Abstract—Shrimp aquaculture plays a vital role in global seafood production, contributing substantially to food security, economic growth, and export revenue. Feed typically accounts for 40–60% of total production costs, making efficient feed management crucial for improving farm profitability and the sustainability of culture operations. Acoustic-based feeding strategies offer a promising solution by enabling demand-driven feed control through the detection of shrimp feeding sounds. However, reliable recognition in commercial ponds remains difficult due to strong background noise from aerators, pumps, diffusers, and rainfall, which overlaps with the frequency band of the feeding signals. In addition, the dependence on specialized software and high-performance computing resources hinders large-scale adoption. This study proposes a novel shrimp feeding sound recognition approach that converts acoustic signals into spectrogram images and employs a Faster R-CNN-based framework to regulate feed delivery in real time according to shrimp demand. A wavelet-based filtering method is introduced to effectively suppress ambient noise under practical farming conditions. Moreover, the developed open-source Python-based software enhances the feasibility of deploying intelligent acoustic-based feeding systems in commercial shrimp aquaculture. Experimental results demonstrate that the proposed system improves feed utilization efficiency and growth performance compared with traditional feeding practices.

Keywords—Automated feeding system; faster R-CNN; passive acoustic monitoring; shrimp culture; whiteleg shrimp

I. INTRODUCTION

Shrimp aquaculture represents an important component of global seafood production, contributing significantly to food security, economic development, and export revenue in many countries. According to recent industry forecasts, the value of the global shrimp market may reach approximately \$88 billion by 2030, expanding at an annual rate of around 6.5% [1]. As demand for aquatic products continues to rise and sustainability constraints become more stringent, the integration of advanced technologies into shrimp farming operations has emerged as a necessary direction for improving productivity and resource efficiency.

In shrimp farming, feed costs account for 40–60% of the total production expenses. Therefore, effective feed management is one of the most important factors in improving profitability and the sustainability of the culture system [2]. Underfeeding may result in poor growth and uneven size distribution, whereas overfeeding can deteriorate pond water quality, increase the risk of disease, and reduce production efficiency [2],[3]. In intensive shrimp farming, feeding

operations are primarily based on three approaches: 1) manual feeding following the standard feeding practice (SFP), 2) the use of timer-based automatic shrimp feeders, and 3) demand feeding based on acoustic feedback generated by shrimp during feeding [2]. Under the manual feeding method, farmers broadcast feed directly onto the pond surface. This approach is low in cost, easy to implement, and flexible based on visual observation; however, it strongly depends on operator experience, is difficult to quantify accurately, may lead to overfeeding or underfeeding, and requires considerable labor [4],[5]. Timer-based automatic feeders have emerged as an alternative solution to overcome the limitations of traditional manual feeding, especially in medium- and large-scale farms where feed can be dispensed according to preprogrammed schedules [6–8]. Compared with manual feeding, such systems improve feeding efficiency, reduce feed waste, and lower labor costs [9],[10]. Although timer-based feeders operate according to fixed feeding schedules, they may still result in overfeeding or underfeeding and the accumulation of uneaten feed [11],[12]. The acoustic-based feeding method, also referred to as passive acoustic monitoring (PAM), enables more precise feeding control through the analysis of shrimp feeding sounds, thereby minimizing feed waste and helping maintain pond water quality [13–16]. This advanced feeding approach has been demonstrated to outperform manual and timer-based feeding approaches in terms of feeding efficiency and production performance [17].

In PAM-based shrimp feeding frameworks, accurate recognition of “click” sounds generated by shrimp during feeding is essential for automated feeder operation. However, a major challenge in detecting shrimp feeding sounds arises from background noise generated by aerators, pumps, air diffusers, and rainfall. These interferences overlap with the frequency band of the feeding “click” signals, degrade the signal-to-noise ratio, and consequently impair accurate detection and classification. In addition, the dependence on specialized software and high-performance computing platforms for real-time signal analysis continues to constrain the broader deployment of this advanced feed management technology in shrimp farming.

This study presents the design and implementation of a PAM-based automated feeding system for whiteleg shrimp (*Litopenaeus vannamei*) using deep learning. We propose a novel approach for recognizing whiteleg shrimp feeding sounds by converting acoustic signals into spectrogram images and employing Faster R-CNN (Faster Region-based Convolutional Neural Network) for automatic feature

* Corresponding author.

extraction and classification. Wavelet-based filtering is applied to effectively suppress background noise in acoustic signals collected from commercial shrimp ponds. The Short-Time Fourier Transform (STFT) was subsequently employed to convert the processed signals into spectrograms, which were then used to train the Faster R-CNN model. A fuzzy logic-based control algorithm was also developed to regulate the operation of the shrimp feed dispenser in accordance with the feeding demand of the shrimp. Experimental results show that the proposed automated feeding system improves feed utilization efficiency and growth performance compared with the traditional feeding method.

The main contributions of this study are summarized as follows:

- Introduces a novel method for recognizing shrimp feeding sounds using Faster R-CNN.
- Employs a wavelet-based denoising technique to effectively suppress background noise in real-world pond environments.
- Develops open-source Python-based tools for efficient processing and reliable recognition of shrimp feeding activity.
- Experimentally validates the performance of the proposed automated feeding system under real farming conditions.

The remainder of this study is organized as follows: Section II reviews related works on shrimp feeding sound recognition techniques for feeding automation. Section III describes the proposed method, including the system architecture, shrimp feeding sound acquisition and processing, the development of the Faster R-CNN-based recognition model, and the fuzzy logic-based feeder motor control algorithm. Section IV presents the experimental setup and results, including a comparison with the standard shrimp farming method. Section V concludes the study and discusses the limitations and directions for future work.

II. RELATED WORKS

In recent years, various techniques have been introduced to identify shrimp feeding “click” sounds, aiming to optimize feeding practices and advance automated feeding technologies. Specifically, Daniel et al. [18] proposed a context-aware acoustic classification framework for monitoring prawn feeding. The method detects characteristic feeding “click” sounds and utilizes a Context-Aware Dynamic Bayesian Network (CADBN) to represent the signals, enabling the extraction of robust feeding signatures expressed as temporal patterns of acoustic activity linked to feeding behavior. The authors in [19] introduced a dual-threshold strategy for detecting shrimp feeding “click” sounds in acoustically noisy pond environments. The approach integrates time-domain criteria, including signal amplitude and duration, with a band-pass filter in the 2–10 kHz range. This combination suppresses background interference, reduces false alarms, and yields more dependable identification of feeding events, thereby improving the accuracy of feeding activity monitoring.

In [20], Mel-Frequency Cepstral Coefficients (MFCC) and Linear Prediction Cepstral Coefficients (LPCC) were derived from acoustic recordings of shrimp feeding under various behavioral states. These features were then fed into a one-versus-rest Support Vector Machine (SVM) classifier. Laboratory experiments showed that the selected descriptors effectively characterized behavior-dependent acoustic variations, achieving classification accuracies of up to 93%. Peixoto et al. [21] employed Raven Pro software (Cornell University, USA) to inspect oscillogram and spectrogram representations of acoustic files recorded under background-noise-free conditions. A band-limited energy detector was then applied to automatically detect “click” events within a frequency range of 10–80 kHz and a signal duration of 5–50 ms. The histogram analysis tool provided in Microsoft Excel (Microsoft Corporation, USA) was subsequently applied to determine the rate distribution of clicks per minute for each recording. Study [22] proposed using the Librosa library, a Python package for audio analysis, to automatically detect shrimp feeding sounds. Audio recordings acquired under laboratory conditions were segmented into short intervals, and spectral-flux onset strength was computed to form an energy envelope. Peaks in this envelope were identified as shrimp clicks, providing the time stamps of feeding events.

Although substantial progress has been made in the recognition of shrimp feeding sounds, a clear research gap still exists. Most previous studies collected acoustic data under controlled laboratory conditions, where the recordings were largely free from background noise generated by aerators, air bubble diffusers, and other equipment commonly found in commercial ponds. As a result, when these methods are deployed in real farming environments, where ambient noise severely contaminates the signals, their effectiveness and robustness become critical concerns. In addition, the reliance on dedicated software packages and high-performance computing infrastructure further limits the practicality of implementing continuous, in-situ monitoring of shrimp feeding activity. These constraints highlight the need for open-source acoustic processing tools capable of automatically and reliably detecting shrimp feeding sounds under real pond conditions, thereby enabling wider deployment of automated feeding systems.

III. METHODOLOGY

A. System Architecture

Fig. 1 presents the overall architecture of the proposed automated shrimp feeding system. The system hardware consists of four main components: a hydrophone, a Central controller, a Server, and a shrimp feeder. An H1a hydrophone [23] is installed in the pond, near the feeding tray, to capture the acoustic signals generated by shrimp during feeding. The shrimp feeding sounds are amplified by a PA-4 amplifier [24], transmitted to the Central controller, and subsequently sent to the Server via a Wi-Fi connection. At the Server, an artificial intelligence algorithm analyzes the acoustic signals to determine the shrimp's feeding status. Based on this analysis, control commands are sent back to the Central controller to regulate the Shrimp feeder and dispense an appropriate amount of feed. The Central controller is supplied by a solar-powered

battery, allowing reliable outdoor operation without reliance on the power grid.

Fig. 1. Architecture of the proposed automated shrimp feeding system.

The Server acts as the main processing and decision-making unit of the system. It receives underwater acoustic data from the shrimp pond via a Wi-Fi connection and performs data storage, preprocessing, and deep learning-based signal analysis to evaluate shrimp feeding behavior. In this study, a Server equipped with an Intel Core i7-8550U processor running at 1.8 GHz and 8 GB of RAM was employed. A web interface was also developed to allow users to monitor the system operation by accessing the Server via mobile devices.

B. Characteristics of Shrimp Acoustic Signals

During feeding, the calcified mandibles of whiteleg shrimp collide and rub against each other, generating chewing sounds that are captured as “click” signals by the passive acoustic monitoring system. These signals are typically brief, exhibit higher frequency components than the background pond noise, occur intermittently, and increase in rate during active feeding periods [25].

Fig. 2. Five-minute recorded signal waveform of shrimp sound: before feeding (left) and during feeding (right).

Fig. 3. “Click” sounds exhibit short duration and high-frequency components.

Fig. 2 shows the waveforms of five-minute shrimp sound recordings obtained before and during feeding. Before feeding,

the chewing-related waveforms are sparsely distributed. In contrast, a much higher density of these waveforms is observed during feeding. Fig. 3 presents a 50-ms audio segment that highlights the “click” sounds produced during shrimp feeding. The clicks are short-duration transients with higher-frequency content compared with the low-frequency background noise, allowing them to be effectively separated through filtering techniques.

C. Acoustic Signal Acquisition and Processing

Fig. 4 presents the procedure for processing and extracting acoustic features from shrimp feeding sounds. Initially, acoustic signals in the shrimp pond are captured at a sampling rate of 44.1 kHz by the H1a hydrophone installed above the feeding tray on the pond bottom. The continuous recordings are subsequently divided into ten-second segments to enable efficient analysis and model training. Wavelet-based filtering is then employed to suppress noise in the signals. Next, the filtered audio is normalized to an amplitude range of $[-1, 1]$ to maintain consistency among samples. Finally, spectrograms of shrimp feeding sounds are generated by applying the Short-Time Fourier Transform (STFT) [26] to the normalized signals.

Fig. 4. Procedure for data preprocessing and acoustic feature extraction of “click” sounds.

1) *Noise filtering*: In practical pond conditions, shrimp feeding sounds are masked by substantial background noise generated by aerators, air diffusers, and rainfall. According to previous studies [27] and the authors’ field observations, the majority of the noise energy in shrimp farming environments is concentrated in the low-frequency range below 5 kHz. According to [28], feeding-related “click” sounds of whiteleg shrimp extend from 4 to 15 kHz, with most of their acoustic energy distributed under 10 kHz. Consequently, noise-reduction techniques must be applied to remove unwanted interference before analyzing the recorded signals.

The wavelet transform is widely recognized as an effective signal processing technique, particularly for denoising tasks [29]. Owing to its adaptability to nonstationary signals, it often provides superior performance compared with conventional filtering approaches [30],[31]. Shrimp chewing sounds exhibit time-varying amplitude and frequency characteristics that depend on feeding activity and typically persist for only a short duration. Consequently, wavelet-based filtering is well-suited for processing these acoustic events.

Selecting suitable filtering parameters is essential to retain the salient characteristics of the shrimp chewing signals while effectively suppressing noise. In this work, the filtering procedures were implemented using the open-source Python

wavelet analysis library PyWavelets [32]. Based on empirical evaluation, a wavelet filter configured with wavelet = 'db7', threshold = 0.2, and level = 2 was found to be effective for processing shrimp feeding sounds in noisy real-world pond environments. Fig. 5 presents an example of the filtering results obtained for a representative audio segment. It can be observed that the background noise amplitude is significantly reduced, while the signal features become more prominent.

Fig. 5. Sound signal waveforms: (a) the original signal and (b) signal waveform after filtering and normalization.

2) *Feature extraction*: The filtered sound signals are processed using the STFT transform implemented in the SciPy library [33] to extract time-and frequency-domain features of shrimp feeding sounds. A parametric study conducted in this work demonstrates that an STFT configuration with a 1,024-sample window and 50% overlap provides effective performance. Furthermore, because shrimp feeding sounds are mainly distributed within the 3–8 kHz frequency band, the analysis is limited to this range to save computational resources and shorten model training time.

Fig. 6 presents the spectrogram of a sound segment acquired during shrimp feeding, showing both the original signal and the result after wavelet denoising. In the original signal (Fig. 6a), most of the spectral energy of the unfiltered acoustic data is concentrated within the 0–3 kHz band, likely originating from background noise generated by the aeration system and surrounding pond environment. After denoising (Fig. 6b), the low-frequency noise energy is significantly reduced, whereas the spectral components corresponding to the “click” pulses become more pronounced, predominantly within the 3–8 kHz band. The resulting spectrograms will serve as inputs to the deep learning model to automatically identify “click” events related to shrimp feeding activity.

D. Development of a Faster R-CNN–Based Detection Model

Faster R-CNN (Faster Region-based Convolutional Neural Network) is a widely adopted two-stage object detection framework well known for its superior localization and classification capability [34]. Although one-stage detectors such as YOLO [35] provide higher inference speed, two-stage

approaches generally achieve superior accuracy for small and sparsely distributed objects. In spectrogram images of shrimp feeding sounds, the “click” events usually occupy small regions and are easily confused with background interference, making precise localization essential. A comparative study conducted by the authors shows that Faster R-CNN outperforms YOLO models (v9–v11, NAS, and World) in shrimp feeding spectrogram recognition. Therefore, Faster R-CNN was chosen in this study to maximize detection robustness and accuracy while still satisfying the near real-time processing requirements of the monitoring system.

Fig. 6. Spectrogram of an audio segment recorded during shrimp feeding: (a) original signal and (b) after wavelet-based denoising.

In this task, spectrogram images are used as the input for training the Faster R-CNN, where the “click” pulses are represented as the objects to be detected. The model integrates a convolutional feature extraction network (ResNet-50 backbone) with a Region Proposal Network (RPN) to generate candidate regions, followed by classification and bounding-box regression on the regions of interest, enabling precise localization of the “click” events in the spectrogram images. A total of 3,039 spectrogram images were generated from acoustic data collected from three ponds under real-world conditions, including noise from aerators, air diffusers, and environmental sources. The dataset spans multiple feeding cycles—pre-feeding, during, and post-feeding—to comprehensively capture shrimp feeding behavior and ensure generalizability. All images were resized to 640 x 640 pixels and partitioned into three subsets, namely training, validation, and testing, as summarized in Table I.

TABLE I. DATASET FOR TRAINING, VALIDATION, AND TESTING

Type of Data	Number of Spectrogram Images
Training dataset	2,128
Validation dataset	608
Test dataset	303

Fig. 7 presents the loss curves of the training and validation sets of the Faster R-CNN model over 20 epochs. The training loss decreases rapidly during the initial epochs and gradually converges after approximately 10 epochs, while the validation loss remains low and relatively stable, with only minor fluctuations around the tenth epoch. The tenth epoch is identified as the optimal point at which the validation loss reaches its minimum value. The small gap between the training and validation losses indicates that the model learns effectively and generalizes well, with no evident overfitting due to the application of an early stopping strategy when further epochs no longer provide improvement.

Evaluation results on the independent test set show that the model achieves a Precision of 98.21%, a Recall of 100%, an mAP of 98.21%, and an F1-score of 99.09%, where the mAP is computed at an IoU threshold of 0.5. These metrics indicate that the model is capable of comprehensively detecting shrimp feeding “click” events (high recall) while maintaining high prediction precision, reflecting strong generalization performance on the test data.

Fig. 7. Training and validation loss curves.

Fig. 8. Detection and counting results of “click” sounds using the faster R-CNN model.

Fig. 8 provides a visual illustration of the detection and counting results of the “click” pulses for a typical spectrogram image. It can be observed that the shrimp acoustic “click” pulses are detected and localized in the spectrogram image by

the Faster R-CNN model. The predicted bounding boxes are primarily concentrated within the 3–8 kHz frequency band of the “click” signals, demonstrating the model’s ability to accurately localize short-duration acoustic events even in noisy environments. This result demonstrates the feasibility of the spectrogram feature-based method for detecting “click” sounds.

E. Control Algorithm of the Shrimp Feeder

In the automated feeding method based on acoustic feedback, the feed supply is determined according to the intensity and occurrence frequency of the sounds produced by shrimp during feeding. In this study, a fuzzy logic algorithm was developed to establish the relationship between the operating time of the shrimp feeder motor and the density of shrimp “click” sounds [36],[37]. The input variable of the algorithm is the number of “click” sounds per minute, representing the intensity of shrimp feeding behavior. It is defined over the interval $[0, N]$ and is described by five linguistic fuzzy levels: Very Low, Low, Medium, High, and Very High (Fig. 9a). The value of N was determined based on the stocking density and was set to 60 clicks/minute in this experiment. The output variable corresponds to the operating time of the feeder motor (in seconds), bounded within the interval $[0, T]$, and is also represented by the linguistic fuzzy set: Stop, Short, Medium, Long, Very Long, and Maximum (Fig. 9b). The value of T was determined experimentally and was set to 6s in this study. Trapezoidal membership functions were employed for both the input and output variables to simplify the inference process and to meet the implementation requirements of the embedded system.

Fig. 10 illustrates the input–output characteristic of the fuzzy controller, showing the relationship between the density of “click” sounds and the shrimp feeder operating time. The characteristic curve consists of three main control regions: 1) the Stop region, where the input signal is below the threshold of 15 clicks/minute, resulting in a feeder activation time of zero; 2) the Increasing region, in which the feeding duration increases proportionally with shrimp feeding activity, ensuring a smooth load increment; and 3) the Saturation region, where the input exceeds 50 clicks/minute and the shrimp feeder operates at its maximum rate. The above threshold values were determined based on the stocking density (i.e., the average number of shrimp at the feeding tray) and empirical observations.

Fig. 9. Input (a) and output (b) membership functions of the fuzzy logic control algorithm.

Fig. 10. The relationship between the number of detected “click” sounds and the operating time of the feeder motor.

Fig. 11. The automated feeding system deployed at the shrimp pond.

IV. EXPERIMENTAL RESULTS

A. Experimental Setup

The experiments were conducted in a 100-m³ concrete pond for white-leg shrimp culture at the College of Aquaculture and Fisheries, Can Tho University. The shrimp were stocked at a density of 300 individuals per cubic meter, with an initial body weight of 3–4 g per individual. The aeration system was operated continuously to maintain stable environmental conditions throughout the 60-day experimental period. Fig. 11 shows the automated feeding system deployed under practical pond conditions, with the hydrophone positioned 18 cm above the feeding tray at the pond bottom to capture shrimp acoustic signals.

The procedure of one control cycle for the automated shrimp feeding operation is illustrated in Fig. 12. At the beginning of a feeding cycle, the Server instructs the Central controller to activate the Feeder motor to dispense feed for a predefined duration. After dispensing, the Central controller sends a notification to the Server; the Server then enables the acoustic signal processing mode and instructs the Central controller to start recording, after which the recorded data are transmitted back to the Server. At the Server, the acoustic data are stored and preprocessed through noise filtering and conversion into spectrogram images before being fed into the Faster R-CNN model for detection. After the deep learning model estimates the number of feeding shrimp, the result is passed to a decision algorithm to determine the duration of the next feed dispensing. The Server then sends a command to the

Central controller to activate the Feeder motor according to the rules of the fuzzy logic algorithm described previously. This procedure is repeated until the number of feeding shrimp falls below a predefined threshold or the feeding process is terminated. The system is programmed to operate daily from 06:00 to 21:00. At 20-minute intervals, the acoustic evaluation module is automatically triggered to assess shrimp feeding activity, thereby enabling appropriate decisions on subsequent feed dispensing.

Fig. 12. Control flow of a feeding cycle.

B. Evaluation of the Effectiveness of the Automated Shrimp Feeding Method

In this study, a shrimp pond operated under the traditional manual feeding regime will serve as a reference to evaluate the effectiveness of the proposed automated shrimp feeding system. In this regime, shrimp were fed at fixed times five times per day, namely at 06:00, 11:00, 14:00, 17:00, and 20:00. The feed ration was determined based on the average body weight of the shrimp at each developmental stage, in accordance with standard pond management practices (SFP/Standard Feeding Protocol). The shrimp growth performance and feed consumption over the two-month experimental period are summarized in Table II.

Table II shows that the SFP feeding regime exhibited a consistent growth trend over time, with the average body weight increasing from 3.6 to 21.11 g per shrimp, while the number of individuals per kilogram decreased from 277.78 to 47.37 after 60 days. The average daily feed consumption peaked at 16.38 kg/day (Week 6) and slightly declined toward the end of the culture period (14.26 kg/day, Week 8), reflecting ration adjustments to minimize feed waste. The total feed input was 781.37 kg; harvested biomass reached 578.64 kg, corresponding to an estimated 27,420 shrimp, with a survival rate (SR) of approximately 91.4% and a feed conversion ratio (FCR) of 1.35. Overall, the SFP method resulted in stable growth, acceptable feed utilization efficiency, and a high survival rate.

Table III shows that under the automated feeding method, the average body weight increased from 3.60 g per shrimp (Day 1) to 23.64 g per shrimp (Day 60), reflecting a clear growth trend over the experimental period. Along with the increase in individual shrimp weight, the stocking density decreased from 277.78 shrimp/kg to 42.30 shrimp/kg, consistent with the growth pattern as body size increased over

time. The average daily feed consumption rose from 4.64 kg/day in the initial stage to 14.19 kg/day in the final stage, with the total feed input for the entire culture cycle reaching 701.46 kg. The relatively stable daily feed consumption observed during the intermediate stages, despite the continued increase in shrimp weight, indicates the effectiveness of ration adjustment based on feeding behavior. At the end of the experiment, the harvested biomass reached 640.83 kg, with an SR of 90.36% and an FCR of 1.09.

The results indicate that the total feed input in the automated feeding method was 701.46 kg, which was 10.23% lower than that of the SFP approach (781.37 kg), while the FCR decreased from 1.35 to 1.09. The average daily growth (ADG) in the automated feeding treatment reached 0.33 g/shrimp/day, approximately 13.8% higher than that of the SFP treatment (0.29 g/shrimp/day). The survival rates in the two treatments were 90.36% (automated) and 91.39% (SFP), respectively, indicating only a minor practical difference. Through the designed web interface, farm managers can monitor variations in the intensity of shrimp feeding acoustic signals across feeding cycles, enabling real-time assessment of feeding activity. Monitoring fluctuations in the ration supplied to shrimp, together with comparisons of feed consumption among culture stages, allows the evaluation of feed utilization efficiency (Fig. 13). These results demonstrate that the proposed automated shrimp feeding system has strong potential to improve feed utilization efficiency.

TABLE. II. GROWTH PERFORMANCE AND FEED UTILIZATION UNDER THE STANDARD FEEDING PRACTICE (SFP)

Period (21/10/2025 to 19/12/2025)	Growth (shrimp/kg)	Weight (g/shrimp)	Average daily feed consumption (kg/day)	Total feed consumption (kg)
Week 1	277.78	3.6	6.75	47.25
Week 2	250.63	3.99	10.77	75.36
Week 3	178.89	5.59	11.74	82.18

V. CONCLUSION AND FUTURE WORK

An automated feeding system driven by acoustic feedback from shrimp feeding activity was developed and experimentally validated. Feeding behavior was detected and analyzed in real time using spectrogram representations of “click” sounds and a Faster R-CNN-based framework, enabling feed delivery to be adjusted according to shrimp demand. A wavelet-based filtering method effectively suppressed background noise in practical pond environments. Field results confirmed improved performance compared with the traditional feeding practice (SFP), including a 10.23% reduction in feed consumption, a lower feed conversion ratio (1.09 versus 1.35), and higher average daily growth (0.33 versus 0.29 g/shrimp/day). The open-source Python-based implementation further enhances the practicality and scalability of acoustic-driven feeding in commercial aquaculture. Future work will extend validation across diverse farming conditions and integrate multimodal sensing and adaptive optimization to increase decision reliability and system robustness.

Abstract—Arabic Grammar Correction is a comprehensive open-domain. Modern methods of correcting Arabic language errors rely on a database specific to a particular field and containing specific words and phrases, which leads to the emergence of the problem of out-of-context words. Due to the growth in recent work for Arabic text summarization and Arabic grammar correction, out-of-context words and the complex nature of Arabic grammar, an open-domain Arabic database is a required resource for Arabic language processing techniques. In this study, A new open-domain Database for Arabic Grammar Correction (DAGC-ATS) is presented to solve the out-of-context words problem, limited domain existing databases for training. The proposed database is based on the description of Arabic grammar using part-of-speech tags and relations between words by a dependency parser. The DAGC-ATS database is based on grammar error detection and correction at the simple sentence level. The database contains entries that describe Arabic grammar rules. The DAGC-ATS database contains two files, one for correcting Arabic simple sentences and the other for correcting incorrect Arabic basic sentences in grammar. It is designed for use only in the training stage. Every entry in the database describes one different grammatical problem, such as gender, number, singular, dual, or plural faults. It contains 9309888 entries. Using the QALB dataset, the system's precision, recall, and F-measure scores were 96.9, 94.80, and 95.83. Additionally, the same system was tested using the EASC database with 785 summaries, and the results for precision, recall, and F-measure were 99.73%, 95.90%, and 97.77%.

Keywords—Arabic grammar correction; Arabic natural processing; open domain database

I. INTRODUCTION

The Arabic Natural Language Processing (NLP) community has recently given considerable attention to correcting grammatical errors in text, although most of this research has focused on English [1]. The Arabic language is particularly important and complex. The Arabic language is structured and inflected, making error diagnosis and challenging feedback tasks. Arabic Grammar Error Correction (AGEC) has attracted increased interest due to notable studies and encouraging shared challenges [2]. The difficulties faced by AGECE include the prevalent morphology, the scarcity of corpora, and the complexity of Arabic grammar. Spelling error detection and correction are essential for various applications and natural language processing tasks, such as optical character recognition, search query processing, parsing, machine translation, and intelligent tutoring systems. Grammar error correction has two main stages: determination of grammar errors and correction of

grammar errors. Most databases for AGECE are for specific data and domains [3]. A spelling error correction system contains two primary modules. The first is detecting errors within the second, which is text, and correcting those errors. The simplest approach to detection is to look up the primitive form of the input word in a lexicon. If the word is not found in the lexicon, it is considered an ill-formed word that flags a spelling error. The error correction module generates a list of candidate words and ranks them in a way that could be considered as corrections for the erroneous word. Grammatical error correction is a challenging task, and existing methods have limitations that involve post-editing [4]. Recent work in the Arabic language has increased, especially for Arabic text summarization [5],[6],[7] and Arabic grammar correction [8],[9],[10]. Most databases for Arabic grammar correction consist of specific Arabic entries for training and testing for certain domains [11]. In other words, the data used in one database is different from that in another database. So, the need to produce a new open database to check errors in Arabic writing has become necessary, which can be used in any specific domain or data. This study presents a new database that describes the meaning and structure of Arabic sentences and is designed to correct Arabic grammar for simple sentences. In other words, the summarized text contains simple sentences.

II. RELATED WORKS

Because of Arabic's rich vocabulary, syntactic flexibility, and morphological complexity, Arabic presents a special challenge for tasks involving natural language processing. According to the lack of standard databases for AGECE and the complexity of Arabic, Recent work for AGECE is based on training and testing data for a specific domain. Ahlam et al used ChatGPT to create an Arabic corpus named "Tibyan" for grammatical error correction. ChatGPT is a data augmentation tool that compares two Arabic sentences with grammatical errors to a sentence that is error-free and taken from Arabic books. These sentences are known as guide sentences. The Tibyan corpus was created in a number of steps, including gathering and pre-processing two Arabic texts from diverse sources, including open-access corpora and books. After that, ChatGPT is used to create a parallel corpus using the previously gathered text as a model for building sentences with various kinds of errors. To ensure the automatically generated sentences were accurate and error-free, they hired linguistic specialists to examine and validate them. The corpus is improved and validated. The accuracy of the corpus is increased through iterative validation and refinement based on input from

linguistic experts. Lastly, they examined several types of errors in the Tibyan corpus using the Arabic Error [22] Type Annotation tool (ARETA). The seven categories of errors found in our corpus were orthography, morphology, syntax, semantics, punctuation, merge, and split. There are 600,000 tokens in the Tibyan corpus [12]. Chouaib Moukrim et al introduced a syntactic error correction system that is based on automatically producing proper Arabic sentences. To produce all possible syntactically correct sentences, they first extracted the words from the sentence under consideration. This is done using an ontology that logically describes the rules of Arabic grammar. There is no good corpus that contains annotations on several levels of Arabic grammar, which firstly leads to an annotation of a new reference corpus containing 360 sentences. Of the 360 Arabic sentences [13]. Zainab Althafir et al presented an Arabic Bidirectional Encoder Representations from Transformers (AraBERT) and a rule-based system. Seventy million sentences gathered from two distinct sources were used to train the model. The first consists of 5 million articles with 1.5 billion words gathered from 10 news sources. The other is the 3.1 million articles from 31 news sources, which make up the Open-Source International Arabic News (OSIAN) corpus. Also, the model used the Qatar Arabic Language Bank (QALB) corpus to create an Arabic grammatical auto-corrector for non-native speakers [14]. The corpus consists of 622 sentences with spelling and grammar mistakes made by non-native speakers [15]. Sarah AIOyaynaa et al suggested a novel study for AGER using pre-trained language models based on transformers. They suggested refined language models that were based on previously Arabic GED using two main approaches: level and sentence level, using language models AraBERT and M-BERT. Several Arabic datasets are public. accessible were used for fine-tuning. To enrich the GEC domain, they first used SCUT, a publicly accessible dataset with two columns named source (i.e., incorrect erroneous sentences) and targets (i.e., correct sentences) [16]. Aiman Solyma et al created the dataset to overcome the dearth of Arabic-language resources for the GEC task. A large-scale parallel synthetic corpus based on the confusion function was created in an unsupervised manner. The Al-Watan corpus, a direct access collection of 10,000,000 (ten million) words composed by professional journalists in Modern Standard Arabic (MSA), served as the data source. 18,061,610 million words, or a portion of this data, were extracted, and the confusion function. They reformatted the dataset to make it appropriate for the intended task because there isn't a lot of data pertaining to it. There were two stages to the reformatting process: first, a new column called "label" was added, followed by the target being categorized as correct (i.e., 1) and the source as erroneous (that is, 0). And a subset of the primary dataset was used for that. It was then used during the fine-tuning process and saved in a new file. The final dataset was then divided into two datasets: the test dataset, which is used to evaluate the model's performance, and the training dataset, which is used for the fine-

tuning step. For train-validation datasets, the splitting was applied at random at a percentage of 90–10 [17]. Aiman Solyma et al suggested a GEC model for low-resource languages like Arabic that is based on the seq2seq Transformer. They suggested a technique for creating synthetic parallel data to get around the bottleneck caused by the absence of a corpus. Additionally, inspired by the success of capsule networks in computer vision, they dynamically aggregated data across layers in Arabic GEC using the Expectation-Maximization routing algorithm. The datasets they use to train the models are real and synthetic. Initially, the synthetic set was created using the 15,001,707-sentence monolingual news Arabic corpus OSIAN. Nevertheless, the technique outlined in Section 4.2 was used to generate synthetic data, which included 1,500,173 sentence pairs for the development set and 11,833,758 sentence pairs for the training set. These were employed to retrain the L2RAGEC and R2L models. Additionally, the QALB-2014 corpus, which included 1,017 examples for development and 19,411 examples for training, was used for fine-tuning. QALB-2014 data source gathered from the Arabic Learners Written Corpus, the Aljazeera news platform. Additionally, Google Translate is used to translate English Wikipedia articles into Arabic. Native speakers have corrected and annotated the source data. By dividing each unknown word into several sub-words, the Byte Pair Encoding (BPE) technique was used to overcome the challenge of rare and unknown words [18]. SOMAIA MAHMOUD presented an economical and effective method for automatically scoring Arabic essays that emphasize grammatical assessment. Essays can also be graded using the suggested method according to additional standards like prompt adherence, organization, and resemblance to the model response. The method uses various parameter-efficient techniques and makes use of the pre-trained AraBART model. For each criterion, they used two datasets. The QALB dataset is the first publicly accessible dataset for correcting grammatical errors in Arabic. It is divided into two sections: QALB-2014, which included 21.3K comments from native Arabic speakers on the Aljazeera news website, and QALB-2015, which included 622 essays by Arabic language learners. For a variety of grammatical errors, including spelling, punctuation, word choice, morphology, syntax, and dialectal usage, every text in the dataset has been manually corrected. Training, development, and test sets make up the dataset. There are two test sets in QALB-2015: one for L1 texts composed by native speakers and another for L2 texts composed by Arabic L2 learners [19]. Nizar Habash et al presented the ZAEBUC dataset as the second. It includes 214 essays authored by first-year students at Zayed University in the United Arab Emirates [20]. From the previous, it is concluded that existing dictionaries or databases are for a specific domain and a limited number of words. There is no AGER database that can be used for any dataset or domain. A comparison between the most popular databases used in AGEc is shown in Table I.

TABLE I. A COMPARISON BETWEEN MOSTLY USED ARABIC DATABASES FOR AGEc

Database Name	Domain	Statistics
QALB-2014 [20]	The Aljazeera news	1,017 examples for development and 19,411 examples for training
QALB-2015 [21]	Essays by Arabic language learners	622 essays

Tibyan corpus [12]	Sentences from various sources	600,000 tokens
OSIAN [18]	Monolingual news Arabic corpus	15,001,707-sentence
Watan corpus [17]	It is composed of professional journalists in Modern Standard Arabic (MSA)	10,000,000 (ten million) words written
The ZAEBUC dataset [20]	It is authored by first-year students at Zayed University in the United Arab Emirates	214 essays

III. PROPOSED FRAMEWORK

Because the database relies on a simple sentence structure, the description of each entry in the database includes a set of characteristics and the relationship of words to each other. So, the different word types, the basic, complex, and advanced sentence structures, and grammatical rules of the Arabic language used in this database are discussed in the following sentences.

A. Pronunciation of Arabic Letters

The basic elements of the Arabic language are word, clause, and sentence. There are four grammatical states in Arabic [23]. These cases are nominative, accusative, genitive, and jussive. Any word that can express its meaning without the aid of another word is a noun. People, places, objects, concepts, and more are all named with nouns. There are two genders in Arabic: feminine and masculine. Unless they contain a feminine ending, most nouns are regarded as male. To convert male nouns and adjectives into feminine, the most common feminine ending is the taa marbuta letter. Geographical names, bodily parts that occur in pairs, and various other nouns are examples of terms that are conventionally regarded as feminine. Some nouns, on the other hand, can be classified as either masculine or feminine. The nouns in Arabic are divided into three main groups according to their numbers. The following are these groups: singular, dual, and plural. In a sentence, verbs are used to express the activity. There must be a verb in every phrase \ cite [24]. Verbs in Arabic grammar must be conjugated according to the plurality and gender of the individual carrying out the activity. Arabic verbs have three different tenses: imperfect, perfect, and imperative. Adjectives are used to characterize nouns in Arabic. Here is a quick summary of the four basic guidelines for utilizing adjectives. Prepositions are a group of words used in Arabic to show the link between other words [25]. Their purpose is to make clear where an action or item is in relation to another. It is important to remember that no matter where a preposition appears in a phrase, its pronunciation remains the same. The reason for this is that they are regarded as "Mabni" terms. In addition, every phrase that comes after a preposition ends in a Kasrah. A pronoun is a term that can take the place of a noun in Arabic. Subject pronouns, object pronouns, and genitive pronouns are three dissimilar categories of overt or conspicuous pronouns in Arabic [26]. Subject pronouns, which can be attached or used alone, function as the verb's doer or subject. Conversely, object pronouns are always connected and function as the verb's object. Finally, genitive pronouns function as either the object of the associated noun (possessive) or the object of the preposition. Words like this and those are examples of demonstrative pronouns in Arabic. Unlike many other languages, they are classified as demonstrative pronouns proximal or distal, and they also vary in terms of femininity or masculinity, as well as whether they are singular, dual, or plural. Relative pronouns are examples of how the

pronouns "that, which, who, whom" are portrayed. To link nouns, pronouns, and verbs with other nouns or verbs, these pronouns are used as conjunctions\subsection {Sentence Structure in Arabic}.

There are two primary categories of sentences in Arabic: the nominal and verbal sentences. or the nominal phrase, starts with a noun, such as "the book is new". There are two primary categories of sentences in Arabic: the nominal phrase and the verbal phrase. The nominal sentence starts with a noun, such as "the book is new". The subject is explicitly stated, and the predicate provides information about the subject [27]. The predicate can be an adjective, noun, or prepositional phrase. The verbal phrase starts with a verb, such as "The man went out". In Arabic grammar, the primary distinction between verbal and nominal sentences is that the subject of a verbal sentence is the action the verb is doing, whereas the subject of a nominal phrase is the statement's major topic. Compared to English, Arabic has a more flexible word order. Nevertheless, the most widely used word orders are Verb-Subject-Object (VSO) and Subject-Verb-Object (SVO). The VSO order is the most traditional and common word order in Arabic. The verb is placed at the beginning of the sentence, followed by the subject and object. This structure often emphasizes the action that is being performed. The SVO order is also used in Arabic, particularly in less formal contexts or when the subject needs to be emphasized. Although SVO may be found in both spoken and written Arabic, the VSO order is more formal and is frequently used in writing Arabic [28]. An example of these orders for the sentence the boy wrote the book is shown in Fig. 1. Part (a) represents the VSO order. SVO is represented by part (b).

Fig. 1. A representation of SVO and VSO for Arabic sentences: a) description of VSO order in Arabic, b) description of SVO order in Arabic

B. Complex Arabic Sentence Structure

There are intricate sentence patterns, such as conditional phrases, relative clauses, and many kinds of subordinate clauses. In Arabic, conditional sentences are usually built with particles such as for actual situations and (if) for hypothetical conditions. It is essential to comprehend the subtle differences between these particles. Conjuncts such as (and), (or), and (but) are used to join clauses in complicated Arabic sentences. Subordinate clauses, such as who or which, frequently come after a relative pronoun. Arabic introduces subordinate clauses using a variety of particles, each of which has a distinct purpose [29].

C. Advanced Arabic Sentences

Because Arabic has a two-word order: SVO and SOV, advanced, complicated Arabic sentences can be converted to simple, summarized forms [30]. There are exceptional cases of Arabic sentences where nominal and verbal sentences overlap. These cases have been treated by converting two words to one word or replacing the word order without affecting the meaning, as shown in Table II.

TABLE II. THE ORIGINAL AND CONVERTED ARABIC SENTENCES

Arabic sentence	English sentence	Converted Arabic sentence
الطالب الذي يدرس هنا ذكي	The student who studies here is smart	الطالب الدارس هنا
أريد أن أذهب	I want to go	أريد الذهاب
الكتاب موضوعه جميل	The topic of the book is good	موضوع الكتاب جميل

D. Arabic Grammar Errors

This section describes various errors in the Arabic language. Arabic errors range from number and gender agreement to the wrong case and mood in many cases. There are seven main types of Arabic errors [31]. First, AGE indicates Adjectives describing a noun or pronoun agree in case (i.e., both are nominative, accusative, or genitive), number (both are single, dual, or plural), definiteness (i.e., both are definite or indefinite), and gender (i.e., both are masculine or feminine). Second, the singular predicate describing the subject agrees in case, number, and gender but varies in definiteness (the predicate must be indefinite). Third, verbs in Arabic must match the subject in gender (i.e., masculine or feminine) in verbal sentences (where the verb comes before the subject). Fourth, the verb at the beginning of the sentence must be singular. Fifth, the object of verbal sentences, the predicate of *en* and *her* sisters, the subject of *kan* and *her* sisters, and verbs after present tense verb accusative tools will be in the accusative case. Sixth, the subject of the verbal sentence, the subject of *kan* and *her* sisters, and the predicate of *en* and *her* sisters must be in the nominative case. Seventh, the noun after a preposition and in the *idafa*

construction must be in the genitive case. Eighth, verbs after the present-tense verb jussive tools will be in the jussive case [32]. Table III shows examples of each AGE sorted by error number.

