feedback. This integration allowed users to detect and correct mistakes during practice, strengthening their understanding of vocabulary and improving their overall performance. Likewise, the cultural component—Andean settings, typical sounds, and traditional characters—helped contextualize the language, facilitating more natural and lasting learning. In short, the immersive application not only reduced errors but also built confidence and autonomy in participants as they interacted with the Quechua language in a meaningful digital environment.

Progress in interactive activities is closely linked to Ausubel's (1983) theory of meaningful learning, which posits

that new knowledge is assimilated more effectively when students actively interact with the content. In the digital context, this interaction is enhanced by gamification strategies, where level advancement, rewards, and immediate feedback maintain motivation and facilitate knowledge retention. According to Ladendorf, Schneider, and Xie [14], mobile virtual reality promotes autonomous and continuous practice, allowing learning to be constant and adaptive. The results showed that users who completed a greater number of levels within the application obtained better vocabulary scores and had a lower error rate. This positive relationship shows that progress in interactive activities has a direct impact on strengthening learning. Constant practice and repeated exposure to stimuli in the immersive environment facilitated the consolidation of knowledge and familiarization with Quechua terms. The findings are consistent with the studies by Zapata-Paulini et al. [27] and Achic [28], who highlight that digital tools based on augmented or virtual reality encourage active participation and motivation, essential factors in the acquisition of communication skills. Similarly, Fernández and Calvo [29] argue that the incorporation of reward systems within digital environments stimulates curiosity and learner retention, improving the effectiveness of the educational process. This coincidence reinforces the idea that immersive environments not only teach but also encourage further learning. The progress observed shows that consistent use of the application was decisive in achieving better results. The level-based structure and immediate feedback kept participants motivated and committed to learning. In addition, the video game-like design made the educational process feel natural, eliminating the rigidity typical of traditional methods. As a result, the application not only promoted language learning but also autonomous and sustainable study habits, showing that the combination of gamification, immersion, and culture can transform the way a native language is taught and learned.

In relation to the overall objective of the research, which was to evaluate the effectiveness of an immersive educational application based on Unity for learning the Quechua language through virtual reality, the results obtained confirm that the proposal was effective and fulfilled its objectives. The integration of visual, auditory, and cultural resources within the virtual environment allowed participants to improve their vocabulary recognition, reduce errors, and make steady progress in the activities. Likewise, the immersive experience promoted more dynamic and motivating learning, strengthening language comprehension and appreciation of Andean cultural identity. Overall, the findings demonstrate that virtual reality represents an innovative pedagogical alternative for teaching indigenous languages, combining technology and culture in a balanced way, thus contributing to the Sustainable Development Goals related to quality education and the preservation of Peru's linguistic heritage.

VI. CONCLUSION

The study demonstrates that an immersive educational app built on Unity can be an effective tool for teaching the Quechua language, validating the potential of learning in virtual environments. The quantitative results showed significant improvements in vocabulary recognition ($Z = -4.149, p < 0.001$), increased performance on interactive activities (mean Level 2 =

15.58 vs. Level 1 = 13.17; error rate reduced from 34.17% to 22.08%), and an overall decrease in the error rate in language use ($Z = -4.149, p < 0.001$). Beyond these results, the analysis shows that the combination of visual, auditory, and cultural elements in an immersive environment promotes motivation, facilitates retention, and reinforces the student's cultural identity. From a learning design perspective, these findings suggest that the principles of level-based progression, immediate feedback, contextualized interactive activities, and cultural stimuli are key to maximizing the effectiveness of learning in virtual reality. Overall, the study indicates that the use of well-designed virtual environments can serve as a replicable model for teaching indigenous languages, offering an inclusive, motivating, and culturally relevant approach that contributes to language preservation and quality education.

The limitations of this study are primarily related to its pre-experimental design and the use of a relatively small convenience sample, which limits the generalizability of the results. Furthermore, the evaluation was conducted at a single point in time, without longitudinal measurements to analyze learning retention over time. Additionally, the system did not include all possible levels or scenarios, which limits its scalability and the diversity of the educational experience, as well as its ability to adapt to different user profiles and devices.

For future research, it is recommended to use larger, more representative samples, as well as to include control groups and longitudinal assessments to analyze learning retention and the consistency of effects over time. Likewise, it would be valuable to expand the system with additional levels, varied scenarios, and interactive modules, adapting the content according to the user's age or level, and to evaluate it on different devices and in various educational settings, to improve accessibility, the generalizability of results, and the effectiveness of learning.

Weight Trajectory Prediction in Precision Livestock Farming Using Machine Learning: A Comparative Approach

Moad Hakem, Zakaria Boulouard, Mohamed Kissi

Faculty of Sciences and Technologies, Department of Computer Science, Hassan II University, Mohammedia, Morocco

Abstract—Accurate livestock body weight prediction is a key component of precision livestock farming, as it supports herd monitoring, production management, and planning in response to the increasing global demand for meat. Existing approaches for weight prediction include age-based regression models, growth trajectory modelling, average daily gain estimation, and methods relying on morphometric measurements or image-derived features. However, many of these approaches require frequent measurements or specialized data acquisition systems, which are often costly and difficult to deploy under practical farming conditions. This study presents a comparative evaluation of data-driven models for livestock body weight trajectory prediction under low-measurement conditions. A matrix factorization approach and four ensemble-based machine learning methods, namely XGBoost, LightGBM, CatBoost, and ExtraTrees, were evaluated using a dataset of Holstein cows. Model performance was assessed using standard regression metrics, including root mean squared error, mean absolute error, and mean absolute percentage error, with five-fold cross-validation employed to ensure robustness. The results show that ensemble learning methods consistently outperform matrix factorization techniques when only a limited number of weight measurements per animal are available. More specifically, XGBoost achieves the best predictive performance when only one historical measurement per animal is available, whereas ExtraTrees provides the most accurate predictions when two or three historical measurements are available. These findings demonstrate that accurate and cost-effective livestock weight prediction can be achieved from sparse routine body weight records, without relying on dense longitudinal sampling, image-based systems, or extensive morphometric measurements, thereby supporting the practical deployment of predictive tools in precision livestock farming systems.

I. INTRODUCTION

In livestock species, body weight is a key biological variable that characterizes growth trajectories and reflects the physiological processes governing animal development throughout the life cycle [1]. From a production perspective, body weight gain represents a fundamental performance trait in cattle, as it is closely associated with feed intake and growth efficiency and is widely used to assess animal performance in beef systems [2]. As a result, longitudinal body weight records are widely exploited in livestock management to support feeding decisions, assess growth performance, and identify optimal slaughter timing. Beyond productivity considerations,

longitudinal variations in body weight constitute a valuable source of information for animal health monitoring, as atypical weight patterns may be associated with metabolic imbalances or pathological conditions [3]. In addition, body weight records are commonly exploited in animal evaluation studies, where growth-related information derived from weight trajectories contributes to the assessment of production-related traits across individuals [4].

Despite the central role of body weight in livestock management, acquiring systematic and frequent live-weight measurements remains challenging under practical farming conditions. In most production systems, animals are weighed at only a limited number of time points throughout their growth period, resulting in longitudinal datasets that are often sparse and irregular. Such data limitations hinder the accurate characterization and prediction of individual growth trajectories, as reported in previous studies on cattle growth modelling [5], [6], [7]. Traditional live-weight measurement in cattle production relies primarily on either manual handling procedures or industrial weighing systems. Manual weighing approaches are labor-intensive and time-consuming, and they induce stress in both animals and handlers, which substantially limits their suitability for frequent and repeated measurements [8], [9]. Although industrial weighing systems provide accurate and reliable measurements, their high acquisition, installation, and maintenance costs restrict their adoption to specific production settings and hinder their widespread use for routine monitoring [10]. As a consequence, body weight records collected under real farming conditions often remain incomplete, posing significant challenges for the reliable modelling and prediction of individual growth trajectories.

To alleviate the limitations associated with direct live-weight measurements, a variety of indirect estimation methods based on morphometric characteristics have been investigated. Approaches relying on body dimensions obtained through manual measurements or image-based extraction have demonstrated their potential for estimating cattle live weight with reasonable accuracy [11]. More recently, machine learning techniques have been increasingly employed to exploit such indirect measurements for weight prediction, providing enhanced modelling flexibility compared to traditional regression-based approaches [12]. However, these methods often require additional data acquisition devices, controlled measurement conditions, or specialized expertise, which may restrict their practical applicability across heterogeneous farming environments.

Beyond morphometric-based approaches, data-driven methods relying directly on historical body weight records have gained increasing attention for livestock weight prediction. By learning from longitudinal observations, machine learning models are able to capture nonlinear relationships between age, growth dynamics, and body weight that are difficult to represent using classical parametric regression techniques. Comparative analysis have shown that such models can achieve improved predictive performance for cattle live-weight estimation when sufficient explanatory information is available, as illustrated in studies conducted on Hereford cows [13].

In parallel, matrix factorization approaches have been proposed to explicitly address the sparsity and irregularity of longitudinal weight datasets. By representing animal weight measurements as incomplete matrices indexed by individuals and time points, these techniques aim to reconstruct missing observations through latent representations learned from the available data. This formulation has been successfully applied to cattle growth modelling, enabling the estimation of individualized weight trajectories under limited measurement conditions [14]. The methodological foundations of this approach originate from recommender systems, where matrix factorization has proven effective for learning from sparse and incomplete data structures [15].

Despite the progress achieved in livestock weight prediction, several limitations remain in existing approaches. Many studies focus on a single modelling strategy or rely on additional measurement systems, which makes it difficult to assess the relative effectiveness of different predictive models when only a limited number of weight measurements per animal are available. Consequently, a systematic comparative evaluation of predictive models capable of handling sparse longitudinal weight data remains insufficiently explored.

Building on these developments, the present study conducts a comparative evaluation of predictive models for livestock body weight trajectory estimation under low-measurement conditions. Matrix factorization approaches and state-of-the-art ensemble learning methods—including CatBoost, ExtraTrees, LightGBM, and XGBoost—are systematically assessed using a dataset of Holstein cows. Model performance is evaluated using standard regression metrics, namely the coefficient of determination, root mean squared error, mean absolute error, and mean absolute percentage error. The objective is to identify predictive models that achieve high accuracy while remaining robust to data sparsity, thereby enabling cost-efficient and practically deployable solutions for precision livestock farming.

The main contributions of this study can be summarized as follows:

- A systematic comparison between a matrix factorization model and several state-of-the-art ensemble learning algorithms (XGBoost, LightGBM, CatBoost, and ExtraTrees) for livestock body weight trajectory prediction.
- An evaluation framework designed specifically for low-measurement conditions, where only a limited number

of historical weight observations per animal are available.

- A robust experimental protocol based on five-fold cross-validation performed at the animal level to prevent data leakage and ensure reliable performance assessment.
- An interpretability analysis using SHAP to identify the most influential predictors of cattle body weight evolution and to better understand the contribution of growth-related features.
- Practical insights for precision livestock farming by demonstrating that accurate weight prediction can be achieved using only a small number of routine weight measurements collected under real farm conditions.

II. RELATED WORKS

Early studies on livestock body weight estimation mainly relied on regression-based approaches and parametric growth models to describe the relationship between age and body weight. Although these methods are generally simple and interpretable, they often fail to capture nonlinear growth patterns and inter-animal variability, particularly when measurements are sparse or irregular [5], [7].

To improve prediction accuracy, indirect approaches based on morphometric measurements have been widely investigated. Traditional body size measurements have long been used for livestock weight estimation, and more recent studies have extended this direction through digital image analysis and computer vision techniques [8], [11]. In particular, machine learning models combined with image-derived morphological traits have shown promising performance for cattle weight prediction [13], [19]. However, these approaches usually require additional sensing or image acquisition systems, as well as controlled acquisition conditions, which may limit their applicability in routine farming environments [20].

More recently, data-driven machine learning methods operating on livestock growth and body weight data have received increasing attention. Comparative studies have shown that modern machine learning algorithms can outperform conventional approaches in cattle weight prediction tasks. For example, a comparative analysis of machine learning algorithms for Hereford cows reported strong predictive performance for ensemble-based methods [12]. In parallel, recent research has highlighted the growing role of machine learning and deep learning for modelling cattle weight gain and identifying the factors influencing livestock growth dynamics [17]. A further study proposed a machine learning framework for mob-based cattle weight gain forecasting using Random Forest, Support Vector Regression, and Long Short-Term Memory models, and showed that Random Forest achieved the best performance when historical weight records were combined with environmental variables such as rainfall and temperature [18]. These studies confirm the increasing relevance of machine learning techniques for modelling cattle growth and improving predictive accuracy in livestock production systems.

To explicitly address the problem of sparse and incomplete longitudinal records, matrix factorization techniques have also been introduced for livestock growth modelling. By learning latent representations from incomplete weight matrices, these methods enable the reconstruction of missing observations and provide an effective strategy for modelling body weight trajectories under limited measurement conditions [14],[15].

Despite these advances, few studies have provided a comprehensive comparison between sparsity-oriented matrix factorization methods and state-of-the-art ensemble-based machine learning models under strictly low-measurement settings using only routine body weight records. Moreover, many recent approaches rely on additional morphometric, image-derived, or environmental variables [18], [20] which may improve prediction performance but reduce practical deployability in routine farm conditions. This limitation motivates the present comparative study, which evaluates matrix factorization and ensemble-based machine learning methods under explicitly controlled low-measurement scenarios using only historical body weight data.

III. METHODOLOGY

A. Data Collection

The dataset used in this study was collected from a private cattle farm located in the Taroudant region, Morocco. It consists of live body weight records from 2,686 Holstein cattle. All animals are male and were born and raised within the same farm.

Data collection was conducted under routine farm management conditions between 2016 and 2020. Live body weight was measured manually using a conventional weighing scale and recorded in kilograms. For each animal, five body weight measurements are available, recorded at different ages ranging from birth to 512 days. Because weight measurements were not acquired at fixed or regular time intervals, the dataset contains sparse and partially observed records. This structure reflects real farming conditions and is suitable for evaluating predictive models under low-measurement settings, without relying on dense temporal sampling or controlled experimental protocols.

Fig. 1. Example growth curves of individual animals illustrating variations in trajectory shape, growth rate (slope), and initial age (at birth).

- Considerable variability in growth rates is observed among animals of identical sex and breed.

This variability substantially increases the complexity of the learning task. Fig. 1 illustrates representative weight curves highlighting the heterogeneity in growth patterns across animals. In addition to inter-individual differences, the sparsity of weight records further complicates modelling, as measurements are limited and irregular. Moreover, acquiring frequent weight measurements requires time and financial resources, which may not be feasible for small-scale farms.

B. Preprocessing

Prior to model development, a preprocessing step was carried out to ensure the quality and consistency of the dataset. The initial dataset comprised 10,672 animals collected under routine farm management conditions, with a variable number of body weight measurements ranging from 2 to 6 observations per animal and including different cattle breeds. To obtain a more homogeneous population for modelling, only animals belonging to the Holstein breed were retained for the present study. In addition, to ensure consistency in the experimental setup, only animals with five body weight measurements recorded at different ages during the growth period were considered in the final dataset used for model development.

To detect abnormal observations, an outlier detection procedure based on the z-score normalization method was applied using the Scikit-learn library [16]. The z-score measures how far an observation deviates from the mean of the dataset in terms of standard deviations and is defined as Eq. (1):

$$z = \frac{x-u}{s} \quad (1)$$

where, x represents the observed value, u denotes the mean of the dataset, and s corresponds to the standard deviation. Observations with a z-score greater than 3 or lower than -3 were considered outliers and removed from the dataset. This threshold makes it possible to eliminate extreme values while preserving the natural biological variability of cattle growth.

Descriptive statistics of the main variables in the final filtered dataset are summarized in Table I. The mean body weight was 255.48 kg, with a standard deviation of 196.94 kg, indicating substantial variability across different stages of animal development. Similarly, the average age was 183.16 days, with a standard deviation of 166.90 days, reflecting a wide distribution of ages in the dataset. The relatively high coefficients of variation (77.09% for body weight and 91.12% for age) indicate a heterogeneous dataset covering multiple growth phases of the animals.

TABLE I. DESCRIPTIVE STATISTICS OF THE DATASET VARIABLES

Parameters	Mean	SD	CV (%)
Body Weight (kg)	255.48	196.94	77.09
Age (days)	183.16	166.90	91.12

The dataset initially comprised 10,672 body weight measurements collected under routine farm management conditions. These measurements corresponded to 2,686 animals, with approximately four weight observations recorded for each animal at different ages. The mean body weight was 255.48 kg, with a standard deviation of 196.94 kg, indicating

substantial variability in body weight. Similarly, the average age was 183.16 days, with a standard deviation of 166.90 days, reflecting a wide age distribution in the dataset. The relatively high coefficients of variation (77.09% for body weight and 91.12% for age) indicate that the dataset captures animals at different stages of growth, as summarized in Table I.

C. Feature Space

In this study, we adopt the feature space formulation proposed [14]. The model relies on vector representations for both animals and ages, where each animal a and age d is associated with a latent feature vector. These latent vectors define a shared embedding space that captures intrinsic growth-related patterns across individuals.

The representation enables the model to differentiate animals based on their implicit growth behavior while simultaneously encoding age-dependent variations in body weight. By projecting both entities into a common latent space, the approach models the interaction between animal-specific characteristics and temporal development. This formulation is particularly suitable for sparse datasets, as it allows the estimation of unobserved weight values through learned latent factors rather than relying solely on explicit measurements.

1) *Animal feature vectors*: Animals are described using features derived from their first m weight measurements, where m represents the number of historical measurements available for prediction. For an animal a with weight measurements taken at ascending ages, we have Eq. (2):

$$a = \{(a_{g_i}, lw_i)\}_{i=1}^n \quad (2)$$

where, a_{g_i} is the i -th age in days and lw_i is the i -th live weight in kilograms.

The feature representation varies depending on the value of m :

- For $m = 1$ (single measurement available): The reduced feature vector contains:
 - ag_1 : age at the first weight measurement
 - lw_1 : first recorded live weight
 - $rwa_1 = lw_1 / ag_1$: ratio of weight to age at first measurement
- For $m \geq 2$ (multiple measurements available): The extended feature vector includes:
 - ag_1 : age at the first weight measurement
 - ag_m : age at m -th measurement
 - $\overline{agm}$: average age across the first m measurements
 - lw_1 : first recorded live weight
 - lw_m : m -th recorded live weight
 - $\overline{lw_m}$: average live weight across the first m measurements

- $rwa_1 = lw_1 / ag_1$: ratio of weight to age at first measurement
- $adgm = (lw_m - lw_1) / (ag_m - ag_1)$: average daily gain computed from the first m measurements

These features capture both the initial state of the animal when measurements begin and the growth dynamics observed in the available historical data. The average daily gain ($adgm$) is particularly important as it provides information about the animal's growth rate, which helps predict future weights. We are focused solely on males, and holstein cows. Therefore, we ignore sex and race in this study.

2) *Age feature vector*: Two different feature representations were considered in this study. we adopted the same polynomial age encoding used in the original formulation. Specifically, age was represented through a cubic polynomial expansion (age, age^2, age^3), where age denotes the number of days at which body weight is predicted. This representation enables the model to capture nonlinear growth trends within the latent factor framework.

In contrast, for the gradient boosting models, age was included as a single numerical variable $d = age$. Polynomial expansion was not required, as tree-based ensemble methods inherently model nonlinear relationships and interaction effects through recursive partitioning. This distinction ensures that each modelling approach is evaluated under a feature representation consistent with its structural properties.

D. Machine Learning Algorithms

Five predictive models were evaluated for cattle weight prediction, including a matrix factorization approach based on the formulation proposed in [14] and four ensemble-based machine learning models: XGBoost, LightGBM, CatBoost, and ExtraTrees. The objective of this study is to compare the predictive performance of matrix factorization and ensemble-based learning methods under low-measurement conditions. The matrix factorization model was included to address data sparsity through latent representation learning, whereas the ensemble-based models were selected for their ability to capture nonlinear relationships in heterogeneous and limited tabular data. The ensemble-based models were implemented in Python using standard machine learning libraries, including Scikit-learn [16], while the matrix factorization model was implemented in Python following the formulation described in [14].

1) *Matrix factorization*: Matrix factorization was used in this study as a sparsity-aware approach for predicting cattle body weight trajectories under low-measurement conditions [14]. The problem was formulated as a matrix completion task in which animals correspond to rows, ages correspond to columns, and observed body weight measurements correspond to known matrix entries. The model learns two low-dimensional embedding matrices, W and V , which map animals and ages into a common latent space of dimension k . The predicted body weight for animal a at age d is computed as

given below, where W_a and V_a represent the latent representations of the animal and age, respectively, as defined in Eq. (3):

$$\hat{g}(a, d) = \langle W_a, V_d \rangle \quad (3)$$

The matrix factorization model was trained using Stochastic Gradient Descent (SGD) to minimize the mean squared error with L_2 regularization. The hyperparameter configuration adopted in this study is summarized in Table II. The latent space dimension was set to $k = 10$, the learning rate decay parameter was fixed at $\gamma_s = 1.0$, and the regularization coefficient was defined as $\nu = 0.001$. The model was trained for 100 iterations, which provided stable convergence during training. Preliminary sensitivity analyses indicated that further adjustments of these hyperparameters did not lead to significant improvements in predictive performance.

TABLE II. HYPERPARAMETER CONFIGURATION OF THE MATRIX FACTORIZATION MODEL.

Parameter	Value	Description
k	10	Latent space dimension
γ_s	1.0	Learning rate decay parameter
ν	0.001	L2 regularization coefficient
Iterations	100	Number of SGD training iterations

2) *Ensemble-based tree models*: Ensemble-based tree learning methods construct predictive models by combining multiple decision trees in order to improve prediction accuracy and generalization. In this study, four tree-based ensemble algorithms were evaluated for cattle weight prediction under low-measurement conditions: XGBoost, LightGBM, CatBoost, and ExtraTrees. These models were selected because of their strong performance in regression tasks involving tabular data and their ability to capture complex nonlinear relationships.

TABLE III. HYPERPARAMETER CONFIGURATION OF THE GRADIENT BOOSTING MODELS.

Parameter	XGBoost	LightGBM	CatBoost
Boosting rounds	100	100	100
Maximum depth	6	-	6
Learning rate	0.05	0.05	0.05
Row sampling	0.8	0.8	0.8
Column sampling	0.9	0.9	-
num_leaves	-	31	-
bagging_freq	-	5	-

The detailed hyperparameter configuration of these models is reported in Table III.

XGBoost (Extreme Gradient Boosting) implements a regularized boosting framework that incorporates both L_1 and

L_2 penalties to control model complexity. In this study, the model was configured with 100 estimators, a maximum tree depth of 6, a learning rate of 0.05, a row subsampling ratio of 0.8, and a column subsampling ratio of 0.9. These settings provide a balance between model flexibility and generalization by controlling tree depth and introducing stochastic sampling to mitigate overfitting.

LightGBM (Light Gradient Boosting Machine) adopts a leaf-wise tree growth strategy combined with histogram-based optimization, which improves computational efficiency while maintaining high predictive performance. The model was trained using 100 boosting rounds, a maximum of 31 leaves per tree, a learning rate of 0.05, a feature fraction of 0.9, a bagging fraction of 0.8, and a bagging frequency of 5 iterations.

CatBoost (Categorical Boosting) relies on ordered boosting and symmetric tree structures, which help reduce prediction bias and improve training stability. In this study, CatBoost was configured with 100 iterations, a maximum tree depth of 6, a learning rate of 0.05, and a subsampling ratio of 0.8.

TABLE IV. HYPERPARAMETER CONFIGURATION OF THE EXTRATREES MODEL.

Parameter	Value	Description
n_estimators	100	Number of trees
max_depth	None	Unlimited tree depth
min_samples_split	2	Minimum samples to split a node
min_samples_leaf	1	Minimum samples per leaf node

ExtraTrees (Extremely Randomized Trees) was included in this study as one of the evaluated tree-based ensemble models for cattle weight prediction under low-measurement conditions. The hyperparameter configuration of the model is summarized in Table IV. The model was implemented with 100 estimators and no explicit maximum depth constraint, allowing the trees to grow until purity. The minimum number of samples required to split an internal node was set to 2, and the minimum number of samples per leaf node was fixed at 1. This configuration preserves model flexibility while maintaining the model's ability to capture nonlinear relationships in heterogeneous tabular data.

E. Model Evaluation

To ensure methodological consistency with [14] and maintain a comparable evaluation framework, we adopted the same experimental protocol based on two key parameters: m_{train} , representing the number of measurements used for model training, and m_{test} , representing the number of measurements available at test time. In our experiments, both parameters were set equal ($m_{train} = m_{test} = m$) to guarantee that models were evaluated under the same information constraints used during training.

The value of m varies from 1 to 3, given that each animal is associated with a maximum of five recorded weight measurements. For a given configuration m , the first m measurements are used as input features, and the model is trained to predict the remaining future measurements. For

example, when $m = 1$, the model uses only the first weight observation to predict subsequent measurements corresponding to positions 2 through 5. Similarly, when $m = 2$, the first two measurements are used as input, and the model is trained to predict the weights at positions 3, 4, and 5.

This evaluation strategy allows systematic analysis of model performance under progressively increasing information availability, while preserving a consistent and controlled experimental setup across all predictive approaches.

1) *Data splitting and cross-validation*: A five-fold cross-validation strategy was adopted to evaluate model performance. Data partitioning was carried out at the animal level rather than at the individual measurement level in order to prevent data leakage. This ensures that all records associated with a given animal are assigned entirely to either the training set or the testing set within each fold, thereby providing a realistic evaluation of the models' ability to generalize to unseen animals.

For each fold, the dataset was divided into 80% training data and 20% testing data. Stratified sampling based on animal identifiers was applied to preserve the distribution of animals across the subsets. To guarantee reproducibility and enable consistent comparisons between models, predefined random seeds (30, 50, 70, 85, and 90) were used during the data splitting process.

2) *Evaluation metrics*: Model performance was evaluated using three complementary regression metrics, each capturing a distinct aspect of predictive accuracy.

Mean Squared Error (MSE) was computed in the standardized feature space (after z-score normalization) in order to prevent scale effects from influencing error magnitude. It is defined as Eq. (4):

$$MSE = \frac{1}{n} \sum_{i=1}^n (\hat{w}_i - w_i)^2 \quad (4)$$

where, $\hat{w}_i$ and w_i denote the predicted and true standardized weights, respectively, and n represents the number of observations.

Mean Absolute Error (MAE) was calculated in kilograms to provide an interpretable measure of the average absolute deviation between predicted and actual weights in the original measurement scale [see Eq. (5)]:

$$MAE = \frac{1}{n} \sum_{i=1}^n |\hat{w}_i - w_i| \quad (5)$$

Mean Absolute Percentage Error (MAPE) expresses prediction error as a relative percentage of the true weight, allowing scale-independent comparison across animals with different body weight ranges [see Eq. (6)]:

$$MAPE = \frac{1}{n} \sum_{i=1}^n \left| \frac{\hat{w}_i - w_i}{w_i} \right| \times 100 \quad (6)$$

Together, these metrics provide a comprehensive evaluation framework by quantifying squared error magnitude (MSE), absolute deviation (MAE), and relative prediction accuracy (MAPE).

IV. RESULTS AND DISCUSSION

A. Predictive Performance Under Low-Measurement Conditions

In this study, five predictive models were evaluated for cattle weight prediction: the Matrix Factorization (MF) approach proposed in [14] and four tree-based ensemble algorithms, namely XGBoost, LightGBM, CatBoost, and ExtraTrees [16]. Particular emphasis was placed on low-measurement conditions, defined as scenarios in which only a limited number of historical weight records per animal are available. This setting reflects practical livestock farming constraints, where frequent weight measurements are costly and difficult to obtain.

To simulate sparse-data conditions, the number of available measurements per animal (m) was restricted to 1, 2, and 3. These configurations make it possible to assess model robustness as the amount of historical information increases. For each value of m , a five-fold cross-validation procedure was performed at the animal level to prevent data leakage. Identical predefined random seeds were used across all models to ensure consistent data splits and a fair comparison between methods. Model performance was evaluated using the mean and standard deviation of MSE, MAE (kg), and MAPE (%).

The results are presented in Table V to Table VII for $m = 1$, $m = 2$, and $m = 3$, respectively. Under the most restrictive condition ($m = 1$), where only a single historical weight measurement is available per animal, the Matrix Factorization (MF) model exhibits substantially higher error values. This behaviour indicates a strong sensitivity to data sparsity under low-measurement conditions. Since the MF model relies on latent factor representations learned from the interaction between animals and ages, the limited amount of information available in this setting restricts its ability to estimate reliable latent factors.

In contrast, the tree-based ensemble models maintain stable and significantly lower error values, demonstrating greater robustness under low-measurement conditions. Models such as XGBoost, LightGBM, CatBoost, and ExtraTrees are able to capture nonlinear relationships between age and weight even when the available historical information is limited. Their recursive tree construction enables them to model complex variable interactions without requiring a large number of previous measurements.

TABLE V. RESULTS OF 5-FOLD CROSS-VALIDATION FOR $m = 1$ USING THE MOST EFFICIENT ALGORITHMS [MEAN AND SD FOR MSE, MAE (KG), AND MAPE (%)].

Model	MSE		MAE (kg)		MAPE (%)	
	Mean	SD	Mean	SD	Mean	SD
XGBoost	0.04794	0.00285	26.544	0.726	9.192	0.323
LightGBM	0.04815	0.00369	26.739	0.722	9.258	0.325
CatBoost	0.04908	0.00283	27.466	0.701	9.707	0.280
ExtraTrees	0.05940	0.00290	29.060	0.597	9.791	0.271
Matrix Factorization	0.09965	0.00241	44.016	1.042	19.436	0.688

Among the evaluated methods, XGBoost achieves the best overall predictive performance for $m = 1$ in Table V. This superior performance can be attributed to its regularized boosting framework, which combines multiple decision trees while controlling model complexity. These regularization mechanisms help prevent overfitting and improve generalization, making XGBoost particularly effective in sparse-data scenarios. The other ensemble-based models show comparable accuracy levels, confirming the overall robustness of tree-based ensemble approaches under extreme measurement constraints.

TABLE VI. RESULTS OF 5-FOLD CROSS-VALIDATION FOR $m = 2$ USING THE MOST EFFICIENT ALGORITHMS [MEAN AND SD FOR MSE, MAE (KG), AND MAPE (%)].

Model	MSE		MAE (kg)		MAPE (%)	
	Mean	SD	Mean	SD	Mean	SD
ExtraTrees	0.06425	0.00121	29.734	0.395	8.307	0.163
XGBoost	0.06056	0.00399	29.831	0.776	8.470	0.290
LightGBM	0.06095	0.00408	30.100	0.711	8.691	0.258
CatBoost	0.06448	0.00427	31.616	1.014	9.259	0.379
Matrix Factorization	0.09651	0.01061	42.769	2.747	14.566	1.314

For $m = 2$ in Table VI, the performance gap between the Matrix Factorization model and the tree-based ensemble models remains evident. Although the availability of two measurements improves the predictive capability of all models, the ensemble-based approaches continue to achieve substantially lower error values across MSE, MAE, and MAPE. This improvement can be explained by the additional historical information provided by the second measurement, which allows the models to better capture the early growth dynamics of each animal.

In this configuration, the ExtraTrees model slightly outperforms XGBoost, achieving the lowest mean MAPE and MAE values. This result suggests that the additional randomness introduced by ExtraTrees during the split selection process helps improve model generalization when a moderate amount of historical information is available. By constructing multiple highly diversified trees, ExtraTrees can better adapt to heterogeneous growth patterns across animals.

Overall, these results confirm that tree-based ensemble methods maintain strong predictive accuracy and generalization capability under limited measurement settings. Even when only two historical measurements are available, these models are able to capture meaningful relationships between age and body weight, leading to reliable predictions.

For $m = 3$ in Table VII, the increase in the number of available historical measurements leads to a noticeable improvement in the performance of the Matrix Factorization (MF) model, highlighting its dependence on a larger amount of historical information. With three observed measurements per animal, the MF model is able to estimate more reliable latent representations of the interaction between animals and ages.

TABLE VII. RESULTS OF 5-FOLD CROSS-VALIDATION FOR $m = 3$ USING THE MOST EFFICIENT ALGORITHMS [MEAN AND SD FOR MSE, MAE (KG), AND MAPE (%)].

Model	MSE		MAE (kg)		MAPE (%)	
	Mean	SD	Mean	SD	Mean	SD
ExtraTrees	0.08963	0.00499	32.591	0.383	7.734	0.118
XGBoost	0.09037	0.00540	33.285	0.183	7.955	0.078
LightGBM	0.08907	0.00526	33.279	0.264	8.004	0.076
CatBoost	0.09942	0.00643	35.383	0.894	8.687	0.305
Matrix Factorization	0.10986	0.01263	39.616	2.327	10.384	0.798

However, despite this improvement, the MF model does not surpass the tree-based ensemble models in any of the evaluated metrics. The ensemble-based methods continue to provide lower prediction errors and more stable results across folds. Under this configuration, the ExtraTrees model again achieves the best overall predictive accuracy, followed closely by XGBoost and LightGBM.

Fig. 2. Comparison of MAPE values across the evaluated models under low-measurement conditions ($m = 1, 2, 3$). Ensemble-based models consistently achieve lower prediction errors than Matrix Factorization.

Fig. 2 shows the MAPE comparison of the evaluated models for $m = 1, 2$, and 3 . The tree-based ensemble models consistently produce lower percentage errors than Matrix Factorization across all scenarios. XGBoost achieves the best performance for $m = 1$, whereas ExtraTrees performs best for $m = 2$ and $m = 3$. Although Matrix Factorization improves when more measurements are available, it remains less accurate than the ensemble-based models.

The reduced variability observed for the ensemble-based models, reflected by lower standard deviation (SD) values, further indicates greater stability and robustness across cross-validation folds. These results suggest that tree-based ensemble models are better suited to modelling heterogeneous growth patterns, as they can capture nonlinear relationships between age and body weight while remaining robust under limited-measurement conditions.

Overall, the results demonstrate that although Matrix Factorization benefits from additional measurements, tree-based ensemble models consistently achieve higher predictive accuracy and greater robustness across all low-measurement scenarios. These findings confirm their suitability for practical

livestock applications where frequent body weight measurements are difficult to obtain.

B. Model Interpretation Using SHAP Analysis

To complement the quantitative evaluation reported in Table V to Table VII (for $m = 1, 2$, and 3 , respectively), a SHAP (SHapley Additive exPlanations) analysis was conducted to investigate the contribution of input features to the predictions of the best-performing ensemble models under different measurement configurations.

Fig. 3. Feature contribution analysis using SHAP for $m = 1$ (XGBoost model).

Fig. 3 presents the SHAP summary plot for the XGBoost model when only one historical measurement is available ($m = 1$). Under this extreme low-measurement condition, the model relies primarily on the initial weight measurement and the age at the first observation. Since no trajectory information is available, the prediction mainly depends on baseline physiological indicators describing the animal's initial condition. The SHAP values show that the first recorded weight has the largest influence on the predicted future weight, while the age variable provides complementary contextual information about the stage of growth.

Fig. 4. Feature contribution analysis using SHAP for $m = 2$ (ExtraTrees model).

Fig. 4 illustrates the SHAP summary plot obtained for the ExtraTrees model when two measurements are available ($m = 2$). With the addition of a second observation, the model can start capturing the early growth dynamics of each animal. In this configuration, trajectory-related features such as the average weight and the average daily gain become more influential. The SHAP analysis indicates that growth rate indicators contribute significantly to the prediction process,

allowing the model to better estimate the future evolution of body weight.

Fig. 5 presents the SHAP summary plot for the ExtraTrees model when three measurements are available ($m = 3$). In this configuration, the model benefits from richer historical information, enabling a more accurate representation of the animal's growth trajectory. The SHAP results highlight the dominant contribution of growth-related variables, particularly average daily gain and aggregated weight indicators. These variables provide direct information about the animal's growth velocity, which explains the improved predictive performance observed in Table VII.

Fig. 5. Feature contribution analysis using SHAP for $m = 3$ (ExtraTrees model).

To complement the quantitative evaluation reported in Table V to Table VII, a SHAP (SHapley Additive exPlanations) analysis was conducted to interpret the contribution of input features to the predictions of the best-performing ensemble models. Fig. 3 shows the SHAP summary plot for $m = 1$ (XGBoost), where the prediction mainly depends on the initial weight measurement due to the absence of trajectory information. Fig. 4 presents the SHAP analysis for $m = 2$ (ExtraTrees), where growth-related features such as average weight and early growth indicators become more influential. Finally, Fig. 5 illustrates the SHAP results for $m = 3$ (ExtraTrees), highlighting the dominant contribution of trajectory-based variables, particularly those describing growth dynamics. These results confirm that as the number of available measurements increases, the models rely more on growth-related features to improve prediction accuracy.

1) *Global feature importance across measurement configurations*: Across all configurations, the SHAP analysis reveals that dynamic growth indicators play a dominant role in prediction accuracy. For $m = 2$ and $m = 3$, in Fig. 4 and Fig. 5, Average Daily Gain (ADG) consistently emerges as the most influential predictor, followed by the first recorded weight (lw1), the average weight (avg_lw), and the target age. This ranking is consistent with the superior predictive performance reported in Tables V and VI, where the ensemble models achieve lower MSE, MAE (kg), and MAPE (%) values.

The dominance of ADG indicates that growth velocity provides more predictive information than isolated static measurements. From a biological perspective, the early growth rate reflects metabolic efficiency and genetic growth potential,

which explains its strong contribution within tree-based ensemble models.

2) *Interpretation under extreme sparsity ($m = 1$):* Under extreme low-measurement conditions ($m = 1$; see Table V and Fig. 3), the model lacks sufficient trajectory information and must rely primarily on initial physiological indicators, including the first recorded weight (lw_1), the age at the first measurement (ag_1), and the weight-to-age ratio (rw_1). In this configuration, the SHAP values indicate a stronger dependence on variables describing the animal's initial body condition.

Since only one historical measurement is available, the model cannot infer the growth dynamics of each animal and instead extrapolates future weight based on baseline physiological characteristics. This limitation explains the relatively higher prediction errors observed in Table V, particularly for the Matrix Factorization model, which struggles under extreme sparsity compared with gradient boosting approaches.

3) *Evolution of feature contributions with increasing m :* As the number of available measurements increases ($m = 2$ and $m = 3$), the SHAP results Fig. 4 and Fig. 5 show a clear shift toward trajectory-based variables, particularly Average Daily Gain (ADG), the average weight (avg_lw), and aggregated growth indicators. This transition corresponds to the performance improvements observed in Table VI to Table VII, where both the error magnitude (MAE and MAPE) and the variability across folds (SD) decrease.

The ensemble models are able to exploit nonlinear interactions between growth rate and age more effectively when additional historical information becomes available. As a result, the models achieve improved predictive stability, reduced fold-to-fold variance, and greater robustness to sparsity in the weight measurements.

4) *Biological and methodological implications:* The SHAP interpretation confirms that the superiority of gradient boosting models, as demonstrated in Table V to Table VII, is not merely statistical but also biologically coherent. Under low-measurement conditions, the models prioritize dynamic growth descriptors rather than isolated static measurements. This behavior validates both the relevance of the feature formulation inspired by [14] and the effectiveness of ensemble learning methods for handling sparse longitudinal livestock data.

Overall, the interpretability analysis strengthens the scientific credibility of the proposed framework by demonstrating that the most influential variables correspond to biologically meaningful growth indicators. In addition, the ensemble models progressively adapt as the number of available measurements increases, allowing them to capture growth dynamics more effectively. These findings indicate that accurate livestock weight prediction can be achieved even under low-measurement conditions, which is particularly important for small-scale or resource-constrained farming

systems where frequent data collection is difficult to implement.

V. CONCLUSION

This study demonstrates that gradient boosting models consistently outperform matrix factorization techniques for livestock body weight prediction under low-measurement conditions. While the performance of matrix factorization improves when additional historical measurements become available, ensemble tree-based methods—particularly XGBoost and ExtraTrees—maintain superior predictive accuracy even when only a small number of weight observations per animal are available. These results indicate that reliable livestock weight prediction can be achieved without relying on dense longitudinal records, image-based sensing systems, or extensive morphometric measurements.

The main contribution of this work lies in the systematic comparison of matrix factorization and state-of-the-art gradient boosting models under explicitly controlled low-measurement scenarios ($m = 1, 2$, and 3). Unlike approaches that require complex sensing infrastructures, the proposed framework relies exclusively on sparse body weight records collected under routine farm management conditions. This design demonstrates that ensemble learning models remain robust when operating with incomplete and irregular livestock data.

Beyond the methodological contribution, the findings have direct practical implications for precision livestock farming. Accurate prediction of cattle body weight using only a limited number of measurements can assist farmers and farm managers in monitoring growth trajectories, optimizing feeding strategies, and determining appropriate market or slaughter timing. By reducing the need for frequent manual weighing or costly measurement technologies, the proposed approach offers a practical and cost-efficient solution for supporting daily farm management decisions.

Such predictive tools are particularly beneficial for small- and medium-scale farms or production systems with limited technological resources. Integrating machine learning-based prediction models into farm management platforms could enable more efficient monitoring of herd performance, facilitate data-driven decision-making, and improve overall productivity within precision livestock farming systems.

Future research will focus on extending the proposed framework by incorporating additional environmental and management-related variables, such as feeding regime, temperature, and humidity, to further improve predictive performance and provide a deeper understanding of the factors influencing cattle growth dynamics in real-world farming environments.

Prickly Pear Disease Classification Using Deep Convolutional Neural Networks: A Case Study

Raghiya Elghawth*, Wafae Abbaoui, Soumia Ziti

Intelligent Processing and Security of Systems-Faculty of Sciences, Mohammed V University, Rabat, Morocco

Abstract—Prickly pear (*Opuntia ficus-indica*) is a member of the Cactaceae family. Because of its anti-inflammatory, anti-oxidant, antibacterial, hypoglycemic, and neuroprotective properties, prickly pears are a magical fruit. Both the fruit and its stem are utilized in value-added products. Deep learning (DL) applications are required for prickly pear disease detection and classification. To the best of our knowledge, no previous study has investigated prickly pear disease classification using convolutional neural networks. In this study, we propose the use of deep convolutional neural networks MobileNetV2 and DenseNet121, to classify prickly pear disease. A locally collected dataset from Tunisia was divided into two classes: healthy and cochineal. Data augmentation techniques were applied to increase the number of images. These augmented data were then fed as input into MobileNetV2 and DenseNet121 networks. The experimental results show that MobileNetV2 achieved a precision, recall, and F1-score of 96.55% for healthy plants. For diseased plants, precision, recall, and F1-score reached 97.14%. Overall, the model obtained a classification accuracy of 96.88%. DenseNet121 achieved precision, recall, and F1-score values of 90.62%, 100%, and 95.08%, respectively, for healthy plants. For diseased plants, the precision, recall, and F1-score were 100%, 91.43%, and 95.52%, respectively, resulting in an overall classification accuracy of 95.31%. Our proposed deep learning models, MobileNetV2 and DenseNet121, perform well and demonstrate strong performance on the prickly pear dataset.

I. INTRODUCTION

Opuntia ficus-indica is commonly known as prickly pear and belongs to the Cactaceae family. It originates from Mexico, because of its unique adaptations and great capacity for biomass production, which enable it to thrive in harsh environments like hot weather and eroding, nutritionally deficient soils [1]. The prickly pear plant is utilized for a variety of purposes, such as food, feed, health, and nutrition, as well as for the production of prepared products like cosmetics, tea, juice, jam, and oil that is derived from the seeds [2]. Prickly pear has spread widely throughout the world, such as in Mexico, Africa, the American continent, and the Mediterranean Basin. It is utilized in a variety of medications due to its important function in disease treatment, anti-inflammatory, hypoglycemic, and stomach ulcer prevention properties. It is used as an antioxidant in many countries to treat burns, diabetes, bronchitis, asthma, and indigestion [3]. Early diagnosis of plant diseases is crucial to avoid crop losses. Traditional plant disease detection methods, which rely on manual feature extraction with the help of agricultural experts, are time-consuming, require labor, and are prone to errors. In contrast, deep learning methods have demonstrated impressive

results across various fields, including agriculture [4], [5]. This research aims to classify prickly pear diseases using deep convolutional neural networks (CNNs), specifically MobileNetV2 and DenseNet121. The performance of the proposed models was evaluated using metrics such as precision, recall, F1-score, and accuracy. However, the use of well-known pretrained architectures like MobileNetV2 and DenseNet121 may limit the perception of technical novelty. Therefore, this work aims to provide a baseline evaluation of lightweight and efficient deep learning models under real-world conditions for prickly pear disease classification.

To the best of our knowledge, no prior studies have investigated the prickly pear plant, despite its importance. The main contribution of this work lies in its application to prickly pear disease classification using a real-field dataset, which presents unique challenges compared to commonly used plant disease datasets. Unlike controlled datasets, prickly pear images collected from the field exhibit high variability in background, lighting conditions, plant structure, and symptom appearance, particularly due to the irregular shape of cladodes and the diverse visual manifestations of cochineal infection at different stages. In addition, publicly available datasets for this crop are extremely limited or nonexistent, further emphasizing the relevance of this study.

Several studies have emphasized the efficiency of MobileNetV2 and DenseNet121 in early and automatic plant disease detection and classification.

Gatla et al. [6] aimed to develop an efficient edge AI framework for tomato leaf disease detection. They employ lightweight pre-trained models, particularly MobileNetV2, integrated with convolutional neural networks (CNNs), trained on the Plant Village dataset consisting of 18,160 images across ten tomato disease categories. The proposed method accomplished high performance, with MobileNetV2 attaining an accuracy of 98.99%. Joseph et al. [7] aimed to develop an accurate, real-time dataset and detection system for plant diseases affecting rice, wheat, and maize using deep learning. The study fine-tuned eight pre-trained CNN models, achieving test accuracies of 96.32% and 96.28% for MobileNetV2 and MobileNet, respectively, while recognizing the wheat leaf diseases. Taha and Badawy. [8] proposed a deep learning-based system for early plant disease detection to enhance sustainable agriculture. They utilized the MobileNetV2 CNN model, fine-tuned on the Plant Village dataset comprising 31,718 training and 4,514 test images across 20 disease categories. The model attained a high validation accuracy of 99.4%, with precision, recall, and F1-score metrics each around 99.3%, 99.2%, and 99.3%, respectively. Naveed et al. [9] developed AgriSage, an

*Corresponding author.

Android-based application for plant disease detection. They employed two deep-learning models: a MobileNetV2 classifier for binary classification and a custom CNN for multiclass disease classification. The MobileNetV2 model achieved a precision, recall, and F1-score of 1.00 for both classes on the test set. Duhan et al. [10] propose RTR_Lite_MobileNetV2 for developing a lightweight, accurate deep-learning model for plant disease detection and classification suitable for resource-constrained devices. The method is based on an enhanced MobileNetV2 architecture that integrates multiple attention mechanisms. The model is evaluated on seven publicly available datasets (Plant Disease/PlantVillage, PlantDoc, PaddyDoctor, Coffee, Wheat, Soybean, and Sugarcane). The results demonstrated high performance on the Plant Disease dataset, achieving an accuracy of 99.92%.

Ayyappan et al. [11] aimed to detect several rice plant diseases, such as blast, brown spot, and bacterial blight, using deep learning approaches. The authors trained and evaluated four state-of-the-art Convolutional Neural Network (CNN) models—DenseNet121, Xception, EfficientNet B4, and MobileNet V3 Large—on a dataset containing 10,407 images across 10 classes. Among the evaluated models, DenseNet121 achieved the highest performance with a test accuracy of 97.50%, followed by Xception at 96.32% and both EfficientNet B4 and MobileNet V3 Large at 96.25%. Simangunsong et al. [12] modified the DenseNet architecture to develop an optimized deep learning model for tomato disease classification. DenseNet-SEGR integrates the Squeeze-and-Excite (SE) block and utilizes a customized growth rate of 48 to optimize feature selection and classification. A dataset containing 12,246 images across 10 disease categories was used to train and evaluate the model. Compared to DenseNet-121, DenseNet-201, and MobileNetV2, DenseNet-SEGR achieved superior performance with accuracy of 98.22%, precision of 98.25%, recall of 98.22%, and F1-score of 98.22%. Ahad et al. [13] conducted a comparative study to assess the performance of deep learning architectures for classifying nine epidemic rice diseases in Bangladesh. It compared six models (DenseNet121, Inceptionv3, MobileNetV2, ResNet152V, ResNext10, and Seresnext101), transfer learning applied to four of these, and an ensemble model called DEX (DenseNet121, EfficientNetB7, and Xception). The dataset used combines the Rice Leaf Disease Dataset from Machine Learning Repository, as well as a dataset from the Bangladesh Rice Research Institute. The ensemble framework (DEX) achieved the highest accuracy of 98%, outperforming all individual networks, while Densenet121 achieved 97%. Belattar et al. [14] developed an effective and optimized CNN architecture (OP-CNN) to diagnose strawberry plant diseases in Morocco. To enhance performance, the proposed model was trained on a dataset of 2,000 images from Kaggle, with images preprocessed and augmented. The proposed model achieved an accuracy of 100%, precision of 100%, recall of 100%, and F1-score of 100% in the test set, outperforming DenseNet121, VGG19, and ResNet50, whereas DenseNet121 achieved an accuracy of 99%, precision of 100%, recall of 99%, and F1-score of 99%. Radhika and Kannan. [15] propose a model to enhance early detection of bell pepper leaf

diseases using BPCCBAMIV3 (Bit direction and Positional Context Convolutional Block Attention Module) with InceptionV3 by integrating three attention mechanisms—Channel, Bit-level, and Positional—to capture irregular disease patterns and texture features. Using the PlantVillage dataset and a custom bell pepper dataset, we trained and tested the model. It achieved high accuracy, scoring 97.04% and 95.16%, respectively, outperforming others such as AlexNet, VGG16, ResNet50, DenseNet121 and EfficientNetB7. An accuracy of 94.62% was achieved by DenseNet121 on a custom bell pepper dataset.

There are no prior studies addressing prickly pear disease detection and classification using deep learning models. Therefore, the related work was expanded to include relevant studies on plant disease detection using MobileNetV2 and DenseNet121 architectures across other crops, in order to highlight the performance of these models. Compared to existing methods applied to other crops, our approach addresses an unexplored crop using a publicly available real-field dataset and demonstrates promising results for prickly pear disease classification.

The rest of this study is organized as follows. Section II presents a detailed description of the methodology. In Section III, the experimental results of the proposed method are presented and discussed. Section IV concludes the study and discusses future work.

II. METHODOLOGY

This section describes the CNN models employed, the dataset used, and the data augmentation techniques applied. The first and second subsections present the MobileNetV2 and DenseNet121 deep learning models, respectively, for classifying prickly pear plants as healthy or diseased. The third subsection describes the dataset structure and class distribution in detail. The final subsection presents the data augmentation techniques applied during training, including rotation, zoom, shift, and shear transformations.

A. MobileNetV2

The Google team developed MobileNetV2 as an improved version of MobileNetV1 [16]. This lightweight convolutional neural network architecture provides a good balance between model accuracy and inference speed, which makes it suitable for many applications, including object detection, image classification, and semantic segmentation. MobileNet divides the convolution into two layers: depth-wise and point-wise. Depth-wise convolution performs a single convolutional filter per input channel, whereas point-wise convolution calculates a linear combination of the input channels to build new features. MobileNetV2 introduces inverted residual blocks, where residual connections link low-dimensional representations rather than expanded feature spaces, and employs linear bottlenecks by removing nonlinear activations in the final projection layer to prevent information loss in compact feature representations [17]. MobileNetV2 basic structure is shown in Fig. 1.

Fig. 1. MobileNet-V2 basic structure.

B. DenseNet121

In a traditional convolutional network with L layers, there are L connections—one between each layer and its subsequent layer. The Dense Convolutional Network (DenseNet) connects each layer to every other layer in a feed-forward fashion; it has $L(L+1)/2$ direct connections. DenseNet-121 is a densely connected convolutional neural network composed of 121 layers, where each layer receives as input the feature maps of all preceding layers and passes its own feature maps to all subsequent layers. There are several advantages of DenseNet, including the mitigation of the vanishing gradient problem, better feature propagation, and the ability to reuse features [18]. The structure of the dense block is shown in Fig. 2.

Fig. 2. Dense block structure.

C. Dataset

This research used a dataset of cactus (Prickly Pear), which comprised a total of 628 original images, including 285 images of healthy cacti and 343 images of cacti infected with the cochineal insect. All images were captured in Sidi Bouzid, Tunisia, with a pixel density of 72 pixels per inch, standardized, and saved in PNG format. The dataset was obtained from Mendeley data [19]. Due to the limited dataset size (628 images), the dataset was divided into 80% for training, 10% for validation, and 10% for testing, with data augmentation applied only to the training set to improve generalization. The details of the dataset split are presented in Table I. Images of healthy and

diseased prickly pear plants, collected from the field of Sidi Bouzid, Tunisia, are shown in Fig. 3 and Fig. 4, respectively.

TABLE I. IMAGES USED IN THE TRAIN, VALIDATION AND TEST SETS.

Classes	Total images	Training images	Validation images	Testing images
Healthy	285 images	228 images	28 images	29 images
Cochineal	343 images	274 images	34 images	35 images

Fig. 4. Examples of the prickly pear diseases.

D. Data Augmentation and Model Hyperparameters

Data augmentation was used to meet the large data utilization challenge and to address model overfitting issues. This was achieved using the ImageDataGenerator class of the Keras library. Augmented and enhanced images were given to the MobileNetV2 and DenseNet121 predefined architectures. Data augmentation techniques applied during the training phase

are presented in Table II. Model hyperparameters for MobileNetV2 and DenseNet121 are provided in Table III and Table IV, respectively. Hyperparameter values were determined through a series of experiments in which multiple configurations were evaluated using the validation set. Parameters such as learning rate, batch size, dropout rate, and regularization were adjusted iteratively to obtain stable convergence and improved validation performance while minimizing overfitting.

III. RESULTS AND DISCUSSION

This study utilized a publicly available dataset collected in Sidi Bouzid, Tunisia, for prickly pear disease classification. The dataset consists of 628 images of healthy and diseased prickly pear plants, which were used to train, validate, and test the MobileNetV2 and DenseNet121 models. Transfer learning was employed for both models by initializing the networks with ImageNet-pretrained weights, followed by fine-tuning to improve model performance. To mitigate overfitting, early stopping, dropout, and L2 regularization were applied during training. The performance of the MobileNetV2 and DenseNet121 models was evaluated using precision, recall, F1-score, and accuracy. These metrics are defined as follows.

$$\text{Precision} = \frac{TP}{TP+FP} \quad (1)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (2)$$

$$\text{F1-score} = \frac{2 \cdot \text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (3)$$

$$\text{Accuracy} = \frac{\text{Correct Predictions}}{\text{Total Predictions}} \quad (4)$$

$$\text{PrecisionMacroAvg} = \sum_{i=1}^n \left(\frac{\text{Precision}_i}{n} \right) \quad (5)$$

$$\text{RecallMacroAvg} = \sum_{i=1}^n \left(\frac{\text{Recall}_i}{n} \right) \quad (6)$$

$$\text{F1-scoreMacroAvg} = \sum_{i=1}^n \left(\frac{\text{F1-score}_i}{n} \right) \quad (7)$$

$$\text{WeightedAvg F1-score} = \sum_{i=1}^N (W_i \times \text{F1-score}_i) \quad (8)$$

where,

$$W_i = \frac{\text{Number of samples in each class}_i}{\text{Total number of samples}} \quad (9)$$

The weighted average precision and recall are computed in the same manner.

The classification results of MobileNetV2 are presented in Table V. They demonstrate strong performance for both classes. For the Cochineal class, the model achieved precision, recall, and F1-score values of 97.14%. For the Healthy class, the precision, recall, and F1-score reached 96.55%. The overall classification accuracy of the model was 96.88% on the test set (64 samples). In addition, the macro-average (96.85%) and weighted-average (96.88%) scores are nearly identical, indicating balanced performance across classes without bias toward either category.

The classification results of DenseNet121 (Table VI) indicate strong performance on the prickly pear dataset. For the Cochineal class (35 samples), the model achieved a precision of 100%, a recall of 91.43%, and an F1-score of 95.52%. For the Healthy class (29 samples), the model obtained a precision of 90.62%, a recall of 100%, and an F1-score of 95.08%. The overall classification accuracy was 95.31% on the test set (64 samples), corresponding to three misclassified images. The macro-average F1-score (95.30%) and weighted-average F1-score (95.32%) are nearly identical, indicating relatively

balanced performance across both classes without significant class bias.

TABLE V. DETAILED CLASSIFICATION RESULTS OF MOBILENETV2 MODEL ON THE PRICKLY PEAR DATASET

	Precision	Recall	F1-score	Support
Cochineal	0.9714	0.9714	0.9714	35
Healthy	0.9655	0.9655	0.9655	29
accuracy			0.9688	64
macro avg	0.9685	0.9685	0.9685	64
weighted avg	0.9688	0.9688	0.9688	64

TABLE VI. DETAILED CLASSIFICATION RESULTS OF DENSENET121 MODEL ON THE PRICKLY PEAR DATASET

	Precision	Recall	F1-score	Support
Cochineal	1.0000	0.9143	0.9552	35
Healthy	0.9062	1.0000	0.9508	29
accuracy			0.9531	64
macro avg	0.9531	0.9571	0.9530	64
weighted avg	0.9575	0.9531	0.9532	64

The final test set contains only 64 images across two classes, which may affect the stability of the reported performance, as small changes in predictions could influence the evaluation metrics. This limitation is mainly due to the relatively small size of the available dataset. To the best of our knowledge, the dataset used in this study is currently one of the few, if not the only, publicly available real-field datasets for the prickly pear plant. However, we acknowledge that the dataset was collected from a single location in Tunisia, which may limit the generalization of the models to different farms, seasons, cameras, lighting conditions, or plant growth stages. Future work will focus on expanding the dataset by collecting additional images from diverse environments to further evaluate the robustness and generalization capability of the proposed models.

The MobileNetV2 and DenseNet121 models were chosen based on their proven effectiveness in plant disease detection and classification reported in previous studies (Table VII). They demonstrated outstanding results across various datasets and crops, achieving accuracy levels of up to 99% in some cases. However, other computer vision architectures, such as ResNet, EfficientNet, Inception, and Vision Transformer-based models have also shown strong performance in plant disease detection and classification tasks and may be explored for prickly pear disease classification.

The training and validation accuracy graphs for both models (Fig. 5) demonstrate a rapid increase during the initial epochs, which indicates the quick learning features. After this early phase, the curves progressively stabilize, reflecting convergence and effective learning. For MobileNetV2, training and validation accuracies show good generalization with minor fluctuations. After the fine-tuning phase, a small temporary decrease in training accuracy appears, but the validation accuracy continues to improve slightly. For DenseNet121, the training accuracy increases steadily from the first epochs and

reaches a high value (≈ 0.96) toward the end. However, the validation accuracy shows noticeable fluctuations. After the fine-tuning phase ($\approx$ epoch 21), both curves become closer and more stable, but the validation accuracy does not continuously increase; instead, it slightly decreases and then stabilizes around ~ 0.90 – 0.92 while the training accuracy continues to improve, which indicates mild overfitting.

TABLE VII. TMOBILENETV2 AND DENSENET121 MODELS FOR PLANT DISEASES DETECTION AND CLASSIFICATION.

References	AI model	Dataset	Crop	Accuracy
[20]	MobileNetV2	Publicly available dataset	Multi-Crop	99.57 %
[21]	MobileNetV2 MobileNet-SE (Squeeze and Excitation)	Fig leaf dataset	Fig	90.74% 92.90%
[22]	MobileNetV2	Secondary publicly available datasets	Apple	97.13 %
[23]	DenseNet121	Maize leaf dataset	Maize	97.14%
[24]	Fine-tuned DenseNet121	Plant leaf dataset from the PlantVillage dataset	Apple	98.9%
[25]	DenseNet121	Cherry Dataset	Cherry	99.9%

The training and validation loss graphs (Fig. 6) for MobileNetV2 and DenseNet121 demonstrate strong generalization performance. MobileNetV2's training and validation loss curves both exhibit a strong decline in the first epoch. After this first stage, losses continue to decrease more gradually with minor variations. Around epoch 40, there is a discernible brief rise in training loss, while validation loss keeps declining before leveling off. In the last epochs, validation loss stays low or close to training loss, indicating that there isn't any significant overfitting. The DenseNet121 loss curves decrease smoothly from the beginning, demonstrating stable and efficient convergence. The validation loss decreases quickly in the early epochs and remains close to or slightly below the training loss for most of the training process. Around the fine-tuning phase ($\approx$ epoch 21), only minor fluctuations are observed in both curves, but they quickly stabilize again. In the final epochs, the training loss continues to decrease slightly while the validation loss levels off with small fluctuations.

As shown in Fig. 7, the confusion matrices of MobileNetV2 and DenseNet121 demonstrate robust classification performance. MobileNetV2 indicates balanced classification, with only one misclassification in each class, while DenseNet121 achieves the best classification performance for healthy samples but misclassifies a small number of infected images as healthy (three images). These few misclassifications are mainly due to variations in lighting, background, glare, and image quality, which can obscure important features and affect model predictions. From a biological perspective, the variability in the manifestation of cochineal infection—including early-stage or partial symptoms—can increase classification difficulty.

Fig. 6. Training and validation loss of MobileNetV2, and DenseNet121.

Fig. 7. Confusion matrices of MobileNetV2, and DenseNet121 on the prickly pear dataset.

Finally, both MobileNetV2 and DenseNet121 show strong overall performance for prickly pear disease classification on the cactus dataset.

IV. CONCLUSION

This study evaluates, through a case study, the performance of MobileNetV2 and DenseNet121 for prickly pear disease classification. A publicly available dataset collected in Sidi Bouzid, Tunisia, was used to assess the effectiveness of the models. The results demonstrate strong model performance for classifying prickly pear plants using MobileNetV2 and DenseNet121, achieving comparable classification accuracies of 96.88% and 95.31%, respectively. This study successfully demonstrates that convolutional neural network models can be effectively applied to prickly pear disease classification, despite the limited availability of prickly pear datasets. This highlights the adaptability of deep learning approaches to new agricultural contexts. The main contribution of this work lies in being, to the best of our knowledge, the first study to address disease classification in prickly pear plants using deep learning techniques. In future work, we intend to collect a large, balanced dataset from diverse environments for prickly pear plants and use it to train and evaluate a new reliable deep learning (DL) model, along with other DL models, to identify and classify additional prickly pear diseases, as well as to assess the generalization capability of these models.

CEEMDAN–SSA–RWKV–SMA: A Robust Hybrid Model for Long-Term Wind Speed Forecasting in India

Dr. S.Vidya

Associate Professor, Department of Computer Science and Engineering, Sri Sai Ram Engineering College, India

Abstract—Reliable long-term wind speed forecasting is a critical requirement for the strategic deployment and operational stability of wind energy systems, particularly in meteorologically diverse regions like India. This study proposes a novel hybrid framework, CEEMDAN–SSA–RWKV–SMA, which integrates advanced signal decomposition, deep sequence modeling, and metaheuristic optimization. Initially, the raw wind speed time series is decomposed using Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) to extract multi-scale Intrinsic Mode Functions (IMFs). To enhance signal clarity and reduce dimensionality, each IMF is further processed using Singular Spectrum Analysis (SSA). The resulting denoised and trend-extracted components are modeled using the Receptance Weighted Key Value (RWKV) neural network, a recent Transformer-RNN hybrid designed to capture long-range temporal dependencies efficiently. To optimize RWKV hyperparameters and SSA windowing parameters, the Slime Mould Algorithm (SMA) is employed as a global metaheuristic optimizer. Empirical evaluations on multi-regional Indian wind datasets demonstrate that the proposed framework consistently outperforms conventional models such as LSTM, Transformer, and CEEMDAN-LSTM in terms of MAE, RMSE, and MAPE. The proposed CEEMDAN–SSA–RWKV–SMA framework is a reliable forecasting strategy for improving wind energy integration in non-stationary and resource-critical environments.

Keywords—Wind speed forecasting; Complete Ensemble Empirical Mode Decomposition with Adaptive Noise; Singular Spectrum Analysis; RWKV neural network; Slime Mould Algorithm; Renewable energy integration

I. INTRODUCTION

Wind energy is rapidly becoming a key player in India's renewable energy strategy, driven by its cost-effectiveness and environmental benefits. At 100 m hub height, the National Institute of Wind Energy (NIWE) estimates the country's wind potential at over 300 GW, making precise long-term wind speed forecasting essential for grid integration, operational planning, and policy-making. The basic wind speed map of India is shown in Fig. 1.

However, wind speed data are inherently non-linear, non-stationary, and stochastic, making accurate forecasting a challenging task [1]. Traditional models like ARIMA and persistence-based methods often fall short in capturing long-term temporal dependencies [2].

To address these challenges, a new generation of hybrid forecasting approaches is proposed, combining signal

decomposition, deep learning, and optimization techniques. Notably, models integrating CEEMDAN with neural networks have demonstrated improved accuracy in wind forecasting [3]. Similarly, SSA-based decomposition coupled with BiLSTM has achieved enhanced performance in handling trend extraction and noise reduction [4].

In deep learning, Transformer and graph-based architectures have been effectively applied in wind speed prediction, with models like Autoformer and GNNs showing superiority in capturing spatio-temporal dynamics [5]. Yet, these models often face computational limitations for long-term forecasting tasks.

Fig. 1. Basic wind speed map of India [6].

RWKV (Receptance Weighted Key Value) is a breakthrough architecture combining RNN-like inference efficiency with Transformer-like parallelism. It is proposed in 2023 that RWKV scales to tens of billions of parameters while maintaining constant memory usage [7] for long-sequence time series modeling.

A critical aspect of such hybrid models lies in tuning their hyperparameters. While there are Particle Swarm Optimization and various genetic-inspired optimizers, the Slime Mould Algorithm (SMA) offers a novel, bio-inspired approach that balances exploration and exploitation dynamically oscillatory behaviors, showing promising results in global optimization tasks [8].

In this study, an innovative framework, CEEMDAN–SSA–RWKV–SMA, is proposed, which is specifically designed for long-term wind speed forecasting in India. Its key contributions include:

- Two-stage signal decomposition (CEEMDAN + SSA) for extracting denoised, trend-reflective components.
- Application of RWKV for efficient, long-context sequence modeling.
- Adoption of SMA for hyper-parameter tuning of both decomposition and modeling modules.
- Extensive benchmarking on multi-regional Indian wind datasets against state-of-the-art baselines, including LSTM, Transformer, and hybrid decomposition models.

Wind speed forecasts work better when using hybrid methods compared to single methods. The proposed hybrid framework significantly outperforms the other methods in forecasting accuracy and computational efficiency, paving the way for its integration into smart grid planning and renewable energy management. This hybrid model is a new one that has never been used before for wind speed forecasting. The effectiveness of this new model is checked by comparing it with other existing methods.

II. METHODOLOGY

A. Ceemdan Decomposition

Wind speed series are inherently nonlinear and non-stationary, making it challenging for conventional forecasting models to capture the full spectrum of variability. Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) is adopted in this study as the first stage of preprocessing, owing to its superior capability in adaptively decomposing complex time series into physically meaningful oscillatory components [9].

CEEMDAN is an advancement over the original Empirical Mode Decomposition (EMD) and its improved variant, Ensemble Empirical Mode Decomposition (EEMD). While EMD suffers from mode mixing, where a single Intrinsic Mode Function (IMF) contains oscillations of widely disparate scales, and EEMD reduces this problem by introducing noise-assisted ensembles, CEEMDAN further refines the process by:

- Ensuring a complete and unique set of IMFs with reduced residual noise,
- Adding adaptive white noise at each iteration to improve mode separation, and
- Maintaining perfect reconstruction of the original signal.

Given a raw wind speed series $x(t)$, CEEMDAN produces n IMFs and a final residual $r_n(t)$ as shown in Eq. (1).

$$x(t) = \sum_{i=1}^{\{n\}} c_i(t) + r_n(t) \quad (1)$$

where $c_i(t)$ denotes the i^{th} IMF, representing oscillatory components from high to low frequency, and $r_n(t)$ represents the long-term trend [10].

The decomposition is performed iteratively as follows:

- IMF Extraction: For each iteration k , white noise is adaptively added to the signal to generate an ensemble

set. EMD is applied to each noisy realization to extract the first IMF.

- Ensemble Averaging: The IMF obtained from all realizations is averaged to yield $c_k(t)$.
- Residual Update: The averaged IMF is subtracted from the current residual to form the new residual signal for the next iteration.
- Stopping Criterion: The process continues until the residual becomes monotonic or contains at most one extremum.

By employing CEEMDAN [11], the original wind speed signal is decomposed into multi-scale components that isolate distinct oscillatory patterns. This decomposition reduces signal complexity, allowing subsequent processing stages—such as SSA denoising and RWKV modeling—to operate on cleaner, more interpretable components, thereby improving forecast accuracy [12].

B. Singular Spectrum Analysis (SSA) Denoising

After CEEMDAN decomposition, the resulting Intrinsic Mode Functions (IMFs) may still contain measurement noise and small-scale fluctuations that can obscure underlying trends. To enhance signal quality, each IMF is processed using Singular Spectrum Analysis (SSA), a non-parametric technique for time series decomposition that is effective for trend extraction, periodicity detection, and noise suppression [13].

SSA operates in four stages:

1) *Embedding*: The one-dimensional IMF $c_i(t)$ is transformed into a multi-dimensional trajectory matrix X using a sliding window of length L shown in Eq. (2).

$$X = \begin{bmatrix} c_1 & \cdots & c_K \\ \vdots & \ddots & \vdots \\ c_L & \cdots & c_N \end{bmatrix} \quad (2)$$

where $K=N-L+1$ and N is the length of the IMF.

2) *Singular Value Decomposition (SVD)*: The trajectory matrix is decomposed as shown in Eq. (3).

$$X = \sum_{j=1}^d \sigma_j U_j V_j^T \quad (3)$$

where σ_j are the singular values, U_j are the left singular vectors, and V_j are the right singular vectors.

3) *Grouping*: The decomposed components are grouped into signal (trend + oscillatory modes) and noise subspaces based on the magnitude of their singular values. The dominant singular values correspond to meaningful structures, while smaller values represent noise.

4) *Reconstruction*: The selected signal subspace components are recombined to form the denoised IMF $\hat{c}_i(t)$.

By applying SSA to each IMF individually, both high-frequency components and low-frequency trends are preserved while random noise is suppressed [14]. This hybrid CEEMDAN-SSA preprocessing yields a set of clean, scale-separated signals that serve as inputs to the RWKV neural

network, improving the model's ability to learn temporal dependencies and reducing the risk of over-fitting to noise.

C. RWKV Neural Network

After decomposition and denoising, the cleaned IMFs are used as inputs to the forecasting model. In this study, the Receptance Weighted Key Value (RWKV) neural network, a recent hybrid architecture that combines the temporal recurrence of Recurrent Neural Networks (RNNs) with the context modeling of transformers, is adopted [15]. This design makes RWKV particularly effective for long-sequence forecasting tasks, such as multi-year wind speed prediction, where both local fluctuations and long-term dependencies must be captured. The structure of the RWKV Neural Network is shown in Fig. 2.

Fig. 2. Structure of the Receptance Weighted Key Value (RWKV) neural network.

Unlike conventional RNNs, which suffer from vanishing gradients, or transformers, which are computationally expensive for long inputs, RWKV achieves a balance by integrating linear recurrence with attention-style updates [16]. At each time step t , the hidden state update can be expressed as shown in Eq. (4).

$$h_t = f_{mix}(W_{rec}h_{t-1} + W_{in}x_t) + f_{attn}(Q_t, K_t, V_t) \quad (4)$$

where:

- h_t is the hidden state at time t ,
- W_{rec} and W_{in} are recurrent and input weight matrices,
- $f_{mix}(\cdot)$ denotes the recurrent time-mixing operation,
- $f_{attn}(\cdot)$ represents the attention mechanism with queries (Q), keys (K), and values (V).

The output forecast for IMF i is shown in Eq. (5).

$$\hat{c}_i(t+1) = g(h_t) \quad (5)$$

where $g(\cdot)$ is the RWKV output projection function.

The time-mixing module ensures sequential consistency, similar to RNN recurrence, while the channel-mixing module provides global context aggregation, analogous to transformer-style self-attention but with linear complexity. This makes RWKV computationally efficient even for very long time series.

For each denoised IMF $\hat{c}_i(t)$, a dedicated RWKV sub-model is trained. The outputs of these sub-models are later aggregated during reconstruction to obtain the final forecasted wind speed series.

By leveraging RWKV's ability to preserve temporal continuity and long-range dependencies simultaneously, the forecasting stage gains significant robustness compared to classical LSTM, GRU, or even transformer-based approaches.

D. Slime Mould Algorithm (SMA) Optimization

Neural networks and decomposition methods typically involve several hyperparameters, such as the number of hidden units, learning rate, dropout ratio, decomposition noise amplitude, and SSA window length. Selecting these parameters manually can be suboptimal and time-consuming [17]. To overcome this challenge, the Slime Mould Algorithm (SMA) is employed to automatically optimize both the decomposition and forecasting stages.

SMA is a bio-inspired metaheuristic algorithm that mimics the oscillatory foraging behavior of slime mould organisms. It adaptively balances exploration (searching new regions in the solution space) and exploitation (refining promising solutions), making it well-suited for high-dimensional, nonconvex optimization problems such as neural network training [18].

The optimization process begins with an initial population of candidate solutions, each representing a possible set of hyperparameters $\theta = \{\theta_1, \theta_2, \dots, \theta_m\}$. At iteration t , the position of each candidate is updated based on three main mechanisms:

- **Weight Updating:** mimicking slime mould thickness, adaptive weights are assigned according to the fitness ranking of candidates.
- **Oscillatory Foraging:** candidates are attracted toward the global best solution or repelled from poor solutions, using a probability-driven update rule.
- **Exploration/Exploitation Balance:** oscillatory search radius gradually decreases, allowing wide search in early iterations and fine-tuning in later stages.

The objective (fitness) function is defined as a weighted combination of error metrics shown in Eq. (6).

$$\text{Fitness} = \alpha \cdot \text{MAE} + \beta \cdot \text{RMSE} \quad (6)$$

where α and β are non-negative coefficients ensuring that both absolute and squared errors are minimized. The procedure of Slime Mould Algorithm (SMA) Optimization is shown in Fig. 3.

Fig. 3. Flowchart of Slime Mould Algorithm (SMA) optimization.

During optimization, SMA evaluates each candidate by training the RWKV model on denoised IMF components and calculating its forecast error [19]. The process iterates until convergence or until the maximum number of iterations is reached. The best-performing hyperparameter set θ^* is then selected for final forecasting.

By integrating SMA, the proposed framework avoids reliance on manual trial-and-error tuning and ensures robust, data-driven hyperparameter selection, thereby enhancing the overall predictive accuracy and generalization ability of CEEMDAN-SSA-RWKV-SMA.

E. Steps of Wind Speed Forecasting

The proposed CEEMDAN-SSA-RWKV-SMA framework follows a systematic multi-stage forecasting process, combining decomposition, denoising, deep learning, and intelligent optimization is shown in Fig. 4. The steps are as follows:

Step 1: Signal Decomposition

The original non-stationary wind speed series is first decomposed using CEEMDAN (Complete Ensemble Empirical Mode Decomposition with Adaptive Noise). This yields multiple Intrinsic Mode Functions (IMFs) and a residual component, each capturing oscillatory patterns at different frequency scales.

Step 2: Denoising with SSA

To eliminate high-frequency noise while retaining dominant dynamics, each IMF is denoised using Singular Spectrum Analysis (SSA). This enhances the signal-to-noise ratio and improves the quality of features provided to the forecasting model.

Step 3: Forecasting with RWKV Neural Network

Each denoised IMF component $\hat{c}_i(t)$ is independently modeled using the Receptance Weighted Key Value (RWKV) neural network. RWKV combines recurrent-style time-mixing with transformer-like channel-mixing, enabling efficient long-sequence learning. A dedicated RWKV sub-model is trained for each IMF.

Step 4: Hyperparameter Optimization using SMA

The Slime Mould Algorithm (SMA) is employed to optimize critical hyperparameters across both decomposition and forecasting stages (e.g., SSA window length, RWKV learning rate, hidden units, dropout ratio). SMA adaptively balances exploration and exploitation to identify the best-performing parameter set.

Fig. 4. Flowchart of the proposed wind speed forecasting model combining CEEMDAN-SSA-RWKV-SMA.

Step 5: Reconstruction of Forecasted Series

The individual forecasts of denoised IMFs are aggregated together with the residual to reconstruct the final forecasted wind speed series. This ensures that both local fluctuations and long-term trends are preserved. Finally, the predicted IMFs and residuals are aggregated to obtain the final wind speed forecast shown in Eq. (7).

$$\hat{X}(t) = \sum_{i=1}^n \hat{c}_i(t) + \hat{r}(t) \quad (7)$$

Step 6: Performance Evaluation

The accuracy of the proposed hybrid model is evaluated using standard statistical measures such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Mean Absolute Percentage Error (MAPE). Lower error values indicate superior forecasting performance compared to classical LSTM, GRU, or transformer-based methods.

III. STATISTICAL CRITERIA TO EVALUATE THE FORECASTING PERFORMANCE

The accuracy of the proposed CEEMDAN-SSA-RWKV-SMA framework is evaluated using widely adopted statistical measures in wind speed forecasting. These metrics assess both absolute and relative prediction errors and model explanatory power.

A. Mean Absolute Error (MAE)

MAE measures the average absolute difference between the actual and predicted wind speed values shown in Eq. (8).

$$\text{MAE} = \frac{1}{N} \sum_{t=1}^N |o_t - \hat{o}_t| \quad (8)$$

Where o_t is the original wind speed and o_t^* is the predicted wind speed at time period t . The period of forecasting is represented by N .

B. Root Mean Square Error (RMSE)

RMSE penalizes larger errors more heavily, making it suitable for evaluating the model's robustness, as shown in Eq. (9).

$$RMSE = \sqrt{\frac{1}{N} \sum_{t=1}^N (o_t - o_t^*)^2} \quad (9)$$

Where o_t is the original wind speed and o_t^* is the predicted wind speed at time period t . The period of forecasting is represented by N .

C. Mean Absolute Percentage Error (MAPE)

MAPE normalizes errors as percentages, facilitating comparison across different datasets shown in Eq. (10).

$$MAPE = \frac{1}{N} \sum_{t=1}^N \left| \frac{o_t - o_t^*}{o_t} \right| \times 100\% \quad (10)$$

Where o_t is the original wind speed and o_t^* is the predicted wind speed at time period t . The period of forecasting is represented by N .

IV. CASE STUDY

A. Wind Speed Dataset Collection

The proposed framework is evaluated using long-term wind speed datasets obtained from NASA [20] representing diverse climatic conditions across India. Hourly wind speed measurements from 2013 to 2022 are collected at selected sites, including coastal, semi-arid, and inland regions. In India, the wind speed data of 9 cities are collected. The meteorological parameters such as wind speed (m/s), wind direction (degrees), air temperature ($^{\circ}\text{C}$), atmospheric pressure (hPa), relative humidity (%), and time index are considered as inputs for forecasting wind speed. Wind speed (m/s) is the primary target variable. The dataset is divided into training (70%) and testing (30%) to ensure robust generalization and maintain geographic and climatic diversity across India. Table I shows the selected cities for wind speed forecasting with train-test allocation.

TABLE I. SELECTED CITIES FOR WIND SPEED FORECASTING WITH TRAIN-TEST ALLOCATION

City	Region	Latitude	Longitude
Chennai	Coastal (East)	13.08°N	80.27°E
Mangalore	Coastal (West)	12.91°N	74.85°E
Visakhapatnam	Coastal (East)	17.68°N	83.21°E
Jaisalmer	Semi-Arid	26.91°N	70.90°E
Bhopal	Inland Plains	23.25°N	77.41°E
Ooty	Hilly Region	11.40°N	76.69°E
Bhuj	Semi-Arid	23.25°N	69.66°E
Nagpur	Inland Plains	21.14°N	79.08°E
Shillong	Hilly Region	25.57°N	91.89°E

The training set comprises six locations- Chennai, Mangalore, Visakhapatnam, Jaisalmer, Bhopal, and Ooty, while the testing set includes Bhuj, Nagpur, and Shillong.

B. Steps of Forecasting

Step 1: The original non-stationary wind speed series is first decomposed into a finite set of Intrinsic Mode Functions (IMFs) and a residual using Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN). This eliminates high-frequency noise and captures oscillatory modes. The resulting decomposition is shown in Fig. 5.

Fig. 5. CEEMDAN decomposition of original wind speed series.

Step 2: The decomposed IMFs are further refined using Singular Spectrum Analysis (SSA). The embedding matrix of each IMF is reconstructed, and noise-dominated components are filtered out. This denoising ensures only physically meaningful oscillatory signals are retained for forecasting. The denoised IMF series is presented in Fig. 6.

Fig. 6. SSA denoising of IMF.

Step 3: The denoised IMFs and residual are used as inputs to the RWKV neural network, which combines the memory retention capability of RNNs with the parallelism of transformers. Each IMF is predicted separately, and its reconstructed series produces the overall forecast. The hyperparameter optimization process of RWKV is summarized in Table II.

TABLE II. OPTIMIZED RWKV HYPERPARAMETERS WITH SMA WINDOW SIZE

Component	Learning Rate	Hidden Size	ContextLength	Layers	Dropout	Batch Size	Epochs	SMA Window size
IMF1	0.001	64	32	4	0.05	64	120	5
IMF2	0.0008	80	48	4	0.05	64	120	5
IMF3	0.0008	96	64	4	0.05	64	130	5
IMF4	0.0006	128	80	4	0.07	64	140	5
IMF5	0.0006	144	96	4	0.07	64	140	5
IMF6	0.0005	160	112	4	0.08	64	150	5
Residual	0.0005	192	128	4	0.08	64	150	5

Step 4: Finally, a Simple Moving Average (SMA) smoothing layer is applied to the RWKV outputs to reduce short-term fluctuations and improve long-term stability. This hybrid adjustment provides more reliable forecasts for practical applications. The complete comparison framework of decomposition and prediction models is illustrated in Fig. 7. The purple curve shows the raw RWKV predictions with short-term fluctuations. The green curve shows the smoothed output after applying SMA, which improves long-term stability.

Fig. 7. SMA smoothing applied to RWKV outputs.

Step 5: The forecasted outputs of each IMF and the residual are integrated to generate the final prediction series.

A comparative evaluation of different hybrid models (LSTM, GRU, Transformer, RWKV, and Proposed CEEMDAN-SSA-RWKV-SMA) is shown in Fig. 8. The proposed hybrid framework CEEMDAN-SSA-RWKV-SMA produces the closest match to the actual values, outperforming LSTM, GRU, Transformer, and standalone RWKV models. The integration of CEEMDAN decomposition and SSA denoising eliminates noise and non-stationarity, while the RWKV neural network captures long-term dependencies efficiently. The SMA adjustment layer further enhances prediction stability by smoothing short-term fluctuations.

Fig. 8 demonstrates that the CEEMDAN-SSA-RWKV-SMA model consistently aligns with the actual wind speed series, whereas the other models show larger deviations. Consequently, the proposed hybrid model is recommended for reliable long-term wind speed forecasting in India, as it achieves superior accuracy and robustness compared to existing deep learning and hybrid baselines.

Fig. 8. Prediction results of wind speed.

C. Performance Evaluation of Forecasting Models

To validate the effectiveness of the proposed CEEMDAN-SSA-RWKV-SMA framework, its forecasting results are compared with benchmark deep learning models, namely LSTM, GRU, Transformer, and RWKV. The evaluation is carried out on the testing dataset using multiple error metrics and statistical measures. The purpose of this analysis is to demonstrate how the hybrid decomposition–denoising–forecasting–adjustment pipeline enhances prediction accuracy and robustness.

The accuracy estimation results are summarized in Table III. Relative errors are categorized as less than 10%, 10–20%, and greater than 20%. For better prediction reliability, hybrid models are expected to have the majority of samples within the <10% error range. In the proposed hybrid model CEEMDAN-SSA-RWKV-SMA, 232 data samples (77.33%) have a relative error less than 10% (out of 300 testing samples), 58 samples (19.33%) fall in the 10–20% category, and only 10 samples (3.34%) are in the greater than 20% category. More than 77% of the predictions from the proposed model fall within a 10% error margin.

In contrast, RWKV achieves 66.67%, Transformer 60.00%, GRU 50.00%, and LSTM only 46.67%. Only 3% of the predictions of the proposed model fall beyond a 20% error range, whereas LSTM and GRU exceed 13%. This demonstrates the higher reliability of the hybrid framework.

Compared to other deep learning models, the proposed hybrid model achieves the highest proportion of accurate

predictions within the <10% relative error band. This demonstrates that the proposed model provides a superior forecasting strategy that can be practically deployed in grid-connected wind farms for accurate wind speed prediction. The predicted wind speed by the proposed CEEMDAN-SSA-RWKV-SMA model matches most closely with the actual wind speed data compared to the LSTM, GRU, Transformer, and standalone RWKV models. The performance of the models is quantitatively assessed using Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and the Mean Absolute Percentage Error (MAPE) to validate forecasting accuracy. These statistical indicators are summarized in Table IV.

The proposed CEEMDAN-SSA-RWKV-SMA achieves the lowest RMSE, MAE, and MAPE, confirming its superior forecasting capability compared to other models. The proposed CEEMDAN-SSA-RWKV-SMA reduces RMSE to 0.415 and MAPE to 5.76%, representing a substantial improvement over

RWKV (RMSE: 0.582, MAPE: 8.45%). LSTM and GRU models show considerably higher error values, while Transformer performs better but still falls short of RWKV and the proposed hybrid model. RWKV performs better than Transformer, GRU, and LSTM, yet it is significantly improved when enhanced with CEEMDAN decomposition, SSA denoising, and SMA smoothing.

From Table III and Table IV, it is evident that the proposed hybrid model substantially outperforms other approaches. The integration of decomposition (CEEMDAN) and denoising (SSA) with RWKV ensures that both temporal dependencies and noise components are addressed effectively. The SMA adjustment provides an additional smoothing layer that improves the long-term stability of forecasts. Thus, the CEEMDAN-SSA-RWKV-SMA framework demonstrates its potential as a reliable solution for long-term wind speed forecasting in India.

TABLE III. ACCURACY ESTIMATION OF FORECASTING MODELS

Prediction models	Less than 10%		10 to 20 %		Greater than 20 %	
	Samples	%	samples	%	samples	%
LSTM	140	46.67%	120	40.00%	40	13.33%
GRU	150	50.00%	110	36.67%	40	13.33%
Transformer	180	60.00%	90	30.00%	30	10.00%
RMKV	200	66.67%	80	26.67%	20	6.67%
Proposed (CEEMDAN-SSA-RWKV-SMA)	232	77.33%	58	19.33%	10	3.34%

TABLE IV. STATISTICAL PERFORMANCE METRICS OF FORECASTING MODELS

Model	RMSE	MAE	MAPE (%)
LSTM	0.812	0.645	12.84
GRU	0.768	0.602	11.73
Transformer	0.693	0.554	10.12
RWKV	0.582	0.487	8.45
Proposed (CEEMDAN-SSA-RWKV-SMA)	0.415	0.329	5.76

The forecasting results clearly indicate that intelligent hybrid models combining decomposition, denoising, advanced neural architectures, and smoothing outperform traditional statistical or standalone machine learning models. To forecast non-stationary and nonlinear wind speed series, the integration of CEEMDAN effectively decomposes the signal, SSA removes noise, RWKV efficiently captures long-term temporal dependencies, and SMA enhances stability through smoothing. This hybrid adjustment significantly improves forecasting capacity. The proposed model, through its improved accuracy and stability, can serve as a valuable tool for researchers, policy makers, industry, and system planners in conducting wind speed assessments before siting wind turbines.

Thus, the optimized CEEMDAN-SSA-RWKV-SMA model produces better results than existing deep learning models. By reducing noise, improving generalization, and

stabilizing long-term forecasts, the proposed model is verified as a simple, efficient, and highly accurate forecasting method for long-term wind speed prediction. Such a framework is necessary and highly desirable for the reliable development and planning of wind energy systems in India.

V. CONCLUSION

In this study, a novel hybrid framework, CEEMDAN-SSA-RWKV-SMA, is proposed for long-term wind speed forecasting in India. The model integrates CEEMDAN decomposition to address non-stationarity, SSA denoising to eliminate noise, the RWKV neural network to capture long-term temporal dependencies efficiently, and a final SMA adjustment layer to improve prediction stability. This multi-stage design enhances forecasting accuracy and robustness compared to traditional and existing deep learning models.

The experimental results demonstrated that the proposed hybrid model consistently outperformed benchmark models such as LSTM, GRU, Transformer, and standalone RWKV. By providing more accurate and stable long-term wind speed predictions, the model supports the reliable development of grid-connected wind farms and contributes to efficient renewable energy integration.

Future work may extend this framework to multi-step-ahead forecasting, cross-regional validation, and integration with hybrid optimization techniques to further enhance predictive performance. The adaptability of the model also opens possibilities for its application in other renewable energy

forecasting domains, such as solar power and hydropower generation.

Scaled Agile Process Improvement Recommendations with CMMI 2-Based Agile Scaling Model: A Case Study of the Indonesia National Single Window Agency

I Made Aditya Pradnyadipa Mustika, Betty Purwandari, Alex Ferdinansyah
Faculty of Computer Science, Universitas Indonesia, Depok, Indonesia

Abstract—The Indonesia National Single Window System (SINSW) is a platform developed by the Indonesia National Single Window Agency (LNSW) using Agile methodology, specifically the Scrum framework. Several challenges were identified during its development, including deviations from the Scrum Guide and the absence of formal, regular events necessary for effective team coordination and alignment. These issues revealed gaps in Scrum implementation and broader difficulties associated with scaling Agile practices beyond the team level. Therefore, this study applied a scaling Agile model based on Capability Maturity Model Integration (CMMI) 2 to evaluate the agency's existing Agile process and recommend targeted improvements to Agile practices. The evaluation involved qualitative interviews with key stakeholders, including the Project Management Officer, System Analyst, and developers. The interviews were subsequently quantified using the Key Process Area (KPA) rating framework. The findings led to actionable recommendations to optimize the Agile process, improve team collaboration, and support SINSW's success.

Keywords—Scaling Agile; CMMI; Scrum; KPA rating; software engineering

I. INTRODUCTION

Recently, digital transformation has significantly influenced government administrative processes, particularly in customs services. A Single Window System is an integrated digital platform that allows businesses, traders, and government agencies to submit and process information through a single entry point. It is widely used in trade facilitation, customs clearance, and regulatory approvals to streamline processes, reduce paperwork, and improve efficiency [1]. Indonesia's single window system is called the Indonesia National Single Window System (SINSW). The management and operation of SINSW are regulated by the Minister of Finance [2], who assigns the Indonesia National Single Window Agency (LNSW) the responsibility for system governance and development.

SINSW serves as a critical, unified web-based integration hub that streamlines national trade and logistics. The operational scale of this environment is significant, as it consolidates 42 distinct application systems, known as Single Submission modules. These modules facilitate data exchange and synchronization across 18 different Government Ministries and Agencies. To manage this complexity, the development effort is distributed among six dedicated development teams working

concurrently to ensure a seamless "single-entry point" for all stakeholders. This multi-agency architecture creates a high-stakes development environment where technical alignment and cross-team synchronization are paramount to maintaining the integrity of Indonesia's digital trade infrastructure.

Despite its strategic importance, the implementation of SINSW faces challenges in meeting development goals, particularly in fulfilling its sprint goals. Although the implementation is imperfect, LNSW utilizes Scrum to manage SINSW development projects. Several issues hinder the full realization of Agile principles, including the lack of structured coordination events and inconsistencies in Scrum implementation. Reports from the second semester of 2023, specifically across eight observation sprints [3], indicate that many sprint goals were not met, with unfinished tasks carried over into subsequent sprints, delaying system development and deployment.

The issue of coordination and alignment between teams in SINSW development underscores challenges beyond team-level Agile implementation. The issue highlights the intricacies of scaling Agile practices in a large, multi-stakeholder environment. Agile methodologies at the team level emphasize iterative development, flexibility, and responsiveness. However, scaling Agile across multiple teams introduces organizational dependencies, workflow synchronization challenges, and cross-functional misalignment [4], [5]. The complexities often lead teams to focus on their deliverables rather than collaborate effectively with other teams. Moreover, silos are one of the key inhibitors of Agile transformation at scale [6].

In the specific context of LNSW, these theoretical challenges manifest through several critical processes. General scaling misalignment is evidenced here by inconsistent Standard Operating Procedures and a lack of uniform process assets. Technical coordination is frequently compromised by ad-hoc synchronization of dependencies. The absence of documented Success Criteria also complicates the identification of architectural issues and diminishes the effectiveness of Agile workflows. Furthermore, technical estimation remains limited to time-based metrics that fail to account for resource availability and complexity.

This study aims to evaluate the current scaling of Agile implementation in SINSW development, identify key

bottlenecks, and propose improvements to enhance Agile implementation in large-scale government digital transformation projects. This research will examine two primary problems. The first is the absence of formal and regular cross-team coordination events, which hinders alignment and efficiency; the second is the deviation from Scrum best practices, which diminishes the effectiveness of Agile workflows. Ignoring best practices in the scrum process can lead to increased risks, poor team collaboration, ineffective communication, and suboptimal product delivery. Ultimately, it hampers project success, reduces stakeholder satisfaction, and may lead to higher costs and longer development timelines [7]. To address these challenges, this study seeks to answer the following research questions:

RQ1: What are the evaluation results of the Scaled Agile process in the SINSW development?

RQ2: What recommendations can be proposed to improve the Scaled Agile process in the SINSW development?

This research improves Agile implementation for large-scale, multi-stakeholder government projects through a unique Indonesian case study. By using the Capability Maturity Model Integration (CMMI) 2-Based Agile Scaling Model to quantify gaps, the study provides a validated, phased roadmap for digital transformation rather than generic advice. Ultimately, this research aims to assist the LNSW in achieving greater agility and efficiency in managing Indonesia's digital trade facilitation infrastructure, thereby contributing to the broader goal of streamlining public service delivery through technology-driven governance.

II. LITERATURE STUDY

The primary challenge in digital transformation is balancing Agile flexibility with rigorous oversight. Ferdinansyah and Purwandari [8] argue that while Agile provides adaptability, models like CMMI are essential for an organization to minimize risk and ensure process stability. Raharjo and Purwandari [9] further classify these challenges through the lens of PMBOK, identifying stakeholder management as a critical governance hurdle.

As organizations transition from individual teams to a broader scaled environment, these challenges become significantly more complex. Managing dependencies across multiple teams requires specialized coordination that goes beyond standard Scrum ceremonies. Conboy and Carroll [16] identify nine core challenges in large-scale frameworks, noting that communication breakdowns and rigid procedures are frequent obstacles. These challenges often worsen in environments with high architectural coupling, where a change in one software module can trigger unexpected failures in others. Consequently, Dikert et al. [17] emphasize that success depends on how well development teams synchronize with other units, such as Quality Assurance and Operations. This synchronization ensures that integrated modules meet shared quality standards and security protocols before deployment.

The organizational structure of a transformation determines its long-term sustainability and scalability. Sońta-Drączkowska and Krogulec [18] suggest that managerial tensions at the organizational, top management, and team levels must be

resolved through clear structural alignment. This alignment is essential because large organizations frequently experience a cultural conflict between traditional top-down hierarchies and decentralized Agile decision-making. Furthermore, Fissalima et al. [19] demonstrate that, in the Indonesian context, localized or customized frameworks are often more effective than commercial solutions such as SAFe or LeSS. This effectiveness stems from the framework's ability to account for local regulatory requirements and specific organizational cultures within Indonesian agencies.

To provide the necessary stability and minimize risk within these complex structures, models like CMMI are employed. CMMI remains a leading framework for software process improvement [10], [11]. Since the release of version 2.0 in 2018, it has formally integrated Agile principles to ensure that standardized workflows enhance, rather than hinder, flexibility and responsiveness [12], [13], [14]. The CMMI capability levels range from Level 0 (Incomplete) to Level 5 (Optimizing), as shown in Fig. 1. Using the CMMI 2.0 framework helps organizations strengthen their processes and scale their agile practices, with a focus on performance [15]. To operationalize this for the LNSW, the CMMI 2-Based Scaling Agile Model is utilized, which leverages the Essence Language Key to define 29 essential Scaled Agile elements. This model provides a structured benchmark for assessing the capability of Scaled Agile adoption within the organization [16]. Rather than addressing the entire framework, this study focuses on high-impact elements specifically chosen to target the issues identified within LNSW's Agile implementation. The relationship between these selected elements and their corresponding CMMI 2 Practice Areas is shown in Table I.

Level 5 Optimizing	- Builds on Level 4 practices - Uses statistical and other quantitative techniques to optimize performance and improvement to achieve quality and process performance objectives
Level 4 Quantitatively Managed	- Builds on Level 3 practices - Uses statistical and other quantitative techniques to understand performance variation and detect, refine, or predict the area of focus to achieve quality and process performance objectives - Identifies and understands variation, and predicts and improves the ability to achieve quality and process performance objectives
Level 3 Defined	- Builds on Level 2 practices - Uses organizational standards and tailoring to address project and work characteristics - Projects use and contribute to organization assets - Focuses on achieving both project and organizational performance objectives
Level 2 Managed	- Subsumes Level 1 practices - Simple, but complete set of practices that address the full intent of the Practice Area - Does not require the use of organizational assets - Identifies and monitors progress towards project performance objectives
Level 1 Initial	- Initial approach to meeting the intent of the Practice Area - Not a complete set of practices to meeting the full intent of the Practice Area - Begins to address performance issues
Level 0 Incomplete	- Incomplete approach to addressing the intent of the PA - May or may not be meeting the full intent of any practices

Fig. 1. CMMI 2 capability level for practices [15].

III. METHODS

This research employed a case study approach focusing on the development process of SINSW at the LNSW. The study integrated mixed methods, combining qualitative and quantitative data collection to provide a comprehensive evaluation. The research analyzed real-world problems and proposed solutions to improve them [17]. The study followed a

structured applied research framework [18] comprising four stages, as depicted in Fig. 2.

A. Research Definition

This stage involved two key steps: understanding the problem and identifying research questions. The process began by comprehensively understanding the issue and its surrounding context. In understanding the problem phase, researchers conducted interviews and analyzed internal documents to identify gaps between the current state and expected outcomes. These gaps helped pinpoint root causes, shaping the study's primary focus. Using a fishbone diagram, researchers formulated key research questions based on the identified root causes in the identification phase [19]. The questions defined this study's objectives and expected contributions.

B. Research Design / Plan

The Research Design/Plan stage focuses on developing a structured research approach based on the previously identified key research questions. This stage consisted of three essential steps: choosing the design and data collection approach, inventorying resources, and developing research instruments. Each step ensured the research methodology aligned with the objectives and provided a comprehensive framework for evaluating Scaled Agile implementation.

Fig. 2. Applied research framework [18].

The first step, choosing the design and data collection approach, involved conducting a literature review to explore previous studies and applying the Compare, Contrast, Criticize, Synthesize, and Summarize (3C+2S) analysis method. This process helped establish a theoretical framework and research methodology for subsequent steps. Through the Compare and Contrast phases, it was identified that while existing models provide frameworks for capability measurement, they often lack the specific organizational context of large-scale government agencies managing multi-stakeholder infrastructures. The Criticize phase highlighted a significant gap in prior SINSW evaluations. The gap often focuses on isolated services rather than the organization-wide coordination between all 42 integrated systems. Consequently, the Synthesize and Summarize phases led to the selection of the CMMI 2-Based Scaling Agile Model as a suitable foundation for this study.

Next, the inventorying resources integrated literature reviews and interviews to gather essential inputs for the study. The researchers combined the theoretical framework and methodology from the previous step with additional insights, including organizational expectations, key roles in the development process, and the organization's current state of Scaled Agile implementation. The output of this step was a comprehensive resource inventory listing the necessary elements for understanding the organization's Scaled Agile implementation and identifying areas for improvement.

The final step, composing research instruments, involved refining and validating the collected resources to create practical tools for data collection. The process included defining key Scaled Agile Framework elements, formulating interview questions based on the CMMI 2 practice area, and selecting

appropriate appraisal tools. It ensured that the research instruments aligned with the study's objectives and enhanced the reliability and depth of the evaluation.

Table II lists the appraisal participants, who were purposively selected as subject-matter experts with cross-team oversight. While the sample size is small, these individuals provide a holistic view of the 42 integrated systems. Specifically, the PMO (RespA) manages governance for all six teams; the System Analyst (RespB) serves as Product Owner for two teams; and the developers (RespC, RespD) serve as Technical Leads across different units. Their collective leadership roles ensure a representative analysis of systemic gaps within the LNSW.

Meanwhile, Table III outlines the key focus issues in the Scaled Agile implementation at the LNSW and maps them to their respective Scaled Agile essence elements. These identified issues primarily relate to process coordination and organizational structure rather than direct technical or deployment failures. While these procedural gaps can create coordination overhead, they do not indicate a lack of technical capability or a failure in the underlying deployment infrastructure.

C. Implementation

The Implementation stage consists of two key steps derived from the Research Design phase: evaluating the Scaled Agile process and formulating improvement recommendations. This stage aimed to assess the current state of Agile implementation within the organization and develop strategies to enhance its effectiveness in line with industry's best practices.

The first step involved evaluating the Scaled Agile process using the CMMI 2-Based Scaled Agile Model [16]. Then, the evaluation results were quantified using the Key Process Area (KPA) Rating to assess the Agile implementation's capability and identify areas for improvement [20]. This structured approach utilizes a questionnaire to measure the implementation of Agile practices, with the final capability level determined by a percentage-based Eq. (1):

$$KPA\ Rating = \frac{\Sigma(Y_n) + \frac{1}{2} \Sigma(P_n)}{\Sigma(T_n) - \Sigma(NA_n)} \times 100 \quad (1)$$

where, each notation is explained as follows:

- Y_n : Number of "Yes" responses (Practice has been fully implemented)
- P_n : Number of "Partially" responses (Practice has been partially implemented)
- T_n : Total number of questions
- NA_n : Number of "Not Applicable" responses (Practice is not relevant)

By applying this equation, the organization's adoption of Scaled Agile practices was mapped to specific capability levels based on the percentage ranges shown in Table IV. This evaluation provided a benchmark for assessing how well the organization had optimized its methodologies and pinpointed key gaps or inefficiencies for future improvement.

Based on these findings, the next step was to formulate improvement recommendations to align Agile adoption with the organization's expectations and long-term goals. These recommendations were derived from an extensive literature review, with CMMI-2 as the primary reference to ensure a structured, systematic approach to process enhancement. Additionally, best practices from popular Scaled Agile frameworks and models helped refine the proposed solutions.

TABLE. II. PROFILE OF THE RESOURCE PERSON FOR THE APPRAISAL PROCESS.

Code	Position/Role
RespA	Section chief of Information Systems Governance and Program Management, also acts as the SINSW Project Management Officer
RespB	Section chief of Information System Design and Evaluation, also acts as the SINSW System Analyst
RespC & RespD	Developer 1, Developer 2.

TABLE. III. SELECTED SCALED AGILE ESSENCE ELEMENTS BASED ON FOUND ISSUES.

Issues in the Scaled Agile Process at the LNSW	Scaled Agile Essence Elements	Resource person for appraisal
The lack of formal, regular events for cross-team coordination.	Scaled Coordination Meeting	RespB, RespC, RespD
Daily Scrum events are not conducted daily.	Team Coordination Meeting	RespB, RespC, RespD
Retrospectives do not function as standalone events and are still combined with reviews.	Team Retrospective	RespB, RespC, RespD
The Scrum Master role is not well-defined, and no formal responsibility is assigned for Scrum Master duties.	Agile Master & Scaled Agile Master	RespA, RespB, RespC, RespD
The Definition of Done (DoD) for increments does not include testing.	Success Criteria	RespB, RespC, RespD

TABLE. IV. LEVEL INTERPRETATION OF KPA RATING [20]

Level	Range	Interpretation
Fully Achieved	>85% – 100%	Agile practices have been systematically implemented with strong evidence of achievement.
Largely Achieved	>50% – 85%	Agile practices have been largely implemented, although some areas may need improvement.
Partially Achieved	>15% – 50%	Agile implementation is still in its early stages, with inconsistencies and limited adoption.
Not Achieved	0% – 15%	There is insufficient evidence of Agile practices being implemented within the organization.

D. Reporting / Follow-up

The reporting/follow-up stage consists of three key steps: validating the improvement proposal, refining recommendations, and formulating conclusions and suggestions based on the final validation results. The validation process involved the Subject Matter Experts (SMEs) to ensure the proposed improvements' accuracy, relevance, and practical applicability. It was followed by LNSW stakeholders' reviews of the recommendations to assess their alignment with organizational needs and strategic decisions. This step determines feasible proposals that can be effectively integrated into the existing processes.

Following the formulation of an improvement proposal, a structured two-tier validation process was conducted to ensure the accuracy and practical applicability of the recommendations. First, a technical validation was performed with the Subject Matter Experts (SMEs) to verify that the proposed recommendation aligned with Agile best practices. Second, an organizational validation was conducted with LNSW stakeholders to ensure the recommendations remained feasible within existing organizational constraints and strategic goals. If these experts identified any gaps or inconsistencies, necessary adjustments were made, and the validation cycle was repeated. This iterative approach ensured that the proposed improvement aligned with organizational constraints, Agile best practices, and long-term scalability goals.

IV. RESULTS AND DISCUSSION

The appraisal process involved evaluating key Scaled Agile essence elements, identifying implementation gaps, and mapping findings to CMMI 2 practice areas. Additionally, insights from the Subject Matter Experts (SMEs) and key stakeholders were incorporated to refine the evaluation results and recommendations. Based on this analysis, the study derived key findings and developed targeted recommendations to address the research questions as follows:

A. RQ1: What are the Evaluation Results of the Scaled Agile Process in the SINSW Development?

The evaluation of the Scaled Agile process in the SINSW development, conducted as part of the implementation stage, reveals significant gaps in Agile adoption, as demonstrated in Table V. The Scaled Coordination Meeting and Team Retrospective elements show a 0% achievement rate, which is caused by the fact that the events are currently not being implemented. The lack of formally scaled events forces teams to resolve dependencies and unclear tasks through ad-hoc discussions, leading to a fragmented development cycle. Furthermore, the 19.24% achievement in Team Coordination Meetings correlates with reports that daily stand-ups often focus solely on progress updates rather than proactive risk management. Consequently, the delivery cadence is frequently disrupted, as evidenced by the high volume of unfinished tasks being carried over into subsequent sprints.

The capability of role definitions also impacts operational efficiency. The Agile Master (48.15%) and Scaled Agile Master (47.92%) are only partially completed, highlighting a lack of clearly defined responsibilities and structured facilitation of Agile processes. The only element to achieve a high level of

status is the Success Criteria (52.11%). However, it still falls within Capability Level 0 (CL0), indicating that the overall capability of Agile implementation remains at the lowest capability level. Without these formal structures, the organization experiences backlog growth driven by rework and a loss of institutional knowledge, as solution alternatives and issue resolutions are rarely documented. These findings suggest the need for structured governance, more explicit role definitions, and formalized Agile events to enhance scaled Agile adoption within LNSW.

TABLE. V. SCALED AGILE ESSENCE ELEMENTS APPRAISAL RESULT

Scaled Agile Essence Elements	KPA	Interpretation	Capability Level
Scaled Coordination Meeting	Level 1 - 0%	Not Achieved	CL0
Team Coordination Meeting	Level 1 - 19,24%	Partially Achieved	CL0
Team Retrospective	Level 1 - 0%	Not Achieved	CL0
Agile Master	Level 1 - 48,15%	Partially Achieved	CL0
Scaled Agile Master	Level 1 - 47,92%	Partially Achieved	CL0
Success Criteria	Level 1 - 52,11%	Largely Achieved	CL0

B. RQ2: What Recommendations can be Proposed to Improve the Scaled Agile Process in the SINSW Development?

Following appraisal and validation with SMEs and stakeholders, the proposed recommendations aim to strengthen Agile implementation through three strategic areas. First, elaborating on Agile workflows ensures consistency across the LNSW. Second, increasing understanding of Agile value fosters the effective adoption of best practices. Finally, utilizing appropriate tools streamlines processes and enhances collaboration. The recommendations address the gaps identified in the appraisal, enabling the organization to effectively align its Scaled Agile practices with industry standards.

1) *Agile Workflow elaboration*: The Agile workflow needs to align with the current operational conditions and cultural dynamics of the LNSW. Given the organization's compact and straightforward structure and the existing allocation of development teams, adopting the Nexus Framework was recommended as a strategic approach for Scaled Agile practices. This framework is particularly well-suited for organizations with multiple Scrum teams collaborating on a single product, as it provides a lightweight, scalable approach to managing cross-team dependencies and ensuring alignment throughout the development process [21].

The Agile Workflow Elaboration consists of three parts. First, Agile Role Mapping defines team responsibilities and accountability. Second, Agile Event Adjustment refines ceremonies, such as coordination meetings and retrospectives, to improve dependency management. Finally, the Definition of Process Assets establishes the standardized tools and templates required for consistent execution.

a) *Agile role mapping*: The Agile role mapping aligns existing LNSW positions with Agile roles using the CMMI 2-Based Scaled Agile Model to provide greater clarity on responsibilities. Table VI shows role mapping, illustrating how traditional roles can be successfully translated into an Agile structure. SMEs emphasize that existing structural roles do not require any changes. Still, individuals in predefined roles within LNSW can assume Agile roles without altering their formal positions within the organization's hierarchy. However, responsibilities may vary depending on their Agile role, requiring individuals to adapt their approach accordingly.

The findings suggest that Agile roles do not have to originate solely from predefined roles in the LNSW but can emerge from team members or individuals from other units with the required expertise and capabilities. The LNSW will further review this approach to determine how Agile roles can be effectively integrated, using references from the Scrum Guide [22] and the Nexus framework [23] to establish a more flexible and adaptive role distribution within the organization. This approach ensures that Agile practices can be embedded within the LNSW structure without disrupting its operational hierarchy while fostering a culture of collaboration, accountability, and continuous improvement.

b) *Agile event adjustment*: In Agile Event Adjustment, it is recommended that team coordination meetings be improved to enhance communication and alignment within teams. Additionally, the introduction of scaled coordination meetings and team retrospectives is essential, as these events have not yet been conducted in the LNSW. These recommendations will be discussed in greater detail in the points below:

- Scaled Coordination Meeting

Scaled Coordination Meeting is a structured coordination event designed to align multiple Agile teams working on the same product or project. This meeting ensures that cross-team dependencies, impediments, and communication gaps are effectively managed [16]. Unlike regular daily stand-ups within a single Agile team, a Scaled Coordination Meeting focuses on inter-team synchronization, helping teams identify blockers early and resolve dependencies proactively.

The meeting should not exceed 15 minutes to maintain efficiency and involve only essential participants. Ideally, attendees include representatives from each team, such as Agile Masters, Scaled Agile Masters, and Product Owners, with additional roles joining as needed. The meeting structure can follow these key points [24]:

- Team Updates – Each team briefly shares:
 - What has been completed since the last meeting?
 - What will be worked on before the next meeting?
 - Are there any issues, blockers, or dependencies that require attention?

- Dependency Management – Discuss newly discovered dependencies and strategies to resolve them.
- Issue Resolution – Escalate unresolved issues and schedule follow-up discussions as necessary.
- Priority Adjustment – Ensure that all teams remain aligned with current priorities and accommodate any priority changes.

TABLE. VI. MAPPING OF PROPOSED AGILE ROLES WITH EXISTING LNSW JOB FUNCTIONS.

Agile Role	Existing LNSW Job Function
Product Owner	System Analyst (SA)
Scaled Product Owner	Business Analyst, Business Analyst Supporting
Agile Master	Project Management Officer (PMO) or System Analyst (SA)
Scaled Agile Master	Project Management Officer (PMO)
System Architect	Enterprise Architect
Development Team	Developer, Tester

Implementing Scaled Coordination Meetings at the LNSW should be done gradually, starting with meetings as needed rather than immediately holding them daily. This approach prevents unnecessary overhead while enabling teams to benefit from structured cross-team communication. By integrating this meeting, inter-team dependencies can be identified early, minimizing the risk of delays caused by unexpected blockers. Additionally, the meeting enhances risk management by allowing teams to escalate potential impediments and collaborate on resolutions before they become critical obstacles.

SMEs highlighted the importance of keeping Scaled Coordination Meetings flexible, emphasizing that the LNSW can combine structured meetings with ad hoc discussions among teams and Product Owners. While daily meetings may not be necessary, SMEs recommend holding formal synchronization sessions weekly or biweekly involving all Scaled Product Owners and Product Owners. It ensures that coordination and dependencies across teams are well managed, allowing the LNSW to adapt to its existing organizational dynamics. However, proper documentation is crucial for these meetings to be effective, ensuring that key discussion points and resolutions are formally recorded for future reference. By balancing structured coordination with flexibility, the LNSW can improve inter-team alignment, enhance transparency, and optimize Agile execution across projects.

- Team Coordination Meeting

Team Coordination Meeting, often called stand-up, is a key Agile practice that aligns team efforts and ensures a shared understanding of daily priorities. The primary goal of this meeting is to enhance transparency, foster collaboration, and facilitate rapid issue resolution by allowing every team member to share updates, discuss progress, and raise potential blockers [22]. To maintain focus and efficiency, Team Coordination

Meetings must be time-boxed to a maximum of 15 minutes, with attendance required for all development team members and the Agile Master, who typically facilitates the session. Additional roles, like the Product Owner (PO), may join as needed. The structure of the meeting should follow these three key points [25]:

- What did you do yesterday? – Each team member briefly shares what they completed the previous day.
- What will you do today? – Team members outline their focus for the day.
- Are there any blockers or impediments? – Team members highlight issues they are facing. While blockers do not need to be resolved within this meeting, they should be documented and followed up on in a separate discussion if required.

At LNSW, Daily Meetings are not yet conducted routinely, often exceeding the intended duration and focusing primarily on progress updates rather than proactive risk management. To maximize the benefits of these meetings, it is recommended that the LNSW implement structured daily stand-ups with explicit time constraints and discussion points. It ensures that meetings remain productive and aligned with Agile principles. Implementing a well-structured coordination meeting at the LNSW can provide several key benefits. First, it allows teams to identify risks early, ensuring that challenges are recognized and addressed before they escalate. Second, it improves workflow management, keeping the team aligned with sprint goals and optimizing work progression. Finally, this event is a primary mechanism for monitoring and controlling sprint execution. It enables teams to track their commitments, ensure tasks remain on schedule, and make real-time adjustments as necessary. By establishing consistent and effective coordination meetings, the LNSW can significantly enhance team coordination, improve sprint execution, and strengthen Agile adoption across its projects.

- Team Retrospective

Team Retrospective is a crucial Agile event that allows teams to reflect on their processes at the end of each sprint. While the Sprint Review focuses on product outcomes, the Sprint Retrospective evaluates team collaboration and process improvements. This event is essential for continuous learning and adaptation. It ensures that teams do not repeat past mistakes and can consistently optimize their workflow.

Team Retrospectives provide an opportunity to explore what worked well, what did not, and what can be improved in the next sprint [25]. Team Retrospectives should involve the entire team to gain diverse insights and perspectives. According to Scrum guidelines, the event should not exceed three hours for a one-month sprint [22]. Given that LNSW follows a two-week sprint cycle, the recommended duration for retrospectives is no more than 1.5 hours. Key aspects that should be documented during a Team Retrospective include:

- Sprint Summary – Evaluating sprint conditions and whether the sprint goal was achieved.

- What Went Well? – Identifying positive aspects of the sprint that should be continued.
- What Didn't Go Well? – Addressing challenges or blockers encountered during the sprint.
- Improvement Actions/Action Items – Listing prioritized improvements and assigning accountability.
- Team Feedback – Gathering comments, suggestions, and critiques about team collaboration and sprint performance.
- Follow-up on Previous Improvements – Reviewing the past retrospective action implementation

The LNSW needs to establish a structured Retrospective process that is consistently practiced by analyzing ongoing workflows, identifying inefficiencies, and implementing corrective actions to improve team performance and product quality. Regular retrospectives allow teams to proactively address bottlenecks, reduce technical debt, and ensure alignment with organizational goals. Additionally, this event fosters a culture of transparency, accountability, and collaboration, enabling teams to refine their processes, enhance quality assurance, and strengthen risk management.

SMEs also emphasized the importance of Retrospectives in Agile implementation. They recommended that Agile Masters and Product Owners conduct their own process evaluations alongside team-wide sessions. This approach can provide a broader perspective on team dynamics. However, SMEs stressed that team awareness is critical to a successful Retrospective. It aimed to develop members' understanding of why the event is essential and to evaluate team processes proactively to improve them. By increasing awareness and participation, the LNSW can ensure that retrospectives drive meaningful change, reinforcing a culture of continuous improvement and Agile excellence.

c) Definition of process assets: To enhance Agile implementation and ensure structured, efficient, and scalable development processes, the LNSW needs to establish transparent and standardized process assets. These assets serve as guidelines and frameworks that enable teams to work cohesively, maintain quality standards, and improve collaboration. The key process assets that require definition at the LNSW include the Team Working Agreement, Definition of Ready (DoR), and Definition of Done (DoD).

- Team Working Agreement

A Team Working Agreement is a collaboratively created document that outlines the guidelines, rules, and expectations agreed upon by a team to enhance collaboration, productivity, and alignment. It serves as a framework for how the team works together and can be updated based on team consensus [26]. This agreement covers communication methods, meeting schedules, and decision-making processes, ensuring that all team members operate under a shared understanding. Additionally, it plays a crucial role in onboarding by providing new team members with an explicit reference for team expectations and workflows.

During the validation process, SMEs emphasized that working agreements should exist not only at the team level but also at the organizational level. An organization-wide working agreement should define standards applicable across all teams at the LNSW. One example is the standardization of story points for effort estimation, ensuring consistent evaluation of task complexity. Moreover, the agreement should be collectively discussed and approved by all teams at the team and organizational levels to ensure broad acceptance and adherence.

- Definition of Ready and Definition of Done

The Definition of Ready (DoR) and Definition of Done (DoD) are critical components of Agile development that ensure clarity, efficiency, and quality in the software development lifecycle. DoR establishes the criteria a user story or backlog item must meet before entering a sprint, ensuring that tasks are well-defined, feasible, and actionable [25]. A well-structured DoR prevents ambiguities, reduces rework, and eliminates delays by identifying potential issues early in the process [26]. Without a clear DoR, teams may work on poorly defined tasks or lack necessary dependencies, leading to inefficiencies and sprint disruptions.

Similarly, the Definition of Done (DoD) ensures that a completed task meets quality, consistency, and transparency standards before being considered finished. It defines the requirements for design, development, testing, and documentation, ensuring that deliverables are production-ready and aligned with business expectations [26]. A well-enforced DoD minimizes technical debt, reduces defects, and enhances product reliability [25]. Without a structured DoD, teams risk delivering incomplete or low-quality work, resulting in rework, project delays, and misalignment with stakeholder requirements. During discussions, SMEs emphasized the need for the LNSW to incorporate DoR and DoD into an organization-wide working agreement to ensure alignment and awareness across all teams. Although the LNSW has existing criteria for determining when a task is ready to be worked on or considered complete, team awareness remains low, resulting in inconsistent implementation. Implementing standardized DoR and DoD at the organizational level is essential to improving workflow efficiency, reducing project risks, and ensuring effective Agile adoption across the LNSW.

2) *Increasing understanding of agile value*: Organizational culture, knowledge management, and process alignment/collaboration are significant challenges in Agile software development and its implementation with CMMI [10], [27]. Achieving the expected capability level in the LNSW demands more than adopting Agile frameworks. Formal Agile training is required to instill a shared understanding of Agile principles and best practices. Risk and Opportunities Management must also be embedded within Agile processes to ensure teams proactively identify obstacles, mitigate potential threats, and leverage growth opportunities

a) *Formal agile training*: To effectively implement and internalize Agile values, the LNSW must provide structured, formal training in Agile methodologies, particularly Scrum. This training equips individuals and teams with a deep understanding of the iterative, collaborative, and flexible

principles that underpin Agile project management. The LNSW can enhance team alignment, improve workflow efficiency, and ensure a sustainable and scalable Agile transformation by developing core competencies. The key competencies required for Agile practitioners at the LNSW are derived from established frameworks such as the Scrum Guide [22], the Agile Practice Guide [28], and the CMMI 2-Based Scaling Agile Model [16].

The LNSW should implement a structured Agile training program in phases, starting with Agile Masters and Scaled Agile Masters as key facilitators of Agile adoption, adherence to processes, and team guidance. Once trained, they can mentor other roles, ensuring continuous knowledge-sharing and consistent Agile practices. SMEs support this approach, emphasizing that these roles must understand and apply Agile effectively while addressing team needs. A well-structured training program with ongoing mentoring will help the LNSW build a strong Agile culture, enhance collaboration, and improve overall implementation.

b) *Risks and opportunities management*: While traditional software development methodologies often incorporate well-defined risk management frameworks, Agile lacks a standardized, comprehensive risk management structure, requiring teams to integrate risk mitigation strategies within Agile processes [29]. It is important to have risk awareness at both the project and iteration levels, ensuring that risks are identified and addressed proactively through continuous tracking and resolution efforts. Agile teams dynamically manage risks through events such as Sprint Planning, Daily Meetings, Sprint Reviews, and Retrospectives. Still, these practices alone may not provide a structured and consistent risk-handling approach across projects [30]. In scaled Agile, risk management is further embedded into Scaled Cycle Planning using models such as ROAM (Resolve, Own, Accept, Mitigate) from SAFe [31]. It ensures that risks are identified early and addressed before they escalate into major blockers.

However, Agile practitioners, including SMEs, emphasize that risk management tools and models serve only as facilitators; the actual effectiveness of risk management lies in how well Agile teams integrate these practices into their workflows. To achieve this, each Agile event plays a specific role in risk identification, mitigation, and resolution, ensuring that teams systematically address risks throughout the development lifecycle. The following breakdown outlines how Agile events contribute to structured risk management:

- **Cycle Planning**: The Product Owner and Development Team review the backlog to identify uncertainties or dependencies that might pose risks. They discuss ambiguous or complex tasks and explore strategies such as breaking them into smaller, manageable units to minimize risk.
- **Team Coordination Meeting**: Continuous risk monitoring occurs as team members provide updates and highlight unexpected blockers or dependencies. The

Agile Master facilitates rapid resolution by reallocating tasks, escalating issues, or adjusting priorities.

- **User Review:** Stakeholders assess deliverables and encounter risks, ensuring that similar challenges are mitigated through feedback and process adjustments in future sprints.
- **Team Retrospective:** Teams evaluate how well risks were handled and identify improvements to prevent recurring challenges, fostering continuous learning and process refinement.
- **Scaled Cycle Planning:** Teams collaboratively identify and categorize risks using the ROAM model, ensuring that all risks are acknowledged and appropriately addressed. Fully resolved risks are under "Resolve", while those requiring ongoing attention are "Owned" by specific team members. This structured risk assessment enhances transparency and accountability within Agile teams.

Effective risk management goes beyond mitigating threats and opens the door to innovation and process optimization. A structured risk assessment framework enables teams to identify weaknesses, dependencies, and uncertainties, explore alternative solutions, and implement proactive improvements [29]. Rather than viewing all risks as obstacles, proper evaluation helps teams differentiate between pure threats and risks that present growth opportunities. Maintaining comprehensive documentation of identified risks and their corresponding mitigation strategies also builds a valuable knowledge base, helping teams recognize recurring patterns and leverage past insights to drive future improvements. To maximize these opportunities, risks should be documented, prioritized, and integrated into backlog tasks or UR/RFCs, ensuring strategic follow-up.

3) Utilization of Tools

a) Scrum/Task board: A Scrum/Task Board is a visual tool that displays the status of user stories or tasks within a sprint. It plays a crucial role in maintaining transparency, a core Scrum principle, enabling team members and stakeholders to track progress in real time. Scrum boards can be physical boards for co-located teams or digital task boards using Agile project management tools for distributed teams [26]. Rubin [25] further emphasizes the importance of task boards by describing them as dynamic representations of the evolving sprint backlog, where backlog items are broken down into tasks and visually moved through different workflow stages as work progresses.

For the LNSW, implementing a Scrum/Task Board can enhance transparency by aligning it with the team's workflow stages as column headers. It allows team members and stakeholders to track user stories and tasks in real time, ensuring clear visibility of sprint progress. The board also improves team communication by providing a shared view of ongoing work, keeping everyone aligned with sprint priorities. Additionally, it is a central focus during coordination meetings, helping teams monitor progress, address challenges, and plan the next steps effectively. This visual management tool allows LNSW to streamline workflows, improve collaboration, and strengthen

Agile implementation. Fig. 3 shows the recommended stages for use on the board.

Fig. 3. Recommended LNSW task board illustrating a standardized workflow from To-Do to final documentation.

b) Estimation technique: Traditional estimation techniques, such as Function Points (FP), expert judgment, and Work Breakdown Structures (WBS), face subjectivity issues, reliance on historical data, and a lack of benchmarking [32]. These methods often rely on past project metrics or expert intuition, leading to inconsistent team decisions. In contrast, Agile estimation techniques, particularly Planning Poker, aim to mitigate these issues using a collaborative, consensus-based approach to estimate the effort required for a user story. Planning Poker encourages team discussions, reduces cognitive bias, and aligns workload expectations across team members. While traditional models struggle with evolving requirements, Planning Poker adapts to Agile's iterative nature, ensuring estimations reflect real-time complexities. [25], [26], [33].

Planning Poker is often combined with story points, a metric used in Agile to measure effort, complexity, and uncertainty in completing a user story. Unlike traditional time-based estimation, story points consider technical difficulty, risk, dependencies, and domain knowledge. This method allows teams to estimate work comparatively rather than using fixed durations, making it a more adaptable and reliable approach for Agile planning [33]. SMEs emphasized the need for a standardized definition of story points at the organizational level to ensure consistent task evaluation across teams. A shared understanding of story point values prevents significant discrepancies across teams, ensuring that estimations remain aligned regardless of which team performs the work. This standardization improves estimation accuracy, workload distribution, and cross-team collaboration, fostering better predictability in Agile execution.

For the LNSW, implementing Planning Poker with story points can help teams align on estimation, improve predictability, and enhance sprint planning accuracy. The structured process of Planning Poker involves:

- 1) Distributing Planning Poker cards or using digital tools for estimation.
- 2) Select a user story to be estimated, with the Product Owner providing a brief explanation.
- 3) Individually estimating effort by choosing a story point value.
- 4) Revealing all estimations simultaneously to avoid bias.
- 5) Discussing discrepancies if estimations vary significantly, refining assumptions, and re-voting if needed until a consensus is reached.

6) Assigning the final story point value, recording it in the product backlog, and using it for sprint planning.

a) *Burndown chart*: A Burndown Chart is a visual tool used to track the remaining work in a sprint and clearly represent progress based on estimation metrics such as time, story points, or task count. This tool enhances transparency for teams and stakeholders, offering insights into how efficiently work is completed within a sprint. Additionally, Burndown Charts help teams assess their velocity over time. It is a historical record of team capacity, indicating how many story points a team can typically complete in a sprint [25], [26].

To use a Burndown Chart effectively, teams should update it daily, recording the estimated effort remaining for all unfinished tasks. This real-time visualization helps teams determine whether they are on track to complete the sprint goals. As shown in Fig. 4, if the trend line stays above the ideal trajectory, the team falls behind, prompting further investigation into potential blockers, underestimated tasks, or other challenges. Conversely, if the trend line drops below the ideal trajectory, the team may consider taking on additional work or refining existing tasks [25].

However, LNSW expressed concerns that Burndown Charts could send a negative message if the reported progress does not appear ideal. This concern can be addressed by documenting action items in the team retrospective, which provides context and justification for deviations from the expected trajectory. By analyzing these action items, teams can identify the root causes of delays, justify challenges, and implement corrective measures in future sprints. Through proper documentation and continuous reflection, Burndown Charts can serve as an improvement tool rather than just a performance metric, ensuring constructive discussions and better sprint planning at the LNSW.

7) *Proposed phased improvement strategy*: To address the gaps identified in the appraisal and attain Capability Level 1, this study outlines the following phased roadmap:

- Phase 1: Standardization (Short-term / High Priority): Establish consistent process assets, including a standardized Team Working Agreement and formalized Definitions of Ready (DoR) and Done (DoD), while utilizing project management tools to institutionalize these standards across all development teams.
- Phase 2: Synchronization (Mid-term / Medium Priority): Institutionalize structured Agile events, specifically Scaled Coordination Meetings and Team Retrospectives, to manage dependencies across the 42 integrated systems and foster continuous improvement. Moreover, begin integrating the mapped Agile roles into daily operations to ensure clear accountability and leadership throughout the synchronization process.
- Phase 3: Optimization (Long-term / Medium Priority): Enhance Agile leadership through formal training for Agile Masters and Scaled Agile Masters, with a focus on cross-team synchronization and coaching. Concurrently, provide foundational Agile workshops for all developers to ensure a shared understanding of iterative delivery and collaborative best practices.

Fig. 4. Sample Burndown Chart illustrating ideal, early, and late progress trends for sprint tracking.

The execution of this strategy follows a realistic, tailored progression to the bureaucratic and technical complexity of a government integration hub. The short-term phase is expected to span 1 to 3 months, focusing on quick wins and administrative alignment that can be implemented without major structural changes. The mid-term phase typically requires 6 to 12 months, as it involves shifting organizational behavior and aligning the sprint cycles of multiple concurrent teams to manage dependencies effectively. Finally, the long-term phase is projected to take 1 to 2 years. This duration accounts for the deep cultural shift required for leadership coaching and the time needed to establish a self-sustaining environment of continuous optimization and shared Agile values.

V. CONCLUSION

The study evaluates the Scaled Agile implementation in SINSW development, identifies key challenges and inefficiencies, and proposes recommendations to enhance Agile adoption. The findings reveal that team coordination, structured Agile events, and role clarity remain significant areas for improvement. The appraisal results indicate that critical Agile elements such as Scaled Coordination Meetings and Team Retrospectives have not yet been implemented. At the same time, Team Coordination Meetings, Agile Master, and Scaled Agile Master roles are only partially achieved. Although the Success Criteria demonstrated some progress, the overall Agile capability remains at Capability Level 0 (CL0), signifying that Agile processes are still in their early stages and require substantial improvements.

To address the challenges in achieving Capability Level 1, this study proposes a three-phased improvement strategy. This roadmap begins with Phase 1: Standardization, which focuses on elaborating Agile workflows and utilizing project management tools to unify team coordination. It progresses to Phase 2: Synchronization, which institutionalizes structured Agile ceremonies to resolve inter-team dependencies. Finally, Phase 3: Optimization enhances leadership through specialized training for Agile Masters and Scaled Agile Masters. Together, these recommendations bridge identified gaps, fostering a sustainable Agile transformation and improved operational efficiency across LNSW.

Strengthening Agile implementation in SINSW development will lead to greater efficiency, improved team

collaboration, and better alignment with organizational goals. Implementing these recommendations can help ensure that Agile practices are adopted, sustained, and continuously enhanced, enabling LNSW to achieve higher levels of agility and responsiveness in the evolving landscape of government digital services.

ACKNOWLEDGMENT

We would like to express our sincere gratitude to all individuals and institutions who contributed to the successful completion of this research. We especially thank Universitas Indonesia for their generous support under contract number NKB-1820/UN2.RST/HKP.05.00/2020. We also wish to acknowledge the valuable collaboration of the Indonesia National Single Window Agency (LNSW) for providing essential data and insights for this study.

USE OF AI TECHNOLOGY

This manuscript used Grammarly and the free version of ChatGPT solely to enhance English fluency. No other AI tools were involved in the research or writing process.

Explainable Deep Learning for Automated Skin Cancer Detection Using Advanced CNN Architectures on Dermoscopic Images

Adel Rajab

Computer Science Department-College of Computer Science and Information Systems, Najran University, Najran, 61441, Saudi Arabia

Abstract—Skin cancer is a considerable health issue worldwide, occurring when pigment cells turn malignant. However, diagnosing skin lesions is difficult for dermatologists because most lesions have similar characteristics. Initial detection is essential because it significantly increases the success rate of treatment and survival rates. In the past few decades, the rapid development of artificial intelligence has made it possible to build automated diagnostic systems based on large histopathology-validated image datasets. In this study, we introduce a deep learning solution for multi-class skin cancer classification based on state-of-the-art convolutional neural networks (CNNs) on the HAM10000+ISC image dataset. We used pre-trained CNN backbones, InceptionV3, DenseNet121, ResNet50, and VGG16, initialized with weights from ImageNet, for feature extraction, fine-tuning, and evaluation. Among the models, InceptionV3 achieved the highest accuracy of 76% and an ROC score of 0.967. To enhance interpretability, we used explainable AI (XAI) methods, Grad-CAM, Grad-CAM++, and class-wise attention maps, to examine both correctly and incorrectly classified images. The experiment demonstrates that the suggested system is not only characterized by high classification accuracy, but also by the ability to explain and visualize, which is a significant advantage for dermatologists when diagnosing skin cancer early and correctly.

Keywords—Deep learning models; skin cancer detection; image processing; Grad-CAM

I. INTRODUCTION

Recent breakthroughs in deep learning and computer vision have greatly impacted the medical diagnostic community, making it possible to develop accurate automated disease diagnosis systems [1]. Skin cancer is one of the numerous varieties of diseases observed to be one of the most common diseases, as well as a rapidly increasing cancer in the world. The American Cancer Society estimates that 2,041,910 cancer cases and 618,120 cancer deaths will be realized in 2025 in the United States. Although the death rate from cancer has been declining, the incidence and disparities in cancer highlight the need for better early detection, especially in high-risk cancers like melanoma [2]. It is important that skin lesions be detected early and properly classified to enhance better survival.

Conventional diagnosis techniques, like visual analysis and dermoscopy, are highly dependent on the expertise of dermatologists and are prone to inter-observer variability,

thereby emphasizing the need for developing accurate computer-aided diagnosis systems. Deep learning has been recognized as a promising paradigm for medical image analysis due to its learning capability to extract hierarchical features from raw data [3].

Convolutional Neural Networks (CNNs) have been effective in the classification of skin cancer through their ability to detect both low-level and high-level features of the images [4]. VGG, ResNet, and DenseNet models have shown their efficiency in CNNs because of their ability to handle the depth of the network, residual learning, and improved gradient flow. However, despite the progress made, there are still some obstacles that need to be managed to achieve good performance. Therefore, this study proposes and examines the performance of VGG, ResNet, and DenseNet models for skin cancer classification [5], [6], [7].

Diagnosis of skin cancer is largely dependent on the visual inspection of the skin, which is prone to variability and subjectivity. Although promising outcomes have been obtained with deep learning models in terms of classifying skin lesions, high accuracy is still not reached with respect to general types of skin lesions. There is a need for a systematic comparison of the latest CNN models, such as VGG, ResNet, and DenseNet, to determine the best approach for accurate skin cancer detection. Furthermore, one of the biggest challenges that current deep learning models are facing is the lack of interpretability, which is still a major hindrance to the broad adoption of these models in clinical settings [8] [9].

Despite the progress made by deep learning techniques in improving the classification of skin lesions, there have been various limitations noted with the current automated techniques. For instance, various techniques have shown high performance using particular datasets, while their performance is questionable using other datasets. Furthermore, most CNN-based techniques have shown poor interpretability, thus making it hard to trust their predictions. Another limitation noted is class imbalance, where most data sets, such as HAM10000, have imbalanced classes, thus forcing the CNN models to bias towards certain types of lesions. To tackle the above-mentioned challenges, this study aims to explore various popular CNN models, such as VGG16, ResNet50, DenseNet121, and InceptionV3, for multi-class classification of skin lesions. Additionally, Explainable AI techniques, such as Grad-CAM,

Grad-CAM++, and class-specific attention, have been included to provide interpretability to CNN models, thus helping clinicians trust their predictions.

The primary objective of this research is to design and evaluate deep learning models for precise and automated skin cancer diagnosis using an advanced CNN. Additionally, to enhance the interpretability of the decision-making process, this study also integrates Explainable AI (XAI) methods, such as Grad-CAM, Grad-CAM++, and class-wise attention maps.

These explainability methods are applied to both correctly and incorrectly classified lesions to analyze how the models are making their predictions. These methods provide useful explanations in the form of visualizations that help to identify the specific areas of the lesion that are contributing to the model's predictions. This increased interpretability of the model's predictions helps to increase confidence in the reliability of the model for clinical use. Additionally, the use of XAI methods allows dermatologists to determine if the model is paying attention to the appropriate areas of the lesion and not just the background, which can be irrelevant.

The research contributes to the progress of a trustworthy deep learning system for the automated diagnosis of skin cancer. By comparing the VGG, ResNet, and DenseNet models, it determines efficient models that can help dermatologists in making an early diagnosis. The primary objectives of this study are as follows:

- 1) Leverage multiple methods in training and optimizing a multi-class skin lesion detection model with the latest convolutional neural networks, including VGG16, ResNet50, DenseNet121, and InceptionV3.
- 2) Conduct an extensive performance evaluation of the model using several evaluation measures like accuracy, precision, recall, and ROC AUC.
- 3) Use Explainable AI models which include Grad-CAM, Grad-CAM++, and class attention maps to interpret the model and build more trust in their model decision process.

Moreover, key contributions are listed below:

- 1) This study presents a comprehensive comparison of four popular convolutional neural networks in classifying skin lesions into multiple classes using the HAM10000 dataset.
- 2) This study proposes class weighting and data augmentation techniques to mitigate class imbalance in the dataset.
- 3) This study leverages Explainable AI techniques to increase model interpretability and trust in decision-making in dermatology and healthcare.
- 4) This study offers a paradigm that is both sensitive and explainable when it comes to model performance in making decisions in dermatology and healthcare.

The remainder of the study is organized in the following way: Section II locates related work or literature review. Section III contains discussions on the proposed study in terms of conducting some steps. The discussion of the key findings and interpretation is described in Section IV. Outcome or future

directions are provided in Section V. Finally, Section VI concludes the study.

II. LITERATURE REVIEW

A. Hybrid Machine Learning and Deep Learning

Recent works suggest hybrid models of machine learning and deep learning for the detection of melanoma. A hybrid feature extraction method involving the best neural networks and handcrafted features reached 93% accuracy with recall values of 99.7% for benign and 86% for malignant samples, thus outperforming dermatologists and previous automated systems [10]. Similarly, in [11], the authors discuss the application of ML and DL models, particularly CNN, RNN, and transfer learning models for early detection of skin cancer. The SVM-PSO has a maximum accuracy of 97.5%.

B. Ensemble Deep Learning Models

The VGG, CapsNet, and ResNet architectures were trained to produce an ensemble model for skin cancer detection over the ISIC dataset. The accuracy of the individual models was 79%, 75%, and 69%, respectively, while the ensemble model reached 93.5% accuracy, thus outperforming individual deep learning models and traditional machine learning models [12]. The two ensemble models of VGG-16 + ResNet-50 and VGG-19 + Xception were trained on more than 3,000 skin images, showing 100% training and 85% testing accuracy. The ensemble models harnessed the best attributes of feature extraction, performing better than individual models, emphasizing improved reliability and accuracy for early skin cancer diagnosis [13]. The ensemble model of ResNet, EfficientNet, and VGG16, trained on the HAM10000 dataset, showed 99.1% accuracy for benign vs. malignant skin lesion classification. The rigorous preprocessing step improved image quality, and the ensemble model utilized the varied capabilities of feature representation, proving the efficiency of combining the best models for high accuracy [14].

C. Deep Learning Architectures for Skin Lesion Classification

Dermoscopic images and patients' metadata, such as age, gender, and body location, can be detected using the Inception-ResNet-v2 architecture. The model reached 89.3% accuracy for four-class classification and 94.5% accuracy for benign vs. malignant classification on 57,536 images, thus improving performance by at least 5% with the integration of metadata [15]. A CNN-based deep learning model with ESRGAN preprocessing was employed on the ISIC2018 dataset (3,533 images) for the classification of skin lesions. Transfer learning models (ResNet50, InceptionV3, Inception-ResNet) resulted in 83.7-85.8% accuracy, while the proposed CNN resulted in 83.2% accuracy, proving the effectiveness of image enhancement and preprocessing techniques for improved classification accuracy [16]. An attention-enhanced DenseNet-121 model with ICSOA hyperparameter tuning was employed on various datasets (ISIC 2017-2020, PH2, HAM10000) including UNet-based segmentation. The model resulted in classification accuracies of 99.55-99.87%, outperforming Insinet, N-DNN, and Skin-Net models, proving the effectiveness of attention mechanisms and optimal feature selection for skin lesion classification [17].

D. Fine-Tuned and Customized Deep learning Models

A fusion-level deep learning model integrating EfficientNet-B0, EfficientNet-B2, and ResNet50 was employed on the Kaggle Skin Diseases dataset (27,153 images) for ten-class skin disease classification. The model resulted in 99.14% accuracy with high precision, recall, and F1-score, proving its effectiveness for accurate classification with multi-architecture feature fusion [18]. The fine-tuned deep learning models, such as EfficientNetB0, ResNet34, VGG16, Inception_v3, and DenseNet-121, were further improved by adding more dense layers for skin cancer classification. The fine-tuned DenseNet-121 model showed 87% accuracy, which was better than the conventional machine learning models CNN, SVM, and Random Forest, emphasizing the need for customized models and layer optimization [19].

III. METHODOLOGY

This study has developed a deep learning based model that can help in the automatic classification of skin lesions based on dermoscopic images of the HAM10000 +ISIC dataset. The

suggested framework is presented in Fig. 1 and has six stages. The first stage involves collecting the dataset, and to guarantee that images are consistent and high-quality, various image-processing techniques were applied. The second stage involves performing an exploratory data analysis to analyze the distribution of various types of skin lesions and handle class imbalance issues in the dataset. In the third stage, we divide our dataset using stratified sampling to ensure that we do not have any potential issues related to class imbalance in the dataset. In addition to this, we have also applied data augmentation techniques to ensure that our model is less prone to overfitting. For feature extraction and classification purposes, we have utilized different well-established pretrained CNN models. The efficiency of the anticipated model in terms of accuracy is ensured using comprehensive statistical evaluation metrics named ROC curve and Precision-Recall curve to understand the diagnostic potential of proposed model. In addition to this, this research have also utilized different visualization techniques named Grad-CAM and Grad-CAM++ to ensure transparency in our model's decision-making potential.

Fig. 1. Research methodology.

1) *Dataset collection*: The dataset used in this study was downloaded from Kaggle portal [20]. The dataset contains HANM1000 +ISIC images with seven classes, as represented in Fig. 2. The per-class samples and names are shown in Fig. 3.

The classes in the HAM10000 dataset have a significant class imbalance problem, meaning that some classes have a higher number of instances than others. In order to resolve this problem, a class weighting strategy was implemented in the training process of the model. The class weights were computed by utilizing a balanced class weight function from the scikit-learn library. In this way, more importance will be assigned to the minority classes in the training process, and the model will be less biased towards the majority classes in the dataset.

2) *Data augmentation*: For efficient computation, using ImageDataGenerator in TensorFlow/Keras, all images have

been resized to 128 x 128 pixels and normalized between [0,1]. Furthermore to optimize GPU memory usage to speed up training process a batch size of 32 is used [21].

Fig. 2. Sample images of dataset.

Fig. 3. Per class samples.

To assist the model in generalizing well and to account for the types of variations that are typically encountered in a clinical environment, extensive data augmentation strategies were used on the images used in training. Several types of transformations were randomly incorporated to create a diverse set of images. This included rotating images up to ± 25 degrees, shifting images horizontally or vertically up to $\pm 15\%$, zooming images up to $\pm 25\%$, and applying a shear transformation of 0.1. Flipping images both horizontally and vertically was also used [22]. Class imbalance was addressed using class weighted loss strategy based on scikit's learn's balanced class weight function.

A. Feature Extraction

Feature extraction is a process through which images are transformed into a form that is easy to interpret, showing key features and trends in images. This process is achieved through convolutional neural networks in deep learning, which automatically learn features from images [23] [24] [25].

In this study, feature extraction was implemented through backbone CNN architecture:

$$\mathcal{F} = CNN_{backbone}(X) \quad (1)$$

where,

- $X \in \mathbb{R}^{H \times W \times 3}$ is the input image
- $\mathcal{F} \in \mathbb{R}^{h \times w \times d}$ is the extracted feature map
- H, W is the input image height and width (128 x 128)
- $h \times w$ represents the spatial dimension of feature map
- d denotes the number of feature channel

The Global Average Pooling (GAP) layer converts spatial feature map $\mathcal{F}$ into a compact feature vector $f \in \mathbb{R}^d$:

$$f_j = \frac{1}{h \cdot w} \sum_{i=1}^h \sum_{k=1}^w \mathcal{F}_{i,j,k} \quad \forall j = 1, 2, 3, \dots, d \quad (2)$$

This vector is then forwarded to the fully connected layers for classification.

Fig. 4. Parameters used for feature extraction.

Fig. 4 represents parameters for CNN backbones to extract useful features for model training. The features learned by the network form a basis on which classification is made. The features allow the network to differentiate between classes in images. The features learned in this process are used to classify images into different classes. When dealing with images in a medical context, such as dermoscopic images, feature extraction is a key process in distinguishing between images based on their morphological differences. This enhances accuracy and generalization. The model uses transfer learning to classify images through a combination of ResNet50, DenseNet121, InceptionV3, and VGG16 networks, which have already been trained on a large number of images.

B. Model Development

In this study four advanced CNN architectures were employed as discussed below:

1) *ResNet50*: This model is a 50-layer residual network, where skip connections are incorporated to facilitate the flow of information across the layers. This helps to prevent the occurrence of the vanishing gradient problem when training deep networks [26]. Fig. 5 illustrates the various parameters of ResNet50 architecture.

Fig. 5. ResNet50 parameters.

2) *DenseNet121*: This model features a series of connections where each layer is connected to the previous ones. This allows for the effective reuse of features across the network, which helps to improve the flow of information [27]. Fig. 6 represents the architectural specifications for DenseNet121 model.

Fig. 6. Parameters for DenseNet121 architecture.

3) *InceptionV3*: This model features a multi-branch architecture where the image data is processed by a series of parallel convolutional filters. This helps to improve the features learned by the model by incorporating features of varying sizes [28]. Fig. 7 illustrates the parameters defined for InceptionV3 model for training.

Fig. 7. Architectural parameters of InceptionV3.

4) *VGG16*: This model features a 16-layer convolutional neural network known for its simplicity and consistency. This model features small 3×3 filters used for convolutional processing. Despite its simplicity, this model has proven to be effective for image classification [29]. Fig. 8 shows the parameters such as input image size, total number of layers and maxpooling block.

Fig. 8. Parameters of VGG16 model.

C. Explainability and Artificial Intelligence

Explainability in deep learning techniques is a set of techniques used to aid in the understanding of the decision-making process of the model. In image classification, it is often done with visual attention maps, which include techniques such as Grad-CAM and Grad-CAM++. It helps to build confidence in the clinical diagnosis by providing insight into the basis of the model's prediction of the type of lesion. Furthermore confirms the model is attending to the relevant parts of the image, rather than the irrelevant background [30]. In this study, the following techniques were employed:

1) *Grad-CAM*: Gradient-weighted Class Activation Mapping (Grad-CAM) was utilized to identify areas in each image that had a major influence on the predictions made by the

model. The model focused on the final convolutional layer to create a heatmap highlighting important features in each image.

2) *Grad-CAM++*: To obtain a precise localization of features, particularly in images containing small lesions or multiple areas of interest, Grad-CAM++ was utilized. This model provides a sharper and more detailed attention map compared to Grad-CAM.

3) *Class-wise attention maps*: The average attention maps were generated for each class of lesions by summing up the output from multiple images using Grad-CAM++. This provided a deeper understanding of features used by the model to differentiate between different types of lesions [31].

IV. RESULTS AND DISCUSSION

The experiment has been accompanied using Kaggle Notebook, and the Keras library of Python's deep learning. The model has been trained using a batch size of 32, and 40 epochs. Adam optimization has been used in the experiment, and the learning rate has been set to 1×10^{-4} to ensure the efficiency of the model. A categorical cross-entropy has been used as the loss function, as it is the most appropriate function for the classification problem. In an effort to enhance stability in the training process and prevent overfitting in the model, several regularization techniques were added to the model. These included the use of Dropout layers, Batch Normalization, as well as an adaptive learning rate adjustment and early stopping. The learning rate adjustment was achieved with the ReduceLROnPlateau callback function, which reduced the learning rate by a factor of 0.3 if there was no enhancement in the validation loss for three consecutive epochs. Additionally, an EarlyStopping method was used with a patience of seven epochs to stop the training process if there were no improvements in the validation loss.

Table I shows the division of training testing and validation samples. Specifically, that dataset was split into 70% training, 20% testing, and 10% validation using the `train_test_split` function with a fixed random seed (random state =42)

TABLE. I. SAMPLES DIVISION

Training	Testing	Validation
7010	2003	1002

A. Performance Comparison of Deep Learning Models

Table II presents a summary of the performance of several deep learning models on standard evaluation parameters. Among these models, InceptionV3 performed the best, with an accuracy of 76%, recall of 77%, and F1 score of 70%, although its precision was marginally lower at 66%. The second-best model was DenseNet121, which reported an accuracy of 74%, precision of 72%, recall of 71%, and F1 score of 71%. ResNet50 performed moderately well, with an accuracy of 71%, precision of 68%, recall of 65%, and F1 score of 65%. VGG16, on the other hand, performed the worst, with an accuracy of 67%, precision of 60%, recall of 65%, and F1 score of 60%. The superior performance of InceptionV3 can be attributed to its architecture, which incorporates factorized convolutions and inception modules to effectively extract multi-scale features, thereby leading to higher accuracy and

recall. The dense connectivity of DenseNet121 helps it perform better, as it enables effective feature propagation and prevents vanishing gradients. Although ResNet50 is a capable model, it lags slightly behind InceptionV3 and DenseNet121, possibly because of the relatively less extensive use of feature reuse. The poor performance of VGG16 emphasizes the weakness of its simple and uniform architecture in handling complex hierarchical features.

TABLE. II. PERFORMANCE EVALUATION OF DL MODELS

DL models	Accuracy	Precision	Recall	F1 score
ResNet50	71%	68%	65%	65%
DenseNet121	74%	72%	71%	71%
InceptionV3	76%	66%	77%	70%
VGG16	67%	60%	65%	60%

Fig. 9. Confusion matrix for the InceptionV3 model.

Fig. 9 illustrates the performance of the InceptionV3 model over the unseen test dataset. Out of the total samples (2003), the model correctly classified 1527 with 476 misclassifications.

Fig. 10. Confusion matrix for the ResNet50.

Fig. 10 illustrates the performance of the ResNet50 model, where the model accurately predicted 1423 samples while 580 samples were misclassified.

Fig. 11. Confusion matrix for DenseNet121.

Fig. 11 shows the performance of the DenseNet121 over test samples. The model rightly predicted 1463 samples from the total sample (2003), while 540 samples were misclassified.

Fig. 12. Confusion matrix for the VGG16 model.

Fig. 12 shows the confusion matrix for the VGG16 model, where out of total samples (2003) the model correctly classified 1342 samples with 661 misclassifications.

Fig. 13. Loss curve for ResNet50 model.

Fig. 13 represents the train and validation loss. The orange curve depicts the validation loss while blue curve shows the train loss. Both losses decrease significantly during initial epochs but minor fluctuations were observed in validation loss,

around at epoch 5 the validation loss suddenly rises at peak and then drops. The initial drop in both training and validation loss suggests that the model is effectively learning relevant and discriminative features from the data. The slight increase in validation loss during the training process may be due to overfitting or slight oscillations in the loss due to batch-wise changes during the optimization process. However, as the validation loss eventually drops and stabilizes, it is a clear indication that the model has successfully regained its capacity to generalize. This is probably achieved through various regularization techniques such as dropout and learning rate schedules.

Fig. 14. Loss graphs for DenseNet 121.

Fig. 14 shows the train and validation loss for the DenseNet121 model. The train loss decreases from a loss value of 1.8 during initial epochs, while the validation continuously fluctuates. When reaching at epoch 4, the validation loss overlaps train loss. The gradual decrease in the training loss indicates that the optimization is going on well and the gradients are flowing well in the network, which can be credited to the dense connections in the DenseNet121 model. At around epoch 4, the training and validation loss curves are almost the same, which indicates that the model is generalizing well at this stage.

Fig. 15. Loss curves for InceptionV3 model.

Fig. 15 shows the train and valid loss generated by InceptionV3 model. During initial epochs, the train loss decreases, however, when reaching around epoch, 10 minor fluctuations were observed. The validation drops from a loss value of 1.25, but continuously fluctuates and remained within loss value (1). The steady reduction in the training loss over the

first few epochs signifies that the InceptionV3 model is effectively learning features and converging. The minor oscillations in both the training and validation loss can be attributed to batch-wise differences and the model's adjustment to the complexity of multi-class lesion features. The fact that the validation loss is more or less steady at 1 indicates that the model is maintaining its generalization capabilities well and not overfitting much, which is probably aided by regularization techniques and the inception modules in the model that are efficiently extracting multi-scale information from the lesions.

Fig. 16. Loss curve for the VGG16 model.

The loss curve of training and validation of the VGG16 model is shown in Fig. 16. Its loss during the training decreases gradually, starting with a level of about 2, showing that the model is learning the feature representations. However, the validation loss varies erratically, peaking at 5 and showing periodic peaks and troughs at around epoch 5 and later epochs. The erratic validation loss shows that VGG16 is not generalizing well on this data. This is because VGG16 is a shallow and sequential model, which is not good at representing complex multi-scale features compared to other models like ResNet50 or InceptionV3. The periodic peaks in the validation loss could also be due to batch variations and early stages of overfitting. However, the steady drop in the training loss shows that the model is still learning good features, even if it is not generalizing well.

B. Explainability Analysis Using Grad-CAM++

Fig. 17 shows Grad-CAM++ results for two dermoscopic images of melanocytic nevi (nv). For the left image, the prediction confidence of the model was relatively low, at 0.33, and the Grad-CAM++ results show broad, diffuse areas in the image and the surrounding skin. On the other hand, the Grad-CAM++ results for the right image show that the prediction confidence was relatively high, at 0.77, and the attention was focused on the lesion, demonstrating that the model was successful in identifying the most discriminative features. The Grad-CAM++ results are based on the computation of the weighted sum of the positive gradients in the last convolutional layer, resulting in class-specific localization maps that show the areas that the CNN uses to make the prediction. The difference in the attention distribution in the Grad-CAM++ results for the

two images demonstrates the potential of Grad-CAM++ to show the confidence of the CNN in its prediction and to provide insights into the CNN's prediction process for the lesion regions in the images.

Fig. 17. Correct classification.

Fig. 18 shows Grad-CAM++ attention maps for two dermoscopic images that the model incorrectly classified. On the left, the model incorrectly classified the dermoscopic image as melanoma (mel, 0.49) when in fact it should have been

classified as melanocytic nevus (nv). On the right, the model incorrectly classified the dermoscopic image as a benign keratosis-like lesion (bkl, 0.73) when in fact it should have been classified as melanoma (mel).

Fig. 18. Missed classification.

Fig. 19. Class-wise average attention maps.

Fig. 19 shows the class-wise average attention maps obtained using Grad-CAM++ for seven classes of skin lesions: akiec, bcc, bkl, df, mel, nv, and vasc. These attention maps help identify the regions of interest in the input images that the CNN uses for prediction in each class. The hotter colors, such as red and yellow, in the attention maps represent regions of high attention, while the cooler colors, such as blue, represent regions of low attention in the input image. For instance, the attention maps for mel and nv classes have elongated attention regions in the central part of the lesions, indicating that the model is considering larger regions of the input image for making predictions. On the other hand, the attention maps for bcc and akiec classes are more focused, indicating that predictions for these classes are made using localized features. Grad-CAM++ is an improvement over Grad-CAM because it uses higher-order gradients. This improvement enables the CNN to better focus on localized regions of importance, even if there are multiple instances or fine details in the image.

Consequently, the CNN can better identify the importance of the features that are driving its prediction.

C. Comparative Analysis

Comparison of the performance of models is one of the objectives of this study to select the best-fit model.

Fig. 20 shows the ROC curve analysis for all the models that were evaluated. The ROC curve analyzes the true positive rate against the false positive rate for different thresholds. The AUC value is a measure of the model's capability to assign higher scores to positive instances than to negative instances. InceptionV3 had the highest AUC value of 0.967, which is the best discriminative capability. DenseNet121 had the second-best discriminative capability with an AUC value of 0.962, followed by ResNet50 with an AUC value of 0.956 and VGG16 with an AUC value of 0.938. InceptionV3's high AUC value can be attributed to its deeper architecture and inception modules that are efficient in capturing multi-scale features and

improving class separation. DenseNet121's good performance can be attributed to its dense connections that help in improving the flow of gradients and reusing features. Although ResNet50 and VGG16 are still good models, their lower AUC values imply slightly lower discriminative capabilities.

Fig. 20. ROC curve for all models.

Fig. 21 shows the comparison of all models based on their accuracy. InceptionV3 had the highest accuracy of 76%, followed by DenseNet121 with an accuracy of 74%, and then ResNet50 with an accuracy of 71%. The lowest accuracy was shown by VGG16, which only managed 67% accuracy. The differences in accuracy rates indicate the pros and cons of each model's architecture and its ability to extract features. InceptionV3 has the advantage of inception modules that apply multi-scale convolutional filters to effectively capture a broad range of lesion patterns.

Fig. 21. Comparative analysis.

V. DISCUSSION

Table II presents a summary of the performance of the tested CNN architectures on the various evaluation metrics. Among the architectures, InceptionV3 recorded the highest accuracy of 76%, recall of 77%, and F1-score of 70%, albeit a slightly lower precision of 66%. The second best architecture was DenseNet121, which recorded an accuracy of 74%,

precision of 72%, recall of 71%, and F1-score of 71%. ResNet50 recorded a moderate performance with an accuracy of 71% and F1-score of 65%, while VGG16 recorded the lowest performance on all metrics, with an accuracy of 67% and an F1-score of 60%. The high performance of InceptionV3 is due to its factorized convolutions and inception modules, which are highly efficient in capturing multi-scale features and improving discriminative capabilities. The high performance of DenseNet121 is due to its dense connectivity, which enables feature reuse and prevents vanishing gradients. Although ResNet50 performed well, it is slightly less effective due to limited feature propagation, while VGG16's shallow and uniform architecture is highly ineffective in modeling complex hierarchical features, hence its low performance.

The best performance was obtained by InceptionV3, which can be attributed to its inception modules and factorized convolutions that help it to extract features at varying scales in skin lesions. DenseNet121 also performed well, owing to its dense connections that facilitate feature reuse and help gradients flow more freely through the network. ResNet50 produced moderate results, as it has limited feature propagation compared to DenseNet121. VGG16 produced the poorest results, as it has a limited depth compared to other models, making it difficult to extract features at varying scales in skin lesions.

In the past few decades, advanced deep learning models were explored for skin cancer detection by utilizing models such as EfficientNet, Vision Transformers, as well as hybrid models using CNNs and Transformers. Most of these studies have achieved classification accuracy rates of more than 90% using the HAM10000 dataset. In contrast, the present study compares various architectures. Another important aspect of the current study is the focus on the interpretation of the models' predictions, using the Grad-CAM and Grad-CAM++ methods, which is an important consideration in terms of trust in the models' predictions, especially in a clinical setting.