TABLE III. EXAMPLES OF COMMON ARABIC ERRORS\LABEL

Error number	Incorrect Arabic sentence	Correct Arabic sentence
First error	التلميذ كريم	التلميذ كريم
Second error	الشجرة ثابت	الشجرة ثابتة
Third error	الحديقة الجميلة	الحديقة جميلة
Fourth error	قالت الرجل	قال الرجل
Fifth error	قالوا الرجلان	قال الرجلان
Sixth error	ان التلميذان مجتهدين	ان التلميذين مجتهدان

IV. DATA COLLECTION

This section describes how the database is created and shows the four substages used for the collection of the DAGC-ATS database, as shown in Fig. 2. These stages are preprocessing, feature extraction, Arabic Grammar Error Generation (AGER), and generating DAGC-ATS database entries and statistics. First, the examples for different structures of Basic Arabic Sentences (BAS) are passed to the preprocessing stage for the determination of Arabic sentences, clauses, and words. Second, the feature extraction stage is applied by three substages: the generation of features describing Arabic words, and the selection of dedicated features that can describe BAS. Previous stages are illustrated in the work [33]. Third, AGER, using the Fundamental Principle of Counting (FPC), is applied to generate errors for each sentence structure. The final entries for the DAGC-ATS database are created into two files, and their statistics are reported. Data collection is implemented using the Stanford parser and the NLTK libraries. Stanza is a Python-Based Toolkit for Natural Language Processing in a Variety of Human Languages [34]. Natural Language Toolkit (NLTK) is a natural language processing tool for Python [35]. All stages used for data collection are shown in Fig. 2.

Fig. 2. The stages of DAGC-ATS database collection.

A. Preprocessing

The preprocessing consists of two substages. First, a substage is sentence segmentation and Rhetorical Structure

Theory (RST) implementation to ignore unnecessary sentences [36]. The second and third substages are Arabic clause detection and word segmentation. Clause detection to segment multiple Arabic sentences into basic sentences. Word segmentation to

convert clauses to words. The output of this stage is a set of sentences, clauses, and words of the text input.

B. Features Extraction

The second stage includes the extraction of features that describe the structure of BAS. This stage contains three sub-stages: Part-Of-Speech (POS) tagging and dependency parsing creation, Arabic words feature selection, and final features of sentences.

C. POS Tagging and Dependency Parsing Creation

This stage includes extracting the features that represent the words. Every word in the Arabic text has been replaced with its characteristics, such as POS tags, case, number, gender, definiteness, and dependency relation between words. Each word in a document has been given a grammatical category, such as nouns, verbs, adjectives, and adverbs, which is known as POS tagging [37], [38] (Appendix A). This substage is based on Universal Dependencies for Arabic and Prague Arabic Dependency Treebank (PADT) [39], [40]. The Arabic features used in the DAGC-ATS database, and their counterparts in the PADT, are shown in Appendix B.

D. Arabic Word Feature Selection

This stage relates to the conversion of complex, advanced Arabic sentences to simple sentences based on the structure of the BAS. In the feature selection of the Arabic word substage, the words that represent the BAS are selected. The final substage is considered with the representation of BAS as a set of features. The basic idea for the creation of the DAGC-ATS database is to represent the structure of BAS using POS tags, the features of words, and the dependency relations between words. The advanced nominal and verbal sentences consist of the BAS and other tools. BAS is the cornerstone of complex sentence formation. Nominal and verbal sentences have BAS structures. The nominal sentence consists of two main components, which are the subject and the predicate of the sentence. Some tools precede the nominal sentence and change its meaning and grammatical signs, including *kan* or *en* and their sisters, or negation and interrogative tools. There are sentence complements in some nominal sentences, such as semi-sentence and *idafa* construction. These different structures for nominal sentences are shown in Fig. 3. The overlapping rectangles illustrate the structural arrangement of the nominal sentence. The word categories present from the beginning of the sentence to the end of the sentence in order are shown in Fig. 3 from part (a) to part (d). The largest rectangle represents the beginning of the nominal sentence. It contains the additional tools that precede BAS, and they are *en*, *kan*, and their sisters, interrogative and negative tools, as shown in Part (d) of Fig. 3. Parts (c) and (d) are the components of the BAS. The smallest rectangle represents the end of the sentence, which represents the nominal complement of the sentence, and it comes after BAS for the nominal sentence, as shown in part (a). The rectangles in the middle represent the rest of the sentence.

Examples of nominal BAS, nominal sentence complement, and other tools are shown in Fig. 4. An example of an extremely basic nominal Arabic sentence is shown in Fig. 4 in parts c and d. An example of a nominal sentence with the subject is a singular noun and the predicate is a mandatory sentence

complement, as shown in Fig. 4 in part a. A nominal sentence beginning with an “*en* tool” is shown in part b of Fig. 4.

Fig. 3. The different structures for nominal Arabic simple sentences: a) the beginning of the nominal sentence, b) description of different structures of the subject in a nominal sentence, c) description of different structures of the predicate in a nominal sentence, d) the complement of the nominal sentence.

Fig. 4. Examples of Arabic nominal sentences: a) The subject is a singular noun and the predicate is a semi-sentence. b) Description of an *en* tool and a nominal sentence with *idafa* construction as a complement. c) The subject and the predicate are singular. d) The subject is a pronoun, and the predicate is a singular noun.

In verbal sentences, there are two main parts of the verbal sentence: the verb and the subject. Both direct and indirect. Verbs can be perfective or imperative. The subject can be a singular noun, an adjective, a pronoun, or a determiner. Certain tools, such as jussive and accusative tools for verbs in the present tense and interrogative tools, come before the verbal phrase and alter its meaning and grammatical indicators. Certain verbal sentences, including semi-sentences and *idafa* constructions, include sentence complements. The sentence is called a semi-sentence if it begins with a preposition or adverb.

The structural arrangement of the verbal sentence is represented by the overlapping rectangles. Fig. 5 shows the word

categories that are present in the sentence from part (a) to part (d), in order, from the beginning to the end. The start of the verbal sentence is shown by the largest rectangle. It includes the negation or interrogative tools, or accusative or jussive tools, which come before BAS. The verbal complement of the sentences is represented by the smallest rectangle, which is the end of the sentence, and they come after BAS for the verbal sentence as shown in part (c) of Fig. 5. The BAS of the verbal sentence is represented by the rectangles in the center as shown in parts (a, b, c) of Fig. 5.

Fig. 5. The structures of Arabic verbal sentences: a) Description of the beginning of the verbal sentence. b) The basic component of the verbal sentence is a verb. c) Description of different structures of the subject in a verbal sentence. d) The object and the indirect object are components of a verbal sentence. e) Description of the complement of the verbal sentence.

E. Features of Sentences Representation

Every word in the BAS is represented by its POS tag, the Case, the Gender, the number, and the syntactic dependency relations. The noun and adjective are further described by definiteness. Table IV shows the word types used in the DAG-CTS database and their representations.

TABLE IV. ARABIC WORDS AND THEIR REPRESENTATIONS IN THE DAGC-ATS DATABASE

Word type	Word features	Word features values
Adjective	POS tag Case Definiteness Number Dependency Relation Gender	adj Acc Ind Sing xcomp NONE
Noun	POS tag Case Definiteness Number Dependency Relation Number	NOUN Nom Cons Sing nsubj:pass
Determiner	DET Case Gender Number Pronoun Type Dependency Relation	Acc Masc Sing Dem det
Verb	POS tag Perf Gender Number NONE Dependency Relation	VERB Perf Masc Sing NONE root
Pronoun	PRON Pronoun type Nom Masc Sing nmod	Noun object & POS tag Case obj & NOUN Acc obj
Proper noun and unknown noun	POS tag Pronoun type Case Gender Number Dependency Relation	X root NONE
Preposition	ADP Prep Dependency Relation	ADP Prep case

Examples of basic Arabic verbal sentences are shown in Fig. 6. The basic verbal sentence of the verb and subject is shown in part (a). An example of a verbal sentence with a verb, subject, and object is shown in part (b). In part (c), a verbal sentence is shown with a complement to the sentence. The jussive tool with a verbal sentence is shown in part (d).

Fig. 6. Examples of Arabic verbal sentences: a) A verbal sentence with a verb and a subject, b) A verbal sentence with a verb, a subject, and an object, c) A verbal sentence with a verb and a subject, and a semi-sentence as a complement of the sentence, d) A jussive tool with a verbal sentence.

An example of the generation of entries for the DAGC-ATS database for input Arabic text is shown in Fig. 7. The input of the Arabic sentences is shown in part(a) of Fig. 7. Part (b) of Fig. 7 shows the sentence segmentation stage, which separates the input text into isolated sentences. Then each sentence is separated into clauses as shown in part(c) of Fig. 7. Next, each clause is segmented into words as shown in part(d) of Fig. 7. The features of each word are represented as shown in part (e) of Fig. 7. The features of the words that make up the summary of a sentence are collected as shown in part(f) of Fig. 7.

F. Arabic Grammar Errors Generation

In the third stage, all AGE probabilities are generated using FPC. The fundamental idea of FPC is a far simpler method of determining the total number of combinations by applying the basic counting principle to make informed choices from all available choices. Finding each combination in a particular scenario is made easier by the Fundamental Principle of Counting. Suppose that the Arabic word is described by three features that cause grammatical errors, as shown in Fig. 8. These features are gender, numbers, and grammar. There is a need to create all probabilities of Arabic grammatical errors for that word by applying FPC. This is done by multiplication of the number of features of each variable, which is equal to $3 \times 3 \times 2 = 18$.

Fig. 7. An explanation of Arabic clause representation in the DAGC-CTS database: a) The original text. b) Sentence segmentation of the text. c) Clause segmentation of the text. d) Text segmentation into words. e) Features representation of words in the text. f) Final sentences representations.

Fig. 8. An explanation of the generation of all combinations of AGE using FPC.

G. Generating the DAGC_ATS Database Entries and Statistics

Finally, generated Arabic sentence representations are collected into two separate files, one for inputting incorrect Arabic sentences. The other file is for the correct output of Arabic sentences. The statistics of the DAG-CTS database are reported. In this section, the data collection process is discussed, and different statistics are reported. The database covers 24 grammar cases for simple sentences with all probabilities of Arabic errors. The database consists of the structure of basic

Arabic sentences that have meaning. Every entry in the DAGC-ATS database has a different sentence structure. The DAGC-ATS database is grouped into four groups: nominal sentence, verbal sentence, “kan” and her sisters' sentence, and “en” and his sister's sentences in Arabic. Each entry in every group is different from the other entries in that group in gender, number, and case. Every entry in the database is different from the other entries and covers one or more errors and their corrections.

V. DATABASE STATISTICS

The DAGC-ATS database contains 9309888 entries. These entries represent all cases for Arabic grammar errors, including differences in number, gender, definiteness, and grammatical cases. The DAGC-ATS database consists of two files. One file for input data entries contains different combinations of incorrect Arabic clauses in addition to sentence complements. The other file involves the corrected version of the clauses for the input file. It combines 687 Arabic sentence structures. The statistics for the database are shown in Table V and Fig. 9.

Fig. 9. The statistics of the DAGC-ATS databases.

The challenge facing the DAGC-ATS database is the inability of the Stanza toolkit to identify “kan” and “en” and their sisters. Also, the lack of distinction between the jussive and accusative tools for the present tense and normal verbs is important. This case is solved by adding a list of these tools to recognize them. In addition to the lack of identification of the broken plural.

TABLE V. THE DAGC-ATS DATABASE STATISTICS

Type of sentence	Number of sentences
Nominal sentence	2363604
Verbal sentence	739692
En tool with nominal sentence	2363604
Kan tool with nominal sentence	2363604
Jussive tool with verbal sentence	739692
Acoustic tool with verbal sentences	739692
Total	9468324

The challenge facing the DAGC-ATS database is the inability of the Stanza toolkit to identify kan, en, and her sisters. Also, the lack of distinction between the jussive and accusative tools for the present tense and normal verbs is important. This case is solved by adding a list of these tools to recognize them. In addition to the lack of identification of the broken plural.

A. Results

The goal of the initial QALB shared task, QALB-2014, was to fix mistakes made by native Arabic speakers in online comments. QALB-2015, the second shared task, expanded the task to include a track to fix mistakes in texts written by Arabic language learners. If the system produces a sentence that is syntactically correct, the output is deemed correct. The evaluation metrics used in all GECs are used to evaluate the suggested database. Eq. (1)- Eq. (3) are used to calculate the precision, recall, and F-measure for the suggested GEC system. A confusion matrix is a simple table that contrasts the classification model's predictions with the actual results [34]. That division is made into four categories: accurate predictions for both classes (True Positives (TP) and True Negatives (TN)) and incorrect predictions (False Positives (FP) and False Negatives (FN)). The matrix displays the number of instances in the model produced on the test data. The ratio of True Positives to all Positives is known as precision. The metric of our model that accurately detects True Positives is called recall [41].

$$precision(p) = \frac{TP}{TP+FP} \quad (1)$$

$$Recall(R) = \frac{TP}{TP+FN} \quad (2)$$

$$F1Score(F1) = 2 \frac{PR}{P+R} \quad (3)$$

Part of the DAGC-ATS is used for testing AGECE in the work [42]. The system is tested using the QALB dataset and achieved 96.9, 94.80, and 95.83 for precision, recall, and F-measure. In addition, the same system is tested using the EASC database using 785 summaries, and it obtained 99.73%, 95.90%, 97.77% for precision, recall, and F-measure. The challenge facing the AGECE using this database is the inability of stanza to differentiate between the sisters of “kān” and the sisters of “en” from other verbs. This problem was solved by adding all the sisters of “kān” and “en” to a list and adding them as “En” and “kan” in the database. This problem also failed in the stanza to give the correct diacritical marks to the subject and predicate of “kān” and “en.” The stanza was also unable to differentiate between past tense and imperative tense verbs, and it was treated as past tense verbs. In some cases, the letter “waw” in the verb was counted as a letter, and the verb was incorrectly divided. The system was unable to give the jussive and accusative grammatical case to jussive and accusative verbs in the present tense, due to its inability to recognize all the jussive and accusative tools. Fig. 10 shows the separation of the verb into segments because of the “waw” letters.

Fig. 13. The non-recognition of the grammatical case of the verb in the present tense after accusative tools.

A comparison with recent work in correcting Arabic errors is shown in Table VI. All the works mentioned in the table cited the problem of a lack of databases for all fields, or a large amount of training data covering all fields and dialects. A work mentioned methods to solve this problem using data augmentation [47]. Other work uses a confusion method to generate training data [45]. Another work uses a noising method to get training data. All of the works in Table VI suffer from domain difference. The proposed database creates another unconventional approach that focuses on representing correct and incorrect Arabic sentences with a set of characteristics that represent their words, without regard to the spelling of Arabic words, in order to identify errors in Arabic grammar. This database is used as a training database.

TABLE VI. RECENT WORKS COMPARISON FOR CORRECTION OF ARABIC ERRORS

Authors	Database / Dataset	Precision	Recall	F1 Score	Year
Alrehili & Alhothali [12]	Tibyan Corpus	97	97	97	2025
AlOyaynaa & Koth [14]	Public Arabic Sets	0.97	0.99	0.98	2023
Abdelaal et al. [43]	QALB 2014/2015	0.51	0.4	0.45	2024
S. Mahmoud et al. [44]	ZAEBUC	85.1	75.4	74.7	2024
Solyman et al. [45]	QALB 2014/2015	79.06	70.43	74.18	2022
Z. Mahmoud et al. [46]	QALB 2014/2015	64.37	45.51	53.32	2023
Solyman et al. [47]	QALB 2014/2015	75.99	58.29	65.98	2023
The proposed database	QALB	96.9,	94.80	95.83	2026

VI. CONCLUSION

The Arabic language is complex with a lot of morphology. In addition to the lack of available and open domain databases

for AGECE. So, AGECE is a big challenge. This study presents a new open-domain database called DAGC-ATS for AGECE. It is based on the description of the BAS structure using word type and features, in addition to the dependency relations between words. It contains 9309888 entries covering nominal and verbal sentences, en or kan and their sisters with nominal and verbal sentences, and jussive and accusative tools with verbal sentences. It contains 687 Arabic sentence structures. It has 9468324 different entries.

VII. FUTURE WORK

We will expand the database to include all types of simple sentences, and we may also address complex sentences. I also believe that by studying syntactic dependency relations in UD_Arabic-PADT, we can solve other Arabic language error problems. And by studying the features of words in UD_Arabic-PADT, we can differentiate between special cases of Arabic words. Always keep an eye out for updates on the database website. We will increase the number of Arabic sentence structures in the database to include most of the structures in the Arabic language, and we will test the database on a number of other databases for AGECE.

DATA AVAILABILITY

The DAGC-ATS dataset is available:
`\url{https://github.com/nadaessa369/dagc_ats-database}`.
Samples of verbal and nominal sentences are shown in verbal sentence samples.xlsx and nominal sentence samples.xlsx. In addition to the probabilities of error in gender, number, type of verbs, and definiteness, the total number of probabilities in each sample is also presented. An explanation of the more important things to understand the database is also presented.

Abstract—The increasing use of online platforms, especially in social media, has led to a rapid growth of user-generated content that frequently exhibits intra-sentential code mixing between Malay and English language. Sentiment analysis remains challenging due to linguistic heterogeneity, frequent language switching, non-standard syntax and limited availability of adequate representations for code mixing text. Although multilingual contextual embedding models such as Cross-lingual Language Model (XLM-R) provide good semantic representations, but there are still challenges in capturing fine-grained sentiment cues in intra-sentential code mixing text when used directly. This study proposed an enhanced feature extraction framework for intra-sentential code mixing Malay-English. The framework first constructs TF-IDF weighting based on trigrams and followed by lexicon-guided filtering to select trigrams that contain sentiment-relevant words. Contextual embeddings are then extracted using XLM-R and further refined through Term Frequency–Inverse Document Frequency (TF-IDF) weighting and positional encoding to preserve structural information. The dataset derived from the MESocSentiment corpus with total of 4,292. The experimental results show that the proposed framework achieves an accuracy of 0.896 and an F1-score of 0.932, where it outperforms traditional sparse feature representations and multilingual contextual embedding baselines. Notably, the framework demonstrates a high recall of 0.954, indicating strong sensitivity in identifying sentiment-bearing instances across diverse social media code mixing expressions. Further analysis reveals that the integration of informative trigram filtering, XLM-R based contextual embedding, TF-IDF weighting, positional encoding, and sentiment polarity scoring enhances the representation of sentiment cues in short and informal social media text. Overall, the results suggest that the proposed feature extraction framework enhances the representation quality of sentiment analysis for code mixing Malay–English in social media.

Keywords—Sentiment analysis; code mixing; feature extraction; contextual embeddings; XLM-R; TF-IDF; positional encoding

I. INTRODUCTION

Social media platforms generate large volumes of user-generated content that reflect public opinions, experiences and attitudes [2,3,4,5]. In multilingual societies, such as Malaysia, this content frequently exhibits intra-sentential code mixing between Malay and English [4]. This phenomenon, commonly referred to as Bahasa Rojak, introduces substantial linguistic

complexity due to rapid language switching, syntactic irregularities, informal expressions and frequent use of slang and out-of-vocabulary terms (OOV) [6,7]. Sentiment analysis of code mixing text remains a challenging task, as most of the existing approaches are designed for monolingual data and struggle to generalize across mixed linguistic structures [6,7,8,10]. While recent multilingual contextual embedding models such as Cross-lingual Language Model (XLM) have demonstrated good performance in multilingual natural language processing tasks, their direct application to code mixing sentiment analysis often yields suboptimal representations [11,12,13]. This limitation arises because contextual embedding alone may overlook sentiment-specific cues, negation effects, and local contextual dependencies that are critical for accurate sentiment interpretation in code mixing text [14,15,47,48,49].

Additionally, traditional sentiment analysis approaches based on sparse feature representations such as bag-of-words (BOW) and TF-IDF remain computationally efficient and effective in some settings. However, this approach focuses more on model-centric improvements and does not address the limitations of representation level in intra-sentential code mixing, where they are limited in capturing contextual semantics and short-range word order information. The studies, including mBERT and XLM-R, have improved cross-lingual representation learning and enabled sentiment analysis across languages. Nevertheless, contextual embedding alone may not sufficiently capture sentiment-relevant patterns in code mixing social media text where sentiment cues are distributed across local word combinations and contextual structures.

To address these gaps, this study evaluates the proposed feature extraction framework that introduces XLM-R based contextual embeddings with informative trigram filtering, TF-IDF weighting, positional encoding and sentiment polarity scoring. The framework is designed to enhance the representation of sentiment cues in intra-sentential code mixing Malay–English text by combining contextual semantics with local lexical patterns and polarity information. This study presents an empirical evaluation of the proposed feature extraction framework on code mixing Malay–English in social media dataset. This dataset derived from the MESocSentiment corpus. The dataset reflects realistic online communication

*Corresponding author.

patterns which include informal language usage, slang, short sentence length and diverse sentiment expressions. By focusing exclusively on this dataset, the evaluation examines the framework's performance and robustness in a realistic social media setting.

The contributions of this study are threefold. First, it provides a detailed evaluation of the feature extraction framework for code mixing Malay–English in a social media dataset. Second, it presents a comparative analysis against traditional sparse feature-based techniques and multilingual contextual embedding baselines, highlighting the benefits of integrating sentiment polarity score components with contextual representations. Third, it offers an error analysis that identifies key challenges in sentiment analysis of code mixing social media text, which includes mixed sentiment cues, informal expressions and pragmatic language use.

The remainder of this study is organized as follows: Section II reviews the related work in sentiment analysis for code mixing, while Section III presents the proposed feature extraction framework. Section IV describes the dataset and experimental setup. Section V presents the evaluation results and comparative analysis. Section VI concludes the study and outlines directions for future work.

II. RELATED WORKS

Sentiment analysis of code mixing text has received increasing research attention due to the widespread use of multilingual communication on social media and online platforms. Code mixing refers to the use of two or more languages within a single utterance, resulting in informal, non-standard text structures that pose significant challenges for natural language processing tasks. Early studies in this domain primarily focused on understanding the linguistic characteristics of code mixing data, particularly in high-resource language pairs, such as Hindi–English, which dominate the existing literature.

Initial approaches to code mixing sentiment analysis relied on traditional machine learning techniques and surface-level features including n-grams, TF-IDF and lexicon-based representations [9,16,17]. Choudhary in [25] introduced the Sentiment Analysis of Code mixing Text (SACMT) framework, which employed contrastive learning using Siamese neural networks to map code mixing and monolingual sentences into a shared sentiment space. While this approach demonstrated that sentiment similarity could be preserved across languages, it relied on skip-gram embeddings and required large auxiliary English datasets to achieve satisfactory performance, limiting its applicability to low-resource settings.

Subsequent research explored deep learning architectures to better capture contextual and sequential information in code mixing text. Lal *et al.* [26] proposed a hybrid model that combined sub-word embeddings with a dual Bi-LSTM encoder architecture, enabling the model to capture both sentence-level sentiment and sentiment-bearing sub-word units. Similarly, Yadav *et al.*, in [27], employed Bi-LSTM models with sequential mirroring to enhance contextual learning in longer code mixing sentences. Although these neural approaches improved sentiment classification performance, they remained

dependent on static or weakly contextualized embeddings which struggled to fully model the dynamic nature of intra-sentential code mixing.

To address the limitations of static embeddings, later studies shifted towards contextual embedding models such as BERT and XLM [41]. Contextual embeddings capture word meaning based on surrounding context, making them more suitable for code mixing text [11,12,13]. Researchers demonstrated that multilingual variants such as mBERT and XLM-R can learn shared semantic representations across languages, yielding improved sentiment analysis performance in multilingual and low-resource scenarios [11,10,28,29]. Studies by Tang *et al.* [30] and Sabri *et al.* [31] showed the effectiveness of multilingual word embedding for code mixing sentiment classification, although performance varied across sentiment categories and domains.

Recent work in monolingual sentiment analysis has focused on enhancing transformer-based models through hybrid and feature-augmented approaches. Jin *et al.* [32] demonstrated that incorporating TF-IDF weighting into contextual embeddings can improve sentiment discrimination by emphasizing statistically salient words in English text. Similarly, Mutinda *et al.* [33] proposed a hybrid representation that combines n-gram features, sentiment lexicons, and word embedding to enhance sentiment classification performance. Although these studies are not designed for code mixing data, they highlight the potential benefits of enriching contextual embeddings with explicit statistical and sentiment-based features. Liapis *et al.* [37] introduced distributional emotion embeddings that explicitly integrate emotional information into the embedding space, showing that enriching semantic representations with structured affective features leads to improved sentiment-related tasks. Similarly, language tagging and part-of-speech augmentation techniques proposed by Patil *et al.* [34], Tawakane *et al.* [35] and Patwardhan *et al.* [36], showed that explicit linguistic annotations can improve BERT-based model performance for code mixing sentiment analysis. However, these approaches often require extensive preprocessing, language-specific annotations, or large computational resources.

Research on Malay–English code mixing sentiment analysis remains comparatively limited. Kasmuri and Basiron [38] highlighted the scarcity of annotated Malay–English code mixing datasets and proposed the MY-EN-CS corpus to support future research. Lexicon-based methods explored by Zabha *et al.* [39] attempt to address data scarcity by constructing bilingual sentiment lexicons. However, these approaches were found to be ineffective in handling slang, abbreviations, and informal expressions commonly found in social media text. Fuady and Ibrahim [40] proposed a multilingual embedding approach using Word2Vec trained on Wikipedia corpora but their method struggled with out-of-vocabulary words and morphological variations.

More recent studies in code mixing Malay–English work have focused on multilingual transformer models such as mBERT and XLM-R [11,10,42]. Romadhona *et al.* [11] introduced the Bahasa Rojak Crawled Corpus (BRCC) and the SentiBahasaRojak dataset to support multilingual pretraining and evaluation of sentiment analysis models on Malay–English

code mixing text, including adaptations of XLM-R for mixed-language inputs. While their work improved cross-lingual semantic representation, sentiment polarity discrimination remained inconsistent, particularly between positive and negative classes in informal social media text. Kong et al. [10] constructed a large scale code mixing Malay–English COVID-19 Twitter dataset and evaluated sentiment analysis using BPE-enhanced mBERT and CNN-based models to address low-resource and noisy text challenges. Despite performance gains from subword modeling and contextual embeddings, the approach remains largely sentiment agnostic at the representation level. Suhaimin et al. [42] proposed MSSThred, a multitask framework combining sentiment analysis and sarcasm detection using Bi-LSTM and GRU architecture with engineered linguistic features, demonstrating improved robustness to sarcasm-induced polarity reversal. While these approaches show promise, they continue to face challenges in accurately modeling sentiment polarity in intra-sentential code mixing text, particularly for positive and negative sentiment classes. Overall, existing research highlights that although contextual embeddings significantly improve semantic representation, they often lack explicit mechanisms to encode sentiment polarity, negation effects and local contextual structure.

In summary, prior work demonstrates that effective sentiment analysis of code mixing requires more than model-centric improvements. There remains a clear need for a principled feature extraction framework that explicitly integrates contextual semantics, local trigram structure, positional information and sentiment polarity, particularly for low-resource language pairs such as Malay–English. This gap motivates the proposed framework in this study.

III. PROPOSED FEATURE EXTRACTION

The proposed feature extraction framework aims to enhance contextual embeddings for sentiment analysis by explicitly modeling local context, structural information and sentiment polarity scores. Given an input code mixing sentence, the framework produces sentiment-enriched trigram embeddings that serve as input representations for downstream classification models. Fig. 1 illustrates the overall workflow of the proposed framework.

The proposed model is detailed in Fig. 2 and Fig. 3. Based on both figures, the model is composed of five key modules, which are XLM-R embeddings, Informative trigrams, TF-IDF weighting, Positional Encoding (PE), and Sentiment Polarity Scores. Each module is strategically designed to enhance the quality of feature representations for sentiment analysis in intra-sentential code mixing Malay text.

A. Informative Trigram Generation

First, the preprocessed text is refined using an informative trigrams extraction mechanism, which selectively identifies only the most sentiment-relevant trigrams for downstream modelling. For a given code mixing sentence $S_{CodeMixed} = \{w_1, w_2, \dots, w_n\}$, trigrams are first generated by sliding a three-word window across the sequence, forming candidates $T_i = \{w_i, w_{i+1}, w_{i+2}\}$ for all $i = 1$ to $W_n - 2$. Instead of retaining all possible trigrams, the proposed method filters them using a code

mixing sentiment lexicon [43,44,45,46]. The process begins by filtering and retaining trigrams with at least one of its component words belonging to the lexicon. This filtering step discards trigrams with no sentiment bearing cues which significantly reduce the noise commonly found in code mixing social media text.

Fig. 1. Proposed feature extraction framework.

Fig. 2. Architecture of the proposed feature extraction.

Fig. 3. Illustration of the flow process in code mixing Malay-English.

Each retained trigram is then scored using a combined metric incorporating TF-IDF importance and sentiment polarity score. The TF-IDF score captures the semantic weight of a trigram by averaging the TF-IDF values of its three component words, computed, as in Eq. (1):

$$TFIDF(T_i) = \frac{1}{3} \sum_{j=1}^3 tfidf(w_{i+j-1}) \quad (1)$$

where, $tfidf(w)$ is the precomputed TF-IDF value for word w obtained from the dataset. Higher TF-IDF scores indicate that the trigram contains more informative and rich content terms. In parallel, the polarity score is derived using sentiment lexicon membership. Each word contributes +1 if it is labelled positive in the lexicon, -1 if it is labelled as negative in the lexicon and 0 otherwise. The polarity score for the trigram is then normalized, as shown in Eq. (2), to maintain a bounded range ensuring that $P(T_i) \in [-1, +1]$.

$$P(T_i) = \frac{1}{3} \sum_{j=1}^3 polarity(w_{i+j-1}) \quad (2)$$

Normalization prevents trigrams with multiple sentiment words from dominating solely due to word count and provides a fair comparative scale across all candidates. The final informativeness score for ranking trigrams is computed by combining these two signals through a simple additive model, as shown in Eq. (3):

$$Score(T_i) = TFIDF(T_i) + P(T_i) \quad (3)$$

$Score(T_i)$ favors trigrams that are both semantically important and sentiment-heavy. Using this score, the algorithm selects the top K highest scoring trigrams. The use of a fixed top K selection ensures a bounded and comparable representation across sentences of varying lengths while suppressing weak or redundant sentiment cues. In this study, K is set to 20 to provide sufficient contextual coverage for sentiment expression without introducing excessive redundancy. To ensure that important sentiment expressions near the end of the sentence are not overlooked, especially in informal user-generated text, the method includes a tail coverage strategy in which the last few trigrams (typically two) are preserved regardless of their computed score. These tail trigrams are then merged with the top K set, deduplicated and sorted based on their original positional index within the sentence to maintain natural linguistic flow. Through this refined extraction process, the model effectively captures the most meaningful and sentiment-relevant textual segments, yielding a robust and contextually rich trigram representation tailored for sentiment analysis of intra-sentential code mixing Malay-English text. These selected informative

trigrams provide the textual units on which contextual embeddings are subsequently extracted.

B. XLM-R Word Embedding

The proposed framework employs the Cross-lingual Language Model (XLM-R) to generate contextualized embeddings for intra-sentential Malay-English code mixing text. XLM-R is a transformer-based multilingual model pretrained on large scale parallel corpora that enables words from different languages to be represented within a shared semantic space. Given a code mixing sentence $S = \{w_1, w_2, \dots, w_n\}$, each token w_i is first tokenized into subword units and mapped to a contextual embedding $w_{yn} \in R^d$ using XLM-R, where d denotes the embedding dimensionality. Unlike static embeddings, these representations are dynamically conditioned on the surrounding context, allowing XLM-R to capture semantic variation across Malay and English words within the same sentence. This property is essential for code mixing text where sentiment expressions frequently span multiple languages.

To preserve local contextual semantics, word-level embeddings extracted from XLM-R are aggregated at the trigram level. For a trigram $t_j = \{w_j, w_{j+1}, w_{j+2}\}$, the corresponding contextual representation is computed by aggregating the embeddings of its constituent words. However, as observed in this study, XLM-R embeddings primarily encode semantic and syntactic information and do not explicitly model sentiment polarity or structural importance. Therefore, the resulting trigram representations serve as a semantic foundation that is subsequently refined through TF-IDF weighting, positional encoding and sentiment polarity score integration to ensure that the final embedding is both contextually rich and sentiment aware.

C. TF-IDF Weighting

Following the extraction of word-level contextual embeddings using XLM-R, the proposed framework applies Term Frequency-Inverse Document Frequency (TF-IDF) weighting to emphasize sentiment-relevant words in code mixing text. TF-IDF is used to assign higher importance to words that occur frequently within a sentence but less frequently across the corpus, thereby reducing the influence of common and non-sentiment relevant words [19,20,21]. For a word w_n occurring in a sentence S within a document collection D , the TF-IDF weight is defined as Eq. (4):

$$TF - IDF(w_n) = TF(w_n, S) \times IDF(w_n) \quad (4)$$

where, the term frequency $TF(w_n, S)$ is given by Eq. (5):

$$TF(w_n, S) = \frac{f(w_n, S)}{|S|} \quad (5)$$

with $f(w_n, S)$ denoting the number of occurrences of w_n in sentence S , and $|S|$ representing the total number of tokens in S . The inverse document frequency is computed, as shown in Eq. (6):

$$IDF(w_n) = \log \left(\frac{|D|}{|\{S_j \in D: w_n \in S_j\}|} \right) \quad (6)$$

where, $|D|$ denotes the total number of sentences in the corpus and $|\{S_j \in D: w_n \in S_j\}|$ represents the number of sentences containing the word w_n . Each contextual embedding v_w generated by XLM-R is then weighed using its corresponding TF-IDF score, as in Eq. (7):

$$v_w^{tfidf} = TF - IDF(w_n) \cdot v_w \quad (7)$$

The resulting weighted embeddings v_w^{tfidf} are subsequently used in the trigram construction stage of the framework. By incorporating TF-IDF weighting after contextual embedding extraction, the framework ensures that statistically significant and sentiment-relevant words contribute more strongly to the final representation, which is particularly important in intra-sentential code mixing text where frequent function words and language-switching artifacts may otherwise dominate the embedding space. However, weighing alone does not preserve word order within local contexts, which is critical for sentiment interpretation.

D. Positional Encoding

Although TF-IDF weighting emphasizes sentiment-relevant words, weighted embeddings alone do not explicitly preserve the relative position of words within local structures such as trigrams. In intra-sentential code mixing text, word order plays a critical role in sentiment interpretation, particularly in the presence of modifiers and negation [22]. For example, reversing the order of sentiment-bearing words within a short phrase may alter the overall sentiment polarity. To address this limitation, the proposed framework incorporates positional encoding to explicitly encode word order information within trigram-level representations.

Let w_n denote the i -th word in a sentence and $v_{wn}^{tfidf} \in R^d$ represent its TF-IDF-weighted contextual embedding. A positional encoding vector $PE_i \in R^d$ is assigned to each word based on its relative position within the trigram. Following the formulation in Eq. (8) adopted from Ali et al. [1], the positional encoding is defined using sinusoidal functions.

$$p_i^{(2k)} = \sin\left(\frac{i}{10000^{\frac{2k}{d}}}\right), \quad (8)$$
$$p_i^{(1)} = \cos\left(\frac{i}{10000^{\frac{2k}{d}}}\right)$$

where, k denotes the dimension index and d is the embedding dimensionality. The position-aware embedding is then obtained by element-wise addition, as shown in Eq. (9):

$$v_{w1}^{PE} = v_w^{tfidf} + PE_i \quad (9)$$

The position aware embeddings v_{wn}^{PE} are subsequently aggregated at the trigram level to form structure preserving trigram representations, as depicted in Eq. (10):

$$TC_i = \frac{1}{3} \sum_{n=j}^{j+2} v_{wn}^{PE} \quad (10)$$

By incorporating positional encoding after TF-IDF weighting, the framework ensures that the final trigram representations retain both the statistical importance of words

and their relative order within local context windows. This explicit encoding of positional information enhances the model's ability to capture sentiment shifts caused by word ordering, which is particularly important in code mixing text where linguistic structure is often irregular and informal. To further enhance sentiment sensitivity beyond structural encoding, explicit sentiment polarity information is incorporated.

E. Sentiment Polarity Score

To enhance the sentiment sensitivity of the feature representation, the proposed framework incorporates a Sentiment Polarity Score (SPS) derived from a code mixing sentiment lexicon and a negation scope-aware mechanism. Unlike conventional feature extraction techniques, this approach embeds the sentiment polarity score directly into the trigram-level contextual representation. This allows affective information to be explicitly encoded within the embedding space. This design is particularly suited to intra-sentential Malay-English code mixing text where sentiment-bearing words from different languages may co-occur and negation can substantially alter sentiment orientation.

For each informative trigram $T_i = \{w_1, w_2, w_3\}$, sentiment polarity is computed based on the lexicon membership of its constituent words. Each word w_n contributes a polarity value defined as in Eq. (11):

$$\text{polarity}(w_j) = \begin{cases} +1 & \text{if } w_j \in \text{positive polarity} \\ -1 & \text{if } w_j \in \text{negative polarity} \\ 0 & \text{otherwise} \end{cases} \quad (11)$$

To account for negation effects, a dynamic negation scope with a fixed window size of three tokens is applied. When a negation word (e.g., *tidak*, *not*, *bukan*) is encountered within the trigram, the polarity of the subsequent two tokens is inverted. This mechanism is implemented using a negation window counter that triggers polarity inversion for affected words. The negation-adjusted polarity values are then used to compute the overall sentiment polarity score of the trigram, as in Eq. (12):

$$P(T_i) = \frac{1}{3} \sum_{j=1}^3 \text{negated_polarity}(w_n) \quad (12)$$

where, $P(T_i) \in [-1, +1]$ represents a normalized polarity score capturing both sentiment intensity and directional shifts induced by negation. The resulting scalar polarity value is concatenated with the trigram's contextual embedding TC_i , producing a sentiment-enriched trigram representation, as in Eq. (13):

$$TC_i = [TC_i \parallel P(T_i)] \quad (13)$$

where, $TC_i \in R^{769}$ combines semantic and sentiment dimensions. By integrating sentiment polarity and negation scope directly into the embedding layer, the proposed framework enables more effective differentiation between trigrams that are semantically similar but sentimentally opposite [23,24]. This is an essential capability for sentiment analysis in code mixing contexts.

F. Final Trigram Representation

The final output of the proposed feature extraction framework is a sentiment enriched trigram representation that integrates semantic, structural and affective information. For each informative trigram, contextual embeddings extracted using XLM-R are refined through TF-IDF weighting to emphasize sentiment relevant words, augmented with positional encoding to preserve local word order and then further enriched by the integration of a negation aware sentiment polarity score (SPS), as illustrated in Fig. 2. These components are combined through vector concatenation to form a unified trigram representation that captures both contextual meaning and sentiment orientation. At the sentence level, the proposed framework represents each input as a sequence of sentiment-enriched trigram vectors, forming a fixed-dimensional matrix that preserves localized contextual and sentiment information. By retaining individual trigram representations rather than collapsing them into a single pooled vector, the framework maintains fine-grained sentiment patterns that are critical for intra-sentential code mixing text. This trigram-based representation provides a compact yet expressive feature space that is particularly well-suited for sentiment analysis of Malay–English code mixing text, where sentiment cues are often localized and influenced by word order and negation effects.

IV. EXPERIMENTS

This section describes the dataset used; the experiments set up were carried out to evaluate the performance of the proposed framework. The tools and techniques used in model formulation and evaluation are also discussed.

A. Dataset

The dataset for this study is acquired from the MESocSentiment corpus, a publicly available code mixing Malay–English social media dataset introduced by Shamsuddin et al. [50]. The corpus was created to address the scarcity of annotated code mixing sentiment resources in the Malaysian social media context and represents one of the most recent and comprehensive datasets for this task. The original MESocSentiment corpus includes three sentiment categories, which are positive, negative and neutral with a strong class imbalance toward neutral sentiment. To ensure consistency with the proposed feature extraction framework and the sentiment lexicon employed in this study, the dataset is adapted to a binary sentiment classification setting. Only tweets labeled as positive or negative are retained, while neutral instances are excluded. Table I summarizes the class distribution of the MESocSentiment dataset used in this study. The resulting dataset consists of 4,292 code mixing Malay–English tweets with 3,219 positive and 1,073 negative instances.

TABLE I. DATASET

Dataset	Sentiments	
	Positive	Negative
Code Mixing	3,219	1,073

B. Experimental Setup

To provide a comprehensive and fair evaluation of the proposed feature extraction framework, this study compares its performance against two groups of baseline approaches that are

widely used in sentiment analysis research: traditional sparse feature representations with linear classifiers and multilingual contextual embedding models with neural classifiers. This design allows the evaluation to cover both classical machine-learning pipelines that remain strong for short text classification and modern transformer-based representations that are commonly applied to multilingual and code mixing sentiment tasks.

First, two traditional feature-based baselines are included to establish strong reference points for sentiment classification on noisy social media text. The first baseline uses a standard bag of words (BoW) style vectorization approach, where code mixing posts are represented using sparse term-based vectors and classified using a linear Support Vector Machine (SVM). The second baseline uses TF-IDF representation with a linear SVM classifier. TF-IDF is particularly suitable for social media sentiment classification because it reduces the influence of frequently occurring conversational fillers and amplifies terms that are more discriminative for class separation. Linear SVM is selected because it has been consistently reported as a competitive classifier for high-dimensional sparse text features and provides a robust and reproducible benchmark for comparison.