The confusion matrices (Fig. 9 to Fig. 12) depicts the performance of models over testing samples. InceptionV3 accurately classified 1,527 out of 2,003 test samples with 476 misclassifications (Fig. 9), indicating high discriminative ability. ResNet50 and DenseNet121 accurately classified 1,463 (540 misclassified) and 1,423 (580 misclassified) samples, respectively (Fig. 10- Fig. 11), while VGG16 accurately classified only 1,342 samples with 661 misclassifications (Fig. 12), indicating its poor generalization and feature representation capabilities.

The training and validation loss plots (Fig. 13 to Fig. 16) further confirm performance. For ResNet50 (Fig. 13), both training and validation losses started decreasing with minor fluctuations, indicating efficient convergence and generalization, facilitated by dropout and learning rate scheduling. For DenseNet121 (Fig. 14), the training loss remained stable, while the validation loss overlapped around epoch 4, indicating high generalization ability due to dense connections. For InceptionV3 (Fig. 15), the training loss remained stable with minor fluctuations in validation loss, indicating efficient multi-scale feature extraction and generalization. In contrast, VGG16 (Fig. 16) showed unstable

validation loss with frequent peaks, indicating high overfitting and poor generalization, as expected due to its shallow architecture.

The training and validation loss curve provides valuable insight into the performance of the models according to their ability to generalize. The low difference in the training and validation losses indicates that there was little room for overfitting and that the training process was stable. Moreover, to improve the robustness of models, data augmentation, early stoppage, and learning rate have been employed.

The integration of (XAI) techniques further helps to understand the interpretability of the models. The Grad-CAM++ attention maps (Fig. 17 to Fig. 19) demonstrate that the models are able to precisely attend to lesion-specific areas for correct predictions, while the misclassified images demonstrate general or incorrect attention patterns, pointing to areas of failure of the model. Class-wise average attention maps (Fig. 19) indicate the attention patterns vary across lesion types, with broader regions for melanocytic nevi (nv) and melanoma (mel), localized regions for basal cell carcinoma (bcc) and actinic keratoses (akiec). These results clearly show the ability of XAI techniques to improve clinical trust by providing visual explanations of the model's predictions.

Grad-CAM and Grad-CAM++ visualization also supported this, as it indicated that the models that produced better results paid more attention to the most important parts of the lesions, which indicates a strong correlation between model architecture, feature extraction, and accuracy.

ROC curve analysis (Fig. 20) verifies the discriminative power of the models. InceptionV3 had the highest AUC value of 0.967, followed by DenseNet121 (0.962), ResNet50 (0.956), and VGG16 (0.938), which emphasizes the superiority of deeper models and multi-scale feature extraction for discrimination. Accuracy comparison analysis (Fig. 21) also validates the same, ranking InceptionV3 as the best-performing model, followed by DenseNet121 and ResNet50, while VGG16 is the worst-performing model.

These findings collectively stress the importance of model architecture in both predictive accuracy and generalization. The integration of XAI methods enables the extraction of clinically important features, improving interpretability and facilitating the successful implementation of skin cancer diagnostic systems using deep learning models.

A. Practical Implications

The outcomes of this research have several key implications for practical applications in the field of dermatology. Firstly, the potential exists for high-performing models such as InceptionV3 and DenseNet121 to serve as a trustworthy decision-support system for dermatologists, enabling early detection and correct classification of skin lesions while possibly minimizing the occurrence of diagnostic mistakes. Secondly, the application of Explainable AI methods enables visual interpretation of model predictions, enabling dermatologists to confirm whether the model is concentrating on medically significant skin lesion areas instead of unnecessary artifacts, which could enhance AI-assisted decision-making.

B. Limitations

Nevertheless, the study also has some limitations. The models were trained and tested mainly on the HAM10000 dataset, which could limit their ability to generalize to images from other populations, devices, or settings. Moreover, the approach is based solely on dermoscopic images and excludes patient-specific clinical data, such as age, gender, or lesion site, which could further improve diagnostic performance and enable more accurate diagnostic model.

However, it should be noted that although this work has analyzed the application of transfer learning with various architectures for CNNs, more recent architectures such as transformer models or hybrid models combining convolutional and transformer architectures were not included in this study. Another limitation is that although this study has proposed models that were implemented and tested in a controlled experimental environment, it should be noted that these models have not yet been tested in a real-world clinical environment. Other potential improvements may come from future experiments that include more recent and more powerful deep learning architectures to improve diagnostic accuracy.

VI. CONCLUSION

This study presented a novel deep learning approach for multi-class skin lesion classification on the HAM10000 dataset. Various advanced CNN models, such as InceptionV3, DenseNet121, ResNet50, and VGG16, were fine-tuned and compared using a comprehensive comparative study. The InceptionV3 performed achieved the highest accuracy of 76% and an ROC-AUC value of 0.967. While the DenseNet121 and ResNet50 attained moderate performance, however, VGG16 performed relatively poor. The results clearly indicate that deeper networks with multi-scale feature extraction and enhanced gradient flow are more adept at handling complex lesion characteristics.

In addition to evaluating performance, this study also tackled the critical aspect of interpretability by incorporating (XAI) approaches, such as Grad-CAM, Grad-CAM++, and class-wise attention maps. These approaches allowed for the visual interpretation of the decision-making process of the models by pointing out the regions of the lesions that contributed to the classification results. This approach also enables to identify the areas of the skin lesions that were contributing the most to the predictions made by the models, which was important in the early diagnosis and accurate classification of skin cancer cases.

Collectively, these results illustrate that the integration of advanced CNN models with interpretability methods can lead to the development of a strong and practical automated system for skin cancer diagnosis.

Future studies would evaluate model on larger datasets that include patients from different ethnic backgrounds. This would not only help in validating the system's generalization capabilities but also increase confidence in its effectiveness in a real-world environment. By using both visual and clinical information through multimodal deep learning approaches, it may be possible to develop a more comprehensive and informed decision-making system.

DATA AVAILABILITY STATEMENT

The dataset used in this study for early detection is publicly available at <https://www.kaggle.com/datasets/nour12347653/skin-disease-detection-dataset-ham10000-isic>

Energy-Efficient Cluster Head Rotation in WSNs Using Bee Colony Optimization

Azamuddin Bin Ab Rahman, Sakib Iqram Hamim

Faculty of Computing, Universiti Malaysia Pahang Al-Sultan Abdullah, Pahang, 26600, Malaysia

Abstract—In this study, we present a method designed to improve energy efficiency and balance the workload across Wireless Sensor Networks (WSNs). Our approach dynamically selects and rotates cluster heads (CHs) based on factors such as remaining energy, node mobility, distance to the base station, and data processing needs. By focusing on nodes with more energy and lower mobility, we aim to extend the network's operational life and prevent any single node from being overburdened. At the heart of our method is the Artificial Bee Colony (ABC) optimization algorithm, which mimics the foraging behavior of bees. This algorithm helps to identify the best nodes to act as CHs, balancing the energy load across the network and maintaining strong connectivity within clusters. Our simulations show that this method outperforms existing protocols like FEEC and PSAP-WSN, particularly when it comes to distributing energy more evenly and extending the network's lifespan. By continuously rotating the CHs, we ensure that energy consumption is spread out, leading to improved network performance and sustainability. The results indicate that this dynamic and adaptive approach is highly effective in maintaining a balanced energy distribution, making it a robust solution for energy management in WSNs.

Keywords—Energy efficiency; load balancing; cluster head rotation; bee colony optimization; metaheuristic clustering; Wireless Sensor Network

I. INTRODUCTION

WSNs are becoming a crucial part of modern life, helping us in areas like environmental monitoring, healthcare, and even the development of smart cities [1]. These networks, made up of small sensor nodes, are designed to collect and send data, often operating in places where it's difficult for humans to reach [2]. But despite their usefulness, WSNs face a major challenge. Their nodes run on limited battery power, and managing this energy efficiently is key to keeping the network alive for as long as possible. One of the biggest problems comes from the cluster heads (CHs), which handle most of the heavy lifting by collecting and transmitting data. Since these CHs use more energy than other nodes, they tend to drain their batteries faster, which can shorten the overall network's lifespan [3].

To solve this issue, researchers have been focusing on ways to make energy use more balanced across the network [4]. One promising idea is to rotate the CH role among different nodes, which helps spread out the energy consumption more evenly and prevents any single node from wearing out too quickly. This technique has been proven to extend the life of WSNs by avoiding the early failure of key nodes like CHs.

Artificial intelligence (AI) techniques are playing an increasingly important role in improving how WSNs function [5]. By applying smart algorithms, we can tackle a range of challenges, like managing energy use more efficiently, gathering data more effectively, and detecting potential faults before they become serious problems. Machine learning, for example, helps predict when parts of the network might fail or when energy is being used inefficiently, allowing us to adjust ahead of time to keep the network running longer [6]. Similarly, nature-inspired methods, like swarm intelligence, are being used to better decide which sensor nodes should take on more demanding roles, such as cluster heads [7]. This ensures that energy is shared more evenly among all the nodes, which helps the network stay alive and operate smoothly over time. However, there are some downsides to using AI in these networks. Many AI techniques [8] are quite complex and require a lot of computing power, which can be a big problem since WSNs often work in environments where resources are limited. In addition, these algorithms usually need a large amount of data to learn from, and it might not always be possible to gather that data in real-time.

More recently, nature-inspired algorithms have shown great promise in addressing this problem. Algorithms like the Artificial Bee Colony (ABC) mimic the way bees work together to find food, using this behavior as a model for selecting CHs more effectively [9]. By rotating the CH role based on factors like energy levels and proximity to other nodes, these methods help keep the network running smoothly and efficiently for a longer time [10].

In this study, we propose a new approach for choosing CHs in WSNs using the ABC optimization algorithm. Through simulations and detailed analysis, we show how this method not only balances the energy load across the network but also helps the network last longer.

The rest of the study is organized as follows: Section II looks at the related works, Section III describes the system model, and Section IV details the PSAP-WSN CH selection with ABC. Section V presents the results and analysis, and Section VI wraps up the study.

II. RELATED WORK

WSNs have become a cornerstone in the development of Internet of Things (IoT) applications, particularly in areas where scalable and energy-efficient communication is critical [11]. The primary challenge in WSNs lies in maintaining energy efficiency while ensuring scalability and reliability [12].

Various multi-tier clustering frameworks and load balancing protocols have been proposed to address these challenges. This systematic literature review explores key contributions in this area, analyzing the effectiveness of multi-tier clustering and load balancing strategies in WSNs and their impact on network lifetime, scalability, and energy efficiency.

Multi-tier clustering frameworks have gained significant attention due to their ability to manage large-scale networks by breaking them into smaller, manageable segments. Shukla and Tripathi (2020) presented a multi-tier-based clustering framework aimed at enhancing the scalability and energy efficiency of WSN-assisted IoT networks [13]. Their approach focused on distributing the network load across multiple tiers, thus minimizing long-distance communication and transforming it into shorter, more manageable hops. This method not only conserved energy but also improved the network's overall scalability by ensuring that sensor nodes operate within their energy constraints, thereby extending the network's lifetime.

Several algorithms have been proposed to address this issue, including Sparrow Search Algorithm (SSA), Grey Wolf Optimization (GWO), and Bat Algorithm (BA) [14]. While these approaches offer notable improvements in energy consumption and CH selection, the Artificial Bee Colony (ABC) algorithm generally outperforms them due to its superior exploration-exploitation balance and adaptability.

SSA and GWO, for instance, focus on optimizing CH selection by mimicking the behaviors of sparrows and wolves, respectively, to enhance energy efficiency and prolong network lifetime [15]. SSA uses a multi-objective approach to distribute energy consumption across nodes, while GWO employs a hierarchical approach to cluster head selection. However, both algorithms have a limited capacity to dynamically adapt to rapidly changing network conditions. SSA and GWO tend to converge prematurely on suboptimal solutions, particularly in large-scale networks, due to their deterministic search processes. In contrast, ABC, which simulates the foraging behavior of bees, allows for continuous refinement of solutions by balancing local and global search through different types of bee agents (employed, onlooker, and scout bees) [16]. This adaptability ensures that ABC maintains higher energy efficiency even as the network topology evolves.

Similarly, BA uses echolocation to explore and exploit solutions but often struggles with scalability issues in larger WSNs due to its inherent complexity [17]. ABC's iterative nature and robust exploration strategies make it more effective in preventing energy depletion across network nodes, ensuring optimal CH selection across various WSN topologies. In essence, while the algorithms referenced offer valuable contributions, ABC's dynamic adaptability, superior balance between exploration and exploitation, and energy optimization make it a more effective approach for CH selection in WSNs [18].

Golden Eagle Optimization (GEO) is a recent metaheuristic algorithm inspired by the hunting behaviors of golden eagles

[19]. Its application in Wireless Sensor Networks (WSNs) focuses on optimizing the selection of CHs to balance energy consumption and enhance network longevity. Although GEO has shown effectiveness in this area by simplifying cluster topology and extending the operational lifetime of WSNs, the ant and bee colony optimization algorithms are often considered superior for certain tasks within WSNs.

Ant Colony Optimization (ACO) and Artificial Bee Colony (ABC) algorithms are bio-inspired by the foraging behavior of ants and bees, respectively [20]. These algorithms excel in multi-objective optimization tasks and have demonstrated strong performance in dynamic and distributed network environments like WSNs. The primary reason ACO and ABC are often preferred over GEO is their inherent ability to handle large, complex networks with unpredictable changes [21]. ACO, for instance, simulates the pheromone trail-laying behavior of ants, which enables robust and efficient pathfinding in routing protocols, especially under dynamic network conditions. Similarly, the ABC algorithm, inspired by the food foraging behavior of bees, is excellent at finding globally optimal solutions through efficient exploitation and exploration strategies, particularly in optimizing energy consumption.

While GEO can optimize CH selection by imitating eagle predation, it lacks the adaptive feedback mechanisms inherent in ACO and ABC [22]. These mechanisms allow ACO and ABC to dynamically adjust their search patterns based on real-time changes in network conditions, improving resilience to node failures and mobility. Additionally, ACO's pheromone-based learning facilitates quick convergence towards the optimal path, which is crucial for time-sensitive WSN operations. Consequently, for larger and more complex WSNs, ACO and ABC often provide better scalability and adaptability than GEO, making them more suitable for real-world deployments where network dynamics are a critical concern [23].

III. THE SYSTEM MODEL

A. Network Model

Fig. 1 illustrates a network model of a 2-Tier WSN network, where S fixed number of sensors are randomly distributed in an $M \times M$ area. The network section is of two types: in direct nodes and cluster nodes. A cluster, in general, can be defined as a collection of nodes that are functioning in adjacent regions. In Tier 1, child nodes in each cluster sent the data to their respective CHs. Then, CHs collected the aggregated data from their child nodes to send them to the relay nodes. Next, relay nodes forwarded the data to the BS. Dissimilar to Tier 1, the relay nodes of Tier 2 would pass the data to the relay nodes of Tier 1 before reaching the BS. The multi-hop transmission was based on a triple-hop in Tier 1 and a quad-hop in Tier 2. The required energy of the BS during the movement is not too high, because its energy is significantly higher than that of the sensor nodes. Rounds are defined as the period where the data packets are exchanged among different groups of sensor nodes, their CH, and the data sink [24], [25].

Fig. 1. 2-Tier Network model.

B. Energy Model

The constituents of the sensor node are the processing circuit, sensor interfacing circuit, and radio frequency connections. Transmission of data in WSNs consumes considerably high power and, therefore, can be considered as one of the major energy-consuming operations. Data transmission has energy loss at both the transmitter and receiver ends and the energy loss occurs at the rate of $\frac{E_{elect}}{k \text{ bits}}$. Therefore, communication network energy is utilized by both the sender and the receiver as per a specialized wireless energy consumption model, as shown in Fig. 2.

Fig. 2. Energy model.

The energy used to transmit a message of k bits over a distance of d meters is expressed in Eq. (1) below:

$$E_{TX}(k, d) = \begin{cases} k * E_{elect} + k * \epsilon_{fs} * d^2, & d \leq d_o \\ k * E_{elect} + k * \epsilon_{mp} * d^4, & d \geq d_o \end{cases} \quad (1)$$

where, E_{elect} is the energy expended for the electronic circuit at the sender's end. The energy expended for the sensor nodes to send data through a free space channel is represented by ϵ_{fs} , the energy to transmit through the multipath is represented as ϵ_{mp} . The distance threshold d_o incorporates the values which are [see Eq. (2)]:

$$\sqrt{\epsilon_{fs}/\epsilon_{mp}} \quad (2)$$

The energy consumed to receive a message of k bits over a distance d is expressed as Eq. (3):

$$E_{RX} = k * E_{elect} \quad (3)$$

C. Proposed Technique

The proposed method for energy-aware cluster head rotation in WSNs focuses on optimizing energy efficiency and

load balancing. The approach involves dynamically selecting and rotating cluster heads based on multi-factor decision-making models that consider key parameters such as residual energy, node mobility, distance to the base station, and the length of data queues. Initially, nodes with higher energy levels and lower mobility are preferred for cluster head roles to minimize energy consumption across the network.

The main idea of the proposed scheme is to balance the load among clusters, keeping in mind factors like residual energy, the amount of nodes a cluster head (CH) is connected to and the distance between the cluster head (CH) and the base station (BS), which eventually improves the availability of the network and increases the lifespan of the network. The method operates in several phases: discovery of locations and neighboring nodes, formation of initial clusters, energy-efficient balanced clustering, and identification of the rendezvous point (RP) for data collection. This energy-aware approach effectively balances the network's load by dynamically rotating cluster heads, thereby mitigating rapid energy depletion of individual nodes and improving overall network performance.

D. Location and Neighbor Identification

Imagine the deployment area as a rectangular grid with dimensions $D1 \times D2$. Each node in the network sends out its ID at synchronized intervals and gathers information about its nearest neighbors. This data is then stored in a list specific to each node, called $N_List[i]$. The Mobile Data Gathering Unit (MDGU) moves through the area following a planned route to collect details about the location, remaining energy (RE), and neighbors of each node.

The MDGU begins at a point R out of the upper-left of the area and travels to the right at spacing intervals of $R\sqrt{2}$. It proceeds in a left-to-right and top-to-bottom direction until it has occupied the whole area, depending upon the method mentioned in [26]. At each stopping point, the MDGU sends out a signal ("1") to all devices within range. Devices that receive the signal respond with their ID , location (X_i, Y_i) , remaining energy RE_i , and their neighbor list $N_List[i]$.

This process allows the MDGU to gather and organize information on all devices in the area. This data is stored in a table, as shown in Table I. Initially, every node is in an "UNMARKED" state, indicated by $Flag = 0$. When a node is chosen as either a cluster head (CH) or a cluster member (CM), its state changes to "MARKED" ($Flag = 1$). At the same time, the neighbor pointer $NLPointer_i$ is updated. The structure that stores data about device i at the MDGU includes ID_i , (X_i, Y_i) , RE_i , $Flag$, and $NLPointer_j$.

E. Centralized Clustering Formation Algorithm

Here, we present a centralized clustering formation algorithm that is to cluster the devices and identify the initial group of CH. The algorithm is initiated by picking the node that has the most energy to be the initial CH. All the nodes in the neighborhood list of this node ($NL[i]$) will constitute the first cluster. Subsequently, the status of the selected CH and its associated members is updated to "MARKED" ($Flag$ set to 1). The process then iterates, choosing the next CH from the set of "UNMARKED" nodes with high energy, which, together with

its neighbor nodes, forms the subsequent cluster. This iterative process continues until all nodes are transitioned into the "MARKED" state, as detailed in Algorithm 1.

Algorithm 1: Initial Cluster Formation

Input: Nodes Placement [1,...,N]
Output: Set of 'M' CHs [1,...,M]

```
For i=1,...,N do
    Flagi = 0
End For
M = 0
While (there exists i such that 1 ≤ i ≤ N and Flagi = 0) do
    M = M + 1
    CH[M] = {}
    c = MaxEnergyNode()
    CH[M] = c
    Flagc = 1
    For (j = 1,..., n) do
        Flag_neighbor(c,j) = 1
    End For
End
Return CH[1,...,M]
```

In this algorithm, the initial loop sets a flag for all nodes in line 8 of the algorithm, marking them as "UNMARKED". The main loop then proceeds by identifying nodes with the highest residual energy, marking them as CHs, and subsequently marking their neighboring nodes. This process ensures that all nodes are clustered efficiently, based on energy availability, ensuring optimal distribution of CHs across the network. The process concludes when no unmarked nodes remain, indicating the successful formation of all clusters [see Eq. (4)].

$$Centroid = \frac{\sum \mu_i(x) * x}{\sum \mu_i(x)} \quad (4)$$

where, μ_i is the set of membership functions. Finally, a defuzzifier produces a crisp output for the fuzzy system obtained from the inference engine. Thus, the output for CH selection is obtained by a centroid defuzzification method.

F. Concept Behind ABC

ABC is a nature-inspired optimization method based on the way honeybees search for food. There are three kinds of bees used in this technique: employed bees, onlookers, and scouts. The working bees seek sources of food and relay this to the onlookers, who then choose the source to concentrate on depending on the waggle dance of the bees. Scouts explore new areas randomly to find fresh food sources. Throughout the search process, the colony adjusts its focus, starting with a broad exploration of different areas and gradually narrowing down to the best available food sources as they are found. If a better source is discovered during this process, the bees shift their attention to it.

IV. PSAP-WSN CH SELECTION WITH ABC

The first group of CHs is created on the basis of maximum energy by Algorithm 1. It returns 'M' CHs from a given set of 'N' nodes. Therefore, the dimension of the bee's search space is 'M'. Assume that there are 'P' search agents (Bees: Employed Bees B1, B2, ..., BP, B2, ..., B2, ..., BP). Each bee defines a memory of dimension M. The first group of CHs is stored as

the first solution in the memory of the first bee (Bee 1). Other bees are initialized with random node IDs.

TABLE I. AGENT AND ITS DIMENSION IN ABC

Agent	Dimension 1	Dimension 2	...	Dimension M
Bee1	B11	B12	...	B1M
Bee2	B21	B22	...	B2M
...	...	...	...	...
BeeP	BP1	BP2	...	BPM

Every bee, which is employed, estimates the fitness of the current solution (i.e., food source in its memory) and updates it as the best food source that it has ever visited. It then shares this information with the onlooker bees, which decide which food source to focus on based on the fitness evaluation. Onlooker bees move to the new food source and evaluate its fitness. They update the new food source in their memory if it is superior to the stuff they already knew. This process is repeated for all bees. Additionally, scout bees explore new areas randomly to find fresh food sources. If a bee discovers a better food source, the colony shifts its attention to it. After a predefined number of iterations, all bees will have converged towards the best food source with the highest fitness. This method focuses on four parameters for selecting the best solution in each iteration. The objective function is framed using connectivity, average energy of CHs, balancing factor of each cluster, and cohesion between CHs and Cluster Members (CMs).

The objective function of connectivity focuses on ensuring that all nodes are included within at least one cluster, where the total number of CHs and CMs equals the total number of nodes, N. The set CM_j represents the members connected to CH_j , and the aim is to maximize network connectivity by ensuring proper clustering of each node. To further enhance network performance, especially in applications like Low-Rate Wireless Personal Area Networks (LR-WPAN), energy-efficient clustering is vital. The average energy of CHs, defined as the ratio of the total energy of all CHs to their number, helps maintain energy-balanced clusters, contributing to the network's longevity and sustainable operation.

In addition, the balancing factor (BF) and cohesion are critical metrics for optimizing cluster performance. The balancing factor minimizes the variation in the number of nodes connected to each CH by calculating the difference between the actual and optimal node distribution, ensuring even load distribution across clusters. This factor, determined using the formula $BF = |V| \times 0.1$, ranges between [0,1] and helps prevent cluster imbalances. Cohesion, on the other hand, measures the proximity of CMs to their respective CHs by assessing the average distance between them. A higher cohesion value indicates tighter clusters, resulting in better communication efficiency within the cluster structure.

A. Explanation of ABC Objective Functions:

1) *Connectivity (f_1)*: This ensures that every node in the network is connected to a CH, maximizing the cluster

membership and ensuring robust connectivity across the network.

2) *Average anergy* (f_2): This function seeks to maintain a high level of energy across all CHs, which is essential for prolonging network lifetime by ensuring that CHs can sustain their roles effectively.

3) *Balancing factor* (f_3): The balancing factor minimizes the uneven distribution of nodes across CHs. By keeping this factor low, the algorithm ensures that all CHs handle a similar load, which is crucial for network stability and performance.

4) *Cohesion* (f_4): This function aims to minimize the average distance between CHs and their CMs. Lower cohesion values indicate tighter clusters, which enhance communication efficiency within each cluster.

5) *Overall fitness function* (f): The overall fitness function combines these objectives using weighted averages to find the optimal CH selection. The weights w_1 , w_2 and w_3 determine the emphasis on energy, balancing, and cohesion, respectively, ensuring a well-rounded solution that balances network longevity, performance, and efficiency.

B. Key Parameters in the ABC Approach for CH Selection

The final fitness function, f , aims to maximize all the key parameters involved in the ABC approach to CH selection. The sum of the weighted averages of these parameters is computed to derive f , as given in Eq. (5). The weights are assigned as $w_1 = 0.5$, $w_2 = 0.4$, and $w_3 = 0.1$.

The objective functions in the ABC approach for CH selection are as follows:

$$\text{Maximize } f_1 : M + \left[\bigcup_{j \in CH[m]} CM[j] \right] \quad 1 \leq m \leq M \quad (5)$$

Here, f_1 represents the connectivity, ensuring that all nodes are connected to at least one CH.

$$\text{Maximize } f_2 : AvgE = \frac{\sum_{i=1}^M \text{Energy}(CH[i])}{M} \quad (6)$$

In Eq. (6), f_2 calculates the average energy of CHs, which is critical for maintaining energy-efficient clusters [see Eq. (7)].

$$\text{AverageBF, } BF_{mw} = \frac{\text{BF of each CH}}{\text{Total number of clusters}} \quad (7)$$

The balancing BF_H ensures that nodes are evenly distributed across clusters. It is computed using Eq. (8):

$$BF_H = |(n_H - n_{opt})| \times 0.1 \quad (8)$$

And the network-wide balancing factor is given by Eq. (9):

$$\text{Minimize } f_3 : BF_{mw} = \frac{\sum_{j=1}^M \sum_{i=1}^N \text{Dist}(\text{Node}_i \in \text{cluster}_j, CH_j)}{N \times R} \quad (9)$$

This function f_4 measures cohesion, which is the average distance between CHs and their corresponding CMs, aiming to minimize this distance for better intra-cluster communication.

Finally, the overall fitness function f combines these factors [see Eq. (10)]:

$$\text{Maximize } f : f_1 + w_1 f_2 + w_2 (1 - f_3) + w_3 (1 - f_4) \quad (10)$$

V. PERFORMANCE EVALUATION

In this section, we provide a detailed discussion on the experimental setup and evaluate the performance of the proposed method. The cluster-based routing technique is assessed using a range of performance metrics, including the number of alive and dead nodes, average energy consumption, delay, total packets transmitted, throughput, as well as the times to the first, half, and last node deaths (FND, HND, and LND, respectively). The proposed approach was implemented and validated using MATLAB. MATLAB was selected due to its robust capabilities in mathematical operations and data analysis. In the experiment, 300 sensor nodes were randomly deployed across a $100 \text{ m} \times 100 \text{ m}$ sensing area. To analyze the performance of the proposed method in comparison with other routing protocols, we adopted the radio energy model, with key parameters being $E_{\text{elect}} = 50 \text{ nJ/bit}$, $\epsilon_{fs} = 110 \text{ pJ/bit}$, and $\epsilon_{mp} = 0.001310 \text{ pJ/bit}$.

The simulation scenarios' settings are presented in Table II. The primary objective was to minimize the overall energy consumption of each node in the network. To achieve this, a load-balancing approach was developed, employing ABC-based CH selection. The inputs for optimal CH selection through ABC included residual energy, node degree, distance to neighbors, distance to the BS, and node centrality. This proposed method was benchmarked against traditional energy-efficient approaches such as LEACH and DEEC, as these protocols are widely utilized to enhance energy efficiency in WSNs. Additionally, comparisons were made with other existing methodologies, including PSAP-WSN [27], DESK, CIRP, ALOC [28], and FLION [29].

TABLE II. EXPERIMENT SCENARIOS FOR NETWORK LIFETIME

Scenario 1	100 sensor nodes - Initial energy of 1 J
Scenario 2	200 sensor nodes - Initial energy of 1 J
Scenario 3	100 sensor nodes - Random energy (0.5 to 2 J)

Fig. 4. Network model of scenario 2.

Fig. 3 and Fig. 4 show the network mode with distributed nodes for experimental Scenarios 1, 3 and 2 in the simulation.

A. Network Lifetime

The effectiveness of the proposed method is evaluated by testing the performance of active nodes across different scenarios and varying node quantities, comparing it to established algorithms like FEEC and PSAP-WSN. For example, both the proposed method and the existing algorithms were simulated using 100 and 200 sensor nodes. Fig. 5, Fig. 6, and Fig. 7 illustrate the performance of active nodes when using the proposed method in comparison to the FEEC and PSAP-WSN algorithms. These figures demonstrate how long the nodes last in terms of when the First Node Dies (FND) and the Last Node Dies (LND) across three distinct scenarios.

To carry out the evaluation of these two kinds of transmission, the performance criteria of FND, LND, and number of dead nodes were observed.

Fig. 5. The FND and LND of EECR, FEEC, and PSAP-WSN for scenario 1.

In Fig. 5, the FEEC exhibits the earliest First Node Death (FND) at the 827th iteration, followed by PSAP-WSN and EECR at the 4017th and 4024th iterations, respectively. As for the Last Node Death (LND), it was first recorded in FEEC at the 4917th iteration, with PSAP-WSN and EECR reaching LND at the 5227th and 5281st iterations, respectively.

Initially, all sensor nodes had high energy levels, leading to the absence of dead nodes. However, over time, the first node death was observed in FEEC at the 3666th iteration as energy began depleting due to data transmission processes. During this phase, child nodes attempted to transmit data to their respective cluster heads (CHs), then from the CHs to the relay nodes, and finally from the relay nodes to the base station (BS).

A similar pattern of node mortality emerged in PSAP-WSN, FEEC, and EECR, with a gradual increase in the number of dead nodes. Around the 4800th iteration, the number of dead nodes stabilized for PSAP-WSN and EECR, coinciding with the decrease in the number of active nodes. The slow rate of energy dissipation observed in this phase was attributed to the reduced number of active sensor nodes, leading to a deceleration in node death.

Fig. 6. The FND and LND of EECR, FEEC, and PSAP-WSN for scenario 2.

In this scenario, the number of nodes is increased to 800, each with an initial residual energy of 1 J. As illustrated in Fig. 6, the First Node Death (FND) occurred at the 4124th, 3896th, and 966th iterations for EECR, PSAP-WSN, and FEEC, respectively. Similarly, the LND took place at the 5856th, 5742nd, and 4845th iterations for these protocols. This demonstrates a slower trend in the number of dead nodes, which can be attributed to the higher number of nodes, ultimately contributing to an extended network lifetime. Around the 5000th iteration, the trends in EECR and FEEC stabilized and slowed, primarily due to a reduced number of alive nodes, which led to less competition for data transmission. Consequently, the remaining nodes were able to sustain their operation for a longer period.

Fig. 7 illustrates the network lifetime of EECR, FEEC, and PSAP-WSN under a scenario where the initial energy distribution is randomized. In this case, the higher initial energy of certain nodes results in the longest network lifetime across all three scenarios. The FND was recorded at the 4703rd, 4007th, and 1286th iterations for EECR, FEEC, and PSAP-WSN, respectively. Regarding the LND, it occurred at the 11997th, 11260th, and 10144th iterations, respectively. This marks a significant difference in the number of dead nodes compared to Scenario 1. By the steady-state phase, around the 7000th iteration, EECR had only 29 dead nodes, while PSAP-WSN and FEEC recorded 37 and 43 dead nodes, respectively. Due to the randomized initial energy distribution,

the network lifetime for PSAP-WSN and FEEC was approximately twice as long as in Scenarios 1 and 2.

Fig. 7. The FND and LND of EECC, FEEC, and PSAP-WSN for scenario 3.

The proposed method for energy-aware cluster head rotation in WSNs is designed to improve energy efficiency and balance the load across the network. The approach dynamically selects and rotates cluster heads based on several important factors, including the remaining energy of the nodes, their mobility, distance to the BS, and the amount of data they need to process. By prioritizing nodes with higher energy and lower mobility, the method helps reduce energy consumption and extends the overall network lifetime.

At the heart of this method is the goal of evenly distributing the workload across different clusters. It does so by considering key elements like how much energy each node has left, how many devices are connected to each CH, and how far each CH is from the base station. This strategy leads to better network stability and longer operational periods, as it helps prevent individual nodes from draining their energy too quickly. The process unfolds in four main stages: discovering node locations and neighbors, forming the initial clusters, clustering in an energy-efficient manner, and rotating the CHs to collect and transmit data. By continuously rotating the cluster heads, the method prevents any single node from being overburdened, leading to better network performance.

The first phase focuses on gathering information about the network. Each node broadcasts its identity and tracks its closest neighbors. Meanwhile, a mobile data-gathering unit (MDGU) moves through the network, recording each node's location, remaining energy, and its neighboring connections. This data is stored centrally, providing a clear picture of the network's overall status.

Once the information is collected, the network forms its clusters. The node with the most energy is selected as the first cluster head, and its nearby nodes become part of its cluster. This process continues until all nodes are grouped into clusters, ensuring that the nodes are clustered efficiently based on their energy and location.

The method also integrates the ABC algorithm, which further refines the selection of cluster heads. This algorithm

mimics the behavior of bees searching for food, where nodes with the best energy levels and cluster configurations are selected as cluster heads. ABC helps optimize the process by improving the connectivity, balancing the workload, and ensuring that clusters are tightly bound together.

By combining dynamic cluster head rotation with ABC, the method successfully extends the lifespan of the network while ensuring that it runs smoothly and efficiently. This not only enhances energy conservation but also boosts overall performance, allowing the WSN to operate longer and more effectively.

B. Energy Balance

In this section, the energy balance of EECC protocols that utilized the ABC algorithm was assessed under varying data aggregation values. The experimental setups are outlined in Table III.

TABLE III. EXPERIMENT SCENARIOS FOR ENERGY BALANCE

Scenario 1	100 sensor nodes Data aggregation value of 5 nJ/bit/signal
Scenario 2	200 sensor nodes Data aggregation value of 10 nJ/bit/signal

The methodology for calculating data aggregation follows the approach discussed. These parameters were used to quantify the energy consumption in various configurations of input parameters, focusing on the cost of transmission and data aggregation within cluster heads (CHs). Consequently, the scenarios were classified into two categories: 1) Normal data aggregation ratio and 2) High data aggregation ratio. In the analysis of these scenarios, the standard deviation of residual energy (SDRE) served as a key metric, reflecting the energy distribution across sensor nodes. A higher SDRE indicates greater energy imbalance, signifying uneven energy depletion among the nodes. Therefore, minimizing SDRE is a crucial objective for EECC in these evaluations.

Fig. 8 and Fig. 9 illustrate the standard deviation of residual energy (SDRE) for the EECC, FEEC, and PSAP-WSN protocols over multiple iterations in Scenarios 1 and 2. Each scenario exhibited distinct variations in SDRE across the different input parameter combinations.

Fig. 8. The SDRE for scenario 1.

Fig. 9. The SDRE for scenario 2.

In contrast, the SDRE of EECR 2 without the ABC algorithm for 100 nodes experienced a gradual increase up to the 5000th iteration. A similar upward trend in SDRE was observed when the node count increased to 200 in the absence of the algorithm. Conversely, the model integrated with the ABC algorithm for 200 nodes followed the same trend as seen with 100 nodes, with a pronounced drop in SDRE between the 4000th and 5000th iterations. When comparing the two scenarios, the SDRE for EECR 2 with the ABC algorithm and 200 nodes was significantly lower than the model without the algorithm. Meanwhile, the SDRE for EECR 2 without the ABC algorithm with 200 nodes was notably higher than for 100 nodes, displaying a distinct contrast in behavior between the models.

The figures provide clear insights into how much the ABC algorithm enhances the energy balance in the EECR 2 model. When using 100 nodes, the system with the ABC algorithm showed a dramatic improvement in SDRE efficiency, dropping from 0.0346 to 0.0089 after the 4000th iteration. This reflects the impact of integrating the algorithm, achieving almost 94% better energy balance compared to not using it. Without the algorithm, the SDRE values steadily increased across iterations, and this trend only intensified as we added more nodes. Interestingly, for 200 nodes, the ABC algorithm once again proved its effectiveness, as we saw another significant decrease in SDRE, whereas the model without the algorithm showed even higher SDRE values as the node count increased. These results underscore the role of the ABC algorithm in maintaining energy balance, especially as the system scales in complexity.

VI. CONCLUSION

In this study, we introduced an energy-aware CH rotation and load-balancing approach for WSNs that leverages the ABC optimization algorithm. The method was designed to address one of the most pressing challenges in WSNs: the uneven energy depletion across nodes, particularly among cluster heads. By dynamically rotating CHs and considering multiple factors such as residual energy, node mobility, and proximity to the base station, our approach successfully distributes the energy load across the network, thereby enhancing both energy efficiency and network longevity. Through simulations, the proposed method demonstrated significant improvements over

traditional protocols like FEEC and PSAP-WSN. The results show that our method consistently maintains a more even energy distribution across nodes, preventing early node failures and extending the operational lifetime of the network. This is particularly important in large-scale networks where the sustainability and performance of the system are critical. Additionally, the integration of the ABC optimization algorithm provided a robust framework for CH selection, ensuring that the network adapts dynamically to changing conditions without compromising on efficiency. Overall, the proposed method offers a practical and effective solution for energy management in WSNs. By optimizing CH rotation and load balancing, it not only prolongs the network's lifespan but also ensures stable and reliable performance, making it a valuable contribution to the field of WSNs. This work paves the way for future research on enhancing energy efficiency in WSNs through bio-inspired optimization techniques and other adaptive approaches.

ACKNOWLEDGMENT

The authors are grateful to Universiti Malaysia Pahang Al-Sultan Abdullah (UMPSA) for providing the funding under the Fundamental Research Grant Scheme (FRGS Grant (RDU230128)). In addition, we would like to thank the Faculty of Computing (UMPSA) and specifically our Computer Network Research Group (CNRG) for their support and facilities.

An Improved Hybrid CURE–SNE Model for High-Dimensional Data Clustering

Dewi Sartika Br Ginting, T.H.F. Harumy, Ade Sarah Huzaifah, Ivanny Putri Marianto

Department of Computer Science and Technology Information, Universitas Sumatera Utara, Medan, Indonesia

Abstract—Stunting remains a critical public health issue in rural communities, largely driven by inadequate nutrition, poor sanitation, and unfavorable socioeconomic conditions. This study proposes a hybrid clustering approach by integrating Clustering Using Representatives (CURE) with t-distributed Stochastic Neighbor Embedding (t-SNE) to analyze stunting prevalence and support the optimization of child nutrition strategies. Secondary data were collected from publicly accessible national health and nutrition repositories, comprising 500 child records with multiple parameters, including anthropometric indicators, nutritional intake, maternal characteristics, environmental sanitation, and socioeconomic factors. The t-SNE algorithm was employed to reduce the high-dimensional data into a two-dimensional space while preserving neighborhood structures, followed by the application of the CURE algorithm to construct clusters that are robust to noise and outliers. Experimental results indicate that the proposed CURE–SNE approach successfully formed four distinct clusters, namely C1 Very High Stunting Risk with 128 data points (25.6%), C2 High Stunting Risk with 142 data points (28.4%), C3 Moderate/Transitional Stunting Risk with 117 data points (23.4%), and C4 Low Stunting Risk with 113 data points (22.6%). Cluster quality evaluation demonstrates that the hybrid CURE–SNE method achieves a higher Silhouette Score and a lower Davies Bouldin Index compared to the CURE only approach, indicating improved cluster separation and compactness. These findings confirm that combining dimensionality reduction with representative-based clustering enhances the interpretability of stunting patterns and provides a reliable analytical foundation for designing targeted and data-driven child nutrition interventions in rural settings.

Keywords—Hybrid clustering; CURE-SNE; stunting; davies bouldin index; silhouette score

I. INTRODUCTION

Stunting remains one of the most persistent and complex public health challenges affecting child development, particularly in rural communities of developing and low- to middle-income countries [24]. Defined as impaired growth and development resulting from chronic malnutrition, repeated infections, and inadequate psychosocial stimulation during early childhood, stunting reflects long-term nutritional deprivation rather than short-term dietary insufficiency [26]. The consequences of stunting extend beyond physical growth limitations, encompassing cognitive impairment, reduced educational achievement, increased susceptibility to disease, and diminished economic productivity in adulthood [28]. As a result, stunting not only represents an individual health issue but also poses a significant barrier to sustainable social and economic development.

Despite extensive efforts by governments and international organizations, the prevalence of stunting remains high in many rural areas due to a combination of structural, socioeconomic, and environmental factors [25]. Limited access to healthcare services, poor sanitation, low parental education, food insecurity, and poverty contribute to the uneven distribution of stunting cases across regions. These conditions create complex and heterogeneous patterns of malnutrition that vary significantly between communities [29]. Consequently, uniform intervention strategies often fail to address local needs effectively, highlighting the importance of targeted and data-driven approaches for designing nutrition education and intervention programs [30] [31]. In recent years, the increasing availability of large-scale health, demographic, and nutritional datasets has opened new opportunities for applying advanced data analytics and artificial intelligence techniques in public health research [23]. Data-driven methods allow researchers and policymakers to analyze multidimensional data and identify latent patterns that are difficult to capture using conventional statistical techniques [2]. Among these methods, unsupervised learning, particularly clustering, has emerged as a powerful approach for exploring stunting prevalence by grouping regions or populations with similar characteristics [16]. Clustering analysis can support evidence-based decision-making by enabling the identification of high-risk areas, prioritization of interventions, and optimization of resource allocation.

However, the application of traditional clustering algorithms to real-world public health data presents several challenges [21]. Algorithms such as K-Means are sensitive to outliers, require prior knowledge of the number of clusters, and assume spherical cluster shapes, which may not align with the inherent structure of health and nutrition datasets [8]. Hierarchical clustering methods, while more flexible, often suffer from high computational complexity and limited scalability when applied to large datasets [22]. Furthermore, stunting-related data are typically high-dimensional, noisy, and non-linearly distributed, making effective cluster formation and interpretation particularly difficult.

To overcome these limitations, more robust and adaptive clustering approaches are required. Clustering Using Representatives (CURE) is a hierarchical clustering algorithm specifically designed to handle large datasets, arbitrarily shaped clusters, and outliers by representing each cluster using multiple well-scattered representative points [9]. Unlike traditional hierarchical methods, CURE reduces sensitivity to noise and provides improved cluster stability [3]. Nevertheless,

when applied directly to high-dimensional data, CURE may still face challenges related to computational efficiency and cluster visualization [6]. Dimensionality reduction techniques offer a promising solution to these issues [10]. Among them, t-distributed Stochastic Neighbor Embedding (t-SNE) has gained considerable attention for its ability to project high-dimensional data into a low-dimensional space while preserving local neighborhood relationships [14]. t-SNE is particularly effective for visualizing complex, non-linear structures and revealing intrinsic data patterns [15]. However, t-SNE alone is not a clustering algorithm; rather, it serves as a preprocessing or visualization tool that can enhance the performance of clustering methods when used in combination [17]. In this study, a hybrid clustering framework that integrates t-SNE with the CURE algorithm is proposed to analyze stunting prevalence in rural communities [18]. The t-SNE technique is first employed to reduce the dimensionality of stunting-related indicators, thereby improving data representation and computational efficiency [12]. Subsequently, the CURE algorithm is applied to the transformed data to identify meaningful clusters that reflect similarities in nutritional status and associated socioeconomic factors [20]. This hybrid CURE-t-SNE approach aims to improve cluster quality, robustness, and interpretability compared to conventional clustering methods [1]. The motivation for adopting a hybrid CURE-t-SNE framework lies in its ability to address the specific characteristics of stunting datasets, which often involve heterogeneous distributions, outliers, and complex interdependencies among variables. By combining the strengths of both methods, the proposed approach provides a more reliable analytical framework for uncovering hidden patterns in stunting prevalence data. The resulting clusters offer valuable insights into the spatial and demographic distribution of malnutrition, enabling the identification of distinct community profiles that require different intervention strategies.

This research focuses on the use of secondary data obtained from publicly available health and nutrition databases to ensure reproducibility and scalability [29]. The clustering results are evaluated using established internal validation metrics and compared with traditional clustering algorithms to demonstrate the effectiveness of the proposed method. Beyond methodological contributions, this study emphasizes the practical implications of clustering analysis for optimizing child nutrition strategies [27]. By translating cluster characteristics into actionable insights, the findings can support targeted nutrition education programs, community-based interventions, and evidence-informed policymaking in rural settings.

The primary contributions of this study are threefold. First, it introduces a hybrid CURE-t-SNE clustering framework tailored to the analysis of stunting prevalence data [19]. Second, it provides a comprehensive evaluation and comparison of the proposed method against widely used clustering techniques. Third, it demonstrates the relevance of advanced unsupervised learning methods in supporting data-driven nutrition strategies and sustainable public health interventions [33]. Ultimately, this research contributes to the growing body of literature on the application of intelligent

computing techniques for addressing complex societal challenges, particularly in the context of child nutrition and rural development.

II. RELATED WORKS

Research on stunting and child malnutrition has traditionally relied on statistical analysis and epidemiological studies to identify key determinants and assess intervention outcomes [28]. Early studies primarily focused on descriptive statistics and regression-based models to examine the relationship between stunting prevalence and factors such as socioeconomic status, maternal education, sanitation, and food security [26]. While these approaches provide valuable insights into causal relationships, they often assume linear associations and struggle to capture complex interactions among multiple variables in heterogeneous populations, particularly in rural settings. With the increasing availability of large-scale health and demographic datasets, machine learning techniques have been increasingly adopted to enhance the analysis of nutritional status and child growth indicators [5]. Supervised learning methods, including decision trees, support vector machines, and neural networks, have been used to predict stunting risk based on demographic and nutritional variables. Although these models achieve relatively high predictive accuracy, they require labeled data and predefined outcome classes, which may not always be available or reliable in public health datasets. Moreover, supervised models are less suitable for exploratory analysis when the objective is to discover hidden patterns or groupings within the data.

Unsupervised learning, particularly clustering, has therefore gained attention as an effective approach for analyzing stunting prevalence and nutritional patterns without requiring labeled data [13]. Several studies have employed K-Means clustering to group regions or households based on anthropometric indicators and socioeconomic variables [7]. These studies demonstrate the potential of clustering to identify high-risk areas and support targeted interventions. However, K-Means assumes spherical clusters, is sensitive to initial centroids, and requires the number of clusters to be specified in advance. These limitations often result in unstable clusters when applied to complex and noisy health datasets [10]. Hierarchical clustering methods have also been widely used in nutritional and public health research due to their ability to produce a dendrogram that represents nested data structures. Agglomerative hierarchical clustering, in particular, has been applied to classify regions based on stunting prevalence and related indicators. While hierarchical methods offer greater flexibility in cluster shape compared to K-Means, they suffer from high computational complexity and limited scalability for large datasets. Additionally, the merging process in hierarchical clustering is irreversible, making the final cluster structure sensitive to early-stage decisions. To address the shortcomings of traditional clustering algorithms, density-based methods such as DBSCAN have been explored in some health-related studies. DBSCAN is capable of identifying arbitrarily shaped clusters and handling noise, making it suitable for datasets with irregular distributions. Nevertheless, its performance is highly dependent on parameter selection, and it may struggle with datasets that exhibit varying density

levels, which are common in stunting and nutritional data across diverse rural communities.

Clustering Using Representatives (CURE) was introduced as a robust hierarchical clustering algorithm designed to handle large datasets, outliers, and clusters with arbitrary shapes [32]. CURE represents each cluster using multiple representative points that are shrunk toward the cluster centroid, thereby reducing sensitivity to noise and extreme values [5]. Although CURE has been successfully applied in domains such as spatial data analysis and market segmentation, its application in public health and nutritional studies remains limited. This gap highlights the potential of CURE as an alternative clustering approach for stunting prevalence analysis, particularly in heterogeneous rural contexts. Another challenge in clustering stunting-related data lies in the high dimensionality of the datasets, which often include numerous nutritional, demographic, and socioeconomic variables [4]. High-dimensional data can degrade clustering performance due to the curse of dimensionality and reduced distance discrimination [11]. Dimensionality reduction techniques have therefore been increasingly incorporated into clustering frameworks. Principal Component Analysis (PCA) has been widely used to reduce dimensionality in health datasets; however, PCA primarily captures linear relationships and may fail to preserve complex non-linear structures inherent in nutritional data [13]. In contrast, t-distributed Stochastic Neighbor Embedding (t-SNE) has emerged as a powerful non-linear dimensionality reduction technique capable of preserving local neighborhood structures in low-dimensional space [14]. t-SNE has been extensively used for data visualization and exploratory analysis in biomedical and social science research. Several studies have demonstrated that integrating t-SNE with clustering algorithms can enhance cluster separation and interpretability. Nonetheless, most existing works utilize t-SNE in combination with K-Means or DBSCAN, with limited exploration of its integration with robust hierarchical algorithms such as CURE.

Recent hybrid clustering frameworks combining dimensionality reduction and clustering have shown promising results in complex data analysis [32]. These studies suggest that applying dimensionality reduction as a preprocessing step can improve clustering accuracy, reduce computational cost, and enhance visualization. However, in the context of stunting prevalence analysis, existing hybrid approaches remain underexplored and often lack comprehensive evaluation and comparison across multiple clustering algorithms. Based on the reviewed literature, a clear research gap can be identified. While clustering techniques have been applied to analyze stunting prevalence, most studies rely on conventional algorithms that struggle with high-dimensional, noisy, and heterogeneous data. The potential of robust hierarchical clustering methods such as CURE, particularly when combined with advanced non-linear dimensionality reduction techniques like t-SNE, has not been sufficiently investigated in the context of child nutrition and rural health analysis. This study addresses this gap by proposing and evaluating a hybrid CURE-SNE framework to improve clustering quality and support data-driven optimization of child nutrition strategies in rural communities.

III. METHODOLOGY

This study adopts a quantitative and experimental research methodology based on unsupervised machine learning to analyze stunting prevalence patterns in rural communities. A hybrid clustering framework integrating t-distributed Stochastic Neighbor Embedding (t-SNE) and Clustering Using Representatives (CURE) is proposed to address the challenges of high dimensionality, noise, and non-linear data distribution commonly found in nutritional and public health datasets. The overall methodology consists of data collection, preprocessing, dimensionality reduction, clustering, and evaluation stages.

A. Research Framework

The proposed methodology follows a sequential analytical pipeline designed to improve clustering quality and interpretability. Initially, secondary stunting-related data are collected from publicly available health databases. After preprocessing and normalization, t-SNE is applied to project the high-dimensional data into a lower-dimensional space. Subsequently, the CURE algorithm is employed to identify meaningful clusters. Finally, clustering performance is evaluated and compared with conventional clustering algorithms.

B. Dataset and Preprocessing

Let the original dataset be denoted as:

$$X_i = \{x_1, x_2, \dots, x_n\}, X_i \in R^d$$

where,

- n represents the number of observations (regions or communities),
- d denotes the number of features (nutritional and socioeconomic indicators).

Before analysis, missing values are handled using mean imputation, and all features are normalized using Min-Max normalization to ensure equal contribution of each variable:

$$X'_{ij} = \frac{x_{ij} - \min(x_j)}{\max(x_j) - \min(x_j)}$$

C. Dimensionality Reduction Using t-SNE

t-distributed Stochastic Neighbor Embedding (t-SNE) is employed to reduce the dimensionality of the dataset while preserving local neighborhood structures. The similarity between two data points x_i and x_j in the high-dimensional space, it is defined as a conditional probability:

$$p_{j|i} = \frac{\exp\left(-\frac{\|x_i - x_j\|^2}{2\sigma_i^2}\right)}{\sum_{k \neq i} \exp\left(-\frac{\|x_i - x_k\|^2}{2\sigma_i^2}\right)}$$

The joint probability is then computed as:

$$p_{ij} = \frac{p_{j|i} + p_{i|j}}{2n}$$

In the low-dimensional space, similarities are modeled using a student's t-distribution:

$$q_{ij} = \frac{\left(1 + \|y_i - y_j\|^2\right)^2}{\sum_{k \neq l} \left(1 + \|y_k - y_l\|^2\right)^{-1}}$$

The optimal low-dimensional embedding is obtained by minimizing the Kullback–Leibler (KL) divergence between the two distributions:

$$KL(P||Q) = \sum_{i \neq j} P_{ij} \log \left(\frac{P_{ij}}{Q_{ij}} \right)$$

The output of t-SNE is a reduced dataset:

$$Y = \{y_1, y_2, \dots, y_n\}, y_i \in \mathbb{R}^k, k \ll d$$

t-SNE in this study is motivated by its ability to preserve local neighborhood structures in high-dimensional data, which is crucial for identifying complex patterns in stunting-related indicators. t-SNE is capable of capturing non-linear relationships among variables, making it well-suited as a preprocessing step before clustering. In this study, parameter tuning was performed on t-SNE, including the adjustment of perplexity, learning rate, and the number of iterations, in order to obtain an optimal data representation. The parameter selection was conducted empirically based on clustering quality evaluation. Furthermore, to ensure the robustness of the results, multiple experimental runs were carried out, and the findings demonstrated consistent clustering performance, as indicated by relatively stable Silhouette Score and Davies Bouldin Index (DBI) values across experiments.

D. Clustering Using Representatives (CURE)

The CURE algorithm is applied to the reduced dataset Y to identify clusters. Unlike traditional hierarchical clustering, CURE represents each cluster using a fixed number of well-scattered representative points. Initially, each data point is treated as an individual cluster. For each cluster C , a set of representative points $R = \{r_1, r_2, \dots, r_m\}$ is selected such that they are maximally distant from each other:

$$r_1 = \arg \max_{y \in C} \|y - \mu_c\|$$

$$r_k = \arg \max_{y \in C} \min_{r \in R_{k-1}} \|y - r\|$$

where, μ_c is the centroid of the cluster C .

To reduce the effect of outliers, each representative point is shrunk toward the cluster centroid:

$$r'_i = r_i + \alpha(\mu_c - r_i)$$

where, $\alpha \in (0,1)$ is the shrink factor.

The distance between two clusters C_a and C_b is defined as the minimum distance between their representative points:

$$D(C_a, C_b) = \min_{r_i \in R_a, r_j \in R_b} \|r_i - r_j\|$$

Clusters are merged iteratively until the desired number of clusters is obtained.

E. Hybrid CURE-SNE Framework

The hybrid framework integrates t-SNE as a preprocessing step to improve the effectiveness of the CURE algorithm. By operating on a reduced and structured representation of the data, CURE can more effectively identify clusters with arbitrary shapes and varying densities while maintaining robustness against noise.

Fig. 1. CURE-SNE algorithm.

Fig. 1 illustrates the workflow of the proposed hybrid CURE-t-SNE clustering framework for analyzing stunting prevalence patterns. The process begins with data collection and preprocessing, including missing value handling and feature normalization, to ensure data quality and consistency. Subsequently, t-distributed Stochastic Neighbor Embedding (t-SNE) is applied to reduce the dimensionality of the dataset while preserving local neighborhood structures, enabling more effective clustering in a lower-dimensional space. The reduced data are then clustered using the Clustering Using Representatives (CURE) algorithm, which selects multiple representative points for each cluster and applies a shrinkage mechanism to reduce the influence of outliers. Finally, the resulting clusters are evaluated and interpreted to support the optimization of child nutrition strategies in rural communities.

through data-driven insights. Table I presents the pseudocode illustrating the operational process of the CURE–SNE algorithm.

TABLE I. PSEUDOCODE OF THE HYBRID CURE–T-SNE ALGORITHM

Step	Description
1	Collect and preprocess the stunting dataset (handle missing values and normalize features).
2	Apply t-distributed Stochastic Neighbor Embedding (t-SNE) to reduce the dimensionality of the data.
3	Initialize clusters by treating each data point in the reduced space as a single cluster.
4	Select a fixed number of well-scattered representative points for each cluster.
5	Shrink the representative points toward the cluster centroid using a shrink factor.
6	Compute the distance between clusters based on the minimum distance between their representative points.
7	Merge the closest clusters iteratively until the desired number of clusters is obtained.
8	Assign each data point to the nearest cluster representative.
9	Identify and remove outliers that are far from any cluster representative.
10	Output the final clusters along with their representative points for analysis and interpretation.

F. Algorithm Parameter

For the dimensionality reduction stage, the t-SNE algorithm was configured with a perplexity value of 30, a learning rate of 200, and a maximum of 1000 iterations. The output dimensionality was set to 2 to facilitate visualization and clustering in a low-dimensional space. Euclidean distance was used as the similarity metric, with random initialization and an early exaggeration factor of 12 to enhance cluster separation during the initial optimization phase. A fixed random state was applied to ensure experimental reproducibility. For the clustering stage, the CURE algorithm was implemented with the number of clusters set to 4, corresponding to the predefined stunting risk categories. Each cluster was represented by 10 well-scattered representative points to capture complex cluster shapes. A shrink factor (α) of 0.5 was applied to reduce the influence of outliers by moving representative points toward the cluster centroid. The clustering process used Euclidean distance and was iterated until the desired number of clusters was reached. Additionally, outlier handling was conducted based on the distance of data points to the nearest representative points.

G. Clustering Evaluation

Clustering performance is evaluated using internal validation metrics. The Silhouette Coefficient is calculated as:

$$S(i) = \frac{b(i) - a(i)}{\max(a(i), b(i))}$$

where,

- $a(i)$ is the average intra-cluster distance,
- $b(i)$ is the minimum average inter-cluster distance.

Additionally, the Davies–Bouldin Index (DBI) is used:

$$DBI = \frac{1}{c} \sum_{i=1}^c \max_{j \neq i} \left(\frac{S_i + S_j}{D_{ij}} \right)$$

where, K is the number of clusters.

IV. EXPERIMENTAL RESULTS AND ANALYSIS

This section presents the experimental results and analysis of the proposed hybrid CURE–t-SNE clustering approach for identifying stunting prevalence patterns in rural communities. The experiments were conducted using a secondary dataset consisting of 500 village-level records, where each record represents a rural village characterized by seven numerical parameters, including stunting prevalence, underweight prevalence, wasting prevalence, exclusive breastfeeding coverage, access to clean water, and sanitation coverage. These parameters were selected to capture both nutritional outcomes and environmental determinants associated with child growth and development. The dataset used in this study was obtained from publicly available secondary data sources, including reports from the World Health Organization and national statistical agencies. The data represent rural areas in developing regions, particularly in Indonesia, and were collected from 2020 through 2023. All data are aggregated at the village level and do not contain any personally identifiable information. An overview of the dataset and the parameters used is presented in Table II.

TABLE II. TABLE DATASETS

The dataset consists of village-level indicators related to child nutrition and environmental conditions in rural communities. All numerical attributes are used as input features for the clustering process, while village identifiers serve as spatial references. The dataset enables the identification of stunting prevalence patterns and supports data-driven optimization of child nutrition strategies.

Fig. 2. Hybrid CURE-t-SNE algorithm process.

Fig. 2 illustrates the data point distribution produced by the Hybrid CURE-t-SNE clustering process across Iterations 1 to 6. Each iteration demonstrates progressive adjustments in the positions of data points, cluster centroids, and representative points as a result of iterative distance recalculation, cluster refinement, and low-dimensional embedding optimization performed by t-SNE. In the early iterations, significant overlap among clusters is observed, indicating an initial clustering structure that has not yet converged. As the iterations progress, the clusters become increasingly compact and well-separated, reflecting improved intra-cluster cohesion and inter-cluster discrimination. The final iteration represents a stable clustering configuration, where the cluster structure has converged and provides a clearer and more interpretable representation of stunting prevalence patterns in rural communities.

Fig. 3. Data distribution iterations of the hybrid CURE-t-SNE process.

Based on the visualization presented in Fig. 3, it can be observed that during the iterative process of the Hybrid CURE-t-SNE algorithm, the data distribution changes progressively at each iteration across all clusters. These variations reflect the continuous adjustment of data points, centroids, and representative points until a stable and well-separated cluster structure is achieved. After the iterative process reaches convergence, the final cluster configuration is formed, providing a clearer representation of stunting risk patterns. Table III presents the final data partitioning obtained using both CURE-t-SNE and CURE, where the CURE-t-SNE method produces four clusters: C1 (Very High Stunting Risk) with 128 data points (25.6%), C2 (High Stunting Risk) with 142 data points (28.4%), C3 (Moderate/Transitional Stunting Risk) with 117 data points (23.4%), and C4 (Low Stunting Risk) with 113 data points (22.6%). This distribution indicates that the Hybrid CURE-t-SNE method yields a balanced and interpretable clustering structure, which is essential for supporting data-driven child nutrition intervention and education strategies in rural communities.

TABLE III. TABLE CLUSTERING WITH CURE-SNE

Cluster	Cluster Description	Number of Data Points	Percentage (%)
C1	Very High Stunting Risk	128	25.6%
C2	High Stunting Risk	142	28.4%
C3	Moderate/Transitional Stunting Risk	117	23.4%
C4	Low Stunting Risk	113	22.6%

Based on Table IV, the clustering results obtained using the CURE algorithm without t-SNE produce four clusters with a different data distribution compared to the Hybrid CURE-t-SNE approach. Cluster C1 (Very High Stunting Risk) contains 162 data points (32.4%), representing the largest proportion of the dataset. Cluster C2 (High Stunting Risk) consists of 149

data points (29.8%), followed by C3 (Moderate Stunting Risk) with 108 data points (21.6%), and C4 (Low Stunting Risk) with 81 data points (16.2%). This distribution indicates that the standard CURE algorithm tends to form clusters with a higher concentration of data points in the very high and high stunting risk categories, while fewer data points are grouped into the low-risk cluster. The imbalance in cluster sizes suggests that, without dimensionality reduction, CURE may be less effective in preserving local data structures, potentially leading to overlapping clusters and reduced interpretability when analyzing complex, high-dimensional stunting data.

TABLE IV. TABLE CLUSTERING WITH CURE

Cluster	Cluster Description	Number of Data Points	Percentage (%)
C1	Very High Stunting Risk	162	32.4%
C2	High Stunting Risk	149	29.8%
C3	Moderate Stunting Risk	108	21.6%
C4	Low Stunting Risk	81	16.2%

This section presents the clustering evaluation results using the Silhouette Score and Davies-Bouldin Index (DBI) to compare the performance of the CURE and Hybrid CURE-t-SNE methods.

TABLE V. TABLE COMPARISON OF CLUSTER EVALUATION RESULTS

Method	Number of Clusters	Silhouette Score	Davies Bouldin Index
CURE	4	0,41	0,92
CURE-SNE	4	0,63	0,48

Table V presents a comparative evaluation of the CURE-SNE and CURE models. Clustering performance was evaluated by comparing the CURE algorithm and the Hybrid CURE-SNE approach using three primary evaluation metrics, namely the number of clusters formed, the Silhouette Score, and the Davies-Bouldin Index (DBI). Both methods produced four clusters, indicating consistency in the number of clusters and alignment with the predefined clustering objective for stunting risk classification. However, notable differences are observed in the clustering quality metrics. The CURE algorithm achieved a Silhouette Score of 0.41 and a DBI value of 0.92, suggesting that the separation between clusters is relatively weak and that inter-cluster similarity remains high. In contrast, the Hybrid CURE-SNE method demonstrated superior performance, with a higher Silhouette Score of 0.63 and a lower DBI value of 0.48. A higher Silhouette Score indicates stronger intra-cluster cohesion and clearer separation among clusters, while a lower DBI reflects reduced similarity between clusters. These results confirm that the integration of t-SNE into the CURE algorithm significantly enhances clustering quality by effectively capturing complex structures in high-dimensional stunting prevalence data. The comparative evaluation of both methods is further illustrated in the evaluation comparison graph, which visually highlights the differences in Silhouette Score and Davies-Bouldin Index values between CURE and Hybrid CURE-SNE.

Fig. 4. Comparison of clustering evaluation results between CURE and hybrid CURE-SNE using the silhouette score and Davies–Bouldin index.

Based on the evaluation results illustrated in the comparison graph in Fig. 4, the Hybrid CURE-SNE algorithm consistently outperforms the standard CURE method in terms of clustering quality. The Hybrid CURE-t-SNE achieves a lower Davies–Bouldin Index (0.92) compared to CURE (1.31), indicating improved cluster compactness and greater separation between clusters. In addition, the Silhouette Score of Hybrid CURE-SNE (0.63) is substantially higher than that of CURE (0.41), reflecting stronger intra-cluster cohesion and clearer inter-cluster boundaries. These results demonstrate that the integration of t-SNE as a dimensionality reduction stage effectively enhances the performance of the CURE clustering algorithm when applied to stunting prevalence data in rural communities. Consequently, Hybrid CURE-SNE provides more reliable and interpretable cluster structures, which are crucial for supporting data-driven decision-making in the formulation of targeted child nutrition intervention strategies.

V. DISCUSSION

The CURE-SNE approach produces a more compact, balanced, and interpretable clustering structure for stunting prevalence data compared to the standard CURE algorithm without dimensionality reduction. The iterative data distribution visualizations demonstrate a gradual improvement in cluster separation across iterations, ultimately reaching a stable convergence state. This indicates that the integration of t-SNE effectively preserves local data structures in high-dimensional spaces before hierarchical clustering. Quantitative evaluation using the Silhouette Score and Davies–Bouldin Index (DBI) further confirms the superiority of the hybrid approach, as the CURE-SNE model achieves higher Silhouette values and lower DBI scores, reflecting stronger intra-cluster cohesion and clearer inter-cluster separation. Moreover, the final clustering results, which categorize rural communities into very high, high, moderate/transitional, and low stunting risk groups, provide meaningful insights for designing targeted child nutrition intervention and education strategies. However, this study has not fully accounted for potential data bias and the sensitivity of results to parameter variations and the choice of dimensionality reduction techniques. In addition, the study is limited by the use of secondary data and fixed parameter settings. Therefore, future research should focus on parameter optimization, comparative analysis with other clustering methods, and the integration of Explainable AI approaches to

enhance transparency and support evidence-based policymaking.

VI. CONCLUSION

The implementation of the Hybrid CURE-t-SNE algorithm significantly improves the quality of clustering for stunting prevalence data in rural communities compared to the conventional CURE algorithm without dimensionality reduction. Based on the evaluation results, Hybrid CURE-t-SNE achieved a Silhouette Score of 0.63 and a Davies–Bouldin Index (DBI) of 0.48, indicating stronger intra-cluster cohesion and clearer inter-cluster separation. In contrast, the CURE algorithm yielded a lower Silhouette Score of 0.41 and a higher DBI of 0.92, reflecting weaker clustering performance. The final clustering process produced four stunting risk clusters, namely C1 (Very High Stunting Risk) with 128 data points (25.6%), C2 (High Stunting Risk) with 142 data points (28.4%), C3 (Moderate/Transitional Stunting Risk) with 117 data points (23.4%), and C4 (Low Stunting Risk) with 113 data points (22.6%). The relatively balanced cluster distribution and superior evaluation metrics demonstrate that the Hybrid CURE-t-SNE approach is more effective in capturing the underlying structure of stunting prevalence data. Therefore, this method shows strong potential as a data-driven analytical tool to support targeted child nutrition strategies and informed decision-making in rural health intervention planning.

ACKNOWLEDGMENT

We would like to express our sincere gratitude to Talenta, the Research Institution of Universitas Sumatera Utara, Indonesia, for the financial support provided for this research. This study was funded under Research Grant Contract No. 18589/UN5.1.R/PPM/2024, dated May 30, 2024, which enabled the successful completion of this work.

Pedagogical Mediation Through Prompt Engineering: An Expert Evaluation of AI-Generated Feedback on Islamic-Integrated EFL Argumentative Writing

Sari Dewi Noviyanti, Rudi Hartono*, Hendi Pratama, Seful Bahri

English Language Education Department, Semarang State University, Semarang, Central Java 50229, Indonesia

Abstract—This research tested whether prompt engineering could act as a type of pedagogical mediation to enhance the quality of AI-generated student feedback on EFL students' argumentative essays in an Islamic education system. An initial pool of eight expert raters (four primary raters and four inter-raters) scored the AI-generated feedback from Claude Sonnet 4 using 12 systematically developed prompts to elicit feedback. Raters were asked to score feedback produced by these prompts across four areas of evaluation: pedagogy, linguistics, Islamic content, and AI reliability. The highest rated configuration was Prompt 4 (Feedback-only sequencing, English Lecturer Persona), with a mean rating of 31.00 (out of 35) in all categories. A Friedman test showed there were statistically significant differences among the four evaluative categories, $\chi^2(3) = 30.077$, $p < .001$. Additionally, inter-rater reliabilities were high for each of the possible pairs of raters ($r = .89$ -.96). Overall, this research suggests that prompt engineering is a potentially viable method of pedagogical mediation, allowing educators to develop more culturally responsive and pedagogically relevant AI-generated feedback systems for Islamic EFL higher education settings.

Keywords—AI-generated feedback; pedagogical mediation; prompt engineering

I. INTRODUCTION

AI-generated feedback has transformed the landscape of educational technology and second-language writing instruction. The new generation of large language models has allowed language models to create long, well-written, and contextually sensitive text-based feedback, much like human feedback in terms of content and purpose [1], [2]. This has led to an increase in academic interest in using AI-generating feedback to assist students in developing the skills required to write in the English as a foreign language (EFL) context [3], [4], such as accuracy in language use, argumentative coherence, and academic discourse [5], [6].

On the other hand, feedback is seen as the primary means of helping students to evaluate and revise their writing [7]. Traditional methods of giving feedback are, however, hampered by the practical realities of teaching at scale and include large class sizes, short periods of contact between teachers and students, and varying amounts of teacher workloads, leading to either delayed or little feedback [8], [9]. Consequently, researchers have turned to AI-generated feedback as an additional resource for teachers to use when teaching writing to provide immediate and personalized feedback to students [10], [11]. Studies that have examined

learners' views of AI-assisted feedback have generally found them to be supportive of using AI-assisted feedback, citing the potential for improved revision processes [12], [13]. Concerns remain about the pedagogic value, cultural relevance, and epistemological validity of such feedback [14], [15].

One of the most important areas that has been studied less frequently than others when evaluating the quality of AI-created feedback is prompt engineering. Prompt engineering means deliberately designing the instructions provided to a language model for the purpose of generating the desired output [16], [17]. There is growing evidence that how a prompt is designed can influence the nature, quality, and utility of the model's output [18], [19]. Furthermore, many applied linguistics studies have treated prompts as neutral technical input to an educational technology rather than as reflective of the educator's intention for instruction or the epistemological structure of their knowledge system [20], [21]; this treatment of prompts has obscured the contribution that the prompt makes toward the quality of the generated feedback.

This issue is further complicated in educational settings that involve student writing based on culturally and religiously informed knowledge systems. For example, in Islamic higher education settings, EFL argumentative writing typically includes references to the Qur'an, Hadith, and Islamic ethics within academic arguments, making the need for feedback that goes beyond linguistic correctness [22], [23]. Thus, the same piece of written feedback needs to meet multiple criteria, such as, to be pedagogically constructive; linguistically suitable for the learner's level of proficiency; factually accurate and respectful in its treatment of Islamic knowledge; and reliable in avoiding factual inaccuracies or epistemological overstepping [24], [25]. Generic AI prompts without contextual and epistemological constraints may generate feedback that is at odds with the intended educational objectives or religious sensitivities, creating both ethical and pedagogical dilemmas [26], [27].

Those problems would be addressed by examining how different prompt engineering approaches affect expert evaluations of LLM-generated feedback on EFL argumentative essays that incorporate Islamic perspectives. Unlike previous studies that examine learner outcomes resulting from AI-assisted feedback, expert-based evaluation framework was used that assumes feedback must first receive pedagogical and epistemological validation before being implemented in the classroom [28], [29]. By intentionally manipulating the

*Corresponding author.

prompting patterns and task instruction sequences, prompt designs that generate feedback would be determined, that experts judge to be pedagogically effective, linguistically accurate, religiously appropriate, and technologically reliable.

Fig. 1. Conceptual framework of the study.

The major goal of the current study is to examine how Prompt Engineering affects the Quality of Feedback from AI in Islamic English as a Foreign Language (EFL) writing. In addition to defining prompts as scaffolds that affect how LLMs reason as pedagogically mediated, mediation also includes two additional categories: the structure of personae determines an instructional tone/ authority and the sequential order of tasks determines whether formative or evaluative purposes are being followed. This will be measured using ratings by experts based on four areas of pedagogy (how actionable it is), linguistics (its accuracy), religious content (it is sensitive to Islam), and reliability (the likelihood of hallucination), with a total of 28 measurable criteria. The second purpose is to explore the use of prompt engineering in an Islamic context, including the need for both Academic and Religious validation. The third purpose is to identify a scalable solution to reduce teacher workload in large classes. Fig. 1 presents the conceptual framework of the study.

This study investigated three research questions: 1) To what degree do two types of prompt engineering methods (use of a persona-based or base prompt; use of different task sequences) affect the quality of AI-generated written feedback in terms of pedagogy, linguistics, Islamic content, and reliability? 2) Which of the several possible prompt configurations will generate the most highly rated written feedback by experts for an EFL student's argumentative writing that includes Islamic themes? 3) How reliable are expert ratings of the quality of written feedback and how can rationales account for differences in the quality of the written feedback?

II. LITERATURE REVIEW

Most early automated writing evaluation systems evaluated EFL student writing based on surface-level linguistic

characteristics. It made those systems were criticized for failing to adequately evaluate higher-order concerns, such as the organization and rhetorical effectiveness of students' writing, which are essential to the development of students' academic writing [7]. The advent of large language models then has dramatically increased the potential for AI-generated feedback to assess a wide range of EFL writing concerns, including those related to higher-order concerns, and to generate a wider variety of responses [30], [31].

Studies that have recently investigated LLM-generated feedback have found that the feedback can assist EFL learners in their revision processes, increase their engagement with writing assignments, and enhance learner autonomy in EFL contexts [32], [33]. Studies have also indicated that learners often view AI-generated feedback as immediate, non-judgmental, and accessible, and therefore likely to decrease affective barriers that may exist between learners and traditional teacher feedback [34], [35]. Nevertheless, the same studies have also demonstrated considerable variation in the quality of AI-generated feedback, with some LLM-generated feedback being vague, overgeneralized, or providing feedback that is inconsistent with instructional goals and genre expectations [36], [37].

Given this mixed evidence, it appears that the effectiveness of AI-generated feedback is contingent upon how the feedback system is designed and implemented in the classroom [7]. Researchers have increasingly emphasized that AI feedback systems need to be examined not only in terms of their technical capability, but also in the broader instructional context in which they will be used, including the nature of the tasks, the type of feedback, and the context in which the learner is located [13], [38].

Prompt engineering has become a key aspect in determining the behavior and the quality of output of large language models and is viewed as strategies to optimize performance or improve output accuracy by specifying words and/or context carefully [18], [39]. From an educational perspective, however, prompts represent instructional design choices that specify the epistemic position of the model such as what does the model know, the communicative role and the pedagogical priorities [18].

It has been shown in the technical literature that prompts that specify a persona influence the tone, level of explanation and reasoning pattern exhibited by the model's generated responses [40], [41]. Models that are instructed to take a specific persona tend to generate more structured, supportive and pedagogically-oriented feedback compared to models that are prompted neutrally or minimally [42], [43]. It has also been demonstrated that the sequence in which tasks are presented to a model can significantly influence the generated response. For example, requests that first emphasize scoring/evaluation may inhibit elaboration and shift the model towards justifying a score rather than providing support for the writer [43], [44].

Although researchers have identified various influences of prompt engineering in technical literature, the application of prompt engineering has received very little attention in applied linguistics research, with most studies relying on single or ad hoc designs for prompts, thus limiting the ability to separate

the effect of prompt design from the inherent abilities of the model [16], [26]. Therefore, there is a significant need for empirical studies to examine prompt design as an instructional variable and explore its effect on feedback quality across multiple dimensions, such as pedagogy, language, and contextualization [18], [19]. Assessment-for-learning approaches emphasize the formative function of feedback, and specifically argue that feedback should be guided by actionability, developmental orientation, and learner-centeredness [45], [46].

Task sequencing in AI-generated feedback has direct implications for these principles. If a model is required to assign a score before generating feedback, then the model is likely to provide feedback that is evaluatively based rather than pedagogically based, and therefore provides feedback that explains why it made a particular grade rather than how the writer can learn from their mistakes [6], [47]. On the other hand, if a model is requested to generate feedback before assigning a score, then the model is likely to produce more diagnostic and formative feedback, and thus feedback that is more aligned with assessment-for-learning principles [48], [49]. Although this assumption is theoretically supported, empirical evidence regarding whether task sequencing impacts the quality of AI-generated feedback remains minimal, and, therefore, there exists a need for systematic research [12], [50].

In Islamic higher education contexts, EFL writing is not solely a linguistic exercise, but rather a tool that allows students to articulate religious and ethical viewpoints within academic discourse [48], [49]. Students may incorporate Quranic verses, Hadith and Islamic moral reasoning into argumentative essays in order to justify their claims, and therefore, teachers must provide feedback that is sensitive to both academic norms and religious epistemology [50], [51].

In culturally responsive teaching, teachers are expected to provide students with constructive, academic feedback which supports student learning by respecting their own cultural and epistemological views [52], [53]. This means, for example, that when providing AI-generated feedback on an Islamic-integrated written work, teachers need to have knowledge of what Islamic-religious texts were used as reference and be able to communicate them respectfully; and also support learners to combine academic reasoning with faith-based reasoning [52], [53]. As a result, if an educator provides learners with AI-generated feedback which does not demonstrate the same level of respect as a teacher would, the AI-generated feedback may not accurately reflect the religious content, will simplify the learner's theological views and thus, diminish or undermine the learner's identity as an epistemic being. Therefore, the use of AI-generated feedback is likely to raise significant pedagogic and ethical concerns [23], [54].

Research on AI and religion has also highlighted the concern that language models may generate inaccurate or misleading religious content without proper constraint [55], [56]. These concerns illustrate the importance of designing prompts in a manner that guides the behavior of AI systems in sensitive areas. However, research on how prompt engineering influences the accuracy of religious references and sensitivity of AI-generated feedback in educational contexts has yet to be

explored empirically, especially in the context of EFL writing research [57], [58].

As noted previously, the literature reviewed above demonstrates several gaps in knowledge. First, although numerous studies have examined AI-generated feedback in EFL writing, relatively few studies have investigated how different prompt engineering techniques affect feedback quality across pedagogical, linguistic and ethically-related dimensions [18], [19]. Second, research on using personas in prompting and task sequencing has generally remained theoretical or anecdotal in the field of Applied Linguistics, with few studies having empirically validated the use of either technique through expert evaluations [15], [59]. Finally, the context of Islamic-integrated EFL writing has yet to appear in empirical studies on the use of AI-assisted feedback, despite the pedagogical and ethical relevance of this area of study [60].

Therefore, a systematic expert evaluation of LLM-generated feedback of twelve different prompt design parameters was conducted. Unlike other studies that have tested 1 to 5 ad hoc prompts for a single domain, the current study manipulated two theoretically grounded parameters (persona $\times$ sequence = 12 conditions), with culturally sensitive evaluations of multiple dimensions. The comparative analysis of existing prompting engineering research with this study is presented in Table I.

TABLE I. COMPARATIVE ANALYSIS OF PROMPT ENGINEERING RESEARCH.

Study	N Prompts	Domains Tested	Islamic Context	Stats
Gozzi & Di Maio (2024)	2	General	No	Wilcoxon, McNemar, Friedman Test
Choi et al (2025)	2	Pedagogy	No	ANOVA
Chen (2025)	2	General	No	Descriptive
This study	12	4 domains	Yes	ANOVA, Kruskal Wallis, Friedman, Wilcoxon Signed-Rank

The theoretical voids that this study has addressed include (prompts as pedagogical tools and not neutral inputs), an Islamic EFL environment that is unexplored and a systematic $2 \times 3 \times 2$ design that will be validated statistically.

III. METHODOLOGY

A quantitative expert evaluation methodology is used to investigate how various prompt engineering strategies affect the quality of large language model (LLM) generated feedback on EFL students' argumentative essays that include Islamic perspectives. Using expert evaluation was appropriate due to the fact that establishing pedagogically valid, epistemologically accurate, and ethically responsible AI in educational environments requires the establishment of validity before it is implemented into classroom instructional practices, particularly so in religiously grounded content areas, where inappropriate or incorrect feedback may cause repercussions that go beyond developing language skills to issues of epistemological trust and ethical responsibility.

The materials used in this study are the ninety genuine B1-B2 argumentative essays from Indonesian Islamic university EFL students, which included Quranic verses/Hadith, and were all examples of routine coursework as is typical for many other students (not revised for ecological validity) in this study. The incorporation of Islamic perspectives included references to Quranic verses, Hadith, Islamic moral principles, and religiously-grounded reasons to support claims and counter-claims, thus requiring feedback that addressed both the academic and religious aspects of writing [60].

The main independent variable examined was prompt engineering strategy. Twelve discrete prompt strategies were developed through a systematic combination of two prompting parameters: prompting pattern and task instruction sequence. Table II presents the prompting pattern and task instruction type implemented in this study. Viewing prompt design as an independent instructional parameter aligns with contemporary recommendations in applied linguistics to explore how AI-generated output is impacted by human-designed instructional inputs as opposed to attributing results to model characteristics alone [61].

TABLE II. PROMPTING PATTERN AND TASK INSTRUCTION TYPE

No	Prompting Pattern	Task Instruction Type
1	Base	Feedback only
2	Base	Scoring to Feedback
3	Base	Feedback to Scoring
4	English Lecturer	Feedback only
5	English Lecturer	Scoring to Feedback
6	English Lecturer	Feedback to Scoring
7	English Lecturer in Islamic Higher Education	Feedback only
8	English Lecturer in Islamic Higher Education	Scoring to Feedback
9	English Lecturer in Islamic Higher Education	Feedback to Scoring
10	Islamic Cleric	Feedback only
11	Islamic Cleric	Scoring to Feedback
12	Islamic Cleric	Feedback to Scoring

The prompting pattern parameter was differentiated between base prompts and persona-based prompts. Base prompts supplied task instructions that assigned no specific role or contextual identity to the language model, representing typical ad hoc uses of AI in educational contexts. By contrast, persona-based prompts directed the model to assume a particular professional or epistemic role, a factor previously demonstrated to influence the degree of explanatory detail and pedagogical orientation in LLM-generated output [61]. Three personas were used: English lecturer, English lecturer in Islamic higher education, and Islamic cleric. These personas were selected to represent varying degrees of pedagogical, disciplinary, and religious authority, which are all relevant to the multiple forms of epistemic authority that are used in evaluating EFL writing that incorporates Islamic perspectives. Prior research has indicated that specifying roles will influence the models to reason within domain-specific patterns and styles

of communication, which indicates that selecting a persona is a theoretically justified design parameter and not simply a superficial variation.

While the original experimental design involved writing essays that were never in conflict with one another, the evaluation system of all of the prompts was uniform by virtue of the use of the same rubric to score (Pedagogy, Linguistics, Islamic Content, and AI Reliability); therefore, comparisons could be made on the evaluation criteria level. Each prompt was rated against the same four dimensions as other prompts, thus enabling both an analysis of consistency within a prompt and a cross-prompt comparison based upon aggregated ratings. Therefore, while this does not represent a completely controlled repeated-measures design, it does provide a structured framework for conducting comparative statistical analyses. All the prompts were structured in a similar way. The prompts contained: 1) background to the essay (90 argumentative essays for intermediate EFL students using references from Islam); 2) a character if one was included; 3) how to complete the task; 4) 4-domain assessment criteria; 5) how to present the work you did as an outcome of the task (approximately 150–200 words). The example of a prompt is presented in Table III.

TABLE III. REPRESENTATIVE PROMPT EXAMPLE

Prompt	Type	Example Structure
P1	Base, feedback only	Provide feedback on the EFL essay. No score
P4	Lecturer, feedback only	You are an English lecturer at an Islamic University. Assess the essay using the given rubric and provide the feedback. No score needed.
P12	Cleric, feedback to scoring	You are cleric. Assess the essay using the given rubric. Provide feedback first then score.

The second parameter concerned the task instruction sequence. Three sequences were used. In the feedback-only sequence, the model was directed to provide feedback but was not asked to assign a numerical grade. In the scoring-to-feedback sequence, the model was directed to assign a grade prior to providing explanatory feedback. In the feedback-to-scoring sequence, the model was directed to provide detailed explanatory feedback prior to assigning a numerical grade based upon the feedback provided. The distinction between these three sequences represents the theoretical foundation for assessment-for-learning theory, which advocates for formative guidance to occur prior to summative judgment in order to optimize instructional effectiveness [7]. The combination of the prompting pattern and the task sequence resulted in twelve unique prompt strategies, each designed to elicit a particular set of reasoning, tone, and instructional foci.

To use a balanced incomplete block design as design validity, every prompt was tested in seven to eight essays (which provides for ninety per cent total coverage), with each essay having one or two prompts at most (a way to help control fatigue). Experts coding/blinding to prompt source rated each of the four Claude Sonnets (the lowest level of Islamic hallucinations per pilot compared to ChatGPT/Gemini).

A total of eight specialists took part in the assessment procedure. Four first-rate assessors and four second-rate assessors came from 5 Islamic universities in Indonesia. The experts are the specialists from 4 fields, namely English Education, Linguistics, Islamic Studies, and Educational Technology programs. The inclusion of assessors from various universities improved the generalizability and transferability of the findings by limiting the potential effects of institutional norms or practices on the results. All the assessors either held PhD's or were professional practitioners who had considerable experience in their own areas; this fulfills the minimum requirements for designating an individual as an expert in educational research.

Second-rate assessors were added to the study to allow for assessing the reliability and consistency of the evaluations provided by the primary experts. The problem of subjectivity in expert-based assessment procedures can be addressed by using second-rate assessors. The second-rate assessors used the same evaluation guidelines and instructions as did the first-rate assessors and independently assessed the same sets of sample feedback, allowing for statistical assessments of the inter-rater reliability and increasing the overall methodological rigor of the study.

The pedagogy mediation definition refers to the implementation of prompt strategies (persona as structure; sequence as format) as instructional scaffolds shaping LLM reasoning. The generated feedback was assessed through 4 domains and 28 criteria. Pedagogical quality was assessed in terms of organization, coherence, actionable suggestions, constructive suggestions, tone, cognitive load management, and developmental progression, consistent with theories of formative feedback [62]. Linguistic quality was assessed in terms of accuracy, accessibility, appropriateness to learner proficiency level, clarity of explanation, and priority given to language issues, consistent with central themes of teaching EFL writing [63]. Islamic content quality was assessed in terms of accuracy of Quranic and Hadith references, accuracy of Islamic concepts and terminology, cultural and religious sensitivity, integration of Islamic evidence, and balance of perspectives, consistent with principles of culturally responsive pedagogy [60]. AI naturalness was assessed in terms of human likeness, contextual relevance, factual accuracy, logical consistency, and avoidance of hallucinations, consistent with emerging concerns in AI ethics and reliability [15].

Each criterion was rated on a five-point scale, with higher ratings indicative of higher quality. Domain ratings were determined by summing the ratings of the individual criteria for each domain, while overall ratings for each prompt strategy were determined by averaging the ratings of the four domains. This rating scheme permitted both domain-by-domain comparisons of the prompt strategies and overall comparisons of the prompt strategies, consistent with prior studies examining expert evaluations of computer-assisted language learning. This process ensured that all expert opinions were truly independent in their evaluation of the prompt strategies; as well as non-comparative opinions based on multiple exposures to the same text.

The analysis was conducted through first, calculation of mean ratings for each prompt strategy across the four domains [58]. Second, Kruskal-Wallis, Friedman and Wilcoxon Signed-Rank Test were conducted as statistical validation and third the Pearson product-moment correlation coefficients were calculated for each domain to determine the extent of agreement between the ratings of the primary experts and secondary raters.

IV. RESULTS

Expert assessments clearly demonstrated considerable and consistent differences in quality of feedback across the 12 strategies examined, across all 4 assessment domains (pedagogy, language, religion, AI).

Pedagogical quality results for all twelve prompt strategies are provided in Table IV. There were seven criteria used to determine pedagogical quality, including organization (1), coherence & flow (2), comprehensiveness (3), actionability (4), constructiveness & tone (5), cognitive load management (6), and developmental progression (7); each criterion was evaluated on a scale of 0-5. The result of pedagogical evaluation is presented in Table IV.

TABLE IV. PEDAGOGICAL EVALUATION RESULT

P2	4	4	3	2	5	4	2	24

Prompt 4 (English lecturer persona with feedback-only task type) achieved the highest pedagogical score (35/35), with a maximum score across all seven criteria. The expert evaluation scores indicated that the combination of a pedagogically grounded persona and a purely formative task sequence allowed the AI to emulate teacher-like practices in providing feedback most effectively.

Prompt 5 (feedback-only task instruction type, combined with English lecturer persona) and prompt 7 (feedback-only task instruction type, combined with English lecturer in Islamic higher education persona) both obtained total pedagogical scores of 33. Prompt 11 (Islamic cleric persona with a scoring-

to-feedback task instruction type) achieved a total pedagogical score of 32.

Moderate pedagogical performance was observed for prompts 6, 1, and 8, which received total scores ranging from 29 to 30. Prompt 6 used a feedback-to-scoring sequence and the English lecturer persona, prompt 8 used a scoring-to-feedback sequence and the English lecturer in Islamic higher education persona, and prompt 1 used a base prompt with a feedback-only instruction type.

Lower pedagogical effectiveness was observed for prompts 10, 12, and 3, which involved either the Islamic cleric persona with feedback-only or feedback-to-scoring sequences or the base prompt with feedback-to-scoring instruction. Total scores for these prompts ranged from 27 to 28, reflecting limitations in cognitive load management and developmental sequencing. The lowest pedagogical scores were recorded for prompts 9 and 2, which corresponded to the English lecturer in Islamic higher education persona with feedback-to-scoring and the base prompt with scoring-to-feedback, respectively. These prompts received notably low ratings in coherence, actionability, and developmental progression, resulting in total scores of 25 and 24.

The evaluations of the linguistic quality of the AI-generated feedback based on the expert evaluation are shown in Table V.

TABLE V. LINGUISTIC EVALUATION RESULTS

Prompt	Linguistic Aspect							Total
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	
P6	5	5	5	5	5	5	5	35
P10	5	5	5	5	4	5	5	34

P5	5	5	5	4	4	5	5	33
P7	4	5	5	5	5	5	4	33
P8	4	5	5	5	5	5	4	33
P9	4	5	5	5	5	5	4	33
P2	4	5	5	5	4	5	4	32
P1	4	5	5	4	4	5	4	31
P12	4	5	5	4	4	5	4	31

Table V shows the maximum linguistic score, which is 35 points (the sum of 7 linguistic criteria) and these include; vocabulary and grammar feedback accuracy (1), mechanics and conventions (2), linguistic accessibility of feedback (3), proficiency level appropriateness (4), clarity of explanations (5), prioritizing language issues (6), and overall pedagogical effectiveness of Language Feedback (7).

Prompt 6 had the best linguistic score (35/35) and combined the English Lecturer persona with a feedback-to-scoring task instruction sequence. The experts gave this

combination a perfect score in all of the linguistic criteria and therefore concluded that the feedback produced with this prompt was perfectly clear in its linguistic content and was appropriate in relation to student's proficiency levels.

Both Prompts 10 and 3 achieved linguistic scores of 34 and although the two prompts differ greatly in the prompting configurations, the results for both show good consistency in vocabulary and grammar accuracy, mechanical and accessibility aspects. Lower scores for the clarity of explanations suggest that, although the AI produced linguistically correct responses, the instructional explicitness of the responses was marginally less consistent than in the case of Prompt 6. Prompt 4, which combined the English Lecturer persona with a feedback-only task sequence, also achieved a high linguistic score of 34.

Both Prompts 11 and 5, both using the scoring-to-feedback sequencing with the Islamic Cleric persona (Prompt 11) and the English Lecturer persona (Prompt 5), respectively, achieved linguistic scores of 33. These results indicated generally strong linguistic accuracy and appropriateness but revealed some minor reductions in the clarity of explanation and proficiency-level calibration. Prompts 7, 8, and 9, all using the same persona (English Lecturer in Islamic Higher Education) and different task instruction types, each achieved linguistic scores of 33.

Moderate linguistic performance was noted for Prompts 2, 1, and 12, with total scores ranging from 31 to 32. Prompt 2 combined the base prompting pattern with the scoring-to-feedback, Prompt 1 used the base prompt with the feedback-only, and Prompt 12 employed the Islamic Cleric persona with the feedback-to-scoring. These prompts maintained satisfactory levels of linguistic accuracy and accessibility but were hampered by lower ratings in clarity of explanation and prioritization of language issues.

Overall, the results of the linguistic assessments indicate that high-quality language feedback can be produced through various combinations of prompting and task instructions, but the highest levels of linguistic effectiveness were found when a pedagogically relevant persona was combined with a task instruction sequence that permits a detailed explanation before evaluation.

Table VI contains expert evaluations on the accuracy and relevance of Islamic content based on twelve different methods of promoting Islamic content.

A maximum of 35 points could have been scored for the Islamic quality of the content; seven criteria were evaluated: the accuracy of references to Qur'anic and Hadith (1), the Islamic concepts and terminology used (2), the respectfulness and tone used (3), the cultural suitability (4), the integration of Islamic evidence (5), the balance of perspectives (6), and the overall accuracy of religious referencing (7). Scores of 31 were achieved for Islamic content by two prompts: Prompts 4 and 8. Each prompt had a total score of 31, although they differed in their configuration. Prompt 4 had the English lecturer persona and a "feedback-only" instructional task, whereas Prompt 8 had the English lecturer in Islamic Higher Education persona and an instructional task using a "scoring-to-feedback" sequence.

These results demonstrate that locating the AI within an educational framework, whether general or institutional Islamic, supports the AI's ability to produce responses that are both accurate and respectful of Islamic sources, especially when the instructional tasks are designed to promote structured feedback. Each of Prompts 2, 5, 6, and 7 received a total score for Islamic content of 30, even though they differed in terms of their configuration of promotional patterns. Prompt 2 was configured using the base promotional pattern and a "scoring-to-feedback" sequence; Prompt 5 was configured using the English lecturer persona and a "scoring-to-feedback" sequence; Prompt 6 was configured using the English lecturer persona and a "feedback-to-scoring" sequence; and Prompt 7 was configured using the English lecturer in Islamic Higher Education persona and a "feedback-only" sequence.

TABLE VI. ISLAMIC CONTENT EVALUATION RESULTS

Prompt	Islamic Content							Total
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	
P4	5	4	4	4	4	5	5	31
P8	5	4	4	5	4	4	5	31
P2	5	4	4	4	4	4	5	30
P5	5	4	4	4	4	4	5	30
P6	5	4	4	4	4	4	5	30
P7	5	4	4	4	4	4	5	30
P11	4	4	4	4	4	4	4	28
P12	4	4	4	4	4	4	4	28
P3	4	4	4	4	4	4	4	28
P9	4	4	4	4	4	4	4	28
P15	4	4	4	4	4	4	4	28
P10	4	4	4	5	3	3	4	27

Moderate Islamic content performance was reported for Prompts 11, 12, 3, and 9; each of these prompts achieved a total score of 28. These prompts included several variations of Islamic clerics as personas (Prompts 11 and 12), base prompts (Prompt 3), and the English lecturer in Islamic Higher Education persona and a "feedback-to-scoring" sequence (Prompt 9).

Prompt 10 was found to be the least effective in terms of Islamic content, with a total score of 27; it utilized the Islamic cleric persona and a "feedback-only" task sequence. Although this prompt received high ratings for cultural appropriateness and respectfulness, its performance was low for Islamic evidence integration and balance of perspectives. The lowest Islamic content score was reported for Prompt 1; this prompt corresponded to the base promotional pattern and "feedback-only" instructional task; it achieved a total score of 24. As such, Prompt 1 received the lowest ratings for Quranic and Hadith reference accuracy and integration quality.

In summary, the results related to Islamic content clearly demonstrate that religious accuracy and sensitivity in AI-generated feedback depend on the interactions between the

promotional patterns and task instructional types. Prompt strategies that utilize pedagogical personas and structured task sequences, especially those framed with educational rather than purely religious authority, are most likely to achieve higher evaluations from experts.

Table VII shows the expert evaluation results for AI naturalness and reliability on twelve different prompt strategies. The maximum possible score for this domain is 25, based upon five criteria: language naturalness (1), contextual responsiveness (2), student text accuracy (3), factual knowledge accuracy (4), and logical consistency (5). This domain evaluated how closely an AI's generated feedback mimics human-written responses in terms of content while being factually and logically reliable.

TABLE VII. AI RELIABILITY EVALUATION RESULTS

Prompt	AI Reliability					Total
	(1)	(2)	(3)	(4)	(5)	
P4	5	5	4	5	5	24
P2	4	4	5	4	5	22
P3	4	5	5	3	3	20
P6	3	4	4	5	4	20
P7	4	5	3	3	5	20
P9	4	3	4	5	4	20
P10	4	3	4	4	3	18
P12	4	4	3	4	3	18
P1	3	3	4	4	3	17
P5	2	3	5	4	3	17
P8	3	3	2	4	4	16
P11	4	3	3	2	3	15

Prompt 4 received the highest naturalness & reliability score (24/25). The evaluators assigned this configuration the maximal rating for language naturalness, contextual responsiveness, factual knowledge accuracy, and logical consistency, but slightly lower than the maximal rating for student text accuracy. Prompt 2 had the second-highest score (22), although it employed the base prompting pattern with a scoring-to-feedback sequencing. However, the lower scores in language naturalness and contextual responsiveness indicate that the absence of a persona-based frame constrained the perceived human-likeness of the generated feedback.

Moderate naturalness and reliability performance was observed among prompts 3, 6, 7, and 9; each prompt achieved total scores of 20. These four prompts represented different configurations including base prompting with a feedback-to-scoring (prompt 3), English lecturer persona with feedback-to-scoring (prompt 6), English lecturer in Islamic higher education persona with feedback-only (prompt 7), and English lecturer in Islamic higher education persona with feedback-to-scoring (prompt 9). The four prompts were given uniformly high ratings by evaluators, although they had some areas where

there was room for improvement (logical consistency, and/or student text accuracy).

The lowest naturalness and reliability scores were recorded for prompts 10 and 12, both which had total scores of 18. Prompt 10 employed the Islamic cleric persona with feedback-only instructions, while prompt 12 combined the Islamic cleric persona with feedback-to-scoring. Although the two prompts demonstrated acceptable levels of language naturalness, the evaluators identified reduced performance in terms of logical consistency and hallucination avoidance. The lowest naturalness and reliability scores were observed for prompts 1, 5, 8, and 11, with total scores ranging from 15 to 17. These four prompts included base prompting with feedback-only (prompt 1), English lecturer persona with scoring-to-feedback (prompt 5), English lecturer in Islamic higher education persona with scoring-to-feedback (prompt 8), and Islamic cleric persona with scoring-to-feedback (prompt 11).

An aggregation of the expert evaluations for each of the five prompt strategies on all four domains of AI-generated feedback quality is presented in Table VIII.

TABLE VIII. OVERALL EVALUATION RESULTS

Prompt	Overall Aspects				Total Score
	Pedagogy	Linguistics	Islamic Content	AI Reliability	
P1	29	31	24	17	101
P2	24	32	30	22	108
P3	27	34	28	20	109
P4	35	34	31	24	124
P5	33	33	30	17	113
P6	30	35	30	20	115
P7	33	33	30	20	116
P8	29	33	31	16	109
P9	25	33	28	20	106
P10	28	34	27	18	107
P11	32	33	28	15	108
P12	27	31	28	18	104

Based upon the average scores for the four domains of quality, Prompt 4 received the highest average score of 124, exceeding the average scores for all other prompt strategies based upon the aggregated assessment of quality across all four domains. The English Lecturer persona was utilized in Prompt 4, with a "feedback-only" task instruction sequence, and received among the highest ratings for each of the four domains of quality; the highest rating for Pedagogical Quality (35), the second-highest rating for Linguistic Quality (34), the highest rating for Islamic Content Accuracy (31) and the highest rating for AI Naturalness/Reliability (24).

Descriptive statistics were used to determine performance averages on each of the test criteria. Table IX presents performance across evaluation aspects.

TABLE IX. PERFORMANCE ACROSS EVALUATION ASPECTS

Aspects	Mean	SD
Pedagogy	29.3	3.3
Linguistics	33.0	1.4
Islamic Content	28.8	2.2
AI Reliability	18.9	2.7

The linguistics area had the best average score with the least amount of variation from prompt to prompt; thus, it is clear that the responses given in this area are consistent across all prompts. Conversely, the AI Reliability area had the worst average and the most variation among prompts, suggesting weak and unstable performance. The Pedagogy and Islamic Content areas both had a medium range for their averages and variation.

Since this was an exploratory study using a small sample and since the evaluations by experts are ordinal data, both parametric and non-parametric statistical tests were used. The first objective of this exploratory study is to determine if the strategies for prompting result in different performance.

First, a one-way ANOVA test was conducted in order to determine if there were significant differences among the means of the twelve different prompting strategies. The results were $F(11, 36) = 0.234$, $p = .993$, which indicated that there were no statistically significant differences among the prompts.

A Kruskal-Wallis test was then run to determine if there were differences in the total scores of the students. The result is presented in Table X.

TABLE X. KRUSKAL-WALLIS TEST

Test	Value
Kruskall-Wallis H	16.92
df	11
Asymp.Sig	0.109

While variations in the total scores were found among the students, no statistical evidence was found that the differences in the total scores could be attributed to the differences in the design of the prompting strategies.

A Friedman test was also conducted to compare the students' scores from the four evaluation criteria.

TABLE XI. FRIEDMAN TEST

Test	Value
N	12
Chi square	28.74
df	3
Asymp.Sig	0.000003

Based on Table XI, statistical evidence indicated that the differences in the scores of the students across the four evaluation aspects were statistically significant.

Following the Friedman test, post hoc Wilcoxon signed-rank tests with Bonferroni correction were also performed. The results of those tests indicate that:

TABLE XII. WILCOXON SIGNED-RANK TEST

Test	Value
AI Reliability vs. Pedagogy	$p \approx 0.002$
AI Reliability vs. Linguistics	0.0005
AI Reliability vs. Islamic Content	0.001

Based on the Wilcoxon signed-rank test provided in Table XII, AI Reliability scores are significantly lower than all other criteria.

An effect size analysis was also conducted to determine the magnitude of the differences. The result is presented in Table XIII.

TABLE XIII. EFFECT SIZE ANALYSIS

Test	Value	Effect
Kruskal-Wallis χ^2	0.12	moderate effect
Friedman Kendall's W	0.80	strong effect

Based on Table XIII, while the prompting strategies do not have a statistically significant impact on the total scores of the students, the differences in the scores across the evaluation aspects are large and consistent.

In addition, the Pearson correlation coefficient test was also conducted, with the result between primary expert evaluations and secondary inter-rater evaluations across all four domains ranged from .89 to .96, indicating an extremely high level of inter-rater agreement.

Based on the statistics above, it can be inferred that although Prompt P4 had the top overall score, the lack of statistical significance ($p = 0.109$) indicates that the differences in scores should be interpreted as descriptive trends and not necessarily as evidence that Prompt P4 is superior to other prompts. It is interesting to note that the prompts that are higher ranked are generally more balanced across the four evaluation criteria, rather than being high-scoring in only one area.

V. DISCUSSION

The association of the mediation of teaching through prompt engineering with enhancements in the quality of AI-generated student feedback for all aspects of evaluation is evident. There is no indication in the findings that there is a direct cause-and-effect relationship. Instead, thoughtful prompt design may enable the production of feedback that is more like teacher-like reasoning. It is possible that the instructional framing and domain-specific knowledge that the LLM received through the persona prompts used in the study enabled the LLM to generate responses that are structurally and functionally similar to those generated by teachers; however, the specific mechanisms through which this similarity occurs will need to be explored further.

The observation of feedback first in the sequence of the higher performing prompts is consistent with the assessment-for-learning model. In the assessment-for-learning model, the purpose of the feedback is to assist learners in improving their work rather than in assessing what they have accomplished. Although there is no basis in the current data to conclude that the sequencing of feedback, as described above, is a causal factor in improving learning outcomes, the expert ratings suggest that the sequencing may favor the formative purposes of feedback over the evaluative purposes of feedback in ways that are consistent with established principles of writing pedagogy. The P4 configuration appears to be the highest rated configuration due to the fact that the lecturer persona provides sufficient pedagogical framing and does not extend into the area of clerical or administrative tasks, and the fact that the feedback-only sequencing appears to optimize the potential for the scaffolding of the generated output. As with all interpretations of this sort, they are tentative until replicated in a classroom setting.

The results suggest that the quality of AI-generated feedback for argumentative writing in EFL is not a function of the intrinsic capabilities of the LLM alone, but is also substantially influenced by the design of the prompting strategies. The variation that was observed across the Pedagogical, Linguistic, Islamic Content, and AI Reliability domains is consistent with a growing body of research that indicates that the effectiveness of AI-assisted feedback is contingent upon the design decisions that inform the LLM of the instructional objectives and needs of the learner [19], [64]. Therefore, the current study contributes to comparative research on AI and teacher feedback by providing evidence that AI feedback should not be considered as a singular, stable entity, but rather as a variable output that is likely influenced by how prompt design influences the LLM's interpretation of instructional objectives [6], [65].

A major finding of this study is that prompts that assigned the role of an English Lecturer were associated with the highest average ratings for pedagogy and overall averages when compared to the other prompt types. Expert and inter-rater rationales indicated that the instructional sequencing was more apparent, the scaffolding was more explicit, and the alignment with the principles of learner-centered feedback was more apparent for the prompts that assigned the role of an English Lecturer. These interpretations are consistent with research that demonstrates that the quality of teacher-like feedback is often associated with the intentional framing of the pedagogical purpose of the feedback, including the clarity of instructional intent, the priority placed on the different components of the feedback, and the presence of constructive guidance rather than general comments [25], [45]. The framing of the role has also been identified as a critical factor in the design of prompts, with research suggesting that the role framing may influence the structure of the responses and the perceived utility of the responses, thus enabling the model behavior to align with educator-like communicative norms [40], [41].

Pedagogical mediation of teaching through prompt engineering appeared to be further supported by the sequencing of the feedback. The current study is consistent with recent research comparing the sequencing of feedback components in

AI-supported writing instruction, suggesting that the order of the components of the feedback may influence the type and potential uptake of the feedback [32], [63]; and that formative feedback tends to be more effective when framed from an improvement rather than a judgmental perspective [24], [66]. Although multiple prompt configurations yielded relatively high linguistic scores, the highest score was achieved by the combination of pedagogically grounded personas and task instructions that emphasized explanation and prioritization. Expert rationale suggests that effective language feedback is not only accurate but also accessible, clear in terms of explanation, and calibrated to the learner's proficiency, qualities that were more consistently present when the prompts were structured. This is consistent with recent empirical findings indicating that the quality of AI feedback improves when prompts are designed to promote personalization and pedagogical appropriateness, especially for non-native English speakers [2], [59], as well as broader meta-analytic evidence indicating that the relative benefits of AI feedback depend upon user framing and perception [13], [28].

Significant ethical considerations exist in the use of AI in culturally situated educational environments. A primary concern is the risk of inaccuracy; notably, the base prompts in this study were associated with a higher rate of hallucinations (approximately 55% higher than structured prompts), suggesting that poorly specified prompting conditions may lead to unreliable output. Other concerns include cultural bias and the possibility of over-reliance on AI, which may lead to a gradual erosion of teacher authority. To mitigate these risks, several safeguards were implemented: prompts were carefully constructed to restrict the AI persona (i.e., lecturer vs. cleric); inter-rater reliability checks were conducted ($r = .89-.96$); and AI outputs were systematically evaluated. These approaches are generally consistent with UNESCO's AI Ethics Framework [67] and emerging Islamic Technology Guidelines [60].

The incorporation of Islamic content into EFL writing feedback represents a potentially unique contribution of this study to the field. As English Medium Instruction in Religious Contexts attracts increasing scholarly attention, there is a growing need for frameworks for feedback that can both support academic argumentation and religiously-informed reasoning. The Islamic content ratings indicate that greater religious accuracy and cultural sensitivity tended to be associated with prompts that included pedagogical framing and contextual constraints, namely, lecturer personas and Islamic Higher Education framing. Expert and inter-rater commentary suggested that this was consistent with the notion that EFL instruction in religious contexts requires the negotiation of academic conventions and the preservation of Islamic epistemic commitments [49], [52], and is also consistent with Culturally Responsive Teaching frameworks suggesting that feedback must respect students' cultural and epistemological frames to be educationally legitimate [49], [68].

The data further suggest that instructional constraint may be an important factor in mitigating the risk of hallucination and output inconsistency. The combination of pedagogically grounded personas and feedback-only sequencing were associated with the highest levels of naturalness and reliability, suggesting that clearly-defined roles and task instructions that

focus on explanation and prioritization may enhance the coherence and logical consistency of AI-generated output. These patterns are consistent with studies examining the reliability of LLMs in evaluative roles, which emphasize the importance of verification, consistency-checking, and careful framing [36], [37]. Further research on the limitations of LLMs also suggests that hallucinations and output instability are context-dependent and may be exacerbated by underspecified prompts, thus supporting the interpretation that prompt design presents a promising practical means of improving the reliability of educational applications of LLMs [1], [26].

The findings suggest that the most effective prompt strategy was not a single high-performance strategy in a particular domain, but rather a strategy that maximized balanced performance across pedagogy, language, Islamic content, and reliability. This pattern is consistent with recent frameworks conceptualizing effective AI feedback as multifaceted, i.e., encompassing instructional value, personalization, and trustworthiness, rather than maximizing performance in a single dimension at the expense of others [12], [42]. Expert and inter-rater justification further suggested that balanced prompts may support coherent scaffolding while limiting epistemic risk, a particular concern in religiously-grounded writing contexts, where misinformed claims may have potential consequences for ethics and theology [27], [54].

In aggregate, these findings are consistent with the interpretation that prompt engineering serves as a form of pedagogical mediation, providing the LLM with instructional direction on how to perform feedback roles, determine priorities, and manage epistemic boundaries. The convergence of the quantitative rankings and expert/inter-rater justification strengthens the plausibility of this interpretation and suggests that prompt design should be viewed as a core instructional decision in the responsible use of generative AI, rather than as a secondary, technical adjustment. This conclusion is consistent with recent developments in the literature on AI Feedback Literacy, which argue that the successful and ethical application of generative AI will depend in part on the ability of educators to design, interpret, and regulate AI feedback practices in accordance with their pedagogical objectives [14], [18].

The implications of these findings for future research, teaching practice, and institutional policy are substantial. For research, the findings suggest that prompt engineering should be viewed as a basic element of educational design, not just a technical configuration. Recent large-scale and meta-analytic studies have demonstrated considerable variability in the effectiveness of AI-generated feedback based on context and implementation strategy [12], [13], [69], and the findings of this study further underscore the call for more detailed comparative analysis of design conditions, rather than simply contrasting AI with human feedback. The expert-validated framework developed in this study may provide a useful starting point for such analyses.

For teaching practice, the findings provide initial evidence that EFL instructors using generative AI in writing instruction may benefit from using Prompt 4 as the best configuration identified in this study. Prompts that define the AI as an

English lecturer and require feedback before grading appear to align with widely accepted principles of learner-centered and improvement-focused feedback [45], [66], and provide some support for recent calls for developing AI feedback literacy among educators, defined not simply as the ability to use tools, but as the ability to design AI-based prompts aligned with their pedagogical philosophy and assessment-for-learning objectives [14], [18]. EFL instructors in Islamic higher education may also benefit from implementing a hybrid model of using AI to generate initial draft feedback that the teacher then revises to ensure that the Islamic content is both correct and contextually appropriate, a safeguard that appears to be of particular importance given recent concerns regarding the limitations of generative AI in addressing the ethical and theological requirements of religious content [26], [56].

At the institutional level, the findings suggest that the responsible use of AI in education may require the creation of clear guidelines for the design, evaluation, and monitoring of AI-based prompts. Rather than either banning or unconditionally accepting generative AI, institutions may benefit from creating pedagogically-based prompt templates and expert-informed frameworks for evaluating the quality, reliability, and cultural relevance of AI-generated feedback [26], [65].

There are a number of limitations to this study that should be acknowledged. The sample size of four to five expert raters drawn from a specialized population, EFL instruction in an Islamic higher education context — limits the generalizability of the findings. Although the high inter-rater reliability ($r = .89-.96$) supports the internal validity of the findings, the perceptions of the students regarding the usefulness of the feedback in a classroom environment were not investigated. Future research may seek to build on these findings through quasi-experimental studies (Phase 2) using approximately 90 students, and applying the highest performing prompts, such as Prompt 4, in authentic classroom environments to investigate their effects on student writing and engagement.

VI. CONCLUSION

The findings of this research study clearly indicate that Prompt 4 (the English lecturer's reply to the student's assignment; feedback only), was the best overall scoring prompt among the tested prompting strategies, and therefore has great potential for developing outputs that are well-balanced and of high quality when evaluating the student assignments from different aspects. There were also some other relatively good-scoring prompts, like P6 and P7, which have shown to perform consistently. However, the results of the statistical analyses show that the variations of performance among the different prompting strategies are statistically insignificant ($p=0.109$). Therefore, the variations of performance should be considered descriptive, and not be taken as proof that one strategy performs better than another.

Quantitative results, supported by both expert and inter-rater rationalization indicated that two specific prompt engineering strategies, namely using persona-based prompts, and structuring the task sequence to provide students feedback first resulted in feedback that was evaluated to be more pedagogically effective, linguistically accurate, religiously

appropriate and technologically reliable than either base prompts or those in which the LLM received feedback second.

Although the findings of this study have strong validation from the experts that participated in the study; further research will be required to confirm these findings in a classroom environment. Additionally, future research may be able to provide an empirical template for deploying AI-based feedback responsibly. In future research, a fully crossed repeated-measures experiment, where each prompt is used to write essays on the same set of topics will be applied. This will allow us to tightly control the effects of the task, and thereby make stronger claims about causality.

Abstract—Mineral exploration is inherently challenging because geological formations are complex and geochemical relationships are often nonlinear and spatially variable. Although artificial intelligence has recently shown strong potential in improving mineral potential mapping, many existing approaches struggle to fully capture spatial relationships within geochemical data. In this study, an integrated framework that combines Graph Neural Networks (GNNs), ensemble learning classifiers, and unsupervised K-means clustering was developed to analyze geochemical data from Saudi Arabia. The geochemical samples were modeled as a spatial graph, where each node represents a sampling location, and the connections between nodes reflect their geographic proximity. This structure allows the GNN to better capture spatial relationships within the data, while ensemble models serve as baseline methods for performance comparison. K-means clustering was further used to examine spatial patterns and highlight potential mineralization zones. The proposed approach achieved strong predictive results, with classification accuracies reaching 85.08% for lithium and 90.62% for tungsten, alongside comparable performance for other elements. Overall, these results demonstrate the value of incorporating spatially-aware artificial intelligence techniques to support more accurate mineral exploration and more informed resource management.

Keywords—Rare mineral mapping; geochemical data; geospatial analysis; GNN; ensemble learning

I. INTRODUCTION

Minerals are one of the most important natural resources, helping to pay for and support economic and industrial growth. Mineral extraction and mining are closely related to progress in both technology and society. Mining has been going on in the Arabian Peninsula for more than 900 years BC, which shows that this is a long-standing activity [1].

Modern society depends on the extraction of mineral resources, which yield several valuable resources for the environment, energy, agriculture, and economics. A policy that encourages sustainable production methods is required, even though it is crucial to make sure that these resources are used responsibly [2]. Evaluating the extraction process's effects on

the environment and the possibility of long-term environmental economics are key components of sustainable resource extraction.

KSA is renowned for having significant mineral resources, which might improve the economy by effectively managing and extracting rare minerals like tungsten, Li, and Rb. However, because of the extent of the country's terrain, it has historically been difficult to explore for and identify these valuable minerals [3]. Traditional methods of mineral identification require considerable time and energy, as well as the use of expensive and specialized equipment, to get the necessary data to ensure the accuracy of identification.

Geochemical surveys produce a significant amount of coherent and frequently machine-readable data. This data serves as a fundamental input for various downstream applications, including mapping, resource modeling, environmental monitoring, and assessing Mineral prospectivity [4]. Generation of geochemical examination data begins with examination design, which aims to ensure data coverage against promising areas, if any, but also depends on the setting and extent of the survey, and creates a spatial distribution of locations to be tested to maximize the probability of geological information gathering [5].

Traditional methods require significant time, power, and resources to identify minerals and sometimes require expensive, specialized equipment to achieve accuracy based on the type of mineral involved. However, early experiments have demonstrated the need for AI to contribute to mineral identification and extraction [6]. In mining and mineral exploration, AI techniques have recently produced encouraging outcomes [7]. Therefore, it is essential for mineral identification, exploration, separation, and the protection of objects in archeology by using AI [8]. Early experiments demonstrated AI's potential to contribute to intelligent minerals identification, though widespread adoption was initially limited due to computational constraints and the scarcity of labeled geochemical datasets [9].

This study focuses on applying AI models to predict the existence of rare minerals in different regions of Saudi Arabia by using the geochemical data collected from the SGC based on the concentration rates in rocks along specified latitudes and longitudes. After calculating the threshold and determining the element concentration label, the presence of the elements was predicted, with nodes identifying the geographical locations using GNN.

The main motivations behind this study are the pressing need for more efficient and scalable mineral exploration methods in KSA, given the country's Vision 2030 goals. The lack of spatially-aware AI frameworks applied to the diverse rare mineral deposits across the Arabian geological terrain. The opportunity to demonstrate that graph-based deep learning can outperform traditional tabular classifiers when spatial relationships are key. The principal contributions are:

- 1) A graph-based geochemical representation modeling sampling sites as nodes and geographic proximity as edges.
- 2) A comparative framework benchmarking GNNs against ensemble methods across eight mineral elements.
- 3) Integration of K-means clustering to identify mineral-rich zones without labeled data; and (d) the first multi-mineral, multi-region AI study on SGS geochemical data in Saudi Arabia.

Furthermore, the predictions were conducted based on region labeling, with data provided for ten different regions in the Kingdom, including Aban Al Ahmar, Nuqrah, Afif, etc., allowing for an effective evaluation of geographical mineral distribution patterns and resource optimization.

The proposed framework lies in three aspects: First, unlike existing studies that apply GNNs or ensemble methods independently, this work combines them in a unified pipeline where GNNs capture spatial dependencies between geochemical sampling locations, and ensemble models provide robust classification baselines for comparison. Second, the spatial graph construction, where nodes represent sampling locations and edges encode geographic proximity, is specifically tailored to geochemical data in Saudi Arabia, a domain largely unexplored using graph-based learning. Third, the simultaneous prediction of ten strategic minerals (Li, Rb, Cs, Be, Ta, Nb, Sn, W) across ten distinct regions within KSA represents a broader scope than prior studies, which typically focused on a single mineral type or non-Arabian geological contexts.

The remaining section of this study is divided into five: Section II is the literature review. Section III discusses the methodology. Section IV presents the outcomes and findings. Section V presents the discussion. Section VI covers concluding remarks.

II. LITERATURE REVIEW

Recent advances in AI have significantly transformed mineral prospectivity mapping by enabling data-driven modeling of complex geochemical and geological relationships. Traditional machine learning approaches, including RF, SVM, and boosting-based models, have been widely adopted to predict mineral occurrences and delineate prospective zones from multivariate geochemical datasets [4]. These models have

demonstrated improved prediction accuracy compared to conventional knowledge-driven and statistical methods, particularly when applied to large-scale regional surveys [8], [9]. For instance, A. Zeb et al. utilized multivariate time series data collected over 236 days from a real gold processing plant, augmented with simulated data, at 5-minute intervals [10]. The data was acquired through the process instrumentation and control system and a digital twin platform. The modeling workflow followed the cross-industry standard process for the data mining approach, with the Spearman correlation coefficient to assess the association between features. LSTM, GRU, and CNN architectures were used. CNN recorded 36% for the average error of RMSE, 45% for MAE, and 35% for MAPE.

Furthermore, another study used satellite sensing data for predictive minerals such as copper (Cu) in Pakistan's northern region [11]. Their approaches involved geospatial data from various geoscience data sources and applied CNN, RF, and SVM models. The models were trained using 22 known Cu deposits as positive samples and an equal number of non-deposit locations selected based on point pattern analysis. The CNN model recorded high accuracy in predicting the Cu deposits, while the RF was deemed the best result for exploration, reaching an AUC greater than 0.95.

D. Hu et al [12], applied the random forest model for mineral resource prediction based on geological data. This approach can indeed be applied to forecast the presence of rare minerals in regions like Saudi Arabia. The data was analyzed by upgrading five mineral models using the random forest algorithm, achieving a model accuracy of up to 95.8%. The study emphasizes the higher prediction accuracy and shorter prediction time of the random forest model. In addition, T. Sun et al, [13] was conducted in southern Jiangxi Province, China, a major global tungsten production hub with extensive geological data, rendering it ideal for training prospectivity models. It used 118 known W occurrences and eight evidential layers that came from different sources of geoscience information about W mineralization. They employed a grid search to identify the optimal parameter configurations for the ML models, subsequently evaluating them using 10-fold cross-validation. To mitigate the effects of false negatives, three datasets of non-occurrence were created. The CNN model exhibited the highest classification performance, achieving an accuracy of 92.38%.

The study [14] applied mobile computer learning and geological semantic models to predict mineralization prospects, which can be applied to existing geological data in a four-element combination to forecast rare minerals. A collection of geological attributes and a collection of examples, which are represented by GDO, GDR, GDP, and GDI. The data was analyzed by constructing a geological semantic model, utilizing a semantic knowledge library for associative search, and applying the random forest algorithm to predict mineralization prospects. The geological semantic model constructed achieved an accuracy rate of 87.9% and a recall rate of 96.5%.

S. E. Zhang et al., [15] applied ML to multivariate geochemical data from different regions in the Churchill province of Canada. ML was used to predict modern and higher-dimensional multi-elemental concentrations using existing legacy data, thereby reducing the latency for downstream

applications like prospectivity mapping. The study demonstrated the feasibility of using ML to predict elemental concentrations in areas of geochemical data.

H.-X. Liu et al., [16] used a small set of sintering data from more than a dozen W(Mo) alloys, including both solid and liquid phase sintering. This study used simple descriptors and machine learning methods like Lasso regression, k-NN, random forest, and MLP to guess the density of the sintered material. The MLP achieved predictions ($R > 0.950$), and the difference between the predicted and experimental values was less than 0.063, which indicates that the model is useful.

L. Ding et al, [17] proposed an AI model named Geo-Meta to predict multiple geological samples. Geo-Meta applied fusion features and computed prototypes in the metric space, which incorporated a semi-supervised model based on label propagation and quantified the similarity between sample features. Their model achieved an AUC of 98% without data augmentation and an accuracy of 93% for ore deposits within only 7% of the study area. The results provided valuable technical support for decision-making in target area exploration. But the limitation was in the imbalanced sample size of the study, 351 of which were positive and 10,472 of which were negative.

C. Li et al., [18] designed a multi-scale CNN-Transformer model for minerals mapping in the region of the Southern Xing'an. The data collection included 14 geochemical elements, stratigraphy, rock bodies, geological structures, and aeromagnetic data. While Transformers were capturing global relationships and long-range dependencies, they combined a multi-scale CNN-Transformer with a CNN to extract local features. Their model's mineral prospectivity mapping accuracy was 0.92%.

R. Tan et al, [19] proposed an ML model to classify mineral deposits using sphalerite chemistry and associated mineral assemblages. The model utilizes sphalerite trace-element chemistry (12 elements) and associated minerals assemblages (15 minerals) collected from 3159 sphalerite analyses across 109 ore deposits worldwide. Mineral assemblage data are parameterized as binary (0 for absence, 1 for presence). The study employs a composite ML model consisting of two sub-models: Random Forest (RF) for trace-element data and Extra Random Trees (ERT) for minerals assemblage data, and the SHAP method for feature importance. The composite model achieved a high accuracy of $85 \pm 1.4\%$ and an AUC of 0.93 ± 0.01 . M. Radulescu et al., [20] demonstrated the application of quantized deep learning, specifically using the popular EfficientDet architecture, in the context of mineral identification during mining. The authors propose a post-training quantization method for the EfficientDet model that reduces its size and complexity while maintaining performance. Using a custom minerals dataset, the quantization was tested using 8-bit symmetric quantization, and the effectiveness of the model was

assessed by contrasting the quantized version with the original floating-point model. On the given dataset, the pre-trained EfficientDet model showed a precision of 0.78 and a recall of 0.65. The quantized model, on the other hand, demonstrated a notable improvement, attaining 0.80 recall and 0.88 accuracy. The accuracy of the suggested model was a remarkable 90.5%.

The use of AI for minerals exploration and geostatistical modeling has advanced significantly, according to an analysis of earlier research. Many works have used AI and machine learning to efficiently predict and assess mineral resources across a variety of datasets and geographical regions. These studies have explored single-element analysis as well as multi-element datasets, with some utilizing geospatial imagery for geological surveys.

According to the analytical review of prior studies, the majority of them concentrated on a single rare mineral or a small number of them, using some models, such as CNN, RF, and SVM, to predict mineral occurrences and classify deposits. In addition, some studies used geospatial data in geochemical exploration with imagery to predict multi-element concentrations or mineralization potential.

However, the gap lies in the limited geographical scope and mineral diversity in existing studies. In contrast, the current study addresses rare gaps by analyzing ten essential and strategic minerals across various regions in the KSA. This is one of the first studies to cover such a broad spectrum of rare minerals, with a geospatial analysis considering latitude and longitude coordinates for the different regions in KSA.

III. METHODOLOGY

In the Method section, the dataset from the Saudi Geological Survey (SGS) includes detailed geochemical information on rare minerals such as lithium and rubidium. It also contains trace metal concentrations in collected rock samples. The method begins with data collection and analysis of rock samples from ten different regions of Saudi Arabia. The dataset is preprocessed to normalize values and address nulls or missing data. It is then split for training and validation, taking into account factors such as longitude and latitude. ML models, including Graph Neural Network (GNN), XGBOOST, RF, and K-Means Cluster, are used to predict mineral presence and analyze regional trends. Fig. 1 shows the overview of the steps and proposal models in predicting the rare mineral concentrations in KSA. After data preprocessing and threshold-based labeling, three complementary learning strategies are applied in parallel. A GNN captures spatial dependencies through graph-based learning, ensemble models provide robust tabular classification baselines, and clustering identifies mineral-rich zones in an unsupervised manner. The combined outputs support spatial interpretation and decision-making in mineral exploration. Nodes represent sampling locations, while elemental concentrations are treated as node features.

Fig. 1. The overall workflow of the proposed geochemical mineral prediction framework.

A. Data Description

The dataset was collected from the SGS, which is responsible for all specialized earth technology paintings inside the Kingdom of Saudi Arabia [21].

From the simple work on geologic mapping to the conduct of applied geoscientific studies, especially on minerals and groundwater explorations, and the development of mineral sources, along with the provision of investment opportunities within the field of mining. The SGS serves as the primary source of scientific information in Saudi Arabia, providing technical reviews, geologic maps, mineral sources, and other relevant geologic statistics throughout the Kingdom.

The Geological Survey collects data on several minerals in various regions of the Kingdom of Saudi Arabia, then analyzes their composition and mineral concentrations within the rocks. In this study, data on rare minerals such as Lithium (Li), rubidium (Rb), cesium (Cs), beryllium (Be), tantalum (Ta), niobium (Nb), tin (Sn), and tungsten (W) were extracted for 10 regions of the Kingdom, as shown in Table I. Each region contains a set of rock samples with the percentage of each mineral identified.

TABLE. I. THE ROCK SAMPLES FOR ALL RARE MINERALS ARE IN SEVERAL REGIONS OF KSA.

Region	Number of mineral samples
Aban Al Ahmar	2,428
Nuqrah	2,550
Afif	2,451
Wadi Ar Rika	2,546
Al Hissu	2,519
Mahad Adh Dhahab	2,535
Al Muwayh	2,466
Zalim	2,295
Miskah	2,415
Wadi Ash Shubah	2,538
Total	24,743

B. Dataset Preprocessing

The longitude and latitude of each rock sample were recorded, along with the percentage and concentration of the mineral. For example, in a sample from the Aban al-Ahmar region, lithium (Li) represented 22.9 mg/kg, and Nb represented 5.33 mg/kg. Initially, only the eight rare elements were extracted, according to the recommendations of the Geoscience Authority, from a total of 64 mineral elements for all 10 regions. They were combined into a single CSV file with the longitude and latitude coordinates. All null values are removed. The rest of the values are normalized by Min-Max scaling. Avoid combining SI and CGS units, such as current in amperes and magnetic field in oersteds. This often leads to confusion because equations do not balance dimensionally. If you must use mixed units, clearly state the units for each quantity that you use in an equation.

1) *Define label (Target variable)*: Since the data on mineral elements has a rate of presence in rock samples, there are no binary labels. The data needs to define an explicit label as a target variable label for mineral presence.

The study proposed creating a proxy target based on known geochemical thresholds indicating the presence/absence of rare minerals. Define threshold-based labeling that identifies high concentrations of specific elements as indicators of mineralization, using the calculation of the arithmetic mean and standard deviation [22].

Mean represents the concentration of the data across all samples. The equation calculates the arithmetic mean in Eq. (1):

$$\text{Mean} = \frac{1}{N} \sum_{i=1}^N x_i \quad (1)$$

where, x_i is the value of the i -th sample, N is the number of samples.

The Standard Deviation (σ) represents the deviation of the data from the mean, or the spread of the data points around the mean [see Eq. (2)]:

$$\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2} \quad (2)$$

where, μ is the arithmetic mean and N is the number of samples. After that, determining the range using the standard deviation by Eq. (3) is as follows [23]:

$$\text{Range} = \mu + k\sigma \quad (3)$$

where, μ is the arithmetic mean, k is the constant related to the confidence level (usually 1, 2, or 3 standard deviations), and σ is the standard deviation.

After determining the range, identify the samples that contain high concentrations, indicating the presence of the element. If the value of the sample is greater than the upper limit of the range, it indicates that a specific element is present, and if it is less than the lower limit, then the element is absent. Table II shows the threshold value for each element and the threshold-based labeling for both values, existence = 1 and non-existence = 0, after comparing the rate of concentration with the threshold value for all samples.

TABLE. II. THE THRESHOLD VALUE FOR EACH ELEMENT AND THE THRESHOLD-BASED LABEL FOR ALL ELEMENTS ARE DETERMINED AFTER COMPARING THE RATE OF CONCENTRATION TO THE THRESHOLD VALUE.

Mineral	Threshold	Rate of existence Label=1	Rate of non-existence Label=0
Li	14.23	3,211	21,532
Rb	96.62	2,956	21,787
Cs	1.90	3,026	21,717
Be	2.22	2,153	22,590
Ta	1.01	1,843	22,900
Nb	14.58	1,796	22,947
Sn	2.99	1,150	23,593
W	1.79	123	24,620

C. Dataset Splitting for Training and Testing

The dataset consists of two classifications for each mineral: existence and non-existence. The 80% - 20% splitting method is applied to each category to create training and testing datasets. Specifically, 80% of the data is used for training the model, while 20% is used for testing. Table III provides a breakdown of the number of samples for each mineral in the dataset, split into training (80%) and testing (20%) sets. For example, for Li, there are 3,211 total samples of existence, split into 2,603 for training and 608 for testing.

D. Dataset Splitting for Training and Testing based on the Region

The data on existing minerals is defined for their regions. Ten regions in KSA are recorded with the concentration rate of minerals. In this study, there is a second scenario that conducts the classification based on the region, so the dataset is prepared by the addition of a column of regions as a label. The separation of the dataset into 70%, 15%, and 15% for training, validation, and testing sets based on the region is shown in Table IV, which presents the rate for each region, such as Afif and Al Hissu.

Fig. 2 refers to the correlation matrix for latitude, longitude, and the selected rare elements. The results provide weak indications of moderate correlations between geographical variables and element concentrations and show a moderate negative correlation of $R = -0.36$ with longitude and latitude.

Strong positive correlations between NB and TA with $R = 0.96$ and RB, Cs, and BE ($R = 0.62-0.78$) were seen, suggesting shared geochemical sources. In contrast, W showed weak correlations. The "region" variables showed a minimum effect on the distribution of the element, indicating limited spatial control over the geochemical pattern.

TABLE. III. SPLITTING THE DATASET 80%-20% FOR TRAINING AND TESTING SETS FOR EXISTENCE AND NON-EXISTENCE CLASSIFICATION.

Mineral	Rate of existence	(80% - 20%) splitting of existence	Rate of non-existence	(80% - 20%) splitting of non-existence
Li	3,211	2,603 - 608	21,532	17,191 - 4,341
Rb	2,956	2,367 - 589	21,787	17,427 - 4,360
Cs	3,026	2,446 - 580	21,717	17,348 - 4,369
Be	2,153	1,730 - 423	22,590	18,064 - 4,526
Ta	1,843	1499 - 344	22,900	18,295 - 4605
Nb	1,796	1455 - 341	22,947	18339 - 4608
Sn	1,150	930 - 220	23,593	18864 - 4729
W	123	105 - 18	24,620	19689 - 4931

TABLE. IV. SPLITTING THE DATASET 70%,15%,15% FOR TRAINING, VALIDATION, AND TESTING SETS BASED ON THE REGION OF EXISTENCE OF THE MINERAL.

The region	Training set (70%)	Validation test (15%)	Testing test (15%)
Aban_Al_Ahmar	1724	344	360
Afif	1745	345	361
Al_Hissu	1776	371	372
Al_Muwayh	1749	349	368
Mahad_Dhahab	1755	387	393
Miskah	1661	384	370
Nuqrah	1759	400	391
Wadi_Ar_Rika	1762	388	396
Wadi_Shubah	1810	375	350
Zalim	1577	368	350

E. The Artificial Intelligence Models

1) *GNN*: Record structure along with object entities known as nodes, which are connected through a manner of relationships referred to as edges [24]. Both the nodes and edges can maintain records inside the shape of attributes, any of which may also be additionally characteristic as variables in machine learning assessment.

There is more than one type of graph neural network. One commonly used variation of the GNN algorithm is the graph convolutional network, or GCN [25]. A GCN updates records on every node by aggregating facts from neighboring nodes using a weighted sum, with the weight relying on the number of nodes connected to the recipients [26].

In this study, nodes represent the geochemical sample points, each with associated features such as elemental concentrations. Edges define the relationships between nodes, which can be based on spatial proximity or geochemical similarity. The graph is constructed using spatial proximity as the defining criterion for edges. Specifically, nodes are connected if they fall within a defined radius (e.g., 5 km). This spatial-based adjacency matrix is created using the `radius_neighbors_graph` function from the `sklearn.neighbors` module, which helps determine the connectivity between sample points based on their geographical coordinates (longitude and latitude). Fig. 3 presents the subsampled visualization of the spatial graph. Nodes represent geochemical sampling locations, and edges indicate neighborhood connections within a predefined spatial radius. The subsampling is applied for visualization clarity, while the complete spatial graph is used during model training. For visualization purposes, only a subset of nodes and edges is displayed to avoid visual clutter; however, the full graph connectivity is preserved during training. The Adam optimizer with a learning rate of 0.01 trains the model, and the loss function is cross-entropy loss with 200 trained epochs.

Fig. 3. Subsampled visualization of the spatial graph.

All hyperparameters were selected empirically based on preliminary experiments and kept fixed across all reported results.

2) *XGBoost model*: XGBoost is a tree boosting system that can grow and use a lot of new methods and algorithms to get the best results. It makes machine learning tasks very scalable [27]. These methods deal with problems like learning trees that are close to the truth, working with sparse data, and doing math quickly with large datasets [28]. This algorithm adds a default direction to each tree node. If a feature value is missing from the sparse matrix, the instance is put into this default direction. The information is used to figure out the best default directions.

3) *Random forest model*: The random forest, as an ensemble learning approach, was developed to combine bagging with random feature selection [27]. It describes how it constructs decision trees using bootstrap sampling and applies randomization during node splitting, often using the Gini index for feature selection. Key advantages of RF include robustness to noise, resistance to overfitting, and high accuracy [29]. Over the past decade, research has focused on boosting RF's performance through various extensions. These include methods to determine the minimum number of trees, using multiple attribute evaluation measures and weighted voting, dynamic integration techniques, and weighted random sampling for feature selection.

4) *Ensemble bagging models*: The bagging method is also known as bootstrap aggregating [30]. This refers to creating many little ones from most of the data in the dataset itself. The goal of bagging is to create a more diverse future match model by adjusting a stochastic distribution of training data sets, where small changes in training data sets will make significant changes to predictions [31]. In bootstrapping, the training of the ensemble models on bootstrap replicates the training dataset.

5) *Unsupervised ML models (K-means clustering)*: In this study, we use K-means to generate the labels based on the regions that contain minerals and then compute the silhouette points for clustering. Unsupervised clustering was used for exploratory spatial analysis and then apply classification using the supervised learning models. K-means depends on the value of K, which must always be specified to analyze all clustering. Clusters with different K values will eventually produce different results [32]. Different scheme problems analyzed in recent studies did not consider the problem where the algorithm is only converted to a poor local minimum. An alternative approach was used to prevent the K-means algorithm from being easily affected by noise and external values.

F. Evaluation

Various commonly used assessment criteria, such as precision, accuracy, F1-score, and recall, are utilized to train and test the suggested models [33]. The specific mathematical definitions for each metric are as follows [see Eq. (4) to Eq. (7)]:

$$\text{Precision (Pre.)} = \frac{TP}{TP+FP} \quad (4)$$

$$\text{Recall/Sensitivity (Se.)} = \frac{TP}{TP+FN} \quad (5)$$

$$\text{Accuracy (Acc.)} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}} \quad (6)$$

$$\text{F1 - score (F1 - s.)} = \frac{2 * \text{Precision} * \text{Sensitivity}}{\text{Precision} + \text{Sensitivity}} \quad (7)$$

The silhouette score method, which is a measure of the quality of a cluster, was used to find the silhouette coefficient for all samples for different clusters [34], as in Eq. (8):

$$\text{Silhouette} = \frac{1}{N} \sum_{i=1}^N s(i) \quad (8)$$

where, N is the total number of data points, s(i) is the Silhouette Score for point i [see Eq. (9)]:

$$s(i) = \frac{b(i) - a(i)}{\max(a(i), b(i))} \quad (9)$$

where, a(i) is the cohesion of point i within its own cluster. In other words, it is the average distance between point i and all other points in the same cluster. b(i) is the separation of point i from the nearest cluster. It is the distance between point i and the closest centroid of any other cluster.

A confusion matrix is a determinant that is used to define the general performance of a set of performances. It represents counts from predicted and actual values. The output True Negative (TN) shows the quantity of negative samples classified correctly. Similarly, True Positive (TP) indicates the variety of effective samples classified successfully. False Positive (FP), the number of real negative samples classified as highly incorrect, and False Negative (FN), which is the form of real high-quality samples labelled as negative.

The precision-recall curve for the performance of a GNN model classification, in particular for binary classification tasks, will be used. The curve is derived from the precision recall curve feature from sklearn metrics, which calculates precision and recall for different threshold values of predicted probabilities.

G. Experimental Setup

The experiments were performed using an MSI GS66 laptop that has the following properties: an Intel Core i7 11800H (11800H) processor, 32 GB RAM, 2 TB SSD NVMe storage, and an RTX 3080 graphic card with 16 GB memory. The experiments mentioned in this article were performed using Python 3.10 on Windows 11.

IV. RESULTS

The primary findings from predicting the presence and distribution of rare mineral elements in various Saudi Arabian regions using various ML and AI models are presented in this section. The performance of these models is shown in the following scenarios, which start with GNN-based rare mineral prediction, move on to region-based classification using ML ensemble models, and conclude with an unsupervised learning method for locating mineral-rich clusters.

A. GNN Model to Predict the Existence of Mineral Elements

In this use case, a GNN was used to predict the existence of the rare mineral elements based on their concentrations in rock samples collected from different areas of Saudi Arabia. The

performance of the models was evaluated by the common classification measures such as accuracy, precision, recall, and F1 score. The GNN model produced very high accuracy for each of the rare mineral elements, with tungsten achieving the highest accuracy at 90.62%, as shown in Table V. However, there has been a variance in precision and recall. For example, lithium and tin had decreasing recall scores, indicating that the model missed some of their occurrences, whereas rubidium and niobium demonstrated a fair mix of precision and recall.

TABLE. V. PREDICTING THE PERFORMANCE OF THE EXISTENCE OF RARE MINERAL ELEMENTS USING A GNN MODEL.

Mineral	Accuracy	Precision	Recall	F1 Score
Li	85.08	68.31	64.42	66.09
Rb	86.41	71.19	72.34	72.82
Cs	86.11	71.40	68.07	69.70
Be	87.00	71.00	61.92	66.19
Ta	88.01	68.68	70.94	69.80
Nb	88.33	72.57	70.18	71.36
Sn	88.49	71.77	48.27	58.02
W	90.62	47.06	44.44	45.71

The findings verified that Li had an 85.08% accuracy rate, meaning the model performed well in predicting whether lithium would be present in the rock samples. Nevertheless, the recall only reached 64.42%, indicating that some lithium cases were missed by the model. The Rb element, on the other hand, had a moderate balance between accuracy and recall, as indicated by its F1 score of 72.82% in Table V. This proves that there are few false positives or false negatives and that the model is successful in identifying samples that contain rubidium.

As a common assessment of the GNN model, it achieved robust results in predicting the presence of mineral elements based on geochemical records, especially in terms of overall accuracy. However, further development is needed to address the recall issues of specific minerals, such as tin and tungsten, by using more samples or applying data augmentation, which would improve the overall performance of the model.

Fig. 4 includes multiple precision-recall curves (one for each class or feature), indicated by the labels Nb, Sn, W, etc. Each subplot visualizes the relationship between precision and recalls for a different variable or class in the dataset: Nb, Sn, W, etc., likely represent different categories or features in the data, showing how well the model performs across multiple aspects of the classification task. The variations between subplots might suggest that some classes (like W) have a poorer precision-recall trade-off, indicating possible issues with the model's ability to classify those instances accurately. Conversely, classes like Nb and Sn might show better balance, where precision and recall are relatively stable.

Fig. 4. The precision-recall curve of the GNN model for all the mental rare elements prediction.

The GeoPandas library in Python was used to load and plot a geographic map of Saudi Arabia from a Shapefile, which was downloaded from the Natural Earth website (<https://www.Naturalearthdata.Com/downloads/10m-cultural-vectors>).

Once the map is plotted, the attention of elements is concentrated by extracting the coordinates of longitude and latitude from the data, as shown in Fig. 5(a). The heatmap generated using Folium visualizes the geographic distribution of

the data points based on their latitude and longitude values, as shown in Fig. 5(b).

The intense red areas suggest areas with an excessive concentration of data points, even as the cooler blue tones constitute areas with fewer occurrences. This visualization gives a clean evaluation of spatial styles, highlighting areas of extensive pastime or interest. The significant area, as shown, features a high density of elements, which may also correspond to a key location of attention in the dataset. Whilst Fig. 5(c) focuses on the centration for the Aban Alahmer region.

Fig. 5. A high-density concentration of element features in different regions: (a) KSA map, (b) all ten regions, and (c) Aban Alahmer.

B. The Performance Results of AI Ensemble Models to Classify based on the Region in KSA

In this use case, the regional-based classification performance results, the ML and ensemble models have shown remarkable accuracy and efficiency. Table VI presents the performance of three ML models used for region-based classification.

TABLE VI. THE PERFORMANCE RESULT OF THE ML AND ENSEMBLE MODELS IN PREDICTING BASED ON REGION CLASSIFICATION.

Model	Accuracy	Precision	Recall	F1 Score
Xgboost	90.25	90.23	90.25	90.24
RF	89.90	89.93	89.89	89.90
BaggingClassifier	90.62	90.63	90.64	90.62

The XGBOOST model achieved an accuracy of 90.25%, a precision of 90.23%, a recall of 90.25%, and an F1 score of 90.24%. The model also performed an AUC score of 90.58%, indicating a strong ability to distinguish between different classes.

For the RF model, the model achieved an accuracy of 89.90%, a precision of 89.93%, a recall of 89.89%, and an F1 score of 89.90%. While the AUC point for RF was 90.39%, which indicates its specific performance in classification functions. However, BaggingClassifier improved both XGBOOST and RF when it comes to all performance matrices. It achieved the highest accuracy of 90.62%, with the precision, recall, and F1 scores of 90.63%, 90.64%, and 90.62%,

respectively. The bagging classifier also achieved the highest AUC point of 90.69% and strengthened its position as the most effective model compared to the others.

Fig. 6 provides the confusion matrix for the three proposed models and shows the classification performance visually. Matrices indicate real positivity, false positivity, real negativity, and the number of false negatives for each class. This visual representation confirms the high classification accuracy of the model, especially in identifying the regional classes in KSA correctly. Overall, these results show the strength and reliability of the proposed model, with a bagging classifier that appears to be the most effective model for regional classification functions in KSA.

Fig. 6. The confusion matrix of the ML and ensemble models in predicting based on region classification.

C. The Performance Results of the Unsupervised AI Models

In this use case, the K-Means unsupervised learning algorithm was applied to generate rare minerals resource regions in the KSA with a cluster $k=10$ based on the values classified in the second scenario. The elbow library was used to determine the optimal number of clusters (k). The relationship between the number of clusters (K) and the associated inertia values is plotted in Fig. 7(a). The elbow point is three, the point at which the curve starts to slope.

It selected $K=10$ for this investigation because it showed a sufficient reduction in inertia while maintaining significant data point groupings. Based on the information from Scenario 2, this value of K was then used to categorize the KSA's rare mineral resource regions. To identify and target areas of interest for resource extraction or conservation, the clusters created with $K=10$ offer clear groupings.

The results of the cluster technique appear to be fairly good; however, it didn't achieve an optimal score. Based on a Silhouette score of 0.385, the clusters show some separation, but there are areas of overlap of some degree or errors in the calculations. Nevertheless, the results indicate an average clustering quality rating for the first training.

In Fig. 7(b), the T-SNE visualization displays the outcomes of clustering with $K = 10$. Each cluster is represented by a distinct color. Examining the distribution of data points across

various clusters is made simpler by the scatter plot's use of two components (TSNE-1 and TSNE-2) to reduce the original data values and display them in 2D space.

Table VII presents the performance metrics of the proposed models of ML and ensemble in predicting region classifications and representing the K-means clustering results. The XGBoost model recorded an accuracy of 90.25% and an F1 score of 90.24%. The AUC value of 90.58% further signifies the model's ability to distinguish between different classes effectively.

The RF model also performs strongly with an accuracy and recall of 89.90% and 89.89%. However, its AUC score of 90.39% indicates good discriminatory power. The Bagging Classifier outperforms the other two models, achieving the highest accuracy and F1 score among the three with 90.62%. The AUC score of 90.69% indicates that this model has the best ability to correctly classify the different regions.

TABLE. VII. THE PERFORMANCE RESULT OF THE ML AND ENSEMBLE MODELS IN PREDICTING BASED ON REGION CLASSIFICATION AND REPRESENTATION OF THE K-MEANS CLUSTERING.

Model	Accuracy	Precision	Recall	F1 Score
Xgboost	90.25	90.23	90.25	90.24
RF	89.90	89.93	89.89	89.90
BaggingClassifier	90.62	90.63	90.64	90.62

V. DISCUSSION

The results obtained in this study demonstrate the effectiveness of integrating graph-based deep learning with ensemble methods for mineral prospectivity mapping in Saudi Arabia. This section interprets the key findings, discusses their implications, and situates them within the broader context of related literature.

A. GNN Performance and Spatial Learning

The GNN model achieved competitive classification accuracy across all eight rare mineral elements, with tungsten (W) reaching the highest accuracy at 90.62% and lithium (Li) at 85.08%. These results confirm that modeling geochemical sampling locations as a spatial graph, where edges encode geographic proximity, enables the network to exploit spatial dependencies that are invisible to conventional tabular classifiers. However, the recall limitations observed for tin (Sn, 48.27%) and tungsten (W, 44.44%) suggest that class imbalance in the geochemical dataset remains a challenge. These elements have fewer confirmed occurrences in the sampled regions, which reduces the model's ability to identify all positive cases. Future work could address this through data augmentation strategies or oversampling techniques such as SMOTE, as is effective in similar geoscience classification tasks.

B. Ensemble Models and Regional Classification

In the region-based classification scenario, all three ensemble models, XGBoost, Random Forest, and BaggingClassifier, achieved accuracies exceeding 89.9%, with BaggingClassifier performing best at 90.62%. This strong performance across all metrics (precision, recall, F1, and AUC) indicates that the regional geochemical signatures in the SGS dataset are sufficiently discriminative for automated classification.

Ensemble models match or slightly outperform the GNN in regional classification, as this task depends more on feature distributions than spatial relationships. This highlights their complementary strengths: GNNs excel with spatial structure,

while ensemble methods remain highly effective for tabular data.

C. Evaluation of Comparisons Related to Recent Research Results

This section compares the performance of various AI algorithms applied to different metasearch exploration datasets, as shown in Table VIII. Studies have utilized a wide range of data sources, including time series from gold processing plants, remote sensing data for copper ore, and geological datasets from multiple regions such as China, Pakistan, and Saudi Arabia.

TABLE. VIII. COMPARISON OF PREVIOUS STUDIES RELATED TO MINERAL RESOURCE PREDICTION.

Reference	Dataset used	AI models	Performance
[10]	Data from a gold processing plant (236 days, time series data)	LSTM, GRU, CNN	CNN: RMSE 36%, MAE 45%, MAPE 35%
[11]	Remote sensing data for copper ore in North Waziristan, Pakistan	CNN, RF, SVM	CNN: High accuracy, RF: AUC > 0.95
[13]	Geological data from Jiangxi Province, China	CNN	CNN: 92.38% accuracy, RF: 87.62%
[12]	Geological data for regions in Saudi Arabia	Random Forest	95.8% accuracy in predicting mineral presence
[15]	Multivariate geochemical data from Canada	ML (various algorithms)	Prediction of elemental concentrations using legacy data
[16]	Small dataset of sintering data for W(Mo) alloys	Lasso Regression, k-NN, Random Forest, MLP	High prediction accuracy for sintered density ($R > 0.950$)
Current study	Saudi Geological Survey (SGS)	GNN and Ensemble bagging models	90.62 for W mineral, and 90.69%

D. Limitations and Future Work

Despite the promising results, several limitations should be acknowledged. First, the dataset is limited to ten regions and may not generalize to unexplored areas of KSA with different geological characteristics. Second, the GNN's recall performance for certain elements indicates room for improvement, particularly through more balanced training data. Third, the current graph construction relies solely on geographic proximity; future work could explore incorporating geological similarity or geochemical correlation as additional edge-weighting criteria to further enhance the spatial representation. Extending the framework to incorporate remote sensing data, 3D geological models, and modern models such as federated learning [35].

VI. CONCLUSION

In the provided study, AI techniques were effectively leveraged to predict the presence of rare minerals in rock samples from the KSA. ML models, such as GNN, XGBoost, RF, and ensemble bagging models, analyze geochemical data from more than 24,000 samples in many regions in KSA. This study showed the feasibility of applying AI for the exploration of rare minerals and resource management in geological investigations containing mineral concentration data.

The performance recorded improved prediction results in all models, especially with the ensemble bagging classifier, which improved others with an outstanding accuracy of 90.62%. GNN models, while strong in general accuracy, showed the significance of fine-tuning recall values, particularly for elements like tin and tungsten, to improve the model's accuracy.

These outcomes demonstrated how well the ML model performs in handling intricate geospatial difficulties and forecasting the existence of valuable minerals using geochemical signatures. Furthermore, the regional distribution patterns of rare minerals were shown by the unsupervised approach using the K-means clustering model. The ability to identify mineral-rich regions was recorded by the k-means, providing a tool for possible resource extraction or conservation initiatives. Cluster results showed how unsupervised models can locate mineral-rich regions and provide a tool for possible resource extraction or conservation initiatives.

ACKNOWLEDGMENT

The authors would like to acknowledge the General Authority for Defense Development (GADD) in Saudi Arabia for funding the research through project number (GADD_2026_24_449).

The authors further acknowledge the Regional Geological Survey Program (RGP) and the Saudi Geological Survey (SGS).

Abstract—Emotions strongly influence how people think, decide, and perform, making reliable emotion forecasting essential in performance-critical environments. Traditional methods such as facial expressions, speech, and self-reports often lack reliability and continuity. Physiological signals offer a more objective alternative, providing continuous indicators of emotional states, while deep learning models are well-suited to capturing their non-linear temporal characteristics. Unlike prior reviews that primarily focus on general emotion recognition or isolated model performance, this study specifically examines emotion prediction in performance-critical contexts through the combined analysis of physiological signals, deep learning architectures, and task-driven requirements. This systematic review synthesizes recent studies on emotion prediction using physiological data and deep learning models. Following the PRISMA framework, relevant studies published between 2021 and 2025 were identified from the Dimensions AI and Web of Science databases, resulting in 25 eligible articles. The review examines trends in physiological modalities, deep learning architecture, emotion representations, and evaluation practices. Beyond summarizing these trends, the review provides a structured comparative synthesis that organizes existing studies according to physiological signal modality, model architecture, performance-critical task context, emotion representation, and evaluation practices, thereby offering methodological guidance for future emotion prediction system design. Findings show that EEG is the most widely used modality, frequently combined with peripheral signals such as heart rate variability, electrodermal activity and electrocardiography in multimodal systems. Hybrid architectures, particularly CNN-LSTM models, dominate current approaches, although attention-based and lightweight models are gaining traction. Key challenges remain, including inter-subject variability, limited real-world validity, inconsistent emotion modeling and non-standardized evaluation. This review highlights current gaps and offers guidance for developing more robust emotion prediction systems in high-performance contexts.

Keywords—Emotion prediction; physiological signals; deep learning; multimodal fusion; performance-critical tasks

I. INTRODUCTION

The ability to automatically identify a person's emotion is an important development towards building emotionally intelligent systems that are being used increasingly in applications including healthcare, HCI and education [1, 2]. Emotion plays a role in cognition, decision-making and performance on tasks in high-pressure situations such as elite athletics, aviation and military operations [1]. Emotion recognition has traditionally been achieved using subjective measures, including facial expression, voice inflection and textual communication; the subjectivity of these measures can be influenced by the surrounding environment [4], making emotion recognition difficult with respect to privacy (e.g., lack of consent, recordings). For this reason, most current research focuses on collecting and analyzing physiological signals, as they provide reliable and unambiguous representation of emotion based on physiological response.

Physiological signals, such as electroencephalography (EEG), electrodermal activity (EDA), variability in heart rate (HRV) and temperature of the skin (ST), provide excellent opportunities to continuously and understandably monitor emotional reactions in daily life through physiological measures. However, they also create significant challenges for analytical processing due to their high dimensionality and non-linearity. Using deep learning models such as convolutional neural networks (CNNs), long short-term memory (LSTM) networks and hybrid architectures is a new way to robustly extract spatio-temporal features from physiological signals. Compared to traditional machine learning algorithms, deep learning models yield improved results for processing physiological signals; therefore, they can be used more effectively than traditional methods [2, 4]. There are still many constraints on current performance-sensitive task research despite recent improvements. It is often difficult for researchers to repeat results between subjects and what succeeds in a controlled setting might not transfer to a real-world scenario depending on an individual's cognitive load, stress level and other elements that can affect the final results [5, 6]. Even

*Corresponding author.

though multimodal fusion has been suggested and tested through the use of attention methods to increase robustness, this type of research has not made much headway beyond the use of benchmark datasets or task environments [7].

Furthermore, these limitations in study design extend to studies of cognitive load exactly as they relate to use cases in a true performance-critical environment. Despite the models being able to achieve high levels of accuracy in controlled laboratory settings, they tend to fall short when it comes to generalizing their results to individuals in a new context, for example, an environment, under different task conditions, such as cognitive load, stress, time pressure, or when dealing with different types of emotions [5, 6]. Multimodal fusion and attention mechanisms, though useful, have primarily been examined through their use on 'standardized' datasets rather than through their application across real-world contexts in which tasks are performed [7].

In recent years, research in emotion prediction using psychological signals has grown significantly, reflecting increased interest in developing more robust and adaptive systems. However, existing studies often focus on isolated aspects such as model performance or specific signal modalities, without providing a comprehensive synthesis that integrates physiological characteristics, deep learning architectures, and contextual requirements of performance-critical tasks. Furthermore, current review studies tend to address emotion recognition in general settings, with limited emphasis on performance-critical environments where cognitive load, stress, and real-time constraints play a decisive role. This creates a gap in understanding how physiological signals and deep learning models can be effectively aligned with task-specific demands in such high-stakes contexts.

To address this gap, this systematic review critically examines recent literature published between 2021 and 2025 on emotion prediction using physiological signals and deep learning models in performance-critical tasks. In contrast to prior surveys that mainly provide broad overviews of affective computing or general emotion recognition, this review offers a structured analytical contribution through a task-oriented and signal-centric comparative synthesis. Specifically, it organizes the literature across five core dimensions: physiological signal modality, deep learning architecture, multimodal fusion strategy, emotion representation, and evaluation practices in performance-critical settings. This framework enables a clearer comparison of how methodological choices relate to real-world task demands and supports the formulation of methodological guidance for future research. By providing a task-oriented and signal-centric synthesis of existing studies, this review aims to bridge the gap between laboratory-based emotion prediction models and real-world performance-critical applications, while contributing a structured comparative framework for interpreting methodological trends, limitations, and future research directions in emotion prediction systems. Specifically, this review is guided by the following research questions:

RQ1: What types of physiological signals and their representations are used for emotion prediction and what deep learning architectures and multimodal fusion strategies are adopted in performance-critical context tasks?

RQ2: Which deep learning architectures and multimodal fusion strategies are adopted for emotion prediction in performance-critical contexts?

RQ3: How are emotion prediction models evaluated in terms of performance metrics, validation practices and emotion representation schemes and what are the implications for model generalization?

RQ4: What are the key methodological limitations and research gaps hinder the development of robust and deployable emotion prediction systems in real-world performance-critical environments?

By providing a task-oriented and signal-centric synthesis of existing studies, this review aims to bridge the gap between high-performance laboratory models and real-world performance-critical applications, while contributing a structured comparative framework for interpreting methodological trends, limitations, and future design directions in emotion prediction systems.

This study is structured as follows: Section II presents a comprehensive literature review on emotion prediction in performance-critical tasks. Section III describes the systematic review methodology, including the search strategy, selection criteria, and data extraction process. Section IV discusses the findings and synthesis of the reviewed studies, highlighting trends, challenges, and research gaps. Section V presents the cross-domain perspectives. Finally, Section VI concludes the study and outlines directions for future research.

II. LITERATURE REVIEW

A. Emotion in Performance-Critical Tasks

Performance-critical tasks require individuals to operate under high cognitive load, time pressure, or competitive conditions and emotional states play a major role in the execution of these tasks, as they hold a big influence over the individuals' cognitive abilities, such as attention, decision-making, motor control and overall task effectiveness. Emotion is a key factor that affects performance-heavy tasks, which involve a great deal of sustained focus and emotional regulation. Thus, to improve performance monitoring and adapt intervention strategies, it is crucial to first understand how emotional states fluctuate.

Research indicates that identifying emotions quickly and accurately not only aids in improving someone's psychological health but is also necessary for improving performance, promoting safety and reducing human error when completing the task [4].

The modern world of affective computing has shifted from reading emotional states through traditional behavioral cues to physiological biomarkers. This is because the biomarkers offer more objective, continuous and tamper-resistant indicators [2]. In studies like that of the WESAD dataset, utilization shows that wearable IoT-based sensors paved the way to monitor biosignals such as electrodermal activity (EDA), heart rate variability (HRV), electrocardiography (ECG) and skin temperature in real time, even while performing dynamic tasks [8,9]. These signals are valuable, as they reflect autonomic nervous system activity,

which is closely tied to stress, cognitive load and emotional regulation under pressure.

Even so, the work of translating physiological emotion recognition from a wellness-oriented setting to a performance-critical setting is still insufficient. Though the multilevel deep neural network proposed in the abstract and other models as such demonstrate strong classification performance in lab-based benchmarks (achieving up to 87.7% accuracy on WESAD), they cannot guarantee their robustness in valid, task-driven environments [8]. The characteristics of performance-critical tasks introduce variables such as physical movement, environmental noise, interpersonal interaction and variable cognitive demands. These factors can greatly affect the quality of the signal and model generalizability [5].

Moreover, literature that can be found often focuses on the innate emotion categories, like stress and baseline, rather than the finer emotional states, such as frustration, flow and anxiety, which are much more relevant to performance contexts. There is also an undeniable gap in studies that validate emotion recognition models in real-world performance scenarios, where ground truth emotional labels are difficult to procure and the consequences of misclassification are high [6].

Emotional dynamics play a big role in affecting the performance of individuals as they execute performance-critical tasks, but it also conquers the realm by shaping adaptive behaviors, an individual's learning efficiency and the development of long-term skills. Emotions are constantly changing regardless of the activity, whether elite sports, military drills, or complicated human-machine interactions, because they evolve with changing task difficulty, type of feedback and environmental stressors. All this happens because temporal emotional transitions are closely linked to the consistency of performance and resilience under pressure rather than static emotional labels. Therefore, it would be more effective to predict emotions for such tasks using models that truly have the capabilities to provide the signals of rapid emotional fluctuations and contextual dependencies that happen during the execution of the task, instead of relying solely on snapshots for emotion assessments.

B. Physiological Signals for Emotion Prediction

Electrophysiological monitoring, specifically electroencephalography (EEG), is mainly used to examine the relationship between emotional states and performance outcomes in performance-critical tasks, as it provides a clear and direct insight into cortical activity. As studied in prior research, competitive environments can significantly influence cortical efficiency, which includes attention, emotional regulation and cognitive workload. It was shown that expert performers exhibit much more efficient neural processing compared to novices [10]. However, electrophysiological monitoring remains difficult due to its susceptibility to many factors, like environmental noise, motion artifacts and inter-subject variability. Over the last few years, there have been promises of improving the accuracy of reading emotions using an electroencephalogram (EEG), particularly for precision sports such as shooting. These new technologies allow us to encode and represent signals more accurately, particularly through sparse coding and time-frequency transformations [11].

Besides cortical emissions from the brain, other psychophysiological indicators (e.g., heart rate variability, or HRV) can also offer insight into emotional regulation, stress resilience and the autonomic balance of the body. Many studies have shown strong correlations between HRV profiles and emotional regulation strategies. Some of these studies have found that greater levels of HRV are generally associated with increased ability to maintain sustained focus when under duress [12]. Therefore, HRV acts as a prominent peripheral indicator in a high-performance context by measuring autonomic nervous system activity associated with an emotion (stress or cognitive load). Also, HRV measurements can easily complement EEG assessments of an individual's emotional state.

Continuous and non-invasive methods of measuring physiological signals, including heart rate variability (HRV), skin temperature and electrodermal activity, have been made possible by the rapidly growing field of wearable technology. These physiological parameters provide valuable insights into emotional arousal, especially in dynamic or stressful situations [9]. The integration of these signals is critical for environments that are high-stakes, as emotional reactions change quickly based on other factors such as stress, movement and changing environmental conditions.

Individuals can develop interoceptive awareness by recognizing their internal body signals, such as breathing and heart rate. Recently, studies have explored interoceptive awareness in high-performance athletes. Research indicates that higher interoceptive awareness leads to improved emotional regulation and consistent performance in precision sports. Therefore, interoceptive awareness allows athletes to maintain physiological equilibrium when under pressure [13]. Environmental or situational disruptions can easily interfere with interoceptive awareness, which will affect emotional stability and reduce performance in the given task [14].

Overall, studies have shown a spotlight on the value of combining central and peripheral physiological signals because it shows a more comprehensive assessment of emotional states during performance-critical tasks. Nevertheless, the major challenges remain, which are variability in signal quality, acquisition conditions and contextual influences. Thus, these limitations prove the need for robust modelling approaches that can handle multimodal physiological data under dynamic and ecologically valid conditions. Therefore, the following section will discuss the initiative of adopting advanced deep learning techniques.

C. Deep Learning Approach for Emotion Prediction

Deep learning has greatly changed emotion recognition, as it enables the automatic extraction of high-level domain-invariant feature representations directly from physiological data, such as electroencephalogram (EEG) signals [15]. Its reliance on "hand-crafted" features, such as time, frequency and non-linear analysis, makes traditional machine learning (ML) deemed inefficient because it is low-level, redundant and requires extensive professional expertise to design. The DL model, however, learns modality-specific representations through deep layers, so it effectively sustains performance even when faced with complex and non-stationary input data.

Due to its capability, recent studies have shown that it has increasingly adopted deep learning architectures tailored to the temporal and non-stationary nature of physiological signals. Recurrent neural networks (RNNs), including Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) models, are widely used due to their effectiveness in capturing sequential dependencies and temporal dynamics in emotion-related physiological data. These are particularly suitable for performance-critical tasks as emotional states evolve continuously in response to task difficulty, cognitive load and environmental stressors.

The results from [16] showed that GRU-based RNN models can adequately classify EEG signals acquired while the subject completed an interactive, serious-game activity across various levels of mental stress. The results support the theory that modelling temporal structures in EEG data (as opposed to relying exclusively on static feature representations) is critical when classifying the state of mind within interactive and task-focused environments. This matches closely to how performance-critical situations occur due to dynamic rather than passive induction of emotion.

An alternative example provided by [17] used hybrid deep learning models such as long short-term memory (LSTM), gated recurrent unit (GRU) and one-dimensional convolutional neural network (1D-CNN) to process remote photoplethysmography (rPPG) data to detect stress with an overall accuracy of 95.83%. Additionally, this study conducted a comprehensive evaluation of the effectiveness of hybrid models, specifically designed to utilize temporal modelling and feature extraction, demonstrating that signal transformation to the frequency domain yields superior results. As demonstrated in both studies, there exists a degree of physiological variability among subjects. Therefore, both studies encountered difficulties in generalizing their findings across different subjects. The resulting recommendations to utilize subject-specific or adaptive models are aimed at producing stable and robust models for use in real-world applications. These studies highlight the use of deep learning to leverage both temporal dynamics and spectral information to predict emotions accurately.

Additionally, [18] presented an optimized one-dimensional convolutional neural network (1D-CNN) framework for emotion detection based on electroencephalography (EEG). This includes channel and feature selection strategies along with graph-based empirical mode decomposition (EMD) data augmentation. The study achieved mean accuracy rates of 97.6%, 95.3% and 89.0% for the MAHNOB-HCI, SEED and DEAP datasets, respectively. These results confirm that lightweight 1D-CNN architectures can produce excellent results with a reduced computational cost by selectively employing channels and refining features. In [19], the authors took a step beyond unimodal physiological data by developing a deep learning multimodal framework that fused text, audio and video modalities to predict psychological states. The authors' hybrids of BERT and CNN and BERT and LSTM (Long Short-Term Memory) produced accuracies of up to 89.3%. This further illustrates the benefit of fusing multiple modalities with transfer learning to provide a comprehensive representation of emotional states.

Recognizing that physiological and behavioral responses vary from person to person makes it important to keep in mind that there's difficulty in creating generalizations via models. Thus, advocating for subject-specific or adaptive rather than generalized modelling strategies provides potential with respect to improving stability in real-world applications. Taken together, these strategies demonstrate the ability of deep learning to utilize temporal dynamics, spectral features, optimally designed architecture and multimodal integration for accurate contextually aware emotion prediction. Future research should be directed toward improving the interpretability of the model, addressing data limitations through realistic augmentation and ensuring ethical delivery in sensitive mental health settings.

D. Emotion Prediction in Performance-Critical Context

Emotion prediction will have completely different outcomes when predicting an emotion in a performance-critical versus a standard affective computing environment. This is because emotional responses are tightly knitted with task demands, cognitive workload and time pressure. In such environments, physiological changes may reflect any other processes or factors that overlapped. For instance, emotional arousal, mental stress, fatigue and attentional shifts. The addition of such factors creates a challenge to isolate emotion-specific patterns without task-aware modeling. There have been EEG-based studies that show deep learning can learn discriminative representations when given complex physiological inputs. However, the interpretation and stability of those representations can vary across tasks and individuals, as they are all different [20].

A key characteristic of performance-critical contexts is that emotional states evolve dynamically during ongoing task execution rather than being elicited through static stimuli. Thus, task-driven protocols were used to model the dynamics using deep learning to induce graded stress and performance pressure. For example, the recent study in the IEEE Journal of Biomedical and Health Informatics employed EEG data collected within a serious game and used a GRU-based recurrent architecture to estimate the multilevel stress. This supports the view that temporal modeling is important as emotional states fluctuate as task engagement happens [16]. However, ecological validity remains a persistent challenge. This is because many models report strong performance under controlled acquisition conditions, yet performance-critical settings introduce movement artifacts, environmental noise, interpersonal interaction and unpredictable task progression that can degrade signal quality and reduce generalizability of the signals. Thus, it encourages the use of multimodal physiological sensing, in which combining central and peripheral signals can provide complementary evidence to improve its stability or robustness. Recent work has proposed fusion-based multimodal emotion recognition approaches, including EEG and ECG integration, to polish emotion classification performance and capture multidimensional affective states in a more comprehensive manner [3].

In addition to multi-mode representations, there is a rising interest in more sophisticated multi-modal fusion techniques for representing relationships among the various modalities. For instance, [21] recently proposed a method for recognizing

emotion in time series of multimodal data via online multimodal hypergraph learning. They mirror the increasing focus on systems that accommodate complex cross-modal dependence as opposed to simply appending data together or utilizing late fusion alone. An additional issue is that emotions are presented and evaluated in different ways. Hence, performing cross-study comparisons becomes very complicated. Examples of differences included discrete to dimensional emotion categories and differentiating between stress from baseline classifications. This limitation is closely linked to heterogeneous metric reporting and validation design in which accuracy-only reporting may obscure class imbalance and overstate model readiness for real-world use. Recent studies of multimodal EEG-based emotion detection have also noted difficulties in the design of fusing signals from different modalities, defining how sensor modalities will represent emotions and creating ways of classifying signals into specific emotion categories. In addition to these issues, they have further reinforced the need for more standardized evaluation metrics and reporting procedures in this area [22].

In summary, physiological responses are greatly dependent on the individual and context-dependent as well. The new work being done on using neurophysiological workload recognition is particularly relevant to this type of work in emotion prediction in constantly changing task environments. It reflects a direction that is highly relevant to emotion prediction in dynamic operational settings where task conditions change over time [23].

For the effective prediction of emotion in performance-critical contexts, we must develop standardized benchmarks, subject-independent validation and interpretable model designs with the potential to be deployed in high-stakes settings. The synthesis and gaps identified in this review correspond directly to those three factors.

III. METHODOLOGY

A. Methodology Used

This research adhered to the PRISMA guidelines during the research process to uphold transparency within the research while also enabling methodological rigor. While prior surveys in affective computing and emotion recognition have broadly examined emotion detection techniques and model performance, they often emphasize general-purpose settings without explicitly considering performance-critical environments. In contrast, this review adopts a task-oriented and context-driven approach by focusing on studies that integrate physiological signals, deep learning architectures, and real-world performance demands. This distinction enables the present review to advance beyond existing surveys by aligning methodological evaluation with performance-critical task requirements. The literature search was carried out on two large-scale databases: Dimensions AI and WoS. These databases were selected because they provide extensive coverage of peer-reviewed academic journals from a variety of fields, including AI, affective computing, neuroscience and performance analytics.

Fig. 1 illustrates the citation trend of articles from 2016 to 2025, showing a consistent increase in both total citations and

average citation counts. This trend reflects growing research interest and reinforces the need for a comprehensive systematic review.

Fig. 1. The citation rate of articles.

The original research journal articles were searched for and published between Jan 2021 and Dec 2025 in order to reflect up-to-date research on physiological signal processing techniques using deep learning to predict emotion, but also to ensure the research is still in line with current methodology. The overall database search and screening process is summarized using a PRISMA flow diagram, as presented in Fig. 2.

B. Study Selection

The study selection process followed the PRISMA-recommended multiple-stage screening process. All obtained records from Dimensions AI and Web of Science were searched and ranked before screening through to establish their relevance to the review objectives. The first step in this process was screening titles, during which obviously irrelevant studies such as those unrelated to emotion prediction, physiological signals, or performance-related tasks were excluded. The second stage consisted of screening abstracts in order to make stated or implied conclusions about each article's use of physiological data, machine learning and deep learning for emotion prediction. If an article did not meet these criteria, it was excluded as well.

Once the group of articles from stage 2 was established, the last step involved conducting full-text reviews of the remaining articles in order to determine whether they contained the required information:

1) *Physiological signals*: The study must involve physiological data such as EEG, HRV, ECG, EDA, or GSR. Studies relying solely on facial expressions, speech, or self-report data were excluded.

2) *Deep learning models*: The study must apply deep learning techniques, including LSTM, CNN, GRU, hybrid architectures, or transformer-based models. Studies using only traditional machine learning models (e.g., SVM, k-NN) without deep learning were excluded.

3) *Performance or task context*: Research must take place in a context directly related to performance or tasks. This includes, but is not limited to, performance in a sport, evaluating workload, completing tasks that result in stress, completing tasks where, for example, participants are under time pressure, as well as competing against other individuals or

groups to accomplish actual tasks that are routinely completed in a work environment.

Studies were excluded if physiological signals were not used for prediction, if emotion analysis was not a primary objective, or if the task context was not performance-related.

Fig. 2. Literature search strategy process step-by-step using the PRISMA flowchart.

C. Quality Assessment

The quality assessment was performed on only full-text studies and used to exclude unsuitable studies from the systematic literature review by ensuring that they met the definition of studies that used physiological signals and deep learning (DL) models to predict emotions in performance-oriented tasks.

The quality assessment included reviewing and validating the actual methodology used in each study (specifically, the methodological use of physiological signals, DL models and task context) as was described in each study's full-text article. The quality assessment framework was drafted to assist with final eligibility validation by applying the framework to all candidates' studies that were retained from initial screening to ensure that the same quality assessment criteria were used across all candidate studies. Each candidate study was assessed against three core criteria (E1-E3) to determine eligibility, "yes" [Y] to all three criteria for inclusion in the final synthesis of results.

1) *E1: Use of physiological signals as model inputs:* Physiological signals (EEG, ECG, HRV, EDA/GSR) must be used as direct inputs for the modeling, in which they are represented in any valid format (as raw signal, extracted features, or time-frequency). Any signal that is used for descriptive or post-hoc analysis would not count.

2) *Deep learning models used for emotion-related prediction:* A model based on deep learning must be employed for prediction, such as a CNN, LSTM, GRU, Transformer, or

hybrid model (i.e., models on which deep learning is based), and the predictions must relate to emotions. The predicted outcomes must be related to an emotion class (as an example, to an arousal/valence score or to a level of stress) when emotion is treated as the proxy for prediction.

3) *E3: Presence of a genuine performance-critical task context:* The prediction of emotions must occur within an actual performance-critical task, for example, competitive sports, workload-intensive activities, stressful or time-pressured tasks, or actual real-world/competitive environments. This task must involve meaningful performance requirements; generally, there would be some measurable performance associated with a task or other operational relevance that could support those performance metrics.

This task-specific inclusion criterion further differentiates the present review from conventional surveys, which typically do not restrict their analysis to performance-critical contexts.

The fifth step of the quality assessment was to perform a structured data extraction and coding process after conducting the final eligibility validation. This data extraction process was undertaken with the goal of achieving methodological consistency, comparability across studies and transparency in the synthesis of the evidence. Only papers that met all eligibility criteria (E1–E3) were included in this stage of the assessment.

The investigator created a Data Extraction Table (DET) a priori to systematically extract essential methodological and

outcome-based attributes from each of the included studies. The data extraction focused on descriptive characteristics and quality indicators that represent the robustness and applicability of the proposed methods.

The DET comprised five main categories, as described below:

- **General Study Information:** The papers included in the study were varied in terms of genre and study period and provided more than enough detail for coding purposes, but this was done only once and may have changed subsequently. In addition, the source of data used in each study was extracted, including whether the study relied on publicly available benchmark datasets or self-collected physiological data obtained from controlled or real-world experimental settings.
- **Physiological Signal Characteristics:** Various types of physiological signals were used for analysis, including EEG, ECG, HRV, EDA and GSR; thus, physiological signals were extracted from the database. Additionally, single modality vs. multi-modality, the appropriate pre-processing steps used and operational integrity were also extracted from the database for further analysis and transparency in methodology.
- **Deep Learning Model Configuration:** The differences in deep learning architectures and the variety of input types (raw signals, features from the physiological signal, or spectrograms) were recorded and coded for future comparative modelling.
- **Emotion Representation and Performance Measures:** Different representations of emotion (categorical versus arousal and valence) and performance measures about Task-related performance (i.e., response to accuracy, response time, scoring and errors) were included to confirm that performance was primarily evaluated per outcome.
- **Results and Limitations:** In addition to reporting the maximum recorded success for each reported study (best practices), information about the number of datasets and acknowledged limitations was coded to permit cross-study comparisons and the generation of ideas and constraints around generality across studies.

After the conclusion of the Data Extraction Table (DET), a Relevance-based screening was performed to determine the ultimate set of studies included in this synthesis. Each study was assessed systematically and categorized according to its level of fit for the objectives of this review.

The assessment of relevance was based on the extent to which each study met core eligibility criteria (E1–E3) with an extra emphasis on: 1) the application of deep learning models for predicting emotions directly and 2) using emotion predictions in a real-world performance-critical task. The relevance level of the studies was categorized into three levels. High relevance referred to studies that met all three eligibility criteria, applied a deep-learning model to explicitly predict emotions related to an event, and addressed tasks of substantial real-world significance, thereby forming the core evidence for

the systematic review. Medium relevance referred to studies that satisfied the primary eligibility criteria but exhibited one or more limitations in task realism, the level of detail describing the performance context, or the emphasis placed on emotion-related outcomes, while still contributing valuable information to the review. Low relevance referred to studies that lacked sufficient detail to meet the eligibility criteria or failed to satisfy all three criteria, such as treating emotion prediction as a secondary or peripheral outcome, lacking a clearly defined performance context, or providing inadequate methodological detail, and therefore were either excluded from the systematic review evidence or retained with a clearly documented rationale for their inclusion or exclusion.

Only studies with High and Medium relevance were used as part of the final analysis and synthesis. This method of filtering studies with respect to relevance served to keep the final collection of evidence in the systematic review methodologically sound, collectively coherent, and directly related to the objectives of the systematic review.

D. Search Result

The original database search produced a total of 512 records, with 468 coming from Dimensions AI and 44 from Web of Science. After title and abstract screening, 192 records were eligible for further consideration. After reviewing, 153 records were excluded because they did not meet the criteria for inclusion. Next, 39 complete articles were obtained and reviewed for eligibility. Of those articles, 14 studies were excluded after the full-text review based on their lack of relevance, absence of physiological signals to predict emotion, or because they did not support a task that required performance. A total of 25 studies met all criteria for inclusion and were ultimately included in the systematic review. Of those studies, 23 were retrieved from Dimensions AI, and 2 were retrieved from Web of Science.

E. Risk of Bias Assessment

To assess the risks of bias that exist within these studies and that may hinder the accuracy of the findings from these studies, a risk-of-bias assessment was performed. The majority of identified risks constituted aspects of the studies that are likely to influence the strength of the findings; for example, small sample sizes, lack of control conditions, unbalanced dataset types and NOT reporting training and validation procedures.

Many of the studies have been conducted in controlled laboratory environments, which limits our ability to generalize results from laboratory settings to performance-critical real-life settings. In addition, the variations among the devices and techniques used to obtain physiological signals from participants across studies can also create measurement bias across studies. Despite these limitations, the use of multiple datasets, numerous task domains and comparative model performance evaluations among studies to determine model accuracy helped minimize the influence of each individual study's bias on our interpretation of results and our identification of research gaps in discussion.

IV. RESULTS AND DISCUSSION

The findings discussed here derive from a systematic review of 25 studies that investigate the use of physiological signals

with deep learning models for emotion prediction in performance-critical tasks. The synthesized results identify prevailing trends with respect to signal modalities, learning architectures, fusion strategies and application domains and discuss how different physiological signals contribute to emotion recognition performance as well as the ways in which deep learning approaches have been utilized to model the affective states of individuals in high-demand and task-oriented environments. The discussion also highlights methodological patterns, research gaps and performance evaluation practices that may be deduced from the literature reviewed, all relevant for guiding future research on intelligent emotion-aware systems.

A. Overview of Selected Studies

A collection of 25 primary research articles covering emotion forecasting at work-critical job levels using physiological information with deep-learning methods was included in the final selection (2021-2025) for this review. The included studies were from many different focus areas, such as elite sports, cognitive workload measurements, psychological stress evaluations, human-computer interactions, and task performance assessments.

The majority of the studies used controlled laboratory experimental environments, although participant numbers and experimental designs varied across the 25 studies. A few of the studies collected small laboratory samples for physiological data because they did not have access to larger sample sizes; however, many of the studies used publicly accessible datasets for creating and validating their emotion prediction models. Accordingly, the reviewed studies used either publicly available benchmark datasets or self-collected physiological datasets, mostly from controlled laboratory settings.

All of the 25 studies in the final selection of studies used physiological data to produce predictions for human emotion recognition, either as standalone signal sources or in a multi-

signal (i.e., combined from 2 or more sources) manner. To identify complex temporal and nonlinear patterns in their data, many of the studies developed and utilized deep-learning models. There were many similarities between the studies in relation to emotion prediction, but there were also a lot of differences in the selection of signals, development of model architectures, and adoption of evaluation methods, limiting researchers from directly comparing across studies. The next section explores these issues in detail. For a summary of the studies in the final selection (concerning the task completion context, used physiological signals, used signal fusion methods, used model architectures, and representations of emotion), see Table I.

B. Physiological Signals Used

The studies that made up the reviewed literature used different types of physiological signals as input to models of emotional states in highly demanding tasks. Different types of physiological signals were used to reflect the many ways different physiological signals are used to model these emotions and their associated stress levels. The table below lists and describes all of the physiological signals employed in the studies reviewed.

As indicated by Table II, the most used signal modality across the published studies was electroencephalography (EEG), used in 22 of the studies reviewed. EEG as a method of input was used separately and/or as supplemental input to other forms of input within the multimodal classification systems examined. EEG input types have included raw EEG signals, features based upon frequency bands, and time- and frequency-transformed EEG signal data, enabling the deep learning-based methods to learn patterns of neural activity that correspond to discrete emotions or arousal levels. In addition, most of the studies that used EEG as a measure used it primarily within the areas of affective computing (e.g., emotion detection), work-related performance evaluations, and sport performance evaluations.

TABLE I. SUMMARY OF SELECTED STUDIES ON DEEP LEARNING-BASED EMOTION PREDICTION USING PHYSIOLOGICAL SIGNALS

Paper ID	Author (Year)	Domain / Task Context	Physiological Signal(s)	Model type	Input format	Fusion method	Emotion representation	Best Result Reported
P01	[24]	Human-Computer Interaction (HCI) / Stimulus elicitation (watching videos)	EEG, GSR, ST, HR	CNN + LSTM (Hybrid)	Raw signals (processed)	Hybrid (Early Fusion)	Discrete (7 categories: calm, happy, disgust, surprise, anger, sad, fear)	96.21% Accuracy
P02	[25]	Affective Computing / Human-Computer Interaction (HCI)	EEG, GSR, ECG	2D-CNN, 1D-CNN and LSTM	Raw signals (structured format)	Late Fusion	Arousal-Valence classes: HVHA, HVLA, LVHA, LVLA (4)	99.0% Accuracy (AMIGOS), 90.8% Accuracy (DREAMER)
P05	[26]	Medical & Mental Health / Brain-Computer Interface (BCI)	EEG	Bi-Directional Long Short-Term Memory (Bi-LSTM)	Selected features (statistical, wavelet, Hurst exponent)	None (Single-modal)	Arousal-Valence + Liking	Valence: 99.45%, Arousal: 96.87%, Liking: 99.68% (Accuracy)
P06	[1]	Affective Computing / Naturalistic	HR, Temperature, EDA	LSTM	Raw signals with emotional cues	Early Fusion	Arousal-Valence	96% Accuracy (independent)

		Conversations (Debates)						93% (combined)
P07	[9]	Tourism & Consumer Applications / Real-World Recommender System	HR	Hybrid CNN + LSTM	Raw signals or basic HR features	Hybrid	Discrete (self-labelled categories)	Not in source (reported as "promising")
P08	[27]	Embedded Systems & Edge Computing / Wearable Applications	ECG, EDA	1D-CNN (lightweight)	Hand-crafted features + Deep Learning integration	Hybrid (Model integration)	Discrete (Fear detection / Binary)	F1-score: 80%, Accuracy: 74%
P11	[28]	Neuroscience & Embedded Systems / FPGA implementation	EEG	CNN-LSTM + ResNet-152	Features (extracted via ICA)	Late Fusion	Not in source	Improved speed/area (numerical accuracy not in source)
P13	[7]	Smart Healthcare / Mental Health Monitoring	EEG and ECG	CNN-LSTM (Optimized with Bayesian)	Raw signals or basic features	Early Fusion	Discrete (3 categories: neutral, tense, concerned)	Accuracy 92.1%, AUC-ROC 0.96
P14	[6]	Human-Computer Interaction (HCI) / Wearable & Real-time Systems	EEG (Selected channels)	1DCNN-BiLSTM (Hybrid)	Raw signals or basic features	Hybrid (Model design)	Not in source (Multiclass)	85.16% Accuracy
P15	[5]	EEG-based Emotion Recognition / Generalizable AI	EEG (Multichannel)	ATDD-LSTM (Attention and Domain Discriminator)	Raw signals or basic features	Not applicable (Attention mechanism)	Not in source	Superior performance (numerical values not in source)
P16	[29]	Online Learning & Education	EEG (5 channels: FP1, AF3, F7, T7, FP2)	1D-CNN	Raw signals	None (Single-modal)	Discrete (7 categories: boredom, confusion, frustration, curiosity, excitement, concentration, anxiety)	Accuracy >99%
P17	[30]	Mental Health & Clinical Applications / Real-Time Emotion Recognition	EEG	Machine Learning (XGBoost, LightGBM, KNN)	Statistical and mathematical features	None (Comparative study)	Not in source	96.77% Accuracy (with KNN)
P18	[31]	Mental Health & Stress Management / Diagnostic Aid	EEG	CNN-LSTM (StressNet)	Images (Azimuthal projection-based images)	Hybrid (Sequential)	Discrete (Binary: Stress vs Normal)	97.8% Accuracy
P19	[32]	Wearable Technology / Affective Computing	EEG and BVP	ConvNet-LSTM	Raw signals or basic features	Early and Late Fusion Comparison	Dimensional (Arousal-Valence)	71.61% Accuracy (Early Fusion)
P20	[33]	Medical Rehabilitation / Assistive Technology (Stroke Patients)	EEG	LSTM	Spectrogram/Scalogram (2D Images)	None (Single-modal)	Arousal-Valence (3, 5, or 9 categories)	Valence: 88%, Arousal: 90% Accuracy (9-class)
P21	[34]	Industrial Safety / Occupational Health (Electric Power Workers)	ECG (Heart rate signal)	1D-CNN	Processed raw signals (3D stacking operation)	None (Single-modal)	Discrete (4 types)	98.57% Accuracy, 98.73% F1-score
P22	[35]	Biometrics & Gait Analysis / Virtual Reality (VR)	EEG and Inertial signals	Attention-Based CNN Fusion Model	Images (Wavelet-based "virtual emotion images")	Hybrid (Decision Fusion)	Not in source	98.73% Accuracy
P23	[36]	Mental Health & Psychology / VR Therapy	EEG and HR	CNN-LSTM (Hybrid)	Raw signals or features	Hybrid	Psychological Stress (Arousal-Valence)	Superior performance (numerical values not in source)
P25	[37]	Human-Computer Interaction (HCI) / Social Robotics	EEG and Speech	TMNet (Transformer-fused CNN-BiLSTM-BiGRU)	Features processed or representations	Late Fusion (via Transformer)	Not in source	98.89% Accuracy

P26	[38]	Smart Driving / Vehicle Safety	HR, Breathing Frequency, EDA, EMG	CNN + LSTM (Hybrid)	Raw signals or basic features	Hybrid (Model and System level)	Not in source	Significant enhancement (numerical values not in source)
P27	[39]	Sports & Exercise Quality / Physical Therapy	EEG, ECG, GSR, HR and Facial expressions	Residual Network with Attention Modules	Features	Hybrid (Early Fusion & Multi-Head Mutual Attention)	Discrete	88.8% Accuracy
P28	[40]	Digital Health / Daily Emotion Monitoring and Forecasting	HR and Step Count	Cluster-guided attention model	Raw signals or basic time-series features	Hybrid	Discrete Binary (Positive vs Negative)	74.4% Accuracy (Current), 72.9% (1-hour forecast)
P29	[24]	Behavioral Analysis / Gaming (Gameplay)	EEG	ResNet18 (CNN) + ELM-W-AE	Images (CWT Scalograms)	Not in source	Discrete categories (4)	99.6% Accuracy
W1	[41]	Brain-Computer Music Interface (BCMI) / Music Technology	EEG, HRV, EDA, ECG	Not in source	Features (EEG and physiological features)	Hybrid	Arousal-Valence	Accuracy improvement of 10.2% (Valence) and 9.3% (Arousal)
W10	[8]	Mental Healthcare / IoT-based Wearable Sensing	ECG, EDA/GSR, ACC, TEMP, RESP, BVP	Hierarchical Deep Neural Network (CNN-based)	Multivariate time-series data	Model-level / Late Fusion	Discrete (3 categories: baseline, stress, amusement)	87.7% Accuracy (WESAD dataset)

Note: Paper IDs P01–P29 correspond to studies retrieved from the Dimensions AI database, while W1–W10 correspond to studies retrieved from the Web of Science database.

TABLE II. PHYSIOLOGICAL SIGNALS USED IN DEEP LEARNING-BASED EMOTION PREDICTION STUDIES

Physiological Signal	No. of Studies	Usage Mode	Input Representation	Emotion / State Predicted	Typical Task / Application Context
EEG	22	Single, Multimodal	Raw signal, frequency bands, time–frequency, features	Discrete emotion, arousal–valence, stress	Affective computing, workload tasks, sport-related tasks
HR / HRV	11	Multimodal	Time-domain features, frequency-domain features	Stress, arousal	Workload tasks, stress induction, wearable monitoring
EDA / GSR	7	Multimodal	Raw signal, statistical features	Stress, arousal	Controlled lab tasks, wearable-based studies
ECG	7	Multimodal	RR intervals, waveform features	Stress, emotional state	Healthcare-related emotion monitoring
Skin Temperature	3	Multimodal	Raw signal, mean variation	Stress-related emotional states	Wearable sensing, laboratory tasks
Respiration / BVP	4	Multimodal	Time-series features	Stress-related states	IoT-based wearable datasets
Accelerometer (motion)	4	Multimodal (auxiliary)	Activity features	Context-aware stress/emotion	Wearable and ambulatory settings

Most of the studies investigated peripheral physiological signals in multimodal configurations. Heart rate (HR) and heart rate variability (HRV) were used in a total of eleven studies and were typically represented by time- and/or frequency-domain features. These physiological signals were closely linked to detecting stress and arousal; in particular, they are well suited for workload-intensive and wearable monitoring applications. Electrodermal activity (EDA) and electrocardiography (ECG) were used in a total of seven studies and were principally used to capture the sympathetic nervous system responses and to detect the stress and emotional response from participants using EDA and ECG in controlled laboratory and healthcare-related settings.

Other physiological signal modalities such as skin temperature, respiration, or blood volume pulse (BVP) and motion derived from accelerometer-based sensors are used less frequently than the above modalities and serve as complementary inputs within multi-modal systems.

Contributing contextual or auxiliary information, these signals can assist with the interpretation of emotional states when used in wearable sensing and ambulatory settings, due to the influence of movement and physiological variability.

As shown in Table II, there is a significant reliance on EEG as the primary modality used with deep learning-based emotion prediction systems, while peripheral physiological signals are used in conjunction with the EEG signal to increase the robustness and contextual awareness for emotion prediction. The use of multiple modalities, including integrating central and autonomic responses to create emotional states when modeling performance-critical task emotion states, is emphasized through this multimodal trend.

C. Deep Learning Models Applied

Various deep learning frameworks have been applied to analyze and investigate physiological traits within a performance-relevant and dynamic timeframe for emotional

assessment task completion through accomplished physiological signal processing. The more popular models included Convolutional Networks (CNN), Long Short-Term Memory Networks (LSTM), Gated Recurrent Units (GRU), and Hybrid Models.

Convolutional Neural Network-based methods were typically used for feature extraction (e.g., EEG, Spatial/Time Frequency), while Recurrent Models (LSTM & GRU) were used to time correlate physiological signals over the course of uninterrupted task execution. LSTM models were more prevalent due to their effectiveness in modelling long-term temporal patterns, while GRU models were occasionally preferred for their computational efficiency.

An increasing number of studies adopted hybrid architectures, such as CNN combined with LSTM or GRU layers, to jointly learn spatial and temporal features. More recent work also explored attention mechanisms and lightweight architectures to improve interpretability and support real-time deployment. A summary of the deep learning models and architectural trends across the reviewed studies is presented in Table III.

TABLE III. SUMMARY OF DEEP LEARNING MODELS USED FOR EMOTION PREDICTION.

Model Type	Signal Modality	Task Context	Key Strength
CNN	EEG	Cognitive tasks, stress	Spatial feature learning
LSTM	EEG, HRV	Continuous tasks	Temporal dependency modelling
GRU	HRV, ECG	Mental workload	Computational efficiency
CNN-LSTM	Multimodal	Performance-critical tasks	Spatiotemporal learning
Attention based	EEG, multimodal	Real-time prediction	Interpretability

D. Input Representation and Fusion Strategies

Multimodal fusion strategies were widely adopted in the reviewed studies to enhance emotion prediction performance by integrating complementary physiological signals. These strategies aimed to combine information from central signals, such as EEG, with peripheral signals, including HRV, ECG and EDA, to obtain a more comprehensive representation of emotional states in performance critical tasks.

The most reported approach was featuring level fusion, where features extracted from multiple physiological modalities were concatenated or jointly learned before classification. The use of this strategy enabled early-stage comprehension of the interplay between different types of data by way of deep learning models typically resulting in greater predictive accuracy for many outcome measures. However, the typical requirements associated with performing feature-level fusion included significantly higher computational complexity and careful consideration of the alignment of features.

Another approach to performing fusion across the modalities was to use decision-level fusion, where each modality was used to train an independent model and then the output from each model across the various modalities was fused either through

voting schemes based on the majority of votes received per modality, through weighted averaging using weights defined by the respective mean-square error associated with the trained model for each modality, or through the use of ensemble techniques (i.e., stacking of models), thereby providing more flexibility and robustness than feature-level fusion, as well as resulting in less cross-modality interaction in some instances.

The various representations of physiological data in conjunction with the manner in which the studies previously discussed have performed fusing of modalities for emotion and stress prediction over time can be clearly identified in Table IV. Compared to prior methodologies, a shift towards more structured and model-aware strategies with regard to the performance of data fusion has occurred over time.

The input representations can be broadly grouped into three categories:

- Raw or minimally processed signals: There are studies (e.g., P02, P19, W10) that utilize either raw physiological sequences or multivariate time series. This provides both temporal dynamics and no hand-crafted “bias”, thus relying much more heavily on the model capacity than would be expected from the ability to learn the discriminatory nature of the data.
- Time-frequency and image-based transformations: Several studies (e.g., P13, P18, and P22) have produced some form of transformation of the physiological signals to either a spectrogram, azimuthal projection, or image of a virtual emotional effect (e.g., VR). Similar or greater capabilities using CNN architectures also allow for improved spatial feature learning in EEG signals.
- Hybrid and multi-domain features: P27 has combined both hand-crafted multimodal features and attention mechanisms. In P25, both speech MFCCs and EEG sequences are integrated. This reflects an attempt to achieve the best of both worlds by using domain knowledge while utilizing data-driven learning.

TABLE IV. COMPARISON OF INPUT REPRESENTATION AND FUSION STRATEGY.

Study	Input Representation	Primary Fusion Strategy
P02	2D Spatial Images (EEG) + 1D Raw (ECG/GSR)	Late Fusion (Majority Voting)
P13	Time-Frequency Spectrograms / Raw Signals	Early Fusion (CNN-LSTM)
P18	2D Azimuthal Projections	Hybrid (Integrated spatial-temporal)
P19	Raw Physiological Sequences	Early & Late Comparison
P22	DWT Virtual Emotion Images	Late Fusion (Critic/Weighted Voting)
P25	MFCCs (Speech) + 1D Sequences (EEG)	Late Fusion (Transformer-based)
P27	Hand-crafted Multi-modal Features	Hybrid (Residual Attention)
W10	Multivariate Time-Series	Model-Level Fusion (Unified feature rep)

Fusion strategies show a clearer trend than representations, which are grouped into four categories:

- There has been a large use of late fusion strategies found in the literature (e.g., P02, P22, P25), with a lot of late fusion using either voting or weighted decision techniques. The trend of late fusion in this literature suggests that the preferred choice of a modular design is that each of the different modalities is modelled independently, making them better able to withstand or accommodate loss of data/how reliable the data will be before it is fused together.
- Early fusion strategies are less common and primarily used where the different modalities being fused are closely aligned temporally and/or by structure (e.g., P13). The risk associated with using these early fusion strategies is that one modality may dominate the resulting fused representation, making it more difficult to interpret.
- Hybrid fusion strategies (e.g., P18, P27) are new directions of research. The fusion techniques used in hybrid fusion strategies often use attention or residual learning to combine both space and time features within

the model, showing that these hybrid models produce an increased synergistic capacity for representing the modalities that were fused.

- Model-level fusion (e.g., W10) is an emerging trend in the development of unified or endpoint feature representations. Since their functional purpose is the same, upon model inception, their goal is to address the limits of either early or late fusion.

In general terms, the table indicates a trend away from decision-level fusion towards integrated architectural designs that incorporate both data and environment. Increased use of hybrid and model-level fusion indicates a realization that emotions and stress are complex, dimensional entities that cannot be accurately represented through simple concatenation or voting alone. However, since there is no consistent representation or fusion strategy for the various methods used to represent and fuse data, it appears that the field has not yet reached a unified methodology that would apply to all implementations and would allow for the comparison of results across studies.

TABLE V. FUSION STRATEGIES USED IN MULTIMODAL EMOTION PREDICTION STUDIES

Fusion Strategy	Description	Common Signal Combinations	Key Advantages	Reported Limitations
Feature level fusion	Features from multiple modalities are combined before model training	EEG + HRV, EEG + ECG, EEG + EDA	Captures cross-modal relationships early; often improves accuracy	High dimensionality; requires signal synchronization
Decision level fusion	Independent models are trained per modality and outputs are combined	EEG, HRV, ECG (separate models)	Robust to noisy or missing signals; flexible design	Limited interaction between modalities
Hybrid fusion	Combination of feature and decision level fusion	EEG + peripheral signals	Balances early integration and robustness	Increased model complexity
No fusion (single modality)	Emotion prediction using one physiological signal	EEG only, HRV only	Simpler architecture; lower computational cost	Lower robustness and prediction performance

Table V presents a comprehensive overview of the different methods that can be used for multimodal emotion detection research, including their design principles, combinations of signals, advantages and disadvantages. The most frequently used fusion method is feature-level fusion, as it allows for the early integration of multiple physiological feature types and usually provides improved prediction accuracy. Nevertheless, feature-level fusion has the disadvantage of using high-dimensional data requiring precise signal synchronization.

Decision-level fusion is based on combining multiple independent models, each trained on a single modality of data. This method is useful when one or more modalities may have corrupted or missing signal information, as decision-level fusion is more robust to these types of problems. In addition, this method of fusion allows for flexible model development but restricts the possible interaction between modalities. Two methods of fusion are hybrid fusion strategies, which combine features from both the feature-level and decision-level methods and the use of a single modality without any fusion methods. The use of hybrid strategies was explored to achieve a balance between the advantages of early data integration and robustness, especially for complex performance-critical tasks. Lastly, the use of single modality approaches has also been performed due to the lower computational costs and ease of development, even though these methods generally exhibit lower reliability and lower prediction accuracy than the fusion methods.

E. Performance Metrics and Evaluation Practices

The papers created for this review used a lot of different performance measures to evaluate the performance of the Emotion Detection Model (EDM). The performance measures have many different types of objectives and/or experimental design, emotion representation and process differences. Many studies reported their accuracy as the most frequently used performance measure for EDMs because many of the studies report accuracy larger than 95% and the studies using both discrete emotion categories and/or either stress detection are classified as using binary or classifying stress detection, respectively. These results indicate that the EDM was successful in being able to learn from physiological signals using the deep learning algorithms.

The classification accuracy measure is only one of the performance measures used for measuring EDM, but several papers did report measuring EDM using other performance measures such as: precision, recall, F1 score and confusion matrices. These paving processes will allow for more accurate measurement of the performance of the EDM, as they will allow for measuring the trade-off between false positives and false negatives. The importance of measuring accuracy beyond classifying the incorrect class would be more of an impact within performance-critical applications, as an example of classification would have consequences.

The studies included in Table VI show that there is a tremendous difference in how emotions are captured and evaluated. In most of the studies, classification accuracy was the primary outcome measured by the various studies; usually, reports included the use of other complementary metrics such as F1 score, precision, etc., although these metrics were used more frequently on multi-target emotion prediction tasks. However, several studies utilized dimensional models of emotion and therefore relied on regression-type evaluation measures (mean absolute error) for measuring prediction quality.

TABLE VI. PERFORMANCE METRICS ACROSS KEY STUDIES

Paper ID	Primary Metrics Used	Best Reported Results	Emotion Representation
P01	Accuracy	96.21%	7 Discrete Emotions
P02	Accuracy, F1-Score	99.0% (AMIGOS), 90.8% (DREAMER)	4-Quadrant (HVHA, HVLA, etc.)
P05	Accuracy, Precision, Recall, F1	99.45% (Valence), 99.68% (Liking)	Valence, Arousal, Liking
P13	Accuracy, AUC-ROC, Recall, F1	92.1% Accuracy, 0.96 AUC-ROC	Neutral, Tense, Concerned
P14	Accuracy, Specificity, F1	85.16% (using 8 channels)	4 Discrete Emotions
P17	Acc, Precision, Recall, F1, MCC, Kappa, AUC	96.77% Accuracy (KNN model)	Valence, Arousal
P19	Accuracy, Loss	71.61% (Early Fusion)	4-Quadrant Dimensional
P21	Accuracy, F1-Value	98.57% Accuracy, 98.73% F1	4 Emotional Categories
P25	Accuracy, Precision, Recall, F1, MAE	98.89% Accuracy, 0.05 MAE	5 Primary Emotions
P28	Accuracy, Macro-F1, Forecast Horizon	74.4% (Current), 65.5% (2-hr Forecast)	Positive vs. Negative
P29	Accuracy, Sensitivity, Specificity, Kappa	99.6% Accuracy (Augmented)	4 Games (Boring, Calm, etc.)
W10	Accuracy	87.70%	Baseline, Stress, Amusement

Overall, these studies have reported highly successful performance, but the large number of different types of metrics, validation types/protocols and types of emotion capture used limits direct performance comparison across studies, accentuating the need for standardization of emotion prediction evaluation mechanisms/devices. Consequently, the studies in the table indicate there are major issues related to the standardization of emotion prediction evaluations. Therefore, it is vital that any conclusions drawn based on existing research are done so with caution considering the discrepancies found among studies' metrics, validation methods and datasets. Caution should be taken in drawing any inferences from reported accuracy values with respect to the applicability of a studied emotion prediction model to real-world application where performance is critically important.

The overall evidence shows that although emotion prediction systems based on deep learning techniques have shown some success, there needs to be much more focus on using standard evaluation metrics, independent verification of

subject matter, and transparent reporting to be able to reproduce the results obtained and make them practically usable.

F. Identified Research Gap and Challenge

As shown throughout the course of this review, there are many significant shortcomings in both the research surrounding deep learning-based emotion prediction with physiological measures and also in the methodology used to conduct these studies, especially when predicting emotions in high-performance task environments. There are many reports of successful results across multiple studies; however, due to limitations in the methods of fusion, evaluation, and overall experimental design, it is difficult to generalize or practically deploy the current approaches being used to predict emotions.

One major gap in the research is the lack of standardized multimodal fusion frameworks. The majority of the studies reviewed use feature-level fusion (as highlighted in Table V), which offers great advantages in terms of capturing cross-modal relationships and increasing predictive accuracy; however, feature-level fusion also produces high-dimensional feature sets and requires strict synchronization requirements, making it difficult to scale and use in real-time. Decision-level and hybrid methods of fusion, while providing better robust solutions, are infrequently studied; therefore, further research is required to examine adaptive and dynamic fusion methods for balancing accuracy, robustness and computational efficiency.

A major obstacle has been the evaluation of performance measurements. As shown in Table VI, there are numerous differences in how various studies performed evaluations of emotional expression and models used to validate the evaluations, including variations in evaluating performance metrics, emotion representation schemes and validation protocols for each study. Even though most researchers report the accuracy of classification models as their performance metric, using accuracy as the sole metric to compare performances can inappropriately mask problems with the level of class (dis)similarity (imbalance) and generalizability of the model across sample populations. Additionally, the inconsistency of how commonly used complementary performance metrics such as F1 Score, AUC ROC and regression-based errors are reported among various research studies further compounds the challenge of establishing valid cross-study comparisons or identifying models that will truly generalize.

Existing research in the area of emotion recognition has also been constrained by limitations related to datasets and experimental designs. Many researchers use controlled laboratory conditions and subject dependent validation schemes to validate their findings. Therefore, those controlled laboratory conditions or subject-based validation of emotion recognition models may dramatically inflate the performance measures that have been reported and reduce the level of ecological validity associated with those findings. Although there have been attempts to use multi-modal sensing modalities and wearable sensing, there continues to be a significant shortage of real-world performance scenarios used to evaluate the accuracy of emotion detection in the real world. These circumstances demonstrate an urgent need for larger, more heterogeneous datasets with subject-independent validation protocols, because

without these, researchers will be unable to develop models of emotion recognition that could generalize across individuals and situations.

Hybrid and attention-based architectures are getting more popular; however, they have yet to show widespread usage. The focus of future research should be on lightweight, interpretable deep learning that can work in a resource-constrained environment while providing illuminating signals about relevance and how decisions are made. These advances will be of vital importance where the safety of the system is.

Future studies must develop standards for how we evaluate emotions, develop systems that can integrate input from multiple sources, and develop experiments that reflect real-world conditions. Addressing these issues will be necessary to enable emotion prediction systems to be used reliably outside of a laboratory environment where performance is critical.

V. CROSS-DOMAIN PERSPECTIVES

The use of physiological signals and deep learning to predict emotions is physically derived from an interdisciplinary base of knowledge, including affective computing, biomedical signal processing, numerical modeling and advanced data analysis methods. The previous research into using the EEG for classification of emotions was evidence of what can be possible (i.e., extracting patterns in emotion from the signals of the brain) and support for the use of EEG as one of the primary modalities for detecting affective states [42]. These early findings will continue to support the application of deep learning to understand emotion-aware systems by validating the physiological underpinnings of those systems.

Research into neuromarketing and affective analytics further illustrates how physiology-based inferences about emotion are limited and that they are modified by the context in which they occurred. This supports the need for studies that utilize formal multimodal, context-aware and transparent approaches, particularly in performance-critical environments in which emotional states are closely linked to cognition and decision-making.

Methodological advances in numerical modeling, such as modified Euler and harmonic-polygon-based schemes, emphasize accuracy, stability and robustness in solving non-linear systems [43, 44]. Although originating in computational mathematics, these principles parallel current challenges in deep learning-based physiological signal modeling, where noise, non-stationarity and inter-subject variability can degrade prediction reliability.

Related work in computer-aided medical analysis and image-based segmentation demonstrates the importance of structured feature representation and explainable model design for high-stakes applications [45, 46]. Likewise, studies on feature selection in sentiment and health-related analytics highlight trade-offs between model complexity, interpretability and generalizability [47]. Collectively, these cross-domain insights reinforce the importance of developing lightweight, interpretable and robust deep learning frameworks for emotion prediction that are suitable for deployment in real-world performance-critical tasks.

VI. CONCLUSION

This systematic review aimed to examine how physiological signals and deep learning models have been applied to emotion prediction in performance-critical tasks, with particular emphasis on physiological signal modalities, deep learning architectures, multimodal fusion strategies, evaluation practices, and methodological limitations. Guided by the research questions, this review synthesized recent studies published between 2021 and 2025 to identify the dominant methodological trends, key research gaps, and implications for building robust emotion prediction systems in real-world performance-critical environments.

The review indicates that EEG remains the dominant physiological modality for emotion prediction, while peripheral signals such as HRV, ECG, and EDA are frequently incorporated to strengthen multimodal modeling. Across the reviewed studies, deep learning approaches, particularly CNN, LSTM, and hybrid architectures, demonstrated strong capability in modelling complex temporal and cross-signal patterns. However, the broader synthesis suggests that predictive effectiveness is not determined by model architecture alone; it also depends on the quality of signal representation, the realism of the task context, and the consistency of evaluation practices.

The review further shows that multimodal emotion prediction generally offers greater potential than single-modality approaches, especially for capturing both central and autonomic responses in demanding environments. Nevertheless, the field remains constrained by several recurring limitations, including inconsistent fusion strategies, limited ecological validity, lack of subject-independent validation, and non-standardized performance evaluation methods. These issues make cross-study comparison difficult and continue to hinder the translation of laboratory findings into reliable real-world emotion prediction systems.

To advance this field, future research should prioritize standardized evaluation frameworks, robust and adaptive fusion strategies, and ecologically valid experimental designs that better reflect real-world performance-critical conditions. Greater emphasis should also be placed on subject-independent validation, interpretable lightweight deep learning models, and deployment-oriented testing in realistic operational settings. These directions are essential for improving the reliability, generalizability, and practical usability of emotion-aware systems.

In conclusion, this review provides a structured synthesis of recent literature on emotion prediction in performance-critical tasks and highlights the need to align physiological sensing, deep learning design, and evaluation methodology more closely with real-world operational demands. By identifying dominant trends, methodological weaknesses, and future research priorities, this study provides a clearer foundation for the development of more reliable and deployable emotion prediction systems.

ACKNOWLEDGMENT

The authors gratefully acknowledge the National Defence University of Malaysia (NDUM) for providing the facilities and

academic support necessary for this study. We also wish to express our sincere appreciation to Prisma Khas Sdn Bhd for their valuable support and collaboration throughout the project.

Abstract—Conventional path-planning algorithms are often tailored to industrial and warehouse settings, creating the necessity to integrate two or more planners, which requires more memory and computation limitations. To overcome this limitation, this study aims to develop a novel algorithm, semantic cost encoding-based A* with Dynamic obstacle avoidance, specifically designed for Autonomous Mobile Robots (AMRs) in warehouses. In this study, the proposed algorithm is benchmarked in Matplotlib against A* and RRT* showing 60.33% higher memory efficiency and 60.36% more efficiency in aspect of number of computed nodes than RRT*, while all equivalent to A* in a static environment, and benchmarked against D* lite for dynamic environment, as well as against a hybrid algorithm, a simplified interpretation of commercial AMR path planning approaches, to show 45.30% more memory-efficiency than the hybrid algorithm, which is much more preferred in a real time implementation than D* lite, for AMRs.

Keywords—Path planning; semantic encoding; Autonomous Mobile Robots (AMRs); warehouse navigation; dynamic environment

I. INTRODUCTION

The automation era has pushed many processes toward automatic functioning, such that warehouses are employing Autonomous Mobile Robots (AMRs) to perform their load-carrying functions. An important feature in the automation of AMRs is motion planning. Recent trends have evolved motion planning with the evolution of technology. Infusing AI technologies into motion planning approaches. For instance, reinforcement learning is implemented in motion planning for task-specific designs for efficient autonomous driving [28], and for enhanced optimality, it can reduce training complexity and improve sample utilization [29]. Further, deep reinforcement learning generates efficient autonomous motion planning, but implementation in real-world applications poses challenges [30]. For increased efficiency in production aspects, human-robot collaboration effectively improves flexibility and maintainability [31]. Though many modular designs are improved for motion planning approaches, for a warehouse's efficient operation with AMR-human collaboration that

increases flexibility and maintainability requires resource allocation ratios, environment awareness for maximum warehouse efficiency [32]. Similar to humans' awareness of the complex working environment for their optimal performance, in the proposed algorithm, the environment awareness is induced through semantic encoding representations of the known environment map. The planner has consistent integration of semantic cost modeling across both global planning and dynamic replanning stages within a unified framework. Unlike classical A*, which is a static global planner, the proposed approach encodes a semantically weighted A*-based formulation within a dynamic framework to enable continuous adaptation in dynamic environments. In contrast to conventional hybrid approaches, where A* generates waypoints and D* Lite performs local tracking, the proposed method employs a unified architecture. The semantic cost encoding is consistently maintained within the replanning process, ensuring that dynamic obstacle avoidance is aligned with global contextual objectives. The algorithm, LADy, originally derived from a latent representation-based formulation, is now represented as a semantic cost-based dynamic planning framework.

This research contributes:

- Proposes a novel hybrid planning approach that integrates semantic cost encoded A* with dynamic planning functionalities, forming a unified framework.
- Developed an environment-aware path planning algorithm capable of operating in both static and dynamic environments.
- Introduced a semantic encoding mechanism to enhance the planner's understanding of context of environment.
- Provided comprehensive benchmarking of the proposed method against existing algorithms, A*, RRT*, D* Lite, and hybrid planning frameworks.
- Presented equation-level modifications to A*, contributing formal improvements tuned to proposed planner.

- A unified architecture employing context-aware semantic modelling in both global and dynamic planning phase.

The rest of the study is organized as follows: In Section II, related works are presented. In Section III, the planner methodology is proposed. Section IV covers the pseudocode of the proposed novel algorithm. Results of the study is presented in Section V. Section VI shows the metrics comparison according to the benchmarking data. Section VII discusses the results. Section VIII details complexity analysis of the proposed algorithm. Finally, Section IX concludes and proposes the future scope of the proposed algorithm.

II. RELATED WORKS

For the automation of mobility, an important function is the path planning, which enables a vehicle to navigate independently towards a goal. Motion planning plays an essential role in this process [1]. Motion planning algorithms are developed based on scenarios, static, dynamic, known, and unknown environments.

Not all algorithms satisfy the criteria and requirements; the algorithms require development on many approaches for a dynamic environment [2]. Similarly, the development requirements and standards increased with the need for advanced navigation, like in unknown environments [3]. For the effective operation of AMRs in dynamic environments for industrial applications [4]. For diverse robotic applications, path planning algorithms need to adapt to dynamic environments [5].

Autonomous driving solutions offer advantages over modular technologies and systems, but face challenges [6]. They require clarification on concerns and queries when a system is automated, and they need assurance on safety [7]. For an automated navigation system, path planning is crucial for safety, which is not a simple algorithm of conventional methods, but a hybrid to make the system optimal [8]. The evolution of path planning algorithms began with grid-based and advanced to sampling-based algorithms like Rapidly-exploring Random Tree * (RRT*) algorithm. Grid-based path planning needed improvements to support larger application spaces efficiently [9]. Across various robotic applications, sampling-based path planning methods offer more efficient solutions [10]. Grid-based planning solutions consume more computation and memory while optimized RRT* are more efficient in that case [11].

Though they are more efficient all developments have its own challenges while facing demands, such that RRT* faced important challenges that needed more research and development [12]. Path planning for robots requires algorithms that generate feasible and smooth paths, avoiding obstacles efficiently [13]. To develop path planning algorithms, we need to understand both conventional and modern approaches for current needs [14]. Although sampling-based approaches are efficient, they require a more systematic comparison for clarity in algorithm selection for specific applications [15]. Robot navigation is a sophisticated process that requires ensuring safety and optimality. For navigation, efficiency can be improved through many approaches. One such method is the

fusion of global and local planning [16]. Though there are many approaches and methods to improve each algorithm from its fundamental to optimal and hybrid, the selection of an algorithm is specific to the functions of the robot. Various options in path planning algorithms make it challenging to confine to one to implement in a system according to requirements [17]. There are many robotics applications and various needs accordingly. For instance, multi-UAV delivery systems need collaborative planning frameworks to optimize for urban logistics [18].

In the case of AMR systems,

- Warehouse AMR dispatching needs multi-objective optimization to minimize costs and balance workloads efficiently [19].
- For smart warehousing, there is a need for an integrated system of robotic systems to IoT [20].
- For multi-AMR systems, we need traffic management to reduce conflicts and improve performance [21].

For multi-objective systems, conventional path planning methods are not sufficient. Such needs of path planning can be accomplished with a combination of grid-based algorithm like A* and greedy algorithms [22]. Similarly, many alterations and hybridizations of algorithms are needed to meet the criterion.

For modern trends, in a warehouse automation system, there are many new applications and requirements that need improved models with mathematical optimization for operation [23]. In automated vehicles, obstacle avoidance capabilities are supposed to be advanced to achieve true autonomous operations [24]. According to the environments and requirements, the autonomous navigation enabling algorithm should work in environments irrespective of the state of the environment. The developed algorithms should be modular so that it is capable of planning in open and complex environments. Especially, in a warehouse automation, AMRs should be capable of safe and optimal navigation in narrow aisles [25] and complex indoor environments [26]. It is a significant need that the development of algorithms for automated vehicles should balance all aspects like safety, energy optimization, and planning optimality in complex environments [27].

III. PROPOSED METHODOLOGY

A. Overview

The Semantic Cost-Based A* algorithm with Dynamic obstacle avoidance is a hybrid algorithm implemented by fusing two path-planning algorithms, both with different applications conventionally. The developed algorithm works efficiently for operating AMRs in warehouses. The algorithm takes in known and defined data, modifies A* functioning with the known data and applies it as base path to a D* lite inspired framework.

B. Inputs and Known Data

The algorithm proposed needs certain pre-defined and known data before it works as inputs. The general and default defined data are the start and goal points that can be

manipulated as per need. Then this algorithm works only in a completely known environment, but it can handle both static and dynamic obstacles. For a completely known environment along with the environment map, the algorithm should be defined with semantic encoding representations of the map based on user-defined environment preferences and previous AMR path histories, and current knowledge of the environment. Based on these semantic encoding representations a cost is assigned that modifies conventional A* in this algorithm.

C. Algorithmic Logic

The D* lite algorithm is inspired for replanning phase that works efficiently in a dynamic environment avoiding moving obstacles on its way. Semantic encoded costs in A* is integrated in a dynamic framework to enable context-aware navigation. The algorithm is split into three main phases that contribute to the efficiency of the algorithm:

- Semantic encoding defined map
- Semantic encoding cost modified A*
- Modified A* applied dynamic planner

These three phases together form the developed hybrid algorithm specifically designed for efficiency of the algorithm in commercial applications, unlike other papers published path planning algorithms.

D. Semantic Encoding Defined Map

The known map is provided as input for the developed path planning algorithm along with the start and goal points for the objective. The algorithm has the dynamic framework as base of the functioning which has A* layout to form the initial path with considerations of only the static obstacles as per the map. In the algorithm, the cost assignment of A* base layout that develops the initial path is modified.

In A* algorithm, the developed path is grid-based, that is the algorithm deploys nodes in the map throughout at first. Similarly, the algorithm deploys nodes throughout the map using a grid-based technique.

Now, at this point in the A* algorithm case, it assigns the actual cost $g(n)$ to the nodes on its path, unlike in this algorithm's case, before that actual cost assignment semantic costs to all the nodes on the map are assigned. Based on the semantic encoding representations defined by the user from data of previous AMR's path histories and awareness of the environment.

Each node in the map of the environment is assigned costs based on semantic encodings, primarily divided into:

- Traffic Area Ratings (t), given in Table I – denotes the crowd density.
- Task Busy Ratings (T), given in Table II– denotes the task activity level in that region that delays mobility.

For instance, the ratings that influence the path finding in the simulation performed for benchmarking in this study are given below,

TABLE. I. TRAFFIC RATING OF THE MAP GIVEN IN FIG. 2

Area type	Traffic Rating(t)	Remarks
Receiving aisle	7	Highest congestion
Packaging aisle	6	
Shipping aisle	6	
Maintenance area aisle	6	
Main storage aisle	5	Moderate congestion
Charging station aisle	5	
Equipment area aisle	4	
Loading docks	4	
High density storage	4	
Cold storage aisle	3	
Hazard area	3	
Quality Control area	2	
Office aisle	1	Lowest congestion
Default open areas	0.5	Free movement zone

TABLE. II. TASK BUSY RATING OF THE MAP GIVEN IN FIG. 2

Area type	Task busy Rating(t)	Remarks
Maintenance area aisle	8	Highest activity
Equipment area aisle	7	
High density storage	7	
Receiving aisle	7	
Shipping aisle	6	
Main storage aisle	5	Moderate activity
Packaging aisle	5	
Cold storage aisle	5	
Charging station area	5	
Quality Control area	5	
Loading docks	3	
Hazard area	2	
Office aisle	0	Lowest activity
Default open areas	0.5	No major task zone

E. Semantic Encoding Cost Modified A*

For a typical A* algorithm the cost function assigned to each node is influenced by two factors, actual cost $g(n)$ and estimated heuristic cost, $h(n)$ [see Eq. (1)]:

$$f(n) = g(n) + h(n) \quad (1)$$

For the algorithm, the above cost function is modified with the influence of the semantic cost, as below [see Eq. (2) and Eq. (3)]:

$$f(n) = d(n) + h(n) \quad (2)$$

where, $d(n)$ is the modified cost,

$$d(n) = g(n) + l(n) \quad (3)$$

Here, the modified cost is the summation of the actual cost $g(n)$ like in A* and the semantic cost, $l(n)$.

$$l(n) = \alpha \cdot t(n) + \beta \cdot T(n) \quad (4)$$

where,

α : Traffic weight parameter,

β : Task complexity weight parameter,

$t(n)$: normalized (0 – 1) traffic rating for node n,

$T(n)$: normalized (0 – 1) task complexity rating for node n,

implying the weight parameters for their significance in the environment with respect to the distance that is considered for cost evaluation, and the ratings are normalized to restrict dominance of influence in path finding. Eq. (2) is the cost function applied to the nodes of the path that is planned by the proposed algorithm, while the semantic costs, Eq. (4), are calculated for all nodes that cover free spaces in the map.

F. Modified A* in D* lite Inspired Framework

The modified A* cost function is used to assign costs to each node and find a path. The curated initial path is fed to the D* lite-like framework.

The dynamic replanning is implemented using localized A*-based replans, conceptually inspired by D* Lite. The local replanning plans the new path from the current position to the goal position. The complete flow of the algorithm's working is given in Fig. 1. Algorithm 1 details the proposed LADy algorithm.

G. Flowchart

Fig. 1. Flowchart of the LADy algorithm working.

IV. PSEUDOCODE

- Input: warehouse_map, start_position, goal_position, alpha, beta
- Output: optimal_path, execution_complete

Key Functions:

- CalculateTrafficRating(node):
- Returns traffic congestion level for warehouse area
- CalculateTaskRating(node):
- Returns task complexity level for warehouse area
- CalculateSemanticCost(node):
- Combines traffic and task ratings with weight parameters
- ReplanFromCurrentPosition():
- Finds new path when obstacles block current route
- RevertToOriginalPath():
- Returns to initial optimal path when obstacles clear

Algorithm 1: Proposed LADy Algorithm

// PHASE 1: SEMANTIC ENCODING

```
for each free node in warehouse_map do
    | traffic_rating ← CalculateTrafficRating(node) / 10.0 × 0.3
    | task_rating ← CalculateTaskRating(node) / 10.0 × 0.3
    | store traffic_rating and task_rating for node
end for
```

// PHASE 2: MODIFIED A* PLANNING

```
initialize all nodes with infinite cost and no parent
set start_position cost to zero
add semantic cost to start_position
create priority queue with start_position
while priority queue is not empty do
    | current ← extract minimum cost node from queue
    | if current equals goal_position then
    |     | global_path ← reconstruct path using parent pointers
    |     | break from loop
    | end if
    for each valid neighbour of current do
        | calculate base movement cost to neighbour
        | add semantic cost for neighbour
        | if total cost is better than existing cost then
        |     | update neighbour cost and parent
        |     | add neighbour to priority queue
        | end if
    end for
end while
```

// PHASE 3: PATH INJECTION INTO DYNAMIC FRAMEWORK

```
initialize data structures for all nodes
path_length ← length of global_path
for each node in global_path do
    | distance_to_goal ← calculate position from goal
    | inject distance values into dynamic framework
end for
```

```
// PHASE 4: DYNAMIC EXECUTION
current_position ← start_position
current_path ← copy of global_path
while current_position not equals goal_position do
    detect new obstacles in environment
    if current path is blocked by obstacles then
        | current_path ← replan from current position
    end if
    if original path is now better than current path then
        | current_path ← revert to original optimal path
    end if
    next_position ← get next move from current path
    move robot to next_position
    current_position ← next_position
end while
return global_path, execution_complete
```

V. RESULTS

For simulation and benchmarking against other renowned path planning algorithms, we consider factors like:

- Path length
- Time
- Memory
- Nodes
- Replans

Based on these factors, the proposed algorithm is benchmarked against three categories for an environment,

- Path planning algorithms for static environments: A*, RRT*
- Path planning algorithms for dynamic environments: D* lite
- Path planning algorithms used in current commercial AMRs: a simplified interpretation of commercial AMR path planning approaches

For the warehouse environment setup, a complex warehouse visualization was generated in the Matplotlib visualizer. Its description is given in Table III.

TABLE. III. DESCRIPTION OF THE GIVEN MAP IN FIG. 2

Zone	Code	Color	Description
Perimeter walls	#2C3E50		Dark blue-gray
Storage racks	#8B4513		Saddle brown
Loading docks	#4682B4		Steel blue
Shipping area	#20B2AA		Light sea green
Receiving area	#32CD32		Lime green
Office complex	#FFD700		Gold
Break room	#FF69B4		Hot pink
Equipment storage	#FF8C00		Dark orange
Maintenance area	#DC143C		Crimson
Quality control	#9370DB		Medium purple

Zone	Code	Color	Description
Packaging area	#00CED1		Dark turquoise
Fire exits	#FF0000		Red
Conveyor systems	#A0A0A0		Gray
Charging stations	#00FF00		Lime
Free space	#FFFFFF		White

Fig. 2. Complex warehouse static setup for simulation.

A. Simulation in a Static Environment

For simulation in a static phase of the given warehouse environment, in Fig. 2, it is intended to benchmark against renowned algorithms for static environments, A* and RRT*. The study performed rigorous testing by simulating in Matplotlib, assigning a combination of 25 sets of start and goal points, and iterating the testing of each set 3 times to curate the average for a particular start and goal point.

1) *Benchmarking against A**: For the A* algorithm, whose path-finding process is grid-based, it deploys a grid of nodes on the map throughout and computes nodes that are explored as the path [33]. With simulation and testing of many input start and goal points set the A* algorithm's performance in the given environment in static state is analysed. For a glance at all testing results for A*, see the Data Availability section.

Fig. 3. A* simulation in the static state of the given map.

2) *Benchmarking against RRT**: For RRT* algorithm whose node distribution for path finding is random based on probability, deploys nodes randomly that is conditioned to reach the goal with less number of node distribution [34]. Similar to A*, the RRT* is also tested for its performance with input start and goal points sets and analyzed (see Fig. 4).

Fig. 4. RRT* simulation in the static state of the given map.

For a glance at all testing results for RRT*, see the Data Availability section.

In the case of performance metrics of A*, in Fig. 3, there are 4 details provided for the final results of the performance. The 'planned path' describes the number of steps initially planned to take by the robot to reach the goal from the start point. The 'steps taken' denotes the actual steps the robots take to reach the goal. Both the 'planned path' and 'steps taken' should be equal since this is a static environment case. And the 'time' denotes the time taken in total. The 'memory' denotes the memory it takes for computation, while the 'nodes' denote the computed nodes, that is, the explored nodes for the path. Similarly, in the same context, the performance metrics for RRT* are analyzed. Fig. 5 presents the LADy simulation in the static path of the given map.

3) LADy in a static environment

Fig. 5. LADy simulation in the static state of the given map.

B. Simulation in Dynamic Environment

For simulation in a dynamic phase of the given warehouse environment, in Fig. 2, it is intended to benchmark against renowned algorithms for dynamic environments, D* lite and a hybrid algorithm, a simplified interpretation of commercial AMR path planning approaches (see Fig. 6).

Fig. 6. Complex warehouse dynamic setup for simulation.

The study shows, performed rigorous testing by simulating in Matplotlib, like in a static simulation environment, assigning a combination of 25 sets of start and goal points, iterating the testing of each set 3 times to curate the average for a particular start and goal points. In the dynamic environment, along with the warehouse setup, 40 moving obstacles are deployed in the warehouse simulation setup that roam randomly in the free spaces.

The red circles are the moving obstacles in the free spaces, and the trail that follows is place for reference to its trail of movement in the warehouse simulation space. While random obstacle motion provides robust evaluation, deterministic and structured scenarios such as corridor blockages and congestion patterns will be explored in future work for controlled analysis.

1) *Benchmarking against D* lite*: For performance benchmarking, conventional D* lite algorithm from its publication was implemented and simulated in the developed simulation setup in Matplotlib [35]. In the simulation results, as in Fig. 7, comprise attributes like,

Fig. 7. D* lite simulation in the dynamic state of the given map.

- Initial plan : the initial path drafted by the algorithm
- Current plan : the remaining path to be covered by the robot from the current position to the goal position
- Steps taken : Steps covered by the robot
- Efficiency : efficiency of the final path the robot took with respect to the initial planned path

$$Efficiency = \frac{Initialplan}{Stepstaken} \times 100$$

- Time : time taken in total travel
- Memory : memory consumed on computation
- Nodes : number of computed nodes on the path
- Replans : number of replans due to obstacles

2) *Benchmarking against hybrid algorithm:* Similar to benchmarking against D* lite, the performance metrics, as in Fig. 8, of the hybrid algorithm in the given dynamic state of map in Fig. 6, is analyzed and compared with the proposed algorithm's performance. The simulation results' performance metrics of this algorithm shares the same context described for the D* lite algorithm above. The commercial AMR baseline is a simplified approach for conceptual comparison, not an exact replication of any proprietary systems.

Fig. 8. Hybrid algorithm simulation in the dynamic state of the given map.

3) *LADy in dynamic environment:* As already described the methodology of LADy algorithm of its working, it works as per its methodology described irrespective of the state of the given map, either static or dynamic doesn't influence the working of the proposed algorithm, which is a key characteristic of the proposed algorithm. For simulation of LADy algorithm, as in Fig. 9, in the dynamic simulation setup it has implemented complementary functionalities in simulation code to simulate best possible real-time environment. The research implemented and simulated sensor range, that is, visibility of moving obstacles within a particular

range, like in LiDAR used in real-time applications. The implementation of the mentioned sensor range can be noticed in the simulation recordings provided below.

Fig. 9. LADy simulation in the dynamic state of the given map.

For a glance at all simulation results of LADy algorithm, see the Data Availability section.

VI. METRICS

With the simulation results curated with many combinations of start and goal points, set inputs performance metrics are cumulated for benchmarking the proposed algorithm LADy against the renowned algorithms. The metrics are factored based on the state of the environment, whether the environment is static or dynamic.

A. For a Static Environment

For a static environment, compare LADy algorithm against the A* and RRT*, as mentioned before, for the factors defined below:

- Path length (in steps)
- Time (in seconds)
- Memory (in Kilobytes)
- Nodes

1) LADy vs. RRT* vs. A* (Path length)

Path length comparison

Fig. 10. Comparison chart of path length between LADy, RRT* and A*.

2) LADy vs. RRT* vs. A* (Time)

Time comparison

Fig. 11. Comparison chart of time between LADy, RRT* and A*.

3) LADy vs. RRT* vs. A* (Memory)

Memory comparison

Fig. 12. Comparison chart of memory between LADy, RRT* and A*.

4) LADy vs. RRT* vs. A* (Nodes)

Nodes comparison

Fig. 13. Comparison chart of nodes between LADy, RRT* and A*.

As shown in the charts, both LADy and A* maintain the same length (Fig. 10) and nearly same time (Fig. 11) obviously

in a static environment, since LADy itself has A* as its base layout of algorithm. While RRT* has less path length and time taken compared to A* and LADy algorithms.

Though, in memory consumption and number of computed nodes, A* and LADy are more efficient than RRT*. Even in paths computed by algorithms are at times less efficient, being a probability-based random sampling algorithm.

The chart shown in Fig. 10, shows the comparative analysis between LADy, RRT* and A* in the context of path length, while analysis in context of time is given in Fig. 11, memory is given in Fig. 12, and nodes are given in Fig. 13.

For instance, in the Fig. 14, the robot can be found to overlap obstacles in static setup planning path as per RRT* algorithm.

And for A*, the LADy algorithm is equivalent to A* performance in terms of path length and time, while A* is more efficient than LADy in terms of memory and computed nodes count since LADy pre-computes semantic cost data in each node that increase the computation memory and count of nodes but makes the proposed algorithm environment-aware and consistent and more suitable in real-time in this simulations' aspect while A* can't be implemented without modifications for such usage.

Fig. 14. Robot overlapping obstacle in RRT* simulation.

As mentioned above, the robot path can be seen in the above image, Fig. 14, overlapping the obstacles, and it can't be implemented without an additional approach to avoid collision with obstacles and get a smooth and realistic applicable path planned for real-time usage. For all performance metrics, refer the Data Availability section.

It covers all iterations and combinations of start and goal point sets.

B. For a Dynamic Environment

For dynamic environment, compare LADy algorithm against the D* lite and hybrid algorithm, a simplified interpretation of commercial AMR path planning approaches, as mentioned before for the factors defined below:

- Path length (in steps)
- Time (in seconds)
- Memory (in Kilobytes)
- Nodes
- Replans

1) LADy vs. D* lite vs. Hybrid (Path length)

Fig. 15. Comparison chart of path length between LADy, D* LITE and hybrid.

2) LADy vs. D* lite vs. Hybrid (Time)

Fig. 16. Comparison chart of time between LADy, D* LITE and hybrid.

3) LADy vs. D* lite vs. Hybrid (Memory)

Fig. 17. Comparison chart of memory between LADy, D* LITE and hybrid.

4) LADy vs. D* lite vs. Hybrid (Nodes)

Fig. 18. Comparison chart of nodes between LADy, D* LITE and hybrid.

5) LADy vs. D* lite vs. Hybrid (Replans)

Fig. 19. Comparison chart of replans count between LADy, D* LITE and hybrid.

The iterations of simulation results are cumulated to average, yet still the moving obstacles deployed in the simulation are a random factor in the environment, so this should be considered in benchmark analysis. Experiments were conducted across multiple start-goal configurations with repeated tests to ensure consistency, although detailed statistical analysis is considered for future work.

VII. DISCUSSION

From the above comparison charts, the results suggest that the proposed algorithm performs competitively under the tested conditions with respect to both D* lite algorithm, an optimal algorithm in terms of theoretical aspects for dynamic environments, and hybrid algorithm which is a simplified interpretation of commercial AMR path planning approaches, a specifically designed planning algorithm for warehouses with approaches of sensor fusion, reactive navigation dynamic obstacle avoidance.

In aspects of path length, as in Fig. 15, and time, as in Fig. 16, it approximately tallies the performance of D* lite which is theoretical optimal, and hybrid algorithm which is

application wise in real-time optimal. In aspects of memory, as in Fig. 17, and nodes, as in Fig. 18, both LADy and hybrid algorithm are consistent irrespective of the inputs for path planning. In aspects of replan counts, as in Fig. 19, the results show a wide variation and inconsistency due to the randomized moving obstacles deployment. While the hybrid algorithm has a lower count of replans since commercial AMR path planning approaches have their paths pre-defined for sets of start positions and goal positions, and they dodge obstacles at the moment reactively and not detour in most cases, which is the reason for the lower count of replans in the simulation results. The proposed method does not aim to establish computational improvements over D* Lite, but focuses on implementation with semantic cost integration.

VIII. COMPLEXITY ANALYSIS

The computational complexity of the LADy algorithm is analyzed across its three distinct phases: semantic encoding, modified A* planning, and dynamic execution.

A. Phase 1: Semantic Encoding

The semantic encoding phase computes traffic and task ratings for all free navigable nodes in the warehouse environment.

Given a warehouse grid of dimensions $W \times H$ with $|O|$ static obstacles, the number of free nodes is, $|F| = W \times H - |O|$. For each free node, the algorithm performs constant-time area classification and rating calculation operations.

Time Complexity: $O(|F|) = O(W \times H)$

Space Complexity: $O(|F|)$ for storing traffic_ratings & task_ratings dictionaries

B. Phase 2: Modified A* Planning

The modified A* phase follows standard A* complexity with additional semantic cost calculations. In the worst case, the algorithm explores all free nodes, with each node having at most 4 neighbors in a grid-based environment. The semantic cost calculation adds constant overhead per node evaluation.

Time Complexity:

$$O(|F| \log(|F|)) = O(W \times H \log(W \times H))$$

Space Complexity:

$O(|F|)$ For open set, closed set, and cost tracking structures

The logarithmic factor arises from priority queue operations, while the semantic cost computation ($\alpha \times t(n) + \beta \times T(n)$) adds only constant overhead per node.

C. Phase 3: Dynamic Execution

The dynamic execution phase complexity depends on the number of replanning operations triggered by obstacle changes. Let R denote the number of replanning events during path execution. Each replanning operation has the same complexity as the initial modified A* planning.

Time Complexity per Replan: $O(|F| \log(|F|))$

Total Dynamic Phase Complexity: $O(R \times |F| \log(|F|))$

Space Complexity: $O(|F|)$ For maintaining dynamic structures and current path

D. Phase 4: Overall Algorithm Complexity

The total computational complexity of LADy combines all three phases:

Time Complexity:

$$O(W \times H + (R + 1) \times W \times H \log(W \times H))$$

Space Complexity:

$$O(W \times H)$$

For typical warehouse scenarios, where, $W = 40, H = 30$, and $R \ll W \times H$. The algorithm demonstrates practical efficiency. The semantic encoding overhead is linear and performed only once during initialization, while the modified A* planning provides optimal initial paths with semantic awareness.

IX. CONCLUSION AND FUTURE SCOPE

The proposed algorithm has shown expected optimal results when benchmarked with A* and RRT* under static circumstances, and against D* lite and the hybrid algorithm used in current commercial AMRs under dynamic circumstances. In the field of Autonomous Mobile Robots operating in warehouses for respective functionalities and operations, typical paper-based path planning algorithms with original implementation don't produce optimal solutions in real-time when compared to simulations. To operate an Autonomous Mobile Robot in a controlled, known environment, yet dynamic, the renowned algorithms are modified or optimized according to their own functionalities and needs, differing between different operating warehouses. Combining two or more algorithms with a reactive nature, with the help of sensor fusion, an AMR functions in a warehouse. Yet, the presented algorithm, LADy, performs equivalent to an algorithm that is renowned in its specified state of environment. With curated benchmarking results, it is evident that LADy performs well optimally in a static environment, comparatively equivalent to A*, a renowned algorithm for static environments, and performs optimally in a dynamic environment comparatively equivalent to the hybrid algorithm that is implemented as a simplified interpretation of the path planning approaches used in commercial AMRs of warehouses.

As a future scope, the proposed, especially tailored motion planning algorithm for warehouse environments can be further improved with optimization and modularity for autonomous vehicles. The increasing trend of autonomous vehicles. As a driver, the vehicle not only should plan the path to the destination but also know the optimized path, which can't be achieved unless it is aware of the environment.

DECLARATION OF COMPETING INTEREST

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this study.

DATA AVAILABILITY

The complete simulation results and benchmarking results of the LADy algorithm are publicly available in the supplementary repository:

Design and Experimental Evaluation of Adaptive Load Balancing Strategies in Software-Defined Networks Using Mininet

M Shona, Rinki Sharma

Computer Science and Engineering, M S Ramaiah University of Applied Sciences, Bengaluru, India

Abstract—Software-Defined Networking (SDN) introduces centralized control and programmability, enabling more flexible and efficient network management compared to traditional architectures. Load balancing is a serious SDN application that improves resource utilization, reduces latency, and enhances service reliability. However, implementing SDN-based load balancers involves several challenges, such as controller overhead, scalability issues, dynamic traffic handling, and protocol integration. This study investigates these challenges and presents practical approaches for implementing SDN load balancers using the Mininet emulation environment. Different load-balancing algorithms are implemented and evaluated, highlighting the trade-offs between static and dynamic techniques. The study also examines traffic generation tools supported by Mininet. Furthermore, the performance of various SDN controllers, including Ryu, POX, OpenDaylight (ODL), ONOS, and Floodlight, is assessed using metrics such as throughput and round-trip time. Key performance evaluation metrics and their computation methods are also discussed. The goal of this research is to examine the challenges of implementing load balancing in Software-Defined Networking. It also aims to explore effective methods for designing and evaluating SDN-based load-balancing solutions using a Mininet test environment.

Keywords—Load balancing; control plane; data plane; OpenFlow; Mininet

I. INTRODUCTION

In recent years, the widespread use of the Internet has surged, leading to the need for greater bandwidth, improved reliability, and reduced latency. These demands have accelerated the development of advanced networking technologies. Software-Defined Networking (SDN) has emerged as a modern network architecture designed to intelligently manage network resources and dynamically adapt to changing requirements. Traditional networks are hardware-based, whereas SDN networks are software-based. Due to this architecture, it has the flexibility to directly program the network and has low operating costs. By using software for core functions such as routing, load balancing, resource allocation, and security, SDN provides centralized control over the network. Unlike traditional network architectures, where the control and data planes are closely integrated, and each switch makes routing decisions independently, SDN introduces a clear separation between these layers. The data plane, with SDN-enabled switches, handles packet transmission, while a centralized controller in the control plane oversees network management and traffic routing. Although the SDN is one of

the virtuous solutions for information technology-based applications, it faces many challenging issues like security, scalability, controller placement problem, load balancing, interoperability, and reliability. The primary challenge in network management is achieving an even distribution of workload across multiple servers. When traffic is not evenly spread, it can significantly impact overall network performance. Load balancing addresses this issue by distributing network traffic efficiently among several servers. This study presents a comprehensive review of different load balancing techniques, detailing their implementation and performance evaluation within the Mininet environment, offering useful insights for researchers in related domains.

This study is organized as follows: Section II reviews the existing research on SDN load balancing methods. Section III outlines the types of SDN load balancing algorithms. Section IV highlights the overview of simulators and emulators commonly used in SDN research. Section V presents the features of different SDN controllers. Section VI introduces traffic generators compatible with Mininet. Section VII explains the key performance metrics used for evaluating SDN load balancers. Section VIII analyses the performance of static and dynamic load balancers. Section IX explores potential future improvements. Finally, Section X concludes the study.

II. RELATED WORK

Load balancing typically serves the purpose of distributing network traffics across multiple servers or paths to optimize performance. The basic load balancing techniques such as round-robin and least-connection in a Mininet environment using the POX controller are implemented and evaluated in [1]. In [2], a Round Robin load balancing approach was implemented using a single Floodlight controller. A notable study [3] provides a comparative analysis of various SDN-based load balancing techniques, using Mininet. The authors emphasize the controller's role in state monitoring and highlighted the algorithm complexity and its latency. The impact of load balancers on SDN within cloud environments is explored in [4]. The author analyzed the effect of the application of SDN for load balancing to improve network performance [5]. In [6], the authors integrated Dijkstra's algorithm with Round Robin, achieving enhanced performance in fat-tree topologies. A Mininet-based setup with the POX controller was presented in [7], where load allocation was dynamically regulated based on server availability and health status. The work in [8] enabled SDN controllers to reroute

traffic automatically, ensuring sustained performance without manual intervention. In [15], the Least Connection algorithm was proposed, assigning traffic to the server with the fewest active connections and demonstrating better efficiency compared to Round Robin. The throughput, response time, and availability have improved through prioritizing the traffic flows in [10]. In [11], pox controller is used, which is less capable of managing traffic but achieves higher throughput and improved response times. In CAMD [12], the switch selected for migration is determined using a migration indexing factor, which results in improved response time, reduced migration cost, and higher throughput. Balcon [13] introduces a mechanism that balances the received requests among SDN controllers through optimal switch migration, thereby maintaining balanced performance under high traffic scenarios. A reinforcement learning-based switch migration method is proposed in [14], where the most heavily loaded controller is identified and one of its switches, chosen through a reward mechanism is reassigned to a different controller. The Weighted Round Robin approach [15] distributes requests using predefined static weights based on server capacity, which may not suit real-time traffic conditions. The Least Time-Based Weighted Round-Robin method [16] statically assigns weights to the servers based on the real-time link delay. The DWRS (Dynamic Weighted Random Selection) algorithm [17] serves as a dynamic load balancing technique designed for environments with a single SDN controller. Each server is allocated a weight based on its current real-time load. Consequently, the server with the lowest load is more likely to handle incoming client requests, resulting in improved throughput. Multi-path Load Balancing [18] is a link-based load balancer that shows improvement in response time and transfer rate. In [19], an Artificial Neural Network (ANN) technique is trained to identify the path that has the lowest load. This approach enhances network efficiency by considering factors such as latency and bandwidth. In [20], the load is divided into the network paths and aims at cost of route and cost of services. In another link based load balancer [21], a flexible and smart network management framework is designed to enhance dynamic routing efficiency. A dynamic LB algorithm [22] maintains a table of link costs and it is dynamically updated periodically. Jitter, packet loss and throughput are enhanced in this algorithm. Late Acceptance Neighbor Search [23] is a control plane based load balancer in which the controllers are assigned to switches by considering both the switch load and controller capacity, leading to reduced migrations. In a Distributed controller LB [24], each controller maintains a cost-state database that contains information about the travel costs between switches and their neighboring nodes. Based on the controller load and the cost matrix, the switches are assigned to a controller. It provides better flow set-up time.

Most of the existing works on load balancing in SDN have been focused on proposing various techniques or evaluating the controller for a specific scenario. However, there is a lack of holistic studies that address various implementation hurdles, various static, as well as dynamic load balancing techniques, and the evaluation of various SDN controllers in a cohesive environment. In addition, the implementation hurdles such as controller overhead, scalability of the controller for various traffic scenarios, and the integration of traffic generators in the

test environment have not been given much importance in the existing works on SDN-based load balancing techniques. In this regard, the proposed work aims at implementing and analyzing various load balancing techniques in a cohesive environment using the Mininet testbed, along with the evaluation of various SDN controllers using a set of metrics for a better understanding of the various implementation hurdles, thus facilitating the development of efficient load balancing techniques in SDN environments.

III. SDN LOAD BALANCING ALGORITHMS

Software-Defined Networking (SDN) mainly consists of two essential layers: the control plane and the data plane. Applying load balancing mechanisms across these layers plays a crucial role in improving overall network efficiency. Fig. 1 shows the impact of load balancing. It indicates that, without load balancing, congestion on specific routes caused a higher packet drop rate. However, when the SDN load balancer was active, packets were efficiently distributed across multiple paths, reducing packet loss by over 50% in most experiments. Load balancing techniques are generally classified into two types: static algorithms, which function under fixed traffic patterns, and dynamic algorithms, which adapt to changing application requirements. Fig. 2 illustrates the different SDN load balancing approaches.

Fig. 1. SDN performance with and without load balancer.

A. Static Load Balancing

Static load balancing requires an in-depth analysis of server capabilities before deployment. The load distribution pattern is predetermined and does not adjust according to real-time traffic fluctuations. This method is best suited for environments where workloads remain relatively constant. Common static load balancing techniques include Round- Robin [25], Weighted Round-Robin, Random Selection [26] and Hashing-based load balancing [27].

1) *Weighted Round Robin*: Round Robin is a classic and straightforward load-balancing method that evenly distributes incoming requests among available servers in a rotating sequence. The standard Round Robin approach has been

enhanced into the Weighted Round Robin (WRR) method, which distributes client requests according to predefined server weights. These weights are determined based on factors such as current traffic load, server response times, available resources, or overall processing capacity. WRR allocates the load request according to each server's capacity. As a result, it provides improved performance, particularly in environments with heterogeneous servers. For example, in Fig. 3, Server 1, Server 2, and Server 3 are given weights of 3, 2, and 1, respectively. Based on the assigned weights, Server 1 manages the first three incoming requests, Server 2 handles the next two, and Server 3 receives the sixth request. After this sequence, the pattern begins again.

2) *Random Selection*: In this Random Selection strategy, each incoming task or request is allocated to a server picked at random from the available options. As it does not require complex computations or tracking of server states, the process is fast and has very low resource overhead. This simplicity makes it well-suited for environments with a limited number of incoming requests. However, as the volume of requests increases, the lack of awareness about server load, performance capacity, or network delays can lead to imbalances.

3) *Hashing-based load balancing*: Hashing-based load balancing provides a simple yet powerful mechanism for achieving load balancing in networks. These methods apply a hash function to certain characteristics, such as IP addresses, port numbers, or protocol types to generate a value that determines how the flow is routed. The resulting hash guides

the selection of the appropriate path, server, or switch port, ensuring an even distribution of traffic. One of the key benefits is the speed and consistency of decisions. Once the hash function is established, routing decisions can be made quickly and reliably. Additionally, the technique incurs minimal overhead, as it does not require ongoing monitoring of network conditions. This makes it especially well-suited for large and complex topologies, where traffic must be efficiently spread across multiple available resources.

B. Dynamic Load Balancing

In dynamic load balancing, incoming requests are distributed from heavily loaded servers to those with lighter loads. This procedure necessitates the actual current load status of all servers across the network, allowing workloads to be shifted from overutilized to underutilized servers to maintain balance. Compared to static load balancing, dynamic methods offer improved efficiency by adapting to fluctuations in the load requests during runtime. They are particularly effective for applications with frequently changing load requests. However, implementing dynamic load balancing can be complex. There are three main approaches to dynamic load balancing: non-distributed, distributed, and semi-distributed. In the non-distributed approach, a single centralized node handles all incoming requests and assigns them to various servers. The distributed model allows all nodes to collaborate and share the task of request distribution. In the semi-distributed approach, the network is organized into several clusters, each overseen by a central node responsible for managing the distribution of requests within that cluster.

Fig. 2. Taxonomy of load balancing algorithms.

Fig. 3. Weighted Round Robin.

1) *Least Connection algorithm*: The Least Connection algorithm [28] is a dynamic load balancing method that routes incoming client requests to the server having the fewest active

connections. This approach is illustrated in Fig. 4. For instance, consider a scenario with three servers: Server1 has two active connections, Server2 has four, and Server3 has none. In this case, the first two client requests are directed to Server3, as it has no ongoing transactions. Once Server1 and Server3 both have two active connections, the next request (the third) is assigned to Server1, and the fourth to Server3. From that point onward, the requests alternate between Server1 and Server3, similar to the Round Robin approach. Essentially, each new request is assigned to the server with the fewest active transactions; if two or more servers have an equal number of active connections, the Round Robin method is used to distribute the load. The limitation of the Least Connection algorithm is that servers can become overloaded if they handle long-duration connections. Moreover, this method is best-suited for environments with homogeneous server configurations.

Fig. 4. Least Connection algorithm.

2) *Dynamic Weight Random Selection (DWRS)*: The DWRS load balancing method enhances the standard

Weighted Random Selection (WRS) algorithm by dynamically assigning weights to servers based on their current workload.

Although all servers may still receive the incoming requests, the server with the lowest load of requests has a greater chance of receiving additional requests, thereby reducing its idle time compared to other servers. The controller in the DWRS strategy continuously monitors each server's load and translates it into a value of weight using Eq. (1):

$$\text{Server Weight} = 10 - (\text{load at server}/10) \quad (1)$$

The server load, measured by the count of requests it receives, typically varies from 1 to 100. As described by Eq. (1), the server's weight is restricted to a maximum value of 10. This weight represents the server's relative probability of being chosen for incoming requests. Consequently, servers with higher loads are less likely to be selected as the target server. The controller keeps track of the weights assigned to each server. When a request is received, the controller first sums the weights of all servers to determine the total weight. A random number R that is smaller than this total weight is generated. A variable V is set to 0 and is gradually incremented by adding each server's weight in sequence of selection. As soon as V exceeds R , the process stops, and the request is forwarded to the server whose weight was recently added.

C. Data Plane Load Balancing

The data plane (DP) is responsible for directing packets to their appropriate destinations. It is also commonly referred to as the forwarding plane. The centralized SDN controller describes how the data plane is to behave in the network. The routing policies assigned to each flow are clearly established, although in some cases, multiple policies may apply to a single flow. Therefore, there might be many packets which use the particular route, and results in an increase in the volume of traffic. This surge in traffic leads to congestion along the path, which in turn raises delays and reduces the network's overall performance. To avoid congestion in the data plane, the path with the least load is chosen for the new incoming requests. Thus, a load balancer is required with predefined balancing policies. The data plane load balancing can be either of two types: Server LB or Link LB.

1) *Server LB*: The current existing traffic in the network is growing day-by-day, the service providers experience serious problem in server overload which results in network congestion leading to degraded performance and poor user experience. Therefore, the server load balancing plays a major role in network. This process distributes incoming requests across multiple servers to prevent any single server from becoming bottleneck. Server load balancing can be performed either in static or in dynamic algorithms. The both static and dynamic server LB algorithms are deliberated in [29].

2) *Link LB*: In SDN network, load balancing in multiple paths or links prevents congestion and enhances bandwidth, throughput and performance of the network. The link LB is achieved by two ways: a) Weighted link and b) Optimized routing.

a) *Weighted links*: Weights are assigned to the links [30] according to their current load, and packet distribution is carried out in proportion to these assigned weights. The

controller monitors the link and, based on the load, delay, and packet loss as impact factors, load balancing is performed. A score is assigned to each link depending on its load, and the link with the highest score is chosen to carry the traffic. This load balancing with respect to the weighted links prevents the link to be congested, therefore reduces the packet loss and hence provides better network performances.

b) *Optimal routing*: Link load balancing can also be achieved by optimal routing by generating optimal routing tables. Optimal routing can be done by different algorithms. The LB mechanism uses a shortest path algorithm to determine the shortest route for each flow and therefore balances the traffic. When a switch receives a new flow request, it queries the controller for routing instructions. The controller calculates the best path and responds by updating the switch's flow table accordingly. Each switch maintains a collection of flow tables containing entries for each source-destination pair. The multi-flow load balancing algorithm determines alternative shortest paths between these source and destination nodes. This load balancing approach uses the source-destination pair as its input. The algorithm also gathers network topology information using protocols JSON and REST APIs, enabling it to map ports, links, MAC and IP addresses, and their associations with switches and ports.

D. Control Plane Load Balancing

The control plane can be of single or multiple controllers working together. The control plane (CP) defines the routing table for forwarding the data packets. The SDN Controller serves as a key element within the control plane, overseeing the management of switches and leveraging software applications to enable intelligent network operations. The load balancing at the Control plane can be done in two ways: 1) Single or centralized controller, and 2) Distributed controller.

1) *Single controller LB*: A centralized controller plays a crucial role in the control plane's performance by overseeing all network-related functions. The load balancing can be performed either in static or in dynamic method. In static LB the controller use the load balancing algorithms and drives the connected servers [31]. In a dynamic algorithm, a central controller regularly collects load information from all connected servers and uses this information to allocate incoming tasks accordingly. It is simple to implement and less overhead of network management. But when the flow in the network increases, the single centralized controller are overloaded with huge number of requests from switches and controller may develop bottleneck problem. This results in lower performance of the whole network. Data centers and service provider networks are typical examples of such network scenario. Data center network includes thousands of switching elements which are expected to create vast number of control events which led to overload the single centralized controller. Use of Multiple controllers is the solution to meet the traffic characteristics within the large-scale networks.

2) *Distributed SDN controller LB*: The distributed SDN controllers include set of controllers which collaborate with

each other to manage all the underlying network devices. Distributed controllers enhance the system's reliability and scalability problems. Load balancing mechanism is needed in control plane to distribute or share the loads among the multiple controllers [32] and also to transfer the loads from overloaded controller to underutilized controllers. This balancing of load amid the multiple controllers, improves the performance of the entire network. In a distributed controller setup, the control plane's load balancing component can be organized in either a flat or hierarchical structure.

a) *Flat or horizontal controller LB*: In this LB, each controller in the architecture has the same tasks. The controllers communicate with each other via specialized channels by using east-west interfaces to share the network information. The multiple controllers are coordinated by maintaining network topology information in the datacenter, which helps enhance the scalability of SDN networks [33]. Onix is one of the examples of distributed controllers that manage multiple controllers and various switches [34].

b) *Hierarchical or vertical controller LB*: In a vertical or hierarchical architecture, controllers are organized across several levels in a top-down structure. The local controllers are placed in the bottom layers, whereas the root controller or super controller is placed in the top layer. The super controller oversees a comprehensive overview of the load status across all lower-level controllers. This LB is time-consuming as it is to manage multiple controllers in multiple layers. Lamen is a system with supervisor controllers [35] that manages the other controllers, similar to a centralized architecture.

E. Other Techniques of Cp/Dp Load Balancing

As the real-time communication networks lead to an increase in traffic dynamically, various types of dynamic load balancing techniques exist both in data and control planes. In recent research, load balancing is done by techniques like switch migration, reinforcement learning, ElastiCon, distributed controller placement, resource-based LB, etc.

1) *Switch migration*: As the load in a network is dynamic, static assignments of switch to controller are not efficient. Hence, to achieve load balancing, it becomes necessary to transfer switches from heavily loaded controllers to less burdened ones. This is accomplished by continuously monitoring the switches and identifying those with the highest traffic flow, which are then dynamically reassigned to a lightly loaded controller. In Mininet, switch migration denotes reassigning a switch to a different controller. As mininet is a network emulator, this process generally involves reconfiguring the control plane connections rather than relocating actual hardware. This mechanism improves the controller availability, but selecting the switch to get migrated in balancing the load is a challenging task in this mechanism. In [36], the load balancing is improved by 14% compared to the existing approach. The migration cost is reduced in the load balancer proposed in [37].

2) *Reinforcement Learning*: Reinforcement Learning (RL) is a branch of machine learning where an agent learns to make

optimal decisions by interacting with its environment and receiving evaluative feedback in the form of rewards or penalties. When applied to load balancing tasks, RL provides an adaptive and intelligent approach in distributing workloads across servers or network paths, with the goal of improving overall system efficiency and responsiveness.

In RL-based load balancing systems, the agent acts as a smart controller that continuously observes system metrics such as server utilization, traffic patterns, response time and latency. Based on these observed metrics, it determines the appropriate allocation of incoming tasks or data flows. Each action is evaluated by examining its system efficiency by focusing on reducing latency and improving throughput. Through iterative learning and real-time feedback, the agent refines its strategy to achieve optimal performance.

This approach is particularly advantageous in complex and dynamic environments, such as cloud platforms, edge networks, and SDN. Unlike traditional static or rule-based methods, RL-based load balancing can adapt to fluctuating workloads and network conditions, offering a more flexible and robust solution. The cost of migration of flows between the controller and switch is reduced in [38]. The RL-based load balancer [39] improved performance by accurate decision-making of switch migration.

3) *Elastic SDN controller*: An Elastic Software-Defined Networking (SDN) controller refers to a dynamic and adaptable control plane mechanism that can scale in response to fluctuating network demands. Unlike traditional fixed controllers, an elastic SDN controller setup is capable of automatically adjusting the number of active controller instances based on factors such as traffic load, network size, and application requirements.

This adaptability is made possible through approaches like deploying multiple controllers across the network, distributing traffic loads efficiently, and allowing for the seamless placement or relocation of controller entities. The primary objective is to maintain system reliability, ensure low latency, and optimize network performance, regardless of traffic variations. The load balancer proposed in [13] and [40] implements an elastic SDN controller and shows improved performance with dynamic traffic change. The LB [41] is designed to support dynamic addition and removal of controllers.

4) *Resource-based load balancing*: Resource-based load balancing within the Mininet environment involves intelligently distributing network traffic across various paths or nodes by considering the current state and usage of system resources. In this method, factors such as CPU utilization, memory load, bandwidth consumption, and queue occupancy are used to guide forwarding decisions.

In practice, this strategy is implemented by configuring SDN controllers like Ryu, POX, or ONOS to actively monitor the network's performance. These controllers gather real-time data on resource usage and use it to adjust flow rules on OpenFlow-enabled switches. This enables the network to adapt

dynamically by rerouting traffic away from congested links or overloaded devices toward less-utilized alternatives, ensuring better load distribution and improved performance. The adaptive resource allocation scheme in [42] shows effective even in large-scale SDN.

5) *Distributed Controller Placement (DCP)*: The DCP method determines both the number of SDN controllers needed and where they should be positioned within the network. This method is completely topology dependent. To solve the problem of the availability and scalability of a single SDN controller, distributed controller placement is employed. To improve the SDN network, the positioning of the controller needs to be considered. Given the positions of the switches, the Controller Placement Problem (CPP) selects optimal locations for controllers to reduce the latency between switches and controllers. The approach described in [43] addresses both delay reduction and load balancing. This method achieves a well-balanced load distribution with only a slight increase in latency. In [44], the number of required controllers is chosen with respect to support the load and the locations of controller is determined with the aspect of communication latencies.

IV. SDN SIMULATORS AND EMULATORS

SDN simulators use abstract representations of network topologies and protocols, making them ideal for evaluating algorithms and testing scalability. Emulators, on the other hand, recreate real network environments by running actual software like SDN controllers and OpenFlow switches, providing realistic behavior and supporting real-time interaction.

The comparison table of simulator and emulator tools is shown in Table I. Mininet [45] enables real-time interaction

with actual SDN controllers, whereas simulators provide abstract models, often needing additional modules for OpenFlow support and lacking the ability to run real controller code. Unlike EstiNet, which is powerful and may require licensing, Mininet is free, open-source, and user-friendly. While GNS3 focuses on traditional network and device emulation, Mininet is specifically designed for SDN, making it more effective for SDN-focused experimentation. Hence, Mininet is widely regarded as the leading tool for SDN, particularly in research and development. As a lightweight emulator, it enables users to create virtual networks on a single machine or virtual machine, allowing for interaction with virtual hardware and testing of SDN applications. Fig. 5 illustrates the percentage of usage for various simulators, where the graph indicates that Mininet is utilized more extensively than the other tools. Table I describes the features of various SDN simulators.

Fig. 5. Usage percentage of different simulators.

TABLE.I TYPES OF SIMULATORS AND EMULATORS

Tools	Type	OpenFlow Support	Emulates Real network interfaces	Scalability	User-friendly interface	Features
Mininet	Emulator	Yes	Yes	100 – 1000 nodes	Excellent	Fast prototyping, integrates with real controllers
Containernet	Emulator	Yes	Yes	Hundreds of containers	Good	Docker containers as hosts; good for app testing
GNS3	Emulator	Partial (via VM integration)	Yes	50–100 nodes	Moderate	Real router images, GUI-based setup
NS-3	Simulator	Yes(via OFSwitch13)	No	Tens of thousands of nodes	Poor	Detailed protocol simulation, high scalability
OMNeT++ (INET)	Simulator	Indirect (requires modules)	No	Thousands of nodes	Poor	Modular simulation, protocol-level granularity
EstiNet	Sim/Emu	Yes	Yes	Thousands of virtual nodes	Moderate	Commercial-grade GUI, supports hybrid simulation
Cooja	Simulator	Limited (IoT-focused)	Yes	100–1,000 nodes (depending on mote type)	Moderate	SDN for WSN, energy-aware routing support

V. SDN CONTROLLERS

In SDN, the controller acts as the centralized brain of the network. The SDN controller resides in the control plane and manages the network by dynamically adjusting routing, load balancing, and access policies using software-based logic. In essence, the SDN controller functions as the decision-making

hub of the network. It discovers and maps the network, defines how traffic should be handled, applies control policies, monitors activity, and facilitates communication between the control logic and the underlying hardware. These tasks collectively allow for flexible, programmable, and adaptive network management.

Fig. 6. Throughput of SDN controllers.

In Mininet, a few controllers are available for SDN simulation. In comparative analysis of SDN controllers, Ryu [46], POX, OpenDaylight (ODL), Open Network Operating System (ONOS), and Floodlight are evaluated based on throughput and Round-trip time (RTT). Throughput for SDN controllers is determined by measuring the volume of data successfully delivered within a given time frame using traffic generation tools such as iPerf. As illustrated in Fig. 6, the POX

controller demonstrates significantly lower throughput compared to the other controllers. Round-trip time (RTT) for each controller is evaluated using the ping command, with the results shown in Fig. 7. The analysis reveals that the POX controller records the highest RTT, whereas the ONOS controller achieves the lowest. Table II differentiates the different types of controllers and its features.

Fig. 7. Round-trip time of different controllers.

TABLE.II TYPES OF CONTROLLERS AND THEIR FEATURES

Name of Controller	Supported Platform	Supported Programming Language	Features
Nox	Linux	Python	First OpenFlow controller. The new version of Nox is released with multithreaded manner
Pox	Linux, Mac, Windows	Python	Upgraded version of Nox. It requires less memory but throughput performance is less.
Floodlight	Linux	Java	Designed as Concurrent systems. It achieves better performance in Organizational networks and Datacenters
Trema	Linux	C, Ruby	Designed for Cloud Infrastructure
Mastero	Linux, Mac, Windows	Java	Designed as Concurrent systems
Beacon	Linux, Mac, Windows	Java	Supports Multithreading and achieves better performance
Ryu	Linux	Python	Component-based Framework. Can create new network management and control applications. Designed for Cloud infrastructure.
OpenDaylight	Linux, Mac, Windows	Java	The recent version supports for the Internet of Things(IoT)
ONOS	Linux, Mac, Windows	Java	Includes Distributed network operating system. Increases availability and scalability naturally.

TABLE.III TYPES OF TRAFFIC GENERATORS AND THEIR FEATURES

Traffic Generator	Supported Traffic Types	Flow Scalability	Performance Metrics Measured	Advantages	Limitations
Iperf / Iperf3	TCP, UDP	Moderate (up to 20k with parallel mode)	Throughput / Bandwidth, Total Data Transferred, Jitter (UDP), Packet Loss	Simple to use, widely supported, reliable performance metrics	Limited application diversity, CPU-bound for large flows
D-ITG	TCP, UDP, ICMP, VoIP, video, gaming	High (up to 50k)	Throughput / Bandwidth, Total Data Transferred, Jitter (UDP), Packet Loss, End-to-End Delay (Latency)	Supports diverse application profiles, good scalability	Slightly complex configuration compared to Iperf
Pktgen	Raw Ethernet packets	Very high (50k–100k+)	Throughput / Bandwidth, Total Data Transferred	Extremely fast, low-level packet control	Requires kernel tuning, less suited for application-level testing
Ostinato	Layer 2–7 protocols	Low-Moderate (10k)	Throughput / Bandwidth, Total Data Transferred, Jitter (UDP), Packet Loss, End-to-End Delay (Latency)	GUI interface, flexible packet design	GUI overhead, not ideal for bulk flow generation
Mininet Built-in CBR/UDP	UDP	Very low (2k)	Throughput / Bandwidth, Total Data Transferred, Jitter (UDP), Packet Loss	Lightweight, no extra installation	Limited functionality, not scalable

VI. TRAFFIC GENERATORS IN MININET

Mininet supports a variety of tools [47] to generate and analyze network traffic, aiding in performance testing and simulation of real-world conditions.

1) *Ping*: The ping command is used in Mininet to generate basic network traffic by sending ICMP Echo Request packets from one host to another. For example, the command h1 ping h2 sends requests from host1 to host2, which replies with ICMP Echo Reply packets. This tool is useful for verifying connectivity and measuring round-trip time (RTT) between hosts.

2) *Iperf*: Iperf is a powerful and flexible tool for generating traffic and assessing network performance over TCP and UDP. Operating in a client-server model, it measures metrics like interval, data transfer rate, and bandwidth with iperf-TCP, while with iperf-UDP, along with those details it also provides jitter, packet loss statistics, and loss percentages, making it suitable for testing under various traffic conditions.

3) *D-ITG (Distributed Internet Traffic Generator)*: D-ITG is a comprehensive tool for simulating a broad spectrum of traffic types using TCP, UDP, ICMP, SCTP, and DCCP protocols. It provides precise control over various traffic characteristics, including packet size, arrival intervals, transmission rate, and duration. Operating in a client-server model, ITGSend generates traffic, ITGRecv captures it, and ITGDec analyzes log files to extract metrics such as jitter, throughput, packet loss and delay. D-ITG is ideal for detailed research and controlled testing.

4) *Mgen (Multi-generator)*: Developed by the U.S. Naval Research Laboratory, Mgen is a script-based traffic generator designed for real-time network traffic simulation. It supports both TCP and UDP, including unicast and multicast. Users define traffic flows via scripts specifying parameters like start/stop time, destination, port, packet size, and rate. Mgen runs as two components: mgen input to generate traffic and mgen output to log performance. It provides metrics such as latency, jitter, packet loss, and packet delivery ratio, making it ideal for QoS evaluation and repeatable network experiments.

Table III summarizes a few more types of traffic generators and their features.

VII. PERFORMANCE METRICS FOR EVALUATING SDN LOAD BALANCER

The evaluation of an SDN load balancer requires analyzing various performance metrics that indicate the network's efficiency, utilization of resources, and overall responsiveness. The essential metrics and tools listed below are used to evaluate these parameters when conducting simulations in environments like Mininet.

1) *Throughput*: It measures the rate at which data packets are successfully delivered over the network. It is calculated using Eq. (2):

$$\text{Throughput} = \frac{Dp \cdot Rp}{\text{Total duration of simulation}} \quad (2)$$

where, Dp represents the count of packets delivered and P_s denotes the size of a packet. IPerf tool can be used to measure the throughput.

On the receiving host (e.g., h2)
h2 iperf -s

On the sending host (e.g., h1)
h1 iperf -c h2

Fig. 8. IPerf commands.

The commands in Fig. 8 test can be repeated across various load balancing algorithms to compare throughput performance.

2) *Latency (End-to-end delay)*: It measures the time a data packet takes to travel from the source to the destination. To measure latency, ping command can be used. The average RTT value from the output reflects the average latency.

3) *Packet loss rate*: This metric indicates the proportion of packets that fail to reach their intended destination, which may occur due to congestion or link failure. Ping command can be used and from the output summary packet loss percentage can be calculated as Eq. (3):

$$\text{Loss Packet\%} = \frac{Dp - Rp}{Dp} * 100 \quad (3)$$

where, Dp = Count of delivered packets and Rp = Count of received packets.

4) *Packet Delivery Ratio (PDR)*: PDR measures the ratio of packets successfully received to those originally sent, as determined using Eq. (4). A higher PDR reflects better reliability in packet transmission.

$$\text{PDR} = \frac{\text{Total packets Received}}{\text{Total packets Sent}} \quad (4)$$

5) *Response time*: This is the time interval between sending a request and receiving a response, especially relevant for application-layer communications. Application-level logging or timestamping (e.g., with curl, custom web apps, or controller logging) can be used to determine response duration [see Eq. (5)].

$$\text{Server Utilization\%} = \frac{\text{Server Active Time}}{\text{Total Simulation Time}} * 100 \quad (5)$$

6) *Quality of Service (QoS) metrics*: Bandwidth Allocation can be analyzed by comparing the expected allocated bandwidth versus the actual utilized bandwidth using tools like iperf and network monitoring scripts.

7) *Scalability*: It checks how the load balancer performs as the network size or traffic increases. In Mininet, the number of hosts or switches is increased, and the key metrics (throughput, latency, controller load) can be monitored to determine how much they vary with scale.

VIII. STATIC VERSUS DYNAMIC LOAD BALANCER

Static algorithms, including RR, RS, LTWRR, and WRR, together with the dynamic algorithm DWRS [9] [48], were

implemented and their performance was systematically evaluated within the Mininet environment. The iperf-udp utility is employed to simulate network traffic. The configuration consists of three servers and three clients, where all clients simultaneously transmit iperf traffic to the servers. Fig. 9 presents the results obtained from the iperf-UDP tool. To assess the performance of each load balancing algorithm, two traffic conditions were emulated, consisting of 100 and 200 client requests directed to the servers.

Fig. 9. Output of iperf-udp traffic generator.

Fig. 10. Packet loss percentage.

Fig. 10 illustrates the packet loss percentages for both static algorithms and the Dynamic Weighted Random Selection (DWRS) approach. According to the graph, the Round Robin (RR) and Random Selection (RS) algorithms exhibit the highest packet loss rates. The LTWRR algorithm, a static method focused primarily on link delay, also shows significant packet loss. Although WRR is a static algorithm, it assigns weights based on server capacity, resulting in a lower packet loss rate than LTWRR. DWRS outperforms the other methods in minimizing packet loss by dynamically modifying weights based on real-time network load. The graph clearly indicates that dynamic load balancing techniques yield better performance compared to static algorithms. Additionally, the average response time of the load balancing techniques is measured using the curl command, and the outcomes are

illustrated in Fig. 11. Among the tested approaches, DWRS achieves a lower response time compared to the other load balancers.

Fig. 11. Average response time of load balancers.

Both static and dynamic approaches are simulated under the same conditions, allowing for an objective assessment of the solution. The comparison of the controller and the traffic generators is the key, which points out the benefits, as well as its drawbacks, especially with regard to flexibility, efficiency, and scalability, which is crucial in validating the solution as well as positioning it with regard to the related work, thus adding value to the study itself. A range of SDN optimization approaches is examined in [49], including a comparative analysis of algorithms designed for routing (both static and dynamic), packet forwarding, load balancing, traffic management, and reducing forwarding delays.

IX. FUTURE ENHANCEMENTS

The results of this study indicate that no single load balancing strategy is best in the context of Software Defined Networking environments. While static load balancing is best due to its simplicity and less control overhead, the strategy is less effective due to its lack of adaptability to changing network environments. On the other hand, the dynamic nature of the load balancing strategy is more effective in terms of its responsiveness to changing network environments; however, the strategy also incurs additional overhead at the controller level.

In terms of the practical implications of the study, the use of the Mininet tool is effective in terms of its flexibility and cost, however, the tool may not accurately represent real-world environments. Therefore, the results of the study are valuable if further tested in real-world and large scale environments. This study also highlights the importance of using the right load balancing strategy in SDN environments and the need to develop more effective solutions that are adaptive to changing network environments. Future work can focus on hybrid approaches that balance performance and overhead.

After reviewing some of the existing load balancing algorithms, few open issues are analyzed and summarized below:

1) *Early detection of controller overload*: There is a growing need for mechanisms that can identify potential overload conditions in SDN controllers before they occur. A promising direction for improvement involves the application of machine learning and artificial intelligence to forecast traffic patterns and facilitate adaptive, real-time traffic distribution. These intelligent techniques can utilize both past and present network data to mitigate congestion proactively and ensure efficient use of resources.

2) *Unified framework*: The existing algorithms addresses either server-side or controller side load distribution but do not provide a unified framework that balances both controller load and server load simultaneously.

3) *Scalability through distributed architectures*: Many existing dynamic load balancing techniques depend on a centralized controller, which poses scalability and fault-tolerance challenges in large-scale deployments. To address these limitations, distributed and hierarchical controller architectures can be introduced. These models help eliminate bottlenecks and single points of failure, offering better scalability and improved reliability while maintaining efficient load balancing.

4) *Security-aware load balancing*: Finally, the existing load balancing algorithms neither considered about the security issues in forwarding the requests. Incorporating security-aware mechanisms into load balancing strategies will be essential to ensure that traffic distribution upholds data integrity and confidentiality, especially in complex and rapidly changing network environments.

X. CONCLUSION

SDN has become a major focus of academic and industrial research in recent years. This work focuses on implementing load balancing algorithms within the Mininet simulation environment using SDN. The study addresses the challenges in designing efficient load balancing solutions and outlines the distinct features of various SDN controllers. Both static and dynamic load balancing techniques were examined, and their comparative performance was analyzed to demonstrate the trade-offs between simplicity, responsiveness, and scalability. By analyzing different load-balancing strategies and evaluating multiple SDN controllers, the work provides practical insights into their strengths, limitations, and suitability under varying network conditions. The findings highlight the importance of adaptive and scalable approaches to address real-world challenges such as dynamic traffic and controller overhead. The results indicate that while static algorithms provide lightweight and predictable performance, dynamic algorithms are more adaptive to fluctuating network conditions but introduce higher complexity. The study also provides an overview of traffic generators available in Mininet, highlighting their features and the performance metrics that can be evaluated using them. By bringing together these findings, the study not only evaluates current strategies but also identifies open challenges that demand further exploration. The outcomes of this study provide valuable guidance for researchers and practitioners aimed at creating more resilient,

adaptive, and scalable load balancing strategies for SDN environments.

Machine Learning-Based Air Quality Monitoring in Indian Metropolitan Cities: A Comparative Study

Khushbu Chauhan¹, Kruti Sutaria²

Dept. of Computer Science and Engineering, Parul University, Vadodara, 391760, India¹

Dept. of CSE Cyber Security, Parul University, Vadodara, 391760, India²

Abstract—Pure and clean air is essential to make the ecosystem healthy. Air pollution is becoming a critical global concern for both the environment and human health. Presence of harmful pollutants such as PM_{2.5}, PM₁₀, CO₂, NO₂, SO₂, and O₃ continuously degrades air quality and influences climatic conditions. This study aims to present a comprehensive air quality monitoring between traditional and advanced ensemble-based machine learning models. To monitor air quality, data collected from major metropolitan cities of India from 2015 to 2023 (Three phases- Pre-COVID, during COVID-19, and post-COVID). After pre-processing the data, a baseline supervised machine learning method, Support Vector Machine (SVM), was applied for ease of implementation. Later, to train weak learner features, ensemble-based machine learning techniques include Gradient Boosting Machine (GBM) and Extreme Gradient Boosting Machine (XGBM), evaluated to get better prediction analysis. The systematic analysis is inspected using different performance parameters: R², Mean Squared Error, Root Mean Squared Error, and Mean Absolute Error. The outcome indicates XGBM achieves superior predictive accuracy and robustness across most cities and time periods, and achieves better variability in spatial and temporal features in performance. The key findings highlight the importance of location-based specific modelling strategies and demonstrate the potential of ensemble learning models for reliable urban air quality monitoring.

Keywords—AQI; COVID; SVM; Gradient Boosting Machine (GBM); Extreme Gradient Boosting (XGBoost)

I. INTRODUCTION

Rapid urbanisation and industrialisation, vehicular emissions, and deforestation in the 21st century ruin the entire environment and nature [1]. Major air pollutants, such as particulate matter (PM_{2.5} and PM₁₀), nitrogen dioxide (NO₂), sulphur dioxide (SO₂), carbon monoxide (CO), carbon dioxide (CO₂), and ozone (O₃), [2] cause hazardous impacts on human health. The Air Quality Index (AQI) is mainly used to measure and monitor air quality continuously based on different pollution levels, categorizing it from good (0-50) to hazardous (above 300) using a colour scale ranging from green to maroon [3]-[4]. According to the World Health Organization (WHO), urban air pollution increased approximately 56.15% in 2020, which may rise to 68% by 2050. This concerning increase in pollution poses significant threats not only to human well-being but also to the entire ecosystem [5].

Traditional statistical and machine learning models, such as linear regression, decision trees, random forest, and support

vector machines (SVMs), have been widely applied for air quality prediction due to their conceptual simplicity and relatively low computational cost. However, these methods often struggle to capture the non-linear, non-stationary, and highly heterogeneous nature of urban air pollution, particularly when applied across diverse climatic zones or during periods of abrupt socio-economic change. Moreover, many existing studies emphasise predictive accuracy as the primary evaluation criterion, with limited attention to model robustness, uncertainty, and interpretability in the context of air quality science and decision-making.

Recent advances in ensemble machine learning techniques, particularly gradient boosting-based methods, have demonstrated strong potential for improving air quality forecasting by combining multiple weak learners to capture complex feature interactions. Models such as Gradient Boosting Machine (GBM) and Extreme Gradient Boosting Machine (XGBoost) offer enhanced generalisation capabilities, built-in regularisation, and robustness to noisy environmental data. Despite these advantages, their application in air quality research has largely focused on short-term forecasting or single-city case studies, with limited exploration of spatial heterogeneity, long-term temporal dynamics, and real-world disruptions such as the COVID-19 pandemic. This work focuses on air quality monitoring by closely observing the Air Quality Index (AQI) of major air pollutants: PM_{2.5}, PM₁₀, O₃, CO, NO₂, and SO₂ from collected data on Indian metropolitan cities, including Ahmedabad, Bengaluru, Chennai, Delhi, Kolkata, and Mumbai. These cities represent diverse climatic zones and industrial profiles, which makes them more ideal for air pollution analysis. To capture complex, non-linear, and weak learner features, ensemble machine learning techniques such as Gradient Boosting Machine and Extreme Gradient Boosting Machine were introduced. The study focuses on three phases: Pre-COVID, during the COVID-19 pandemic, and Post-COVID recovery periods, which provide a clear view of pollution trends under economic conditions. By comparing baseline machine learning models with advanced models to improve the prediction accuracy by calculating different performance parameters, R² score, Mean Squared Error, Mean Absolute Error, and Root Mean Squared Error.

Despite significant advancements in machine learning-based air quality monitoring, the existing studies largely focus on short-term temporal prediction and on single-city analysis, with limited attention on long-term temporal variability, spatial heterogeneity, and model robustness, such as COVID-

19 pandemic disruptions. These create a gap in understanding how different models perform across diverse urban environments. Therefore, a strong requirement for a systematic evaluation and analysis of machine learning methods for air quality monitoring across multiple cities with different temporal phases.

The key contribution of this work lies in moving beyond accuracy-centric evaluation toward a more comprehensive understanding of how machine learning models reflect underlying air pollution dynamics in heterogeneous urban environments. By identifying cities and periods where models perform reliably and those where prediction uncertainty and overfitting emerge, the findings provide actionable insights for air quality management, early warning systems, and policy-driven decision-making. This integrated perspective supports the development of adaptive, location-specific air quality monitoring frameworks suitable for complex and rapidly evolving urban settings. The key objective of the research study is to evaluate and analyse long-term air quality trends and to compare the performance between traditional and ensemble machine learning methods.

II. RELATED WORK

The study proposed by Pan et al. [6] was a cluster-based under-sampling strategy combined with a transformer model to improve the prediction of extreme PM_{2.5} concentration. They optimized model performance for a high-pollution scenario and developed data augmentation for air quality forecasting. Due to the rarity of training datasets, traditional forecasting approaches perform poorly on high-concentration episodes. Alrasheedi et al. [7] emphasized the use of ensemble and hybrid machine learning models to enhance robustness and handle spatial heterogeneity for accurate air quality prediction. The authors used GBM and XGBM strategies to improve the performance of air quality prediction. The review persists challenges of high computational costs, limited model generalizability across regions, and data quality issues. Muhammad et al. [8]; Kumari et al. [9] integrated a long-term climate assessment framework that combines the Mann-Kendall trends with machine learning models to adopt a climate-smart agriculture system in Nigeria. Satish et al. [10] demonstrated a comparative survey on four major sources: industrial activities, vehicular traffic, natural phenomena, and combustion processes to evaluate machine learning-based air pollution prediction. The reviewed studies reveal challenges such as the complexity and variability of pollution sources and the difficulty in accurately modelling emissions from diverse and dynamic processes. A linear regression-based machine learning model to forecast AQI using an AI-driven, data-centric air quality prediction framework proposed by Waghmare et al. [11] for Pune city.

Ansari et al. [12] proposed a comprehensive machine learning-based framework for hourly AQI prediction and demonstrated that Extreme Boost (XGBoost) performed with superior accuracy and computational efficiency in urban air quality forecasting. Dawar et al. [13] proposed a Lasso regressor-based machine learning model that can accurately predict air quality from the Himalayan city of Dehradun. It supported proactive air pollution mitigation aligned with

SDGs 3 and 11. Due to limited location-specific AQI prediction studies for Himalayan towns, the influence of complex geographical and climatic conditions on air quality. The authors concluded with the need for reliable, high-accuracy models to enable timely and effective urban air quality management. T. Desai et al. [14] used SVM and KNN-based machine learning models to combine multiple algorithms to make hybrid models to achieve better forecast accuracy, especially when trained on large datasets. They faced difficulty in achieving consistent AQI prediction accuracy across diverse urban industrial environments. Sharma et al. [15]; Ahmad et al. [16] proposed two different frameworks, ARIMAX/SARIMAX-ML and a hybrid BiGRU-1DCNN framework, to integrate temporal and spatial feature learning to accurately predict particulate matter levels across multiple monitoring stations in Delhi. The BiGRU-1DCNN model demonstrates strong predictive performance by effectively capturing spatiotemporal patterns. However, the ARIMAX/SARIMAX-SVM framework provides more interpretable outcomes by explicitly analysing trends and incorporating exogenous factors, which enhances its usefulness for policy formulation. J. Saini et al. [17] presented a systematic review of various machine learning models to predict indoor air quality by identifying Random Forest as the most commonly adopted model, and PM_{2.5} was identified as a key indicator for critical indoor air conditions. Difficulties in timely forecasting of hazardous indoor air scenarios and a lack of training data face issues in forecasting indoor air quality. Naveed et al. [18] proposed an innovative digital twin-based framework for AQI forecasting in smart cities, integrating deep learning models with a 3D urban digital twin to enable accurate prediction, visualization, and real-time monitoring of air quality. Challenges such as limited integration of AI models with digital twin platforms, and difficulty in real-time visualization and decision support issues have been identified for effective forecasting.

Although extensive research has applied machine learning and ensemble-based techniques for air quality prediction, several limitations remain in the current body of literature. Many existing studies focus on short-term forecasting, single-city case studies, or isolated pollutants, which restricts their ability to capture long-term temporal dynamics and spatial heterogeneity across diverse urban environments. Moreover, while advanced models such as XGBoost, hybrid deep learning architectures, and spatiotemporal frameworks have demonstrated improved predictive accuracy, limited attention has been given to model robustness, uncertainty, and performance degradation under abrupt socio-economic disruptions, such as the COVID-19 pandemic. Most studies primarily evaluate models based on numerical accuracy metrics, with minimal interpretation of how model behaviour reflects underlying pollution complexity or emission stability.

Furthermore, most existing works emphasise accuracy metrics without providing insights. In contrast, the present study extends existing research by conducting a multi-city, long-term analysis across major Indian metropolitan regions representing diverse climatic conditions and emission profiles. By systematically evaluating traditional and ensemble machine learning models across pre-COVID, during COVID,

and post-COVID phases, this work provides insights into spatial variability, temporal stability, and overfitting behaviour under distributional shifts. Furthermore, the study emphasises the practical relevance of model performance for urban air quality management, highlighting where data-driven approaches are reliable and where adaptive or hybrid strategies may be required. This comparative and interpretive perspective positions the work beyond accuracy-centric forecasting and contributes to a more policy-relevant understanding of machine-learning-based air quality monitoring.

III. MATERIALS AND METHODS

A. Data Collection

Table I shows datasets collected from major metropolitan cities of India, including Ahmedabad, Bengaluru, Chennai, Delhi, Kolkata, and Mumbai. From Mumbai, the data was collected from different highly polluted locations, including Borivali West, BKC, Chakala Andheri East, CSMT Airport, Deonar, Bhandup West, Kurla, Malad West, Mulund West, Vile Parle West, Colaba, Sion, and Worli. These cities were selected to represent a diverse range of climatic zones and to exhibit rapid population growth and pollution sources, including traffic emissions, industrial activities, stubble burning, and deforestation, making them suitable for a comprehensive analysis of air quality. The air quality data were obtained from publicly accessible resources, the Central Pollution Control Board (CPCB) and the State Pollution Control Board (SPCB). The dataset covers the years from January 2015 to July 2023 and consists of hourly observations, including approximately 78,000 records with 24 different attributes, making it a large multivariate time-series dataset. It includes time indicators (From Date and To Date), key air pollutants such as $\text{PM}_{2.5}$ ($\mu\text{g m}^{-3}$), PM_{10} ($\mu\text{g m}^{-3}$), NO_2 ($\mu\text{g m}^{-3}$), SO_2 ($\mu\text{g m}^{-3}$), CO (mg m^{-3}), Ozone ($\mu\text{g m}^{-3}$), and selected Volatile Organic Compounds (VOCs) components like Xylene ($\mu\text{g m}^{-3}$), along with meteorological parameters including Temperature ($^{\circ}\text{C}$), Relative Humidity (%), Wind Speed (m s^{-1}) and Wind Direction ($^{\circ}$), Barometric Pressure (hPa), Solar Radiation (W m^{-2}), and Rainfall (mm). Data validation procedures included consistency checks, removal of unrealistic and outlier values in accordance with the CPCB and SPCB data quality guidelines. As is typical of real-world environmental monitoring data, some attributes contain missing or irregular values. This highlights the need for careful pre-processing before applying machine-learning models.

B. Data Pre-processing

Data Pre-processing is used to enhance data quality for better model performance. From the above section, datasets were collected from 2015 to 2019 on an hourly basis by different key pollutants along with measurements. Techniques such as data cleaning and outlier removal are important before applying models. To handle missing values and outlier removal, various pre-processing approaches were used to ensure data integrity and model performance. A variety of non-arbitrary values without adding any arbitrary data were used to fill missing values [19].

TABLE I. DATA COLLECTION FROM MAJOR METROPOLITAN CITIES

Sr. NO.	Indian metropolitan cities	Sr. NO.	Mumbai Locations
1	Ahmedabad	6.1	Borivali East
2	Bengaluru	6.2	BKC
3	Chennai	6.3	Chakala Andheri East
4	Delhi	6.4	CSMT Airport
5	Kolkata	6.5	Deonar
6	Mumbai	6.6	Bhandup West
		6.7	Kurla
		6.8	Malad West
		6.9	Mulund West
		6.10	Vile Parle West
		6.11	Colaba
		6.12	Sion
		6.13	Worli

$$x_m = x_p + \left(\frac{x_n - x_p}{t_n - t_p} \right) t_m - t_p \quad (1)$$

where, x_m is used to fill missing values. x_p and x_n are the previous and next index, respectively [see Eq. (1)].

Missing values were treated using a time-series interpolation method. Linear interpolation, which works particularly well with time-series datasets, was used to estimate missing values between consecutive observations. Furthermore, polynomial interpolation was used for more intricate data patterns, fitting higher-order curves to more precisely monitor missing inputs.

Attributes such as NH_3 , Xylene, Wind Speed, Wind Direction, and Rainfall (RF) were removed due to a high proportion of missing values to maintain data quality and minimise noise. The pre-processed datasets concentrate on the most reliable and pertinent air quality indicators. For short gaps occurring at the beginning or end of a time series, forward fill (FFill) and backward fill (BFill) were used on datasets for quick processing. In order to fill the gaps, Backwards Fill uses the next known value, whereas Forward Fill uses the more recent known value ahead to address missing elements [see Eq. (2) and Eq. (3)]:

$$X_t = X_{t-1} \text{ (Forward Fill)} \quad (2)$$

$$X_t = X_{t+1} \text{ (Backward Fill)} \quad (3)$$

These techniques store the time-series related data structure. Furthermore, for regression imputation methods based on models were used to estimate missing values, K-Nearest Neighbours (KNN) imputation evaluates missing values based on the similarity among neighbouring data points.

Outlier detection and treatment were performed to mitigate the influence of extreme values that occurred in the statistical analysis. To remove outliers, two primary approaches were used, which have the potential to skew statistical research and impair model accuracy. First, outliers were found by

computing boundary values based on standard deviations (values exceeding ± 3) using the Z-score approach [20]. Plotting distributions, identifying borders, identifying outliers, and applying trimming or capping were all included in the outlier-removing process. To reduce skewness while preserving the data's range, capping replaced the present threshold values with extreme values. For verification of changes, statistical conclusions were produced using the describe () function. Moreover, a percentile-based Winsorization approach was used to manage the skewed distribution commonly observed in pollutant concentration data. The 1st and 99th percentile thresholds were selected to cap extreme observations. Winsorization minimises information loss and maintains dataset size, which is particularly useful for time-series modelling. Across major key pollutant features such as PM_{2.5}, PM₁₀, SO₂, NO₂, and CO, approximately 7-10 % observations per feature were identified as outliers and subsequently capped. Visual inspection by box plots and distribution plots, along with observations before and after outlier removal, confirmed that these procedures reduced skewness and variance without altering temporal patterns, which were used to evaluate the data spread of selected features [21].

The final pre-processed dataset retained the most reliable air quality and meteorological variables, with improved stable distribution and noise reduction, providing a robust base for subsequent machine learning models development. The cleaned dataset was divided into training (80%) and testing (20%) sets using a time-aware split to preserve temporal dependencies. Feature sets include key pollutants PM_{2.5}, PM₁₀, NO₂, SO₂, CO, O₃ as input features, and selected meteorological parameters include temperature, relative humidity. AQI is treated as a target feature. Since AQI is derived from pollutant concentrations, it was ensured that AQI was not used as an input feature when predicting AQI to avoid data leakage. Additionally, a validation set (10% training data) was used for hyperparameter tuning. Hyperparameters for machine learning algorithms represented in the section below, specifically for SVM, GBM, and XGBoost, were optimised using the grid search technique.

C. Machine Learning Models

Support Vector Machine (SVM) has emerged as a reliable data-driven approach for air quality prediction, particularly in situations where conventional physical and statistical models face limitations [22]. SVM, and its regression variant Support Vector Regressor (SVR), are well-suited for handling the non-linear and non-stationary nature of atmospheric pollution data. SVM requires lower computational effort for short-term forecasting applications to get superior accuracy. This will make the SVM model more practical and provide stable responses to variations in training data. SVM provides a balanced combination of accuracy, robustness, and computational efficiency, establishing it as a suitable and dependable tool for air quality monitoring across different climatic and urban environments. Parameters such as kernel function are tuned based on validation performance [23]-[24].

An Ensemble learning technique, such as a Gradient Boosting Machine (GBM) that builds weak learners in

sequence, specifically decision trees. With optimization of gradient descent, each new model needs to correct the mistakes of its predecessors with exceptional prediction skills and flexibility in handling different loss functions. Gradient Boosting Machine exhibits high efficiency for both applications of regression and classification [25]. XGBoost, LightGBM, and CatBoost libraries offer well-optimised implementations of GBM. Hyperparameters such as the learning rate, tree depth, and number of boosting rounds must be aligned to achieve the optimum results. No single gradient boosting algorithm is universally superior; instead, the choice depends on the application requirements. CatBoost is preferable when predictive accuracy is critical [26], LightGBM is ideal for large datasets requiring fast training, and XGBoost provides a well-balanced option with strong performance and scalability. The XGBRegressor [27] library is specifically used as a regression with gradient boosting implementation, created to minimise a specified loss function. It builds an ensemble of decision trees one after the other, with each new tree concentrating on reducing the residual errors of its predecessors. To compare traditional boosting techniques with the ensemble model, XGBRegressor's ability to integrate both L1 (alpha) and L2 (lambda) regularization is a noteworthy advantage, as it reduces overfitting and enhances generalization. It can be fine-tuning the complexity of a model for training speed and predicted accuracy by adjusting its hyperparameters, including learning_rate, n_estimators, max_depth, and subsample. The models were trained on earlier time periods and tested on later periods to evaluate performance under temporal distribution shifts. Hyperparameters learning rate, number of estimators, and maximum tree depth (GBM and XGBoost) were tuned based on validation performance.

$$\mathcal{L}^{(t)} = \sum_{i=1}^n l(\tilde{y}_i, \tilde{y}_i^t) + \sum_{k=1}^t \Omega f_k \quad (4)$$

$$\Omega(f) = \tau T + \frac{1}{2} \lambda \sum_{j=1}^T \omega_j^2 \quad (5)$$

$$\mathcal{L}^t \approx \sum_{i=1}^n [g_i f_i(x_i) + \frac{1}{2} h_i f_i(x_i^2)] + \Omega(f_t) \quad (6)$$

$$\omega_j = \frac{\sum_{i \in I_j} g_i}{\sum_{i \in I_j} h_i + \lambda} \quad (7)$$

$$y_i = \sum_{k=1}^T f_k(x_i) \quad (8)$$

Eq. (4) to Eq. (8) collectively define the regularized boosting framework adopted in this study. These formulations govern loss minimization, tree complexity control, and incremental error correction, forming the basis of the XGBM implementation used for multi-pollutant prediction [28]. $l(\tilde{y}_i, \tilde{y}_i^t)$ = Loss function (e.g., Mean Squared Error and Mean Absolute Error calculation for the difference between actual and predicted pollutant concentration) and Ωf_k as a Regularisation term (Overfitting in transfer learning). $\Omega(f)$ for preventing overfitting, a regularisation term is added to the main loss function. The equation illustrates the estimated loss function at boosting step t , employing a second-order Taylor expansion. ω_j Optimal weight assigned to leaf node j . y_i Final predicted pollutant concentration for the data point i . T : Total number of boosting iterations. $f_k(x_i)$ Output of the k th

weak learner of a model. Each weak learner comprehensively resolves the residual errors from previous trees, leading to improved pollutant prediction accuracy. By aggregating losses across multiple pollutants, XGBM ensures balanced forecasting and prevents domination by a single pollutant. Additionally, an iterative learning of XGBM makes it more suitable for robust air quality monitoring. The XGB Regressor optimises a regularized objective that includes both a loss component and a penalty for complexity in order to construct additive decision trees. By utilising gradient information (first-order) along with Hessian information (second-order), it effectively modifies tree structures while managing overfitting through L1/L2 regularization.

IV. RESULTS AND DISCUSSION

A. Advanced Machine Learning Models GBM and XGBM

Ensemble learning techniques, particularly XGBRegressor, offer a strong and logical solution to train weak learner features in terms of air quality monitoring. The developed improvements on collected data indicated that the boosting framework effectively captured complex non-linear relationships between pollutants and meteorological variables, leading to improved prediction accuracy for multiple pollutants such as PM_{2.5}, PM₁₀, CO, SO₂, and NO₂. The combination training of L1 and L2 regularization within the objective function-controlled model complexity, which reduced the overfitting issue and gave stable performance across major metro cities and three different phases, includes pre-COVID, COVID-19, and post-COVID. An aggregated loss across major pollutants allowed the model to maintain balanced forecasting without bias toward a single pollutant, to

support more effective evaluation of air quality. The model's performance was evaluated using MSE, MAE, R², and RMSE, as defined in Eq. (9) to Eq. (12):

$$\text{MSE} = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2 \quad (9)$$

$$\text{MAE} = \frac{1}{n} \sum |y_i - \hat{y}_i| \quad (10)$$

$$\text{Coefficients of determination (R}^2 \text{ score)} = 1 - \frac{\sum (y_i - \bar{y})^2}{\sum [y_j - \bar{y}]^2} \quad (11)$$

$$\text{RMSE} = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2} \quad (12)$$

The graph presented in Fig. 1 showed R² score comparisons of GBM and XGBM models across five major metropolitan cities, Bengaluru, Chennai, Delhi, Kolkata, and Ahmedabad, within time periods pre-COVID, COVID-19, and post-COVID. Bengaluru consistently performed best across all phases, while Kolkata and Ahmedabad achieved lower prediction accuracy in the pre-COVID and during COVID phases, with some post-COVID improvement. During COVID, it showed sharp variations across cities, particularly XGBM showed exceptionally high R² score in Chennai and Delhi, even exceeding unity in Chennai, which indicated possible overfitting due to limited pandemic data. XGBM generally outperformed GBM, particularly in the post-COVID period, with notable gains in cities like Delhi and Chennai. Overall, model performance varies across cities and timeframes due to different pollution dynamics, with XGBM proving more robust, especially after COVID.

Fig. 1. Comparison of R² scores for GBM and XGBM models from metropolitan cities in the time of Pre-COVID, COVID-19, and Post-COVID.

Fig. 2. R^2 and MSE values of GBM and XGBM models across various locations of Mumbai city.

The graph shown in Fig. 2 of different regions of Mumbai city compares the R^2 analysis for GBM and XGBM. The GBM model consistently demonstrated superior R^2 scores when compared to XGBM, signifying better or similar performance. Locations such as Chakala, Malad(W), and Kurla showed relatively lower R^2 scores between 0.25 and 0.5 for both models, particularly for XGBM, which may reflect higher variability in emissions, traffic influence, or data noise in these areas. Notably, regions such as BKC and Borivali(E) highlighted better R^2 scores, nearly around 1 for both models, while Vile Parle(W) achieved particularly out-of-the-ordinary results, recording R^2 scores greater than 2 for both, which showed overfitting challenges in all temporal phases. Conversely, locations like Chakala, Bhandup, and Worli revealed considerably lower scores for XGBM, indicating a weak model fit. It concludes that GBM surpasses or equals XGBM in predictive accuracy across the majority of locations.

GBM provided more consistent and stable performance across Mumbai locations, while XGBoost's performance was more location-dependent, excelling in some areas but underperforming in others. Specifically, the locations Vile Parle West and Bandra Kurla Complex (BKC) indicate an overfitting and calculation issue. This indicated that spatial heterogeneity played an important role in model performance and that model selection may need to be location-specific for urban air quality forecasting.

B. Comparison between the Existing Performance of SVM and the Model Performance

The two line graphs, in Fig. 3, illustrate the performance trends of Gradient Boosting Machine (GBM) and Support Vector Machine (SVM) models from 2015 to 2019, along with their cumulative totals. In the first graph [Fig. 3(a)], which presented R^2 values, the SVM model (represented by the red dashed line) consistently surpassed the GBM model (indicated

by the blue solid line) throughout all years, with R^2 values ranging from approximately 0.76 to 0.81, signifying a stronger model fit.

Fig. 3. (a) R^2 trend for GBM and SVM, (b) RMSE trends of GBM and SVM in 2015-2019.

The highlighted R^2 score of the GBM model presented lower R^2 values, peaking at around 0.74 in 2017 and showing a significant decline of roughly 0.51 throughout 2019, implying that it may lack consistency overall. Fig. 3(b) shows RMSE (Root Mean Squared Error) results with GBM and SVM. The outcomes from SVM continue to perform better, consistently achieving lower RMSE values, which reflect lower prediction errors throughout all years from 2015 to 2019. The GBM, on the other hand, demonstrated higher RMSE, with the error fluctuating and escalating sharply in the total metric, exceeding $10 \mu\text{g m}^{-3}$.

Fig. 4. Year-wise comparison of R^2 score and RMSE performance from 2015 to 2019 of GBM, SVM, and XGBM.

Fig. 4 highlights model performance trends comparison between existing results and outcomes from Indian metro cities over the years by a line plot of R^2 (coefficient of determination) values from 2015 to 2019 for three machine-learning models, GBM, SVM, and XGBoost, used for prediction tasks. XGBoost overall consistently achieved the highest R^2 values across all years, indicating the strongest explanatory power and best predictive performance among the three models. Its performance remained relatively stable, peaking around 0.82 in 2018, followed by a slight decline in 2019. SVM showed moderate and fairly stable performance, with R^2 values generally ranging between 0.78 and 0.81. It showed improvement from 2015 to 2017, and highlighted a slight decrease afterwards. In contrast, GBM listed the lowest R^2 values throughout that period, starting nearly at 0.69 in 2015, improving to about 0.74 in 2017, and then declining again by 2019.

The graph highlighted two key insights: first, XGBoost outperformed both GBM and SVM in terms of prediction accuracy and model consistency, and second, all models experienced a slight performance drop in 2019. Overall, the plot supported the conclusion that XGBoost provided more reliable and robust predictions over time compared to the other approaches. XGBM typically surpassed GBM in all three phases, especially during the pre-COVID and COVID-19 phases. However, the performance of a model in the post-COVID period declined noticeably across various cities. This may improve with possible alterations in data patterns or difficulties in model generalization following the pandemic [29].

Fig. 5. Mean absolute error of air quality monitoring across five indian metropolitan cities (Ahmedabad, Bengaluru, Chennai, Delhi, and Kolkata) during three different periods: Pre-COVID (2018), During COVID-19 (2019-20), and Post-COVID (2021-23).

Fig. 5 highlights that in Ahmedabad, the Pre-COVID MAE was approximately 6.9, which surged to about 14 during the COVID-19 period and slightly declined to 13.2 in the Post-COVID phase [30]. This indicated a significant increase in prediction errors during the pandemic, with only a small improvement afterwards. In contrast, Bengaluru indicated a steady improvement with MAE values dropping from approximately 3.5 Pre-COVID to 2.4 during COVID-19, and further down to 0.8 in Post-COVID. This showed a superior result in all three phases in Bengaluru. Chennai showed variations, with a very low MAE of about 0.1 in Pre-COVID, a sharp increase to approximately 9 during COVID-19, and a return to around 0.2 in the Post-COVID phase. This pattern

highlights temporary disruption during the pandemic, possibly due to sudden changes or anomalies in the data. Delhi, however, saw a steep increase from 3.5 in Pre-COVID to 15 during COVID-19, with only a slight reduction to 12.5 in Post-COVID. The persistently high MAE due to very high AQI during the winter season implies ongoing challenges in modelling or underlying unpredictability. MAE performance in Kolkata dropped notably during COVID-19 from around 9.9, pre-COVID, to 4.7, and increased again to 8.7 in post-COVID, indicating that while the pandemic might have temporarily simplified patterns [31], complexity resumed in the following years. Ahmedabad and Delhi show high values in Post COVID, while Bengaluru and Chennai show recovery.

Fig. 6. Mean absolute error of air quality monitoring across thirteen locations of Mumbai city during three different periods: Pre-COVID (2018), During COVID-19 (2019-20), and Post-COVID (2021-23).

TABLE II. COMPARISON OF EXISTING AIR QUALITY PREDICTION STUDIES WITH THE PROPOSED WORK

Aspect	Existing studies	Present study
Geographic Scope	Mostly single-city or limited regional studies	Multiple Indian metropolitan cities (Ahmedabad, Bengaluru, Chennai, Delhi, Kolkata, Mumbai)
Temporal Coverage	Short-term or limited historical data	Long-term data (2015–2023)
Modelling focus	Prediction accuracy-centric	Accuracy, robustness, and spatial–temporal variability
Algorithms	ML, ensemble, and hybrid DL models	SVM, GBM, and XGBoost with comparative evaluation
Consideration of socio-economic disruptions	Rarely considered	Explicit analysis of pre-COVID, COVID, and post-COVID phases
Spatial heterogeneity analysis	Limited	City-wise and location-specific performance analysis
Scientific interpretation	Minimal	Interpretation of pollution dynamics and model behaviour
Practical relevance	Primarily forecasting	Decision support for air quality management and policy

An analysis of comprehensive Mean Absolute Error (MAE) across all locations of Mumbai is shown in the graph in Fig. 6, which highlights the predicted accuracy of a particular model on the dataset. Various regions, such as Bandra-Kurla Complex (BKC), highlight the highest MAE

value, which shows a major difference between actual and predicted values. This indicated that there may be inconsistencies in the data or that environmental or contextual elements are complicated. Deonar and Chakala Andheri (East) highlighted equal prediction accuracy challenges. In contrast,

locations such as Kurla, CSMT Airport, and Sion showed relatively lower MAE values, which reflect better model accuracy or more stable data conditions. Overall, the graph highlighted the spatial variability of prediction performance across Mumbai, underlining the importance of location-specific analysis and potential model refinement to improve accuracy in high-error zones.

Exploring the factors of air pollutants concentration and predicting Major air pollutants, such as particulate matter (PM_{2.5} and PM₁₀), nitrogen dioxide (NO₂), sulphur dioxide (SO₂), carbon monoxide (CO), carbon dioxide (CO₂), and ozone (O₃), and AQI index more accurately is a common concern for the scientific community and policymakers. To make a more accurate prediction of air quality, this study addressed the problem of air quality monitoring from different Indian metropolitan cities, including Ahmedabad, Bengaluru, Chennai, Delhi, Kolkata, and Mumbai (from various highly polluted locations). The study analysed a comparison between traditional baseline and ensemble machine learning techniques such as SVM, GBM, and XGBM [32]-[35]. After the feature extraction, an XGBoost model is constructed, and the extracted features are used as input to monitor the air quality. The obtained prediction accuracy is much higher than that of the support vector machine and gradient boosting machine [36]-[38].

Table II shows the comparison of existing air quality prediction studies with proposed machine learning methods. Support vector machine, Gradient boosting machine, and Extreme gradient boosting machines explicitly analyse city-wise and location-specific performance on different evaluation metrics within three different temporal phases of pre-, during-, and post-COVID.

V. IMPLICATIONS FOR POLICY AND DECISION MAKING

The results of this study highlight that machine-learning models for air quality monitoring can offer value beyond numerical prediction accuracy when their performance is interpreted in relation to local pollution characteristics. Cities such as Bengaluru and Chennai showed stable and consistent model behaviour across different time periods, suggesting that data-driven forecasting approaches can be effectively used to support routine air quality advisories and short-term planning in these regions. In contrast, large metropolitan areas such as Delhi, Ahmedabad, and several locations within Mumbai exhibited higher prediction variability, reflecting complex and rapidly changing emission patterns that are more difficult to capture using meteorological data alone. These can be attributed to seasonal factors such as winter smog, industrial emissions, and vehicular density. These findings suggest that policymakers should prioritise region-specific interventions, such as stricter emission control during peak pollution seasons and enhanced monitoring in high-variability zones.

These outcomes recommend that a single, uniform forecasting strategy may not be appropriate for all urban environments. For cities with highly variable pollution dynamics, machine-learning predictions should be complemented with additional information such as seasonal emission patterns, local activity data, and expert-driven thresholds. Periods of sudden socio-economic change, such as

the COVID-19 lockdown, further demonstrate that predictive models need regular reassessment to remain reliable under changing conditions.

At a practical level, the observed location-specific differences in model performance support the need for zone-level air quality management rather than city-wide generalizations. Areas with consistently higher prediction errors may require improved monitoring coverage or targeted mitigation efforts. The models rely primarily on pollutant and meteorological data, without incorporating external factors such as traffic density or industrial activity, which may influence prediction accuracy. Overall, this study reinforces the importance of using machine-learning tools as part of a broader decision-support framework, where model outputs inform but do not solely determine air quality management and policy actions, including those guided by agencies such as the Central Pollution Control Board (CPCB). Potential data inconsistencies and missing values in real-world datasets may affect model generalization.

VI. CONCLUSION

This research work successfully presented a comprehensive analysis of traditional and advanced ensemble machine learning techniques to monitor air quality across major Indian metropolitan cities using long-term, high-resolution air quality data spanning pre-COVID, COVID-19, and post-COVID phases. The work provides valuable insights into how pollution patterns and model performance evolve under varying urban and socio-economic conditions. The comparative evaluation demonstrated that ensemble-based approaches, particularly Extreme Gradient Boosting Machine, consistently outperform traditional models such as Support Vector Machine by capturing complex, non-linear relationships between meteorological variables and different pollution dynamics. The results further disclose pronounced spatial heterogeneity in predictive performance, with cities such as Bengaluru, Kolkata, and Chennai exhibiting stable and improved accuracy, while substantially populated and industrialized metropolitan cities like Delhi, Ahmedabad, and several Mumbai zones, such as Vile Parle(W) and Bandra Kurla Complex, remain challenging due to highly dynamic emission patterns. The COVID-19 period uncovered significant disruptions in pollution behaviour, underscoring the limitations of logical models trained solely on meteorological data. These findings emphasise the need for adaptive, location-specific modelling strategies in urban air quality surveillance. Overall, the study emphasizes the need for location-specific and adaptive air quality modelling strategies. Machine-learning models can serve as effective decision-support tools when their limitations are clearly understood and when they are used alongside domain knowledge and regulatory frameworks.

To ensure robustness, each model was evaluated over multiple runs, and average performance metrics were reported. Although confidence intervals were not explicitly calculated, performance consistency across multiple cities and temporal phases provides a reliable assessment of model stability. Future work will incorporate statistical significance testing and confidence interval estimation. Future scope can expand

the model to include more cities and larger labelled datasets to further strengthen prediction performance. Further move to deep learning frameworks to train larger datasets by improving the integrity of the domain-adaptation mechanism so that it can perform more effectively across regions with different pollution dynamics. With these advancements, the overall system can evolve into a more reliable and scalable air-quality monitoring solution that supports policy development and public-health awareness planning.

AUTHORS' CONTRIBUTION STATEMENT

The corresponding author (Khushbu Chauhan) was primarily responsible for collecting datasets and pre-processing them and also, developing the proposed algorithms and conducting a detailed performance assessment to verify their alignment with the study's research goals. Khushbu Chauhan also prepared the initial version of the manuscript, carried out the visual interpretation of the results, and assisted in shaping the overall organization of the study. The second author (Kruti Sutaria) provided ongoing supervision, guided the formulation of the methodological framework, and undertook the formal analytical components of the study. Kruti Sutaria further reviewed, revised, and enhanced the manuscript to ensure technical soundness and completeness.

ACKNOWLEDGMENT

The authors would like to sincerely appreciate the Engineering and Technology department of Parul University (Gujarat) for providing them with the opportunity to work on this latest issue. We would also like to express our gratitude to the Central Pollution Control Board (CPCB), State Pollution Control Boards (SPCBs), and Multiple Corporations for supplying accurate, real-time data on Ahmedabad, Bengaluru, Chennai, Delhi, Kolkata, and Mumbai cities for the research and analysis.

DECLARATION STATEMENTS

The author declares that there are no conflicts of interest related to this research. Additionally, the authors did not receive any funding. This manuscript is the author's original work and has not been previously published or submitted for review to any other journal or conference.

Cloud-Based Replication Models Using AI Techniques for Enhanced Data Management

Moneef M. Jazzar, Aws I. Abueid*

Faculty of Computing Studies, Arab Open University, Kuwait

Abstract—Elastic cloud infrastructure relies on dynamic replication mechanisms to maintain service availability and performance under fluctuating, non-stationary workloads. However, conventional threshold-based and static replication strategies frequently fail to maintain latency stability and Service Level Agreement (SLA) compliance in highly dynamic environments characterised by bursty, peak-stress traffic. This study introduces a Q-learning-based adaptive replication framework that formulates replication control as a sequential decision-making problem. The system is modelled as a Markov Decision Process (MDP), where replication adjustments are selected to maximise cumulative discounted reward, integrating latency minimisation, SLA violation penalties, and replica cost regularisation within a unified optimisation objective. A controlled cloud simulation environment was developed to emulate phased stochastic workload patterns, including normal, burst, sustained peak, and recovery intervals. The reinforcement learning controller was trained over 5000 episodes and subsequently evaluated under fixed-policy conditions against a reaction-delayed rule-based baseline controller. Experimental results demonstrate substantial improvements in performance stability. The proposed learning-based controller achieves a significant reduction in average latency, strong suppression of 95th percentile tail latency, and complete elimination of SLA violations under dynamic workload conditions. Unlike reactive threshold-based mechanisms, the learned policy anticipates workload transitions and proactively adjusts replication levels through long-term reward optimisation. These findings confirm that learning-driven replication control provides a structurally superior paradigm for latency-sensitive elastic cloud systems. By embedding SLA awareness directly into the reward formulation, replication management is transformed from a static configuration task into an adaptive, intelligent control process.

Keywords—*Q-learning; elastic cloud replication; SLA-aware control; latency optimization; adaptive replication; reinforcement learning*

I. INTRODUCTION

Elastic cloud computing has become the foundational infrastructure for modern distributed data management systems, enabling scalable replication across geographically dispersed data centres. While elasticity enhances availability and resource flexibility, it also introduces substantial performance variability. In latency-sensitive environments—such as interactive cloud services, distributed ledgers, and real-time data platforms—maintaining stable response time under fluctuating workloads and heterogeneous network conditions remains a critical challenge.

At the replication-protocol level, recent advances in low-latency Byzantine Fault Tolerant (BFT) mechanisms

demonstrate that reducing the number of communication rounds and enabling optimistic execution paths can significantly decrease end-to-end delay while preserving consistency guarantees [1]. These findings highlight the importance of communication complexity and fast-path execution in wide-area deployments. However, protocol-level optimisation alone does not eliminate latency bottlenecks, particularly when workload intensity varies dynamically.

Storage-layer restructuring has been shown to substantially reduce execution delay even when replication protocols remain unchanged, reinforcing the impact of state-access architecture on end-to-end performance [2]. Similarly, communication-centric redesign in distributed infrastructures reveals that synchronisation imbalance and data-movement overhead frequently dominate latency behaviour, particularly under cloud-like network conditions [3]. These studies collectively confirm that replication performance depends on coordinated optimisation across multiple system layers rather than isolated protocol enhancements.

In elastic cloud environments, replication and scaling decisions inherently involve multi-objective tradeoffs. Minimising latency must be balanced with resource utilisation, operational costs, and system resilience. Multi-objective optimisation frameworks demonstrate that response time and resource efficiency are competing objectives requiring Pareto-aware decision strategies rather than single-metric tuning [4]. From a Quality of Service (QoS) perspective, dynamic service placement and provisioning mechanisms emphasise that latency constraints must be enforced explicitly as Service Level Agreement (SLA) requirements under volatile workload conditions [5].

Recent developments in AI-driven orchestration suggest that intelligent control agents can provide adaptive decision-making capabilities beyond traditional rule-based management [6]. Learning-based approaches are particularly effective for modelling nonlinear and time-varying system behaviour across distributed environments [8], while structured AI deployment frameworks underscore the importance of measurable performance improvements in real-world infrastructures [7]. Despite these advances, existing work typically addresses protocol efficiency, storage optimisation, resource orchestration, or SLA monitoring independently. Few studies integrate SLA constraints, adaptive replication control, and learning-based decision-making within a unified latency-centric framework.

Motivated by this gap, this study formulates elastic cloud replication as a sequential decision-making problem. Instead of

*Corresponding author.

treating latency as a passive monitoring metric, it is modelled as an explicit control variable within a reinforcement learning objective. Replication degree adjustment is formulated as a Markov Decision Process (MDP), where decisions are optimised to minimise latency, penalise SLA violations, and regulate replica cost simultaneously by maximising cumulative discounted rewards.

To operationalize this formulation, a tabular Q-learning-based adaptive replication controller is implemented and evaluated in a controlled geo-distributed cloud simulation environment. The learning agent dynamically adjusts replication degree in response to phased stochastic workload patterns, including normal, burst, peak, and recovery intervals. Performance is compared against a reaction-delayed rule-based baseline controller to isolate the impact of learning-driven adaptation.

The contributions of this study are as follows:

- A unified SLA-aware elastic replication framework formulated as a discrete-time MDP.
- A mathematically grounded reinforcement learning objective integrating latency minimisation, violation penalties, and replica cost regularisation.
- An implemented Q-learning adaptive controller was evaluated under reproducible workload conditions.
- A controlled comparative analysis demonstrating substantial improvements over reaction-based replication strategies.

Experimental results confirm that the proposed learning-based controller significantly reduces average and tail latencies, while eliminating SLA violations under bursty workload conditions. These findings demonstrate that embedding SLA-awareness directly into the reinforcement learning objective transforms replication management from a reactive threshold mechanism into an adaptive intelligent control process for latency-sensitive elastic cloud systems. Experimental results confirm that the proposed learning-based controllers significantly reduces average and tail latencies while eliminating SLA violations under bursty workload conditions.

Unlike existing replication approaches that treat latency as a monitored metric, this work formulates replication as a sequential decision-making problem and embeds SLA constraints directly into the learning objective.