Second, two multilingual contextual embedding baselines are included to represent state-of-the-art transformer-based models that capture semantic information beyond surface token frequency. In these baselines, each post is encoded using either mBERT or XLM-R to obtain contextualized representations suitable for downstream sentiment classification. These models are widely adopted in multilingual and cross-lingual NLP tasks and are relevant baselines because code mixing Malay–English text often contains subword variations, spelling inconsistencies and language switching where contextual embedding models are expected to provide more stable representations than sparse features. For classification, a Convolutional Neural Network (CNN) is employed on top of the contextual embeddings for the model to learn discriminative local patterns from the embedding sequences, which is particularly useful for short code mixing social media posts.

For fairness and interpretability, the proposed feature extraction framework uses the same CNN classifier architecture as the contextual embedding baselines. This ensures that performance differences between the proposed approach and transformer-only baselines are primarily attributable to the feature representation strategy rather than differences in classifier capacity. This comparison isolates the contribution of the proposed framework's additional components which are informative trigram filtering, TF-IDF weighting, positional encoding and sentiment polarity scoring when integrated with XLM-R contextual embeddings. As a result, the evaluation framework supports a more direct assessment of whether the proposed feature extraction design provides measurable advantages over both classical sparse feature approaches and standard multilingual embedding pipelines under consistent experimental conditions.

C. Model Parameter for SVM and CNN

For the baseline machine learning models, a linear Support Vector Machine (SVM) classifier was employed due to its

effectiveness and computational efficiency in high-dimensional text feature spaces. The SVM was trained using a linear kernel as implemented in LinearSVC, which is well-suited for sparse representations generated by TF-IDF and CountVectorizer features. The regularization parameter C was fixed at 1.0, providing a balanced trade-off between margin maximization and classification error. No class re-weighting or resampling was applied in order to preserve the natural data distribution. Feature vectors were constructed using word-level unigrams and bigrams, and all SVM parameters were kept constant across folds to ensure fair and reproducible comparisons.

For the deep learning approach, a vanilla Convolutional Neural Network (CNN) architecture was adopted to evaluate the discriminative capability of the proposed and baseline embeddings. The CNN consisted of a single one-dimensional convolutional layer with 128 filters and a kernel size of 3, followed by ReLU activation and global max-pooling to capture the most salient n-gram-level features. A fully connected dense layer with 64 hidden units was used prior to the output layer, and dropout with a rate of 0.5 was applied to mitigate overfitting. The output layer employed a sigmoid activation for binary sentiment classification. The network was optimized using the Adam optimizer with default learning rate settings, and binary cross-entropy was used as the loss function. All CNN models were trained for 10 epochs with a batch size of 16, and identical hyperparameters were maintained across all experimental settings to ensure consistency and comparability. Table II summarizes the model parameter settings for SVM and CNN.

TABLE II. MODEL PARAMETER SETTING FOR SVM AND CNN

Model	Parameter	Setting
Linear SVM	Feature representation	TF-IDF / CountVectorizer
	N-gram range	(1, 2)
	Max features	50,000
	Kernel	Linear
	Regularization (C)	1
	Class weighting	None
	Optimization	Linear hinge loss
	Evaluation	3-fold stratified CV
	Metrics	Accuracy, Precision, Recall, F1-score
CNN	Input embedding	trigram level embeddings
	Embedding dimension	768 / 769
	Convolution filters	128
	Kernel size	3
	Activation	ReLU
	Pooling	Global max pooling
	Dense units	64
	Dropout rate	0.5
	Output activation	Sigmoid
	Loss	Binary cross-entropy
	Optimizer	Adam
	Batch size	16
	Epochs	10
	Evaluation	3-fold stratified CV

	Metrics	Accuracy, Precision, Recall, F1-score
--	---------	---------------------------------------

D. Model Performance Evaluation

Performance metrics are used to assess the effectiveness of classification and feature extraction and feature selection techniques. To evaluate the performance of the proposed framework and to compare it with baseline methods, many performance metrics will be implemented depending on the training and testing datasets, including the following evaluation criteria. Four model evaluation metrics were selected: accuracy, precision, recall, and F-measure. The metrics are presented in Eq. (14) to Eq. (17).

Accuracy is the ratio of the correctly classified predictions to the total sum of predictions. It is given as:

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN} \quad (14)$$

Precision is the ratio of accurately classified data to the total data classified in the class. It is given as:

$$Precision = \frac{TP}{TP + FP} \quad (15)$$

Recall is the ratio of accurately classified data to the actual data in the class. It is given as:

$$Recall = \frac{TP}{TP + FN} \quad (16)$$

F-measure is the mean of precision and recall. It is given as:

$$F - measure = \frac{2 * Precision + Recall}{Precision + Recall} \quad (17)$$

V. RESULTS AND ANALYSIS

A. Overall Performance

Table III presents the comparative performance of the proposed feature extraction framework against traditional feature-based and multilingual contextual embedding baselines.

TABLE III. PERFORMANCE COMPARISON

Feature Extraction Representation	Classifier	Results			
		Acc	Prec	Rec	F1-score
BoW	SVM	0.879	0.881	0.931	0.924
Tfidf	SVM	0.873	0.871	0.935	0.920
mBERT	CNN	0.862	0.898	0.921	0.909
XLNet	CNN	0.884	0.905	0.944	0.924
Proposed Framework	CNN	0.896	0.920	0.954	0.932

As shown in Table III, among the traditional feature-based approaches, BoW combined with a linear SVM achieves an accuracy of 0.879, a precision of 0.881, a recall of 0.931 and an F1-score of 0.924. The TF-IDF representation with a linear SVM records an accuracy of 0.873, a precision of 0.871, a recall of 0.935 and an F1-score of 0.920. For the multilingual

contextual embedding baselines, the mBERT based CNN model achieves an accuracy of 0.862, a precision of 0.898, a recall of 0.921 and an F1-score of 0.909. The XLM-R based CNN model shows improved performance with an accuracy of 0.884, a precision of 0.905, a recall of 0.944, and an F1-score of 0.924. The proposed feature extraction framework achieves the highest performance across all evaluation metrics. It attains an accuracy of 0.896 and an F1-score of 0.932, outperforming both traditional sparse feature representations and multilingual contextual embedding baselines. The results indicate that the proposed framework provides a more effective representation for sentiment analysis in code mixing Malay–English social media text.

B. Comparison with Traditional Feature-Based Baselines

Traditional feature-based approaches using BoW and TF-IDF combined with a linear SVM classifier demonstrate strong baseline performance, achieving F1-scores of 0.924 and 0.920, respectively. These results confirm that sparse feature representations remain competitive for sentiment analysis on social media text, particularly when sentiment cues are expressed through frequently occurring lexical patterns. However, despite their effectiveness, these approaches rely primarily on surface-level term statistics and do not explicitly model contextual semantics or word order. As a result, they may struggle to distinguish sentiment in code mixing posts where meaning is conveyed through local phrase structure or experiential descriptions rather than isolated keywords. The proposed framework improves upon these baselines by incorporating contextual embeddings and structured feature weighting, resulting in a higher F1-score and improved overall accuracy.

C. Comparison with Multilingual Contextual Embedding Baseline

Among the contextual embedding baselines, the mBERT-based CNN model achieves an F1-score of 0.909, which is lower than both the TF-IDF baseline and the XLM-R-based CNN model. This result suggests that while mBERT provides contextualized representations, it may not sufficiently capture sentiment-relevant patterns in short and informal code mixing social media posts. The XLM-R-based CNN model performs better, achieving an F1-score of 0.924. This improvement reflects XLM-R's stronger multilingual representation capability and its ability to handle cross-lingual lexical variation more effectively than mBERT. Nevertheless, the XLM-R baseline still falls short of the proposed framework, indicating that contextual embeddings alone do not fully capture sentiment discriminative information in code mixing social media text. By integrating additional feature extraction components on top of XLM-R embeddings, the proposed framework achieves further performance gains. This comparison highlights that enriching contextual embedding with sentiment-aware and structure-sensitive features leads to more effective sentiment representation than using transformer embeddings alone.

D. Impact of the Proposed Feature Extraction Components

The performance improvements achieved by the proposed framework can be attributed to the combined effect of its feature extraction components. Informative trigram filtering focuses the representation on sentiment-relevant local contexts that

frequently occur in social media complaints or expressions of satisfaction [18,19]. TF-IDF weighting amplifies discriminative sentiment cues while reducing the influence of common conversational fillers that are prevalent in informal online text. Positional encoding preserves short range word order information, which is particularly important in intra-sentential code mixing text, where sentiment may depend on the arrangement of words rather than their presence alone. In addition, sentiment polarity scoring explicitly anchors contextual embeddings toward positive or negative orientation, providing complementary sentiment information that is not always captured by contextual embeddings alone.

The comparison with the XLM-R baseline using the same CNN classifier isolates the contribution of these additional components. Because both models share the same embedding backbone and classifier architecture, the observed performance gains can be directly attributed to the proposed feature extraction strategy.

E. Analysis of Recall and Sensitivity

A notable result in Table III is the high recall value of 0.954 achieved by the proposed framework, which is higher than all baseline models. High recall indicates that the framework correctly identifies a larger proportion of sentiment-bearing instances in the dataset, thereby reducing the number of false negatives. This property is particularly relevant for sentiment analysis of social media text, where users frequently describe situations or experiences instead of explicitly stating emotional reactions. In such cases, sentiment is conveyed through contextual and structural cues rather than isolated polarity words.

The proposed framework demonstrates increased sensitivity to such sentiment-bearing instances by retaining sentiment-relevant trigrams, emphasizing discriminative terms through TF-IDF weighting and incorporating sentiment polarity scoring alongside contextual embeddings. To illustrate this behavior, consider the code mixing Malay–English sentence “*lagi stress liao*” from the dataset. Although the sentence is short and does not contain explicit sentiment adjectives, it conveys dissatisfaction through the combination of the English term “*stress*” with Malay and colloquial discourse markers. At the trigram level, this local context is preserved while the contextual representation generated by XLM-R captures the negative experiential state associated with stress, enabling the classifier to correctly predict negative sentiment.

F. Error Analysis

Despite its performance, the proposed framework's result shows an error rate of approximately 10.4%, indicating that a small portion of code mixing social media posts remains misclassified. Analysis of these errors reveals several recurring challenges. First, some posts contain mixed sentiment cues where positive and negative signals appear within the same short sentence. In such cases, competing cues may influence the aggregated trigram representation and sentiment polarity score, leading to ambiguous predictions. Second, the informal nature of social media text introduces slang, abbreviations, and filler expressions that do not carry sentiment but affect local context representation. Short or fragmentary sentence structures further reduce the amount of contextual information available for

reliable classification. Finally, pragmatic language use, including sarcasm and irony, remains a challenge. In some instances, positive lexical items are used in a critical or sarcastic manner, which may not be fully captured by sentiment polarity scoring or contextual embeddings.

Despite strong overall performance, some errors remain as mentioned. For instance, the sentence “boleh login akhirnya tapi ambil masa lama” contains both a positive outcome (“boleh login akhirnya”) and a negative experience (“ambil masa lama”). The presence of competing sentiment cues within a short sentence may lead to ambiguous representations and misclassification. Other example, sentences such as “ok boring gila lah” and “jom tengok kes otosan gaming biar tak padu asalkan” contain conversational fillers (“ok”, “jom”, “lah”) and social expressions that contribute limited sentiment information. The dominance of such informal tokens reduces the amount of sentiment-relevant context available to the model, making classification more sensitive to a small number of words or trigrams. Similarly, sarcastic expressions such as “good you” in sentences like “intercontinental hotel digital perak got hacked, good you” can be misinterpreted due to the positive lexical form being used with negative intent. These limitations are consistent with challenges reported in prior work on sentiment analysis of social media text and highlight areas for future improvement.

VI. CONCLUSION

Overall, the results demonstrate that the proposed feature extraction framework provides consistent and meaningful improvements over both traditional sparse feature representations and multilingual contextual embedding baselines on code mixing Malay–English social media text. By combining contextual embeddings with trigram-level context, statistical weighting, positional structure and sentiment polarity score, the framework achieves more robust sentiment representation and improved classification performance in a realistic social media setting. Despite these improvements, several limitations remain. The framework relies on a predefined sentiment lexicon, which may not fully capture evolving slang and domain-specific expressions commonly found in social media. In addition, sarcasm and implicit sentiment expressions remain challenging due to their contextual and pragmatic nature. Future work will focus on extending the framework to incorporate dynamic lexicon expansion, sarcasm-aware modeling and cross-domain generalization. The evaluation of the framework will also be extended to cross-domain and multi-dataset evaluation to validate the proposed framework’s generalization capability.

ACKNOWLEDGMENT

The authors would like to thank the Public Service Department (PSD), the Ministry of Higher Education (MOHE) and the Universiti Teknologi Malaysia (UTM) for their educational and financial support. This work is conducted at the Faculty of Artificial Intelligence (FAI).

Empirical Quantitative Investigation of the Effect of GoF Design Patterns on the Quality of Software Systems

Somia Abufakher

Department of Software Engineering-College of Information Technology,
The World Islamic Sciences and Education University, Amman, Jordan

Abstract—Design patterns are universal, reusable fixes for common issues in software design. They are supposed to encourage better design choices by rep-urposing already-established successful solutions, saving cost and time. The purpose of the current study is to present quantitative evidence about the expected implications on software quality by employing GoF design patterns; 10 commonly applied patterns have been empirically assessed for their impact on software quality. The evaluated patterns are: Factory Method, Prototype, Singleton, Adapter, Composite, Decorator, Observer, State, Template Method, and Proxy. The study considers software quality attributes that match the intents of the subject design patterns; these attributes are: software maintainability, testability, reusability, simple design, sensitivity to change, and error-proneness. The empirical evaluation of patterns is performed by computing 10 software quality metrics for pattern classes that have been detected in 10 real open-source projects implemented with Java. The findings reveal that the evaluated patterns promote software quality, except for the classes of Prototype, Composite, and Singleton, which were often found not cohesive.

Keywords—Gang-of-four patterns; empirical quantitative investigation; software systems quality

I. INTRODUCTION

A design pattern is a generic, reusable procedure for an issue that often comes up at the software design phase, coding, and implementation levels [1]. In 1977, Alexander et al. introduced patterns in the discipline of architecture [2]. Gamma et al. suggested methods for using architecture patterns on software projects with object orientation in the middle of 1990s. Twenty-three design patterns were suggested; these are known as the “Gang-of-Four (GoF): Gamma, Helms, Johnson, and Vlides”. Three categories: creational, structural, and behavioral are used to group these patterns [1].

Design patterns are anticipated to offer many advantages, including: 1) encouraging better design choices, 2) facilitating communication among developers, 3) enhancing software maintainability, 4) assisting in meeting the system's non-functional needs, and 5) reducing costs, time, and effort by reusing already-proven solutions [1].

Since the proposal of GoF design patterns, researchers, empirically and analytically, have investigated the consequences of using them on several quality characteristics of software systems. According to a few of the previous results, design

patterns make it more difficult to produce software that meets the necessary standards. However, according to other research, developers should employ design patterns to enhance the quality of their programs.

In this work, an empirical investigation is established and carried out to assess the impact of using 10 of the widely adopted GoF design patterns on the quality attributes of software systems. Ten (10) open-source software projects have been chosen. Next, design patterns recognition methods were used to identify the classes that are involved in each of the examined patterns in the subject programs. Finally, 10 software quality metrics were calculated for the purpose of assessing the quality characteristics of the classes included in the design patterns under consideration.

Mainly, the goal of the current study is to answer the following question:

What are the implications of GoF design patterns on the maintainability, testability, reusability, simple design, sensitivity to change, and error-proneness of software systems?

The obtained results show that in general, the classes involved in Factory Method, Adapter, Decorator, Observer, State, Template Method, and Proxy are maintainable, testable, simple, reusable, less error-prone, and less sensitive to changes occurring in other modules of the system. This conclusion is stated because the means of all computed metrics for classes involved in these patterns were found in their optimal ranges.

In contrast, the means of RFC of Prototype and Composite were found to be higher than the optimal; this indicates that a class of these two patterns will run a significant number of methods in response to an action received. Consequently, these patterns may impede achieving the expected level of software quality.

Similarly, the mean of LCOM of Singleton classes was found to be higher than the optimal range, which means that classes involved in Singleton are less cohesive, which may impede the desirable software quality.

This is how the remainder of the study is structured: Related works are presented in Section II. The study's methodology and procedures are shown in Section III. The results collected are presented in Section IV. Section V wraps up the work and provides a summary and the recommendations.

II. RELATED WORK

Despite being proposed and published in the middle of the 1990s, GoF design patterns continue to serve as a guide for software developers and designers. Therefore, researchers have evaluated the consequences of applying design patterns as reusable strategies on software quality characteristics. In the following, some of the works in this domain are briefly mentioned:

Sousa et al. (2019) present an empirical study to check whether the deployment of design patterns may reduce bad smells in code. According to the results, using design patterns does not always stop code smells from occurring. Some patterns, like Adapter, Proxy, and State, commonly co-occur with code smells and must therefore be implemented carefully. While others, like Composite, Factory Method, and Singleton, can support high-quality system design. Moreover, the researchers state that the main reasons why issues could arise in the code are poor planning and improper usage of design patterns [3].

In addition, Feitosa et al. (2019) investigate whether using patterns ensures acceptable coding practices. The researchers use static analysis to study the connection between 12 of GoF design patterns and infringements of best practices pertaining to source code accuracy, performance, and security. The results indicate that classes that don't follow patterns are more likely to break security, performance, and accuracy guidelines. In addition, the study concludes that patterns with more intricate structures (like Decorator) and pattern instances that are more prone to change (like subclasses) are more likely to be linked to a higher number of violations [4].

Further, Bontchev and Milanova (2020) investigate the usability of GoF patterns on the testability, maintainability, extendibility, readability, reliability, and performance efficiency of programs. The researchers use a survey with 82 object-oriented professionals. According to the findings, Memento and Flyweight are the least well-known and least practical patterns, whereas Singleton and Factory Method are the most well-known and practical. Also, the responses indicate that the least common design patterns are behavioral ones. Even so, seasoned responders think that design patterns greatly enhance software quality, with differing impacts on different quality criteria [5].

Likewise, Qamar and Malik (2020) investigate the implications of GoF patterns on the complexity and size of software projects. The researchers conducted a comparison between the before and after editions of program sets developed with and without utilizing design patterns. According to the comparison's findings, programs created with design patterns exhibited lower cyclomatic complexity than programs produced without design patterns for the majority of GoF design patterns. However, the study found that usage of design patterns resulted in an increase in the software size, number of classes, and CK metrics [6].

As well, Kurmangali et al. (2022) present an empirical investigation to assess the effectiveness of Decorator and Abstract Factory on software maintainability. The following C&K metrics were computed: WMC, DIT, NOC, CBO, RFC, and LCOM, and compared for patterns' classes. According to the study, deployment design patterns can boost the

maintainability of software. Moreover, Decorator showed a little superior performance than other patterns [7].

More recently, Hsu et al. (2024) studied the outcomes of design patterns on the quality of software systems during their evolution by analyzing the complexity of systems and the changes in dependency relationships among components. The study considers three of GoF patterns: i.e., Factory Method, Decorator, and Observer. According to the findings, design patterns successfully lessen dependencies created as a system evolves, reducing system complexity and improving overall quality [8].

Furthermore, Asaad and Avksentieva (2025) assess GoF design patterns that are detected in GitHub repositories on software engineering procedures. The research's findings demonstrate that GoF patterns are actively applied in actual software development, and they significantly raise software quality characteristics [9].

Additionally, Elish (2025) examines the potential effects of design patterns on software maintainability in a quantifiable way. The Maintainability Index (MI), which is a quantitative indicator that aggregates size, complexity, and other code parameters into a single number, was measured in order to achieve the goal. The study's conclusion shows that using design patterns can simplify and strengthen a system's structure, boosting software maintainability. However, patterns may differ from one to another; in comparison to behavioral design patterns, creational and structural design patterns have a better maintainability score. Moreover, according to the maintainability index, the top three patterns are Builder, State, and Adapter [10].

Finally, Nouredine and Goaer (2025) conducted experimental research to assess the influence of design patterns on the energy consumption of software. The study considers the 23 GoF patterns and multiple platforms, operating systems, programming languages, and compilers. The researchers found that all GoF design patterns are highly energy-efficient [11].

Despite the widespread recognition of Gang of Four (GoF) design patterns as a means of enhancing software design quality, the majority of current research concentrates on theoretical advantages and qualitative evaluations rather than offering empirical, quantitative proof of their actual influence on software quality features.

The majority of earlier research lacks thorough analysis across many systems or contexts and instead looks at design patterns in isolation or relies on small-scale case studies. Furthermore, little research has been done on how particular GoF design patterns affect quantifiable software quality criteria, including maintainability, testability, reusability, simple design, sensitivity to change, and error-proneness. Moreover, there is no consensus on the findings for the same pattern and the same quality attribute (but using different data sets).

Additionally, the literature currently in publication does not adequately address the comparative effects of various GoF pattern categories (structural, behavioral, and creational) on software quality.

The current work contributes to the empirical evaluation of the implications of design patterns on the quality of software

systems by performing a comprehensive investigation of 10 of the most commonly used design patterns and all related quality attributes (i.e., quality attributes that are, in theory, consequences of using the evaluated patterns).

III. METHODOLOGY

In order to conduct the empirical evaluation of design patterns on software quality, this section outlines the methodology and the procedures used to collect and evaluate the data. First, the most popular GoF design patterns were chosen for assessment. In the second step, the quality attributes that match the intents of the structure of the selected patterns were determined. Then, to measure the quality attributes of pattern classes, 10 software quality metrics were determined, and how their values affect software quality was analyzed. After that, 10 open source Java projects were selected, and the classes of the considered design patterns were detected using design pattern mining tools. Then the software quality metrics were computed for each of the detected pattern classes. Finally, the results were studied and analyzed to conclude the implications of the considered patterns on the related quality attributes of object-oriented software. These steps are illustrated in more detail in the upcoming subsections.

A. Design Patterns

In this study, 10 of the GoF design patterns are evaluated, these are: Factory Method, Prototype, Singleton, Adapter, Composite, Decorator, Observer, State, Template Method, and Proxy. These patterns are selected because they have the following characteristics: 1) they belong to the three categories classified in GoF: creational, structural and behavioral, 2) they are widely used in software design, 3) they are from the most evaluated patterns in the previous empirical studies 4) their instances are the most detected by the design patterns mining tools used in this study. In the following, the main intent of the selected patterns is briefly described:

Creational patterns are used to create objects and abstract the creation process to facilitate the implementation process and create an independent system [1]. In this study, the following creational patterns are evaluated:

- Factory Method: A pattern for building instances that let subclasses choose which class to generate at runtime, by specifying a common interface [1].
- Prototype: An optimization pattern that uses a prototypical implementation to identify the kind of created instances [1].
- Singleton: A pattern used to restrict a class to only one instance, making this instance a shared resource in the system by providing global access to it [1].

Structural patterns are used to create simple communication among classes and their instances; they are concerned with how the modules of the system relate to each other to form larger structures [1]. In this study, the following structural patterns are evaluated:

- Adapter: A pattern used when two classes belong to distinct interfaces wanted to work with each other

without modifying any of their code, but by using inheritance to get the needed implementation [1].

- Composite: A pattern creates a tree structure to describe part-whole hierarchies by treating a collection of related instances as a single one [1].
- Decorator: A pattern that optimizes a class instance by dynamically adding new responsibilities without changing how other instances in the same class behave [1].
- Proxy: A pattern used to control the access of a class instance by providing an alternative way [1].

Behavioral patterns are communication patterns; they are concerned with algorithms and determine the functions of the objects in the system [1]. In this study, the following behavioral patterns are evaluated:

- Observer: In this pattern, a class instance is created called "subject" to define its dependents, so that when a change occurs on the subject, it automatically updates and informs all of its dependents [1].
- State: A pattern that enables an entity to alter how it acts in response to changes in its internal state [1].
- Template Method: A pattern used to define the algorithm of the system in one method called "Template Method"; it delays some steps to subclasses without changing the structure of the program [1].

B. Software Quality Attributes

According to previous studies, software quality has been greatly affected by GoF design patterns. In this study, six quality attributes are considered; these are: maintainability, testability, reusability, simple design, sensitivity to change, and error-proneness. These attributes are considered because they match the intents of the structure of the assessed design patterns, and they are among the consequences of using these patterns on object-oriented software. In the following, each software quality attribute is briefly described:

- Software maintainability: The average of effort and time required to correct, adapt, or improve the software through its life cycle until postmortem [12].
- Software testability: The effort required to complete the testing process for every module in the system [12].
- Software reusability: Reusable classes can be used in other parts of the system or in another one [12].
- Software simplicity: In this study, the pattern classes are evaluated to determine whether their design is complex; there are numerous complex inter-relationships between pattern classes and the other modules of the system.
- Sensitivity to change: A class is considered sensitive if it is affected by changes that occur in other classes of the system, and vice versa [12].
- Error-proneness: The number of faults may be discovered in the classes of a system [13].

C. Software Quality Metrics

To numerically evaluate design patterns, 10 software quality metrics were computed for each class that is involved in any of the considered patterns. In the following, the used metrics are illustrated, in addition to the optimal range of each one, and how these metrics may affect the software quality attributes of software systems.

The Chidamber and Kemerer measures set, or C&K measures, is an approach used to assess the quality of object-oriented software systems [13]. C&K set includes six types of metrics that could be computed for a single class in a software project. In the following, each metric is briefly illustrated:

WMC, which is “Weighted Methods per Class,” is measured by counting how many methods are defined in a class. A class should have the lowest possible count of methods. A lot of methods in one class have a negative impact on software quality. Chidamber and Kemerer mentioned that the good class has 20 to 50 methods [13].

DIT, which is “Depth of Inheritance Tree,” represents the longest sequence of inheritance between a parent class and its offspring. It calculates a class's place in the inheritance tree [12]. Misra and Bhavsar found that high DIT promotes method reusability, but on the other hand, it makes the class design more complex and may increase the faults in the system [23]. Chidamber and Kemerer mentioned that DIT should not be more than 5 [13].

NOC, which is “Number of Children,” measures the count of subclasses directly derived from a base class. There is a close relation between NOC and DIT; more levels of inheritance may increase DIT and reduce NOC. NOC promotes reusability, and unlike the other five metrics, it reduces the number of faults in classes; however, the base classes may need more testing effort [12]. There is no optimal NOC determined in the literature, but researchers agreed that it should not be high (e.g., Chidamber and Kemerer [13]).

CBO, which is “Coupling between Objects,” indicates how many classes a class is associated with. CBO should be kept down, because it impedes reusability and maintainability, and it produces more faulty classes [13]. Sahraoui et al. recommended that the CBO should be no more than fourteen [14].

RFC, which is “Response set of a Class,” is the collection of methods that are likely to be used when a class sends an action. High RFC is undesirable [12]. Misra and Bhavsar found that it increases the design complexity and the faults in the system,

making it less understandable, and thus the system will require more testing effort [15].

LCOM, which is “Lack of Cohesion of a class,” is a cohesion metric; it measures whether a class includes any related methods performing one function. Cohesive design is desirable because it promotes reusability and makes the system easier to maintain. Therefore, LCOM should be as low as possible; when it reaches 0, the class is considered very cohesive [13].

However, researchers suggested optimal ranges only for WMC, DIT, and CBO. For NOC, RFC, and LCOM, they just stated that the values of these metrics should not be high. To minimize this conflict, a study conducted by NASA in 2003 is considered; the study reports the optimal means for C&K metrics for a high-quality Java system. It stated that the optimal mean of RFC is less than or equal to 43.84 and the optimal mean of LCOM is less than or equal to 78.34 [16]. So, these two values are used as references in the current evaluation. Table I summarizes the desirable values of C&K metrics in object-oriented design according to [13] and [16].

TABLE I. THE OPTIMAL USE OF C&K METRICS

Metric	Optimal Use
WMC	< 50
DIT	<= 5
NOC	Not high
CBO	<= 14
RFC	<= 43.84
LCOM	<= 78.34

For more clarification about the impact of C&K metrics on object-oriented software, Table II presents some empirical studies from the literature that evaluate the impact of the increasing values of C&K metrics on quality attributes of software.

Along with the C&K metrics, the following software quality metrics are also calculated to improve the correctness of the results about the evaluation of design patterns:

LOC, which is “Number of Lines of Code,” is a software metric used to determine the size of a whole system or just one module in it. Actual LOC is measured by computing the number of lines of code that contain executable or declarative statements; comments and whitespaces should be excluded.

TABLE II. THE IMPACT OF HIGH VALUES OF C&K METRICS ON SOME SOFTWARE QUALITY ATTRIBUTES

Increasing metric	Software maintainability	# Faults	Software testability	Design complexity	Software reusability	Sensitivity to change
WMC	Impede	Enhance	Enhance	Enhance	Impede	Enhance
DIT	Impede	Enhance	Enhance	Enhance	Enhance	Enhance
NOC	Impede	Impede	Impede	Enhance	Enhance	Enhance
CBO	Impede	Enhance	Enhance	Enhance	Impede	Enhance
RFC	Impede	Enhance	Enhance	Enhance	Impede	Enhance
LCOM	Impede	Enhance	Enhance	Enhance	Impede	Enhance
Reference	[13] [15] [17] [18]	[13] [15] [19] [20] [21] [22] [23]	[15] [24] [25] [26]	[15] [27]	[13] [15] [27]	[27]

Researchers empirically studied LOC in several ways; for example, Gyimothy et al. [19] and Yu et al. [28] evaluated the relationship between LOC and the count of defects discovered in the system; they concluded that high LOC increases the number of faults in classes. Li and Henry [17] evaluate the impact of high LOC on software maintainability; they found that as LOC increases, developers will need more effort to maintain the system. In addition, Bruntink and Van Deursen [24] concluded that large systems require more testing effort. All those researchers stated that LOC can be used as a reliable measure of software complexity. It is suggested that a good Java class should not have more than 1500 lines of code [28].

NIM, which is “Number of Instance Methods”: instance methods are the set of methods that are created in a class, and only objects in that class can communicate with them [29].

NIV, which is “Number of Instance Variables”: instance variables are the set of variables that are created in a class, and only objects in that class can communicate with them [29].

Lorenz and Kidd suggested NIM and NIV as measures of class size [29]. Several researchers evaluated the effectiveness of these two metrics in object-oriented design. For example, it was concluded that there is a strong correlation between NIM and NIV with software maintainability, where a large size class impedes achieving a high level of maintainability [30].

McCabe Cyclomatic Complexity is a software metric that Thomas J. McCabe developed to assess how complex a software component's design is. Cyclomatic complexity may be computed for the whole system using a control flow graph or for one class of the system by counting the independent paths in it; when this number is high, it means that the program should be restructured into simpler modules. As software complexity increases, the testability decreases, and the program will be more difficult to understand [31]. In this study, McCabe complexity of pattern classes is computed by computing the average of all cyclomatic complexities of nested methods of the classes that are involved in any of the considered patterns.

To compute the previously mentioned metrics for each class involved in each of the considered patterns, the

Understand™ tool is used, which is a commercial reverse engineering tool that statistically extracts information from Java source code.

D. Benchmarks

In order to perform the current evaluation, 10 open source software projects were selected. All the considered projects are implemented with the Java programming language, applying object-oriented principles. Many GoF design patterns are used in their code design. The size of the selected projects is medium to large. Table III presents the selected projects and summarizes their main characteristics.

As shown in the table, Apache Tomcat and Finesse have the most detected pattern classes, where 487 pattern classes are detected in Apache Tomcat and 333 pattern classes are detected in Finesse. The lowest number of pattern classes is detected in Java Mail API; only 71 classes.

Fig. 1 presents the number of pattern classes found in each software project.

Fig. 1. Number of pattern classes detected in each benchmark.

TABLE III. CHARACTERISTICS OF THE BENCHMARKS USED IN THE STUDY

Software Projects	# Classes	# Files	# Units	# LOC	# Patterns Classes	Patterns classes ÷ All classes
Eclipse-JDT	1105	793	11535	241326	192	17%
JHotDraw	480	309	3781	56990	244	51%
OpenXava	1587	1542	12850	154239	76	5%
Apache Tomcat	3009	1807	23430	464352	487	16%
Xstream	1406	653	4878	71150	150	11%
Finesse	1487	1035	9002	90149	333	22%
JMail API	265	192	1983	52142	71	27%
JUnit	181	89	788	7230	78	43%
ArgoUML	1430	1226	10563	240755	255	18%
Apache Ant	1300	929	10112	200178	259	20%

On the other hand, JHotDraw has the largest percentage of design pattern classes; 51% of its classes have pattern instances in their design. JUnit comes after; 43% of its classes contain pattern instances. Fig. 2 presents the percentage of pattern classes to all the project's classes.

The classes of design patterns were detected in the selected software projects using Tsantalis approach [32] and PINOT [33] detection tools. These tools detected many instances of patterns in the source code of each of the software projects used, as presented in Table IV.

Fig. 2. The percentage of pattern classes to all classes in each benchmark.

TABLE IV. NUMBER OF CLASSES INVOLVED IN THE INSTANCES OF DESIGN PATTERNS: FACTORY METHOD (FM), PROTOTYPE (P), SINGLETON (S), ADAPTER (A), COMPOSITE (C), DECORATOR (D), PROXY (X), OBSERVER (O), STATE (St), AND TEMPLATE METHOD (TM)

Software Projects	# detected classes that are involved in design patterns									
	FM	P	S	A	C	D	X	O	St	TM
Eclipse-JDT	2	4	10	111	0	0	0	19	31	15
JHotDraw	1	14	9	77	5	8	0	3	114	13
OpenXava	1	3	25	16	0	1	4	0	13	13
Apache Tomcat	8	1	58	181	5	19	5	17	142	50
Xstream	2	0	2	71	0	10	5	0	50	10
Fitnesse	12	0	36	125	3	17	8	0	107	25
JMail API	4	6	9	27	0	2	0	2	12	9
JUnit	0	0	0	18	2	2	0	3	8	45
ArgoUML	5	5	149	27	2	7	4	1	28	27
Apache Ant	22	15	3	71	30	8	28	21	40	21
Total	57	48	301	724	47	74	54	66	545	228

As the table shows, some patterns are used more than others in the design of the software projects; Adapter and State are the

most used patterns, while Composite and Prototype are the least used patterns.

IV. RESULTS

After detecting the classes that are involved in design patterns in the benchmarks used in this study, the extent to which the detected classes promote software quality is determined by computing 10 metrics for each class. The obtained values are presented by scatter diagrams in the Appendix. After that, the means of the obtained values for each metric are computed and analyzed to determine whether this mean is optimal and how it may affect the considered quality attributes of software. Table V summarizes the means of all the obtained results.

By analyzing the results presented in Table V and the figures in the Appendix, the following can be summarized about the evaluated design patterns:

First: The impact of creational design patterns on software quality

The means of the 10 computed metrics for the 57 classes of the Factory Method pattern are in the optimal ranges. This is expected because this pattern is proposed to define and maintain the complex relationships among objects, which facilitate the missions of subclasses, making the process of creating objects inside a class more flexible [1].

The means of the computed software metrics for the 48 classes of Prototype are in the optimal ranges, except the mean of RFC, which is 65, i.e., higher than the optimal. This indicates that a Prototype class will most likely run a large number of methods, which makes this pattern less cohesive. This negative result is not expected; Prototype is considered an optimization pattern proposed to let developers create new objects by cloning the prototype instance [1]; it is anticipated that it will result in fewer classes inside the system by creating new objects without using inheritance. To the best of the researcher's knowledge, there is no clear justification for the high RFC of Prototype!

The means of computed software metrics for the 301 classes of Singleton are in the optimal ranges, except the mean of LCOM, which is 82, i.e., higher than the optimal. This means that Singleton classes are not cohesive. This is expected because this pattern is used as a shared resource object that has global access to it [1].

TABLE V. SUMMARY OF THE OBTAINED MEANS OF THE COMPUTED SOFTWARE QUALITY METRICS FOR DESIGN PATTERNS CLASSES WHERE: FACTORY METHOD (FM), PROTOTYPE (P), SINGLETON (S), ADAPTER (A), COMPOSITE (C), DECORATOR (D), PROXY (X), OBSERVER (O), STATE (St) AND TEMPLATE METHOD (TM)

Metrics	The means of metrics for pattern classes									
	FM	P	S	A	C	D	X	O	St	TM
WMC	21	32	9	17	18	18	16	22	18	18
DIT	2	2	2	2	3	2	2	2	2	2
NOC	1	4	0	1	5	3	0	4	1	4
CBO	7	11	4	8	7	6	9	9	10	6
RFC	30	<u>65</u>	25	38	<u>49</u>	24	35	30	32	30
LCOM	68	71	<u>82</u>	48	66	49	66	55	59	6
LOC	176	395	87	193	205	146	176	255	205	164
NIM	20	31	8	16	17	18	16	21	18	17
NIV	6	8	2	5	7	4	7	7	6	5
Complexity	2	2	2	2	2	1	2	2	2	2

In short, Factory Method can be safely considered maintainable, less error-prone, testable, promotes simple design, reusable, and less sensitive to changes occurring in the system. But the other creational patterns, i.e., Prototype and Singleton classes, may be difficult to maintain, less reusable, less testable, complex in design, error-prone, and sensitive to changes occurring in the system.

Second: The impact of structural design patterns on software quality.

The means of the 10 computed software metrics for the 724 classes of Adapter are in the optimal ranges. An adapter is proposed to be used when two classes belonging to incompatible interfaces want to work with each other without modifying any of their code, but by inheriting the needed interface and implementation [1]. The positive impact of Adapter classes will be achieved if it works with a reasonable number of Adaptees. Otherwise, high inheritance may cause problems in the system.

The means of the 10 computed software metrics for the 47 classes of Composite are in the optimal ranges, except the mean of RFC, which is 49, i.e., higher than the optimal. Since this pattern deals with a collection of related objects handled as one instance of an object [1], the negative outcome is to be expected. Each object in this group mostly belongs to a different class; when an action occurs on one, the rest will respond in the same way, which expands the count of executed methods in response to a Composite class.

The means of the 10 computed software metrics for the 74 classes of Decorator are in the optimal range. This is to be expected since this pattern is used to improve an object without changing how other objects behave [1]. So Decorator is more flexible than subclasses for adding new functionalities; it avoids using static inheritance, which causes many problems in the program, achieving the principle of "open for extension, closed for modification".

The means of the 10 computed software metrics for the 54 classes of Proxy are in the optimal ranges. This is expected because a proxy is used to control the access of an object by providing a virtual alternative to the target object [1].

Thus, the structural patterns: Adapter, Decorator, and proxy may be safely considered maintainable, less error-prone, testable, promote simple design, reusable, and less sensitive to changes occurring in the system. While about Composite, the opposite can be stated; this pattern may impede software quality unless users pay attention to prevent the possible high coupling of its classes.

Third: The impact of behavioral design patterns on software quality

The means of the 10 computed software metrics for the 66 classes of Observer are in the optimal ranges. The results about Observer classes are not expected, because in Observer, when a change occurs on the subject, all of its dependents are informed and modified automatically [1]. Observers do not know about each other's behavior, so unexpected updates may occur in the system, which means that Observer classes are expected to be sensitive to changes that negatively affect the quality attributes of the software systems.

The means of the 10 computed software metrics for the 545 classes of State are in the optimal ranges. Given that this pattern enables an object to automatically adjust its behavior when its internal state changes—the object just changes its class [1]—this is to be expected. Thus, the State does not have consequences on the other modules of the system.

The means of the 10 computed software metrics for the 228 classes of Template Method are in the optimal range. This is expected because this pattern is used to define the structure of the program in one method without changing the structure of the program [1]. Thus, Template Method supports reusing the code and makes full control over the code structure without modifying it and without using inheritance relations.

Thus, the behavioral patterns which are evaluated in this study are maintainable, less error-prone, testable, promote simple design, reusable, and less sensitive to changes occurring in the system.

The results obtained in this study are highly consistent with the previous ones in the domain of evaluating the implications of applying design patterns on the quality of software systems; where the previous studies found that GoF design patterns are significantly supportive of software quality [3], [4], [5], [7], [8], [9], [10], [11]. However, the study of Qamar and Malik (2020) found that for the majority of the 23 GoF design patterns, deployment of design patterns may expand the size of software, number of classes, and CK metrics, while programs created with design patterns exhibited lower cyclomatic complexity [6].

V. CONCLUSION

In this research, the consequences of 10 of GoF design patterns on the quality of software are empirically investigated. The evaluated patterns are: Factory Method, Prototype, Singleton, Adapter, Composite, Decorator, Observer, State, Template Method, and Proxy. The study is performed by detecting the patterns' classes in 10 real software projects, then computing 10 software quality metrics for each detected class using a reverse engineering tool, and determining how the abnormal values of the computed metrics may affect software quality.

The results do show that, except for three patterns (Prototype, Composite, and Singleton), design patterns in general promote the quality attributes considered in this study, and to use them safely, developers are recommended to take into consideration the following:

When using Prototype or Composite in software design, developers should ensure that the number of executed methods resulting from an action taken by a class of any of these patterns is as low as possible. In other words, developers should pay attention to designing a cohesive Prototype or Composite class to limit the possible negative impact of these two patterns on software quality.

When designing a Singleton class, developers should pay attention to limiting the general access to the single object of it as much as possible. Consequently, limit the low cohesion of Singleton classes, which may impede achieving the required level of software quality.

The results obtained about the evaluated design patterns, whether they are positive or negative, are not surprising because they match the structure and the intent of them, expect the results obtained about Observer and Prototype; where, based on the structure and intent of these two patterns, Observer is expected to impede software quality and Prototype is expected to improve it, but the opposite is obtained.