II. LITERATURE REVIEW

A. AI in Distributed Replication Control

Artificial intelligence has increasingly been incorporated into distributed data management architectures to enhance structural decision-making and system adaptability. AI-assisted frameworks for dynamic fragmentation, allocation, and replication have demonstrated improved efficiency and reliability in distributed database systems, even when workload characteristics are partially unknown during the design stage [9]. These approaches highlight the potential of intelligent control mechanisms to optimise structural decisions and reduce manual configuration overhead.

However, most existing AI-assisted replication models primarily target database-level optimisation rather than latency-sensitive elastic cloud environments. They often focus on data placement and fragmentation efficiency without explicitly modelling Service Level Agreement (SLA) constraints or latency dynamics under fluctuating workloads. Moreover, reinforcement learning-based closed-loop adaptive replication control remains largely unexplored in these contexts.

B. Latency-Aware Replica Placement

Latency-bound replica management strategies have been proposed for decentralised edge-cloud systems, where replica placement decisions aim to minimise delay while reducing coordination and resource overhead [10]. These models emphasise proximity-based placement, communication efficiency, and decentralised coordination to stabilise response time in distributed infrastructures.

Although latency is explicitly considered in these approaches, it is typically treated as a constrained performance metric rather than as an optimisation variable within a sequential adaptive control framework. Furthermore, many of these strategies rely on deterministic rules or heuristic placement algorithms rather than learning-based controllers that can adapt to non-stationary workload phases and evolving system states.

C. Multi-Objective Optimisation in Elastic Clouds

Elastic cloud replication inherently involves competing objectives, including minimising latency, reducing storage overhead, improving resource utilisation efficiency, and ensuring availability. Multi-objective optimisation frameworks confirm that response time must be jointly optimised with operational cost and resource balancing rather than treated independently [11]. Pareto-based approaches provide structured mechanisms to manage these trade-offs under dynamic cloud conditions.

Despite these advancements, many multi-objective models operate primarily at the scheduling or provisioning layer and do not explicitly account for adjusting the replication degree in SLA-constrained elastic environments. In addition, optimisation strategies are frequently static, heuristic-based, or rule-driven rather than policy-learning-based. The integration of multi-objective trade-offs into a reinforcement learning-driven replication policy remains insufficiently investigated.

D. Elastic Auto-Scaling and Adaptive Resource Control

Auto-scaling mechanisms dynamically adjust computational capacity to maintain performance stability in the face of workload variability [12]. Learning-based scaling strategies have demonstrated greater responsiveness than static threshold-based policies, particularly in bursty-demand scenarios. However, conventional auto-scaling approaches predominantly focus on computational resource allocation (e.g., virtual machine scaling or container orchestration) rather than replication control. The interaction between replication degree, workload dynamics, and SLA compliance is rarely modelled as a unified sequential decision-making problem. Consequently, replication and scaling policies are often optimised independently rather than coordinated within a single adaptive control framework.

E. SLA-Aware Monitoring and Proactive Management

SLA-aware systems incorporate monitoring and anomaly detection mechanisms to identify performance degradation before contractual thresholds are violated [13]. Machine learning-based monitoring frameworks enable proactive detection of anomaly patterns and potential SLA risks. Nevertheless, most SLA-aware solutions operate at the diagnostic or supervisory layer. SLA compliance is typically treated as an output metric or a post-hoc evaluation criterion rather than embedded directly into the optimisation objective. Few systems integrate SLA-violation penalties into the control policy itself, limiting their ability to perform proactive adaptation via learning-based optimisation.

Recent advances in multi-objective optimisation and intelligent system design further reinforce the importance of adaptive control in distributed environments. Differentiable architecture search techniques have demonstrated the effectiveness of jointly optimising competing objectives such as performance and latency, highlighting the importance of automated decision optimisation under resource constraints [14]. Similarly, Pareto-based optimisation approaches have been successfully applied to fog-cloud task offloading, enabling systematic trade-offs between latency, resource utilisation, and operational cost in distributed infrastructures [15].

In addition, reinforcement learning has been effectively applied to dynamic replication and reliability optimisation, where the number of replicas is adaptively adjusted based on runtime system conditions, demonstrating the effectiveness of learning-based control policies in improving system robustness and efficiency [16].

From an SLA perspective, foundational work has established formal frameworks for SLA evaluation and composition in service-oriented architectures [17], while recent studies emphasise the need for dynamic and adaptive SLA management in cloud and fog environments characterised by high variability and non-stationary workloads [18]. These developments collectively indicate a shift toward intelligent, optimisation-driven, and SLA-aware adaptive system management.

F. Research Gap and Motivation

Although substantial progress has been achieved in cloud replication, latency optimisation, auto-scaling, and SLA monitoring, these research directions are predominantly pursued in isolation. Existing solutions tend to optimise individual system components—such as replicaplacement, cost efficiency, or anomaly detection—without integrating them into a unified adaptive control architecture capable of holistic decision-making. In elastic cloud environments, replication management is fundamentally a sequential control problem. The replication degree directly influences latency, infrastructure cost, and SLA compliance over time. Nevertheless, most current approaches treat latency as a passive performance indicator rather than as an actively controllable decision variable. Replication adjustments are typically triggered by predefined thresholds or heuristic rules, leading to reactive behaviour, delayed adaptation, and instability under bursty or non-stationary workload conditions.

Furthermore, multi-objective trade-offs between latency minimisation and cost efficiency are commonly addressed

through static optimisation or rule-based heuristics, rather than through adaptive policy learning. SLA-awareness is frequently implemented at the monitoring layer, functioning as a diagnostic mechanism rather than being embedded directly into the optimisation objective. Most critically, reinforcement learning-based closed-loop control for dynamic replication adjustment remains insufficiently explored in latency-sensitive elastic cloud systems. Few existing studies formulate replication as a Markov Decision Process in which control actions explicitly influence future system states and long-term cumulative performance.

This research gap motivates the proposed framework, which formulates replication control as a sequential optimisation problem and addresses it via Q-learning. By embedding latency, cost regularisation, and SLA violation penalties directly into the reward function, the model enables proactive, learning-driven replication management that adapts to non-stationary workload dynamics and minimises long-term performance degradation.

III. PROBLEM FORMULATION AND Q-LEARNING-BASED ADAPTIVE REPLICATION MODEL

A. System Model and Objective

In elastic cloud environments, the number of active replicas directly influences response latency, SLA compliance, and infrastructure cost. Let:

- $R(t)$ denotes the number of active replicas at time step t
- $W(t)$ denotes workload intensity
- $L(t)$ denotes observed latency
- $L_{\max}$ denotes the SLA latency threshold

Latency is modelled as inversely proportional to replication capacity and proportional to workload intensity:

Latency is modelled as inversely proportional to replication capacity and proportional to workload intensity [see Eq. (1)]:

$$L(t) = \frac{W(t)}{R(t)} + \varepsilon_t \quad (1)$$

where, $\varepsilon_t \sim \mathcal{N}(0, \sigma^2)$ represents stochastic network noise. An SLA violation indicator is defined as Eq. (2):

$$V(t) = \begin{cases} 1, & \text{if } L(t) > L_{\max} \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

The control objective is to adjust dynamically. $R(t)$ in order to:

- Minimise average latency
- Reduce SLA violations
- Avoid excessive resource provisioning

This yields a sequential decision-making problem under uncertainty.

B. Markov Decision Process Formulation

The adaptive replication problem is modelled as a discrete-time Markov Decision Process (MDP), defined by the tuple.

$$(\mathcal{S}, \mathcal{A}, \mathcal{P}, r, \gamma)$$

where,

- $\mathcal{S}$ = state space
- $\mathcal{A}$ = action space
- $\mathcal{P}$ = state transition dynamics
- r = reward function
- $\gamma \in (0,1)$ = discount factor

1) *State space*: The system state at time t is defined as Eq. (3):

$$S(t) = (R(t), W_{\text{bin}}(t), V(t)) \quad (3)$$

To enable tabular Q-learning, the workload is discretised [see Eq. (4)]:

$$W_{\text{bin}}(t) = \left\lfloor \frac{W(t)}{\Delta_w} \right\rfloor \quad (4)$$

where,

- Δ_w = workload discretisation interval
- $\lfloor \cdot \rfloor$ = floor operator

In the implemented simulation: $\Delta_w = 30$
This discretisation reduces state dimensionality while preserving phase information about the workload.

2) *Action space*: At each time step, the agent selects [see Eq. (5)]:

$$A(t) \in \{-1, 0, +1\} \quad (5)$$

where,

- $-1 \rightarrow$ decrease replica count
- $0 \rightarrow$ maintain current replicas
- $+1 \rightarrow$ increase replica count

Replica update rule [see Eq. (6)]:

$$R(t+1) = \min(R_{\text{max}}, \max(1, R(t) + A(t))) \quad (6)$$

where, R_{max} is the maximum allowed replication degree.

C. Reward Function Design

The reward function integrates three control objectives:

- Latency minimisation
- SLA violation penalty
- Replica cost regularisation

The immediate reward at the time t is defined as Eq. (7):

$$r(t) = -\frac{L(t)}{L_{\text{norm}}} - \lambda_v V(t) - \lambda_r R(t) \quad (7)$$

where,

- L_{norm} is a latency normalisation constant
- λ_v is the SLA violation penalty coefficient

- λ_r is the replica cost penalty coefficient

This reward formulation ensures that:

- Higher latency reduces the reward value
- SLA violations incur strong penalties
- Excessive replication is discouraged

By embedding latency and violation penalties directly into the reward structure, the model transforms SLA compliance from a monitoring constraint into an optimisation objective. Consequently, replication control becomes a reward-driven adaptive process within the reinforcement learning loop.

D. Q-Learning Algorithm

The Q-learning algorithm estimates the optimal action-value function $Q(S, A)$.

The update rule is Eq. (8):

$$Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha \left[r_t + \gamma \max_{a \in \mathcal{A}} Q(S_{t+1}, a) - Q(S_t, A_t) \right] \quad (8)$$

where,

- α = learning rate
- γ = discount factor

The learned policy is defined as Eq. (9):

$$\pi(S) = \arg \max_{a \in \mathcal{A}} Q(S, a) \quad (9)$$

This policy selects the action with the highest expected long-term cumulative reward.

E. Training Configuration

The agent was trained using:

- 5000 episodes
- 400 time steps per episode
- Learning rate $\alpha = 0.1$
- Discount factor $\gamma = 0.95$
- ϵ -greedy exploration strategy

Total episodic reward convergence was monitored to ensure stable learning behaviour.

F. Q-Learning Adaptive Replication Algorithm

To operationalize the mathematical formulation described above, the adaptive replication strategy is implemented using a tabular Q-learning algorithm (see Algorithm 1). The algorithm iteratively updates the action-value function $Q(S, A)$ based on observed rewards and state transitions.

The learning process follows a ϵ -greedy exploration strategy to balance exploitation of learned policies and exploration of new state-action pairs.

Algorithm 1: Q-Learning Adaptive Replication

Initialize

Input:

- Learning rate α
- Discount factor γ
- Exploration rate ε
- Maximum replicas R_{max}

Initialize Q-table $Q(S, A)$ arbitrarily

Compute

For each episode = 1 to N do

— Initialize environment

— Observe initial state S

— While (not terminal) do

— Select action A using ε -greedy policy

— Execute action A

— Observe reward r and the next state S'

— Update Q-value

$$Q(S, A) \leftarrow Q(S, A) + \alpha[r + \gamma \max_a Q(S', a) -$$

$Q(S, A)]$

— Set $S \leftarrow S'$

End

Return learned policy:

$$\pi(S) = \arg \max_a Q(S, a)$$

G. Rule-Based Baseline Controller

To isolate the impact of AI-driven learning, a rule-based controller was implemented.

The rule-based strategy:

- Increases replicas when latency exceeds the threshold
- Decreases replicas when latency falls below a safe margin
- Includes a fixed reaction delay
- Unlike Q-learning, the rule-based controller:
- Reacts only after performance degradation
- Does not optimise long-term reward
- Does not anticipate workload transitions

This enables controlled comparative evaluation between adaptive AI control and reactive heuristic control.

IV. REINFORCEMENT LEARNING-DRIVEN ADAPTIVE REPLICATION FRAMEWORK

A. Environment Definition

To validate the adaptive replication strategy formulated in Section III, a controlled simulation environment was implemented to emulate a geo-distributed elastic cloud system.

The system evolves in discrete time steps.

$$t = 1, \dots, T.$$

At each time step, the environment is defined by Eq. (10):

$$L(t) = \frac{W(t)}{R(t)} + \varepsilon_t \quad (10)$$

where,

- $W(t)$ = workload intensity
- $R(t)$ = number of replicas
- $\varepsilon_t \sim \mathcal{N}(0, \sigma^2)$

An SLA violation occurs if [see Eq. (11)]:

$$V(t) = \begin{cases} 1, & L(t) > L_{\max} \\ 0, & \text{otherwise} \end{cases} \quad (11)$$

The replication degree is bounded [see Eq. (12)]:

$$1 \leq R(t) \leq R_{\max} \quad (12)$$

B. Workload Phases

Workload intensity follows a phased stochastic pattern:

- Normal phase
- Burst phase
- Sustained peak phase
- Recovery phase

Formally [see Eq. (13)]:

$$W(t) = W_{base}(t) + \eta_t \quad (13)$$

where, $\eta_t \sim \mathcal{N}(0, \sigma_W^2)$.

This design creates realistic workload volatility for evaluating adaptive control.

C. Reinforcement Learning Control Policy

The Q-learning agent selects replication adjustment actions [see Eq. (14)]:

$$A(t) \in \{-1, 0, +1\} \quad (14)$$

Replica update [see Eq. (15)]:

$$R(t+1) = \min(R_{\max}, \max(1, R(t) + A(t))) \quad (15)$$

The reward function is defined as Eq. (16):

$$r(t) = -\frac{L(t)}{L_{norm}} - \lambda_v V(t) - \lambda_r R(t) \quad (16)$$

This ensures:

- Latency reduction

- SLA compliance
- Resource efficiency

D. Learning Objective

The agent maximises expected cumulative discounted reward [see Eq. (17)]:

$$\mathbb{E} \left[\sum_{t=0}^T \gamma^t r(t) \right] \quad (17)$$

where, $\gamma \in (0,1)$.

Policy [see Eq. (18)]:

$$\pi(S) = \arg \max_a Q(S, a) \quad (18)$$

Training uses ϵ -greedy exploration.

E. Rule-Based Baseline

For comparative evaluation, a rule-based controller was implemented.

The baseline:

- Increases replicas when latency exceeds the SLA threshold
- Decreases replicas when latency drops below a safe margin
- Includes reaction delay

Unlike RL, it does not optimise long-term cumulative reward.

V. EXPERIMENTAL ARCHITECTURE AND WORKLOAD MODEL

A. Experimental Architecture

1) *Environment overview*: To evaluate the theoretical framework introduced in Section 4, the mathematical model is instantiated within a controlled cloud simulation environment. The implementation follows the latency model defined in Eq. (10), the SLA constraint in Eq. (11), and the replication bounds in Eq. (12)

The system evolves in discrete time steps:

where, the simulation horizon is fixed as Eq. (19):

$$T = 400 \quad (19)$$

At each time step, the workload intensity $W(t)$ is generated, the replication degree $R(t)$ is updated by the controller, and the observed latency $L(t)$ is computed.

Latency is modelled as Eq. (20):

$$L(t) = \frac{W(t)}{R(t)} + \varepsilon_t \quad (20)$$

where,

- $W(t)$ denotes workload intensity
- $R(t)$ denotes the number of replicas

- where, $\varepsilon_t \sim \mathcal{N}(0, \sigma^2)$ represents stochastic network noise.

An SLA violation indicator is defined as Eq. (21):

$$V(t) = \begin{cases} 1, & \text{if } L(t) > L_{\max} \\ 0, & \text{otherwise} \end{cases} \quad (21)$$

The replication degree is bounded [see Eq. (22)]:

$$1 \leq R(t) \leq R_{\max} \quad (22)$$

This implementation instantiates the theoretical formulation presented in Section IV within a reproducible experimental environment, enabling systematic evaluation of adaptive replication behaviour under controlled stress scenarios.

Fig. 1. Q-learning-based adaptive replication framework.

Fig. 1 illustrates the closed-loop architecture. A phased workload generator produces dynamic demand. The cloud environment computes latency as a function of workload and replica count. The SLA monitor detects violations. The Q-learning controller selects replication adjustments. The execution module applies the action and updates the system state, forming a continuous adaptive loop.

2) *Architectural components*: The architecture consists of:

- Workload Generator – produces phased stochastic demand.
- Cloud Environment – computes latency as a function of workload and replication.
- SLA Monitor – detects violation conditions.
- Q-Learning Agent – learns an optimal replication policy.
- Replica Controller – applies action $A(t)$.

TABLE. I. SYSTEM COMPONENTS DESCRIPTION

Component	Role
Workload Generator	Produces phased stochastic demand
Cloud Environment	Computes latency based on replica count
SLA Monitor	Detects violation conditions
Q-Learning Agent	Learns optimal replica adjustment policy
Replica Controller	Applies action A(t)

Table I presents the main functional components of the Q-learning-based control framework and summarizes the specific role of each module within the adaptive cloud replication system.

B. Workload Model

1) *Workload dynamics*: Workload intensity is modelled as a time-varying stochastic process with four structured phases:

- Normal Phase
- Burst Phase
- Peak Stress Phase
- Recovery Phase

This structure ensures evaluation under both transient and sustained overload conditions.

2) *Stochastic workload generation*: Workload intensity is defined as Eq. (23):

$$W(t) = W_{base}(t) + \eta t \quad (23)$$

where,

$$\eta_t \sim \mathcal{N}(0, \sigma_W^2)$$

The baseline workload follows a piecewise definition [see Eq. (24)]:

$$W_{base}(t) = \begin{cases} W_N, & 0 \leq t < T_1 \\ W_B, & T_1 \leq t < T_2 \\ W_P, & T_2 \leq t < T_3 \\ W_R, & T_3 \leq t \leq T \end{cases} \quad (24)$$

This formulation produces controlled non-stationary demand patterns suitable for adaptive learning.

Fig. 2. Simulated workload variation.

Fig. 2 shows the generated workload trajectory across 400 time steps, illustrating normal, burst, peak, and recovery phases.

TABLE. II. WORKLOAD PHASE CHARACTERISTICS

Phase	Baseline Intensity	Duration Range	Stress Level
Normal	W_N	Long	Low
Burst	W_B	Short	Moderate
Peak Stress	W_P	Medium	High
Recovery	W_R	Medium	Low

Table II summarises the structured workload phases used in the experimental setup. The phased modelling ensures systematic evaluation of adaptive replication policies under controlled stress scenarios.

C. Experimental Protocol

1) *State representation*: The Q-learning agent observes a discretised state [see Eq. (25)]:

$$S(t) = (R(t), W_{bin}(t), V(t)) \quad (25)$$

Workload discretisation is defined as Eq. (26):

$$W_{bin}(t) = \left\lfloor \frac{W(t)}{\Delta W} \right\rfloor \quad (26)$$

where, ΔW is the workload bin size used for state abstraction.

2) *Action space*: The action space is [see Eq. (27)]:

$$A(t) \in \{-1, 0, +1\} \quad (27)$$

Replica update follows [see Eq. (28)]:

$$R(t+1) = \min(R_{max}, \max(1, R(t) + A(t))) \quad (28)$$

3) *Reward function*: The reward function used in the implemented environment is defined as Eq. (29):

$$r(t) = -\frac{L(t)}{L_{norm}} - \lambda_v V(t) - \lambda_r R(t) \quad (29)$$

where,

- L_{norm} is a normalisation constant,
- λ_v penalises SLA violations,
- λ_r penalises excessive replication.

This formulation ensures simultaneous optimisation of:

- Latency reduction
- SLA compliance
- Resource efficiency

This integrates latency minimisation, SLA penalties, and resource cost control.

4) *Q-learning update rule*: The Q-table is updated according to Eq. (30):

$$Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha \left[r_t + \gamma \max_a Q(S_{t+1}, a) - Q(S_t, A_t) \right] \quad (30)$$

where,

- $\alpha = 0.1$ is the learning rate,
- $\gamma = 0.95$ is the discount factor.

Action selection follows a ε -greedy exploration strategy [see Eq. (31)]:

$$\pi(S) = \begin{cases} \text{random action,} & \text{with probability } \varepsilon \\ \arg \max_a Q(S, a), & \text{otherwise} \end{cases} \quad (31)$$

with initial exploration rate $\varepsilon = 0.2$.

Training was conducted for [see Eq. (32)]:

$$\text{Episodes} = 5000 \quad (32)$$

Episodic cumulative reward was recorded to verify convergence behaviour.

5) *Q-learning update rule*: For comparison, a reactive rule-based controller was implemented.

The baseline decision rule is Eq. (33):

$$A_{\text{rule}}(t) = \begin{cases} +1, & L(t) > L_{\text{max}} \\ -1, & L(t) < L_{\text{safe}} \text{ and } R(t) > 1 \\ 0, & \text{otherwise} \end{cases} \quad (33)$$

To introduce a realistic response lag, actions are applied after a fixed delay d [see Eq. (34)]:

$$A_{\text{applied}}(t) = A_{\text{rule}}(t - d) \quad (34)$$

This delay models monitoring and scaling latency commonly observed in practical cloud systems.

6) *Evaluation procedure*: After training convergence:

- a) Exploration was disabled.
- b) The learned greedy policy was fixed.
- c) Both RL and rule-based controllers were evaluated under identical workload realisations.

For each policy, the following metrics were computed:

Average latency [see Eq. (35)]:

$$L_{\text{avg}} = \frac{1}{T} \sum_{t=1}^T L(t) \quad (35)$$

95th percentile latency [see Eq. (36)]:

$$L_{95} = \text{Percentile}_{95}\{L(t)\} \quad (36)$$

Total SLA violations [see Eq. (37)]:

$$V_{\text{total}} = \sum_{t=1}^T V(t) \quad (37)$$

D. Experimental Evaluation Protocol

To empirically validate the proposed Q-learning-based adaptive replication framework, a structured evaluation procedure was designed.

Each experimental run follows two phases:

1) *Training phase*: The Q-learning agent is trained for:

- 5000 episodes
- 400 time steps per episode

Training uses the update rule defined in Eq. (30), with ε -greedy exploration as specified in Eq. (31). Episodic cumulative reward is monitored to verify convergence stability.

2) *Evaluation phase*: After convergence:

- Exploration is disabled ($\varepsilon = 0$)
- The learned greedy policy is fixed
- The policy is evaluated over a 400-step workload trace generated according to Eq. (21).

For fair comparison:

- The rule-based controller [Eq. (33) to Eq. (34)] is evaluated under the same workload realization
- Each scenario is repeated 30 times using independent random seeds

3) *Performance metrics*: For both controllers, the following metrics are computed:

- Average latency [Eq. (35)]
- 95th percentile latency [Eq. (36)]
- Total SLA violations [Eq. (37)]

These metrics collectively measure:

- System responsiveness
- Worst-case latency behaviour
- SLA compliance under burst conditions

This evaluation protocol ensures a direct empirical validation of the mathematical formulation presented in Section III and Section IV, linking the reinforcement learning update mechanism [Eq. (30)] to measurable performance improvements under controlled workload dynamics.

VI. RESULTS AND COMPARATIVE ANALYSIS

A. Experimental Overview

This section presents the quantitative evaluation of the proposed Q-learning-based adaptive replication controller. The learned policy is compared against a reaction-delayed rule-based baseline controller defined in Section III-G.

Training was conducted for 5000 episodes using the Q-learning update rule defined in Eq. (8). After convergence, the learned greedy policy was fixed and evaluated over a 400-step workload trace generated according to Eq. (21).

Each evaluation scenario was repeated 30 times using independent random seeds to ensure statistical robustness. Reported results represent mean values.

Performance evaluation is based on:

- Average latency [Eq. (35)]
- 95th percentile latency [Eq. (36)]
- Total SLA violations [Eq. (37)]

This focused comparison isolates the impact of reinforcement learning-based adaptive control relative to reactive threshold-based replication.

B. Learning Convergence Behaviour

Training stability was verified by monitoring cumulative episodic reward [see Eq. (38)]:

$$R_{\text{episode}} = \sum_{t=1}^T r(t) \quad (38)$$

Reward convergence demonstrates stabilisation of Q-values under the update rule in Eq. (30), indicating that the policy approaches a steady control strategy.

Fig. 3. Q-learning reward convergence curve.

Fig. 3 illustrates episodic cumulative reward over 5000 training episodes. Early exploration produces variability, while later episodes show stabilisation, confirming policy convergence.

This validates the correctness of the reinforcement learning process before performance evaluation.

C. Performance Evaluation

Performance was evaluated using three primary metrics derived from Eq. (39) to Eq. (41):

$$L_{\text{avg}} = \frac{1}{T} \sum_{t=1}^T L(t) \quad (39)$$

$$L_{95} = \text{Percentile}_{95} \{l(t)\} \quad (40)$$

$$V_{\text{total}} = \sum_{t=1}^T V(t) \quad (41)$$

TABLE. III. PERFORMANCE COMPARISON BETWEEN Q-LEARNING AND RULE-BASED CONTROLLERS.

Model	$L_{\text{avg}}(ms)$	$L_{95}(ms)$	Violations
Q-Learning	33.55	54.82	0
Rule-Based	72.59	150.62	72

Table III summarises the comparative performance results. The Q-learning controller substantially outperforms the reaction-delayed rule-based baseline across all evaluation dimensions.

Specifically:

- Average latency is reduced by more than 50%.
- Tail latency is reduced by more than 60%, indicating improved stability under burst and sustained peak conditions.
- SLA violations are eliminated under the learned adaptive policy.

Fig. 4. Average latency comparison.

Fig. 4 illustrates the significant reduction in mean latency achieved by the RL-based controller. The improvement results from long-term reward optimisation [Eq. (30)], rather than from threshold-triggered reactions.

Fig. 5. 95th Percentile latency comparison.

Fig. 5 demonstrates strong suppression of tail latency amplification. Unlike the reactive controller, which increases replicas only after performance degradation, the RL agent proactively adjusts replication before SLA thresholds are exceeded.

Fig. 6. SLA violation comparison.

Fig. 6 confirms that the rule-based controller experiences repeated violations during burst intervals due to reaction delay [Eq. (34)]. In contrast, the RL controller anticipates high-load regions through learned workload-to-replica mapping.

D. Mechanism-Level Interpretation

The observed performance improvements are directly attributable to the Q-learning update mechanism defined in Eq. (30).

The RL agent:

- Learns workload-to-replica mapping patterns.
- Anticipates burst transitions.
- Penalises SLA violations within the reward formulation [Eq. (29)].
- Balances latency reduction and replica cost.

In contrast, the rule-based controller evaluates thresholds only at each time step and lacks temporal credit assignment.

Consequently, replication management transitions from a reactive threshold mechanism to a predictive, adaptive control strategy optimised over expected cumulative discounted reward.

E. Structural Comparison and Summary of Findings

The comparative analysis reveals a fundamental structural distinction between reinforcement learning-based control and reactive threshold-based mechanisms.

TABLE IV. STRUCTURAL COMPARISON BETWEEN Q-LEARNING AND RULE-BASED CONTROLLERS.

Feature	Q-Learning	Rule-Based
Long-term optimization	Yes	No
Violation anticipation	Yes	No
Reward-driven adaptation	Yes	No
Reaction delay sensitivity	Low	High

Table IV shows that the rule-based controller operates solely

on instantaneous latency thresholds and reacts only after performance degradation occurs. Because it lacks temporal credit assignment, it cannot anticipate burst transitions and therefore suffers from repeated SLA violations during high-load intervals are observed in Section VI-C.

In contrast, the Q-learning agent optimises expected cumulative discounted reward [Eq. (30)], enabling proactive replication adjustments. Through repeated interactions with the environment, the agent internalises the workload structure and learns stable workload-to-replica mappings.

This structural difference explains the empirical improvements

The experimental results confirm:

- Significant reduction in average latency [Eq. (35)].
- Strong suppression of tail latency [Eq. (36)].
- Complete elimination of SLA violations [Eq. (37)].
- Stable convergence under the Q-learning update rule [Eq. (30)].

Collectively, these findings provide empirical validation of the mathematical formulation introduced in Section III and Section IV, demonstrating that adaptive replication, when framed as a sequential decision-making problem, yields superior control behaviour compared to reactive threshold mechanisms.

VII. DISCUSSION AND THEORETICAL IMPLICATIONS

A. Interpretation of Empirical Results

The experimental results demonstrate that modelling elastic replication as a sequential decision-making problem yields substantial performance gains over reactive threshold-based control.

The Q-learning controller consistently outperformed the rule-based baseline in:

- Average latency [Eq. (39)],
- Tail latency [Eq. (40)],
- SLA compliance [Eq. (41)].

These improvements are not merely numerical; they reflect a structural transformation in control behaviour. While the rule-based controller reacts to instantaneous latency violations, the Q-learning agent optimises expected cumulative discounted reward according to Eq. (30). This long-term optimisation objective enables proactive replication adjustments before SLA thresholds are exceeded.

Embedding the violation indicator directly into the reward formulation converts SLA constraints from passive monitoring conditions into active optimisation signals. As a result, SLA compliance becomes an intrinsic learning objective rather than an external enforcement mechanism.

B. Why Q-Learning Improves Replication Control?

The performance improvement emerges from three fundamental mechanisms:

1) *Temporal credit assignment*: Through the Bellman update rule [Eq. (30)], the agent evaluates future consequences of current replica adjustments. This enables:

- Anticipation of burst transitions,
- Early replica scaling before peak load,
- Avoidance of oscillatory behaviour.

Reactive controllers lack this temporal reasoning capability and therefore incur repeated violations during workload surges.

2) *Structured state abstraction*: The discretised state representation (Section III) encodes:

- Replica count,
- Workload intensity bin,
- SLA violation flag.

This compact representation preserves essential system dynamics while enabling tractable learning. Over multiple episodes, the Q-table converges to a stable workload-to-replica mapping that generalises across recurring workload phases.

3) *Reward-driven multi-objective balancing*: The reward formulation integrates:

- Latency minimisation,
- SLA violation penalties,
- Replica cost regularisation.

This implicitly performs multi-objective balancing without requiring explicit runtime Pareto optimisation. The agent learns to stabilize performance while controlling replication overhead within a unified scalar objective.

C. Theoretical Contributions

This study contributes to elastic cloud replication research in several ways:

Contribution 1: Replication as an MDP

Replication control is formally modelled as a Markov Decision Process rather than a static configuration problem. This reframing enables learning-based adaptation under dynamic workload conditions.

Contribution 2: Latency as an Optimised Control Variable

Latency is embedded directly within the reward function, transforming it from a monitored metric into an actively optimised variable aligned with SLA constraints.

Contribution 3: Empirical Validation of Learning-Based Replication

Unlike conceptual AI-orchestration proposals, this work implements and experimentally validates a concrete Q-learning controller that delivers measurable performance gains across reproducible workload scenarios.

D. Implications for Elastic Cloud Systems

The findings suggest that:

- Static replication policies are insufficient under dynamic demand.
- Threshold-based scaling cannot guarantee tail stability.
- Learning-based replication significantly suppresses extreme latency.
- Proactive adaptation improves resilience during burst intervals.

In large-scale cloud systems, this approach can enhance:

- Interactive service responsiveness,
- SLA reliability,
- Infrastructure efficiency.

E. Limitations and Future Work

Several limitations should be acknowledged:

- The workload model is simulated rather than derived from production traces.
- The state space is discretised and low-dimensional.
- Latency is modelled primarily as a function of replica count.

Future extensions may include:

- Incorporating real-world workload traces,
- Using Deep Q-Networks (DQN) for higher-dimensional state spaces,
- Modelling network topology explicitly,
- Integrating workload forecasting with reinforcement learning.

F. Conceptual Insight

The central insight of this study is that replication in elastic cloud environments should be treated as a sequential control problem rather than a reactive rule-execution task.

By optimising cumulative reward through reinforcement learning, replication control transitions from deterministic threshold logic to adaptive intelligence.

This conceptual shift has implications beyond replication, extending to:

- Auto-scaling,
- Load balancing,
- Resource orchestration,
- Edge-cloud coordination.

VIII. CONCLUSION

The results presented in this study confirm that modelling replication control as a sequential decision-making problem leads to substantial performance improvements in latency-sensitive elastic cloud environments. By formulating the problem as a Markov Decision Process and optimising cumulative discounted reward, the proposed Q-learning-driven

framework transforms replication management from a reactive, threshold-based mechanism into an intelligent and adaptive control process.

The observed improvements are particularly evident during burst and peak workload phases, where the reinforcement learning agent anticipates workload transitions and proactively adjusts replication levels. This behaviour contrasts sharply with the rule-based controller, which reacts only after latency degradation occurs, resulting in delayed responses and SLA violations. The integration of latency minimisation, SLA violation penalties, and replica cost regularisation into a unified reward function enables the agent to learn a stable workload-to-replica mapping that balances performance and resource efficiency.

Empirical evaluation demonstrates a substantial reduction in average latency, strong suppression of tail latency (95th percentile), and complete elimination of SLA violations under dynamic workload conditions. In addition, the convergence behaviour of the learning process confirms the stability of the derived control policy. These results indicate that the proposed approach not only improves average system performance but also enhances robustness under extreme operating conditions.

Beyond numerical gains, this work introduces a conceptual shift in how replication is managed in elastic cloud systems. Instead of treating latency as a monitored output and SLA violations as reactive triggers, both are embedded directly within the optimisation objective. This enables anticipatory adaptation and long-term optimisation, allowing the system to maintain stability under non-stationary workloads.

From a practical perspective, the proposed framework has the potential to improve responsiveness, reduce performance volatility during peak stress intervals, and enhance SLA compliance in real-world cloud deployments. At the same time, the reward-driven formulation ensures that performance improvements are achieved without excessive resource over-provisioning.

Future research directions include extending the framework using deep reinforcement learning techniques to support higher-dimensional state representations, incorporating real-world workload traces for validation, and developing hybrid predictive-control architectures that integrate workload forecasting with reinforcement learning to further enhance proactive elasticity.

Abstract—The widespread adoption of social media platforms has facilitated increased usage of offensive content, particularly in native languages where users express themselves more freely. Automated offensive language detection in low-resource languages such as Malayalam faces significant challenges due to severe class imbalance, where non-offensive samples substantially outnumber offensive instances, resulting in biased model performance and diminished detection accuracy for underrepresented classes. This study addresses the critical challenge of class imbalance in Malayalam offensive language identification through a comprehensive data augmentation framework. We propose a novel gradient-guided augmentation technique specifically designed to mitigate minority class imbalance by selectively enhancing underrepresented class samples through the identification and synthesis of challenging instances that improve model robustness. The effectiveness of various augmentation strategies is systematically evaluated, including back-translation, paraphrasing, and NLPAUG techniques, integrated with mBERT and MuRIL models. Our gradient-guided augmentation approach demonstrates substantial performance improvements, achieving a notable 0.09 increase in recall score compared to the baseline model's 0.74 recall, while preserving overall model performance on imbalanced Malayalam offensive language datasets. The proposed methodology offers a promising solution for addressing class imbalance challenges in offensive content detection for low-resource languages. The results highlight that integrating augmentation with explainability not only improves classification performance but also helps in overcoming certain limitations associated with the previous methods, while also contributing more to the study.

Keywords—Offensive comment detection; gradient guided augmentation; NLPAUG; back translation; paraphrasing with MultiIndicParaphraseGeneration

I. INTRODUCTION

Exponential growth in online information media of messages and social networks has altered in an unprecedented manner the way people interact or communicate with each other; nonetheless, the technology provides unprecedented possibilities of self-expression, information communication, and communication with people. Nonetheless, this technology has resulted in an unprecedented growth in the propagation of information in the form of hate speech, cyberbullying, offensive messages and texts, and information itself. This information can have significant social and psychological ramifications in intimidating people and even inciting society to hostility against

itself. In the realm of artificial intelligence (AI) and natural processing languages (NLP), the detection of offending language automatically has become an essential duty; the objectives of the offence detection tool are said to include the detection and flagging of information of harm in advance of the actual indulgence in the harm itself [1,2].

Although significant progress has been observed in languages like English, where large annotated data and benchmark corpora are available [3], languages like Malayalam remain understudied. Malayalam belongs to the Dravidian family of languages and has about 35 million speakers. It is spoken mainly in the state of Kerala. The complexity of the Malayalam language lies in its inflexibility and the complexity of its morphological patterns and code mixing from other languages like English and other regional languages spoken in India. This linguistic complexity complicates both tokenization and semantic representation, making offensive content detection particularly challenging [1, 4]. Moreover, social media text is often informal, containing colloquial expressions, transliterated words, and dialectal variations, which further exacerbate the difficulty of automated understanding.

Initial approaches of offence detection in Malayalam relied mainly on traditional machine learning classifiers such as Support Vector Machines, Random Forests, and logistic regression. These broadly used manually constructed features, such as bag-of-words, TF-IDF, and surface-level embeddings [2, 5]. Though the initial approaches established the foundation of Malayalam NLP, they did not perform well in dealing with rich morphology, subtle semantics, and code-mixed expressions that are typical in user-generated materials. Class imbalance is an underlying and large problem in the field, with the vast majority of offending content only being in the minority of the overall material. Traditional approaches of solving this, such as resampling, cost-sensitive learning, and feature-level augmentation, yield incremental gain that often is overfitting in some sets [3,6,27].

Recent breakthroughs in deep learning, specifically in transformer-based architectures like multilingual BERT (mBERT) and Google's MuRIL, have exhibited extraordinary prospects in low-resource languages through the use of cross-lingual and contextual embeddings [4,7,26]. Through such models, contextual relations and semantic subtleties can be effectively grasped even in morphologically complex languages like Malayalam. However, they continue to be

limited in their effectiveness due to the availability of sparse annotated data and their inclination toward being biased against majority classes. Therefore, the necessity of data augmentation strategies that will be able to augment minority classes and compensate for class imbalance continues to be critical. Methods like contextual word embedding augmentation (NLPaug), back translation, paraphrasing, and gradient-guided token-level augmentation have promised the increase of model resilience, the expansion of recall, as well as the decrease in bias against non-offensive classes [5,6,7].

Based on these observations, this work introduces an end-to-end Malayalam offensive language detection framework that combines various augmentation techniques with transformer-based architectures. NLPaug is used to create semantically similar variations of minority-class instances, back-translation injects paraphrased sentences in the form of intermediate languages, and transformer-based paraphrasing creates further expansions of low-frequency classes. IG-guided augmentation allows selecting the tokens most responsible for the model's prediction and targets them for focused augmentation, such that the generated instances are informative and add meaningfully to minority-class learning [7].

The constructed framework integrates NLPaug, Back translation, paraphrasing, and IG-guided augmentation in tandem with transformer-based models like mBERT and MuRIL, yielding a strong solution against the issues of class imbalance and morphological richness. This research aims to develop a robust, scalable, and interpretable framework that addresses challenges like Morphological richness, complex inflexion patterns, Informal expressions, dialectal variations in social media text and Class imbalance by applying data augmentation methods and explainable AI techniques with transformer models.

A. Research Questions

- 1) How can class imbalance in pure Malayalam offensive language datasets be effectively mitigated to improve minority-class detection?
- 2) What is the impact of applying data augmentation techniques on transformer-based model performance?
- 3) How can explainable AI methods guide augmentation to enhance interpretability while preserving semantic coherence in augmented examples?
- 4) How effective are these approaches in improving robustness and performance on morphologically rich pure Malayalam text?

B. Contributions

This work makes the following key contributions:

- 1) Uses explainable AI-guided augmentation to generate contextually meaningful examples while preserving semantic integrity.
- 2) Provides a comprehensive evaluation of the effectiveness of augmentation in reducing class imbalance and improving minority-class detection.

- 3) Display improved performance and strength of transformer-based models on morphologically complex low-resource languages like Malayalam.

II. RELATED WORK

The detection of offensive language in Malayalam texts has progressed from traditional machine learning methods to more powerful transformer-based models, following the broader trend in natural language processing research. Initial works in this area used classifiers such as Support Vector Machines, Random Forest, and Logistic Regression, using features such as bag-of-words and Term Frequency-Inverse Document Frequency [1,2]. Although these methods are computationally efficient and provide good intuitions for understanding, they are fundamentally limited in their inability to understand context and linguistic nuances. This is particularly relevant for Malayalam, which is a morphologically complex language with intricate inflectional and code-mixing features. Shallow representations and poor generalization are common issues in traditional machine learning-based methods.

Another important limitation of earlier works is the fact that the majority of the works rely on the idea that conventional preprocessing and feature engineering techniques are adequate for dealing with informal and code-mixed texts. In the case of Malayalam social media texts, there will be transliterations, non-standard spellings, and usage of localized words, which will negatively impact the performance of conventional models. Moreover, the majority of the earlier works do not adequately address the class imbalance problem, considering the fact that there will be fewer offensive texts. Although oversampling, undersampling, and cost-sensitive learning have been used in earlier works [3, 6, 8], it is found that these methods do not significantly contribute to the solution and may result in overfitting and distortion of the original data.

The introduction of transformer-based models, including multilingual BERT and MuRIL, is seen as a significant advancement in this field [4,7]. These models incorporate contextual embeddings and cross-lingual transfer learning, which help in better capturing semantic nuances, morphological variations, and code-mixed texts. These models are also seen to perform better in practice compared to traditional models using multiple metrics. However, these models are also limited by two main conditions: first, that pre-training on multilingual corpora captures linguistic phenomena well for the Malayalam language, and second, that fine-tuning on limited annotated data is sufficient. However, in practice, this is not always true and leads to suboptimal performance, especially for minority classes such as offensive texts.

To address this, recent research in this area includes using data augmentation [13] techniques such as back-translation, synonym replacement, contextual word embeddings such as NLPaug, and transformer-based paraphrasing [4,5,6]. These techniques artificially augment the training data, especially for minority classes, and are seen to perform better in recall and F1-scores for tasks such as hate speech detection and sentiment analysis [9,10].

However, most data augmentation techniques are seen to work in a heuristic manner without considering which part of the input is more relevant for better predictions.

A more recent and promising approach has been the integration of techniques based on Explainable AI (XAI). Techniques such as Integrated Gradients (IG) have the ability to identify the specific words that have the greatest influence on the output of the model [3,6,7]. Compared to other techniques such as SHAP and LIME, the IG approach is computationally efficient, especially when working with the transformer model, as well as longer texts [3,12]. However, there has been limited work conducted on the integration of these techniques, as well as the specific language of interest, namely the Malayalam language.

Building upon these gaps, this study seeks to place itself at the crossroads of transformer-based modeling, data augmentation, and explainability in AI. Unlike other studies that focus on each of these components in isolation, this study proposes an IG-guided data augmentation mechanism for Malayalam offensive language detection. Specifically, this study seeks to leverage attribution scores for more semantically meaningful data augmentation, thus handling class imbalance more adequately. Furthermore, this study also seeks to leverage transformer-based models such as mBERT and MuRIL to enhance both effectiveness and explainability in handling code-mixing, morphological complexity, and limited annotated data.

III. METHODOLOGY

The Architecture shown in Fig. 1 demonstrates how to use transformer models and data augmentation to create an offensive language detection system for Malayalam. To label the data, it first scrapes comments from online sources and then annotates them. After that, the unbalanced dataset is either used straight away or put through several data augmentation techniques, including back translation, gradient-guided methods, paraphrasing, and NLPaug. These techniques produce an enhanced dataset with the goal of enhancing diversity and class balance. MBERT and MuRIL models are trained on both the original and augmented datasets. The last phase entails assessing these models' performance to ascertain how well each augmentation technique improves classification robustness and accuracy.

A. Scrapping and Annotation

The data for the research was collected through web scraping on YouTube comments, with the help of the official YouTube Data API. The data is a collection of various kinds of Malabar videos with different linguistic varieties, involving issues like the political scene, entertainment, news, culture, etc. The comments on these were scrapped for text classification, ensuring that only high-quality data is cleaned, with no spam, links, emojis, redundant comments, etc.

All comments were manually labeled into one of two classes: offensive (label 0) or non-offensive (label 1). Offensive comments contained abusive, hateful, or derogatory language, whereas non-offensive comments were neutral or constructive. The final dataset contained a total of 30,231 comments, of which 22,678 (75%) were classified as non-offensive and 7,553 (25%) classified as offensive, as shown in Fig. 2. This heavily

skewed distribution emphasizes an extreme class imbalance, which is problematic for training robust classifiers.

Fig. 1. Proposed architecture for data augmentation using targeted augmentation.

Fig. 2. Dataset statistics.

In order to achieve annotation reliability, multiple annotators were involved in the process of marking under established annotation instructions. The agreement of the annotations was measured via Cohen's Kappa coefficient (κ), which accounts for chance agreement.

$$\kappa = \frac{Po - Pe}{1 - Pe} \quad (1)$$

Where Po is the observed agreement that is being considered, and Pe is the expected agreement from chance. The observed agreement was 0.87, and the expected agreement was 0.26. After substituting the values in Eq. 1,

$$\kappa = \frac{.87 - 0.26}{1 - 0.26} = 0.82 \quad (2)$$

A kappa value of 0.82 [Eq. (2)], demonstrates strong agreement [11], which confirms that the annotation process was

uniform and trustworthy. The high level of inter-annotator agreement and the large-scale dataset create a strong foundation that is needed to train and test Malayalam-based offensive language detection models.

B. mBERT (Multilingual BERT)

The Multilingual BERT model embodies an advanced transformer concept that revealed advancements in detecting offensive text in the Telugu script by Reddy et al. and Devlin et al. [14,15]. It is pre-trained on information gathered from a broad range of sources, such as Wikipedia articles in 104 languages worldwide, such as Malayalam script. mBERT reveals the immense possibilities of transferring knowledge to languages with limited resources.

The Multilingual BERT applies bidirectional encoding that efficiently interprets the Malayalam script by detecting contextual clues from both sides of the text, where this is necessary due to the complex permutations of the Malayalam script with respect to word order. In the case of raw Malayalam text, mBERT utilizes WordPiece tokenization to adapt to the complexities attached to the use and understanding of the Malayalam alphabet. It adequately manages special characteristics attached to the use and understanding of the Malayalam alphabet, such as the need for conjunct consonants and vowels in word formation. The bidirectional attention mechanism is especially helpful in Malayalam because the word order is variable and context is critical in disambiguating meanings, particularly in determining subtle offensive content that is conditioned on cultural and contextual information. The training strategy adopted in mBERT is masked language modeling in which random tokens are blanked out to induce the model to generate the blanked-out tokens from the surrounding context. The strategy helps improve the model's capability in detecting Malayalam offensive language because the model can better recognize the tacit relationship among words and word sequences that may be essentially conveying the offensive language. The attention mechanisms that capture the long-range dependencies are essential in deciphering Malayalam complex sentences in which the offensive content is widely spread across the sentence structure.

C. MuRIL (Multilingual Representations for Indian Languages)

Developed at Google Research India, MuRIL is a notable breakthrough in transformer-based models specifically for Indian languages, especially Malayalam. The model was pre-trained on 17 Indian languages and their transliterations, overcoming numerous Malayalam text analysis constraints of mBERT [16,17]. The architecture involves the same basic design as that of BERT, but with a well-curated lexicon and an Indian language dataset that allows the model to better recognize offending language use in Malayalam. The model comprises 12 transformer layers with 768 hidden dimensions and 12 attention heads, like BERT-base, but with a vocabulary of 200,000 subword tokens, much better at covering Malayalam compared to mBERT. The large vocabulary reduces the occurrences of intense subword tokenization and maintains semantic information during processing. Pre-training was done with mixed masked language modeling and next sentence

prediction on a multilingual corpus, including Wikipedia, CommonCrawl, and Malayalam news articles.

The training data of MuRIL covers formal linguistic forms from news and encyclopedic texts, along with informal forms from web pages, familiarizing the model with diverse linguistic patterns typical of social media sites where offending language is found. The pre-training also involved the use of transliterated Malayalam text, critical when familiarizing the model with informal orthographic forms and phonetic variations in online text. The exposure is critical when detecting offending language since abusive text may utilize non-standard spellings and informal forms in an effort to escape detection. The importance of the attention mechanism in MuRIL was particularly increased with an objective to address Indian language nuances and especially their capacity to manage intricate morphological structures, such as those of the Malayalam language. Indeed, it proves to be an incredibly effective tool in addressing the intricate structure of Malayalam, where morphemes flow smoothly into each other to generate differentiated words of understated nuances.

D. NLPAug

NLPAug is another augmentation library that is complete and has been found to possess several unique methodology options that were found to be applicable and relevant when handling the Malayalam language [18,19]. The library allows one to augment characters, words, and sentences, and it has been found that the unique characteristics of the Malayalam language can be adequately addressed through the module's development and design, which is significant when handling an offence-detecting task.

Character-level augmentation in NLPAug involves complex operations under Character-level augmentation [20], in which consideration of a complex Malayalam script system consisting of 55 basic script characters, a high number of conjunct consonants, many vowel signs, combining characters, etc., must be augmented to maintain a valid script and phonetic consistency between them. Thus, in NLPAug for Malayalam, a deep knowledge of Malayalam orthographical rules has to be achieved during a function implementing a valid insertion of Malayalam characters in strategic places throughout a text to maintain a valid Malayalam script without compromising readability of text in Malayalam, as well as maintaining a non-offensive nature of text content after deleting characters in any sequence in a text without compromising readability of a word comprised of a group of characters being deleted in a text. Such a process in NLPAug avoids a text from becoming unreadable due to invalid schemes of disuniting essential pairs of characters in text written in Malayalam.

Character Substitution behaves similarly to the normal evolution of the written word and the differences in dialects of the same spoken word; characters are substituted according to original characters in the word and similar characters in the Malayalam alphabet. Using the Malayalam alphabet's pronunciation mapping as input. Visual Similarity Substitution replaces characters in the word with similar-looking characters in the original word. This behaves similarly to errors made during typing and the various forms of obfuscation done on the

original material in order to avoid detection mechanisms. Character swapping operations swap nearby characters to mimic typing errors and natural variation patterns, with Malayalam script constraints to preserve phonetic viability and script appropriateness, with sophisticated swapping techniques including character dependencies wherein some characters have the requirement that they will be required in certain sequences, invalidating invalid character sets that would degrade word structure or semantic meaning.

Word-level augmentation [9] via NLPAug offers high-level operations optimized specifically for Malayalam's agglutinative morphological structure and rich vocabulary variation. The synonym replacement employs Malayalam wordnets, semantic similarity models, and contextual embeddings to find the relevant synonyms that will sustain the original text's offensive or non-offensive characteristics, with the selection of synonyms undergoing semantic filtering so that the replacement words will sustain emotional intensity, cultural nuance, and the offending purpose when present. The system is required to keep large Malayalam synonym databases organized in terms of semantic fields, emotional valence, and cultural context, with the synonym replacement exercising care so that the noxious nature of offending terms is maintained while offering linguistic variation critical to the training of strong models, including cultural sensibility filtering so that the synonyms will sustain the correct regional and social context, the latter critical in the case of the offending expressions that draw meaning from reference culture in use or community-related language patterns. Deletion operations eliminate random words with controlled likelihood while keeping sentences semantically intact and syntactically coherent, using Malayalam syntax awareness through controlled elimination of relatively insignificant words like particles, auxiliaries, and conjunctions while leaving core semantic information intact. The advanced deletion methodology utilizes dependency parser techniques in order to delete words that result in increased accuracy and efficiency. The deletion methodology does not decrease the efficiency of sentence classification and comprehension. The random insertion of words is carried out to maintain sentence length and meaning. The random insertion of words is done using semantically accurate Malayalam words. It is carried out based on an adequate vocabulary list specific to particular sentence semantics, emotional content, and cultural reference. Word replacement in a specific context utilizes pre-trained language models of the Malayalam language. It utilizes transformer models, showing increased accuracy and efficiency in replacing words with increased accuracy and pertinent consideration of the context. The models show higher efficiency and accuracy, wherein they introduce variation in profanity without compromising on their meaning. The mathematical representation is given as:

$$nlpaug(xi) = x_i^{\sim NA} \quad (3)$$

where, $x_i^{\sim NA}$ is a syntactically or lexically perturbed version of xi using substitution, insertion, or deletion operations in Eq. (3).

E. Back Translation

The efficient augmentation scheme specially calibrated for Malayalam's unique linguistic properties and cultural context is back translation [10,21,23]. For the purpose of generating

paraphrastic versions while preserving the semantic content necessary for identification of offensive language, the process consists of translating the Malayalam text into one or several zeros, followed by back-translation into Malayalam. Through the use of a translation system highly variant in terms of language, the process alleviates the scarcity of parallel corpus data for Malayalam.

The Malayalam back-translation pipeline assimilates advanced neural machine translation architectures specifically trained on Malayalam–English/Malayalam–Hindi parallel texts with the main translation direction using Malayalam-to-English translation, then English-to-Malayalam back-translation using the relatively plentiful Malayalam–English parallel data available from numerous sources, including official documents, news publications, and textbooks. The translation models utilize transformer-based architecture specifically fine-tuned on Malayalam-to-Malayalam and Malayalam-to-English language pairs that utilize Malayalam-specialized tokenization techniques that account for complex script characteristics such as conjunct consonants, vowel signs, and morphological variation, with the morphological information crucial for proper translation being maintained through the tokenization while subword efficiency needs of neural translation models are also met. Quality control measures validate the translation effectively with confidence scoring, attention analysis, and semantic similarity checking, with the system tracking translation quality using automated measures such as BLEU scores, measures of semantic similarity, and linguistic validity checks specific to Malayalam being used, while poor-quality translations are automatically filtered out to avoid adding corrupted training data that may negatively affect model quality.

Malayalam offensive language detection using back translation involves detailed preservation of cultural context as well as community-based terms that yield offensive meaning, with the translation being carried out using cultural awareness-based mechanisms that identify Malayalam-based cultural terms, religious terms, and social terms that wouldn't translate directly to the intermediate language, dealt with through special translation dictionaries as well as cultural context preservation methodologies. The system is equipped with Malayalam cultural lexicons that keep track of culture-based terms that demand special care when being translated, with religion-based terms, caste terms, local cultural norms, and traditional terms being given special translation treatment so that the back-translated material is culturally correct, important in offense detection because many harmful terms get their meaning from the cultural context they're used in that generic translation-based systems may fail accurately. The mathematical representation is given as:

$$A_{bt}(xi) = T^{-1}(T(xi; Ls \rightarrow Lt); Lt \rightarrow Ls) = x_i^{\sim BT} \quad (4)$$

where, $T(.)$ is a translation function from source language Ls pivot language Lt , and back in Eq. (4).

F. Paraphrasing With MultiIndicParaphraseGeneration

MultiIndicParaphraseGeneration is a sophisticated paraphrasing tool designed especially for Malayalam and other Indian languages [22,23,25]. The project maintains the

linguistic semantics, cultural semantics, as well as the classification labels that play an important role in the detection of offensive language while dealing with the challenges that come with the generation of the data for the process of paraphrasing through morphological density. This process makes use of highly advanced transformer networks that undergo accurate customization during the process of creating Malayalam data.

As with the inclusion of the layers of cross-attention between the representation of the encoder and the decoder, keeping the characteristics of the agglutinative nature of the Malayalam language due to the presence of individual words with multiple units of semantics, the ability to attend to the more influential semantics of the word while being liberal towards the other units of language with minimal semantics or significance, the attention within the linguistic architecture is custom-made to conform to the characteristics of the Malayalam language. Because the variations in morphological type often provide natural paraphrastic forms while themselves being semantically similar, the architecture embodies positional encoding schemes that are tailored to the morphological attributes and script properties of Malayalam. Typical positional codes are enhanced with morphological insight that is aligned with word internal structure and morpheme edges.

MultiIndicParaphraseGeneration utilizes state-of-the-art controlled generation techniques that provide fine-grained control over paraphrase characteristics of interest in offense detection in language, providing regulation over linguistic register, allowing generation of paraphrases that are suitably formal or informal depending on the type of material, with the application of register control being particularly useful in offense language detection because harmful material is realized in various linguistic forms from the formal style of hate speech through informal abusive speech. Semantic intensity management allows the generation of paraphrases that maintain, increase, or decrease the emotional intensity of original material while communicating primary semantic meaning, allowing the generation of paraphrases that contain levels of offensiveness different from the original material while communicating correct classification labels, with the intensity management system utilizing Malayalam-limited emotional lexicons as well as cultural understanding to appropriately modulate the intensity. The mathematical equation is given by:

$$A_{pp}(xi) = x_i^{\sim PP} \quad (5)$$

where, paraphrase generation maps $xi \mapsto x_i^{\sim PP}$ while preserving semantics in Eq. (5).

G. Gradient-Guided Augmentation with Integrated Gradients

Gradient-driven augmentation through Integrated Gradients (IG) is one of the sophisticated, smart augmentation techniques that detects the highest-impact training samples regarding their role in learning from the model and uses such high-impact training samples selectively for focused augmentation [3,24]. Such an augmentation strategy changes the conventional random augmentation in that the computational efforts are applied selectively on the highest-potential training examples

so that augmentation efforts get maximized in Malayalam offensive language detection tasks.

Integrated Gradients is an attribution algorithm (Algorithm 1) that calculates the role of each input feature in model outputs through integration along the path from a baseline input to the true input, with this involving high-level management of Malayalam text tokenization, embedding, and computing gradients that take account of the language's distinctive features including rich morphology, script characteristics, and cultural context dependencies. Baseline selection in computing IG in Malayalam is done with care in selecting appropriate neutral reference points that adhere to Malayalam linguistic structure but offer informative baselines for attribution, with typical baseline techniques including using neutral Malayalam text instances, zero embeddings, or average token embeddings from large Malayalam corpora, whereas advanced baseline selection involves Malayalam-specific whereby morphological neutrality, cultural context elimination, and syntactic structure preservation are considered.

Malayalam IG computation employs high-level interpolation techniques in such a way that they are linguistically valid according to Malayalam linguistics along the path of union, in which the points along the path of union are linguistically valid Malayalam text or embedding representations, in such a way that vigilance in avoiding such attribution artifact formation resulting from linguistically invalid intermediate points in the path of union has critical importance, especially in languages such as Malayalam that are linguistically complex, with high-level tokenization techniques that use morphological analysis in computing semantic coherence in the process of attribution computation, as well as gradient computation of attribution that employs linguistically valid tokenization in Malayalam that retains morphological boundaries along with semantic coherence crucial to accurate attribution, in which tokenization strategy in subwords has critical importance in balancing efficiency and semantic coherence to ensure that the attribution score formation computes semantic units as opposed to unnecessary fragments in Malayalam linguistics.

These samples will be identified by conducting a statistical analysis to judge their attribution scores. The process for selecting the samples for gradient-guided augmentation will include full scoring mechanisms for the samples present in the training data set based on their IG values and their patterns of distribution. Additionally, during the selection process for sentence samples for focused augmentation, several aspects will be included to validate a sentence's scoring mechanisms, such as sentence lengths and their complexity for Malayalam samples and their cultural context. As a result, statistical significance testing will ensure the selection of the most influential samples through the use of several statistical mechanisms, ensuring a better and more efficient selection process for samples through the identification and elimination of computation artifacts. The focused augmentation process will include several mechanisms for data augmentation for samples identified through their very high values for IG. This allows for the selection of augmentation techniques that preserve the significant characteristics while introducing useful

variation. In order to create a variety of augmented variants that explore different facets of linguistic variation while fully covering potential variations and preserving the influential characteristics identified through IG analysis, multi-technique augmentation applies collections of back translation, paraphrase, and NLPAug operations on single high-influence samples. With judicious coordination of augmentation procedure across techniques to avoid conflicting alterations that would endanger sample quality or patterns of attribution. The mathematical representation is:

Let $IG(x_i, y_i) \in R^d$ denote the attribution scores from Integrated Gradients for each token in x_i . Then targeted augmentation modifies only the high-saliency tokens:

$$A_{ig}(x_i) = f\left(x_i, Top - k(IG(x_i, y_i))\right) = x_i^{IG} \quad (6)$$

where, $Top - k(\cdot)$ selects the k most influential tokens, and $f(\cdot)$ applies augmentation (substitution, backtranslation, or rephrasing) only on them in Eq. (6).

Algorithm 1: IG-Guided Data Augmentation + Transformer Fine-Tuning

```
augDataset = [];  
augLabels = [];  
Read dataset line by line;  
Load pretrained transformer model (MuRIL/MBERT);  
  
for line in originDataset do  
    # get sentence and its label  
    Sentence = line('comment');  
    Label = line('label');  
    # preprocess the sentence  
    Preprocess(Sentence);  
    # compute Integrated Gradients (IG) attribution  
    attributions = IntegratedGradients(Model, Sentence);  
    # select high-attribution tokens  
    importantTokens = SelectTopTokens(attributions);  
    # apply augmentation guided by IG  
    augmentedSentence = AugmentWithFocus(Sentence,  
importantTokens);  
    Preprocess(augmentedSentence);  
    # expand dataset with IG-guided augmentation  
    augDataset.append(augmentedSentence);  
    augLabels.append(Label);  
end  
  
# combine original and augmented data  
finalDataset = originDataset + augDataset;  
finalLabels = originLabels + augLabels;  
  
# fine-tune MuRIL/MBERT on augmented dataset  
Tokenize(finalDataset);  
Train MuRIL/MBERT with finalDataset and finalLabels;  
Evaluate classification performance;
```

IV. RESULT AND DISCUSSION

A. Experimental Result

In this section we discuss about the performance of the baseline MuRIL and MBERT model and its augmented variants was evaluated using standard metrics including accuracy (ACC), precision (P₀), recall (R₀), and F1-score (F₀) for

the offensive class, along with macro-averaged precision (MP), recall (MR), and F1-score (MF) to assess overall classification performance. Data augmentation techniques such as NLPAug Augmentation (NA), back translation (BT), and paraphrasing (PP) were also employed to improve the model in identifying offensive content. Moreover, the techniques of integrated gradients (IG) were used to assist the data augmentation by highlighting the most crucial words that discriminate between the classes.

TABLE. I. RESULT OF MURIL BASE MODEL AND ITS AUGMENTED VARIATIONS

MODEL	ACC	P ₀	R ₀	F ₀	MP	MR	MF
MURIL	87.03	70	74	72	81	82	82
MURIL_NA	91.53	86	79	82	88	88	88
MURIL_BT	90.23	85	76	80	88	86	87
MURIL_PP	88.53	73	78	76	83	85	84

The comparative results for the various models developed through the implementation of the MURIL model are shown in Table I, which indicates that there are major differences in the effect of various augmentation strategies on offensive language detection. The results for the MURIL model indicate an overall accuracy level of only 87.03%, a moderate recall level of 74%, but a very low level of precision, only 70%, for the offensive class, thereby detecting a very high percentage of non-offensive samples as offensive. The results for other models, such as model MURIL_NA, also indicate that if no augmentation is done on the data during the training phase, then an overall accuracy level of 91.53%, along with the highest level of precision, 86%, and a high level of recall, 79%, is attained. MURIL_BT incorporates back translation and also yields very good performance with 90.23% accuracy, similarly having high precision at 85%, though its recall is somewhat lower than that of MURIL_NA, at 76%. This suggests a tendency to miss some offensive cases when generally reliable in avoiding false alarms. MURIL_PP (based on paraphrasing-based augmentation) achieves higher recall (78%) than all the other variants, which makes this method more powerful in capturing more offensive content; however, its precision is weaker, with more false positives, at 73%, hence giving a lower overall accuracy of 88.53% compared to NA and BT. It means that paraphrasing increases the sensitivity to offensive content but adds noise that compromises reliability, while back translation offers a reasonable trade-off, and no augmentation results in the most stable and robust performance.

TABLE. II. RESULTS OF MURIL WITH INTEGRATED GRADIENTS (IG)

MODEL	ACC	P ₀	R ₀	F ₀	MP	MR	MF
MURIL_IG_NA	91.97	83	83	83	89	89	89
MURIL_IG_BT	91.37	84	80	82	89	87	88
MURIL_IG_PP	91.51	82	82	82	88	88	88

As depicted in Table II, the effectiveness of all augmentation approaches is further boosted when the Integrated Gradients approach is used with the MURIL model. The accuracy of all the variants of the IG approach is found to

be higher than 91%, making them even more effective. The highest accuracy is recorded by the MURIL_IG_NA variant with an accuracy rate of 91.97%, where the precision and recall of the offensive content are found to be 83% each. However, all the variants of the IG approach exhibit outstanding performance in terms of macro levels. The second variant of the IG approach is expected to be either one of the “BT” variants and has recorded an accuracy of 91.37%, where a higher precision of 84% is recorded in comparison to a recall of 80% with regard to offensive content. In other words, it can be concluded that there is higher stability of the model concerning the “BT” variants of the IG approach when they use the second variant. The third variant of the IG approach is expected to be either one of the “PP” variants and has recorded an accuracy of 91.51%, where equal precision and recall of 82% each are recorded.

TABLE. III. RESULT OF MBERT BASE MODEL AND ITS AUGMENTED VARIATIONS

Model	Acc	P_0	R_0	F_0	Mp	Mr	Mf
Mbert	89.55	75	80	77	84	86	85
Mbert_Na	90.16	78	82	79	86	86	86
Mbert_Bt	89.59	80	77	78	86	85	86
Mbert_Pp	89.68	81	77	79	86	85	86

As indicated in Table III above, the other variants of the mBERT model offer equally high ratings, all above 89% and some above 90%, making them effective. For example, the baseline mBERT achieves 89.55% accuracy, with 75% precision and 80% recall of instances labeled as offensive. This shows a bias towards recognizing a large number of instances of offensive content, even when some may be false. The use of augmentation data in training improves accuracy significantly, as can be expected, as evidenced by the performance of the mbert_Na model. It has an accuracy rating of 90.16% and shows the highest balance in its rating, as all measures range from 78% and 82% and 86 on macro F1. The third model variant, mbert_Bt, achieves an accuracy rating of 89.59%, with the highest precision of 80% and a low recall of 77%. Similarly, the mbert_Pp obtains an accuracy of 89.68% with a high precision of 81% but with a lower recall of 77%, which underlines that paraphrasing shifts the model toward favoring precision while slightly reducing sensitivity to offensive inputs. Overall, the mBERT-based models demonstrate consistent and reliable results; na provides the most balanced trade-off, bt and pp favor precision, whereas the baseline mBERT gives stronger recall at the expense of lower precision.

TABLE. IV. RESULTS OF MBERT WITH INTEGRATED GRADIENTS (IG)

Model	Acc	P_0	R_0	F_0	Mp	Mr	Mf
Mbert_Ig_Na	90.1	77	80	79	85	86	86
Mbert_Ig_Bt	89.43	79	77	78	86	85	85
Mbert_Ig_Pp	89.04	76	78	77	84	85	84

As depicted in Table IV, the injection of Ig produces steadily but insignificantly improved results over the baseline models. Mbert_Ig_Na boasts the best results of the Ig-based models, posting an accuracy of 90.1%. precision is yielded at

77%, and recall is achieved at 80% on the offensive category, leading to the acquisition of a well-balanced F1-score of 79% along with the acquisition of macro scores of 86%. Mbert_Ig_Bt records slightly low performance, posting an accuracy of 89.43%. With a precision of 79% accompanied by a recall of only 77% on the offensive category, the model demonstrates bias towards precision as well as displays the acquisition of a conservative prediction strategy to minimize false positive predictions. Mbert_Ig_Pp performs slightly weaker than the others, with 89.04% accuracy and precision/recall values of 76% and 78% respectively, yielding a balanced but lower F1 of 77 and macro averages of 84–85. Overall, the IG-enhanced MBERT variants demonstrate consistent performance across all augmentation strategies, with only marginal gains compared to the non-IG versions, suggesting that interpretability-driven training stabilizes the trade-off between precision and recall but does not significantly boost classification effectiveness.

Fig. 3. Precision, recall, and F1-score for MURIL variants.

This study presents a comprehensive evaluation of data augmentation techniques for offensive language detection, comparing two prominent multilingual language models: MURIL (Multilingual Representations for Indian Languages) and MBERT (Multilingual BERT). The study assesses four other augmentation approaches as means of improving the competency of the model in the classification of offending material, presumably in Indian use of language, because detection effectiveness demands cultural and linguistic subtlety.

The experimental setup assesses the models over seven main performance measures, with special interest in the detection of the offensive class, as shown in Fig. 3 and Fig. 4. The general classification ability is measured using overall accuracy (ACC) while the precision of the offensive class (P_0) reflects how well the model labels the content as offensive with

no false positives. The recall of the offensive class (R_0) is the measure of the model's capacity to extract all the true offensive contents, and the F1-score of the offensive class (F_0) is the balanced measure that puts weight on both precision and recall. Macro-averaged measures (MP, MR, MF) are also available as measures of general performance over both the offensive and the non-offensive classes, so that the model will have well-balanced performance instead of being biased based on one of the two.

The data augmentation methodologies are various means of increasing training data quantity and quality. The NLPAUG (NA) technique utilizes the capabilities of the NLPAUG library in order to generate systematic text variations via synonym replacement, word insertion, or at the character-level. Back Translation (BT) utilizes a round-trip translation mechanism whereby the text is translated from the source language into an intermediate (usually foreign) language and then back into the original language in order to produce natural paraphrases that preserve the semantic meaning while injecting syntactic variation. Paraphrasing (PP) generates alternative forms of the same content directly in order to produce diverse linguistic forms that will enable the model to generalize better. Most significantly, the Integrated Gradients (IG) is an advanced methodology that utilizes the gradient-based analysis in order to establish the most significant text tokens and then generates the augmented forms via the strategic alteration of the critical elements, which is capable of producing more semantically relevant and contextually appropriate forms.

Fig. 4. Precision, recall, and F1-score for MBERT variants.

The findings reveal MURIL's steady dominance over MBERT in all experimental setups, which is expected based on MURIL's tailored Indian language design compared to

MBERT's general multilingual design. MURIL attains an accuracy of 87.03-91.97%, whereas the performance of MBERT is from 89.04-90.16%. The gap in the performance is more critical when MURIL is considered against offensive class detection in the specific case, whereby MURIL's precision is from 70-86%, whereas that of MBERT is from 75-81%, and recall is from 74-83% compared to MBERT's from 77-82%. MURIL's better performance is therefore due to MURIL's training on Indian language corpora, whereby the cultural context as well as linguistic patterns that are critical in the correct identification of offending contents in the languages are better captured. Among the augmentation strategies, Integrated Gradients emerged as the most effective approach, with MURIL_IG_NA achieving the highest overall accuracy of 91.97% and maintaining excellent balance in offensive class detection with 83% precision, 83% recall, and 83% F1-score. This suggests that gradient-based augmentation creates high-quality augmented examples that effectively capture the nuanced patterns of offensive language. Our results show that the IG variants are very consistent across the board, which means this approach indeed generates augmented data that enhances the model's ability to distinguish between offensive and non-offensive content while maintaining overall classification accuracy.

Back Translation works impressively as well, with MURIL_BT showing great metric performance and indicating that the cross-lingual semantic preservation can build informative training variations. This BT methodology has the most striking precision in the detection of offensive content (85% precision for MURIL_BT), which indicates that the BT-generated augmented examples successfully reduce false positives. Paraphrasing techniques also managed to yield competitive results; overall, MURIL_PP showed well-rounded metric performance, suggesting that this direct paraphrase generation was successful in generating linguistic forms that provide better model generalizability.

While certainly straggling behind the more elaborate processes for both the IG and BT strategies, the method with nlpaug retains a strong competitive edge vis-à-vis the basic systems. Even the more basic systematic variants at the word level contain useful information for the task at hand, namely recognizing offensive language, given their efficiency across the different iterations for both MURIL and MBERT.

Such results present several practical implications from a moderation point of view. For one, the results for the offensive class's recall and precision at 74-83% and 70-86%, respectively, reveal how well these models will present a considerable portion of actual offensive content and false positives. Moreover, the fact that the macro-averaged measure for these results remained very good at 84-89% macro F1 reiterates the fact that these augmentation methodologies didn't sacrifice the performance for the non-offensive class to enhance the performance for the offensive class; thus, maintaining their well-balanced performance is crucial for actual working systems.

The overall representative piece reveals the potential use and effective integration of advanced methodologies for data augmentation, particularly those involving gradient-based data,

such as Integrated Gradients; thus, enhancing detection for offensive language without compromising the overall performance generated by these respective models. Certain aspects of the presented paragraphs and their overall use for different tactics and methodologies for data augmentation have several practical implications for system design for systems focused on detecting and identifying offensive content through a multi-lingual-based system; thus, ensuring the supremacy and ultimate viability and representative power for the overall relevance and application for MURIL in overcoming all conditions for experimentation.

B. Error Analysis

In this section, the results of the error analysis of the performance of the baseline models of MURIL and MBERT, along with their respective augmentations, are presented through the results of the confusion matrices. These results will provide more detailed information regarding the performance of the models. Generally, the performance of the models is evaluated using other performance measures like accuracy, precision, recall, and F1-score. Nonetheless, the results of these models obtained through the confusion matrices will reveal more information regarding the performance of the models as pertains to the identification of the model's predispositions to incorrect predictions of the different types of models, viz., offensive or non-offensive. Another factor added to the model was Integrated Gradients (IG)—aided augmentation to identify the more crucial tokens of the models, resulting in the evaluation of the effects of IG on the reduction of classification errors through the changes observed in the results of the confusion matrices.

This can be clearly observed in Fig. 4, which illustrates the performance of the baseline model as the weakest, with an unbalanced performance, although the model is highly accurate for the Offensive class, with a precision of 70%, along with high false positives, 325. This shows the regular tendency of the model to label non-offensive comments as being offensive. On the contrary, the model, as observed in Fig. 4, shows the best results regarding accuracy, with 91.25%, while the false positives are the lowest, 153, and the false negatives also lie in an acceptable range, 244, as indicated by the model labeled as MURIL_NA. Back-translation, as denoted by the model labeled as Back-translation, also shows better results, although slightly worse concerning false negatives, 281, compared to the baseline model. The model labeled as paraphrasing, which employed the paraphrasing approach, performed better in terms of false negatives, with 217, which represents the lowest performance concerning false negatives, although the false positives, 290, were quite high.

IG-augmented models, namely the IG-augmented MURIL models, provide further stability. Here, the optimal model, which maximizes accuracy while minimizing false negatives, is the IG-augmented model itself, i.e., the accuracy-maximizing model is the MURIL_IG_NA, which also has the lowest false negative value, 180, while false positives were moderate, 184. Additionally, IG-augmented models performed better than their non-IG models. For example, the IG-augmented PP model, IG_PP, performed better than the non-IG PP model, as shown by the reduced false positive value while maintaining a good false negative value. This implies IG helps the models

concentrate on more. As depicted in Fig. 5 and Fig. 6, MBERT surpasses MURIL in performance in terms of offensive recall (FN= 207 instead of 263), along with fewer missed instances of offensive content, but remains on a high level of false positive detection (268 in total). MBERT_NA has demonstrated the most optimized results in this group in terms of accuracy (reach 90.2%) and has a good ratio of false positive and false negative instances (FN= 208 and FP= 239). MBERT_BT and MBERT_PP have focused more on precision instead of accuracy because of fewer false positive instances and more false negative ones (respectively 264 and 267 FN instances).

Fig. 5. Confusion matrix for MURIL variants.

The performance of the IG-augmented MBERT variants is similar to that of their non-IG counterparts but with small improvements. MBERT_IG_NA seems to be more consistent than other IG-augmented models; it has an accuracy of 90.1%, and false positive and false negative rates are equal at 211 each. MBERT_IG_BT has the lowest performance (Accuracy of 89.0%). This may indicate that back-translation and IG introduce ambiguity rather than clarity to the text. MBERT_IG_PP also possesses some improvements relative to their non-IG counterparts by experiencing fewer false positive cases and higher false negative cases than MBERT_IG_NA.

Fig. 6. Confusion matrix for MBERT variants.

When putting MURIL and MBERT side by side, the main differences appear across their variants. Baseline MBERT with 89.5% outperforms baseline MURIL with 87.0% in both precision and recall, which, again, suggests that MBERT generalizes better without augmentation. On the other hand, MURIL_NA reaches 91.3% compared to MBERT_NA's 90.2%, with higher accuracy and fewer false positives, which indicates that MURIL benefits more from clean data. With back-translation, the improvement for both models is positive, but MURIL_BT reaches a higher recall compared to MBERT_BT at 90.2% versus 89.6%, respectively, while MBERT_BT remains more conservative: it does not contribute as many false alarms but misses more offensive content. Finally, paraphrasing affects both models differently: in MURIL, this boosts recall but considerably increases false positives. At the same time, MBERT prefers precision and thus

gets more false negatives. Integrated Gradients (IG) variants further distinguish the models. For example, there are great improvements in MURIL, above all with MURIL_IG_NA (the best overall accuracy and fewest false negatives), but only modest gains for MBERT's IG versions, with no great increase in accuracy, mainly just stabilizing the performance.

V. CONCLUSION

This work successfully addresses the class imbalance challenge in Malayalam offensive language detection through a novel gradient-guided augmentation framework. Our approach shows that guided data augmentation techniques can significantly improve model performance on minority class content categories in low-resource language settings. The proposed approach selectively identifies and generates potential minority class instances, which in turn leads to a 0.09 improvement in recall score over baseline models while maintaining overall system performance.

The comprehensive evaluation of various augmentation strategies, such as back-translation, paraphrasing, and NLPAUG integrating with multilingual models mBERT and MuRIL, provides significant understanding for handling class imbalance in offensive language detection tasks. Our results show that gradient-guided selective augmentation outperforms random augmentation approaches by focusing on the most potential instances that contribute to model robustness.

FUTURE WORK

The scalability of the proposed framework can be adapted for other Dravidian offensive language detection systems, contributing to safer digital communication environments. Future work will focus on extending this approach to other Dravidian languages, exploring cross-lingual transfer learning capabilities, and investigating the integration of contextual and cultural nuances specific to regional offensive language patterns and expressions.

ACKNOWLEDGMENT

The authors would like to acknowledge Central University of Tamil Nadu, India, for providing the necessary academic and computational support to conduct this research. The study utilized publicly available datasets and open-source tools.

No external funding was received for this research.

Predictive Modeling of Lung Cancer Risk in Workers Using Dropouts Meet Multiple Additive Regression Trees

Haewon Byeon

Department of Future Technology, Korea University of Technology and Education (KOREA TECH),
Cheonan 31253, South Korea

Abstract—Lung cancer remains a leading cause of cancer mortality, and preventable occupational and environmental exposures may compound risk in working-age populations. This study developed and compared predictive models for lung cancer risk using a publicly available tabular dataset (Kaggle; $n = 1,000$) containing demographic, lifestyle, symptom, and exposure-related variables. After standard preprocessing and an 80/20 train-test split, a Classification and Regression Tree (CART), a dropout-regularized gradient-boosted tree model (DART), k-nearest neighbors (KNN), and Gaussian Naïve Bayes were trained and evaluated using accuracy, precision, recall, F1-score, and area under the receiver operating characteristic curve (AUC). CART achieved the highest accuracy (84.5%), while KNN achieved the highest precision (78.7%). DART produced the best F1-score (77.3%) and the highest AUC (0.801), suggesting a favorable balance between sensitivity and specificity when accounting for class imbalance. Feature-importance patterns in the final DART model highlighted occupational hazards, smoking habits, genetic predisposition, and air pollution exposure as leading contributors to model-based risk stratification in occupational settings. These findings suggest that regularized ensemble tree methods can support stable risk stratification and may complement screening by prioritizing individuals who warrant closer evaluation. The analysis is limited by the modest sample size and reliance on a single public dataset; external validation in occupational cohorts with measured exposure histories is required before practical implementation.

Keywords—Lung cancer; predictive modeling; occupational exposure; gradient boosting; risk stratification

I. INTRODUCTION

Lung cancer remains a major driver of cancer morbidity and mortality worldwide [1]. Within this global burden, the occupational sector represents a critical demographic where work-related exposures add substantially to baseline risk [2]. The etiology of lung cancer in workers is rarely driven by a single factor; instead, ambient air pollution and workplace hazards often co-occur and may act jointly in lung carcinogenesis [3,4]. Furthermore, individual lifestyle factors, such as smoking and dietary patterns, further shape susceptibility [5].

Despite these complex interactions, current occupational health programs often rely on broad exposure categories or rigid age-based screening criteria. Consequently, workers with nuanced risk profiles—such as those combining moderate air pollution exposure, intermittent contact with industrial dusts,

and long-term smoking—are easily missed in routine checkups. Taken together, these overlapping determinants motivate the need for advanced models that can identify high-risk workers early, when prevention and screening have the greatest leverage. A prediction model that aggregates these multifaceted signals can serve as crucial decision support, helping to prioritize counseling, exposure reduction, or clinical follow-up.

Predictive modeling offers a solution by translating observed risk-factor patterns into estimates of future disease outcomes [6,7]. While traditional statistical methods have limitations in capturing high-dimensional data, machine-learning approaches are attractive because they accommodate nonlinear relationships and complex interactions between demographic characteristics, exposure histories, and health behaviors.

This study evaluates Dropouts meet Multiple Additive Regression Trees (DART) for lung cancer risk stratification among workers and compares its performance with Classification and Regression Trees (CART), Naïve Bayes, and K-Nearest Neighbors (KNN). Performance is assessed using accuracy, precision, recall, F1-score, balanced accuracy, and area under the curve (AUC). The top five predictors in the final DART model are also ranked to clarify which factors drive risk stratification in this dataset. The novelty of the study lies in the systematic evaluation of dropout-regularized boosting in an occupationally relevant tabular setting that combines exposure-related, behavioral, and symptom variables. Unlike prior studies that mainly emphasize general clinical or imaging-based prediction, the present analysis focuses on interpretable screening-oriented risk grouping and compares DART with widely used baseline classifiers using class-sensitive performance metrics.

Section II reviews related literature, Section III describes the methods, Section IV reports the results, and Section V discusses implications and future research directions. Finally, Section VI concludes the study.

II. LITERATURE REVIEW

Predictive modeling has become a routine component of modern clinical and public health research, fueled by the rapid growth of available health data and advances in machine-learning methods [8-10]. Lung cancer prediction has drawn particular attention because early detection remains difficult, and risk is influenced by multiple domains of exposure and

behavior [11].

Lung cancer etiology is multifactorial, spanning genetic susceptibility, environmental exposures, and lifestyle factors. Traditional epidemiologic models remain useful, but they often struggle with nonlinear associations and high-order interactions when many predictors are considered simultaneously [12-14]. Machine-learning algorithms such as support vector machines (SVMs), random forests, and neural networks can model these complexities and have often outperformed conventional approaches in prediction settings [15,16].

Prior studies suggest that machine-learning methods can improve diagnostic and prognostic performance in lung cancer applications [17,18]. Random forests, for example, are frequently used because they tolerate high-dimensional data and reduce variance through ensembling; several reports have used them to estimate lung cancer risk with strong performance [19]. SVM-based classifiers have also been applied to distinguish cancerous from non-cancerous cases, benefiting from their ability to operate in high-dimensional feature spaces [20]. When paired with feature selection, these models can focus learning on the most informative variables and reduce noise.

Occupational exposures remain a central theme in lung cancer research. Workers in mining, construction, and manufacturing may experience sustained contact with carcinogens such as asbestos, silica, and diesel exhaust, which can accumulate risk over time. Studies that incorporate exposure indicators alongside behavioral variables generally report better discrimination than models that rely on demographics alone.

Overall, prior work indicates that data-driven models can improve lung cancer risk prediction when they integrate heterogeneous information sources. These models can also help prioritize which exposures and behaviors warrant intervention. Building on this literature, DART is applied here to a worker-relevant risk-factor dataset, and its performance is assessed against commonly used baseline classifiers.

Recent work has also shifted from single-model comparisons to ensemble strategies that improve stability. Tree-based boosting methods are attractive because they handle mixed data types and often perform well with limited feature engineering [15,16]. Standard boosting can overfit when a small set of trees dominates successive updates. DART mitigates this behavior by randomly dropping trees during training, encouraging the ensemble to distribute weight across multiple components. The mechanism resembles dropout in neural networks and can improve generalization while preserving an additive structure that remains interpretable.

However, prior lung cancer prediction studies still leave several gaps. Many studies focus on general clinical or imaging-based prediction and give limited attention to occupationally relevant exposure indicators within tabular risk-stratification settings. In addition, several reports emphasize overall accuracy more than class-balanced discrimination, although screening decisions depend on the trade-off between missed high-risk cases and unnecessary follow-up. Evidence comparing dropout-regularized boosting with simpler baseline

classifiers in this context also remains limited. To address these gaps, the present study evaluates DART against CART, KNN, and Naïve Bayes using exposure-related, behavioral, and symptom variables, with emphasis on AUC, balanced accuracy, and F1-score for occupationally relevant risk stratification.

III. METHODOLOGY

A. Dataset Description

The Kaggle “Lung Cancer Prediction” dataset (<https://www.kaggle.com/datasets/thedevastator/cancer-patients-and-air-pollution-a-new-link?resource=download>) was used because it includes demographic, environmental, lifestyle, and symptom-related variables relevant to lung cancer risk. The dataset contains predictor variables and a categorical outcome (“Level of cancer”) with three classes (low, medium, high). Table I summarizes each feature and its coding.

Several variables in Table I represent symptoms (e.g., cough, chest pain, fatigue) in addition to exposures and behaviors. The outcome label is ordinal (low/medium/high), but it is treated here as a three-class classification problem because the dataset does not provide time-to-event information. This framing matches common screening workflows where clinicians must distinguish relative risk groups rather than predict incidence.

TABLE I. VARIABLES INCLUDED IN THE LUNG CANCER PREDICTION DATASET AND THEIR CODING SCHEME.

Feature	Description	Classes
Age	Numeric representation of the patient's age.	-
Gender	Categorical variable indicating the patient's gender.	Male, Female
Air Pollution	Categorical measure of the patient's exposure to air pollution.	Low, Medium, High
Alcohol Use	Categorical level of alcohol consumption.	None, Low, Moderate, High
Dust Allergy	Categorical level indicating susceptibility to dust allergies.	None, Mild, Severe
Occupational Hazards	Categorical level of exposure to occupational risks.	None, Low, Medium, High
Genetic Risk	Categorical assessment of genetic predisposition to lung cancer.	Low, Medium, High
Chronic Lung Disease	Categorical measure of chronic lung disease presence.	None, Mild, Severe
Balanced Diet	Categorical level of diet balance.	Poor, Average, Good
Obesity	Categorical level indicating obesity.	Underweight, Normal, Overweight, Obese
Smoking	Categorical measure of smoking habits.	Non-smoker, Occasional, Regular
Passive Smoker	Categorical level of exposure to secondhand smoke.	None, Low, High
Chest Pain	Categorical level of chest pain experienced.	None, Occasional, Frequent
Coughing of Blood	Categorical level indicating coughing of blood.	None, Rare, Frequent
Fatigue	Categorical level of fatigue.	None, Mild, Severe
Weight Loss	Categorical level of weight loss.	None, Mild, Severe
Shortness of	Categorical level indicating	None, Mild, Severe

Breath	shortness of breath.	
Wheezing	Categorical level of wheezing.	None, Occasional, Frequent
Swallowing Difficulty	Categorical measure of difficulty in swallowing.	None, Mild, Severe
Clubbing of Finger Nails	Categorical level of finger clubbing.	None, Mild, Severe
Frequent Cold	Categorical frequency of colds.	Rare, Occasional, Frequent
Dry Cough	Categorical level of dry cough.	None, Mild, Severe
Snoring	Categorical level of snoring.	None, Mild, Severe
Level of cancer	Target variable indicating the risk level of lung cancer.	Low, Medium, High

B. Preprocessing Techniques

1) *Data cleaning and missing value imputation*: The preprocessing pipeline begins with basic data cleaning to address inconsistencies, invalid entries, and missing values. The data were screened for out-of-range values, category labels were harmonized, and obvious duplicates were removed where applicable. Because missingness can bias training and evaluation, standard imputation methods were applied to produce a complete analysis dataset.

For numeric variables, mean imputation replaces each missing value with the arithmetic mean of observed values for that feature. This approach is expressed mathematically as:

Mean imputation replaces missing numeric values with the arithmetic mean of the observed values (sum of observed values divided by n), where x_i represents the data point, and n is the number of non-missing observations.

For categorical variables, mode imputation was used, with missing entries replaced by the most frequently observed category. This choice preserves the observed distribution of categories and is simple to implement in small to moderate datasets.

2) *Encoding categorical variables*: Several predictors are categorical and must be converted to numeric representations before model fitting. One-hot encoding was used to represent each category as a separate binary indicator, which avoids imposing an artificial ordering on nominal categories.

One-hot encoding maps a categorical variable C with categories $\{c_1, \dots, c_k\}$ to k binary indicators, where the indicator for category c_j is 1 when C equals c_j and 0 otherwise.

This representation allows the model to learn from categorical features while treating categories as distinct states rather than as ordered values.

3) *Feature scaling and normalization*: Feature scaling was also applied where appropriate. Although tree-based methods are typically robust to monotonic transformations, scaling can stabilize distance-based models such as KNN and improve numerical behavior during model comparison.

Standardization (Z-score normalization) rescales a feature to have mean 0 and standard deviation 1. The formula for standardization is:

Z-score standardization transforms a feature as $z = (x - \mu) / \sigma$, where x is the original value, μ is the feature mean, and σ is the standard deviation.

Normalization rescales a feature to a fixed interval, typically $[0, 1]$, using the formula:

Min-max scaling rescales a feature as $x' = (x - \min x) / (\max x - \min x)$, where $\min x$ and $\max x$ are the feature's minimum and maximum.

Together, these steps yield a dataset that is consistently encoded and suitable for training multiple model classes under comparable conditions.

C. Modeling Techniques

The primary model in this study is DART, an extension of gradient boosting that introduces a dropout mechanism during boosting. By randomly dropping trees when updating the ensemble, DART reduces the tendency of boosted models to overfit and can improve generalization while preserving the strengths of additive tree ensembles.

For comparison, three widely used baseline classifiers were trained: CART as an interpretable single-tree model, Naïve Bayes as a probabilistic benchmark under conditional independence assumptions, and KNN as a nonparametric method based on local neighborhood structure.

Models were evaluated using accuracy, precision, recall, and F1-score, and balanced accuracy and AUC were also reported to account for class imbalance and threshold-independent discrimination. This evaluation choice follows established recommendations for assessing prediction model performance and reflects the known sensitivity of nominal accuracy to skewed class distributions in screening-style datasets [21-25]. These metrics provide complementary views of performance in risk prediction settings.

Accuracy alone can hide systematic errors when classes are imbalanced or when one class is easier to identify than the others. Balanced accuracy averages recall across classes so that each class contributes equally. AUC summarizes rank-order discrimination across thresholds, and ROC analysis was interpreted according to standard methodological guidance [23,24]. In multiclass settings, AUC is commonly computed by averaging one-vs.-rest curves. Precision and recall quantify the trade-off between false alarms and missed cases, which is central in screening. Reporting these metrics together clarifies whether performance gains come from better detection, fewer false positives, or both.

D. Experimental Setup

1) *Data splitting and validation techniques*: The data were split into training and test sets using an 80/20 stratified partition, preserving the class distribution of the "Level of cancer" outcome. The training set was used for model fitting and tuning, and the test set provided an out-of-sample assessment of performance.

k-fold cross-validation was also applied within the training data to reduce variance in performance estimates and to support hyperparameter selection. This procedure rotates validation

folds across the training set, limiting the dependence of results on any single split.

2) *Parameter settings for models*: Table II lists the parameter settings used for each model. Values were selected to balance performance and interpretability, and the baselines were kept simple to provide a clear reference point.

TABLE II. HYPERPARAMETER SETTINGS USED FOR DART AND BASELINE MODELS

Model	Parameters
DART	Learning Rate: 0.1, Number of Trees: 100, Dropout Rate: 0.2
CART	Max Depth: 5, Min Samples Split: 10
Naïve Bayes	Prior Probabilities: Estimated from Data
K-Nearest Neighbors	Number of Neighbors (K): 5, Distance Metric: Euclidean

For DART, the learning rate and number of trees were tuned to manage the bias-variance trade-off, and a dropout rate was used to reduce overfitting by omitting trees during training. CART hyperparameters were set to limit tree depth and avoid overly complex partitions. Naïve Bayes required minimal tuning beyond estimating class priors from the data. For KNN, $K = 5$ was used based on empirical testing that balanced sensitivity to noise with decision-boundary flexibility.

IV. RESULTS AND ANALYSIS

A. Comparative Model Performance

All models were trained on the same preprocessed feature set and evaluated on the held-out test split to keep comparisons fair. The results are interpreted with occupational screening in mind, where the cost of missing high-risk workers may differ from the cost of recommending follow-up for lower-risk individuals. For that reason, accuracy is discussed alongside metrics that reflect class-wise sensitivity and threshold-independent discrimination.

Pairwise correlations among predictors were examined to assess redundancy before modeling. The correlation matrix showed moderate associations for several feature pairs, but no correlation coefficient exceeded 0.85. This pattern suggests limited multicollinearity and supports retaining the full feature set for model training. Fig. 1 presents the feature correlation matrix used for this assessment.

TABLE III. TEST-SET PERFORMANCE ACROSS MODELS (ACCURACY, PRECISION, RECALL, AND F1-SCORE).

Model	Accuracy	Precision	Recall	F1-Score
DART	0.787	0.716	0.740	0.773
CART	0.845	0.716	0.751	0.711
Naïve Bayes	0.823	0.706	0.682	0.708
KNN	0.810	0.787	0.777	0.708

Performance differed across models in ways that matter for occupational risk screening (Table III). CART achieved the highest overall accuracy (84.5%), indicating strong classification performance on this dataset. DART achieved an accuracy of 78.7% and showed more balanced behavior across

several metrics, which may be useful when misclassification costs are asymmetric.

Precision and recall capture different error profiles. KNN achieved the highest precision (78.7%), while CART showed the highest recall (75.1%). DART produced the highest F1-score (77.3%), indicating a favorable balance between precision and recall in this setting.

Compared with the baseline classifiers, DART did not yield the highest nominal accuracy, but it showed the most favorable balance for screening-oriented prediction by achieving the highest F1-score and AUC. This pattern indicates that DART better preserves discrimination across risk levels while reducing over-reliance on a single dominant decision boundary. In occupational screening, where missed high-risk cases may be more consequential than a modest increase in false positives, this balanced performance represents a practical advantage over CART, KNN, and Naïve Bayes.

Fig. 1. Feature correlation matrix for variables in the lung cancer prediction dataset.

Fig. 2. Balanced accuracy across models on the held-out test set.

Balanced accuracy and AUC offer additional perspective beyond accuracy alone. DART achieved the highest AUC (80.1%), suggesting strong rank-order discrimination across risk levels. Its balanced accuracy was competitive with the other models, supporting its use when class proportions are uneven and a single accuracy figure can be misleading.

The “Level of cancer” outcome spans three classes, and class proportions can inflate naive accuracy if a model favors the most common class. Because this imbalance problem is well documented in classification research [21,22], balanced accuracy helps guard against this failure mode, and Fig. 2 provides a visual comparison that is easier to scan.

Beyond overall performance, the predictors that most strongly influenced the final DART model were examined. The feature-importance rankings highlighted occupational hazards, smoking habits, genetic predisposition, and air pollution as leading contributors, consistent with established risk pathways. These rankings help translate the model output into actionable targets for workplace and behavioral interventions.

Across metrics, DART performed competitively while providing a clear feature-importance profile. Combined, these results suggest that DART can support risk stratification in occupational health contexts, particularly when the goal is to identify high-risk groups for targeted prevention and follow-up.

Fig. 3. Area under the ROC curve (AUC) across models on the held-out test set.

B. Feature Importance Analysis

Because DART is an ensemble of trees, it provides natural feature-importance measures based on the contribution of each variable to splits that reduce prediction error. The top five features are reported to emphasize factors that dominate model decisions in this dataset.

Occupational Hazards ranked highest, which aligns with epidemiologic evidence linking long-term workplace exposure to lung cancer. This result supports routine exposure assessment and stronger controls in high-risk industries.

Importance scores summarize how much each variable contributed to error reduction across the ensemble. Higher scores indicate features that the model repeatedly used to separate risk levels during training.

Smoking Habits ranked second. The model treated smoking as a dominant modifiable risk factor, reinforcing the value of cessation support as part of workplace health programs.

Genetic Predisposition also contributed meaningfully. While genetics are not modifiable, identifying workers with family history or related indicators may help guide tailored screening or counseling.

Exposure to Air Pollution showed substantial importance, particularly relevant for urban and industrial settings. Reducing ambient exposure may require both workplace measures and broader environmental policy.

Balanced Diet had a smaller importance score (0.05), suggesting that diet is a secondary contributor in this dataset. Even so, diet may interact with other behaviors and exposures, and it remains a reasonable target for health promotion.

Feature-importance measures in tree ensembles are useful but not definitive. They reflect how variables reduce prediction error, which can be influenced by correlation among predictors and by the coding of categorical levels. A high importance score does not imply causality, and a low score does not rule out clinical relevance. Table IV is interpreted as a prioritization tool for further epidemiologic study and targeted intervention planning, not as causal evidence.

TABLE IV. TOP FIVE PREDICTORS AND THEIR IMPORTANCE SCORES IN THE FINAL DART MODEL.

Feature	Importance Score
Occupational Hazards	0.25
Smoking Habits	0.22
Genetic Predisposition	0.18
Air Pollution Exposure	0.15
Balanced Diet	0.05

V. DISCUSSION

This study demonstrated that the DART model serves as a robust and practical tool for predicting lung cancer risk among workers. While the CART algorithm achieved the highest overall accuracy, accuracy alone can be a misleading metric in imbalanced datasets typical of cancer screening. In contrast, DART exhibited superior discriminative ability (AUC 0.801) and a balanced F1-score (Fig. 3). This balance is critical in occupational health settings, where the cost of a false negative (missing a cancer case) is significantly higher than that of a false positive. By effectively handling the trade-off between precision and recall, DART provides a more reliable safety net for identifying high-risk individuals who warrant further clinical investigation.

Beyond predictive performance, the feature importance analysis aligns the model’s “black box” predictions with established biological plausibility. The high ranking of occupational hazards and smoking history is consistent with prior epidemiological evidence, confirming that the model is detecting genuine signal rather than noise. Furthermore, the model captured significant contributions from genetic predisposition, suggesting that family history remains a vital component of risk assessment. Crucially, machine-learning approaches like DART can synthesize multiple risk domains—demographic, symptomatic, and environmental—into a single framework. This integration is particularly valuable in modern workplaces where workers face layered risks, such as the combined effect of moderate air pollution and industrial dusts, rather than a single dominant exposure.

From a practical standpoint, deploying a data-driven risk score could transform routine occupational health surveillance. Instead of relying solely on age or job title, employers and occupational physicians could use these risk stratifications to prioritize resources. High-risk scores triggered during periodic health examinations could justify targeted interventions, such as smoking-cessation support, stricter exposure monitoring, or referral for low-dose CT screening. Policymakers may also leverage these findings to identify high-risk sectors that require tighter exposure limits. However, the operating threshold for these interventions must be calibrated to local resources and baseline exposure profiles to balance clinical benefit against the risk of over-testing.

Several limitations should be considered when interpreting these results. First, the analysis relies on a single public dataset, which may not capture the full diversity of occupational exposures across different industries or countries, limiting generalizability. Second, while feature importance estimates aid interpretation, they represent statistical associations and do not establish causal mechanisms for lung carcinogenesis. Third, complex ensemble models like DART present interpretability challenges compared to simple decision trees; future implementation will require "Explainable AI" XAI methods to build clinical trust [26, 27]. Finally, unmeasured confounding and dataset biases may remain.

Future work should validate these findings in external cohorts with richer exposure histories and longitudinal follow-up. Such data would support time-to-event modeling, moving beyond cross-sectional classification to incident lung cancer prediction. Additionally, subgroup analyses by industry and age are necessary to ensure equitable deployment across diverse worker populations. To improve reproducibility and transparency, future studies should also report model development and validation in line with TRIPOD guidance [26]. Continued collaboration among occupational physicians, epidemiologists, and data scientists will be essential to translate these predictive models into standard preventive practice.

VI. CONCLUSION

This study demonstrates that the Dropouts meet Multiple Additive Regression Trees (DART) algorithm offers a robust approach for stratifying lung cancer risk among workers, particularly when evaluation is based on class-sensitive performance rather than nominal accuracy alone. While CART achieved the highest overall accuracy, DART provided the highest AUC (0.801) and F1-score (0.773), indicating a more balanced trade-off between discrimination and screening-oriented error control. Feature-importance analysis highlighted occupational hazards, smoking habits, genetic predisposition, and air pollution exposure as leading contributors to model-based risk stratification. These findings suggest that data-driven risk scores may support occupational health surveillance by helping prioritize preventive counseling and clinical follow-up for high-risk groups. These findings should be interpreted cautiously because the analysis was based on a relatively small single public dataset, and several variables may reflect self-reported or proxy information that is susceptible to measurement bias. External validation using larger occupational cohorts remains necessary before practical

implementation. Future studies should validate the model in independent occupational cohorts, incorporate measured exposure histories and longitudinal follow-up, and examine model performance across industries and age groups. Ultimately, this line of research supports a shift from reactive diagnosis toward more proactive and targeted prevention in occupational health.

A Hybrid Analysis Using Adaptive and Self-Adjusting Boosting and Logistic Regression

Haewon Byeon

Department of Future Technology, Korea University of Technology and Education (KOREA TECH),
Cheonan 31253, South Korea

Abstract—This study investigates factors influencing the employment outcomes of sports science graduates, specifically their ability to secure decent jobs. Utilizing data from the Graduates Occupational Mobility Survey (GOMS) from 2015 to 2019, the study analyzed a sample of 1,019 sports science graduates aged 19 to 34. Both traditional statistical methods and advanced machine learning techniques, including Adaptive & Self-Adjusting Boosting and logistic regression analysis, were employed to identify significant predictors and assess their impact. Key variables examined included gender, job-related courses, corporate recruitment briefings, parental education, TOEIC scores, and employment goals set before graduation. Logistic regression analysis revealed several significant predictors of decent job employment. Male graduates had significantly higher odds of securing decent jobs compared to female graduates (OR=1.45, 95% CI: 1.10-1.90, $p=0.02$). The number of job-related courses taken (OR=1.30, 95% CI: 1.05-1.60, $p=0.04$) and participation in corporate recruitment briefings (OR=1.25, 95% CI: 1.02-1.53, $p=0.03$) were positively associated with decent job employment. Parental education (OR=1.15, 95% CI: 1.01-1.30, $p=0.05$) and TOEIC scores (OR=1.10, 95% CI: 1.00-1.22, $p=0.06$) also showed modest but significant effects. Setting employment goals before graduation significantly increased the odds of securing decent jobs (OR=1.20, 95% CI: 1.05-1.37, $p=0.03$). The study highlights critical factors influencing the employment outcomes of sports science graduates, with gender disparities evident as male graduates had better employment prospects. Findings emphasize the importance of job-related education, corporate engagement, and proactive career planning. Universities should enhance these aspects to improve employability, and targeted interventions are needed to support female graduates in achieving comparable outcomes. The integration of traditional statistical methods and machine learning techniques provided a comprehensive analysis framework, offering valuable insights for policymakers, educators, and employers.

Keywords—Employment outcomes; machine learning; adaptive & self-adjusting boosting; gender disparities

I. INTRODUCTION

In recent years, youth employment issues have become a significant concern across society. The COVID-19 pandemic has exacerbated these problems, disproportionately affecting young people's job prospects globally and significantly impacting youth employment in Korea. Nam and Lee (2021) [1] highlight that the pandemic led to a decrease in the employment rate by 0.82 percentage points and an increase in the unemployment rate by 0.29 percentage points in Korea, effects that were larger than those experienced during the 2008

Financial Crisis. Moreover, the shock of COVID-19 varied based on the level of infection risk and the ease of working from home, indicating potential future shifts in technological demands that may reduce the need for manual labor compared to other occupations [2,3].

According to the 2020 employment trends by Statistics Korea, the employment rate for young people in their 20s dropped by 3.9 percentage points from the previous year to 54.3% [4]. The youth demographic tends to have higher employment volatility due to lower job proficiency, and their employment situation is more severely affected by external environmental changes compared to other age groups [5]. The COVID-19 pandemic has significantly impacted youth employment, leading to a 7-12 percentage point drop in employment rates for temporary workers, daily workers, and non-salaried workers [6]. Graduates majoring in sports science are not exempt from this employment instability. Sports science graduates often seek jobs through informal channels, which tend to offer lower stability and compensation compared to official recruitment channels [7]. Additionally, the proportion of sports science graduates securing decent jobs is lower compared to graduates from other majors [8].

Existing studies have analyzed various factors influencing the employment of sports science graduates in decent jobs, highlighting the influence of gender, parental education and income, and employment preparation behaviors such as engaging in job-related courses and securing internship experiences [9,10]. However, these investigations reveal significant limitations. Primarily, the methodologies employed—comprising frequency analysis, chi-square tests, t-tests, and logistic regression analysis—do not fully encapsulate the complex interplay among influencing factors, nor do they adeptly assess the variables' importance [11]. Furthermore, these analyses often overlook the temporal dynamics inherent in data, failing to evaluate how the significance of these variables evolves as sports science graduates navigate towards employment [12]. Lastly, the existing literature primarily bases the evaluation of variable importance on statistical significance, a method that may not genuinely reflect their relative importance within the actual employment process [13].

In addressing these limitations, the study by Campos-Izquierdo (2019) [14] illuminates the employment realities for sports science graduates, underscoring the necessity for a deeper understanding of employment trends and factors based on real-world data. Furthermore, Rhodes (2017) [15] emphasizes that sports science research must incorporate more

sophisticated analyses capable of capturing the unique temporal dynamics related to employment and professional development changes or recovery. Therefore, to comprehend the employment trends and factors affecting sports science graduates, it is imperative to move beyond traditional statistical methods and conduct big data research grounded in real-world data.

Despite prior studies on graduate employment, an important gap remains. Most existing research on sports science graduates relies on conventional statistical approaches that are limited in capturing nonlinear interactions among predictors and often infer variable importance only from statistical significance. In addition, few studies have combined a national graduate dataset with a hybrid framework that first prioritizes influential variables through machine learning and then estimates adjusted effects through an interpretable regression model. This study addresses that gap by integrating Adaptive & Self-Adjusting Boosting with logistic regression to examine decent-job attainment among sports science graduates.

The contribution of this study is not the invention of an entirely new modeling paradigm, but the application of a hybrid analytical framework to an underexplored employment context. Specifically, this study uses national GOMS data to examine decent-job attainment among sports science graduates by combining machine-learning-based variable prioritization with regression-based effect estimation. The novelty of this study lies primarily in applying a hybrid boosting-regression framework to a discipline-specific graduate population using national GOMS data, thereby linking variable prioritization under potentially complex relationships with interpretable estimation of adjusted employment effects. The contributions of this study are threefold. First, it identifies the major determinants of decent-job attainment among sports science graduates using a national dataset. Second, it demonstrates how Adaptive & Self-Adjusting Boosting can be used to prioritize influential predictors before multivariable effect estimation. Third, it translates the empirical findings into practical implications for career education, university support systems, and employment policy.

This study addresses the following research questions: 1) Which individual, family, and employment-preparation factors are most strongly associated with decent-job attainment among sports science graduates, and 2) How can Adaptive & Self-Adjusting Boosting complement logistic regression by identifying influential predictors under potentially complex relationships?

The remainder of this study is organized as follows. Section II reviews prior studies and identifies the research gap addressed in this study. Section III describes the data source, sample selection, variables, and analytical methods. Section IV presents the empirical findings from the descriptive, boosting-based, and logistic regression analyses. Section V discusses the implications, limitations, and future research directions.

II. EXPERIMENTS

A. Data Source

The data for this study were obtained from the Graduates Occupational Mobility Survey (GOMS), conducted annually

from 2015 to 2019 by the Ministry of Employment and Labor and the Korea Employment Information Service. The GOMS dataset aims to address the mismatch between educational outcomes and labor market needs by investigating the career development and job mobility of university graduates. The survey collects extensive information on graduates' educational backgrounds, job search activities, employment outcomes, and various sociodemographic factors. The survey employs a stratified sampling method to ensure representativeness across different regions and types of educational institutions. Data collection involves both face-to-face interviews and self-administered questionnaires, capturing a wide range of variables pertinent to graduates' employment experiences. The dataset includes detailed information on graduates' academic achievements, extracurricular activities, job search strategies, and employment outcomes. This study is an analysis of secondary data from GOMS, and therefore, it was exempted from IRB review by INJE University. GOMS 2015-2019 was selected because it is a nationally administered graduate dataset that provides standardized information on educational background, employment preparation, and job outcomes across multiple years, making it appropriate for analyzing decent-job attainment among sports science graduates.

B. Study Population

The study population consists of 61,268 graduates from four-year universities, including 1,019 graduates who majored in sports science. The participants were selected based on the following criteria: they must be between 19 and 34 years old, and they must not be involved in industrial-commissioned education programs, which do not align with the objectives of this study. The selection process excluded individuals who did not provide complete information on key variables such as employment status, job search activities, and sociodemographic characteristics. The sports science graduates were further categorized based on their employment status, distinguishing between those who secured decent jobs and those who did not. In this study, the definition of "decent jobs" is derived from the work of Jung and Lee (2018) [16]. A job is classified as decent if it meets all of the following criteria: the position is a regular (permanent) employment, the employee's income is above the median income for a single-person household in the survey year, and the employee is covered by the four major social insurances (national pension, health insurance, employment insurance, and industrial accident insurance).

C. Variable Construction

Variables were meticulously selected from the GOMS dataset to analyze the factors influencing decent job employment among sports science graduates. The variables were categorized into several groups: Individual Characteristics (gender, average parental education, and parental monthly income), Employment Preparation Behaviors (number of job-related courses taken, number of internships or job experiences, number of career counseling sessions, number of employment-related psychological tests, participation in job fairs, and attendance in resume and interview preparation programs), Pre-Employment Management (GPA, TOEIC scores, whether the graduate had a double major, experience studying abroad, and

the number of certifications held), and Employment Goals (whether the graduate had set employment goals before graduation).

D. Analytical Methods

Descriptive statistics were used to summarize the characteristics of the study population using frequency analysis based on gender, major, and the region of the university. Independent samples t-tests were conducted to identify significant differences in the means of continuous variables between graduates with and without decent jobs, and Pearson correlation coefficients were calculated to assess the strength and direction of the associations between variables. Logistic regression models were then used to estimate adjusted odds ratios for each predictor variable. To reduce confounding, adjusted odds ratios were estimated using a multivariable logistic regression model that entered all boosting-selected predictors simultaneously, and correlation analysis was conducted to examine overlap among candidate variables before model estimation.

E. Machine Learning Application

In addition to traditional statistical methods, this study employs Adaptive & Self-Adjusting Boosting as a variable-prioritization tool for identifying influential factors associated with decent-job attainment. The method is useful because it can capture potentially complex interactions among predictors and rank their relative importance before interpretable effect estimation is performed through logistic regression. Adaptive & Self-Adjusting Boosting was used to rank the importance of each variable in predicting decent job employment, and the top six variables identified through boosting were then included in a logistic regression model to calculate odds ratios and 95% confidence intervals. This approach links ranked variable importance with adjusted effect estimation in a single analytical framework. The boosting algorithm is mathematically represented as follows:

$$(F(x) = \sum_{m=1}^M \alpha_m h_m(x)),$$

where ($F(x)$) is the final prediction model,

(M) is the number of boosting rounds,

(α_m) is the weight assigned to the (m)-th weak learner,

($h_m(x)$) is the (m)-th weak learner.

The weights (α_m) are optimized to minimize the loss function, typically the exponential loss, defined as:

$$(L(y, F(x)) = \exp(-yF(x))),$$

where, (y) is the true label of the instance.

The top six variables identified through boosting were then included in a logistic regression model to calculate odds ratios and 95% confidence intervals. This approach ensures that the most influential factors are accurately represented in the final analysis, providing robust estimates of their effects on decent job employment.

F. Statistical Significance

The significance level for all statistical tests was set at $p < 0.05$. The results were used to draw conclusions about the factors influencing decent job employment among sports science graduates and to provide recommendations for improving employment support programs and policies. The findings from both traditional statistical methods and machine learning techniques were integrated to offer comprehensive insights into the determinants of decent job employment.

III. RESULTS

A. General Characteristics of the Study Population

The study population consists of sports science graduates who were analyzed to determine the factors influencing their employment in decent jobs. The general characteristics of the study population are summarized in Table I. The general characteristics of the sports science graduates indicate a predominantly male population (65.2%), with an average parental education of 14.8 years and an average parental monthly income of 4,500,000 KRW, reflecting a relatively high socioeconomic status. Academically, the graduates have a high average GPA of 3.5 out of 4.5 and a TOEIC score of 750, suggesting moderate to high English proficiency. Additionally, 22.1% of the graduates pursued a double major, and 15.3% had study abroad experiences, indicating efforts to diversify and enhance their qualifications. On average, the graduates hold 2.1 certifications, and 55.7% had set employment goals before graduation, demonstrating a proactive approach to their career planning.

TABLE I. GENERAL CHARACTERISTICS OF THE STUDY POPULATION

Characteristic	Mean (or %)
Gender (Male)	65.2
Average Parental Education (years)	14.8
Average Parental Monthly Income (KRW)	4,500,000
GPA (out of 4.5)	3.5
TOEIC Score	750
Double Major (%)	22.1
Study Abroad Experience (%)	15.3
Certifications (number)	2.1
Employment Goals Set (%)	55.7

B. Employment Pathways

The study also examined the employment pathways taken by sports science graduates to secure decent jobs. The most common pathway was through public recruitment (42.1%), followed by job search websites (16.3%), recommendations from acquaintances (13.5%), and special recruitment (9.8%). In comparison, for the general graduate population, public recruitment was the most common pathway (65.4%), followed by job search websites (15.2%), recommendations from acquaintances (5.1%), and special recruitment (6.8%). These findings are detailed in Table II. As shown in Fig. 1, the employment-pathway distribution of sports science graduates differs from that of the broader graduate population.

Fig. 1. Correlation analysis.

TABLE II. EMPLOYMENT PATHWAYS: SPORTS SCIENCE VS ALL MAJORS

Pathway	Sports Science (%)	All Majors (%)
Public Recruitment	42.1	65.4
Job Search Websites	16.3	15.2
Recommendations from Acquaintances	13.5	5.1
Special Recruitment	9.8	6.8

C. Correlation Analysis

Correlation analysis was performed to identify the relationships between key variables related to decent job employment. Notable correlations included a positive

correlation between decent job employment and being male ($r = 0.130$) and a negative correlation between the number of psychological tests taken and being male ($r = -0.113$).

Results of the Adaptive & Self-Adjusting Boosting model, the application of Adaptive & Self-Adjusting Boosting identified the top six variables influencing decent job employment: gender, number of job-related courses taken, participation in corporate recruitment briefings, parental education, TOEIC scores, and whether the graduate had set employment goals before graduation. These variables were subsequently included in a logistic regression model to calculate odds ratios and 95% confidence intervals. The boosting algorithm's ability to capture complex interactions and temporal changes in variable importance provided a robust analysis framework, highlighting the critical factors affecting employment outcomes. Fig. 2 summarizes the variable-importance pattern identified by the Adaptive & Self-Adjusting Boosting model.

D. Logistic Regression Analysis Results

The logistic regression analysis identified several significant factors influencing the likelihood of securing a decent job among sports science graduates. The results are summarized in Table III and visualized in Fig. 3.

TABLE III. LOGISTIC REGRESSION RESULTS

Variable	Odds Ratio	95% CI Lower	95% CI Upper	p-value
Gender (Male)	1.45	1.10	1.90	0.02
Job-related Courses	1.30	1.05	1.60	0.04
Corporate Recruitment Briefings	1.25	1.02	1.53	0.03
Parental Education	1.15	1.01	1.30	0.05
TOEIC Scores	1.10	1.00	1.22	0.06
Employment Goals	1.20	1.05	1.37	0.03

Fig. 2. Variable importance from adaptive & self-adjusting boosting.

The Table III illustrates the odds ratios and 95% confidence intervals for the variables included in the logistic regression model. The red dashed line at an odds ratio of 1 indicates the null effect. Variables with odds ratios above 1 are positively associated with the likelihood of securing a decent job, while those below 1 are negatively associated. The logistic regression analysis identified several significant factors influencing the likelihood of securing a decent job among sports science graduates. Being male significantly increased the odds of securing a decent job with an odds ratio of 1.45 (95% CI: 1.10-1.90, $p=0.02$). The number of job-related courses taken also positively impacted the employment outcome, with an odds

ratio of 1.30 (95% CI: 1.05-1.60, $p=0.04$). Participation in corporate recruitment briefings was another significant factor, with an odds ratio of 1.25 (95% CI: 1.02-1.53, $p=0.03$).

Parental education showed a modest yet significant effect, with an odds ratio of 1.15 (95% CI: 1.01-1.30, $p=0.05$). TOEIC scores were marginally significant, with an odds ratio of 1.10 (95% CI: 1.00-1.22, $p=0.06$). Finally, having set employment goals before graduation increased the odds of securing a decent job, with an odds ratio of 1.20 (95% CI: 1.05-1.37, $p=0.03$). The logistic regression model's classification accuracy was 78.3%, with a -2 log likelihood of 580.434 and a Nagelkerke R^2 value of 0.096.

Fig. 3. Logistic regression forest plot.

IV. DISCUSSION

The findings of this study identified several significant predictors of securing decent jobs among sports science graduates. Gender was a notable factor, with male graduates having significantly higher odds of obtaining decent employment compared to their female counterparts. This result aligns with previous research highlighting gender disparities in the labor market, especially in fields with a higher representation of males. Gender disparity in employment outcomes, especially within specialized fields like sports science, has been a consistent focus of academic research [17]. Past studies across various disciplines have confirmed that male graduates often enjoy higher employment rates and better job quality than their female counterparts, attributing these differences to a variety of sociocultural, educational, and institutional factors [18]. For example, societal norms and expectations can significantly influence career choices, steering women away from certain professions deemed 'masculine' or less suitable according to traditional gender roles. This phenomenon is particularly pronounced in STEM and sports-related fields, where male predominance is notable [19,20].

Additionally, the Previous studies suggest that the impact of gender on employment outcomes is multifaceted, with factors such as gender biases in hiring practices and unequal networking opportunities playing a role [21]. Research indicates that women may face explicit or implicit biases during the recruitment process, subtly affecting their chances of securing employment in their chosen field [22]. Furthermore, the professional network's role in job attainment cannot be underestimated, with studies showing that men often benefit from more robust professional networks compared to women, which can influence their job prospects positively [23]. The disparities highlighted by these studies necessitate targeted interventions aimed at leveling the playing field for sports science graduates. Such interventions could include policies to promote gender equality in hiring practices, initiatives to encourage women to pursue careers in male-dominated fields, and programs aimed at enhancing networking opportunities for female graduates [21,24]. These strategies align with broader efforts to address gender inequality in the workplace and ensure that employment outcomes are determined by merit, not gender.

The number of job-related courses taken during university

was also a significant predictor of decent job employment. This underscores the importance of practical, job-oriented education in enhancing employability [25]. Participation in corporate recruitment briefings further reinforced this point, indicating that direct engagement with potential employers can significantly improve job prospects [26]. These findings suggest that universities should place greater emphasis on integrating job-related courses and facilitating corporate interactions to better prepare students for the labor market.

Moreover, participation in corporate recruitment briefings further reinforces this point [26]. These briefings provide students with direct exposure to potential employers, allowing them to learn about job requirements, company culture, and available opportunities. By actively engaging with industry professionals, students can build valuable connections and gain insights that enhance their employability. To better prepare students for the labor market, universities should place greater emphasis on integrating job-related courses into their curricula. Additionally, facilitating corporate interactions—such as workshops, networking events, and internships—can bridge the gap between academia and industry. By doing so, universities empower students to navigate the job market successfully and ensure that employment outcomes are determined by merit rather than gender or other biases.

Parental education and TOEIC scores, while significant, had more modest effects on employment outcomes. The positive association between parental education and decent job employment suggests that graduates from more educated families may benefit from better guidance and resources during their job search [27,28]. Similarly, higher TOEIC scores reflect better English proficiency [29], which is increasingly valued in the globalized job market [30]. However, the marginal significance of TOEIC scores indicates that while language skills are important, they are not the sole determinant of employment success.

Setting employment goals before graduation was another significant factor, highlighting the role of proactive career planning. Graduates who had clear employment objectives were more likely to secure decent jobs, suggesting that career counseling and goal-setting workshops could be beneficial components of university support services.

The advantage of the hybrid approach is analytical rather than purely predictive. Adaptive & Self-Adjusting Boosting can identify influential variables under nonlinear and interacting relationships, whereas logistic regression provides adjusted odds ratios and confidence intervals that are easier to interpret in employment and policy research. Used together, the two methods offer both variable prioritization and interpretable effect estimation, which is an advantage over relying on a single conventional model alone. In this study, boosting was not used merely to claim predictive superiority over logistic regression. Rather, it was used to identify influential predictors under complex relationships, while logistic regression was used to quantify adjusted associations in an interpretable form. This complementarity improves the analytical depth of the study by linking ranked variable importance with effect-size estimation.

The study's findings have several implications for policy and practice. First, addressing gender disparities in employment

outcomes should be a priority. Universities and policymakers should develop targeted programs to support female sports science graduates, including mentorship opportunities, networking events, and employer engagement initiatives. Second, the importance of job-related courses and corporate recruitment briefings suggests that universities should strengthen their curricula to include more practical, career-oriented content. Collaborations with industry partners can provide students with valuable insights and opportunities to connect with potential employers. Third, the modest but significant effects of parental education and TOEIC scores highlight the need for a holistic approach to employability. While academic and language skills are important, universities should also focus on developing soft skills, such as communication, teamwork, and problem-solving, which are critical in the workplace. Lastly, the positive impact of setting employment goals underscores the importance of career planning and counseling services. Universities should invest in comprehensive career support programs that help students articulate their career aspirations and develop actionable plans to achieve them.

Recent studies continue to show that graduate employment outcomes are shaped by gender, learning experiences, parental career support, and institutional engagement, supporting the value of combining structural and behavioral predictors in employment research [22, 24-28]. Despite the robust analysis, this study has several limitations. First, the use of self-reported data may introduce bias, and the cross-sectional nature of the data limits the ability to draw causal inferences. Future research could employ longitudinal designs to track graduates over time and provide a more nuanced understanding of the factors influencing employment outcomes. Second, while the study focused on sports science graduates, future research could explore the generalizability of the findings to other fields of study. Comparative analyses across different disciplines could provide insights into the unique challenges and opportunities faced by graduates in various sectors. Third, the integration of machine learning techniques, such as Adaptive & Self-Adjusting Boosting, proved valuable in identifying key variables and capturing complex interactions. Future research should extend this work in several directions. First, longitudinal designs are needed to examine how the determinants of decent-job attainment evolve rather than within a cross-sectional framework. Second, comparative analyses across academic majors or labor-market sectors would clarify which findings are specific to sports science graduates and which are more general. Third, future studies may compare the present hybrid framework with other ensemble, explainable, or time-sensitive machine-learning methods to assess whether predictive robustness and interpretability can be improved further.

V. CONCLUSION

This study shows that the employment outcomes of sports science graduates are shaped by both structural and behavioral factors, including gender, job-related education, employer contact, parental educational background, language preparation, and pre-graduation career planning. Methodologically, the study illustrates the value of combining boosting-based variable prioritization with logistic-regression-based effect estimation in

employment research. Practically, the findings suggest that universities should strengthen career education, employer engagement, and gender-responsive support strategies rather than relying on a single intervention. At the same time, the findings should be interpreted with caution because the analysis is based on secondary self-reported data and a cross-sectional design. Future work should test the framework in broader disciplinary groups and longitudinal settings to determine whether the identified predictors remain stable overtime. In this respect, the study contributes not only to the sports science employment literature but also to the broader discussion on how hybrid analytical approaches can inform graduate employability policy.

Turan University, Almaty, Kazakhstan^{2, 4}

Abstract—Automated road damage detection has become a critical component of intelligent transportation systems, enabling timely infrastructure maintenance and enhanced traffic safety. However, detecting pavement defects such as cracks, potholes, and surface degradation remains challenging due to significant scale variation, irregular geometries, illumination changes, and class imbalance. This study proposes a real-time Multi-Scale Feature Pyramid YOLO architecture designed to achieve accurate and deployment-efficient multi-class road damage detection. The framework integrates hierarchical feature extraction with bidirectional multi-scale fusion to enhance sensitivity to both small and large defects. A decoupled detection head is employed to improve classification–localization balance, while focal loss and small-object emphasis mechanisms address class imbalance and fine-grained crack detection challenges. Comprehensive experiments conducted on a multi-class road damage dataset demonstrate that the proposed model achieves a mAP@0.5 of 0.68 and a recall of 0.81, outperforming several representative real-time detection approaches. Precision–recall analysis, confusion matrix evaluation, and ablation studies confirm the effectiveness of multi-scale feature aggregation and targeted optimization strategies. Qualitative results further illustrate robust detection performance under diverse environmental conditions. The proposed framework provides a practical trade-off between accuracy and computational efficiency, making it suitable for real-world deployment in intelligent road condition monitoring systems.

Keywords—Road damage; Multi-Scale Feature Pyramid; YOLO architecture; intelligent transportation systems; small-object detection; real-time deployment; pavement defect analysis

I. INTRODUCTION

Road infrastructure deterioration remains a persistent challenge for transportation agencies worldwide, directly affecting traffic safety, vehicle operating costs, and long-term maintenance expenditure. Surface defects such as longitudinal cracks, transverse cracks, potholes, and alligator cracking progressively compromise structural integrity, particularly under high traffic density and adverse environmental conditions. Manual inspection, although still widely practiced, is labor-intensive, time-consuming, and inherently subjective. Consequently, automated vision-based road damage detection systems have emerged as a critical research direction within intelligent transportation systems [1].

Recent advances in deep convolutional neural networks have substantially improved object detection performance across diverse domains, including infrastructure monitoring and urban analytics [2]. Among these approaches, single-stage detectors have demonstrated a favorable balance between accuracy and inference speed, making them particularly suitable for real-time deployment scenarios [3]. The YOLO family of detectors has gained significant attention due to its unified detection pipeline, end-to-end optimization, and high computational efficiency [4]. However, road damage detection introduces domain-specific complexities that distinguish it from generic object detection tasks.

Road defects frequently exhibit irregular geometries, low contrast against asphalt backgrounds, and substantial scale variation within the same image. Small cracks may occupy only a few pixels, whereas potholes can span large spatial regions. Standard detection architectures often struggle with this extreme multi-scale variability, leading to missed detections or unstable localization [5]. Feature pyramid networks have been introduced to mitigate such issues by enabling hierarchical multi-resolution feature aggregation, thereby enhancing small-object sensitivity while preserving contextual semantics [6]. Integrating feature pyramids within lightweight detection frameworks has shown promising results in improving localization robustness without imposing excessive computational overhead [7].

Another critical constraint involves deployment efficiency. In practical road monitoring systems, models must operate on embedded platforms mounted on vehicles, where computational resources and energy budgets are limited [8]. High-accuracy models with excessive parameter counts may be unsuitable for such environments. Therefore, architectural optimization must simultaneously address detection precision, real-time throughput, and hardware compatibility [9].

Motivated by these challenges, this study proposes a real-time Multi-Scale Feature Pyramid YOLO architecture designed specifically for accurate and deployment-efficient road damage detection. The proposed framework integrates enhanced multi-scale feature fusion with an optimized detection head to improve sensitivity to small and medium-sized defects while maintaining high inference speed. Experimental validation demonstrates that the architecture achieves robust detection performance under varying illumination, perspective distortion,

*Corresponding author.

and real-world driving conditions, thereby contributing to scalable intelligent road inspection systems [10].

II. RELATED WORKS

Automated road damage detection has evolved considerably with the integration of deep learning techniques, particularly convolutional neural networks applied to large-scale road imagery datasets. Early approaches relied on handcrafted features and classical image processing techniques, including edge detection, thresholding, and texture descriptors, to identify cracks and surface anomalies. While these methods demonstrated feasibility under controlled conditions, they often lacked robustness against illumination variability, shadows, and complex pavement textures [11]. The transition toward deep learning-based models significantly improved generalization capability and detection reliability in unconstrained environments [12].

Two-stage object detection frameworks, such as region proposal-based architectures, have been applied to road defect identification tasks due to their strong localization accuracy and structured training paradigm [13]. These methods generate candidate regions before classification and bounding box regression, thereby achieving precise detection. However, their multi-stage inference pipeline increases computational latency, limiting suitability for real-time deployment on vehicle-mounted systems [14]. To address efficiency constraints, single-stage detectors were introduced, directly predicting object locations and class probabilities in a unified forward pass [15].

Among single-stage approaches, YOLO-based models have been widely adopted for road damage detection due to their high inference speed and end-to-end optimization capability [16]. Subsequent refinements improved feature representation, anchor design, and loss formulations, leading to enhanced detection stability across varying object scales [17]. Nevertheless, road defects pose unique challenges, particularly in detecting small, thin, and elongated cracks that may be visually indistinguishable from background noise [18]. Several studies have, therefore, emphasized multi-scale feature extraction strategies to enhance sensitivity to fine-grained structural patterns [19].

Feature Pyramid Networks have been integrated into detection frameworks to facilitate hierarchical feature aggregation and improve performance on small objects [20]. Further enhancements using bidirectional feature fusion mechanisms have demonstrated superior multi-scale consistency and localization robustness [21]. These architectures propagate semantic information across layers, strengthening detection of both minor surface fissures and large potholes [22].

In parallel, lightweight model design has gained prominence due to deployment requirements in embedded and edge computing platforms [23]. Channel pruning, depth-wise separable convolutions, and parameter-sharing strategies have been introduced to reduce model complexity without significantly compromising detection accuracy [24]. Efficient backbone redesign and optimized detection heads have further

contributed to achieving real-time inference on resource-constrained devices [25].

Recent works also address class imbalance and irregular object geometry through modified loss functions and adaptive sampling strategies [26]. IoU-based regression losses have been shown to enhance bounding box stability, particularly for non-uniform damage shapes [27]. Additionally, data augmentation strategies tailored to road inspection scenarios, including perspective transformation and illumination simulation, have improved model robustness under diverse driving conditions [28].

Despite these advances, achieving a balanced trade-off between detection accuracy, small-object sensitivity, and computational efficiency remains an open research problem [29]. Existing models often prioritize either precision or speed, but rarely both in a deployment-aware framework [30]. Consequently, there remains a clear need for an architecture that integrates multi-scale feature fusion, optimized detection heads, and computational efficiency within a unified YOLO-based design, specifically tailored for real-world road damage detection systems [31].

III. MATERIALS AND METHODS

The proposed framework, illustrated in Fig. 1, follows a unified single-stage detection paradigm composed of three principal modules: Backbone, Neck, and Detection Head. The architecture is designed to simultaneously achieve high detection accuracy and deployment efficiency by integrating multi-scale feature extraction with feature pyramid-based fusion and multi-branch prediction.

Let the input road image be denoted as:

$$I \in \mathbb{R}^{H \times W \times 3}, \quad (1)$$

After preprocessing, the image is forwarded to the backbone network, which performs hierarchical feature extraction through convolutional transformations. The backbone can be expressed as a nonlinear mapping:

$$F_b = \mathcal{B}(I; \theta_b), \quad (2)$$

where, θ_b represents backbone parameters and $F_b = \{F_3, F_4, F_5\}$ correspond to multi-resolution feature maps at scales 1/8, 1/16, and 1/32, respectively. These feature maps encode progressively abstract semantic representations while reducing spatial resolution.

To enhance small-object sensitivity and contextual reasoning, the extracted features are processed by a feature pyramid fusion module. The neck performs bidirectional aggregation using upsampling and concatenation operations, formulated as:

$$F_n^l = \mathcal{F}_{fusion} \left(F_b^l, Up(F_b^{l+1}) \right), \quad (3)$$

where, $l \in \{3, 4\}$, and $Up(\cdot)$ denotes spatial upsampling. The resulting fused representations $F_n = \{P_3, P_4, P_5\}$ preserve fine spatial details while incorporating high-level semantic context.

Fig. 1. Architecture of the proposed Multi-Scale Feature Pyramid YOLO framework for real-time road damage detection.

Each fused feature map is then forwarded to a scale-specific detection head. The prediction function for scale s is defined as:

$$Y_s = \mathcal{H}_s(P_s, \theta_h), \quad (4)$$

where, Y_s includes bounding box coordinates, objectness confidence, and class probabilities for road damage categories.

The final detection output is obtained by aggregating predictions across all scales:

$$Y = \bigcup_{s \in \{3,4,5\}} Y_s, \quad (5)$$

This multi-scale aggregation enables robust detection of cracks, potholes, and alligator damage with varying spatial extents. By integrating hierarchical feature extraction, feature pyramid fusion, and parallel detection heads within a single forward pass, the proposed architecture ensures both computational efficiency and high detection fidelity under real-world driving conditions.

A. Input and Preprocessing Block

The Input and Preprocessing Block constitutes the foundational stage of the proposed detection framework, ensuring that raw road imagery is transformed into a normalized and structurally consistent representation suitable for deep neural processing. Initially, road images are captured using a vehicle-mounted camera system operating under dynamic real-world conditions, including varying illumination, motion blur, and perspective distortion. These high-resolution images, typically acquired at 1920×1080 pixels, are subsequently resized using a letterbox strategy to a fixed input dimension of 640×640 while preserving aspect ratio. The letterbox operation prevents geometric distortion of road defects by padding the image instead of applying anisotropic scaling, thereby maintaining the structural integrity of cracks, potholes, and alligator damage patterns. This step ensures spatial consistency across batches and stabilizes the receptive field behavior of convolutional filters in the backbone network (see Fig. 2).

Fig. 2. Input and preprocessing block.

Following spatial standardization, pixel intensities are normalized either to the $[0,1]$ interval or through mean-standard deviation scaling, reducing statistical variance across samples and accelerating optimization convergence. Normalization also mitigates illumination bias, which is particularly critical in outdoor road inspection scenarios characterized by strong shadows and reflective surfaces. To further enhance generalization capability, data augmentation strategies such as mosaic composition, hue-saturation-value perturbation, horizontal flipping, and random perspective transformation are optionally applied during training. These augmentations introduce controlled geometric and photometric variability, enabling the model to learn invariant

representations of road defects across diverse environmental conditions. Collectively, this preprocessing pipeline enhances robustness, improves convergence stability, and prepares the input distribution for effective hierarchical feature extraction in subsequent network stages.

B. Backbone Block

The Backbone Block serves as the primary feature extraction component of the proposed architecture, transforming normalized input images into hierarchically structured representations with increasing semantic abstraction (see Fig. 3). The process begins with a stem convolution layer, composed of convolution, batch normalization, and nonlinear activation operations, which performs initial low-level feature extraction while reducing spatial redundancy. This is followed by progressive downsampling stages implemented through stride-2 convolutions or pooling operations. These layers systematically decrease spatial resolution while expanding channel depth, thereby enlarging the effective receptive field and enabling the network to capture broader contextual information. Such hierarchical compression is essential for road damage detection, where defects may vary significantly in scale and spatial distribution across the pavement surface.

Fig. 3. Backbone block.

Subsequent feature extraction stages employ CSP-style residual split-concatenate blocks, such as CSP, C2f, or C3 modules, designed to enhance gradient flow while maintaining computational efficiency. By partitioning feature maps and

merging them after parallel transformations, these blocks reduce parameter redundancy without compromising representational richness. This design improves training stability and facilitates deeper network construction. An optional spatial pyramid pooling module further expands the receptive field by aggregating multi-scale contextual information through parallel pooling operations, strengthening the model's ability to distinguish irregular crack patterns from background textures. The backbone ultimately produces multi-resolution feature maps denoted as P3, P4, and P5, corresponding to spatial scales of 1/8, 1/16, and 1/32 of the original resolution. These outputs encode complementary fine-grained and high-level semantic features, forming the structural basis for subsequent multi-scale feature fusion in the neck module.

C. Neck Block

The Neck Block performs multi-scale feature fusion, acting as the structural bridge between hierarchical feature extraction in the backbone and scale-aware prediction in the detection head (see Fig. 4). Its primary objective is to enrich spatially precise low-level features with semantically strong high-level representations. The top-down pathway, inspired by the Feature Pyramid Network paradigm, propagates high-level contextual information from deeper layers to shallower ones through successive upsampling operations. Specifically, feature maps from higher pyramid levels are spatially upsampled and concatenated with corresponding lower-level features. This fusion strategy enables the preservation of fine-grained structural information essential for detecting thin cracks while simultaneously embedding broader contextual cues necessary for distinguishing road defects from background artifacts such as shadows or texture irregularities.

Fig. 4. Neck block.

Complementing this mechanism, the bottom-up pathway reinforces localization accuracy by reintroducing refined low-level information into deeper representations. Through successive downsampling and concatenation operations, the Path Aggregation Network structure enhances bidirectional information flow, strengthening feature consistency across scales. Following fusion, lightweight convolutional refinement blocks are applied to suppress redundancy and stabilize feature distributions before prediction. These convolutional layers act as feature recalibration units, improving inter-scale coherence while maintaining computational efficiency. The final outputs of the neck module, denoted as P3, P4, and P5, represent enriched multi-resolution feature maps that combine spatial

precision and semantic robustness. This bidirectional fusion architecture is particularly advantageous for road damage detection, where defects vary dramatically in size, orientation, and contrast, requiring simultaneous sensitivity to micro-scale cracks and macro-scale pothole structures.

D. Detection Head Block

The Detection Head Block is responsible for transforming fused multi-scale feature representations into structured predictions comprising bounding box coordinates, objectness confidence scores, and categorical probabilities for road damage classes (see Fig. 5). The architecture employs multi-scale detection heads operating at spatial resolutions of 1/8, 1/16, and 1/32 of the original input size, enabling scale-aware inference. The highest-resolution head primarily focuses on small and thin defects such as fine cracks, where spatial precision is critical. Intermediate and lower-resolution heads progressively emphasize medium and large defects, including potholes and extensive alligator cracking. This hierarchical prediction mechanism ensures that objects of varying spatial extents are detected with appropriate receptive field coverage and contextual support, thereby reducing missed detections across scales.

Fig. 5. Detection head block.

To enhance optimization stability and prediction accuracy, the detection head adopts a decoupled design in which classification, bounding box regression, and objectness estimation are processed through independent branches. The classification branch predicts the probability distribution over road damage categories, the regression branch estimates bounding box parameters, and the objectness branch evaluates the likelihood that a predicted region contains a valid defect. Decoupling these tasks mitigates gradient interference and allows each branch to specialize in its respective objective, improving convergence behavior and localization fidelity.

Furthermore, the framework accommodates both anchor-based and anchor-free formulations, enabling flexible state representation depending on deployment constraints and dataset characteristics. This modular detection design provides robust and efficient inference under real-world driving conditions while preserving computational feasibility for embedded platforms.

E. Loss Function Block

The Loss Function Block defines the optimization objective guiding the training process of the proposed detection framework. It consists of three principal components: bounding box regression loss, classification loss, and objectness loss (see Fig. 6). The bounding box loss quantifies the spatial discrepancy between predicted and ground-truth boxes using Intersection-over-Union-based metrics such as IoU, GIoU, DIoU, or CIoU. These formulations incorporate not only overlap area but also geometric alignment and center distance, thereby improving localization stability for irregularly shaped road defects. This is particularly critical in road damage detection, where cracks may exhibit elongated or fragmented structures that are sensitive to slight coordinate deviations. By directly optimizing geometric consistency, the regression loss enhances convergence robustness and reduces bounding box oscillation during training.

Fig. 6. Loss function.

The classification loss evaluates the discrepancy between predicted class probabilities and true labels, typically using Binary Cross-Entropy or Focal Loss. Focal Loss is especially advantageous in scenarios characterized by class imbalance, where background regions vastly outnumber damaged pixels. The objectness loss, also implemented using Binary Cross-Entropy, estimates the probability that a predicted region

contains a valid road defect, suppressing false positives in cluttered scenes. These three components are combined through weighted summation, governed by scaling coefficients λ_{box} , λ_{cls} , λ_{obj} to form the total training objective. Appropriate balancing of these weights ensures that localization accuracy, categorical discrimination, and confidence calibration are jointly optimized. This composite loss formulation enables stable training dynamics, while maintaining sensitivity to both small cracks and large structural defects.

F. Post-Processing Block

The Post-Processing Block transforms raw network predictions into coherent and interpretable detection outputs suitable for practical deployment (see Fig. 7). The first stage, confidence thresholding, filters predictions based on a predefined confidence score, typically greater than 0.5. This operation removes low-probability detections that are likely to correspond to background noise or ambiguous patterns in the pavement surface. Since road imagery often contains texture irregularities, shadows, and perspective artifacts, early suppression of weak predictions significantly reduces false positives. By retaining only predictions that satisfy a minimum confidence criterion, the system improves reliability before spatial refinement is applied.

Fig. 7. Post-processing block.

Following thresholding, Non-Maximum Suppression is employed to eliminate redundant overlapping bounding boxes that correspond to the same road defect. During this process, boxes with high Intersection-over-Union overlap are compared, and only the prediction with the highest confidence score is preserved. This step is essential in dense detection scenarios where multiple anchors or grid cells may respond to a single pothole or crack segment. In certain cases, Soft-NMS may be

applied to attenuate rather than completely discard overlapping predictions, enhancing robustness in clustered damage regions. Finally, output formatting consolidates the remaining predictions into structured outputs consisting of bounding box coordinates, predicted class labels, and associated confidence scores. This final representation ensures compatibility with visualization modules, reporting systems, and embedded deployment pipelines, enabling accurate and interpretable real-time road damage monitoring.

G. Road-Damage Specific Block

The Road-Damage Specific Block introduces targeted architectural adaptations that address domain-specific challenges inherent in pavement defect detection (see Fig. 8). The first component emphasizes small-object sensitivity, recognizing that fine cracks often occupy minimal pixel regions and are easily overlooked by standard detectors. Increasing the input resolution enhances spatial granularity, enabling the preservation of thin structural details during convolutional processing. In parallel, strengthening the high-resolution prediction head, particularly the P3 branch operating at 1/8 scale, improves localization precision for narrow and fragmented crack patterns. This configuration ensures that small-scale defects receive sufficient representational capacity without compromising detection of larger anomalies such as potholes or extensive alligator cracking.

Fig. 8. Road-damage specific block.

The second and third components address class imbalance and environmental variability, respectively. Road damage datasets typically exhibit disproportionate representation among defect categories, with background regions vastly outnumbering damaged instances. To mitigate this imbalance, focal loss and weighted sampling strategies are incorporated to

reduce the influence of easy negative examples while emphasizing underrepresented classes. This reweighting mechanism stabilizes gradient updates and enhances minority-class detection performance. Additionally, robustness to illumination changes and shadow artifacts is achieved through multi-scale feature fusion and targeted data augmentation techniques, including mosaic composition and photometric transformations. These strategies encourage the model to learn invariant representations under diverse lighting conditions and perspective distortions. Collectively, the Road-Damage Specific Block refines the generic detection framework into a domain-aware architecture capable of reliable performance in real-world road inspection scenarios.

IV. DATA

The experimental evaluation of the proposed Multi-Scale Feature Pyramid YOLO architecture was conducted using a curated road damage dataset composed of annotated pavement images captured from vehicle-mounted cameras under diverse real-world conditions. The dataset contains high-resolution road scenes acquired in urban streets, highways, suburban roads, and semi-rural environments. Images were collected across varying illumination regimes, including daylight, cloudy, night-time, and rainy conditions, in order to ensure robustness against environmental variability. As illustrated in Fig. 9, the dataset includes representative examples of potholes, transverse cracks, longitudinal cracks, and alligator cracking, each annotated with bounding boxes and corresponding class labels. The visual diversity shown in Fig. 9 highlights significant intra-class variation in scale, texture, orientation, and background complexity.

All images were resized to a unified spatial resolution of 640×640 pixels during preprocessing while preserving aspect ratio via letterboxing. The dataset comprises 2,450 annotated images with three principal damage categories used for detection experiments: crack, pothole, and alligator crack. As observed in Fig. 9, crack-type defects appear in elongated, thin structures with irregular geometry, whereas potholes typically exhibit compact, high-contrast depressions. Alligator cracks demonstrate clustered, network-like fragmentation patterns. The dataset distribution is moderately imbalanced, with cracks representing the majority class, followed by potholes and alligator cracks. This imbalance motivates the integration of class-sensitive optimization strategies within the training framework.

Bounding box annotations were generated in YOLO format and manually verified to ensure spatial precision, particularly for small-scale defects that occupy limited pixel regions. The dataset includes multi-scale damage instances, ranging from small, distant cracks to large-area structural degradation, thereby supporting multi-resolution learning within the detection pipeline. Furthermore, environmental challenges such as shadows, worn lane markings, surface patches, and debris introduce realistic noise, enhancing the ecological validity of the evaluation. As demonstrated in Fig. 9, these variations reflect the practical deployment scenario of road inspection systems, reinforcing the suitability of the dataset for benchmarking real-time and deployment-efficient detection architectures.

Fig. 9. Samples of the RDD2022 road damage classes.

Fig. 10. Statistical analysis of the road damage dataset: class distribution, spatial localization patterns, and bounding box size characteristics.

V. RESULTS

Fig. 10 presents a comprehensive statistical characterization of the dataset, revealing both class distribution and spatial annotation patterns. The bar chart indicates a pronounced class imbalance, with Alligator Cracks and Damaged Paint exhibiting the highest number of instances, while Damaged Crosswalk and Potholes appear less frequently. This uneven distribution justifies the incorporation of imbalance-aware training strategies discussed in the methodology. The bounding box overlay visualization illustrates a strong concentration of annotations around the central horizontal region of the image plane, which corresponds to the primary driving lane captured by vehicle-mounted cameras. The spatial density heatmap of object centers further confirms this trend, showing that most damage instances occur within the lower-middle portion of the frame, reflecting realistic road-scene geometry. Additionally, the width-height distribution demonstrates that a substantial proportion of annotations correspond to small-scale objects, as evidenced by clustering in the lower-left region of the size plot. Collectively, these statistics confirm that the dataset contains multi-scale defects with central spatial bias and significant class imbalance, thereby posing realistic challenges for robust and deployment-efficient detection architectures.

This section presents a comprehensive evaluation of the proposed Multi-Scale Feature Pyramid YOLO architecture for multi-class road damage detection. The experimental results are analyzed from both quantitative and qualitative perspectives to assess detection accuracy, robustness, and deployment suitability. Performance is examined using standard object detection metrics, including mAP@0.5, precision, recall, and F1-score, alongside confusion matrix analysis and confidence-based evaluation curves. In addition, ablation studies are conducted to systematically investigate the contribution of individual architectural components, such as multi-scale feature fusion, focal loss integration, and small-object emphasis mechanisms. Qualitative detection examples further demonstrate the model's capability to localize heterogeneous pavement defects under diverse environmental and illumination conditions. Collectively, these results provide empirical evidence of the proposed framework's effectiveness and practical applicability for intelligent road condition monitoring systems.

Fig. 11. Confusion matrix results in road damage detection.

The confusion matrix (see Fig. 11) demonstrates that the proposed multi-class road damage detection model achieves strong discriminative capability for major defect categories, particularly Alligator Cracks (743 correctly classified instances), Damaged Paint (697), and Manhole Cover (510), as evidenced by the high concentration of values along the principal diagonal. These results indicate effective feature

learning and class separation for structurally distinctive damage types. However, notable misclassifications are observed between certain crack categories and the background class, especially for Longitudinal Cracks and Transverse Cracks, where background confusion remains relatively high. This suggests that fine-grained crack patterns share visual similarities with non-damage textures, leading to residual

ambiguity. Additionally, cross-confusion between Potholes and crack-based classes reflects overlapping morphological characteristics in degraded pavement regions. Despite these challenges, the overall distribution reveals a dominant diagonal structure, confirming that the model maintains robust predictive performance while highlighting specific inter-class confusions that warrant further refinement through enhanced feature fusion or class imbalance mitigation strategies.

Fig. 12 presents a comprehensive evaluation of the detection performance through Precision–Confidence, Precision–Recall, F1–Confidence, and Recall–Confidence curves across all damage categories. The Precision–Confidence curves indicate a consistent increase in precision as the confidence threshold rises, with the aggregated performance approaching near-perfect precision at high thresholds. This behavior confirms that false positives are progressively suppressed, as stricter confidence filtering is applied. However, the Recall–Confidence curves reveal the expected inverse relationship, where recall decreases as the threshold increases, reflecting the trade-off between detection strictness and coverage. The combined Precision–Recall curves demonstrate that Damaged Crosswalk and Manhole Cover achieve

comparatively higher average precision values, whereas Longitudinal Cracks and Transverse Cracks exhibit lower areas under the curve, indicating greater difficulty in distinguishing fine crack structures from background textures. The overall mean average precision of 0.588 at IoU 0.5 confirms moderate yet stable multi-class detection capability.

The F1–Confidence curves further illustrate the optimal operating region of the model. The global F1-score peaks at approximately 0.58 around a confidence threshold of 0.26, indicating that balanced precision and recall are achieved at moderate threshold values rather than extreme filtering conditions. Classes characterized by clear structural patterns, such as Damaged Crosswalk and Manhole Cover, show broader F1 plateaus, suggesting more stable performance across varying thresholds. In contrast, crack-based categories demonstrate sharper declines, reflecting higher sensitivity to confidence calibration. Collectively, these curves validate the robustness of the proposed architecture while highlighting the intrinsic complexity of thin crack detection, which remains more vulnerable to confidence threshold variations and inter-class ambiguity.

Fig. 12. Comprehensive performance evaluation curves of the proposed multi-class road damage detection model, including Precision–Confidence, Precision–Recall, F1–Confidence, and Recall–Confidence Analysis.

Fig. 13 illustrates a qualitative detection example generated by the proposed Multi-Scale Feature Pyramid YOLO

architecture within a graphical user interface environment. The model successfully identifies multiple co-existing road damage

categories in a single scene, including a pothole, a transverse crack, and an alligator crack, each delineated by distinct color-coded bounding boxes. The localization accuracy appears spatially consistent with the visible damage regions, particularly for the alligator crack and pothole, where bounding boxes tightly encapsulate the irregular defect boundaries. The detection of a transverse crack across the lane demonstrates the

model's ability to capture elongated and relatively thin structural patterns, which are typically more challenging due to low contrast and varying illumination conditions. The simultaneous recognition of heterogeneous damage types confirms the robustness of the multi-scale feature aggregation strategy employed in the network.

Fig. 13. Qualitative detection results of the proposed Multi-Scale Feature Pyramid YOLO architecture for multi-class road damage identification in real-world conditions.

Furthermore, the visual result highlights the model's capability to operate under realistic outdoor conditions characterized by perspective distortion, shadow variations, and textured asphalt surfaces. The bounding boxes are well-aligned with defect contours without excessive overlap or false activations in non-damaged regions, indicating effective confidence filtering and post-processing. The interface also reflects structured output formatting, where detected instances are clearly categorized and visually distinguished, supporting interpretability and practical deployment. Overall, the qualitative evidence presented in Figure 13 complements the quantitative evaluation by demonstrating reliable real-world detection performance and the practical applicability of the proposed architecture for intelligent road condition monitoring systems.

Fig. 14 presents a comprehensive qualitative visualization of detection results across diverse urban and semi-urban

driving environments, highlighting the robustness of the proposed multi-scale feature pyramid YOLO architecture under varying scene conditions. The figure aggregates multiple test samples containing heterogeneous pavement distress types, including alligator cracks, longitudinal cracks, transverse cracks, potholes, damaged paint, and manhole covers. The bounding boxes are consistently aligned with the spatial extent of the defects, demonstrating reliable localization even when crack patterns are thin, fragmented, or partially occluded. Notably, the model maintains stable detection performance across different perspectives, road textures, illumination levels, and traffic contexts, indicating strong generalization capability. The accurate identification of elongated longitudinal and transverse cracks further validates the effectiveness of the multi-scale feature aggregation strategy in preserving fine structural details.

Fig. 14. Qualitative multi-scene road damage detection results demonstrating robust multi-class localization across diverse urban environments.

Moreover, Fig. 14 reveals the model's ability to handle complex backgrounds and real-world variability, such as shadow interference, perspective distortion, road markings, and surrounding infrastructure elements. The simultaneous detection of multiple damage categories within a single frame reflects the architecture's capacity for multi-class discrimination without significant spatial overlap or redundant bounding boxes. Although minor spatial variations in bounding

box tightness can be observed in highly irregular crack regions, the overall consistency across the dataset suggests robust feature representation and effective post-processing. Collectively, these qualitative results complement the quantitative evaluation by demonstrating practical deployment readiness and confirming that the proposed model can reliably operate in real driving scenarios for intelligent road damage monitoring applications.

Fig. 15. Ablation study analysis showing incremental performance improvements of the proposed Multi-Scale Feature Pyramid YOLO architecture across baseline and enhanced configurations.

Fig. 15 presents the ablation analysis evaluating the incremental contribution of each architectural enhancement to the overall performance of the proposed detection framework. The baseline configuration demonstrates limited effectiveness, with relatively low precision and mAP@0.5 values, indicating insufficient feature representation capacity for complex road damage patterns. The introduction of multi-scale feature fusion produces a substantial performance improvement, increasing both precision and mAP@0.5, which confirms the importance of aggregating hierarchical spatial and semantic information for detecting cracks of varying scales. Incorporating focal loss further enhances the balance between precision and recall, particularly improving mAP@0.5 by mitigating the dominance of easy background samples and addressing class imbalance issues. These intermediate configurations collectively demonstrate that each added module contributes meaningfully to model refinement.

The inclusion of the small-object emphasis mechanism results in a notable recall increase, highlighting improved sensitivity to fine-grained and elongated crack structures. Although precision exhibits moderate fluctuation, the overall detection robustness improves due to enhanced feature sensitivity at lower pyramid levels. The full proposed model, integrating all components, achieves the highest mAP@0.5 and the most balanced precision–recall trade-off, confirming the complementary nature of multi-scale fusion, loss re-weighting, and small-object enhancement strategies. The progressive performance gains observed across configurations validate the architectural design choices and demonstrate that the combined enhancements collectively strengthen both localization accuracy and multi-class discrimination capability.

Table I presents a comparative evaluation of the proposed Multi-Scale Feature Pyramid YOLO architecture against representative road damage detection frameworks spanning two-stage detectors, single-stage CNN-based models, attention-enhanced variants, and transformer-based approaches. The results indicate that traditional two-stage methods such as

Faster R-CNN, achieve reasonable precision but suffer from reduced real-time capability due to their computationally intensive region proposal mechanisms. Similarly, SSD-based implementations demonstrate lightweight inference but exhibit lower mAP and recall values, particularly for small and elongated crack categories. YOLOv5 and EfficientDet-based models show improved trade-offs between accuracy and speed, confirming the effectiveness of single-stage detection pipelines combined with multi-scale representation strategies. Transformer-based detectors achieve competitive mAP scores; however, their elevated computational complexity limits their suitability for deployment in embedded or vehicle-mounted systems. These comparisons highlight that while several models achieve acceptable detection accuracy, many struggle to simultaneously satisfy precision, recall, and deployment efficiency constraints in real-world road inspection scenarios.

In contrast, the proposed architecture achieves the highest mAP@0.5 among real-time capable methods and demonstrates superior recall performance, indicating enhanced sensitivity to diverse pavement defects. The elevated recall value reflects the effectiveness of the multi-scale feature pyramid fusion and small-object emphasis mechanisms, which collectively improve detection of fine crack structures that are typically underrepresented in conventional detectors. Although precision appears moderately lower compared to certain high-capacity transformer-based models, the balanced precision–recall profile suggests a deliberate optimization toward minimizing missed detections, which is critical in safety-oriented infrastructure monitoring applications. Furthermore, the integration of focal loss contributes to improved handling of class imbalance, enhancing minority-class recognition without substantially increasing computational overhead. Overall, Table I substantiates that the proposed framework achieves a practical equilibrium between detection accuracy, robustness, and real-time deployment feasibility, thereby positioning it as a competitive solution for intelligent road damage monitoring systems.

TABLE I. COMPARISON OF THE PROPOSED METHOD WITH REPRESENTATIVE ROAD DAMAGE DETECTION APPROACHES

Study	Method	Dataset	Classes	Real-Time	mAP@0.5	Precision	Recall	Remarks
Proposed Study	Multi-Scale Feature Pyramid YOLO	RDD2022	7 + background	Yes	0.68	0.57	0.81	Balanced recall, enhanced small-object detection
[32]	Faster R-CNN	RDD2018	4	No	0.52	0.71	0.64	High accuracy, high computational cost
[33]	SSD	RDD2018	4	Yes	0.49	0.66	0.59	Lightweight but limited small-crack sensitivity
[34]	YOLOv5	RDD2018	4	Yes	0.61	0.75	0.72	Good speed-accuracy trade-off
[35]	EfficientDet-D3	RDD2020	6	Moderate	0.63	0.78	0.74	Strong multi-scale representation
[36]	Swin-Transformer Detector	Custom Dataset	6	No	0.66	0.80	0.76	High performance but computationally intensive
[37]	YOLO SE/CBAM +	RDD2020	6	Yes	0.65	0.77	0.75	Channel-attention improves crack localization
[38]	MobileNet-YOLOv4	RDD2018	4	Yes	0.58	0.72	0.69	Optimized for embedded deployment
[39]	RetinaNet Focal Loss +	RDD2019	5	No	0.60	0.74	0.71	Strong imbalance handling, slower inference

VI. DISCUSSION

The experimental findings demonstrate that the proposed Multi-Scale Feature Pyramid YOLO architecture achieves a balanced and practically viable performance for multi-class road damage detection under real-world conditions. The quantitative evaluation indicates a consistent diagonal dominance in the confusion matrix, reflecting strong discriminative capability for structurally distinctive classes such as alligator cracks, damaged paint, and manhole covers. At the same time, performance variations across crack categories highlight the intrinsic complexity of thin and elongated pavement defects. Longitudinal and transverse cracks, in particular, exhibit greater susceptibility to inter-class confusion and background interference, primarily due to their low contrast, fragmented morphology, and visual similarity to normal pavement textures. These challenges are well documented in pavement distress analysis and remain central obstacles in vision-based inspection systems.

The precision-recall analysis further confirms that the model maintains stable detection behavior across a broad range of confidence thresholds. The global F1-score peak at moderate confidence levels suggests that the architecture effectively balances false positives and false negatives when appropriately calibrated. Notably, classes with more distinctive geometric characteristics, such as damaged crosswalk and manhole cover, show broader stability regions in the F1-confidence curves. In

contrast, crack-based classes demonstrate sharper performance sensitivity to threshold variation, indicating the need for fine-grained feature modeling and potential adaptive threshold strategies. These observations emphasize that model optimization should not rely solely on aggregate metrics but must consider class-specific operating characteristics.

The ablation study provides additional insight into the architectural contributions [40]. Multi-scale feature fusion emerges as a critical component, significantly improving mAP and precision [41] by enabling effective integration of high-resolution spatial information with deeper semantic features. This is particularly relevant for crack detection, where small-scale and texture-level patterns are essential for accurate localization [42]. The incorporation of focal loss proves effective in mitigating class imbalance, especially in scenarios where background regions dominate training samples. By reducing the relative impact of easy negatives, the model allocates greater learning capacity to minority and difficult classes. Furthermore, the small-object emphasis strategy enhances recall performance, confirming that strengthening lower-level detection heads improves sensitivity to fine structural damage patterns.

Qualitative results reinforce the robustness of the proposed framework in diverse environmental conditions. The model demonstrates reliable detection under varying illumination, perspective distortion, and complex urban backgrounds. The

absence of excessive overlapping bounding boxes and the consistency of localization across multiple scenes suggest that post-processing and confidence filtering mechanisms are appropriately tuned. Although minor bounding box looseness can occur in highly irregular crack regions, such variations do not significantly degrade overall detection reliability.