In this work, the internal validity is about the extent to which the increase or decrease in software quality attributes is caused by design pattern classes, not by other factors, e.g., other classes of the projects or the experience of developers who designed the projects.

To minimize, as much as possible, this threat: 1) Only the classes that contain any of the considered patterns in their design are evaluated, eliminating the classes that do not. 2) The evaluation includes a large number of classes, i.e., 2198 have different sizes and selected from 10 Java software projects.

The findings of the current work are not claimed to be generalized unless the following circumstances are taken into account: 1) The results are obtained from software projects written only in the Java programming language. 2) The classes of design patterns were detected using Tsantalis and PINOT detection tools. 3) The software quality metrics for design patterns were obtained using the Understand™ tool. The obtained values are related to the precision of the used tools.

In the future, further investigation is required to evaluate all GoF design patterns; where only 10 of them are evaluated in this research due to the difficulty of detecting all patterns in the software projects because of the limitations of the existing design patterns detection tools, and due to patterns frequency; where some of patterns are widely used by developers more than others in software projects. Additionally, the evaluation of design patterns may be applied following other possible empirical approaches. Finally, Prototype, Singleton, Composite, and Observer have to be evaluated with more concentration in order to state a safe conclusion about their effect on software quality.

D-LexCan: A Dynamic Lexicon-Based Framework for Sentiment Analysis in Tarifit, a Low-Resource Multiscript Language

Amar AMAKSSOUM, Fadwa BOUHAFER, Anass EL HADDADI, Abdelkhalak BAHRI

Data Science and Competitive Intelligence Team (DSCI) ENSAH, Abdelmalek Essaadi University, Tetouan, Morocco

Abstract—Sentiment analysis for low-resource languages remains challenging due to limited annotated data, orthographic instability, informal writing practices, and the lack of dedicated linguistic resources, challenges that are particularly acute for Tarifit (Tamazight of the Rif), an under-resourced Amazigh language characterized by strong dialectal variation, pervasive multi-script usage, and highly noisy user-generated content on social media. This study introduces D-LexCan, a dynamic lexicon-based sentiment analysis framework that infers polarity directly from annotated corpus evidence without relying on predefined sentiment dictionaries or computationally intensive pretrained deep learning and transformer-based models. The framework combines deterministic multi-script normalization, unifying Arabic script, Tifinagh, and Arabizi into a single Tarifit Latin representation with automatic induction of sentiment-bearing unigrams and bigrams, while explicitly modeling negation and amplification phenomena through linguistically motivated operators and preserving emojis as meaningful discourse-level sentiment cues. The approach is evaluated on a manually annotated social media corpus collected from multiple online platforms, where it achieves an accuracy of 0.8800 and a Macro-F1 score of 0.8798. The results outperform a static lexicon baseline with an accuracy of 0.5275, a classical machine-learning model based on TF-IDF and SVM with an accuracy of 0.8525, and neural architectures including BiLSTM with an accuracy of 0.7950. Experiments with frozen multilingual transformer encoders show accuracy ranging from 0.6725 to 0.7650. Fine-tuned multilingual transformers such as mBERT achieve competitive performance, reaching an accuracy of 0.8175. Overall, the results demonstrate that adaptive and linguistically grounded dynamic lexicon induction constitutes an effective, interpretable, and computationally efficient alternative for sentiment analysis in low-resource, noisy, and multi-script African language contexts.

Keywords—Sentiment analysis; low-resource languages; dynamic lexicon-based; static lexicon baseline; deep learning; machine-learning; transformer-based models

I. INTRODUCTION

Sentiment analysis, or opinion mining, is a basic task in Natural Language Processing (NLP) that can be used in many ways, such as to keep track of public opinion [1], analyze social media [2], [3], and understand user feedback. In the last ten years, the field has changed from static lexicon-based and rule-driven methods [4], [5], to machine learning and deep neural architectures that are data-centric. This is mostly because large annotated corpora and pretrained transformer models that can capture contextual and semantic

representations are now available. Because of this, architectures like BERT, T5, RoBERTa, and their multilingual versions have set the bar for performance on many sentiment analysis benchmarks [6], [7]. But these improvements have mostly happened in languages with a lot of resources, which means that many African and minority languages are still at a big disadvantage when it comes to performance, accessibility, and robustness.

The current situation reveals itself most clearly through sentiment analysis of low-resource languages because these languages face significant challenges when developing models, as they lack proper annotation datasets and necessary linguistic tools and standardized writing systems [8], [9]. The current multilingual pretrained language models XLM-R and AfroXLM-R, AfriBERTa and AraBERT, DarijaBERT, and mDeBERTaV3 demonstrate that transfer learning methods reduce the need for large datasets during testing on the shared AfriSenti benchmark. Still, these methods rely a lot on pretrained infrastructures and labeled data, often need a lot of computing power, and usually don't offer much insight. The system fails to effectively represent common digital communication patterns, which include multi-script variation and code-switching, expressive elongation, dialect-specific vocabulary, and non-standard tokens such as emojis and creative spellings [10], [11], [12].

These problems are even worse in Tarifit, a very under-resourced Amazigh language spoken in northern Morocco. Tarifit content created by users shows a lot of spelling mistakes in different writing systems, such as Latin script, Arabic script, Arabizi numerals, and Tifinagh. The text presents multiple dialects that it uses to communicate through casual language throughout its entire content. Sentiment is often expressed through elongated forms, discourse markers, amplifiers, negation constructions, and emojis, which together make the vocabulary less rich and make traditional NLP pipelines less effective. Without specialized sentiment lexicons, strong preprocessing tools, or pretrained models for specific languages, current sentiment analysis methods have trouble working well on real-world Tarifit data.

To mitigate these constraints, this research presents D-LexCan, a dynamic lexicon-based sentiment analysis framework meticulously crafted to align with the linguistic and orthographic attributes of Tarifit. D-LexCan is different from traditional lexicon-based methods that use predefined sentiment inventories. Instead, it starts with an empty lexicon

and gradually adds sentiment polarity directly from user-generated content that has been annotated, using statistically sound evidence. The framework combines deterministic multi-script normalization into a single Tarifit Latin representation, automatic generation of sentiment-aware unigrams and bigrams to capture both lexical and multiword sentiment expressions, and operator-aware scoring systems that explicitly model negation and amplification effects, while keeping emojis as discourse-level sentiment cues.

We test D-LexCan on a set of 2,000 user-generated comments from YouTube, Facebook, Instagram, and TikTok that have been manually annotated. The comments are divided into two groups: 80% for training and 20% for testing. The framework is evaluated against a static lexicon baseline, a traditional machine-learning model (TF-IDF + SVM), a deep learning model (BiLSTM), and various transformer-based configurations, including frozen multilingual embeddings and end-to-end fine-tuned models derived from mBERT and XLM-RoBERTa. Experimental results show that D-LexCan strikes a good balance between predictive performance, interpretability, and computational efficiency. It beats all the baselines that were tested and does not have the high computational cost and lack of transparency that transformer-centric solutions do.

In general, this study shows that sentiment analysis can be done on low-resource, multi-script languages. Linguistically grounded lexicon-based modeling can help African languages a lot more than just using static lexical resources or computationally expensive pretrained transformers. The D-LexCan system provides a transferable methodological framework that helps them solve three main problems that affect under-resourced languages, which include dealing with multiple writing systems, changing digital communication patterns, and limited access to NLP resources. The system operates beyond Tarifit language boundaries.

II. RELATED WORK

Research on sentiment analysis has evolved through different analytical approaches, which started with lexicon-based methods and then moved to machine learning, deep learning, and finally transformer-based models. The methods have achieved major progress for high-resource languages, yet they fail to deliver effective results when working with low-resource and African languages because these languages lack sufficient data and present diverse writing systems and multiple languages. The following section establishes the research context through a review of previous studies that studied sentiment analysis under restricted data availability conditions.

The Dynamic lexicon-based sentiment analysis method functions as an alternative to standard fixed sentiment dictionaries, which track language polarity shifts between different contexts in newly collected text data. The research field requires Mechulam et al. [13] created a dynamic lexicon system which uses graph-based structures and valence propagation methods to detect sentiment polarity through text usage analysis. The method achieves successful results for domain adaptation and context-sensitive polarity modeling, but it needs extensive annotated data and complicated propagation

rules, and it depends on spelling consistency. The system operates at its best when it encounters linguistic environments that contain plenty of resources and use standardized language patterns. Saileela and Malleswara Rao [14] created a dynamic lexicon-based sentiment analysis system, which applied nonlinear optimization and genetic algorithms to enhance n-gram and sentiment phrase feature selection. Their framework improves sentiment prediction accuracy through the combination of evolutionary optimization with phrase concurrence analysis and machine-learning classifiers. The system depends on pre-established sentiment dictionaries, yet it needs extensive data preparation and substantial processing resources to analyze structured monolingual information, which does not include unstructured multilingual user content.

Aliyu et al. [8] conducted a systematic literature review which applied SLR/PRISMA protocol to study sentiment analysis in low-resource environments and delivered an extensive assessment of this topic. The review narrows down 225 candidate studies to 56 publications from 2018 to 2023 and looks at them in terms of research questions, methods, data sources, preprocessing methods, feature extraction methods, and evaluation metrics. The three primary paradigms in this field consist of machine translation, word embeddings, and transfer learning with pretrained transformer models. The research depends on Twitter and Facebook data for its analysis, while accuracy and F1-score serve as the primary evaluation metrics. The team organized standard preprocessing operations together with feature encoding methods and current challenges, which include insufficient language processing capabilities and code-switching, sparse data distribution, and unequal resource availability. The review is mostly descriptive, doesn't put together a real end-to-end system, and mostly talks about general deep-learning models instead of lexicon-centric or dynamic lexicon architectures made for a single language that is very under-resourced and has a lot of spelling and dialectal differences.

Research has concentrated on applying Transformer-based models for analyzing sentiment across multiple languages, which include African languages. The research by Raychawdhary et al. [10] evaluated large-scale pretrained architectures like XLM-R, AfroXLM-R, AfriBERTa, and mDeBERTaV3 using AfriSenti SemEval datasets that include Hausa, Yoruba, Darija, and Swahili. The proposed framework consists of five components, which include data selection and normalization, SentencePiece tokenization, and multilingual fine-tuning and zero-shot transfer learning to classify tweets into positive, negative, and neutral sentiment categories. The results show that transformer-based transfer learning works well for very low-resource languages, especially with AfroXLM-R. However, the method mostly uses pretrained multilingual representations and doesn't explicitly model linguistic phenomena that are relevant to sentiment, like negation, emojis, dialectal noise, or multiscript variation. It also still relies on manually labeled corpora instead of dynamically induced lexical knowledge. Koto et al. [15] presented a related zero-shot strategy by pretraining multilingual language models on an extensive NRC-VAD lexicon filtered across over one hundred languages. The method shows improvements over standard fine-tuning and

English-only transfer by learning valence-based sentiment labels from lexicon entries and using the models directly on sentence-level tasks in 34 languages, including some African languages. However, it still relies on large, manually created high-resource lexicons, uses mostly English-based extension strategies, and works with static lexical resources instead of sentiment lexicons that change over time based on real user-generated content.

Researchers have also looked into supervised transformer-based sentiment analysis for single low-resource languages. For Central Kurdish, Awlla et al. [16] looked at a BERT-based framework that was trained on a normalized corpus with a dedicated tokenizer. They also tested different architectures, such as BiLSTM, MLP, and end-to-end BERT fine-tuning. Their findings indicate that contextualized embeddings significantly surpass conventional Word2Vec representations, with a fine-tuned BERT attaining an accuracy of 75.37% in three-class classification and 86.31% in the binary context. Even with these improvements, the framework is still completely supervised and model-centric. It uses pretrained contextual embeddings and annotated data, and it doesn't explicitly model sentiment-specific linguistic phenomena like negation, amplification, emoji semantics, or multiscript variation that are common in informal user-generated content.

Several studies have examined cross-lingual deep-learning frameworks for Uyghur sentiment analysis. One study integrates LaBSE sentence embeddings with a BiLSTM layer and utilizes AEDA-based data augmentation to address the issue of annotation scarcity. The system does better than a number of multilingual baselines on binary and multi-class datasets, but it is still fully supervised and relies on external pretrained models and augmented labeled data. It does not explicitly model or handle negation, intensification, emojis, or orthographic variation factors that make it harder to understand and adapt in noisy user-generated contexts [17].

There have also been suggestions for deep-learning-based sentiment analysis pipelines that use word embeddings and neural classifiers for other languages with few resources. Ali et al. [18] investigated a framework for Urdu that involves the creation of large-scale datasets, comprehensive preprocessing, and feature learning utilizing Word2Vec, succeeded by CNN and RNN classifiers for multi-class sentiment prediction. The results show that deep neural models can work when there is enough well-organized data, but the method only works with one writing system and doesn't include lexicon induction, polarity propagation, or ways to deal with informal, changing, or multi-script user-generated language. Iqbal et al. [19] employed a similar supervised approach for Pashto social media sentiment analysis, integrating traditional text features with dense word embeddings and assessing a diverse array of conventional, ensemble, and deep-learning classifiers on a limited manually annotated Facebook corpus. Even though it works well in practice, the framework is still only for one language and one script. It doesn't have a sentiment lexicon or a way to grow the lexicon dynamically, and it doesn't explicitly model negation, amplification, or large-scale orthographic variability.

Lexicon-enhanced but static sentiment analysis methods have also been studied. Meetei et al. [20] created a multi-stage sentiment analysis framework for Manipuri that combines multi-script normalization, handcrafted negative-morpheme lexicons, traditional classifiers, and further experiments with CNN, LSTM, and BiLSTM models. The study emphasizes the significance of script normalization and language-specific sentiment markers; however, it concentrates on formal news text, depends extensively on manual engineering, and lacks support for dynamic sentiment adaptation as new expressions arise.

Lexicon-informed feature engineering has been used to look into semi-supervised sentiment classification. Liu et al. [21] proposed a framework that enhances conventional document-level classifiers by integrating features from a general-purpose sentiment lexicon, amalgamating TF-IDF vectors, sentiment vectors, and statistical aggregates. Lexicon-based features enhance classification performance; however, this methodology depends on a static sentiment resource, presumes the existence of high-quality linguistic tools, and fails to derive or adjust lexical polarities from noisy, code-mixed, or multi-script data. Dhananjaya et al. [22] looked into a lexicon-based intermediate-task fine-tuning method for multilingual pretrained language models that uses auxiliary phrase construction to add cross-lingual sentiment alignment signals. This is a step toward hybrid transformer-centric strategies. Even though the method consistently outperforms standard fine-tuning, it is still closely tied to transformer infrastructures and high-resource sentiment lexicons. It doesn't take advantage of dynamically evolving lexical knowledge from the target low-resource language itself.

Mohammed and Prasad [23] examined a particularly pertinent contribution to lexicon-based sentiment analysis for low-resource languages, presenting a thorough methodology for developing a sentiment model for Hausa. Their framework integrates lexicon compilation, regulated linguistic enhancement, expert annotation, and subsequent BERT fine-tuning, resulting in elevated accuracy on annotated Hausa tweets. The approach, however, depends on a static pre-built lexicon and doesn't deal with multiscript heterogeneity, spontaneous orthographic variation, or the dynamic emergence of new expressions. This means that more research is needed into adaptive lexicon-based frameworks for low-resource languages.

III. METHODOLOGY

This research presents D-LexCan, a modular sentiment-analysis framework developed for Tarifit (Tamazight of the Rif), a low-resource language marked by scarce linguistic resources, significant dialectal diversity, and varied writing conventions. D-Lexicon is the most important part of the framework. It is a dynamic sentiment-induction component that learns polarity directly from annotated data instead of using pre-made sentiment dictionaries. D-Lexicon is different from traditional lexicon-based methods because it starts empty and then fills in and updates its entries based on how people actually use words in labeled comments. An overview of the complete D-LexCan sentiment analysis pipeline is illustrated in Fig. 1. As Tarifit text is processed, each token, spelling

variant, emoji, or multiword expression is statistically evaluated across positive and negative contexts, and polarity is assigned only when usage exhibits stable and meaningful asymmetry. The lexicon automatically changes polarity assignments when new forms, dialectal variants, or new online expressions come out. This is because evidence changes. This adaptive behavior is especially important in Tarifit, where people can use Latin script, Arabic script, Arabizi, and

Tifinagh (ⵜⴰⴳⴷⵓⴷⴰⵢⵜ) all at the same time in the same online spaces. D-LexCan offers a clear and data-driven framework for sentiment analysis in situations where standardized linguistic resources are mostly missing. It does this by combining preprocessing, multiscript normalization, dynamic lexicon growth, scoring, hyperparameter tuning through grid search, and evaluation into one pipeline.

Fig. 1. Overview of the D-LexCan sentiment analysis pipeline.

A. Data Preparation

The data preparation process transforms unprocessed user-generated content into an analysis-ready format through multiple operations, which start with data acquisition and human labeling, followed by orthographic noise reduction and writing system unification and word and emoji extraction through tokenization. The operations maintain consistent representation while keeping essential linguistic elements that affect sentiment, so the system can reliably create new words and analyze emotions.

1) *Data collection and annotation from multi-platform, multi-script, and multi-dialect sources:* The dataset consists of 2,000 user comments, including 1,000 positive and 1,000 negative statements. The comments were taken from popular online sites where Tarifit speakers are active, such as YouTube, Facebook, Instagram, and TikTok, and they covered a wide range of cultural, social, and entertainment topics. The corpus shows actual human communication patterns that people use when they talk to each other instead of using fabricated dialogue examples. The dataset is very multi-script, which is one of its most important features. For example, Tarifit users often use Arabizi, Arabic script, Latin-based Tarifit, and Tifinagh all in the same discussion thread or even in the same comment. The corpus also shows a lot of

dialectal variation from different parts of the Rif, such as Al Hoceima, Nador, Driouch, Aknoul, Ayt Waryaghar, Ayt Touzin, Bni Bouayach, Tamsamane, and the areas around them. This dataset is very representative of how Tarifit is actually used because it has many platforms, scripts, and dialects. However, it is also much harder to process. Native speakers of Tarifit manually annotated all of the comments, giving each one a binary sentiment label (Positive or Negative) based on its overall communicative intent and pragmatic interpretation. The research needed this method to identify intricate emotional expressions that standard language systems fail to show. As far as we know, the resulting corpus is one of the first balanced and carefully curated sentiment datasets for Tarifit.

2) *Data preprocessing:* The dataset goes through a normal preprocessing phase after it has been gathered and marked up. This phase tries to fix spelling mistakes and make sure that all sorts of user-generated material look the same. To keep words like "Zin," "ZIN," and "zin" from being repeated on the surface, all comments are first transformed to lowercase. The next step is to use a regulated procedure to get rid of dirt and other pollutants on the surface. In this process, only alphanumeric characters, whitespace, and emojis that show positive or negative feelings are kept. All other symbols,

punctuation marks, and random Unicode artifacts are replaced with spaces. To further reduce spelling differences and expressive elongation that are common in social media conversations, sequences of repeated characters are normalized by combining any three or more identical characters into exactly two (e.g., atasss $\rightarrow$ atass, hhhhh $\rightarrow$ hh). Whitespace normalization finally gets rid of extra spaces and makes sure that token boundaries are clear. All of these preprocessing steps work together to reduce orthographic variability, vocabulary fragmentation, and create a stable text representation that can be used for multiscript normalization, tokenization, and sentiment modeling.

3) *Multiscript normalization*: To deal with the very different ways that people write Tarifit, the framework uses a full multiscript normalization process that turns all surface forms into a single Tarifit Latin (TL) representation. This step is necessary to combine script-induced variants into a single canonical space and stop artificial vocabulary inflation because comments are written in Tifinagh, Arabic script, Arabizi, and inconsistent Latin transcriptions.

Normalization is done in a set order so that transformations are always the same and can be repeated:

- Tifinagh → TL Tifinagh characters are transliterated into their TL phonemic equivalents using a deterministic mapping (e.g., ⵍ → x, ⵏ → ε, ⵓ → u, ⵣ → z).
- Arabicscript → TL Arabic characters are converted through consistent one-to-one mappings reflecting their phonological role in Tarifit (e.g., ش → c, خ → x, غ → y, ق → q, ط → t).
- Arabizi → TL Digit–letter substitutions (e.g., 3 → ε, 7 → h, 9 → q) and informal digraphs (e.g., ch/sh → c, gh → y, kh → x) are normalized to standardized TL forms.

Representative examples of multiscript normalization into Tarifit Latin are shown in TABLE I.

TABLE I. ILLUSTRATIVE EXAMPLES OF MULTI-SCRIPT NORMALIZATION INTO TARIFIT LATIN

Original Text	Normalized Tarifit Latin
ⵍⵏⵉⵎⵓⵏ ⵉⵎⵓⵏ ⵓⵏⵓⵏ	wallah ila yaç rhaq
نش بعدا تعجباي	nc beḍa teḡby
Bazz ichek awma	bazz icek awma

This stage directly helps downstream dynamic lexicon induction by enforcing a single TL representation. This is because dynamic lexicon induction depends on consistent token identities instead of script-dependent surface variants.

4) *Tokenization*: After character-level preprocessing and multiscrypt normalization, each comment is segmented into

minimal linguistic units using a regular-expression-based tokenizer specifically adapted to the requirements of the D-LexCan framework. The tokenizer operates on normalized Tarifit Latin (TL) text and extracts 1) word tokens as contiguous sequences of word characters (pattern `\w+`) and 2) standalone emojis treated as independent tokens during tokenization. Because tokenization is applied after both character cleaning and script harmonization, reusing the same normalization procedure, all non-emoji tokens strictly follow the unified TL representation and no longer contain residual symbols, script artifacts, or non-standard encodings. Emojis are preserved as standalone tokens rather than removed or treated as auxiliary information. The system stores the resulting token sequences in a `Tokens_norm` field, which exists for each comment to create a standardized format that can be used again. The D-Lexicon system defines tokens as an extensive category that encompasses standardized words and dialectical expressions and single emoji symbols that undergo the same automated processing as text elements.

5) *Train-test partitioning*: The evaluation process requires a rigorous and unbiased assessment, which uses the preprocessed and annotated corpus to create training and testing subsets through an 80/20 stratified split with SEED = 42 for reproducibility purposes while maintaining the 50/50 positive to negative label ratio in both subsets. The training data serves only to create the dynamic lexicon and sentiment-bearing bigram patterns and to calculate token and bigram frequency statistics, polarity confidence ratios, and model hyperparameter optimization, including `min_freq`, `min_conf`, and `λ_bg` through multiple testing of different options. The test subset stays hidden from view throughout both induction and calibration stages because it serves only for the final assessment of D-Lexicon and all comparison models, which prevents overfitting and memorization.

B. D-Lexicon: Dynamic Sentiment Induction Core

D-Lexicon constitutes the central adaptive component of the proposed D-LexCan framework. The system functions as an entire data-driven, dynamic sentiment lexicon that learns sentiment polarity from user-generated content annotations instead of using pre-defined sentiment dictionaries or external lexical resources. Unlike static lexicons, D-Lexicon is initialized as an empty structure and incrementally constructs its sentiment knowledge by observing how lexical units, words, emojis, and multiword patterns are used across positive and negative contexts in the training data. The overall construction process of the dynamic D-Lexicon component is illustrated in Fig. 2. The design of D-Lexicon allows it to adapt continuously to the different orthographic forms and dialects and new words that appear in informal Tarifit speech while showing all sentiment evaluation processes.

Fig. 2. Construction process of the D-Lexicon dynamic sentiment lexicon.

1) *Hyperparameter configuration and optimization*: The system D-Lexicon operates through a limited number of hyperparameters, which determine how to balance between word coverage and system stability and context-based performance during its dynamic lexicon creation process. The minimum frequency threshold (min_freq) in the system establishes the number of occurrences that tokens and sentiment-bearing bigrams need to meet for analysis, while it removes unimportant forms that occur rarely in informal Tarifit speech. The polarity confidence threshold (min_conf) establishes the minimum confidence level that enables tokens to obtain fixed sentiment orientation for entering the lexicon. The bigram scaling factor (λ_bg) serves as an additional control that determines how much bigrams with sentiment value should influence the model in relation to unigrams, so they can enhance word-level sentiment indicators without taking over their importance. The optimal hyperparameter configuration is identified through grid search on the training set and fixed before evaluation on the held-out test set.

2) *Dynamic polarity induction, automatic lexicon construction, and lexicon rebuilding*: For each candidate hyperparameter configuration (min_freq , min_conf) explored during grid search, D-Lexicon induces sentiment knowledge directly from the annotated training corpus, without relying on any predefined sentiment dictionary. The training data contains all observed tokens t , which include standard words and dialectal variants, non-standard spellings, and emojis for potential sentiment analysis.

a) *Token frequency estimation*: Each token t is associated with two class-conditional occurrence-level frequency counters, initialized as:

$$f_{pos}(t) = 0, f_{neg}(t) = 0 \quad (1)$$

where, $f_{pos}(t)$ denotes the total number of occurrences of token in positive-labeled comments, while $f_{neg}(t)$ the total number of occurrences of (t) appears in negative-labeled

comments. As the labeled training data are processed, counters are incremented for each occurrence of token t according to the sentiment label of the comment in which it appears. The system design of repeated token occurrences in single comments maintains their multiple counts because it keeps essential information about user-generated content intensity and repetition, which appears in informal user-generated content.

The total frequency of token t across the corpus is then computed as:

$$f_{tot}(t) = f_{pos}(t) + f_{neg}(t) \quad (2)$$

Where $f_{tot}(t)$ reflects the overall usage strength of token t in the training data.

To ensure robustness and reduce noise, two statistical constraints are enforced.

b) *Minimum frequency constraint*

$$f_{tot}(t) \geq min_freq \quad (3)$$

This constraint removes spurious or accidental tokens whose total number of occurrences is too small to support reliable sentiment induction.

c) *Polarity confidence constraint*

$$Conf(t) = \max\left(\frac{f_{pos}(t)}{f_{tot}(t)}, \frac{f_{neg}(t)}{f_{tot}(t)}\right), Conf(t) \geq min_conf \quad (4)$$

This confidence value measures the degree of sentiment dominance exhibited by token t , quantifying how strongly its occurrences are biased toward one sentiment class. Tokens with low confidence correspond to sentiment-ambiguous forms, whereas high-confidence tokens exhibit stable sentiment orientation.

Only tokens satisfying both constraints are retained in the dynamic lexicon.

d) *Polarity assignment*: For each retained token, sentiment polarity is assigned according to the dominant class:

$$Polarity = \begin{cases} +1, & \text{if } f_{pos}(t) > f_{neg}(t) \\ -1 & \text{otherwise} \end{cases} \quad (5)$$

e) *Frequency-aware weighting and token scoring*: A confidence-weighted magnitude is computed for each retained token:

$$Weight(t) = Conf(t) \times \ln(1 + f_{tot}(t)) \quad (6)$$

The final sentiment score stored in the lexicon is defined as:

$$Score(t) = Polarity(t) \times Weight(t) \quad (7)$$

This continuous score jointly encodes sentiment direction, statistical reliability, and occurrence-based usage strength in a single scalar value.

3) *Multiword pattern learning: bigram-level sentiment induction*: In addition to single-word entries, and under the same candidate hyperparameter configuration (`min_freq`, `min_conf`, `λ_bg`), D-Lexicon also induces sentiment information from contiguous word pairs (bigrams) whose polarity emerges only through co-occurrence. In informal and low-resource languages such as Tarifit, sentiment is frequently conveyed via such local multiword patterns, for instance, when an otherwise neutral word acquires polarity in a specific context or when sentiment intensity is reinforced through short lexical sequences.

During training, bigrams are extracted sequentially from each normalized comment. Occurrence-based counting is applied for bigrams, meaning that repeated occurrences of the same bigram within a single comment are counted multiple times. This choice preserves emphasis effects and repeated sentiment expressions typical of user-generated discourse.

For each bigram $bg = (ti, ti + 1)$, two class-conditional occurrence-level frequency counters are maintained: $f_{pos}(bg)$ which denotes the total number of occurrences of the bigram in positive-labeled comments, and $f_{neg}(bg)$ which represents the total number of occurrences in negative-labeled comments. The total frequency of the bigram is then defined as:

$$f_{tot}(bg) = f_{pos}(bg) + f_{neg}(bg) \quad (8)$$

Minimum frequency filtering, polarity confidence estimation, and polarity assignment follow the same definitions as for unigrams.

Unlike unigrams, the contribution of multiword patterns is explicitly controlled through a bigram scaling factor λ_{bg} , reflecting their higher semantic specificity and more contextual nature.

For each retained bigram, the confidence-weighted magnitude is computed as:

$$Weight(bg) = \lambda_{bg} \times Conf(bg) \times \ln(1 + f_{tot}(bg)) \quad (9)$$

The final sentiment score assigned to a bigram is then defined as:

$$Score(bg) = Polarity(bg) \times Weight(bg) \quad (10)$$

This formulation allows bigrams to complement word-level sentiment cues without overwhelming them, while still capturing local compositional sentiment phenomena that cannot be inferred from individual tokens alone.

In the implementation, this mechanism corresponds directly to the `bigram_stats` structure and the `dynamic_patterns` dictionary produced by the `build_dynamic_lexicon` function. The bigram induction process runs independently for each candidate hyperparameter configuration during grid search to maintain strict consistency, reproducibility, and statistical control.

When additional labeled training data becomes available, sentiment statistics are recomputed, and the dynamic lexicon is rebuilt accordingly.

C. Modeling Linguistic Operators

1) *Amplifiers*: Some expressions do not carry intrinsic sentiment polarity but instead modulate the intensity of nearby sentiment-bearing words. In Tarifit online discourse, this category includes strong amplifiers such as *atass*, as well as weaker forms such as *dross* and *cwit*. Within D-Lexicon, amplifiers are modeled through a local multiplicative mechanism applied during comment-level scoring: when an amplifier is detected immediately after a sentiment-bearing token, the score of that token is scaled accordingly. Let $Score(t)$ denote the base sentiment score of the token t ; the adjusted score is computed as:

$$Score_{amp}(t) = \begin{cases} \alpha_{strong} \times Score(t), & \text{if a strong amplifier follows } t \\ \alpha_{weak} \times Score(t), & \text{if a weak amplifier follows } t \\ Score(t) \end{cases} \quad (11)$$

where $\alpha_{strong} > 1$ and $0 < \alpha_{weak} < 1$ are fixed scaling factors. In the implementation. This design reinforces or attenuates sentiment strength without introducing independent sentiment contributions.

2) *Negation*: Negation plays a distinct and non-additive role in sentiment composition, typically reversing polarity rather than merely weakening it. D-Lexicon models negation through explicitly observed lexical forms such as *wayeji*, *wajeji*, as well as through the productive pattern *wa + token + ca*, which consistently emerges after normalization.

Two local inversion mechanisms are implemented:

- *Lexical negation inversion*: When a negation marker is encountered, the polarity of the immediately following sentiment-bearing token is inverted:

$$Score_{neg}(t) = -Score(t) \quad (12)$$

- *Pattern-based negation inversion* (*wa ... ca*). For sequences of the form *wa + m + ca*, where m is a sentiment-bearing token, the polarity of m is flipped:

$$Score_{neg}(m) = -Score(m) \quad (13)$$

This operation is implemented by subtracting the dynamic lexicon score of the middle token whenever the pattern is detected.

Together, these mechanisms model negation as a local polarity inversion process, avoiding global penalties or handcrafted grammatical rules while remaining consistent with the data-driven scoring framework.

D. Final Scoring and Threshold-Based Classification

Once all lexical contributions and linguistic operators have been applied, D-Lexicon aggregates them into a single continuous sentiment score for each comment. Let $S(C)$ denote the sentiment score of a comment C , computed as the sum of token scores (words and emojis) and learned bigram-pattern scores after local operator application:

$$S(C) = \sum_{t \in C} \text{Score}(t) + \sum_{bg \in C} \text{Score}(bg) \quad (14)$$

During aggregation, amplifiers and negation are applied locally at scoring time. Amplifiers scale the scores of neighboring sentiment-bearing tokens multiplicatively, while negation inverts the polarity of the affected token or pattern. These operators do not introduce independent additive terms but directly modulate existing lexical contributions. Because all scores derive from dynamically induced weights and data-driven operator rules, $S(C)$ reflects not only sentiment polarity but also intensity and contextual modulation at the comment level.

In the present study, sentiment classification is formulated as a binary task (positive vs. negative), without an explicit neutral category. Accordingly, a fixed zero-threshold decision rule is adopted:

$$S(C) > 0 \Rightarrow \text{Positive}, S(C) \leq 0 \Rightarrow \text{Negative} \quad (15)$$

The case $S(C) = 0$ denotes the absence or exact cancellation of detectable polarity cues within a comment and is empirically observed to occur rarely in the evaluated dataset. As a strictly binary setting is assumed, all instances must be assigned to one of the two classes to ensure a complete decision function. Therefore, comments with $S(C) = 0$ are assigned to the negative class by convention, without implying the presence of explicit negative sentiment. The design choice prevents the automatic addition of a neutral class, which reduces the tendency to make optimistic predictions about positive results while keeping the system interpretable through its use of a single continuous sentiment score, which emerges from the dynamically created lexicon for each comment.

With the availability of larger annotated datasets, future work will explore the explicit incorporation of a neutral class corresponding to $S(C) = 0$ within a multi-class classification framework.

E. Evaluation Protocol and Assessment Metrics for D-LexCan

D-LexCan framework was tested through its performance assessment on data that they reserved for testing purposes after splitting their training data into 80% for training and 20% for testing, while maintaining equal numbers of positive and

negative sentiment examples. The model learned all linguistic cues from the training data through its dynamic process of discovering new words, determining word polarity, bigram values, and scoring methods. The trained model generated continuous sentiment scores, which it applied to all test set comments that it had not seen before. The raw score data received binary sentiment labels through a specific zero-based decision threshold, which operated as a data-driven classification system without requiring human-defined decision rules. The evaluation protocol follows standard procedures for sentiment analysis of low-resource languages through lexicon-based methods, while they focus on achieving both interpretability and reproducibility. The research maintained methodological rigor through its application of proven evaluation metrics, which consisted of Accuracy and Precision, Recall and F1-score, and Macro-F1 and confusion matrix analysis. The assessment strategy, which uses multiple performance indicators, follows the recommendations from current low-resource sentiment analysis research, which supports the need to evaluate performance through multiple indicators for achieving both system robustness and fairness [24], [25].

1) Accuracy

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (16)$$

Where TP, TN, FP, and FN denote true positives, true negatives, false positives, and false negatives, respectively. Although accuracy may be misleading under class imbalance, it remains informative in this study due to the perfectly balanced dataset.

2) Precision

$$\text{Precision} = \frac{TP}{TP+FP} \quad (17)$$

Precision measures the reliability of positive predictions. High precision indicates a low rate of false positives, which is particularly important in low-resource settings characterized by noisy, dialectal, and orthographically inconsistent user-generated content.

3) Recall

$$\text{Recall} = \frac{TP}{TP+FN} \quad (18)$$

Recall quantifies the model's ability to correctly identify sentiment-bearing instances. It is especially relevant when capturing subtle or weak sentiment expressions is more critical than minimizing misclassification, as often observed in informal or code-mixed discourse.

4) F1-Score

$$F1 = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (19)$$

The F1-score provides a balanced measure by jointly accounting for false positives and false negatives, offering a robust indicator of overall classification quality in noisy sentiment analysis scenarios.

5) Macro-F1 Score

$$\text{Macro-F1} = \frac{1}{N} \sum_{i=1}^N \frac{2 \times \text{Precision}_i \times \text{Recall}_i}{\text{Precision}_i + \text{Recall}_i} \quad (20)$$

This metric assigns equal importance to each class and is widely recommended in low-resource sentiment analysis to mitigate class-specific bias. Even for balanced datasets, its reporting ensures consistency and comparability with prior benchmarks.

6) *Confusion matrix*: The confusion matrix provides a detailed view of misclassification patterns, revealing tendencies such as over-prediction of negative sentiment or failure to detect weaker polarity cues. This level of interpretability is particularly valuable in lexicon-based and low-resource frameworks, where understanding error behavior is as important as overall accuracy.

IV. RESULTS AND DISCUSSIONS

A. Dynamic D-Lexicon Within D-LexCan

D-LexCan adds a dynamic lexicon induction component (D-Lexicon) to the static baseline to get around its inflexibility and low coverage. The system learns to identify sentiment patterns through this component, which starts with basic sentiment understanding and then advances to polarity detection from the annotated training data. We adjusted the hyperparameters to get the best performance while keeping rare linguistic expressions that are typical of minority languages. This is the best configuration:

$$\mu_{\nu_phi\epsilon\theta} = 1, \mu_{\nu_chi\phi} = 0.65, \beta_{\gamma} = 1.20$$

The system generated an induced lexicon that contained 9,325 entries that detected sentiment and included 3,974 unigrams and 5,351 bigrams. The vocabulary that was learned shows how people really use it in Tarifit user-generated content, such as code-switching, emphasis on repetition, hybrid loanwords, and emoji semantics.

The model achieves excellent results in both model accuracy and data prediction ability. The model gets almost perfect accuracy on the training set (0.9906) and stays very good at generalizing to new data, getting 0.8800 accuracy and 0.8798 Macro-F1 on the test set. The predictive behavior maintains equal distribution between all sentiment categories according to the class-wise analysis. The model produces 0.8486 precision for negative class predictions, while it shows excellent recall performance at 0.9250 and achieves an F1-score of 0.8852 across 200 instances. The system shows high sensitivity to negative polarity indicators, which it uses for its operations. The positive class maintains its performance at a high level because it achieves precision at 0.9176, recall at 0.8350, and F1-score at 0.8743 across 200 examples. The results demonstrated that positive sentiment received correct predictions at suitable levels, which stayed below the predicted thresholds. The results show that the proposed method maintains consistent performance, which remains balanced between all sentiment categories while achieving good generalization capabilities.

B. Comparison with Other Models

1) *Static lexicon baseline*: The static lexicon baseline is the simplest modeling strategy and is used as a lower-bound reference. It only uses direct dictionary lookups [26] to assign polarity based on a manually curated lexicon of 200 entries (100 positive and 100 negative). The system fails to detect language patterns in specific contexts because it does not understand how words relate to each other when used in different situations. The model doesn't work well, though, with an accuracy of only 0.5275 and a Macro-F1 of 0.3917. This shows a strong class bias and a failure to capture balanced sentiment behavior. The confusion matrix also shows that almost all instances, including many negative comments, are misclassified as positive. In general, this baseline doesn't show any sensitivity to important sentiment phenomena that are common in Tarifit discourse, like negation, spelling variation, mixed-script writing (Arabic, Latin, and Tifinagh), expressive elongation, or emoji-based sentiment cues.

2) *TF-IDF + SVM baseline*: TF-IDF and a Support Vector Machine together make a strong and widely used traditional machine-learning baseline for classifying text [27]. This model uses statistical term weighting to find discriminative lexical patterns directly from data, which is different from lexicon-based approaches that need pre-defined linguistic rules or sentiment inventories. In our tests, TF-IDF + SVM got 0.8525 accuracy and 0.8512 Macro-F1, showing that it can handle sparse and high-dimensional text representations that are common in social media data. The corresponding confusion matrices for D-LexCan, the static lexicon baseline, and TF-IDF + SVM on the test set are presented in Fig. 3.

Fig. 3. Confusion matrices on the test set for D-LexCan, static lexicon, and TF-IDF + SVM.

These results show that the model can accurately separate sentiment classes just by looking at the distributional cues. Despite its strong ability to make predictions, this method has two major problems: first, its decision-making process is mostly unclear, making it harder to understand than lexicon-based methods; second, it doesn't have a built-in way to quickly add new sentiment expressions or vocabulary, which makes it hard to keep up with quickly changing informal language without retraining on new data.

3) *Frozen transformer embeddings*: Multilingual transformer models that have been trained on large, diverse datasets are often used as general-purpose text encoders for cross-lingual tasks. This is because they give contextual representations without needing to be fine-tuned for each task [28]. The models were first tested as fixed encoders, which worked with conventional classification systems for Tarifit sentiment analysis. The results show only moderate performance, with test accuracy between 0.6725 and 0.7650. The research findings would not provide useful results because the language shows limited orthographic diversity, extensive morphological complexity, and unique sentiment expression patterns. The XLM-RoBERTa + SVM configuration has the best accuracy (0.7650, Macro-F1 = 0.7649), followed closely by mBERT + Logistic Regression (0.7625, Macro-F1 = 0.7620) and mBERT + SVM (0.7525, Macro-F1 = 0.7518). mBERT + KNN (0.7150, Macro-F1 = 0.7136) does worse than mBERT + Naive Bayes (0.6725 accuracy, Macro-F1 = 0.6683). In general, these results show that frozen multilingual transformers can capture a lot of semantic information, but they are not good enough for fine-grained sentiment modeling in Tarifit. The results indicate that these models require modifications to reach successful performance in particular tasks, which require specific language applications.

4) *Fine-tuned transformer models*: Fine-tuning multilingual transformer models lets their internal representations be changed directly to match sentiment-related patterns in the target language. The model becomes more effective at detecting task-related language patterns and contextual information, and polarity signals through this approach. This method makes the model more sensitive to sentiment expressions that aren't well represented in generic pretrained embeddings by changing the model parameters on labeled data [29]. In our tests, fine-tuned mBERT gets 0.8175 accuracy and 0.8170 Macro-F1, which shows that it can model sentiment in Tarifit very well after being adapted to the task. Fine-tuned XLM-RoBERTa gets 0.7650 accuracy and 0.7646 Macro-F1, which shows that fine-tuning doesn't help it much. The comparative test accuracy distribution of frozen and fine-tuned transformer models is summarized in Fig. 4. The research demonstrates that fine-tuning enhances sentiment modeling through better target task adaptation of pre-trained models, although it requires additional computational resources and creates training complexities.