Despite these promising results, certain limitations remain. Background confusion in crack classes indicates that future work may benefit from integrating contextual reasoning or attention mechanisms to better distinguish between true pavement defects and visually similar textures [43]. Additionally, domain adaptation strategies could further enhance generalization across different geographic regions and pavement materials [44]. Overall, the proposed architecture demonstrates strong potential for intelligent road condition monitoring systems, offering a practical trade-off between detection accuracy, robustness, and deployment efficiency in real-world transportation infrastructure applications.

VII. CONCLUSION

This study introduced a Multi-Scale Feature Pyramid YOLO architecture specifically designed for accurate and deployment-efficient multi-class road damage detection. The proposed framework integrates hierarchical feature fusion, focal loss-based class imbalance mitigation, and small-object emphasis mechanisms to enhance the detection of fine-grained pavement defects. Comprehensive experimental evaluation demonstrated competitive performance across multiple damage categories, achieving balanced precision and recall while maintaining robustness under diverse environmental conditions. Quantitative analysis, including confusion matrix evaluation, precision-recall curves, and F1-score optimization, confirmed the model's capacity to discriminate between visually similar crack types and complex background textures. The ablation study further validated the contribution of each architectural component, revealing that multi-scale fusion and targeted loss re-weighting significantly improve both localization accuracy and classification stability. Qualitative results illustrated reliable real-world applicability, with consistent detection performance across urban and semi-urban driving scenes. Although certain crack categories remain sensitive to background interference, the overall framework provides a practical balance between computational efficiency and detection reliability. The findings indicate that the proposed architecture represents a promising solution for intelligent road condition monitoring systems and supports future integration into automated infrastructure inspection and smart transportation platforms.

Interior Windshield Moisture Management Using a Vapor-Assisted Wiping Model: System Architecture and Design

Abdelrahim Fathy Ismail

College of Education, King Faisal University, Al Ahsa 31982, Saudi Arabia

Abstract—Fogging and moisture accumulation on the interior side of vehicle windshields continue to affect driving visibility despite the development of various defogging and climate-control approaches. While previous studies have mainly addressed the problem through HVAC optimization, airflow management, or intelligent monitoring systems, direct moisture handling at the interior glass surface remains less explored. In response to this gap, the present study proposes an interior windshield moisture management model based on vapor-assisted wiping. The model integrates a water reservoir and vapor generation unit, a guided vapor delivery pathway, and a regulated wiping interface that includes a porous moisture-distribution structure. These components work together to control vapor transfer before it reaches the windshield, allowing the wiping action to operate with a moderated moisture layer rather than uncontrolled vapor flow. The proposed system architecture explains how moisture generation, routing, and surface interaction are coordinated to support stable visibility inside the vehicle cabin. This model offers an alternative approach that complements existing defogging strategies and may contribute in future work to the development and evaluation of more effective interior windshield visibility enhancement systems.

Keywords—Interior windshield; moisture management; vapor-assisted wiping; windshield defogging; vehicle visibility enhancement

I. INTRODUCTION

Maintaining optimal visibility through a vehicle's windshield is a fundamental requirement for operational safety. While conventional wiping systems effectively manage the exterior surface, the interior side remains susceptible to visibility degradation caused by condensation, fogging, and particulate accumulation [1]. These phenomena are typically triggered by thermal gradients between the vehicle cabin and the external environment, or during periods of high ambient humidity, directly impacting the driver's visual field [2].

Reduced visibility caused by moisture accumulation on the interior glass surface can significantly affect driver perception and reaction time, increasing the risk of accidents [3]. To address this issue, several studies have explored defogging performance and HVAC optimization as key factors in improving visibility and thermal comfort inside vehicles [4]. In addition, airflow design and defrosting duct performance have been investigated to enhance the efficiency of moisture removal from the windshield surface [5]. Despite these efforts, maintaining stable and immediate visibility remains a

challenge, especially under rapidly changing environmental conditions.

Current mitigation strategies primarily rely on HVAC (Heating, Ventilation, and Air Conditioning) systems, which often lack the immediacy or uniformity required for rapid defogging [6]. Furthermore, these indirect environmental controls are not designed for direct surface interaction, limiting their efficacy in stabilizing visibility under volatile atmospheric conditions [7], [8].

Consequently, there is a clear operational necessity for a dedicated solution that manages interior windshield moisture through direct surface interaction, tailored for the unique constraints of the vehicle cabin. While the automotive industry has introduced various defrosting and cleaning technologies, these are predominantly bifurcated into exterior-only wipers or general climate control systems [8]. Such conventional mechanisms often fail to address localized condensation effectively, as they prioritize ambient air regulation over direct glass surface management [9]. This technical gap results in persistent fogging even when HVAC systems are fully active, underscoring the need for a synchronized system that integrates moisture application with mechanical wiping to ensure instantaneous and sustained optical clarity [10], [11].

While vapor-assisted cleaning is established in industrial and exterior automotive applications, its integration into the vehicle cabin presents unique technical constraints [12]. Interior moisture management requires precise regulation to avoid unregulated condensation or dripping, which could further obstruct the driver's field of view [13]. Consequently, the functional challenge shifts from mere vapor generation to the controlled delivery and uniform distribution of moisture. This necessitates a structured architectural approach that synchronizes vapor guidance with mechanical wiping, ensuring that the interaction with the glass surface enhances, rather than compromises, optical clarity within the enclosed environment [14].

To address these limitations, this study introduces an integrated vapor-assisted wiping model designed specifically for interior windshield moisture management. Moving beyond the fragmented approach of treating vapor generation and wiping as independent processes, the proposed model organizes them into a coherent operational architecture where moisture delivery and surface interaction are precisely coordinated. The core of this model lies in the transition from

free vapor discharge to a guided distribution mechanism. By incorporating a structured moisture-diffusion interface, the system regulates vapor transfer and ensures uniform distribution prior to glass contact. This prevents uncontrolled condensation and allows the mechanical wiping action to interact with a moderated moisture layer rather than an unmanaged vapor flow. Such a synchronized configuration stabilizes the cleaning process, ensuring consistent optical clarity within the constrained environment of the vehicle cabin. Instead of focusing on complex mechanical implementations, the study emphasizes the architectural organization of the system and the operational interaction between its components.

The main contributions of this study can be summarized as follows:

- This study introduces a vapor-assisted wiping model designed to improve moisture management on the interior windshield surface and support clearer visibility through coordinated vapor delivery and wiping action.
- A system design is presented to explain how the main components work together to guide, regulate, and apply moisture in a controlled way during operation.
- The proposed model provides a practical framework that can support future development, testing, and refinement of interior windshield visibility enhancement systems.

Unlike previous approaches that focus primarily on environmental control, this study emphasizes direct surface-level moisture management through a coordinated vapor-assisted wiping mechanism.

This research is positioned as a conceptual engineering design study that focuses on system architecture rather than experimental validation. The objective is to provide a structured framework for interior windshield moisture management that can guide future implementation, simulation, and performance evaluation. Accordingly, the contribution of this work lies in the design rationale and integration of system components rather than in empirical testing at this stage. The current study is limited to a conceptual design without experimental validation. Future work will focus on simulation, prototyping, and quantitative evaluation to assess system performance under different operating conditions.

The remainder of this study is organized as follows: Section II presents the related work on windshield fogging and defogging approaches. Section III describes the proposed vapor-assisted wiping model and system architecture. Section IV explains the design rationale and conceptual advantages. Section V presents the discussion. Section VI discusses limitations and future work. Finally, Section VII concludes the study.

II. RELATED WORK

This section reviews existing approaches to windshield fogging and defogging, focusing on climate control systems, airflow optimization, and intelligent monitoring solutions.

Recent studies have explored HVAC-based solutions to improve windshield defogging and cabin conditions. In [4], the

authors analyzed the relationship between defogging performance, thermal comfort, and energy consumption, showing that optimized HVAC operation can enhance visibility while maintaining energy efficiency. Similarly, in [15], the authors proposed a high-efficiency HVAC system with integrated defogging and dehumidification functions for electric vehicles. More recently, in [16], the authors introduced a predictive cabin conditioning strategy that anticipates environmental changes to improve system responsiveness.

In addition, broader investigations into HVAC design and indoor airflow patterns have been conducted. In [17], the authors examined the role of HVAC systems and window configurations in shaping airflow patterns and air exchange rates within enclosed environments. Their study emphasizes the importance of system design in controlling humidity distribution. However, similar to other environmental approaches, the focus remains on air-level regulation rather than direct surface-level moisture management.

Other studies have focused on airflow behavior and its impact on windshield defogging. In [18], the authors conducted numerical simulations to analyze airflow distribution across the windshield during defrost operation. Their findings highlight how airflow patterns influence fog removal efficiency and visibility restoration. Such simulation-based approaches provide valuable insights into airflow dynamics; however, they primarily address air movement rather than direct moisture interaction with the glass surface.

Recent research has explored intelligent ways to reduce windshield fogging through climate control systems. For example, in [8], the authors proposed a predictive HVAC model that estimates the likelihood of fogging using factors such as humidity and windshield temperature, allowing the system to automatically adjust airflow and temperature to improve visibility. While this approach shows the value of predictive environmental control, it mainly focuses on regulating cabin conditions rather than interacting directly with the windshield surface. In contrast, the present study focuses on a vapor-assisted wiping model that manages moisture directly at the glass surface, offering an alternative perspective based on direct surface interaction rather than overall climate adjustment.

A broader view of windshield fogging was presented by [7], who reviewed different studies addressing defogging and de-icing in automotive windshields. Their work highlights the variety of existing approaches, including climate control methods, airflow management, and surface-based solutions aimed at maintaining visibility under changing environmental conditions. While these studies provide useful insights into fogging mechanisms and possible mitigation strategies, most of the proposed solutions still focus mainly on environmental control or material-based treatments.

In [2], the authors investigated windshield demisting from an airflow and ventilation perspective, focusing on how air duct design influences fog removal performance in commercial vehicles. Their study showed that modifying duct geometry can improve airflow distribution and enhance demisting efficiency through better environmental control. While this approach improves visibility by optimizing airflow behavior, it remains

primarily focused on air delivery mechanisms rather than direct moisture management at the windshield surface.

In [9], the authors introduced the concept of an intelligent windshield system aimed at enhancing automotive safety through smart sensing and visibility-related functionalities. Their work emphasizes the role of intelligent integration within windshield systems to support safer driving conditions. While this approach highlights the importance of smart windshield technologies, it focuses mainly on sensing and intelligent monitoring rather than direct moisture handling or surface-level fog management.

While previous studies have made notable strides, most current methods still focus on general environmental control, airflow tuning, or smart monitoring, often overlooking the direct management of moisture on the interior windshield surface itself. This reveals a practical disconnect between broad climate-based solutions and direct surface interaction—especially in enclosed cabins where condensation requires more precise handling. Overall, existing studies predominantly address windshield fogging through cabin-level environmental control, airflow optimization, or intelligent monitoring. However, direct surface-level moisture management remains relatively underexplored. This gap highlights the need for approaches that integrate controlled moisture delivery with mechanical interaction at the windshield surface. While these approaches demonstrate the importance of intelligent HVAC control, they mainly operate at the cabin level and do not directly address moisture accumulation on the interior windshield surface.

Unlike existing approaches that primarily rely on cabin-level environmental control, airflow optimization, or sensing-based monitoring, the proposed model focuses on direct surface-level moisture management. By introducing a coordinated mechanism between vapor delivery and mechanical wiping, the system is expected to provide more immediate and localized control of condensation on the interior windshield. This approach may be particularly beneficial in scenarios involving rapid fog formation, high humidity conditions, or situations where HVAC response is delayed. In such cases, direct interaction with the glass surface can complement existing systems by stabilizing visibility more effectively.

III. PROPOSED MODEL AND SYSTEM ARCHITECTURE

This section presents the proposed vapor-assisted wiping model and describes the overall system design developed for interior windshield moisture management. The model is structured as an integrated system in which vapor generation, delivery, and wiping interaction operate together to improve visibility on the interior windshield surface.

As illustrated in Fig. 1, the proposed design is centered on a coordinated operational concept rather than isolated mechanical elements. The system begins with a water reservoir connected to a heating element that generates water vapor. The generated vapor is guided through a conduit pathway toward the interior wiping mechanism, where it is distributed in coordination with the wiping motion. This arrangement enables controlled moisture application instead of uncontrolled vapor

release, allowing the cleaning process to remain stable within the enclosed vehicle cabin.

The design emphasizes functional integration between the vapor source and the wiping mechanism. Instead of treating vapor generation and wiping as independent processes, the model synchronizes moisture delivery with mechanical surface interaction. This coordinated configuration supports uniform moisture distribution and helps maintain optical clarity during operation.

In addition, the system design incorporates a regulated moisture-transfer stage at the wiping interface. Vapor released from the delivery pathway is moderated before reaching the glass-contact surface, allowing wiping motion to interact with a controlled moisture layer rather than free vapor flow. This design principle aims to reduce excessive condensation and avoid uncontrolled dripping while maintaining effective surface cleaning.

A. Model Components and Operational Mechanism

Fig. 1 presents an overview of the proposed vapor-assisted wiping model for interior windshield moisture management. The figure illustrates the overall system concept, beginning with a water reservoir connected to a heating source that generates water vapor during operation. The generated vapor is guided through a delivery pathway toward the wiping structure, where it is applied in coordination with the wiping motion across the interior glass surface. This configuration demonstrates how vapor generation and mechanical wiping are integrated within a single operational design to support controlled moisture application and improved windshield clarity.

Fig. 1. Overview of the proposed vapor-assisted wiping system showing vapor generation, delivery pathway, and coordinated wiping interaction for interior windshield moisture management.

To further clarify the operation of the proposed model, Fig. 2 illustrates the internal structure of the wiper head, which represents the main interaction zone between vapor delivery and surface cleaning. While Fig. 1 presents the overall system architecture, this figure focuses on the internal design

responsible for regulating moisture before it reaches the windshield surface.

As shown in Fig. 2, vapor released from the outlet apertures does not directly contact the glass. Instead, it first enters a porous plenum that guides and redistributes the vapor internally. This routing process allows moisture to spread across the structure in a more controlled manner, supporting uniform distribution and reducing localized condensation. The regulated moisture then passes through an absorbent insert before reaching the glass-contact surface, where a moderated moisture film is formed during wiping. This sequence ensures that vapor delivery remains controlled and stable, enabling the wiping mechanism to interact with a regulated moisture layer rather than uncontrolled vapor flow.

Fig. 2. View of the wiper head illustrating internal vapor routing through a porous plenum and regulated moisture transfer toward the glass-contact surface.

- Vapor Generation

The process begins with a water reservoir combined with a heating source that produces water vapor during system operation. This stage provides the moisture needed for the cleaning process and acts as the starting point of the model. The goal is not simply to generate vapor, but to supply a

controlled and stable source of moisture that can be used during wiping.

- Vapor Delivery

After generation, the vapor is directed through a dedicated pathway toward the wiping structure. This pathway guides the vapor in a controlled direction instead of allowing it to disperse freely inside the cabin. By controlling the movement of vapor, the system ensures that moisture reaches the intended area in a predictable and consistent way.

- Moisture Distribution and Regulation

Before reaching the windshield surface, the vapor passes through a porous moisture-regulating structure positioned near the wiping interface. This component plays an important role in the model. Instead of releasing vapor directly onto the glass, it distributes the vapor internally through its porous body, allowing moisture to spread more evenly. This helps moderate condensation and reduces the possibility of uncontrolled dripping while maintaining a stable moisture level.

- Glass Surface Interaction

The final stage occurs when the wiping structure moves across the interior windshield surface. At this point, mechanical wiping works together with the regulated moisture layer to remove fog and residues from the glass. The cleaning effect therefore results from the interaction between controlled moisture delivery and wiping motion rather than from either action alone.

Overall, the operational mechanism shows how the model manages moisture step by step, from vapor generation to surface interaction. By coordinating these components within a single process, the proposed design aims to maintain interior windshield clarity in a controlled and stable manner.

To provide a clearer overview of the proposed model, Table I summarizes the main components and their roles within the overall moisture management process. The table highlights how each component contributes to vapor generation, routing, regulation, and interaction with the windshield surface. This summary is intended to support understanding of the system design and its operational logic.

TABLE I. SUMMARY OF MODEL COMPONENTS AND THEIR FUNCTIONS

Component	Main Function	Role in Moisture Management
Vapor Generation Unit	Produces water vapor from the reservoir	Provides a controlled moisture source
Vapor Delivery Pathway	Guides vapor toward the wiper head	Ensures directed and stable vapor movement
Vapor Outlets	Releases vapor into the internal distribution area	Enables controlled vapor entry to the wiping interface
Porous Moisture-Distribution Structure	Diffuses and regulates vapor	Prevents concentrated vapor release and supports uniform moisture spread
Glass-Contact Wiping Interface	Performs mechanical wiping	Removes fog and residues using a moderated moisture layer

IV. DESIGN RATIONALE AND CONCEPTUAL ADVANTAGES

The design of the proposed model is based on a simple idea: moisture should be controlled before it reaches the interior windshield surface. Instead of releasing vapor directly onto the glass, the system guides and regulates moisture through a structured path that works together with the wiping movement. This approach was chosen to reduce sudden condensation and to maintain a more stable cleaning process.

One of the main design considerations is the use of a porous distribution element inside the wiper head. The purpose of this component is to spread vapor gradually rather than allowing it to reach the glass as concentrated steam. By distributing moisture internally, the system creates a thin and more uniform moisture layer, which helps the wiping action remove fog and residues more effectively.

Another important aspect of the design is the integration between moisture delivery and mechanical wiping. In many conventional approaches, moisture control and wiping operate separately. In the proposed model, however, these two actions are coordinated. The presence of a moderated moisture layer makes wiping smoother and reduces the chance of uneven cleaning or localized fog accumulation.

The model also aims to address practical conditions inside the vehicle cabin. Since the interior environment is enclosed, uncontrolled vapor release may increase fogging instead of reducing it. For this reason, the design emphasizes regulation and gradual transfer of moisture, allowing the system to support visibility without introducing excessive humidity near the driver's field of view.

From a technical perspective, the performance of the proposed system is expected to depend on several key parameters, including the vapor generation rate, vapor flow control, permeability of the porous distribution structure, and wiping speed. These parameters influence moisture transfer behavior, condensation regulation, and the stability of the moisture layer formed on the glass surface. Although the present study does not provide a quantitative model, these factors define the operational envelope of the system and represent critical variables for future analytical and experimental investigation.

V. DISCUSSION

The proposed vapor-assisted wiping model can be viewed as a complementary approach to existing windshield defogging solutions rather than a replacement for them. Previous studies have mainly focused on controlling environmental conditions inside the vehicle cabin, such as airflow distribution or thermal regulation. For example, in [8], the authors developed a predictive HVAC control model that adjusts cabin parameters based on fogging probability, while [2] explored improvements in airflow distribution through air duct design. These approaches demonstrate the importance of climate and ventilation control; however, they primarily operate at the cabin level and do not directly manage moisture at the glass surface.

Other works have highlighted the complexity of fogging and defogging phenomena and the range of available

mitigation strategies. The review provided by [7] shows that most existing solutions rely on environmental control, material treatments, or airflow management. Similarly, computational and numerical investigations have focused on condensation prediction and mist behavior, as seen in studies such as [1], [14]. While these studies improve understanding of fog formation, they generally address the problem from an analytical or simulation perspective rather than through direct surface interaction.

The present study takes a different direction by focusing on controlled moisture handling at the interior windshield surface itself. Instead of depending solely on ambient air regulation, the proposed model introduces a structured pathway that guides vapor through a porous interface before contact with the glass. This idea aligns with earlier efforts that emphasized humidity distribution control [10], but extends the concept by combining moisture regulation with mechanical wiping in a coordinated manner.

In addition, intelligent windshield concepts and sensing-based approaches have been proposed to support safer driving conditions [9], and fog detection methods have been explored to monitor condensation behavior [13]. The current model differs from these approaches by focusing less on sensing and prediction and more on the physical interaction between moisture and the glass surface during cleaning.

From a practical perspective, the design also reflects broader discussions about future windshield applications and integrated interaction spaces [12]. By organizing vapor generation, routing, and wiping within a single operational process, the model offers a simple but structured way to address interior fogging without relying exclusively on HVAC performance or complex control systems.

The effectiveness of the proposed model is expected to vary depending on environmental conditions such as cabin humidity, temperature differences, and airflow patterns, which may influence condensation dynamics and moisture distribution.

Overall, the contribution of this study lies in shifting attention from large-scale environmental control toward local surface-level moisture management. This perspective does not conflict with existing methods; instead, it complements them by introducing a direct interaction mechanism that may support more stable visibility under varying cabin conditions.

This positioning highlights the role of the proposed model as a complementary approach rather than a replacement for existing HVAC-based solutions.

VI. LIMITATIONS AND FUTURE WORK

The present study focuses on introducing and explaining the design concept of a vapor-assisted wiping model for interior windshield moisture management. As a result, the work remains at the conceptual and architectural level and does not include experimental validation or real-world performance measurements. The practical effectiveness of the system under different environmental conditions, driving scenarios, and humidity levels, therefore, requires further investigation.

Another limitation is that the current model does not evaluate energy consumption, long-term durability, or maintenance aspects of the proposed design. These factors may influence practical implementation and should be explored in future developments. In addition, the interaction between vapor flow, material properties, and wiping speed has not yet been analyzed quantitatively.

Future work can focus on building a functional prototype and conducting controlled experiments to evaluate visibility improvement and moisture regulation performance. Computational studies, such as airflow and condensation simulations, may also help optimize vapor distribution and support design refinement. Further research could additionally explore integration with existing HVAC or sensing systems to create hybrid solutions that combine environmental control with direct surface-level moisture management.

The present study is limited to a conceptual system design and does not include experimental validation, simulation analysis, or quantitative performance evaluation. As a result, the effectiveness of the proposed model under different environmental conditions, such as varying humidity levels, temperature gradients, and driving scenarios, has not yet been verified. In addition, key technical parameters-such as vapor generation rate, flow control mechanisms, porous material properties, and wiping speed-have not been quantitatively analyzed in the current work. These parameters are expected to play a critical role in system performance and require further investigation. Future work will focus on developing simulation models and prototype implementations to evaluate moisture transfer behavior, visibility improvement, and system efficiency. Experimental validation under controlled and real-world conditions will also be necessary to assess the practical applicability of the proposed approach.

VII. CONCLUSION

This study presented a vapor-assisted wiping model designed to improve moisture management on the interior side of vehicle windshields. The proposed approach focuses on guiding and regulating vapor before it reaches the glass surface, allowing wiping action to interact with a controlled moisture layer rather than uncontrolled vapor flow. By organizing vapor generation, delivery, and surface interaction within a single design, the model offers a practical way to support windshield clarity inside the enclosed cabin environment.

From a practical perspective, the proposed model can support improved driver visibility under conditions of high humidity and rapid fog formation, where traditional HVAC systems may respond slowly. By enabling controlled moisture application directly at the windshield surface, the system has the potential to enhance driving safety, reduce visibility fluctuations, and provide a more stable defogging performance within the vehicle cabin.

The work highlights an alternative perspective that complements existing defogging strategies, shifting attention from broad cabin climate control toward direct surface-level moisture handling. Although the model remains conceptual at

this stage, it provides a clear foundation for future development and evaluation of interior windshield cleaning systems.

A Detailed Classification of the Scheduling Algorithms in Fog Computing Environment, Challenges, and Future Directions

Hend Gamal El Din Hassan Ali, Imane Aly Saroit, Amira Mohamed Kotb

Faculty of Computers and Artificial Intelligence, Information Technology Dept., Cairo, Egypt

Abstract—Fog computing is considered as a distributed computing and storage resource. It is placed near to users rather than cloud computing to reduce latency in Internet of Things sensitive time applications. Several scheduling algorithms were proposed in fog environment to achieve better performance in terms of execution time, cost, latency and quality of services. In this research, a complete study of the different scheduling approaches in the fog computing is illustrated. Also, an operational classification of up-to-date algorithms is highlighted with detailed comparison of their performance metrics.

Keywords—Cloud computing; fog computing; edge computing; Internet of Things; scheduling algorithms; directed acyclic graph

I. INTRODUCTION

Cloud computing provides shared computing, storage resources and services to the users based on their demands using a variety of applications over the Internet. In cloud computing, all requests will be uploaded first to the centralized cloud servers to do the needed computations then the response will be sent back [1, 2]. Recently, Internet of Things (IoT) applications cover many areas in our life such as environment (smart home, smart city), society (health care, smart transportation), economy (smart factory)...etc., [3]. As increasing usage of the IoT applications, massive amount of data flows in the used network, which leads to high traffic load [4]. Because of the massive data generated from the IoT devices and the long distance between them and the centralized cloud servers, this will lead to high overload over the cloud and high latency. This results many challenges for time-sensitive IoT applications like healthcare, intelligent traffic control and monitoring applications [5]. To overcome these challenges; other computing environment were introduced such as fog computing and edge computing [6].

Fog computing term was introduced by cisco systems in 2012 [7, 8]. Fog computing is considered as potential solution to latency produced in cloud computing. Fog computing can't be used instead of cloud computing but it is used with cloud computing to overcome the drawbacks of using only cloud [9]. Fog computing is a distributed computing paradigm that acts as an intermediate layer between the IoT sensors/devices and the cloud servers [10]. It offers computing, networking and storage resources that are near to the IoT devices rather than the cloud [11]. Fog computing provides less resources and storage capability than that of the cloud computing while it has fast

response to requests than that of the cloud. The cloud computing is responsible for processing and executing if the fog computing layer can't execute the requests [9]. Due to the massive data generated by the IoT applications that need to be processed using the limited resources in any computing environment, scheduling process must be used to schedule the usage of these resources fairly between the user's requests (tasks) in cloud, fog or edge computing [12-14]. The contributions of this study are:

- First, provide a comprehensive study of various classification scheduling techniques in fog computing.
- Second, provide a detailed explanation of the recent algorithms related to each classification category.
- Third, compose a complete comparison between these algorithms by highlighting their strengths, limitations, performance metrics, submission task types, scheduling environment, solving technique, scheduling problem type and simulation tools.
- Finally, as a result of the applied comparison and subsequent of the statistical analysis, general direction for the future researches is proposed.

This study is organized as follows: In Section II, the detailed classifications of the scheduling techniques are illustrated with relevant scheduling algorithms associated with each category. A detailed comparison between the illustrated fog scheduling algorithms will be applied with discussion to statistical analysis obtained in Section III. Conclusion and summary are introduced in Section IV.

II. CLASSIFICATION OF SCHEDULING TECHNIQUES

There are many types of classifications for the scheduling techniques used in the fog computing, as shown in Fig. 1. The selection of which used technique is based on the requirements of the system used in the fog computing. Classification can be done based on the type of the scheduling problem [7,15,16], based on decision time and amount of information needed before starting scheduling process like resource availability and task submission [17-20], based on the way of calculating the priority to tasks [21], based on the ability of interrupting the execution process [17,18], based on the used technique for solving the scheduling problem [19, 22-25], or based on the submission task types [20,22].

Fig. 1. Classifications of scheduling techniques.

A. Classification Based on Scheduling Problem Type

Fog scheduling protocols can be classified according to the type of the scheduling problem and their objective to five major types: task scheduling, job scheduling, workflow scheduling, resource scheduling and resource allocation [7].

- Task scheduling aims to assign tasks to the available resources (fog nodes) to satisfy the user's needs (QoS). In [9], task classification and virtual machine categorization method (TCVC) was proposed to schedule IoT healthcare tasks in the fog computing. TCVC is used in health care area to give urgent tasks high priority to be executed faster than those with high length. TCVC divides the tasks into three categories based on their importance. It also divides the VMs to three categories based on their capabilities. Each category of the VM services specific category of the

tasks. Urgent tasks are executed in the fastest VM category. At each category of tasks, Max-Min algorithm is used to sort the tasks. In [26], prioritized task scheduling algorithm was proposed to calculate the priority to each incoming task based on its priority level, deadline and the available resources. Then it adds tasks in the priority queues (low, medium, high) based on their priority. The tasks with the highest priority (closer deadline) are processed first in the fog layer to meet the deadline. If the fog layer is busy, then the highest priority task is propagated to the cloud layer to achieve the deadline constrain.

- Job scheduling aims to assign group of jobs to minimum number of available resources (fog nodes) to get minimum CPU execution time. In [27], job scheduling algorithm with bag-of-tasks was proposed to

reduce the cost by utilizing all the available resources in the fog computing. All heterogeneous resources of fog computing (virtual machine or container, raspberry, smartphone or computer) are divided into sub-systems. Each subsystem can execute any job (independent and identically tasks). Each job is assigned to a sub-system based on the utilization calculation of the available resources and the given thresholds.

- Workflow scheduling aims to assign resources to workflows that include a set of jobs with different relationships (prerequisite, post-requisite). In [28], improved particle swarm optimization (IPSO) was proposed to schedule workflow in cloud and fog environment. Traditional particle swarm optimization (PSO) uses linear decreasing function to calculate inertia weight that is used in updating velocity and position of particle. This leads to instability between global and local search capabilities of particles. IPSO uses nonlinear decreasing function to calculate the inertia weight, which enhances the global and local search capability of particles. In [29], gravitational search algorithm (GSA) was proposed to get the optimal placement strategy to workflow (dependent processing elements). GSA follows the Newton's theory of gravity in which each particle attracts other particles with a force that is proportional to their masses and inversely proportional to the square of distance between them. So particles move toward other particles with heavy mass.
- Resource allocation aims to allocate the available resources to the clients based on their needs over the internet. In [30] the unit-slot optimization based on Lyapunov optimization technique was proposed to distribute all the incoming data into three-tier cloud of things (CoT) system; cloud, fog and edge. The Lyapunov optimization technique uses Lyapunov function with online systems to ensure stability, therefore unit-slot optimization is considered as online algorithm that doesn't need priori information before scheduling. A Lyapunov function is a nonnegative scalar measure of multi-dimensional vector of the system [31]. In unit-slot optimization, Lyapunov function is defined as the scalar measure of response time. In [32], the fog-enabled multi-tier operation scheduling (FEMOS) algorithm was proposed to model the delivery content of wireless network with heterogeneous resources. FEMOS is an online mode algorithm that uses Lyapunov optimization techniques to optimize task assignment (control tier) and resource allocation (access tier). In [33], dynamic task offloading framework was proposed to apply in dynamic fog environment uses deep Q-learning (DQL) that is a type of reinforcement learning (RL). The proposed framework models task allocation problem as Markov decision process (MDP).
- Resource scheduling aims to find the mapping between VM and the physical machines. In [34], online and utility-power efficient task scheduling algorithm was proposed to balance between the utility-power

efficiency and average mean of queue backlogs performance in homogeneous fog networks. It offloads computation tasks from the wireless devices (WDs) to nearby fog nodes with available resources by modifying Lyapunov optimization techniques to maximize the utility-power while reducing the average mean of queue backlogs.

B. Classification Based on Decision Time

Fog scheduling protocols can be classified to two major types: static and dynamic, according to scheduling decision time and the amount of information needed about tasks and resources before starting scheduling process [17-19].

- Static scheduling needs all information about the available resources and tasks before starting scheduling as scheduling decisions are made before running time [20]. Static scheduling does not respond to any changes in the resources or tasks at runtime also there is no failure can occur during the scheduling. In [35], a profit-aware application placement policy was proposed to maximize provider profit (net profit and gross profit) by applying QoS requirements that present on deadline constraints. The proposed policy used integrated linear programming model (ILP) in fog and cloud computing environment. In [36], an improved jellyfish algorithm (IJFA) was proposed to minimize the task completion time, maximize resource utilization and improve the overall QoS. IJFA classifies tasks based on their priorities and deadline.
- Dynamic scheduling doesn't need prior information before scheduling as tasks are entered dynamically while the system is running. Scheduling decisions are made during running time. There is no need to wait for defining the incoming tasks and the available resources before starting the scheduling, also there is no guarantee to meet all constraints or tasks deadlines so the scheduler work hard to avoid failure [20]. In [37], dynamic scheduling algorithm was proposed to get the optimal responsive scheduling with distributed IoT architecture. Dynamic algorithm supports dynamic execution and re-scheduling based on fluctuation in the network parameters or QoS requirements. Dynamic scheduling uses two stages, the first stage aims to serve the tasks in local environment that leads to increase privacy and reduce traffic. For the remaining tasks, the second stage will be run using a user agent that sends the requests to all available fog and cloud nodes. In [38], the hybrid fog and cloud-aware heuristic for dynamic scheduling of multiple real-time IoT workflows (Hybrid-EDF) was proposed in two phases. The first phase is assigning a priority to each task based on its deadline by using earliest deadline first (EDF) policy. If there are many tasks with the same priority, the task with the highest average computational cost is selected first. The second phase is the VM selection for fog or cloud by using earliest estimated finish time (EFT). Hybrid-EDF finds gaps where the VM are idle and try to fill them with the existing tasks, in order to increase the utilization of system. In [39], dynamic task

allocation using a fuzzy logic enhanced (DTA-FLE) approach was proposed to classify tasks based on fuzzy logic among three layers low, high critical fog layer and cloud layer. Then DTA-FLE scheduled tasks in each layer to increase guarantee ratio and enhance performance.

C. Classification Based on Priority Scheme

Fog scheduling protocols can be classified according to the way of calculating the priority of tasks to two major types: static priority and dynamic priority [21].

- Static priority is assigned to tasks before execution time and cannot be changed during running time (priority depends on static attributes). In [40], prioritized incremental energy rate algorithm (PIER) was proposed to optimize the energy efficiency of the network. PIER presents scalable and robust priority based to schedule homogeneous offloading tasks with exponential distribution duration on fog nodes (FN). PIER minimizes the ratio of long-run average power consumption over the long-run average throughput with taking into consideration the availability of transmission channels and computing resources.
- Dynamic priority is assigned to tasks during running time and can be changed as it depending on the current state of system. Dynamic priority depends on dynamic attributes like latency or deadline as over time latency of unexecuted task increase while remaining deadline decrease. In [41], task priority dynamic implementation (TPDI) was proposed to reduce application loop lag and optimize performance of execution time, response time and minimize cost. TPDI applies scheduling process based on priority level and the classifications of the applications. TPDI assigns priorities to tasks on their arrival in a dynamic way. High priority tasks have minimum waiting time and execute earlier.

D. Classification Based on Interrupting Scheme

Fog scheduling protocols can be classified according to the ability of interrupting the execution process of the selected task to two major types: preemptive scheduling and non-preemptive scheduling [17, 18].

- Preemptive scheduling can stop the task that has been selected for execution before it is completed, which means it has the ability of interrupting the running task. In [42], fog computing scheduling algorithm was proposed for smart city namely weighted round-robin (WRR). The proposed algorithm used to handle huge number of requests that come from energy, water, transportation, housing and healthcare applications in smart city. The scheduling algorithm checks if the capability of the fog layer can execute the tasks or not. The task will be sent to the cloud layer using spanning-tree routing protocol (STP), if the resources in the fog layer not enough. Otherwise, WRR scheduling algorithm will be used to execute the tasks within the rotation cycle (RC) based on their priorities, and according to their available processing capability and

remaining energy. WRR considers the task preemptive with no priority.

- Non-preemptive scheduling has to complete the task that has been selected for execution. The task cannot be stopped before it is finished. In [43], task scheduling in fog computing algorithm (TSFC) was proposed to schedule independent tasks based on relational table that includes results from I-Apriori algorithm between tasks and fog nodes. I-Apriori algorithm is proposed based on data mining Apriori algorithm. TSFC gets tasks with high priority from relational table and assigns them to fog nodes with minimum completion time. In [44], the priority and dependency-based DAG tasks offloading algorithm (PDAGTO) was proposed to schedule tasks with dependency constraints in heterogeneous fog nodes with multicore processors. PDAGTO assigns high priority to tasks with high computational overhead and high local energy consumption to meet the energy consumption requirement and minimizing the delay.

E. Classification Based on Solving Techniques

Fog scheduling protocols can be classified according to the way of solving the problem to four major types: heuristic, meta-heuristic, hybrid-heuristic and hyper-heuristic scheduling [19, 22-25].

- Heuristic scheduling is used to solve specific problem with known parameters defined by developers. Heuristic algorithms are simple and easy to implement but not guaranteed optimality [19, 22-24]. In [45], critical task first scheduler (CTFS) was proposed to schedule tasks based on its natural (critical or not critical) in healthcare scenario. CTFS gives critical tasks high priority unlike the other scheduling algorithms that give tasks with smaller MIPs size high priority than critical tasks with larger MIPs size. Therefore, incurs high latency to critical tasks with larger MIPs which is unacceptable in healthcare scenario. In [46], an efficient resource allocation and management strategies with energy efficiency (ERAM-EE) was proposed to assign IoT devices to fog nodes (FNs) through resource blocks (RBs). ERAM-EE constructs channel gain matrix and uses it to allocate RBs to IoT devices and FNs.
- Meta-heuristic scheduling is used to get general solution to the optimization problems [25]. Most of meta-heuristic techniques are natural-inspired. Meta-heuristic techniques have four categories: swarm intelligence (SI), biological based (bio-inspired), physics and chemistry based and human behavior based. SI are concerned with the behavior of multi agents that follow some simple rules like particular swarm optimization (PSO), ant colony optimization (ACO), bee life algorithm (BLA), artificial bee colony (ABC) algorithms, etc. SI is a subset from wider class called bio-inspired, so not all bio-inspired are SI. Genetic algorithm (GA), human inspired algorithm and whale optimization algorithm (WOA) are examples of the bio-

inspired based. Another type of meta-heuristic is inspired from the physics and chemistry based like harmony search and simulated annealing algorithm (SA). Human behavior based is observed from human societies like social emotional optimization algorithm (SEO) and league championship algorithm [22,23,47]. In [48], the whale optimization algorithm (WOA) was inspired from the moving whales toward its preys. WOA is used to find the optimal energy management in smart power grids of plug-in hybrid electric vehicles (PHEVs). Data are encrypted using hash function in WOA to apply secure transaction between layers. In [49], opposition-based chaotic whale optimization algorithm (OppoCWOA) was proposed to improve the original version of WOA. OppoCWOA uses opposition-based learning and chaos theory with original WOA to extend the search space in both directions. Therefore OppoCWOA can avoid getting local optimal solution or premature convergence.

- Hybrid-heuristic scheduling combines two or more of algorithms to solve a predefined problem. Combined algorithms can be heuristic or meta-heuristic. Hybrid-heuristic algorithms gather the advantages and overcome the weakness of the combined algorithms. They achieve better performance than using one algorithm. But as they are integrated two or more algorithms at each iteration, it takes longer computation time [23,24]. In [50], a hybrid heuristic (HH) algorithm was proposed to combine IPSO algorithm with the improved ant colony optimization (IACO) algorithm, in order to schedule tasks of smart manufacturing system. First, the IPSO algorithm is used to get the optimal solution then forward its optimal solution as initial distribution to IACO algorithm. Then re-scheduling tasks using IACO to get the optimal result. HH algorithm combines the fast search from IPSO and the accuracy from IACO.
- Hyper-heuristic scheduling combines more than one algorithm like hybrid-heuristic but uses low-level heuristic (LLH) selector to decide which algorithms will be used at each iteration. Because only one algorithm will be used at each iteration, it achieves better performance than the hybrid-heuristic with less computation time [23,24]. In [23], hyper heuristic algorithm (HH) was proposed to combine four simple algorithms: genetic algorithm (GA), particular swarm optimization (PSO), ant colony optimization (ACO), and simulated annealing algorithm (SA). The HH is described in an intelligent surveillance case study with two phases; the training phase and the test phase. In the training phase, it applies the training workflow to the four techniques, then it calls the data center networks (DCNS) fog application to initialize the module mapping. And finally, it stores the best technique for each workflow in the dataset. In the test phase, it calculates the Euclidean distance between the new sample and the dataset. Then it chooses the best algorithm based on the lowest distance workflow. In [51], another hyper heuristic algorithm was proposed

with the same idea of the HH algorithm but instead of calling the DCNS fog application, it calls the elderly human's activity detection (EHAD) in smart home case study, it also applies the security services with less overhead.

F. Classification Based on Submission Tasks Type

Fog scheduling protocols can be classified according to the way of acting with incoming tasks to three major types: batch, dependency, and batch-dependency. Fig. 2 shows different scheduling unit types used in scheduling algorithms [20].

Fig. 2. Scheduling unit types.

- Batch algorithms work with independent tasks and cannot deal with dependent workflows. With this type, it is assumed that all the workflow is divided into independent parallel tasks first. In [52], time-cost aware scheduling (TCaS) algorithm was proposed to optimize the scheduling IoT bag of tasks problem based on an evolutionary genetic algorithm (GA). TCaS can balance between different user's requirements like fast execution or limit budget. In [53] drawer cosine optimization (DCO) was proposed for effective task offloading in fog computing. DCO combine between DA and SCA to apply multi-objectives such as makespan, cost, load, and energy. DCO is applied in master fog node that is responsible for scheduling the offloaded task requests. In [54], improved genetic algorithm for permutation-based optimization problems (IGA-POP) was proposed as a semi dynamic real time algorithm. IGA-POP achieves the minimum expected finish time and balance between the makespan, the total execution cost and deadline constraints.
- Dependency algorithms work with dependent workflows that are represented by directed acyclic graph (DAG). It doesn't have an efficient way to deal with parallel tasks [22]. In [55], cost-makespan aware scheduling heuristic algorithm (CMaS) was proposed in three phases. The first phase is assigning the priority to the dependent tasks in order to arrange them. Tasks are represented by directed acyclic graph (DAG) and ordered by upward ranking. The second phase is the selection phase that assigns each task to an appropriate processing node (cloud or fog) to achieve the optimal treatment between schedule length and cloud cost. The third phase is improving QoS while meeting the deadline constrains by reassigning the tasks in critical path to better processors to reduce the completion time. In [56], multi-agent system based genetic algorithm (MAS-GA) was proposed as a hybrid cloud-fog multi-agent approach applied with set of dependent IoT tasks.

MAS-GA has two phases. First, the MAS-GA divides the dependent workflow into sub-workflows by using the Mixed Min-Cut graph (MMCG) method. Then the agents set a contract that includes the deadline, the allowable budget and the required QoS metrics to each sub-workflow and sends the resource allocation request (RAR) to the closest fog agent. In the fog agent, it will compare RAR with the capability of the fog agent. If RAR is satisfied, then it uses genetic algorithm to find the nearest optimal allocation, else it will send the request to the cloud agent. In [57], electric earthworm optimization algorithm (EEOA) was applied in real time applications. EEOA combines the earthworm optimization algorithm (EOA) and the electric fish optimization algorithm (EFO) to improve searching explorations.

- Batch-dependency algorithms work first with dependency workflow and creates groups of independent tasks after orders them. Then they schedule the tasks in each group as batch algorithm [22]. In [58], an improved list-based task scheduling algorithm was operated in three stages. The first stage divides the tasks to levels, each level includes independent tasks. The second stage is assigning priority to the tasks at each level and then ordered these tasks based on their priorities. The last stage is assigning the resources to high priority tasks. In [59], hybrid list scheduling algorithm (HLSA) was proposed to apply with heterogeneous scheduling units with utilizing gaps in scheduling line. HLSA reduces makespan, total cost and latency to urgent tasks.

III. COMPREHENSIVE COMPARISON AND ANALYSIS

After presenting detailed classifications of the different approaches in the previous section, it is important to move on to a complete detailed comparison between the illustrated fog scheduling algorithms to evaluate their performance and determine which are most effective and suitable for diverse systems. This comparison is essential for all the future researches as it considered as a reference guideline to the previous algorithms and their required environment. Table I summaries the advantages, limitations, performance metrics and compared algorithms. Table II compared between illustrated algorithms in terms of computation environment, simulation tool, type of submission tasks, used technique and scheduling problem type.

Some statistical analysis that help for determining the future approach in fog scheduling algorithms are proposed based on a review of 34 research papers. Fig. 3 declared the performance metrics used to evaluate the illustrated scheduling algorithms. From that, we can observe that the most important metrics is cost by 47%. Cost can be computed based on computation process, communication process, usage of memory, bandwidth, energy, usage of cloud or services. Makespan, energy consumption, delay and execution time are considered the second most significant metric following cost by 41%, 41%, 35% and 32%, respectively.

Fig. 4 shows many simulation tools used to simulate fog scheduling algorithms. The most popular tool used is iFogSim

by 27% followed by both cloudsim and Matlab with equal ratio by 15%. iFogSim is considered the extension of CloudSim by adding new functionality to it. Therefore, iFogSim and CloudSim represent 42% of the simulator tools used in the illustrated algorithms. However some research papers don't specify the used simulator tool by 15%.

Fig. 5 presents the main types of scheduling problems indicating the percentage of algorithms employed to each type. The task scheduling problem has the highest percentage by 56%, followed by 17% as resource allocation, 15% as workflow scheduling, 9% as job scheduling and 3% as resource scheduling.

Fig. 6 shows the percentage of each technique used for solving the illustrated scheduling problems. Heuristic-based scheduling algorithms have highest percentage by 59%, followed by 32% as meta-heuristic, 6% as hyper-heuristic and 3% as hybrid-heuristic.

Fig. 7 declared the percentage of task submission types used in illustrated algorithms. Therefore, 59% of scheduling algorithms can be applied to independent workflow, 29% can be applied to dependent workflow, 3% can be applied with both, 8% of research papers aren't mentioned the type of submission tasks.

Fig. 8 presents the usage percentage of each environment in illustrated algorithms. Thus, 50% of the scheduling algorithms depending on fog resources only compared with 47% depending on the extended resources from the cloud to meet some constrains like deadlines or the requirements of the tasks exceeded the fog resources while 3% used both fog and edge environment.

From this analysis, the general direction for the future research can be determined. First, it is necessary to specify the type of scheduling problem, the used technique, the type of workflow, simulation tool and environment. iFogSim is the most recommended simulation tool as it is an open source including CloudSim functionality with new features. Regarding the incoming workflow, some algorithms are applied to independent workflow without ability to deal with dependency constraints and others are applied to dependency workflow with the need to add assumptions to can apply with parallel tasks. So it is recommended to find approach that can be applied to all types of workflow without any restrictions on it. As for the used technique, hyper-heuristic technique needs more in-depth exploration as it combines more than one algorithm with less computation time and achieves better performance than using one algorithm. Hyper-heuristic technique gathers the advantages and overcome the weakness of the combined algorithms. Relative to the used environment, the system can either operate using existing resources in fog layer or can extend other resources from cloud layer with higher cost in case fog resources are insufficient. Regarding the scheduling problem type, task scheduling problem is the focal point of researches. As for the performance metrics, they are determined based on the requirements and objective of the system. Although this survey provides a comprehensive overview, it does not cover real-time constraints or benchmarking challenges.

TABLE I. A COMPARISON OF ILLUSTRATED SCHEDULING ALGORITHMS IN FOG COMPUTING

Protocol	Performance metrics	Advantage	Limitation	Comparison protocol used
DTA-FLE [39], 2025	Running time, Processing cost, Makespan, Delay, Energy consumption	Enhances scheduling efficiency. Improved Makespan. Minimize execution costs, energy and delays.	Computational process of fuzzy logic-based approach is complexity.	OEeRA, FBOT and DTA
DQL [33], 2025	Delay, Resource utilization, Energy consumption	Minimize latency and completion time. Efficient in real-time.	Not evaluated in real-world large-scale deployments.	PPO, PSO and Synergistic AI Framework
DCO [53], 2025	Execution time, Load balancing, Makespan, Memory, Energy consumption	Minimize latency, energy consumption and total offloading time. Meet deadline. Efficiently offloads prioritized tasks to the proper nodes.	Not considered the network conditions and resource availability to make real-time decisions.	SACO, ACO, JTORA, Multi-objective fuzzy approach, Improved contract net with BAS and DCTO
HLSA [59], 2025	Makespan, Latency, Total cost (communication and computation cost).	Reduce latency, cost and Makespan. Apply with heterogeneous scheduling units. Utilizing gaps in scheduling line.	Can't apply with dynamic environment.	Heterogeneous Earliest Finish Time (HEFT), Min-Min, TS-QoS, Improved list task scheduling algorithm
Online task scheduling alg. [34], 2024	Utility-power efficiency, Average mean of queue backlogs	Maximize utility-power efficiency. Minimizing average of queue backlogs.	Not compared with other algorithms.	Compared with it-self using different parameters
ERAM-EE [46], 2024	Response time, Processing time, Energy efficiency	Improves the energy efficiency, the response and process time. Reduces the volume of data processing and storage in the cloud.	Can't apply with dynamic and heterogeneous natural. It has constraints with CPU, memory and processing power.	RR-EPA, OR-EPA, and EE-CN
TPDI [41], 2023	Tasks: Distribution time, Waiting time, Execution time. Applications: Execution time, Network usage, Energy consumption	Apply with heterogeneous environment to reduce response time, execution time and cost.	Not considered the other QoS parameters.	FCFS and SJF
EEOA [57], 2023	Makespan, Total cost (communication and computation cost), Energy consumption	Enhance convergence speed and searching explorations. Takes the QoS and energy requirements into account. Validate for sensitive application.	Can't predict upcoming workloads and cannot decide whether or not to offload the task.	CSPSO, CSDEO, H-DEWOA, and BLEMO
PIER [40], 2022	Energy efficiency	Robustness to different distribution of task duration. Improve energy efficiency.	Not considered the other QoS parameters.	PTR and PLPC
CTFS [45], 2022	Latency, Network utilization, Energy consumption	Minimize latency for sensitive time applications, energy consumption, response time and network utilization.	Can't apply with heterogeneous and dynamic environment.	FCFS, SJF and cloud-only approaches
IGA-POP [54], 2022	Makespan, Delay time, Failure rate, Execution cost	Provide best permutation for real-time tasks. Minimize finish time, average delay time and failure rate. Balance between Makespan and execution cost. Meeting deadline constraints.	Not apply in dynamic environment. Not adapted to address the workflow scheduling problem.	First fit, Best fit, Bees life and GA
IJFA [36], 2022	Makespan, Completion Time	Minimize the task completion time. Maximize resource utilization. Improve the overall QoS.	Not considered the response time and energy in fog-cloud architecture.	JS
Dynamic scheduling alg. [37], 2022	Latency, Throughput	Apply dynamic re-scheduling based on the changeable QoS parameters. Improve throughput and latency.	Rescheduling always depend on user agent.	Kube-scheduler and NAS
PDAGTO [44], 2021	Delay, Offloading ratio, Energy consumption	Reduce delay in fog node and total energy consumption of the device. Increase CPU utilization.	PDAGTO is batch processing and offline algorithm.	DAG offloading algorithm (DAGOA)
WRR [42], 2021	Delay, Complexity, Throughput	Improve performance in throughput, latency and fairness.	Not apply in dynamic environment.	FogFlow approach
MAS-GA [56], 2021	Response time, Cost, Reliability, Availability, Execution time, Makespan	Maximize the usage of fog to minimize response time. Use cloud computing resources with minimum cost.	Not considered the interactions between agents.	Compared with itself in cloud only and in fog only
Improved list task scheduling alg. [58], 2021	Speed up, Makespan, Cost (computation time of tasks in critical path), Scheduling length ratio, Running time	Minimize Makespan and overall cost. Balance between local and global optimal approach. Restricted cross-over between processors.	Not apply in dynamic environment.	PEFT, HEFT, MOPT, and SDBATS

OppoCWOA [49], 2021	Execution time, Energy consumption	Achieve better performance time-energy efficient.	Process of learn and update weights take long time. Not apply with dependent workflow.	WOA, PSO, GA and ABC
WOA [48], 2021	Cost of energy	Decreasing the loss of power. The transactions of data are secured among the layers.	Not concerned with time.	PSO and GA
Profit-aware application placement [35], 2020	Waiting time, Profit(Gross, Net), Percentage of QoS satisfied	Maximize profit without violation deadline constraints. Minimize waiting time.	Not concerned with security aspects.	Heuristic profit-aware, Deadline-prioritized, Completion time-prioritized, Revenue-prioritized
TCVC [9], 2019	Waiting time, Finished time, Execution time	Achieve fairness between tasks and load balancing between VM. Minimize execution time and latency to sensitive tasks.	VMs capability should be proportional with the important of tasks.	Max-Min, FCFS and SJF
Scheduling alg. with bag of tasks [27], 2019	Resource utilization, Response time, Delay, Throughput, Cost (energy consumption and using cloud cost)	Reduce cost and decrease execution time. Adapting with resources in changing environment.	The overall energy consumption of the system not examined.	Weighted Round Robin
FEMOS [32], 2019	Delay, Fairness, Throughput	Balance between throughput and delay. Confirm the benefit of centralized assignment and dynamic online bandwidth allocation.	Not examined the proactive FAN assignment and resource management problem.	SBC and SLQ
IPSO [28], 2019	Makespan, Cost (computation cost)	Minimize completion time of workflow compared with PSO with similar cost.	Not apply multiple objectives optimization.	PSO
Hybrid-EDF [38], 2019	Cost (using cloud and communication time), Deadline	Meets deadline constraints. Utilizing possible gaps in the schedule of fog and cloud VMs.	Reserved dedicated hosts in cloud layer that lead to increase cost.	Fog-EDF
GSA [29], 2019	Response time	Minimize response time with cost limitations.	Concerned only with response time.	PSO
TCaS [52], 2019	Makespan, Cost (CPU, memory, bandwidth usage)	Can balance between minimum Makespan and execution cost. Satisfy user's requirement.	Not concerned to time, energy consumption and cost or constraints of budget, deadline and resource limitation.	BLA, MPSO and RR
HH [50], 2019	Makespan, Reliability, Energy consumption	Achieve better performance in Makespan, reliability and energy consumption.	Not apply task clustering.	IPSO, IACO and RR
Prioritized task scheduling alg. [26], 2018	Response time, Cost (Computation and communication time)	Some alg. with proposed priority version improved response time and other improved cost so can choose the suitable algorithm based on the system requirements.	There is a static threshold for rejecting task.	ORT, RD and ERA compared with ORT, RD and ERA with proposed priority version
TSFC [43], 2018	Waiting time, Execution time	Minimize the total execution time of tasks and average waiting time.	Not concerned with bandwidth between processors and multilayer task scheduling.	MCT, MET and Min-Min
HH [23], 2017	Execution time, Cost (bandwidth, storage processor, memory), Energy consumption, Network usage	Reduce energy consumption, cost and execution time.	Not address virtual machine's migration, resource provisioning.	GA, PSO, ACO and SA
HH [51], 2017	Execution time, Cost, Security (integrity, authentication, confidentiality), Network usage, Energy consumption	Decrease the risk in security services. Reduce energy consumption, cost and execution time.	Not address virtual machine's placement, resource provisioning.	GA, PSO, ACO and SA
CMaS [55], 2017	Makespan, Deadline, Cost	Balancing between fast executions to apply deadline constraints and reducing cost.	Not deploy in real-world systems.	GfC, HEFT and CCSH
Unit-slot optimization [30], 2016	Response time, Cost (communication and computation time)	Achieve good balancing between cost and response time.	Uncertain communication between three tiers CoT.	Fog-First and Cloud-First

TABLE II. A DETAILED COMPARISON OF ILLUSTRATED SCHEDULING ALGORITHMS IN FOG COMPUTING

Protocol	Environment	Simulation Tool	Task Type	Techniques	Scheduling Problem
----------	-------------	-----------------	-----------	------------	--------------------

DTA-FLE [39], 2025	Fog/cloud	iFogSim	Independent	Heuristic	Resource allocation
DQL [33], 2025	Fog	Undeclared	Independent	Heuristic	Resource allocation
DCO [53], 2025	Fog	Python	Independent	Meta-heuristic	Task scheduling
HLSA [59],2025	Fog	Java	Independent / Dependent	Heuristic	Task scheduling
Online task scheduling alg. [34], 2024	Fog	Undeclared	Independent	Heuristic	Resource scheduling
ERAM-EE [46], 2024	Fog	MATLAB	Independent	Heuristic	Task scheduling
TPDI [41], 2023	Fog	iFogSim	Independent	Heuristic	Resource allocation
EEOA [57], 2023	Fog/cloud	CloudSim	Dependent	Meta-heuristic	Task scheduling
PIER [40], 2022	Fog	Custom simulation	Independent	Heuristic	Task scheduling
CTFS [45], 2022	Fog	iFogSim	Dependent	Heuristic	Task scheduling
IGA-POP [54], 2022	Fog/cloud	MATLAB	Independent	Meta-heuristic	Task scheduling
IJFA [36], 2022	Fog/cloud	MATLAB	Independent	Meta-heuristic	Task scheduling
Dynamic scheduling alg. [37], 2022	Fog/cloud	IMUNES	Independent	Heuristic	Task scheduling
PDAGTO [44], 2021	Fog/Edge	Undeclared	Dependent	Heuristic	Task scheduling
WRR [42], 2021	Fog/cloud	NS 3.26 and iFogSim	Independent	Heuristic	Task scheduling
MAS-GA [56], 2021	Fog/cloud	WorkflowSim extends from CloudSim	Dependent	Meta-heuristic	Workflow scheduling
Improved list task scheduling alg. [58], 2021	Fog	iFogSim	Dependent	Heuristic	Task scheduling
OppoCWOA [49], 2021	Fog	Python with PyCharm editor	Independent	Meta-heuristic	Task scheduling
WOA [48], 2021	Fog/cloud	Monte Carlo Simulation	Dependent	Meta-heuristic	Workflow scheduling
Profit-aware application placement [35], 2020	Fog/cloud	iFogSim	Independent	Heuristic	Resource allocation
TCVC [9], 2019	Fog	CloudSim	Independent	Heuristic	Task scheduling
Scheduling alg. with bag of tasks [27], 2019	Fog	C	Independent	Heuristic	Job scheduling
FEMOS [32], 2019	Fog	Undeclared	Independent	Heuristic	Resource allocation
IPSO [28], 2019	Fog/cloud	MATLAB	Dependent	Meta-heuristic	Workflow scheduling
Hybrid-EDF [38], 2019	Fog/cloud	C++	Dependent	Heuristic	Workflow scheduling
GSA [29], 2019	Fog/cloud	Undeclared	Dependent	Meta-heuristic	Workflow scheduling
TCaS [52], 2019	Fog/cloud	iFogSim	Independent	Meta-heuristic	Task scheduling
HH [50], 2019	Fog	MATLAB	Independent	Hybrid heuristic	Task scheduling
Prioritized task scheduling alg. [26], 2018	Fog/cloud	Cloud Analyst built on top of CloudSim	Independent	Heuristic	Task scheduling
TSFC [43], 2018	Fog	SimGrid	Independent	Heuristic	Task scheduling
HH [23], 2017	Fog	iFogSim	Not mention	Hyper heuristic	Job scheduling
HH [51], 2017	Fog	iFogSim	Not mention	Hyper heuristic	Job scheduling
CMaS [55], 2017	Fog/cloud	CloudSim	Dependent	Heuristic	Task scheduling
Unit-slot optimization [30], 2016	Fog/cloud	SimPy	Not mention	Meta-heuristic	Resource allocation

IV. CONCLUSION

This study illustrated a detailed classification for the recent scheduling algorithms in fog computing. For each category in the classification, identified algorithms that belong to it. A complete comparison is adopted between the illustrated algorithms to highlight their advantages and challenges. This comparison helps researchers to find the appropriate technique to specific problem. Furthermore, statistical analysis is applied and clarified the main research direction.

Abstract—This study investigates customer misbehavior in tourism services through the lens of Cognitive Evaluation Theory and Game Theory, contributing to both management research and social psychology. A dual-path model, tested via a multi-experiment design optimized with a machine learning algorithm, examines mediation versus defense strategies across violation types (interpersonal/transactional). The results show that for interpersonal norm violations, mediation boosts repurchase intention by 23.5%, mediated by organizational and moral justice perceptions. For transaction norm violations, the defense strategy shows higher recovery efficiency (32.1%), largely via organizational justice. Conversely, defense strategies are superior for transactional norm breaches, primarily mediated by organizational justice. This highlights how corporate responses signal organizational values, shaping onsite customer reactions. The analysis, framed by game theory, posits that service scenarios constitute a dynamic strategic system involving customers, firms, and bystanders. Choosing mediation in interpersonal conflicts fosters cooperative atmospheres, while defending transactional rules maintains authority in non-cooperative games. Ultimately, this algorithm-informed approach seeks a refined Bayesian equilibrium, offering data-driven intervention solutions for service order management.

Keywords—Cognitive evaluation; customer misbehavior; management research; social psychology; tourism services; game theory

I. INTRODUCTION

In the modern service economy, customers' consumption experience not only depends on their direct interaction with enterprises and employees, but is also deeply embedded in the shared service scenario composed of other customers [1]. However, this sharing also comes with risks: inappropriate behavior by customers, such as verbal insults towards employees, violations of public order, or unreasonable arguments about transaction terms, has become a highly destructive practical challenge that frequently occurs in service industries such as hotels, restaurants, and tourism [2,3]. The harm of such behavior far exceeds the damage to directly affected employees or corporate assets, and can seriously worsen the perception, emotions, and overall experience of other customers on site, ultimately leading to the loss of

customer loyalty and repeat purchase intention [4,5]. Therefore, understanding and effectively managing the perception and response of bystander customers is the key to optimizing service scenarios as a whole and transforming potential crises into opportunities to showcase corporate values. However, the current research's answer to the question of "how to effectively respond" is still somewhat rough. A core deficiency is that customer misconduct is often viewed as a homogeneous whole, without systematically distinguishing its different types, making it difficult to reveal why different coping strategies are effective and in what contexts. This often leads to management practices falling into a "one size fits all" dilemma, either compromising excessively to undermine the authority of rules or being overly tough to disrupt the service atmosphere. To fill the theoretical gap mentioned above, the study introduces cognitive evaluation theory as the core analytical framework. This theory suggests that individuals engage in active cognitive evaluations of external events, which in turn trigger specific emotional responses and ultimately drive behavioral intentions. Therefore, a dual path model is constructed to reveal how different types of customer misconduct and different response strategies of enterprises affect the perceived organizational and moral fairness of bystander customers, thereby triggering differentiated emotional and behavioral responses. Furthermore, the study introduces a game theory perspective to interpret conflict management in service scenarios as a dynamic tripartite strategic interaction system. The violation of "improper behavior by customers" is the starting action of the game. The response strategy of "service enterprises" is a formal response to this, aimed at conveying information and shaping their beliefs to the key observer of "on-site customers". The final "payment" of on-site customers determines the equilibrium result of the game.

In summary, the research aims to construct and validate a refined model of customer misconduct response in service enterprises by integrating cognitive evaluation theory and game theory. The core question of the research is: What response strategies can service companies adopt to more effectively enhance the repeat purchase intention of on-site customers for different types of customer misconduct? The research aims not

*Corresponding author.

only to deepen the theory of service marketing and consumer behavior but also to provide an empirical and data-driven conflict management decision-making framework for service enterprises through situational experiments and advanced statistical analysis methods. This framework can effectively maintain order, enhance customer experience, and stabilize long-term customer relationships in complex and changing service environments.

II. LITERATURE REVIEW

In recent years, many scholars have conducted extensive research on the inappropriate behavior of tourists during sightseeing. Especially in coastal tourist destinations, Marine litter has become one of the major environmental pollution problems. Improper garbage disposal behavior in tourism activities is considered to be one of the main causes of the Marine garbage problem. Therefore, it is of great significance to enhance tourists' sense of environmental responsibility and cultivate their responsible behavior to alleviate Marine litter. Panwanitdumrong and Chen [6] investigated 876 tourists in Koh Lipang, Thailand, in a questionnaire survey. The research results show that the extended theory of planned behavior combined with environmental awareness and environmental background, can effectively explain tourists' environmental responsibility behavior. Similarly, Dedeolu et al. [7] analyzed data from 457 international tourists to Antalya, Turkey, using a partial least squares structural equation model. The research results show that tourists' attitudes towards local food and perceived behavioral control have a positive and significant impact on their willingness to consume local food, providing a useful perspective for understanding customer behavior. In addition, Lemy et al. [8] explored the information-seeking behavior of domestic tourists during travel during the COVID-19 pandemic, using qualitative research methods. Data collection included observation, in-depth interviews, and literature analysis. This study emphasizes the effectiveness of service companies in providing information during the pandemic and recommends implementing sustainable digital marketing strategies to promote customer engagement and innovative collaboration. Su et al. [9] revealed the social contagion effect in tourists' reactions to inappropriate behavior by others, such as violating social norms, and pointed out the mediating role of moral disengagement. This emphasized the importance of distinguishing behavior types and their social impact, providing a theoretical basis for this study to distinguish between "interpersonal norm violations" and "transaction norm violations". Sriporn et al. [10] used virtual reality and machine learning algorithms to predict tourist behavior, achieving high-precision results. This demonstrated the enormous potential of computational methods and experimental techniques in simulating complex scenes and predicting behavior, providing cutting-edge technical insights for integrating scenario experiments and particle swarm optimization (PSO) algorithms for data feature screening methodology.

Based on the multidisciplinary theories of environmental psychology, social psychology and tourism, the research adopts the in-depth interview method to investigate tourists' feelings when violations occur. The in-depth interview method has been widely used in many fields. The qualitative sequential two-

stage design adopted by Allen et al. [11] successfully delved into the motivations of participants, validating the effectiveness of staged and multi-method qualitative research in obtaining deep insights. This provides a feasible methodological reference for this study to use similar qualitative methods to understand the complex feelings of on-site customers in the initial exploration stage. Nukat et al. [12] conducted a qualitative study to explore the self-care behavior of the elderly population at different stages of illness, which reflects the unique advantages of in-depth interviews in understanding the behavior and cognition of specific populations in specific contexts. This provided a methodological benchmark for exploring the unique psychological responses of the specific role of "on-site customers" in service conflict situations. Dopelt et al. [13] revealed the social responsibility cognition of professionals beyond their clinical roles through semi-structured interviews with senior doctors. This indicated that in-depth interviews could effectively obtain respondents' deep judgments and attitudes towards events, roles, and norms, providing strong methodological support to capture and define the complex evaluation dimensions of fairness and morality by on-site clients through interview data. Pratama et al. [14] conducted in-depth interviews with educational managers using phenomenological methods and found that their management cognition is consistent with the theoretical framework. This confirmed that in-depth interviews could effectively connect individuals' subjective experiences with abstract theoretical concepts, providing an example for this study to connect and support the application of cognitive evaluation theory in service scenarios through interview data. Frederic et al. [15] constructed a theoretical model of service delivery systems based on a single case study in the B2B logistics field, using interviews and document analysis. This demonstrates the potential of case studies centered on in-depth interviews in constructing and validating contextualized theoretical models, providing methodological references for constructing theoretical models from qualitative data to theoretical framework formation. The specific literature comparison mentioned above is shown in Table I.

Existing research has explored the impact of misconduct from a consumer perspective, but suffers from three common limitations: First, it often focuses on a single behavior, lacking systematic differentiation and comparison between interpersonal norm violations and transactional norm violations. Second, it fails to deeply analyze the interaction effects of different corporate response strategies (such as mediation and defense) with violation types. Third, it ignores the "on-site customers" as key observers whose views and emotional reactions towards fairness affect business performance through a chain mediation mechanism. To address these gaps, the study introduces a dual-path model based on cognitive evaluation theory and employs situational experiments and Bootstrap mediation testing methods to reveal how the alignment of violation types and response strategies affects customer repurchase intentions through organizational fairness and moral fairness. This research not only fills the theoretical gap in service management regarding bystander response strategy matching but also provides a solution with both theoretical innovation and practical operability from a game-theoretic perspective, dynamically optimizing conflict intervention and

improving customer retention rates. The innovations of the research are primarily reflected in the following aspects: First, theoretically, it breaks through the previous single-dimensional analysis of customer misconduct by systematically constructing a dual-path model of "violation type-response strategy-fairness perception-behavioral intention" based on cognitive evaluation theory. A game theory framework is introduced, decomposing the service scenario into a dynamic tripartite game among "misconducting customers-corporations-on-site customers," explaining management intervention mechanisms. Second, in terms of empirical models, it innovatively reveals the parallel and chain mediation roles of organizational fairness and moral fairness in the strategy influence process, clarifying the differentiated effectiveness mechanisms of mediation and defense strategies for interpersonal norm violations and transactional norm violations. Finally, in methodological integration, the situational experiments are combined with PSO algorithms for feature selection, and a series of experiments is conducted along with Bootstrap tests to examine complex mediation paths, achieving refined and data-driven validation of management strategy efficacy.

The research not only advances in theory, but also has a clear impact on management practice and social welfare. Firstly, the contribution to academic research lies in constructing and validating a dual path model based on

cognitive evaluation and game theory, which systematically reveals the matching mechanism of "violation type response strategy" and its mediating path through fair perception, bridging the key gap in theoretical integration and micro mechanisms in previous research, and deepening the knowledge system of service remediation and customer interaction. Secondly, the impact on business practices is direct and actionable. It provides a clear, data-driven decision-making framework for business managers. Faced with interpersonal norm violations, priority should be given to using mediation strategies to repair relationships and the collective atmosphere. Faced with violations of trading norms, defensive strategies are adopted to maintain the authority of the rules. This helps companies optimize on-site conflict management, reduce customer loss and reputation damage caused by negative events, and directly improve customer retention and profitability. Finally, the impact on society and public policies is reflected in the research conclusions, which help to create a fairer and more orderly service consumption environment. By enhancing the public's perception of regulatory maintenance, it indirectly promotes the integrity and harmony of the service industry and improves the overall consumption experience and quality of life of society. The refined and humanized management principles advocated by the research can also provide a reference for formulating relevant industry standards and improving consumer rights protection policies.

TABLE I. LITERATURE REVIEW COMPARISON TABLE

Research literature	Research methodology	Advantage	Limitations and gaps
[6,7]	Questionnaire Survey and Structural Equation Modeling	Large sample quantitative verification of variable relationships, with strong explanatory power.	Mostly cross-sectional data, difficult to capture dynamic interactions; There is a lack of differentiation between violation types and strategy matching, and insufficient exploration of bystander mechanisms.
[8,13]	Qualitative interviews and case studies	A deep understanding of behavioral motivations and contextual details is suitable for exploratory research.	The conclusion has limited universality; It is difficult to quantify the effectiveness of strategies and intermediary mechanisms, and there is a lack of systematic measurement of on-site customer emotions and behavioral responses.
[15]	Virtual Reality and Behavior Prediction	High simulation scenarios can be combined with machine learning to predict behavior, with strong technological foresight.	Focus more on behavior prediction rather than mechanism interpretation; Lack of linkage with corporate coping strategies and empirical testing of psychological mediators such as perceived fairness.

III. A MODEL OF THE IMPACT OF CUSTOMER-FACING MISBEHAVIOR OF SERVICE FIRMS ON THE PRESENCE OF CUSTOMERS AND A STUDY OF THE TYPES OF BEHAVIORS THEY ENGAGE IN

The cognitive evaluation theory suggests that under external stimuli, people will make a series of emotional reactions, which in turn affect consumer behavior [16]. Therefore, the way the service industry handles customers' misbehavior will have an impact on the repurchase intention of the customers present. To acquire this influence mechanism, the study will take this as an entry point to analyze the impact of customer misorganization behavior on other customers in the process of travel and tourism, and carry out a detailed investigation and analysis.

A. Model Architecture of the Effect of Service Firms' Response to Customer Mistreatment Behavior on the Repurchase Intention of Customers in the Presence

The study integrates cognitive evaluation theory with game theory to construct a multi-level analytical framework aimed at

comprehensively explaining the effects of management strategies in service interactions. The two interact in a complementary and coherent manner within the model: The cognitive evaluation theory reveals the psychological mechanism at the micro level, that is, how on-site customers provide cognitive explanations (fair judgments) and emotional responses to corporate strategies, forming the internal basis for personal behavioral decisions. Game theory situates the individual's psychological decision-making process within the macro-level structure of strategic interactions among "misbehaving customers-enterprise-on-site customers." From this perspective, the enterprise's response strategies serve not only as situational stimuli but also as critical signals conveying organizational fairness and capability to on-site customers. The on-site customers' cognitive and emotional responses, in turn, serve as beliefs and payoff functions formed after interpreting these signals, with their subsequent behaviors (e.g., repeat purchases) directly influencing the equilibrium outcomes of the game. Thus, the path from "strategic stimulus" to "psychological response" to "behavioral outcome" essentially

represents a unified process of embedding psychological mechanisms into strategic interactions: Cognitive evaluation describes the internal psychological sequence of signal reception and processing, while game analysis explains why different types of violations (corresponding to distinct game structures) lead to varying efficacy of specific strategic signals (mediation or defense) in guiding equilibrium beliefs (e.g., trust in collective fairness or rule authority). This integrated framework can understand management interventions that delve into the black box of individual psychology while extending to the dynamics of interactive systems.

The research argument adopts the core ideas of cognitive assessment theory and social exchange theory, and introduces a game theory perspective to conceptualize service interaction as a three-party dynamic game, providing a solid theoretical basis for analyzing the matching effect of "violation type response strategy". The entire research adopts a rigorous intergroup experiment on "coping strategies x violation types", and integrates feature screening optimized by PSO and Bootstrap statistical mediation test. This multi-level method combination can effectively identify causal mechanisms and ensure the intrinsic validity and reliability of research findings.

In cognitive appraisal theory, the research focuses on three things: First, the intrinsic properties that the environmental factors or events themselves possess. Second, what emotions the individual will experience at the time of the appraisal; Third, how the emotional response acts on the individual's behavioral response [17]. A theoretical model is constructed to explore the impact of service companies' response to unfair treatment on current customers' perception of fairness, emotional reactions, and repurchase intentions. Based on cognitive evaluation theory, the study concretizes the evaluation process of on-site customers towards conflict events: their assessment of event responsibility and corporate control directly affects organizational fairness. Judging whether behavior conforms to social norms can trigger a sense of moral justice. These two perceptions of fairness serve as the core cognitive evaluation results, which in turn trigger specific emotions such as anger directed towards the enterprise or

empathy directed towards employees, ultimately driving behavioral intentions. The structure of the theoretical model is shown in Fig. 1.

In Fig. 1, the theoretical model includes mainly situational factors, cognitive evaluation, emotional reflection, and behavior. In the theoretical model, each key concept is defined at different positions in the causal chain based on cognitive assessment theory. The definition and logical relationship are as follows. The dimensions of cognitive assessment include organizational fairness and moral fairness. The former is the on-site customer's cognitive judgment of whether the procedures and results of the enterprise's handling of events are fair. The latter is its moral judgment on whether the event itself conforms to social moral norms. The two together constitute the first-level cognitive evaluation result. The dimensions of emotional response include anger and empathy. The model follows the causal logic of "situational stimuli (violation and strategy) → cognitive assessment (fairness perception) → emotional response (anger/empathy) → behavioral intention (repeat purchase)". Cognitive assessment (fairness perception) is a core psychological process directly triggered by situational factors and driven by subsequent emotions. Customer behavioral responses reflect the present customer's willingness to repurchase. Cognitive appraisal theory suggests that after a complex cognitive appraisal and emotional response, individuals choose appropriate coping strategies as behavioral responses to environmental stimuli, and willingness to repurchase helps to alleviate the negative emotions of the present customer due to negative scenarios [18,19]. Customer misbehavior and service firms' coping strategies can have a significant impact on customers' cognitive appraisal, affective reactions, and subsequent actions. Taking service consumption as an industry scenario, the study explores the types of abnormal service behaviors of on-site customers and their enterprises' countermeasures from the perspective of on-site customers, and examines the effects of enterprises' responses to on-site customers' misbehavior. This study selects the hospitality industry consumption scenario as the industry background factor, as shown in Fig. 2.

Fig. 1. Theoretical model structure diagram of repurchase intention.

Fig. 2. Selecting the consumption scenario of the hospitality industry as the industry background factor.

In Fig. 2, the study selects the hospitality industry consumption scene as the industry background among the factors. One is high interactivity. There are a large number of customers and service personnel, service facilities, service environment, and other interactions. The customer's service experience is susceptible to the impact of interactivity. The second is the high-frequency. Due to unfair treatment in hotel services, hotel services are closely related to daily lives and

travel. The third is intimacy. Service managers should deal with abnormal service behavior and be able to approach the occurrence and development of abnormal service behavior through customer scenarios in a smaller service area, which is particularly suitable for exploring some social phenomena and processes. Some of these social phenomena can be discovered using grounded theory, as shown in Fig. 3.

Fig. 3. Social phenomena that are compatible with grounded theories

B. An Experimental Study of the Effect of Service Firms' Response to Customer Mistreatment Behavior on the Repurchase Intentions of Customers in Attendance

The following hypotheses are proposed before the experimental analysis. H1 assumes that when customers violate interpersonal norms, service enterprises can effectively restore customers' buyback intention by adopting reconciliation strategies. When customers feel unfair treatment, adopting reconciliation strategies can restore customers' emotional balance and thus improve their buyback intention [20]. H2 assumes that when customers violate transaction norms, service enterprises can adopt defensive strategies to effectively restore customers' buyback intentions [21]. When customers face unfair transactions, defensive strategies can reduce accumulated negative emotions and restore customers' trust in enterprises. H3 assumes that when customers violate interpersonal norms and transaction norms simultaneously, service enterprises can adopt defensive strategies to more effectively restore customers' buyback intentions. When multiple unfair behaviors occur, defensive strategies can help alleviate customers' anger and restore their trust [22]. This study examined the impact and mechanism of service companies' reactions to customer mishandling on existing customers' purchase intentions through three sets of experiments. This study reveals the impact of service companies' mishandling of customers on existing customers' willingness to repurchase from organizational fairness, obligation fairness, anger, and empathy. The main research content of Experiment 1 is: 1) To examine the interactions between unfair treatment behaviors and the responses of service firms when facing different types of unfair treatment behaviors through two strategies: mediation and defense. Experiment 1 uses a 3 (coping strategies: silence strategy vs. mediation strategy vs defense strategy) x 3 (violation of interpersonal norms vs. transactional norms vs. violation of both interpersonal and transactional norms) between-groups experiment (silence strategy was the control group). After the experiment, all participants completed the manipulation check and reality assessment. The study tests the effectiveness of manipulation through multiple-choice questions (asking participants to identify "types of inappropriate behavior" and "coping strategies adopted by the enterprise"), and the correct

identification rates are all above 94%, indicating successful experimental manipulation. Participants use a 7-point scale to rate the "realism" and "credibility" of the scene ($M=5.82$, $SD=0.91$), confirming the good realism of the scene materials and effectively supporting the internal validity of the experiment. The subjects were randomly divided into nine groups, and the data obtained from Experiment 1 are organized and analyzed using Excel and SPSS 24.0. The specific groupings of the nine groups are shown in Table II.

TABLE II. SPECIFIC GROUPING OF EXPERIMENT 1

Experimental group number	Types of customer misconduct treatment	Coping strategies
1	Violating interpersonal norms	Silence strategy (control group)
2	Violating interpersonal norms	Reconciliation strategy
3	Violating interpersonal norms	defensive strategy
4	Violating transaction norms	Silence strategy (control group)
5	Violating transaction norms	Reconciliation strategy
6	Violating transaction norms	Silence strategy
7	Simultaneously violating interpersonal and transactional norms	Silence strategy (control group)
8	Simultaneously violating interpersonal and transactional norms	Reconciliation strategy
9	Simultaneously violating interpersonal and transactional norms	Silence strategy

In Table II, the customer mistreatment behaviors and coping strategies in Experiment 1 are categorized and numbered to facilitate the statistics of the experimental results. The research data comes from a series of studies that combine laboratory-controlled experiments with online scenario surveys. All 324 valid data points are obtained through strict subject recruitment and procedural control. The participants are undergraduate students from two comprehensive universities in China, with professional backgrounds covering management, economics, and social sciences. The reason for choosing this group is that they have higher familiarity and representativeness with hotel service scenarios, and are easy to conduct controlled experiments in academic environments. Participants voluntarily register through the course system in exchange for course credits. The descriptive texts of the violation scenarios (interpersonal norms, transaction norms, and double violations) and coping strategies (silence, mediation, and defense) are adapted by the research team based on real service conflict cases, and are reviewed and revised for content validity by three experts in tourism and hotel management to ensure the authenticity and typicality of the scenarios. Experiments 1 and 2 (laboratory research): Conducted in a campus laboratory using a paper-and-pen questionnaire. Participants were randomly assigned to different experimental groups. After reading situational materials, they filled out questionnaires including manipulation tests, fairness scales, and repeat purchase intention scales on the spot. Experiment 3 (Online Survey): Implemented through a widely used professional online survey platform in China to expand the sample collection scope and simulate a more natural

reading environment. The platform sets IP address and device restrictions to prevent duplicate responses. Attention check items were embedded in the questionnaire to ensure data quality. Participants ranged in age from 18 to 25 years, with a near-equal gender distribution (160 males and 164 females). Grouping was performed using a random number table to ensure balanced sample sizes across groups (ranging from 33 to 39 participants per group). Before the experiment, participants signed informed consent forms, and data were anonymized to comply with ethical standards.

Experiment 1 consisted of four main steps. First, participants were briefed on relevant information and prohibited from discussing their answer sheets. Second, experimental materials were randomly distributed, requiring participants to imagine themselves in the described scenarios. Third, participants evaluated the improper behaviors and response options presented, as well as their repurchase intentions. Fourth, the experiment supervisor monitored the process and addressed any questions. The experimental materials consisted of scenario descriptions featuring three types of improper behavior: violation of interpersonal norms (e.g., "A customer loudly berates a service staff member in the hotel lobby for slow service"), violation of transactional norms (e.g., "A customer refuses to pay for breakfast, claiming the fee was not disclosed in advance"), and simultaneous violation of both (e.g., "A customer insults a staff member for an uncleaned room and refuses to pay the service fee"). Coping strategies included silence (e.g., "The staff member does not respond and continues working"), reconciliation (e.g., "The staff member apologizes and offers a complimentary drink"), and defense (e.g., "The staff member warns the customer and threatens to call the police"). Scenarios were crafted by the research team, each approximately 100 words, and reviewed by three tourism management experts to ensure authenticity. The experiment was conducted in a laboratory setting, lasting about 20 minutes, using paper-and-pencil questionnaires. Data from Experiment 1 were organized using Excel and analyzed with SPSS 24.0. Analytical methods included descriptive statistics (calculating means and standard deviations) and two-way ANOVA (testing main and interaction effects), with a significance level set at $p < 0.05$. Missing data (<1%) were imputed with mean values, and outliers were removed using boxplots. Since general demographic variables such as gender and age had minimal impact on the results, they were not further analyzed.

This study further explores the interaction between customer improper behavior and enterprise coping strategies and their effects on existing customers' repurchase intentions. Experiment 2 investigated the interaction between different types of customer improper behavior and enterprise coping strategies, focusing on the relationship between organizational justice and moral justice perceptions among on-site customers. Experiment 2 employed a 3 (coping strategies: silence vs. reconciliation vs defense) $\times$ 3 (violation of interpersonal norms vs. transactional norms vs. both) between-subjects design, with silence as the control group. A 7-point Likert scale (1 = strongly disagree, 7 = strongly agree) was used. On-site customers' perceptions of organizational justice, moral justice, and repurchase intentions were assessed. Participants were the same as in Experiment 1, with consistent scenario designs and

coping strategies. Measurement tools included organizational justice (7 items, e.g., "Is the staff's handling fair?" adapted from Colquitt), moral justice (6 items, e.g., "Is the customer's improper behavior handled reasonably?" adapted from Folger, 2001), and repurchase intention (2 items, e.g., "I would stay at this hotel again," adapted from Zeithaml et al., 1996). A pretest ($n = 30$) showed that Cronbach's α values exceeded 0.8 for all scales, indicating good reliability. The procedure mirrored Experiment 1, conducted in a laboratory, with an additional emotion assessment post-questionnaire (e.g., "I feel angry about the customer's behavior," 3 items). Data analysis incorporated mediation effect testing using the SPSS PROCESS macro (Model 4), with 5,000 Bootstrap samples and a 95% confidence interval to verify the mediating role of justice perceptions.

Experiment 3 utilized an online questionnaire survey to examine the impact and mechanisms of service enterprise responses to improper customer behavior on maintaining customer purchase intentions in a hotel service context. It adopted a 3 (coping strategies: silence vs. reconciliation vs defense) $\times$ 3 (confrontational behaviors: violation of interpersonal norms vs. transactional norms vs. both) experimental design. Addressing unreasonable customer behaviors, this study approached the issue from the perspective of customer violations, selecting interpersonal and transactional norm breaches and their combinations. The procedure was identical to Experiment 1. Data were collected via the Wenjuanxing platform, with participants from the same student cohort required to enter a verification code to ensure authenticity. Scenarios and measurement tools aligned with Experiment 2, with an empathy emotion variable (3 items, e.g., "I sympathize with the staff's situation"). The online survey was conducted in November 2023, yielding 324 valid responses, with each session lasting approximately 25 minutes. Beyond ANOVA, data analysis included chain mediation effect testing (PROCESS Model 6) to validate the pathway from justice perceptions to emotions to repurchase intentions. The experimental design was approved by the university ethics committee, and all data were used solely for academic purposes.

The goal of the research is to test theoretical models and psychological mechanisms, rather than building a real-time algorithmic decision-making system. Therefore, PSO serves as a data-driven feature filtering tool for subsequent statistical analysis (such as Bootstrap mediation testing), and its value lies in enhancing the robustness of statistical conclusions through optimization methods, rather than directly providing deployable management automation solutions.

This study recognizes that measuring all variables through self-assessment questionnaires during the same period may pose a common risk of methodological bias. To alleviate this issue, the following procedural measures were taken in the design and data collection process: A clear commitment was made to all participants that the questionnaire would be completely anonymous and the data would only be used for academic research to reduce their tendency to provide consistent answers based on social expectations. Disrupt the order of different construct measurement items in the

questionnaire and insert some reverse scoring questions to interrupt the participants' thinking patterns and reduce automated responses; Emphasize in the guidance that there is no right or wrong answer, and encourage participants to answer independently based on their true feelings.

IV. EFFECTS OF THE INTERACTION BETWEEN SERVICE FIRMS' COPING STRATEGIES AND TYPES OF MISTREATMENT BEHAVIORS ON CUSTOMERS IN THE ROOM

Three experiments explore the effects of service firms' misbehavior on the willingness to repurchase of those present and its mechanisms. First, the effect of organizational fairness of the presence on repurchase intentions is investigated. The reactions of individuals participating in the experiment when faced with unfair treatment are observed, and the mediating role of organizational fairness in influencing the willingness to repurchase is analyzed. Attention is paid to the participants' anger and empathy, and their mediating role in the service company's handling of the speaker's willingness to repurchase is analyzed.

A. Results of the Interaction Between Coping Strategies and Types of Mistreatment Behaviors on the Repurchase Intentions of Customers in Attendance

The effect of the interaction of misbehavior type and coping strategy on the repurchase intention of the customers present in Experiment 1 is shown in Fig. 4.

Fig. 4. The impact of the interaction between types of inappropriate behavior and coping strategies on the repurchase intention of present customers.

In Fig. 4, when coupled with appropriate customer misbehavior, it can help to modify the effect of such inappropriate behavior on the willingness of those present to repurchase. Specifically, service firms are more effective in modifying customers' willingness to repurchase for behavior that violates interpersonal norms than for defensive strategies. Relative to resolution strategies, service firms are better able to restore customers' willingness to buy by adopting defensive strategies for violations of transactional norms as well as for simultaneous violations of interpersonal norms. The reliability and validity tests of the scales in Experiment 2 are shown in Table III.

TABLE III. RELIABILITY AND VALIDITY TESTING OF THE SCALE IN EXPERIMENT 2

Variable	Measure Item	Factor loading	Cronbach's α	Composite reliability
Sense of fairness in organizing customers present	OJ1	0.806	0.904	0.941
	OJ2	0.839	/	/
	OJ3	0.829	/	/
	OJ4	0.816	/	/
	OJ5	0.706	/	/
	OJ6	0.679	/	/
	OJ7	0.675	/	/
Sense of moral fairness among customers present	DJ1	0.821	0.932	0.927
	DJ2	0.811	/	/
	DJ3	0.751	/	/
	DJ4	0.785	/	/
	DJ5	0.781	/	/
	DJ6	0.796	/	/
Present customers' willingness to repurchase	R11	0.859	0.869	0.939
	R12	0.847	/	/

In measurement tools, different constructs use different scoring criteria mainly based on two reasons: Firstly, OJ and DJ are multidimensional and continuous cognitive evaluation constructs, and their mature scales usually use multi-point Likert scales (such as 1-7 points or 1-6 points) to finely capture subtle differences in participant levels and ensure the discriminative validity of the measurements. Secondly, although the prototype scale of RI is a multi-item 7-point scale, after pre-testing, its two core items can still clearly distinguish

between "intentional" and "unintentional" decision-making tendencies on a simplified binary score (1-2 points). Therefore, in Table III, OJ1-OJ7 are the ratings of 1-7 on the Likert scale for organizational fairness of the customers present, DJ1-DJ6 are the ratings of 1-6 on the Likert scale for the moral fairness of the customers present, and R11-R12 are the ratings of 1-2 on the Likert scale for the willingness of the customers present to repurchase. The Cronbach's α for organizational fairness, moral fairness, and repurchase willingness of present customers are

all greater than 0.7. The data have reached a good internal consistency. Combined reliability is used to judge the internal quality of the data, correct the bias of the coefficients, and make the reliability estimation more accurate and reasonable. The combined reliability is required to reach the judgment standard of at least 0.7. According to the results, the smallest combined reliability of organizational fairness, moral fairness, and repurchase willingness of the customers present is $0.925 > 0.7$. The research data meet the requirements of better reliability. The data structure has better internal consistency, which facilitates subsequent data analysis. The reliability and validity tests of the scale are shown in Table IV.

In Table IV, OJ1-OJ7 are 1-7 points on the Likert scale for customer organizational fairness, DJ1-DJ6 are 1-6 points on the Likert scale for customer moral fairness, and R11-R12 are 1-2 points on the Likert scale for customer repurchase intention. The convergent validity can be judged by the standardized factor loadings of the validated factor analysis and the average extraction rate of the factors. When the factor loading coefficient of each question item is significantly greater than 0.5, and the AVE is greater than 0.5, the scale has a good convergent validity. The correlation coefficients and AVE values between the subjects' fairness evaluation and repurchase intention variables are shown in Table V.

In Table V, H1, H2, and H3 are further examined, and the interaction between customer abuse behavior types and service

company response strategies is examined for their impact on the perceived organizational and moral fairness of present customers. According to the results, the arithmetic square root of the present customers' sense of organizational fairness, sense of moral fairness, and willingness to repurchase were greater than the correlation coefficients of each variable. The interaction between the type of mistreatment behavior and coping strategies has an impact on the repurchase intention, sense of organizational fairness and sense of moral fairness of the present customers, as shown in Fig. 5.

From Fig. 5, the type of customer inappropriate treatment behavior has a significant main effect on subjects' repurchase intention, while the coping strategy has a significant main effect on repurchase intention. The interaction between the type of customer, inappropriate treatment behavior and the coping strategy will also have a significant effect on repurchase intention. Based on cognitive appraisal theory, the fairness appraisal of the customers present is a key factor influencing their affective response. Taking this as an entry point, the fairness appraisal of the customers present and their affective response act as a chain mediating effect, which influences their repurchase intention by influencing the inappropriate response of the service companies. The mediating effect values and effect sizes are shown in Table VI.

TABLE IV. RELIABILITY AND VALIDITY TESTING OF THE SCALE

Variable	Measure Item	Factor loading	Variance Contribution	AVE
Sense of fairness in organizing customers present	OJ1	0.806	31.052%	0.692
	OJ2	0.839	/	/
	OJ3	0.829	/	/
	OJ4	0.816	/	/
	OJ5	0.706	/	/
	OJ6	0.679	/	/
	OJ7	0.675	/	/
Sense of moral fairness among customers present	DJ1	0.821	29.367%	0.715
	DJ2	0.811	/	/
	DJ3	0.751	/	/
	DJ4	0.785	/	/
	DJ5	0.781	/	/
	DJ6	0.796	/	/
Present customers' willingness to repurchase	R11	0.859	12.893%	0.875
	R12	0.847	/	/

TABLE V. COMPARISON OF CORRELATION COEFFICIENTS AND AVE VALUES BETWEEN FAIRNESS EVALUATION AND REPURCHASE INTENTION VARIABLES OF PRESENT CUSTOMERS

Latent Variable	Repurchase intention	Organizational justice	Moral fairness
Repurchase intention	0.924	/	/
Organizational justice	0.561	0.835	/
Moral fairness	0.416	0.528	0.819

Fig. 5. The impact of the interaction between inappropriate treatment behavior types and coping strategies on present customers.

TABLE VI. MEDIATION EFFECT VALUE AND EFFECT QUANTITY

Effect	Mediation Path	Effect value	BootSE	95% CI
Direct effects mediate effects	Interaction item - repurchase intention	-0.0354	0.0196	(-0.0747, 0.0037)
	Interaction item - organizational fairness - willingness to repurchase	0.0637	0.0114	(0.0442, 0.0860)
Total effect	Interaction item - sense of moral fairness - willingness to repurchase	0.0374	0.0078	(0.0216, 0.0562)
		0.1105	0.0124	(0.0735, 0.1352)

In Table VI, the mediating effect of organizational fairness is 0.0637, 95% CI (0.0442, 0.0860), excluding 0. This indicates that the perceived organizational fairness of present customers plays a mediating role in the interaction between customer mistreatment behavior types and service enterprise response strategies on the influence of present customers' repurchase intention. The mediating effect of moral fairness is 0.0374, 95% CI (0.0216, 0.0562), excluding 0. This indicates that the moral fairness of present customers plays a mediating role in the interaction between customer abuse behavior types and service company response strategies on present customers' willingness to repurchase. The results in Fig. 5 and Table VI clearly reveal the matching effect between violation types and coping strategies: Mediation strategies are most effective in enhancing dual justice under interpersonal violations, while defense strategies under transactional and dual violations play a dominant role through organizational justice pathways. This

directly validates H1-H3, indicating that the effectiveness of the strategy is not universal, but highly dependent on the violation, providing a data foundation for subsequent mechanism analysis. The study aims to provide a more comprehensive report on the statistical details, effect size, and confidence intervals of hypothesis testing, and clearly explains the interaction effects. The specific results are shown in Table VII.

TABLE VII. STATISTICAL TEST RESULTS OF THE MAIN HYPOTHESIS

Hypothesis	H1	H2	H3
Violation situation	Violating interpersonal norms	Violation of transaction norms	Simultaneously violating both
Effective strategies for prediction	Mediation strategy	defense strategy	defense strategy
dependent variable	Repeated purchase intention	Repeated purchase intention	Repeated purchase intention
Statistical test (ANOVA)	F(2,162)=18.733, $p<0.001$	F(2,160)=15.420, $p<0.001$	F(2,157)=25.109, $p<0.001$
Effect size (η^2)	zero point one eight	zero point one six two	zero point two four two
95% CI for η^2	[0.086, 0.290]	[0.065, 0.260]	[0.134, 0.345]
Simple Effect Comparison (Mediation vs Defense) Mean Difference [95% CI]	0.87 [0.52, 1.22]	-1.05 [-1.42, -0.68] (Defense>Mediation)	-1.32 [-1.70, -0.94] (Defense>Mediation)
Conclusion	Support	Support	Support

The results in Table VII not only confirm the statistical significance of the three hypotheses, but also provide the effect size (η^2) and confidence interval, indicating that the strategy effect has practical significance. In the case of violating interpersonal norms, mediation strategies can significantly enhance repeat purchase intention compared to defense strategies (mean difference=0.87, $\eta^2=0.188$, moderate to large effect). Under the violation of trading norms and double violation, the defense strategy is significantly better than the mediation strategy (with mean differences of -1.05 and -1.32, and η^2 of 0.162 and 0.242, respectively, all of which are moderate to large effects). These findings clearly reveal a significant matching interaction effect between violation types and coping strategies: The effectiveness of strategies is not universal, but highly dependent on the nature of the violation behavior. This quantitatively confirms the theoretical prediction that mediation strategies respond to interpersonal conflicts by repairing harmonious relationships, while defense strategies respond to transactional conflicts by maintaining the authority of rules, providing empirical evidence for precise intervention by enterprises.

B. Chain Mediation of Organizational Fairness, Moral Fairness, Anger, and Empathy Among Present Customers

In Experiment 3, the effect of the interaction between the type of mistreatment behavior and coping strategy on the repurchase intention is shown in Fig. 6.

Fig. 6. The impact of the interaction between inappropriate treatment behavior types and coping strategies on the repurchase intention of present customers

The chain-mediated effect is tested through analysis of variance. Consumer improper service methods have a significant main effect on repurchase intention ($F(2486) = 6.594$, $p=0.001$). In scenarios involving violations of interpersonal norms, ANOVA reveals a significant main effect of coping strategies on repurchase intention ($F(2,162)=18.733$, $p<0.001$, $\eta^2=0.188$). Post hoc comparisons indicate that mediation strategies ($M=5.41$) significantly enhance customers' repurchase willingness compared to defensive strategies ($M=4.54$) (mean difference=0.87, 95% CI [0.52, 1.22]). This is consistent with the H1. This result statistically confirms that when faced with relational conflicts, the "repair relationships" strategy centered on mediation outperforms the "maintain rules" strategy centered on confrontation in restoring bystander customers' intentions. In the case of violating transaction

regulations, coping strategies have a significant impact on on-site customer purchase intentions. H2 passes the test. In both cases of violating interpersonal relationships and violating transaction norms, coping strategies have a significant impact on the repurchase intention of present customers ($F(2157) = 25.109$, $p<0.001$). Therefore, H3 passes the test. Overall, experiment 3 examined the impact and mechanism of service companies' response to customer misconduct on retention intention in the context of hotel services. Research has found that compared to defensive strategies, compromise strategies adopted by service companies that violate interpersonal norms are more conducive to the repurchase intention, organizational fairness, and sense of responsibility of on-site customers. The Bootstrap test revealed a significant sequential mediation path of "organizational fairness perception $\rightarrow$ empathy $\rightarrow$ repurchase intention" (effect size = 0.032, 95% CI [0.012, 0.058]). This not only statistically validates the sequential process where cognitive evaluation (perceived fairness) precedes emotional response (empathy) and subsequently drives behavior, but also elucidates the mechanism: By maintaining procedural fairness through defensive strategies, enterprises can first foster positive cognitive perceptions of organizational normativity (organizational fairness) among bystander customers, thereby evoking empathy for employees who have been mistreated, and ultimately translating into higher repurchase intentions. This sequential pathway provides micro-level evidence for applying cognitive evaluation theory in complex service interactions. Compared to mediation strategies, service companies have adopted more defensive strategies against violating transaction norms and interpersonal and transaction norms, which can better restore on-site customers' willingness to repurchase, organizational fairness, and sense of obligation, and generate a chain regulatory effect through organizational fairness and empathy. To fully evaluate the effectiveness of the PSO algorithm in feature selection of questionnaire data, it is compared with principal component analysis (PCA) and least absolute shrinkage and selection operator (LASSO) regression. The comparative experiment is based on standardized data collected from Experiment 1, which includes 20 initial predictor variables (measurement items covering constructs such as organizational fairness, moral fairness, and demographic variables). The study aims to predict the repeat purchase intention of on-site customers. After processing the features using PSO, PCA, and LASSO, a logistic regression model is used for prediction, and the average performance index is calculated through 5-fold cross-validation. The comparison results are shown in Table VIII.

In Table VIII, PSO has three key indicators: accuracy, AUC, and CV-MSE. The selected feature sets are superior to PCA and LASSO methods, with higher AUC values (0.901) indicating excellent discriminative ability of the model, while lower CV-MSE reflects better predictive stability. PSO identified 10 key features, achieving a more concise set of variables while maintaining the highest predictive performance. Although LASSO screens slightly more features (12) than PSO, its predictive performance is slightly lower than that of PSO in all metrics. PCA extracts principal components through linear transformation. Although it can preserve most of the variance, the obtained principal components often lack clear semantic explanations, which is an important deficiency in management

research that focuses on theoretical mechanism interpretation. In summary, the PSO algorithm demonstrates comprehensive advantages over PCA and LASSO in the application scenarios of this study: it can not only select feature subsets with strong

predictive power and simplified scale, but also maintain the theoretical interpretability of features, providing a more reliable and focused data foundation for subsequent mediation analysis based on cognitive evaluation theory.

TABLE VIII. COMPARISON OF PREDICTION PERFORMANCE OF DIFFERENT FEATURE SELECTION/DIMENSIONALITY REDUCTION METHODS

Method	Number of filtered features	Accuracy	Area Under Curve (AUC)	Cross-validation mean square error (CV-MSE)
PSO	10	0.852 ± 0.021	0.901 ± 0.018	0.132 ± 0.015
PCA	8	0.823 ± 0.024	0.865 ± 0.022	0.151 ± 0.017
LASSO	12	0.841 ± 0.023	0.887 ± 0.020	0.141 ± 0.016

The core theoretical basis of the chain mediation sequence of "fairness perception $\rightarrow$ emotion $\rightarrow$ behavioral intention" proposed in the study is derived from cognitive evaluation theory. This clearly states that an individual's cognitive evaluation of an event (such as judgment of fairness or unfairness) is the premise and motivation for triggering specific emotions (such as anger or empathy based on causation), which then lead to behavioral response. Although emotions may also have a reverse impact on cognition (i.e., there may be bidirectional or alternative pathways), this model follows the dominant logical framework of this theory for validation. Therefore, the current chain mediation test aims to verify whether this theory-driven pathway holds, and its findings provide confirmatory evidence for understanding sequential psychological processes in service interactions, while also acknowledging that future research can further explore other possible causal dynamics.

The statistical significance and effect size revealed in the above research go beyond the scope of theoretical verification and have clear practical significance, which can be directly transformed into profound insights into customer behavior and management decisions. Firstly, the effect size reveals the magnitude of changes in customer behavior. Taking core findings as an example: in the context of interpersonal norm violations, adopting mediation strategies can increase the repeat purchase intention of on-site customers by 0.87 points compared to defense strategies (7-point scale), corresponding to a bias η^2 of 0.188. Cohen's d is about 0.72, indicating a moderate to large effect size. This means that in actual service scenarios, when a customer publicly insults an employee, the company chooses to have the manager mediate, apologize, and provide care (rather than directly confronting), which can increase the probability of other customers who witnessed the incident choosing the company again in the future by about 23.5% (estimated based on the average proportion). On the contrary, when violating transaction norms (such as chargeback disputes), defense strategies have a greater intention enhancement than mediation strategies ($d \approx 0.87$). These are not small statistical fluctuations, but substantial differences that can significantly affect customer retention and lifetime value in a fiercely competitive service market.

These differences can and should effectively change management decisions. The quantified "strategy violation" matching effect in this study provides a key basis for the shift of conflict management in service enterprises from relying on intuitive experiential models to evidence-based precision interventions. Firstly, the findings support constructing a

concise on-site decision tree, where frontline employees or managers quickly determine the core nature of the violation (whether it is a "harmful relationship" or a "rule breaking"), and then initiate pre-set response protocols (mediation priority or defense priority) to improve response speed and consistency. Secondly, the effect size provides priority guidance for training and resource allocation. For example, in-depth training on "mediation skills" should focus on departments with high interpersonal interaction, such as the front desk and restaurants. Strengthen the "rule communication and execution procedures" in areas such as settlement and service signing that are prone to transaction disputes. Thirdly, enterprises can go beyond the single indicator of "quickly quelling incidents" and incorporate the feedback from bystander customers' experiences or repurchase intentions into the evaluation system of conflict management effectiveness, thereby making it the core responsibility of managers to maintain the loyalty of the "silent majority" of customers.

The Bootstrap analysis based on the PROCESS macro shows that the indirect effects of paths such as "organizational fairness $\rightarrow$ empathy $\rightarrow$ repeat purchase intention" are significant. These statistical patterns are consistent with the mechanism pathways derived from the cognitive assessment theory on which this study is based. This theory suggests that cognitive assessment takes precedence over emotional responses, providing important supporting evidence for understanding the psychological sequence in service interactions. Given that this study uses cross-sectional scenario experiments and self-assessment questionnaires, although efforts are made to control for design and statistics, the obtained mediation pathway still belongs to the relevant nature in a strict sense, revealing a theoretical association pattern between variables rather than a conclusive causal relationship. Therefore, the conclusion about the chain mechanism of specific fairness perception leading to specific emotions and subsequently driving behavior should be regarded as a powerful inference within the theoretical framework.

V. CONCLUSION

The study revealed through a series of experiments that the response effect of service companies to customer misconduct is not universal, but strictly depends on the type of violation: For interpersonal norm violations, mediation strategies are more effective by enhancing the organizational and moral justice of bystander customers. For trading norms or double violations, defense strategies mainly restore customer trust by maintaining organizational fairness. This empirically confirms the

effectiveness of the "strategy violation" matching model constructed based on cognitive evaluation theory and game theory. The theoretical contribution lies in systematically elucidating the internal mechanism of how strategies affect bystander behavior through differentiated fairness perception paths, breaking through the previous research's single focus on strategy effects or behavior types. The management inspiration is that enterprises should upgrade on-site conflict management from a standardized response to diagnostic intervention: First, quickly identify the core nature of violations, and then initiate corresponding response modes, to maintain on-site order while maximizing the willingness of bystander customers to stay.

The research conclusion fully addresses the core question raised: How can service companies manage the impact of different types of customer misconduct on bystander customers through differentiated response strategies? The research findings not only fill the research gap on the interaction effect of "violation type response strategy" and its chain mediation mechanism, but also confirm from the perspectives of cognitive evaluation and game theory that effective management essentially reshapes bystanders' fairness perception and emotional reactions through strategic signals, thereby optimizing customer retention in strategic interactions. This provides new empirical support and theoretical extension for applying social psychology theory and game theory to service recovery scenarios. However, there are still shortcomings: The valid data for the study are all sourced from college students aged 18-25. This group is mainly based on their representativeness as young and active service consumers, as well as their high compatibility with experimental controls, which is conducive to clearly testing the intrinsic validity of theoretical mechanisms in the exploratory stage. However, this sample feature may also limit the external validity of research conclusions. Compared to other social consumer groups, such as business people, family tourists, elderly consumers, etc., there may be systematic differences in consumption experience, economic independence, social experience, and tolerance and judgment criteria for service conflicts among college student samples. For example, their understanding of "organizational fairness" may be more idealized, and their acceptance of "defensive strategies" may differ from that of mature consumers who have experienced more commercial disputes. Future research can conduct cross-cultural comparisons in societies with different cultural dimensions. For example, in collectivist cultures, the effectiveness of mediation strategies against violations of interpersonal norms may be more prominent, as maintaining harmonious relationships has higher social value. In individualistic cultures, defensive strategies against violations of trading norms may be more commonly seen as a fair and professional expression. Exploring the cultural boundary conditions of fairness perception, emotional reactions, and strategic preferences will make theoretical models more globally interpretable and provide refined guidance for localized conflict management in multinational service enterprises. In addition, future longitudinal studies can examine the long-term and cumulative effects of different coping strategies on customer loyalty (such as actual repeat purchase behavior, wallet share) and brand reputation (such as word-of-mouth communication, online evaluation). For example, defense strategies may effectively maintain rules in

the short term, but in the long run, will they be perceived as lacking warmth and damaging emotional connections? In the long run, may mediation strategies be misunderstood as "mismanagement" while repairing relationships and encouraging more inappropriate behavior? Through panel data, on-site tracking, or archive data analysis, the long-term effectiveness and potential risks of management strategies can be more comprehensively evaluated.

AVAILABILITY OF DATA AND MATERIALS

The datasets generated during and/or analyzed during the current study are available from the corresponding author on reasonable request.

COMPETING INTERESTS

The authors declare no potential conflict of interest.

ETHICAL STATEMENT AND INFORMED CONSENT

I hereby certify that the experiments in the study entitled A Managerial Study on the Impact of Travel and Tourism Customers' Improper Organizational Behavior on Other Customers and Corporate Response (TTRC) were conducted with the informed consent of all participants.

It is hereby certified that informed consent was obtained from all participants for the experiments in the study entitled A Managerial Study on the Impact of Travel and Tourism Customers' Improper Organizational Behavior on Other Customers and Corporate Response.

It has been reviewed by the Department of Industrial Engineering and Management, National Kaohsiung University of Science and Technology Science and Technology Department and found to comply with the ethical requirements and agreed to be published.

Convolutional Neural Network for Chili Plant Disease Classification: A Deep Learning Approach

Erna Dwi Astuti, Widowati, Aris Sugiharto

Doctoral Program of Information System, Postgraduate School-Universitas Diponegoro, Semarang, Indonesia

Abstract—Chili peppers are a high-value horticultural crop that is highly susceptible to foliar diseases, which can significantly reduce yield and market quality. This study proposes and evaluates a Convolutional Neural Network (CNN) model based on the MobileNet-V2 architecture for chili leaf disease classification. A combined dataset consisting of 2,690 images collected from two public repositories and one field-acquired source was used in this research. The dataset was divided into training, validation, and testing subsets using an 80:10:10 ratio and underwent preprocessing steps including image resizing, data augmentation, and normalization. The proposed model was implemented using TensorFlow 2.15 and trained on the Google Colab platform. Experimental results demonstrate strong classification performance, achieving 95.6% validation accuracy and 96.8% test accuracy with a low loss value of 0.1011. All evaluated classes, anthracnose, yellow virus, leaf spot, leaf curl, and healthy leaves achieved precision, recall, and F1-scores exceeding 0.90, accompanied by near-perfect AUC values. These findings indicate that the MobileNet-V2-based CNN exhibits effective discriminative capability and generalization across heterogeneous visual conditions, highlighting its potential applicability for AI-assisted agricultural disease monitoring systems based on image processing techniques.

Keywords—Convolutional neural network; MobileNet-V2; chili plant disease; image processing

I. INTRODUCTION

Chili peppers are a high-value horticultural commodity that plays a critical role in local consumption and regional economies [1]. Disease outbreaks in chili crops can therefore have substantial economic and social impacts, including reduced yield and quality, disrupted supply chains, price volatility, and implications for inflation and food security [1], [2]. Previous studies have reported that certain chili diseases are capable of reducing crop yields by up to 90% [3]. While fungal pathogens alone may cause losses ranging from 10% to 80%, depending on cultivar susceptibility and environmental conditions [4]. In addition, infestations by mites and other pests have been shown to degrade fruit quality and result in yield losses exceeding 60%, reaching as high as 96.4% under severe conditions [4]. These impacts represent a global challenge, constraining agricultural productivity across diverse agroecosystems rather than being confined to specific regions [4], [5], [6].

Chili plant diseases are caused by a wide range of factors, including viral, fungal, and bacterial pathogens, as well as environmental stressors such as extreme climate variability that weaken plant defense mechanisms and accelerate disease

progression [7], [8]. In practice, disease diagnosis often relies on manual inspection by trained experts, whose services may be costly, limited in availability, or inaccessible to small-scale farmers in developing regions [9]. Moreover, visual assessment performed manually is prone to inconsistency, subjectivity, and misdiagnosis [10]. Since many chili diseases manifest through observable symptoms such as leaf discoloration, lesions, curling, and fungal growth, image-based analysis offers an effective medium for capturing diagnostically relevant features [10]. Consequently, automated image-based detection systems have the potential to provide faster, more affordable, and more consistent diagnoses, helping farmers bridge expertise gaps while maintaining crop quality and meeting increasing market demands [2], [9].

Advances in image processing and deep learning have enabled significant progress in automated plant disease detection. Image-based techniques can quantify symptomatic regions, analyze color and texture variations, and identify early-stage infections more reliably than manual observation [11]. Deep learning-based image analysis, in particular, provides a scalable and fully automated framework capable of large-scale monitoring and rapid disease identification under field conditions [12]. Among deep learning approaches, Convolutional Neural Networks (CNNs) are well-suited for visual classification tasks due to their ability to hierarchically learn discriminative features directly from raw pixel data [13], [14], [15], [16]. Through convolutional operations, weight sharing, and pooling mechanisms, CNNs efficiently capture disease-related patterns ranging from low-level textures to high-level morphological indicators without requiring handcrafted feature extraction [14], [15], [16].

In agricultural settings, real-world implementation introduces constraints that are often underestimated. Farmers typically use devices with limited computational capacity, such as smartphones or low-power edge systems, and agricultural image datasets are usually small and highly diverse due to differences in illumination, background, camera specifications, and field environments. These limitations emphasize the need for lightweight CNN models that achieve a balance between predictive accuracy and computational efficiency. MobileNet-V2 fulfills this requirement by employing depthwise separable convolutions, inverted residual structures, and linear bottlenecks, which substantially reduce computational complexity and memory demands while preserving strong feature representation capabilities [10], [17], [18]. Therefore, MobileNet-V2 is well-suited for mobile or edge-based agricultural deployment scenarios [19].

Several previous studies have explored CNN-based approaches for chili leaf disease classification. Reported methods range from custom CNN architectures achieving accuracies above 95% [20] to evaluations of pre-trained models such as DenseNet, EfficientNet, and NasNet-Mobile on curated datasets [21]. Comparative studies have also shown that MobileNet-V2 can outperform conventional CNN baselines and achieve competitive performance relative to heavier architectures [10]. Despite these encouraging results, most existing studies rely on single-source datasets or images collected under controlled conditions. Such experimental setups increase the risk of overfitting and limit the evaluation of model robustness when applied to heterogeneous real-world scenarios. To date, no prior work has systematically evaluated MobileNet-V2 using a combined dataset integrating multiple public sources with field-collected images.

Motivated by these limitations, this study proposes an image-based chili disease classification approach using a MobileNet-V2-based CNN evaluated on a heterogeneous multi-source dataset composed of two public repositories and one field-collected dataset. This design enables the model to be assessed under diverse visual conditions, including variations in illumination, background complexity, and image quality, which more closely reflect real deployment environments. The objective of this study is to evaluate the performance of MobileNet-V2 across standard classification metrics, including accuracy, precision, recall, and F1-score [22], [23], and ROC-AUC, following preprocessing steps such as resizing, data augmentation, and normalization. The primary contribution of this work lies in evaluating a lightweight MobileNet-V2 architecture under a heterogeneous multi-source dataset, providing empirical insight into cross-domain robustness and performance consistency across different acquisition environments, which remains underexplored in existing studies. This study provides practical insight into how lightweight CNN models behave under heterogeneous real-world data conditions, particularly in terms of robustness, generalization, and suitability for resource-constrained deployment.

The remainder of this study is organized as follows. Section II describes the dataset, preprocessing procedures, and the proposed CNN architecture. Section III presents the experimental results and discussion. Finally, Section IV concludes the study and outlines directions for future research.

II. METHODS

This section presents the dataset construction, preprocessing steps, and model training strategy used in this study. A composite dataset of 2,690 chili leaf images was compiled from two public repositories and one field-observed source to capture variability in image quality and acquisition conditions. After preprocessing, the dataset was split into training, validation, and test sets using an 80:10:10 ratio. The training and validation sets were used for model learning and performance monitoring, while the test set was reserved for final evaluation. A MobileNet-V2-based Convolutional Neural Network (CNN) was employed due to its computational efficiency and effective feature representation.

Fig. 1. Workflow diagram of the proposed method.

Based on Fig. 1, the research workflow is elaborated in detail to provide a comprehensive understanding of the methodological processes undertaken in this study, as follows:

A. Dataset

The dataset used in this study is a composite collection obtained from multiple sources. It comprises 400 images from the Kaggle dataset “Penyakit Cabai”, 318 images from the Roboflow dataset “PENYAKIT PADA CABAI Computer Vision Model”, and 756 images from the “Tanaman Cabai Computer Vision Model”, resulting in a total of 1,074 publicly sourced images. In addition, 1,616 images were collected through direct field observations conducted in Kampung Sayur Bledaran and Desa Mlandi, Garung District, Wonosobo, between 27 April 2025 and 12 May 2025. Overall, the final dataset consists of 2,690 images categorized into five classes: healthy, anthracnose, yellow virus, leaf spot, and leaf curl. To provide a clear overview of the dataset composition across different sources, the distribution of images is summarized in Table I.

TABLE. I. DATASET COMPOSITION BY SOURCE

Source	Distribution Data		
	Train	Val+Test	Total
Kaggle	320	80	400
Roboflow	-	-	1.074
Field Observation	-	-	1.216
Total			2.690

The integration of heterogeneous data sources was intentionally designed to assess model robustness under diverse visual conditions. This design enables evaluation not only on overall accuracy but also on the model's ability to generalize across different acquisition domains. As shown in Table I, the dataset combines publicly sourced and field-acquired images, with a larger proportion of field data, supporting evaluation under realistic acquisition environments.

B. Dataset Composition and Balancing Strategy

The initial dataset exhibited noticeable class imbalance, with several classes containing substantially more samples than others. To mitigate biased learning, a controlled balancing strategy was applied before model training. Samples from the majority classes were randomly reduced, while minority classes were expanded through data augmentation to achieve a uniform target size.

Data augmentation was applied exclusively to the training set using lightweight geometric transformations, including limited rotations ($\pm 10^\circ$) and horizontal and vertical flipping. No augmentation was applied to the validation or test sets to preserve unbiased evaluation. To further prevent potential data leakage, dataset splitting was performed before augmentation, ensuring that no augmented samples derived from the same original image appeared across different subsets.

Following the balancing process, 2,500 images were retained, evenly distributed across the five disease classes. All images were resized to 224×224 pixels and normalized using the MobileNet-V2 preprocessing function, scaling pixel values to the range $[-1, 1]$. Table II summarizes the dataset size before and after balancing to ensure transparency and reproducibility.

TABLE. II. DATASET BALANCING SUMMARY

Description	Number of Images
Total dataset (before balancing)	2.690
Total dataset (after balancing)	2.500
Number of classes	5
Samples per class (after balancing)	500

Due to the integration of multiple data sources, the exact per-class distribution before balancing is not reported in detail. However, the final dataset was carefully balanced to ensure an equal number of samples (500 images) for each class.

The balanced dataset was subsequently split into training, validation, and test subsets using an 80:10:10 ratio. Only the training set was shuffled during data generation, while the validation and test sets remained unshuffled to ensure consistent evaluation.

C. Data Preprocessing

Data preprocessing was conducted to ensure that all input samples were compatible with the MobileNet-V2-based CNN and suitable for efficient feature learning. The preprocessing pipeline focused on image initialization, resizing, normalization, and dataset partitioning.

All chili leaf images were first loaded and converted into numerical tensor representations required for CNN computation. Each image was then resized to 224×224 pixels with three RGB channels to conform to the input specifications of the MobileNet-V2 architecture, ensuring uniform dimensionality and computational efficiency during convolutional operations.

Input normalization was subsequently applied using the MobileNet-V2 preprocess_input function, which scales pixel values to the range $[-1, 1]$. This step aligns the input distribution with the expectations of the pre-trained network, improves numerical stability, and accelerates training convergence.

Dataset balancing and data augmentation were performed before preprocessing, as described in the dataset composition stage. After preprocessing, the dataset was partitioned into training, validation, and test subsets using an 80:10:10 ratio. Class labels were encoded using a one-hot representation to support multi-class classification. During data generation, only the training set was shuffled to enhance generalization, while the validation and test sets remained unshuffled to ensure consistent and reproducible evaluation.

D. Training Using MobileNetV2-Based CNN

Model training was performed using a Convolutional Neural Network based on the MobileNet-V2 architecture with a transfer learning approach. The base MobileNet-V2 network was initialized with ImageNet pre-trained weights, enabling the model to leverage generic visual features learned from large-scale natural image data and thereby improve convergence efficiency when applied to a moderate-sized agricultural dataset.

To adapt the pre-trained backbone to the chili leaf disease classification task, several task-specific layers were added on top of the base network. These included a Global Average Pooling layer to aggregate spatial feature maps, followed by a fully connected Dense layer with 256 neurons and ReLU activation to learn high-level discriminative representations. Two Dropout layers with a rate of 0.3 were inserted to reduce overfitting by introducing regularization during training. The final classification layer employed a Softmax activation function to output class probabilities for the five disease categories.

The network was trained using the Adam optimizer with a learning rate of 1×10^{-4} and categorical cross-entropy as the loss function, while classification accuracy was used as the primary evaluation metric. This configuration was selected based on preliminary experimentation and aligned with commonly reported settings in lightweight CNN-based classification studies.

To further control overfitting and avoid unnecessary computation, an EarlyStopping mechanism was employed by monitoring the validation loss with a patience of 25 epochs and restoring the best-performing model weights. Training was automatically terminated when no improvement in validation loss was observed over consecutive epochs.

Overall, the adopted training strategy was designed to achieve an effective balance between predictive accuracy, computational efficiency, and model robustness, supporting reliable deployment in automated chili plant disease classification applications.

E. Training Configuration and Implementation Details

This subsection clarifies the exact training configuration and implementation details used in the experimental setup to ensure methodological transparency and reproducibility.

The MobileNetV2 backbone was initialized with ImageNet pre-trained weights and employed strictly as a fixed feature extractor. All convolutional layers of the backbone were frozen during training, and no fine-tuning was performed. This design choice was adopted to preserve the general visual representations learned from large-scale natural images and to reduce the risk of overfitting, given the moderate size of the chili leaf dataset. As a result, the model serves as a strong, lightweight baseline for evaluating performance under heterogeneous multi-source data without additional architectural modifications.

A custom classification head was constructed on top of the frozen backbone. This head consists of a Global Average Pooling layer to aggregate spatial feature maps, followed by a fully connected Dense layer with 256 neurons and ReLU activation. Dropout regularization with a rate of 0.3 was applied to the classifier to improve generalization by limiting co-adaptation of neurons. The final output layer uses a Softmax activation function to produce probability distributions over the five disease classes.

Model optimization was performed using the Adam optimizer with a learning rate of 1×10^{-4} and categorical cross-entropy as the loss function. The model was trained using a batch size of 42 for a maximum of 100 epochs. Although an EarlyStopping mechanism with a patience of 25 epochs was configured to monitor validation loss, the stopping criterion was not activated, and training proceeded until the maximum number of epochs was reached. This indicates that no abrupt validation performance degradation was observed during training.

All experiments were conducted on the Google Colab platform, and the total training time required to complete 100 epochs was approximately 5,779.30 seconds. This relatively efficient training process highlights the suitability of the MobileNetV2-based architecture for practical deployment scenarios where computational resources may be limited. The implementation details and training configuration are reported to facilitate reproducibility and future comparative studies.

F. Model Evaluation Strategy

The model evaluation strategy was designed to assess both the learning behavior during training and the generalization

capability of the trained MobileNetV2-based CNN on previously unseen data. Two independent datasets, namely the validation and test sets, were employed for this purpose.

During training, model performance was monitored using the validation set, which was completely excluded from the optimization process. Validation accuracy and validation loss were used to track learning progress, detect overfitting, and support early stopping decisions. This evaluation stage provides insight into the model's ability to generalize beyond the training data while maintaining stable convergence.

After training completion, the final model was evaluated using the independent test set, which had not been exposed to the model during either training or validation. Model predictions were compared with ground-truth labels to compute quantitative performance metrics, including accuracy, precision, recall, F1-score, and the area under the receiver operating characteristic curve (AUC-ROC). These metrics collectively characterize the model's classification effectiveness, sensitivity to minority classes, and overall robustness.

To further analyze classification behavior across disease categories, a confusion matrix was employed to visualize correct and incorrect predictions for each class. This analysis enables a detailed examination of misclassification patterns and provides a comprehensive assessment of the model's reliability for practical chili plant disease identification. In addition, to assess generalization across different acquisition environments, the test set was further analyzed by grouping samples based on their source (public datasets and field-acquired images). This source-aware evaluation provides additional insight into cross-domain robustness.

III. RESULTS AND DISCUSSION

This section reports the experimental results and provides an in-depth discussion of the learning dynamics and generalization behavior of the proposed MobileNetV2-based CNN for chili plant disease classification. Using a heterogeneous dataset compiled from public sources and field observations, the evaluation focuses not only on overall classification performance but also on training stability, class-wise prediction behavior, and potential limitations of the experimental protocol.

A. Analysis of Training Performance

This subsection analyzes the training behavior of the proposed MobileNetV2-based CNN to evaluate learning convergence, stability, and generalization characteristics. The model was trained for a maximum of 100 epochs using the Adam optimizer with a learning rate of 1×10^{-4} and a batch size of 42. Although an EarlyStopping mechanism with a patience of 25 epochs was configured to monitor validation loss, the stopping criterion was not triggered, and training proceeded until the maximum number of epochs was reached. This behavior suggests that the model maintained stable validation performance without abrupt degradation.

Table III summarizes the classification accuracy and loss obtained on the validation dataset at the final training epoch.

TABLE. III. EVALUATION RESULTS ON THE VALIDATION DATA

Metric	Value
Accuracy	0.9560
Loss	0.1113

The validation accuracy of 95.6%, accompanied by a low loss value of 0.1113, indicates that the model achieves a favorable balance between predictive performance and training stability. The relatively low validation loss suggests that the discrepancy between predicted probabilities and ground-truth labels remains limited, reflecting effective optimization rather than memorization of training samples.

To further examine learning dynamics, accuracy, and loss curves for both training and validation phases were analyzed, as illustrated in Fig. 2.

Fig. 2. Training and validation accuracy and loss curves.

As shown in Fig. 2, both training and validation accuracy increase rapidly during the initial training phase and begin to stabilize after approximately the 30th epoch. This early stabilization suggests that the pre-trained MobileNetV2 backbone is able to extract discriminative low- and mid-level visual features efficiently, even when applied to a moderately sized agricultural dataset. Importantly, the gap between training and validation accuracy remains small and consistent throughout the training process, indicating stable generalization behavior.

The absence of divergence between training and validation loss, despite training reaching the full 100 epochs, can be attributed to several architectural and training design choices. These include freezing the pre-trained MobileNetV2 backbone to limit the number of trainable parameters, the use of global average pooling to reduce model complexity, and dropout regularization with a rate of 0.3 applied to the fully connected layers. Collectively, these mechanisms constrain model capacity and reduce sensitivity to noise or dataset-specific artifacts, thereby mitigating overfitting even during extended training.

From a computational perspective, the total training time was approximately 5,779.30 seconds when executed on the Google Colab platform, highlighting the computational efficiency of the MobileNetV2-based architecture for practical deployment scenarios.

Overall, the observed convergence behavior demonstrates that the proposed CNN achieves stable learning dynamics and consistent validation performance, providing a reliable foundation for subsequent evaluation on completely unseen test data.

B. Analysis of Model Testing Outcomes

Testing was conducted on a held-out test set to evaluate the generalization capability of the proposed MobileNetV2-based CNN on previously unseen data. The test dataset was strictly separated from both training and validation processes to minimize evaluation bias. Although a source-wise breakdown was considered, no significant performance variation was observed across sources based on qualitative inspection. The overall classification accuracy and loss obtained on the test set are reported in Table IV.

TABLE. IV. PERFORMANCE EVALUATION ON THE TEST SET

Metric	Value
Accuracy	0.9680
Loss	0.1011

The test accuracy of 96.8%, accompanied by a loss value of 0.1011, indicates that the trained model maintains strong predictive performance when applied to unseen chili leaf images. Interestingly, the test loss is slightly lower than the validation loss, which may be attributed to random variation in dataset splitting, where the test set may contain slightly less complex samples. Such variation is common in single-split evaluation settings and does not necessarily indicate model bias. This result suggests that predicted class probabilities remain well aligned with ground-truth labels, reflecting stable generalization rather than overconfident or random predictions.

To provide a more granular assessment, per-class performance metrics including precision, recall, and F1-score were computed for each disease category, as summarized in Table V.

TABLE. V. PER-CLASS PERFORMANCE ASSESSMENT

Class	Matrix		
	Precision	Recall	F1-Score
Healthy	0.96	1.00	0.98
Anthraco nose	1.00	1.00	1.00
Yellow Virus	0.96	0.94	0.95
Leaf Spot	0.98	0.98	0.98
Leaf Curl	0.94	0.92	0.93

The results indicate consistently strong performance across all disease categories. The Anthracnose class achieves perfect scores, suggesting that its visual characteristics are highly distinctive and easily separable by the model. Other classes also demonstrate balanced precision and recall values above 0.90, indicating reliable classification performance without severe class-specific bias. Slightly lower recall values observed in the Yellow Virus and Leaf Curl classes may be attributed to visual similarities among disease symptoms, which can introduce ambiguity even for human observers.

To further analyze prediction behavior, a confusion matrix was generated to visualize correct and incorrect classifications across all categories. The results are shown in Fig. 3.

Fig. 3. Confusion matrix of model predictions on the test set.

The confusion matrix reveals that most predictions are concentrated along the main diagonal, confirming high overall classification accuracy. Minor misclassifications occur primarily among visually similar disease categories, such as Yellow Virus and Leaf Curl, suggesting that remaining errors are associated with subtle inter-class feature overlap rather than systematic model failure.

In addition, multiclass ROC–AUC analysis was performed to evaluate the model’s discriminative capability across all categories. The ROC curves and corresponding AUC values are presented in Fig. 4.

Fig. 4. Multiclass ROC–AUC evaluation results.

The obtained AUC values are notably high, with scores of 1.00 for the Healthy, Anthracnose, Yellow Virus, and Leaf Spot classes, and 0.99 for the Leaf Curl class. These results indicate strong class separability and confirm that the model achieves a high true positive rate while maintaining a low false positive rate. However, such near-perfect AUC values should be interpreted with caution, given the evaluation protocol.

It is important to acknowledge that the reported results are based on a single random train–validation–test split without repeated experiments or cross-validation. While data augmentation was applied exclusively to the training set to prevent data leakage, the absence of confidence intervals, repeated runs, and source-aware evaluation may limit the

statistical robustness of the reported metrics. Consequently, future work will focus on incorporating cross-dataset validation, repeated experiments with multiple random seeds, and confidence-based statistical analysis to further strengthen the reliability and generalizability of the proposed approach.

Overall, despite these limitations, the testing results demonstrate that the MobileNetV2-based CNN exhibits strong and consistent classification performance on unseen chili leaf images, supporting its potential applicability for automated plant disease identification under controlled deployment scenarios.

C. Error and Failure Mode Analysis

This subsection examines the error characteristics and failure modes of the proposed MobileNetV2-based CNN to better understand the limitations of the model beyond aggregate performance metrics. Rather than focusing solely on overall accuracy, this analysis aims to identify systematic misclassification patterns and their potential causes, as revealed by the confusion matrix and per-class evaluation results.

An inspection of the confusion matrix indicates that misclassifications are not randomly distributed across classes. Instead, most errors are concentrated among visually similar disease categories, particularly Yellow Virus, Leaf Spot, and Leaf Curl. In contrast, the Healthy and Anthracnose classes exhibit near-perfect classification performance, suggesting that their visual features are more distinctive and consistently captured by the model.

The observed confusion among Yellow Virus, Leaf Spot, and Leaf Curl can be attributed to overlapping visual symptoms, especially during early disease stages. In several test samples, these diseases present subtle color variations, mild texture irregularities, or partial leaf deformation, making class boundaries less distinct. Such characteristics may limit the discriminative power of convolutional features extracted by a lightweight architecture when symptom severity is low.

In addition, qualitative inspection of misclassified samples reveals that many errors occur in images captured under non-uniform lighting conditions, varying contrast levels, or complex backgrounds. These environmental factors can suppress or distort disease-specific visual cues, causing the model to rely on incomplete or ambiguous feature representations. This effect is particularly pronounced in field-acquired images, where illumination and background consistency are harder to control compared to curated public datasets.

Importantly, the relatively high precision and recall values reported in Table V indicate that these failure cases represent a small fraction of the overall predictions. However, their consistent occurrence within specific disease pairs suggests an inherent challenge in distinguishing morphologically similar symptoms rather than random model instability or data leakage.

Overall, this error analysis demonstrates that the limitations of the proposed model are primarily associated with visual overlap between disease categories and early-stage symptom ambiguity, rather than deficiencies in the training process or

model convergence. These findings highlight the need for future enhancements, such as incorporating attention mechanisms, multi-scale feature extraction, or temporal disease progression analysis, to improve robustness under challenging real-world conditions.

D. Qualitative Robustness Analysis Under Data Variability

This subsection provides a qualitative analysis of the model's robustness when exposed to data variability arising from heterogeneous image acquisition conditions. Unlike quantitative robustness assessment, which typically requires source-wise cross-validation or repeated experimental runs, this analysis focuses on observable performance consistency across diverse data characteristics present in the dataset.

The dataset employed in this study was constructed from heterogeneous sources, including publicly available repositories and field-acquired images. As a result, the input samples exhibit substantial variability in terms of image resolution, background complexity, illumination conditions, and capture devices. Public datasets generally contain images acquired under relatively controlled conditions, whereas field observations introduce natural variations such as uneven lighting, shadows, cluttered backgrounds, and differences in camera distance and orientation.

Despite this variability, the proposed MobileNetV2-based CNN demonstrates consistently strong performance across all disease classes, as reflected in the per-class precision, recall, and F1-score values reported in Table V. All classes achieve F1-scores above 0.90, indicating that classification effectiveness is maintained across a wide range of visual conditions rather than being dominated by a specific subset of images.

The confusion matrix further supports this observation, showing that correct predictions are heavily concentrated along the main diagonal for all classes. Misclassifications are limited in number and primarily occur among visually similar disease categories, rather than being associated with a particular acquisition source or extreme image degradation. This suggests that the model's performance degradation, when present, is driven more by intrinsic visual overlap between disease symptoms than by external variations such as lighting or background noise.

Although no explicit source-aware evaluation or cross-dataset validation was conducted, the stable validation and test performance, combined with high AUC values across all classes, provide indicative evidence of performance consistency under heterogeneous image conditions within the evaluated dataset introduced by heterogeneous acquisition conditions. This behavior can be partially attributed to the use of a pre-trained MobileNetV2 backbone, which has been shown to learn generalizable low- and mid-level visual features that are less sensitive to superficial image variations.

Overall, this qualitative robustness analysis suggests that the proposed approach is capable of maintaining reliable classification performance under diverse real-world imaging conditions. However, future work may further strengthen this assessment by incorporating source-wise evaluation protocols

or domain adaptation techniques to explicitly quantify robustness across acquisition environments.

E. Discussion

This study investigates the effectiveness of a MobileNetV2-based convolutional neural network for chili plant disease classification using heterogeneous image data. The experimental results demonstrate that the proposed approach achieves high classification performance while maintaining stable learning behavior and computational efficiency, which are critical factors for real-world agricultural applications.

From a training perspective, the observed convergence behavior indicates that the transfer learning strategy plays a crucial role in enabling effective feature extraction from a moderately sized dataset. The early stabilization of both training and validation accuracy, combined with the absence of loss divergence even after extended training, suggests that the pre-trained MobileNetV2 backbone provides a strong inductive bias toward generalizable visual features. Architectural constraints such as global average pooling and dropout regularization further contribute to controlling model complexity, thereby reducing the risk of overfitting despite the limited variability typically associated with agricultural image datasets.

The testing results confirm that the learned representations generalize well to unseen data. The high-test accuracy and consistently strong per-class precision, recall, and F1-score values indicate that the model does not disproportionately favor specific disease categories. In particular, the perfect classification performance observed for the Anthracnose class suggests that diseases with distinctive visual manifestations are effectively captured by the convolutional features. Meanwhile, slightly lower recall values for Yellow Virus and Leaf Curl highlight the inherent difficulty of distinguishing diseases with overlapping visual symptoms, especially when severity levels vary across samples.

Error and failure mode analysis further reveals that misclassifications are systematic rather than random. Most errors arise from morphological similarity between disease symptoms or from images acquired under challenging environmental conditions. This finding underscores a key limitation of lightweight CNN architectures: while they offer computational efficiency, their representational capacity may be constrained when fine-grained visual distinctions are required. Nevertheless, the relatively small number of such errors indicates that the proposed model maintains robust overall performance without exhibiting instability or class-specific collapse.

The qualitative robustness analysis provides additional insight into the model's behavior under data variability. Despite being trained and evaluated without source-aware validation, the model demonstrates consistent performance across images with varying resolutions, backgrounds, and lighting conditions. This suggests that the learned features are not overly sensitive to superficial image characteristics and can tolerate moderate domain shifts commonly encountered in field-acquired agricultural data. Importantly, this robustness is

presented as indicative rather than absolute, acknowledging the methodological limitations of the evaluation protocol.

Compared to previous studies employing convolutional neural network approaches and pre-trained models for chili leaf disease classification [10], [21], the proposed MobileNetV2-based model achieves comparable classification performance while maintaining lower computational complexity. While some studies report strong accuracy using alternative CNN configurations, these approaches often involve increased model complexity or parameter tuning, which may limit their applicability in resource-constrained agricultural environments. The observed performance differences may be attributed to variations in dataset composition, particularly the use of heterogeneous multi-source data in this study, which introduces higher variability compared to controlled datasets used in prior work. This efficiency, combined with stable convergence behavior, highlights the suitability of MobileNetV2-based models for deployment in resource-constrained environments such as mobile devices or edge-based agricultural monitoring systems.

Despite these strengths, several limitations must be acknowledged. The evaluation relies on a single train-validation-test split, without repeated experiments or cross-dataset validation. Additionally, the absence of temporal disease progression data limits the model's ability to distinguish early-stage symptoms that exhibit high visual similarity. Addressing these limitations through repeated experiments, domain adaptation strategies, and multimodal or temporal data integration represents an important direction for future research.

Importantly, this study highlights the practical value of evaluating lightweight CNN architectures under heterogeneous multi-source data conditions, which more closely reflect real-world agricultural scenarios compared to controlled datasets.

Overall, the findings of this study demonstrate that a carefully designed lightweight CNN, supported by transfer learning and appropriate regularization strategies, can achieve reliable and consistent performance for chili plant disease classification. The results support the feasibility of deep learning-based approaches for practical agricultural disease monitoring while highlighting avenues for further methodological refinement.

F. Disclosure and Conflict of Interest

The author declares no conflict of interest related to this research. There are no financial interests, personal relationships, or competing affiliations that could have influenced the conduct or outcomes of this study. This manuscript is original, has not been published previously, and is not under review by any other journal or conference.

ACKNOWLEDGMENT

This activity is supported by the High-Performance Computing Laboratory and the Research Cluster for Mathematical Modeling and Optimization, Diponegoro University, Indonesia.

Blockchain-Based Secure Data Sharing Framework: Dual Validation Through Content Validity and Thematic Analysis

Azman Azmi¹, Farashazillah Yahya^{2*}, Nur Afrina Azman³

Faculty of Computing and Informatics, Universiti Malaysia Sabah, Malaysia^{1, 2}

School of Mathematical, Physical and Computational Sciences, University of Reading, United Kingdom³

Abstract—Blockchain technology applied to digital government services platforms has introduced new possibilities for secure data sharing for public sector agencies. However, the verification and validation of critical security factors remain underexplored, leading to inconsistent security factors for implementations and theoretical gaps. This study addresses this issue by conducting a double validation analysis of security factors relevant to blockchain-based data sharing in e-government applications using thematic analysis and content validity index. Drawing from an extensive literature review, 54 security items from nine factors were evaluated by a panel of six domain experts using the methodological triangulation. The results indicate that key factors of confidentiality, integrity, availability, decentralisation, interoperability, transparency, auditability, and governance exhibit strong content validity and themes for thematic analysis. Immutability factors are outside the Universal Agreement (UA) scale and require further refinement. The validated framework contributes to both academic and practical domains by offering concrete fundamentals for secure system design and policy formulation. Future research directions include operational testing of validated factors and exploration of user-centric verification.

Keywords—Blockchain; content validity; data sharing; e-government; thematic analysis

I. INTRODUCTION

Recent years have witnessed a growing academic interest in integrating digital emerging technologies to support public sector services, potentially affecting the business and the citizens [1], [2]. Integrating social, legal, technological, and economic dimensions has demanded an increasing complexity of security and data protection, requiring a comprehensive approach in this digital era [3]. The widespread digitisation of services and the proliferation of data-driven e-government systems have created the demand for secure data sharing. The current trend of utilising decentralised platforms in public sectors is increasing to ensure reliability in sharing sensitive information, necessitating mechanisms that ensure data security [4]. Secure data sharing integration in information systems between government agencies in a seamless information sharing addresses new security challenges for data sharing. The transaction involves data sharing between agencies and entities [5], [6].

An increasing number of incidents and attacks have shown increasing threats to data sharing. MyCERT Cyber Incident

Quarterly Summary report released on 10 June 2025 showed 195 data breach incidents reported in Q1 2025 compared to 151 in Q4 2024. This shows an increase in incidents by 29% [7]. Interest in blockchain technology for government data sharing security has grown rapidly, but the literature still lacks clear validation of the security factors for secure data sharing. Most existing studies present conceptual frameworks or technical models without rigorous empirical validation, leaving gaps in practical applicability [8], [9], [10]. However, employing a qualitative approach allows for deeper exploration of recurring themes, perspectives, and concepts among domain experts; the research is moving towards accuracy and credibility [11].

To address these limitations, this study applies methodological triangulation using thematic analysis and content validity assessment to examine and refine a set of security factors for blockchain-based e-government data-sharing applications. By engaging subject matter experts and utilising established validation techniques, the research seeks to deliver a robust and empirically grounded framework. The findings aim to advance both theoretical understanding and practical implementation by providing a validated framework that enhances the security and reliability of blockchain-enabled public services, while also guiding future system design, policy formulation, and research in the fields of information systems, government administration, and cybersecurity.

II. BACKGROUND

A. Blockchain in E-Government: Opportunities and Challenges

Blockchain technology has gained traction in e-government initiatives due to its potential to enhance transparency, decentralisation, and provide immutability [12], [13], [14]. Studies by [15] and [16] highlight its use in digital identity management, public records, and inter-agency data sharing. Blockchain can reduce the reliance on central authorities due to its decentralised nature. This in turn will mitigate risks which are associated with single-point failures [17]. However, challenges remain, including privacy and data integrity [18], [19], [20], which hinders widespread adoption in public sector environments.

B. Blockchain-Based Data Sharing Security

Data sharing security is a cornerstone for trusted and effective e-government systems. Blockchain offers mechanisms such as smart contracts, cryptographic hashing, and distributed

*Corresponding author.

consensus to ensure data confidentiality and integrity. The authors in [21], [22] emphasise the role of blockchain in enabling trustworthy data exchange across organisational boundaries. Despite these advancements, the literature reveals a lack of standardised security factors frameworks tailored to the unique needs of e-government, particularly in multi-jurisdictional contexts.

Data sharing environments are inherently vulnerable to a wide range of security threats that may compromise confidentiality, integrity, and availability. Therefore, it is essential to systematically identify these threats and evaluate their potential consequences to inform the development of

effective security solutions. Prior research has extensively addressed this domain, with initiatives such as the Open Web Application Security Project (OWASP) providing comprehensive classifications of common security attacks and MyCERT Cyber Incident Quarterly Summary report Q2 2025 (SR-031.082025) release on 6 August 2025 showed 103 data breach incidents reported in Q2 2025 compared to 195 in Q4 2024, a decrease of incidents by 47.18%. Data breach incidents reported in Q1 2025 are 29% higher compared to 151 in Q4 2024 [7]. The following threat categories in Table I are identified for the data sharing security by OWASP Top 10 [23] and the literature:

TABLE I. DATA SHARING THREATS

Threats	Issue
False Data Injection Attacks (FDIA)	Unauthorised actors exploit system vulnerabilities to inject malicious code or commands, compromising data integrity and confidentiality. False data injection attacks (FDIA) pose a significant threat to the microgrids by corrupting information exchange among controller units [24].
Broken Authentication and Access Control	Centralised authentication and access control systems are prone to single-point failure, security threats, and privacy and scalability issues [25].
Data Breaches	Unauthorised disclosure, leakage, or theft of sensitive data, resulting in compromised confidentiality and potential legal and reputational consequences.
Insider Threats	Malicious or inadvertent actions by authorised personnel (e.g., employees or contractors) leading to data misuse, exposure, or unauthorised access.
Insecure Data Handling	Improper practices in data storage, transmission, or disposal that may result in accidental exposure, leakage, or loss of sensitive data.
Non-Compliance with Data Protection Regulations	Failure to adhere to relevant legal, regulatory, and industry standards exposes organisations to legal risks, penalties, and reputational damage.
Exposing the contents of the sensitive files to sharing parties	Sensitive data is exchanged between organisations, and we require auditability and traceability of actions taken to assure compliance with signed legal agreements. In study [26], conflict resolution may require exposing the contents of the sensitive files to this party.
Single point of infrastructure failure	The Blockchain uses a Peer-to-Peer network, where all the nodes share their resources with each other. This will also increase the Blockchain availability; if one of the nodes goes down, others are available. The blockchain operators are unknown, and the objective of the network is not clear; through validation control, they can exclude and compromise some nodes that affect their network availability [27].
Lack of standardisation and an interoperable system	In a nationalised healthcare infrastructure, a lack of standardisation and interoperable Electronic Health Records has led to medical errors, diminishing the well-being of patients [28].

C. Security Factors in Blockchain-Based Data Sharing System

Several theories on the origin of data-sharing security factors have been identified in [29]. Nine blockchain-based data-sharing security factors have been critically identified: confidentiality, integrity, availability, transparency, auditability, decentralisation, immutability, interoperability, and governance, as in Fig. 1. The description reviews also presented solutions which emerged in various industries, as an understanding of blockchain's ability to overcome constraints that have been discussed in previous literature [29]. As a continuation of the literature synthesis, a content validity was conducted in this study.

D. Validation of the Theoretical Framework

Given the fact that valid and reliable factors are needed to theoretically design and evaluate blockchain-based data sharing security factors. Validity is the extent of accuracy with which the sub-factors of the target main security factors.

1) Thematic analysis: A powerful approach used in research. Research involving the analysis of qualitative data widely uses this methodology qualitative (Mohd Noor et al., 2025; Proudfoot, 2023). Patterns, themes and meaning which

are embedded in the data could be uncovered by researchers when this method is used as an inductive approach. This will allow a deeper understanding to be facilitated based on the event [31], [32]. Thematic analysis is being used by [33] on blockchain-related agri-food business news and expert opinions from the Ovid database's Agricola section, while [34] applied a thematic network analysis approach for blockchain adoption effectiveness. The weakness of the research by [34] is that it used collected data from secondary sources, where there were no in-depth interviews with the targeted audience that were conducted to gain further understanding of the behavioural elements that impact the application of blockchain in supply chain management. Both researchers agreed that there is a need to conduct further empirical research that investigates various other perspectives

2) Content validation: A widely used method in the research validation process. Preliminary evidence of the validity of the instrument can be provided through this approach. Previous research using Aiken's V with Content Validity Index (CVI) has established a robust quantitative process validation [10]. Another approach by [35] adopted a two-stage content validation using Content Validity Ratio (CVR) and Content Validity Index (CVI), both are quantitative

methodologies. However, both studies restricted the range of methodological approaches, which did not incorporate quantitative and qualitative analysis.

Fig. 1. Blockchain-based data sharing security factors.

III. METHODOLOGY

A. Research Design

This research applied methodological triangulation, as shown in Fig. 2. Methodological triangulation is a technique defined as the combination of two or more methods in a study [11], [36]. The study employs a double validation method using thematic analysis for qualitative data analysis and a content validity approach to empirically assess the relevance and clarity of security factors associated with blockchain-based data sharing in e-government applications. By using triangulation and drawing on multiple viewpoints, this research is moving towards accuracy and credibility as it involves several sources, confirmation, and processes of data collection.

Fig. 2. Methodological triangulation methodology.

B. Instrument Development

The generation of items during questionnaire development requires considerable pilot work to refine wording and content. To assure content validity, items are generated from a number of data sharing security factors and subfactors that were compiled through an extensive literature review [29], [37], focusing on blockchain applications in public sector data sharing. 54 subfactors were translated into an open-ended questionnaire and measurable items. The items were categorised under nine key factors: confidentiality, integrity, availability, decentralised,

immutability, transparency, auditability, interoperability and governance. The instrument has gone through a test by an undergraduate student studying computer science.

C. Expert Panel Selection

A group of subject matter experts was assembled, comprising IT professionals from various backgrounds and industries in government information system security practice, to ensure robust validation. Selection criteria included:

- Minimum of ten years of experience in the Information Technology field, focusing on e-government information systems.
- Prior involvement in data and information security-related projects.
- Different types of government departments and agencies diversity to capture contextual variations.
- Government or Industry expert in Blockchain Technology or Data Security.

A total of six (6) experts participated in the validation process, as mentioned in Table II.

TABLE II. EXPERT PANEL INFORMATION

N o	Expert Initial	Domain	Expertise Area	Experienc e	Institution
1	Expert 1	Government	Information Security	> 15 years	Public University
2	Expert 2	Government	Information Security	> 15 years	Public University
3	Expert 3	Government	Blockchain, Cyber Security	> 15 years	Federal Government
4	Expert 4	Government	Blockchain, Network Security	10 - 15 years	State Government
5	Expert 5	Government	Blockchain, Fintech	10 - 15 years	State Government
6	Expert 6	Industry	Blockchain, Database, Information Security	10 - 15 years	Private Sector

D. Expert Interview

Data were collected from experts' review using interviews and questionnaire methods. The interview is done face-to-face with each and every single expert. Each session takes about two to three hours to complete. Subsequently, the results obtained were compared to identify similar answering patterns [38].

E. Thematic Analysis

Thematic analysis is a popular qualitative research approach that focuses on recognising, examining, and interpreting patterns or themes found in a dataset. A systematic, multi-step process has been used to enhance the rigour and replicability of the analysis, often culminating in a conceptual model that explains the research findings [39]. Qualitative thematic analysis was performed using Atlas.ti. The information security and blockchain technical experts all reviewed and coded data in the coding process.

1) *Key stages of thematic analysis*: Six key stages for thematic analysis are defined by [39], [30] [40], [41] using Fig. 3:

Fig. 3. Six key steps in conducting thematic analysis.

The thematic analysis process adopted in this study is characterised as systematic, as it follows a structured and sequential approach to the interpretation of qualitative data. While a clearly defined analytical framework enhances transparency and provides logical progression from raw data to codes and themes, each stage of the process inevitably relies on the researcher's interpretive judgement, which influences how meanings are constructed and prioritised. In this research, the systematic nature of the analysis facilitates consistency and allows the analytical decisions made to be traced and does not entirely eliminate potential bias. By maintaining an explicit audit trail and adhering. Nevertheless, given the complex and context-dependent nature of expert perspectives, alternative interpretations are possible, and therefore, the findings should be viewed as one plausible interpretation rather than a definitive account.

The first step is to get familiar with the transcript data. The transcript will be read several times to ensure that all terms used and explanations are well understood. The interpretation of the transcript is noted. The second step is identifying and labelling significant features of the data that are relevant to the main factors and sub-factors. The coding framework will be generated for further analysis. The next step is to search for themes. In this research, themes are determined by the main factor used in the Blockchain-based data sharing. In step 4, reviewing the theme includes the sub-factors in the main theme that have been determined before. In step 5, each theme is clearly defined and named, giving a clarification on each theme represented in relation to the factors and subfactors. In the final step, a report of the themes is presented to show the findings and implications for the factors in the research field.

F. Content Validation Procedure

Content Validity Index (CVI) can be categorised into two types, the I-CVI (item level) and S-CVI (scale level). The definition and formula were based on the recommendation by Lynn(1986), Davis (1992), Polit & Beck(2006) and Poliy et al. (2007), as cited in [42]. The instrument designed is subjected to the expert to evaluate the CVI for item (I-CVI) and scale (S-CVI) that have S-CVI/Ave and S-CVI/UA. To quantify the expert level agreement, we use the Item level of CVI on the relevance of each individual item in the measurement instrument. Each item will be rated by an expert on a 4-point ordinal scale for relevance. The 4-point scale is used to avoid a "neutral" middle point, forcing clearer judgments [42]. To calculate the I-CVI, each of the items rated as 3 (quite relevant) or 4 (highly relevant) by the experts will be counted and divided by the total number of experts shown in the formula below:

$$I - CVI = \frac{\text{No. of experts rating item as 3 or 4}}{\text{Total no. of experts}} \quad (1)$$

Scale-level Content Validity Index (S-CVI), which extends the item-level CVI (I-CVI) to the *entire instrument*. It shows overall content validity across all items. There are two main approaches: S-CVI/Ave and S-CVI/UA. S-CVI (Scale-level CVI) is used to summarise how well the *whole set of items* in an instrument reflects the construct. S-CVI/Ave (Average method). The average of the I-CVI values for all items in the instrument:

$$S - CVI/Ave = \frac{\sum I-CVI}{N} \quad (2)$$

where, N= total number of items and $\sum I-CVI$ = Sum of sub-factors in a main factor.

The S-CVI/Ave provides a mean proportion of agreement across all sub-factors in the main factors. It is more lenient than universal agreement, since it allows some items to have lower I-CVI values. A value of ≥ 0.90 is typically considered excellent overall content validity [42]. S-CVI/UA (Universal Agreement method), the proportion of items that achieved universal agreement among experts (i.e., *all* experts rated them as 3 or 4 = relevant) for the main factors evaluated in this research.

$$S - CVI/UA = \frac{\text{Number of items with } I-CVI = 1.00}{\text{Total number of items}} \quad (3)$$

Universal Agreement is much stricter than S-CVI/Ave. If even one expert rates an item as not relevant, it won't count toward universal agreement. Often produces lower values, especially when panel sizes are larger. Recommended cutoff= ≥ 0.80 because it is harder to achieve [42].

TABLE III. THE NUMBER OF EXPERTS AND THEIR INFLUENCE ON THE ACCEPTABLE CUT-OFF SCORE OF CVI.

No of experts	Acceptable CVI Values	Recommendations
2	At least 0.8	Davis (1992)
3 to 5	Should be 1	Polit & Beck (2006) Polit et. Al (2007)
At least 6	At least 0.83	Polit & Beck (2006) Polit et. Al (2007)
6-8	At least 0.83	Lynn (1986)
At least 9	At least 0.78	Lynn (1986)

Note : The definition and formula were based on the recommendation by Lynn (1986), Davis (1992), Polit & Beck (2006) and Poliy et al. (2007), as cited in [42].

Table III shows the content validity reference for the acceptable cut-off score. The correlation between the number of experts on a review panel affects the acceptable cutoff values for Content Validity Index (CVI). The reference is also shown in the table, where it refers to Davis (1992), Polit & Beck (2006), Polit et al. (2007) and Lynn (1986), as cited in [42].

In this research, we are engaging with six experts. The work we are referring to (Polit & Beck, 2006; Polit et al., 2007) and Lynn (1986), as cited in [42]. Both references agree that for at least six experts, the CVI must be equal to or higher than 0.83. The threshold to get more than 0.83 or 83% agreement is that there must be at least 5 out of 6 experts who must agree on the sub-factors. With 6 experts, some disagreement is tolerable because the chance of random agreement is much lower.

G. Ethical Considerations

For ethical consent, all the experts' participation was voluntary. Anonymity and confidentiality were maintained throughout the process. Revision and approval of the study protocols have been provided by the university, and a pilot test was conducted before it was answered by the experts.

IV. FINDINGS AND ANALYSIS

A. Overview of Experts

The expert panel evaluated a total of 9 security factors with 54 sub-factors for data sharing security-related items across nine main factor dimensions: confidentiality, integrity, availability, decentralised, immutability, transparency, auditability, interoperability and governance. Each expert shares their review for each factor and subfactor. Then, for relevance and clarity, each item was rated using a 4-point Likert scale by the experts.

B. Demographics of Experts

The demographic profile of the respondents was gathered using five questions, and the analysis is presented in Table I. Of the experts interviewed, 83.3% were from the public sector, with 33.3% representing State Government, 33.3% from Public Universities, 16.6% from Federal Government, and the remaining 16.6% from industry. All experts are from an IT Technical background and are involved in government IT and Information security projects. 50% of the experts have more than 15 years of experience, and another 50% have 10 to 15 years of experience in IT and security. All of the expert responses have 2000 to 15,000 transactions per day involving data sharing in the government information system. 66.7% of the expert are using blockchain in their environment. They used a private and consortium blockchain platform running Ethereum in a private cloud environment. The concern of using blockchain in the e-government system is security, authenticity, integrity, tamper-proof records, public verifiability, compliance, and fault tolerance.

C. Thematic Analysis Coding Result on Expert Review Interview

The theme of audibility emerged as a significant dimension underpinning system traceability and auditability. Experts 1 and 4 uniformly affirmed that "allowing traceability" and "tracking transactions" help identify the keyword for the code. These findings underline the crucial function of traceability mechanisms in data sharing auditability. It is also shown and recognised that data trackable or normally defined as audit also enables thorough post-event auditability, thereby enhancing data sharing security needs. In Fig. 4, experts noted that it "ensures that all transactions can be traced back to their origin," which is the keyword of "essential for auditability and security," and emphasised how "data are tracked and can be audited." These remarks suggest that audibility not only supports technical oversight but also provides evidentiary value. Consequently, systems designed with robust traceability features are better equipped to manage demands, ensure fairness, and uphold stakeholder confidence in data sharing.

Confidentiality was identified as a theme, bridging the codes of secure access, data privacy, trust, confidentiality, privacy,

authenticity, authentication, authorisation and sovereignty. Experts highlighted that "verifying authenticity is important to ensure data validity and access control" and that "Transparent data ensures that shared information is authentic and free from manipulation" has the key findings of authenticity with secure access control as the code used for this result. The experts also highlighted "Data openness helps build trust between parties sharing data" and "architecture and cryptographic safeguards ensure data confidentiality", for trust and confidentiality. The keyword of privacy is critically important, and the proper authentication keyword is highlighted by the expert for privacy and authentication. While for authorisation, the expert stated "consensus mechanism will authorise which node will write or read data", which can be coded for authorisation in confidentiality themes.

Fig. 4. Thematic analysis result for auditability.

Integrity emerged as a comprehensive theme incorporating reliability, validity, credibility, accountancy, accuracy and verifiability. Experts consistently remarked that digital public services must be "secure, accountable, transparent, and reliable," while emphasising the importance of "ensuring data validity and data integrity". These insights suggest that integrity is the backbone of trustworthy systems, covering technical correctness and ethical stewardship. In public sector applications, data integrity is essential to uphold service productivity.

Moreover, ensuring integrity is closely linked to building trust and institutional legitimacy. Experts conveyed that improving data integrity is vital "to build trust and credibility" and "enforce accountability". They also highlighted accurate data input and verifiability as prerequisites for maintaining stakeholder confidence. This reflects a recognition that integrity encompasses both accuracy and the perception of fairness. Consequently, designing systems that ensure and demonstrate integrity is essential for public accountability and trust.

The availability of data consistently emerged as a foundational requirement for effective digital systems. Experts emphasized that "making data consistently available is... a cornerstone for data sharing", and that stakeholders must be "able to control data access in and out". These findings highlight the importance of both technical accessibility in ensuring functional utility. In environments where timely information is critical—such as governmental decision-making systems—any interruption in availability could severely undermine operational effectiveness, as shown in Fig. 5.

Fig. 5. Thematic analysis result for availability.

In addition, one expert remarked that “participants trust that the data being shared is accurate and consistent”, illustrating how availability underpins both confidence in e-government systems and their actual performance. This implies that design strategies aimed at ensuring continuous access must also safeguard data integrity. Ensuring consistent availability thus fosters not only immediate usability but also long-term trust and system credibility.

The analysis also revealed decentralisation as a theme in the blockchain-based data sharing security factors. Expert 3 emphasised that blockchain “unlocks the full potential... to deliver credible, real-time, and decentralised data sharing across industries”, highlighting the importance of decentralised infrastructure for enhancing transparency and credibility. Similarly, Expert 6 noted that “fault tolerance and decentralised enable recovery and readiness data”, indicating that decentralisation also contributes to system robustness and continuity. These statements were coded under “Decentralise” and contributed to the overarching theme of Decentralise, which encompasses both technical and operational benefits of decentralised systems. Additional insights from Expert 3 regarding “distributed ledger architecture” and from Expert 5 referencing data being “securely stored in a separate location” were coded as “Distributed”, reinforcing the decentralised theme. Collectively, the data suggest that experts view decentralisation not only as a structural feature of blockchain but also as a critical enabler of data security, trust, and recovery in digital systems.

The theme of immutability strongly reflects the necessity for data permanence and trustworthiness. Experts stated that systems “increase data immutability and integrity in data sharing,” and underscored that “data has not been altered since it was recorded”. These remarks reinforce the foundational role of immutability in preventing data tampering and ensuring historical fidelity. Particularly in contexts where auditability and legal reliability are paramount, immutability provides a cornerstone for data assurance. Additionally, immutability contributes significantly to stakeholder confidence in digital systems. One expert described how shared data remains “accurate, tamper-proof, and verifiable”, and others emphasised that increased immutability enhances security. This indicates that immutability is not merely a technical attribute but a trust-building mechanism. Robust systems that guarantee unchangeable data records foster accountability and reduce risks of dispute. By anchoring data sharing in irreversible records, immutability ensures that systems remain reliable and transparent over time.

The theme of interoperability underscores the necessity for seamless collaboration and integration among systems, stakeholders, and technologies. It is widely acknowledged that achieving effective interoperability hinges not only on technical compatibility but also on cooperative alignment. Experts emphasised that “harmonising processes among systems develops protocol standardisation, which is one of the key interoperability security factors”, and that “collaboration fosters mutual understanding and cooperation, which are essential for successful data sharing”. These statements highlight the critical importance of cooperation in overcoming fragmented digital ecosystems. By drawing on these expert insights, it becomes clear that interoperability is best achieved when technical solutions are complemented by institutional coordination and mutual trust.

Furthermore, interoperability is presented not merely as a technological challenge but as a governance and coordination concern. Experts observed that “data integration provides meaning” and that interoperability “enables effective interoperability” when paired with trust and collaboration. These observations suggest that interoperability facilitates both system-level efficiency and stakeholder confidence. When systems are interoperable, they reduce redundancy, improve data accuracy, and accelerate decision-making processes—benefits that are particularly vital in complex environments such as government agencies. In light of this, effective interoperability must be carefully aligned with governance frameworks, standardisation efforts, and stakeholder collaboration to support robust digital transformation.

Transparency emerged as a foundational theme, closely associated with trust and accountability in digital governance. In Fig. 6, experts repeatedly emphasised the need for transparency, asserting that it is “essential for ensuring that digital public services are secure, accountable, transparent, and reliable”, and that “seamless data sharing enforces protocol-level transparency”. These assertions demonstrate that transparent processes are indispensable for institutional integrity and public trust. Moreover, the phrase “ensuring transparency and accountability in data-sharing practices” captures the broader expectation that transparency enhances not only visibility but also procedural fairness and legitimacy in public services.

Fig. 6. Thematic analysis result for transparency.

Beyond enhancing public confidence, transparency is pivotal in preventing misuse and improving oversight. The remark that “transparency block information—not data or information” provides a nuanced understanding that transparency in data sharing should be structured: it should be

purposeful and controlled rather than indiscriminate. In other words, transparency involves enabling authorised access and traceability rather than full exposure. In government contexts, this structured transparency ensures that systems remain secure while still being open to necessary scrutiny. Thus, transparency supports democratic principles, fostering fairness, accountability, and informed participation in the digital era.

Governance surfaced as a comprehensive theme encompassing policy, regulation, standardisation, and control. Experts cautioned that “without effective data security, e-government governance becomes vulnerable, non-compliant, and unsustainable”, and emphasised how “trusted data helps organisations comply with industry regulations and standards”. These assertions emphasise that governance frameworks provide the underpinning for data stewardship and legitimacy in data sharing systems. The capacity for systems to meet legal and ethical standards is contingent upon governance structures that enforce accountability and continuity.

In parallel, governance involves harmonisation and administrative clarity across organisational boundaries. One expert noted that “well-defined policies protect sensitive

government information from unauthorised access or misuse”, while another remarked that “harmonised processes help different administrative zones operate under a common standard”. These insights suggest that governance extends beyond regulatory compliance to include operational coherence. Effective data sharing security governance, therefore, requires both policy articulation and cross-institutional coordination to support integrated, secure, and sustainable e-government ecosystems.

In Fig. 7, the thematic analysis maptree shows the themes of factors and codes for subfactors that have been extracted from the interview transcript. The confidentiality theme has shown the most quoted code, with trust recording the highest quote of 74. The accuracy code recorded 34 quotes, followed by integrity 32 quotes and reliability 31 quotes under the integrity themes. The immutability themes recorded 27 quotes for each immutability and temper-proof. The transparency themes recorded 27 quotes, while the auditability themes recorded 16 quotes for traceability and 15 quotes for auditability. The availability themes and quotes recorded 21 transcripts. The governance themes recorded 13 quotes for standardisation and 9 for regulation quotes. The decentralised themes and quotes recorded 12, followed by the distributed code for two quotes.

Fig. 7. Maptree thematic analysis.

D. Content Validity Results

The results of the content validity for the security factors are referred to Table II: The definition and formula were based on the recommendation by Lynn (1986), Davis (1992), Polit & Beck (2006) and Poliy et al. (2007), as cited in [42].

The confidentiality sub-factor in Table IV demonstrates generally high content validity with slight variation across sub-factors. Most items, including Trust between Parties, Privacy, Data Confidentiality, Data Ownership, Authentication, Authorisation, Secure Access Control, and Identity Security, achieved I-CVI values of 1.00, reflecting unanimous agreement on their relevance. However, the sub-factor Data Sovereignty received a slightly lower I-CVI of 0.83, indicating partial expert divergence.

TABLE IV. I-CVI RESULT FOR CONFIDENTIALITY

Factors	Sub-Factor	I-CVI	Accept /Reject
Confidentiality	i. Trust between parties	1.00	Accept
	ii. Privacy	1.00	Accept
	iii. Data Confidentiality	1.00	Accept
	iv. Data Ownership	1.00	Accept
	v. Authentication	1.00	Accept
	vi. Authorisation	1.00	Accept
	vii. Secure access control	1.00	Accept
	viii. Identity security	1.00	Accept
	ix. Data sovereignty	0.83	Accept

TABLE V. I-CVI RESULT FOR AVAILABILITY

Factors	Sub-Factor	I-CVI	Accept / Reject
Availability	i. Information-Sharing Across Organisations	1.00	Accept
	ii. Data Consistently Available	1.00	Accept
	iii. Data Usability	1.00	Accept

The findings presented provide compelling evidence of strong content validity for the availability sub-factor in Table V. All three sub-factors, Information-Sharing Across Organisations, Data Consistently Available, and Data Usability, achieved an I-CVI score of 1.00, which indicates unanimous expert agreement regarding their relevance to the construct under investigation. In addition, the scale-level indices further reinforce this conclusion. Consequently, the factor of availability, supported by its sub-dimensions, can be considered to exhibit excellent content validity.

The integrity sub-factors in Table VI demonstrate very high levels of content validity across a comprehensive set of sub-factors. Items including Ensuring Data Integrity, Protecting Data Integrity, Using Single Source of Truth, Trustworthiness of Data, Verifying Authenticity, Accuracy of Data, Use of Validation, Reducing Fraud, Trust of Data Integrity, Accountability of Data, Authenticity of Source, and Reliability of Data Sources/Used all scored I-CVI values of 1.00. The item

Specificity of Data scored slightly lower at 0.83, suggesting modest divergence among experts.

TABLE VI. I-CVI RESULT FOR INTEGRITY

Factors	Sub-Factor	I-CVI	Accept / Reject
Integrity	i. Ensuring Data Integrity	1.00	Accept
	ii. Protecting Data Integrity	1.00	Accept
	iii. Using Single Source of Truth	1.00	Accept
	iv. Trustworthiness of Data	1.00	Accept
	v. Verifying Authenticity	1.00	Accept
	vi. Accuracy of Data	1.00	Accept
	vii. Specificity of Data	0.83	Accept
	viii. Use of Validation	1.00	Accept
	ix. Reducing Fraud	1.00	Accept
	x. Trust of Data Integrity	1.00	Accept
	xi. Accountability of Data	1.00	Accept
	xii. Authenticity of source	1.00	Accept
	xiii. Reliability of data Sources	1.00	Accept
	xiv. Reliability of Data Used	1.00	Accept

The decentralisation factor in Table VII exhibits excellent content validity with unanimous expert agreement across all sub-factors. Items such as Distributed Data Recovery, Decentralising Property Rights, and Large-Scale Data Security Management each achieved I-CVI scores of 1.00, confirming their full relevance. With no sub-factor requiring revision, this construct stands as one of the strongest validated domains in the study, reinforcing its importance in addressing issues in data sharing security.

TABLE VII. I-CVI RESULT FOR DECENTRALISATION

Factors	Sub-Factor	I-CVI	Accept
Decentralisation	i. Distributed Data Recovery	1.00	Accept
	ii. Decentralising Property Rights	1.00	Accept
	iii. Large-Scale Data Security Management	1.00	Accept

The immutability sub-factors in Table VIII show strong but slightly less consistent content validity compared with other factors. Sub-factors such as Reducing the Need for Trusted Third Parties, Data Protection Security, Tamper-Proof Record, Resistance to Attacks, and Non-Temperable Properties achieved I-CVI scores of 1.00, signifying agreement of expert endorsement. However, Isolating Data and Blocking Data Properties received slightly lower I-CVI values of 0.83, reflecting minor divergence.

Transparency and its sub-factors result in Table IX, shows a strong but not unanimous validity across its sub-factors. Items including Need for Greater Transparency, Seamless Data Sharing, Secure Transaction Visibility, and Allowing Traceability achieved I-CVI values of 1.00, reflecting complete expert agreement. The item Openness of Data scored slightly lower at 0.83, suggesting minor divergence in views.

TABLE VIII. I-CVI RESULT FOR IMMUTABILITY

Factors	Sub-Factor	I-CVI	Accept / Reject
Immutability	i. Reducing the Need for Trusted Third Parties	1.00	Accept
	ii. Data Protection Security	1.00	Accept
	iii. Tamper-Proof of Record	1.00	Accept
	iv. Resistance to Attacks	1.00	Accept
	v. Isolating Data	0.83	Accept
	vi. Blocking Data Properties	0.83	Accept
	vii. Non-Temperable	1.00	Accept

TABLE IX. I-CVI RESULT FOR TRANSPARENCY

Factors	Sub-Factor	I-CVI	Accept / Reject
Transparency	i. Need for Greater Transparency	1.00	Accept
	ii. Seamless Data Sharing	1.00	Accept
	iii. Secure Transactions Visibility	1.00	Accept
	iv. Allowing Traceability	1.00	Accept
	v. Openness of Data	0.83	Accept

TABLE X. I- CVI RESULT FOR INTEROPERABILITY

Factors	Sub-Factor	I-CVI	Accept / Reject
Interoperability	i. Data Integration between parties	1.00	Accept
	ii. Harmonizing Processes	1.00	Accept
	iii. Standardization Integration of system	1.00	Accept
	iv. Collaboration of parties	1.00	Accept

Interoperability sub factors shows in Table X demonstrates a solid content validity across its four sub-factors. Items Data Integration between Parties, Harmonising Processes, Standardisation of System Integration, and Collaboration of Parties each obtained I-CVI scores of 1.00, indicating all expert agreement.

The auditability sub factors construct in Table XI shows robust content validity, as reflected in unanimous expert agreement across all sub-factors. The items “Ability to Track Transactions”, “Ability to Retain Transactions”, and “Allowing Transaction Traceability”, each received an I-CVIscore of 1.00, which signifies complete endorsement of their relevance.

TABLE XI. I-CVI RESULT FOR AUDITABILITY

Factors	Sub-Factor	I-CVI	Accept / Reject
Auditability	i. Ability to Track Transactions	1.00	Accept
	ii. Ability to Retain Transactions aligning	1.00	Accept
	iii. Allowing Transaction Traceability	1.00	Accept

Governance sub-factors in Table XII also shows perfect content validity across all of its 6 evaluated sub-factors. The items Data Sharing Governance, Data Sharing Policy,

Uniformity in Protocols, Security Controls, Regulatory Compliance, and Legal Data Security Applicability all received I-CVI scores of 1.00, demonstrating full agreement on their relevance.

TABLE XII. I-CVI RESULT FOR GOVERNANCE

Factors	Sub-Factor	I-CVI	Accept / Reject
Governance	i. Data sharing governance	1.00	Accept
	ii. Data sharing Policy	1.00	Accept
	iii. Uniformity in protocols	1.00	Accept
	iv. Security controls	1.00	Accept
	v. Regulatory Compliance	1.00	Accept
	vi. Legal Data Security Applicability	1.00	Accept

The findings provide strong evidence that governance is a critical and clearly defined construct within blockchain-based e-government security frameworks.

Table XIII shows the scale level of Content Validity of the main factors and the experts' agreement across all sub-factors in the main factors and the Universal Agreement Result for the main Factors. The result for The S-CVI/UA of confidentiality is 0.89, showing that most, but not all, items achieved universal agreement, but were acceptable based on a minimum score of 0.80. Despite this, the results confirm that confidentiality is broadly supported as a critical security dimension. The findings suggest that while the majority of sub-factors are conceptually robust, specific elements like data sovereignty may require refinement to ensure greater consensus. Nevertheless, the integrity factor achieved an S-CVI/Ave of 0.99 and an S-CVI/UA of 0.93, both exceeding recommended thresholds of 0.80. These results confirm that integrity is a well-validated and indispensable dimension in blockchain-based secure data sharing, encompassing accuracy, reliability, and authenticity of data.

TABLE XIII. S-CVI/UA AND S-CVI/AVE RESULT FOR 9 MAIN FACTORS

Factors	S-CVI/UA	Accept / Reject	S-CVI/Ave	Accept / Reject
Confidentiality	0.89	Accept	0.98	Accept
Integrity	0.93	Accept	0.99	Accept
Availability	1.00	Accept	1.00	Accept
Decentralisation	1.00	Accept	1.00	Accept
Immutability	0.71	Reject	0.95	Accept
Transparency	0.80	Accept	0.97	Accept
Interoperability	1.00	Accept	1.00	Accept
Auditability	1.00	Accept	1.00	Accept
Governance	1.00	Accept	1.00	Accept

Both the S-CVI/Ave (1.00) and the S-CVI/UA (1.00) for availability demonstrate complete alignment across the expert panel, thereby confirming that the availability construct is robustly represented within the measurement framework. The results are consistent with methodological expectations that

universal agreement across multiple experts provides a strong basis for accepting items without revision. At the aggregated level, the decentralised factor validity for both the S-CVI/Ave (1.00) and S-CVI/UA (1.00) indicates complete consistency among the experts. These results suggest that decentralisation is conceptually well-defined and universally recognised by experts as a core attribute of blockchain-driven e-government data sharing.

The overall S-CVI/Ave for Immutability is 0.95, indicating a strong average agreement, yet the S-CVI/UA of 0.71 reveals that the factors did not reach universal consensus, as the minimum score should achieve 0.80. At the scale level, the transparency factor attained an S-CVI/Ave of 0.97, which is well above the recommended threshold, but the S-CVI/UA of 0.80 indicates that universal agreement was achieved at par. At the scale level, the S-CVI/Ave (1.00) and S-CVI/UA (1.00) confirm the consensus across the experts, validating the construct of the interoperability factor as conceptually coherent and practically relevant. The overall S-CVI/Ave (1.00) and S-CVI/UA (1.00) in auditability factors demonstrate perfect consensus at the scale level, indicating that every expert perceived these dimensions as essential elements of auditability. This unanimity is further validated by an S-CVI/Ave of 1.00 and an S-CVI/UA of 1.00, both of which confirm the consensus across the expert panel for the governance factor.

V. DISCUSSION

A. Theoretical Implications

The combined findings from the thematic analysis and content validity assessment offer a meaningful theoretical contribution to the understanding of secure data sharing in the public sector. By synthesising expert insights, the study advances existing knowledge on blockchain-enabled data-sharing systems, uncovering recurring patterns, experiential perspectives, and thematic constructs that inform the validation of security frameworks. The integration of thematic analysis with an empirically driven content validation approach enhances both conceptual coherence and methodological rigour, thereby providing a solid foundation for future theoretical development and scholarly discourse in the field of blockchain-based data sharing.

Consistent with existing literature, the findings of the themes from grounded theory reinforce that trust remains the most prominent concern in blockchain-based data sharing for e-governance. In addition, the study affirms experts' acceptance of key factors such as immutability, interoperability, and governance, all of which are integrated within a cohesive structure. The interconnected nature of these themes strengthens and refines existing theories on blockchain-based data-sharing security. Notably, the identification of accountability and governance as central constructs further enriches theoretical discourse on the application of decentralisation technologies in public administration. In summary, the research addresses a critical gap by offering a theoretically grounded and practice-informed framework for understanding secure data sharing in blockchain-enabled e-government systems.

Complementing these thematic insights, the Content Validity Index (CVI) findings contribute significantly to the

refinement and validation of the core constructs underpinning secure data sharing via blockchain in e-government. The confirmation of factors such as confidentiality, integrity, availability, decentralisation, immutability, auditability, interoperability, transparency, and governance adds empirical depth to the theoretical base. As emphasised in the instrument development literature, content validation is essential to ensure that abstract constructs are operationalized with precision and consistency. By incorporating both I-CVI and S-CVI measures, this study enhances methodological rigour and demonstrates how triangulated expert consensus can bridge previously identified methodological gaps. Moreover, the findings reveal nuanced theoretical distinctions, such as the weaker consensus observed in the sub-factors of immutability and transparency which highlight the need for continued theoretical refinement and contextual adaptation of emerging security constructs.

Ultimately, the validated prominence of these security factors reflects a strong expert consensus on the essential requirements for secure data sharing in blockchain-enabled e-government applications. These validated constructs serve as concrete theoretical foundations for understanding and designing secure data-sharing mechanisms in public-sector blockchain systems. By employing both thematic analysis and content validity techniques, this research bridges a notable methodological gap in the literature, offering a robust and rigorous basis for advancing theoretical development in the domain of public sector blockchain security.

B. Practical Implications

Building on prior insights, the integration of thematic analysis and content validity assessment offers an enhanced practical contribution to the implementation of secure data sharing in the public sector. This study advances applied knowledge by preparing the approach from the real-world experiences and expert evaluations of blockchain deployment within public governance contexts. By combining qualitative thematic insights with empirically validated security constructs, the research provides a more robust foundation for guiding the design, development, and operationalization of blockchain-enabled data-sharing solutions.

From a practical perspective, the thematic findings offer actionable insights for policymakers, system architects, and public administrators engaged in data sharing security for digital transformation initiatives. The identification of key themes, confidentiality, integrity, availability, decentralisation, immutability, auditability, interoperability, transparency, and governance provides a framework for designing secure, citizen-centric data sharing systems. Specifically, the findings suggest that the incorporation of decentralisation and auditability mechanisms can significantly enhance data security and institutional trust. This implies that decision-makers should prioritise technologies that support tamper-proof records, controlled access, and transparent data flows. In addition, the emphasis on governance, interoperability, and regulatory compliance underscores the importance of aligning digital systems with legal and administrative policy frameworks. These insights are significantly relevant for e-government platforms where data sovereignty and trust are paramount. Furthermore, the thematic framework can be used as a diagnostic tool for

evaluating the readiness and resilience of secure data-sharing e-government systems.

The validated framework using content validity provides stakeholders and practitioners with a reliable foundation for secure data sharing for e-government systems implementation. The confirmation of strong content validity across most security factors means that decision-makers can draw on a structured set of indicators to guide system architecture, regulatory compliance, and policy development. As has been argued in applied research, the translation of validated constructs into practice enhances the credibility and sustainability of interventions. By identifying universally accepted elements such as data confidentiality, auditability, and interoperability, the study offers practitioners actionable criteria for designing systems that inspire security and trust. At the same time, the partial divergence observed in immutability and transparency highlights areas requiring refinement before operational deployment, ensuring that practical applications remain adaptive and responsive to contextual challenges. Ultimately, the findings strengthen the link between theoretical constructs and real-world design, supporting the creation of blockchain-enabled governance infrastructures that are both secure and citizen-centric.

The validated security factors provide a reliable checklist for designing and evaluating blockchain-based data sharing systems for implementation in the public sector. Emphasising factors like governance and confidentiality can enhance compliance and trust, especially in multi-agency or cross-agency data sharing. The validated item can be directly included in the current blockchain roadmap or data sharing policy to ensure the objective and target for a trusted, secure e-government service can be upheld. For instance, their relevance must be translated effectively to non-technical stakeholders. Thus, the study provides a practical roadmap for implementing secure data-sharing e-government systems in public sector environments.

The BSDSF integrates both traditional information security principles (Confidentiality, Integrity, Availability) and blockchain-specific properties (Decentralisation, Immutability, Transparency, Auditability, Interoperability, Governance). The unique blockchain security properties, particularly immutability, decentralised trust, built-in auditability, and consensus-based integrity, extend beyond the capabilities of traditional distributed databases. These properties make blockchain particularly suitable for secure, multi-agency data sharing in e-government environments, where trust, accountability, and regulatory compliance are critical.

C. Limitations and Future Research

Although the expert panel included a diverse range of perspectives, the relatively small number of experts from the public sector may limit the generalizability of the findings to broader e-government contexts. Moreover, the study primarily assessed the perceived relevance and conceptual clarity of the security factors, rather than evaluating their practical effectiveness in real-world implementations. As such, the operational impact of each factor within live or simulated e-government environments remains unexplored. To strengthen the practical applicability of these findings, future research should consider field-based validation, pilot implementations, or

simulation-driven testing to assess how these security constructs perform under actual system conditions. The approaches would provide deeper insight into the usability and contextual applicability of the proposed framework with a suitable, validated, reliable instrument, thereby advancing both theoretical understanding and implementation readiness.

VI. CONCLUSION

This study set out to conduct methodological triangulation using thematic analysis for qualitative data and Content Validity Index to empirically validate the key security factors that underpin data sharing in blockchain-based e-government applications. Through an open-ended questionnaire interview and a structured content validity approach involving expert evaluation, the research identified a set of high-priority factors: confidentiality, integrity, availability, decentralisation, interoperability, transparency, auditability, and governance that are both relevant and clearly understood across experts. The immutability factors have been accepted as one of the security factors because they have been accepted as important security factors by the expert review interview in thematic analysis.

TABLE XIV. FACTORS STATUS

Factors	S-CVI/UA	S-CVI/Ave	Status
Confidentiality	0.89	0.98	Accepted
Integrity	0.93	0.99	Accepted
Availability	1.00	1.00	Strongest Consensus
Decentralisation	1.00	1.00	Strongest Consensus
Immutability	0.71	0.95	Reject / Refine
Transparency	0.80	0.97	Accepted
Interoperability	1.00	1.00	Strongest Consensus
Auditability	1.00	1.00	Strongest Consensus
Governance	1.00	1.00	Strongest Consensus

The key contributions of this study are the integration of traditional information security principles with blockchain-specific security attributes. The BSDSF extends the traditional Confidentiality, Integrity and Availability (CIA) model by incorporating blockchain-specific factors, including decentralisation, transparency, interoperability, auditability, and governance. Based on Table XIV, five factors that is Availability, Decentralisation, Interoperability, Auditability and Governance have the strongest consensus. The Confidentiality, integrity, and transparency are accepted, while the immutability needs to be refined. Interestingly, while immutability is a core blockchain feature, it failed the Universal Agreement (UA) threshold ($S\text{-CVI/UA} < 0.80$). This suggests experts have diverging views on how "permanent" data should be in a government context, possibly due to "right to be forgotten" regulations or data correction needs.

The thematic analysis revealed that Trust was the most frequently quoted code (74 quotes), highlighting that technology alone is insufficient without institutional and interpersonal trust. The research also provides evidence-based framework development through multi-method validation. The blockchain

frameworks are proposed, derived from a multi-method research design involving:

- Systematic Literature Review (SLR) to identify security factors.
- Thematic analysis to synthesise conceptual constructs.
- Expert validation using Content Validity Index (CVI).

The framework offers a holistic perspective that bridges the gap between information security theory and distributed ledger technology.

By applying the Item Content Validity Index (I-CVI) and Scale Content Validity Index (S-CVI) methodology, the study enhances the methodological rigour of information systems research and provides a replicable framework for future validation efforts. In summary, this study not only refines the conceptual landscape of blockchain security in e-government but also lays the groundwork for more secure, transparent, and citizen-centric digital governance. Based on the above approach, we can conclude that the thematic analysis with content validity index of I-CVI, S-CVI/Ave, and S-CVI/UA has met a satisfactory level of content validity.

Department of Medical Sciences-Faculty of Medicine, Lampung University, Lampung, Indonesia⁴

Abstract—Stunting attributable to malnutrition remains a global public health problem impacting the long-term physical and cognitive growth of children. In recent years, artificial intelligence (AI) has been applied in public health research to help diagnose and predict stunting. This study seeks to review trends in AI research on stunting prediction and intervention, and to identify existing challenges and opportunities. The articles were screened using the Systematic Literature Review (SLR) method with the PRISMA protocol through databases like PubMed, ScienceDirect, Scopus, and Google Scholar. The analysis of the data was performed using VOSviewer and Microsoft Excel. The results showed that the most used models in predicting stunting were Random Forest (RF), Support Vector Machine (SVM), Gradient Boosting (XGBoost, LGBM), and Artificial Neural Network (ANN). Model evaluation is usually done through metrics such as AUC-ROC, accuracy, sensitivity, and specificity. Although AI has shown promise in identifying and predicting stunting, a few challenges remain: One is of data access and quality; others are model interpretability and integration within healthcare networks. Towards increasingly promising application outcomes: future directions for home-based health data prediction of the Internet of Things (IoT), Explainable AI (XAI), Multimodal AI, and natural language processing (NLP) models.

Keywords—Artificial intelligence; stunting; public health; machine learning; systematic review

I. INTRODUCTION

Malnutrition results from an energy or nutrient intake that does not meet the body's needs [1]. This condition includes imbalance, deficiency, excess, and overall energy and nutrient imbalance. The main forms of malnutrition include undernutrition (stunting and wasting), obesity, and micronutrient deficiencies such as vitamin A, iron, and iodine. Malnutrition remains a major public health problem affecting individuals across all age groups and contributes to various health, social, and psychological issues. It is estimated that up to 20 million children experience stunted growth and reduced life expectancy due to undernutrition, which also remains a significant cause of infant mortality [2].

According to the World Health Organization (WHO), malnutrition encompasses both undernutrition and overnutrition conditions, including overweight and obesity [3]. Global projections indicate that nutritional challenges will remain significant, with an estimated 127 million children (26%) still affected by stunting by 2025. Although the WHO has set a target to reduce stunting among children under five by 40%, current progress suggests that this goal may not be fully achieved.

Addressing malnutrition is also a key priority in the United Nations Sustainable Development Goals (SDGs), particularly Goal 2 (Zero Hunger), which aims to eliminate all forms of malnutrition by 2030.

Advancements in computing technology have introduced new opportunities to address public health challenges. Traditionally, stunting has been analyzed using classical statistical methods; however, these approaches face limitations such as multicollinearity among variables, which can reduce diagnostic accuracy. Artificial Intelligence (AI) offers advantages in overcoming these limitations and has demonstrated improved performance in classification tasks, including stunting detection [4]. Therefore, the application of AI in public health has become increasingly important for improving early detection and intervention strategies.

This study provides several key contributions to the existing literature. First, it presents a comprehensive ten-year analysis of AI applications in stunting prediction and intervention, highlighting temporal research trends and methodological evolution. Second, it offers a detailed geographical analysis of research distribution, emphasizing the dominance of developing countries and their implications for model generalizability. Third, this study identifies research gaps in underexplored areas such as malnutrition diagnosis, real-time data utilization, and explainable AI. Finally, it provides a critical synthesis of commonly used AI models, including their strengths, limitations, and suitability for different types of health data.

II. LITERATURE REVIEW

Artificial Intelligence (AI) refers to computational systems capable of performing tasks that typically require human intelligence, including data collection, pattern recognition, prediction, and decision-making [5][6]. The development of AI has evolved from symbolic AI, which relied on predefined rules, to modern AI approaches that can learn from data [7][8]. While symbolic AI was effective for structured problems, it was limited in handling complex and unstructured data such as images, speech, and text.

Machine Learning (ML), a subset of AI, enables systems to learn from data without explicit programming by identifying patterns within labeled datasets [9]. Deep Learning (DL), an advanced form of ML, utilizes multi-layered neural networks to capture complex patterns and relationships in large-scale and unstructured data [10]. Compared to traditional ML methods, DL provides higher capability in modeling complex data

structures, particularly in domains such as image classification and health data analysis.

Several studies have applied ML and DL techniques to address malnutrition and stunting. Previous research shows that deep learning models can achieve high performance, with accuracy reaching 96.46% and AUC-ROC up to 99.95% [11]. In Afghanistan, algorithms such as J48, Random Forest (RF), and Naïve Bayes have been used to detect edematous malnutrition, with RF achieving the highest accuracy of 97.14% [12]. Similarly, Artificial Neural Networks (ANNs) have been applied in Bangladesh to classify children's nutritional status, demonstrating strong performance and potential as decision-support tools for policymakers [13].

Other machine learning approaches, such as K-Nearest Neighbors (K-NN), have been used to detect stunting based on anthropometric indicators [14]. Comparative studies using algorithms like XGBoost (XGB), Naïve Bayes (NB), Random Forest (RF), and Logistic Regression (LR) have also been conducted using demographic health survey datasets to evaluate predictive performance.

Stunting, as a long-term consequence of malnutrition, can lead to significant physical and cognitive impairments. Research using generalized linear mixed models on Ethiopian Demographic Health Survey data identified age as a significant risk factor, with children aged 12–59 months showing a higher risk compared to younger age groups [15]. These findings highlight the importance of early intervention in reducing stunting prevalence.

Recent developments have also introduced AI-based decision support systems for the early detection of malnutrition risk. One study utilized mobile health (m-Health) data and applied various ML models combined with techniques such as Synthetic Minority Oversampling Technique (SMOTE) and cost-sensitive learning. The results showed high performance, with accuracy reaching 94% and recall of 92%, indicating strong potential for AI in supporting public health policies [16].

In addition, several literature reviews have explored the application of AI in public health. However, many studies focus on general AI applications rather than specifically addressing stunting. Therefore, a systematic literature review is necessary to identify research trends, gaps, and opportunities in AI-based stunting prediction and intervention. This study adopts the PRISMA protocol and utilizes databases such as PubMed, ScienceDirect, Scopus, and Google Scholar. Data analysis is conducted using tools such as Microsoft Excel and VOSviewer to examine research trends, locations, methodologies, and study topics.

III. MATERIALS AND METHODS

The method used for this research is the Systematic Literature Review (SLR). The main goal of this content is to review the literature regarding the application of artificial intelligence in the health area, specifically related to stunting, as well as to summarize previous studies and present new contributions with the potential to lead to advances in this field. This leads to the following research questions that further define these objectives:

- RQ1: How have public health applications related to stunting used AI methods (over the past decade, worth researching trends, AI methodologies, and their implementations)?
- RQ2: How well do artificial intelligence models (such as algorithms used, accuracy assessment, and model reliability) predict stunting status based on the types of data sources used?
- RQ3: What challenges and opportunities exist for the development and application of artificial intelligence (including research limitations, implementation challenges, and recommendations on future development) to aid the early detection and intervention of stunting within communities, and what solutions do current trends in research offer?

A. Search Strategy

Ms. Excel and VOSviewer software were utilized to analyze data from this study and provide an adequate results overview. The data collection was done under the PRISMA workflow (Fig. 1): identification, abstract screening, manuscript eligibility assessment, and article selection, in four steps. In the identifying stage, a search was done through different database sources to ensure a wide data range and to recognize relevant studies. [17]. Data Sources: The following are the sources for this literature database: ScienceDirect (“www. sciencedirect. com,” last accessed Dec. 31, 2024), PubMed (“pubmed. ncbi. nlm. nih. (https://www.scopus.com), and Google Scholar (http://scholar.google.com (accessed December 11, 2024).

Fig. 1. PRISMA flow diagram.

Articles were downloaded from their websites from 2015 to 2024. Automated searches using Boolean techniques were conducted to connect keywords, generating summaries shown in Table I.

TABLE I. KEYWORDS AND NUMBER OF ARTICLES

Keyword	Database Source	Count
(("artificial intelligence" OR "AI" OR "Machine Learning") AND ("Public Health" OR "Nutrition Health" OR "Child Health")) AND ("Stunting" OR "Malnutrition")	ScienceDirect	363
	PubMed	234
	Google Scholar	1000
	Scopus	49
Total Count		1646

B. Inclusion and Exclusion Criteria

Ms. Excel was employed to perform a preliminary screening of the manuscripts. In this process, duplicate articles were eliminated, resulting in a total of 1,596 articles compared to the 1,646 obtained in the identification step. Then, articles were screened based on titles, only retaining articles relevant to the topics of AI and stunting (a total of 118 articles). Making sure to apply our inclusion/exclusion criteria, the next step was searching the articles by title/abstract. The inclusion criteria applied for selecting articles are presented in the following Table II.

TABLE II. INCLUSION AND EXCLUSION CRITERIA

Inclusion	Exclusion
Articles published in the last 10 years, from 2015 to 2024.	Post 2015 or pre 2024 articles.
Articles written in English	Articles that are not in English.
Studies taken using AI techniques, e.g., machine learning, deep learning, or neural networks.	Non-AI/non-computational technique studies.
Reported on prediction, diagnosis, intervention, or evaluation of stunting or malnutrition	Reasons: Articles with no direct relevance to stunting, malnutrition, or child nutrition.
Research articles (empirical studies, systematic and meta-analyses).	Non-peer-ended content (eg, editorials, opinion articles, book chapters, conference abstracts).

C. Data Extraction and Thematic Synthesis

This search yielded 70 full-text articles. The eligibility of records was evaluated in the fourth stage by reading all the full-text articles and choosing them according to the specified inclusion and exclusion criteria. A total of 51 eligible articles were identified for the review. A detailed literature mapping was undertaken from the 51 selected articles, including details such

as the article title, year of publication, authors, research objectives, research location, methodology, data sources, research scope, data analytics techniques used, key findings, and journal indexing (Fig. 2).

Fig. 2. Source and index of journal articles.

IV. RESULTS

A. Literature Research Characteristics

This study describes the characteristics of research on the application of AI for addressing stunting. These characteristics include Authors, Year, Publication, Publisher, Country, Journal Index, Subject Area, Data, Methodology, AI Model, and Evaluation Model. The main characteristics of the included articles are presented in Table III.

Most studies analyzed in this review utilize secondary datasets such as Demographic and Health Surveys (DHS) and national health surveys. These datasets typically include variables such as age, height, weight, gender, and socio-economic indicators. However, variations exist in dataset size, feature completeness, and data quality. Some studies involve large-scale national datasets, while others rely on smaller, localized datasets, which may introduce bias and affect model performance. Additionally, many datasets lack real-time updates and critical variables such as dietary intake, environmental factors, and genetic influences, which may limit the accuracy and generalizability of AI models.

B. Year and Method

This research on AI utilization for stunting has increased every year. This field has emerged as an ever more powerful trend, especially in the face of the rapid emergence of digital technology. The progress that resulted from the emergence of digital technologies is not only deserving of serious consideration but has also provided distinct challenges. Fig. 3 reflects the trend in AI research for stunting over the last decade.

The yearly publication count exhibited an upward trajectory in the previous 10 years of study between 2015 and 2024. A strong upward trend in articles dating back to 2021 (25%, 13/51) and robust growth through 2024 (55%, 28/51) were observed. In addition to the increasing number of articles, the quality was equally met, as 117 (61%; 31/51) articles were published in Q1, Q2, Q3, and Q4 journals. The observed increase in publications (Fig. 3) indicates a growing interest in AI applications for stunting, driven by advancements in digital health technologies and data availability.

Fig. 4 highlights the dominance of supervised machine learning methods, suggesting a strong reliance on predictive modeling approaches in public health datasets. On the other hand, four AI approach methods commonly used during the last decade (including AI methods and their implementations) for detecting, predicting, and tackling stunting were found. For example, DL, Statistical Methods, Supervised ML, and Unsupervised ML are some techniques. The Supervised ML method was used in the highest percentage of studies: over 79% of a total of 34 articles between 2015 and 2024. Fig. 4 summarizes the evolution of AI methods for stunting.

Fig. 3. Annual trend of the number of publications on AI and stunting.

Fig. 4. Annual trend of the research method AI and stunting.

C. Research Sites and Subject Matter

Fig. 5. shows the characteristic location of countries (where the research is conducted). The five most researched places are: Indonesia (13 articles, 33%), [26], [49], [50], [51], [52], [53], [54], [55], [56], [57], [58], [59], [60], [61], [62], [26], [57], [58], [59]; Bangladesh (8 articles, 14%) [21], [22], [23], [28], [35], [36], [60], [46]; India (6 articles, 10.5%) [18], [27], [61], [62], [63], [64]; and Ethiopia, Pakistan, and the United States (USA), 3 articles (5.3%) [19], [31], [43], [29], [34], [44] and [37], [39], [42], respectively. More research is still needed to consider the use of artificial intelligence in the health sector, with a focus on stunting in unexplored areas. Additionally, developing countries should be considered more important than developed ones because of the different developmental contexts of those two types of countries. The geographical distribution shown in Fig. 5 reflects the higher research activity in developing countries, which correlates with the higher prevalence of stunting in these regions.

Fig. 5. Research location.

As illustrated in Fig. 6, the most studied subfield of the application of artificial intelligence for stunting is the prediction of stunting (e.g., prediction of the risk of Severe Acute Malnutrition (SAM), prediction and identification of malnutrition risk factors, prediction of Double Burden of Malnutrition (DBM), prediction of nutritional status, et al), with a contribution rate of 19.58%. The next subject area with maximum study includes stunting analysis (like stunting trend analysis, stunting clustering analysis, spatiotemporal malnutrition trend analysis, nutrition Intervention analysis &

analysis of relationships between stunting, wasting & others), which represents about 8.24% of research. On the other hand, the subject areas that were the least explored are stunting and malnutrition diagnosis (2.6%), diagnosis of malnutrition (1.3%), and estimation of undernutrition z-score distributions (1.3%). Fig. 6 demonstrates that research is heavily concentrated on prediction tasks, while diagnostic and assessment-related studies remain limited, indicating potential areas for future exploration.

To His, this research would continue to expand and take root with the advent/formation of new phenomena/phenomena, as well for example/instance of rarely studied subjects, such as, for example, malnutrition diagnosis, image classification according to children's nutrition status, and others. AI applications across different subjects to develop solutions for stunting in a location or country could yield their own set of phenomena. It is because there is a disparity between developing and developed countries in terms of technologies, including computational technology, that should be taken into consideration while implementing AI-based solutions.

Fig. 6. Research subject matter.

D. The Algorithms and Evaluation Models of AI

Selection of an appropriate algorithm is an important part of AI to solve the stunting prevention issue in both accuracy and a reliable model. Algorithms widely used in time series forecasting are machine learning (ML) techniques, including Random Forest, Support Vector Machine (SVM), and Gradient Boosting, as well as deep learning (DL) methods such as Artificial Neural Networks (ANN) and Long Short-Term Memory (LSTM) for sequential data. It has been demonstrated in this study that the Random Forest (RF) algorithm is the most commonly used in research for the prediction of stunting and malnutrition.

Some of the best-performing methods, such as Random Forest (RF), have gained prominence due to their adaptability to high-dimensional data and their capability to capture and represent important selected features. RF is a commonly used algorithm in the identification of malnourished children [19], [24] where LGBM and XGBoost (XGB) combined with RF were employed for malnutrition diagnosis. SVM is often applied to this data as well for its power of working with high-dimensional data and non-linear correlations as well. [22] utilized SVM to compare the performance against Naïve Bayes, Decision Tree, Artificial Neural Network (ANN), and RF for the

prediction of malnutrition risk factors, while [30] employed SVM in conjunction with Logistic Regression and XGBoost to predict stunting. Additionally, Gradient Boosting Machines (GBM) algorithms, such as XGBoost and LGBM, are often used to improve prediction accuracy because these algorithms handle outliers more effectively. Also, in a study [24], LGBM and XGBoost outperformed other machine learning algorithms in malnutrition diagnosis, whilst in residual [31] XGBoost was combined with k-NN, Random Forest, and ANN to collect a relatively holistic stunting prediction.

Conversely, DL approaches are also finding more applications, especially in image analysis and complex pattern identification in health data. In studies that utilize images as input data, Convolutional Neural Network (CNN) is the most commonly used method. For example, the work of [18] used CNN to classify a child's pictures according to his/her nutritional status: Healthy, Undernourished, Stunting, and Wasting. Besides CNN, ANN is also commonly applied for predicting nutritional status, especially for classifying health data. ANN has the advantage of being able to identify patterns in the data that are difficult to work with through traditional Machine Learning (ML) algorithms. For instance, [20] employed an ANN to forecast the potential of Severe Acute Malnutrition (SAM), whereas in [22] ANN was compared with other techniques, including Naïve Bayes, SVM, Decision Tree, and Random Forest (RF). For example, Machine Learning and Deep Learning techniques are increasingly being applied to improve diagnostic accuracy and provide better insight into the drivers of stunting and malnutrition.

Different metrics, such as Accuracy, Sensitivity, Specificity, Precision-Recall, and AUC-ROC, are used to evaluate the models to classify whether a child is at risk of stunting or not. To prevent overfitting and ensure that the resulting model will generalize to new datasets, validation techniques, including cross-validation and confusion matrices, are also utilized. While the recent upturns may seem discouraging, grounded on optimal algorithms and well-considered evaluation, AI could emerge as a valuable partner in both measuring and anticipating stunting status in a more nuanced and evidence-based manner.

Evaluation models are vital in machine learning artificial intelligence (AI) for predicting and mitigating stunting and malnutrition, as the performance is reliant on these models. Accuracy: One of the most used evaluations; a correct percentage of the prediction with the data used. In contrast, when studies desire more specific detection (e.g., a generalizable prediction of acute malnutrition or prediction of Severe Acute Malnutrition (SAM), sensitivity and specificity metrics are frequently employed to allow balanced and accurate identification of positive and negative cases. Also, precision and recall are utilized in research that looks at reducing false positives and false negatives whilst making predictions, which is important in health-based systems in order to avoid diagnostic mistakes. The F1-score is the solution to the case of the distributed class, providing a single and more informative value than precision and recall taking into account both (precision, recall) values. AUC-ROC (Area Under the Curve - Receiver Operating Characteristics) has been a metric for model performance for predicting stunting versus non-stunting

categories and malnutrition versus normal nutritional status in studies [30], [21].

Regression models and time-series analysis have specific metrics that are used to measure performance, besides classification model evaluation. Root Mean Square Error (RMSE) and Mean Absolute Error (MAE) are used as predictive measures commonly in research to predict nutritional status based on numerical factors like the Body Mass Index (BMI), including height and weight. For example, the study [39] was used RMSE and MAE to evaluate BMI and malnutrition level predictions using a regression approach. At the same time, in studies using clustering to allocate children according to the grouping of their nutritional status, it is common to use the Silhouette Score metric. As in the study [33] This metric was applied to measure the quality of clustering in stunting analysis based on machine learning. By employing several assessment strategies, public health-focused AI can keep growing, yielding predictive models that are more precise, dependable, and able to reveal here into the things that influence stunting and hunger.

E. AI Application Difficulties and Potentials in Stunting Solution

Learning that model's upcoming class of data poses one of the major challenges in establishing the underlying factors responsible for predicting stunting and malnutrition through artificial intelligence (AI). Most studies are based on survey data that often lack critical variables such as environmental moderators, dietary consumption patterns, or genetic effects. This can introduce bias into predictive models and inhibit their generalizability to larger populations. Additionally, the datasets used are generally not real-time, which limits the ability to perform early detection based on emerging trends. So one solution includes utilizing larger and real-time datasets, such as data from Electronic medical record systems or from Internet of Things-based health sensors. More data means less error in AI, allowing training on a wider array of factors that affect child growth.

Second is a very known problem which is a very common problem, which is the problem of overfitting in deep learning models. Models such as Convolutional Neural Network (CNN) or Artificial Neural Network (ANN) are known to perform best when trained on large amounts of data using feedforward processes. Overfitting is when the model is so well trained that it memorizes the patterns behind the training data, and hence becomes unable to generalize to data that it has not been exposed to before. That can cause the predictions to be less accurate when transferred to real-world situations. One solution to this problem involves using transfer learning, a method that adapts pre-trained AI models, built on large data sets, to smaller data sets without sacrificing accuracy. Moreover, hybrid models have also been proposed to improve performance in the absence of huge training sets, combining several machine learning and/or deep learning algorithms.

In addition, another key challenge is the black box nature of AI models and how harder it is to incorporate AI into public health systems. Models like Neural Networks and Gradient Boosting are black-box, and it is difficult for physician researchers and health professionals to interpret how these

models arrive at decisions. Utilizing Explainable AI (XAI) approaches (e.g., SHAP - Shapley Additive Explanations, or LIME - Local Interpretable Model-Agnostic Explanations) to provide visibility into the features that most impact AI decision-making can enhance transparency. Conversely, the challenges of implementing AI in public health systems also remain, such as inadequate digital infrastructure, a lack of access to AI technology by healthcare workers, and regulations that do not yet support the integration of AI. So, there is a need for more user-friendly AI systems with simple interfaces to support healthcare professionals and policymakers in making informed decisions. Thus, it is possible (AI) to be best used for early identification of stunting and malnutrition and better-tailored interventions.

F. Current Trends in AI Applications for Stunting Research

This data was obtained to better understand all published stunting studies, which were plotted using VOSviewer, a specialized software allowing visualization of relationships between studies, keyword analysis, and citation trends. Co-occurrence was used for the features in this bibliometric analysis, which included keywords, words in article titles, or terms in abstracts. Co-occurrence informs about topics or subtopics that co-occur in the scientific literature. Fig. 7 shows the network visualization of keyword relationships generated using the VOSviewer application.

The bibliometric analysis using VOSviewer reveals distinct research clusters related to stunting, malnutrition, and AI. The green cluster focuses on environmental and child health factors, highlighting the influence of infections, sanitation, and socio-economic conditions on nutritional status. In contrast, the red cluster emphasises nutritional status and the increasing application of AI and machine learning for predicting stunting risk, reflecting a growing trend toward AI-based predictive models in public health research.

Fig. 7. Network visualization.

The yellow cluster highlights emerging stunting research areas, particularly the use of sentiment analysis and natural language processing (NLP). Keywords such as COVID-19 and

food security indicate studies examining the pandemic's impact on child nutrition. These findings suggest that stunting research is increasingly integrating artificial intelligence, data analytics, and NLP techniques beyond traditional nutritional and health determinants, providing a foundation for future interdisciplinary research on stunting prevention and intervention.

The Overlay Visualization generated using VOSviewer (Fig. 8) shows a rapid increase in research on stunting, malnutrition, and artificial intelligence in recent years. The color gradient represents temporal differences in keywords, with blue indicating earlier research themes (2018–2019) and yellow reflecting more recent trends (2021–2022). Based on this visualization, three major research trends in stunting can be identified according to their temporal evolution.

Fig. 8. Overlay visualization

The blue–green cluster (2018–2020) indicates that earlier studies focused on basic health determinants such as nutrition, infections, and socio-economic conditions. More recent trends (2021–2022), represented by the yellow cluster, highlight the application of artificial intelligence, particularly machine learning and health prediction. In addition, text-based and data analytics approaches, including natural language processing and sentiment analysis, have increasingly emerged, with COVID-19 and food security acting as key drivers of recent stunting and malnutrition research. These patterns reflect a growing multidisciplinary, AI-driven approach to understanding and addressing stunting.

V. DISCUSSION

The findings of this study demonstrate a significant increase in the application of Artificial Intelligence (AI) for stunting research over the last decade. The upward trend in publications, particularly after 2021, indicates a growing recognition of AI as a powerful tool in addressing complex public health problems. This surge is closely associated with the rapid advancement of digital technologies and the increased availability of health-related data. Moreover, the fact that the majority of studies were published in indexed journals (Q1–Q4) reflects not only the growing quantity but also the improving quality and scientific rigor of research in this field.

From a methodological perspective, supervised machine learning dominates the landscape, accounting for more than 79% of the reviewed studies. This dominance suggests a strong preference for predictive modeling approaches, particularly in structured datasets commonly found in public health. While deep learning methods are gaining attention, their adoption remains limited compared to traditional machine learning techniques. This may be attributed to the higher computational requirements and the need for large-scale datasets in deep learning applications, which are often unavailable in many public health contexts, especially in developing countries.

Geographically, the concentration of studies in developing countries such as Indonesia, Bangladesh, and India highlights the urgency of addressing stunting in these regions. These countries share similar socio-economic conditions, healthcare infrastructures, and nutritional challenges, which explains the high research activity. However, this concentration also raises concerns regarding the generalizability of AI models. Models developed using data from developing countries may not perform optimally when applied to populations in developed countries due to differences in demographic characteristics and health systems. Therefore, cross-country validation and the use of more diverse datasets are essential to enhance model robustness and applicability.

In terms of research focus, the predominance of stunting prediction (19.58%) indicates that early detection remains the primary objective of AI applications in this domain. This aligns with public health priorities, where early identification of at-risk children is crucial for timely intervention. However, other important areas, such as diagnosis and nutritional status estimation, remain underexplored. This imbalance suggests a research gap and highlights opportunities for future studies to expand into less-studied areas, including image-based diagnosis and advanced nutritional assessment methods.

Regarding algorithm selection, Random Forest emerges as the most frequently used method due to its robustness, ability to handle high-dimensional data, and interpretability. Other algorithms, such as Support Vector Machine (SVM) and Gradient Boosting (e.g., XGBoost and LGBM), are also widely used, particularly for their strong predictive performance and ability to manage complex, non-linear relationships. Meanwhile, deep learning approaches such as Convolutional Neural Networks (CNN) and Artificial Neural Networks (ANN) show promising results, especially in image-based and complex data analysis. However, their effectiveness is often constrained by limited data availability and the risk of overfitting.

Evaluation metrics play a crucial role in ensuring model reliability. The frequent use of metrics such as accuracy, precision, recall, F1-score, and AUC-ROC indicates a comprehensive approach to performance assessment. In addition, validation techniques such as cross-validation and confusion matrices are widely applied to prevent overfitting and ensure generalizability. For regression and clustering tasks, metrics such as RMSE, MAE, and Silhouette Score further support the robustness of AI models in different analytical contexts.

Despite these advancements, several challenges remain. One major issue is the limited availability of high-quality and real-

time datasets. Most studies rely on survey-based data, which may lack important variables such as environmental factors, dietary patterns, and genetic influences. This limitation can reduce model accuracy and hinder early detection capabilities. Furthermore, the black-box nature of many AI models presents challenges in interpretability, making it difficult for healthcare professionals to trust and adopt these systems. The integration of Explainable AI (XAI) techniques, such as SHAP and LIME, is therefore essential to improve transparency and usability.

Another critical challenge is the implementation of AI in real-world public health systems. Issues such as limited digital infrastructure, lack of technical expertise among healthcare workers, and insufficient regulatory frameworks can hinder the adoption of AI-based solutions. Consequently, there is a need for more user-friendly AI systems with simple interfaces to support healthcare professionals and policymakers in making informed decisions.

Finally, bibliometric analysis reveals a shift toward more interdisciplinary and data-driven research trends. The integration of AI with natural language processing (NLP), sentiment analysis, and big data analytics reflects the evolving nature of stunting research. Emerging topics such as COVID-19 and food security further demonstrate how global events influence research directions. This indicates that future research will likely adopt a more holistic and multidisciplinary approach, combining traditional public health knowledge with advanced AI techniques to address stunting more effectively.

In summary, while AI has shown great potential in improving stunting prediction and intervention, further efforts are needed to address data limitations, enhance model interpretability, and ensure practical implementation. Strengthening collaboration across countries and disciplines will be key to maximizing the impact of AI in tackling stunting as a global public health challenge.

VI. CONCLUSION

Artificial intelligence (AI) in public health research has come a long way in the past 10 years. Machine learning (ML) and deep learning (DL) are among the many prediction methods used to forecast children's nutritional condition based on variables. Some of the applied algorithms include Random Forest (RF), Support Vector Machine (SVM), and Gradient Boosting, which have demonstrated effectiveness for high-accuracy processing of health survey data. Within this context, deep learning (DL) methods, followed by CNN and artificial neural networks (ANN), are being progressively used for image data manipulation and children's nutritional status classification. Different metrics, such as accuracy, sensitivity, specificity, AUC-ROC, and F1-score, are used to evaluate the model to maintain the model's reliability among diverse research settings.

While the potential of AI is evident from its proven efficacy, several challenges need to be overcome. One significant challenge is streamlining data, as much existing research still depends on survey data that do not always mirror present-day conditions and typically do not sufficiently take environmental and genetic contributors into consideration. Furthermore, complicated AIs, most notably deep learning, are often not interpretable to health practitioners and policymakers. Thus, the

need for the development of Explainable AI (XAI) to improve model intelligibility. The bibliometric mapping analysis provided by VOSviewer indicates that future research trends will involve the integration of AI with the Internet of Things (IoT) for real-time nutritional status monitoring and the application of multimodal AI models encompassing clinical, genetic, and socio-economic factors research areas. With these advancements, AI could potentially play a greater role in advancing better global health policy and scaling interventions.

ACKNOWLEDGMENT

The authors would like to thank the Institute of Informatics and Business Darmajaya for its support of this work. The authors also sincerely thank the anonymous reviewers for their valuable comments and constructive suggestions, which significantly improved the quality of this study. Their insightful feedback is greatly appreciated.

Research Office, National College of Automotive Technology, Muscat, Oman²

Abstract—The rapid adoption of generative artificial intelligence (AI) in higher education offers significant learning benefits while raising serious concerns about academic integrity. This study was conducted to examine undergraduate students' perspectives and their awareness, attitudes, usage behaviors, perceived educational impact, policy awareness, and intentions to misuse AI tools in academic contexts in Oman. Using a cross-sectional survey design, data were collected from 200 undergraduate students across multiple academic levels. The survey measured six constructs using Likert-scale items, and data were analyzed using descriptive statistics, correlation analysis, group comparisons, and hierarchical multiple regression. Results indicated that students demonstrated moderate to high awareness of AI tools and generally positive attitudes toward their use for learning-related tasks such as grammar checking, summarization, and brainstorming. Correlation analysis showed that AI awareness, perceived educational impact, and policy awareness were significantly and negatively associated with intentions to misuse AI. Hierarchical multiple regression revealed that ethics-related variables, specifically perceived impact and policy awareness, explained substantial additional variance in misuse intentions beyond baseline predictors of awareness, attitudes, and usage frequency. Gender differences were observed, with male students reporting higher intentions to misuse AI, while senior students demonstrated higher awareness and policy understanding than early-year students. The findings highlight the critical role of AI literacy, ethical awareness, and clear institutional policies in mitigating unethical AI use. Integrating AI ethics education early in undergraduate curricula and strengthening communication of academic integrity policies may promote responsible AI engagement. These results contribute empirical evidence from the Middle Eastern context and offer practical implications for higher education institutions.

Keywords—Artificial intelligence; academic integrity; student perspectives; ethical AI use; policy awareness

I. INTRODUCTION

Artificial intelligence (AI) has recently gained an important role in shaping higher education institutions, providing innovative and useful tools for the teaching/learning process and academic support for both students and instructors. The use of Generative AI tools and applications, such as ChatGPT, Google Gemini, and Grammarly, has become widely used and accessible, offering opportunities to improve brainstorming, writing, and problem-solving skills. On the other hand, while these applications and tools can enhance efficiency and support learning, they raised some concerns related to academic integrity, especially when these tools are used without proper acknowledgment [1] [2].

Students are one of the major pillars of the teaching/learning process. Their awareness, perceptions, and behavior toward AI play a critical role in determining whether AI tools are used wisely and responsibly or misused in any way that compromises ethical standards and academic integrity. Recent studies suggested that training in AI literacy and students' awareness are associated with more ethical and responsible use, however institutional policies or the ethical implications of AI-assisted academic works are still not clear for many students [3] [4] [5].

The Sultanate of Oman is experiencing a rapid national digital transformation that has accelerated the need for integration of artificial intelligence across the higher education sector in compliance with Oman Vision 2040. And despite the increased and growing attention about the use of AI in higher education, empirical research in the Middle East region, specifically Oman, remains limited, leading to a gap in understanding the students' perspective and how they perceive and interact with AI applications in relation to academic integrity. This study utilized the Omani context to examine the redefinition of traditional academic integrity values in society's transition towards the digital era. Understanding students' perception is essential for the effective development of policies, educational strategies, and interventions, which promote both making use of the educational benefits of AI tools and maintaining an acceptable level of academic integrity. In this context, this study aims to explore students' perspectives on artificial intelligence and academic integrity in higher education institutions in Oman, including students' awareness, attitudes, usage patterns, ethical considerations, and understanding of related institutional policies. By studying and investigating these factors and dimensions, this research seeks to provide insightful and actionable information for educators, policymakers, and institutions to promote and foster responsible use of AI among students.

II. ARTIFICIAL INTELLIGENCE IN HIGHER EDUCATION

It is a fact now that AI has been transforming the higher education sector rapidly, providing promising innovative tools for Teaching/Learning, assessment, and academic support. Many of such tools, like Google Gemini, ChatGPT, and Grammarly, have thus turned out to be widely adopted and increasingly integrated into the academic process, facilitating the generation of ideas, writing, and problem solving [1], [2], offering opportunities to improve the process of teaching/learning but simultaneously raising a challenge in maintaining and ensuring academic integrity [6]. As a result, AI has become an integral component in the daily academic routine

of students, enhancing their productivity and helping them tackle heavy workloads.

Ease of use and growing accessibility of AI have been contributing factors to an unexpected shift in learning expectations and behavior. AI is increasingly viewed by students as their personal and personalized learning assistant, capable of offering instant and real-time academic support that reduces learning barriers related to language proficiency, enabling self-learning. For example, the use of AI writing tools has been shown to improve clarity, coherence, and grammatical accuracy in students' writing significantly, supporting non-native speakers in particular [7]. Generating examples, language, and academic concepts in simple and clear language, and assisting with brainstorming AI abilities, enhanced students' academic engagement and confidence.

Despite all the benefits mentioned above, students' understanding and awareness of AI technologies are still inconsistent. While many students report that they have general familiarity with AI tools, the conceptual understanding of how AI works (Limitations, biases, ethical implications, and appropriate usage) widely varies among them [3], [4]. Previous studies argue that students who received proper training and guidance demonstrated higher levels of AI literacy, associated strongly with more ethical and responsible usage [8]. On the other hand, students with informal and limited exposure to AI may overestimate its capabilities or misuse it due to a misunderstanding about what the acceptable academic assistance of AI is, posing and creating challenges for striving institutions to promote informed and ethical integration of AI within the academic environment.

Students' attitudes towards using AI in higher education tend to be broadly positive, reflecting enthusiasm about academic support and efficiencies that AI offers. Perceived usefulness, ease of use, and the belief that AI technologies reduce academic pressure, helping students organize their ideas and produce well-structured academic work [9] [10] [11] [6] [12] [13] [7]. In particular, undergraduate students often express their appreciation for AI's capability to assist them in language, summarization, and fundamental writing skills, support areas where they feel insufficiently prepared. However, positive attitudes are often accompanied by uncertainty or concern regarding more complicated issues such as authenticity, originality and academic dependency. On the other hand, some students are concerned that the excessive reliance on AI may subvert their learning or reduce their critical thinking abilities, while others express some concerns about the fairness of AI use in an assessment context, where rules and expectations widely vary across instructors or courses [14].

Students' patterns of using AI highlight the complexity of integrating AI within the academic process. Research indicated that most of the students responsibly use AI as a supporting and supplementary tool for enhancing their learning (Grammarly, refining ideas, gaining more clarity on difficult concepts) [15]. However, a significant minority of the students reported that they use an AI tool to generate full essays, solve assignments, or perform some tasks that they present as their own work. This raises some concerns about honesty, especially when it happens without declaration or reflection on ethical boundaries. Misuse

motivations are diverse, ranging from academic pressure, confidence issues, and institutional policies, and are mostly higher among undergraduate students in the early stages, who may lack the necessary academic skills.

III. METHODS

This research used a cross-sectional survey method to collect students' perspectives on artificial intelligence (AI) and academic integrity in higher education [16]. Six constructs (factors) were included in the survey: Awareness, Attitudes, Usage, Perceived Impact, Intention to Misuse, and Policy Awareness. The survey included 29 items based on a 5-point Likert scale. Some demographic data (Major, Age, Level of Study, Prior AI Training) were also collected. After that, a validity and reliability test was conducted, the survey was sent for three reviewers to check its face and content validity, a total of 200 undergraduate students participated in the survey, and they were distributed across different levels (Foundation, Year 1, year 2, Year 3, Year 4 and year 5) from two different higher educational institutions in Oman.

The participants completed the survey online via Google Forms, which provides a secure and user-friendly platform for data collection. Before responding to the survey, students were presented with a bilingual consent form detailing the study purpose, confidentiality, voluntary participation and the right to withdraw at any time. All responses were automatically anonymized.

Collected data was analyzed using both descriptive and inferential statistics. Descriptive statistics summarized students' responses across all constructs, frequencies including means, standard deviations, and percentages. Cronbach's alpha coefficients were used to evaluate internal consistency of each construct, with $\alpha \geq 0.70$ as acceptance criteria. To ensure the validity of constructs, Exploratory factor analysis (EFA) was conducted to confirm that all survey items appropriately load onto their intended constructs; items that do not satisfy factor loading thresholds (≥ 0.40) may be removed or revised.

For inferential analysis, to examine the relationship between key constructs (Awareness, Attitude, and Self-reported AI usage), Pearson correlation was conducted. An independent sample t-test was conducted to evaluate group differences across demographics. Additionally, Hierarchical multiple regression (HMR) was performed to evaluate the incremental predictive power of ethics-related constructs (perceived impact and policy awareness) on students' intention to misuse AI. HMR allows for theoretically driven sequential testing of predictors and assessment of their impact on the outcome variable. This sequential approach allows for a more detailed understanding of academic integrity by isolating policy awareness (knowing the rules), providing a significant statistical increase while controlling for the general technological proficiency of students. Therefore, this approach provides a deeper look at the psychological and institutional factors that actually deter misuse, which primary correlation analysis cannot distinguish. Also, one-way ANOVA was conducted to test the differences across academic levels, and independent-sample t-tests were used to examine gender differences; all analysis tests were conducted under a significant level of $p < 0.05$.

IV. RESULTS

A total of 200 students participated in this study, from different undergraduate levels, Foundation (7%), Year 1 (20.5%), Year 2 (22%), Year 3 (11.5%), Year 4 (22.5%), and Year 5 (16.5%), approximately 36.5% were female and 63.5% male.

Mean and standard deviations for the constructs are shown in Table I. The results indicated a moderate to high awareness of AI tools ($M=4.1$, $SD=0.6$) and positive attitudes toward AI use as a learning aid ($M=3.8$, $SD=0.7$). The Behavior & Usage constructs indicated that most of the students use AI tools for summarizing readings, brainstorming, and grammar checking, while not too many admitted the use of AI tools in drafting assignments without disclosure.

TABLE I. DESCRIPTIVE STATISTICS OF SURVEY CONSTRUCTS

Construct	Mean (M)	SD	Cronbach's α
Awareness & Knowledge	4.10	0.60	0.82
Attitudes & Beliefs	3.80	0.70	0.78
Usage & Behaviors	3.45	0.75	0.81
Perceived Impact on Learning	3.70	0.68	0.79
Intent to Misuse / Academic Dishonesty	2.60	0.85	0.72
Policy Awareness & Perceived Enforcement	3.20	0.80	0.77

Internal consistency across all constructs scored an acceptable level (Cronbach's ranging from 0.72 to 0.88), while the survey item loading onto their intended constructs was confirmed using Exploratory factor Analysis (EFA). Pearson correlations indicated that more responsible AI usage is significantly associated with higher awareness ($r = 0.52$, $p < 0.001$), and early years students reported higher AI usage than senior students (Year 3 and more) ($F = 5.42$, $P = 0.005$).

A. Hierarchical Multiple Regression Analysis

As stated before, HMR was chosen because it allows for a theoretical and sequential testing of predictors. Two models were tested:

Model 1: Awareness, Attitudes, and Usage

This is the baseline model, which significantly predicted intention to misuse, $F(3,196) = 18.24$, $p < .001$, accounting for 23% of variance ($R^2 = 0.23$). Attitudes ($\beta = -.26$, $p < .001$) and Awareness ($\beta = -.2$, $p = .002$) were significantly negative predictors, while usage was not significant ($\beta = .07$, $p = .18$).

TABLE II. HIERARCHICAL MULTIPLE REGRESSION PREDICTING INTENTION TO MISUSE AI (N = 200).

Predictor	Model 1 β	Model 1 p	Model 2 β	Model 2 p
Awareness (AW)	-.21	.002	-.12	.04
Attitudes (AT)	-.26	<.001	-.14	.03
Usage (US)	.07	.18	.05	.31
Perceived Impact (PI)	—	—	-.31	<.001
Policy Awareness (PA)	—	—	-.27	<.001

Model 2: Adding Policy Awareness and Perceived Impact

By adding policy awareness and perceived impact the model is significantly improved, as shown in Table II, $\Delta R^2 = .16$, $F(5,194) = 25.38$, $p < .001$, leading to increase the total explained variance to 39% ($R^2 = .39$). Policy Awareness ($\beta = -.27$, $p < .001$) and Perceived Impact ($\beta = -.31$, $p < .001$) were the strongest predictors. Attitudes ($\beta = -.14$, $p = 0.03$) and Awareness ($\beta = -.12$, $p = .04$) remained significant, and Usage also remained not significant ($\beta = .05$, $p = .31$).

B. Gender Differences

Female students ($M = 2.40$, $SD = 0.85$) reported lower intention to misuse than male students ($M = 2.94$, $SD = 0.91$), $t = 5.12$, $p < 0.001$, while no significant differences were found in Awareness, Attitudes, or Policy awareness as shown in Table III:

TABLE III. INDEPENDENT SAMPLES T-TEST: GENDER DIFFERENCES IN INTENTION TO MISUSE (N = 200).

Gender	N	M	SD	t	df	p
Male	127	2.94	0.91	5.12	198	<.001
Female	73	2.41	0.87	—	—	—

C. Academic Level Differences

The one-way ANOVA differences examination (Table IV) in Awareness and Policy Awareness across the five undergraduate levels (Foundation, Year1, Year2, Year3, Year4/5) resulted:

- Awareness: Foundation Students had the lowest awareness, while Year4/5 had the highest [$F(4,195) = 7.12$, $p < .001$].
- Policy Awareness: year 4/5 students showed the highest policy awareness also [$F(4, 195) = 5.78$, $p < .001$].
- No significant differences were found in attitudes ($p = .24$) or intention to misuse ($p = .23$).

TABLE IV. ONE-WAY ANOVA: ACADEMIC LEVEL DIFFERENCES IN AWARENESS AND POLICY AWARENESS (N = 200).

Variable	Source	df	F	p
Awareness (AW)	Between Groups	4	7.12	<.001
	Within Groups	195	—	—
Policy Awareness (PA)	Between Groups	4	5.78	.001
	Within Groups	195	—	—

V. FINDINGS

The results of the data analysis in this study reveal several significant and important insights regarding students' perspectives on AI usage and academic integrity. Correlation analysis (Pearson) showed that students' awareness about AI, their attitudes to use it and usage frequency are positively related to the perceived impact and policy awareness. On the other hand, intention to misuse AI tools was negatively correlated with awareness, perceived impact, and policy awareness, implying that students with a higher knowledge, stronger appreciation of AI educational benefits and appreciation of AI, and more understanding of institutional policies related to AI were less

likely engaged in unethical behaviors. These indicated the importance of students' knowledge and policy awareness as a defensive and protective factor against students' intentions towards academic misconduct in an AI-supported teaching/learning environment.

Hierarchical multiple regression analyses additionally explained the relative effect of different factors on students' intentions to misuse artificial intelligence. While the basic model, which included awareness, attitudes, and usage, reported a significant portion of the variance in intentions to misuse, emphasizing the role of general acceptance of technology.

On the other hand, the inclusion of perceived impact and awareness of policy factors in the second model significantly improved the explained variance from 23% to 39%, highlighting that ethical-related factors add significant predictive power. Particularly, perceived impact and awareness of policy factors emerged as the strongest negative predictors, while awareness and attitudes remained as a moderate predictive impact. Frequency of use retained a statistically insignificant. This pattern suggests that students' understanding of the ethical and educational implications of artificial intelligence, along with their familiarity with institutional policies, is more critical in discouraging misuse than merely their frequency of using AI tools or their general attitudes toward them.

Comparing gender groups indicated a significant difference; female students reported lower intentions to misuse AI than male students, while regarding attitudes, awareness, and policy knowledge, there were no significant differences among male or female groups. Based on the students' academic level Year 4/5 students showed the highest awareness and policy understanding, and Foundation students had the lowest, reflecting the effect of cumulative exposure to institutional policies and guidelines and educational content over time. In summary, the findings raised the need for necessary interventions to enhance students' knowledge, ethical awareness, and adherence to institutional policies at the early stages of undergraduate education, particularly.

VI. CONCLUSION

This study investigated the factors influencing the undergraduate students' intention to misuse AI in the context of academic integrity within higher educational institutions in Oman, utilizing a cross-sectional survey collected from 200 students across different academic levels. Hierarchical multiple regression was used to isolate the predictive power of ethical and institutional variables.

The findings revealed that students' awareness of AI, attitudes toward using it, and their understanding of institutional policies significantly affect students' intention to misuse AI tools in their academic activities. Moreover, Policy Awareness and Perceived Impact (ethics-related constructs) were found to be highly significant and effective factors in reducing and predicting unethical behaviors. The findings also raised the need to integrate AI literacy, ethical educational usage, and clear AI-related policies into the institutional curriculum to promote and foster responsible ethical usage of AI technologies and tools.

Early interventions, particularly for foundation and first-year students, should be prioritized by educational institutions to build students' awareness about educational and ethical implications of AI in the academic process. In addition, clear publishing, communication, and reinforcement of policies (academic integrity, AI usage, etc.) can act as an efficient and effective deterrent against AI tools misuse. Future research could be beneficial in exploring the longitudinal changes in the students' perceptions and behavior as they advance through academic levels, and to investigate the faculty role in guidance and institutional culture and environment in forming ethical AI usages. Finally, promoting the culture of ethical and responsible use of AI is very crucial in ensuring academic integrity in higher educational institutions in the age of smart and intelligent learning tools.

A. Recommendations

1) *Integration of AI knowledge and ethics in the curriculum early*: The findings of this study showed that students in the early years had the lowest AI awareness and policy knowledge, which means that Institutions need to integrate AI literacy workshops or classes and provide ethical guidance on AI usage in early stages of undergraduate education. In these sessions, the emphasis should be on both the educational potential of AI and the academic consequences of unethical practices, promoting a strong foundation for responsible AI use.

2) *Enhance policy dissemination and implementation*: As the findings of this study indicate that Policy awareness is a key predictor of reducing students' intention to misuse AI, based on that, higher educational institutions should ensure the clear communication of academic integrity policies, and ensure easy access and regular support. Training sessions, online tutorials, workshops, and policy reminders may be helpful in improving understanding and compliance among students.

3) *Promote and evaluate the perceived educational value of AI tools*: If the students understand the positive educational impact of AI tools, they will be less likely to misuse it. In this regard, the educators should explain practical applications of AI in the learning process, such as improving research skills, enhancing critical thinking, or supporting collaborative projects. Also, it is their responsibility to highlight the benefits of responsible use of AI tools, which could motivate the students to be ethically engaged with AI.

Web System Based on Convolutional Neural Networks to Support Early Identification of Ocular Pterygium

Justo Oscar Salcedo-Enriquez, Keyla Guadalupe Yataco-Argomedo, Rosalynn Ornella Flores-Castañeda
Facultad de Ingeniería y Arquitectura, Universidad César Vallejo, Lima, Perú

Abstract—This research aligned with SDG No. 9, “Industry, Innovation, and Infrastructure,” as it promotes health and well-being using innovative technologies. The objective was to determine whether the development of a web-based system based on convolutional neural networks improves the early identification of pterygium. Sensitivity, specificity, and accuracy metrics were used to measure the results, yielding excellent incremental values of 96%, 98%, and 97%, respectively. The study was applied research with a quantitative approach and an experimental design, specifically pre-experimental. The study variable was the early identification of ocular pterygium, consisting of a sample of 100 images, which were divided into 50 images corresponding to individuals with ocular pterygium and 50 from healthy individuals. The type of sampling used was non-probabilistic convenience sampling. The results obtained showed an increase in sensitivity of 4.35%, specificity of 2.80%, and accuracy of 3.56%. It is concluded that the proposal positively improves support for the early identification of pterygium, thanks to the high results obtained with the indicators evaluated, which makes it executable and scalable for future research.

Keywords—Ocular pterygium; web system; convolutional neural networks; early identification; technology

I. INTRODUCTION

In the field of visual health, eye diseases such as pterygium pose a constant risk to people's quality of life, especially when they are not detected and treated in time. This is because the condition can develop silently, affecting vision if not treated early. Considering this reality, a proposal has been put forward to develop a web-based system using convolutional neural networks to aid in the early identification of pterygium based on images previously captured with a cell phone and subsequently uploaded to the web-based system for automatic analysis.

Pterygium, commonly known as “surfer's eye,” is a lesion characterized by the growth of triangular-shaped fibrovascular tissue that advances from the conjunctiva toward the corneal surface [1]. It is classified into the following grades: Grade 1, mild appearance between the limbus and the edge of the pupil. Grade 2 begins to invade the edge of the pupil. Grade 3 completely affects the pupil, causing blurred vision and more intense discomfort. Finally, in grade 4, the pterygium invades beyond the pupil [2].

Pterygium is considered one of the most common ophthalmic conditions worldwide [3], whose origin and

hereditary factors still raise questions, despite years of study on its symptoms and treatments [4]. Although initially asymptomatic, pterygium can cause discomfort such as irritation, redness, and foreign body sensation, and can lead to vision loss when its growth compromises the optical axis [5].

Various studies have estimated that the frequency of this condition varies widely worldwide, ranging from 1.2% to approximately 40%, depending on environmental and demographic conditions [6], most commonly affecting middle-aged men, who tend to spend more time outdoors without adequate eye protection. In addition, those who suffer from allergic or inflammatory diseases in the eye area are at greater risk, as constant inflammation leads to changes in the surface of the eye that can facilitate the development of pterygium [7].

It is more common in tropical and subtropical regions, where conditions such as exposure to ultraviolet (UV) light, dust, wind, and dry climates predominate [8]. In addition, the progression of pterygium can vary significantly in symptoms between patients, making timely detection even more difficult [9]. Despite advances in ocular imaging techniques, challenges remain associated with the subjectivity of clinical evaluation and the lack of standardized diagnostic criteria for ocular conditions [10].

For this reason, we propose designing a web-based system based on convolutional neural networks, which processes images previously taken with a cell phone, uploads the images to the system, and finally performs a diagnosis based on the percentage of ocular pterygium presence. The model extracts the specific features of the lesion, prioritizing the following dimensions: sensitivity, which reliably examines true positives; specificity, reinforced to reduce the number of false positives as much as possible; and finally, optimizing diagnoses with absolute accuracy. In this way, it provides an accessible resource for both ophthalmology professionals and patients with this type of condition, intending to facilitate diagnoses through technology, combined with the accessibility and clinical rigor required for the effective detection of ocular pterygium.

In this regard, this valuable alternative has emerged thanks to the system's use of Artificial Intelligence (AI), mainly convolutional neural networks, to optimize the speed and accuracy of ocular pterygium diagnosis, enabling medical professionals to perform interventions more effectively and in a timelier manner [11].

Therefore, this initiative contributes to the improvement of preventive diagnosis, aligning with Sustainable Development Goal (SDG) No. 9, which promotes health and well-being through the use of innovative technologies.

For this reason, the objective is to develop a web-based system based on convolutional neural networks to support the early identification of ocular pterygium.

II. RELATED WORKS

According to [12], a mobile application based on convolutional neural networks was developed with the aim of improving the early diagnosis of rosacea. This research used a pre-experimental design with a quantitative approach. The sample consisted of 100 images, divided between 50 patients with rosacea and 50 healthy individuals. Observation was used as the data collection technique, and the metrics of sensitivity, specificity, and accuracy were evaluated, resulting in positive values of 2.7%, 1.97%, and 0.10%, respectively. It was concluded that the mobile application based on convolutional neural networks efficiently improves the early diagnosis of rosacea, optimizing the evaluated indicators.

Regarding [13], they investigated the use of convolutional neural networks with the aim of detecting pterygium from eye images. In this research, an in-depth analysis of previously existing systems was carried out, highlighting the transition from classical algorithms to more accurate models. They demonstrated high effectiveness in the segmentation, classification, and localization of the condition thanks to the use of computer vision techniques. They demonstrated that the implementation of these models can positively contribute to the early diagnosis of eye diseases, even using cell phone cameras in areas with limited resources.

Regarding [14], they developed a system based on convolutional neural networks to detect ocular pterygium based on cell phone images. Six pre-trained networks were evaluated using 10-fold cross-validation and a Softmax classifier. The data showed that the VggNet16-wbn model had the best results in the calculated metrics, achieving an accuracy of 99.22%, a sensitivity of 98.45%, and a specificity of 100%. They concluded that the proposed system has high performance in terms of pterygium detection, making it scalable for future work and useful in areas and centers where medical resources are limited.

As mentioned in [15], they implemented the use of smartphones through an integration approach to improve pterygium detection with images. They achieved an accuracy of 95.24%, showing a result similar to that of experts in the field, due to the combination of more than 20,000 clinical images with 1,094 mobile images, using learning prototypes such as Faster R-Convolutional Neural Network (CNN) and SRU-Net. This validated the effectiveness of the model, highlighting its ability to provide early diagnosis of pterygium.

On the other hand [16], two systems were developed using AI, one to detect whether an image of the eye shows pterygium, using a binary classification model, and another to determine the affected area in these images, which would correspond to segmentation. To do this, neural network

architectures such as VGG16 and PSPNet were used, training them with 734 photographs to determine their functionality, measuring their performance using indicators such as accuracy, detection capability, and mean intersection over union (MIOU). The VGG16 system was able to correctly diagnose 99.0% of the images, while PSPNet managed to segment the affected areas with an accuracy of 86.57%. Therefore, these systems are considered to have great potential for practical use in the medical field, as they facilitate evaluation and support for specialists in diagnosis in order to plan early interventions.

As for [17], they analyzed how to improve the diagnosis of ocular pterygium using AI, beginning with an exploration of different techniques, including computer vision, deep learning, and machine learning. The final result highlighted the efficiency and accuracy of these tools in achieving a good diagnosis. Finally, they concluded that the use of AI allows for the optimization of advanced medical systems for the early detection of pterygium.

According to [18], they evaluated the use of tools for imaging studies in the field of telemedicine with the aim of establishing a diagnosis for corneal diseases, including pterygium. A review of 51 technological tools was conducted, including smartphones and slit lamps, highlighting their ability to identify eye conditions remotely. They concluded that only some of the devices have been clinically validated despite showing great potential, which emphasizes the need for much more meticulous studies to support their use for actual diagnoses.

On the other hand [19], they emphasized the crucial role that AI plays in the field of ophthalmology, as it is capable of analyzing medical images, even using a smartphone, thus providing accurate diagnoses. This allows specialists to make determinations and facilitates long-distance evaluations. Although it is often presented as a challenge, the evolution of technology in terms of applications is increasingly predictive.

According to [20], they explored the existence of diseases present on the ocular surface using AI. Although they were initially focused on studying the posterior segment of the eye, they were able to demonstrate the usefulness of AI in conditions such as dry eye and ocular pterygium. Using models such as deep neural networks, which increase the accuracy of diagnoses, especially in environments where ophthalmic professionals are scarce. They concluded that despite all of the above, AI currently appears to be a viable tool for enhancing eye treatments and diagnoses.

Regarding [21], they studied the progress of AI in identifying conditions affecting the surface of the eye, such as keratitis, keratoconus, dry eye, and pterygium. Although AI has been used largely for diseases of the fundus, its application to the surface reflects an increase due to its ability to identify, classify, and segment various lesions. Therefore, it is concluded that, despite current challenges, such as the demand for reliable databases and validation in clinical settings, its great capacity to improve access to diagnosis is recognized, especially in regions or localities with limited resources and a shortage of healthcare professionals.

III. METHODOLOGY

The methodology chosen for the development of the web system is the Waterfall methodology.

The Waterfall methodology is a model that allows for the sequential simulation of software development, enabling the identification of bottlenecks in each phase, starting from the requirements phase through to product maintenance [22].

1) Phase 1: Analysis

Phase in which the functional requirements as well as the non-functional requirements of the system are collected and documented, with the participation of customers and users [23].

This first phase comprises the requirements that define the essential functionalities that the system will have for the identification of ocular pterygium.

a) Scope definition: Develop a web-based system using convolutional neural networks for the early identification of ocular pterygium.

Table I shows the functional requirements that the system must fulfill.

TABLE I. TABLE OF FUNCTIONAL REQUIREMENTS

Code	Requirement	Description
RF001	User Registration	The system must allow new users to register by providing personal data and access credentials.
RF002	User Authentication	The system must allow users to authenticate themselves using their email address and the password they initially created.
RF003	Reliable information	The application should provide reliable information about ocular pterygium and offer links to additional resources.
RF004	Perform evaluations	The system must allow the user to upload images of the eye in compatible formats (.jpg, .png, .tiff).
RF005	Process images	The system must process the images using a convolutional neural network to detect signs of pterygium.
RF006	Display evaluation results	The system must display the result of the diagnosis to the user with a visualization of the affected areas.
RF007	Data recording	The system will automatically save the diagnostic results, the analyzed image, the date, and the patient's user in the database.
RF008	Clinical History	The system will allow users to access a history of previous analyses, viewing uploaded images, results, and dates.
RF009	User Update	The system will allow users to modify personal information such as names, email addresses, and passwords.
RF010	Logout	The system will allow users to log out securely.
RF011	Error Handling	The system must notify the user with a message when the model cannot process the uploaded image, either due to an error or incorrect formats.

2) Phase 2: System design

The second phase involves transforming the requirements obtained in the analysis phase into a technical architecture that defines how the system works internally. The aim is to have a basic functional initial version of the system and adjust it to the end user's expectations [23].

a) CNN-based web system workflow diagram: Fig. 1 illustrates the workflow of the proposed web system based on a convolutional neural network (CNN). The process begins when the user accesses the interface using their credentials. If the user is successfully authenticated, they can upload the eye image. The image will be sent to the server, where it will be processed with the previously trained CNN model for analysis. Finally, the result will be received by the system, stored in the database, and displayed to the end user.

Fig. 1. CNN-based web system workflow diagram.

b) Web system architecture: Fig. 2 shows the diagram of the web system's technological architecture. The system is built with technologies such as HTML, CSS, PHP, and JavaScript for the user interface. The data is sent to the MySQL database, which is part of the back end, to later use web services and a model developed in Python to process information and generate a response.

Fig. 2. Architecture of the proposed system.

c) *Final system design*: The final design is based on the initial prototype, with each of the modules initially proposed.

Fig. 3 shows the final design of the system login interface with the option to log in using a registered username and password.

Fig. 3. Final design of the login interface.

Fig. 4 shows the final design of the system's main interface, which displays the total number of cases analyzed, along with the severity level of each case analyzed.

Fig. 4. Final design of main interface.

d) *Environment configuration*: The following are the components that were necessary for configuring the web system development environment:

Hardware:

PC used for development with the following characteristics:

- Processing: Intel Core i7 4790k.
- RAM: 32GB DDR3 1866mhz RAM.
- Graphics Card: NVBIDEA GeForce RTX 4060TI 8GB DDR6.

- Storage: 1TB NVMe SSD by MSI. Ensures fast access speeds for managing data sets, models, and files required by the system.

- Camera: Teros FHD camera.

Software:

- Operating System: Windows 10 Pro 64-bit.

Integrated Development Environment (IDE):

- Front-End: HTML, CSS, JavaScript, PHP. These enable the development of the system interface, facilitating user interaction with web functionalities in a dynamic and accessible way.
- Back-End: MySQL, REST API. These manage structured data storage and enable secure and efficient communication between the server, the database, and the client application.
- AI: Python, Google Colab. These are used for the implementation, training, and validation of the computer vision model, leveraging libraries and computing resources in the cloud.
- Complementary Tools: Visual Studio Code, Web Browser. These facilitate code editing, functional testing, and application deployment during development.

3) Phase 3: Implementation

a) *Graphical interface development*: The start window was implemented, providing access to view the number of pterygium cases analyzed within the system.

b) *MobileNetV2 neural network integration*: The MobileNetV2 neural network model, which is already pre-trained for object detection, was integrated and adapted for the identification of the medical problem.

History log:

The validation window was developed, which provides access to the history of all pterygium cases analyzed by severity, allowing the information to be downloaded in a PDF or Excel file.

4) Phase 4: Testing

In this phase, we thoroughly validate that the system complies with each of the requirements initially set out. Basically, we validated that each of these points is being met as planned. See Table II.

5) Phase 5: Maintenance

During this phase, errors identified during the testing phase were corrected, and adjustments were made to improve the accuracy and performance of the web system. Likewise, improvements were analyzed to refine the design of a more intuitive graphical interface to offer a better user experience. The most important information was duly recorded in the system and user manual to ensure an accessible and clear guide for use.

TABLE. II. STATUS OF TESTING BASED ON REQUIREMENT

Code	Functional Requirement	Description
RF001	The system must allow new users to register by providing personal data and login credentials.	Meets the requirement
RF002	The system must allow users to authenticate using their email address and the initially created password.	Meets the requirement
RF003	The application must provide reliable information about ocular pterygium and offer links to additional resources.	Meets the requirement
RF004	The system must allow users to upload images of the eye in compatible formats (.jpg, .png, .tiff).	Meets the requirement
RF005	The system must process the images using a convolutional neural network to detect signs of pterygium.	Meets the requirement
RF006	The system must show the user the diagnosis result with a visualization of the affected areas.	Meets the requirement
RF007	The system will automatically save the diagnostic results, the analyzed image, the date, and the patient's user information in the database.	Meets the requirement
RF008	The system will allow the user to access a history of previous analyses, viewing uploaded images, results, and dates.	Meets the requirement
RF009	The system will allow the user to modify personal information such as names, email, and password.	Meets the requirement
RF010	The system will allow users to log out securely.	Meets the requirement
RF011	The system must notify the user with a message when the model cannot process the uploaded image due to an error or incorrect formats.	Meets the requirement

IV. RESULTS

The objective of this research is to determine whether a web-based system based on convolutional neural networks supports the early identification of ocular pterygium.

A. Calculation of Indicators

Table III shows the confusion matrix corresponding to the system's performance in supporting the identification of

ocular pterygium with a set of 100 images. It shows that of 50 images of people with pterygium, 48 were correctly classified as positive, while 2 of the results were incorrectly classified as negative. As for the 50 images of people without pterygium, 49 were correctly classified, and only 1 had an erroneous result, classifying it as positive. This resulted in a sensitivity of 96%, a specificity of 98%, and demonstrated that the model has an accuracy of 97%.

TABLE. III. CONFUSION MATRIX

	Prediction					
Current		Sensitivity	Specificity	Total	Function test	
		Person with pterygium	A person without pterygium			
	Positive	48	1	49	0.96	Pterygium
	Negative	2	49	51	0.98	Without pterygium
	Total	50	50	100		
	Laboratory test	0.96	0.98		0.97	

From the confusion matrix analyzed, the following results are obtained for the metrics proposed:

% Sensitivity = 96%

% Specificity = 98%

% Accuracy = 97%

1) *Analysis of the ROC curve and the area under the curve (AUC):* Fig. 5 corresponds to the ROC curve, showing the blue line approaching the upper left axis, which indicates that the model's performance has high capacity, with high specificity and sensitivity values. In contrast, the red line represents the behavior of a test to make predictions without discrimination, i.e., an AUC of 0.5.

The notable distance between the two curves demonstrates that the model performs excellently ($AUC = 0.985$; $p < 0.001$), indicating that it is capable of efficiently differentiating between people with and without pterygium, as shown in Table IV.

Fig. 5. ROV curve.

TABLE. IV. AREA UNDER THE CURVE

Area	Std. Error	Asymptotic significance	95% asymptotic confidence interval	
.985	.010	.000	Lower limit	Upper limit
			.966	1.000

B. Analysis of the Pre-Experimental Design

a) *Pre-test*: Table V presents a comparison of the different CNN architectures studied for the binary

TABLE. V. PRE-TEST VALUES RESULT

Model	AlexNet		VGG16		ResNet18		ResNet50	
Evaluation indicators	Normal	Pterygium	Normal	Pterygium	Normal	Pterygium	Normal	Pterygium
Sensitivity	98.00%	96.00%	99.33%	98.67%	95.33%	92.00%	93.33%	92.67%
Specificity	96.00%	98.00%	98.67%	99.33%	92.00%	95.33%	92.67%	93.33%
F1-score	97.03%	96.97%	99.00%	99.00%	93.77%	93.56%	93.02%	92.98%
AUC	0.97		0.99		0.94		0.93

Kappa	94.00%		98.00%		87.33%		86.00%	
Accuracy	97.00%		99.00%		93.67%		93.00%	

TABLE. VI. RESULTS OF THE INDICATORS FOR THE POST-TEST

Quantity	V P	V N	F N	F P	Sensitivity	Specificity	Accuracy
100	48	49	2	1	96%	98%	97%

Table VII shows a comparison of the results between the percentages of the specificity, sensitivity, and accuracy indicators between the ResNet18 model and the web system.

TABLE. VII. COMPARISON OF RESULTS

Indicator	ResNet18	Web System
Sensitivity	92%	96%
Specificity	95.33%	98%
Accuracy	96.67%	97%

C. Hypothesis Testing

a) *Specific scenario HE1*: HE1₀: A web-based system based on convolutional neural networks does not increase sensitivity in supporting the early identification of ocular pterygium.

HE1₁: A web-based system based on convolutional neural networks does not increase sensitivity in supporting the early identification of ocular pterygium.

$$\% \text{ Sensitivity variation} = (96-92) / 92 \times 100 = 4.35\%$$

There is a 4.35% increase in sensitivity, indicating that the system has a greater capacity to correctly identify cases. Therefore, the alternative hypothesis is accepted, and the null hypothesis is rejected.

classification of pterygium and non-terygium cases, considering the sensitivity, specificity, and accuracy metrics of Zhu's ResNet18 model [16] selected as a reference, comparing them with the ocular pterygium values of the proposed web system model.

b) *Post-test*: For the post-test, 100 images obtained from datasets were used, with the results obtained through the web system report. Table VI shows the metrics and percentages for each indicator, with a sensitivity of 97%, a specificity of 98%, and an accuracy of 97%.

b) *Specific scenario HE2*: HE2₀: A web-based system based on convolutional neural networks does not increase specificity in improving early identification of ocular pterygium.

HE2₁: A web-based system using convolutional neural networks increases specificity in improving early identification of ocular pterygium.

$$\% \text{ Change in specificity} = (98-95.33) / 95.33 \times 100 = 2.80\%$$

There is a 2.80% increase in specificity, indicating that the system has a greater capacity to correctly identify cases. Therefore, the alternative hypothesis is accepted, and the null hypothesis is rejected.

c) *Specific scenario HE3*: HE3₀: A web-based system based on convolutional neural networks does not increase accuracy in improving early identification of ocular pterygium.

HE3₁: A web-based system using convolutional neural networks increases accuracy in improving early identification of ocular pterygium.

$$\% \text{ Variation in accuracy} = (97-93.67) / 93.67 \times 100 = 3.56\%$$

There is a 3.56% increase in accuracy, indicating that the system has a greater capacity to correctly identify cases. Therefore, the alternative hypothesis is accepted, and the null hypothesis is rejected.

D. Results of Indicator Increments

Table VIII shows the results of the variation for each indicator, whose results show that a positive number is grounds

for accepting the hypotheses, whereas a negative result would automatically reject the hypotheses.

TABLE. VIII. RESULTS OF THE INCREMENTS FOR EACH INDICATOR

SENSITIVITY VARIATION (%)	SPECIFICITY VARIATION (%)	ACCURACY VARIATION (%)
+4.35%	+2.80%	+3.56%

E. General Hypothesis

HG0: A web-based system based on convolutional neural networks does not improve early identification of ocular pterygium.

HG1: A web-based system based on convolutional neural networks improves early identification of ocular pterygium.

Evidencing the results of HE1, HE2, and HE3, the general hypothesis is accepted.

V. DISCUSSION

The results showed a sensitivity of 96%, resulting in a variation of 4.35% compared to the ResNet18 model, which achieves a sensitivity of 92%. This was mainly due to improvements in the training of the MobileNetV2 architecture, which contributed to more accurate feature extraction in images of eyes with and without the condition. This result is slightly higher than that obtained by Y. Liu et al. [15], who presented a sensitivity of 93.60% in their fusion segmentation model trained with smartphone and slit lamp images for the accurate detection and classification of pterygium. This difference could be due to the incorporation of better performance techniques in the training of the MobileNetV2 network, minimizing generalization loss and optimizing accuracy in the correct analysis of the characteristics of the condition. Similarly, the results obtained by S. Zhu et al. [16] are compared, who report a sensitivity of 98.67% using the VGG16 neural network model. This difference in values may be due to the high complexity of the model, as it requires greater computational capacity than that used in the research. However, the result obtained achieved a significant increase in sensitivity for the preliminary diagnosis of ocular pterygium, demonstrating that it is feasible to achieve competitive levels of sensitivity using a more competent and less resource-intensive neural network, making it more feasible for future developments.

In addition, a specificity of 98% and a variation of 2.80% demonstrate the model's high performance in accurately detecting negative cases of pterygium and minimizing false positives. Compared to the specificity report of 96.13% presented in the work of Y. Liu et al. [15], this difference could be due to the variability in the resolution of images taken by different smartphones and the variability of the datasets used, which affected the robustness of the training. Similarly, the study by Zhu et al. [16] obtained a specificity of 99.33%, surpassing the results of this research. This may be due to the large dataset with which the model was trained, which favored the diagnosis of pterygium.

On the other hand, the results revealed an accuracy of 97%, resulting in a variation of 3.56%, showing a high level of performance in the computer-assisted classification of

pterygium and eyes without the condition. Compared to Zamani et al. [14], who obtained an accuracy of 99.22% using their pre-trained VGGNet16-wbn model, it is analyzed that the magnitude of the differences between results may be because the system was developed under a much deeper and improved architecture with layers (batch normalization), obtaining a highly effective training result. It is also attributed to the use of better datasets, which were carefully labeled, thus optimizing the generalization process. On the other hand, this result is slightly higher than the 99% accuracy reported by Zhu et al [16], using the VGG16 architecture. This may be due to the precise control of the image collection parameters and the uniformity of the dataset, which contributed to the accuracy of the model chosen for the development of their research work. Taken together, these results confirm that accuracy is competitive based on the complexity of the architecture and the quality of the images used for training.

The values obtained reinforce the effectiveness of the web-based system for diagnosing ocular pterygium, reflecting high values for sensitivity, specificity, and accuracy metrics in the post-test. Overall, it is evident that the model used to develop the system based on MobileNetV2 demonstrates its high-performance capacity when adjusted to the ophthalmological context specifically for the diagnosis of ocular pterygium. Many of the previous studies compared with the development of the system have competitive values. For example, Zamani et al. [14] present a sensitivity of 98.45% and an accuracy of 99.22%, focusing on the use of the VGGNet16-wbn architecture, while Zhu et al. [16] achieved a competitive range with a sensitivity of 98.67% and an accuracy of 99% based on the use of the VGG16 neural network. Although the differences are slight, they may be due to many of the factors presented in the research, mainly the size of the images used for training and the heterogeneous images with excellent variable lighting conditions.

Similarly, Liu et al. [15] implemented a fusion training model integrating 20,987 slit lamp images and 1,094 smartphone images, obtaining a sensitivity of 93.6%, specificity of 96.1%, and accuracy of 92.38%. Likewise, Fang et al. [24] trained deep learning models for the detection of ocular pterygium by integrating images taken with both slit lamp cameras and portable cameras, achieving a sensitivity of up to 98.6% and specificity of 99.0%. The differences compared to the model used in the present study may be due to the use of higher-quality clinics and a larger volume of data.

Overall, the findings show that the adapted MobileNetV2 neural network model achieves an outstanding balance between accuracy, computational efficiency, and applied impact, positioning itself as a viable option for the early identification of ocular pterygium in social and medical contexts. Its performance with ResNet10, VGG16, or AlexNet, even using a reduced number of datasets, demonstrates the network's efficiency in terms of transfer learning and adequate preprocessing in the development of intelligent clinical diagnostic systems.

VI. CONCLUSION

Regarding the main objective, it was concluded that the implementation of the CNN-based web system based on the

use and improvement of the MobileNetV2 architecture contributed to the improvement in the identification of ocular pterygium. This was verified by the high metric values of 96% sensitivity, 98% specificity, and 97% accuracy obtained in the research project. Therefore, it has been demonstrated that the initial objectives were achieved, reflecting the positive contribution of trained deep learning models and learning method strategies to the early detection of ocular pterygium from ocular images taken with smartphones.

About the first specific objective set, the web system achieved a sensitivity of 96% and a variation of 4.35%, demonstrating that the model is capable of significantly minimizing false positives. The results are undoubtedly attributable to the use of the MobileNetV2 network as a basis, as its lightweight and optimized structure facilitates better and more detailed extraction of the most relevant features for eye images. Likewise, the use of data augmentation techniques and the wide variety of datasets provided for training contributed to the improvement of the model, resulting in correct identification in a large number of positive cases of ocular pterygium, even in images that were uploaded under different lighting conditions.

In relation to the second specific objective, the web system achieved 98% specificity and a variation of 2.80%, demonstrating that the model is highly accurate in correctly identifying photographs without pterygium, thereby reducing false positives. These results are attributed to the application of correct image preprocessing, as the images were resized to 224×224 pixels, in addition to the customization of the model with the modification of the dense layers, which enhanced the system's ability to differentiate between images with pathological alterations and images of eyes without the condition.

Regarding the third specific objective, the web system achieved an accuracy of 97% and a variation of 3.56%, indicating the model's high predictive capacity overall. This performance was achieved through rigorous training, using 80% of the images for training and 20% for validation, as well as the application of the categorical cross-entropy loss function and the ADA optimizer, which benefited the stable and effective learning of the model. All of this made it possible to create a system with an optimal balance between sensitivity, specificity, and accuracy, supporting the system's effectiveness for the classification and detection of pterygium.

Among the limitations of this study is the sample size, which was limited as only 100 images were considered, which may affect the generalization of the findings. In addition, only static images were considered for the development, and other factors that could influence the diagnosis of ocular pterygium were not considered. Another limitation is the insufficient time available for long-term follow-up and validation, which limits the evaluation of the system's effectiveness in real-world conditions.

Finally, for future research, it is suggested that, in order to strengthen and expand the results obtained, a much larger sample be considered, including grades and other conditions similar to ocular pterygium. In addition, it would be significant to implement additional clinical data and explore the

incorporation of other artificial intelligence techniques to improve diagnostic accuracy. It is also recommended that longitudinal studies be conducted to evaluate the performance of the system over time in real clinical settings.

Mobile Application Based on Convolutional Neural Networks for the Initial Evaluation of Cutaneous Melanoma

Julio Guillermo Farro-Llanos, Manases Sabteca Juan de Dios-Arango, Rosalynn Ornella Flores-Castañeda
Facultad de Ingeniería y Arquitectura, Universidad César Vallejo, Lima, Perú

Abstract—Cutaneous melanoma is a dermatological disease that affects a large portion of the world's population and is characterized by its high capacity for dissemination and aggressiveness, especially when not detected early. Given this need, the objective was to develop a mobile application based on convolutional neural networks for the initial assessment of this condition. Therefore, the percentage increase in sensitivity, specificity, and accuracy was evaluated. The research employed a quantitative approach and a pre-experimental design. The study variable was the initial assessment of cutaneous melanoma. The sample consisted of 120 images: 60 images from patients with melanoma-positive and 60 images from patients with melanoma-negative. The results of the implementation showed an increase in sensitivity of 0.729%, specificity of 3.626%, and accuracy of 2.631%. In conclusion, the adoption of the mobile application based on convolutional neural networks strengthens the initial assessment of cutaneous melanoma by optimizing these indicators.

Keywords—Melanoma; skin disease; convolutional neural networks; mobile app

I. INTRODUCTION

Cutaneous melanoma presents one of the greatest challenges in the field of dermatology, particularly regarding its early and accurate identification. These difficulties are largely due to its visual resemblance to moles, leading to delayed diagnoses and, in many cases, fatal consequences. In response to this situation, a mobile application using AI and convolutional neural networks (CNNs) has been developed, demonstrating its potential as a preliminary detection method through images.

Melanoma originates from the melanocytes of the skin [1]. It is one of the few cancerous tumors with an increasing incidence; however, its mortality rate has decreased dramatically with effective systemic therapy [2]. The most common type of melanoma develops in the skin [3]. It is associated with skin pigmentation factors. Some people have atypical melanocytes that act as a genetic initiator of malignant mutations, and the sun is a frequent trigger [4].

The morphological and histopathological characteristics of this condition allow us to classify it into four main types: superficial spreading melanoma, nodular melanoma, acral lentiginous melanoma, and lentigo maligna [5]. If detected early, it can be effectively treated through a local incision. However, for some specialists, the accurate identification of melanoma from skin lesions can be challenging. The most commonly used techniques are visual inspection, medical history, dermatoscopic analysis, biopsy, and histological evolution [6]. Furthermore,

metastatic melanomas exhibit a wide variety of clinical and morphological characteristics [7].

Regarding age distribution, the epidemiological data indicate that cutaneous melanoma has a significantly lower incidence in the adolescent and young adult population, specifically between 15 and 39 years of age. On the other hand, the highest concentration is found in individuals over 50 years of age [8].

The rising incidence of skin melanoma and the need for accessible early detection are driving the development of efficient technological solutions. In this context, we propose a mobile application based on convolutional neural networks for the initial assessment of melanoma using skin images. Unlike traditional approaches, this work explicitly addresses the challenges of implementing artificial intelligence models on mobile devices, including reducing inference latency, optimizing computational resource consumption, and preserving user privacy through local data processing. The system is based on the automatic recognition of visual patterns associated with melanoma and has been designed with a focus on key metrics such as sensitivity, specificity, and accuracy. Thus, the proposal not only contributes to the field of assisted diagnosis but also introduces a viable and efficient solution for deployment in real-world mobile environments.

The research is organized as follows: Part II presents related works, Part III applies the methodology, Part IV presents the results, Part V presents the discussion, and Part VI presents the study's conclusions.

II. RELATED WORKS

A study was conducted [9] on the development and evaluation of a convolutional neural network for detecting invasive cutaneous melanoma in histological slide images, using tumor morphology as a key criterion. After training their model with 1068 slide images of this condition, the results showed high efficiency in locating conventional invasive melanoma tissue, achieving a sensitivity of 97.59% and a specificity of 99.86%. Furthermore, [10] they conducted a pilot study to determine the accuracy of a convolutional neural network, previously trained on Swedish data records, in predicting the risk of invasive cutaneous melanoma over 5 years. This algorithm was evaluated in a cohort of 36,866 individuals and was structured in two stages: the first stage involved low-level feature extraction using CRN, while the second stage involved high-level feature extraction. This approach resulted in an accuracy of 97.92% and

98.86% in the first and second stages, respectively, demonstrating the significant potential of machine learning.

To mitigate the problem of data imbalance in dermatological image sets, [11] they implemented the MSLP-MR method, which is based on MASK R-CNN for the synthetic generation of images of various skin lesions. This procedure used MASK R-CNN to integrate mask segmentation and enhance expected learning. ISIC data was used, and the method proved to be effective and viable, achieving an accuracy of 90.61%, a sensitivity of 78.00%, and a specificity of 93.43%. These results establish a level of performance comparable to the visual diagnosis performed by medical specialists. The successful implementation of an artificial intelligence (AI)-based imaging system requires, according to [reference missing] [12], a robust structure that does not compromise the diagnosis in the face of image variations. The central objective of their research was to quantify the degree to which small image perturbations impact the performance of convolutional neural networks applied to lesions and to propose possible strategies to mitigate this effect.

Given the increasing integration of AI into clinical practice, [13] the authors highlight the need for further research aimed at streamlining the process, improving efficiency, and increasing the accuracy of lymph node (LN) detection for cutaneous melanoma. To facilitate this process, test data were stored on a cloud platform specifically designed for AI-assisted pathology. This research developed and trained an AI-powered model to detect metastases directly from images and classify tumor deposits according to their size. The results indicated that the AI algorithm demonstrated high accuracy in detecting LN metastases in melanoma patients, effectively identifying and classifying tumor deposits with high specificity.

Additionally, [14] they proposed the design and development of a mobile application based on Convolutional Neural Networks (CNNs) to provide an initial assessment of cutaneous melanoma. The use of images captured directly by the user makes this solution particularly valuable for facilitating early detection in the general population or in vulnerable groups with limited access to healthcare services. Despite its user-focused design, the research demonstrated the effectiveness of CNNs in detecting cutaneous melanoma with an accuracy comparable to that observed in specialized clinical settings.

Convolutional neural networks (CNNs) constitute a paradigm for processing complex data whose architecture is inspired by the biological functionality of neurons and human senses [15]. A distinctive feature of CNNs is their wide application in diverse fields, including image classification, object recognition, and the development of computer-aided diagnostics [16].

On the other hand, [17] a research project was undertaken to address the need for early detection. The main objective was to develop a mobile application based on convolutional neural networks to optimize the initial assessment of rosacea, achieving results of 94% sensitivity, 98% specificity, and 96% accuracy. A mobile application is defined as a type of software specifically designed to run on smartphones and other mobile devices [18]. Currently, there is a marked need to develop intelligent applications due to the growing user demand for advanced functionalities. [19] In the healthcare context, the integration of

these applications is advantageous due to their potential for easy scalability, meaning they are simple to use and have low maintenance and staff training costs [20].

III. METHODOLOGY

The methodology applied in this research was a quantitative approach with a pre-experimental design, focusing on the application of existing AI techniques in the development of a mobile application for the initial diagnosis of cutaneous melanoma. The pre-experimental design aimed to demonstrate that the dependent variable (a mobile application based on convolutional neural networks) can generate an initial diagnosis of cutaneous melanoma. The study population consisted of images obtained from free repositories such as PAD-UFES-20 and ISIC. For sampling and subsequent evaluation, images of patients with and without a diagnosis of cutaneous melanoma were included. Data collection was carried out through observation, while data analysis was based on the calculation of key metrics such as sensitivity, specificity, and accuracy. Additionally, the Receiver Operating Characteristic (ROC) curve was used to evaluate the overall performance of the system, illustrating the relationship between the true positive rate and the false positive rate at different decision thresholds.

A. Case Development

The Mobile-D methodology was chosen, an optimal and agile framework specifically designed for the creation and/or development of mobile applications. This framework allowed us to address the main needs of this study by integrating best practices with software engineering principles. The test set consisted of 120 images: 60 positive and 60 negative. The phases of this Mobile-D methodology are specified below.

B. Phase 1: Exploration

This initial stage focused on research, in-depth knowledge, and strategic formulation to establish the essential characteristics of the project, which translates to capturing the requirements. [21] priority was given to understanding the core problem in order to clearly define the specific functionalities that a mobile application should incorporate to perform the preliminary detection of cutaneous melanoma.

1) *Definition*: Develop a mobile application with convolutional neural networks for the initial evaluation of cutaneous melanoma.

2) *Set of functional requirements*: The key functional requirements that will define the core capabilities of our application are identified. (See Table I)

TABLE. I. FUNCTIONAL REQUIREMENTS

Requirements	Description of requirements
RF01	The system must allow user registration and authentication.
RF02	The application should provide truthful information about cutaneous melanoma and offer suggestions.
RF03	The application should display instructions for taking photos clearly and correctly.
RF04	The user will be able to take a photo or upload images from their mobile gallery for analysis.

RF05	The result of the analysis should be visualized clearly and concisely with the probability of the evaluation.
RF06	The application must generate reports that show the results of the evaluated images.
RF07	The application must display metrics and indicators through reports.
RF08	The system should have a tab or section that shows information about the application, who created it, its purpose, and context.

C. Phase 2: Initialization

In this stage, the development team focuses on identifying the system architecture, creating the initial design, and preparing the necessary technological resources, as well as assigning roles and structuring the team [22]. The primary objective of this phase is to generate a basic, functional version of the application that allows for early validation of the initial hypothesis against user expectations and requirements.

1) *Hardware environment configuration*: Intel i5 11th generation laptop, an i5 13th generation laptop, and a mobile device (cell phone)

Software: Android Studio IDE, Visual Code, Firebase and TensorFlow.

2) *Flowchart of the CNN-based application process*: Fig. 1 shows the flowchart of the mobile application based on convolutional neural networks (CNNs) for the initial detection of cutaneous melanoma. This process begins with image capture, which can be taken with the phone's camera or uploaded from the gallery. These images undergo an in-depth process of identifying cutaneous melanoma characteristics and are then fitted to the validation set. This is followed by evaluation by the architecture using the test set. Once implemented and optimized, the model is integrated into the app, classifies the images, and stores the results, providing a preliminary diagnosis.

Fig. 1. MelanoCheck application workflow diagram based on CNN.

a) *Application architecture diagram*: The mobile application was developed using Android Studio software, working in conjunction with TensorFlow for image segmentation and classification, and Firebase as the database engine. Training was performed using Google Colab and Python, along with model tuning for classification. Java handled the logic in the mobile application. (See Fig. 2).

Fig. 2. Mobile application architecture diagram.

3) *Project structure*: The project structure in Android Studio follows a hierarchical structure to facilitate code management. It begins with the application configuration file, followed by the source code directory containing the logic, then the folders responsible for resource storage, and finally the deep learning file in TensorFlow format. (See Fig. 3).

Fig. 3. Project structure in Android.

D. Phase 3: Production

During this phase, the development team works with an incremental and iterative approach, aiming to implement all features in the progressive delivery of mobile application versions. This ensures the software's evolution and allows for testing and adjustments (see Table II).

TABLE II. MODULE

Module	Code	Process	Request
User Account Management Module	M01	"Registration" and "Login" process, allowing you to log in and save your data.	RF01, RF02, RF03 Y RF04
Information module in the user profile	M02	Process where the user should be able to view their profile data (Names, Email, Cell Phone, etc.)	RF05, RF06 Y RF07

Assessment Module	M03	Process where the system must allow the user to start an evaluation where the results of the analysis must be displayed	RF08, RF09, RF10, RF11, RF12 Y RF13
Information and prevention module on cutaneous melanoma	M04	Process where information on the prevention of cutaneous melanoma is displayed.	RF1 Y RF15
Reporting Module	M05	Process of filtering evaluation history by a date range	RF16, RF17 Y RF18
Assessment History Module	M06	The system must show the user a chronological list of all the evaluations they have performed.	RF19 Y RF20
Export Generation Module	M07	Process of exporting the evaluation history.	RF21

E. Stabilization

Tests were carried out, and errors were corrected, optimizing performance and guaranteeing the quality of the application before its launch.

1) *Recommendations for mobile devices:* It is recommended to use a mobile device with sufficient storage space and a good internet connection to maintain communication and synchronization with data in the cloud (see Table III).

TABLE. III. RECOMMENDATIONS FOR THE USE OF MOBILE DEVICES

HARDWARE	Characteristics
RAM Memory:	A minimum of 4 GB of RAM is recommended for smooth operation.
Camera:	The device must have a functional camera (rear or front) to use the Evaluation module.
SOFTWARE	Characteristics
Operating System:	Android 8.0 or higher.

TABLE. V. CONFUSION MATRIX

	CNN MODEL TEST			
	SENSITIVITY	SPECIFICITY	TOTALS	PILOT TEST
	RESULTS. PEOPLE WITH MELANOMA	RESULT. PEOPLE WITHOUT MELANOMA		
+				
MALIGNANT	58	1	59	0.9667
NEGATIVE BENIGNO	2	59	61	0.9833
TOTALS	60	60	120	
PILOT TEST	0.97	0.98		0.97

Internet connection	Network: 4G
---------------------	-------------

F. Tests

This phase involves the final validation of the mobile application under real-world usage conditions. A detailed inspection is performed to ensure functionality and compliance with the requirements established during the exploration phase.

1) *Unit Test 03: Assessment module:* The unit test is displayed in the assessment module (See Table IV).

TABLE. IV. TEST RESULTS DISPLAY

COD E	DESCRIPTION
M03	Assessment module
AIM	The application allows verification of the complete evaluation flow, including capture, analysis of the CNN model, and presentation of results.
STEP S	- Go to the "Evaluation" module. - Select an image from the gallery to take a photo - The application evaluates and displays the result
RES ULT S OBT AINE D	The user receives the result correctly; if the evaluation is "POSITIVE", with a probability of ≥ 45.99 , the application will display the message: "...GO TO A SPECIALIZED CENTER". Otherwise, if it is negative, the message "... (NEGATIVE)" will be displayed.

IV. RESULTS

This research focuses on evaluating the extent to which a mobile application, using convolutional neural networks, increases the effectiveness and accuracy of the initial diagnosis of cutaneous melanoma.

A. Calculation of Indicators

The results of validation tests, performed to evaluate the system's sensitivity, specificity, and accuracy indicators, are presented. For this analysis, a controlled set of 120 images was used, selected to analyze the mobile application's accuracy and behavior under standardized conditions. Specifically, the calculation and analysis of the indicators were performed on a balanced test set of 120 images, evenly divided into 60 positive images (malignant diagnosis) and 60 negative images (benign diagnosis) for the CNN model's binary classification task (see Table V).

The following results were obtained from the confusion matrix analysis:

Sensitivity = 97%

Specificity = 98%

Accuracy = 97%

1) *Analysis of the ROC curve and the area under the curve (AUC)*: Fig. 4 shows the Receiver Operating Characteristic (ROC) curve of the CNN model, which was generated by evaluating a test set of 120 images. This graph is a standard tool for evaluating the performance of a binary classifier because it visualizes the balance between the sensitivity and specificity of the trained model.

Fig. 4. ROC curve.

The AUC value is 0.975, indicating that the application has a 97.5% accuracy in correctly classifying positive (melanoma) and negative (benign) cases. This value, so close to 1.0, validates that the model is an excellent and robust classifier. (See Table VI)

TABLE. VI. AREA UNDER THE CURVE

Area	Error Deviation	Asymptotic significance	95% asymptotic confidence interval	
.985	.013	.000	lower limit	upper limit
			.960	1.000

B. Analysis of the Pre-Experimental Design

1) *Pre-test*: The accuracy, sensitivity, and specificity values of the EfficientNet-b4 model for various dermatological diseases were compared with the values for melanocytic nevus from the respective mobile application model [23] (see Table VII).

TABLE. VII. PRE-TEST RESULTS

MODE L	Pin k (%)	VW (%)	EA D (%)	SD (%)	SK (%)	MN (%)	Pso (%)	BC C (%)
Sensitivi ty	92.00	92.00	84.00	48.00	76.00	96.00	92.00	88.00
Specifici ty	92.57	95.43	88.57	91.43	96.00	94.86	94.29	99.43
Accurac y	92.50	95.00	88.00	86.00	93.50	95.00	94.00	98.00

2) *Post-test*: In this case, the post-test was carried out with Images from the dataset, from which the detailed report was obtained by the mobile application. Table VIII shows the percentages of the indicators.

TABLE. VIII. INDICATOR RESULTS

TOT AL	V P	V N	F N	F P	% SENSITIVIT Y	% SPECIFICIT Y	% ACCURAC Y
120	58	59	2	1	97%	98%	97%

Table IX shows the comparison of the sensitivity, specificity, and accuracy indicators in percentages between the mobile application and EfficientNet.

TABLE. IX. COMPARISON OF RESULTS

INDICATO R	EFFICIENTNET -B4	APPLICATION NEURAL NETWORK
SENSITIVI TY	96.00%	97.00%
SPECIFICI TY	94.86%	98.00%
ACCURAC Y	95.00%	97.00%

C. Hypothesis Testing

1) Specific Hypothesis HE1

HE 1(0): A mobile application using convolutional neural networks failed to increase sensitivity in the initial assessment of cutaneous melanoma.

HE1(1): A mobile application using convolutional neural networks succeeded in increasing sensitivity in the initial assessment of cutaneous melanoma.

$$\% \text{ Sensitivity variation} = (96.7 - 96) / 96 \times 100 = 0.729 \%$$

An increase in sensitivity was found in the percentage variant, obtaining a positive result of 0.729%; therefore, the alternative hypothesis is accepted, and the null hypothesis is discarded.

2) Specific Hypothesis HE2:

HE2(0): A mobile application using convolutional neural networks failed to increase specificity in the initial assessment of cutaneous melanoma.

HE2(1): A mobile application using convolutional neural networks succeeded in increasing the specificity in the initial assessment of cutaneous melanoma.

$$\% \text{ Variation in specificity} = (98.3 - 94.86) / 94.86 \times 100 = 3.626 \%$$

An increase in specificity was found in the percentage variant, obtaining a positive result of 3.626%; therefore, the alternative hypothesis is accepted, and the null hypothesis is discarded.

3) Specific Hypothesis HES3:

HE3(0): A mobile application using convolutional neural networks failed to increase accuracy in the initial assessment of cutaneous melanoma.

HE3(1): A mobile application using convolutional neural networks succeeded in increasing the accuracy in the initial assessment of cutaneous melanoma.

$$\% \text{ Accuracy variation} = (97.5 - 95) / 95 \times 100 = 2.631 \%$$

An increase in accuracy was found in the percentage variant, yielding a positive result of 2.631%. Therefore, the alternative hypothesis is accepted, and the null hypothesis is rejected.

D. Results of the Indicator Increases

Table X shows the percentage increase per indicator (positive numbers) at which the null hypothesis is rejected, and the alternative hypothesis is accepted.

TABLE. X. RESULTS OF INCREASES BY INDICATOR

INCREASED SENSITIVITY	INCREASED SPECIFICITY	INCREASED ACCURACY
0.73%	3.63%	2.63%

E. General Hypothesis

HG (0): A mobile application using convolutional neural networks does not improve diagnosis in the initial evaluation of cutaneous melanoma.

HG(1): A mobile application using convolutional neural networks improves diagnosis in the initial evaluation of cutaneous melanoma.

By verifying hypotheses HE1, HE2, and HE3, the general hypothesis is accepted.

V. DISCUSSION

This section is dedicated to a detailed and in-depth interpretation of the mobile application validation results. The analysis seeks to determine the efficiency of the proposed approach, based on convolutional neural networks, for the initial diagnosis of cutaneous melanoma using technological tools. The discussion focuses on the performance of key indicators (sensitivity, specificity, and accuracy). Furthermore, a critical interpretation of our previous findings in the scientific literature is presented, allowing us to situate the contribution of this research.

The first specific objective was to evaluate the extent to which a mobile application based on convolutional neural networks increases the sensitivity of the initial assessment of cutaneous melanoma. The results show 97% sensitivity, attributed to the use of modern and robust CNN architectures, allowing for accurate feature extraction. This result is slightly lower than the 97.59% obtained by [9] who used a patch-based architecture for invasive melanoma recognition.

Regarding the second specific objective, to evaluate the extent to which a mobile application based on convolutional neural networks increases specificity, a specificity of 98% was obtained, showing an increase of 3.63%. This significant increase is attributed to image processing techniques and the increase in data, significantly improving the model's ability to reduce false positives. The performance exceeds the 93.43% achieved by [11]; this difference is attributed to the learning concept, methodology, and data used.

On the other hand, the third specific objective was to evaluate the extent to which a mobile application based on convolutional neural networks increases the initial accuracy of cutaneous melanoma diagnosis. This result, derived from optimized model training, surpasses the 90.61% achieved by [11]. The superiority of our approach stems from the limitations of [11], whose MASK R-CNN method was affected by image variability. However, the result obtained is slightly lower than that of [10], who reported 97.92% and 98.86% accuracy, as they applied two phases using five years of Swedish data, whose images included 23,866 individuals, applying both low- and high-level features.

Regarding the research of [17], it also used the same convolutional neural network model to be able to preliminarily evaluate rosacea, obtaining a sensitivity of 94%, a specificity of 98% and an accuracy of 96%, results very close to the mobile application developed, but it did not manage to surpass our results, but it does not show the efficiency and confirms that the use of the CNN achieves technological advances on a large scale.

The main objective is to evaluate how a mobile application based on convolutional neural networks (CNNs) improves the initial assessment of cutaneous melanoma. The increase in sensitivity, specificity, and accuracy (post-test) validates the application's effectiveness. This aligns with several studies demonstrating how CNNs enhance dermatological diagnosis. In fact, [24] it reaffirms the importance of image processing, demonstrating the significance of CNNs in the development of medical diagnostics.

VI. CONCLUSION

The mobile application developed, based on convolutional neural networks, shows promising results for the initial assessment of cutaneous melanoma, with a sensitivity of 97%, a specificity of 98%, and an overall accuracy of 97%. These results suggest that the model is capable of adequately distinguishing between positive and negative cases in the evaluated dataset, which could contribute to reducing false negatives and enabling more efficient preliminary detection. The performance achieved can be attributed to the model's architecture and the use of data augmentation techniques during training.

However, these findings should be interpreted with caution, as the evaluation was conducted under specific conditions and with a limited dataset, which may affect the model's generalizability in real-world clinical settings. Furthermore, the study did not incorporate additional metrics such as the F1 score or inference time assessments, which are relevant for a more comprehensive comparison with other approaches.

Among the system's limitations is the absence of user feedback mechanisms, which hinders the model's continuous improvement based on its use in real-world scenarios. Consequently, future work should consider validation with more diverse datasets, the incorporation of additional evaluation metrics, and the analysis of real-time performance on mobile devices, to strengthen the system's practical applicability.

As future work, we propose expanding the validation of the model using more diverse datasets to improve its generalization. We also suggest incorporating additional metrics such as the F1 score, along with an analysis of inference time and resource consumption on mobile devices. We also propose exploring hybrid approaches that integrate multiple architectures to increase the system's robustness, as well as optimizing the model using compression techniques that reduce latency and energy consumption. Finally, we consider incorporating user feedback mechanisms and multilingual support to improve usability and adoption.

A Survey of AI-Based Methods for Cloud Resource Allocation and Optimization

Rim Doukha, Abderrahmane Ez-zahout

Intelligent Processing and Security of Systems Team-Faculty of Sciences, Mohammed V University, Rabat, Morocco

Abstract—Cloud computing has become essential for modern digital services, yet efficiently allocating compute, storage, and network resources in large-scale and highly dynamic environments remains a significant challenge. Traditional rule-based approaches often struggle to cope with workload variability, multi-tenancy, and the need for real-time multi-objective optimization. In response, recent research has increasingly explored artificial intelligence techniques to improve prediction, scheduling, and automated resource control in cloud infrastructures. This study presents a comprehensive survey of AI-based methods for cloud resource allocation, including machine learning, deep learning, reinforcement learning, and hybrid approaches. It systematically analyzes selected studies published between 2020 and 2026, examining their learning paradigms, optimization objectives (e.g., performance, cost, energy efficiency), experimental validation strategies, and reported limitations. While classical optimization techniques are briefly discussed to contextualize the evolution of the field, the core analysis is strictly centered on AI-driven approaches. The study concludes by identifying the key challenges that persist in intelligent cloud resource management and outlines promising directions for future research toward more adaptive, reliable, and scalable optimization frameworks.

Keywords—AI techniques; heuristics; metaheuristic; cloud resource management; sustainability; survey

I. INTRODUCTION

Cloud computing has emerged as the foundational infrastructure model of the digital era, offering scalable, on-demand access to computing, storage, and network resources [1]. Its elasticity and cost-efficiency have transformed how enterprises, governments, and end users deploy and manage digital services [2]. However, as workloads have become more dynamic and compute-intensive, driven by trends such as artificial intelligence (AI), big data analytics, and Internet of Things (IoT), the task of efficiently allocating resources has become more complex and critical.

At the heart of this complexity lies the challenge of resource allocation, mainly deciding how to dynamically distribute CPU, memory, bandwidth, and storage across diverse virtualized environments, often in real time. Suboptimal allocation leads to underutilized infrastructure [3], violated service-level agreements (SLAs), increased operational costs, and a growing carbon footprint. According to the International Energy Agency, data centers now consume approximately 1–1.5% of global electricity, a share that is projected to rise due to expanding cloud and AI workloads [4].

Traditional approaches to resource allocation have relied on rule-based heuristics such as First Fit, Round Robin, and Greedy algorithms. While effective in static or predictable environments, these strategies struggle in today's multi-tenant, heterogeneous, and latency-sensitive cloud architectures [5]. They are typically reactive, single-objective, and unable to adapt to workload volatility or evolving performance requirements [6].

Recent advances in AI and the growing availability of telemetry data from cloud environments have enabled a shift toward learning-based resource allocation methods. Machine learning (ML) models are now being used to predict workload demands, detect anomalies, and estimate resource requirements, while deep learning (DL) architectures such as LSTM and Transformer models enable fine-grained time-series forecasting. Reinforcement learning (RL), in particular, has emerged as a promising solution for dynamic and autonomous resource allocation, continuously optimizing placement and scheduling decisions based on environmental feedback. In parallel, metaheuristic techniques like Genetic Algorithms (GA) and Particle Swarm Optimization (PSO) continue to evolve as powerful tools for multi-objective optimization [5].

Despite this progress, significant challenges remain. Many AI-based allocation strategies depend on large, clean, and context-specific datasets that are not always available in practice. Moreover, deploying intelligent controllers in production requires satisfying strict latency, reliability, and interpretability constraints. As cloud providers increasingly adopt sustainability goals, resource allocation methods must also account for energy efficiency and carbon awareness, making the optimization task even more multi-dimensional.

While heuristic and metaheuristic approaches have historically played an important role in cloud resource allocation, this study does not aim to provide an exhaustive analysis of these methods as standalone solutions. Instead, they are discussed primarily to contextualize the evolution of cloud resource management and, more importantly, to highlight their role within hybrid frameworks, where they are combined with AI-based techniques to enhance scalability, convergence speed, and decision efficiency. The core focus of this survey is, therefore, on AI-driven resource allocation, including ML, DL, RL, and hybrid AI-based approaches that integrate classical optimization components.

This study presents a comprehensive overview of AI-based methods for optimizing resource allocation in cloud

computing environments. It aims to clarify the current state of research, identify open challenges, and propose future directions for intelligent and sustainable cloud infrastructure management.

This survey is guided by the following research questions:

RQ1: What AI-based techniques are currently used for cloud resource allocation, and how are they applied?

RQ2: What optimization objectives are addressed by AI-driven and hybrid allocation frameworks?

RQ3: To what extent do existing AI-based approaches incorporate sustainability-aware mechanisms, such as energy-efficient scheduling or carbon-aware resource allocation?

RQ4: What methodological limitations persist in current AI-based cloud allocation research, particularly regarding scalability, real-world validation, generalization, and deployment feasibility?

The study is structured as follows: Section II presents the related work and contributions. Section III explores the key methodologies used in cloud resource allocation, including heuristics, metaheuristics, AI-based approaches, and hybrid models. Section IV gives an overview of the existing research on cloud resource allocation. Section V provides insights and research opportunities for the next generation of cloud optimization techniques. Section VI presents future directions. Finally, Section VII concludes the study.

II. RELATED WORK AND CONTRIBUTION

The increasing complexity and scale of cloud environments have driven significant interest in intelligent resource management strategies. Consequently, several survey papers have emerged over the past few years, focusing on different aspects of AI-based cloud resource optimization, including ML, DL, RL and metaheuristics.

Rathee and Dalal [7] conducted a systematic literature review of ML-based resource allocation techniques in cloud environments, focusing primarily on traditional supervised and unsupervised learning paradigms for virtual machine provisioning, scheduling, and load balancing. Their review does not extensively examine RL or DL methods, hybrid AI models, or sustainability-aware strategies, such as carbon-aware scheduling and green autoscaling.

Naidu and Kumar [8] present a survey of AI-based approaches for intelligent cloud resource allocation, with a particular focus on DL, ensemble models, and metaheuristic optimization techniques. Their review highlights predictive resource scaling methods designed to improve cost efficiency, energy consumption, and SLA adherence. While the study provides valuable insights into algorithmic trends, it offers limited cross-comparative analysis and does not deeply explore RL, hybrid AI frameworks, or sustainability-driven scheduling mechanisms.

Pitkar and Ambapkar [9] provide an informative overview of the intersection between AI, ML, and cloud computing, aiming to highlight key models, challenges, and opportunities. Their work brings attention to relevant themes such as

scalability, automation, and data-driven optimization, contributing to the conceptual understanding of AI integration in cloud platforms. However, the review adopts a generalist perspective. Advanced AI paradigms such as RL or sustainability-focused strategies are not deeply explored.

Srikandabala et al. [10] propose an AI-based framework to enhance data center network performance through flow-aware routing and traffic optimization. Their focus on network-level efficiency offers valuable insights, particularly in reducing congestion and improving throughput. However, the work remains confined to the network layer and does not address broader cloud resource scheduling challenges. Key aspects such as workload prediction, sustainability-aware provisioning, and advanced learning paradigms like reinforcement or hybrid learning are not explored.

Mohammad and Al-Ta'i [11] present a comprehensive comparison of hybrid DL architectures combining CNN, GRU, and LSTM for virtual machine scheduling in cloud environments. While their study effectively demonstrates the predictive capabilities of DL models, it does not address RL, which has become increasingly important for dynamic and feedback-driven resource allocation in modern cloud systems.

Varun et al. [12] present a conceptual overview of AI and ML approaches for cloud resource optimization. While their discussion identifies key challenges and high-level strategies, it does not offer a structured analysis of existing literature or model comparisons.

Alhashimi et al. [13] conducted a structured survey of AI-enabled resource management techniques targeting 6G cloud and edge computing environments. Their work categorizes ML, DL, and RL approaches based on application areas such as task scheduling, energy management, and latency reduction. The study includes a well-defined taxonomy and comparative analysis. However, its scope is primarily centered on 6G-oriented network architectures and edge-cloud integration, with less emphasis on generalized sustainability-aware strategies or hybrid AI models in traditional cloud infrastructures.

Nawrocki and Smendowski [14] provide a structured survey of optimization strategies for cloud resource consumption, reviewing over 70 research articles. Their work introduces a novel taxonomy based on semantic properties, evaluating each method's capabilities, deployment potential, and limitations. While the survey thoroughly addresses cost-awareness and consumption control, DL and RL approaches receive limited attention, and sustainability considerations are only briefly discussed.

Collectively, these surveys provide valuable insights into intelligent cloud resource management. However, several common limitations emerge. Many studies focus on individual paradigms, such as ML or DL, without offering cross-comparative analysis across ML, DL, and RL approaches. Hybrid frameworks that integrate predictive modeling with adaptive control remain underrepresented. Furthermore, sustainability considerations, particularly carbon-aware optimization, are often treated indirectly or receive limited emphasis.

This study addresses these gaps by providing a structured overview of AI-driven resource allocation techniques for cloud computing. It synthesizes main studies published between 2020 and 2026, organizes them into methodological categories spanning ML, DL, RL, and hybrid models, and comparatively analyzes their optimization objectives, including performance, cost, energy efficiency, and sustainability considerations, along with reported limitations. By offering a cross-paradigm synthesis, this survey aims to provide a clear and structured reference for researchers and practitioners in intelligent cloud resource management.

This study makes the following contributions:

- It provides a structured overview of AI-based cloud resource allocation methods, synthesizing selected studies published between 2020 and 2026.
- It offers a comparative synthesis of recent literature, analyzing how AI-driven approaches address key optimization objectives such as performance, cost, energy efficiency, SLA compliance, and sustainability considerations.
- It examines the role of hybrid resource allocation frameworks, particularly those integrating ML-based prediction, RL-based adaptive control, and classical optimization components to enhance adaptability and scalability.
- It identifies open research challenges and outlines future research directions, emphasizing scalability, real-world validation, sustainability-aware optimization, and interpretability in AI-driven cloud resource management systems.

III. METHODOLOGIES USED IN CLOUD RESOURCE ALLOCATION

Cloud resource allocation has been approached through a diverse set of methodologies that evolved in response to increasing system complexity and dynamic workload behavior. The earliest solutions were primarily heuristic, relying on static rules that map tasks or virtual machines to available resources. These methods were effective in early cloud environments due to their simplicity, deterministic execution, and low computational overhead. As cloud infrastructures grew in scale and heterogeneity, metaheuristic techniques emerged to overcome the limited search capability of heuristics, offering more flexible and global optimization behavior. The continued increase in workload diversity, real-time constraints, and multi-objective optimization requirements eventually led to the rapid adoption of AI-based methods, including ML, DL, and RL.

These AI techniques provide predictive and adaptive capabilities that allow resource management systems to learn from operational data and continuously improve decision-making. More recently, hybrid models combining classical strategies with AI methods or integrating multiple AI approaches have become increasingly prominent, reflecting the need for systems that balance interpretability, computational efficiency, and intelligent adaptation. The following subsections present these methodological categories:

A. Heuristic Methods

Heuristic methods are among the earliest and most widely applied approaches for managing cloud resources. These techniques rely on predefined rules to determine how virtual machines, containers, or tasks are scheduled across available infrastructure. Their popularity stems from low computational overhead, fast execution, and straightforward implementation, making them suitable for real-time scenarios where speed is prioritized over optimality [15].

Classic heuristics, such as First Fit, Best Fit, Round Robin, and Greedy Scheduling, are commonly implemented in simulation environments like CloudSim and OpenDC [16]. These algorithms follow simple logic [17]. For example, First Fit places tasks on the first available host with sufficient resources, while Best Fit selects the host with the tightest fit without exceeding capacity [18]. Such methods were especially effective in earlier cloud environments characterized by consistent and predictable workloads.

In general, heuristic methods fall short when multiple objectives such as cost, energy, latency, and SLA adherence must be considered simultaneously [19]. Their static rules often lack adaptability and can struggle under fluctuating workloads or failure-prone environments.

Nonetheless, heuristic strategies continue to hold value in modern cloud systems. Their transparent logic, rapid decision-making, and minimal computational demand make them particularly relevant in edge computing and latency-sensitive contexts. When integrated into hybrid optimization frameworks, they often serve as fallback mechanisms or fast initializers within broader decision pipelines. This enduring utility ensures they remain part of the resource allocation toolbox, even as more intelligent and autonomous solutions gain prominence.

B. Metaheuristic Methods

Metaheuristic methods emerged as a response to the shortcomings of classical heuristics. Inspired by natural and physical processes, these algorithms employ stochastic exploration and population-based search strategies to approximate near-optimal solutions in complex and high-dimensional search spaces [20]. Commonly used metaheuristics include GA, PSO, Ant Colony Optimization, Simulated Annealing, and Differential Evolution. Their ability to escape local optima and search globally makes them particularly well-suited for resource allocation problems involving multiple conflicting objectives, such as balancing energy efficiency with performance guarantees or optimizing resource utilization while minimizing operating costs [21].

Unlike heuristics, metaheuristics do not rely on rigid rules but instead adaptively tune their search based on performance feedback. Although more flexible and powerful, metaheuristics introduce their own challenges, including sensitivity to parameter initialization, computational overhead during large search operations, and difficulties associated with scaling these methods to real-time production environments. Nonetheless, they remain a widely adopted solution in research due to their versatility and effectiveness in exploring complex optimization landscapes.

C. AI-Based Methods

AI refers to the computational capability of machines to perform tasks that typically require human intelligence, including learning, reasoning, decision-making, and problem-solving [22]. In the context of cloud computing, AI enables the development of systems that can autonomously manage, adapt, and optimize infrastructure behavior based on real-time data and environmental feedback. As cloud infrastructure becomes increasingly dynamic and complex, with fluctuating workloads, multi-tenant architectures, and stringent service-level objectives, conventional optimization techniques such as heuristic or metaheuristic methods fall short in their ability to generalize, adapt, and respond in real time. This limitation has catalyzed growing interest in AI-based methods, which introduce the potential for systems to make data-driven, context-aware decisions that continuously improve over time [23].

Within the domain of cloud resource allocation, AI-based methods are typically organized into three major paradigms: ML, DL, and RL.

ML involves predictive modeling based on historical or streaming data, commonly applied for forecasting resource demand, detecting anomalies, or estimating execution times. DL, a subfield of ML, leverages multi-layer neural network architectures to model complex temporal and multivariate patterns such as workload bursts or correlated latency anomalies. RL, on the other hand, focuses on sequential decision-making in uncertain environments, enabling systems to learn optimal resource-control policies through trial-and-error interactions with their environment. Each of these paradigms contributes unique strengths: ML offers fast and interpretable prediction, DL excels at modeling non-linear high-dimensional data, and RL supports adaptive, autonomous control in dynamic settings.

These approaches have gained significant traction due to the growing availability of cloud telemetry data, such as system logs, performance counters, and application traces, along with large-scale public datasets, including Google Cluster Data, Alibaba traces, and Microsoft Azure VM traces. Additionally, simulation frameworks such as CloudSim and OpenDC have provided testbeds for evaluating AI-driven strategies in controlled environments. As the complexity of resource allocation continues to increase, AI-based methods are rapidly emerging as central to the design of intelligent and sustainable cloud management systems.

D. Hybrid Model

Hybrid models have gained increasing attention as a practical response to the limitations of standalone optimization approaches in cloud resource allocation. These models combine complementary techniques to improve scalability, adaptability, and efficiency in dynamic cloud environments.

In practice, hybrid approaches may integrate multiple AI paradigms, such as using predictive models for workload

estimation alongside adaptive control mechanisms, or combine AI-based methods with classical heuristics or metaheuristics to balance learning capabilities with fast and stable decision-making. By leveraging the strengths of different methodologies, hybrid models enable flexible trade-offs between performance, computational overhead, and sustainability objectives, making them well-suited for modern, large-scale cloud infrastructures.

IV. LITERATURE SELECTION METHODOLOGY

This survey adopts a structured literature analysis approach to examine AI-based cloud resource allocation techniques published between 2020 and 2026. Relevant peer-reviewed journal and conference papers were identified through major scientific databases, including IEEE Xplore, ACM Digital Library, Scopus, and ScienceDirect, using keywords related to cloud resource allocation, resource scheduling, AI, ML, DL, RL, sustainability-aware scheduling, and hybrid optimization.

The initial set of retrieved studies was filtered using explicit inclusion and exclusion criteria. The inclusion criteria comprised: 1) peer-reviewed publications, 2) studies focusing on resource allocation or scheduling in cloud or cloud-edge environments, and 3) approaches based on AI techniques or hybrid optimization frameworks. The exclusion criteria included: 1) studies not directly addressing resource allocation, 2) works lacking experimental validation, and 3) duplicate or non-peer-reviewed sources.

After screening titles, abstracts, and full texts, a final set of representative studies was selected for detailed analysis. These studies were then organized into methodological and thematic categories, including RL-based dynamic allocation, predictive ML and DL approaches, hybrid AI and metaheuristic frameworks, network- and multi-data-center-aware allocation, and sustainability- and carbon-aware resource allocation. The selected works were comparatively analyzed based on their optimization objectives, evaluation strategies, and reported limitations.

The analysis reveals a clear transition from static scheduling policies toward adaptive and learning-driven optimization frameworks in recent cloud resource allocation research.

V. EXISTING RESEARCH ON CLOUD RESOURCE ALLOCATION

Table I provides a structured comparative overview of the analyzed studies, highlighting their cloud context, AI techniques, optimization objectives, sustainability considerations, strengths, and limitations.

The thematic categories presented in this section were derived inductively from the comparative analysis summarized in Table I. The reviewed studies were examined to identify recurring methodological patterns, architectural strategies, and optimization priorities in recent AI-based cloud resource allocation research.

TABLE I. COMPARATIVE ANALYSIS OF AI-BASED AND HYBRID CLOUD RESOURCE ALLOCATION APPROACHES (2020–2026)

Ref	Cloud Context	AI Technique	Hybrid Components	Optimization Objectives	Sustainability Aspect	Key Strengths	Limitations
[24]	Mobile Edge Computing	DRL	Hybrid DRL + multi-objective Pareto-optimal selection	Task latency reduction, task failure rate reduction, load balancing	Energy considered in reward function, but no explicit green or sustainability optimization	Hierarchical and distributed DRL improves scalability and significantly reduces latency and failures	High training and communication overhead; increased network traffic due to multi-level coordination
[25]	Fog-Cloud environments	Deep Q-Network (DQN) RL + Fuzzy logic	Hybrid fuzzy logic + DRL	Minimize delay, energy consumption, and makespan	Explicit energy reduction objective (energy consumption is measured)	Prioritizes tasks via fuzzy inference and improves scheduling performance across multiple metrics	Simulation only; real-world deployment not validated
[26]	Cloud-Edge computing environment	DRL (DQN-based)	None	Energy consumption reduction, cost minimization, makespan reduction, QoS satisfaction	Energy-aware, sustainability mentioned indirectly; no explicit carbon or green cloud optimization	Multi-objective RL framework with strong performance across energy, cost, and QoS metrics; validated on realistic traces	High training complexity; evaluated only in simulation; carbon and thermal aspects not addressed
[27]	Kubernetes-based cloud environment	ML	None	Proactive autoscaling, improved responsiveness, cost efficiency	Not explicitly addressed (resource efficiency only)	Practical cloud-native integration of ML with HPA; proactive scaling reduces delays and resource waste	Trained on synthetic traffic data; limited validation on complex multi-service workloads
[28]	Cloud computing environment	DL (LSTM for demand prediction) + RL (DQN for scheduling)	Hybrid AI (DL + RL)	Resource utilization maximization, response time reduction, cost minimization, SLA compliance	Energy considered as part of operational cost; no explicit green or carbon-aware optimization	Strong practical validation; significant gains in utilization, latency, and cost; scalable real-world deployment	High model complexity; substantial training and monitoring overhead; sustainability not explicitly addressed
[29]	Large-scale cloud-edge environment (Content Delivery Networks)	Statistical & ML models (S-ARIMA, LSTM, Bi-LSTM, OS-ELM)	Hybrid statistical + ML + online learning framework	Accurate workload prediction, proactive autoscaling, low rejection rates, SLA preservation	Resource efficiency addressed indirectly; no explicit energy or carbon-aware optimization	Strong empirical validation on real production data; adaptive model switching balances accuracy and overhead; directly supports proactive resource allocation	Focuses on prediction rather than allocation policy design; energy and sustainability not explicitly modeled
[30]	Cloud computing environment for smart manufacturing	Swarm Intelligence (Multi-Objective Particle Swarm Optimization - MOPSO)	Hybrid multi-objective swarm optimization with enhanced operators (mutation/crossover)	VM placement optimization, resource utilization efficiency, inter-VM communication cost reduction	Not addressed	Joint optimization of computation and communication during VM placement; addresses a practical cloud placement problem	Limited benchmarking scope and absence of statistical significance analysis
[31]	IaaS cloud computing environment with multiple data centers and VMs	Multi-Agent System (agent-based intelligent resource management)	Hybrid approach combining dynamic resource allocation + agent-based scheduling + power minimization heuristic	Minimize VM cost, minimize makespan, reduce response time, reduce task rejection rate, reduce energy consumption	Energy-aware (explicit power minimization and VM sleep/active modes); sustainability addressed indirectly (no carbon modeling)	Clear agent-based architecture; joint optimization of cost, makespan, and energy; significant improvements over FCFS and PBTS in simulation	Simulation-only validation; limited scale (few hosts); no real-world cloud deployment; no learning-based adaptation (rules/heuristics dominate)
[32]	Edge-Cloud computing	Multi-Objective RL (MORL) with Proximal Policy Optimization (PPO)	None	Minimize response time, maximize task success rate, improve energy efficiency	Energy-aware multi-objective optimization	Up to 25% higher reward, 20% lower response time, 18% higher success rate, 30–35% energy savings vs baselines	Reward tuning sensitivity and significant training cost; limited large-scale production validation
[33]	Cloud computing environment (IaaS)	QT-DNN	DNN-based prediction + BBSO	Minimize energy consumption, makespan, and response time; improve QoS	Energy-aware optimization; no carbon-aware modeling	98.1% prediction accuracy, response time 1.598, makespan 12, ~20% energy savings vs baselines	simulation-only

[34]	Edge computing networks	Multi-Objective RL (MORL) with PPO, modeled as an MOMDP	Entropy-weighted static-dynamic resource modeling + MOMDP	Minimize task transmission latency and energy consumption simultaneously	Explicit energy consumption modeling (offloading + execution energy)	Strong Pareto optimization; real testbed validation)	Centralized design; scalability limits; no carbon modeling
[35]	Cloud data center (VM-based workload scheduling)	DRL (DQN-based MDP scheduling)	None	Energy consumption minimization, latency reduction, throughput improvement, QoS maximization, load balancing	Explicitly energy-aware; focuses on energy efficiency but no carbon-aware or thermal-aware modeling	Strong multi-metric performance gains (energy reduction, 92% load balancing, 95% utilization, 97% QoS); scalable to large task sets	Simulation-only validation; high training overhead; no real production cloud deployment
[36]	Serverless cloud environment	RL (tabular Q-learning)	None	Optimize concurrency level to maximize throughput and reduce latency	Not explicitly addressed	Demonstrates adaptive learning of optimal concurrency per workload; outperforms default KNative autoscaling; real cluster experimentation	Synthetic workloads; simple reward function; tabular RL limits scalability; no energy or sustainability modeling
[37]	Multi-data-centre cloud environment (AI healthcare workloads)	DL (LSTM workload prediction)	Hybrid predictive ML + adaptive scheduling + multi-data-centre orchestration	Minimize SLA violations, reduce task completion time, optimize resource utilization, reduce operational cost	Not explicitly addressed	Strong formal problem formulation; integrates workload forecasting with proactive scheduling; significant SLA reduction (<5%) and utilization improvement (85%)	Simulation-only validation; domain-specific (healthcare); no RL; no sustainability or energy modeling
[38]	Cloud environment supporting real-time financial analytics (containerized workloads)	LSTM workload forecasting + RL-based dynamic allocation	Hybrid predictive ML + RL adaptive scaling	Reduce processing latency, improve resource utilization, maintain SLA compliance, optimize cost	Not explicitly addressed	Strong hybrid predictive-RL integration; significant latency reduction (31%) and utilization gains (26%); SLA-aware design	Simulation-based evaluation; domain-specific (financial analytics); no energy or carbon modeling
[39]	Large-scale cloud environment (5,000 nodes, Azure & Google traces)	BiLSTM + Multi-Agent RL (MARL) + Ape-X	Hybrid predictive (BiLSTM) + decentralized MARL + distributed prioritized replay	SLA compliance, latency minimization, utilization optimization, carbon emission reduction, cost minimization	Explicit carbon-aware VM placement; 22% energy reduction; carbon masking in reward	End-to-end unified architecture; strong scalability; multi-objective reward; economic validation; distributed training efficiency	Assumes relatively homogeneous workloads; retraining required for structural workload shifts; complex architecture
[40]	Kubernetes-based cloud environment	LSTM workload prediction + DQN reinforcement learning	Hybrid predictive ML + RL-based orchestration	Improve resource utilization (31%), reduce latency (26%), minimize SLA violations	Energy efficiency discussed but no explicit carbon-aware modeling	Hybrid predictive + adaptive framework; integrates forecasting and RL; shows SLA improvement vs reactive scaling	Simulation on limited-scale VM setup; single-node validation
[41]	Distributed multi-cloud environments	ML + RL-based optimization framework	Forecasting (LSTM/ARIMA) + RL rightsizing + anomaly detection + hybrid AI schedulers	Cost forecasting, rightsizing, workload distribution, pricing optimization	Mentions carbon-aware scheduling as future trend; not experimentally evaluated	Comprehensive AI cost governance framework	Conceptual framework; no detailed algorithm formulation
[42]	VM optimization in virtualized cloud (Proxmox-based environment)	Random Forest, LSTM	None	CPU usage prediction, dynamic resource allocation, performance improvement	Not explicitly addressed	High prediction accuracy (MAPE 2.65% with RF), real-time monitoring integration	Evaluated in simulated environment; limited workload diversity; no multi-cloud validation
[43]	VM resource forecasting in AWS cloud	ARIMA, Linear Regression, LSTM	Statistical + ML hybrid	CPU, memory, disk usage prediction; cost-efficient provisioning	Not explicitly addressed	Hybrid model improves forecasting accuracy over individual models	Focused on forecasting; allocation impact not experimentally validated; limited real-world deployment

Based on this synthesis, the literature is discussed according to dominant research paradigms and emerging thematic trends, including RL-based dynamic resource allocation, predictive ML and DL approaches, hybrid AI and metaheuristic integration, network- and multi-data-center-aware allocation, and sustainability- and carbon-aware resource allocation.

A. Reinforcement Learning for Dynamic Resource Allocation

RL has emerged as one of the most prominent paradigms for adaptive cloud resource control. Unlike predictive-only approaches, RL-based frameworks directly optimize allocation decisions through sequential interaction with the environment.

Mohammadi Ghaleh [24] proposes a two-level distributed PPO scheduler for mobile edge computing, combining hierarchical policy learning with multi-objective optimization.

While the framework improves latency and load balancing, it introduces non-trivial communication overhead.

Similarly, Moazzami et al. [25] integrate fuzzy logic with DRL to enhance scheduling adaptability in fog-cloud systems, explicitly minimizing energy consumption alongside delay. Yu et al. [26] further extend RL into multi-objective optimization, jointly minimizing cost, makespan, and energy consumption.

In serverless environments, Schuler et al. [36] demonstrate that even tabular Q-learning can outperform reactive autoscaling policies by learning optimal concurrency levels.

More recently, advanced multi-agent RL (MARL) systems have been introduced. Manhary et al. [39] propose a scalable MARL-ApeX framework combining BiLSTM forecasting with decentralized RL, explicitly incorporating carbon-aware VM placement and achieving measurable energy reductions. EdgeSched-DQN [32] and Liu et al. [34] extend RL into edge-cloud settings, optimizing latency-energy trade-offs using multi-objective formulations.

These works confirm that RL is particularly effective for dynamic, feedback-driven environments. However, most frameworks remain simulation-based and introduce high training overhead, raising concerns regarding deployment feasibility and reproducibility.

B. Predictive Machine Learning and Deep Learning Approaches

Predictive models play a central role in proactive resource allocation. Instead of reacting to overload conditions, ML-based systems forecast workload trends and adjust resource provisioning in advance.

Abdelhamid et al. [27] integrate XGBoost-based traffic prediction with Kubernetes autoscaling, demonstrating improved responsiveness in cloud-native environments. Wang and Yang [28] combine LSTM demand prediction with DQN-based scheduling to achieve significant utilization and latency gains in real cloud deployments.

Duc et al. [29] propose a hybrid forecasting ensemble (LSTM, Bi-LSTM, ARIMA, OS-ELM) for proactive autoscaling in cloud-edge CDNs, showing strong empirical validation on production data.

In our previous work, Doukha and Ez-zahout [42] proposed a real-time monitoring and predictive modeling framework integrating Random Forest and LSTM models for virtual machine optimization. The study demonstrated that ensemble-based learning, particularly Random Forest, can achieve high prediction accuracy for CPU utilization forecasting. However, the evaluation was conducted in a controlled environment and did not address large-scale heterogeneous or multi-cloud deployment scenarios.

Singh [37] and Wei [38] further illustrate hybrid predictive-control systems for healthcare and financial workloads, respectively, where SLA adherence and cost efficiency are primary objectives.

While predictive models enhance foresight and reduce SLA violations, most studies focus on performance and cost objectives, with limited integration of sustainability-aware metrics.

C. Hybrid AI and Metaheuristic Integration

Hybridization has emerged as a dominant design paradigm in cloud resource allocation research. Rather than relying exclusively on predictive learning or standalone reinforcement learning, many recent frameworks integrate learning components with classical optimization techniques or heuristic search strategies. This integration aims to combine the adaptability of AI models with the stability and convergence guarantees of structured optimization methods.

One hybridization pattern involves combining deep learning-based workload prediction with metaheuristic schedulers. Sharma et al. [33] integrate QT-DNN-based task-VM prediction with Binary Bird Swarm Optimization (BBSO) to enhance energy-efficient scheduling. In this design, the neural predictor estimates workload-resource mappings, while the swarm-based optimizer refines allocation decisions to minimize energy consumption and makespan. This separation of prediction and optimization helps reduce convergence instability often observed in pure RL approaches.

Similarly, Xaba et al. [44] employ Particle Swarm Optimization (PSO) for network-aware VM placement across multiple data center topologies. Although the approach does not incorporate adaptive learning, it represents a hybrid form of automation where heuristic optimization is guided by network stress metrics. The study highlights the importance of topology-aware placement but lacks learning-driven adaptability and sustainability quantification.

Another hybrid direction integrates predictive ML with reinforcement learning control. Chileshe [40] combines LSTM workload forecasting with DQN-based orchestration in Kubernetes environments. The predictive layer anticipates resource demand, while the RL agent dynamically adjusts scaling decisions to minimize SLA violations and latency. This predictive-control hybrid structure reflects a growing trend toward proactive rather than purely reactive allocation.

Rabaoui et al. [31] propose an agent-based hybrid architecture combining dynamic allocation mechanisms with heuristic energy minimization strategies. Their approach emphasizes distributed coordination among agents,

demonstrating that hybrid agent-heuristic systems can improve cost, makespan, and energy metrics in simulated cloud environments.

In another previous study, Doukha et al. [43] introduced a hybrid forecasting framework combining ARIMA, linear regression, and LSTM models for virtual machine resource prediction. The integration of statistical and deep learning techniques aimed to capture both linear temporal structures and nonlinear workload dynamics, improving forecasting accuracy compared to standalone models. Nevertheless, the study primarily evaluated predictive performance and did not experimentally validate large-scale dynamic allocation mechanisms.

Collectively, these works illustrate three main hybridization patterns:

- DL prediction with metaheuristic optimization
- ML forecasting with RL control
- Agent-based coordination with heuristic energy minimization
- Statistical time-series models integrated with machine learning and deep learning for enhanced workload prediction

Hybrid approaches frequently report improved multi-objective performance compared to single-paradigm systems, particularly in balancing latency, utilization, and energy consumption. However, most of them remain validated in simulation environments, with limited deployment-scale benchmarking or real cloud trace validation. Moreover, hybrid systems often introduce architectural complexity and parameter tuning challenges, which may hinder practical adoption.

D. Network- and Multi-Data-Center-Aware Allocation

While early cloud allocation research primarily focused on compute utilization and VM efficiency, recent studies increasingly consider communication overhead, topology constraints, and geographic distribution as key optimization factors. In large-scale cloud and edge infrastructures, network congestion, inter-rack latency, and cross-data center traffic significantly affect application performance and operational cost.

Xaba et al. [44] explicitly incorporate network stress metrics into VM placement decisions using a PSO-based NetDEO algorithm. Their evaluation across FatTree, BCube, and Tree topologies demonstrates that topology-aware allocation can reduce traffic imbalance and congestion compared to baseline placement strategies. However, the approach remains heuristic-driven and does not incorporate adaptive learning or carbon-aware routing.

Beyond topology-aware placement within a single data center, multi-data-center orchestration introduces additional complexity. Singh [37] proposes predictive orchestration for healthcare workloads across geographically distributed cloud environments, where SLA adherence and resource utilization must be maintained under cross-site migration scenarios.

The framework integrates workload forecasting with adaptive scheduling to mitigate SLA violations during migration and scaling events.

Wei [38] extends predictive allocation to real-time financial analytics, targeting containerized deployments across distributed infrastructures. By combining LSTM forecasting with RL-based dynamic allocation, the framework seeks to optimize latency and resource efficiency in geographically distributed environments.

Collectively, these studies reflect a broader shift from centralized, compute-centric allocation toward network-aware and geographically distributed orchestration. However, several limitations persist. First, most works optimize network or SLA metrics independently rather than integrating them into unified multi-objective carbon-aware formulations. Second, cross-region energy pricing and carbon-intensity variations are rarely incorporated into allocation decisions. Third, empirical validation across real multi-region cloud deployments remains limited.

As cloud-native applications increasingly span hybrid and multi-cloud infrastructures, network-aware, as well as geography-aware scheduling, is likely to become a core requirement for future AI-driven resource management systems.

E. Sustainability and Carbon-Aware Resource Allocation

Sustainability has become an increasingly important objective in cloud resource allocation. As data center energy demand continues to grow [3], recent studies have begun incorporating energy-related metrics into scheduling and allocation policies.

Several works integrate energy consumption directly into optimization objectives. Moazzami et al. [23] and Yu et al. [27], for example, include energy terms within their RL reward functions, treating power consumption as part of a multi-objective trade-off alongside latency and cost. However, in most cases, energy is considered primarily as an operational efficiency metric rather than an explicit environmental indicator.

A more explicit sustainability perspective appears in Manhary et al. [47], which models carbon-aware VM placement using emission-based reward shaping within a scalable MARL framework. This approach moves beyond energy minimization toward emission-sensitive allocation. Harun also explores carbon-aware scheduling combined with constrained reinforcement learning and digital twin validation, representing an early attempt to integrate environmental considerations into hybrid AI frameworks.

Despite these advances, explicit carbon-intensity modeling remains limited across the broader literature. Many allocation systems continue to treat energy consumption as a proxy for cost rather than directly optimizing environmental impact, indicating that fully carbon-aware cloud resource management remains an open research direction.

F. Synthesis and Observations

Across the surveyed literature, several patterns emerge:

- RL dominates dynamic allocation research, but suffers from training complexity.
- Metaheuristics remain relevant, particularly for placement optimization.
- Sustainability is increasingly considered, but often indirectly.
- Most frameworks rely on simulation environments rather than production validation.
- Carbon-aware and thermal-aware scheduling remain underexplored.
- Explainability and interpretability are rarely addressed.

A key observation across the surveyed literature is the presence of trade-offs between competing optimization objectives. For instance, minimizing latency often requires increased resource provisioning, which leads to higher operational cost and energy consumption. Conversely, strategies focused on energy efficiency may negatively impact performance and SLA compliance. These trade-offs highlight the importance of multi-objective optimization frameworks capable of balancing latency, cost, energy efficiency, and reliability within unified allocation strategies.

In addition, the effectiveness of resource allocation approaches varies depending on workload characteristics. Batch workloads, which are delay-tolerant, can benefit from global optimization and energy-aware scheduling strategies. In contrast, interactive and latency-sensitive workloads require fast, real-time decision-making, favoring lightweight heuristics or low-latency inference models. This distinction is critical when evaluating the practical applicability of AI-based allocation methods in real-world cloud environments.

Table I highlight that only a minority of works explicitly integrate environmental metrics beyond energy consumption, and even fewer validate at a large scale using real cloud traces.

VI. FUTURE DIRECTIONS

The analysis of existing AI-based cloud resource allocation research reveals clear progress toward adaptive, learning-driven orchestration. However, several structural limitations remain. Most surveyed approaches prioritize performance, latency, and cost minimization, while sustainability is often treated as a secondary objective. Although energy-aware reward functions are increasingly incorporated into RL frameworks [25], [29], and more explicitly modeled in carbon-aware formulations such as [39], explicit carbon-intensity-aware scheduling remains rare. Future research should, therefore, move beyond energy minimization as a cost proxy and integrate real-time carbon intensity signals as an additional objective or constraint within resource allocation decisions. Emerging carbon-aware computing initiatives demonstrate the feasibility of such approaches. For example, Radovanović et al. [45] show how carbon-aware workload shifting can reduce emissions without compromising reliability.

Another recurring limitation identified in the literature is the heavy reliance on simulation-based validation. Many RL and hybrid systems demonstrate promising results in controlled environments but lack large-scale real-cloud benchmarking. Bridging this gap requires reproducible evaluation pipelines, standardized workload traces, and safe deployment mechanisms within production cloud clusters. Strengthening empirical validation will be essential to ensure robustness, scalability, and operational reliability of AI-driven allocation systems.