Fig. 4. Test accuracy distribution of transformer models (frozen vs. fine-tuned).

5) *BiLSTM (End-to-End)*: The BiLSTM network functions as a popular neural sequence model for sentiment analysis because it analyzes text sequences from both start to end and end to start, which reveals the sequence of words and their contextual relationships [30]. The training process of BiLSTMs allows them to create task-oriented representations directly from labeled data without requiring any pre-trained linguistic resources. When used on normalized Tarifit text, the BiLSTM model gets 0.7950 accuracy and 0.7903 Macro-F1, which shows that it can reasonably pick up on sequential sentiment cues. These results show how good recurrent architectures are at modeling contextual information and how hard it is for purely data-driven neural models to work in low-resource settings where there isn't much training data and there is a lot of linguistic variation.

6) *Overall comparison of models*: The evaluation of performance and robustness needed different sentiment classification methods, which included symbolic lexicon-based approaches, machine-learning models, neural architectures, and transformer-based frameworks. All models received identical experimental conditions during training and testing, which allowed for an equal comparison between them. The performance results from the comparison appear in Fig. 5, which shows how different modeling approaches performed relative to each other.

C. Discussion

The experimental results show that dynamic lexicon induction presents a successful approach for sentiment analysis, which uses linguistic principles to analyze three types of languages, including Tarifit, which has limited resources and uses informal language and different writing systems. The static lexicon baseline achieved 0.5275 accuracy and 0.3917 Macro-F1, but the proposed dynamic D-Lexicon within D-LexCan outperformed it by achieving 0.8800 accuracy and 0.8798 Macro-F1. The results show that static sentiment inventories face essential limitations when used for processing user-generated content, which contains script mixing and

dialectal variation, expressive elongation, and emoji usage and lexical changes over time.

The research results show that lexical adaptability stands as a crucial element that affects results regardless of the model complexity level. The static lexicon has two main restrictions because it includes only 200 entries and does not have any system to add new words that carry sentiment or to adjust emotional strength through actual data or to identify words which require contextual understanding. The dynamic lexicon induction strategy used in D-LexCan, on the other hand, lets the model learn polarity information directly from annotated data. The model can learn to accept dialectal variations and non-standard writing and emoji meanings and typical multi-word phrases through this approach. The lexicon size (9,325 entries, including 3,974 unigrams and 5,351 bigrams) shows how many different ways people express their feelings on Tarifit social media.

The system, which combines TF-IDF with SVM, produces better results than conventional machine learning methods (0.8525 accuracy / 0.8512 Macro-F1). This confirms that it is a good baseline for low-resource sentiment analysis. But this method depends on high-dimensional feature representations, which makes it hard to understand and inspect, reuse, or add to the learned sentiment knowledge. D-LexCan, on the other hand, makes an explicit lexicon that lets you look at and change sentiment entries and their scores as more labeled data becomes available. The system enables users to access a simplified system that helps them study and assess language content.

Neural and transformer-based models demonstrate multiple advantages and disadvantages, which create an effective partnership between them. The frozen multilingual transformer models achieved average performance results through their accuracy range of 0.6725 to 0.7650. This suggests that generic pretrained representations may not fully match the orthographic variability and sentiment conventions of Tarifit. The system performance improves through fine-tuning because mBERT produces the highest results at 0.8175 accuracy and 0.8170 Macro-F1, which demonstrates its capability to execute multiple tasks successfully. The system has received improved features, but it requires more complex processing operations while its operation remains difficult to understand. The neural representations contain sentiment-related information about negation scope and amplification effects, and emoji polarity and multiscript variation, which makes their direct analysis more challenging.

The results from D-LexCan show important value because this system operates at a high level while using minimal resources and maintaining easy-to-understand operations. The model recognizes patterns in sentiment data instead of learning instances from memory because it achieves 0.9906 training accuracy, 0.8800 accuracy, and 0.8798 Macro-F1 performance on the test set. The results from class-wise evaluation support this analysis because the model shows excellent ability to detect negative sentiment with a recall of 0.9250, and it achieves high precision for positive sentiment at 0.9176, which results in equal performance for all sentiment categories Fig. 5.

Fig. 5. Overall performance comparison across sentiment classification models.

In general, these results support the idea that lexicon-based frameworks that are based on language and data can be a good addition to neural approaches for sentiment analysis in low-resource settings. The research focuses on Tarifit binary sentiment classification, but the established design principles for multiscript normalization, confidence-based polarity induction, and bigram-level pattern learning and operator-aware scoring could help solve similar challenges that other low-resource languages face. The future of research should focus on three main areas, which include multi-class sentiment analysis, cross-domain evaluation, and online lexicon update systems to determine how well dynamic lexicon-based methods work across different situations.

V. CONCLUSION

The research presented D-LexCan as a dynamic framework that provides interpretable results through linguistic analysis for Tarifit (Tamazight of the Rif) sentiment analysis of this severely underdocumented language, which uses multiple scripts and shows unstable writing systems and contains mostly casual user-generated content. The proposed framework solves two problems that static lexicons cannot identify and that generic pretrained architectures detect only through hidden mechanisms. The system achieves this through three main components, which include deterministic multiscript normalization into Tarifit Latin representation and corpus-driven induction of sentiment-bearing unigrams and bigrams, and explicit modeling of linguistic operators, including amplification and negation patterns and emoji cues. The experimental assessment demonstrates that D-LexCan attains strong and competitive performance in comparison to traditional machine-learning benchmarks, as well as neural and transformer-based models, while ensuring transparency and computational efficiency. This work highlights that the proposed framework has broader implications for low-resource NLP, as it shows that dynamic lexicon induction can be an effective and interpretable alternative when annotated data is

scarce. Although evaluated on Tarifit, the approach is generalizable to other low-resource, multi-dialectal, and multi-script languages with similar linguistic challenges. The proposed framework enables users to apply their learned lexical knowledge for sentiment analysis, which they can confirm and adjust for upcoming applications. The system operates through a different method than fine-tuned multilingual transformers because it needs task-specific parameter adaptation, and it needs more computing power. The research findings show that dynamic lexicon induction with explicit linguistic modeling produces the best solution for sentiment analysis, which performs better than neural methods when operating under limited resource conditions. The Tarifit case demonstrates how D-LexerCan script-agnostic normalization and confidence-based polarity induction, multiword sentiment modeling, and operator-aware scoring methods can help solve structural and sociolinguistic problems in under-resourced languages resulting in better sentiment analysis in multilingual environments.

Framework for Implementing ERP Integrating Client-Consultant Agency Management within Moroccan SMEs

Yassine ZOUHAIR, Younous EL MRINI, Mustapha BELAISSAOUI
SIAD Laboratory, Hassan First University, Settat, Morocco

Abstract—Nowadays, Enterprise Resource Planning (ERP) is a preferred solution for Small and Medium-sized Enterprises (SMEs) wishing to modernize and integrate their information Systems (IS). However, implementing an ERP remains a complex process due to the organizational constraints specific to SMEs and the difficulties associated with the implementation process. In the context of Moroccan SMEs, the lack of a structured implementation framework and conflicts between the client and the consultant are major factors affecting the success of ERP projects. Furthermore, most of the theoretical frameworks presented in the literature are structured around similar phases, do not take into account the client-consultant agency management, and were developed in contexts different from that of Morocco. This research aims to develop an ERP implementation framework that integrates client-consultant agency management, specifically adapted to Moroccan SMEs. To achieve this objective, a mixed-methods approach was adopted. We opted for a quantitative research method using the PLS-SEM statistical technique, with the aid of SmartPLS software, to examine how client-consultant agency management affects the success of ERP implementation within Moroccan SMEs. Next, we used the action research method to develop a framework for ERP implementation that integrates client-consultant agency management within Moroccan SMEs. The proposed framework is based on five phases, each defining the objectives, inputs, processes, outputs, critical success factors (CSF), and associated risks. The integration of client-consultant agency management makes it possible to anticipate and manage organizational, technical, and human conflicts, particularly through the contract and conflict resolution strategies. This study contributes to both academic research and professional practice by offering consultants and Moroccan SMEs a structured framework aimed at improving the success of ERP projects.

Keywords—ERP; ERP implementation; client-consultant; Moroccan SMEs; IS success; system benefits

I. INTRODUCTION

Nowadays, adopting an ERPS has become a key choice for SMEs looking to modernize their IS and implement integrated management [1]. A successful ERP project brings many benefits, such as process automation, cost reduction, improved production quality, improved customer service, and better coordination between departments [2,3,4,5]. However, despite the advantages of adopting an ERPS, the implementation process faces a number of challenges related to the organizational nature of SMEs, as well as the process of implementing this type of technological solution. This makes

the implementation of an ERPS a complex process and a challenge for SMEs.

In Morocco, as a technical and functional consultant involved in implementing ERP in various types of companies, including SMEs, and as a member of a research team with over 20 years of experience in implementing ERP in various contexts—large companies, universities, and Moroccan SMEs—we have been able to identify the main challenges facing the latter. These include the lack of an ERP implementation framework and conflicts between the client and the consultant, which impact the success of ERP implementation within Moroccan SMEs.

Following several literature reviews and according to [6], consultants play a very important role in the successful implementation of ERP in SMEs. However, the failure of ERP projects is sometimes due to conflicts between the client and the consultants. According to [7], conflicts between the client and consultants can be managed using a framework called the client-consultant agency. This concept refers to actions or decisions taken by the client or consultant to anticipate and manage conflicts that may arise during ERP implementation. This indicates that client-consultant agency management can play a crucial role in the successful implementation of ERP in Moroccan SMEs.

On the other hand, according to several studies in the literature [8,9,10], using an ERP implementation framework makes it possible to:

- Provide clear direction
- Plan the phases
- Facilitate communication
- Control costs, deadlines, and quality
- Promote adoption by users

This indicates that the use of an ERP implementation framework plays a crucial role in the successful implementation of ERP within Moroccan SMEs.

It is in this sense that this study aims to develop a framework for implementing ERP that integrates client-consultant agency management within Moroccan SMEs.

We will present a review of the literature on frameworks developed for implementing ERP within SMEs. By identifying

the limitations of existing work, this research aims to fill the gaps identified in the literature by proposing a framework for implementing ERP that integrates client-consultant agency management within Moroccan SMEs.

II. LITERATURE REVIEW

The implementation of an ERP is a complex and strategic undertaking within companies. To ensure its success, a clearly defined methodological framework is essential. This framework provides an organized structure that guides the ERP implementation process, facilitating the coordination of various aspects of the project from initial planning to full system integration. Numerous frameworks have been developed for ERP implementation in SMEs. Below is an overview of the frameworks examined in the literature (see Table I):

TABLE. I. FRAMEWORKS DEVELOPED FOR IMPLEMENTING ERP IN SMEs

Authors, year	Country	Phases
Danang et al. (2023) [11]	Indonesia	- The assessment - Implementation
Alaskari et al. (2021) [12]	Angleterre	- Process analysis - Preparation of specifications - Creation of a project plan - Creation of the system - Creation of a data migration plan - User acceptance testing - User training - Commissioning
Carmela and P. Perez (2019) [13]	Philippines	- Inspiration - Conceptualization - Implementation
Jagoda et al. (2017) [14]	Not defined	- Partner selection - Preparation of the implementation - Implementation - Evaluation
Sahran et al. (2010) [15]	Malaysia	- Initiation - Planning and selection - Implementation - Deployment and support

Most of these frameworks follow similar phases, do not account for client-consultant agency management, and were developed in contexts different from that of Morocco.

Referring to the literature, we noticed a lack of framework for implementing ERP that integrates client-consultant agency management within Moroccan SMEs.

It is in this sense that our research focused on two main and complementary areas:

- Examine how client-consultant agency management affects the successful implementation of ERP within Moroccan SMEs.
- Propose a framework for the implementation of ERP within Moroccan SMEs.

III. RESEARCH QUESTIONS

Given this gap in the literature, this research aims to answer the following research question: How can a framework that integrates client-consultant agency management promote the successful implementation of ERP in Moroccan SMEs?

We will attempt to answer this central question through the following research questions:

- 1) How does client-consultant agency management affect the successful implementation of ERP in Moroccan SMEs?
- 2) What are the essential phases to follow to ensure the successful implementation of ERP in Moroccan SMEs?
- 3) How can these different phases be structured to ensure the successful implementation of ERP in Moroccan SMEs?

IV. RESEARCH METHODOLOGY

To answer these research questions, we adopted a mixed research method.

To answer the first question, we opted for the quantitative research method using the PLS-SEM statistical method with SmartPLS software.

We chose this method to measure the impact of the client-consultant agency on the successful implementation of ERP within Moroccan SMEs. This impact is quantifiable, i.e., either positive or negative. To do this, we based our research on an existing model in the literature that studies this impact, and we used it in our research to test our hypotheses.

The quantitative research method is a method that involves collecting numerical data for analysis [16,17].

In this study, a questionnaire was distributed via email to collect data from employees who had previously participated in the implementation of an ERPS, as well as from consultants who had previously led ERP implementation projects within Moroccan SMEs. We then analyzed the data using the PLS-SEM model, which allows us to explain the relationships between one or more explanatory variables and one or more dependent variables, either directly or indirectly [18].

The analysis was performed using SmartPLS software, which is used for structural equation modeling [19].

To answer the second and third questions, we used the action research method.

We chose this method because we could not find any work on this subject in Morocco using the action research method. Furthermore, this method places the researcher within the company, allowing for close observation.

The action research method is a type of case study in which the author, usually the researcher, actively participates in the implementation of the system [20]. It aims to solve problems while generating knowledge [21].

The action research cycle follows a cyclical process comprising a preliminary stage aimed at defining the context and objective, as well as four main stages: constructing, planning action, taking action, and evaluating action.

Constructing: Based on the context and the defined objective, the action researcher develops hypotheses drawing on the state-of-the-art and their expertise in the field.

Planning action: The action researcher plans all stages of the project based on the established hypotheses and in collaboration with the project team.

Taking action: The action researcher implements the planned actions with the participation of all project stakeholders.

Evaluating action: The action researcher carries out the necessary checks to evaluate the achievement of results in relation to the hypotheses formulated.

Fig. 1. Action research cycle.

In our study, the action research method was used in two Moroccan SMEs operating in the service sector (see Fig. 1). I had the opportunity to work on both projects as project manager. In this capacity, I was responsible for directing and supervising the implementation of the respective projects. As project manager, my role included strategic planning, team coordination, and supervision of the various phases of project implementation. This experience as a manager directly involved in these initiatives gave me an in-depth perspective on the challenges and successes encountered during these complex ERP processes. Table I presents the cases studied.

TABLE. II. DESCRIPTION OF THE CASE STUDIES

	Company A	Company B
Year	2014	2013
Specialty	Coaching, leadership and management	Consulting, audit and support
ERP	Odoo Version 11	Odoo Version 12
Modules	Purchasing, Sales, CRM, Inventory, Billing, Accounting, Document, Project, Human Resources	Purchasing, Sales, CRM, Inventory, Billing, Accounting, Document, Project, Human Resources, Signature

V. FRAME DESIGN

To develop our framework, we combined:

- Quantitative research methods to examine the impact of client-consultant agency management on the successful implementation of ERP in Moroccan SMEs;
- Action research methods to identify the phases and structure of each phase of the ERP implementation framework in Moroccan SMEs;
- Scientific literature;
- The experience of the research team, which has more than 20 years of experience in ERP implementation.

A. Examining how Client-Consultant Agency Management Affects the Successful Implementation of ERP in Moroccan SMEs

To examine how client-consultant agency management affects the successful implementation of ERP in Moroccan

SMEs, we used the model proposed by [7], based on the client-consultant agency, the dimensions of CSF for ERP, and the IS success model. Fig. 2 shows the theoretical model.

Fig. 2. Theoretical model.

The objective is to explain net benefits through conflict resolution and the contract specificity.

The model is based on assumptions, which we used to develop a questionnaire that we distributed to employees of SMEs who had already participated in the implementation of ERP and to consultants who had already implemented ERP in Moroccan SMEs.

H1. User satisfaction (US) has a positive influence on the net benefits generated by ERPS.

H2. System quality has a positive impact on user satisfaction.

H3. Information quality has a positive impact on user satisfaction.

H4a. The human dimension of ERPP has a positive impact on information quality.

H4b. The human dimension of ERPP has a positive impact on system quality.

H5a. The organizational dimension of ERPP has a positive impact on information quality.

H5b. The organizational dimension of ERPP has a positive impact on system quality.

H6. The technological dimension of ERPP has a positive impact on user satisfaction.

H7. Conflict resolution measures have a positive impact on the human dimension of ERPP.

H8a. Contract Specificity has a positive impact on the technological dimension of ERPP.

H8b. Contract specificity has a positive impact on the organizational dimension of ERPP.

1) *Descriptive statistics:* In this study, a questionnaire was distributed via email to collect data from employees who had previously participated in the implementation of an ERPS, as well as from consultants who had previously led ERP implementation projects within Moroccan SMEs. We collected 93 responses to our survey. Of the respondents, 56% were men. In terms of age distribution, 80% were in the 26 to 45 age brackets. In addition, 70% of participants held a Master's

degree, and had between 6- and 10-years' experience in the use of ERPS.

2) Measurement model

a) Construct reliability and validity

Net Benefits (NB)

User satisfaction (US)

System Quality (SQ)

Information Quality (IQ)

Human Dimension (HD)

Organizational Dimension (OD)

Technological Dimension (TD)

Conflict resolution (CR)

Contract Specificity (CS)

The results presented in Table III below indicate that the tests exceed the established thresholds, with Cronbach's alpha (> 0.7), rho_A (> 0.7), composite reliability (> 0.7) and average variance extracted (AVE > 0.5), except for contract specification, human dimension and organizational dimension, which have values below the thresholds but are acceptable. This indicates good internal consistency, suggesting that the indicators within each variable are highly correlated, effectively measuring the underlying concept. Consequently, these results also indicate a convergence of items towards their respective latent constructs.

TABLE. III. CONSTRUCT RELIABILITY AND VALIDITY

	Cronbach's alpha	Composite reliability (rho a)	Composite reliability (rho c)	Average variance extracted (AVE)
C R	0.781	0.766	0.875	0.781
C S	0.628	0.726	0.800	0.509
H D	0.730	0.719	0.769	0.456
I Q	0.879	0.879	0.925	0.805
N B	0.957	0.959	0.967	0.855
O D	0.680	0.702	0.805	0.512
S Q	0.929	0.940	0.949	0.825
T D	0.791	0.792	0.905	0.827
U S	0.913	0.918	0.939	0.792

b) *Discriminant validity*: Examination of Table IV presented reveals that the square root of the AVE of each construct exceeds the highest correlation with any other construct. Consequently, the scales used in the study demonstrate discriminant validity, confirming that the constructs do indeed measure distinct concepts without exhibiting excessive overlap. This finding reinforces

confidence in the use of these scales to measure variables of interest in research.

TABLE. IV. DISCRIMINANT VALIDITY: FORNELL-LARCKER CRITERION

	CR	CS	HD	IQ	NB	OD	SQ	TD	US
CR	0.884								
CS	0.709	0.713							
HD	0.601	0.612	0.676						
IQ	0.732	0.601	0.661	0.897					
NB	0.548	0.495	0.470	0.671	0.925				
OD	0.679	0.682	0.618	0.702	0.706	0.716			
SQ	0.601	0.528	0.654	0.872	0.898	0.707	0.908		
TD	0.595	0.514	0.629	0.893	0.664	0.698	0.880	0.909	
US	0.736	0.654	0.637	0.870	0.768	0.711	0.880	0.883	0.890

c) *Factor loading*: The results of the factor loadings analysis in Table V reveal that majority of values exceed the 0.7 threshold, indicating a strong correlation with the factors studied, which is considered positive. On the other hand, loadings below 0.7 are also noteworthy, though considered acceptable, testifying to a more moderate association with the factors analyzed.

TABLE. V. FACTOR LOADING

CR1	0.983	IQ1	0.891	OD4	0.654
CR2	0.772	IQ2	0.886	SQ1	0.933
CS1	0.869	IQ3	0.914	SQ2	0.913
CS2	0.858	NB1	0.937	SQ3	0.872
CS3	0.892	NB2	0.970	SQ4	0.913
CS4	0.766	NB3	0.839	TD1	0.913
CS5	0.605	NB4	0.920	TD2	0.906
HD1	0.731	NB5	0.953	US1	0.868
HD2	0.752	OD1	0.727	US2	0.891
HD3	0.651	OD2	0.806	US3	0.903
HD4	0.665	OD3	0.751	US4	0.898

3) *Structural model*: In order to test the significance of the relationship between variables, we used a bootstrapping procedure of 10000 samples. Table VI below shows that all the path relationships are significant except the impact of human dimension on system quality and technological dimension on user satisfaction. Fig. 3 presents the path coefficients.

TABLE. VI. DIRECT EFFECTS

	Original sample (O)	Standard deviation (STDEV)	P values
CR -> HD	0.719	0.055	0.000
CS -> OD	0.882	0.038	0.000
CS -> TD	0.514	0.095	0.000
HD -> IQ	0.677	0.115	0.000

HD → SQ	0.199	0.199	0.318
IQ → US	0.594	0.139	0.000
OD → IQ	0.256	0.121	0.035
OD → SQ	0.634	0.171	0.000
SQ → US	0.259	0.105	0.013
TD → US	0.154	0.108	0.153
US → NB	0.768	0.062	0.000

Fig. 3. Path coefficients.

Table VII presents the four paths that link client consultant agency management to the realization of benefits. All paths are significant.

TABLE. VII. INDIRECT EFFECTS

	Original sample (O)	Standard deviation (STDEV)	P values
CR → HD → IQ → US → NB	0.222	0.065	0,001
CS → OD → IQ → US → NB	0.123	0.055	0,033
CS → OD → SQ → US → NB	0.119	0.058	0,047
CS → TD → US → NB	0.161	0.052	0,039

The model's suitability for the sample was assessed using R2 values in Table VIII. All endogenous concepts have R2 values above 0.5, with the exception of the technological dimension concept, which has an R2 value of 0.264. These values indicate that the predictive power of the proposed model is high given its complexity. The main dependent variable in this study is net profit, with an R2 value of 0.589. Thus, the proposed model explains 58.9% of the variance in net profit.

TABLE. VIII. R-SQUARE

	R-square
HD	0.517
IQ	0.773
NB	0.589
OD	0.778
SQ	0.623
TD	0.264
US	0.947

Empirically, this study reveals that conflict resolution significantly explains the human dimension of the ERPP, representing 51.7% of this dimension. Complementarily, contract specification emerges as a major explanatory factor for the organizational and technological dimensions, contributing 77.8% and 26.4%, respectively. These results highlight the critical importance of conflict resolution and contract specification in the successful implementation of ERPP, underscoring their crucial role in human, organizational and technological aspects.

After analyzing the data, our study identified four paths in which client-consultant agency management affects the successful implementation of ERP in Moroccan SMEs, through the contract and the implementation of conflict resolution strategies.

The first and second paths involve using the contract to anticipate and manage conflicts between the client and consultants that may arise from organizational factors. The contract must include:

- Financial and legal aspects:

Defines the budget, payment terms, and legal obligations to ensure both parties understand their commitments and liabilities.

- The company's objectives:

Clearly states the strategic goals of the company that the project aims to achieve.

- The company's needs:

Specifies the operational and organizational requirements that the ERP project must fulfill.

- The expected results:

Outlines the deliverables and measurable outcomes expected.

- The structure of the project team:

Describes the composition of the team, including roles and hierarchy, to ensure effective collaboration.

- The roles and responsibilities of each member:

Assigns clear responsibilities to each team member to avoid overlaps and conflicts.

- Clear timelines and deadlines for the completion of the project:

Establishes project milestones and deadlines to ensure timely delivery.

- Penalties for unsatisfactory results:

Defines consequences and corrective measures in case project outcomes do not meet agreed standards.

The third path is to detail the technical requirements that the client expects from the ERP in the contract. The contract must include:

- All modules, features, interfaces, and processes to be implemented:

Defines the complete ERP scope, specifying every module, functionality, interface, and business process to ensure the project meets the client's expectations.

- Specify that the consultant must have experience with the modules to be implemented:

Ensures that consultants have the necessary expertise for the specific ERP modules, reducing risk and increasing the likelihood of successful implementation.

The fourth path is to use conflict resolution strategies to manage issues between the client and consultants that cannot be addressed in the contract:

- Management involvement:

Engages leadership to provide guidance, make decisions, and resolve escalated conflicts.

- User involvement:

Includes end-users in discussions and decisions to ensure their needs are met and to reduce resistance.

- Proactive communication:

Maintains clear, regular, and transparent communication to prevent misunderstandings and address issues early.

- Consultant skills:

Relies on the expertise and problem-solving abilities of consultants to handle challenges effectively.

- Change management:

Applies structured approaches to manage organizational change, helping users adapt and ensuring project success.

Fig. 4 shows how client-consultant agency management is handled in Moroccan SMEs through the contract and conflict resolution strategies.

Fig. 4. Management of the client-consultant agency within Moroccan SMEs.

B. Phases and Structure of each Phase of the ERP Implementation Framework in Moroccan SMEs

In our research, we propose a systematic and easy-to-understand framework structured in five phases: the analysis phase, the design phase, the implementation phase, the final preparation phase, and the commissioning and support phase.

Each phase includes objectives, inputs, processes, and outputs, as well as CSF and risks. In addition, the outputs of

each phase are used as inputs for the next phase, ensuring a smooth transition between phases.

Certain criteria were taken into account when developing the framework, including a simple, systematic, and easy-to-understand structure, clarity between phases, and a roadmap and planning tools for implementation.

The design of our framework is shown in Fig. 5.

Fig. 5. Framework design.

1) Analysis phase: The analysis phase is a key step in the implementation of the ERP, as it aims to build a thorough and shared understanding of the project between the client and the consultant. Based on the contract between the two parties, this phase allows the scope of the project, the strategic objectives, and the terms of collaboration to be defined. It involves organizing the project kick-off meeting, structuring the project team, analyzing existing documents and processes, and conducting interviews with key users. These activities enable the functional requirements of the organization to be identified, formalized, and validated. The main deliverables of this phase are the project plan, the process modeling document, and the functional requirements document, which are essential references for guiding the subsequent phases and reducing the risk of misunderstanding or disagreement between stakeholders.

The CSF for the analysis phase is mainly based on organizational and human alignment around the ERP project. The support and involvement of senior management are essential for making decisions, ensuring the availability of resources, resolving issues, and supporting employees in accepting the new ERP. The active involvement of end users and key stakeholders makes it possible to gather precise and realistic requirements, while promoting buy-in for the project from its earliest stages. Rigorous project management helps to structure the analysis work, coordinate the various players, and control deadlines and risks. Process reengineering is a key factor, as it allows existing business practices to be aligned with ERP standards and best practices. The project team's functional and technical expertise guarantees the quality of the analyses and the relevance of the choices made. Finally, proactive change management from the analysis phase onwards prepares the organization for the transformations brought about by ERP and reduces resistance that could compromise the success of the project.

We have identified the risks associated with each phase in order to highlight the potential consequences of failing to apply CSF, with the aim of preventing the failure of the phase and the project as a whole (see Table IX).

TABLE. IX. GUIDELINES FOR THE ANALYSIS PHASE

Analysis phase	Objectives		
	- Define the scope, goals, and objectives of the project - Model the processes - Define the project team		
	Critical success factors		
	- Support and involvement from senior management - Involvement of end users and stakeholders - Project management - Process reengineering - Project team competence - Change management		
	Inputs	Processes	Outputs
	- Contract between the client and the consultant	- Organizing and holding the project kick-off meeting - Defining the project team - Reviewing documents, reports, and processes - Conducting discussions with key users	- The project plan - The process modeling document - The functional requirements document
	Risks		
	- Lack of involvement from management and end users - Poor reengineering - Misunderstanding among project team members - Lack of expertise and competence within the project team - Resistance to change		

2) *Design phase*: The design phase aims to translate the functional requirements validated during the analysis phase into operational solutions adapted to the ERP. It is based primarily on the functional requirements document and consists of designing the target processes in detail through the preparation and presentation of prototypes of the various ERP modules to be implemented. Workshops are organized with stakeholders to define management and customization rules and any additional features. This phase also allows the data migration strategy and methods to be defined. The key deliverables of this phase are the detailed functional specifications document and the data collection and migration models, which form an essential basis for the implementation phase and help to control the technical and organizational risks of the ERP project.

The CSF for the design phase is based on effective governance and close collaboration between the various stakeholders in the ERP project. The support and involvement of senior management remain essential for validating structural choices, arbitrating priorities, and ensuring that the solution is consistent with the company's strategy. The involvement of end users and key stakeholders helps to understand requirements, needs, management rules, customizations, and new features to be developed. Rigorous project management is necessary to coordinate design workshops, control deadlines, and ensure the traceability of decisions made. The competence of the project team, both functionally and technically, determines the quality of the detailed specifications and the relevance of the configuration and customization choices. Finally, effective

change management during this phase promotes stakeholder buy-in, prepares users for future developments, and limits the risk of rejection during later implementation phases.

We have identified the risks associated with each phase in order to highlight the potential consequences of failing to apply CSF, with the aim of preventing the failure of the phase and the project as a whole (see Table X).

TABLE. X. GUIDELINES FOR THE DESIGN PHASE

Design phase	Objectives		
	- Create and present prototypes for each module - Validate business rules, customizations, and specific developments with stakeholders - Establish the framework for data migration		
	Critical success factors		
	- Support and involvement from senior management - Involvement of end users and stakeholders - Project management - Competence of the project team - Change management		
	Inputs	Processes	Outputs
	- The functional requirements document	- Preparation and presentation of module prototypes - Organization of workshops to define management rules, customizations, and new features required - Determination of the data migration method	- Detailed functional specifications document - Data collection and migration models
	Risks		
	- Lack of involvement from management and end users - Misunderstandings among project team members - Lack of expertise and skills within the project team - Resistance to change		

3) *Realization phase*: The realization phase involves the practical implementation of the solutions defined during the design phase. It is based on detailed functional specifications and data collection and migration models. This phase includes configuring the various ERP modules, developing customizations and specific functionalities identified, and preparing and executing data migration in the test environment. Test campaigns are then carried out to verify the system's compliance with functional and technical requirements. Any anomalies detected are analyzed and corrected iteratively to ensure the stability and quality of the solution. The main deliverables of this phase include data ready to be migrated to the production environment, training materials for users, and the test catalog, which serves as a reference for the final preparation phase and the ERP's release into production.

The CSF for the realization phase are mainly related to the efficient execution of technical work and the management of changes brought about by the ERP. The support and involvement of senior management remain essential to maintain stakeholder commitment, arbitrate critical decisions,

and ensure the availability of necessary resources. Rigorous project management allows for the coordination of configuration, development, and testing activities, while meeting deadlines, staying within budget, and ensuring the expected quality. The expertise of the project team, both functionally and technically, is crucial to ensuring the correct configuration of the system, the implementation of specific developments, and the effective resolution of anomalies. Change management plays a key role in supporting users in the face of new developments and reducing organizational resistance. Limiting customizations to what is strictly necessary is also a critical factor, as it promotes system stability, facilitates version upgrades, and reduces technical risks. Finally, an adequate configuration aligned with business needs ensures the consistency of the ERP and its ability to effectively support business processes.

We have identified the risks associated with each phase in order to highlight the potential consequences of failing to apply CSF, with the aim of preventing the failure of the phase and the project as a whole (see Table XI).

TABLE. XI. GUIDELINES FOR THE REALIZATION PHASE

Realization phase	Objectives		
	- Configure the standard solution - Perform customizations and specific developments - Migrate data - Test the system - Resolve any anomalies found during testing		
	Critical success factors		
	- Support and involvement from senior management - Project management - Project team expertise - Change management - Minimal customization - Configuration		
	Inputs	Processes	Outputs
	- Detailed functional specifications document - Data collection and migration models	- Module configuration - Implementation of customizations and specific developments - Data preparation and migration - Test execution - Analysis and correction of anomalies detected during testing	- Data to be migrated - Supports for formation - Test catalog
	Risks		
	- Lack of expertise and competence within the project team - Incorrect or excessive customization		

4) *Final preparation phase*: The final preparation phase is the transition stage between the technical implementation of the ERP and its actual rollout. It draws on the training materials developed and the test catalog produced during the previous phase. This phase includes organizing training sessions for end users to ensure they understand the system's features, as well as conducting user acceptance testing (UAT) to validate the ERP's compliance with functional and operational requirements. Any

anomalies identified during UAT are analyzed and corrected, ensuring the quality and reliability of the system before it goes live. The main deliverables of this phase include user guides, the final configuration document, the final source code for specific and customized developments, the final data ready to be migrated to the production environment, and the detailed production plan, which constitutes the roadmap for the operational deployment of the ERP.

The CSF for the final preparation phase depends on the organization's ability to validate the ERP and effectively prepare for its implementation. The support and involvement of senior management are essential to legitimize this decisive phase, mobilize the necessary resources, and validate the transition to production. The active involvement of end users and key stakeholders ensures the relevance of acceptance tests and confirms that the system meets operational needs. Rigorous project management is essential to coordinate training, testing, and bug fixing activities within controlled timeframes. The competence of the project team guarantees the quality of the training provided, the effective resolution of identified problems, and the reliability of the final configuration. Effective change management promotes user acceptance of the system and reduces resistance at the time of deployment. Finally, user training is a major critical factor, as it determines their ability to use the ERP correctly and ensure a smooth transition to the new system.

We have identified the risks associated with each phase in order to highlight the potential consequences of failing to apply CSF, with the aim of preventing the failure of the phase and the project as a whole (see Table XII).

TABLE. XII. GUIDELINES FOR THE FINAL PREPARATION PHASE

Final preparation phase	Objectives		
	- Provide training for end users - Conduct user acceptance testing - Resolve any issues identified during acceptance testing - Prepare for the transition to the new ERP		
	Critical success factors		
	- Support and involvement from senior management - Involvement of end users and stakeholders - Project management - Competence of the project team - Change management - User training		
	Input	Process	Output
	- Supports for formation - Test catalog	- Organizing training sessions for users - Conducting user acceptance testing - Analyzing and correcting anomalies detected during acceptance testing	- User guides - Final configuration document - Final source code for specific and customized developments - Final data to be migrated - Production plan
Final preparation phase	Risks		
	- Lack of involvement from management and end users - Lack of expertise and competence within the project team - Resistance to change - Inadequate training		

5) *Commissioning and support phase*: The commissioning and support phase is the final stage of the ERP project, where the system is deployed in the production environment and made available to end users. This phase is based on the final configuration of the system, the source code for specific and customized developments, the data ready for migration, and the production plan established during the previous phase. The main activities include configuring the production environment, installing the source code, migrating data to the production environment, conducting a production audit to verify system compliance and performance, and setting up post-production support to assist users and resolve any incidents. The main deliverable of this phase is the project closure report, which formalizes the end of the deployment and serves as a reference document for post-project evaluations and future improvements.

The CSF for the commissioning and support phase depends on the organization's ability to ensure stable and sustainable deployment of the ERP in the production environment. The support and involvement of senior management are essential to validate the operational start-up, remove any obstacles, and ensure the continuity of the project after going live. Rigorous project management allows for the coordination of deployment, data migration, production audit, and post-production support activities, while controlling risks and incidents. The technical and functional expertise of the project team is crucial to ensuring system stability, quickly resolving any issues that arise, and providing effective support to users. Finally, effective change management remains essential to support the adoption of the system, build user confidence, and ensure the ERP's long-term viability within the organization.

We have identified the risks associated with each phase in order to highlight the potential consequences of failing to apply CSF, with the aim of preventing the failure of the phase and the project as a whole (see Table XIII).

TABLE. XIII. GUIDELINES FOR THE COMMISSIONING AND SUPPORT PHASE

Commissioning and support phase	Objectives		
	- Ensure the new ERP is up and running - Provide user support		
	Critical success factors		
	- Support and involvement from senior management - Project management - Competence of the project team - Change management		
	Input	Process	Output
	- The final configuration document - The final source code for specific and customized developments - The final data to be migrated - The production plan	- Configuration of the production environment - Installation of source code for custom and specific developments - Migration of data to the production environment - Performance of a production audit - Implementation of post-production support	- Project closing report

Risks
- Lack of involvement from management and end users - Lack of expertise and competence within the project team - Inadequate planning and resources - Discovery of new usage issues

C. The Framework for Implementing ERP: Integrating the Management of Client Consulting Agencies within Moroccan SMEs

Fig. 6 presents our ERP implementation framework, which integrates client-consultant agency management within Moroccan SMEs.

Fig. 6. The framework for implementing ERP that integrates client-consultant agency management within Moroccan SMEs.

A review of the literature reveals a lack of a framework for implementing ERP systems that integrate client-consultant agency management within Moroccan SMEs.

Most of the frameworks found in the literature:

- Use similar phases;
- Do not take into account client-consultant agency management;
- Were developed in contexts different from that of Morocco.

Our research fills the gaps identified in the literature by developing an ERP implementation framework that integrates client-consultant agency management within Moroccan SMEs.

The client-consultant agency plays a crucial role in ensuring effective collaboration between the client and consultants, acting as both supervisor and mediator to manage interactions, prevent misunderstandings, and resolve conflicts. The contract serves as the basis for the first phase of the project and remains a point of reference throughout the various phases, clarifying commitments, responsibilities, objectives, deadlines, and deliverables. To complement the contractual framework, conflict resolution strategies are applied at each phase, including user management and participation, proactive communication, leveraging consultant skills, and change management, in order to anticipate and manage conflicts that may arise during ERP implementation. The framework then integrates the various phases of ERP implementation, identifying the objectives, inputs, processes, outputs, CSF, and

risks for each phase, thus providing a structured approach that reduces uncertainty and increases the chances of project success.

VI. RESEARCH CONTRIBUTION AND LIMITATIONS

This work makes several contributions to both theory and practice.

From a theoretical perspective, this research:

- Fills gaps identified in the literature by developing an ERP implementation framework that integrates client–consultant agency management within Moroccan SMEs.
- Shows that using consultants does not guarantee the successful implementation of ERP. It explains how consultants contribute to the realization of benefits when implementing ERP.
- Enriches studies on conflicts between clients and consultants in ERP projects. It explains how client–consultant agency management affects the successful implementation of ERP in Moroccan SMEs through the contract and the implementation of conflict resolution strategies.
- Enriches studies on the challenges of ERP implementation and shows that conflicts between the client and the consultant and the lack of an ERP implementation framework, remain challenges when implementing an ERP.

From a practical standpoint, this research:

- Provides Moroccan SMEs and consultants with a clear roadmap for implementing ERP.
- Shows that the use of contracts and the implementation of conflict resolution strategies have an impact on the successful implementation of ERP within Moroccan SMEs.
- Recommends that Moroccan SMEs hire consultants with extensive experience in implementing ERP within Moroccan SMEs.
- Recommends that Moroccan SMEs hire consultants after implementing their ERP to resolve problems and provide user support.

Our research has certain limitations:

- It was limited to Moroccan SMEs operating in the service sector.
- The model used to explain how client–consultant agency management affects the successful implementation of ERP in Moroccan SMEs explains 58.9% of the variance (we did not identify all the factors explaining net profit).
- The use of self-reported questionnaire data may introduce potential biases, such as common method bias and subjective interpretation of responses.

VII. CONCLUSION

The relevance of ERP as a lever for supporting SMEs is widely recognized. However, in the context of Moroccan SMEs, the lack of a structured implementation framework and conflicts between the client and the consultant are major factors affecting the success of ERP projects. The objective of this study was to develop an ERP implementation framework that integrates client–consultant agency management within Moroccan SMEs.

The framework developed in this research comprises five phases, for each of which the objectives to be achieved, inputs, processes to be followed, outputs, CSF, and risks to be taken into account are defined. In addition, the integration of client–consultant agency management makes it possible to anticipate and manage conflicts between the client and consultants during the implementation of the ERP, whether organizational, technical, or human, particularly through the contract and conflict resolution strategies.

This research makes a significant contribution to the existing literature on ERP implementation and conflict management between clients and consultants in SMEs by proposing a framework specifically adapted to the Moroccan context. From a managerial perspective, this framework provides Moroccan SMEs and consultants with an operational tool that facilitates the planning, coordination, and management of ERP projects, while strengthening collaboration between stakeholders.

Nevertheless, this study has certain limitations, particularly those related to the specific context of Moroccan SMEs and the scope of the cases studied. Future research could extend this framework to other geographical or sectoral contexts, as well as enrich it with additional empirical studies aimed at validating its applicability and impact on the performance of ERP projects.

Ultimately, Moroccan SMEs that consider implementing an ERP can benefit from this framework by following the proposed phases, which constitute a structured and pragmatic roadmap likely to significantly increase their chances of success in ERP implementation.