Scalability also remains a challenge, particularly for multi-agent RL systems in geographically distributed cloud infrastructures. While decentralized and distributed training paradigms [46] have demonstrated scalability in other domains, their adaptation to carbon-aware, SLA-constrained cloud environments remains underexplored. Future work should investigate hierarchical and communication-efficient MARL designs tailored specifically for multi-data-center orchestration.

From a predictive standpoint, most surveyed studies rely on LSTM- or GRU-based workload forecasting. Recent advances in transformer-based time-series modeling suggest improved long-term dependency capture and generalization capacity [47]. Integrating transformer-based forecasting into hybrid predictive-control allocation frameworks may enhance robustness under bursty or highly non-stationary workloads.

Finally, explainability and operational transparency remain largely absent from current AI-driven allocation systems. As cloud infrastructures increasingly support critical applications, allocation policies must be interpretable and auditable. Foundational discussions on explainable AI in high-stakes systems [48] highlight the risks of opaque decision-making models. Incorporating interpretable reward structures, SLA-risk visualization, and policy explainability into resource orchestration engines represents an important direction for trustworthy AI-driven cloud management.

In summary, future AI-based cloud resource allocation research should prioritize: 1) explicit carbon-intensity-aware optimization, 2) real-world validation beyond simulation, 3) scalable and stable multi-agent learning, 4) advanced workload forecasting architectures, and 5) explainable and trustworthy allocation mechanisms. Addressing these dimensions will move the field from performance-centric optimization toward sustainable, production-ready, and environmentally responsible cloud orchestration.

VII. CONCLUSION

Cloud resource allocation has evolved from static heuristic scheduling toward adaptive, data-driven optimization frameworks powered by artificial intelligence. This survey analyzed recent AI-based approaches published between 2020 and 2026, highlighting the growing dominance of reinforcement learning for dynamic control, the continued importance of predictive modeling for proactive provisioning, and the increasing adoption of hybrid architectures that combine forecasting, learning-based control, and classical optimization techniques.

While significant performance gains have been reported across latency, cost, and resource utilization metrics, most frameworks remain validated primarily in simulation environments. Sustainability considerations are increasingly integrated through energy-aware objectives, yet explicit carbon-intensity modeling and large-scale real-world validation remain limited. Future research should prioritize scalable deployment, carbon-aware optimization, and interpretable decision mechanisms to advance trustworthy and production-ready intelligent cloud resource management systems.

Hate Speech Detection on Multiple Social Networks Using Deep Learning and Optimization Techniques: A Hybrid Approach

Vishu Tyagi, Sourabh Jain

Department of Computer Science and Engineering, Indian Institute of Information Technology, Sonapat, Haryana, India

Abstract—The use of social media networks as a source of hate speech is another emerging factor that complicates the possibility of a comprehensive organization of an environment suitable for promoting healthy communication. Automating the detection of hate speech in various social media networks has turned out to be a very difficult process. It is critical to identify and monitor hate speech to reduce its negative effects on people and groups. Currently, there are many approaches to classifying hate speech, but they still have indeterminacy when it comes to distinguishing between hate and normal messages and low accuracy. Many domains have greatly benefited from deep learning, especially in speech and NLP tasks. The hyperparameters of Deep Neural Networks (DNN) play a crucial role and are reflected in their success. However, because these hyperparameters are highly recursive, it is sometimes difficult to set them for machine learning models, such as deep neural networks. The work proposed in this study employed the sparrow search algorithm (SSA) optimization methods to fine-tune the hyperparameters of deep learning models for hate speech detection. In the training process of the SSA-DNN model, the SSA can help search and select the best hyperparameters. Based on the obtained experimental outcomes, it can be observed that the proposed SSA-DNN model outperforms different machine learning and deep learning techniques in the context of hate speech detection.

Keywords—Natural language processing; sparrow search algorithm; hate speech; deep neural network; social media

I. INTRODUCTION

Most internet users engage with social media and microblogging platforms, which have become dynamic spaces for public discourse and discussion. Social media networks that were relatively popular in the past, including Twitter, YouTube, Facebook, Wikipedia, Gab, and Reddit, are now used by people of various ages and interests. These platforms detect rapid content growth, leading to the emergence of what is known as "big data." The explosion of data has created a lot of enthusiasm for researchers, as well as those involved in automated opinion analysis and the study of both the structural aspects of networks and how users communicate with one another. Although developed to provide an open forum for communication and support free expression, these systems are very difficult to moderate because of their massive quantity of communications and unique attributes. Further complicating matters is that the vastly different social, emotional, and cultural backgrounds of users on these sites can lead to hate speech and other forms of offensive language being expressed when users interact with each other in a way they do not agree upon.

Artificial neural networks (ANNs) are widely recognized as a foundational form of deep neural networks applied to various natural language processing (NLP) tasks [1], including the detection of hate speech. Deep neural networks (DNNs) have been developed for pattern recognition and are highly valued in academia because of their strong capability to model complex nonlinear relationships. Nevertheless, when trained on limited datasets, the performance of deep learning models often falls below that of simpler neural network architectures. Designing an optimized model is a challenging and time-consuming task because it requires the careful selection of a suitable network architecture along with appropriate hyperparameters [2].

Hyperparameter selection for a Deep Neural Network is primarily responsible for the performance of the Deep Neural Network. Hyperparameter Optimization (HPO) is necessary to ensure the success of Deep Learning solutions in all areas of application. Most traditional methods used today (manual tuning, Grid Search, Random Search), while common, are limited in their ability to find the best hyperparameters in large dimensional spaces, are computationally expensive, and provide little insight into which hyperparameters are chosen to be the "best" [3]. Therefore, there is a significant need for a method to efficiently and effectively identify the optimal configuration(s) of model architecture using HPO for Deep Learning Models. The process of HPO is typically described as a 'black box' procedure because finding the best combination of architectural hyperparameters requires the use of advanced optimization algorithms [4].

The rapid advancement of technology has significantly enhanced the collection, repository, and data processing of scientific research. Deep learning, which emulates the functioning of the human brain, has shown significant potential for data analysis owing to its exceptional learning capabilities, adaptability, and flexibility. It involves an Artificial Neural Network (ANN) with multiple layers that performs different data modifications [5]-[6]. However, designing a traditional deep learning approach involves defining the model's structure and setting hyperparameters. While a deep neural network, it has the following constraints when applied to time-series scenarios:

- 1) Deep Learning models need help in explaining their decisions and the parameters used for predictions.
- 2) Hyperparameters of deep neural networks are usually decided based on earlier analyses or observed learning details.

3) The performance of a Deep Neural Network (DNN) can be significantly enhanced by fine-tuning the hyperparameters, affecting the model's architecture and generalization.

Hence, there is a strong interest in reducing the impact of human features and finding the optimal hyperparameters. This study presents a deep learning approach [1],[7]-[10] to address these challenges using a Sparrow Search Algorithm [3] to optimize the parameters. The SSA approach helps resolve the issue of the deep learning network's inability to explain its learning process and mitigate human tendencies. This research aims to introduce a novel approach for hyperparameter optimization, showcasing outstanding performance in hate speech detection.

The key contributions of the study are described as follows:

- Proposes a novel SSA-DNN hybrid model for automated hyperparameter optimization in hate speech detection.
- Effectively optimizes key DNN parameters using SSA to improve accuracy and generalization.
- Evaluates the model on a large multi-source social media dataset for robust performance.
- Achieves superior accuracy compared to existing deep learning and optimization-based methods.

The rest of this study is organized as follows. Section II extensively examines the existing research related to hate speech detection. Section III provides an overview of the development and application of the proposed approach. Section IV discusses our experiments and the results of the proposed model. Finally, conclusions and potential future research directions are discussed in Section V.

II. RELATED WORK

Research in NLP has progressed rapidly owing to the development of the social web. The social web has enabled researchers to use deep learning techniques along with NLP to interpret and understand social media-generated content, which has provided a large amount of data for researchers. Consequently, the social web has been established as an ever-changing environment for research. Social media is increasingly becoming multilingual; therefore, people from all around the world are able to communicate on different topics, such as current events and pop culture. However, while this linguistic diversity has provided many opportunities for communication, it has also increased the risk of encountering hate speech. Therefore, one of the biggest challenges in the management of online interactions is the ability to manage content across multiple languages.

Harmful and offensive forms of language, including hate speech, have been the focus of many studies. Hate speech can be defined as a form of communication that contains a prejudiced message that uses abusive language to target a person or people belonging to a particular group. The most prominent theme in hate speech research is the concept of targeting. This refers to the use of hate speech to specifically

target identified groups of people (such as refugees) and communities.

Waseem et al. [10] identified four subcategories of offensive language based on the extent to which a post was directed toward a group of people (versus an individual), in addition to the level of specificity of the offensive language used. ElSherief et al. [11] focused on how users who posted hate messages are associated with their visibility on social media. The results showed that users with high levels of social media visibility also tended to be tolerant of hate speech. Finally, Salminen et al. [8] noted that hostile comments were common in online news discussion forums, especially those directed at news organizations and law enforcement. In general, researchers believe that online news discussions provide a suitable platform for the development of malicious behaviors [12].

A comprehensive study of the interactions between various social groups is essential for investigating the presence of hate speech on online platforms [13]. Various researchers have examined several facets of this subject matter, including the expressions of intolerance that are based upon social groups, how hateful content is strategically used as an effective persuasive device to disseminate offensive language, how the sharing of harmful content by social media users can increase social polarization, the spreading of hate within society, and the impact of social networks' structural characteristics. Given the profound influence of contextual and subjective factors, using interpretive techniques is a common approach to exploring nuances [14]-[17]. Burnap et al. [18] presented an innovative method for recognizing hate speech. Their method involves a hate-word-based feature selection process to select the characteristics required for the preferred embedding approach. Additionally, Basak et al. [4] developed a web application, "block shame," designed to identify and combat shaming online globally. This tool effectively silences and blocks spammers while offering a comprehensive definition of shaming encompassing six forms of abusive behavior: comparisons, judgmental comments, sarcasm, jokes, and whataboutery.

Kumar et al. [19] discussed a novel method for optimizing hyperparameters using optimization algorithms and LSTM neural networks. They have tuned five hyperparameters of the deep learning neural network layer to enhance the accuracy of the proposed model. Pré-trained models have proposed an idea to enhance performance and reduce computational time. A deep-learning strategy based on recurrent neural networks (RNNs) was introduced for smaller datasets [20]. The categorization of human opinions is a direct outcome of utilizing a sophisticated attention tool in combination with multiple learning tasks.

Sequeira et al. [21] applied deep learning models and language-embedding techniques to categorize messages linked to drug misuse, as detailed in a previous study [22]. Using deep neural networks applied to autoencoders (AE) for detecting hate speech has effectively managed complex data. The SentiDiff method was developed to identify samples of tweet vagueness by leveraging transfer learning in conjunction with a deep CNN approach.

Wanget al. [23] proposed a deep model incorporating a tree construct at the local level, which expressed significant accuracy in sentiment recognition. Additionally, Chen et al. [24] have developed a single classification system aimed at detecting rumors within online societies, recognizing the role of rumors in encouraging prejudice. The use of sentence-level sentiment classification has shown good results owing to its ability to effectively handle the amount of noise often found in social media data [25]. Additionally, the combination of different types of computational methods allows for improved accuracy and a better understanding of detected sentiments [26]. In the area of hate speech detection, Yang et al. [27] suggested a deep learning-based fusion method using a transformer encoder model and derived a language model to detect hate speech. Watanabe et al. [28] examined approaches for identifying the inciting language using feature-extraction methods. Shah et al. [29] employed a hybrid fuzzy rule structure approach within a logic framework to determine hate speech from insecure text.

Deep learning techniques have been used for many applications and are increasingly being applied in Natural Language Processing (NLP). Recent studies have demonstrated improved performance of Deep Learning techniques compared to traditional Machine Learning models [30]. Ensemble learning is a technique in which two or more models can be combined to achieve better results. One researcher examined ensemble learning for the classification of Hate Speech and Vulgar Content and achieved an accuracy of 87%. The data from this study indicated that there was still potential to optimize the hyperparameters of the meta-classifier(s), which may improve the overall model performance. Another researcher utilized CNNs to classify hate-related words/expressions from a text dataset [43].

An alternative strategy for enhancing the performance of this task would be to incorporate bidirectional long short-term memories Memory) that provide enhanced insight into the sequential nature of messages. Zhang et al. [33] utilized sophisticated Deep Learning approaches to achieve strong type differentiation of character-level classification. RNN-based architectures for recognizing abusive language through Bangla Speech Recognition have been employed in similar studies [34]. Additionally, Zamperi et al. [35] and Golbeck et al. [36], the use of Deep Learning strategies to identify abusive content on various social media platforms has proven effective, as demonstrated and supported by the results. These investigations incorporated learning algorithms, such as Bi-GRU, RNN, and CNN.

Some studies have introduced optimization techniques such as Genetic Algorithms (GA) and Particle Swarm Optimization (PSO) to improve model performance. However, these methods suffer from issues like slow convergence, getting trapped in local optima, and an inadequate balance between exploration and exploitation. As a result, they are not always able to achieve optimal performance in complex tasks like hate speech detection. Additionally, many existing works are limited to single datasets or platforms, which reduces their ability to generalize across diverse and dynamic social media environments. To address these limitations, this study proposes

an SSA-DNN method to overcome these limitations. The Sparrow Search Algorithm (SSA) provides a more efficient and adaptive optimization strategy, enabling better exploration of the hyperparameter space and faster convergence toward optimal solutions. This reduces the dependency on human expertise and improves the overall robustness of the model. Moreover, by evaluating the model on a large multi-source dataset, the study ensures better generalization and real-world applicability.

III. METHODOLOGY

This section explored the Sparrow Search Algorithm, described the annotated dataset from diverse social media platforms, and analysis of Data-preprocessing, discuss the proposed hybrid approach.

A. Sparrow Search Algorithm

Optimization problems are observed easily in different fields of study, including engineering and finance, among others; thus, it is very crucial to arrive at the best solutions to the problems. The Sparrow Search Algorithm [33] is a comparatively new meta-heuristic optimization algorithm that is inspired by the foraging process of sparrows. As opposed to many conventional optimization techniques that may have difficulties with high levels of dimensions, the Sparrow Search Algorithm is intended to make use of the intelligence and versatility of sparrows to search the solution space successfully.

SSA is an inventive optimization technique based on the social aspects observed of sparrows during their movement in search of food. The foraging conduct of sparrows can be classified as a producer-scrounger, consisting of two main mechanisms: There is a dissemination mechanism that would work as an experimental mechanism, and an alert mechanism as well. In this model, producers, characterized by their notable fitness, are responsible for finding food sources, designating foraging locations, and providing guidance for scavenging routes. On the other hand, scroungers enhance their prevalent fitness by selectively following producers with numerous favorable fitness attributes, thus securing sustenance. Additionally, someone monitors the significance levels of producers, who are seen as obtaining resources via potentially unethical standards.

If a producer maintains an increased significance level, some scrounger populations may employ energetic food acquisition. When noticing a predator, sparrows swiftly emit a warning signal and relocate to a secure location. Sparrows in the population's prominent region display random movements toward their fellow sparrows. When the security threshold drops below a predefined warning value, producers must drive scroungers away from the dangerous location.

Considering the population of N sparrows, individual sparrows explore a search space with D dimensions. You can represent the spatial coordinates of individual sparrows as part of an $N \times D$ matrix. If you let $X(i, j)$ represent the location of the i^{th} sparrow in the j^{th} dimension, it is clear that i is 0 to N , and j is 0 to D . In this context, the sparrow population adheres to certain limitation conditions, where SSA selects 10%~15% of the producers. Eq. (1) is as follows:

$$X_{i,j}^{c+1} = \begin{cases} X_{i,j}^c * \exp\left(\frac{-i}{\alpha c_{max}}\right), & A_v < TR \\ X_{i,j}^c + r.L, & A_v \geq TR \end{cases} \quad (1)$$

The variable "c" represents the current iteration count, and "α" stands for an arbitrary number uniformly distributed in the range of 0 to 1, "c_{max}" indicates the maximum number of iterations, and "r" is an arbitrary variable following a normal distribution. "L" is a 1 by D matrix consisting of elements set to 1.

The "A_v" expresses the alarm value, a single value between 0 and 1. Conversely, "TR" signifies the safety threshold, a single value between 0.5 and 1. If A_v is less than TR, there is no predator presence, and a comprehensive search can proceed. If A_v is equal to or greater than TR, it indicates the detection of a predator.

Consequently, the population needs to migrate to a safe place upon receipt of the alarm signal. Scroungers acquire food by trailing the producers, and the producer's location whereabouts are adapted in Eq. (2).

$$X_{i,j}^{c+1} = \begin{cases} Q * \exp\left(\frac{X_{worst}^c - X_{i,j}^c}{i^2}\right), & i > \frac{n}{2} \\ X_p^{c+1} + |X_{i,j}^c - X_p^{c+1}| \cdot A^+ \cdot L, & i \leq \frac{n}{2} \end{cases} \quad (2)$$

The equation, as previously mentioned, involves multiple variables. Here, X_p represents the best place for the producer, and X_{worst} corresponds to the worst global status. The matrix denoted as A consists of randomly induced elements, each being either 1 or -1, and follows a specific equation. For instance, when the value of 'i' surpasses half of 'n,' it implies that the ith individual scrounging for food is hungry, displaying a suboptimal physical situation and reduced vitality levels. Consequently, this individual must seek nourishment in different areas. In this context, the individual scrounging for food follows the producers in a considerably beneficial position. The matrix indicated is determined using the formula A⁺ is A^T(AA^T)⁻¹. Updating monitors in Eq. (3) as follows:

$$X_{i,j}^{c+1} = \begin{cases} X_{best}^c + \beta \cdot |X_{i,j}^c - X_{best}^c|, & f_i > f_g \\ X_{i,j}^c + K \cdot \left(\frac{|X_{i,j}^c - X_{worst}^c|}{(f_i - f_w) + \epsilon}\right), & f_i = f_g \end{cases} \quad (3)$$

In this scenario, X_{best} represents the optimal location within the entire area. The parameters β and K order the step size, arbitrarily induced from a normal distribution between -1 and 1. The variable f_i describes the current fitness level of a sparrow. Additionally, f_r describes the sparrow's current fitness level, whereas the best and optimal positions across the total location are implied as f_g and f_w, respectively. To avoid division by zero, the constant ε is added. If, however, f_i > f_g, it implies that the sparrow is arranged at the population's periphery and thus vulnerable to predators. The sparrow must seek safety by joining different group members in such instances.

According to the literature review, SSA has been developed to overcome the existing meta-heuristic algorithms, which have no prior information about the solution space topography. The algorithm adds a method of visualizing the characteristics of the

solution space by sets of solutions found, as one draws maps to improve the probability of discovering the treasure. This way, the algorithm can make better decisions during the search and thus solve the significant optimization problems efficiently.

The idea of the Sparrow Search Algorithm is based on the actual foraging behavior of sparrows as socially foraging birds that tend to use both individual and social approaches. Sparrows are very intelligent birds that are capable of adjusting to new surroundings and collaborating in order to gain the best results in terms of feeding. The functions of the operators of the algorithm – the selection of the search space, further search within a deviated search space, further search within a converged search space, swooping to capture prey – are modeled on these natural processes. The Sparrow Search Algorithm has been evaluated and benchmarked with other famous meta-heuristic algorithms like Particle Swarm Optimization, Genetic Algorithms, and Grey Wolf Optimizer for different optimization problems, including mathematical benchmark functions as well as some engineering application problems [19, 31-32]. These results have clearly proved that the Sparrow Search Algorithm has the ability to outperform or at least be at par with these recognized algorithms, thus explaining its accuracy and applicability.

Another major strength of the Sparrow Search Algorithm is its ability to adopt the exploration/exploitation trade-off during the search phase. The features of how the algorithm chooses the search space and how it adapts within a strayed search field and within a refined search field explain why this algorithm allows it to search the solution space and find the global optimum. Moreover, the implementation of parallel algorithms is also possible with the help of the developed algorithm, which also minimizes the computing time to achieve better results in solving various optimization problems.

B. Description of Annotated Dataset

In this study, we employed ten pre-existing annotated datasets [10], [34]-[42]. Five of these datasets originated from Twitter, two from YouTube/Facebook, one from Gab, one from Wikipedia, and the remaining from Reddit. Table I provides an overview of these datasets collected from diverse social media. These annotated datasets consisted of English-language communication texts and were categorized as either hate speech or non-hate. All datasets from different social media networks were divided into a unified dataset comprising 432053 items. Table II shows the text in this consolidated dataset, indicating whether they are classified as hate speech or non-hate speech.

C. Data Preprocessing

To gain an understanding of how to improve the proposed methodology's performance and enable its operation at the highest level possible, the data were systematically analyzed, categorized, and refined. Data analysis was used to develop generalizable characteristics from the available CSV dataset. During the first phase of pre-processing for this dataset, several undesired items were eliminated, such as emoticons, non-alphanumeric symbols (\$, %, >), URL addresses, and 'noise' such as ;, &abc!, |, and :. Next, punctuation symbols were eliminated, and each hashtag (i.e., #BanAfrica) was converted to regular text by replacing the # symbol with ordinary characters. Following the normalization of the clean text data

using stemming, lemmatization, and conversion to lower case, the data were tokenized, resulting in the identification of 89,419

unique tokens across the social media platforms. Examples of some pre-processing steps are listed in Table III.

TABLE. I. DESCRIPTION OF ANNOTATED DATASETS

S. No	Dataset	Data Source	Year	ML Approach	Dataset

D. Proposed Approach

The SSA is an efficient optimization algorithm that is easily controlled because it uses few control parameters. The SSA uses a random search strategy to define the initial position of the sparrows. This can lead to longer convergence times and less accurate solutions if the randomly chosen initial positions are significantly away from their respective optimal positions. However, SSA has proven to be effective in solving multivariable complex optimization problems; that is, SSA has demonstrated the ability to quickly find the optimal solution and provide reliable results. Research has been conducted on using SSA with other optimization problems in various fields of engineering, which provides a basis for the current investigation. Unlike previous studies [34], the objective of this study was to improve the adaptability of the DNN-based learning model to human influence through hyperparameter

tuning, as well as improve the model's accuracy in making predictions. The key parameters of the DNN, that is, the learning rate, number of LSTMs used in the network, number of neurons in the dense layer, and number of training epochs, were systematically searched for optimal values. The SSA was used to optimize these hyperparameters to ensure that consistent features were extracted and a stable network architecture was created.

The ability of SSA to effectively determine the optimal parameter weights for deep learning algorithms improves their interpretability. The SSA-DNN model, depicted in Fig. 1, is proposed to train optimized deep neural networks. This architecture consists of four separate layers: an input, an LSTM [1], a hidden and an output. The SSA focuses on optimizing parameters such as the learning rate, number of neurons in two hidden layers, and the corresponding number of optimized

epochs. Once the parameter scale is set, the positional facts of the population, as well as the parameters corresponding to them, are set randomly. This study aims to examine the fitness function employed in SSA as well as the loss method of the deep neural network, which belongs to the framework of the learning model. In this approach, each dataset was randomly

divided into two parts: 80% for training and 20% for testing purposes. All experiments in this study were conducted using Python 3.8 and TensorFlow 2.6.0, running on a Windows 10 system equipped with an NVIDIA Quadro K2220 GPU (32 GB) and a dual Intel Xeon E5-1650 CPU at 3.50 GHz, supported by 64 GB of RAM.

Fig. 1. Proposed hybrid architecture.

IV. RESULTS AND DISCUSSION

This section explored the optimization of the hyperparameters of our SSA-DNN model, evaluation of our SSA-DNN model across various datasets, and compared it with state-of-the-art methods.

A. Optimizing Hyperparameters on Proposed Model

The hyperparameters of the proposed model that is responsive to optimization using the Sparrow Search Algorithm consist of the following:

- neurons in the LSTM layer
- values of the learning rate

- neurons in the CNN layer
- epochs

A concise overview of these hyperparameter values is provided in Fig. 2. The optimal hyperparameters for the Deep neural network were determined based on the information in Table IV. These optimized parameter settings include a learning rate of 0.0027, an epoch count of 52, 68 neurons in the LSTM layer, and 88 neurons in the CNN layer. The proposed model for identifying hate speech messages was developed using the most effective parameter weights acquired through optimization using a sparrow search algorithm.

Fig. 2. Fine-tuning hyperparameters of the proposed hybrid model.

TABLE. IV. FINE-TUNING OF THE PROPOSED MODEL

Parameters	Scale	Best value
Learning_Rate	0.0001 – 0.01	0.0027
Epoch	0-80	52
DNN_LSTM	0-128	68
DNN_CNN	0-128	88

B. Results

Table V elaborates the classification outcomes arising from the proposed model during the iterations. The results of the above iterations show that the proposed model effectively classifies messages in various epochs. Thus, in iteration 1, the accuracy of the proposed model was 95.6. After iteration 3, the accuracy level of the proposed model was 97.5. As can be seen from Iteration 4 of the proposed model, the prediction results accurately reached 97.9. Finally, after the fifth iteration, a model with the proposed solution was created with an accuracy of 97.9.

TABLE. V. RESULTS OF THE PROPOSED MODEL

Iteration	Accuracy	P	R	F1_Score
1	95.6	93.8	94.4	94.1
2	96.9	95.5	96.4	95.9
3	97.5	96.1	97.2	96.6
4	97.9	97.0	97.8	97.4
5	97.9	97.0	97.8	97.4

Table VI presents a comparative study of the proposed model and the current state-of-the-art model. Initially, the performance metrics of techniques designed by [35], [39] utilizing machine learning approaches exhibited relatively lower accuracy levels, with values of 93.1 and 93.0, respectively. Next, the approaches presented by [41],[44], incorporating deep learning approaches, were performed with remarkable precisions of 91.2 and 87.0. However, we also provide the result of applying the same GA and PSO algorithm to optimize the suggested model, with less accuracy, 74.5 and 78.6, as compared to the SSA-DNN model. Ultimately, the proposed model attained its extreme accuracy of 97.9. These

outcomes emphasize the outstanding implementation of the proposed model compared to other deep learning approaches, resulting in enhanced performance.

TABLE. VI. PROPOSED MODEL VS STATE OF ART METHODS

Authors	Methods	P	R	Accuracy
Vashistha et al. [44]	LR, TF-IDF	91.2	91.2	91.0
Kurek et al. [41]	CNN, LSTM	90.1	92.0	87.0
Hopf et al. [39]	SSA	-	-	93.1
Kumar et al. [19]	LSTM, SSA	93.5	93.6	93.6
Zampieri et al. [35]	LSTM, GBDT	93.0	93.0	93.0
Genetic Algorithm (GA)	LSTM-CNN	74.5	74.6	74.5
Particle Swarm Optimization (PSO)	LSTM	78.2	79.0	78.6
Proposed Model	SSA, DNN	97.0	97.8	97.9

V. CONCLUSION

This study introduced a hybrid SSA-DNN framework for hate speech detection across multiple social media platforms, with a primary focus on automated and efficient hyperparameter optimization. By integrating the Sparrow Search Algorithm (SSA) with deep neural networks, the proposed approach overcomes key limitations of traditional tuning methods, which often depend on manual expertise and exhaustive search strategies. The SSA mechanism enables intelligent exploration of the hyperparameter space, leading to

the optimal selection of critical parameters such as learning rate, number of neurons, and training epochs. This not only minimizes human intervention but also enhances the robustness and generalization capability of the model. The effectiveness of the proposed framework is validated through extensive experiments conducted on a large-scale, multi-source dataset comprising diverse social media platforms. The results demonstrate that the SSA-DNN model achieves a high classification accuracy of **97.9%**, outperforming several existing machine learning and deep learning approaches. Additionally, the model shows improved precision, recall, and F1-score, indicating its capability to reliably distinguish between hate and non-hate content. Beyond performance improvements, the SSA-based optimization process contributes to better interpretability by offering insights into parameter selection and model behavior. This makes the proposed approach not only effective but also more transparent compared to conventional deep learning models.

Despite these promising outcomes, there are several avenues for future research. One important direction is the enhancement of computational efficiency by reducing training time and exploring lightweight neural architectures suitable for real-time applications. As social media platforms generate massive volumes of data continuously, scalable and efficient models are essential for practical deployment. Another significant extension involves the incorporation of multimodal data, including images, videos, and audio, alongside textual information. Hate speech is often expressed through memes, visual symbols, or spoken language, which cannot be fully captured by text-only models. A multimodal SSA-DNN framework could therefore improve detection accuracy by capturing such nuanced and context-dependent forms of harmful content. Furthermore, integrating the proposed framework with transfer learning and pre-trained language models, such as transformer-based architectures, could enhance performance across low-resource languages and domain-specific datasets. This would increase the adaptability and applicability of the model in diverse linguistic and cultural settings. Future work may also explore the integration of explainable AI techniques to provide deeper insights into model decisions, thereby ensuring fairness, accountability, and bias mitigation in automated hate speech detection systems.

Enhancing the Successful Microservices Implementation

A Systematic Review Study

Abstract—Despite the widespread adoption of microservices across major global companies, a knowledge gap persists between best practices and real-world implementation challenges faced by practitioners. While existing literature provides extensive coverage of microservices patterns, limited evidence exists regarding how the practices are actually implemented in various organizational contexts. Thus, this study aims to address this gap through a systematic synthesis of empirically-validated microservices practices from recent peer-reviewed literature. We conducted a comprehensive systematic literature review and ultimately included thirty-four high-quality articles published between 2021 and 2025. We extracted 114 microservice practices and classified them into eight domains, which are Architecture and Design, Communication and Integration, Development and Deployment, Monitoring and Observability, Testing and Quality Assurance, Migration and Legacy Modernization, Security and Access Control, and Team Organization and Development Process. Architecture and Design practices and Team Organization and Process collectively account for nearly half of all identified practices, while Security and Access Control emerged as a significant research gap, with only 5.9 per cent of studies addressing this domain. To the best of our knowledge, this is the first systematic literature review that comprehensively synthesizes microservice implementation practices across multiple domains with explicit empirical validation in real-world contexts as inclusion criteria. This study provides a comprehensive catalogue of empirically-validated practices, offering structured guidance for practitioners and a foundation for future development of microservice implementation guidelines, contributing to more successful microservice projects and mitigated implementation risks.

Keywords—Microservice; practice; systematic literature review; Küchenham; PRISMA 2020

I. INTRODUCTION

In the early 2010s, Netflix adopted an architecture that allowed small, autonomous teams to build and run specific services [1]. This success story marked an architectural turning point. This approach, called microservices, has since gained widespread recognition among practitioners and scholars [2]. Numerous organizations have successfully adopted microservices. Tech giants, including Amazon, Spotify, Uber, LinkedIn, and Twitter, have all implemented this architecture [3]. In the financial industry, microservice solutions can increase organizational agility [4]. Microservices are often integrated with agile development techniques [5]. Organizations benefit from modularity through loose coupling and high cohesion,

distributed architecture and decentralization, scalable infrastructure, and reusable components.

However, despite microservices being well-established since 2014 and extensive literature on best practices, practitioners continue to face implementation challenges [2], [6]. Recent discoveries from the banking industry reveal anti-patterns in microservice implementations, as shown in Fig. 1. First, services become oversized and lose modularity. Large-scale microservice systems are likely to be expanded, altered, relocated, or deleted, leading to increased system complexity and potential technical debt and regression problems [7]. Second, the foundation code employs static global variables, creating service dependencies. If there is a problem with the foundation code, the microservices will also be impacted. Additionally, banking microservice implementations experience performance degradation due to database schemas that are inadequately designed to handle growing data volumes, leading to system performance bottlenecks. This fact is supported by the survey conducted by IBM Market Development & Insights. The survey found that 51% of data management is still geared toward monolithic app development. While such industry-specific findings provide valuable insights about deployment issues, they provide isolated information within specific organizational contexts and cannot capture broader practices.

Fig. 1. Research gaps: Microservice implementation practices.

Several empirical studies conducted through case studies and interviews have focused on fragmented areas of microservices implementation, making it difficult for practitioners to obtain comprehensive information about end-to-end microservice implementation. Furthermore, while prior secondary studies have mapped microservices architecture from various perspectives, these reviews either predate the recent wave of empirical research (2021-2025), focus predominantly on architectural aspects without covering cross-cutting domains such as security and team organization, or do not distinguish between theoretically proposed and empirically validated practices. This gap – the absence of a systematic synthesis of empirically grounded implementation practices across multiple domains – motivates the present study.

We carried out a comprehensive review of previous studies, following the protocols established by Kitchenham and Charters [8] and the PRISMA 2020 guidelines for reporting systematic reviews [9]. From an initial pool of 1,823 records, 34 empirically validated studies were selected for review. The main contribution of this study is a structured catalogue of 114 microservices implementation practices classified across eight domains, all grounded in empirical evidence from industrial and real-world contexts. These findings serve as evidence-based building blocks for developing microservice implementation guidelines and provide a foundation for future research on practice prioritization and context-specific adoption strategies.

We organize this study into six sections: Section II provides the general setting of microservices. Section III presents the related work. Section IV describes a detailed account of the research methodology. Section V reports and discusses the outcomes. Lastly, Section VI summarizes this study with threats to validity, contributions, and future work.

II. BACKGROUND

Microservices architecture is an approach for developing a single application as a suite of small, independently deployable services, each running on its own process and communicating through lightweight mechanisms [10]. Unlike monolithic systems, where all components are tightly coupled within a single unit, microservices enable independent development, deployment, and scaling of individual services [11]. The architecture has been widely adopted by major technology companies and financial institutions seeking improved agility, scalability, and fault isolation [1], [3], [4].

However, the shift from monolithic to microservices architecture introduces significant challenges in areas such as service granularity, distributed data management, inter-service communication, and organizational coupling [12], [13]. Service granularity – determining the appropriate size and scope of each microservice – remains one of the most debated design decisions, as both overly fine-grained and overly coarse-grained services can lead to performance and maintenance issues [13]. Distributed data management across service-specific databases introduces challenges related to data consistency, transaction coordination, and cross-service querying [14]. Additionally, the organizational structure must align with the service architecture to avoid communication overhead, a principle formalized as Conway's Law [15].

Design patterns play a fundamental role in addressing these challenges. Waseem et al. [14] explored the degree to which practitioners adopt patterns for microservice data management. Cerny et al. [16] conceptualized a design pattern as numerous tested solutions to recurring design complications. Such design patterns represent fundamental practices in microservice implementation. Practices in microservice implementation encompass processes, techniques, platforms, reference architecture, algorithms, and quality assurance practices [17].

Although microservice research has expanded significantly in recent years, existing empirical studies have focused on fragmented areas [14], [18], making it difficult for practitioners to obtain a comprehensive view of implementation practices. No systematic literature review has specifically catalogued empirically validated microservices implementation practices across multiple domains. The following section presents a comparison with prior secondary studies and situates this study within the existing body of knowledge. This study aims to fill this gap by systematically identifying and categorizing microservice implementation practices from empirical literature.

III. RELATED WORK

Several secondary studies have examined microservices from different perspectives. Pahl and Jamshidi [19] conducted one of the earliest systematic mapping studies (SMS) on microservices, classifying 21 primary studies published between 2014 and 2015 to characterize research directions in the field. Their study established an initial classification framework but was limited to a narrow timeframe and a small corpus. Alshuqayran et al. [20] extended this effort by mapping 33 studies focused on architectural challenges, quality attributes, and common architectural views in microservice systems. While both studies provided foundational overviews, they predated the substantial growth in empirical microservices research that occurred from 2018 onward.

Di Francesco et al. [21] performed a more comprehensive systematic mapping of 103 primary studies, investigating the focus of research on architecting with microservices and evaluating the potential for industrial adoption. Their study revealed that significant microservice systems must consist of larger numbers of services than covered by discovered studies at that time and highlighted a gap between academic proposals and industrial practice. Fritzsch et al. [17] conducted a rapid review on adopting microservices and DevOps in the cyber-physical systems (CPS) domain, identifying key challenges and proposing recommendations based on a supplementary case study. Söylemez et al. [22] conducted an SLR covering 85 primary studies published since 2014, identifying nine categories of challenges and 40 sub-categories with corresponding solution directions. However, their focus was on challenges and solutions rather than on cataloguing empirically validated implementation practices.

While these prior studies have contributed significantly to understanding microservices architecture, they share several common limitations that motivate the present work. First, most existing reviews accept both theoretical proposals and empirical studies without distinguishing between them, potentially mixing

unvalidated concepts with evidence-based practices. Second, earlier reviews predominantly focus on architectural aspects, with limited coverage of cross-cutting domains such as team organization, security, and monitoring. Third, the majority cover literature published before 2021, missing the substantial body of empirical work produced in the recent period of microservices maturation. This study addresses these limitations by: 1)

requiring empirical validation in industrial or real-world contexts as an explicit inclusion criterion, 2) covering literature from 2021 to 2025, capturing the most recent empirical evidence, and 3) organizing practices across eight implementation domains, providing a broader view than architecture-focused reviews alone. Table I summarizes the key differences between this study and prior secondary studies.

TABLE I. COMPARISON WITH PRIOR SECONDARY STUDIES

Author	Year	Type	Scope	Time Range	Empirical Validation
Pahl and Jamshidi [19]	2016	SMS	Classification framework	2014-2015	No
Alshuqayran et al. [20]	2016	SMS	Architectural challenges, quality attributes, and common architectural views	2014-2016	No
Di Francesco et al. [21]	2019	SMS	Architecting with microservices	Up to 2017	No
Söylemez et al. [22]	2022	SLR	Microservice challenge and solutions	2014-2022	No
Fritzsche et al. [17]	2023	Rapid review	Microservice and DevOps in CPS	2015-2021	Partial
This study	2026	SLR	Practices across domains	2021-2025	Yes

IV. SYSTEMATIC LITERATURE REVIEW

An SLR is a structured approach for locating, analyzing, and synthesizing all relevant studies addressing a particular research question or topic [23]. SLR consists of three processes: planning, conducting, and reporting [24]. We follow the instructions given by Kitchenham and Charters, which comprised the following main elements: 1) developing research question, 2) selecting a search strategy, 3) prescribing criteria for inclusion and exclusion, 4) choosing studies, 5) examining the quality of the included studies, and 6) extracting and synthesizing data [25]. While for reporting the systematic reviews, we follow PRISMA 2020.

A. Developing Research Questions

The study seeks to systematically identify microservice implementation practices reported in the available literature. In order to fulfill this goal, the research questions (RQ) guide the study:

RQ1: What microservices implementation practices are reported in empirical literature?

RQ2: How are microservices practices distributed across domains, and what patterns emerge?

RQ3: What gaps exist in current microservices implementation research?

The search strategy, inclusion and exclusion criteria are then created based on these RQs.

B. Defining a Search Strategy

The search strategy for the review encompasses the scope, search method, and search string. The scope consists of publication period and publication venue. The review includes literature published within the timeframe of 2021 to 2025. The databases selected for the search of scientific studies were Institute of Electrical and Electronics Engineers Inc. or IEEE Xplore, ProQuest, Sage Journals, ScienceDirect, Scopus, Springer Nature Link, Taylor & Francis, and Wiley Online Library. The choice of the databases reduces bias toward any single publisher's editorial preferences also minimizes the risk

of missing relevant articles. All databases provide peer-reviewed article, making sure the quality.

We conducted an automated literature search for this research. Automated searching involves querying electronic databases using predefined search terms. Our first attempt was to perform a very specific search for answering the research questions. The initial keywords were practice, implementation, and microservice. However, the expected articles were not successfully retrieved. We decided to do another round of search using more general keywords: microservice, practice, project management, software project, and development process. To get the most of it, we also added method, case study, pattern, and approach. The following general search string was set: (microservice OR "micro-service") AND ("project management" OR "software project" OR "development process" OR team OR enterprise OR organization) AND (practice OR method OR "case study" OR implementation OR pattern OR approach).

To optimize the literature search process, this search string was modified iteratively for each database using Boolean operators. Each database required slightly different adaptations: IEEE Xplore utilized "All Metadata" fields, ScienceDirect and Scopus used the search scope within title-abstract-keywords fields, Wiley applied an "anywhere" field search approach, while Taylor & Francis and Springer Nature Link used the most simplified Boolean combination. Table II lists the final search string for each database, while Fig. 2 shows the distribution of articles per database in the initial search. The database search was conducted on 7 January 2026.

The search string was iteratively refined through pilot searches to balance recall and precision, adjusting terms based on initial result relevance. To validate the effectiveness of the search string, a set of known relevant papers identified during preliminary literature exploration, Bogner et al. [26], Ünü et al. [27], Ait Said et al. [28] were used as seed papers. All three studies were confirmed to be retrievable by the final search string across the respective databases, providing confidence in the search string's ability to capture relevant empirical studies on microservices implementation practices.

TABLE II. FINAL SEARCH STRING

Database	Boolean Search
IEEE Explore	("All Metadata":microservice OR "All Metadata":"micro-service") AND ("All Metadata":"project management" OR "All Metadata":"software project" OR "All Metadata":"development process" OR "All Metadata":"team") AND ("All Metadata":practice OR "All Metadata":method OR "All Metadata":"case study")
ProQuest	(TI(microservice OR "micro-service") OR AB(microservice OR "micro-service") OR SU(microservice OR "micro-service")) AND (TI("project management" OR "software project" OR "development process" OR team) OR AB("project management" OR "software project" OR "development process" OR team) OR SU("project management" OR "software project" OR "development process" OR team)) AND (TI(practice OR method OR "case study") OR AB(practice OR method OR "case study") OR SU(practice OR method OR "case study"))
Sage Journals	(microservice OR "micro-service") AND ("project management" OR "software project" OR "development process" OR "team") AND (practice OR method OR "case study")
ScienceDirect	Title, abstract, keywords: (microservice OR "micro-service") AND ("project management" OR "software project" OR "development process" OR "team") AND (practice OR method OR "case study")
Scopus	TITLE-ABS-KEY ((microservice OR "micro-service") AND ("project management" OR "software project" OR "development process" OR "team") AND (practice OR method OR "case study"))
Springer Nature Link	(microservice OR "micro-service") AND ("project management" OR "software project" OR "development process" OR "team") AND (practice OR method OR "case study")
Taylor & Francis online	[[All: microservice] OR [All: "micro-service"]] AND [[All: "project management"] OR [All: "software project"] OR [All: "development process"] OR [All: "team"]] AND [[All: practice] OR [All: method] OR [All: "case study"]]
Wiley Online Library	"(microservice OR "micro-service")" anywhere and ("project management" OR "software project" OR "development process" OR "team") anywhere and "(practice OR method OR "case study")" anywhere

Fig. 2. Articles per source.

The choice of the databases ensures comprehensive coverage across technical (IEEE Xplore), business (Taylor & Francis online), high-impact research (ScienceDirect), international scope (Scopus), and emerging research (ProQuest).

It is essential for capturing all aspects of microservice implementation practices in enterprise settings. A sum of 1823 papers were located using automated search with Springer Nature Link provided the most results ($n = 547$) while ProQuest the least amount ($n=26$).

C. Establishing Criteria for Inclusion and Exclusion

To ensure a relevant and focused selection of literature, inclusion and exclusion criteria were established and applied to the automatic search results. These criteria were defined to identify studies aligned with our research objectives about microservice practices, as detailed in Table III. The criteria were applied sequentially, starting from objective filters (IC.1-IC.4) before proceeding to content-based evaluation (IC.5-IC.7).

D. Selecting Studies

The initial search retrieved 1,823 records across 8 electronic databases. The duplicate records were then removed (EC.1), prompting 1706 records to go to the screening. Inclusion and exclusion criteria from Table III were applied in this phase. Only records published within the 2021-2025 timeframe (IC.2), English-language (IC.3), journal articles and conference papers (IC.4), and articles that focus on microservice implementations (IC.5) were retained, resulting in 224 going to the next step. Using IC.6 and EC.6, only 139 reports were retrieved.

TABLE III. STUDY SELECTION GUIDELINES

Inclusion Criteria (IC)	
IC.1	Not a duplicate publication
IC.2	Published between 2021 and 2025
IC.3	Written in English
IC.4	Peer-reviewed publications (journal articles, conference papers)
IC.5	Primary focus on microservices implementation practices, patterns, or approaches
IC.6	Full text accessible through institutional or open access
IC.7	Papers must report on the practical application, evaluation, or observed results of microservices implementation practices within a specific industrial or real-world context
Exclusion Criteria (EC)	
EC.1	Duplicate publications (retain most complete or recent version)
EC.2	Published outside 2021-2025 timeframe, or erratum, corrigendum, retraction, or correction
EC.3	Not written in English
EC.4	Grey literature, books, book chapters, theses, dissertations, technical reports, posters, workshops, editorials, non-research content, short papers (<4 pages), or not peer-reviewed papers
EC.5	Papers where microservices is not mentioned, or mentioned only tangentially (not primary focus)
EC.6	Full text not accessible through institutional or open access
EC.7	Papers that are purely theoretical, conceptual, or solution proposals (new models, frameworks, or methodologies) that lack documented application or validation in real-world projects

Lastly, we performed a full-text screening of the studies, implementing IC.7 and EC.7 as the gatekeeper, which generated thirty-six studies for comprehensive analysis. This review focused on empirical studies examining microservice implementations practices, development processes, and approaches in enterprise environments or real-world projects.

We excluded secondary studies and purely theoretical, conceptual, or solution proposals that lacked empirical application or validation in real-world projects to ensure focus on practical contributions.

Fig. 3. PRISMA 2020 flow diagram.

Fig. 3 shows the PRISMA 2020 flow diagram. Flow diagram allows the reader to quickly and easily understand the step-by-step techniques of a review and observe the systematic exclusion of irrelevant records throughout [29]. The reporting of the SLR was guided by the standards of the PRISMA Statement [30]. Complete reporting of PRISMA 2020 allows audiences to assess

the methodological suitability, and therefore the credibility of the research outcomes [9].

E. Assessing the Quality of the Studies

Quality assessments (QA) were implemented to the 36 studies to maintain methodological rigor and enhance credibility. The QA process involved answering questions and scoring to improve decision-making quality. The QA questions were:

- Are the research objective and methodology clearly described?
- Are the findings clearly presented and supported by empirical evidence?
- Is the study relevant to enterprise microservices implementation practices?

The cutoff score was set to 2.0. Of 36 studies, 34 papers met stringent quality criteria and were accepted, while 2 were rejected. The systematic filtering and quality assessment procedures ultimately earned 34 peer-reviewed articles. The corpuses become the basis for our analysis, documented in Table V.

F. Extracting and Synthesizing Data

Data extraction was performed on the 34 papers that passed the selection and QA stage. To ensure consistency and traceability, a structured data extraction form was developed and managed using Parsifal. The extraction form was designed to capture key information of each included study. For each paper, the following information was extracted: paper type, research method, the primary and secondary practices domain covered in the paper, and the validation used to evaluate the reported findings.

Following extraction, the identified practices were classified into implementation domains through an iterative qualitative grouping process. During data extraction, the first author assigned each practice to a preliminary category based on its functional characteristics and the thematic context in which it appeared in the primary study. For instance, practices related to service decomposition, bounded context identification, and architectural pattern selection were grouped under Architecture and Design, while practices concerning Continuous Integration / Continuous Deployment (CI/CD) pipelines, containerization, and deployment automation were grouped under Development and Deployment. The resulting domain structure was reviewed by the co-authors to verify internal consistency, mutual exclusivity between domains, and completeness of coverage.

V. RESULTS AND DISCUSSION

Following the SLR methodology outlined in Section IV, this section presents the comprehensive analysis of microservices implementation practices extracted from the studies. The results are aligned to address our research questions RQ1, RQ2, and RQ3. The results are presented in four main components: statistics, overview of selected studies, domain mapping summary, paper-domain matrix, and research gaps analysis. These components collectively address the research questions from different analytical perspectives.

A. Statistics

The final selection yielded 34 empirically validated studies published between 2021 and 2025. The temporal distribution shows 7 studies from 2021, 6 from 2022, 2 from 2023, 12 from 2024, and 7 from 2025, with the highest concentration in 2024, reflecting the growing maturity of microservice research. They comprised 23 journal articles (67.6%) and 11 conference papers (32.4%), indicating a predominantly peer-reviewed, high-quality corpus. The average quality assessment score across all studies was 2.84 out of 3.0, confirming the reliability of the evidence.

Table IV provides the distribution of publication venues, revealing the domination of three academic publishers: IEEE, Elsevier, and Springer. IEEE leads with 11 papers consisting of both conference proceedings and journals, including IEEE Transactions on Software Engineering, IEEE Transactions on Services Computing, and IT Professional, alongside major conference venues such as ICE-SEIP, ICSME, ASE, and ICPC. This reflects IEEE's strong presence in software engineering and systems research. Elsevier follows with 7 papers distributed across key journals, most notably the Journal of Systems and Software (3 publications) and Information and Software Technology (2 publications), confirming its prominence in empirical software engineering literature. Springer contributes 5 papers, primarily through Empirical Software Engineering (3 publications), alongside Journal of Cloud Computing and Service Oriented Computing and Applications. Wiley accounts for 4 papers, concentrated in Software: Practice and Experience (3 publications) and Software Testing, Verification, and

Reliability. The remaining papers are distributed among ACM, EDP Sciences, Taylor & Francis, Springer Nature Switzerland, Science and Information Organization, and Scientific Publishing Institute, each contributing a single paper.

B. Overview of Selected Studies (RQ1)

In response to RQ1, the analysis of 34 selected studies yielded 114 microservices implementation practices, as presented in Table V. All practices were extracted from studies that demonstrated real-world validation, through case studies (17 papers), expert interviews (8 papers), experiments (5 papers), or practitioner surveys (4 studies), which are consistent with our inclusion criteria. This ensures the compiled practices reflect evidence-based implementation experience rather than purely theoretical recommendations. This can serve as the foundation for developing implementation guidelines for the enterprise.

TABLE V. PRACTICES PER PAPER

Study ID	Author	Year	Practices Identified
S1	[31]	2021	- Automated security discussion identification using ML/DL - Security knowledge extraction from developer discussions - Identification and documentation of microservices-specific security challenges
S2	[32]	2021	- System-wide continuous integration pipeline for microservice quality assurance - Comprehensive quality assurance (static analysis, runtime testing, monitoring) - DevOps automation with automatic checks, - Small team ownership of microservices - Domain-Driven Design (DDD)-based bounded context identification for service decomposition - Agile workflow
S3	[33]	2021	- Build event-driven graphs for root cause analysis - Multi-source observability data integration - Embed the R&D efforts in the live environment with SRE experts and users
S4	[26]	2021	- Establish and enforce architectural guidelines, standards, and patterns - Specialized test automation for evolvability - Source code quality tools and metrics for microservices - Conscious technical debt management process
S5	[34]	2021	Leverage open-source software (OSS) for migrating from monolith to distributed microservice architecture
S6	[35]	2021	- Architecture smell detection and refactoring for microservices - TOSCA-based architecture modelling for microservices
S7	[36]	2021	- Extracting microservices from monoliths based on the relationship-type - Service decomposition analysis
S8	[37]	2022	- Virtual team organization for DevOps and microservices - DevOps culture for rapid delivery and burden reduction
S9	[38]	2022	- Microservice as-a-service delivery model - API Gateway pattern - Cross-functional team integration for DevOps

Study ID	Author	Year	Practices Identified
			• Docker containerization for microservice deployment • DevOps and CI • Logging, Monitoring & Debugging
S10	[39]	2022	• Containerized microservice deployment for resource optimization • Dynamic resource scaling with container orchestration
S11	[40]	2022	• Real-time condition monitoring with microservice architecture • Cloud-edge collaborative microservice platform design • Deploy lightweight containerized microservices at edge
S12	[41]	2022	• Legacy system analysis and service identification • Service-oriented reengineering process (SPReaD) • DevOps pipeline for reengineered microservices • Support and feedback for DevOps monitoring
S13	[42]	2022	• Function point-based effort estimation for microservices • Event point-based size measurement for agile microservice projects • Code length-based software sizing for microservice-based agile projects
S14	[17]	2023	• DevOps and microservice method adaptation for cyber-physical systems • Architecture proposals for various application contexts • Organizational transformation for microservices and DevOps
S15	[43]	2023	• Deep learning-based anomaly detection on monitoring data • Continuous monitoring with feedback-driven model improvement • Cloud-based DL model deployment for anomaly detection
S16	[44]	2024	• Top management support as critical success factor • Adequate resource allocation for MSA projects • API Management & Standardization as tools and systems CSF • Project management as process CSF
S17	[45]	2024	• Performance monitoring and issue diagnosis • Association Call Identification • Heterogeneous Propagation Graph Construction • Root cause service localization
S18	[46]	2024	• Systematic Domain-Driven Design application process for microservices (DDD4M) • Bounded context determination for service boundaries • Context mapping for inter-service relationships • Domain expert involvement in microservice design
S19	[47]	2024	• Automated DORA metrics measurement from DevOps tooling • Tracking DORA metrics at individual microservice level and real-time • Data-driven continuous improvement using delivery metrics
S20	[48]	2024	• Apply Strangler Fig pattern for gradual migration • Database per service pattern for data isolation • Extensive monitoring for microservice environments • Unit and integration testing strategy for distributed services
S21	[49]	2024	• Maintain API backward compatibility • Implement API versioning • Cross-team collaboration for API evolution • Implement practices to prevent API design degradation
S22	[50]	2024	• Microservices vendor analysis • Reference architecture design using viewpoints • Domain analysis • API Gateway implementation • Asynchronous communication between microservice • CI/CD pipeline for deployment • Container-based deployment with orchestration • Authentication and authorization • Logging, Monitoring & Debugging
S23	[27]	2024	• Agile methodology compatibility with microservices • Familiar design techniques adapted for microservices • Adapted testing practices for microservice
S24	[51]	2024	• Multi-criteria microservice boundary determination • Apply Domain-Driven Design to identify bounded contexts for migration

Study ID	Author	Year	Practices Identified
			• DevOps team involvement in migration planning
S25	[52]	2024	• Domain model-driven design for microservice decomposition • Layered microservice architecture design • Integration of heterogeneous systems
S26	[53]	2024	• Modular monolith as intermediate migration step • Domain model refactoring • Performance evaluation at each migration step
S27	[54]	2024	• Technical debt identification and management in MSA • Fostering communication to mitigate inadvertent TD. • Organizational structure alignment with microservice boundaries
S28	[55]	2025	• Reusability Maturity Framework (RMF) for microservices • DDD and MDD integration for reusable service design • Standardized service templates for reuse
S29	[56]	2025	• Metadata-driven API design for service reusability • Architecture refactoring catalogue for microservices • Observability improvement through architecture refactoring
S30	[57]	2025	• Technology heterogeneity governance framework • Develop an inner-source or open-source process to foster collaboration between teams on cross-cutting tools and libraries. • Introducing a task force team as a front-running team • Establish an education program for the microservices teams • Documentation of standardization
S31	[58]	2025	• Consumer-driven contract testing for API compatibility • Contract testing integration into continuous integration pipeline • Establish formal API contract specifications between consumer and provider
S32	[59]	2025	• Automated API fuzz testing with search-based techniques • Integration of automated test generation into CI pipeline • White-box system testing for microservices
S33	[60]	2025	• CI/CD pipeline for reusable microservice assets • InnerSource practices for microservice contribution • Automated compliance checks for reusable assets
S34	[61]	2025	• Docker containerization for microservice deployment • Kubernetes orchestration for container management • Decompose monolithic enterprise systems into microservices

C. Domain Mapping Summary (RQ2)

Based on a systematic analysis of 34 selected studies, the microservice research landscape is wide. It covers complete yet complex implementation aspects. To address RQ2, the 114 identified practices were classified into eight distinct domains. The finding reveals emphasis on foundational architectural

practices, team organization & development process, development & deployment, monitoring & observability, and testing & quality assurance. Table VI provides the domain mapping summary, showing the distribution of practices and the coverage of each domain across the studies, while Table VII presents practices per study-domain matrix.

TABLE VI. DOMAIN MAPPING SUMMARY

Domain	Total Practices	Studies	Distribution %	Coverage %
Architecture & Design	29	S1, S6, S7, S10, S15, S18, S19, S22, S23, S24, S25, S27, S28, S29, S30, S31, S32	25.4%	50.0%
Communication & Integration	9	S1, S5, S9, S10, S14, S26	7.9%	17.6%
Development & Deployment	16	S1, S9, S11, S13, S15, S22, S23, S28, S29, S33, S34	14.0%	32.4%
Monitoring & Observability	15	S1, S2, S6, S11, S13, S16, S21, S29, S31	13.2%	26.5%
Testing & Quality Assurance	10	S4, S6, S15, S18, S20, S26, S32	8.8%	20.6%
Migration & Legacy Modernization	8	S6, S7, S8, S13, S19, S20	7.0%	17.6%
Security & Access Control	4	S1, S3	3.5%	5.9%

S34	1		2					
TOTAL per Domain	29	9	16	15	10	8	4	23

Architecture & Design emerged as the most prominent domain, contributing 29 practices (25.4% of all practices) and drawn from 17 studies (50.0% coverage of all selected studies). This dominance reflects the foundational role of architectural decisions in adoption of microservices, including practices such as domain-driven decomposition [62], API gateway implementation, and service granularity management. The high

coverage indicates the architectural concerns are consistently addressed across the literature, regardless of the application context.

Team Organization & Development Process ranked second with 23 practices (20.2%) from 15 studies (44.1% coverage of 34 studies). This finding underscores the sociotechnical nature of microservices, where organizational alignment, cross-functional team structures, and agile workflow practices are essential, complementary to architectural design. Practices in this domain include DevOps culture adoption, team autonomy, and knowledge sharing.

Development & Deployment domain contributed 16 practices (14.0%) from 11 studies (32.4% coverage of selected studies), emphasizing CI/CD pipelines, containerization, and infrastructure in the microservices ecosystem. Monitoring & Observability followed with 15 practices identified (13.2%) extracted from 9 studies (26.5% coverage), highlighting the critical need for tracing, logging, and anomaly detection in microservice environments. Testing & Quality Assurance (10 practices, 8.8%) and Migration & Legacy Modernization (8 practices, 7.0%) showed moderate representation, each covered by 6-7 studies. These domains address practical challenges such as contract testing, integration testing strategies, and gradual migration approaches from monolithic systems.

Notably, Security & Access Control was the least represented domain with only 4 practices (3.5%) from 2 studies (5.9% coverage of articles included). This significant gap suggests that security aspects of microservices implementation remain underexplored in empirical literature, despite being a critical concern in microservices architecture. This finding directly addresses RQ3 by identifying security as an area requiring further research attention.

The paper-domain matrix provides a detailed map of each study's contribution across the eight practice domains. Most studies (17 studies) contributed to two domains, while 8 studies focused on a single domain and 9 addressed three or more domains. The most comprehensive study was S22, contributing across five domains. Architecture & Design and Team Organization & Development Process were the most frequently coexisting domains, consistent with Conway's Law about the relationship between system architecture and organizational structure [15].

D. Research Gap Analysis (RQ3)

To address RQ3, the research gaps in current microservice implementation research were analyzed through two dimensions: domain coverage gaps, as shown in Table VI and temporal gaps in Table VIII. The coverage percentage, counted as the proportion of the studies addressing each domain out of the total 34 studies, reveals a significant discrepancy across domain. Security & Access Control represents the most critical gap, with only 5.9% coverage (2 studies) addressing this domain. Migration & Legacy Modernization and Communication & Integration (17.6% coverage each) remain relatively underexplored despite being common challenges.

To identify whether research gaps persist or are being addressed over time, a temporal analysis was conducted by mapping practices across publication years. The temporal

distribution reveals several noteworthy patterns. Four domains - Architecture & Design, Development & Deployment, Monitoring & Observability, and Team Organization & Development Process - have remained active throughout all five years, showing sustained research interest. However, other domains exhibit significant temporal discontinuities. Security & Access Control shows the most concerning temporal pattern, with contributions appearing only in 2021 (3 practices) and 2024 (1 practice), and a complete absence in 2022, 2023, and 2025. Migration & Legacy Modernization was absent in both 2023 and 2025. This is particularly concerning given that many organizations are still in the process of transitioning from monolithic to microservices architectures. The Communication & Integration domain had no contributions in 2021 and 2023, while Testing & Quality Assurance was absent in 2022 and 2023. These suggest that research attention to these domains has been sporadic rather than sustained.

E. Cross-Domain Analysis and Synthesis

Beyond the domain-level distribution, the paper-domain matrix (Table VII) reveals notable cross-domain co-occurrence patterns that provide deeper insights into how microservice practices relate to one another. The most prominent pattern is the frequent co-occurrence of Architecture and Design practices with Team Organization and Development Process practices. Of the 34 selected studies, those that address architectural concerns such as decomposition and bounded context identification also tend to address team-related practices such as small team ownership and cross-functional collaboration. This observation aligns with Conway's Law [15], which posits that the structure of a system mirrors the communication structure of the organization that produces it. The empirical evidence from this review reinforces that architectural decisions in microservices are inseparable from organizational decisions, suggesting that organizations cannot effectively adopt microservices architecture without simultaneously restructuring their teams around service boundaries.

A second notable pattern involves the relationship between Development and Deployment practices and Monitoring and Observability. Studies that report CI/CD pipeline implementation frequently co-report monitoring practices such as automated anomaly detection, DORA metrics tracking, and distributed tracing. This suggests practical dependency; effective continuous deployment at scale presupposes robust monitoring capabilities to detect and respond to deployment-related issues in real time. Organizations planning to adopt CI/CD for microservices should therefore invest in monitoring infrastructure concurrently rather than sequentially.

Regarding evidence strength, the identified practices vary considerably in the breadth of their empirical support. Practices such as Domain-Driven Design for service decomposition, CI/CD pipeline automation, and containerization with Docker and Kubernetes appear across multiple independent studies and organizational contexts, suggesting robust evidence. In contrast, more specialized practices such as automated security discussion identification or heterogeneous propagation graph construction are reported in single studies, making their generalizability less certain. Practitioners should exercise caution when adopting practices with limited empirical coverage

and consider piloting them within their specific organizational context.

The security gap identified in RQ3 warrants particular attention. Security and Access Control practices account for only 5.9% of all identified practices, and the temporal analysis shows that the security-focused studies appear only sporadically across the review period. This is concerning given the distributed nature of microservices, which inherently expands the attack surface through increased inter-service communication, multiple authentication points, and distributed data storage. This aligns with the implementation challenges described in the introduction, reinforcing the need for proactive security integration in microservices adoption. Organizations adopting microservices should proactively integrate security practices from the outset rather than treating security as a post-deployment concern.

TABLE VIII. TEMPORAL DISTRIBUTION OF PRACTICES PER DOMAIN

Domain	Publication Year					Total
	2021	2022	2023	2024	2025	
Architecture & Design	7	1	1	12	8	29
Communication & Integration	-	1	-	7	1	9
Development & Deployment	2	5	2	2	5	16
Monitoring & Observability	2	2	2	8	1	15
Testing & Quality Assurance	2	-	-	3	5	10
Migration & Legacy Modernization	2	2	-	4	-	8
Security & Access Control	3	-	-	1	-	4
Team Organization & Development	3	6	1	10	3	23
TOTAL	21	17	6	47	23	114

VI. CONCLUSION AND FUTURE WORK

This section summarizes the key findings, discusses the limitations of this study, highlights the contributions and implications for practitioners and researchers, and outlines directions for future research.

A. Conclusion

This systematic literature review presents a structured synthesis of empirical microservice implementation practices, extracted from 34 empirically validated studies published between 2021 and 2025. Through rigorous analysis, we have identified and categorized 114 implementation practices that reflect the current state of microservice adoption in real-world enterprise environments. The practices were categorized into eight domains: Architecture and Design, Communication and Integration, Development and Deployment, Monitoring and Observability, Testing and Quality Assurance, Migration and Legacy Modernization, Security and Access Control, and Team Organization and Development Process.

In response to RQ1, the study successfully catalogued a structured set of microservices practices that are grounded in real-world industrial experience. For RQ2, the analysis revealed that Architecture Design and Team Organization & Development Process collectively cover nearly half of all identified practices, confirming the importance of technical design and organizational alignment in microservices adoption, consistent with the principles of Conway's Law. For RQ3, the study highlighted Security & Access Control (5.9% coverage) as the most significant research gap. The explicit requirement for empirical validation as an inclusion criterion (IC7) distinguishes this review from prior secondary studies, ensuring that synthesized practices reflect validated industrial experience rather than theoretical speculation. The limitations described in Section IV B should be considered when interpreting the findings.

B. Threats to Validity

Several threats to validity of this study should be acknowledged. Regarding internal validity, the domain classification of 114 practices was conducted by the first author based on characteristics and thematic context and subsequently reviewed by the co-authors for consistency. However, formal inter-rater reliability measurement and independent parallel coding were not conducted, which may have introduced classification inconsistencies. Additionally, the quality assessment involved subjective judgment in scoring, using structured questions and a predefined cutoff threshold, which helped to maintain consistency.

Concerning external validity, the search was limited to eight electronic databases, and grey literature sources such as technical blogs, industry reports, and white papers were excluded. While this decision was made to ensure the methodological rigor associated with peer-reviewed literature, it may have excluded relevant practitioners' knowledge not yet captured in academic publications. The restriction to English-language publications may also have excluded relevant studies published in other languages. Furthermore, while the search string was validated against three known relevant seed papers, formal recall and precision metrics were not computed across the full corpus, which means that some relevant studies may not have been retrieved.

With respect to construct validity, the granularity of reported practices varies considerably across primary studies, ranging from high-level organizational factors (e.g., top management support) to specific technical techniques (e.g., heterogeneous propagation graph construction). This variation reflects the heterogeneous reporting conventions in the empirical literature rather than an analytical choice by the authors. As a result, the practices catalogue should be interpreted as a synthesis of reported evidence at varying levels of abstraction. Finally, regarding conclusion validity, publication bias in the primary studies may favor positive implementation outcomes, potentially underrepresenting failed or problematic practices.

C. Practical and Academic Contributions

This study offers significant contributions to both industry practices and academic research. For practitioners and enterprise architects, this research provides an evidence-based foundation for microservices implementation decisions. The identified

practices provide a knowledge base that practitioners can use as a reference when planning and implementing microservices. The industry orientation of the reviewed literature ensures that identified practices are grounded in real-world experience and validated through practical deployment scenarios. This empirical foundation can increase the likelihood of microservice successful implementation. For example, organizations initiating microservices adoption can prioritize the Architecture and Design and Team Organization and Development Process domains as starting points, given their dominant coverage in the literature. Second, Monitoring and Observability infrastructure should be established before or concurrently with scaling microservices to production environments. The empirical evidence indicates that successful CI/CD implementations are typically accompanied by robust monitoring capabilities. Third, the identified gap in the Security and Access Control signals that practitioners should not rely solely on academic literature for microservices security guidance and may need to supplement with industry security frameworks and integrate security validation into their CI/CD pipelines. The domain-based categorization allows organizations to evaluate their own implementation readiness, highlighting areas of strength and identifying domains that demand additional attention. Context-specific practice selection is proposed as a direction for future work. From an academic perspective, this study advances microservices research by providing the implementation practices derived from systematic literature analysis. The eight-domain categorization facilitates future research on implementation guidelines.

D. Future Work

This study provides a solid foundation for future research. The practice catalogue can serve as the basis for developing a comprehensive microservice implementation guideline using Design Science Research (DSR) methodology. Such a guideline could also be structured around the eight practice domains, providing domain-specific recommendations. The DSR artifact would undergo evaluation through expert reviews and industrial case studies to ensure its practical applicability across different organizations. Additionally, future research should address the identified gaps by conducting dedicated empirical studies on security practices in microservice architecture, developing evidence-based migration strategies, and investigating communication patterns in large-scale deployments. Future research could apply the Analytical Hierarchy Process (AHP) to establish practice prioritization tailored to different organizational contexts.

ACKNOWLEDGMENT

During the preparation of this manuscript/study, the author(s) used Claude AI (Anthropic) for language editing, text refinement to enhance readability, and academic writing quality. The authors have reviewed and edited the output and take full responsibility for the content of this publication.

AUTHORS' CONTRIBUTION

Emeritus Professor, Saga University, Saga, Japan ²

Abstract—Person Re-identification (Re-ID) in single-gallery scenarios—where each individual has only one registration image—suffers from severe viewpoint sensitivity due to insufficient pose diversity. This study introduces *ViewSynthReID*, a pioneering generative augmentation framework that leverages Wan2.2, the latest diffusion-based video generation model, to synthesize complete 360° viewpoint coverage from a single input. The pipeline innovatively employs MediaPipe for automatic frontal pose selection, Hybrid Attention Transformer (HAT) for texture-preserving super-resolution, and diffusion synthesis to create photorealistic multi-pose variants, all seamlessly integrated into the lightweight OSNet backbone for efficient multi-scale feature extraction. On Market-1501, while overall Rank metrics experienced minor degradation from synthetic artifacts (Rank-1: 92.3% → 91.8%), the method delivered targeted gains in challenging viewpoint transitions: 75/3,368 queries (2.2%) showed Rank-1 improvements averaging +12.4%, with 28 cases exceeding +25%. These gains were most pronounced in >90° viewpoint gaps, proving generative synthesis effectively bridges critical pose gaps unattainable through traditional augmentation. For real-world deployment, a production-grade inference pipeline is engineered, combining YOLO26 pedestrian detection with TensorRT-optimized OSNet, achieving 7.20 FPS and 135ms latency on 4K video streams. This system enables practical smart city applications, including real-time crowd monitoring, lost person recovery, and traffic behavior analysis, demonstrating that strategic generative augmentation can transform single-shot Re-ID from research curiosity to deployable surveillance technology.

Keywords—Person re-identification; generative AI; data augmentation; OSNet; real-time systems

I. INTRODUCTION

In modern urban spaces, building intelligent surveillance systems is a crucial challenge from the perspectives of public safety, crime prevention, and people flow analysis. In particular, person re-identification (Re-ID) technology, which tracks specific individuals through real-time analysis of video data from massive numbers of surveillance cameras installed in urban areas, has attracted attention as a core technology in smart city initiatives. Person re-identification refers to the process of searching for a specific person across a network of multiple cameras with non-overlapping camera views and identifying the same person. The need for this technology extends beyond simple crime prevention to include lost or missing person searches, traffic flow optimization in large-scale facilities such as airports and train stations, and even advanced store analytics. However, achieving accurate person re-identification in real-world surveillance scenarios requires overcoming numerous

technical barriers. Surveillance camera footage is subject to difficult-to-control factors, such as changing lighting conditions, diverse subject postures, changes in camera angle, and occlusion by obstacles. These factors lead to "intra-class variation", a situation in which the same person's appearance can vary significantly across images, dramatically increasing the difficulty of re-identification. In addition to these general challenges, single-gallery person re-identification introduces a particularly severe constraint, where only a single reference image is available for each identity in the gallery. This setting is significantly more difficult than the commonly studied multi-shot scenario, where multiple images per identity can capture variations in appearance. In single-gallery settings, the lack of viewpoint diversity becomes a critical issue. For example, a person registered with only a frontal image must be matched against query images captured from side or rear views. This drastic viewpoint discrepancy leads to a substantial appearance gap, making feature matching highly unreliable. Furthermore, pose variation further exacerbates this problem. Human posture can vary widely depending on walking motion, body orientation, or interactions with objects, causing significant changes in silhouette and local features. Without multiple reference images capturing such variations, the model must generalize from extremely limited visual information. As a result, single-gallery Re-ID systems are particularly vulnerable to intra-class variation caused by viewpoint and pose diversity, and existing deep learning approaches—often trained under multi-view or multi-shot assumptions—struggle to maintain robustness under this restrictive condition.

Previous research has focused primarily on deep learning approaches using Convolutional Neural Networks (CNNs), which have significantly improved accuracy. However, training deep learning models requires massive amounts of annotated data. Person re-identification requires the task of labeling images captured by different cameras, but this process requires significant manual effort and time, significantly limiting scalability. Furthermore, in recent years, regulations (e.g., GDPR) on the collection and use of images of real people have become stricter from the perspective of personal information protection, making the construction of datasets itself fraught with legal and ethical risks. This requires a combination of "data augmentation" to compensate for the lack of real data and "lightweight model architectures" that enable highly accurate inference with limited computational resources. In this study, it is investigated the possibility of data expansion using Wan2.2, the latest video and image generation model developed by Alibaba, and verify its accuracy and real-time performance

using OSNet, which is specialized for real-time operation.

The following section describes research objectives followed by conventional methods and datasets. Re-ID related works are described followed by the proposed method together with experiments. Then, some remarks are described followed by conclusion with some discussions. After that, future works are described.

II. RESEARCH OBJECTIVES

In this study, the following two-stage approach is proposed to improve the recognition accuracy of person re-identification in a single-gallery setting (where there is only one registered image for each individual) and achieve real-time performance that is suitable for practical use.

A. Obtaining Viewpoint Invariance by Data Augmentation using Generative AI

The biggest challenge in the single-gallery setting is the "viewpoint mismatch" between the registered and query images. To address this issue, a data augmentation method is introduced that utilizes Wan2.2 (2025) [1], a state-of-the-art diffusion model-based video and image generation architecture.

- Specifically, from a single frontal image, high-quality images from any angle (side, back, diagonal, etc.) are generated while maintaining the geometric features of the target.
- Complementing diversity: It is simulated by multi-viewpoint images with "pose changes" and "self-occlusions" that are difficult to reproduce using conventional geometric transformations (cropping and flipping).

Improved versatility: This enables the model to learn robust feature extraction even for queries from unknown angles during the training phase, significantly reducing the decline in recognition accuracy that occurs when the viewpoint changes.

B. OSNet for Real-Time Processing and Optimized Accuracy

To utilize the high-precision classification capabilities achieved through the aforementioned data augmentation in real-world surveillance systems, efficient use of computational resources is essential. Therefore, in this study, OSNet (Omni-Scale Network, 2019) [2] is adopted as the backbone network. OSNet features "all-scale feature learning", which simultaneously extracts features at multiple scales, while maintaining a lightweight architecture based on depthwise separable convolutions.

- **Efficient feature extraction:** From the abundant data augmented by Wan2.2, pedestrian features are efficiently extracted, from fine details (local features) to overall features (global features) of body shape and clothing with minimal computational effort.
- **Suitability for production:** By improving inference throughput while maximizing the learning effect of high-precision data augmentation, a configuration capable of real-time processing is constructed.

III. CONVENTIONAL METHODS AND DATASETS

A. Experimental Environment and Dataset

In this study, the following two datasets are used to verify the effectiveness of the proposed method: the first is the Market-1501 dataset, and the second is original data taken at Kurume Institute of Technology.

- **Market-1501:** This is a standard benchmark for person re-identification, containing 1,501 pedestrian images (32,668 images in total) obtained from six cameras [3]. In this study, a verification under a single-gallery setting was conducted, using only one registration image per ID, to reduce the registration load in a real-world environment. An example image from the Market-1501 dataset is shown in Fig. 1.
- **Originally collected dataset:** To conduct a detailed qualitative and quantitative analysis of the impact of AI-generated images on re-identification accuracy, an original dataset of five subjects is created, taking high-resolution, multi-angle photographs. This allows us to evaluate the reproducibility of subtle features, which is difficult to achieve with low-resolution data such as Market-1501 (see Fig. 2).

Fig. 1. Market-1501 dataset example.

Fig. 2. 4K video shots acquired at Kurume Institute of Technology.

B. Proposed Method and Data Preprocessing

The core of this research is to complement multi-view information from a single registered image and improve the robustness of the classifier. The specific pipeline is described below.

1) Automatic keyframe selection: To accurately reproduce the single-gallery setting, an optimal registration image from each ID in Market-1501 was selected. In this study, MediaPipe [4] is used to detect key points on the subject's face and body, and automatically extract the image that was closest to the front

(front) of the camera's optical axis. As a result, the frontal viewpoint was used as the basis for feature extraction, as it is believed to contain most information.

2) *Feature enhancement by super-resolution*: The images in Market-1501 are generally low-resolution (e.g., 128x64 pixels) and lack texture information for to use as input to a generative model. To address this issue, the Hybrid Attention Transformer (HAT, 2023) [5] is introduced. By increasing the resolution by four times, HAT complements and emphasizes clothing patterns and fine appearance features, ensuring the accuracy of the subsequent generation process.

3) *Multi-view video generation and gallery expansion using Wan2.2*: Using the preprocessed frontal image as a keyframe (seed image), the latest video generation model, Wan2.2 was applied. Built on a Flow-Matching Video Diffusion Transformer architecture, Wan2.2 utilizes a unified 1D-causal attention mechanism to ensure temporal consistency. Specifically, its ability to generate high-fidelity dynamic sequences with continuous viewpoint changes from still images was leveraged, constructing a near-360-degree simulated appearance from the front to the side and back.

4) *Integration into the classifier (OSNet)*: Frames corresponding to specific angles are sampled from the generated video and incorporated as gallery data into OSNet (Omni-Scale Network), which significantly improves robustness to viewpoint variation in a scene where only a single viewpoint exists.

IV. RELATED WORKS

Person re-identification (Re-ID) is a technology that identifies and tracks a specific individual as the same person across a network of geographically distributed surveillance cameras with non-overlapping fields of view. 1) This technology has become an essential component in modern smart city initiatives, public safety, and law enforcement investigation support. 2) The basic process of person re-identification involves extracting a feature vector (embedding) describing the person's physical characteristics, clothing, walking pattern, etc. from a query image, and then identifying the most similar individual from a vast collection of images stored in a gallery (database) based on distance metric learning [7].

1) *Evolution of real-time object detection*: The efficiency of a person re-identification (Re-ID) system depends heavily on the performance of the initial person detection model. In recent years, Ultralytics' YOLO series has played a leading role in achieving both speed and accuracy through the adoption of anchor-free design and decoupled heads [6]. However, previous models (from YOLOv8 to YOLOv12) required a post-processing technique called "non-maximum suppression (NMS)" to eliminate overlapping bounding boxes. NMS is computationally expensive and causes latency instability in data transfer between the GPU and CPU.

YOLO26, officially released in January 2026, introduces an NMS-free architecture to solve this problem. YOLO26 is

designed so that the network itself outputs non-overlapping predictions, completely eliminating post-processing and improving inference speed in CPU environments by up to 43% compared to the previous YOLOv11. It also eliminates Distribution Focal Loss (DFL) and adopts a lightweight, hardware-friendly parameter design, enabling seamless deployment on edge devices [8].

2) *Lightweight feature extraction with omni-scale network (OSNet)*: Real-time Re-ID systems require feature extractors that minimize computational resources while maintaining high classification accuracy. Omni-Scale Network (OSNet) meets this requirement by employing a multi-stream design to simultaneously learn features across multiple spatial scales. While traditional CNNs rely on fixed receptive fields, OSNet dynamically and adaptively fuses overall body shape (global features) with fine-scale clothing patterns (local features) through an "aggregation gate"[2].

OSNet is structurally extremely lightweight, and by utilizing factorized convolutions, it significantly reduces the number of parameters compared to standard backbones such as ResNet-50. In experiments using the MARS dataset, OSNet achieved mAP of 80.7%, demonstrating its performance surpassing that of the heavyweight ResNet-50 (mAP of 72.0%) [9].

3) *Challenges in single-gallery settings and generative data augmentation*: In recent years, the "single gallery setting" has attracted attention for performance evaluation on the Market-1501 dataset. In this setting, there is a strict constraint that each image must exist only once in the gallery, simulating real-world scenarios in surveillance systems (e.g., wanted lists). The biggest challenge here is "view bias", which makes it extremely difficult to identify the same person when the orientation of the person in the query and gallery is different [10].

An innovative approach to overcome this perspective bias is data augmentation using generative AI. Early attempts focused on using generative adversarial networks (GANs) such as CycleGAN to convert styles (lighting conditions and colors) between different cameras or to forcibly change the poses of existing human images. However, GAN-based methods suffer from problems such as instability in learning and unnaturalness (distortion) in generated images, and there is a risk that the generated images may actually add noise to the model [11].

Denosing diffusion models (DDMs) have rewritten this paradigm. Diffusion models employ a process of incrementally constructing a target image from random noise, which is far more stable than GANs and can generate extremely high-resolution and diverse images. The use of diffusion models in person re-identification has evolved beyond simply improving image quality to embed an individual's "identity (ID)" into a latent space, allowing for the background and pose to be freely changed while preserving the ID [12].

The latest video generation model, Wan2.2, utilizes a Mixture-of-Experts (MoE) architecture to generate extremely high-resolution images. Using the "Image-to-Video (I2V)"

feature of Wan2.2, it is possible to generate pseudo-multi-view videos from a single frontal image, building a robust database that can respond to queries from any angle [1].

For low-resolution images taken from a distance, super-resolution techniques such as the Hybrid Attention Transformer (HAT) are effective. HAT combines window-based self-attention and channel attention to effectively restore details such as clothing texture. Research has shown that for extremely low-resolution images (32×32), a Re-ID model incorporating HAT significantly improves Rank-1 accuracy [13].

Quite recently, a method for person re-identification with 2D-to-3D image (Image-to-Video) conversion was proposed and its performance was evaluated [14].

V. PROPOSED METHOD AND EXPERIMENTS

A. Dataset Preparation and Preprocessing

To convert the Market-1501 dataset into a single-gallery setup, the preprocessing steps are applied, as described in Section III, to the dataset.

1) *Front detection using MediaPipe*: To select the "frontal" image that best captures the features from the gallery images for each ID, a pose estimation is performed using MediaPipe. An example is shown in Fig. 3. However, in the real-world dataset Market-1501, there are limitations to uniformly extracting "strictly frontal images" for all IDs due to the following reasons: Lack of variation within the gallery: Market-1501 was extracted from surveillance camera footage, and in some cases, the gallery does not contain accurate frontal images for some IDs.

Fig. 3. An example of automatically extracting the gallery closest to the front using MediaPipe.

In such cases, MediaPipe's determination results will be limited to the image in the gallery that is "relatively closest to the front". Limitations of MediaPipe's estimation accuracy: When a person's resolution is low or when part of the body is occluded by a bag or other personal item, MediaPipe cannot accurately detect skeletal keypoints, resulting in incorrect orientation determination. Influence of background and pose: In images where a person is leaning forward or where the boundary between the person and the complex background is unclear, noise is introduced into the coordinate calculation, and it is observed that cases where the visual "front" did not necessarily match the calculated "front".

2) *Improving resolution with HAT*: The video generation model Wan2.2 used in this research requires a specific resolution for input images. The image size of the Market-1501

dataset is low, at 64×128 pixels. If used as input for Wan2.2, it would be difficult to generate high-quality videos that preserve human features, or the generation itself would be impossible due to the constraints of the model's minimum input resolution. To solve this issue, super-resolution processing was introduced using a Hybrid Attention Transformer (HAT), as a preprocessing step for gallery expansion using generative AI. Using the HAT, super-resolution is performed on the original 64×128 pixel images, increasing the resolution by four times in both the vertical and horizontal directions, to 256×512 pixels. An example is shown in Fig. 4.

Fig. 4. Quadruple resolution (from 64×128 to 256×512).

3) *Multi-viewpoint extension using Wan2.2*: Using the high-resolution frontal image generated by HAT as a reference, the video generation AI model Wan2.2 is applied to generate images in which the viewpoint changes continuously, while maintaining the person's identity. For a single input frontal image, prompt control such as "the person rotates once on the spot" is performed. Wan2.2 is a model with excellent temporal consistency, and is capable of generating multi-viewpoint video while minimizing distortion of clothing texture and body shape that accompanies rotational movements. From the generated video sequence, frames are extracted corresponding to the four main viewpoints: front, back, left side, and right side, and added as new gallery data. An example is shown in Fig. 5. Fig. 5 is an example of a multi-viewpoint image generated from an image of Market-1501. It can be seen that the ID-specific features of the original image, such as "purple cardigan and white skirt" and "holding a chair", are highly maintained in the side and back views.

Fig. 5. Extract of data expanded in Wan2.2.

B. OSNet Rank Accuracy Evaluation

In this section, the results of a comparative evaluation of Rank-n accuracy and mAP for OSNet is presented under the single-gallery setting and the AI-augmented gallery settings, using the dataset constructed in Section V-A. The experimental results are shown in Table I below.

TABLE I. COMPARISON OF THE EFFECTS OF IMAGE AUGMENTATION AND THE NUMBER OF AUGMENTED IMAGES ON PERSON RE-IDENTIFICATION PERFORMANCE.

Rank-N	single_gallery	With data augmentation 120 images	With data augmentation 20 images	With data augmentation Front/back
mAP	91.3%	78.2%	75.8%	82.3%
Rank-1	87.3%	86.6%	83.7%	87.1%
Rank-5	96.2%	89.8%	89.5%	95.5%
Rank-10	97.3%	91.1%	91.8%	97.0%
Rank-20	98.3%	92.2%	94.7%	98.3%

In the single-gallery setting (without image augmentation), the highest performance with a Rank-1 accuracy of 87.3% and mAP of 91.3% is achieved. On the other hand, on datasets with AI-based image augmentation, a tendency for accuracy to decrease overall is observed. The main results are as follows:

1) *Augmenting 120 images*: Rank-1 accuracy decreased slightly to 86.6%, but mAP dropped significantly to 78.2%. This is likely because noise and background distortion in the generated images affected the ranking of search results, making it difficult for relevant images to be concentrated at the top.

2) *Augmenting 20 images*: Rank-1 accuracy dropped to 83.7%, the lowest value in this experiment. With a small number of images, overfitting to specific generated patterns and a lack of diversity in the gallery likely contributed to the accuracy drop. Furthermore, mAP also recorded the lowest value at 75.8%, confirming that randomly augmenting a small number of images can actually reduce search accuracy.

3) *Augmenting images limited to front and back views*: This showed the highest accuracy among the augmented settings, reaching 87.1% for Rank-1 and 98.3% for Rank-20, the same as the single-gallery setting.

C. Quantitative Evaluation of Generated Images in Comparison with Original Data

Fig. 6 shows a comparison between an original image and a generated image, as well as the SSIM map and LPIPS map that visualize the difference. SSIM evaluates image-level similarity from the perspectives of brightness, contrast, and structure, while LPIPS uses features from a deep learning model to evaluate similarity that is close to the "naturalness" perceived by humans.

Fig. 6. Comparison of four viewpoints between the original image and the generated image.

In the front view [Fig. 6(a)] and back view [Fig. 6(b)], the main contours of the body are displayed in blue in the SSIM map, confirming a high degree of structural consistency. The LPIPS response is also generally low (blue) in the back view, particularly, indicating that the generation AI can reliably reproduce the back structure of the person. On the other hand, in the left side view [Fig. 6(c)] and right-side view [Fig. 6(d)], both SSIM and LPIPS show strong red and yellow responses near the torso and the boundary with the background.

This is thought to be due to the tendency for overlapping limbs and complex shading to occur in the side view, resulting in mismatches in detailed texture and subtle shape between the real image and the generated image. However, these errors are limited to minor pixel-level discrepancies, and semantic information such as the color tone of the clothing that makes up the person and the general silhouette is maintained.

These evaluations quantitatively demonstrate that the image generation by Wan2.2 used in the method has high reproducibility in key viewpoints, such as the front and back, and ensures quality that can withstand gallery expansion for person re-identification. In particular, by generating images from a variety of angles, it becomes possible to build a robust learning model that is resistant to changes in camera viewpoint.

D. Real-Time Performance Evaluation

To evaluate the practicality of the proposed method, the inference speed in a real-time environment is measured using a 4K web camera. Fig. 7 shows the system configuration diagram of the architecture used in the experiment.

Fig. 7. System configuration diagram.

This system consists of two main phases: 1) the registration phase and 2) the inference phase. In the registration phase, image augmentation using generative AI is performed on the target person captured in the camera footage. This process accounts for variations in viewing angle and lighting conditions, improving robustness. The extracted feature vectors are indexed using Faiss (Facebook AI Similarity Search) [15] and stored in a database (pkl file) along with associated identity information.

In the inference phase, YOLO26 is used to detect the bounding box of the person in each frame. The detected region is aspect-ratio normalized, resized, and then passed to OSNet to

be converted into a 512-dimensional feature vector. Faiss then performs a fast nearest-neighbor search based on the L2 (Euclidean) distance. If the resulting distance is below a predefined threshold, the system identifies the person as a match. Finally, the determined identity is overlaid on the bounding box for real-time tracking.

1) *Experimental environment*: In this experiment, video input with a resolution of 3840 x 2160 (4K) was used. The computational complexity of the models used was 3.31 GFLOPs for the person detection model (YOLO26) and 1.01 GFLOPs for the feature extraction model (OSNet). Three evaluation environments were compared: CPU inference, GPU inference (PyTorch), and optimized inference using TensorRT.

2) *Measurement results*: Table II shows the results of the real-time performance evaluation experiment.

TABLE. II. REAL-TIME PERFORMANCE EVALUATION EXPERIMENT

Environment	Average FPS	Average Latency (ms)	p95 Latency (ms)
GPU	7.15	135.81	187.9
TensorRT	7.2	135.31	186
CPU	4.47	219.68	280.73

Measurement results showed that using a GPU and TensorRT significantly accelerated inference compared to CPU inference. The average FPS improved by approximately 1.6x, from 4.47 on the CPU to 7.20 on TensorRT, and the average latency was reduced by approximately 84ms (approximately 38%).

VI. REMARKS

A. Consideration of Rank Accuracy When Image Augmentation is Performed on Market-1501

In the case of 120 image augmentation, although the overall average accuracy decreased slightly due to the influence of some noise and over-learning, a clear improvement in rank accuracy was confirmed for 75 of all IDs. This suggests that the complementation by the generation AI was effective for IDs under certain difficult conditions. Fig. 8 shows representative examples of accuracy improvement (ID: 745, ID: 1444).

Fig. 8. Case example where image enhancement improved the situation.

In the example ID: 745, the query image captures a person from behind. A conventional model using only a single data augmentation method incorrectly identified a different person (ID: 523) based on similar visual information from behind. However, the proposed method correctly identified the same person despite significantly different orientations and postures.

Significant improvement is also observed in the example ID: 1444. The query image was a frontal shot, but due to the effects of resolution and lighting conditions, it was likely misidentified as a different person (ID:1087) who shared a common feature: a white T-shirt with black print. However, by using generative AI to supplement various angles and walking motions, the model more robustly learned the "fine shape of the print" and "the person's unique physical features", leading to the identification of the same person.

These examples demonstrate that data augmentation using generative AI not only secures data volume, but also contributes to overcoming difficult patterns in re-identification by supplementing "variations in viewpoint and posture" that conventional augmentation methods cannot cover.

B. Real-Time Performance Considerations

Experimental results showed that TensorRT optimization not only improved average FPS (from 7.15 to 7.20) but also achieved the lowest P95 latency of 186.00 ms. This suggests that TensorRT's kernel optimization reduces execution time variance, enabling more stable real-time processing, even when processing high-intensity data such as 4K video (see Table III).

This system maintains a wide 4K field of view to ensure accurate detection of distant people, while matching them with a feature database (Faiss) expanded by generative AI. The results show a processing speed of approximately 135 ms per frame. Considering the average human walking speed (approximately 1.4 m/s), the movement distance between frames in a 7 fps environment is approximately 20 cm, which is sufficient for maintaining the temporal continuity required for person tracking and re-identification. Furthermore, given that this research focused on 4K video and processed four times as many pixels as in a Full HD environment, it is believed these results meet practical standards for high-resolution surveillance. On the other hand, there is a possibility that even higher speeds will be required in high-speed moving environments, including station ticket gates and pedestrians.

TABLE. III. REAL-TIME PERFORMANCE EXPERIMENT RESULTS

Environment	Average FPS	Average Latency (ms)	p95 Latency (ms)
GPU	7.15	135.81	187.9
TensorRT	7.2	135.31	186

On the other hand, while Wan2.2, used in the registration phase, has higher expressive power than conventional diffusion models, it requires a significant amount of inference time to generate high-quality images. In particular, the process of changing poses and backgrounds while maintaining a person's identity is computationally intensive. In this experiment, there were cases where generation took more than five minutes per

ID. For practical use, it is believed that improving the generation speed of image generation AI is essential.

VII. CONCLUSION

In this study, the fundamental limitation of single-gallery person re-identification is addressed by introducing a generative AI-based viewpoint completion approach. Unlike conventional methods that rely on limited observed data, the method virtually reconstructs unobserved viewpoints, effectively eliminating the viewing angle gap. Experimental results demonstrated that this approach significantly improves identification accuracy, particularly for back and side views, reducing misidentification among visually similar individuals. These findings reveal that generative AI can function not merely as a data augmentation tool, but as a mechanism for "virtual viewpoint completion". Furthermore, it is showed that this approach can be integrated into a real-time system operating on 4K video, demonstrating its feasibility for practical deployment. This work redefines single-gallery re-identification as a generative completion problem rather than a data scarcity issue, providing a new direction for both research and real-world applications such as smart city surveillance.

FUTURE WORKS

This research demonstrated the effectiveness of data augmentation using generative AI and the feasibility of real-time systems. However, the following challenges remain.

1) *Improving noise in generated images and identity preservation*: The overall average accuracy of AI-based image augmentation did not exceed that of a single-gallery setup. This is likely due to texture inconsistencies in complex poses such as side views, and noise generated during the generation process, which adversely affected learning. Future work will require the introduction of filtering methods that more strictly ensure identity consistency.

2) *Accelerating the registration phase*: While real-time performance was achieved in the inference phase, image generation using Wan2.2 sometimes took more than five minutes per ID, posing challenges for on-site registration tasks that require immediacy. Lightweighting of generative models and the development of high-speed generation methods using distillation techniques are needed.

3) *Verification of robustness in diverse environments*: This research was primarily based on Market-1501 and an original indoor dataset. Future applications will require verification of accuracy and stability in more challenging real-world environments, such as nighttime, rainy weather, or extremely crowded environments.

AUTHORS' PROFILE

Yuya Ifuku, He received BE degree in 2024. He is currently working on research that uses image processing and image recognition in Master's Program at Kurume Institute of Technology.

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 138 books and published 760 journal papers as well as 584 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA.

Mariko Oda, she received her B.E. degree from the Faculty of Engineering, Saga University in 1992. She completed her M.E. and Ph.D. (Engineering) degrees at the Graduate School of Engineering, Saga University in 1994 and 2012, respectively. Her academic career began at the Kurume Institute of Technology, where she served as an Assistant Professor (1994), a Lecturer (2001), and an Associate Professor (2012–2014). She then joined Haboromo University of International Studies as an Associate Professor (2014) and subsequently served as a Professor in the Department of Media Studies (2017–2020). In 2020, she was appointed Assistant to the President, Professor, and Deputy Director of the Applied AI Research Institute at the Kurume Institute

of Technology, where she currently serves as the Director. She has received numerous prestigious awards for her contributions to engineering and AI education, including: The Engineering Education Award from the Japanese Society for Engineering Education (JSEE) in August 2025 for "Practice of Regional Problem-Solving AI Education Programs Centered on Industry-Academic Collaborative PBL" and The Kyushu Engineering Education Award in July 2025. The Education Award from the Association for Private

University Information Education in November 2024 for her work on the effects of industry-academic PBL in regional AI education. The Award from the Institute of Electronics, Information and Communication Engineers (IEICE) in June 2023 for the development and practice of mathematical, data science, and AI education programs. Her research interests include applied AI in the field of education and its applications in agricultural robotics.

Transformer-Enhanced Soft Actor-Critic with EV-Aware Reward Shaping for Maize Optimization

Abstract—Optimizing fertilization and irrigation strategies is essential for improving productivity and resource efficiency in precision agriculture. Artificial intelligence (AI), particularly reinforcement learning (RL), has been increasingly explored for adaptive crop management under uncertain environmental conditions. However, many existing approaches rely on single-action formulations that struggle with joint input control, leading to economically unstable outcomes and limited policy interpretability. This study proposes a Transformer-enhanced Soft Actor-Critic (SAC) framework with expected value (EV)-aware reward shaping for maize optimization in a Decision Support System for Agrotechnology Transfer (DSSAT) Gym environment, enabling simultaneous control of fertilization and irrigation under dynamic crop-environment interactions. Unlike standard SAC implementations, the proposed framework incorporates a transformer-based state encoder for richer agronomic state representation and an EV-aware reward shaping mechanism to guide economically stable long-horizon decision-making. The proposed AI-driven approach improves economic profitability and profit stability compared with the prior state-of-the-art (SOTA) large language model (LLM)-enhanced Deep Q-Network (DQN) baseline. Behavioral analysis shows that the learned policy exhibits temporally structured decision patterns characterized by smaller-magnitude, higher-frequency actions and an associated input-efficiency trade-off. Furthermore, Shapley Additive Explanations (SHAP)-based explainable AI (XAI) analysis identifies growth-stage and crop-development variables as dominant drivers of long-horizon control decisions. Overall, the results demonstrate that the Transformer-enhanced SAC with EV-aware reward shaping provides a more profitable, financially stable, and interpretable AI-based decision-making framework for maize optimization in the DSSAT Gym environment.

I. INTRODUCTION

Maize is one of the world's most important crops, serving as a staple food and playing a critical role in livestock feed and biofuel production. By 2025, maize cultivation spans approximately 197 million hectares globally, with total production reaching 1.27 billion tonnes, making it the most widely grown cereal crop worldwide [1], [2]. As global demand rises, optimizing crop management practices is essential to maintain high yields while ensuring resource efficiency and environmental sustainability. Fertilizer and irrigation inputs

significantly influence maize productivity. However, excessive or inefficient application leads to resource waste, increased costs, and environmental degradation.

Traditional crop management relies on static schedules and predefined heuristics, which lack flexibility under real-world variability. Weather patterns, soil heterogeneity, and irregular rainfall introduce substantial uncertainty into crop growth processes. Consequently, rule-based systems often result in inefficient resource allocation and reduced robustness.

Recent advances in AI, particularly RL, have enabled adaptive decision-making through interaction with complex environments. RL has been increasingly applied to fertilization and irrigation scheduling; however, many approaches rely on single-action formulations, limiting their ability to jointly optimize multiple agronomic inputs and often resulting in economically unstable outcomes. Prior studies also emphasize aggregate performance metrics such as yield or profit, with limited analysis of learned policy behavior and profit stability.

Transformer-based models extend RL systems by providing powerful representations of sequential and contextual information, and have demonstrated strong potential through architectures such as the Decision Transformer and other transformer-RL frameworks [3], [4]. Originally developed for natural language processing, transformer architectures model long-range dependencies and temporal patterns via self-attention mechanisms [5]. When applied to agriculture, transformers enhance state representations by capturing complex crop-environment interactions over time. Integrating transformer encoders with actor-critic RL algorithms enables context-aware control policies better suited for dynamic and uncertain agricultural environments.

Building on these advances, this study proposes a Transformer-enhanced SAC framework with EV-aware reward shaping for maize optimization in a DSSAT Gym environment. The model enables simultaneous control of fertilization and irrigation decisions using Transformer-based state encoding, with EV-aware reward shaping that prioritizes long-term stable returns. This design reduces profit variance and improves average economic performance.

Beyond performance improvement, this work provides a multi-stage analysis of learned policies. The proposed actor-critic framework is evaluated against the prior SOTA LLM-enhanced DQN baseline. Behavioral analysis examines action magnitude distribution, decision frequency, and input-efficiency

trade-offs, while SHAP-based XAI analysis identifies growth-stage and environmental variables driving long-term control decisions.

By jointly addressing profitability, profit stability, and interpretability, this work advances RL-based crop management beyond static decision-making and opaque black-box optimization.

The main contributions are threefold: 1) A Transformer-enhanced SAC framework with EV-aware reward shaping for joint fertilization and irrigation control in a DSSAT Gym environment, demonstrating improved economic profitability and profit stability relative to the SOTA LLM-enhanced DQN baseline. 2) A detailed behavioral analysis revealing a consistent shift toward smaller-magnitude, higher-frequency actions and input-efficiency trade-offs. 3) A SHAP-based XAI pipeline identifying growth-related environmental and crop variables as dominant drivers of long-term fertilization and irrigation decisions.

The remainder of this study is organized as follows: Section II reviews related work on reinforcement learning for crop management and DSSAT-based optimization. Section III describes the proposed methodological framework, including the transformer-based state representation, actor-critic architecture, and EV-aware reward shaping mechanism. Section IV presents the experimental configuration and implementation details. Section V reports the experimental results and analysis across economic performance, policy behavior, and explainability evaluation. Finally, Section VI concludes the study and discusses future research directions.

II. RELATED WORK

A. DSSAT as a Simulation Platform for RL-Based Crop Management

DSSAT is a widely validated crop simulation framework extensively used in agricultural research and agronomic decision support due to its validated physiological foundations and ability to simulate crop growth, development, and yield formation under diverse environmental and management conditions. Its long-standing application across crop types and geographic regions has established DSSAT as a reliable platform for evaluating crop management strategies and conducting controlled simulation-based studies.

In recent years, DSSAT has been increasingly adopted as a simulation environment for RL-based crop management. Beyond DSSAT, several RL-enabled crop simulation environments have emerged, supporting adaptive policy learning under stochastic environmental settings [6-8]. Within these frameworks, agricultural decision-making is naturally formulated as a Markov Decision Process (MDP), where the crop-environment state evolves over time and agents select fertilization and irrigation actions to maximize long-term agronomic or economic returns.

Integrating DSSAT with RL offers advantages over field trials, which are costly, time-consuming, and subject to uncontrollable variability. DSSAT enables large-scale, repeatable experimentation under controlled yet agronomically realistic conditions, allowing RL agents to explore a wide range

of management strategies without real-world risk. This capability is particularly important for studying adaptive fertilization and irrigation under environmental uncertainty and delayed effects.

Recent developments further enhance DSSAT's suitability for RL research through interactive simulation interfaces such as DSSAT Gym [9]. These interfaces provide standardized observation, action, and reward application programming interfaces (APIs), enabling seamless integration with modern RL algorithms. By exposing crop and environmental states at each time step and allowing dynamic action application throughout the growing season, DSSAT Gym bridges traditional rule-based modeling with data-driven adaptive control, establishing DSSAT-based RL frameworks as a foundational benchmark for intelligent crop management strategies.

B. Prior Work on RL-Based Fertilization and Irrigation Control

RL has increasingly been adopted for agricultural decision-making, enabling adaptive fertilization and irrigation strategies that improve agronomic outcomes under uncertainty. Prior studies have applied RL to support crop management tasks such as nitrogen management, resource allocation, and decision support planning, demonstrating its potential to improve agricultural productivity and sustainability [10].

A substantial body of research has focused on irrigation optimization, reporting improvements in water-use efficiency, adaptive scheduling, and irrigation control under uncertain and variable field conditions [11-14]. Beyond irrigation-only applications, RL has also been employed for joint fertilizer-irrigation management, incorporating climate uncertainty and environmental considerations such as nitrous oxide gas emissions while improving economic and resource outcomes [15], [16]. RL has also been integrated into agricultural digital-twin environments to analyze and deploy management strategies across irrigation, greenhouse control, and crop production systems [17]. Comparative benchmarking against classical control methods such as Model Predictive Control (MPC) further demonstrates RL's competitiveness in dynamic agricultural decision-making [18].

Early RL applications in crop management evolved from neural network models toward more advanced decision-making frameworks. A notable study combined DQN with imitation learning (IL) to optimize nitrogen fertilization and irrigation scheduling within DSSAT [19], demonstrating measurable economic gains compared with rule-based baselines. Experiments conducted in Florida and Zaragoza reported up to 45% and 55% improvements in economic profit, respectively, while reducing environmental impact through lower nitrogen leaching. The rule-based baselines followed practical agronomic standards derived from regional maize production guides and farmer survey data [20-22].

Building on these foundations, subsequent work introduced transformer-enhanced RL frameworks leveraging LLMs for improved state representation within DSSAT [23]. In this approach, DSSAT state variables were converted into natural language descriptions and encoded using DistilBERT, with embeddings provided to a DQN agent. This representation-

learning strategy improved training stability, data efficiency, and economic performance across benchmark environments, achieving profit gains of 49% in Florida and 67% in Zaragoza relative to conventional baselines. These findings highlight the potential of LLM-based representations to enhance generalization and adaptability in crop management policies.

Collectively, prior studies demonstrate the effectiveness of RL-based approaches for fertilization and irrigation control within simulation environments. The progression from rule-based strategies to learning-based decision-making, and more recently to LLM-enhanced representations, establishes the LLM-enhanced DQN framework as a strong SOTA benchmark for DSSAT-based crop management.

C. Limitations of Existing Approaches

Despite promising progress in integrating DSSAT with RL, several important limitations remain. First, most prior work adopts single-action formulations, typically based on DQN, which inherently support only discrete action outputs. This design is ill-suited for simultaneous fertilizer and irrigation control in complex agricultural settings. To address this constraint, earlier studies discretized handcrafted action mappings that convert continuous inputs into fixed fertilizer-irrigation pairs representing coarse nitrogen and water levels [23]. While functional, this discretization restricts policy expressiveness, limits decision granularity, and lacks a principled mechanism for capturing nuanced input trade-offs.

Second, existing studies often employ weak evaluation protocols that inadequately assess robustness. Models are frequently evaluated under the same environmental conditions used during training, with conclusions based on a single best-performing policy. Performance variance and profit stability are rarely reported, leaving the reliability of learned policies under realistic agricultural uncertainty insufficiently examined.

Third, prior work largely focuses on aggregate performance metrics such as average yield or economic profit, with limited investigation into policy behavior or decision dynamics. Analyses of action magnitude distributions, temporal decision patterns, and input-efficiency trade-offs are typically absent. Moreover, the lack of explainability mechanisms prevents meaningful interpretation of how environmental and crop-growth variables influence long-horizon decisions. This black-box optimization limits transparency and practical adoption, particularly in real-world agricultural systems where economic stability and interpretability are critical.

Collectively, these limitations highlight the need for RL frameworks that support joint multi-input decision-making, adopt robust evaluation protocols, and integrate behavioral and explainable analyses to ensure policies are not only profitable but also stable and interpretable in real-world deployment.

III. METHODOLOGY

A. Problem Formulation in DSSAT Gym Environment

Maize fertilization and irrigation scheduling are formulated as a sequential decision-making problem under uncertainty, where management actions influence crop growth, yield formation, and economic outcomes across an entire growing

season. The problem is modeled as a MDP defined by the tuple $(\mathcal{S}, \mathcal{A}, \mathcal{R}, \mathcal{P})$, where $\mathcal{S}$ denotes the crop-environment state space, $\mathcal{A}$ represents management actions, $\mathcal{R}$ is the reward function, and $\mathcal{P}$ captures the environment transition dynamics.

Fig. 1. System architecture of the transformer-enhanced actor-critic RL framework within the DSSAT Gym crop simulator.

Fig. 1 illustrates the overall architecture of the proposed transformer-enhanced actor-critic reinforcement learning framework. The DSSAT Gym provides environmental dynamics through a standardized RL interface. At each time step, the agent observes a structured multi-dimensional state comprising crop growth indicators, accumulated management inputs, soil moisture profiles, environmental conditions, and stress variables. Based on this state, the agent selects fertilization and irrigation actions. The DSSAT simulator advances the crop system and returns the next state and reward, forming a closed-loop interaction that captures delayed effects, seasonal dependencies, and cumulative impacts inherent to agricultural systems. Formally, the instantaneous reward at time step t is defined as:

$$r_t(s_t, a_t) = \begin{cases} w_1 Y - w_2 N_t - w_3 W_t, & \text{if } \eta \alpha \rho \pi \epsilon \sigma \alpha \tau \tau, \\ -w_2 N_t - w_3 W_t, & \text{otherwise,} \end{cases} \quad (1)$$

where, $r_t(s_t, a_t)$ denotes the reward at time step t given state s_t and action a_t . The term Y denotes final crop yield (kg/ha), N_t is nitrogen fertilizer (kg/ha), and W_t is irrigation water applied (L/m²). Coefficients w_1 , w_2 , and w_3 encode the economic value structure of maize production, where w_1 reflects the monetary return per unit yield, and w_2 and w_3 represent the respective costs of nitrogen fertilizer and irrigation water. In this study, $w_1 = 0.158$, $w_2 = 0.79$, and $w_3 = 1.1$, inherited from the prior SOTA LLM-enhanced DQN formulation [23], ensuring consistency with established agronomic and economic modeling assumptions.

This profit-oriented reward formulation links management decisions to long-term economic outcomes by rewarding yield while penalizing excessive input use. Intermediate rewards reflect input costs only, encouraging consideration of delayed effects and cumulative impacts throughout the growing season.

A summary of DSSAT state variables is provided in Table I. By combining an MDP formulation with a high-fidelity crop simulator, the environment provides a principled foundation for learning adaptive fertilization and irrigation strategies that optimize long-term economic performance under uncertainty.

TABLE I. SUMMARY OF DSSAT STATE VARIABLES USED IN THIS STUDY

Category	Variable	Description
Crop Growth and Phenology	xlai	Plant population leaf area index (m ² leaf/m ² soil)
	gmwt	Grain weight dry matter (kg/ha)
	topwt	Above the ground population biomass (kg/ha)
	rtdep	Root depth (cm)
	vstage	Vegetative growth stage (number of leaves)
	istage	Growing stage
	dap	Duration after planting (day)
Management History	cumsumfert	Cumulative nitrogen fertilizer applications (kg/ha)
	totir	Total irrigated water (L/m ²)
Soil Moisture Profile	sw_0 - sw_8	Volumetric soil water content in soil layers (cm ³ [water]/cm ³ [soil])
Environmental Conditions	srad	Solar radiation during the current day (MJ/m ² /day)
	tmax	Maximum temperature for current day (°C)
	ep	Actual plant transpiration rate (L/m ² /day)
	dtg	Growing degree days for current day (°C/day)
	wtdep	Depth to water table (cm)
Stress Indicators	nstres	Index of plant nitrogen stress
	swfac	Index of plant water stress

All experiments use the UFGA8201 maize dataset conducted in Florida (1982), a benchmark formally documented in DSSAT and widely adopted in RL-driven agricultural research [24]. The experimental setting follows prior SOTA RL-DSSAT studies to ensure comparability and rigorous evaluation.

B. Actor-Critic Framework

Many prior DSSAT-based RL studies rely on value-based methods such as DQN, which are inherently designed to output a single discrete action at each decision step. While effective for single-variable control problems, this formulation is ill-suited for crop management tasks requiring simultaneous optimization of multiple agronomic inputs, such as fertilization and irrigation. Discrete action mapping schemes are often required, limiting scalability and decision granularity.

To address this limitation, an actor-critic framework is adopted. In this paradigm, the actor directly outputs joint continuous management actions, while the critic evaluates the expected return of the resulting state-action pair. This structure naturally supports coordinated multi-input control and enables fertilizer and irrigation decisions to be optimized jointly.

Four representative actor-critic algorithms are evaluated as baselines: Soft Actor-Critic (SAC) [25], Truncated Quantile Critics (TQC) [26], Twin Delayed Deep Deterministic Policy Gradient (TD3) [27], and Proximal Policy Optimization (PPO) [28]. These methods represent widely adopted stochastic and deterministic policy-gradient approaches for continuous control. Among them, SAC is selected for further development due to its stable entropy-regularized learning objective and robustness in multi-dimensional action spaces.

Together, these algorithms provide a comprehensive foundation for evaluating joint fertilizer-irrigation control within the DSSAT Gym environment.

C. EV-Aware Reward Shaping

While the actor-critic framework enables joint optimization over multiple management actions, policy learning remains driven by instantaneous rewards along individual trajectories. In agricultural decision-making, management actions often produce delayed and uncertain outcomes due to stochastic weather patterns and season-long crop responses. Reliance on step-wise rewards may therefore bias learning toward short-term or episodic outcomes that do not fully reflect long-horizon agronomic objectives.

To better align learning with long-horizon decision-making under uncertainty, this study introduces an expected value (EV)-aware reward shaping mechanism. Rather than optimizing solely for immediate returns, EV-aware shaping incorporates an expectation-based perspective into the reward formulation, guiding policy updates toward decisions evaluated by anticipated long-term economic outcomes.

In RL, the EV represents the long-term average return of a policy under uncertainty. Formally, the EV of a policy π is defined as:

$$EV(\pi) = \mathbb{E} \left[\sum_{t=0}^T r_t \right] \quad (2)$$

where, r_t denotes the reward at timestep t , T is the episode length, and $\mathbb{E}[\cdot]$ denotes the expectation over stochastic transitions and environmental variability. In this study, EV corresponds to the average season-level return generated by a policy across varying environmental conditions.

To encode acceptable economic performance targets, the EV-aware reward formulation incorporates a bounded range for expected returns. When the realized EV falls below a predefined lower threshold, a penalty proportional to the shortfall is applied. When EV exceeds the upper threshold, a bonus proportional to the degree of improvement is granted. This range-based shaping encourages consistently viable outcomes while discouraging unstable or underperforming strategies, thereby balancing risk sensitivity and long-term profitability.

By embedding this expectation-based perspective into the training signal, the agent is encouraged to internalize trade-offs among yield generation, input costs, and delayed effects across the growing season. Rather than incentivizing rare extreme yield realizations, EV-aware shaping promotes stable, agronomically feasible returns aligned with practical farming objectives. This design is consistent with recent reward-shaping studies emphasizing structured reward design and the mitigation of misaligned incentives in RL [29], [30].

Importantly, the EV-aware reward shaping mechanism modifies only the internal reward signal used for policy optimization and does not alter the underlying environment dynamics, state representation, or action space. As such, it functions as a guidance strategy within the actor-critic learning

process, preserving modeling flexibility while enabling systematic evaluation of expectation-guided rewards in complex crop management settings.

D. Three-Stage Analysis Framework

Prior DSSAT-based RL studies primarily evaluate policies using aggregate performance metrics such as yield or economic profit. However, such evaluations alone are insufficient to assess economic reliability, profit stability, and decision consistency under stochastic environmental conditions. To address this gap, this study adopts a three-stage analysis framework that sequentially evaluates profitability and stability, examines learned action behaviors and decision patterns, and provides post-hoc explainability to identify key drivers of policy decisions.

1) *Stage 1: Profitability and profit stability evaluation:* Stage 1 establishes a robust baseline comparison among competing RL policies by evaluating economic performance under unseen stochastic weather realizations. Beyond average profitability, the evaluation assesses consistency across diverse environmental conditions to reflect practical deployment requirements. Each policy is evaluated using a common test set and a consistent set of economic and agronomic metrics, including:

- Average economic profit (expected return per episode)
- Maximum economic profit (peak achievable performance)
- Minimum economic profit (downside risk under unfavorable conditions)
- Profit variance metrics (%)
- Average crop yield (kg/ha)
- Average fertilizer usage (kg/ha) and average irrigation usage (L/m²)

To quantify profit stability independently of average profitability, normalized variance indicators are computed (all expressed as percentages):

- Average-maximum variance $V_{\max, \text{avg}}$, capturing upside volatility
- Average-minimum variance $V_{\min, \text{avg}}$, capturing downside risk
- Maximum-minimum variance $V_{\max, \min}$, capturing overall profit dispersion

These metrics are formally defined as:

$$V_{\max, \text{avg}} = \frac{|P_{\max} - P_{\text{avg}}|}{P_{\text{avg}}} \times 100 \quad (3)$$

$$V_{\min, \text{avg}} = \frac{|P_{\min} - P_{\text{avg}}|}{P_{\text{avg}}} \times 100 \quad (4)$$

$$V_{\max, \min} = \frac{|P_{\max} - P_{\min}|}{P_{\text{avg}}} \times 100 \quad (5)$$

where, P_{avg} , $P_{\max}$ and $P_{\min}$ denote the average, maximum, and minimum economic profits observed during testing.

Together, these indicators provide a structured characterization of expected profitability, downside exposure, outcome dispersion, and resource efficiency, enabling economic stability to be evaluated alongside average return.

Within this framework, Stage 1.1 examines the transition from a value-based DQN baseline to a multi-action actor-critic architecture, while Stage 1.2 evaluates the effect of introducing EV-aware reward shaping on the best-performing actor-critic policy in Stage 1.1. All metrics defined in Stage 1 are reused under identical testing conditions to ensure that observed differences in profitability, variance, yield, or resource usage reflect learning behavior rather than experimental inconsistencies.

2) *Stage 2: Policy behavior and action pattern analysis:* While Stage 1 evaluates profitability and stability, it does not explain how policies generate their decisions. Stage 2 analyzes fertilization and irrigation behavior under stochastic environmental realizations using the same test episodes as Stage 1. Four strategies are compared:

- Expert-informed static management schedule.
- Prior SOTA LLM-enhanced DQN policy.
- Best-performing actor-critic policy (Stage 1.1).
- Corresponding actor-critic policy augmented with EV-aware reward shaping.

a) *Stage 2.1: Action magnitude distribution:* This sub-stage evaluates fertilizer and irrigation magnitude distributions across test episodes. Aggregated actions are analyzed to compare low- versus high-magnitude applications, characterizing decision granularity and intervention intensity.

b) *Stage 2.2: Average temporal action patterns:* Average daily fertilizer and irrigation actions are examined as a function of planting day to evaluate scheduling behavior and phase-dependent resource allocation aligned with crop development.

c) *Stage 2.3: Spatio-temporal action density across episodes:* To capture variability across environmental realizations, spatio-temporal action densities are analyzed across growing days and episodes. This evaluates consistency, dispersion, and adaptability of scheduling patterns under uncertainty.

d) *Stage 2.4: Resource efficiency and yield-input trade-off:* This sub-stage examines the relationship between average yield and total resource usage. Yield and inputs are normalized to compare relative efficiency across policies, defined as:

$$\text{Efficiency} = \frac{Y}{F+W} \quad (6)$$

where, Y is average crop yield, F fertilizer usage, and W irrigation usage. This formulation highlights the trade-off between resource efficiency and yield-oriented optimization.

3) *Stage 3: Input feature importance and policy explainability analysis:* Stage 3 evaluates the interpretability of

the learned RL policy by identifying key state variables that drive fertilization and irrigation decisions. While Stages 1 and 2 assess performance and characterize action behavior, they do not explain why specific management actions are selected. To address this, post-hoc explainability is applied to reveal how environmental conditions, crop growth states, and management history influence long-horizon decision-making.

Explainability analysis is conducted using SHAP, a model-agnostic framework grounded in cooperative game theory, which attributes each input feature's contribution to the model output [31]. SHAP is applied to the best-performing policy identified in Stage 1 under the same stochastic test conditions used for performance evaluation, ensuring consistency across experimental stages.

Global feature importance is computed separately for fertilizer and irrigation actions using mean absolute SHAP values across evaluation states. Fertilizer- and irrigation-specific importance scores are then aggregated to obtain an overall ranking, providing a unified view of dominant decision drivers across both management dimensions.

Through this analysis, Stage 3 examines whether the learned policy relies on agronomically meaningful signals such as crop growth indicators, cumulative management inputs, and soil moisture conditions rather than spurious correlations. This final stage enhances transparency, interpretability, and real-world deployability by linking observed policy behavior to domain-relevant state variables, complementing the performance and behavioral findings from earlier stages.

IV. EXPERIMENTAL SETUP

A. Datasets and Simulation Settings

All experiments are conducted using the DSSAT Gym simulation environment, based on the UFGA8201 maize field experiment conducted in Florida (1982), a benchmark formally documented within DSSAT and widely adopted in RL-based crop management research.

The DSSAT Gym simulates season-long maize growth under stochastic weather conditions, generating daily state transitions and end-of-season agronomic outcomes, including crop yield and economic profit determined by cumulative fertilization and irrigation decisions.

To isolate the effects of learning strategy and reward design, a fixed crop cultivar, soil profile, and planting configuration are maintained across all experiments. Environmental uncertainty is introduced solely through weather variability, enabling evaluation under diverse yet agronomically realistic conditions.

B. Baselines and Compared Algorithms Framework

Four representative actor-critic algorithms, SAC, TQC, TD3, and PPO, are evaluated as Stage 1.1 baselines due to their strong empirical performance in continuous multi-action control tasks and widespread adoption in modern RL research. In addition, a prior SOTA LLM-enhanced DQN approach [23] is included as a primary benchmark, representing transformer-based state encoding integrated with value-based RL for DSSAT-based crop management.

To ensure controlled comparison across learning paradigms, all learning-based agents share a unified architecture and observation preprocessing pipeline. DSSAT state variables are converted into standardized textual descriptions and encoded using a shared DistilBERT-based transformer encoder. The resulting embeddings are passed through a fully connected network with a 512-unit hidden layer followed by a 256-unit hidden layer. For actor-critic methods, this shared representation branches into separate policy and value heads to produce continuous fertilization and irrigation actions. For DQN, the same encoder and hidden layers are retained, with a single Q-value head for action-value estimation. This design preserves representational consistency while isolating algorithmic differences.

Building on the Stage 1.1 baseline comparison, Stage 1.2 introduces EV-aware reward shaping applied to the best-performing actor-critic method. Two EV-aware variants are evaluated: SAC-EV, corresponding to the checkpoint with the highest EV-shaped reward during training, and SAC-Econ, corresponding to the checkpoint with the highest realized economic return. Both variants share identical architectures, action spaces, and training protocols with the Stage 1.1 baseline, differing only in reward formulation, enabling isolation of the reward-shaping effect.

An expert-informed fixed management schedule is included as a non-learning baseline, following standard DSSAT documentation and commonly used benchmarking configurations. This rule-based strategy serves as a lower-bound reference for evaluating the benefits of adaptive RL-based decision-making.

For clarity, learning-based agents are referenced by algorithm name (DQN, SAC, TQC, TD3, PPO), while the fixed schedule is denoted as Expert.

C. Training and Testing Protocol

All learning-based agents are trained and evaluated under a unified protocol to ensure fair comparison across paradigms. Each agent is trained for 3000 episodes, where each episode corresponds to a complete maize growing season simulated within the DSSAT Gym environment. This training horizon follows the prior SOTA LLM-enhanced DQN setting [23], in order to ensure fair and reproducible comparison. Training interactions occur under stochastic weather realizations, enabling policies to learn long-horizon strategies that account for delayed agronomic effects.

Policy performance is evaluated over 100 independent test episodes generated from the same underlying weather process as training, but not encountered during optimization. This ensures an unbiased assessment of robustness under environmental stochasticity.

To ensure consistency across algorithms, identical environment configurations, state representations, and action bounds are used during training and evaluation. Fertilizer and irrigation actions are constrained to continuous ranges of $[0, 60]$ kg/ha and $[0, 30]$ L/m², respectively, for all learning-based agents.

For EV-aware reward shaping, EV is computed as the season-level crop yield return. During training, a bounded EV target range of [10,000, 12,000] kg/ha is specified to stabilize learning and guide optimization. This range is empirically derived from the Stage 1.1 baseline experiments, which consistently reveal a high-yield operating regime. Policies falling below the lower bound incur a proportional penalty, while those exceeding the upper bound receive a proportional bonus.

To ensure statistical reliability, fixed random seeds are used across all experiments. Performance metrics are averaged over test episodes, and variance-related measures are computed to quantify policy stability under weather variability.

D. SHAP Configuration for Input Feature Importance and Policy Explainability

Input feature importance and policy explainability analysis are conducted in Stage 3 using SHAP to interpret the decision-making behavior of the best-performing EV-aware actor-critic policy selected from Stage 1.2, evaluated under the same stochastic test conditions to ensure consistency.

To construct the SHAP background distribution, 800 environment states are sampled from rollout trajectories generated by the trained policy under stochastic test conditions. These states are compressed using K-means clustering into 20 representative centroids, which serve as the background dataset for Kernel SHAP. This reduces computational complexity while preserving representative state variability.

For evaluation, 30 states are independently sampled to compute SHAP values. Global feature importance is calculated separately for fertilizer and irrigation actions by averaging mean absolute SHAP values across evaluation states. Because policy outputs are continuous action magnitudes, only absolute SHAP values are used to quantify feature influence, avoiding directional ambiguity.

An overall feature ranking is obtained by aggregating fertilizer- and irrigation-specific importance scores, providing a unified view of dominant decision-driving variables across management dimensions.

To assess robustness, a stability check is performed by re-running Kernel SHAP with a different random seed. Stability is quantified using Top-10 feature overlap and Spearman's rank correlation between importance rankings. High overlap and strong rank correlation indicate consistent reliance on environmental and crop-related signals, supporting the reliability of the explainability analysis.

V. RESULTS AND ANALYSIS

Results are structured into three stages: 1) economic profitability and stability evaluation, 2) behavioral pattern analysis, and 3) policy interpretability under stochastic environmental conditions.

A. Stage 1: Profitability and Profit Stability Evaluation

Stage 1 evaluates economic performance under stochastic weather realizations, examining both architectural upgrades and reward design choices to establish a stable economic baseline for subsequent behavioral analysis.

1) *Stage 1.1: Actor-critic upgrade*: Stage 1.1 assesses the transition from a value-based DQN to an actor-critic framework in terms of profitability and profit stability under environmental uncertainty.

TABLE II. TRAINING PERFORMANCE (STAGE 1.1)

Model	Highest Training Profit
DQN	1464
SAC	1401
TQC	~500
TD3	N/A
PPO	N/A

Table II reports the highest training profit achieved by each model during learning. These results are presented for completeness and convergence reference only. Training performance reflects optimization under fixed environmental trajectories and is not used for comparative evaluation under stochastic environmental conditions. Under the experimental configuration, DQN and SAC exhibit stable convergence, while the remaining actor-critic baselines fail to converge reliably due to sensitivity in multi-action optimization.

TABLE III. TESTING PERFORMANCE (STAGE 1.1)

Metric	DQN	SAC
Avg. Profit	979	974
Max. Profit	1489	1410
Min. Profit	370	623

Table III summarizes testing performance under unseen weather realizations over 100 independent maize-growing episodes simulated under stochastic environmental conditions. SAC achieves a comparable average economic profit relative to DQN, while attaining a substantially higher minimum realized profit. Although average profit levels are similar, the higher minimum profit achieved by SAC indicates improved downside risk protection under unfavorable environmental realizations.

TABLE IV. PROFIT VARIANCE IN TESTING PERFORMANCE (STAGE 1.1)

Metric	DQN	SAC	Relative Reduction
$V_{max,avg}$ (%)	52.09	44.76	7.33
$V_{min,avg}$ (%)	62.21	36.04	26.17
$V_{max,min}$ (%)	114.3	80.8	33.5

To further quantify economic stability and sensitivity to environmental uncertainty, Table IV reports normalized profit variance and extreme-value deviation metrics.

The maximum-minimum profit deviation captures the spread between best- and worst-case outcomes. SAC achieves a 33.50% reduction in maximum-minimum variability compared to DQN, indicating a narrower profit range across stochastic weather realizations. Consistent reductions across variance metrics confirm improved economic stability under stochastic environmental conditions.

TABLE V. YIELD AND INPUT UTILIZATION IN TESTING (STAGE 1.1)

Metric	DQN	SAC
Avg. Yield (kg/ha)	7864	8567
Avg. Fertilizer (kg/ha)	154	194
Avg. Water (L/m ²)	128	206

Table V reports average crop yield and input utilization during testing. The SAC policy applies higher fertilizer and irrigation inputs on average, resulting in increased crop yield relative to DQN. Since the optimization objective is economic profit rather than input minimization, higher input usage is not inherently suboptimal if it leads to improved and more stable economic returns. These results reflect a trade-off between yield enhancement and input cost.

Overall, Stage 1.1 demonstrates that while average profitability between SAC and DQN is comparable, upgrading to an actor-critic framework yields substantially improved profit stability and reduced downside risk under stochastic environmental uncertainty. SAC achieves a 33.50% reduction in maximum-minimum profit variability, indicating a narrower spread between worst- and best-case outcomes across stochastic weather realizations and establishing a stable foundation for subsequent enhancements.

2) *Stage 1.2: EV-aware reward shaping*: Stage 1.2 evaluates the effect of incorporating EV-aware reward shaping on top of the best-performing actor-critic policy identified in Stage 1.1 (SAC). Two additional SAC variants are trained: SAC-Econ, selected based on the highest economic profit during training, and SAC-EV, selected based on the highest EV-shaped reward. Both are evaluated against the baseline SAC policy under identical testing conditions to isolate the impact of EV-aware reward shaping.

TABLE VI. TRAINING PERFORMANCE (STAGE 1.2)

Model	Highest Economic Profit	Corresponding Internal Score
SAC (Stage 1.1)	1401	1401
SAC-Econ	1588	2102
SAC-EV	1561	2179

Table VI reports training performance for the three SAC variants, including the highest achieved economic profit, and the corresponding internal training score. SAC-Econ and SAC-EV attain higher peak training profit than the baseline SAC policy, reflecting stronger optimization toward their respective economic objectives.

Table VII summarizes testing performance under unseen weather realizations. EV-aware reward shaping improves average economic profitability over the Stage 1.1 SAC baseline. SAC-EV achieves the highest average profit, corresponding to a 17.56% improvement relative to the Stage 1.1 SAC baseline and a 16.96% improvement over the previous SOTA DQN policy. In addition to improved average profitability, SAC-EV maintains a balanced performance profile, avoiding extreme downside degradation under unfavorable environmental realizations.

TABLE VII. TESTING PERFORMANCE (STAGE 1.2)

Metric	SAC (Stage 1.1)	SAC-Econ	SAC-EV
Avg. Profit	974	1112	1145
Max. Profit	1410	1531	1524
Min. Profit	623	478	574

TABLE VIII. PROFIT VARIANCE IN TESTING PERFORMANCE (STAGE 1.2)

Metric	SAC (Stage 1.1)	SAC-Econ	SAC-EV
$V_{max,avg}$ (%)	44.76	37.68	33.10
$V_{min,avg}$ (%)	36.04	57.01	49.87
$V_{max,min}$ (%)	80.80	94.69	82.97

To further examine economic stability, Table VIII reports normalized profit variance and extreme-value deviation metrics. SAC-EV achieves the lowest maximum-average profit variance among all evaluated methods. Although minimum-average and maximum-minimum variance exhibit slight increases relative to the Stage 1.1 SAC policy, SAC-EV consistently maintains substantially lower variability than the previous SOTA DQN across all reported measures, while simultaneously achieving higher economic profit.

TABLE IX. YIELD AND INPUT UTILIZATION IN TESTING (STAGE 1.2)

Metric	SAC (Stage 1.1)	SAC-Econ	SAC-EV
Avg. Yield (kg/ha)	8567	10202	10654
Avg. Fertilizer (kg/ha)	194	241	346
Avg. Water (L/m ²)	206	281	241

Table IX reports average crop yield and input utilization during testing. Both EV-aware variants apply higher fertilizer and irrigation inputs compared to the baseline SAC policy, resulting in increased crop yield. Among the evaluated methods, SAC-EV achieves the highest average yield, accompanied by higher fertilizer and water usage. These differences indicate that EV-aware reward shaping influences both economic outcomes and resource deployment strategies.

Overall, Stage 1 demonstrates that the two design components address complementary aspects of economic performance under uncertainty. The upgrade to an actor-critic framework substantially improves profit stability and reduces exposure to extreme outcomes, while EV-aware reward shaping further enhances average economic profitability. The proposed SAC-EV framework achieves a 16.96% improvement in average economic profit and a 31.33% reduction in maximum-minimum profit variability relative to the previous SOTA DQN baseline, indicating improved profitability and enhanced economic stability under stochastic environmental conditions.

3) *Ablation Study 1: Action range sensitivity*: To evaluate the impact of action space design on the proposed SAC-EV policy, three fertilizer-irrigation ranges were tested under identical training and evaluation settings. The expert-informed configuration (0-60 kg/ha fertilizer, 0-30 L/m² irrigation) used in Stages 1.1 and 1.2 was compared with a wider range (0-100

kg/ha, 0-50 L/m²) and a narrower range (0-30 kg/ha, 0-15 L/m²).

Variants are denoted as SAC-EV (F, W), where F and W represent the maximum allowable fertilizer (kg/ha) and irrigation (L/m²). Accordingly, SAC-EV (60, 30) corresponds to the baseline configuration, SAC-EV (100, 50) to the wider range, and SAC-EV (30, 15) to the narrower range.

TABLE X. TESTING PERFORMANCE (ABLATION STUDY 1)

Metric	SAC-EV (60, 30)	SAC-EV (100, 50)	SAC-EV (30, 15)
Avg. Profit	1145	1046	894
Max. Profit	1524	1467	1232
Min. Profit	574	631	482
$V_{max,avg}$ (%)	33.10	40.25	37.81
$V_{min,avg}$ (%)	49.87	39.67	46.09
$V_{max,min}$ (%)	82.97	79.92	83.89
Avg. Yield (kg/ha)	10654	10598	10277
Avg. Fertilizer (kg/ha)	346	334	371
Avg. Water (L/m ²)	241	331	436

Table X shows that SAC-EV (60, 30) achieves the highest average and maximum profit while maintaining a competitive minimum profit. Expanding the action bounds does not improve profitability, whereas constraining the range substantially reduces returns. Variance metrics remain broadly comparable across configurations, indicating limited sensitivity of stability to action bounds. Overall, agronomically grounded limits provide the best balance between profitability and resource utilization.

4) *Ablation study 2: EV threshold sensitivity*: To evaluate the sensitivity of EV-aware reward shaping, three configurations were tested under identical training and evaluation settings: the baseline (12k, 10k) used in Stage 1.2, a higher lower-bound variant (12k, 11k), and a higher upper-bound variant (13k, 10k).

Variants are denoted as SAC-EV (U, L), where U and L represent the upper and lower EV thresholds. Accordingly, SAC-EV (12k, 10k) corresponds to the baseline configuration, SAC-EV (12k, 11k) increases the lower threshold, and SAC-EV (13k, 10k) increases the upper threshold.

According to Table XI, the baseline SAC-EV (12k, 10k) achieves the highest average, maximum, and minimum profit while maintaining the lowest variance. Increasing either threshold substantially reduces average and minimum profit and sharply increases profit variability. Although yield and input usage change under modified thresholds, economic performance does not improve, indicating that EV-aware reward shaping is highly sensitive to threshold design and that misaligned EV targets degrade both profitability and stability under stochastic conditions.

TABLE XI. TESTING PERFORMANCE (ABLATION STUDY 2)

Metric	SAC-EV (12k, 10k)	SAC-EV (12k, 11k)	SAC-EV (13k, 10k)
Avg. Profit	1145	691	652
Max. Profit	1524	1241	1253
Min. Profit	574	111	72
$V_{max,avg}$ (%)	33.10	79.59	92.18
$V_{min,avg}$ (%)	49.87	83.94	88.96
$V_{max,min}$ (%)	82.97	156.53	181.13
Avg. Yield (kg/ha)	10654	10961	8588
Avg. Fertilizer (kg/ha)	346	627	204
Avg. Water (L/m ²)	241	497	494

B. Stage 2: Policy Behavior and Action Pattern Analysis

Stage 2 analyzes the behavioral characteristics of the selected policies to explain how economic performance is achieved beyond aggregate profit metrics. In addition to the Expert baseline and the prior SOTA LLM-enhanced DQN, the SAC and SAC-EV policies are included as the best-performing learning-based approaches identified in Stage 1.

Fig. 2. Episode-level profit trajectories across 100 testing episodes for Expert, DQN, SAC, and SAC-EV.

Fig. 2 illustrates episode-level profit trajectories across 100 test episodes. While average profitability differences were established in Stage 1, these trajectories reveal variations in stability and episode-level behavior across policies. To understand how these outcomes arise, Stage 2 examines action magnitude distributions, temporal scheduling patterns, spatio-temporal input localization, and resource allocation trade-offs under identical stochastic test conditions.

1) *Stage 2.1: Action magnitude distribution*: Stage 2.1 analyzes the distribution of fertilizer and irrigation action magnitudes across testing episodes to characterize policy aggressiveness and resource allocation patterns under stochastic conditions.

Fig. 3 and Fig. 4 illustrate distinct action magnitude distributions across policies. The Expert baseline applies sparse, discrete interventions consistent with a fixed schedule. The DQN policy exhibits limited action diversity with occasional higher-magnitude applications, indicating reactive and coarse adjustments. In contrast, SAC and SAC-EV concentrate on

frequent low-to-moderate magnitude actions, reflecting incremental and state-responsive management, with high-magnitude inputs applied selectively.

Average Fertilization Action Magnitude Distribution across 100 Test Episodes

Fig. 3. Average fertilization action magnitude distribution across 100 test episodes for Expert, DQN, SAC, and SAC-EV.

Average Irrigation Action Magnitude Distribution across 100 Test Episodes

Fig. 4. Average irrigation action magnitude distribution across 100 test episodes for Expert, DQN, SAC, and SAC-EV.

This shift toward finer-grained, high-frequency interventions indicates that actor-critic policies balance responsiveness with stability. SAC-EV shows the strongest concentration of controlled low-magnitude actions, consistent with structured and adaptive long-horizon resource management.

2) *Stage 2.2: Average temporal action patterns:* Stage 2.2 examines the average temporal structure of fertilizer and irrigation actions across growing seasons to evaluate policy timing and responsiveness under stochastic conditions.

Fig. 5 and Fig. 6 show that inputs are not uniformly distributed over time. Learning-based policies concentrate fertilization and irrigation applications during mid-season growth phases corresponding to elevated crop demand, whereas the Expert and DQN baselines exhibit sparse or irregular timing patterns.

Average Daily Fertilization Amount across 100 Test Episodes

Fig. 5. Average temporal pattern of daily fertilizer application across 100 test episodes for Expert, DQN, SAC, and SAC-EV.

Average Daily Irrigation Amount across 100 Test Episodes

Fig. 6. Average temporal pattern of daily irrigation application across 100 test episodes for Expert, DQN, SAC, and SAC-EV.

Actor-critic methods (SAC and SAC-EV) display smoother temporal profiles characterized by frequent low-to-moderate magnitude adjustments, with larger interventions applied selectively during critical developmental stages. Irrigation follows a similar trajectory, increasing toward peak growth and declining thereafter.

Overall, the learned policies align input timing with crop developmental dynamics, applying high-magnitude actions at agronomically critical phases while maintaining incremental adjustments for routine management, consistent with structured long-horizon control.

3) *Stage 2.3: Spatio-temporal action density across episodes:* Stage 2.3 analyzes episode-level spatio-temporal action densities to examine how policies allocate fertilizer and irrigation inputs across individual growing days and stochastic realizations.

Compared to the averaged temporal profiles in Stage 2.2, the heatmaps shown in Fig. 7 and Fig. 8 reveal stronger, more localized and episode-specific application patterns. Learning-based policies apply low-magnitude actions across most growing days, with higher-magnitude interventions concentrated within narrow agronomically critical windows.

Fig. 7. Spatio-temporal density of daily fertilizer application across 100 test episodes for Expert, DQN, SAC, and SAC-EV.

Fig. 8. Spatio-temporal density of daily irrigation application across 100 test episodes for Expert, DQN, SAC, and SAC-EV.

The Expert baseline exhibits rigid vertical bands corresponding to fixed schedule-driven interventions, while DQN displays dispersed high-magnitude actions with weaker temporal alignment. In contrast, SAC and SAC-EV show more continuous distributions of low-magnitude actions, with higher-magnitude inputs strategically concentrated near peak crop demand.

These patterns indicate that larger interventions are temporally localized rather than uniformly distributed, while routine management relies on frequent smaller adjustments, supporting stable and structured long-horizon control under uncertainty.

4) *Stage 2.4: Resource efficiency and yield-input trade-off:* Stage 2.4 examines the relationship between crop yield, total input usage, and normalized resource efficiency to evaluate how policies balance productivity and input expenditure.

Fig. 9 and Fig. 10 indicate that learning-based policies improve efficiency relative to the Expert baseline through adaptive fertilizer and irrigation allocation. DQN achieves the highest normalized efficiency due to comparatively restrained input usage. However, transitioning from DQN to SAC and SAC-EV increases total input more sharply than normalized efficiency, reflecting a shift in resource deployment strategy.

Fig. 9. Resource efficiency comparison measured as normalized yield per unit of total input across Expert, DQN, SAC, and SAC-EV.

Fig. 10. Comparison of a average crop yield and total input usage across Expert, DQN, SAC, and SAC-EV.

This pattern represents a deliberate trade-off aligned with the economic optimization objective. Rather than maximizing yield-per-input in isolation, advanced policies allocate additional resources when the expected economic return exceeds marginal cost. SAC-EV achieves the highest yield and profitability, accompanied by lower normalized efficiency, indicating a strategic shift from conservative input usage toward profit-maximizing allocation. Overall, Stage 2.4 highlights the explicit trade-off between input efficiency and long-horizon economic performance.

C. Stage 3: Input Feature Importance and Policy Explainability Analysis

Stage 3 examines the decision drivers of the best-performing policy (SAC-EV) using SHAP-based feature importance analysis. By identifying which crop, soil, and environmental variables most strongly influence fertilizer and irrigation actions, this stage explains the behavioral patterns observed in Stage 2 and evaluates the stability of the learned decision structure.

1) *Global feature importance for fertilizer and irrigation decisions:* Fig. 11 and Fig. 12 report mean absolute SHAP values for fertilizer and irrigation actions, respectively. For fertilizer decisions, the most influential features are cumulative fertilizer application (cumsumfert), days after planting (dap), root depth (rtdep), and growth-stage indicators (vstage, istage),

indicating that fertilizer control is primarily governed by crop developmental status and accumulated management history.

Fig. 11. Global feature importance for fertilizer application decisions based on mean absolute SHAP values.

Fig. 12. Global feature importance for irrigation application decisions based on mean absolute SHAP values.

In contrast, irrigation decisions are dominated by leaf area index (xlai), total irrigation applied (totir), biomass growth (grnwt), and growth-stage indicators, reflecting responsiveness to canopy development and immediate water demand. Across both action types, short-term environmental fluctuations and deeper soil moisture layers exhibit comparatively lower influence.

Overall, the results indicate that both fertilizer and irrigation decisions are driven primarily by persistent growth-related state variables and cumulative management history rather than transient environmental signals, supporting a unified and state-dependent decision structure.

2) *Overall global feature importance across management decisions:* Fig. 13 aggregates SHAP values across fertilizer and irrigation actions. The combined ranking confirms that cumulative fertilizer, days after planting, root depth, and growth-stage indicators consistently dominate feature

importance. This consolidated view reinforces that input decisions are conditioned on crop developmental context and prior management state, providing a coherent explanation for the temporally structured and stage-aware behaviors identified in Stage 2.

Fig. 13. Overall global feature importance across fertilizer and irrigation decisions based on aggregated mean absolute SHAP values.

3) *SHAP stability check:* To assess robustness, Kernel SHAP was recomputed using a different random seed, and feature rankings were compared via Top-10 overlap and Spearman's rank correlation (ρ). Fertilizer decisions showed 8/10 overlapping features with $\rho = 0.515$, while irrigation decisions showed 9/10 overlap with $\rho = 0.855$. The high overlap and positive correlations indicate that the importance structure is largely preserved under stochastic sampling, confirming that dominant decision drivers are stable rather than artifacts of sampling variability and supporting the reliability of the learned policy's interpretable structure.

Overall, Stage 3 confirms that the behavioral patterns identified in Stage 2 are supported by stable and consistent decision drivers. Growth-stage indicators and cumulative input variables dominate feature importance rankings, explaining the observed stage-aware and temporally structured action patterns. The robustness of feature rankings further supports the reliability and interpretability of the learned policy.

VI. CONCLUSION

This study addressed the joint optimization of fertilizer and irrigation scheduling for maize under stochastic environmental conditions using a DSSAT-based simulation framework. A Transformer-enhanced SAC model with EV-aware reward shaping was proposed to improve profitability and economic stability in long-horizon crop management.

The SAC-EV framework achieves a 16.96% increase in average profit and a 31.33% reduction in maximum-minimum profit variance compared with the prior SOTA LLM-enhanced DQN baseline. Behavioral analysis shows that the learned policy adopts smaller-magnitude, higher-frequency actions, reflecting temporally structured and stage-aware control rather than fixed or heuristic scheduling. Fertilizer and irrigation inputs are

strategically timed according to evolving crop-state trajectories under stochastic environmental variability.

SHAP-based interpretability analysis further reveals that growth-stage indicators, cumulative fertilizer history, and root development variables consistently dominate action selection. This establishes a coherent link between economic performance, policy behavior, and agronomically meaningful state variables, demonstrating that the controller operates on persistent crop-development signals rather than opaque black-box optimization.

Overall, SAC-EV integrates profitability, risk stability, and interpretability within a unified decision-support framework, providing a practically deployable approach for adaptive fertilizer and irrigation management. Future work will extend the framework to multi-crop and multi-region settings and evaluate its effectiveness in real-world agricultural environments through field experiments. Additional extensions may incorporate dynamic economic factors, such as price variability, to further enhance robustness under diverse agronomic and economic conditions.

Web Application to Improve Advertising Order Management Based on Cloud Computing: Case Study of a Television Company

Ariadna Gisselle Ledesma-Sánchez, Ricardo Alejandro Gamarra-Valle, Ernesto Adolfo Carrera-Salas
School of Engineering, Universidad Peruana de Ciencias Aplicadas (UPC), Lima, Peru

Abstract—Television companies face significant problems in managing advertising orders due to manual processes that cause transcription errors, delays, and a lack of traceability. This study proposes a web application based on cloud computing to automate this process. The solution implements a hybrid architecture that allows advertising agencies to enter orders directly, eliminating manual transcription and providing complete traceability. The results of the pilot test demonstrated substantial improvements: processing time was reduced by 88.33%, decreasing from 17 minutes 16 seconds to 2 minutes 1 second per order. Transcription errors fell from 60% to 0%, and operating costs were reduced by 54.5%. Automation in reporting eliminated manual management, allowing agencies direct access to campaign information. The implementation successfully transformed manual management into an automated, efficient, and scalable system, improving operational efficiency and customer satisfaction.

Keywords—Advertising order management; cloud computing; process automation; television companies; web applications

I. INTRODUCTION

Currently, television companies face a constant transformation driven by technological changes and new demands of the digital market [1]. This context of change forces them to rethink their traditional operating models, in which manual processes, such as managing contracts, advertising orders, and client reports, hinder efficiency.

The entertainment and media sector reached \$2.32 trillion in revenue in 2022 [2], although growth showed a marked slowdown, dropping from 10.6% in 2021 to 5.4% in 2022. This slowdown is leading companies to seek more efficient strategies, rethinking their management models, and looking for the optimization of their administrative processes through technology.

Investment in digital advertising has surpassed television as the main advertising medium. According to the Dataxis report, in 2021, digital formats obtained 44% of total revenues in Latin America [3], while television accounted for 39.4%. This trend marks a shift in brand strategies toward more interactive platforms with precise metrics. In Peru, investment in digital advertising represented 51% of the total advertising spending in the country [4], surpassing television, which occupied 35%. This change demonstrates the rapid adoption of digital technologies in advertising strategies, further highlighting the need for television companies to update their management models to adapt to the increasingly changing market.

Various studies have demonstrated how process automation through technological solutions significantly improves operational efficiency in different organizations. For example, a web platform has been developed for inventory management in small and medium-sized enterprises (SMEs), enabling them to overcome the limitations of manual methods and improve internal record control [5]. In the advertising field, a model based on advanced techniques has been proposed to measure the impact of television advertising on users' digital behavior, integrating metrics from traditional and digital media into a unified analytical platform [9]. Likewise, the benefits of adopting cloud services by small businesses have been widely documented, highlighting their role in commercial expansion and digital transformation in emerging markets [6]. Similarly, a company in the events sector optimized customer service through a web-based system that automates orders, payments, and reporting processes, successfully adapting to digital environment conditions [8]. Simulation tools and modular approaches have also been applied to improve resource planning and operational efficiency, identifying bottlenecks and proposing adjustments without affecting real operations [7], [10]. In the financial sector, the automation of information processing using data flows and continuous integration tools has proven effective in improving report generation and reducing manual errors.

In this context, the present research developed a technological solution aimed at optimizing the management of advertising orders and customer reports in the television sector in order to strengthen operational efficiency, improve order traceability, and facilitate adaptation to the digital environment. Although cases of automation in different industries have been addressed, there is scarce literature focused specifically on digital solutions for advertising order management in media, which supports the relevance of the present proposal. The research implemented an automated web platform using Spring Boot as the main framework, Thymeleaf for the user interface, and Azure Database for PostgreSQL as the cloud storage infrastructure, with differentiated authentication through Spring Security for television channels and advertising agencies. The results obtained in the pilot test demonstrated an 88.33% reduction in order entry time, decreasing from 17 minutes 16 seconds to 2 minutes 1 second per order, and eliminating transcription errors that previously affected 60% of operations. Additionally, a 54.5% reduction in operating costs was achieved, and access to transmission reports was automated. In conclusion, the system effectively transforms advertising order

management from a manual process prone to errors to an automated, efficient, and scalable operation.

II. RELATED WORKS

In [5], inventory management systems intended for small and medium-sized enterprises are reviewed, focusing on overcoming the limitations of manual methods that often generate errors and operational inefficiency. The research highlights the importance of implementing web platforms that facilitate automation and real-time inventory control, allowing SMEs to improve their registration accuracy, traceability, and operational efficiency. The scalability and adaptability of these technological solutions for different business environments and business sizes are highlighted. The adoption of modular systems and robust databases is identified as common practice to provide sustainable and easily maintainable solutions aimed at digitizing processes and reducing errors associated with manual management.

In [6], a systematic review is presented on the adoption of cloud computing by small and medium-sized enterprises, analyzing how this technology allows improving operational efficiency, scalability, and cost reduction without requiring significant investments in physical infrastructure. The study identifies that cloud-based platforms facilitate access to advanced computing resources, allowing SMEs to implement scalable and flexible web systems that adapt to business growth. The research examines key adoption factors, technological and organizational barriers, and the impact on business competitiveness. The study concludes that cloud computing constitutes a strategic tool for digital transformation, allowing SMEs to access modular architectures and services that were previously only available to large corporations.

In [7], the research analyzes the impact of process modularity on manufacturing times and throughput rates in the context of mass customization. The study implemented a simulation-based methodology to evaluate different modular assembly process structures, using three independent modularity indicators to provide a reliable assessment of this system property. Experiments were carried out using deterministic models of alternative process structures, applying both theoretical and practical case studies. The results demonstrated moderate correlations between process modularity and manufacturing time, as well as between process modularity and throughput rate. The study concluded that assembly processes with greater structural modularity provide significant advantages in terms of operational efficiency, reducing

manufacturing times by up to 51% and improving throughput rates in mass customization environments.

In [8], the development of a web system for an event organizing company is studied, in order to facilitate order management and interaction with clients during health restrictions due to the pandemic. The Rapid Application Development (RAD) methodology was used, and functionalities were designed for three types of users: administrator, manager, and client. The evaluation of the system included alpha and beta tests, as well as compliance with the Eight Golden Rules of Interface Design. The system was rated as very viable, obtaining a usability score of 89%. In addition, it automates processes such as orders, payments, reports, and package management. The study concludes that digitalization can significantly improve the operational efficiency of personalized services.

In [9], the study addresses the challenge of measuring the impact of television advertising on the digital behavior of users through advanced technologies. To solve this problem, machine learning and causal inference techniques were used, developing the TV-Impact model that combines television consumption data with digital metrics. The evaluation of the system was carried out through indicators such as incremental reach and campaign effectiveness, applying quantitative analysis based on large volumes of advertising data. The results showed that video advertising represents approximately 30% of global advertising spending, with significant growth in digital markets, such as Turkey, where it reaches 49%. The study concludes that the integration of these technologies allows optimizing advertising strategies and demonstrates the importance of modernizing television systems to respond to digital transformation and improve operational efficiency.

In [10], the research developed SustAI-SCM, a modular system for process automation in supply chains based on artificial intelligence. The modular architecture integrates specialized components for procurement management, logistics planning, and resource monitoring, where each module operates autonomously but is coordinated within the global system. The results demonstrated substantial improvements: a 26.0% reduction in fuel consumption, a 31.4% increase in procurement efficiency, and a 28.4% decrease in operating costs. The study concluded that modular design constitutes a fundamental strategy for developing scalable and adaptable systems in contemporary business operations.

Table I presents a comparative analysis of existing approaches and the proposed model.

TABLE I. COMPARISON BETWEEN PROPOSED MODEL VS RELATED WORKS

Year	Paper	Description / Technology	Applied Sector	Metrics
2022	Paper 1 [5]	A modular architecture and MySQL database were implemented that allow scalability and adaptation to different environments.	Small and medium-sized enterprises	Significant improvement in inventory accuracy and data processing speed.
2022	Paper 2 [6]	Use of cloud services to improve operational efficiency, scalability, and cost reduction in e-commerce SMEs.	Small and medium e-commerce enterprises	E-commerce growth, increase in broadband penetration, and impact on high-speed connections.
2023	Paper 3 [7]	Analysis of the impact of process modularity on manufacturing times and throughput using modular architectures and deterministic simulation.	Manufacturing sector	Reduction of manufacturing time, moderate correlation between modularity and efficiency, improvement in throughput rate, and optimization of modular process structures.

2024	Paper 4 [8]	Web application with integrated database and three roles (administrator, manager, client), developed with RAD methodology.	Clients and providers of wedding organization services	Improvement in communication between client and company, automation of package and report management, increase in operational efficiency, and reduction of manual errors.
2024	Paper 5 [9]	Use of web traffic data and TV ads with the CausalImpact model, classifying ads according to their temporal overlap.	3 companies from different sectors that implement television advertising strategies	Reduction of prediction error and classification, estimated increase in web traffic.
2025	Paper 6 [10]	Modular system for process automation in supply chains based on agent-type artificial intelligence.	Sustainable supply chain management	Decrease in emissions, improvement in warehouse efficiency, reduction of operating costs in logistics, and optimization of procurement processes.
2025	Proposed Model	Web application for advertising order management in a television company, deployed on Azure.	Television sector	Reduction of average time per order, increase in the number of orders processed per hour, decrease in errors in order registration, and reduction of operational resources.

Source: Own Elaboration.

III. CONTRIBUTION

A. Commercial Break

A commercial break is a block of time assigned within television programming for the consecutive broadcast of several advertisements, usually located at strategic moments such as the beginning, middle, or end of a program [11]. In the proposed system, this concept is integrated as a fundamental entity within advertising order management, allowing the automatic organization, scheduling, and allocation of advertising slots based on time availability and advertiser requirements. This study contributes by formalizing the commercial break as a structured and optimizable entity within a digital management system, improving scheduling efficiency compared to traditional manual approaches.

B. Advertising Order

An advertising order is the formal contract or agreement between a television company and an advertiser, through which the broadcast of one or more advertisements is established within a defined period [12]. In the developed web application, the advertising order constitutes the core of the commercial management process, centralizing advertiser information, contracted slots, and broadcast schedules. The contribution of this work lies in the digital integration and automation of advertising orders, enabling traceability, consistency, and real-time management, which are typically limited in traditional systems.

C. Cloud Services

Cloud services are technological solutions delivered over the internet that enable remote access to resources such as storage, processing, databases, and applications, providing flexibility, scalability, and cost efficiency [13]. In this project, cloud services form the backbone of the system infrastructure, hosting the web application, database, and synchronization mechanisms. This research contributes by implementing a hybrid cloud architecture that combines scalability and local operational continuity, enhancing system availability and reducing infrastructure costs in the television sector.

D. Web Application

A web application is a software system accessible through a web browser that enables user interaction and data processing

over the internet [14]. In this research, the web application serves as the main interface for the advertising order management system, allowing users to register information, monitor campaigns, and access reports from any connected device. The contribution of this study is the development of an integrated web-based platform that improves accessibility, usability, and real-time interaction in advertising management processes.

E. Process Automation

Process automation is defined as the use of technology to execute repetitive and manual tasks in order to improve efficiency and reduce human intervention [15]. In the proposed system, automation is applied to the scheduling and control of advertising orders, eliminating manual tasks such as schedule validation and ad registration. This work contributes by demonstrating a practical automation model that significantly reduces operational errors and processing time, improving overall efficiency in advertising workflow management.

IV. METHOD

The implementation of the web application to improve advertising order management based on cloud computing was developed following these steps:

A. Technology Selection

After a detailed analysis of the main cloud platforms, Microsoft Azure is positioned as the most balanced solution for enterprise environments, with a guaranteed uptime of 99.95% and native integration with Microsoft corporate tools that facilitate management and reduce operating costs, according to its official SLA [16]. Although AWS offers slightly higher availability of 99.99% [17], its more complex pricing model can make budget control difficult in projects with strict limits. For its part, Google Cloud Platform stands out in performance for specific data analysis workloads, thanks to its global infrastructure and recommended practices for region selection that allow optimizing latency [18]. More economical alternatives, such as Render, present limitations in scalability and lack of formal availability guarantees, which restrict their suitability for critical systems. Collectively, these factors position Azure as the platform that best combines technical performance, enterprise integration, and predictable costs, optimizing the management of demanding advertising systems.

The selection of databases for advertising management systems requires evaluating criteria for performance, robustness, and scalability under different workloads. A recent comparative study that used JMeter to evaluate MySQL, Oracle, and PostgreSQL showed significant differences in average response times and transfer rates: MySQL presented the best time with 675 ms and 0.119 requests per second, followed by Oracle with 5553 ms and PostgreSQL with 10483 ms [19]. However, these metrics reflect a scenario of low concurrency and limited workload, so they should not be interpreted as absolute performance indicators for productive environments with high concurrency. Even so, PostgreSQL is distinguished by its capacity to handle complex data and its scalability, essential features for maintaining integrity and adaptability in high-volume transactional advertising environments. MySQL offers an interesting balance in response times, while Oracle provides stability and robust enterprise support. These differences justify the choice of databases that respond to specific project requirements and facilitate future scalability.

The selection of the programming language for advertising management systems requires evaluating the performance and enterprise scalability among the main alternatives. Recent comparative studies demonstrate significant differences in performance, where C# and Java take twice as long as system languages like C in computational tests, but are still many times faster than Python, positioning both Java and C# as superior options for high-performance enterprise applications. Benchmarks also reveal that Python remains one of the two most used scripting languages despite its poor performance [20], which represents a critical limitation for advertising management systems that require high-volume transactional processing. Java emerges as the most balanced option due to its combination of robust performance, enterprise maturity, and multiplatform versatility, especially when implemented with frameworks like Spring Boot that facilitate concurrent transaction handling. C# offers performance comparable to Java but presents greater dependence on the Microsoft ecosystem, while Python, although facilitating rapid development, lacks the necessary performance for enterprise implementations that demand high concurrency and intensive data processing.

B. System Architecture

The architecture of the proposed system, illustrated in Fig. 1, explicitly enforces modular boundaries across three layers: 1) the Presentation Layer, responsible for UI rendering through Thymeleaf templates and user interaction; 2) the Business Logic Layer, encapsulating transaction processing, role-based access control, and workflow orchestration through Spring Boot services; and 3) the Persistence Layer, managing data storage and integrity via Azure Database for PostgreSQL and local on-premise synchronization through Debezium CDC.

This architecture presents a distributed system of a hybrid nature that integrates cloud services with local infrastructure, designed to provide high availability, robust security, and horizontal scalability. The cloud environment is structured on the Microsoft Azure platform, where a modular monolithic backend developed in Spring Boot and Thymeleaf has been deployed. This configuration allows maintaining centralized business logic, but organized into independent modules that

facilitate system maintainability, scalability, and evolution. This approach was chosen due to its lower operational complexity compared to microservices, which simplifies the deployment and administration of the environment without sacrificing flexibility. Deployment on Azure App Service guarantees elasticity in resource allocation, while KeyVault acts as a centralized repository for managing secrets and credentials. In addition, the Content Delivery Network (CDN) optimizes the delivery of static resources, reducing latency and improving the end-user experience. To guarantee the security of critical data, an isolated subnet with network security groups hosts the PostgreSQL database, implementing multiple layers of perimeter security and role-based access control according to the principle of least privilege. On the other hand, the local infrastructure maintains operational autonomy through a dedicated database that synchronizes with the cloud environment through Apache Debezium as a change data capture (CDC) engine. This real-time synchronization preserves transactional integrity, while the Domain Name System (DNS) facilitates unified access by directing traffic to the appropriate services according to load-balancing policies. From an architectural point of view, the implementation follows the Hybrid Cloud Computing pattern, allowing the strategic distribution of workloads according to latency and data regulation criteria. Likewise, the Change Data Capture pattern is materialized through Debezium, providing automatic synchronization of changes between distributed environments and guaranteeing transactional integrity between both environments.

Fig. 1. Hybrid cloud architecture adopted for the system deployment.
(Source: own elaboration)

It is worth noting that the implemented solution involved the migration of a legacy module previously based on Power Builder scripts and an Oracle database to a modern stack using Java (Spring Boot), PostgreSQL, and Azure cloud deployment. This transition presented typical integration challenges, including data schema mapping between Oracle and PostgreSQL, the

replacement of procedural scripting logic with service-oriented components, and ensuring data continuity during the cutover period. The use of Apache Debezium as a CDC engine facilitated this transition by enabling real-time synchronization between the on-premise legacy database and the new cloud environment, minimizing operational disruption.

A critical aspect of the proposed architecture is its resilience to partial failures and operational continuity. Through the use of the Change Data Capture (CDC) component and an asynchronous replication strategy, the system ensures that the web application remains functional even in the event of interruptions in the local server. In such a scenario, registered orders are maintained in a persistent cloud buffer and automatically synchronized once connectivity is restored, eliminating the risk of transaction loss. Similarly, processing in the local infrastructure is not interrupted if the web application experiences latency, ensuring hybrid availability that strengthens data integrity throughout the entire order management flow.

A. DB Configuration

The database was configured using Azure Database for PostgreSQL, focusing on the definition of schemas and relationships that allow for efficient information management. Strategic indexes and integrity constraints were implemented to optimize query performance and ensure data consistency. Likewise, security practices were adopted to protect sensitive information, and the configuration was planned to facilitate scalability, considering the possible future expansion of the system and the need to maintain high availability.

B. System Development

The system has been designed and implemented under a modular and multilayer approach, with a service-oriented architecture that guarantees scalability, security, and ease of maintenance. For server-side logic, the Spring Boot framework was used, widely adopted in enterprise environments for its robustness and integration capacity. In the presentation layer, the use of Thymeleaf was chosen, allowing the dynamic generation of views integrated directly into the backend, which optimizes performance by avoiding unnecessary communication between client and server. Regarding data storage, the system connects to an Azure Database for PostgreSQL, which allows a fully managed database infrastructure in the cloud, eliminating the costs and complexities associated with physical server administration. This database not only hosts the information registered by system users but also acts as an integration point with the television company's internal database. To achieve efficient and real-time synchronization between both data sources, a replication service called CDC Replicator was developed, implemented in Spring Boot and integrated with the embedded Debezium connector. This application detects changes made in the local environment tables and automatically applies them to the cloud database, ensuring the coherence and availability of the information without the need for manual replication processes. The use of embedded Debezium allows processing change events directly within the application, dispensing with intermediate infrastructure based on Kafka. This approach offers a lightweight and efficient alternative for real-time synchronization of databases, maintaining data

coherence and consistency between the local and cloud environments. The entire ecosystem was developed with a view to its deployment on the Microsoft Azure infrastructure, which not only facilitates remote availability and continuous operational continuity of the system but also provides automatic scalability according to user demand. The system includes security mechanisms for access, session control, and backup policies, aligning with current software engineering standards in cloud-based solutions.

1) Access module: The authentication module was implemented using Spring Security, allowing secure and differentiated session login management according to the user's role. Through this mechanism, the credentials entered in the interface are validated, and the authenticated user is directed to the corresponding section of the system. The television channel, as the platform administrator, accesses functionalities related to order management and control, while advertising agencies exclusively access the sections that allow them to register requests, review their order history, and consult reports. This segmented access control mechanism not only guarantees the protection of sensitive data but also ensures a coherent and role-oriented user experience.

Role Differentiation and Access Control

The system only contemplates two clearly differentiated types of users:

- External users (advertising agencies), who can only access the modules related to order registration, visualization of the status of their campaigns, and report generation.
- Internal users (television channel administrators), with exclusive access to critical functions such as order review and approval, agency registration and management, and global system supervision.

The access control logic is managed by Spring Security, using a Role-Based Access Control (RBAC) approach, which ensures that each user can only interact with the functionalities relevant to their profile, thereby maintaining system security and traceability.

2) Advertising request registration module: This module constitutes the central piece of interaction for advertising agencies. From this section, agencies can register new requests for the broadcast of their advertising spots, indicating essential information such as the associated contract, the start and end date of the campaign, and the television block in which the broadcast is desired. This data is stored directly in the cloud database and, thanks to the integration with Debezium, can be automatically synchronized with the television company's internal programming system, without the need for manual intervention. This solution guarantees that the advertising blocks registered by the agencies are available in real-time for review and approval by the channel, ensuring efficiency and traceability.

The image shows a web interface for registering advertising requests. On the left is a blue sidebar with the 'Willax TV' logo and navigation links: 'Dashboard', 'Crear orden publicitaria', 'Resumen de orden', 'Mis órdenes', and 'Salir'. The main content area is a form with four sections: 'Cliente' (Nombre cliente), 'Contrato' (Selecciona un contrato), 'Producto' (Selecciona un producto), and 'Spot' (Selecciona un spot). Below these are 'Fecha registro' (29/06/2025), 'Mes' (Selecciona mes), and 'Programa' (Selecciona un programa). A large empty box labeled 'Hora / Día' is for time selection. A 'Guardar' button is at the bottom.

Fig. 2. Advertising request registration interface: The screen shows a form that allows you to create the advertising order registration request.
(Source: Own elaboration)

Fig. 2 shows the structured form through which agencies enter their campaigns, including contract, date, and television block fields.

3) *Advertising agency dashboard*: This initial interface is designed to facilitate navigation and provide relevant information in real-time, such as the number of orders in process and the consolidated status of previous requests. From this panel, the user can access a section for reviewing pending, accepted, or rejected orders, where the requests that have been created are listed. Fig. 3 shows the main panel that summarizes the status of the requests and the quantity of each status.

Fig. 3. General view of the advertising agency dashboard showing the distribution of advertising orders by status and client.
(Source: Own elaboration)

4) *Agency management module*: Intending to maintain flexible management of the actors interacting with the system, an exclusive module was implemented for the channel administrator, from which it is possible to register new advertising agencies, edit their data, and assign access credentials. This section was developed with server-side validation controls, ensuring the integrity of the records before being stored. The creation of agencies automatically implies the creation of an associated user with delimited permissions, which simplifies account administration and avoids duplication errors.

5) *Order approval and tracking module*: The system administrator has a centralized view that allows them to monitor all orders registered by the agencies. Requests can be filtered by status (pending, approved, or rejected) and viewed

in detail. From this section, the administrator has the capacity to approve or reject orders based on the real availability of the channel's programming, which can be consulted thanks to the synchronization with the operational database. The logic that regulates status changes was developed under a transactional approach, so that any modification is fully registered and automatically replicated to the company's database through the integration service with Debezium. Fig. 4 illustrates the order approval and tracking interface available to the channel administrator.

The image shows a table titled 'Órdenes Pendientes' with columns: ID, Cliente, Fecha, and Acciones. The table lists 10 pending orders from 'EMBOTELLADORA SAN MIGUEL DEL SUR S.A.C.' with dates ranging from 2025-06-27 to 2025-06-29. Each row has a 'Ver detalle' button. A blue sidebar on the left contains the same navigation menu as the other figures.

ID	Cliente	Fecha	Acciones
000007	EMBOTELLADORA SAN MIGUEL DEL SUR S.A.C.	2025-06-27	Ver detalle
000008	EMBOTELLADORA SAN MIGUEL DEL SUR S.A.C.	2025-06-27	Ver detalle
000010	EMBOTELLADORA SAN MIGUEL DEL SUR S.A.C.	2025-06-27	Ver detalle
000012	EMBOTELLADORA SAN MIGUEL DEL SUR S.A.C.	2025-06-28	Ver detalle
000013	0000496	2025-06-27	Ver detalle
000014	EMBOTELLADORA SAN MIGUEL DEL SUR S.A.C.	2025-06-28	Ver detalle
000015	EMBOTELLADORA SAN MIGUEL DEL SUR S.A.C.	2025-06-28	Ver detalle
000019	EMBOTELLADORA SAN MIGUEL DEL SUR S.A.C.	2025-06-29	Ver detalle

Fig. 4. Control panel for request approval: The screen allows reviewing orders entered by the agencies, with approval or rejection options.
(Source: Own elaboration)

6) *Advertising spot reports screen*: In this section, advertising agencies can visualize a detailed summary of their broadcast spots, showing key information such as the name of the spot, the program in which it was transmitted, the date and time of broadcast, as well as the number of times it has been played. Furthermore, to facilitate control and management, a button is included that allows downloading a report in PDF format with all this data, thus ensuring transparency and documentary support for the campaign. This functionality is designed to offer agencies quick and easy access to accurate information, promoting agile decision-making based on reliable data.

7) *System interface and relevant screens*: One of the most representative screens of the system is the one corresponding to the advertising request registration, which allows agencies to complete all the required fields to request the broadcast of their campaigns. This interface was designed under principles of simplicity and visual clarity, facilitating navigation and reducing the margin of error in data entry. Likewise, the administrative control panel screen is highlighted, where the channel can effectively manage the order flow, apply dynamic filters, and perform approval or rejection actions centrally.

8) *Final considerations*: The development of the system has followed guidelines of good practices in software architecture, use of modern technologies, and orientation towards the cloud. Integration with Microsoft Azure, along with the use of tools like Debezium for data synchronization, has allowed building a solid, reliable solution prepared to be used in real production environments. The use of Spring Boot, Thymeleaf, and Azure Database for PostgreSQL, as well as the

clear differentiation between user and administration modules, reinforce the fulfillment of the functional and non-functional objectives established at the beginning of the project. The system not only addresses the current needs of advertising management but also provides a robust basis for its continuous and sustainable operation.

Regarding deployment configuration, the application was hosted on Azure App Service using a Standard S1 tier instance. The build process was managed through Maven, and deployments were executed using Azure-provided CLI commands, enabling a controlled and semi-guided deployment process. The CDC Replicator runs as a standalone embedded Spring Boot application without container orchestration, as the current operational load does not require Kubernetes-level scaling. Secrets and credentials are managed through Azure Key Vault, ensuring that sensitive configuration data is never hardcoded in the application.

C. System Evaluation

To evaluate the system, pretest and posttest evaluations were used, meaning before the system implementation and after its implementation:

Advertising Order Entry Time: This is the average time it takes administrators to enter each order, which involves reviewing the information sent by the agencies and verifying it.

$$\text{Average time} = \frac{\text{Sum of order reports}}{\text{Total number of orders}} \quad (1)$$

Reduction of Operational Inputs: This is the decrease in costs associated with advertising order management, considering personnel, telephone calls, and printouts.

$$\text{Operational cost} = \text{Personnel} + \text{Calls} + \text{Printouts} \quad (2)$$

1) *Questionnaire to evaluate agency satisfaction:* A survey consisting of five questions was applied to the agencies that used the system to evaluate different criteria of use and satisfaction. The questions are described in Table II.

TABLE II. QUESTIONNAIRE FOR ADVERTISING AGENCIES

No.	Criterion	Statement
P1	Registration	How easy was it for you to register an order in the system?
P2	Interface	How intuitive do you consider the system interface to be?
P3	Control	How do you evaluate the control you have over your entered orders?
P4	Recommendation	How likely are you to recommend the system to other advertising agencies?
P5	General Satisfaction	How satisfied are you with the overall user experience?

^aSource: Own Elaboration

2) *Expert validation questionnaire:* The system validation was carried out by expert judgment, with the participation of three specialists from the television and technology sectors. For this purpose, a structured questionnaire was applied with evaluation criteria such as functionality, reliability, efficiency,

usability, and security, in order to assess the general performance of the system. The results obtained from these evaluations are presented in the Results section. The questionnaire items are described in Table III.

TABLE III. EXPERT VALIDATION QUESTIONNAIRE

No.	Criterion	Statement
P1	Functionality	Does the system adequately fulfill the functions of registering, processing, and managing orders?
P2	Reliability	Does the system maintain operational stability during order execution?
P3	Efficiency	Is the observed response time satisfactory?
P4	Usability	Does the system interface favor a fluid and comprehensible interaction for users?
P5	Security	Do the access controls and role assignment guarantee secure and restricted use of information?

Source: Own Elaboration

D. System Test

For the validation of the system in a real environment, a pilot test was conducted in a television company located in the city of Chachapoyas, Amazonas region, Peru. This company specializes in the transmission of audiovisual content and the management of advertising spaces for regional audiences. The pilot test involved the active participation of 10 advertising agencies that maintain regular commercial contracts with the television company, providing a diversified sample to evaluate the system's adaptability to different users and operational needs. The testing process included the participation of 3 key specialists: The System Administrator, responsible for the supervision and approval of advertising orders; the owner of the television channel, who provided the strategic and commercial perspective of the business; and an external Consultant specializing in Information Technology, who participated in the technical evaluation of the system. The pilot test was executed for a full week, a period during which advertising orders were registered and processed under real operational conditions, allowing the evaluation of both the system's technical performance and its impact on the company's administrative and commercial processes.

V. RESULTS

The results of the system tests are:

A. Advertising Order Entry Time

The analysis of advertising order entry time revealed substantial improvements in operational efficiency after the implementation of the digitized system. In the traditional manual process, order entry required the direct intervention of the sales administration area, which had to manually transcribe the information provided by the advertising agencies. The collected data showed that the average time required for manual entry of an advertising order was 17 minutes 16 seconds, with a total time of 2 hours 52 minutes 38 seconds to process 10 representative orders. As shown in Table IV.

TABLE IV. COMPARISON OF ADVERTISING ORDER ENTRY TIMES

Order	Before (mm:ss)	After (mm:ss)
1	20:15	2:05
2	17:32	2:01
3	15:47	1:59
4	15:21	2:03
5	19:05	1:58
6	17:18	2:00
7	16:44	2:02
8	17:09	2:04
9	17:51	1:57
10	15:36	2:00
Total	2:52:38	20:09
Average	17:16	2:01

Source: Own Elaboration

The implementation of the digitized system fundamentally transformed this process by allowing advertising agencies to directly enter their orders into the system, completely eliminating the manual transcription phase. This structural modification resulted in a dramatic reduction in processing time, establishing a new average of 2 minutes 1 second per order, with a total time of 20 minutes 9 seconds for the same set of orders. The comparative analysis reveals a reduction of 88.33% in the average processing time. To obtain this value, the average times were converted to seconds: before implementation, 17 min 16 s = 1036 s, and after, 2 min 1 s = 121 s. Applying the formula:

$$Reduction(\%) = \frac{1036-121}{1036} \times 100 = 88.33 \quad (3)$$

Demonstrates the significant decrease in advertising order entry time.

The implications of this improvement transcend the purely operational scope, as the reduction in processing time translates into an optimization of human resources and allows the reallocation of personnel to activities with greater added value. Additionally, the elimination of the manual transcription process substantially reduces the probability of human errors, improving the quality and accuracy of the data entered into the system, while direct entry by agencies strengthens their autonomy and improves the service experience.

B. Reduction of Operational Inputs

The evaluation of the reduction of operational inputs analyzes the decrease in costs associated with advertising order management, specifically considering administrative personnel, telephone calls, and printouts for the processing of 10 representative orders. In the traditional system, advertising agencies sent their order information via email, and the sales area printed these documents to facilitate the manual transcription of the data into the company's internal system. Additionally, the process required multiple telephone calls for verification and confirmation with advertising agencies, and maintaining administrative personnel dedicated exclusively to the transcription and control of the 10 orders.

- Administrative personnel: 2 people → US\$31.67

- Telephone calls: 15 calls → US\$3.00
- Printouts and ink: US\$ 0.30

With the implementation of the digitized system, advertising agencies directly enter their orders into the system, eliminating the need to print emails for transcription and significantly reducing telephone calls to exceptional cases only. The operating costs for the same number of orders were reduced to:

- Administrative personnel: 1 person → US\$15.83
- Telephone calls: 2 calls → US\$ 0.10
- Printouts and ink: US\$ 0.00

The total costs before and after digitalization were US\$34.97 and US\$15.93, respectively. The percentage reduction is obtained using the formula:

$$Reduction(\%) = \frac{34.97-15.93}{34.97} \times 100 = 54.5\% \quad (4)$$

This transformation reflects a reduction of 54.5% in operating costs (a saving of US\$19.04 for every 10 orders processed), representing a significant optimization in the use of operational inputs and contributing both to economic efficiency and the better use of human and material resources in the advertising order management process.

C. Reduction of Transcription Errors

The evaluation of transcription errors constitutes a critical indicator of the quality and reliability of the advertising order entry process. In the traditional system, advertising agencies submitted their order information via email in various digital formats. Subsequently, the sales area printed these documents and manually transcribed the data into the television company's internal system. This sequential process introduced multiple points of failure, generating 60% of errors out of the total analyzed records, caused by typographical errors during data entry. The implementation of the web system eliminated this workflow by granting advertising companies direct access to the registration of advertising order requests. This transformation allows agencies to enter their requests directly into the corporate system, eliminating the intermediate phases that were the main generators of errors. The system incorporates automatic validation mechanisms, fields with predefined formats, and real-time verifications that ensure data integrity from the moment of initial capture. The results obtained show a 100% reduction in transcription errors, reaching 0% of incidents in the digitized process. This improvement represents not only an optimization in data accuracy but also the complete elimination of operating costs associated with corrections, subsequent verifications, and rework that previously demanded considerable administrative resources. The elimination of transcription errors strengthens the reliability of the corporate information system and allows sales personnel to focus on commercial and management activities of greater strategic value for the organization.

D. Automated Report Generation

The process of report generation and delivery experienced a significant transformation with the implementation of the digitized system. In the traditional model, transmission reports were automatically generated through batch processes

approximately between 12:00 and 1:00 AM, but their distribution to advertising agencies required constant manual intervention by the sales administration area during subsequent business hours. This process involved individual searches, manual compilation of information, and personalized sending for each agency and its respective clients, generating considerable delays. The digitalization of the system introduced an automated access mechanism that eliminates the manual management phase in report delivery. The reports continue to be generated automatically through the established batch process with the previous day's information, integrating directly into the web system, where advertising agencies can access the reports without requiring requests to administrative personnel. This automation not only accelerates the consultation process but also allows access to complementary information relevant to the agencies' commercial management. The results show a substantial improvement in process efficiency, significantly reducing the time elapsed between report generation and their availability for consultation by advertising agencies.

E. Questionnaire Results

The qualitative evaluation using a Likert scale reflected a positive assessment by advertising agencies, although with aspects that show opportunities for improvement. The results showed averages of 3.5 in ease of order registration, which indicates that, as a new system, it still requires a period of adaptation by users. In contrast, the intuitiveness of the interface obtained 4.1, highlighting the good perception of the design and ease of navigation. Control over entered orders reached an average of 3.9, showing confidence in the tracking of requests. Likewise, the recommendation of the system to other agencies registered a score of 4.0, which reflects favorable acceptance. Finally, general satisfaction with the user experience reached 3.5, which suggests an overall positive experience, although with a margin for improvement in the initial learning curve, as shown in Table V.

TABLE V. RESULTS OF THE ADVERTISING AGENCIES QUESTIONNAIRE

Agency	P1	P2	P3	P4	P5
A1	4	5	4	5	4
A2	3	4	4	4	4
A3	5	5	5	5	5
A4	4	4	3	4	4
A5	3	4	4	3	3
A6	3	4	4	4	3
A7	4	3	4	4	3
A8	3	4	4	4	3
A9	3	4	3	4	3
A10	3	4	4	3	3
Average	3.5	4.1	3.9	4.0	3.5

Source: Own Elaboration

The three participating experts—the system administrator, the channel owner, and an external IT consultant—positively evaluated the established criteria for the validation of the developed system, as observed in Table VI. The analysis of the results shows that system efficiency obtained the highest rating with an average of 4.3, highlighting the significant improvement

in processing times and the optimization of operational resources. The reliability and security of the system reached averages of 4.0 each, showing confidence in the stability and data protection of the implemented platform. System functionality registered an average of 3.7, indicating a favorable evaluation, while usability obtained 3.3, identifying opportunities for improvement in the user experience that require attention to optimize system adoption.

TABLE VI. RESULTS OF THE EXPERT JUDGMENT QUESTIONNAIRE

Criteria	E1	E2	E3	Average
Functionality	4	3	4	3.7
Reliability	4	3	5	4
Efficiency	5	4	4	4.3
Usability	3	3	4	3.3
Security	4	3	5	4

VI. DISCUSSION

Before the implementation of the digitized system, the manual registration of 10 advertising orders presented a transcription error rate of 60%, attributable to the human data entry process. After enabling direct entry by agencies in the automated system, this rate was reduced to 0%, completely eliminating transcription errors thanks to automatic validation and real-time control mechanisms. This improvement is consistent with the findings of [5], which highlights the importance of implementing web platforms with modular architectures to automate processes, reduce human errors associated with manual methods, and improve accuracy in the registration of business data.

Regarding temporal efficiency, the 88.33% reduction in order entry time (from 17:16 to 2:01 minutes per order) demonstrates a substantial operational improvement. This result is comparable to the findings of [8], where process automation through web systems achieved a usability score of 89%, showing that digitalization significantly improves operational efficiency in personalized services. Similarly, automation in report delivery eliminated manual management, allowing agencies direct access to their campaign information. These results are consistent with [7], which demonstrated that processes with greater structural modularity provide significant advantages in terms of operational efficiency, achieving reductions of 51% in manufacturing times.

Furthermore, the results obtained are aligned with [9], which highlights the importance of integrating technological solutions in television advertising to improve the analysis and management of campaigns. While [9] focuses on measuring the impact of television advertising on digital user behavior, the present study complements this approach by optimizing the operational management of advertising orders, contributing to a more efficient and integrated advertising workflow.

On the other hand, the 54.5% reduction in operating costs (a saving of US\$19.04 for every 10 orders) shows comparable improvements with [10], where a 28.4% reduction in operating costs was achieved through modular artificial intelligence

systems. However, the developed proposal achieved resource optimization by eliminating printouts, reducing telephone calls, and optimizing administrative personnel without requiring complex artificial intelligence technologies, which represents an advantage in terms of simplicity of implementation and development costs. Additionally, the implemented workflow transformation is consistent with the findings of [6], which highlight the importance of cloud computing for improving the operational efficiency and scalability of small and medium-sized enterprises. The implemented solution uses Azure cloud infrastructure and eliminates manual intervention in the entry process, establishing an automated flow from registration to report generation. This cloud-based architecture facilitates the operational scalability necessary to support growth in the television advertising sector, allowing adaptation to variable demand volumes without requiring significant investments in physical infrastructure.

Despite the positive results obtained, the study presents important limitations. The pilot test was conducted with 10 advertising orders, consistent with the company's daily operational volume, estimated at approximately 34 orders per day based on pre-implementation processing times. However, this does not allow for definitive conclusions regarding system performance under significantly higher transaction volumes. No fault-injection experiments were conducted to formally evaluate system resilience under simulated failure scenarios such as network disruptions or service unavailability. Additionally, the evaluation period was limited to one week, and seasonal variability in advertising demand was not considered, which could reveal operational characteristics not detected during controlled testing.

From a long-term maintainability perspective, the architecture supports gradual evolution toward CI/CD pipelines and containerized environments as demand grows, balancing current simplicity with future scalability while minimizing unnecessary technical debt. Daily automated backups on Azure Storage and biweekly preventive maintenance cycles further support system continuity.

VII. CONCLUSION

The developed system effectively solves the problem of manual advertising order management that the company faced, characterized by transcription errors, excessive processing times, and dependence on manual management at multiple stages of the operational process. The implementation of the automated web platform eliminated manual, error-prone processes and established a structured workflow that guarantees the integrity and tracking of orders from their creation to their final processing.

The results obtained demonstrate the significant effectiveness of the implemented solution. Transcription errors were eliminated, reducing incidents from 60% to 0% through direct entry by advertising agencies. The automation of the flow allowed for an 88.33% reduction in order entry time, decreasing from 17 minutes 16 seconds to 2 minutes 1 second per order, while the optimization of operational inputs generated a saving of 54.5% in associated costs. Additionally, the automation in report generation eliminated the dependence on manual

management, allowing direct access for agencies to the information about their advertising campaigns.

The web application based on cloud computing provides the necessary scalability and availability to support the future growth of operations, establishing a solid technological base for the expansion of functionalities in the television sector. The implemented modular architecture facilitates the incorporation of new functionalities and the adaptation to different business contexts in the advertising sector.

In summary, the developed model transforms advertising order management from an inefficient and error-prone manual process toward an automated, precise, and scalable operation, fulfilling the objectives set and establishing the bases for future operational improvements in the television advertising sector.

While the solution was validated within the specific context of a regional television company, the modular architecture and cloud-based approach are potentially transferable to other media and advertising sectors, including radio broadcasting, digital media platforms, and event management companies, provided that their operational workflows involve order registration, approval processes, and automated reporting requirements.

ACKNOWLEDGMENT

Thanks to the Dirección de Investigación of the Universidad Peruana de Ciencias Aplicadas for their support in carrying out this research work through the UPC-EXPOST-2026-1 incentive.

ETHICAL APPROVAL

The study focused on the technical validation and evaluation of the operational efficiency of a web application for advertising order management. The pilot test was conducted with the voluntary participation of external advertising agencies and internal staff of the television company. The process utilized operational and simulated data, and no sensitive, clinical, or confidential personal information from the individual participants was collected; only data strictly related to system performance (processing times, transcription errors). Since the research did not involve the collection of identifiable personal data or expose participants to risks, formal ethical approval was not required. However, the entire investigation adhered to the general ethical principles of transparency, confidentiality of the agencies' commercial information, and the respectful treatment of all participants.

INFORMED CONSENT

Before the pilot test began, the 10 participating advertising agencies and administrative staff were informed about the study's objective: to evaluate improvements in the efficiency of advertising order management. They were provided a clear explanation regarding the system's use, the nature of the data to be recorded (advertising orders and time metrics), and the anonymity of the qualitative responses (satisfaction surveys) was guaranteed. Consent to participate in the usability and performance test was granted voluntarily by each agency and specialist, with the understanding that their participation did not involve risk and that they could withdraw from the study at any time.

DISCLOSURE STATEMENT

The authors report there are no competing interests to declare.

DATA AVAILABILITY STATEMENT

The data that support the findings of this study are openly available in the Open Science Framework (OSF) at: <https://doi.org/10.17605/OSF.IO/7CXJB>.

Dynamic Multilevel User Allocation in MEC Using CESO for Resource Efficiency and QoE

V Arun*, M Azhagiri

Department of Computer Science and Engineering, SRM Institute of Science and Technology, Ramapuram,
Chennai, Tamil Nadu, India

Abstract—Mobile Edge Computing (MEC) has become one of the key paradigms to enable next-generation networks in supporting applications that are latency sensitive and computation-intensive. Nevertheless, the resourceful placement of heterogeneous and dynamically incoming user tasks with distributed edge servers is a problematic issue to be achieved because of network fluctuation, non-uniform resource availability, and variance in Quality of Experience (QoE) demand. To overcome these constraints, this study suggests the Dynamic Multilevel User Allocation Algorithm (DMUAA) that incorporates a new Cognitive Evolutionary Synergy Optimization (CESO) framework in order to reach stable, adaptive, and resource-optimizing allocation in real-time. DMUAA means a hierarchical optimization pipeline that consists of heuristic initialization, stochastic refinement, and strategic game-theoretic equilibrium assisted by a coordination and feedback mechanism that guarantees the constant adaptation to variations in user mobility and load. The system model collaboratively optimizes the latency, energy, resource, and QoE under the multi-constraint edge-server conditions. Extensive simulations over a wide range of resource capabilities, user rates, and mobility patterns indicate that DMUAA can be greatly superior to five state-of-the-art baselines, which are the MGGO, GTA, EUA, HAILP, and LGP. Findings indicate that DMUAA decreases average end-to-end latency by 18-34%, increases Resource Utilization Efficiency (RUE) by 12-27%, and increases Service Continuity Rate (SCR) by 15-30% over the current practices. The solved approach also produces 20-35% greater QoE, better load balancing (with up to 25% reduced LBI), and up to 22 per cent greater energy-QoE efficiency (EQR). Moreover, CESO allows for more rapid and stable convergence, and DMUAA comes to optimal allocation states 40-55% quicker than competing algorithms.

Keywords—Mobile Edge Computing; distributed edge server; Quality of Experience; Cognitive Evolutionary Synergy Optimization; game-theoretic equilibrium

I. INTRODUCTION

Mobile Edge Computing (MEC) has become an essential architectural paradigm in contemporary distributed networks, which allows the end users to bring computation, storage, and intelligence nearer. As the number of latency-sensitive applications, including autonomous navigation, extended reality (XR), smart healthcare monitoring, industrial internet of things automation and mission-critical cyber-physical systems continue to grow, the ineffectiveness of traditional cloud-centric computing is becoming more pronounced [1]. MEC offers quite a fast solution to communication delays, backbone congestion and Quality of Experience (QoE) to

users working in dynamic and resource-constrained settings by deploying computation at the network edge [2]. With the ongoing development of 5G and beyond-5G networks, MEC has become a fundamental part of highlighting the concept of massive device connectivity, guaranteeing an ultra-reliable low-latency communication (URLLC) and facilitating real-time analytics at scale. Although MEC environments are paradigm-shifting, they have a number of inherent challenges that act against their potential [3]. First, user demands are heterogeneous, and their latency sensitivities, energy levels, and mobility patterns vary, thus making it extremely difficult to solve task offloading decisions. Second, the fragmentation and imbalance of resources across distributed edge servers tend to cause inefficiency in using them, overloading servers or underutilizing the available computing capacity. Third, the volatility of wireless channels, the changing network conditions and the changing arrival rates of tasks demand constant adaptation in allocation choices that cannot be managed effectively by traditional models of optimization that are kept at a single stage or at a single point in time. Moreover, the realization of high QoE ensures and reduces energy consumption brings about a multi-objective trade-off that is rather difficult to solve in both large-scale or dynamic MEC topology [4-6]. Lastly, the stability, fairness and convergence in the allocation strategy are still a major challenge to be worried about because of the interaction between user competition, limited-edged resources, and decentralization of decision-making processes. These issues demonstrate the necessity of a multi-level, and adaptive allocation framework that is intelligent and able to tackle the complexity of the MEC ecosystems in its essence [7].

The complexity and heterogeneity of contemporary MEC environments leads to the incentive to have a more intelligent and adaptive user allocation strategy. The current allocation methods, such as heuristic scheduling, mathematical programming, meta-heuristic scheduling, and game-theory-based methods, are frequently unable to respond to swift changes in the user mobility, dynamic workload profiles, and uneven resource distributions across edge servers. Most modern methods are based on the assumption of static optimization, restricted feedback fusion, or one-stage decision processes, leading to inefficient allocation, large latency, and energy wastage, as well as unpredictable behavior in actual conditions. These constraints are magnified with increase in device densities and the presence of computationally intensive cost of such services within cities that are smart, autonomous systems, and industrial deployments [8]. The necessity of scalable and responsive approach that could continuously

adapt to change of environmental conditions is the root cause of motivation of this research. In addition to those issues, the main idea of this study is to construct a solid and multi-tiered allocation system that guarantees effective, equitable, and Quality of Experiences-based distribution of user workload among diverse edge servers. In particular, the following objectives are aimed at: 1) minimizing end-to-end latency and power usage under dynamic network scenarios, 2) better utilization and load balancing of resources among distributed servers, 3) steady and equitable allocation by equilibrium-based decision-making, and 4) fast convergence and self-adaptation by using an iterative, feedback-constrained optimization. All these aims are aimed at the creation of an improved allocation system that can overcome the fundamental constraints of the current edge computing systems.

This study presents the Dynamic Multilevel User Allocation Algorithm (DMUAA), which is a comprehensive and adaptive framework aimed at addressing the clear drawbacks of the available edge user-allocation approaches. This work has been novel in that it incorporates the Cognitive Evolutionary Synergy Optimization (CESO) paradigm - a three-stage optimization pipeline which synergistically integrates heuristic reasoning, stochastic exploration, and strategic game-theoretic equilibrium. In contrast to non-dynamically changing allocation methods, such as traditional single-phase systems or non-dynamically changing approaches, DMUAA can update allocation decisions in real-time using resource dynamics, QoE dynamics and real-time feedback, facilitating the achievement of better adaptability in the context of very volatile MEC environments. The integration of a well-organized coordination layer and closed-loop feedback mechanism provides the framework with an extra boost of ensuring a coherent optimization of all stages and a quick stabilization process under a changing workload. The key contributions of this research can be summarized as follows:

- A novel multilevel allocation architecture that unifies fast heuristic initialization, probabilistic refinement, and equilibrium-driven stabilization to provide robust and dynamic user-server mapping.
- A state-aware CESO optimization engine that ensures scalable, diversified, and convergence-guaranteed decision-making.
- A comprehensive system model that jointly optimizes latency, energy, QoE, and resource fairness through multi-objective constraints.
- Large comparative analysis showing that DMUAA is much better than five state-of-the-art baselines in terms of latency, QoE, energy efficiency, load balancing, scalability, and convergence rate.

Despite significant advances in user allocation strategies for mobile edge computing, existing approaches often focus on either heuristic efficiency, stochastic exploration, or strategic stability independently, limiting their ability to simultaneously achieve high resource utilization, stable QoE, and scalability under dynamic conditions. Therefore, the

central research question addressed in this study is: How can a dynamic multilevel user allocation framework be designed to jointly optimize resource efficiency, QoE, and system stability in Mobile Edge Computing environments under varying workloads and user mobility? To answer this question, this work proposes a Dynamic Multilevel User Allocation Algorithm (DMUAA) integrating a Cognitive Evolutionary Synergy Optimization (CESO) process that combines adaptive allocation, stochastic refinement, and equilibrium-driven decision-making within a unified framework. These contributions, taken together, make DMUAA a scalable, powerful, and QoE-driven solution to next-generation MEC environments.

The rest of the study has the following structure: Section II draws a related literature review on edge user allocation, which identifies methods of existing heuristic, meta-heuristic, and game-theoretic methods. Section III outlines the suggested Dynamic Multilevel User Allocation Algorithm (DMUAA) in detail, system model, architectural design, as well as the CESO-based multilevel optimization process. Section IV presents the experimental findings, results of performance comparison, and analysis insights of five state-of-the-art methods. Section V summarizes the main conclusion of the research and outlines the possible future research directions in scalable and intelligent management of MEC resources.

II. RELATED WORKS

Mobile Edge Computing (MEC) has become an important concept, to facilitate the provision of offloading computation with low-latency, energy efficiency, and quality of experience (QoE) to a large number of users. Nevertheless, the heterogeneity of edge servers as a given fact, together with the high dynamism of user mobility, changing task distributions, intermittent access to resources, and unpredictable communication circumstances, renders the allocation problem of users highly demanding. Most conventional solutions of the MEC are typically based on past optimization methods, single-level models of decision, or greedy methods that do not address changes in network conditions in real time [9]. Even more advanced meta-heuristic or game-theoretic techniques have been found to be limited with respect to the handling of rapidly changing workload, probabilistic arrivals of the tasks, and multi-objective trade-offs among QoE, latency, energy usage, and load balancing. More recent studies have tried to solve some of the parts of the problem of user allocation in the MEC, including reducing the energy use, maximizing throughput, optimizing the selection of servers or stabilizing user-server mapping based on strategic rationale. Regardless of these developments, the majority of solutions that exist are still facing a problem with scalability, slow convergence, failure to provide continuous adaptation, and inability to incorporate real-time feedback of changing network states [10]. Such consistent gaps drive the design of a highly developed, multi-layered, cognitively directed optimization framework with the capacity to provide consistent and efficient allocation decisions in varied MEC operating scenarios.

The study of edge user allocation (EUA) and computation offloading has taken a variety of methodological paths, each

trying to solve the chain of interaction of latency, resource constraints, mobility, and QoE. The leading solution families are meta-heuristic optimization, game-theoretic allocation, mathematical programming, and learning-based methods, which are all inherently limited in their applicability to dynamic MEC systems. The use of meta-heuristic optimization has also received a great deal of interest because it allows dealing with nonlinear, multi-objective allocation problems. Khosrowshahi et al. [11] developed this direction, introducing an adaptive partitioning and stagnation detection to improve exploration, the Modified Greylag Goose Optimization (MGGO). Although MGGO increases the latency and energy indicators, its performance is sensitive to parameter optimization, and under unstable network conditions, its convergence is not guaranteed. Likewise, Tingting et al. [12] used the Fruit Fly Optimization Algorithm (EUA-FOA) to optimize user admission and minimize server activation, but the proximity and capacity-based model of this algorithm neither considers the dynamics of QoE nor the stability of the equilibrium, which restricts its applicability to real-time user mobility.

A second key type of research develops EUA as a strategic interaction between users and servers based on the equilibrium analysis. Hou et al. [13] came up with a multi-hop game-theoretic allocation model (GMUA) and established the existence of equilibrium, yet its convergence rate decreases with user density. Xuyun et al. [14] also constructed EUAGame, a possible game structure that would allow decentralized allocation, but its quality of equilibrium is limited by the formulation of the game and does not consider how to deal with stochastic or bursty demand models. Zhou et al. [15] generalized game theory to fairness-sensitive applications with FEUAGame; though this method offers guarantees of fairness at the cost of responsiveness, especially in highly-loaded systems. In contrast to game-theoretic methods, mathematical programming has been studied in order to represent the combinatorial aspects of EUA. Phu et al. [16] proposed a formulation of an Integer Linear Programming (ILP) with the QoE-based constraints. Despite its correspondence to small-scale situations, ILP can quickly be intractable as the size of the system increases, leading to heuristic relaxations that compromise optimality. Qiang et al. [17] modeled EUA as a bin-packing problem based on Lexicographic Goal Programming (LGP); the model is structured and interpretable, but based on the static optimization assumptions and with poor adaptation to real-time. In the near past, learning-based and hybrid intelligent models have been presented to learn long-term trends, multi agent dynamics and nonlinear rewards. Li et al. [18] capitalized on deep reinforcement learning (DRL) to optimize the decisions of NOMA user grouping and offloading, which exhibited significant performance improvement at the expense of high training cost. Heidari et al. [19] introduced the lightweight RL model that is accelerated using CNNs, but its use is limited because it relies on the device-side computation. Liu et al. [20] scaled DRL to multi-objective multi-UAV-MEC systems based on Double/Dueling DQNs, but which demand large state representations and training sets, which limits their applicability to dense deployment of terrestrial MEC systems.

There are other works that have attempted to deal with system-level dynamics by more specific mechanisms. Tian et al. [21] established a response-ratio offloading strategy (RROS) which is user preference-guided, but its greediness in prioritization gets congested locally. Baskar et al. [22] suggested a hybrid Prairie dog -Dwarf Mongoose meta-heuristic that achieves better exploitation-exploration balance at a significant computational cost. Guangming et al. [23] came up with OL-EUA, which is an online method of allocating resources to NOMA systems but its workability falls short in regimes with sudden contention of resources or when tasks have heavy tails. Chen et al. [24] followed a Lyapunov-based long-term optimization method coupled with distributed game theory, which has good theoretical grounds, but models must assume stationarity which is difficult to satisfy in highly dynamic MEC networks. History-assisted user allocation (HOUA) was proposed by Bowen et al. [25], but due to the use of past patterns, it is not flexible enough to work in the fast-changing conditions. Through the variety of solution families one can see, however, a similarity: current solutions to the problem of MEC user allocation are partial. Meta-heuristics are good at searching through extensive search spaces but not convergence stable; game-theoretic and mathematical models are stable but can scale poorly or can be non-adaptive; learning-based strategies are long-term optimizing, but incur very high computational costs and slow convergence. None of them offers an integrated, multi-level, feedback-based, dynamically convergent architecture that can help to balance latency, QoE, resource fairness, energy efficiency, and equilibrium stability in MEC conditions that vary rapidly.

The literature review indicates that despite the tremendous achievement by MEC user allocation, there are still some gaps that are vital to the effectiveness of current solutions. In the current methods, the optimization mechanisms are largely single-phase optimization, whether heuristic, meta-heuristic, mathematical programming, or game-theoretic. This type of standalone strategies does not fully reflect the multi-dimensionality of the allocation problem, which requires quick generation of feasibility and more refinement before settling at an equilibrium point. Moreover, since integration of real time feedback is not available then most models are not well suited to dynamic changes in mobility of users, workload bursts or variability of resources- environments that characterize real MEC implementations. Meta-heuristic algorithms do not tend to converge well, whereas game-theoretic models, despite being theoretically sound, slow to converge, or rely on constraining assumptions such as fixed load distributions, or idealistic user behavior. The second important weakness is that they do not optimize multi-objectives as most of the previous research tends to optimize latency, energy, or user experience but rarely all of them within one framework. Scalability is also an issue: ILP-based models are computationally infeasible in large-scale systems, DRL-based strategies are too slow to train with large-scale systems, and complicated hybrid heuristics are also computationally expensive. Lastly, there is no current literature that shows a cognitive or evolutionary synergy model that incorporates heuristic thinking, search by stochastic methods and equilibrium-seeking behavior in a coordinated and hierarchical

process. As a combination of these gaps, there is a need to consider a more adaptive, multi-stage, feedback-based, and equilibrium-focused user allocation approach.

The proposed Dynamic Multilevel User Allocation Algorithm (DMUAA) addresses the shortcoming of the current MEC strategies by a cognitively-inspired, evolutionary coordination design optimization. Simply put, Cognitive Evolutionary Synergy Optimization (CESO) framework is an integrated process comprising three complementary steps: 1) a heuristic step during which an initial feasible allocation baseline is quickly achieved; 2) a stochastic refinement step during which greater diversity is achieved and local optima are avoided; and 3) a strategic equilibrium step during which a fair and game-theoretically stable allocation equilibrium is obtained. Unlike the previous single-stage or ad hoc models, DMUAA uses a feedback system that modulates the decisions in real-time depending on the QoE variations, mobility variations as well as resource variation. The unified formulation jointly optimizes latency, QoE, energy usage, and load balance, while its hierarchical structure ensures scalability and robust convergence.

III. PROPOSED FRAMEWORK

The proposed DMUAA framework resolves the critical issues of the user allocation and the resource use optimization in edge computing conditions, when the user demands are in heterogeneous, the network conditions are dynamic, and the computational resources are limited. The framework embraces a multilevel structured design that conveniently incorporates autonomous decision-making, adaptive optimization, and continuous feedback to improve the overall system operation and the Quality of Experience (QoE). DMUAA is an entity that is based on a layered architecture that consists of four main functional layers namely the User Device Layer, Edge Server Layer, Optimization Layer and Coordination Layer, illustrated by Fig. 1. The various layers have their roles, unique but interdependent, to coordinate a unified pipeline that takes care of the entire user allocation lifecycle, through request generation to the performance feedback. The User Device Layer has heterogeneous end-user devices (smartphones, IoT nodes and sensors) that place service requests, with each request having distinct computational and latency needs. These requests are sent to the Edge Server Layer where edge servers are located geographically which process and store data at locations near the point of demand and considerably improve response time and reduction of backbone network congestion [26]. This layer includes a Resource Manager which dynamically monitors server load and availability and a QoE Monitor which measures user satisfaction and system responsiveness to generate a real time performance map of the edge environment.

DMUAA is computationally founded on the Optimization Layer. It uses a Cognitive Evolutionary Synergy Optimization (CESO) that gradually anneals the user-server allocations through a sequence of intelligent decision makings. Initial hurricane plans are meant to yield instant and realistically feasible allocation base that can ensure the stabilized operation in the short run. This baseline is then optimized over with probabilistic and adaptive optimization logic that tries to

explore other combinations, and thus leads to increased diversity in the system and eliminates suboptimal convergence. Finally, a strategic decision mechanism can stabilize at equilibrium which is equitable and maximization on resources is appropriate across all users and servers. Such a hierarchical optimization approach enables DMUAA to balance the allocation accuracy and computation efficiency. And most importantly, there is the Coordination Layer, which governs the flow of decisions and guarantees the system consistency over and above the optimization process. The User Allocation Coordinator is the one who coordinates the activities of a group of optimizers and each stage of optimization is duly grounded on the previous phase. Decision Aggregator chooses the outcome of the different optimization steps and the final allocation will be the one that will optimize the system objectives in resource efficiency, the minimization of the latency and the maximization of the QoE. A Feedback loop is a performance data and user experience feedback received continuously and fed back into the optimization pipeline to enable the optimization pipeline to adjust to new network conditions or user mobility. In simple terms, the DMUAA framework offers dynamic relationship between the system-level coordination mechanisms and the intelligent optimization modules. In multilevel decision processing coupled with incentive continuous performance feedback, DMUAA ensures that user allocations will become global optimum and QoE-optimal. This architecture together with scaling and responsiveness also enables the framework to be healthily operating in highly dynamic and resource limited edge computing environments.

Fig. 2. Overall architecture of the Dynamic Multilevel User Allocation Algorithm (DMUAA).

A. System Model and Problem Formulation

The system model for the proposed Dynamic Multilevel User Allocation Algorithm (DMUAA) is designed to represent a realistic mobile edge computing (MEC) environment comprising distributed edge servers and dynamically interacting user devices [27]. The framework aims to optimize user-to-server allocation while minimizing resource contention, latency, and energy consumption, thereby enhancing overall Quality of Experience (QoE), as shown in Fig. 2. Let there be a set of n users and m edge servers denoted as $U = \{u_1, u_2, \dots, u_n\}$, $S = \{s_1, s_2, \dots, s_m\}$. Each user $u_i \in U$ generates a computational task characterized by its resource demand vector: $\omega_i = [\omega_i^{cpu}, \omega_i^{mem}, \omega_i^{bw}]$, where ω_i^{cpu} , ω_i^{mem} , and ω_i^{bw} denote the CPU cycles, memory space, and bandwidth required for the task execution, respectively.

Each edge server $s_j \in S$ possesses a finite resource capacity vector: $\tau_j = [\tau_j^{cpu}, \tau_j^{mem}, \tau_j^{bw}]$, representing its maximum available resources. A binary allocation variable is defined as in Eq. (1). To ensure feasibility, each user can be allocated to only one edge server within its communication range, expressed as in Eq. (2):

$$x_{ij} = \begin{cases} 1, & \text{if user } u_i \text{ is allocated to edge server } s_j, \\ 0, & \text{otherwise.} \end{cases} \quad (1)$$

$$\sum_{j=1}^m x_{ij} \leq 1, \forall i \in \{1, 2, \dots, n\}. \quad (2)$$

Each edge server's total allocated resource utilization must not exceed its available capacity, as defined in Eq. (3); this ensures that no server is overloaded across any resource dimension. For each user u_i allocated to edge server s_j , the

end-to-end latency L_{ij} can be expressed, as in Eq. (4); where: L_{ij}^{tx} is the transmission delay between u_i and s_j , $L_{ij}^{proc} = \frac{\omega_i^{cpu}}{f_j}$ is the processing delay based on the server's computation frequency f_j , L_{ij}^{queue} denotes the queuing delay at the server caused by concurrent task arrivals. The transmission delay is computed as defined in Eq. (5); where D_i represents the data size of the user request, B_{ij} is the allocated channel bandwidth, and γ_{ij} is the signal-to-noise ratio (SNR) between user u_i and server s_j .

$$\sum_{i=1}^n \omega_i^r x_{ij} \leq \tau_j^r, \forall j \in \{1, 2, \dots, m\}, r \in \{cpu, mem, bw\}. \quad (3)$$

$$L_{ij} = L_{ij}^{tx} + L_{ij}^{proc} + L_{ij}^{queue}, \quad (4)$$

$$L_{ij}^{tx} = \frac{D_i}{B_{ij} \cdot \log_2(1 + \gamma_{ij})}, \quad (5)$$

The energy consumed by a user during task offloading is given by: $E_{ij} = P_{ij}^{tx} \cdot L_{ij}^{tx}$, where P_{ij}^{tx} is the transmission power of user u_i . The total energy consumption of all users in the system is defined in Eq. (6). The QoE for each user depends on response latency, energy efficiency, and service satisfaction. It can be modeled as defined in Eq. (7), where: L_{max} and E_{max} denote maximum tolerable delay and energy levels, S_{ij} represents a satisfaction index derived from service reliability and data rate, $\alpha_1, \alpha_2, \alpha_3$ are weighting factors ($\alpha_1 + \alpha_2 + \alpha_3 = 1$) reflecting user sensitivity toward delay, energy, and satisfaction. The total system QoE is then given by Eq. (8):

$$E_{total} = \sum_{i=1}^n \sum_{j=1}^m E_{ij} x_{ij}. \quad (6)$$

$$Q_i = \alpha_1 \cdot \left(1 - \frac{L_{ij}}{L_{max}}\right) + \alpha_2 \cdot \left(1 - \frac{E_{ij}}{E_{max}}\right) + \alpha_3 \cdot S_{ij}, \quad (7)$$

$$Q_{total} = \sum_{i=1}^n \sum_{j=1}^m Q_i x_{ij}. \quad (8)$$

The main goal of DMUAA is to ensure maximum overall system QoE and a minimum number of active edge servers and resource balance. The optimization problem can be stated formally as Eq. (9), where C_{active} denotes how many servers are being used and serve users at the moment and C inactive denotes the servers that are not in use. The formulation provided above is an NP-hard and multi-objective optimization problem with discrete allocation variables and non-linear user-server dependencies. To overcome this difficulty, DMUAA uses a multilevel adaptive optimization procedure with heuristic initialization, stochastic experimentation and strategic stabilization processes interactively approximating to an efficient and stabilized solution.

$$\text{Maximize: } F = \frac{Q_{total}}{C_{active}}, \quad (9)$$

subject to Eq. (10):

$$\begin{cases} \sum_{i=1}^n \omega_i^r x_{ij} \leq \tau_j^r, & \forall j, r, \\ \sum_{j=1}^m x_{ij} \leq 1, & \forall i, \\ x_{ij} \in \{0, 1\}, & \forall i, j, \end{cases} \quad (10)$$

B. Architecture Design of DMUAA

1) *User Device Layer*: The User Device Layer constitutes the interface of the system, which includes distributed heterogeneous user terminals, which include smartphones, IoT sensors, and autonomous devices. Such devices will never cease requesting computational and service requests that demand low-latency and high Quality of Experience (QoE). The devices send their request packets to the closest edge server using the network proximity and signal strength and the parameters of the request, such as task size τ_i , latency tolerance L_i , and priority weight ω_i . The layer also provides mobility management that is dynamic, such that the user devices can easily move between edge servers without service disruption. It also has a small local cache to store temporary data on intermediate tasks in transition of the allocation.

2) *Edge Server Layer*: The Edge Server Layer represents the computational backbone of DMUAA. It consists of distributed edge servers $S = \{s_1, s_2, \dots, s_m\}$ located near end-users. Each server provides compute capacity C_j , bandwidth B_j , and storage M_j . Within this layer, three key sub-modules operate synergistically:

- **Edge Servers**: Process user tasks and queuing requests. Every server has a local task-scheduler which dynamically allocates its resources to the admitted users.
- **Resource Manager**: This is the interface between the edge layer and the optimization engine. It gathers load measurements ρ_j , active connections n_j , and the fraction of available resources. It subsequently sends these measures to the upper optimization layer in order to make decisions.
- **QoE Monitor**: It is a monitoring tool that constantly measures the user experience parameters, including response time T_i , throughput, and perceived satisfaction Q_i . The monitor sends data that is the aggregate QoE feedback to the Feedback Loop in the coordination layer, which can be used in adaptive learning and optimization.

3) *Optimization Layer*: The Optimization Layer represents algorithmic intelligence of DMUAA. It uses Cognitive Evolutionary Synergy Optimization (CESO) to optimize user-server associations by utilizing three processes that are closely linked:

- **Heuristic Optimizer**: Generates an initial feasible allocation by rapidly mapping users to servers based on resource availability, latency thresholds, and service proximity.
- **Stochastic Optimizer**: This is an improvement of the heuristic solution that tries other configurations with controlled randomness. It is likely to settle better allocations that optimize system QoE or balance workloads.

- **Strategic Optimizer:** This establishes a global stable equilibrium between users and server by adjusting the strategy. This makes the allocation final, efficient and stable, in case of dynamic demand.

These optimizers are used in multistage pipeline, wherein the output of one is used as the input of the other. The combination of the two creates a hybrid decision engine, which approaches an optimal and equilibrium-based state of allocation.

4) *Coordination Layer:* The Coordination Layer ensures global coherence, synchronization, and continual adaptation across all lower layers. It integrates three control components:

- **User Allocation Coordinator:** Manages the interaction between optimizers, controls iteration flow, and resolves conflicts when multiple optimization outcomes overlap.
- **Decision Aggregator:** Consolidates intermediate results from the heuristic, stochastic, and strategic optimizers. It selects the most beneficial allocation decision based on predefined evaluation metrics such as total QoE $\sum_i Q_i$, system utility U_{sys} , and resource balance ratio R_b .
- **Feedback Loop:** Gathers real-time system data and QoE reports on the Edge Server Layer. The feedback system is used to adjust the optimization parameters λ , η , and μ dynamically in controlling the sensitivity of each optimizer to the latency, load, and QoE, so that the optimizers can be tuned adaptively.

5) *Inter-layer communication flow:* The DMUAA architecture works with the ongoing two-way communication between the layers. Task requests are passed upwards by user devices to edge servers, which pass system state vectors to the optimization layer through the Resource Manager. Optimizers generate better allocation plans and relay them down via the Coordination Layer. Decision Aggregator completes the strategy and the revised allocation map is sent to the edge servers, where implementation is done. At the same time, QoE measurements and system statistics are passed on up the Feedback Loop, which is a closed-loop adaptive cycle that constantly improves the performance and responsiveness.

C. Cognitive Evolutionary Synergy Optimization (CESO) Process

The DMUAA presents a hierarchical optimization model that applies three complementary computational paradigms, including: heuristic, stochastic and strategic optimization, in a coordinated and closed system. Such a multi-level design ensures that the allocation process is not only computationally efficient but also adaptive, robust and QoE-oriented and balances user demands with the availability of the system resources in real-time. Optimization is done in iterative steps, with every level being the refinement of the output of the previous level, with each step getting closer to the global

optimum. Formally, the Cognitive Evolutionary Synergy Optimization (CESO) can be defined as an iterative function, as defined in Eq. (11), where: $\Phi_{HE}(\cdot)$ represents the Heuristic Optimization Function, producing a feasible initial allocation. $\Phi_{ST}(\cdot)$ denotes the Stochastic Refinement Function, enhancing diversity and escaping local optima. $\Phi_{SE}(\cdot)$ indicates the Strategic Equilibrium Function, ensuring stability and fairness through game-theoretic balancing. $A^{(t)}$ is the allocation matrix at iteration t , and $A^{*(t+1)}$ is the optimized allocation after one complete multi-level cycle. Every optimization stage is based on real-time dynamics of the system that is characterized by mobility of users, changes in workloads and network fluctuations. Therefore, optimization process of DMUAA is state-dependent, in which the system evolves with respect to the following equation: Eq. (12). Here, $S(t)$ is the state of the system (resource usage, load allocation, and latency) in this case, $\mathcal{F}$ is the system transition function, and θ contains adaptive parameters (tolerance thresholds, sensitivity coefficients, and others). The optimization process continues until the equilibrium condition is reached: $\|A^{*(t+1)} - A^{*(t)}\| < \epsilon$ where ϵ is the convergence threshold ensuring that further updates yield negligible improvements in overall system utility U_{sys} . The subsequent sub-sections detail the functioning of each phase within this hierarchical framework, beginning with the Initialization Phase that sets up the foundation for Cognitive Evolutionary Synergy Optimization.

$$A^{*(t+1)} = \Phi_{SE} \left(\Phi_{ST} \left(\Phi_{HE} (A^{(t)}) \right) \right) \quad (11)$$

$$S(t+1) = \mathcal{F}(S(t), A^{*(t)}, \theta) \quad (12)$$

1) *Initialization Phase:* The Initialization Phase is the preparation phase of DMUAA framework. It carries out three basic tasks that are: the collection of system state, parameter configuration, and the allocation matrix initiation. This makes sure that each successive optimization layer works with quality, synchronized and quantifiable inputs. At time t_0 , the system aggregates real-time data from all user devices and edge servers, as defined in Eq. (13), where: $D_i = (\tau_i, L_i, \omega_i, \delta_i)$ denotes the request vector of user i (task size, latency requirement, priority, mobility). $R_j = (C_j, B_j, M_j)$ represents the resource profile of edge server j (CPU cycles, bandwidth, memory availability). N_{ij} signifies the network characteristics (e.g., transmission rate and delay) between user i and edge server j . This normalization makes it possible that different resource properties and user requirements can be combined into the same optimization model without scale prejudice [see Eq. (13) and Eq. (14)]. The initializing step is the one that prearranges the key control values according to which the optimization behavior is handled at all the further levels under listed Table I.

$$\Omega(t_0) = \{D_i, R_j, N_{ij} \mid i = 1, \dots, N_u; j = 1, \dots, N_s\} \quad (13)$$

$$\hat{x} = \frac{x - x_{\min}}{x_{\max} - x_{\min}} \quad (14)$$

TABLE. I. PARAMETER CONFIGURATION

Parameter	Description	Role
λ	Latency Sensitivity Coefficient	Controls trade-off between response time and resource cost.
η	Resource Utilization Weight	Balances workload distribution across servers.
μ	QoE Sensitivity Parameter	Adjusts optimization bias toward user satisfaction.
ρ_{init}	Initial Resource Threshold	Ensures that minimum resource limits are preserved.
ϵ	Convergence Tolerance	Defines the stopping criterion for iterative refinement.

The global objective function at initialization is defined as in Eq. (15), where Q_i is the QoE score of users i , T_i is the total response time, and C_i is the cost of resource consumption. This objective represents the system-wide utility that the optimization process aims to maximize. An initial feasible allocation matrix $A^{(0)} = [a_{ij}]$ is generated, as defined in Eq. (16). This allocation is computed based on the nearest-server heuristic, considering network proximity and available capacity. The resulting $A^{(0)}$ serves as the baseline allocation for the subsequent Heuristic Optimization Phase, ensuring the system begins from a feasible operational state. Finally, the system establishes two dynamic state vectors for iterative updates:

- Resource State Vector: $S_R = [C_j^{used}, B_j^{used}, M_j^{used}]$
- QoE State Vector: $S_Q = [Q_1, Q_2, \dots, Q_{N_u}]$

These vectors are continuously updated during the optimization cycle as user allocations and performance metrics evolve [see Eq. (15) to Eq. (17)].

$$\max_{U_{sys}} = \sum_{i=1}^{N_u} (\mu Q_i - \lambda T_i - \eta C_i) \quad (15)$$

$$a_{ij} = \begin{cases} 1, & \text{if user } i \text{ is assigned to server } j \\ 0, & \text{otherwise} \end{cases} \quad (16)$$

$$j^* = \arg \min_j \left(\frac{L_{ij}}{C_j^{avail}} + \delta_i \right) \quad (17)$$

2) *Heuristic Allocation Phase*: The first level of optimization of the DMUAA is the Heuristic Allocation Phase. The main aim of it is to come up with a workable and nearly optimal baseline allocation that can be optimized later on in later stages. This stage guarantees quick convergence to an effective use of resources and low latency, besides preserving the Quality of Experience (QoE) to all active users, as presented in Fig. 3. The heuristic stage assumes a definite-but-not-rigid allocation approach and is informed through the system parameters that are set in the stage before it. The process trades off computational demand, server capacity and network latency to come up with an initial allocation matrix that meets real-time performance constraints [28]. In this phase, the algorithm is aimed at reducing the total system latency, as well as balancing the computational loads among all edge servers. The optimization objective is expressed, as in Eq. (18), where: L_{ij} = transmission latency between user i and server j , D_i = computational demand of user i , C_j^{avail} = available computation capacity of server j , δ_i = user mobility

coefficient, $\alpha_1, \alpha_2, \alpha_3$ = weighting factors satisfying $\alpha_1 + \alpha_2 + \alpha_3 = 1$. The objective function Ψ_H quantifies the weighted latency-capacity trade-off, enabling efficient load distribution while maintaining low response times.

The allocation is subject to two major constraints defined as in Eq. (19) and Eq. (20). These constraints ensure that each user is assigned to exactly one edge server and that no server exceeds its available capacity.

$$\min_A \Psi_H = \sum_{i=1}^{N_u} \sum_{j=1}^{N_s} a_{ij} \left(\alpha_1 L_{ij} + \alpha_2 \frac{D_i}{C_j^{avail}} + \alpha_3 \delta_i \right) \quad (18)$$

$$\sum_{j=1}^{N_s} a_{ij} = 1, \forall i \quad (19)$$

$$\sum_{i=1}^{N_u} a_{ij} D_i \leq C_j^{avail}, \forall j \quad (20)$$

$$\Pi_i = \beta_1 \left(\frac{1}{L_i^{avg}} \right) + \beta_2 \left(\frac{1}{T_i^{req}} \right) + \beta_3 \omega_i \quad (21)$$

The heuristic algorithm operates through a priority-based allocation mechanism. Each user request is evaluated and ranked according to a priority index that captures urgency and resource sensitivity, as defined in Eq. (21), where, L_i^{avg} = average link latency from user i to all available servers, T_i^{req} = maximum allowable response time for user i , ω_i = service priority weight, $\beta_1, \beta_2, \beta_3$ = weighting parameters reflecting network-QoE trade-offs. Users with higher Π_i values are given precedence in the allocation process, ensuring that latency-sensitive or high-priority tasks are served first [see Eq. (22) and Eq. (23)]. Each user i is then allocated to the most appropriate server j^* according to the Minimum Cost Rule. Here Q_{ij} represents the expected QoE value if user i is served by server j , estimated as defined in Eq. (24). Here, T_{ij} is the expected total response time, and U_{ij} is the user satisfaction utility derived from past allocation feedback. The weighting parameters ζ_1 and ζ_2 are chosen empirically to balance performance and satisfaction, as outlined in Algorithm 1.

$$j^* = \arg \min_j (\Gamma_{ij}) \quad (22)$$

$$\Gamma_{ij} = \alpha_1 L_{ij} + \alpha_2 \frac{D_i}{C_j^{avail}} + \alpha_3 (1 - Q_{ij}) \quad (23)$$

$$Q_{ij} = \zeta_1 \left(\frac{1}{T_{ij}} \right) + \zeta_2 U_{ij} \quad (24)$$

$$\phi_j = \frac{\sum_{i=1}^{N_u} a_{ij} D_i}{C_j^{avail}} \quad (25)$$

Fig. 3. Process flow of Heuristic Allocation Phase.

Once the initial assignments are determined, the heuristic algorithm performs adaptive load correction to maintain equilibrium across servers. Each server j computes its current load factor, as defined in Eq. (25). If $\phi_j > \rho_{init}$ (the predefined utilization threshold), excess user requests are iteratively

redirected to neighboring servers with lower utilization, following: $j' = \arg \min_{k \neq j} (\phi_k)$ until $|\phi_j - \phi_{j'}| < \delta_{bal}$ where δ_{bal} is the load balance tolerance factor. This step prevents localized overloading while maintaining a near-optimal mapping generated by the initial heuristic allocation. The final output of this phase is an initial allocation matrix $A^{(H)} = [a_{ij}]$ and a load distribution vector $\Phi = [\phi_1, \phi_2, \dots, \phi_{N_s}]$, which collectively form the baseline input for the Stochastic Refinement Phase. At the end of this phase: $A^{(H)} \Rightarrow A_0^{(ST)}, \Phi \Rightarrow \Phi_0$ where $A_0^{(ST)}$ denotes the starting allocation for stochastic refinement. This ensures that the DMUAA begins from a stable, feasible, and balanced allocation state, enabling subsequent layers to focus on global optimality and strategic equilibrium refinement rather than feasibility. The notation and semantics used in the proposed work are shown in Table II.

TABLE. II. NOTATION AND MEANINGS

Notation	Explanation
$U = \{u_1, u_2, \dots, u_{N_u}\}$	Set of User Devices
$S = \{s_1, s_2, \dots, s_{N_s}\}$	Set of Edge Servers
D_i	Computational Demand of Each User u_i
C_j^{avail}	Available Computation Capacity of Each Server s_j
L_{ij}	Network Latency Between u_i and s_j
T_i^{req}	Required Maximum Response Time for u_i
ω_i	Service Priority Weight for u_i
$\alpha_1, \alpha_2, \alpha_3, \beta_1, \beta_2, \beta_3, \zeta_1, \zeta_2$	Weight Coefficients
$A^{(H)} = [a_{ij}]$	Initial User-Server Allocation Matrix
$\Phi = [\phi_1, \phi_2, \dots, \phi_{N_s}]$	Load Distribution Vector
$A^{(H)}$	Baseline Allocation
$F(\cdot)$	Fitness Function
τ_0	Initial Temperature
η	Cooling Rate
T_{max}	Iteration Limit
$A^{(S)}$	Refined Allocation
U	User Set
S	Server Set
U_i	Utility
C_j	Cost
ϵ	Threshold
T_{eq}	Max Iterations
$A^{(E)}$	Stable Equilibrium Allocation

ALGORITHM 1: HEURISTIC ALLOCATION PHASE

Input: $U, S, D_i, C_j^{avail}, L_{ij}, T_i^{req}, \omega_i, \alpha_1, \alpha_2, \alpha_3, \beta_1, \beta_2, \beta_3, \zeta_1, \zeta_2$

Output: $A^{(H)} = [a_{ij}], \Phi = [\phi_1, \phi_2, \dots, \phi_{N_s}]$

1. **Initialization:**
2. Set all allocation variables $a_{ij} = 0$.
3. Collect initial system parameters $D_i, C_j^{avail}, L_{ij}, T_i^{req}, \omega_i$.

4. Initialize server load vector $\Phi = [0]_{N_s}$.
5. Define maximum capacity utilization threshold ρ_{init} .
6. Define load balance tolerance δ_{bal} .
7. **Compute Priority Index for Each User:**
8. **For** each $u_i \in U$:
9. | Sort users in descending order of Π_i by utilizing Eq. (21).
10. **End For**
11. **Allocate Users to Candidate Servers:**
12. **For** each user u_i (in sorted order):
13. | Select target server by utilizing Eq. (22).
14. **For** each server $s_j \in S$:
15. | | Compute cost function by utilizing Eq. (23).
16. | | Compute expected QoE by utilizing Eq. (24).
17. | **If** $\sum_i a_{ij^*} D_i + D_i \leq C_{j^*}^{avail}$, then:
18. | | $a_{ij^*} = 1$
19. | | Update $\phi_{j^*} = \phi_{j^*} + \frac{D_i}{C_{j^*}^{avail}}$
20. | **Else:**
21. | | Select next-best server j' with available capacity.
22. **End For**
23. **Adaptive Load Balancing:**
24. **For** each $s_j \in S$:
25. | **If** $\phi_j > \rho_{init}$:
26. | | Find $j' = \arg \min_{k \neq j} (\phi_k)$
27. | | Transfer user with lowest priority load from $s_j \rightarrow s_{j'}$
28. | | Update both ϕ_j and $\phi_{j'}$
29. | **Repeat** until $|\phi_j - \phi_{j'}| < \delta_{bal}$
30. **End For**
31. **Return** allocation matrix $A^{(H)} = [a_{ij}]$
32. **Return** server load distribution vector $\Phi = [\phi_1, \phi_2, \dots, \phi_{N_s}]$

3) *Stochastic Refinement Phase*: In this phase, a stochastic search mechanism is employed to iteratively modify user-server mappings in the allocation matrix $A^{(H)}$ obtained from the heuristic phase. The goal is to explore the solution space probabilistically, accepting new allocations with certain probabilities based on their potential to enhance global performance metrics such as total QoE, load balance, and latency reduction. Each iteration generates a perturbed allocation A' from the current allocation $A^{(t)}$, evaluates the change in the objective function $\Delta F = F(A') - F(A^{(t)})$, and applies an acceptance criterion influenced by a probabilistic parameter called the acceptance temperature τ . This mechanism allows temporary acceptance of slightly inferior allocations, thus enabling the algorithm to bypass local optima as outlined in Algorithm 2. Let $A^{(t)}$ denote the current allocation matrix at iteration t , and $F(A^{(t)})$ be the global fitness function representing total system performance, as defined in Eq. (26), where, $Q_i(A^{(t)})$: achieved QoE for user u_i ; $\Psi_j(A^{(t)})$: resource over-utilization penalty at server s_j ; $L_{iA(i)}^{(t)}$: latency between user u_i and its allocated server; $\lambda_1, \lambda_2, \lambda_3$: weight coefficients satisfying $\lambda_1 + \lambda_2 + \lambda_3 = 1$.

$$F(A^{(t)}) = \lambda_1 \sum_{i=1}^{N_u} Q_i(A^{(t)}) - \lambda_2 \sum_{j=1}^{N_s} \Psi_j(A^{(t)}) - \lambda_3 \sum_{i=1}^{N_u} L_{iA(i)}^{(t)} \quad (26)$$

Perturbation Mechanism

For each iteration t :

- a) Randomly select a subset of users $U_p \subset U$ for potential reallocation.
- b) For each $u_i \in U_p$:
 - o Select a new server $s_k \in S$ randomly from the candidate list S_i , ensuring $C_k^{avail} \geq D_i$.
 - o Temporarily assign $a_{ik} = 1$ and update the load vector $\Phi^{(t)}$.
- c) Evaluate the new fitness $F(A')$ and compute performance difference [see Eq. (27)]:

$$\Delta F = F(A') - F(A^{(t)}) \quad (27)$$

The decision to accept a new configuration follows the acceptance probability function, as defined in Eq. (28). Here, τ is the *stochastic temperature* that controls exploration intensity. It is adaptively reduced over time following a cooling schedule such as: $\tau_{t+1} = \eta \tau_t$, $0 < \eta < 1$. This ensures higher exploration during initial iterations and gradual convergence toward stability as τ decreases.

$$P_{accept} = \begin{cases} 1, & \text{if } \Delta F > 0, \\ \exp\left(\frac{\Delta F}{\tau}\right), & \text{if } \Delta F \leq 0. \end{cases} \quad (28)$$

ALGORITHM 2: STOCHASTIC REFINEMENT

Input: $A^{(H)}, U, S, F(\cdot), \tau_0, \eta, T_{max}$.

Output: $A^{(S)}$

1. **Initialization:**
 2. | Set $A^{(t)} = A^{(H)}$; initialize $F^{(t)} = F(A^{(t)})$.
 3. | Set $\tau = \tau_0, t = 0$.
 4. **While** $t < T_{max}$ **do**
 5. | Randomly select user subset $U_p \subseteq U$.
 6. | **For** each $u_i \in U_p$,
 7. | | Randomly assign to feasible server s_k satisfying capacity constraint $D_i \leq C_k^{avail}$.
 8. | **End For**
 9. | Generate perturbed allocation A' .
 10. | Compute $F(A')$ and $\Delta F = F(A') - F^{(t)}$.
 11. | **If** $\Delta F > 0$,
 12. | | Accept A' ;
 13. | **Else**
 14. | | Accept A' with probability $\exp(\Delta F/\tau)$.
 15. | | Update $\tau = \eta \tau$.
 16. | | Increment $t = t + 1$.
 17. **End While**
 18. **Return** final refined allocation $A^{(S)} = A^{(t)}$.
-

4) *Strategic Equilibrium Phase*: The Strategic Equilibrium Phase constitutes the terminal stage of the DMUAA. After heuristic and stochastic optimizations have produced a high-quality but non-stable allocation $A^{(S)}$, this phase seeks allocation stability by modeling interactive decision-making between users and servers through a game-theoretic framework. Each user strives to maximize its Quality of Experience (QoE), while each server aims to minimize its resource stress and latency overhead. The system achieves

strategic equilibrium when neither users nor servers can unilaterally modify their allocation strategy to gain further benefit, as outlined in Algorithm 3.

Game-Theoretic Formulation

Let the user set be $U = \{u_1, u_2, \dots, u_{N_u}\}$ and the server set be $S = \{s_1, s_2, \dots, s_{N_s}\}$. Each user u_i selects a strategy $a_i \in S$ corresponding to the chosen edge server. The joint strategy profile of all users is represented as $A = (a_1, a_2, \dots, a_{N_u})$ and the utility function of user u_i is defined as Eq. (29), where: $Q_i(a_i)$: experienced QoE of user u_i when connected to server s_{a_i} ; L_{i,a_i} : end-to-end latency for the same connection; $\Psi_{a_i}(A)$: resource utilization penalty (load factor) at server s_{a_i} ; $\alpha_1, \alpha_2, \alpha_3$ are positive weights satisfying $\alpha_1 + \alpha_2 + \alpha_3 = 1$. Each edge server s_j acts as a rational player minimizing its cost function, as defined in Eq. (30), where: $\Phi_j(A)$: total processing load assigned to s_j ; $D_j(A)$: delay induced by processing and queuing; $\Gamma_j(A)$: energy or bandwidth cost; $\beta_1, \beta_2, \beta_3$ are non-negative coefficients.

$$U_i(a_i, A_{-i}) = \alpha_1 Q_i(a_i) - \alpha_2 L_{i,a_i} - \alpha_3 \Psi_{a_i}(A) \quad (29)$$

$$C_j(A) = \beta_1 \Phi_j(A) + \beta_2 D_j(A) + \beta_3 \Gamma_j(A) \quad (30)$$

Nash Equilibrium Condition

A stable allocation (equilibrium) $A^{(E)}$ is achieved when: $U_i(a_i^*, A_{-i}^*) \geq U_i(a_i', A_{-i}^*), \forall i, \forall a_i' \in S$ and $C_j(A^*) \leq C_j(A'), \forall j, \forall A'$ differing in users mapped to s_j . This state guarantees mutual optimality—no user or server can independently improve its objective function. The equilibrium reflects balanced resource utilization, minimized latency, and maximized collective QoE.

Iterative Equilibrium Computation

The equilibrium is reached through iterative best-response updates:

- Initialization: Start from the refined allocation $A^{(S)}$.
- User Update: Each user u_i evaluates potential servers $s_k \in S_i$ and selects the one maximizing $U_i(a_i, A_{-i})$.
- Server Adjustment: Each server updates its admission control policy to minimize $C_j(A)$ based on current load and energy state.
- Convergence Check: The process iterates until the global improvement [see Eq. (31)]:

$$\Delta F = |F(A^{(t+1)}) - F(A^{(t)})| < \epsilon \quad (31)$$

where, $F(\cdot)$ is the system objective and ϵ a small threshold. To ensure convergence toward a stable equilibrium, a potential-function framework is introduced. Let the global potential function be defined as Eq. (32). The update rule follows as per Eq. (33). Since $P(A)$ is designed as a strictly concave potential, the existence of a pure-strategy Nash equilibrium is guaranteed, and the iterative best-response dynamic converges in finite steps.

$$P(A) = \sum_{i=1}^{N_u} U_i(a_i, A_{-i}) - \sum_{j=1}^{N_s} C_j(A) \quad (32)$$

$$A^{(t+1)} = \arg \max_A P(A) \quad (33)$$

ALGORITHM 3: STRATEGIC EQUILIBRIUM COMPUTATION

Input: $A^{(S)}, U, S, U_i, C_j, \epsilon, T_{eq}$.

Output: $A^{(E)}$

1. **Initialization:**
 2. Set $A^{(t)} = A^{(S)}$; $t = 0$.
 3. **Repeat** until convergence or $t > T_{eq}$:
 4. **User Optimization:**
 - a) **For** each $u_i \in U$
 6. **Compute** $U_i(a_i, A_{-i}^{(t)})$ for all $a_i \in S_i$;
 7. **Select** $a_i^* = \arg \max U_i(a_i, A_{-i}^{(t)})$.
 8. **End For**
 9. **Server Optimization:**
 - b) **For** each $s_j \in S$
 11. **Updates** its load distribution and admission policies to minimize $C_j(A^{(t)})$.
 12. **End For**
 13. **c) Update Allocation:**
 14. Combine new a_i^* and server responses $\rightarrow$ form $A^{(t+1)}$.
 15. **Convergence Check:**
 - d) **If** $|F(A^{(t+1)}) - F(A^{(t)})| < \epsilon$,
 17. **terminate.**
 18. **e) $t = t + 1$.**
 19. **Return:** Final allocation $A^{(E)} = A^{(t)}$.
-

D. Coordination and Feedback Mechanism

The Feedback and Coordination in the DMUAA makes sure that all multi-level optimizers work in sync and provides the multi-level optimizers with a consistent ability to adapt to user mobility, network conditions and workload distribution. It constitutes the supervisory and self-regulatory level of the system, combining the decisions made throughout all optimization stages and making sure that the allocations obtained are consistent, stable and reactive. Two major entities, the User Allocation Coordinator (UAC) and the Decision Aggregator (DA) deal with coordination, with the Feedback Loop (FL) used to refine dynamically based on real-time system metrics and user feedback. The User Allocation Coordinator is the key supervisory module that coordinates the serial and mutually dependent implementation of the three optimization steps namely Heuristic, Stochastic, and Strategic Equilibrium. Its primary functions are:

1) *Synchronization of optimization layers:* The UAC ascertains that every step of optimization gets the right input of the step being progressed and that the transitions between the steps do not lead to extraneous calculation or antagonistic goals. Mathematically, if $A^{(H)}$, $A^{(S)}$, and $A^{(E)}$ denote allocations from heuristic, stochastic, and equilibrium phases, respectively, the coordinator enforces, as defined in Eq. (34), where $F(\cdot)$ is the global fitness (system utility) function.

$$A^{(H)} \rightarrow A^{(S)} \rightarrow A^{(E)} \text{ such that } F(A^{(E)}) \geq F(A^{(S)}) \geq F(A^{(H)}) \quad (34)$$

2) *Temporal control and concurrency management*: In large-scale edge environments, multiple optimization tasks may occur concurrently across distributed nodes. The UAC allocates time slices and computational quotas for each optimizer to ensure convergence within bounded latency.

3) *Conflict resolution and policy enforcement*: In case of conflicting allocation proposals of forward movement that arise following the heuristic/stochastic refinements, the UAC manages conflicts by prioritizing the strategy maximizing the global QoE, considering the present resource constraints, as expressed in Eq. (35) with $\mathcal{A}$ being the collection of competing allocations.

$$\text{Select } A_k^* = \arg \max_{A_i \in \mathcal{A}} \sum_{u \in U} Q_u(A_i) \quad (35)$$

4) *Resource consistency verification*: Before the optimized allocation is deployed, the UAC verifies that total assigned resources do not exceed the available capacity [see Eq. (36)]:

$$\sum_{u_i \in U} R_{i,a_i} \leq R_{s_j}^{\max}, \forall s_j \in S \quad (36)$$

Decision Aggregator (DA)

The Decision Aggregator functionality is the ultimate decision consolidator that converts the distributed optimizers into one consistent and deployable allocation map. Whereas every optimizer aims at a local or probabilistic enhancement, the DA allows global consistency by consolidating and standardizing its findings.

5) *Cognitive evolutionary synergy optimization integration*: The DA collects results from each optimization layer—denoted by $\{A^{(H)}, A^{(S)}, A^{(E)}\}$ —and computes the final allocation as: $A^{(F)} = \lambda_1 A^{(H)} + \lambda_2 A^{(S)} + \lambda_3 A^{(E)}$ where λ_i are dynamically adjusted confidence weights satisfying $\sum_{i=1}^3 \lambda_i = 1$.

6) *Consensus-based validation*: The DA applies a consensus mechanism to ensure fairness and stability. If a certain allocation decision is supported by multiple optimization layers, it receives higher reliability, as defined in Eq. (37), where $\mathbb{I}(\cdot)$ is an indicator function and $\Omega(u_i, s_j)$ denotes the confidence of user u_i being allocated to server s_j .

$$\Omega(u_i, s_j) = \frac{1}{3} \sum_{k=1}^3 \mathbb{I}(a_i^{(k)} = s_j) \quad (37)$$

7) *QoE-weighted finalization*: The DA finalizes user-server mappings by maximizing aggregated QoE while maintaining balanced resource utilization, as defined in Eq. (38), where ω_i represents user priority weights and η regulates resource fairness.

$$A^{(F)} = \arg \max_A [\sum_{u_i \in U} \omega_i Q_i(A) - \eta \sum_{s_j \in S} \frac{\Phi_j(A)}{R_{s_j}^{\max}}] \quad (38)$$

E. Feedback Loop (FL)

The core of adaptive intelligence of the DMUAA is the Feedback Loop that allows correcting the use of the user allocation strategies in real-time and continuously improves them. It operates under two-way communication between the QoE Monitor, Optimization Layer, and the Coordination Layer.

1) *Real-time data acquisition*: The FL continuously collects performance indicators such as latency (L_i), throughput (T_i), packet loss (p_i), and actual QoE (Q_i^{obs}) for each active user u_i . The QoE deviation is computed as: $\Delta Q_i = |Q_i^{pred} - Q_i^{obs}|$, which measures the gap between expected and actual experience.

2) *Adaptive model update*: Whenever $\Delta Q_i > \delta$ (threshold deviation), the feedback engine triggers partial re-optimization, adjusting parameters in stochastic or equilibrium layers.

For instance: $\theta^{(t+1)} = \theta^{(t)} + \gamma \cdot \nabla_{\theta} F(A, Q^{obs})$, where θ denotes the internal parameters (e.g., weight vectors or resource biases) and γ is the adaptive learning rate.

3) *Mobility and load adaptation*: In scenarios where user mobility alters network topology or demand patterns, the FL identifies shifting edge-server proximities and dynamically reassigns users. The reallocation rule is expressed as per Eq. (39), ensuring users are redirected to servers offering the optimal trade-off between latency, load, and QoE.

$$a_i^{new} = \arg \min_{s_j \in S} (\lambda_1 L_{i,j} + \lambda_2 \Psi_j + \lambda_3 (1 - Q_i^{obs})) \quad (39)$$

4) *Closed-loop optimization*: The continuous feedback ensures that the system evolves toward higher efficiency and user satisfaction. Each iteration of the FL updates both local optimizers and the global allocation policy, forming a closed-loop adaptive control system, as defined in Eq. (40), where $f(\cdot)$ represents the update function influenced by feedback data, network state, and observed QoE.

$$A^{(t+1)} = f(A^{(t)}, Q^{obs}, R^{state}, L^{net}) \quad (40)$$

IV. EXPERIMENTS AND ANALYSIS

In order to comprehensively evaluate the performance of the suggested DMUAA framework, there were comprehensive experiments that were done in a wide range of dynamic MEC environments. The simulation environment was created to give the simulation an appearance of realistic edge-computing of conditions, including user mobility, intermittent resource availability, inhomogeneous task demand, and multi-server interactions. The implementation was done via Python 3.10 with NumPy, SciPy, NetworkX, and TensorFlow libraries, all algorithmic modules of DMUAA, such as the heuristic initializing stage, the stochastic refinement engine and the strategic equilibrium optimizer. The experiments were run on a workstation with Core i7-11700 CPU @ 2.50 GHz, 32 GB, and Windows 11 (64-bit) to guarantee that the results are those that can be obtained with a typical research grade computer.

An artificial MEC area of 10 km x 10 km was simulated and randomly distributed edge servers, user movement was simulated by the random waypoint mobility model. Computational tasks generated by users were served by a Poisson process, and the capacity of resources in servers was not identical, so as to represent the heterogeneity in real deployment. The DMUAA algorithm was configured according to the Cognitive Evolutionary Synergy Optimization (CESO) structure, where the learning rate $\gamma \in \{0.001, 0.0001, 0.00005, 0.00001\}$ governs parameter adaptation intensity, and the exploration temperature τ was initialized at 1.0 and gradually reduced using a cooling factor $\eta = 0.97$. Other internal parameters were adjusted to maintain a stable optimization behavior: the heuristic utilization threshold ρ_{init} was set to 0.75, the equilibrium convergence tolerance ε to 10^{-3} , and the maximum number of optimization iterations to 1000. The user-priority weighting vector $\{\alpha_1, \alpha_2, \alpha_3\} = \{0.4, 0.3, 0.3\}$ was used to balance latency, energy, and satisfaction components of QoE, while the resource fairness coefficient $\eta = 0.2$ and QoE sensitivity parameter $\mu = 0.5$ guided allocation decisions across the optimization layers. Table III summarizes the key parameters in the simulation carried out in all experiments. These environments were chosen on the basis of the established MEC standards to be able to make fair comparisons with MGGO, GTA, EUA, HAILP, and LGP. Every scenario was repeated 30 times, and the average outcomes were reported to overcome chance deviations due to mobility, task bursts, and variability of load distribution.

TABLE. III. SIMULATION PARAMETERS

Parameter	Value / Distribution
Number of users (U)	300–600
Number of edge servers (S)	10–20
Task size	0.5–5 MB
CPU cycles per bit	200–500 cycles/bit
User transmit power	0.2–1.5 W
Available bandwidth	5–20 MHz
Mobility model	Random waypoint
Maximum learning episodes	1000
DMUAA optimization stages	Heuristic → Stochastic → Strategic
Learning rate (γ)	$\{0.001, 0.0001, 0.00005, 0.00001\}$
Exploration temperature (τ)	1.0 with cooling factor $\eta = 0.97$
Heuristic threshold (ρ_{init})	0.75
Equilibrium tolerance (ε)	10^{-3}
QoE weight factors ($\alpha_1, \alpha_2, \alpha_3$)	0.4, 0.3, 0.3
Fairness weight (η)	0.2
QoE sensitivity (μ)	0.5

The work of the suggested DMUAA framework is measured with an overall collection of metrics that can be used to describe user experience, system efficiency, scalability, energy sustainability, and optimization behavior. End user indicators such as end-to-end latency, average QoE score, User Satisfaction Ratio (USR) and Service Continuity

Rate (SCR) emphasize the responsiveness and perceived quality provided to end users. Resource metrics that are system-based like Resource Utilization Efficiency (RUE), CPU, memory consumption, and bandwidth overhead determines how the MEC infrastructure uses its computational power. Scalability-related measures such as the Load Balance Index (LBI), Server Activation Ratio (SAR) and Scalability Factor reveal how the algorithm can be used to keep the performance steady when network size and user density grow. The energy-awareness of allocation decisions are measured using energy-focused metrics, like the average energy per task ($\bar{E}$), the Energy QoE Trade-off Ratio (EQR), and Server Power Efficiency (SPE). Lastly, optimization and learning dynamics (convergence rate and computation time during the heuristic, stochastic and strategic stages) are used to give information on the fitness and learning efficiency of the CESO-based optimization process. Together, these measures provide an overall overview of the strength and capacity of DMUAA to survive in fluctuating MEC settings.

A. User-Centric Performance Metrics

The concept of user-centric performance measures the effective usage of the system according to the expectations and needs of the end-users working in different conditions of the network and workload. The metrics are direct indicators of the perceived performance of the edge computing environment, as they focus on responsiveness, stability, and satisfaction with the services. This section will reveal that the proposed DMUAA framework provides higher-quality user-level performance than the state-of-the-art allocation methods by analyzing such parameters as latency, QoE, and user satisfaction.

1) *Latency and responsiveness*: The two most basic measures of quality user-experience in edge computing systems are latency and responsiveness. In this subsection, the speed of each method in responding to user requests and computing the efficiency of operations being run close to the network edge is evaluated. Through the study of the trends in end-to-end delay under varying computing capacities, we explain how the DMUAA can greatly shorten the latency of the tasks by various means of adaptive optimization and balanced allocation of resources.

Fig. 4. Average end-to-end latency comparison.

a) *Average End-to-End latency ($\bar{L}$)*: The comparison of the average end-to-end latency makes it clear that the proposed DMUAA framework is more efficient in terms of computation at all levels of computing capacity. As noted in the Fig. 4, DMUAA has steadily the lowest latency with an initial value of around 0.012 units at 0.5 GHz and gradually rising to the 0.035 units at 4.0 GHz. This gradual and controlled growth is quite a contrast to competitive strategies. Next are MGGO and GTA, albeit with quite a large latency corresponding to 0.016-0.020 units and 0.039-0.043 units respectively at lower and higher frequencies, respectively. EUA, HAILP and LGP have increasingly inferior performance with EUA standing at 0.045 units and LGP topping at close to 0.049 units at the maximum capacity. The distinctiveness between the DMUAA curve and any of the baseline approaches proves the efficiency of the multilevel allocation approach employed by the DMUAA to reduce the delays in computation and communication. Generally, the proposed DMUAA has a 15–35% per cent lower latency than the current algorithms, which makes it superior in delay-sensitive and real-time edge computing applications.

b) *Service Continuity Rate (SCR)*: The comparison of the Service Continuity Rate (SCR) is a clear indication that the proposed DMUAA is more stable than all the levels of computing capacity. As in the revised findings, DMUAA is always the highest performing technique, with the initial value of about 0.13 in the low-capacity and then gradually rising to about 0.42 in the highest capacity, as illustrated in Fig. 5. This increasing pattern indicates that DMUAA has a high potential to maintain continuous service execution despite the increase in the size of the computational resources. MGGO and GTA are the second and third-performing companies, although they are still 3 to 6% below DMUAA across all levels. EUA, HAILP and LGP demonstrate relatively lower continuity with only about 0.10- 0.17 at low capacity and 0.33-0.36 at higher capacity. The accelerated trend and the general increase of values of the DMUAA curve indicate only the efficiency of its dynamic multilevel allocation strategy and the adaptive optimization mechanisms in reducing the number of service disruptions. In general, the results prove that DMUAA is much more successful in terms of stability and resilience of the service compared to the baseline methods.

2) *Quality of Experience*: Quality of Experience (QoE) offers an overall measurement of the satisfaction of the user, as it is a holistic approach, which involves the synergetic effects of latency, reliability, and service continuity. The sub section will focus on the QoE distribution and satisfaction ratios realized by various approaches to reveal the effectiveness of various approaches in maintaining a high-quality service experience. The findings indicate that the proposed DMUAA is superior in providing higher levels of QoE in terms of multilevel decision-making, feedback-driven updates, and efficient load balancing.

Fig. 5. Service Continuity Rate (SCR) comparison.

a) *Average QoE score ($\bar{Q}$)*: The cumulative distribution analysis of QoE shows clearly that the proposed DMUAA framework is better than all competing user-allocation algorithms. As it can be seen in the CDF curves, DMUAA has higher QoE values, and over 80% of users were found to achieve the same QoE value of ≥ 0.80 , through the competing methods of MGGO and GTA, the same value is reached only after 65-70 per cent of users, as in Fig. 6. EUA and HAILP also perform poorly, with a broader distribution and slower growth in their distributions, whereas LGP boasts the lowest concentration of QoE, which implies the lack of consistency in its service quality when the load changes. This upward and left-shifting curve of the CDF of DMUAA validates its capability in providing greater and more consistent user satisfaction powered by its adaptive multi-level optimization, effective resource distribution and real-time feedback-incorporation. In general, the distribution tendencies confirm that DMUAA is superior to the current techniques because it provides much more reliable opportunities and user-oriented quality of service under various conditions of operation.

Fig. 6. QoE cumulative distribution analysis.

b) *User Satisfaction Ratio (USR)*: The comparison of the User Satisfaction Ratio (USR) will clearly show the high consistency and reliability of the suggested DMUAA framework at different levels of computing capacity. DMUAA, as indicated in Fig. 7 would have the highest level of satisfaction all along the range with an initial level of about 0.78 in low-capacity environments and a gradual rise to 0.80 in the highest level. This means that DMUAA is effective in maintaining the perceptions of the users on the quality of the service despite the variation in the availability of resources. Next-best performers are MGGO and GTA with the highest USR values of approximately 0.76 and 0.72, respectively, but they also stay below DMUAA because they lack the ability to be highly adaptable in dynamic edge situations. EUA and HAILP are less improved in their satisfaction levels, but have smaller gains and LGP has the lowest USR, right around 0.60, which shows its poorer capacity to optimize. In sum, the proposed DMUAA has the higher user satisfaction ratio section by 5-15% than other competing algorithms, which supports the effectiveness of its multi-level optimization and feedback-based allocation strategy.

B. System-Centric Resource Performance Metrics

System-centric metrics give an overall evaluation of the efficiency of the Multi-Access Edge Computing (MEC) environment in terms of utilizing the resources of the environment under different workloads and network conditions. Whereas user-centric measures emphasize the QoE and perceived responsiveness, system-centric measurements reflect the behavior of the system internally, i.e., how effectively computing, memory, bandwidth, and power are allocated, balanced, and scaled among the heterogeneous edge servers. These measures will enable us to measure the stability, equity, and soundness of the suggested DMUAA

structure to make sure that the improved performance on the part of users is not at the cost of resource wastefulness or system overloading. Through a trend analysis of utilization pattern, load balancing behavior, and scalability features, this section underpins the ability of DMUAA to ensure a high level of efficiency of a system under large scale, dynamic edge intensity conditions.

1) *Resource utilization*: The resource utilization analysis evolved in the four subplots gives an overall assessment of efficiency in handling the computation resources by the various user-allocation algorithms in different conditions of the system, as presented in Fig. 8. As presented in Fig. 8(a), at all computing-capacity levels, the proposed DMUAA continues to record the best Resource Utilization Efficiency (RUE) and hence its better resource allocation capability that neither overloads nor results into underutilization. This benefit is verified by Fig. 8(b), which shows that CPU usage is minimized when DMUAA is used relative to other competing schemes, in terms of processing overhead, which represents its optimal task-server matching, and less processing redundancy. The same trend can be noted in Fig. 8(c) in which DMUAA has minimum memory footprint suggesting that it has efficient state management and lightweight decision structures. Lastly, Fig. 8(d) indicates that DMUAA also reduces bandwidth usage nature unlike the traditional methods whose bandwidth overhead increases significantly with system load. Altogether, the findings indicate that DMUAA provides a consistently high efficiency in terms of CPU, memory, bandwidth, and the overall resource utilization, which proves the functionality of its multilevel optimization pipeline in lowering the stress on the system and ensuring high-quality service performance.

Fig. 7. User Satisfaction Ratio (USR) comparison.

Fig. 8. System-centric resource performance analysis.

Fig. 9. Combined load and scalability analysis: (a) Load balance index (LBI); (b) Server activation ratio (SAR); (c) Scalability factor (SF); (d) Server load balancing performance.

2) *Load and scalability*: The load and scalability analysis gives a deep insight into the efficiency of various allocation algorithms with regard to workload distribution, server activity, and performance when system demands are high, as depicted in Fig. 9. As shown in Fig. 9(a), the proposed DMUAA has the minimal and most consistent Load Balance Index (LBI), which allows the most balanced distribution of tasks among servers, whereas the competing algorithms, especially HAILP, and LGP have more imbalance with the rise in loads. Fig. 9(b) also validates the efficiency of DMUAA with its reduced Server Activation Ratio (SAR) because it can satisfy the demand with fewer active servers

which results in saving energy and also low operational cost. In Fig. 9(c), the Scalability Factor (SF) indicates that DMUAA has the highest ability to retain high performance with increase in the number of users compared to other approaches whose efficiency reduces faster. Lastly, Fig. 9(d) displays the general Server Load Balancing Performance, as DMUAA has much more stable and balanced load trends, as opposed to the more wavy and inefficient balancing trends seen with the other models. Combined, these findings indicate the high scalability of DMUAA, its high load distribution, and less server over-provisioning- these factors indicate the

strength of DMUAA in large-scale and dynamically changing edge computing systems.

C. Energy and Power-Efficiency Metrics

The energy and power-efficiency analysis have offered a thorough analysis of tasks and server level performance of various algorithms with regard to their capacity to handle computational energy, as illustrated in Fig. 10. Fig. 10(a) is a violin-plot representation of the average energy consumption per task ($\bar{E}$), where the proposed DMUAA is least and most concentrated energy-wise, meaning lower energy use and less variability in the energy use among the tasks- a critical quality

in stable large-scale edge environments. Fig. 10(b), which is a comparison of the EnergyQoE Trade-off Ratio (EQR), indicates that DMUAA provides the best conversion efficiency of the energy consumed and the QoE realized. Competing models like MGGO and GTA are moderately efficient, whereas EUA, HAILP, and LGP experience stiffer drops, indicating worse energy usage to user experience improvements, as indicated in Fig. 10. All these measures confirm that DMUAA is always ahead of state-of-the-art benchmarks in energy sustainability, task-level performance and power-sensitive server operation, which are essential in next-generation edge computing infrastructure.

Fig. 10. Energy and power-efficiency comparison across user allocation algorithms.

D. Optimization and Learning Dynamics Metrics

The adaptability of the proposed DMUAA framework, its stability, and the efficiency of its long-term operation under changing edge environments highly depend on the optimization and learning dynamics of this framework. In addition to measuring the task-level performance and user-centric results, it is imperative to determine the level of optimization pipeline learning, stabilization, and convergence to different system conditions. This part is thus concerned with measures which describe internal behavior of DMUAA in the iterative process, both its learning curve and its computability. In Section IV D-1, convergence behavior of DMUAA with different learning rates, exploration temperatures and algorithmic baselines were investigated showing its predictability in terms of faster, smoother and more stable convergence than state-of-the-art methods. In Section IV D-2, the practicality of the computations needed to implement the framework itself was also confirmed by examining computation-time distributions of the heuristic, stochastic and strategic phase, and showed that DMUAA has competitive computation overhead despite its multi-level optimization structure.

1) *Convergence behavior analysis:* The convergence analysis gives a clear insight on the consistency, flexibility and effectiveness of the suggested Dynamic Multilevel User Allocation Algorithm (DMUAA) in the dynamic edge

computing systems. To fully assess the strength of the Cognitive Evolutionary Synergy Optimization (CESO) process convergence behavior is considered in three complementary dimensions: 1) the effect of various adaptive learning rates (γ), which define the aggressive nature of the algorithm in updating its decision policies; 2) the effect of various exploration temperatures (τ) which determine the stochastic refinement and exploration-exploitation ratio in optimization and 3) comparative convergence against state-of-the-art user allocation algorithms. Such a diverse analysis makes sure the suggested framework can be considered through the prism of both its internal learning dynamics and its efficiency in practice and in comparison, with the existing solutions. The learning rate γ controls the magnitude of parameter adjustments based on environmental feedback, where higher γ values accelerate learning but may induce instability, and lower γ values offer smoother but slower convergence. Similarly, the exploration temperature τ governs the acceptance probability of suboptimal moves during stochastic search, influencing the algorithm's ability to escape local optima and reach global equilibrium. Lastly, the comparison of DMUAA to MGGO, GTA, EUA, HAILP, and LGP also indicates that the former has a better convergence speed, is able to maximize rewards, and is resilient to changing workload and mobility rates of users. All in all, these

studies confirm the integrity and robustness of the suggested multilevel optimization plan.

Fig. 11. Convergence performance of the proposed DMUAA under four distinct learning rates ($\gamma = 0.001, 0.0001, 0.00005$, and 0.00001).

a) Performance convergence with various adaptive learning rates (γ)

Fig. 11 shows convergence performance of proposed DMUAA when four learning rates are taken (0.001, 0.0001, 0.00005, and 0.00001). The y-axis is the cumulative reward which is an immediate measure of system utility which is a combination of both the QoE maximization and latency reduction whereas the x-axis is the number of training episodes. The curves that are plotted show us the variation in the value of the reward with the number of iterations until the algorithm reaches a near-optimal solution. During early parts of the learning stage (0 to 200 episodes), all settings will have a sharp rise in reward which indicates an initial rapid adaptation when the DMUAA discovers useful user-server associations. The curve with $\gamma = 0.00005$ (magenta) illustrates the most stable and predictable increase with the highest level of reward approaching 1500 to 1800, which means that it converged quickly with fewer oscillations. The convergent curves with $\gamma = 0.001$ (olive) and 0.0001 (navy) however exhibit moderate fluctuations because of greater sensitivity to instant reward updates. Meanwhile, the 0.00001 (teal) setting has a less bumpy but sluggish growth, which is a conservative learning with a slow convergence. After more than 200 episodes the algorithm reaches the refinement stage with the speed of convergence decreasing, and the oscillations becoming stable reflecting equilibrium between exploration and exploitation. The last convergence levels indicate that DMUAA sustains the values of rewards in the range of (-2000 to +1800) suggesting that it is highly stable in learning at various gamma values. Notably, all the learning rates did not lead to any divergence or overshooting beyond the tolerable reward range, which implies efficient parameter fitting and feedback control.

b) Performance convergence with varying exploration temperatures (τ)

The stability as well as the flexibility of the proposed optimization strategy is reflected in the convergence properties of the DMUAA at various exploration temperatures (τ). As it was shown in the Fig. 12, all the four curves

demonstrate the initial stage of the steep oscillation, which is not surprising because of the large standard deviation at the beginning of exploration. As the learning episodes advance the reward curves tend to stabilize and converge to the higher reward regions, which is a sign of better allocation decisions and less uncertainty. The existence of lower exploration temperatures ($\tau = 0.005$ and $\tau = 0.01$) indicates stronger positive trends and quicker stabilization, as they manage to have an equilibrium between exploration and exploitation. The increased exploration temperature ($\tau = 0.9$) keeps oscillating slightly higher, indicating that the exploration behavior is still present but the behavior approaches the end result of stable performance. The cut-off reward curves are such that large reward spikes, especially with $\tau = 0.005$ and $\tau = 0.01$, are apparent and attest to the effectiveness and high adaptability of DMUAA towards the mid-to-late training period.

Fig. 12. Convergence characteristics of the DMUAA under different exploration temperatures (τ).

c) Performance convergence by comparing with state-of-the-art algorithms

Fig. 13 covers the convergence properties of the proposed DMUAA framework and five state-of-the-art algorithms of user allocation, namely MGGO, GTA, EUA, HAILP and LGP over 1000 training episodes. The proposed DMUAA is always the most rewarding across the entire training horizon and exhibits speed of stabilization as well as learning ability. In contrast to rival methods, where modes of reward acquisition are slower, and volatility is vast in the initial bouts, DMUAA rapidly increases once the initial exploration period ends and retains a markedly higher reward pattern. The sharp spikes present between episode 200 and 1000 are indicative of the dynamic strategic accommodation processes of DMUAA, which were made possible through multilevel heuristic stochastic equilibrium pipeline. On the contrary, MGGO and GTA have a moderate convergence to reward level and EUA, HAILP, and LGP have weaker convergence and permanently lower reward values. In general, the figure substantiates the fact that DMUAA does not only increase the pace of convergence but also maintains high performance level in the long run, which proves its effectiveness and efficiency in learning in comparison to the current allocation plans.

2) *Computation time analysis*: The comparison of the computation time shows that the proposed DMUAA framework has much in common with its structural efficiency even though the optimization design is multi-stage. The three internal phases, as illustrated in Fig. 14, Heuristic (HE), Stochastic (ST) and Strategic Equilibrium (SE) show well-bounded and tight execution times and thus, there exists a stable computational behavior.

Fig. 13. Convergence behavior of the proposed DMUAA framework against five state-of-the-art user allocation algorithms.

Fig. 14. Structural efficiency of the proposed DMUAA framework.

The heuristic phase is lightweight since its operations are priority-based and deterministic whereas the ST phase is moderate overhead since it addresses probabilistic exploration. The SE phase, despite causing convergence of the game-theoretic, has got a controlled runtime due to the potential-function-directed update mechanism. With aggregation, the overall computation time of DMUAA is competitive and in fact lower than most of the competing algorithms, especially the MGGO and GTA that have costly optimization cycles. Even strategies of less complexity, e.g., EUA, HAILP, and LGP exhibit greater variation and reduced predictable run-time behavior. The general findings support the fact that DMUAA can produce much better optimization quality without compromising the level of computational efficiency, which proves the practicability of its multi-level architecture in real-time edge computing applications.

E. Limitations

While the proposed Dynamic Multilevel User Allocation Algorithm (DMUAA) demonstrates improved resource utilization, QoE, and system stability, several limitations provide opportunities for future enhancement. First, the evaluation is conducted using simulation-based environments with controlled workload patterns, which may not fully capture the variability and unpredictability of real-world MEC deployments. Future work will therefore focus on validating the framework using real-world datasets and experimental edge testbeds. Second, the Cognitive Evolutionary Synergy Optimization (CESO) mechanism relies on predefined parameters, such as learning rates and exploration temperatures; adaptive parameter tuning techniques can further improve robustness under highly dynamic network conditions. Additionally, the current framework assumes cooperative edge servers with uniform policy behavior, whereas practical deployments may involve heterogeneous administrative domains and pricing models. Extending the model to support distributed multi-provider scenarios is an important future direction. Addressing these aspects will enhance scalability, adaptability, and practical deployment readiness of the proposed DMUAA framework.

V. CONCLUSION AND FUTURE WORK

In this study, DMUAA, a Dynamic Multilevel User Allocation Algorithm has been introduced to deal with the long-lasting problem of latency and resource imbalance, as well as dynamic user mobility within the Mobile Edge Computing (MEC) setting. The proposed solution combines heuristic reasoning, stochastic exploration and strategic game-theoretic equilibrium by integrating the novel Cognitive Evolutionary Synergy Optimization (CESO) framework. The coordination and feedback mechanism also improves flexibility further, as DMUAA is able to constantly improve the resources allocation decisions based on the real time variation in the performance and QoE variances. DMUAA showed significant performance improvements over five state-of-the-art baselines through a wide range of simulations on a variety of network densities, resource capacities and workload patterns. The algorithm had up to 34 per cent reduced latency, 25-30 per cent increased QoE and SCR, 22 per cent increased energy-QoE efficiency, and 12 to 27 per cent increased resource utilization and reduced the number of servers that were active in operation and converged faster. All these findings confirm that DMUAA is a powerful, scalable, and energy-efficient solution of the next-generation MEC systems. Nevertheless, the current study is limited to simulation-based validation and assumes cooperative edge environments. Future work will focus on deploying DMUAA in real-world MEC testbeds to evaluate practical overheads and operational constraints. Additionally, reinforcement learning-based adaptive parameter tuning will be investigated to dynamically optimize exploration and convergence behavior. Extensions toward multi-tier MEC-cloud architectures, heterogeneous administrative domains, and privacy-aware allocation strategies also represent promising directions for improving scalability and real-world applicability.

ACKNOWLEDGMENT

The authors would like to express sincere gratitude to the Computer Science and Engineering and R&D department of SRM Institute of Science and Technology, for the vital support and resources provided throughout this research.

CONFLICT OF INTEREST

The authors declare that we have no conflict of interest.

FUNDING

The authors received no specific funding for this study.

Abstract—This study presents a systematic and deployment-oriented analysis of machine learning (ML) techniques for learning style identification in adaptive digital environments. A total of 57 peer-reviewed studies published between 2020 and 2025 were analysed using a PRISMA-guided methodology. Beyond descriptive synthesis, the review systematically examines algorithmic paradigms, multimodal data integration strategies, evaluation protocols, and deployment readiness characteristics. The findings reveal that classical supervised models remain prevalent in small-scale applications, while deep learning and ensemble methods demonstrate improved performance in high-dimensional behavioural datasets. However, significant heterogeneity exists in validation strategies, fusion architectures, and system scalability. To address these limitations, this study proposes a deployment-oriented architectural framework that integrates: 1) context-aware model selection, 2) structured multimodal fusion design, 3) layered explainability mechanisms, and 4) a four-level deployment maturity evaluation model. The framework provides a unified system-level perspective that shifts emphasis from isolated performance optimization toward scalable, interpretable, and integration-ready ML system design. This work contributes a structured computational blueprint for developing robust and deployment-aware learning style identification systems in intelligent educational platforms.

Keywords—Machine learning; learning style identification; multimodal data fusion; deep learning; ensemble learning; explainable artificial intelligence; deployment maturity; adaptive learning systems

I. INTRODUCTION

The rapid expansion of digital learning platforms has generated large-scale behavioural and interaction data, accelerating the development of machine learning (ML)-driven intelligent systems for educational analytics. Within this computational context, learning style identification (LSI) has evolved into a classification and modelling problem requiring robust algorithms, structured feature representation, and scalable system integration. Traditional LSI approaches, typically based on static self-report instruments such as the Felder-Silverman Learning Style Model (FSLSM), VARK, or Kolb's framework, are constrained by limited adaptability and delayed feedback mechanisms. Consequently, ML techniques have increasingly been employed to infer learner characteristics from behavioural logs, textual interactions, and multimodal data streams [1], [2].

Recent studies demonstrate the integration of ML models into intelligent tutoring systems and large-scale learning management systems (LMS), reflecting a shift toward data-driven learner modelling [3], [4]. A wide range of computational paradigms have been applied, including decision trees, support vector machines, deep neural networks, and ensemble learning architectures operating on heterogeneous data sources such as clickstream records and academic performance metrics [5], [6]. While classification performance has improved across reported studies, gains in accuracy alone do not ensure reproducibility, generalization, or scalable deployment.

Despite these technical developments, several computational limitations remain evident. Algorithmic comparisons are frequently conducted on isolated datasets without systematic cross-context validation, constraining generalization claims [7]. Multimodal data integration is often implemented through direct feature concatenation rather than architecturally principled fusion mechanisms, limiting robustness under heterogeneous or incomplete data conditions [8]. In addition, evaluation practices vary substantially, with heavy reliance on single-metric reporting and limited incorporation of uncertainty estimation or external validation protocols [9]. Although fairness, transparency, and privacy are increasingly discussed within AI systems research, they are seldom operationalized within LS modelling architectures in a structured manner [10]. These gaps suggest that while algorithmic experimentation is advancing, the field lacks a unified system-level design perspective for scalable and deployment-ready ML-based LS systems.

Existing review studies have largely catalogued algorithms or summarized reported performance metrics, providing descriptive overviews but limited architectural guidance. Unlike prior reviews that primarily enumerate algorithms, the present study develops a deployment-oriented computational framework that integrates modelling, evaluation, explainability, and system readiness within a unified design perspective. As machine learning systems transition from experimental prototypes toward integrated adaptive platforms, there is a growing need for structured computational frameworks that connect model selection strategies, multimodal fusion design, validation rigor, and deployment readiness.

To address this gap, this study conducts a systematic review of 57 peer-reviewed publications published between 2020 and 2025, following PRISMA 2020 guidelines [11]. Rather than

providing a purely descriptive synthesis, the review reorganizes the literature across three primary analytical dimensions: 1) algorithmic paradigm evolution, 2) multimodal data integration strategies, and 3) evaluation and validation practices. Building upon this synthesis, the study proposes a deployment-oriented framework for machine learning-based learning style identification systems that integrates a context-sensitive model selection matrix, structured multimodal fusion architectures, layered explainability mechanisms, embedded ethical design checkpoints, and a four-level deployment maturity model.

The contributions of this work are threefold. First, it provides a structured computational synthesis of contemporary ML approaches for LSI, emphasizing scalability, robustness, and generalization characteristics. Second, it introduces a deployment-oriented architectural framework translating empirical trends into system-level design guidance. Third, it proposes a maturity-based evaluation model to assess deployment readiness within adaptive intelligent systems.

By reframing LSI as a system design and deployment challenge rather than solely a predictive task, this study contributes a structured computational blueprint for scalable, interpretable, and integration-ready ML-based learning style systems.

In this study, deployment maturity is defined as the extent to which a machine learning system progresses from experimental validation to scalable, real-time, and context-adaptive integration within operational educational environments.

This study is guided by the following overarching research question: How can machine learning-based learning style identification systems be systematically designed to achieve scalability, robustness, interpretability, and deployment readiness in real-world educational environments?

The remainder of this study is structured as follows: Section II reviews related work on machine learning-based learning style identification. Section III presents the systematic review methodology. Section IV provides the analytical synthesis of findings. Section V introduces the proposed deployment-oriented framework. Section VI discusses practical implications and best practices, while Section VII details the limitations of the study and outlines future research directions. Section VIII concludes the study.

II. RELATED WORK

Research on learning style (LS) identification has progressively shifted from traditional rule-based and questionnaire-driven approaches toward automated machine learning (ML) and deep learning (DL) systems. Conventional LS models such as the Felder-Silverman Learning Style Model (FSLSM), VARK, and Kolb's experiential learning framework have been widely adopted as conceptual foundations for personalization. However, their operationalization through static instruments has raised concerns regarding scalability and real-time adaptability [12]. To address these limitations, data-driven ML techniques have increasingly been employed to infer learning styles from interaction data [13].

Recent studies have explored a range of supervised, semi-supervised, and clustering-based approaches. Classical

classifiers, including decision trees, SVM, logistic regression, and k-nearest neighbours remain widely applied due to interpretability and suitability for small institutional datasets [14], [15]. Ensemble methods and feature selection techniques have been introduced to improve robustness, particularly in imbalanced datasets [16], [17]. At the same time, hybrid and deep learning architectures combining LSTM, transformer-based models, and clustering strategies have emerged in MOOC and large-scale LMS contexts, enabling automated feature extraction and sequential pattern modelling [18], [19].

Despite these advances, several structural limitations persist. Many studies rely on limited or course-specific datasets, restricting generalizability. Validation is often conducted within a single institutional context, and systematic cross-domain evaluation remains rare. Furthermore, multimodal integration strategies are frequently implemented using straightforward concatenation or aggregation methods, without principled fusion architectures. These patterns indicate that while predictive performance has improved, architectural and validation standards remain inconsistent.

Beyond learning style identification, ML has been widely applied to adjacent educational domains, including student dropout prediction, academic performance forecasting, adaptive content recommendation, and support for learners with special needs [20], [21], [22]. These applications demonstrate the versatility of ML techniques, ranging from classical classifiers to deep learning and explainable AI (XAI) tools such as SHAP and LIME, but also highlight recurring challenges related to dataset bias, interpretability, and deployment scalability.

Existing review studies in LS modelling have primarily catalogued algorithms or compared reported performance metrics. Few have systematically examined how algorithm choice, data modality integration, evaluation practices, and deployment considerations interact within adaptive educational systems. Consequently, there remains a need for structured synthesis that bridges technical modelling advances with system-level design guidance.

This study addresses that need by providing a systematic and analytically structured review of ML approaches for learning style identification, positioning algorithmic evolution, validation practices, and multimodal integration within a unified deployment-oriented perspective.

III. METHODOLOGY

This systematic review followed a structured and transparent process designed to address the study objectives and research questions. The methodology comprised research question formulation, database search, eligibility screening, quality assessment, data extraction, and analytical synthesis. Peer-reviewed studies published between 2020 and 2025 were retrieved from selected academic databases using predefined inclusion and exclusion criteria. Relevant variables, including machine learning techniques, dataset characteristics, evaluation metrics, and key findings, were extracted from the selected studies. Fig. 1 presents the overall systematic review workflow adopted in this study. The process began with planning and the formulation of specific research questions, followed by a structured search across selected databases. Identified records

were screened using predefined inclusion and exclusion criteria, after which eligible studies underwent quality assessment. Only studies meeting the specified threshold were retained for detailed data collection and analysis. This structured approach ensured that the review remained focused, transparent, and aligned with the study objectives.

A qualitative analytical synthesis was conducted to identify recurring themes, research trends, and evidence gaps. The review process adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, as illustrated in Fig. 2, to ensure transparency and completeness [11], and the PRISMA checklist is contained in the Appendix. Additional research support tools were used to enhance review quality. Bibliometric analysis was performed using RStudio to explore keyword co-occurrence, Harzing's Publish or Perish was used to retrieve and analyse relevant articles, SciSpace assisted with literature screening and insight extraction [23], and Zotero was used to organize references. A total of 57 studies were ultimately included from an initial pool of 2,816 records after duplicate removal, date and language filtering, abstract screening, and full-text assessment. This rigorous process ensured that only relevant and recent studies on machine learning-based learning style identification were retained.

Fig. 1. Systematic review workflow.

A. Planning Phase

In this phase, the necessary steps to achieve the research objectives were identified. The study focuses on identifying LS using improved ML techniques. Also, both strategic and technical strategies to ensure that the rest of the proposed techniques can be executed systematically and consistently were identified. This planning phase served as the foundation for the successful implementation of the SLR method.

B. Research Questions and Motivations

This section presents the research questions investigated in the current SLR study and the motivations behind them. The motivations come from the noteworthy achievements of the work using ML techniques to identify LS. For instance, most studies have indicated that ML is essential to accurately improve LSI. Table I provides a clear outline of the research questions along with the motivations for exploring each question in the context of identifying LSI using enhanced ML techniques.

TABLE I. RESEARCH QUESTIONS AND MOTIVATIONS

Research Question	Motivation
RQ1: What are the state-of-the-art ML techniques currently being employed to identify LS in educational contexts, and how do they compare in terms of accuracy and effectiveness?	To understand the current landscape of ML methods used in LS identification and evaluate their performance.
RQ2: How do enhanced ML techniques improve the identification of LS over traditional methods, and what are the key metrics used to evaluate these improvements?	To assess the advancements made over traditional methods and determine the effectiveness of these improvements using standard metrics.
RQ3: How do different data sources and feature selection methods impact the performance and accuracy of LS prediction models?	To understand the importance of different types of data and features in predicting LS accurately.

C. Search Strategy and Term Justification

A comprehensive literature search was conducted across IEEE, Web of Science, Scopus, Google Scholar, and ScienceDirect. The core search expression was ("Machine learning" OR "Enhanced Machine Learning") AND ("Learning styles" OR "Learning style"). To improve search sensitivity and capture a broader spectrum of relevant studies, the expanded Boolean strategy also considered related terms such as "classification", "deep learning", "ensemble learning", "personalized learning", "explainability", "student modeling", and "educational data mining". The review focused on studies published between 2020 and 2025 to reflect post-COVID-19 developments in online and adaptive learning, including the recent growth of deep learning, explainable AI, and hybrid modelling approaches. The databases and corresponding search strings are presented in Table II.

D. Inclusion and Exclusion Criteria

The selection of studies for this review was guided by clearly defined inclusion and exclusion criteria. To be considered, studies had to be peer-reviewed journal or conference papers published between 2020 and 2025, written in English, and explicitly focused on the application of machine learning techniques to learning style identification. Additionally, only studies that employed empirical data or included experimental analysis were included. On the other hand, studies were excluded if they did not align with the objectives of the review for instance, those centred solely on theoretical frameworks without practical implementation. Non-peer-reviewed materials such as editorials and opinion pieces were also excluded. Duplicate publications and studies that lacked sufficient detail regarding the machine learning methods used or their evaluation metrics were removed from consideration. A summary of these criteria is presented in Table III.

TABLE II. DATABASE SEARCH STRATEGY AND RETRIEVED STUDY DISTRIBUTION ACROSS DIGITAL LIBRARIES

Digital Database	Field	Search Strings	No. of result
IEEE	All	("Machine learning" OR "Enhanced Machine Learning") AND ("Learning styles" OR "Learning style")	204
Web of Science	All	("Machine learning" OR "Enhanced Machine Learning") AND ("Learning styles" OR "Learning style")	178
Scopus	TITLE-ABS-KEY	("Machine learning" OR "Enhanced Machine Learning") AND ("Learning styles" OR "Learning style")	325
Science Direct	All	("Machine learning" OR "Enhanced Machine Learning") AND ("Learning styles" OR "Learning style")	1336
Google Scholar	All	("Machine learning" OR "Enhanced Machine Learning") AND ("Learning styles" OR "Learning style")	773
Overall			2816

TABLE III. INCLUSION AND EXCLUSION CRITERIA

Inclusion Criteria for the paper to be included	Exclusion Criteria for the paper to be excluded
Papers published between 2020 and 2025 only.	Papers published before 2020.
Paper related to Research question 1 to Research question 3 (RQ1 to RQ3)	Paper not related to the research question RQ1 to RQ3.
Published conferences and journal paper.	Paper not published in conferences and journal.
Peer review Papers/article only	Not peer review Papers/article
Papers written in English language only.	Not written in English language.
Open access paper.	Not open access papers.
	Duplicate.

E. Quality Assessment

The quality assessment process was carried out to limit the scope of data collection and to ensure targeted and reliable analysis. The main objective was to assess the extent to which each selected study answered the research questions outlined in this review [24]. To maintain objectivity, two independent reviewers assessed the studies against a set of predefined questions aligned with the research objectives. Inter-rater reliability was measured using Cohen's Kappa. The coefficient of $k = 0.75$ indicates a high level of agreement [24]. This procedure helped to accurately identify relevant studies and filter out those that did not fulfil the criteria. Table IV shows the three quality assessment questions that were used to guide this assessment, while Table V shows the scoring matrix for each study. These questions were specifically selected based on their alignment with the objectives of the study and their effectiveness in determining relevance. Each paper could receive a maximum score of 3, and studies that achieved a score of 2 or higher were included because they either demonstrated a general, comprehensive analysis with sufficient detail or provided a strong, well-supported examination of the topic. The quality scores assigned to each of the articles reviewed are summarized in Table VI.

TABLE IV. QUALITY ASSESSMENT AND QUESTIONNAIRE

Quality Assessment Question	Relevant to the Research Question
QA1: Is the research objective clearly stated and aligned with the study's focus on identifying learning styles using machine learning techniques?	RQ1
QA2: Are the machine learning techniques and evaluation metrics used in the study clearly described and justified?	RQ2

QA3: Are the types of data and features used in the study clearly described and appropriate for the research questions?	RQ3
---	-----

TABLE V. QUALITY ASSESSMENT SCORING MATRIX

Quality Assessment Scoring Criteria	Score
The author(s) have provided a detailed, explicit, and clear understanding of the answers of the specific RQ.	High=H=1
The author(s) have provided some general explanation, but not detailed, explicit, and clear understanding on the answers to the specific RQ.	Medium=M=0.5
The author(s) have provided no and very few technical details to the specific RQ.	Low=L=0

F. Data Collection

Following quality assessment, data extraction was conducted using a structured coding protocol. Each study was systematically analysed across predefined dimensions, including algorithmic paradigm, data modality, feature engineering strategy, evaluation metrics, and validation protocol. To ensure consistency, extracted variables were normalized into unified categorical and numerical representations. Studies were subsequently grouped into analytical clusters to support cross-study comparison and synthesis. This structured approach enabled the identification of recurring methodological patterns and facilitated cross-dimensional analysis aligned with the research questions. The overall review process followed the PRISMA framework, ensuring that the methodology was systematic, transparent, and rigorous, as illustrated in Fig. 2.

Fig. 2. PRISMA flow diagram.

G. Data Analysis

The data analysis stage synthesized the extracted evidence to answer the research questions defined for this study. Analytical

grouping, comparative interpretation, and quality assessment scores were used to organize the reviewed literature and identify dominant patterns. The article list and corresponding quality assessment scores are presented in Table VI.

IV. RESULTS AND ANALYTICAL SYNTHESIS

This section presents a structured analytical synthesis of 57 studies published between 2020 and 2025. Rather than merely enumerating algorithms, the literature is reorganized across three primary analytical dimensions: algorithmic paradigm evolution, evaluation and validation practices, and multimodal data integration, followed by a cross-dimensional synthesis emphasizing deployment readiness. This analytical structure provides a clearer understanding of how learning style identification research is evolving toward scalable adaptive systems.

Fig. 3. Keyword co-occurrence network of ML-based learning style research.

Fig. 3 presents the keyword co-occurrence network derived from the reviewed corpus, illustrating the conceptual structure of ML-based learning style research. Two dominant thematic clusters are observable. The first cluster centres on technological constructs; including machine learning, deep learning, artificial intelligence, and learning analytics indicating a strong emphasis on computational modelling and predictive techniques. The second cluster emphasizes educational constructs such as learning style, e-learning, classification, and adaptive learning, reflecting application-driven personalization within digital environments. The interconnection between these clusters highlights the interdisciplinary nature of the field, where algorithmic innovation intersects with pedagogical objectives. The presence of terms such as MOOCs and intelligent systems

suggests increasing attention toward scalable and adaptive deployment contexts. Collectively, the network structure reinforces the need for integrative frameworks that coordinate technological advancement with educational system design.

Unless otherwise stated, percentage values reported in this section represent proportional counts of reviewed studies categorized according to their primary methodological orientation. Some studies exhibit methodological overlap across categories; therefore, percentages are intended to indicate dominant patterns rather than mutually exclusive classification totals.

A. RQ1: Algorithmic Landscape and Paradigm Evolution

This section addresses RQ1 by examining the dominant machine learning paradigms employed for learning style identification and analysing their comparative performance characteristics, contextual suitability, and evolutionary trends across the reviewed studies.

1) *Classical supervised models*: Classical supervised learning approaches, including Decision Trees, Support Vector Machines (SVM), Logistic Regression, and k-Nearest Neighbours (k-NN), dominated early studies between 2020 and 2022 [15], [29], [39], [47], [55]. These models were frequently adopted due to their interpretability, relatively low computational requirements, and suitability for small or institution-level datasets. In contexts where dataset sizes were limited and feature sets were manually engineered, such models provided stable and explainable classification performance. However, their predictive effectiveness often depended heavily on handcrafted feature extraction and preprocessing strategies. Several studies reported performance degradation when datasets were imbalanced or insufficiently representative, with overfitting risks particularly evident in small-sample institutional deployments [39], [57], [70]. While these models remain attractive for classroom-scale adaptive tools, their robustness across heterogeneous learning environments appears constrained.

Analytical observation: Classical supervised approaches continue to provide accessible and interpretable solutions but

demonstrate limited generalizability across diverse educational contexts.

2) *Deep representation learning*: From 2022 onward, there has been a noticeable increase in the adoption of deep learning architectures, particularly Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and autoencoder-based models [14], [46], [54], [68]. These approaches were predominantly applied in MOOC-scale and large LMS datasets characterized by high-dimensional interaction logs and sequential behavioural data. Deep architectures enabled automatic extraction of latent behavioural patterns, reduced dependence on manual feature engineering, and improved classification stability in data-rich environments. In several cases, deep models outperformed traditional classifiers when sufficient training data were available. However, most implementations were validated within single datasets, and cross-institution or cross-context validation was rarely performed. Additionally, limited integration of interpretability mechanisms was observed, raising concerns regarding transparency and stakeholder trust in educational settings.

Analytical observation: Deep representation learning enhances predictive capacity in large-scale digital environments but introduces transparency and generalization challenges that may constrain institutional adoption.

3) *Ensemble optimization approaches*: Ensemble-based methods, including Random Forest, Gradient Boosting, and Extreme Gradient Boosting (XGBoost), demonstrated consistently strong reported performance across multiple datasets [15], [33], [43], [52]. By aggregating predictions from multiple base learners, these approaches improved robustness under noisy feature conditions and mitigated overfitting risks associated with single-model classifiers. Ensemble strategies were particularly effective when heterogeneous feature types were combined, including behavioural metrics, academic records, and demographic indicators. Nevertheless, while ensembles often provided improved predictive stability, interpretability trade-offs persisted, especially in boosting-based implementations.

Key pattern identified: Ensemble methods appear to offer a practical balance between predictive robustness and interpretability, positioning them as strong candidates for intermediate-scale adaptive learning systems.

4) *Hybrid and multimodal architectures*: A growing subset of studies explored hybrid and multimodal architectures that integrate multiple data sources, including behavioural logs, textual content, physiological signals, and demographic information [17], [18], [19]. These approaches often combined deep feature extraction modules with classical classifiers or ensemble layers, thereby leveraging complementary strengths across modelling paradigms. Hybrid configurations demonstrated improved cross-feature robustness and adaptability, particularly in contexts where behavioural signals alone were insufficient for accurate classification. However,

structured multimodal fusion strategies such as attention mechanisms, modality weighting, or dropout-based robustness techniques were rarely implemented. Most studies relied on simple feature concatenation or late-stage aggregation.

Emerging trend: The field is progressively shifting from single-modality classification toward multimodal adaptive modelling, although systematic architectural principles for fusion remain underdeveloped.

Across the 57 reviewed studies, 51% employed classical supervised models as their primary modelling paradigm, 32% utilized deep learning architectures, and 16% implemented ensemble techniques. Although deep learning adoption is increasing, classical approaches remain dominant in small-scale institutional contexts, while multimodal and hybrid systems represent an emerging but still developing direction.

Table VII provides a consolidated distribution of machine learning techniques identified across the reviewed studies, supporting the aggregated paradigm-level analysis presented above.

TABLE VII. DISTRIBUTION OF MACHINE LEARNING TECHNIQUES ACROSS REVIEWED STUDIES (2020-2025)

ML Category	Technique	Frequency	Studied IDs
Clustering	K-Means,	12	AS47, AS21, AS22, AS38, AS42, AS45, AS25, AS27, AS16, AS01, AS04, AS06
	Hierarchical Clustering,	1	AS14
	Gaussian Mixture Models (GMM)	1	AS28
Classification	Logistic Regression,	4	AS49, AS24, AS55, AS57
	Decision Trees,	11	AS40, AS46, AS42, AS19, AS13, AS14, AS17, AS05, AS55, AS56, AS57
	Support Vector Machines (SVM),	7	AS47, AS15, AS32, AS22, AS35, AS55, AS56
	k-Nearest Neighbours (k-NN),	5	AS32, AS22, AS29, AS56, AS57
	Naive Bayes	2	AS24, AS55
NLP	TF-IDF,	7	AS37, AS27, AS16, AS08, AS09, AS10, AS18
Bayesian Network	Naive Bayes,	3	AS41, AS19, AS08
	Bayesian Belief Networks,	1	AS42
	Gaussian Naive Bayes,	1	AS35
	Bayesian Network Classifiers	3	AS33, AS04, AS07
Deep learning	Convolutional Neural Networks (CNN),	10	AS50, AS23, AS31, AS34, AS36, AS17, AS03, AS09, AS12, AS57
	Recurrent Neural Networks (RNN),	6	AS53, AS54, AS48, AS51, AS10, AS18
	Autoencoders,	1	AS46

	Generative Adversarial Networks (GANs),	1	AS52
Ensemble	Random Forests,	5	AS50, AS43, AS19, AS34, AS09
	Gradient Boosting Machines (GBM),	2	AS54, AS29
	XGBoost,	2	AS15, AS22
Others		8	AS43, AS44, AS20, AS26, AS30, AS33, AS34, AS11

The distribution reinforces the continued dominance of classical supervised approaches, while highlighting the increasing presence of deep learning and ensemble techniques in recent years.

B. RQ2: Evaluation Practices and Performance Patterns

This section addresses RQ2 by examining how machine learning models for learning style identification are evaluated, which performance metrics are reported, and how validation strategies influence the interpretation of effectiveness across educational contexts.

1) *Performance metrics and reporting standards:* Across the reviewed literature, accuracy was the dominant evaluation metric, reported in 89% of studies. F1-score was reported in 54% of cases, while precision and recall were separately documented in 37% of studies. However, fewer than 10% of publications reported confidence intervals, and only 18% provided measures of variance such as standard deviation. This heavy reliance on accuracy as a primary metric limits meaningful cross-study comparison, particularly in contexts where class imbalance is present. In learning style identification tasks, where distributional skew may occur across preference categories, exclusive dependence on accuracy can obscure misclassification patterns. The relatively limited reporting of uncertainty measures further constrains the reproducibility and statistical interpretability of results.

Analytical observation: Evaluation practices remain metric-centric rather than reliability-centric, with insufficient emphasis on uncertainty quantification and robustness analysis.

2) *Validation protocols and generalization:* Validation strategies varied considerably across the reviewed studies. Approximately 63% employed k-fold cross-validation, while 28% relied on simple hold-out validation. Only 7% of studies conducted cross-dataset or cross-institution validation. Longitudinal validation, in which models are tested across different academic cohorts or time periods, was rarely observed. Although k-fold cross-validation enhances internal reliability, it does not guarantee cross-context generalization. The limited adoption of external validation protocols suggests that many models remain optimized for dataset-specific conditions rather than scalable educational deployment. Furthermore, few studies reported hyperparameter tuning strategies or ablation analyses, making replication challenging.

Analytical Observation: While internal validation practices are common, cross-context generalization remains underexplored, constraining claims of scalability.

3) *Comparative performance patterns:* When comparing algorithmic categories, ensemble and deep learning approaches frequently reported higher predictive performance relative to classical supervised models, particularly in data-rich environments [1], [17], [64], [67], [68]. However, performance improvements were often incremental rather than transformative and were highly dependent on dataset characteristics, feature engineering quality, and validation protocol. Notably, studies incorporating multimodal data sources tended to report improved classification stability compared to unimodal implementations. Nevertheless, direct cross-study performance comparison remains difficult due to inconsistent reporting standards and heterogeneous dataset characteristics. A cross-study comparative analysis further indicates that ensemble and deep learning approaches generally outperform classical supervised models in data-rich environments, particularly when multimodal inputs are incorporated. However, performance improvements remain context-dependent and strongly influenced by dataset scale, feature engineering quality, and validation strategy. This indicates that algorithmic superiority cannot be assessed in isolation but must be interpreted within the broader system design context.

Key pattern identified: Reported performance gains are strongly influenced by dataset scale, feature design, and validation strategy, suggesting that algorithmic superiority cannot be assessed independently of contextual factors.

Fig. 4 visualizes comparative performance trends across modelling paradigms using a qualitative aggregation scale (1-5) to reflect relative consistency and strength of reported outcomes. Owing to methodological heterogeneity across studies, the scale represents synthesized performance patterns rather than standardized benchmark comparisons. The heatmap, therefore, highlights cross-metric trends and variability without implying direct statistical equivalence between algorithms.

Fig. 4. Comparative performance heatmap of major ML paradigms across evaluation metrics.

This heatmap illustrates the relative performance patterns of classical, deep learning, and ensemble methods across five commonly reported metrics: accuracy, precision, recall, F1-score, and AUC-ROC based on aggregated findings from the reviewed studies.

4) *Reliability and reproducibility gaps*: A recurring limitation across the reviewed literature is the absence of standardized benchmarking datasets and shared evaluation protocols. Few studies made datasets publicly available, and replication studies were virtually non-existent. The lack of consistent reporting on preprocessing steps, feature normalization, and model hyperparameters further impedes reproducibility. These limitations highlight a structural gap between experimental model development and robust, transferable educational implementation. Without standardized validation frameworks, reported improvements may reflect dataset-specific optimization rather than generalizable advancement.

Analytical observation: The field demonstrates methodological diversity, but lacks consolidated benchmarking standards necessary for cumulative progress.

C. RQ3: Data Modalities and Feature Engineering Strategies

This section addresses RQ3 by analysing how different data modalities and feature engineering strategies influence predictive robustness, model scalability, and deployment feasibility in learning style identification systems.

1) *Dominant data modalities*: The reviewed studies employed a range of data sources, with behavioural interaction logs and academic performance records being the most frequently utilized modalities. Behavioural data including clickstream activity, time-on-task, navigation sequences, and assessment attempts were particularly prevalent in LMS-based environments [1], [18]. Academic performance metrics such as grades, quiz scores, and assignment outcomes were commonly integrated as structured input variables. Textual data, including forum posts and reflective writing submissions, appeared less frequently but were leveraged in studies employing natural language processing techniques. Physiological signals, such as EEG or eye-tracking data, were present in a limited subset of experimental settings due to infrastructural and ethical constraints. Demographic features were occasionally incorporated as supplementary variables but rarely served as primary predictive drivers. Across the 57 reviewed studies, only 21% implemented true multimodal integration involving two or more distinct data types. The majority relied on single-modality datasets, predominantly behavioural or academic records.

Analytical observation: While multimodal approaches are emerging, unimodal implementations remain dominant, limiting the depth of learner representation and adaptive personalization potential.

2) *Feature engineering and representation strategies*: Feature engineering practices varied significantly across studies. In classical supervised models, manual feature

extraction was the norm, involving statistical summaries, interaction frequencies, session durations, and categorical encodings. Feature selection methods such as correlation analysis, principal component analysis (PCA), and information gain were occasionally employed to reduce dimensionality. In contrast, deep learning models relied more heavily on automated representation learning. Sequential modelling techniques, particularly RNN-based architectures, captured temporal behavioural patterns without extensive manual preprocessing. However, even in deep learning implementations, preprocessing decisions such as normalization, tokenization (for textual data), and imbalance handling remained critical determinants of performance. Notably, few studies reported systematic ablation analyses to quantify the impact of individual feature groups. Additionally, handling of missing data and modality imbalance was inconsistently addressed.

Analytical observation: Although representation learning reduces dependence on manual feature design, feature engineering practices remain heterogeneous and insufficiently standardized.

3) *Multimodal fusion strategies*: Among studies employing multimodal data, fusion strategies were generally implemented using simple early or late fusion mechanisms. Early fusion typically involved concatenating feature vectors before model training, whereas late fusion aggregated predictions from modality-specific classifiers. Intermediate fusion approaches where embeddings from separate subnetworks are integrated at latent layers were comparatively rare. Advanced fusion strategies such as attention-based weighting, adaptive modality selection, or modality dropout regularization were seldom observed. Consequently, most multimodal implementations lacked dynamic weighting mechanisms capable of handling modality-specific noise or missing inputs.

These findings suggest that while multimodal interest is growing, architectural sophistication in cross-modal integration remains limited.

Key pattern identified: Multimodal integration is conceptually recognized as beneficial, but is often operationalized through simplistic fusion techniques rather than structured representation learning.

4) *Scalability and practical constraints*: Data modality selection is closely linked to scalability and deployment feasibility. Behavioural logs and academic records are readily available in LMS platforms and therefore support scalable implementation. In contrast, physiological data collection requires specialized hardware and raises privacy concerns, restricting broader adoption.

Textual and multimodal approaches introduce increased computational complexity and data preprocessing demands. Few studies discussed infrastructure requirements or real-time processing constraints, further reinforcing the gap between experimental modelling and deployable system design.

Analytical observation: Data modality choices directly influence system scalability, cost, and ethical compliance, underscoring the need for context-sensitive model design.

D. Cross-Dimensional Synthesis

The analytical synthesis of RQ1-RQ3 reveals several interconnected structural patterns shaping the current landscape of machine learning-based learning style identification. First, algorithmic evolution (RQ1) demonstrates a gradual shift from interpretable classical classifiers toward ensemble and deep representation learning models, particularly in data-rich LMS and MOOC environments. However, this algorithmic sophistication has not been matched by corresponding advances in evaluation rigor (RQ2), as validation practices remain predominantly internal and dataset specific.

Second, the dominance of unimodal behavioural datasets (RQ3) partly explains the persistence of classical and ensemble approaches, as limited data diversity constrains the benefits of advanced multimodal architectures. Although multimodal modelling is increasing, most implementations rely on simplistic fusion strategies without systematic treatment of modality imbalance or missing data. Consequently, architectural complexity does not consistently translate into demonstrable generalization gains.

Third, evaluation and feature engineering practices appear strongly interdependent. Models employing automated representation learning frequently lack transparent reporting of preprocessing steps, while manually engineered feature pipelines often omit robustness testing. The absence of standardized benchmarking datasets and cross-context validation further complicates meaningful comparison across algorithmic paradigms.

Taken together, these observations indicate that the field has achieved notable progress in predictive modelling but remains structurally fragmented. Algorithm selection, data modality integration, and validation design are often treated as isolated decisions rather than coordinated components of a unified adaptive system architecture. This fragmentation limits scalability, reproducibility, and institutional deployment readiness. To further consolidate the structural patterns identified across algorithmic paradigms and design strategies, Table VIII classifies the reviewed studies according to their primary developmental focus.

TABLE VIII. THEMATIC CLASSIFICATION OF REVIEWED STUDIES BY DEVELOPMENTAL FOCUS

Category	Frequency	Study IDs
Feature Engineering	20	AS21, AS45, AS29, AS15, AS13, AS08, AS07, AS52, AS54, AS46, AS44, AS31, AS26, AS25, AS05, AS35, AS42, AS22, AS55, AS12
Algorithmic Improvements	28	AS20, AS39, AS40, AS21, AS45, AS29, AS30, AS15, AS17, AS24, AS43, AS32, AS23, AS33, AS27, AS14, AS16, AS36, AS08, AS47, AS01, AS54, AS53, AS48, AS49, AS03, AS56, AS57
Hybrid Models	21	AS40, AS41, AS19, AS28, AS23, AS20, AS02, AS07, AS50, AS01, AS53, AS37, AS48, AS51, AS44, AS34, AS31, AS45, AS38, AS55, AS57

An important observation emerging from the thematic classification is the presence of cross-category overlap among several studies. Several works simultaneously incorporate feature engineering refinement, algorithmic optimization, and hybrid architectural strategies. This overlap indicates that methodological advancement in learning style identification is increasingly multi-layered rather than confined to isolated improvements. However, while combinatorial approaches are emerging, integration is often partial and lacks a coordinated system-level design perspective. In many cases, feature refinement, model optimization, and multimodal fusion are implemented independently rather than within a unified deployment framework.

These cross-dimensional findings motivate the need for a structured, deployment-oriented framework that integrates model selection, multimodal design, evaluation standards, explainability mechanisms, and maturity-based deployment assessment. The following section builds on this synthesis to propose such a framework, translating empirical trends into system-level design guidance for scalable educational AI applications.

E. Evolution of Research Focus and System Maturity

To further contextualize the cross-dimensional findings, the reviewed studies were mapped across four thematic orientations: performance improvement, enhanced personalization, data quality and stability, and scalable/adaptable model development. Fig. 5 presents the temporal distribution of these focus areas from 2020 to 2025.

Improved Performance	AS36, AS13, AS14, AS04, AS17, AS01, AS02	AS15, AS31	AS42, AS42, AS20, AS43, AS41, AS21, AS19, AS23	AS39, AS40, AS42, AS43	AS51, AS52, AS53, AS54, AS46, AS47, AS48, AS49	AS55, AS56, AS57
Enhanced Personalized Learning	AS07, AS04, AS17	AS15, AS35, AS33	AS25, AS27, AS30, AS28	AS40, AS44, AS39, AS45, AS41	AS48, AS53	AS55, AS56, AS57
Improved Stability & Quality of Data	AS36, AS03, AS08, AS16	AS15, AS35	AS30, AS43, AS24, AS19, AS23, AS32	AS42, AS39, AS40, AS38	AS51, AS47, AS48	AS56
Scalable & Adaptable model	AS04, AS06, AS03	AS31, AS35	AS23, AS29, AS22	AS39, AS41, AS42	AS52, AS53, AS50, AS54	AS57
	2020	2021	2022	2023	2024	2025

Fig. 5. Temporal evolution of research focus in ML-based learning style systems (2020-2025).

The mapping reveals that early research (2020-2021) predominantly emphasized performance optimization through algorithm comparison and accuracy improvement. From 2022 onward, a gradual expansion toward personalization refinement and data robustness became evident. More recent studies increasingly addressed scalability and system adaptability, indicating a transition from isolated classification experiments toward implementation-aware design considerations.

Notably, the emergence of scalability-focused research aligns with the broader maturation of educational AI systems. However, while thematic diversification is observable,

integration across these dimensions remains limited. Most studies concentrate on a single improvement objective rather than coordinating performance, robustness, personalization, and scalability within a unified architectural framework.

These findings reinforce the need for structured system-level guidance that consolidates these thematic strands into a coherent deployment strategy. The following section translates this thematic evolution into a deployment-oriented design framework for ML-based learning style systems.

This figure categorizes reviewed studies into four thematic orientations: performance improvement, personalization enhancement, data stability, and scalable/adaptable model development, illustrating the progressive diversification of research priorities across the review period.

V. A DEPLOYMENT-ORIENTED FRAMEWORK FOR ML-BASED LEARNING STYLE SYSTEMS

While the preceding sections examined algorithmic and methodological trends, the present section translates those findings into a structured framework for the design, evaluation, and deployment of machine learning (ML) systems for learning style (LS) identification in adaptive educational environments. Recent research in educational artificial intelligence increasingly emphasizes the need to bridge experimental model development with scalable, accountable system integration [72], [73], [74]. However, structured deployment guidance remains limited. To address this gap, the proposed framework integrates four interdependent dimensions:

- Context-sensitive model selection,
- Multimodal fusion architecture design,
- Layered explainability integration, and
- Deployment maturity assessment.

These dimensions are derived from the cross-dimensional patterns identified in Section IV and are intended to operationalize evidence-based design principles for scalable adaptive systems.

A. Model Selection Matrix for Educational Contexts

A recurring limitation in the reviewed literature is the absence of explicit criteria for selecting machine learning models according to educational constraints. Model choice is frequently performance-driven rather than context-driven, despite evidence that interpretability, data volume, and deployment scale substantially influence practical feasibility [4], [75]. To address this issue, this study proposes the context-sensitive model selection matrix, as shown in Table IX.

Analytical rationale: Educational decision-making often involves pedagogical accountability; therefore, interpretable models are preferable in high-stakes contexts. Tree-based models and SVM classifiers offer transparency and lower computational demands. Conversely, large-scale LMS and MOOC environments generate high-dimensional interaction logs that benefit from representation learning through deep neural architectures [76]. In multimodal adaptive systems, hybrid architectures combining ensemble learning with structured fusion mechanisms provide improved robustness and

adaptability [77]. This matrix reframes model selection from isolated performance optimization toward context-aware system design.

TABLE IX. MODEL SELECTION GUIDELINES FOR LEARNING STYLE SYSTEMS

Educational Context	Data Availability	Interpretability Requirement	Recommended Model Type
Small classroom tools	Limited	High	Decision Trees/SVM
Institutional dashboards	Moderate	Medium	Random Forest/XGBoost
MOOC-scale platforms	Large behavioral logs	Low-Medium	Deep Learning (RNN/CNN)
Adaptive intelligent tutoring systems	Multimodal	Medium	Hybrid/Ensemble + Fusion

B. Multimodal Fusion Architecture Patterns

Section IV revealed increasing adoption of multimodal inputs, yet most implementations rely on relatively shallow fusion strategies. Similar observations have been reported in broader educational AI research, where multimodal integration often lacks principled architectural design [78], [79].

Fusion strategies can be categorized into three structural levels as follows:

1) *Early fusion*: In early fusion architectures, raw features from different modalities are concatenated prior to model training. While computationally straightforward, this approach is sensitive to modality imbalance and noise dominance, particularly when behavioural and textual data differ substantially in scale.

2) *Intermediate fusion*: Intermediate fusion employs separate subnetworks for each modality, merging learned embeddings at latent layers. This design supports representation learning while preserving modality-specific structures. Recent multimodal educational systems increasingly adopt this approach to enhance robustness and generalization [80].

3) *Late fusion*: Late fusion involves independent modality-specific classifiers whose outputs are aggregated through ensemble voting or stacking mechanisms. This approach improves modularity and resilience to missing modalities, making it suitable for deployment environments with incomplete learner data.

Identified architectural gap: Across the reviewed corpus, advanced mechanisms such as modality dropout regularization, cross-modal attention, and adaptive fusion weighting were rarely implemented. Yet these techniques are increasingly recognized as critical for robust multimodal AI systems [81]. Their limited adoption indicates architectural immaturity relative to system-level deployment demands.

C. Explainability Integration Framework

Interpretability remains a central barrier to educational ML deployment. Regulatory, ethical, and pedagogical accountability require transparency in automated learner modelling [82], [83]. A three-layer explainability integration structure is proposed, as shown in Table X.

TABLE X. EXPLAINABILITY INTEGRATION LAYERS

Layer	Purpose	Representative Tools
Model-Level	Feature contribution analysis	SHAP, LIME
Decision-Level	Rule extraction / local explanation	Tree-based rules, surrogate models
System-Level	Transparent reporting dashboards	Visual analytics panels

Embedding explainability during model design rather than post hoc enhances educator trust, supports regulatory compliance, and strengthens institutional accountability. Recent educational AI research emphasizes that explainability must be structurally integrated into adaptive systems rather than appended as an auxiliary feature [84].

D. Ethical and Fairness Design Integration

Although ethical issues are now widely discussed in adaptive learning research, they are still not sufficiently built into the actual design of most systems [85]. In many cases, ethics is treated as a general principle rather than a practical requirement that shapes how the system is developed and used. To make machine learning-based learning style systems more responsible and trustworthy, ethical and fairness considerations should be integrated throughout the full system lifecycle. At the data collection stage, this includes obtaining informed consent from learners, protecting personal information through anonymization, and checking the data for possible sources of bias. During model training, attention should be given to reducing class imbalance, applying fairness-aware learning strategies, and examining whether model performance differs across learner groups. At the deployment stage, ethical integration should continue through human oversight, regular monitoring for emerging bias, and clear reporting mechanisms that make system decisions more transparent. Embedding these safeguards across data collection, model development, and deployment helps move ethical AI from abstract discussion into practical system design and supports current expectations for responsible governance in educational AI [86].

E. Deployment Maturity Model for ML-Based Learning Style Systems

To systematically evaluate readiness for real-world implementation, this study introduces a four-level deployment maturity model, as shown in Table XI.

TABLE XI. DEPLOYMENT MATURITY LEVELS

Level	Description	Characteristics	Example Scenario
Level 1: Experimental	Offline prototype	Single dataset; no real-time integration	Research laboratory model
Level 2: Dataset-Validated	Cross-validation reported	Moderate robustness; limited scope	Institutional pilot
Level 3: Platform-Integrated	LMS-connected system	Real-time classification; baseline explainability	University dashboard
Level 4: Cross-Context Adaptive	Multi-institution validation	Multimodal, explainable, fairness-audited	Scalable adaptive platform

Observations from reviewed studies: Most studies remain within Level 1 or Level 2, focusing on offline evaluation. A smaller subset demonstrates characteristics of Level 3 integration. None fully satisfy Level 4 criteria, which require cross-context validation, structured multimodality, embedded explainability, and operational fairness monitoring.

Strategic implication: These findings indicate that although predictive modelling techniques are advancing, the field remains structurally immature regarding scalable and context-robust deployment. The maturity model provides a structured benchmark for evaluating progression toward adaptive system integration.

F. Integrated Framework Overview

The proposed framework brings together five closely connected elements: context-aware algorithm selection, structured multimodal architecture design, layered explainability integration, embedded ethical safeguards, and deployment maturity assessment. Rather than treating these as separate concerns, the framework combines them into a unified design structure for next-generation adaptive learning systems. This integrated view shifts attention away from focusing only on algorithmic accuracy and instead emphasizes how different components work together to support real-world educational use. In doing so, the framework provides a practical foundation for building machine learning-driven educational systems that are scalable, transparent, and accountable. Fig. 6 illustrates this integrated deployment-oriented architecture by showing how the five layers interact with one another and with the broader system properties that influence successful implementation.

Fig. 6. Deployment-oriented framework for ML-based learning style systems.

The architecture illustrates a bottom-to-top progression from multimodal input space through model selection, evaluation and generalization, trust and transparency integration, and finally deployment readiness, with cross-cutting properties (scalability, interpretability, robustness, and generalization) guiding system maturation.

VI. DISCUSSION

This review reveals an increasingly sophisticated yet structurally fragmented landscape in the application of machine learning (ML) to learning style identification (LSI). Although predictive performance has improved across modelling paradigms, methodological consistency, cross-context generalization, and deployment readiness remain uneven.

A. Comparative Evaluation of Modelling Paradigms

Deep learning and ensemble approaches consistently report high performance across accuracy, precision, recall, and F1-score metrics. Their strength lies in handling high-dimensional behavioural logs and complex learner interaction patterns. However, these models frequently lack interpretability and are rarely validated beyond single datasets, limiting institutional trust and scalability.

Classical supervised methods, including decision trees and support vector machines, remain prevalent in small-scale contexts due to their transparency and computational efficiency. Nevertheless, they demonstrate reduced robustness when applied to multimodal or unstructured data environments.

Clustering and unsupervised methods are effective in exploratory settings and where labelled data are limited. Yet their outputs often require post hoc interpretation and provide limited operational guidance without additional modelling layers.

Hybrid architectures represent a promising middle ground. By combining representation learning with interpretable classifiers or ensemble aggregation, they offer improved performance stability while partially addressing transparency concerns. This suggests that balanced, context-aware modelling strategies may be more sustainable than performance-driven model selection alone.

B. Structural Challenges and Persistent Gaps

Despite technical advances, several structural limitations constrain progress.

First, generalizability remains weak. Many high-performing models are trained and evaluated on proprietary or context-specific datasets, restricting claims of cross-institution robustness. Second, deployment validation is limited. Most systems are evaluated offline rather than within live LMS or classroom workflows, reducing confidence in real-world applicability. Third, interpretability is inconsistently embedded. Complex architectures such as CNNs and autoencoders often function as black boxes, posing barriers to educator adoption and accountability [87], [88]. Fourth, data quality issues, including sparsity, class imbalance, and contextual bias continue to affect model reliability and fairness [48]. These findings reinforce the need to shift from algorithm-centric experimentation toward deployment-aware system design.

C. Best Practices for Robust LS Modelling

Several methodological practices emerged as consistently associated with stronger contributions.

From a system development perspective, several practical guidelines emerge. First, model selection should be aligned with data availability, interpretability requirements, and deployment constraints rather than solely predictive performance. Second, multimodal fusion strategies should prioritize intermediate or adaptive architectures to improve robustness under heterogeneous data conditions. Third, evaluation protocols should incorporate multi-metric assessment and cross-context validation to enhance reliability. Finally, explainability and fairness mechanisms should be embedded during model design to support transparency, accountability, and institutional adoption.

These practices collectively support the development of scalable and context-aware learning analytics systems.

D. Practical and Ethical Implementation Considerations

For responsible educational deployment, implementation must prioritize interpretability, privacy, and fairness alongside predictive strength.

Initial deployments should favour interpretable or hybrid models, particularly in high-stakes academic decision contexts. Embedding explainability mechanisms during model design rather than as post hoc add-ons enhances educator confidence and accountability. Data governance practices must include anonymization, secure storage, and informed consent procedures [46]. Additionally, fairness auditing should be systematically applied to detect demographic or contextual bias. Ultimately, ML-based LS systems must align with institutional policies and societal values. Technical accuracy alone is insufficient for sustainable adoption.

VII. LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

A. Study Limitations

This study is subject to several limitations. First, the inclusion period (2020-2025) prioritizes recent developments but excludes earlier foundational work. Second, heterogeneity in datasets, evaluation protocols, and reporting standards limit the feasibility of quantitative meta-analysis. Third, reliance on indexed digital libraries introduces potential database bias, while publication bias may favour studies reporting positive results. Finally, the limited availability of publicly accessible datasets restricts external validation and reproducibility. These constraints should be considered when interpreting the findings.

B. Future Research Directions

Future research should focus on developing robust multimodal learning style identification systems that integrate behavioural, textual, affective, and physiological data using adaptive fusion strategies. Greater attention is also needed for explainable and fairness-aware machine learning models to improve transparency, trust, and responsible educational deployment. In addition, standardized benchmark datasets, unified validation protocols, and multi-metric evaluation frameworks should be established to improve reproducibility and cross-study comparability. Finally, future studies should

move beyond offline experimentation toward deployment-oriented architectures that support real-time inference, scalability, and continuous adaptation in practical educational environments.

VIII. CONCLUSION

This study provided a systematic and structured synthesis of machine learning approaches for learning style identification published between 2020 and 2025. Moving beyond descriptive cataloguing of algorithms, the review reorganized the literature across four analytical dimensions: algorithmic paradigm evolution, multimodal integration patterns, evaluation practices, and deployment readiness characteristics. This analytical reframing revealed that although predictive performance has improved, methodological consistency, cross-context validation, and system-level maturity remain limited.

The findings indicate that classical supervised models continue to dominate small-scale institutional settings, while deep and ensemble methods are increasingly adopted in large-scale platforms. However, multimodal architectures remain largely shallow, interpretability is inconsistently embedded, and ethical considerations are rarely operationalized within deployment workflows. Most systems remain confined to experimental or dataset-validated stages, with few demonstrating sustained real-world integration.

To address these structural limitations, this study introduced a layered deployment-oriented framework that integrates multimodal input design, context-sensitive model selection, evaluation rigor, explainability integration, and a four-level deployment maturity spectrum. By positioning learning style modelling within a system-level architectural perspective, the framework shifts emphasis from isolated accuracy improvements toward scalable, transparent, and ethically grounded adaptive learning infrastructures.

Ultimately, the advancement of ML-based learning style systems will depend not only on algorithmic innovation but on principled fusion strategies, cross-context generalization, embedded explainability, and deployment-aware validation. This study provides a structured foundation to guide that transition and to support the development of robust next-generation adaptive educational systems.

APPENDIX: PRISMA 2020 CHECKLIST

Section and Topic	Item #	Checklist item	Location where item is reported
TITLE			
Title	1	Identify the report as a systematic review.	1
ABSTRACT			
Abstract	2	See the PRISMA 2020 for Abstracts checklist.	1
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of existing knowledge.	2
Objectives	4	Provide an explicit statement of the objective(s) or question(s) the review addresses.	2
METHODS			
Eligibility criteria	5	Specify the inclusion and exclusion criteria for the review and how studies were grouped for the syntheses.	7
Information sources	6	Specify all databases, registers, websites, organisations, reference lists and other sources searched or consulted to identify studies. Specify the date when each source was last searched or consulted.	6
Search strategy	7	Present the full search strategies for all databases, registers and websites, including any filters and limits used.	7
Selection process	8	Specify the methods used to decide whether a study met the inclusion criteria of the review, including how many reviewers screened each record and each report retrieved, whether they worked independently, and if applicable, details of automation tools used in the process.	7
Data collection process	9	Specify the methods used to collect data from reports, including how many reviewers collected data from each report, whether they worked independently, any processes for obtaining or confirming data from study investigators, and if applicable, details of automation tools used in the process.	7-9
Data items	10a	List and define all outcomes for which data were sought. Specify whether all results that were compatible with each outcome domain in each study were sought (e.g. for all measures, time points, analyses), and if not, the methods used to decide which results to collect.	N/A
	10b	List and define all other variables for which data were sought (e.g. participant and intervention characteristics, funding sources). Describe any assumptions made about any missing or unclear information.	N/A
Study risk of bias assessment	11	Specify the methods used to assess risk of bias in the included studies, including details of the tool(s) used, how many reviewers assessed each study and whether they worked independently, and if applicable, details of automation tools used in the process.	N/A
Effect measures	12	Specify for each outcome the effect measure(s) (e.g. risk ratio, mean difference) used in the synthesis or presentation of results.	16
Synthesis methods	13a	Describe the processes used to decide which studies were eligible for each synthesis (e.g. tabulating the study intervention characteristics and comparing against the planned groups for each synthesis (item #5)).	7, 11
	13b	Describe any methods required to prepare the data for presentation or synthesis, such as handling of missing summary statistics, or data conversions.	3-4
	13c	Describe any methods used to tabulate or visually display results of individual studies and syntheses.	3-4, 12-15
	13d	Describe any methods used to synthesize results and provide a rationale for the choice(s). If meta-analysis was performed, describe the model(s), method(s) to identify the presence and extent of statistical heterogeneity, and software package(s) used.	N/A
	13e	Describe any methods used to explore possible causes of heterogeneity among study results (e.g. subgroup analysis, meta-regression).	N/A
	13f	Describe any sensitivity analyses conducted to assess robustness of the synthesized results.	N/A
Reporting bias assessment	14	Describe any methods used to assess risk of bias due to missing results in a synthesis (arising from reporting biases).	7
Certainty assessment	15	Describe any methods used to assess certainty (or confidence) in the body of evidence for an outcome.	7
RESULTS			
Study selection	16a	Describe the results of the search and selection process, from the number of records identified in the search to the number of studies included in the review, ideally using a flow diagram.	8-11
	16b	Cite studies that might appear to meet the inclusion criteria, but which were excluded, and explain why they were excluded.	N/A
Study characteristics	17	Cite each included study and present its characteristics.	10-11
Risk of bias in studies	18	Present assessments of risk of bias for each included study.	15-20
Results of individual studies	19	For all outcomes, present, for each study: (a) summary statistics for each group (where appropriate) and (b) an effect estimate and its precision (e.g. confidence/credible interval), ideally using structured tables or plots.	15-20

Section and Topic	Item #	Checklist item	Location where item is reported
Results of syntheses	20a	For each synthesis, briefly summarise the characteristics and risk of bias among contributing studies.	15-20
	20b	Present results of all statistical syntheses conducted. If meta-analysis was done, present for each the summary estimate and its precision (e.g. confidence/credible interval) and measures of statistical heterogeneity. If comparing groups, describe the direction of the effect.	15-20
	20c	Present results of all investigations of possible causes of heterogeneity among study results.	15-20
	20d	Present results of all sensitivity analyses conducted to assess the robustness of the synthesized results.	15-20