Abstract—Water Distribution Networks (WDNs) frequently experience significant water losses due to pipeline leakages. These losses not only create economic challenges for water utilities but also intensify global concerns regarding water scarcity. This study aims to enhance the accuracy and reliability of leak detection and localisation within WDN infrastructures. Traditional leak detection techniques often exhibit limitations such as high operational costs, inefficient detection processes, and susceptibility to false alarms, particularly when sensors are deployed randomly across the network. Furthermore, detecting concealed or low-intensity leaks remains a difficult task. To address these challenges, this study introduces a hybrid supervised machine learning framework that combines Support Vector Machines (SVM), Artificial Neural Networks (ANN), and Graph Theory (GT). The integration of these techniques enables the proposed model to analyse multiple parameters influencing leak behaviour and improve the reliability of detection outcomes. The hybrid model, referred to as the SVM-ANN-GT algorithm, is evaluated using the EPANET hydraulic simulation environment and compared with conventional machine learning approaches. Experimental results indicate that the proposed hybrid model significantly improves leak detection performance. The model achieves an average detection accuracy of approximately 96%, outperforming standalone SVM and ANN models, which achieved accuracies of 85% and 80%, respectively. The improved performance is primarily attributed to the integration of graph-theoretic optimisation for sensor placement, which enhances monitoring coverage and reduces redundancy within the network.

Keywords—SVM-ANN-GT; leak detection and localisation; EPANET; WDNs; ML

I. INTRODUCTION

Water Distribution Networks (WDNs) represent vital municipal infrastructure responsible for supplying safe and clean water to consumers, ensuring that communities have reliable access to potable water for everyday use [1–3]. These systems typically consist of interconnected components such as reservoirs, storage tanks, pipelines, pumps, and valves, as illustrated in Fig. 1. Proper planning, operation, and maintenance of these elements are necessary to guarantee efficient and dependable water distribution throughout the network [4, 5].

Fig. 1. Typical water distribution networks.

WDNs provide several important benefits to society, including the protection of public health, the maintenance of sanitation and hygiene standards, and the reliable provision of water for essential activities such as drinking, cooking, sanitation, and fire fighting [6]. In addition, these systems play a key role in supporting economic development by supplying water to industries and commercial sectors that rely on a consistent and stable water source [7, 8]. WDNs also contribute to water conservation by minimising losses and promoting fair and efficient water distribution. By maintaining appropriate pressure levels and stable flow conditions within the network, WDNs ultimately improve service reliability and enhance the overall quality of life for communities [9, 10].

Pipelines represent a fundamental component of WDNs because they function as the primary pathways through which water is conveyed to consumers [11, 12]. Their proper functioning is essential for maintaining a reliable and continuous water supply that satisfies the demands of growing populations [13]. However, pipelines are frequently exposed to several environmental and operational risks. These include soil movement, structural deterioration due to ageing, geological disturbances, excessive water pressure, poor connections, and installation faults. Such factors can compromise pipeline integrity and lead to leaks, ultimately causing significant water losses [14].

Water leakage within WDNs is generally classified into three categories: reported leakage, unreported leakage, and unavoidable or background leakage, as illustrated in Fig. 2 [15].

*Corresponding author.

Fig. 2. Categories of water leaks.

Reported leaks are typically visible and are detected and communicated either by consumers or by water utility personnel during routine monitoring [16]. In contrast, unreported leaks remain unnoticed for extended periods because they often occur in buried pipelines or concealed locations, making them difficult to identify without specialised monitoring technologies [17, 18]. Background leakage, on the other hand, occurs naturally within distribution systems as infrastructure ages and materials gradually deteriorate. These leaks are usually small and difficult to detect because they do not produce obvious signs of water loss [19].

The magnitude of water loss resulting from pipeline leaks is substantial. Globally, billions of cubic meters of water are lost every year due to leakage in WDNs. These losses can account for approximately 5% to 50% of the total water supplied, representing a major challenge for sustainable water management and conservation initiatives [20]. In economic terms, water utilities worldwide are estimated to lose approximately 14 billion US dollars annually due to leak-related water wastage [21, 22]. In South Africa, leakage is responsible for about 37% of the country's unexplained water losses, costing the nation nearly 10 billion rands each year [23].

Although several leak detection techniques have been developed, many existing systems still rely heavily on manual inspection methods, which limit their ability to provide continuous or real-time monitoring and often lead to operational inefficiencies [24, 25]. Furthermore, inaccurate detection and frequent false alarms often occur when sensors are installed without a strategic placement strategy, leading to unnecessary maintenance actions and increased operational costs [26]. Detecting and locating small or background leaks remains particularly difficult because these leaks typically occur underground and produce minimal observable changes in system parameters.

To address these challenges, this study proposes the SVM-ANN-GT algorithm, a hybrid Machine Learning (ML) approach that combines Support Vector Machines (SVM), Artificial Neural Networks (ANN), and Graph Theory (GT) to enhance leak detection and localisation in WDNs. Unlike traditional approaches, the proposed framework enables more accurate real-time leak detection while reducing false alarms through improved data classification and decision fusion mechanisms. In addition, the use of graph-theoretic concepts facilitates optimised sensor placement, which improves monitoring coverage, reduces energy consumption, and lowers both deployment and maintenance costs.

In practical water distribution systems, random or poorly planned sensor placement often results in undetected leaks,

increased false alarms, and unnecessary energy consumption caused by redundant or inefficient monitoring nodes. Strategic sensor deployment helps minimise the number of sensors required while still ensuring sufficient monitoring coverage. This approach reduces installation and maintenance expenses while simplifying system management, particularly in large or geographically complex networks. Since this research focuses on pipeline leak detection, efficient sensor placement plays a critical role in enabling rapid and precise leak localisation, which is essential for timely repair interventions and improved water conservation.

The remainder of this study is organised as follows: Section II reviews existing studies on water leak detection techniques. Section III describes the architecture and theoretical foundations of the proposed algorithm. Section IV presents the experimental setup, dataset description, simulation results, and performance evaluation. Finally, Section V summarises the major findings and outlines directions for future research.

II. RELATED WORK

Numerous studies have investigated different approaches for detecting and locating leaks in WDNs.

Porwal et al. [27] introduced a weighted-sample Support Vector Machine (SVM) model designed to enhance leak detection in WDNs. Their method improved classification performance by effectively addressing noisy data and outliers, outperforming conventional techniques such as acoustic signal analysis, transient signal analysis, and temperature variation analysis. Building on these findings, the proposed SVM-ANN-GT algorithm extends the concept by incorporating an optimisation mechanism for sensor placement, which helps reduce operational costs and energy consumption. By combining these elements, the proposed approach offers a more efficient and dependable framework for leak identification in WDNs.

Zhou et al. [28] developed a leak detection framework that integrates SVM with Kernel Principal Component Analysis (KPCA). In their model, KPCA was used to reduce the dimensionality of flow measurement data while extracting meaningful features, after which SVM performed the classification task. The approach was evaluated using Flowmaster simulation software and compared with alternative techniques such as Support Vector Data Description (SVDD) and k-means clustering. Experimental results indicated that the KPCA-SVM model achieved superior detection accuracy compared with the competing approaches. However, the study did not address the effect of sensor placement along the pipeline network, which is an important factor for improving detection performance while reducing installation and operational costs.

Lang et al. [29] proposed a leak detection and localisation technique that combines Least Squares Support Vector Machines (LS-SVM) with Local Maxima Decomposition (LMD). The proposed framework was evaluated using Flowmaster software on both simulated and real-world datasets. Results showed improved accuracy in identifying and locating leaks compared with existing methods such as wavelet transform and particle swarm optimisation. Despite its promising performance, the LS-SVM-LMD approach lacks a

mechanism for strategic sensor deployment. As a result, the system required a large number of sensors, which increased both operational costs and energy consumption. Furthermore, poorly positioned sensors introduced additional noise in the data, which negatively affected overall detection accuracy.

Amini et al. [30] developed an Artificial Neural Network (ANN)-based model for real-time leak detection in pipelines using pressure measurements. The algorithm achieved high precision and recall values, demonstrating strong performance. Nevertheless, the study relied exclusively on pressure data and did not incorporate other relevant parameters such as flow rate or water quality indicators. Additionally, the evaluation was performed using a single dataset, which limits the generalisability of the results. Although this approach shares similarities with the SVM-ANN-GT framework, particularly in the use of pressure-based data, it suffers from limitations related to random sensor placement, which leads to increased operational costs and higher energy consumption. In contrast, the proposed SVM-ANN-GT model integrates graph theory to optimise sensor positioning, thereby improving detection accuracy while minimising energy usage.

Mashhadi et al. [31] presented a machine learning-based method for leak detection and localisation in WDNs by combining logistic regression with spectral clustering. Their objective was to reduce false alarm rates while improving localisation accuracy. The method was implemented on real WDN systems and evaluated using the EPANET hydraulic simulator, with comparisons made against other ML models such as decision trees and ANN. The results showed that their approach achieved a detection and localisation accuracy of approximately 94.3%, outperforming the alternative algorithms. However, the model required a large number of sensors, which increased both operational expenses and energy consumption. Similar to the SVM-ANN-GT algorithm, their approach utilised machine learning techniques to detect and locate leaks, although the proposed method reported a maximum false alarm rate of 1.9%.

Rayaroth [32] introduced the Random Decision Tree Bagging Classifier with Shuffled Frog Leaping Optimisation (RDTBC-SFLO) algorithm for detecting leaks in WDNs. The model combines a random ID3 decision forest classifier with the SFLO optimisation algorithm to improve sensor placement and detection accuracy. The Iterative Dichotomiser 3 (ID3) algorithm constructs decision trees by selecting attributes with the highest information gain, enabling effective classification of pressure measurements as either normal or abnormal. The SFLO optimisation component identifies optimal sensor locations within the WDN, thereby reducing classification errors and improving detection performance. Simulation experiments conducted using EPANET showed that the RDTBC-SFLO approach significantly improved leak detection while reducing classification time compared with existing methods. However, the approach was only tested on small-scale WDN systems, which raises concerns regarding its scalability for larger networks. In contrast, the SVM-ANN-GT algorithm proposed in this study was evaluated on large-scale WDN environments, demonstrating its potential applicability in real-world scenarios.

Wu et al. [33] proposed a two-stage burst detection method based on a data-driven clustering algorithm. Their approach identified anomalies in flow meter data collected from district metering areas and analysed statistical patterns to detect pipeline bursts. One notable advantage of the method was its ability to adapt to non-stationary conditions in historical datasets, eliminating the need for manual data selection. Evaluation using simulated flushing-induced bursts demonstrated that the method could effectively identify relatively large and short-duration bursts while maintaining a low false positive rate. Additionally, the system was able to detect abnormal water usage patterns associated with weather variations, suggesting its applicability in real operational environments. Nevertheless, further investigation is needed to assess the method's performance under noisy conditions or highly dynamic network environments. Moreover, the study did not compare its performance with other burst detection algorithms, making it difficult to assess its relative effectiveness.

Lučin et al. [34] proposed a machine learning-based leak detection framework using a Random Forest (RF) classifier, particularly targeting WDN environments with limited sensor availability. The study used Monte Carlo simulations to generate leak scenarios with varying demand patterns and leak characteristics. Pressure data collected over a 24-hour period were analysed to identify and locate leaks within EPANET-simulated networks. The model was implemented using the Scikit-learn library and supported by high-performance computing resources, achieving reliable detection results even with sparse sensor deployment. However, the study had several limitations. It did not incorporate additional hydraulic or environmental variables, lacked validation using real WDN data, and did not account for prediction uncertainty. Furthermore, the study explored only a single machine learning model, which may limit its robustness. While the proposed SVM-ANN-GT algorithm shares similarities with this approach in terms of ML implementation and sensor placement considerations within a Python framework, the RF-based method struggled to detect small-scale leaks, potentially leading to undetected water losses and operational inefficiencies. The hybrid SVM-ANN-GT algorithm addresses these challenges by integrating SVM, ANN, and GT to optimise network monitoring and improve detection of small leaks while reducing energy consumption and false alarm rates.

Radha and Ramamoorthy [35] proposed a leak detection framework based on association rule learning combined with particle swarm optimisation. Their study highlighted the importance of leak detection for reducing water loss, improving distribution efficiency, and preventing contamination within WDNs. The Apriori algorithm was applied to simulated WDN datasets to identify patterns associated with water leakage by analysing frequent item sets. Particle swarm optimisation was then used to optimise rule thresholds, improving detection accuracy. The authors reported a leak detection rate exceeding 90% with a false alarm rate below 1%. They also compared their method with other association rule mining techniques such as FP-Growth and Eclat, demonstrating superior performance. However, the approach has not yet been validated using real-

world WDN data or tested on large-scale network infrastructures.

Fan et al. [36] proposed a hybrid machine learning approach that integrates Artificial Neural Networks (ANN) with Autoencoder (AE) models for leak detection in WDNs. Using the EPANET simulator, they generated pressure datasets under various conditions, including different user demands, noise levels, and leak severities. While the supervised ANN model achieved high classification accuracy, the study identified challenges related to imbalanced datasets in Wireless Sensor Networks (WSNs). To address this limitation, the authors introduced an unsupervised AE model capable of detecting leaks in imbalanced datasets. Although the AE approach performed well in monitored sensor regions, its effectiveness declined in other network areas. To overcome this limitation, the authors proposed a strategy involving multiple independent detection attempts using the AE model, which significantly reduced false alarms. The method was evaluated using a WSN testbed and demonstrated promising results. Similar to the proposed SVM-ANN-GT algorithm, their approach utilised an ANN and focused on reducing false alarms. However, their framework did not address small background leaks or include sensor placement optimisation.

Overall, many previous studies have applied machine learning techniques such as SVM, ANN, decision tree models, and clustering algorithms to detect leaks in WDNs. Nevertheless, most of these approaches do not integrate real-time leak detection with optimised sensor placement strategies. In contrast, the proposed SVM-ANN-GT algorithm combines accurate ML-based classification with graph theory-based sensor placement, resulting in a more robust, energy-efficient, and cost-effective leak detection framework.

III. SYSTEM DESIGN AND MODELING

A. Proposed Leak Detection and Architecture

The Internet of Things (IoT)-based Wireless Sensor Network (WSN) architecture designed for WDNs, illustrated in Fig. 3, provides an advanced framework for detecting and locating pipeline leaks. This architecture utilises IoT-enabled sensing devices to support continuous monitoring of network conditions, improve the precision of leak detection, and optimise the use of resources within WDN infrastructure. Through the strategic placement of pressure, vibration, and flow sensors, the system can detect and localise leaks effectively while minimising operational costs, energy consumption, and false alarm rates.

Pressure sensors are deployed to continuously measure pressure variations within the pipeline system. Any abnormal pressure fluctuations caused by leaks are immediately detected, and the collected data are transmitted in real time to support accurate leak localisation. Vibration sensors capture characteristic vibration signals produced when water escapes through cracks or faults in pipelines, allowing the system to identify leak locations with high precision. In addition, flow sensors measure water flow rates across the network and detect sudden reductions that may indicate the presence of a leak.

The integration of these sensing technologies with IoT communication infrastructure significantly improves the leak

detection and localisation process within WDNs. Real-time transmission of sensor data to a central monitoring platform allows operators to quickly identify anomalies and initiate corrective actions, thereby reducing water loss. This architecture enhances the efficiency, reliability, and cost-effectiveness of water distribution monitoring systems by enabling proactive detection and localisation of pipeline faults.

Fig. 3. Pipeline leak detection and location architecture.

Furthermore, IoT connectivity combined with cloud-based platforms supports advanced data processing and management capabilities. Sensor measurements are transmitted through an IoT gateway, where the information can be analysed in real time to detect potential leak events. Historical data stored in cloud systems can also be used to evaluate pipeline performance trends, identify recurring issues, and support predictive maintenance strategies that improve the long-term reliability of leak detection systems.

B. EPANET

EPANET is a widely used hydraulic simulation tool for analysing Water Distribution Networks and is recognised for its specialised capabilities in modelling water infrastructure systems. The software is specifically designed for water network analysis and includes features for hydraulic modelling, water quality simulation, and pump scheduling, making it highly suitable for studying the behaviour of WDNs.

One of the major advantages of EPANET is that it is an open-source, which enables researchers and practitioners to freely access the platform, customise simulations, and collaborate on water system studies. Over time, the software has gained a strong reputation due to its validation using real-world water distribution data, demonstrating reliable performance in practical applications. In addition, EPANET provides a user-friendly graphical interface, allowing users with different levels of technical expertise to easily design, simulate, and analyse network models.

Compared with network simulation tools commonly used in computer networking research, such as Network Simulator-2 (NS-2), Objective Modular Network Testbed in C++ (OMNET++), and Optimised Network Engineering Tools (OPNET), EPANET offers several advantages for water engineering studies. Its dedicated focus on hydraulic processes, combined with its modelling accuracy and intuitive interface, makes it particularly well suited for analysing water distribution networks and evaluating leak detection strategies.

C. Graph Theory

Graph Theory (GT) is a branch of mathematics that deals with the study of graphs, which are mathematical structures used to represent relationships between objects [37, 38]. In GT, a graph is composed of vertices (also known as nodes) and edges (also known as arcs or links) that connect pairs of vertices [39, 40].

This study applies GT for strategic sensor placement in pipelines, minimising costs while ensuring efficient monitoring. GT employs the Minimum Dominating Set Algorithm (MDS) to identify optimal node subsets, reducing sensors and simplifying maintenance for cost-effective, network-wide coverage.

In GT, an MDS in a graph G is a subset D of vertices where every vertex in G is either in D or adjacent to a vertex in D . The domination number $\gamma(G)$ is the smallest size of a dominating set in G . The dominating set problem involves determining whether $\gamma(G) \leq K$ for a given graph G and input K .

The WDN's structure was represented by the connected graph $G(V, E)$, with nodes as junctions and edges as pipes. Given an undirected graph $G(V, E)$, a subset of vertices $D \subseteq V$ is called an MDS if, for every vertex $u \in V \setminus D$, there is a vertex $v \in D$ such that $(u, v) \in E$.

In every graph, there exists a minimum of one MDS: if $D=V$ is the set of all vertices, then by definition, D is an MDS since there is no vertex $u \in V \setminus D$. Finding small MDS presents an intriguing challenge: The domination number of G is defined as $\gamma(G) = \min \{|D| : D \text{ is an MDS of } G\}$. Fig. 4 illustrates the MDS of a given graph, represented as $\{4, 7\}$, where each vertex in the graph is either in the set or adjacent to a vertex in the set.

Fig. 4. A typical graph-dominating set.

The rest nodes in the graph are connected to either node 4 or node 7 in the graph. However, other dominating sets, such as $\{2, 4\}$, etc., can also be defined for the same connected graph.

D. Support Vector Machines

SVM stands as a highly regarded supervised ML algorithm, demonstrating exceptional proficiency in classification and prediction tasks by capitalising on its widespread recognition in both regression and classification domains [41, 42]. Fig. 5 visually illustrates the extensive application of this technique across different tasks, including pattern recognition, data classification, and outlier detection [43].

Fig. 5. Classification process of SVM.

This description demonstrates how the algorithm utilises a hyperplane to distinguish between two classes within a dataset, making it an effective technique for classification problems. SVMs are well known for their capability to accurately categorise data by identifying the optimal separating hyperplane that maximises the margin between classes. Due to this capability, SVMs have been successfully applied in a wide range of fields, including image recognition, text classification, and bioinformatics.

Within the context of WDNs, SVM models have been employed to identify and predict water losses associated with pipeline leaks. By analysing key parameters such as water pressure, flow rate, temperature, and leakage indicators, the algorithm can determine the location of leaks and assess their severity with a high degree of accuracy. The application of SVM in this domain improves leak detection performance and supports better management of water distribution systems, ultimately enhancing operational efficiency and enabling more effective utilisation of resources within WDNs.

Training Phase:

Given a labelled training dataset with input features x_i and corresponding leak information y_i :

x_i : Input features of the i -th instance, including water pressure, flow rates, and temperature.

y_i : Leak information of the i -th instance, such as the presence or absence of a leak and its severity.

The goal is to identify the optimal hyperplane that efficiently distinguishes instances of leaks from non-leaks. This is accomplished by minimising Eq. (1) while adhering to the constraints outlined in Eq. (2), as presented below:

$$\text{Minimize: } \frac{1}{2} \|w\|^2 \quad (1)$$

$$\text{Subject to: } y_i(w \cdot x_i + b) \geq 1 \text{ for all } i \quad (2)$$

where, w represents the vector that is perpendicular to the hyperplane, b is the bias term, and $\|w\|$ is the Euclidean norm of the weight vector.

1) *Dual optimisation problem:* The optimisation problem can be reformulated using Lagrange multipliers α_i to solve the dual problem. This involves maximising Eq. (3) and subjecting it to Eq. (4), as shown below:

$$\text{Maximize: } \sum_i \alpha_i - \frac{1}{2} \sum_i \sum_j \alpha_i \alpha_j y_i y_j K(x_i, x_j) \quad (3)$$

$$\text{Subject to: } \sum_i \alpha_i y_i = 0 \text{ and } 0 \leq \alpha_i \leq C \text{ for all } i \quad (4)$$

where, α_i is the Lagrange multiplier associated with each training instance, y_i is the leak information, $K(x_i, x_j)$ is the kernel function that measures the similarity between two instances, and C is the regularisation parameter.

2) *Decision function and predictions:* Once the SVM model is trained, the decision function for predicting new instances can be represented as follows, utilising Eq. (5):

$$f(x) = \sum_i \alpha_i y_i K(x, x_i) + b \quad (5)$$

To predict the presence and severity of leaks in a new instance x , the sign and magnitude $f(x)$ can be represented by Eq. (6):

$$\text{If } f(x) > 0, \quad (6)$$

The instance is predicted to leak with a certain severity, which can be represented by Eq. (7):

$$\text{If } f(x) < 0, \quad (7)$$

The instance is predicted to be leak-free.

The magnitude $f(x)$ can indicate the severity of the leak.

These equations provide a mathematical representation of the SVM framework used to predict the location and severity of leaks within WDNs. By examining operational variables such as water pressure, flow rate, temperature, and leakage-related data, the SVM model learns underlying patterns and relationships that indicate the presence of leaks. The selection of appropriate kernel functions and parameter settings is adapted to the characteristics of the specific dataset and problem context. This flexibility allows the model to produce accurate and reliable predictions, ensuring that the leak

detection process is well-suited to the dynamic conditions of WDN systems.

E. Artificial Neural Network

ANNs are computational models designed based on the structure and operation of biological neural systems, particularly the human brain [44, 45]. They are extensively applied in ML and AI for tasks such as pattern recognition, classification, regression analysis, and decision-making processes [46, 47]. Fig. 6 illustrates the architecture of a three-layer ANN consisting of four input nodes, five neurons in the hidden layer, and two output nodes, demonstrating how information flows through the network during processing.

Fig. 6. Three-layer ANN architecture with input, hidden, and output layers.

In this study, ANNs were employed to detect and localise leaks within the pipeline infrastructure of WDNs. By leveraging the computational capabilities of ANNs, the proposed model was able to capture complex non-linear relationships present in the sensor data and extract relevant features required for accurate leak detection. Several key operational variables, including water pressure, flow rate, temperature, and leakage measurements, were analysed to identify patterns associated with potential pipeline faults.

The ability of ANNs to support continuous learning, real-time data processing, and resilience to noisy or incomplete data makes them particularly suitable for monitoring complex WDN environments. The primary purpose of the ANN-based model was to analyse the input data obtained from sensors and predict the occurrence of leaks while simultaneously estimating their locations within the distribution network.

The mathematical formulations used in the prediction and detection process are presented as follows:

1) *Weighted Sum Calculation (Single Neuron)* represented by Eq. (8):

$$z = \sum_{i=1}^n (w_i \cdot x_i) + b \quad (8)$$

where, z denotes the weighted sum, w_i and x_i are the weight and input corresponding to the i -th element, n is the number of inputs, and b is the bias term. The weighted sum is obtained by multiplying each input with its corresponding weight, summing these products, and adding the bias.

2) Activation Function (Non-linearity Introduction) can be represented by Eq. (9):

$$a = f(z) \quad (9)$$

where, a is the neuron output, z is the weighted sum, and f is the activation function applied to z . This function introduces non-linearities into the network, allowing it to model complex relationships in the data.

3) Forward Propagation (Layer-wise Output Computation) can be represented by Eq. (10):

$$a^l = f(W^{(l)} \cdot a^{(l-1)} + b^{(l)}) \quad (10)$$

where, $a^{(l)}$ represents the output of layer l , $a^{(l-1)}$ is the output of the preceding layer, $W^{(l)}$ and $b^{(l)}$ are the weights and bias vectors for layer l and f is applied element-wise.

4) Output Layer Calculation can be represented by Eq. (11):

$$h_\theta(x) = a^{(L)} \quad (11)$$

where, $h_\theta(x)$ represents the predicted output or hypothesis function for a given input x . $a^{(L)}$ represents the output of the final layer (output layer) of the ANN. This output is used to make predictions or compute the final result of the ANN model.

5) Thresholding (for leak detection) can be represented by Eq. (12).

$$\text{If } h_\theta(x) \geq \text{threshold}, \quad (12)$$

where, $h_\theta(x)$ represents the output of the leak detection model (such as an ANN) for input x , and the threshold is a predefined value. If the output is greater than or equal to the threshold, it indicates a detected leak.

The threshold value can be selected according to the required sensitivity and specificity of the leak detection system. In this study, a threshold of 0.5 was adopted for binary classification within the leak detection framework. This value was selected to maintain a balance between sensitivity and specificity and aligns with common practice in many machine learning classification models.

The equations presented describe the key mathematical operations used by the ANN to process sensor inputs and predict potential leaks. During the training phase, the network learns optimal values for the weights (W) and biases (b) by adjusting these parameters iteratively to minimise prediction errors. Through this optimisation process, the ANN improves

its ability to accurately detect and predict leaks within the Water Distribution Network.

F. SVM-ANN-GT Algorithm

The proposed SVM-ANN-GT algorithm combines the capabilities of SVM, ANN, and GT to improve the efficiency of sensor deployment along pipelines in WDNs. The main goal of this integrated approach is to optimise leak detection while simultaneously minimising energy consumption within the network. The operational steps of the proposed method are outlined in Algorithm 1.

Algorithm 1: Proposed SVM-ANN-GT algorithm

- 1) Graph Theory:
 1. Construct a connected graph $G(V, E)$ to model the Water Distribution Network (WDN), where V represents junctions and E represents pipes.
 2. Apply the dominating set technique to identify a subset $D \subseteq V$ that can monitor water flow and detect leaks.
 3. Perform optimal sensor placement by selecting nodes in D as optimal locations, minimising installation and maintenance costs while ensuring an effective monitoring system.
 - 2) SVM Training Phase:
 4. Initialise weight vector w and bias term b .
 5. **For each** instance (x, y) in the training dataset:
 6. Set input features $X = x$ and leak information $Y = y$.
 7. Perform optimisation:
 8. **For each** iteration:
Update w and b to minimise the objective function using Eq. (1) and Eq. (2). Store the optimised weight vector w and bias term b .
 9. SVM Decision Function and Predictions:
 10. Function predictLeak(x):
 11. Calculate the decision function $f(x) = w^T x + b$ using Eq. (5).
 12. **If** $f(x) \geq 0$:
 13. **Return** "Leak detected with severity " + $|f(x)|$
 14. **Else:**
 - a. **Return** "No leak detected"
 - 3) ANN for Leak Detection:
 - Set up an Artificial Neural Network (ANN) architecture with the input layer, hidden layers, and output layer.
 17. Initialise weights and biases for each neuron.
 18. **For each** epoch in training:
For each instance (x, y) in the training dataset:
 19. Set input features $X = x$ and leak information $Y = y$.
 20. **For each** layer in the network:
For each neuron in the layer:
Calculate the weighted sum z using Eq. (8).
Apply the activation function ϕ to z using Eq. (9).
Calculate the output of the final layer using Eq. (10).
Return the predicted output or hypothesis function using Eq. (11).
 21. Thresholding (for leak detection):
-

22. If the output of the leak detection model (e.g., SVM or ANN) for input x is greater than or equal to a predefined threshold:
23. **Return** "Leak detected"
- Else:**
- Return** "No leak detected"

IV. SIMULATION RESULTS

In this study, the proposed SVM-ANN-GT algorithm was implemented using the EPANET hydraulic simulation tool (version 2.2). The simulations were conducted on a computer running the Windows 11 operating system with 16 GB of RAM. EPANET 2.2 was configured with appropriate parameter settings to accurately model the behaviour of WDNs. The simulated network consists of 36 nodes, representing different junction points within the distribution system. The network configuration also includes one storage tank and one pump station. The storage tank is located at an elevation of 100 m, with a minimum water level of 20 m and a maximum level of 30 m, as illustrated in Fig. 7.

Fig. 7. EPANET simulation scenario.

The simulation environment was designed to represent a typical urban and peri-urban water distribution system in South Africa. The network incorporates pipelines constructed from ductile iron and PVC materials, with pipe diameters ranging from 100 mm to 300 mm. These pipes are assumed to be installed in heterogeneous soil conditions, including clay, sandy loam, and gravel, each of which influences the likelihood and characteristics of leak formation differently. In addition, environmental factors such as rainfall patterns, temperature fluctuations, and soil moisture levels were considered, as they can increase pipeline stress and the probability of leakage.

More challenging conditions, including high groundwater levels and expansive soil types, were also incorporated into the simulation environment to reflect realistic operational conditions. These variables were modelled within EPANET to

ensure that the performance evaluation of the SVM-ANN-GT algorithm reflects real-world pipeline behaviour and provides a realistic assessment of its leak detection capabilities.

EPANET is a widely recognised hydraulic modelling tool used for analysing WDNs. Despite its strong capabilities in hydraulic simulation, the software has certain limitations when applied to large-scale systems. EPANET operates using a single-threaded architecture, which means it does not utilise multi-core processors or GPU acceleration. As a result, simulations involving large or complex networks may require longer processing times and higher memory usage, particularly on systems with limited computational resources. Additionally, EPANET does not natively support real-time sensor data integration, parallel computing, or concurrent simulations, which can limit its applicability for dynamic monitoring environments or machine learning-driven analysis. To overcome these limitations, researchers frequently integrate EPANET with external platforms such as MATLAB or Python, although this integration increases system complexity and often requires advanced programming expertise.

Within the simulated network, the pump operates according to a pump curve labelled "Pump 1 Curve". The pump functions with an efficiency of 80% and a power rating of 50 kW. It is initially configured in the "On" state and operates at 100% of its nominal speed at the start of the simulation. The pipelines within the network each have a length of 500 m and a diameter of 300 mm. A roughness coefficient of 0.01 is assigned to represent the internal surface condition of the pipes. At the beginning of the simulation, all pipes are configured to remain fully open, allowing unrestricted water flow, and the initial flow rate is set to 0 L/s.

The simulation period spans 24 hours, with a time step of one hour for system calculations. Performance reports are generated at hourly intervals, allowing the monitoring of system behaviour throughout the simulation period. The flow change tolerance is set to 0.001 L/s, representing the allowable variation in flow rate during calculations, while the accuracy tolerance is also defined as 0.001 to maintain high precision in the simulation results.

System pressure is expressed in meters of head (m), and reporting intervals occur every 3600 seconds (one hour). The simulation applies the Hazen-Williams equation to estimate flow behaviour and head losses within the pipes. This empirical formula calculates flow rates and pressure losses based on hydraulic characteristics such as pipe diameter, roughness, and flow conditions.

Table I summarises the key simulation parameters used during the implementation of the proposed model.

TABLE I. SIMULATION PARAMETERS

Parameters	Values
Nodes	36
Tanks	1
Pump Stations	1
Tank Elevation	100 meters
Minimum Water Level	20 meters

pressure levels at these critical nodes can therefore be an effective strategy for mitigating water losses.

Furthermore, when compared with random sensor deployment, the proposed algorithm achieved better detection performance, accurately identifying high-risk leakage zones and enhancing the overall efficiency of leak monitoring and management within the network.

B. Correlation Matrix of System Variables

Fig. 10 displays a correlation matrix as a heatmap, showing the relationships between flow rate, pressure, temperature, and leak.

Fig. 10. Correlation matrix heatmap of flow rate, pressure, temperature, and leak variables.

Each cell in the matrix corresponds to the Pearson correlation coefficient calculated between a pair of variables, with values spanning from -0.2 to 1.0 . Warmer colour tones represent stronger positive relationships, whereas cooler tones indicate negative associations. Lighter colours suggest weak or negligible correlations between the variables. The diagonal entries show perfect correlations (1.00) since each variable is correlated with itself.

The results reveal several noteworthy relationships. For example, temperature shows a moderate positive association with leak (0.40) as well as with flow rate (0.37). Conversely, there is a weak negative relationship between flow rate and leak (-0.21). Meanwhile, pressure exhibits very little correlation with the other variables, indicating a limited direct relationship with the parameters considered in this analysis..

C. Accuracy of Leak Detection

Leak detection accuracy reflects the ability of a water leak detection system to correctly identify the presence of leaks and determine their exact locations within a WDN. Table III presents a comparative analysis of the proposed SVM-ANN-GT algorithm and a baseline approach based on random sensor deployment. The comparison focuses on important performance metrics, including the average detection distance and the total number of network hops, which are used to evaluate the efficiency and effectiveness of the detection process.

TABLE III. PERFORMANCE COMPARISON BETWEEN THE SVM-ANN-GT ALGORITHM AND RANDOM SENSOR DEPLOYMENT.

Parameters	SVM-ANN-GT algorithm	Random Deployment
Average distance (m)	190	340
Total Hops	18	28

The SVM-ANN-GT algorithm demonstrated improved performance compared with random sensor deployment for water leak detection when evaluated using two main metrics: average distance and total network hops. The average distance between sensors and detected leakage points was considerably smaller for the proposed method, measuring approximately 190 metres, whereas the random deployment approach produced an average distance of about 340 metres. This reduction indicates that the sensors selected by the SVM-ANN-GT algorithm are positioned closer to potential leak locations, leading to more effective monitoring and faster leak identification.

Similarly, the total number of hops, which represents the number of intermediate nodes required for data transmission, was also reduced using the proposed method. The SVM-ANN-GT algorithm required 18 hops, while the random deployment approach required 28 hops. Fewer hops facilitate faster communication between sensors and monitoring systems, thereby reducing delays in the detection process and improving overall system responsiveness.

Fig. 11. Accuracy vs. emitter coefficient.

Fig. 11 further illustrates that the SVM-ANN-GT model consistently achieves higher accuracy compared with individual SVM and ANN models across an emitter coefficient range from 0 to 0.5. The hybrid model attains accuracy values between 93% and 98%, with an average accuracy of approximately 96%. In comparison, the standalone SVM model achieves accuracy levels ranging from 89% to 95%, with an average of around 92%, while the ANN model records lower accuracy values between 82% and 89%, averaging about 85%. Although variations in the emitter coefficient do not significantly degrade performance, the hybrid SVM-ANN-GT

approach manages these variations more effectively than the individual machine learning models.

The improved performance of the proposed algorithm can largely be attributed to its strategic sensor placement mechanism, which is based on GT. In particular, the Minimum Dominating Set (MDS) algorithm is applied to identify optimal sensor locations within the network. This approach ensures comprehensive monitoring coverage while minimising the number of sensors required. By reducing redundancy and prioritising structurally important nodes within the WDN, the algorithm improves leak localisation accuracy, shortens detection time, and decreases the likelihood of false alarms. In contrast, the standalone SVM and ANN models lack this optimisation component, resulting in lower detection coverage, a higher number of sensors, and less efficient identification of leakage areas.

WDNs can vary considerably in scale, ranging from small municipal systems to extensive metropolitan infrastructures. When applied to larger networks, leak detection systems often require additional sensors, which can increase computational complexity and data processing requirements. The proposed SVM-ANN-GT framework addresses this challenge by using the MDS algorithm from graph theory to minimise the number of required sensors while still maintaining full network coverage. As a result, the system can scale to larger networks without proportional increases in cost or system complexity.

Furthermore, the hybrid design of the algorithm contributes to its scalability. Within the framework, graph theory manages network topology and sensor placement, SVM performs classification of leak-related patterns, and ANN captures complex non-linear relationships in the sensor data. This modular structure supports parallel processing and localised updates, allowing the system to adapt to network changes without requiring complete retraining of the model. Consequently, the algorithm remains both efficient and accurate as network size increases.

The computational cost associated with the SVM-ANN-GT algorithm increases sublinearly with the number of network nodes due to the optimisation mechanisms embedded in the model. In traditional leak detection systems, computational demands often increase linearly or even exponentially with network size, as each additional sensor contributes new data streams and decision paths. However, by applying the MDS algorithm to select a minimal set of monitoring nodes, the proposed approach reduces the number of sensors and the overall data volume required for analysis. This ensures that computational requirements remain manageable even as the network expands.

Simulation experiments conducted using EPANET further confirm the algorithm's capability to operate efficiently in larger WDNs without causing proportional increases in computational or hardware resource requirements.

WDNs are inherently dynamic systems, influenced by fluctuating water demand, seasonal variations, and ongoing infrastructure expansion. Leak detection algorithms must therefore be able to adapt to changing operating conditions while maintaining high levels of accuracy. The integration of

SVM and ANN models allows the proposed framework to incorporate multiple input variables, including pressure, flow rate, and temperature. In particular, the ANN component is effective at modelling non-linear relationships, enabling the system to adapt to varying network conditions. Additionally, the algorithm's real-time processing capabilities allow it to continuously learn from new data, which supports sustained performance over time.

Despite these advantages, the initial deployment of sensors across a large WDN may still require considerable resources. Although the proposed method optimises sensor placement, installing sensors throughout an extensive network can involve significant costs, particularly in areas with challenging terrain or densely built urban environments. The application of graph-theoretic optimisation reduces this burden by identifying only the most critical monitoring locations, thereby limiting unnecessary expenditure while maintaining effective leak detection coverage.

Another practical challenge encountered in real-world deployments involves noise and faults in sensor data, which can affect the accuracy of leak detection. The ANN component of the proposed algorithm is capable of handling noisy datasets, and the hybrid combination of SVM and ANN increases the system's resilience even when certain sensors malfunction.

In addition, sensor calibration drift may occur over time. Sensors that operate for extended periods without recalibration may produce inaccurate pressure, temperature, or flow measurements, which can degrade detection accuracy. Environmental factors such as heavy rainfall, frost, or extreme heat can also influence ground conditions, potentially affecting sensor stability and the reliability of collected data. These challenges highlight the need for regular sensor maintenance and adaptive algorithms to ensure the long-term reliability of the monitoring system.

Reducing false positive detections is also critical for maintaining operational efficiency, particularly in large networks. Systems based on random sensor placement often generate high numbers of false alarms, leading to unnecessary inspections and maintenance interventions. By strategically positioning sensors, the SVM-ANN-GT algorithm significantly reduces false positive rates and improves the reliability of leak detection, thereby supporting more efficient management of WDNs.

D. Recall

As shown in Fig. 12, recall, also referred to as sensitivity or the true positive rate, evaluates how well a model can correctly identify all relevant positive instances within a dataset. It is computed as the proportion of correctly predicted positive cases relative to the total number of actual positive samples. In this study, the SVM-ANN-GT model achieved the highest recall value of 90%, demonstrating a strong ability to detect the majority of true positive cases. The SVM model obtained a recall of 70%, while the ANN model recorded the lowest performance with a recall value of 60%. These findings emphasise the importance of recall in applications where it is crucial to identify as many true positive instances as possible, such as in leak detection, medical diagnosis, and fraud

detection. The high recall achieved by the SVM-ANN-GT model indicates that it is particularly suitable for scenarios that require strong detection sensitivity. In contrast, the lower recall observed in the ANN model suggests that additional improvements may be necessary to enhance its capability to correctly identify positive cases.

Fig. 12. Recall vs. time steps.

E. F1-Score

Fig. 13. F-score vs. time steps.

As illustrated in Fig. 13, the F1-score provides a comprehensive evaluation of model performance by integrating precision and recall into a single metric. This measure is particularly useful when analysing datasets with imbalanced class distributions, as it considers both the accuracy of positive predictions and the model's ability to detect actual positives. The F1-score is calculated as the harmonic mean of precision and recall, thereby assigning equal importance to both measures. In this evaluation, the SVM-ANN-GT hybrid model achieved the highest F1-score of 87.5%, indicating strong and well-balanced predictive performance. The SVM model

produced a moderate F1-score of 72.5%, whereas the ANN model demonstrated comparatively lower performance with a score of 62.5%. These results highlight the significance of the F1-score in evaluating classification models, particularly in scenarios where both precision and recall are essential, such as in leak detection and other critical monitoring systems.

The superior F1-score achieved by the SVM-ANN-GT model demonstrates its effectiveness as a reliable predictive framework across different application domains. Conversely, the relatively lower F1-score of the ANN model suggests opportunities for improvement, particularly in enhancing both its precision and recall capabilities to achieve better overall performance.

F. False Positive and False Negative Rates

The SVM-ANN-GT algorithm demonstrates strong accuracy in leak detection; however, its overall performance can also be evaluated through its false positive (FP) and false negative (FN) rates. Elevated FP rates may result in unnecessary maintenance activities and increased operational costs, while high FN rates can allow leaks to remain undetected, potentially leading to significant water loss and damage to infrastructure.

Simulation experiments conducted using EPANET produced relatively low error rates, with FP at 3% and FN at 4%, indicating that the proposed approach achieves a good balance between sensitivity and specificity. The incorporation of GT supports optimal sensor placement by ensuring that key areas of the network are effectively monitored, which helps reduce the occurrence of false negatives. At the same time, the hybrid SVM-ANN model improves classification performance, thereby lowering the number of false positives. These combined characteristics make the algorithm well-suited for applications where high detection accuracy and reliability are essential.

G. Balancing Sensitivity and Specificity

The SVM-ANN-GT algorithm is designed to effectively detect genuine leaks while minimising false alarms by integrating accurate classification, sensitivity to relevant features, and optimised sensor placement. First, the SVM component establishes optimal decision boundaries that distinguish between leak and non-leak conditions. By analysing historical patterns in variables such as pressure, flow rate, and temperature, the SVM model helps reduce false positives by clearly separating the two classes.

Second, the ANN component is capable of modelling complex non-linear relationships within sensor data, enabling the system to detect subtle anomalies that might otherwise remain unnoticed. This capability contributes to reducing false negatives by identifying leak-related patterns that simpler models may fail to capture.

Third, the GT component determines optimal sensor locations within the network by applying the Minimum Dominating Set (MDS) algorithm. This ensures that sensors are positioned at structurally important nodes, improving leak localisation accuracy and reducing misclassification that could arise from incomplete monitoring coverage.

By combining these complementary mechanisms, the proposed framework achieves a balanced detection strategy that is both highly sensitive to actual leak events and resistant to false alarms. This balance between precision and recall is reflected in the model's strong performance, as demonstrated by its F1-score of 87.5%.

V. CONCLUSION AND FUTURE WORK

This study introduced the SVM-ANN-GT algorithm, a hybrid machine learning approach that combines SVM, ANN, and GT to enhance leak detection and localisation in WDNs. The method improves monitoring performance by applying the MDS algorithm to optimise sensor placement, ensuring that sensors are positioned at critical nodes within the network. This optimisation strategy contributes to higher detection accuracy, fewer false alarms, and more efficient monitoring coverage.

Experimental results indicate that the proposed framework achieved a detection accuracy of 96%, a recall of 90%, and an F1-score of 87.5%, while maintaining false positive and false negative rates below 5%. These results outperform the performance of standalone SVM and ANN models, demonstrating the advantages of integrating machine learning techniques with graph-theoretic optimisation. The findings suggest that the proposed algorithm has strong potential to support efficient water resource management, reduce operational costs, and minimise energy consumption in WDN monitoring systems.

Despite these promising outcomes, the study has certain limitations. The evaluation was conducted primarily using controlled simulations in EPANET, which may not fully capture the complexities of real-world water distribution systems. Practical challenges such as real-time system operation, large-scale network processing, sensor failures, noisy measurements, and environmental influences were not fully represented in the simulation environment. Consequently, further investigation is required to assess the algorithm's robustness under realistic operating conditions.

Future research will therefore focus on evaluating the proposed approach in dynamic and non-ideal environments to better understand its reliability and adaptability. In practical implementations, the algorithm could be integrated with SCADA systems or IoT-based monitoring platforms, enabling scalable and cost-effective leak detection while supporting broader water conservation strategies. Additional research directions include incorporating advanced deep learning models, deploying the system in large-scale real-world WDNs, and examining its scalability, adaptability, and operational performance within complex infrastructure environments.

ACKNOWLEDGMENT

The authors extend their gratitude to the Tshwane University of Technology for providing financial support essential for the completion of this research. Additionally, the authors declare that no conflicts of interest are associated with the publication of this study.

Abstract—In this study, we investigate a parameterized method to evaluate the Zero Trust (ZT) security model integrated with blockchain networks under dynamic cyberattack conditions. Existing static trust-based security models fail to adapt to evolving adversarial behavior and dynamic attack conditions. To address these deficiencies, a discrete-time simulation model is constructed a discrete-time simulation model is developed to capture dynamic trust evolution, probabilistic attack patterns, and threshold-based access control within a financial network. In this regard, the proposed model considers significant parameters such as the probability of attack, trust decay rate, and access, isolation, and quarantine thresholds to evaluate their impact on network security performance. From the results, a significant correlation is noted between trust, mitigation, adversarial intensity, and policy parameter tuning. For instance, a strict threshold policy results in improved attack mitigation but compromises network participation, while a lenient approach results in improved network participation but compromises network security. The proposed framework is a more adaptive, scalable, and robust approach compared to conventional static approaches in addressing dynamic threats. From the results, optimal tuning of parameters is a fundamental aspect in achieving a balance in security enforcement in blockchain-based zero-trust networks.

Keywords—Zero trust; blockchain security; trust management; cyber-attack simulation; access control; financial networks

I. INTRODUCTION

The security of blockchain technology is ensured by its decentralized nature, cryptographic hashing, and consensus algorithms. However, there are still significant security risks in a distributed environment within financial institutions, and many attack vectors could create either financial/data-related issues, including 51% attacks, smart contract vulnerabilities, double-spending of digital assets, and breaches of privacy [1], [2]. With blockchain applications increasingly utilized beyond just cryptocurrency platforms to protect their integrity and security, there is an urgent need to implement security controls to mitigate risk to digital assets and to all blockchain-enabled

applications. As highlighted in this report, proposed security solutions provide mechanisms to improve blockchain security through enhanced consensus mechanisms, multi-signature wallets, cold storage, zero-knowledge proofs, and periodic security audits [3], [4].

The Ethereum DAO hack, along with Walmart's use of blockchain technology, demonstrates how significantly safe coding, monitoring, and community involvement address exploits within blockchain security [5]. AI-powered threat analysis, quantum-resistant cryptography, and decentralized identity management are improving blockchain security at an accelerating rate. ZT principles introduce new requirements requiring continuous verification in order to provide continuous authentication for every user, device, and transaction, removing implicit trust as a factor for those entities [6]. The principle of least privilege restricts access on a need-to-know basis, limiting the attack surface and any potential consequences of a security incident on the system. Moreover, adaptive isolation or quarantine mechanisms make it possible for the network to react in real time to suspicious activity, thus minimizing the damage potential of compromised hosts [7]. The increased use of blockchain technology in financial and distributed systems has resulted in a significant increase in the attack surface. This makes the process of enforcing security more complex and challenging under adaptive and dynamic attack scenarios. In this regard, the existing perimeter and static trust models are not effective in addressing the challenges, especially in scenarios where attackers are highly adaptive and dynamic. Therefore, there is a critical need to develop adaptive and data-driven security models that can address the challenges while ensuring transparency [8].

When combined, the ZT principles provide a very robust base for a security framework, which can be implemented in a distributed, highly interconnected environment. Modern cyber threats have become more dynamic and sophisticated. Today, they employ random, adaptive, and targeted attack strategies [9]. Random attack strategies exploit vulnerabilities in users, devices, and transactions without targeting them; they do so by

*Corresponding author.

using automated scanning to determine potential targets [10]. Adaptive attack strategies adapt their approach based on the operational performance of existing defenses. Targeted attack strategies identify and exploit high-value resources by way of reconnaissance and tailored malware delivery [11]. The increasing complexity and coordination of these types of attacks have made traditional, static defense systems ineffective. Therefore, adaptive defense approaches such as moving target and mimic are employed to dynamically change system configurations and limit attack success [12], [13].

Fig. 1. Zero-trust blockchain framework illustrating trust decay (ψ), attack probability (ϕ), and attack intensity governing node trust and triggering quarantine thresholds (λ , λ_1 , λ_2).

This research examines a financial network using a ZT Security Policy model for blockchain-enabled networks using a discrete-time simulation framework. Our model records trust evolution, probabilistic cyber-attacks, and threshold-based access control, which enables us to systematically vary our input parameters; i.e., attack probability (ϕ), trust decay rate (ψ), and access, isolation, and quarantine thresholds (λ , λ_1 , λ_2). This analysis quantitatively evaluates how ZT policy tuning influences security effectiveness and resilience against evolving threats. The blockchain security framework using a ZT policy is shown in Fig. 1. A complete mathematical formulation of evaluation parameters has been shown in the system model section. This work has dynamically controlled access permissions based on user activity and device conditions, thereby enhancing security against various forms of insider threats and compromised credentials [17]. Various provisions have been made to quarantine or isolate devices to prevent lateral movement within networks. There have also been provisions for quarantining or isolating devices to prevent lateral movement within networks. Implementing ZTS in distributed, cloud, and hybrid environments has consistently yielded a higher security posture, a smaller attack surface area, and a reduction in risk from both internal and external threats [18]. Traditional centralized architectures are subject to single points of failure data is at risk of being tampered with or accessed by an unauthorized party. Blockchain is a shared and permanent ledger that offers a consolidated solution for the

storage of all network and transaction data, including details of transactions, access logs, and events on the network [19].

Several studies have investigated the use of blockchain technology as a decentralized security layer for financial and distributed networks. This interest arises from its core characteristics, which include immutability, cryptographic security, decentralization, and consensus mechanisms. These features reinforce trust and improve the auditability of transactions [20], [21]. Access independence, decentralized identity management, and secure event logging are three examples of how blockchain technology improves accountability and resiliency against insider threats and data manipulation attacks. The majority of the work done in this area, however, is focused on static security policies and fixed trust assumptions (i.e., fixed levels of trust assigned to each user), with limited views into how dynamically changing levels of trust and changes in attack conditions affect the long-term operational behavior of a system [22].

Despite recent progress in zero-trust architectures and blockchain-based security systems, limited research builds on existing studies. Existing studies primarily rely on static trust assumptions and fail to capture the dynamic interplay among trust evolution, probabilistic cyberattacks, and adaptive countermeasure implementation. Most existing frameworks also fail to conduct a systematic analysis of how variations in trust decay, attack severity, and access control limits affect overall system performance. Furthermore, few efforts have explored how to combine blockchain-based auditability with dynamic ZT enforcement in one simulation model. These issues highlight the importance of developing a comprehensive, parameter-driven analysis to measure security-performance trade-offs under evolving threat conditions [23].

This study defines the key terms below to facilitate clarity and consistency throughout the entire study. The ZT Model defines a paradigm of security whereby no entity (e.g., user, device, or node) is by default trusted, and every access request must be continually verified. Evaluation parameters are those controllable variables used to perform the simulations, including the attack probability (ϕ), trust decay rate (ψ), and threshold values (λ , λ_1 , λ_2). Security metrics are those quantitative measures used to evaluate the performance of a system (e.g., average network trust, number of attacks detected, and number of nodes quarantined). Policy enforcement mechanisms comprise rule-based actions initiated upon reaching predefined trust thresholds, including access authorization, isolation, and quarantine. The definitions provided above are uniformly applied throughout this study to ensure uniformity of interpretation. A list of key terms used in this study is provided in Table I to enhance clarity in the terminology used throughout this study.

TABLE I. KEY TERMINOLOGY AND DEFINITIONS USED IN THE ZT BLOCKCHAIN SECURITY MODEL

Term	Definition
ZT Model	Continuous verification, no implicit trust
Evaluation Parameters	ϕ , ψ , λ , λ_1 , λ_2
Security Metrics	Trust, attacks, quarantines
Policy Enforcement	Access, isolation, quarantine

The major contribution of this study provides five outcomes:

- A simulation-based model of zero-trust security mechanisms in conjunction with an evaluation of a dynamic cyberattack environment and blockchain networks.
- A dynamic trust model that incorporates trust decay, the probabilistic nature of an attack, and threshold-based access controls.
- A systematic study of the sensitivity of overall performance to several factors or variables, including (but not limited to) the attack probability and trust decay rate; fixed thresholds for access control and quarantine; and the isolation thresholds.
- A blockchain-based mechanism for documenting security events, allowing for the processing of security event data into reports that are transparent, traceable, and auditable.
- Finally, this framework offers insight into the trade-off between security and performance so that tuning of parameters can enhance resilience and operational continuity.

The rest of this study has the following organization: Section II - Literature Review; Section III - System Modeling; Section IV - Simulation Design; Section V - Results & Analysis; and Section VI - Conclusion.

II. LITERATURE SURVEY

ZT Security is emerging as a key term in the realm of network security. It solves many of the limitations of traditional perimeter-based security methods. Forrester Research first introduced the concept of ZT Security in 2010, positing that ZTS gives no inherent trust whatsoever to any user, and thus all access requests must be continually authenticated [14], [15]. Some research studies indicate that strict enforcement of policy-based access control without the use of identity management, multi-factor authentication, and the health of trusted devices cannot be carried out consistently. Users and services should also have access only to those resources necessary for them to conduct their business (i.e., as per the principles of attribute-based access control and least privilege) [16].

There have been many innovations regarding dynamic trust-update models, enabling real-time changes in user access permissions based on user activity and device context, enhancing protection from insider attacks and compromised credentials [17]. There have also been provisions for quarantining or isolating devices to prevent lateral movement within networks. Implementing ZTS in distributed, cloud, and hybrid environments has consistently yielded a higher security posture, a smaller attack surface area, and a reduction in risk from both internal and external threats [18]. Traditional centralized architectures are subject to single points of failure data is at risk of being tampered with or accessed by an unauthorized party. Blockchain is a shared and permanent ledger that offers a consolidated solution for the storage of all

network and transaction data, including details of transactions, access logs, and events on the network [19].

Several studies have investigated the use of blockchain technology as a decentralized security layer for financial and distributed networks. This interest arises from its core characteristics, which include immutability, cryptographic security, decentralization, and consensus mechanisms. These features reinforce trust and improve the auditability of transactions [20], [21]. Access independence, decentralized identity management, and secure event logging are three examples of how blockchain technology improves accountability and resiliency against insider threats and data manipulation attacks. The majority of the work done in this area, however, is focused on static security policies and fixed trust assumptions (i.e., fixed levels of trust assigned to each user), with limited views into how dynamically changing levels of trust and changes in attack conditions affect the long-term operational behavior of a system [22], [23].

A. Limitations of Existing Approaches

Many existing evaluation methods have numerous limitations. The majority of ZT frameworks rely upon static or rule-based trust models and thus do not account for dynamic trust changes resulting from evolving attack behaviors. Blockchain methodologies focus primarily on audit capability but do not provide any means of quantitatively measuring the evolving nature of trust over time or adaptive evaluation capabilities of policy. Many studies do not take into account probabilistic modeling of attacks and offer only minor support for systematic evaluation based on security metrics or parameter sensitivity analysis. The framework proposed by this study aims to address these gaps by providing an integrated parameter-driven approach for modeling dynamic trust evolution (i.e., through probabilistic attacks) and enforcing policies based on thresholds. It operates within a single simulation environment to support full evaluation of the trade-offs between security and performance.

B. Comparative Analysis of Existing Frameworks

Currently, most ZT research is focused almost entirely on identity validation and a rules-based access control mechanism. There are little to no quantitative evaluations of presently available ZT mechanisms under dynamic condition variations. Some blockchain-based ZT applications (i.e., smart contracts) offer tangible auditability features. However, minor trust modeling is possible within these implementations. Machine learning-based ZT models currently provide anomaly detection capabilities but do not perform any type of sensitivity analysis on the identification parameters (i.e., ϕ , ψ , λ , λ_1 , λ_2). The framework described within this document expands upon existing models by introducing both a parameter-driven evaluation methodology involving the evolution of dynamic trust and probabilistic attack modeling and policy enforcement based on threshold criteria. The new framework is able to systematically vary the values of evaluation parameters and provide an analysis resulting from these evaluation parameters used in three dimensions and in accordance with well-defined security metrics. A detailed overview of each evaluation category is provided in Table II, which compares the methodologies of existing models to the advantages and

methodologies of the framework contained within this document.

TABLE II. METHODOLOGICAL COMPARISON OF ZT SECURITY EVALUATION MODELS

Aspect	Existing Approaches	Proposed Framework
Trust Modeling	Static / discrete	Dynamic continuous
Attack Modeling	Limited / absent	Probabilistic (ϕ -based)
Evaluation	Qualitative / isolated	Parameter-driven simulation
Sensitivity Analysis	Not considered	Systematic
Security Metrics	Limited	Trust, attacks, quarantine
Policy Enforcement	Rule-based	Threshold-based (λ , λ_1 , λ_2)

III. SYSTEM MODEL

The current study investigates a blockchain-aided, ZT-secured financial ecosystem through a discrete-time simulation model that accounts for trust development, cyber-attack behavior, and responsive adaptive security actions [24], [25]. The underlying representation of the ecosystem is depicted as a directed graph

$$G = (N, E),$$

where $N = \{1, 2, \dots, N\}$ is an entity of the network (e.g., user, device, service, and blockchain node) and E represents logical communications/access relationships between nodes. The discrete time steps of the system are denoted by the numerical sequence:

$$t = 1, 2, \dots, T.$$

At each discrete time interval t , node activity is monitored, trust scores for nodes are updated, node access decision records are maintained, and security incidents may occur within the system. Each node $i \in N$ has an associated dynamic trust score $T_i(t) \in [0, 1]$ that represents, at time t , the level of authorization granted to the node under ZT security principles.

The main evaluation parameters for the ZT Model are defined precisely to describe the mathematical foundations of the model. The attack probability ($\phi \in [0, 1]$) indicates the likelihood that a node will be subjected to a cyberattack during a time period. The trust decay rate ($\psi \in [0, 1]$) measures the level at which a node's trust declines because of behavioral deviations. The access threshold ($\lambda \in [0, 1]$) specifies the minimum amount of trust that must exist for a node to have the same access rights as usual. The two trust threshold values (λ_1 and λ_2) specify the thresholds for intermediate trust (λ_1) and critical trust (λ_2). These values can be defined in general terms as such: $0 \leq \lambda_2 < \lambda_1 < \lambda \leq 1$. All four parameters in total create trust growth, the impact of attacks on trust, and how policy will be enforced in the ZT Policy. Each nodal entity has a summation of baseline behavior patterns defined as Behavior Baseline (B_i). Deviations from how the node is expected to behave ($\Delta(t)$) at time t correspond to anomalous behaviors.

$$D_i(t) = |B_i(t) - B_{1i}| \quad (1)$$

Trust degradation resulting from behavioral drift occurs as follows:

$$T_i(t + 1) = T_i(t)e^{\psi \Delta_i(t)} \quad (2)$$

where $T_i(t)$ and $T_i(t + 1)$ denote the trust score of node i at time steps t and $t + 1$, respectively. Evaluation parameter interactions occur sequentially due to dependence on system dynamics. The probability of an attack ϕ determines whether a node is compromised at each time step and therefore introduces behavioral deviation $\Delta(t)$ that affects the trust update process. The trust degradation rate ψ affects the magnitude of the trust reduction. The trust score $T_i(t)$ after updating will be compared to predetermined threshold parameters (λ , λ_1 , λ_2) to determine policy enforcement actions such as continuing access, isolating, or quarantining. Accordingly, ϕ impacts the evolution of trust through the indirect effect of $\Delta(t)$, and ψ influences how sensitive trust will be to degradation. Therefore, the thresholds of λ -based limits determine the response of adaptive systems to each situation. Trust-based access control decisions are made based on the three thresholds for trust (T) as follows:

- Access to the system is granted where $T_i(t) \geq \lambda$.
- The node will be isolated from the system where $\lambda_1 \leq T_i(t) < \lambda$.
- The node will be quarantined from the system where $T_i(t) < \lambda_2$.

Whereas, $0 \leq \lambda_2 < \lambda_1 < \lambda \leq 1$. Using a tiered response system, it allows for adaptive mitigation without being dependent on complex game theory models. Every security event that occurs will be documented in blockchain format. Blockchain provides an immutable trust log or audit trail for every event occurring and is therefore useful for increased trust, accountability, and analysis of incidents that have occurred in the past, and for increasing trust in the future; this is documented in blockchain technology through the use of consensus mechanisms and cryptography that is simulated.

IV. SIMULATION DESIGN

The simulation framework evaluates how ZT security mechanisms work with blockchain-based node management via the systematic variation of key security parameters and the recording of their impact on network behavior over discrete time steps. A fixed number of nodes compose the blockchain network, and over discrete time steps, all three factors are updated in response to the simulation. All simulations were implemented and executed using MATLAB to model trust evolution, probabilistic attacks, and threshold-based mitigation mechanisms.

1) *Experimental setup*: The simulations were run in MATLAB (R2023a) in a controlled computing environment (Intel i5/i7 processor & 8-16 GB of RAM, Windows/Linux operating system). The blockchain layer was modelled without actually deploying on an external platform to create N nodes (usually $N = 50$) initialized with trust values $T_i(0) \in [0.8, 1.0]$. The simulation runs through a discrete time series of $t = 1$ through $T \approx 100-200$ in order to store the long-term behavior of events in the blockchain. At each time, attacks occur randomly with probability ϕ using Bernoulli trials, resulting in attack behavior changes and then driving trust decreases

through the decay model as they occur. There are multiple trials for each scenario (20-50 trials), and the averages are reported for statistical reliability. Parameters are selected as $\phi, \psi \in [0,1]$ and $\lambda, \lambda_1, \lambda_2 \in [0,1]$, subject to $0 \leq \lambda_2 < \lambda_1 < \lambda \leq 1$. No external datasets are used, as the study relies on a synthetic simulation framework.

The complete evaluation methodology has been built around a structured pipeline. Initially, the various inputs are established ($\phi, \psi, \lambda, \lambda_1, \lambda_2$) and represent both threat and policy conditions. Threat events, generated stochastically based on the ϕ value, may produce behavioral deviations for nodes. As part of the trust updating function, the value for ψ is used to manage the rate at which trust normally degrades. The resulting trust levels are then compared against pre-set thresholds by the policy enforcement module, which then activates appropriate action, for example, retaining access, isolating, and quarantining the node. The changes to trust levels and mitigation decisions will be recorded in the blockchain layer to ensure traceability and auditability. Lastly, the performance of the system will be measured using existing security metrics, which include average trust, average rate of detection of attacks, and average frequency of quarantine.

2) *Parameter variation*: The attack probability (ϕ) is selected over the range of $[0,1]$ to designate varying degrees of adversarial activities. In this study, ϕ will remain constant through each simulation run, thus isolating the impact of the other parameters on the output(s). The rate at which trust disintegrates (ψ), is based on a normalized model for updating trust (via an ODE equation). Due to the need for a sensitivity analysis, the variable ψ is held constant through each experiment (but is varied in small increments when trying to determine the level of aggressiveness or gradualness in which trust deteriorates), while the access and mitigation thresholds (λ, λ_1 , and λ_2) are varied independently on the range of $[0,1]$ to assess the sensitivity of trust regarding the relative security of access controls. To isolate the effect of the strictness of access controls, only the access threshold (λ) is varied independently, while keeping ψ, λ_1 , and λ_2 constant.

In this simulation loop, each time step produces a random attack, using ϕ to make nodes behave differently than normal. These behaviors then generate trust updates based on the decay rate (ψ), after which trust is the result of a threshold for determining access controls. Any nodes whose trust score is below the quarantine threshold (λ_2) will be isolated. One can rely on the blockchain record of Trust updates and attack mitigation actions for the validity and traceability of the system.

Several performance metrics are generated throughout the simulation, such as temporal changes in the average trust score, the number of detected attacks, and the total number of quarantined nodes. These metrics will help characterize the trust dynamics throughout the simulation as well as the activity related to attacks and mitigation efforts. The data will be used for conducting a sensitivity analysis on different parameter settings. To increase reproducibility, simulations are conducted in a manner where the initialization strategy is fixed, and the

pseudo-random number generator is set to reproduce the patterns of attack. The simulation environment is flexible to enable the parameters to be varied independently for sensitivity analysis.

V. RESULTS AND ANALYSIS

This section looks at how various aspects of ZT Security Parameters affect networks being attacked in the dynamic environment of cyberspace. The simulations are evaluated on trust evolution, the detection and mitigation of attacks, the sensitivity of the thresholds used to make those decisions, and how correlation between events is handled using a blockchain. The results presented in this section were produced by varying each parameter to isolate its individual impact. All multi-panel figures in this section are organized into sub-figures labeled (a), (b), and (c) to ensure clarity and consistency in the presentation and interpretation of simulation results.

A. Trust Evolution

As an example, by applying a fixed trust decay rate ($\psi = 0.05$) and assessing the effect on trust transitions across all three threshold values ($\lambda = 0.3, \lambda = 0.5$, and $\lambda = 0.7$) show that they progress in the same way. Thus, regardless of which of the above-mentioned thresholds was employed, the resulting trends of average trust decrease will be identical. This suggests that the dynamics of intrinsic trust are driven mainly by behavioral deviations and decay factors and not by policies relating to access control. Access threshold (λ) changes have an indirect effect on how many nodes are involved in the network. The average trust value for the network over time, based on different access limits, is depicted in Fig. 2. It has been observed that all the curves are declining, representing the decay of trust and attack effects. Higher levels of strictness ($\lambda = 0.7$) have a greater effect on the decline of the active node participation rate than lower levels of strictness ($\lambda = 0.3$).

Therefore, varying the value of λ changes the duration of time during which nodes can remain involved in the network while retaining an acceptable level of trust. When the access threshold is higher (i.e., higher λ), nodes will be more likely to become isolated or removed from the network as their trust scores change. These values also reduce the number of nodes participating in the network and accelerate the decline in the average trust of the network. Conversely, as the level of access/control decreases, there will be an increased ability of nodes to remain active and participate at a higher level of average trust. This demonstrates that the manner in which the access threshold is set impacts trust evolution indirectly through mitigation actions and not through a direct alteration of the trust update process.

The occurrence of attacks during simulation is driven entirely by the attack probability ($\phi = 0.01$). As demonstrated in Fig. 3, there is a relationship between the occurrence of attacks and their quarantine actions. As can be clearly seen, the earlier we set a higher threshold to control entry, the quicker and more often we take action to quarantine an attack. However, the overall distribution of events remains statistically unchanged because the attack probability is fixed. So, the time of attack profile data is the same statistically regardless of the access threshold on the model. This suggests that differences in

the parameters of the security policy have no impact on the production of attacks but have an impact on the system's response to detected attacks.

Fig. 2. (a) Temporal evolution of average network trust for different access thresholds ($\lambda = 0.3, 0.5, 0.7$), (b) corresponding variation in active node participation over time.

Fig. 3. (a) Attack occurrence over time, (b) corresponding quarantine response under different access threshold settings (λ), with fixed attack probability ($\phi = 0.01$).

B. Attack Detection and Mitigation

The most frequent use of quarantine by an access threshold is to produce an early and frequent quarantine action after the trust level exceeds the defined isolation/quarantine limits. In fact, the average number of quarantined nodes will increase significantly faster under a stricter policy than under a relaxed policy.

On the other hand, when the access threshold is lower, the average time to make an isolation decision is extended, and the average number of quarantined nodes is reduced along with the average number of nodes participating in the network. The findings suggest that ZT enforcement regulates the strength of the system and its response to mitigation actions, whereas adversarial strength determines how often an attack is conducted.

C. Threshold Sensitivity

The access control policy can be shown as being sensitive to its access control policy strictness threshold, λ , through variations of λ while holding constant λ_1 (isolation threshold) and λ_2 (quarantine threshold).

Fig. 4. (a) Sensitivity of attack occurrence to threshold variations, (b) corresponding isolation and quarantine response illustrating the impact of access threshold (λ).

The access threshold (λ) provides a measure of the sensitivity of the system, as shown in Fig. 4. The figure illustrates the system's response to varying threshold levels. While lower levels of the threshold prolong the node's active state, higher levels of the threshold lead to faster mitigation action. When λ is a low number, there will still be an increased number of trusted devices/nodes within the network that will be left connected to other users, resulting in fewer devices/nodes from prematurely entering isolation. Thus, although having high tolerance to device/node trust

degradation may additionally leave malicious/suspicious devices/nodes around longer, potentially allowing them to be subjected to additional future attacks, having λ as a high number results in higher levels of security responsiveness due to earlier initiation of isolation/quarantine actions, given the situation of trust degradation. This may limit the extent of damage from malicious or suspicious activities, but may result in increased levels of disruption to the network due to isolating nodes that have not yet been fully compromised.

Therefore, this data supports that the improper selection of one or more threshold values can either delay the mitigation of excessive amounts of network fragmentation. To balance between enforcing security measures and providing a workable operational environment, access to and isolation/quarantining. All require accurate calibration of their respective threshold values. Despite this, the attack and mitigation behavior is connected to Fig. 3 and 4. Fig. 3 specifically focuses on the temporal attack and response, whereas Fig. 4 focuses on the sensitivity of mitigation behavior to changes in the threshold parameters.

D. Network Size Scalability Analysis

To assess the scalability of the designed ZT blockchain security model, simulations were run to simulate three distinct network sizes ($N = 20, 50$, and 100). Attack probability (ϕ) and trust decay rate (ψ) were held constant throughout to evaluate if trust dynamic models and the response to mitigation performed consistently as additional nodes joined the network. Fig. 5a displays the average network trust over time for all network sizes evaluated.

Fig. 5. (a) Average network trust over time for different network sizes ($N = 20, 50, 100$), (b) number of detected attacks, (c) quarantine response, illustrating scalability behavior under fixed attack probability ($\phi = 0.01$).

Even though larger networks experienced more attacks than smaller ones, there were still consistent declines in trust across

all configurations, indicating that trust dynamics remain stable as the number of nodes in a network scales. Fig. 5b and 5c illustrate the count of attack occurrences and quarantine response for all three network sizes evaluated within this experiment. As would be expected, larger networks produced higher counts of detected attacks and quarantined nodes. Though their proportional responses remained stable due to the implementations of threshold-based ZT policies within this framework. Thus, it can be concluded that the proposed framework scales effectively while maintaining both trust stability and mitigation efficiency.

E. Blockchain Event Logging and Correlation

During the simulation, all security events are temporally related and recorded on a conceptual blockchain logging layer. The analysis of the event streams has shown a strong correlation between the increase in attacks, the decrease in trust, and the initiation of quarantine actions due to threshold triggers. Therefore, these correlations demonstrate how blockchain logging can support post-incident audits by providing a transparent record of security-related decisions that cannot be altered. Moreover, these findings also show that blockchain log events provide a structured means for assessing the effectiveness of ZT policy implementation because these records provide the ability to correlate network behavior to specific parameter values. This traceability allows system administrators to perform adaptive security governance by using historical threat-pattern information and mitigation results information to adjust their trust decay rates and thresholds. These outcomes show that blockchain logging provides a reliable method for maintaining a trust ledger that is complementary to enforcing a ZT model through increased accountability, auditability, and the ability to make informed changes to policy.

VI. DISCUSSION

The results of the simulation demonstrate that the overall effect of the intensity of attacks and the dynamic nature of trust determines the enforcement of security controls within the networks of blockchains with ZT Architectures. As the attack probability increases, behavioral deviations increase; also, as the rate at which trust decays increases, so too does the loss of credibility result in earlier threshold crossings and more isolated actions. These parameters are not simply independent of one another; they interact with one another to modify the structure of long-term trust stability and affect how fast parameters contribute to the transition of the system from a state of normal operations to a state of defensive enforcement. These results affirm that trust evolution in ZT Architecture is highly sensitive to both the pressures from adversaries and the tuning of policies. The relationship between parameter settings and their impact on trust dynamics and mitigation behavior is summarized in Table III.

The research provides insight into how an organization needs to manage its computer network by balancing secure access and the use of that network. A conservative approach will quickly identify questionable nodes and therefore prevent them from being able to execute further attacks on a computer network. This allows an organization to prevent a larger attack

from occurring while at the same time building greater resilience against attacker attempts.

TABLE III. EFFECT OF ZT PARAMETER SETTINGS ON TRUST DYNAMICS AND QUARANTINE BEHAVIOR IN BLOCKCHAIN NETWORKS

Parameter Setting	Observed Trust Behavior	Quarantine Response	Security-Performance Trade-off
High attack probability ($\phi \uparrow$)	Rapid trust degradation; lower average trust	Frequent and early quarantines	Improved attack containment but reduced network stability
Aggressive trust decay ($\psi \uparrow$)	Accelerated trust loss under moderate attacks	Increased isolation of nodes	Fast anomaly response but higher false-positive risk
Strict access threshold ($\lambda \uparrow$)	Reduced effective trust participation	Sharp rise in quarantined nodes	Strong security enforcement with higher network disruption
Lenient access threshold ($\lambda \downarrow$)	Slower trust decline; higher participation	Fewer quarantines	Better usability but increased attack exposure
Low quarantine threshold ($\lambda_2 \downarrow$)	Early isolation of marginal nodes	Sustained quarantine growth	Maximized resilience with reduced adaptability
Balanced thresholds ($\lambda, \lambda_1, \lambda_2$ optimized)	Stable trust evolution	Controlled quarantine escalation	Optimal balance between security and continuity

However, implementing these stricter levels of enforcement creates the risk of legitimate users being denied access to the network, thus creating a disconnected computer network. Conversely, an organization that employs a lenient method for determining whether nodes may participate in the computer network will allow bad nodes to remain longer or execute additional attacks on other nodes. Organizations that operate in financial environments, where the continuity of service and the reliability of transaction processing are extremely critical, must balance these competing attributes when creating a trust-based policy. Unlike earlier studies, which have primarily focused on either interaction between ZT security mechanisms or blockchain technologies, this analysis presents a holistic framework for modeling these interactions in dynamic threat environments through the use of parameter-driven approaches. Specifically, it integrates continuous degradation of trust, probabilistic modeling of attacks, and threshold-based mechanisms for mitigating attacks into a blockchain-auditable context to generate a comprehensive understanding of how system-level dynamics related to adaptive mechanisms can influence long-term network resilience.

It is important to note some of the limitations of the proposed framework in relation to the strengths. The research applied a simulation-based model that may not fully represent the complexities of blockchain networks or the nature of dynamic cyberattacks. Fixed attack behavior (as measured with a single probabilistic parameter, ϕ) limits the consideration of many types of highly adaptive adversaries. Additionally, the trust evolution model is based on fixed (defined) decay rates and threshold values between two connected entities. The heterogeneity of the nodes' behavior is not taken into account while presenting the model. Also, the capabilities, latencies, or

constraints of the nodes are not taken into consideration. Lastly, the blockchain layer is conceptually implemented without considering any computational overhead. Consequently, while the model offers insight into how decentralized models of trust evolve, there will need to be further validation of this model through real-world (or scalable) implementations. Future efforts will focus on validating the proposed model with adaptive attack models, heterogeneous networking environments, and considerations of practical implementations of blockchain technology.

The findings reveal that optimal deployments of blockchain employing ZT design principles should avoid extreme configurations of parameters. Appropriately tuning both trust decay and access thresholds will provide control over the escalation of quarantines while also maintaining a minimum threshold of participation from users. The summarized relationship of parameters to their expected behavior assists organizations in establishing configurations of ZT policies for financial networks that utilize blockchain technology. These results provided a framework for continued resilient operation in an ever-changing environment of adversarial activity.

VII. CONCLUSION

This study presented a simulated evaluation of ZT security policies in conjunction with blockchain technology for networks within the financial services sector in dynamic cyberattacks that involve probabilistically modeled behavior of attacks, diminishing trust, and the employment of threshold-based access control. The framework established in this research models the relationships between the key parameters of attack probability (ϕ), trust decay rate (ψ), and access, isolate, and quarantine thresholds ($\lambda, \lambda_1, \lambda_2$) as they apply to the effects on trust evolution, mitigating factors, and network resilience. Additionally, the degree of sensitivity of these parameters has an important role in determining the level of security achieved through ZT-based blockchain solutions. When attack probabilities and the decay of trust are high, continued erosion of trust and a high frequency of quarantines occur. Lower participation in the network can be achieved by using higher levels of access and isolation. When a less strict threshold is used, connections are kept intact, but the attack impact is extended. This research demonstrates that trusting establishment and stability of operations in distributed financial networks depend on careful tuning of trust settings. The model proposed integrates dynamic trust assessments and blockchain-based auditability to enhance transparency and make it possible to analyze the enforcement of security by means of logging events that cannot be altered. The relationship between attack events, trust loss, and threshold-triggered actions to mitigate attacks is an example of how records on the blockchain may assist with post-incident analysis and evaluation of security policies. Future extensions of this work will examine the implementation of quantum-safe technologies, including quantum key distribution and quantum random number generators, as well as an improved adaptive attack model, to more thoroughly test the ZT blockchain environment against next-generation cyber threats. The framework identified is lightweight, extensible, and can be used to comprehensively benchmark ZT blockchain-enabled security policy.

Thread-Sensitive Shared Instruction Cache Analysis for Precise WCET Estimation of Multithreaded Programs

Naveeta Rani, P Padma Priya Dharishini, PVR Murthy

Department of Computer Science and Engineering, MS Ramaiah University of Applied Sciences, Bangalore, India

Abstract—Real-time systems require strict adherence to task deadlines, making Worst-Case Execution Time (WCET) analysis essential. WCET estimation typically involves static analysis of instructions in a program, making use of models of hardware and architectural units such as shared instruction caches that are as precise as possible. Shared instruction caches pose a challenge because cache behaviour depends on access history and inter-core interference in multicore systems. Existing approaches do not fully exploit thread lifecycle and synchronization semantics when modeling shared instruction cache behavior. In contrast, the proposed TP-WCIP model explicitly incorporates these semantics to eliminate infeasible interference scenarios. By confining interference placement to feasible concurrent execution regions, it achieves more precise WCET estimation. Worst-case latency, due to shared instruction cache accesses in the presence of inter-core interferences, is estimated for each thread in a multithreaded program with a focus on start, join, and synchronization (wait and notify) primitives. A highly precise model, termed Threaded Program Worst-Case Interference Placement (TP-WCIP), is proposed for the static analysis of multithreaded programs to estimate Worst-Case Execution Time (WCET). The proposed model is evaluated in comparison with Cache Block Conflict Number (CCN), Worst-Case Interference Placement (WCIP), and Interference Partitioning (IP). TP-WCIP exploits *concurrency* and *happens-before* relationships induced by start, join, and synchronization primitives to accurately characterize inter-core interferences. The TP-WCIP model for shared instruction cache analysis is validated using benchmark programs and compared against approaches reported in the literature. It is established both theoretically and experimentally that the proposed model TP-WCIP leads to more precise worst-case latency measurements. Result analysis of benchmark programs Papabench and extended Mälardalen benchmarks shows that the TP-WCIP model reduces interferences by up to 27% over IP, 53% over WCIP, and 75% over CCN, while preserving up to 16% more Shared Instruction Cache Hits than IP, 48% than WCIP, and 84% than CCN, thereby delivering more precise static WCET estimates for multi-threaded programs on multicore architectures.

Keywords—Synchronization; concurrency; multicore systems; multithreaded program; shared instruction cache analysis; worst-case execution time

I. INTRODUCTION

Real-time systems must satisfy strict timing constraints, ensuring that every task completes within its deadline. Missing a deadline can lead to severe consequences, particularly in safety-critical domains. To guarantee deadline adherence under all circumstances, static analysis [1] is employed to verify

compliance with timing requirements, even in the worst case. As a result, analyzing the Worst-Case Execution Time (WCET) of each task becomes indispensable. Over time, a well-defined framework for WCET estimation has been established [2]. The process typically begins by constructing the program's control-flow graph (CFG) from its binary executable, followed by determining loop bounds. Next, micro-architectural analysis is carried out to account for the effects of hardware components, such as caches and pipelines, on the execution time of individual instructions. The worst-case execution path is then identified to determine the program's WCET. A central objective of WCET research is to achieve high precision by minimizing the gap between the estimated WCET and the actual WCET. To attain this level of precision, accurate modeling of hardware resources, including memory hierarchy, processor pipeline, shared buses, and other shared resources, is essential.

Cache memory plays a vital role in bridging the performance gap between high-speed processors and comparatively slower main memory. In multicore architectures, caches are often organized into multiple levels, with the last-level cache typically shared among all cores. Given the substantial impact of caches on execution time, the precision of cache analysis fundamentally determines the accuracy of the estimated WCET. Accurate prediction of cache behavior is therefore crucial for precise WCET estimation. However, this task is inherently complex, as cache behavior depends heavily on access history. The problem becomes even more challenging due to inter-core interference, where one core may evict the instructions or data of another at any time. Such unpredictable access patterns in multicore systems often lead to overestimation of WCET.

Although both instruction and data caches influence WCET, their behavior differs significantly. Instruction caches exhibit structured and predictable access patterns driven by control flow, whereas data caches depend heavily on input-dependent memory accesses, making their static analysis less precise. Instruction cache behavior is therefore largely deterministic, while data cache behavior is inherently more indeterministic due to imprecise address analysis and the possibility of a single reference accessing multiple memory blocks. Motivated by this distinction, this study focuses on statically modeling shared instruction cache behavior.

A straightforward approach proposed in the literature is the Cache Block Conflict Number (CCN) method [3], which assumes that interferences from other cores occur continuously at all program points. Although simple, this assumption is overly

pessimistic, as in reality, a single interference can cause at most one additional cache miss. Interference Partitioning (IP)-based techniques [4, 5] enhance the analysis by incorporating the knowledge of the happens-before relationship introduced due to synchronization primitives `wait()` and `notify()`. Nevertheless, within each partition, they continue to pessimistically assume that interferences may occur at every program point, indicating the need for further refinement in modeling multicore shared instruction cache. The Worst-Case Interference Placement (WCIP) technique was introduced in [6], formulated as an Integer Linear Programming (ILP) problem. However, ILP-based WCIP suffers from poor scalability when applied to large applications. To address this issue, algorithmic approximations of WCIP [7, 8] were later proposed. These algorithms strategically place interferences from other cores such that instruction accesses corresponding to shared instruction cache hits are prioritized when they are already near eviction. The primary limitation of the WCIP algorithm is that it assumes independent threads execute on separate cores without any dependencies. In reality, multi-threaded programs rarely behave this way. They often contain inter-thread dependencies. In multithreaded programs, certain regions of different threads can never execute concurrently due to happens-before relationships induced by thread lifecycle operations and synchronization primitives such as `start()`, `join()`, `wait()`, and `notify()`. For example, in Fig. 1, the instructions in thread T1 from `begin(T1)` to `start(T2)` can never execute in parallel with any instructions of thread T2. Therefore, considering interference from thread T2 on shared instruction cache (SIC) accesses within the region T1[`begin(T1)` to `start(T2)`] leads to false interference scenarios that cannot occur during actual program execution. The WCIP algorithm does not consider concurrency or happens-before relationships, which can otherwise be exploited to determine a more precise set of potential interferences during the execution of the thread under analysis. To address this limitation, this study proposes a novel approach called Threaded Program Worst-Case Interference Placement (TP-WCIP). TP-WCIP integrates concurrency and happens-before analysis by incorporating thread lifecycle operations (`start()` and `join()`) and synchronization primitives (`wait()` and `notify()`) to identify sequential, concurrent, and competing regions, as well as the resulting concurrent and competing partitions in multithreaded programs. By leveraging this information, TP-WCIP enables a more accurate computation of the interference budget [6–8] by accounting for potential evictions of SIC hits.

Fig. 1. Illustration of valid and false interferences.

The key research gaps addressed in this work are as follows:

- 1) Construction of a precise set of interferences from competing threads or cores for shared instruction cache accesses in a thread by extracting precise concurrency information from the Message Sequence Chart (MSC) representation of a multithreaded program with calls to `start()`, `join()`, `wait()`, and `notify()`.
- 2) Design, verification, and experimental validation of the TP-WCIP model, which uses extracted concurrency information and interference sets to estimate additional shared instruction cache (SIC) misses caused by inter-thread interference for WCET computation of multithreaded programs.

To evaluate TP-WCIP against existing approaches—Interference Partitioning (IP), Worst-Case Interference Placement (WCIP), and Cache Block Conflict Number (CCN), on real-world applications, namely *Papabench* and *extended Mälardalen*, are considered to execute on 4-cores. Experimental results show that TP-WCIP model significantly improves interference analysis accuracy by considering only valid inter-thread interferences. Specifically, it accounts for about 73% of the interferences identified by IP, 47% of those identified by WCIP, and 25% of those identified by CCN, indicating that the IP, WCIP, and CCN approaches include a substantial number of invalid interferences. These correspond to false positives of up to 27%, 53%, and 75%, respectively, in the estimation of worst-case latency for shared instruction cache (SIC) accesses. In addition, TP-WCIP preserves more shared instruction cache hits (SICs), retaining up to 16% more than IP, 48% more than WCIP, and 84% more than CCN. By reducing false interference assumptions and maintaining more valid cache hits, TP-WCIP enables more precise static WCET estimation for multithreaded programs on multicore architectures.

The rest of this study is structured as follows. Section II presents the related work. Section III introduces the relevant terminology and key concepts. Section IV presents the design of the TP-WCIP algorithm and provides a formal proof of its safety and correctness. Section V reports the experimental results. Finally, Section VI concludes the study.

II. RELATED WORK

In the literature, a variety of hardware modeling techniques have been investigated. Among hardware resources, the shared bus is one of the critical resources, as it introduces significant unpredictability in timing analysis. Extensive research has therefore been devoted to the analysis of shared bus behavior [9]. Cache modeling techniques have also received considerable attention. One notable approach is the must and may analysis [10], which determines whether data is guaranteed or potentially present in the cache. Another line of research applies abstract interpretation to approximate concrete cache states, focusing on the maximal and minimal ages of cache blocks [11]. The work in [12] surveys key challenges and static analysis methods for independent programs under different cache configurations, as well as existing tools that implement static cache analysis techniques. The work in [13] introduces a framework that integrates abstract interpretation with program verification,

enabling a wide range of cache analyses spanning both single-core and multicore architectures.

An integrated timing analysis was proposed that accounts for the combined timing effects of the shared bus and shared cache in [14]. This work also represents the first analysis of cache-related preemption delay in multi-level cache hierarchies, with a focus on non-inclusive caches. Subsequently, cache analysis techniques have been extended to multi-level inclusive caches [15]. Studies such as [16, 17] analyze direct-mapped shared instruction caches in multicore systems, while [3] introduces a technique for set-associative shared caches by estimating the number of potentially interfering cache blocks, defined as the cache block conflict number (CCN). In this context, a cache access is classified as a hit if the number of conflicting blocks is less than the associativity minus the block's age. The Worst-Case Interference Placement (WCIP) approach [6-8] refines interference modeling further. Specifically, when core 1 accesses the shared instruction cache, interferences from other cores that have already been accounted for are excluded from further consideration. This is achieved through the concept of an interference budget, where each interference is deducted from the budget once considered, ensuring that it is not double-counted. More recently, [18] incorporates timing information to establish tighter bounds on worst-case interference, while also classifying individual memory accesses as either guaranteed cache hits or potential cache misses. Existing literature largely addresses cache analysis in non-preemptive scheduling contexts, whereas [19] models interference in a preemptive system to categorize accesses as cache hits or possible misses. In [20], a fine-grained shared-cache interference analysis uses path-based basic-block execution times to model memory-access lifecycles and exclude infeasible interferences.

Building on these approaches, integrating thread lifecycle semantics enables more precise interference placement. This is the primary challenge addressed in this study.

III. KEY CONCEPTS AND TERMINOLOGIES

This section outlines the essential definitions and concepts necessary to understand the TP-WCIP approach.

In Fig. 2, the WCET of the thread T_1 is computed. Therefore, thread T_1 is referred to as the reference thread. Threads T_1 , T_2 , T_3 , and T_4 access the shared instruction cache. Therefore, T_2 , T_3 , and T_4 are competing threads relative to thread T_1 .

1) *Interference*: A Shared Instruction Cache (SIC) access issued by a competing thread is termed an interference [6-8] with the instruction in the reference thread.

2) *Sequential region*: A sequential region denotes a contiguous set of instructions in the reference thread during which no other threads are executing concurrently. It captures intervals of sequential execution within an otherwise multithreaded program. For example, in Fig. 2, regions $T_1[\text{begin}(T_1) : \text{start}(T_2)]$, $T_1[\text{join}(T_2) : \text{start}(T_4)]$ and $T_1[\text{join}(T_4) : \text{end}(T_1)]$ are the sequential regions of threads T_1 and are denoted as SR_{11} , SR_{12} and SR_{13} respectively.

3) *Concurrent region*: A concurrent region refers to the instructions between the corresponding start() and join() calls of a reference thread, during which multiple threads execute

simultaneously. This region captures the period of concurrent execution within a multithreaded program. For example, in Fig. 2, regions $T_1(\text{start}(T_2) : \text{join}(T_2))$, $T_1(\text{start}(T_4) : \text{join}(T_4))$ are the concurrent regions of reference thread T_1 , denoted as R_{11} and R_{12} respectively.

4) *Competing region*: A competing region refers to the set of instructions in competing threads that may execute in parallel with the instructions of a concurrent region in a reference thread. These regions represent portions of competing threads that execute simultaneously, potentially accessing SIC during concurrent execution. For example, in Fig. 2, regions $T_2(\text{begin}(T_2) : \text{end}(T_2))$, $T_3(\text{begin}(T_3) : \text{end}(T_3))$ are the competing regions of concurrent region CR_{11} , denoted as CR_{21} and CR_{31} and region $T_4(\text{begin}(T_4) : \text{end}(T_4))$ is the competing region of CR_{12} and denoted as CR_{41} .

In real multithreaded programs, synchronization is not limited to the start() and join() primitives. The wait() and notify() synchronization primitives also induce happens-before relationships. These relationships can be leveraged to further minimize concurrent executions. If concurrent and competing regions contain matching pairs of wait() and notify(), these constructs can be used to further partition execution into concurrent and competing partitions.

5) *Concurrent partitions*: A concurrent partition is a fragment of a concurrent region that interacts with other parallel fragments from competing regions. The concurrent region R_{11} is partitioned in two concurrent partitions, $P_{111} : T_1(\text{start}(T_2) : \text{notify}(T_2))$ and $P_{112} : T_1[\text{notify}(T_2) : \text{join}(T_2)]$ while concurrent region R_{12} , is partitioned in two concurrent partitions $P_{121} : (\text{start}(T_4) : \text{wait}(T_4))$, and $P_{122} : (\text{wait}(T_4) : \text{join}(T_4))$, based on the synchronization primitives.

6) *Competing partitions*: A partition p denotes a parallel fragment whose corresponding fragments in interacting or competing regions are identified through the method `Competing_Partitions(p)`. Concurrent partition P_{111} may execute in parallel to CP_{211} and CP_{311} , but can never execute in parallel to CP_{212} since wait() always happens-before notify(). Similarly, Concurrent partition P_{112} may execute in parallel to CP_{212} but can never execute in parallel to CP_{211} . Therefore, CP_{211} and CP_{311} are competing partitions of P_{111} , and CP_{212} is a competing partition of P_{112} .

7) *Concurrency and interferences in threads*: A multithreaded program P say consists of threads T_1 , T_2 , T_3 , and T_4 . The corresponding Message Sequence Chart [21] is shown in Fig. 2. Assume that T_1 , T_2 , T_3 , and T_4 run on core₁, core₂, core₃, and core₄, respectively. $T_1(\text{start}(T_2) : \text{join}(T_2)) \parallel T_2 \parallel T_3$. SIC accesses in $T_1[\text{begin}(T_1) : \text{start}(T_2)]$ are not subject to interferences, whereas SIC accesses in $T_1(\text{start}(T_2) : \text{join}(T_2))$ are subject to SIC interferences from thread T_2 and T_3 . The SIC accesses $T_1(\text{join}(T_4) : \text{end}(T_1))$ again, not subject to any interferences.

Ideally, a worst-case interference placement (WCIP) algorithm should be aware of both the sequential and concurrent execution regions of the reference thread in a multithreaded program, as well as the competing regions of other concurrently

executing threads. Such awareness allows the algorithm to model interferences only within concurrent regions while excluding them from sequential regions, thereby enabling more precise computation of the worst-case execution time (WCET) of multithreaded programs. However, when a WCIP algorithm does not accurately identify concurrent regions, as in the approaches presented in [6–8], imprecision arises in mapping interferences from competing threads to shared instruction cache (SIC) accesses of the reference thread, as illustrated in Fig. 1.

To analyze and infer information about concurrent regions, competing regions, concurrent partitions, and competing partitions, a Message Sequence Chart (MSC) is used to represent the multithreaded program. In this representation, the program—consisting of the main (reference) thread and competing threads—is modeled as an MSC [21]. The start(), join(), wait(), and notify() method calls are explicitly shown in the MSC to illustrate concurrency. These calls represent thread creation, synchronization, and termination, thereby revealing the concurrent structure of the program. Each corresponding pair of start() and join() calls defines concurrent regions across the involved threads, as illustrated in Fig. 2. The sequential, concurrent, and competing regions of the multithreaded program with respect to the reference thread T_1 in Fig. 2 are summarized in Table I.

IV. DESIGN

The computation of the worst-case execution time (WCET) of multithreaded programs using Integer Linear Programming (ILP) is an NP-hard problem [6, 8]. Algorithm-based approaches estimate the WCET of multithreaded programs by introducing simplifying assumptions, such as assuming that all shared instruction cache (SIC) hits occur along the worst-case execution path. Compared with ILP-based approaches, algorithm-based methods compute WCET more efficiently while maintaining comparable precision. However, the methods reported in the literature do not sufficiently consider the properties specific to multithreaded programs. To overcome this limitation, this section presents a novel algorithm for WCET computation that explicitly incorporates multithreading-specific properties to reduce imprecision.

A. Threaded Program Worst Case Interference Placement

Fig. 3 presents an overview of the TP-WCIP approach. The input to the TP-WCIP consists of a multithreaded program together with information identifying the reference thread. From the source code of the multithreaded program, the Control Flow Graph (CFG) of the reference thread is constructed. Subsequently, a must analysis for multi-level caches is performed on the CFG using abstract-interpretation-based techniques [11]. The must analysis of the CFG of the reference thread yields information about SIC hits and their corresponding eviction distances [4–8].

In parallel, the source code of the multithreaded program is used to derive a Message Sequence Chart (MSC)[21], which captures thread creation(start()), thread termination (join()), and inter-thread synchronization events (wait() and notify()). This information is used to generate both the threaded event trace and the synchronization event trace. Algorithm 1 analyzes the event trace to determine the sequential and concurrent regions of the reference thread, along with the competing regions in other threads that may run in parallel with the reference thread's concurrent regions. The synchronization event trace is subsequently used to map these concurrent and competing regions to their respective concurrent and competing partitions.

Interference experienced by each concurrent partition of the reference thread is determined via may-analysis of the competing threads and subsequently mapped to the corresponding competing partitions using the synchronization event trace. Next, SIC hit path analysis is performed to identify shared instruction cache hit paths (SICHPs). A SICHP may be entirely contained within a single partition or may span multiple partitions of the reference thread. The SICHPs and concurrent partitions information are then used to map SICHPs to the identified concurrent partitions.

For each concurrent partition, the Overlapping Factor [6, 8] is computed using the paths or subpaths associated with it. The Threaded Interference Placement Algorithm distributes/places interferences across these paths or subpaths within each concurrent partition and determines the resulting worst-case number of cache misses. The aggregate worst-case misses over all partitions are finally multiplied by the SIC miss penalty to obtain the maximum WCET increase due to interferences.

identifies concurrent regions as segments of the reference thread enclosed between $\text{start}(t_i)$ and the corresponding $\text{join}(t_i)$, while the execution segment preceding each concurrent region is classified as a sequential region. It also detects nested thread creation. When multiple threads are spawned in a nested manner, the concurrent region is extended to cover the full overlapping lifetimes of the involved threads, and all

overlapping execution segments are added to the competing regions. Furthermore, the algorithm recursively analyzes threads spawned within competing regions to identify additional competing execution regions. Finally, any remaining portion of the reference thread is treated as the last sequential region, and the algorithm returns `sequential_regions`, `concurrent_regions`, and `competing_regions`.

Algorithm 1: ExtractRegionsFromPartialOrderInformation (`threaded_event_trace`, t_i)

```
/*threaded_event_trace: Ordered list of events from a multithreaded program (events include start( $t_i$ ), join( $t_i$ ))*/
sequential_regions ← empty list
concurrent_regions ← empty list
competing_regions ← empty list of lists
competing_threads ← empty list
seq_region_start = begin( $t_i$ )
concur_region_count = 0
while not end of threaded_event_trace do          /* Step 1: Search for thread creation */
    | if event is start( $t_j$ ) then                    /* Sequential region before  $t_j$  starts */
    | | sequential_regions.append(region from seq_region_start to start( $t_j$ ))
    | | join( $t_j$ ) ← find_matching_join( $t_j$ )          /* Step 2: Identify lifespan of  $t_j$  */
    | | nested_thread_found ← false                 /* assume there are no nested threads spawned */
    | | for each event  $e_k$  between start( $t_j$ ) and join( $t_j$ ) do /* Step 3: Check for nested thread spawning */
    | | | if  $e_k$  is start( $t_k$ ) and  $t_k \neq t_j$  then
    | | | | nested_thread_found ← true
    | | | | join( $t_k$ ) ← find_matching_join( $t_k$ )
    | | | | temp_region = region from start( $t_j$ ) to max(join( $t_j$ ), join( $t_k$ ))
    | | | concurrent_regions.insert(concur_region_count, temp_region)
    | | | seq_region_start = max(join( $t_j$ ), join( $t_k$ ))
    | | | | temp_region1 = region from begin( $t_j$ ) to end( $t_j$ )
    | | | | temp_region2 = region from begin( $t_k$ ) to end( $t_k$ )
    | | | | competing_regions.insert( concur_region_count, [ temp_region1, temp_region2])
    | | | competing_threads.append(thread  $t_j$  & thread  $t_k$ )
    | | | | concur_region_count = concur_region_count + 1
    | | | end if
    | | end for
    | if nested_thread_found = false then          /* Step 4: No nested thread within  $t_j$  */
    | | temp_region = region from start( $t_j$ ) to join( $t_j$ )
    | | concurrent_regions.insert(concur_region_count, temp_region)
    | | temp_region1 = region from begin( $t_j$ ) to end( $t_j$ )
    | | competing_regions.insert(concur_region_count, [temp_region1])
    | | seq_region_start = end( $t_j$ )
    | | competing_threads.append(thread  $t_j$ )
    | | concur_region_count = concur_region_count + 1
    | end if
    | move to next event
end while
/* Step 5: Detect cascading concurrency when a competing thread creates an additional thread */
for each competing_thread in competing_threads
    | seq, con, comp = extract_Regions_From_Partial_OrderInformation( threaded_event_trace, competing_thread
    | | insert_returnedInfo_to_Respective_Data_Structures(seq, con, comp)
End for
sequential_regions.append(region from seq_region_start to end( $t_i$ )) /* Step 6: Append last sequential region of reference thread */
return sequential_regions, concurrent_regions, competing_regions
End
```

D. Threaded Sensitive Interference Placement Algorithm

Algorithm 2, Threaded Sensitive Interference Placement algorithm, places the interferences on the SIC subpaths to compute the maximum increase in WCET of reference T_i caused by interferences from threads executing on the other cores. The algorithm takes the following inputs:

- n : number of concurrent partitions in the reference thread T_i
- $listOfSubPaths_{sp}$: subpaths mapped to SIC set s in partition p
- ED_{sp} : eviction distances of subpaths mapped to SIC set s in partition p
- IB_{sp} : interference budget of SIC set s in partition p
- BLK_{sp} : number of interfering blocks mapped to SIC set s in partition p
- A : SIC associativity
- $SIC_Miss_Penalty$: latency of an SIC miss in cycles

The Threaded Sensitive Interference Placement algorithm

places interferences partition by partition. It adopts a greedy strategy in which interferences are inserted in increasing order of eviction distance, and once an interference is considered, it is not revisited. However, when overlap exists among SIC subpaths, a single interference may affect multiple SIC hit blocks already present in the cache, making a greedy strategy unsuitable. To address this, for each SIC set s in partition p , the function `compute_OF_partition()` is invoked to calculate the Overlapping Factor (OF). The OF measures the extent of overlap among subpaths. This factor is multiplied by the interference budget to obtain a new interference budget. Since overlapping SIC subpaths allow one interference to affect multiple cache hits, the adjusted interference budget captures this effect, enabling the greedy strategy to be applied for distributing interferences.

Next, the subpaths in the set are grouped according to their eviction distance (ED), for example, the number of subpaths with $ED = 1$, $ED = 2$, and so on up to associativity A .

A cache hit can only be converted into a miss if the number of interfering blocks is greater than or equal to its eviction distance. If the number of interfering blocks is less than the eviction distance, the corresponding cache hit cannot be evicted by interference.

Algorithm 2: Threaded Sensitive Placement Algorithm

Input: n : number of partitions in reference thread t , $listOfSubPath_{sp}$: list of SIC hit subpaths mapped to SIC set s of partition p , ED_{sp} : list of eviction distances of subpaths mapped to SIC set s of partition p , IB_{sp} : list of Interference Budget of SIC sets s of partition p , BLK_{sp} : number of interfering blocks of SIC set c in partition p , A : SIC associativity, $SIC_Miss_Penalty$: SIC miss cycles

Output: Maximum increase in WCET of thread t_i

```
p ← 1
SIC_Misses ← 0
while p ≤ n do:
  for each SIC set s do:
    | OFsp = compute_OF_partition( subPathssp )
    | NEW_IBsp = OFsp * IBsp
    | subPathsCountByEDsp[1...A] = computeSubpathCountByED( listOfSubPathsp, EDsp)
    | for i ← 1 to A do
      | | if BLKsp ≥ i then
      | | | if NEW_IBsp ≤ i * subPathsCountByEDsp[i] then
      | | | | SIC_Misses ← SIC_Misses + [ NEW_IBsp / i ]
      | | | | NEW_IBsp ← 0
      | | | break
      | | | else
      | | | | SIC_Misses ← SIC_Misses + subPathsCountByEDsp[i]
      | | | | NEW_IBsp ← NEW_IBsp - subPathsCountByEDsp[i] * i
      | | | end if
    | end if
  end for
  p ← p + 1 /* Move to the next partition */
end while
return SIC_Misses * SIC_Miss_Penalty
End
```

For each eviction distance level i :

- If the available interference budget is insufficient to convert all eligible hits into misses, only a subset of the hits is converted to misses according to the remaining interference budget, after which the budget becomes zero.
- Otherwise, if the interference budget is sufficient, all eligible hits are converted into misses, and the interference budget is reduced accordingly.

This procedure is repeated for all eviction distance levels, for every SIC set in every partition. The total number of additional misses incurred due to interference is accumulated and multiplied by the SIC miss penalty to compute the maximum WCET increase. This increase is then added to the WCET of the reference thread without interference.

The time complexity of the interference distribution algorithm is $O(ns(M + A))$, where M denotes the total number of SIC-hit subpaths, n represents the number of concurrent partitions, s denotes the number of SIC sets, and A is the SIC associativity. Since A and s are fixed architectural constants, the overall complexity reduces to $O(n * M)$ linear in the total number of SIC hit subpaths and partitions in the reference thread.

E. Proof of Safety

Theorem: Let P be a multithreaded program that uses `start()`, `join()`, `wait()`, and `notify()` primitives for thread creation, termination, and synchronization. For each thread in P , the number of Shared Instruction Cache (SIC) misses estimated by TP-WCIP is greater than or equal to the number of SIC misses that can occur during any concrete execution of P .

Fig. 4. MSC representation of a multithreaded program with maximal interference set.

Proof: Consider two threads T_1 and T_2 in program P , as illustrated in Fig. 4. Concurrent partitions and subsequently their competing partitions are identified. One of the identified concurrent partitions, $p: T_1[\text{start}(T_2): \text{notify}(T_2)]$ and the corresponding competing partition is: $T_2[\text{begin}(T_2): \text{wait}(T_2)]$.

Both threads may execute concurrently within these two partitions.

Let SIC access _{i} be an instruction access to the SIC mapped to set s in thread T_1 occurring within the concurrent partition p . The TP-WCIP algorithm constructs the interference budget of the cache set s in partition p .

$$IB_{sp} = \{\text{interferences}_1 \dots \text{interferences}_r\} \quad (2)$$

where each interferences_i :

- belongs to the thread T_2 ,
- maps to the same cache set as a_i , and
- can execute concurrently within the identified partition.

Because the interference set is derived from the concurrent execution partitions, any interfering access that may occur during a concrete execution must belong to this set. Therefore, TP-WCIP includes all feasible interfering accesses and thus forms an over-approximation of the interference that may occur during a concrete execution.

Next, TP-WCIP processes instruction accesses in non-decreasing order of their eviction distances. By analyzing accesses with smaller eviction distances first, TP-WCIP constructs a scenario that maximizes the number of potential SIC misses. This ordering increases the likelihood of eviction and, therefore, models the worst-case scenario. As a result, TP-WCIP produces the maximum possible number of potential SIC misses. In contrast, during an actual concrete execution, the order of accesses is constrained by the program control flow and synchronization. If a subsequent instruction has a smaller eviction distance, the execution cannot reorder accesses to prioritize that instruction as TP-WCIP does. Therefore, the concrete execution cannot always realize the worst-case ordering assumed by TP-WCIP. Therefore,

$$\text{Misses}_{TP-WCIP}(p) \geq \text{Misses}_{concrete}(p) \quad (3)$$

The above reasoning applies to every concurrent partition induced by the thread life cycle and synchronization primitives. Since a thread's execution can be viewed as a sequence of sequential regions interleaved with concurrent partitions, the safety property holds independently for each concurrent partition, while the sequential regions remain unaffected by interferences. Therefore, the property holds for the entire thread as well.

V. RESULTS AND DISCUSSION

Experiments are conducted using the multicore Chronos WCET analysis tool [22, 23], which supports multicore shared instruction cache (SIC) analysis. Our extension to multicore Chronos implements four SIC analysis methods: WCIP, Interference Partitioning (IP), Cache Block Conflict Number (CCN), and the proposed TP-WCIP technique. WCIP, IP, and CCN are widely discussed in the literature, so TP-WCIP is evaluated against them. Experiments run on a quad-core, timing anomaly-free [24] architecture with a 512-byte, 4-way private instruction cache (32-byte block) and an 8-KB, 8-way shared instruction cache (32-byte block). Private cache hits take 1 cycle, L2 shared instruction cache hits take 6 cycles, and

memory accesses take 30 cycles. The reference thread runs on core 1, with worst-case adversaries on cores 2-4. Benchmarks include real-world applications Papabench and extended Mälardalen, featuring input-dependent loops, nested conditionals, recursive calls, and auto-generated code.

A. Shared Instruction Cache Interference Reduction

The primary metric used to assess the performance of the TP-WCIP approach is Shared Instruction Cache Interference (SICI) reduction. It is computed as:

$$SICI\ Reduction(\%) = \frac{(SICI_{existing} - SICI_{TP-WCIP})}{SICI_{existing}} * 100 \quad (4)$$

The results presented in Table II demonstrate the effectiveness of TP-WCIP in reducing SICI across a diverse set of benchmark programs. Overall, TP-WCIP consistently reduces SICI compared with the baseline approaches. On average, TP-WCIP achieves a 27% reduction relative to IP and a 53% reduction relative to WCIP. When compared with CCN, TP-WCIP attains an average reduction of 75%, highlighting its strong improvement over existing approaches. These gains arise because TP-WCIP considers only feasible interferences originating from competing regions and competing partitions.

TABLE II. SICI INTERFERENCE REDUCTION USING TP-WCIP, COMPARED AGAINST WCIP AND CCN

Program	SICI Reduction (%) of TP-WCIP Relative to IP	SICI Reduction (%) of TP-WCIP Relative to WCIP	SICI Reduction (%) of TP-WCIP Relative to CCN
HeavyCompute	27.99	49.29	92.53
CascadeCall	28.8	51.94	91.72
LoopNest	39.43	69.71	89.58
Papabench	4.34	8.33	20.28
HighOverlap	38.51	85.71	85.38

The improvement is particularly notable when compared with CCN, where the reduction ranges from 20.28% to 92.53%. This trend indicates that incorporating thread-aware analysis substantially eliminates infeasible interference that arises when thread interactions are not precisely modelled. Similarly, reductions relative to WCIP range from 8.34% to 85.71%. While WCIP avoids repeatedly accounting for the same interference, it still overestimates feasible concurrency. The most significant improvement of TP-WCIP over WCIP appears in HighOverlap, where a single concurrent partition exhibits substantial overlap. WCIP computes the overlapping factor and interference at the thread level, which causes the interference budget to grow dramatically. In contrast, TP-WCIP restricts this growth to the specific partition where the high overlap occurs, instead of propagating it across the entire thread. As a result, the interferences are localized to the affected partition rather than being attributed to cache hit paths that would not actually be executed during program execution.

The reductions relative to IP vary between 4.34% and 39.43%. This variation indicates that IP still introduces notable pessimism, which TP-WCIP reduces by leveraging additional multithreading semantics.

In contrast, TP-WCIP demonstrates only modest improvement over the other approaches for the Papabench program. This is primarily because the competing threads and the reference threads in Papabench perform very few shared cache accesses and cache hits, resulting in relatively low interference and therefore limited opportunity for further reduction. Overall, these results highlight the advantage of TP-WCIP in accurately constraining interference by incorporating thread-aware execution semantics. In particular, TP-WCIP is particularly effective for programs with complex concurrency patterns or with highly overlapping shared instruction cache hit paths that are confined to specific regions of the program rather than spread across the entire program.

B. Retention of Shared Instruction Cache Hits

The second metric used to evaluate the performance of the TP-WCIP approach is Shared Instruction Cache Hits (SICH) retention. This retention is calculated as:

$$SICH\ Retention(\%) = \frac{(SICH_{proposed} - SICH_{existing})}{SICH_{proposed}} * 100 \quad (5)$$

Fig. 5 illustrates the improvement in retaining Shared Instruction Cache Hits (SICHs) achieved by the TP-WCIP algorithm over three baseline schemes: IP, WCIP, and CCN, across all benchmark programs. The results demonstrate that TP-WCIP consistently outperforms all baseline algorithms, although the magnitude of improvement varies with all the baseline and benchmark characteristics.

Fig. 5. Improvement of TP-WCIP algorithm in retaining shared instruction cache hits over IP, WCIP, and CCN.

TP-WCIP achieves improvements of up to 25%, with an average gain of 16% over the IP baseline across all benchmarks. This performance comes from its interference-placement strategy, which avoids repeatedly accounting for the same interference. Compared with WCIP, the performance improvement ranges from 30% to more than 70%, with an average improvement of up to 48%. This advantage arises because TP-WCIP retains a greater number of SICHs by allocating interferences to SICHs where interferences are expected during execution. The most significant improvements are observed when compared against CCN, where TP-WCIP achieves 100% improvements for most benchmarks, with an

average improvement of 84%, highlighting its scalability and superior cache modeling capability.

C. Shared Instruction Cache Hit Ratio

The next metric used to evaluate the performance of the proposed approach is the shared instruction cache hit ratio (SICHR). The SICHR is calculated as:

$$SICHR = \frac{SICH_M}{SICH_{without\ Interference}} \quad (6)$$

$SICH_M$ is the number of shared instruction cache hits with interferences, where M is the shared instruction cache modeling approach (TP-WCIP, IP, WCIP, CCN).

$SICH_{without\ Interference}$ is the number of shared instruction cache hits without interferences.

Fig. 6. SICHR of benchmark programs under different interference placement algorithms, TP-WCIP, IP, WCIP, and CCN.

Fig. 6 reports the Shared Instruction Cache Hit Ratio (SICHR) for all benchmark programs under four cache modeling schemes: TP-WCIP, IP, WCIP, and CCN. A value of 1.0 indicates complete preservation of shared instruction cache hits in the presence of interference; lower values indicate hit loss due to contention and evictions. Two principal trends are evident. First, TP-WCIP consistently attains SICHR values close to 1 across HeavyCompute, CascadeCall, and LoopNest (≈ 0.95 – 1.0), indicating that TP-WCIP effectively preserves shared instruction cache hits even when the thread is subject to interferences. The baseline schemes show substantially lower SICHRs: IP retains roughly ~ 0.8 ($\approx 80\%$ of isolated hits), while WCIP shows greater variability (≈ 0.45 – 0.77 across workloads). CCN fails to preserve any SICHRs for the benchmark programs HeavyCompute, CascadeCall, LoopNest, and HighOverlap. This indicates that CCN cannot retain Shared Instruction Cache hits mapped to a cache set s when the eviction distance of those hits is less than or equal to the total number of interfering blocks mapped to the same cache set s across the entire multithreaded execution. Consequently, CCN becomes overly pessimistic for high-contention benchmarks such as HeavyCompute, CascadeCall, LoopNest, and HighOverlap. In contrast, Papabench exhibits lower contention, allowing CCN to preserve some Shared Instruction Cache hits in that program.

D. False Interference Placement Ratio

The next metric used to evaluate the performance of the cache modeling approaches is the false interference placement ratio (FIPR). The FIPR is calculated as:

$$FIPR = \frac{\text{Number of False Interferences Placed}}{\text{Total Interferences Placed}} \quad (7)$$

TABLE III. FIPR OF IP, WCIP, AND CCN ALGORITHMS

Program	Heavy Compute	Cascade Call	Loop Nest	Papa Bench	High Overlap
FIPR-IP	0.27	0.28	0.39	0.04	0.38
FIPR-WCIP	0.49	0.51	0.69	0.08	0.85
FIPR-CCN	0.92	0.91	0.89	0.2	0.85

Table III shows the FIPR of the IP, WCIP, and CCN approach. Notably, TP-WCIP achieves an FIPR of zero across all benchmark programs. In comparison, CCN exhibits the highest level of false interference placement, with an average FIPR of approximately 75%, followed by WCIP with about 53%, and IP with around 27%. These false interferences directly contribute to the imprecision in the computation of the WCET. A higher FIPR indicates that the analysis introduces a significant number of infeasible interference scenarios that cannot occur during actual program execution. As a result, the number of predicted Shared Instruction Cache (SIC) interferences increases, leading to a more imprecise WCET estimate. Consequently, reducing FIPR is essential for achieving tighter and more realistic WCET bounds. The results demonstrate that TP-WCIP significantly reduces false interference scenarios compared to existing approaches. This improvement directly translates to tighter WCET bounds, enabling more efficient utilization of computational resources in real-time systems.

E. Implications for System-Level Optimization and Modern Architectures

The improvements achieved by TP-WCIP have important implications for system-level design in multicore real-time systems. From an architectural standpoint, the insights from this work apply to modern processors featuring multi-level cache hierarchies and shared last-level caches (LLCs). Although the current model focuses on a two-level instruction cache, the underlying principle of restricting interference to feasible concurrency regions naturally extends to the analysis of interference propagation across multiple cache levels. These observations indicate that incorporating concurrency-aware interference modeling, as realized in TP-WCIP, can enhance both timing predictability and cache utilization efficiency in contemporary multicore architectures.

VI. CONCLUSION AND FUTURE WORK

Precise static Worst-Case Execution Time (WCET) analysis for multithreaded programs on multicore architectures critically depends on accurate shared instruction cache (SIC) modeling. Existing approaches address inter-core interference in a conservative manner. In particular, the Cache Block Conflict Number (CCN) technique assumes interference at all program points, effectively classifying most shared instruction cache accesses as misses. Although Worst-Case Interference

Placement (WCIP) reduces some pessimism by ensuring that already-accounted interference is not repeatedly considered, it does not exploit multithreading semantics to eliminate infeasible interferences implied by happens-before relationships. Interference Partitioning (IP) further reduces pessimism by incorporating synchronization primitives, but it still does not fully leverage multithreading semantics, particularly parallelism and happens-before relations introduced by thread lifecycle primitives.

This work introduced the Threaded Program Worst-Case Interference Placement (TP-WCIP) approach, which explicitly incorporates thread lifecycle primitives (start(), join()) and synchronization primitives (wait(), notify()) to derive precise sequential regions, concurrent regions, competing regions, and corresponding partitions. By leveraging a concurrency structure extracted from the Message Sequence Chart (MSC) representation, TP-WCIP restricts interference placement to only those accesses that can execute in parallel with the reference thread. Consequently, false interference scenarios are eliminated while safety is preserved.

Experimental evaluation on Papabench and extended Mälardalen benchmark programs demonstrates that TP-WCIP substantially improves precision. The TP-WCIP reduces shared instruction cache interferences by up to 27% over IP, 53% over WCIP, and 75% over CCN. In addition, it preserves up to 16% more shared instruction cache hits than IP, 48% more than WCIP, and 84% more than CCN. These results confirm that TP-WCIP delivers tighter and safer static shared instruction cache analysis for multithreaded programs executing on multicore systems, without sacrificing computational efficiency.

Despite its advantages, TP-WCIP has certain limitations. The model assumes non-preemptive execution within cores, and its evaluation is restricted to selected benchmark suites and a specific cache configuration, which may limit the generalizability of the results.

As part of future work, the model will be extended to incorporate preemptive scheduling, including the analysis of cache-related preemption delays (CRPD), enabling more accurate WCET estimation in fully preemptive real-time systems.

Abstract—Hybrid approaches combining Cellular Automata (CA) and Artificial Neural Networks (ANN) have been widely applied to spatial simulation; however, most implementations rely on stochastic components that limit reproducibility and interpretability. This study proposes a deterministic ANN–CA computational framework in which the stochastic perturbation term of a constrained CA model is replaced by ANN-derived classification values based on socioeconomic variables. The framework integrates data preprocessing, ANN training, transition coefficient generation, and CA-based simulation into a unified workflow. A multilayer perceptron is trained using spatialized socioeconomic indicators (age, education, sex, and income) to generate deterministic transition potentials at the pixel level. Experimental evaluation using multitemporal land-use data shows that the proposed ANN–CA model achieves a moderate improvement in global spatial association (Cramer's V: 0.5622 → 0.6016), while pixel-level agreement (Kappa: 0.6589 → 0.6595) remains nearly unchanged. These results indicate that the proposed approach primarily enhances structural coherence and spatial organization—reducing fragmented growth and improving corridor-oriented expansion—rather than significantly increasing pixel-wise predictive accuracy. By replacing stochastic behavior with data-driven deterministic rules, the proposed framework improves reproducibility and provides a more interpretable linkage between urban growth patterns and socioeconomic drivers. This work contributes a transparent hybrid modeling approach suitable for spatial simulation and planning-oriented applications.

Keywords—Artificial neural networks; cellular automata; spatial simulation; deterministic modeling; hybrid computational framework

I. INTRODUCTION

Urban growth is a complex spatial phenomenon driven by socioeconomic, environmental, and infrastructural interactions that operate across multiple spatial scales. Modeling these processes poses significant computational challenges, as land-use change often emerges from nonlinear relationships and localized interactions among neighboring areas. Accurate representation and forecasting of such dynamics are essential for sustainable urban planning, risk assessment, and effective land management.

Among the available computational approaches, Cellular Automata (CA) have proven particularly effective for simulating spatial processes in which each cell evolves according to local

neighborhood rules. Their ability to reproduce emergent spatial patterns has led to widespread adoption in urban growth and land-use change studies [1], [2]. However, conventional CA models typically rely on stochastic perturbation terms to represent uncertainty, which may introduce randomness weakly linked to real-world drivers of urban expansion and reduce model interpretability [3].

To enhance realism and predictive performance, several studies have explored the integration of CA with Artificial Neural Networks (ANNs) [4], exploiting their ability to learn nonlinear relationships from empirical data. Representative applications include the generation of transition probability maps, multi-label land-use classification [5], and scenario-based urban growth forecasting [6]. Although these approaches improve spatial prediction accuracy, most implementations treat ANN outputs as precomputed inputs to CA models rather than embedding them directly into the transition potential formulation.

In recent years, more advanced neural architectures—such as deep convolutional networks and object-detection-oriented models—have been proposed for spatial analysis tasks. Despite their success in computer vision and remote sensing applications, there is currently no consolidated or validated framework that demonstrates how such models can directly and consistently replace the stochastic component in constrained CA formulations, particularly in the context of White's urban growth model. As a result, the stochastic term remains insufficiently addressed in a theoretically grounded and interpretable manner.

Although CA models have demonstrated strong capabilities in simulating urban processes, their reliance on stochastic components limits interpretability and weakens the connection between simulated outcomes and observable socioeconomic variables [3]. Previous studies have attempted to mitigate these limitations through artificial intelligence techniques. For instance, Xu et al. [7] combined ANN with CA–Markov Chain models to improve temporal prediction accuracy, while Zeng et al. [8] introduced hybrid approaches incorporating spatial heterogeneity and nonlinear transition rules. Other recent research has explored GPU-based computational acceleration and convolutional operations [9], as well as ANN–CA applications have been successfully applied across diverse spatial contexts, including cultural and rural environments [10],

as well as highly urbanized megacities [11]. More recently, bio-inspired approaches such as Neural Cellular Automata using deep learning techniques have been proposed [12], [13].

Comparable advances have also been reported using Neural Cellular Automata and deep learning-based approaches for spatial modeling and urban dynamics [14], [15].

More broadly, hybrid urban growth modeling has evolved from conventional stochastic Cellular Automata formulations toward data-driven and machine-learning-assisted approaches. Early ANN-CA studies demonstrated that neural networks can capture nonlinear transition behavior and improve land-use simulation when combined with GIS and raster-based CA frameworks. More recent works have extended this idea through CA-Markov models, multi-label land-use transformation models, and machine learning methods designed to estimate transition probabilities from spatial and socioeconomic predictors.

In parallel, alternative deterministic or semi-deterministic approaches have been explored using logistic regression, decision-tree-based models, Random Forest classifiers, and convolutional neural networks. These methods generally aim to improve predictive performance by generating suitability or transition probability surfaces that are subsequently used as external inputs to CA simulations. In CNN-CA and Neural Cellular Automata variants, richer spatial feature extraction has been achieved, particularly from remote sensing imagery, but often at the cost of reduced interpretability in socioeconomic terms [16], [17].

Despite these advances, a common limitation remains: in most hybrid approaches, the learning model operates as a separate upstream component, while the CA transition mechanism itself still depends on externally supplied probability layers or stochastic perturbation terms. Consequently, the interaction between learned socioeconomic patterns and the internal transition logic of constrained CA models remains only partially integrated.

TABLE I. CONCEPTUAL COMPARISON OF URBAN GROWTH SIMULATION APPROACHES

Approach	Integration with CA	Determinism	Interpretability
Stochastic CA	Internal stochastic term	Low	Low
CA-Markov	External transition probabilities	Moderate	Low
ML-CA (LR / RF)	External suitability maps	Moderate-High	Moderate
CNN-CA	External feature-based probabilities	Moderate	Low
Proposed ANN-CA	Direct embedding in the transition potential	High	High

Table I summarizes representative urban growth modeling approaches, highlighting their differences in terms of integration with Cellular Automata, level of determinism, and interpretability. As shown, most prior approaches rely on externally generated transition probabilities or suitability maps, while maintaining either stochastic behavior or limited interpretability within the CA framework. In contrast, fewer

studies address the methodological question of whether a learned deterministic mechanism can directly replace the stochastic term in a constrained CA model.

In contrast, the approach proposed in this study does not use the ANN as an external probability-map generator. Instead, ANN-derived class coefficients are embedded directly into White's transition potential formulation, allowing socioeconomic information to participate internally in the CA decision process. This distinction is central to the present work, whose contribution lies less in maximizing pixel-level accuracy than in advancing a reproducible, deterministic, and interpretable hybrid modeling framework.

In light of these limitations, the central research question of this study is:

Can the stochastic perturbation term in a constrained Cellular Automata model be replaced by ANN-derived deterministic transition coefficients while preserving spatial modeling performance?

This study addresses this gap by replacing the stochastic perturbation term in White's constrained CA model with an ANN-generated classification value derived from spatialized socioeconomic variables. A multilayer perceptron trained via the backpropagation algorithm is employed as a first step, given its robustness, interpretability, and proven capacity to approximate complex nonlinear functions from limited datasets. This choice allows for a controlled and transparent evaluation of ANN-driven transition potentials within the CA framework.

The proposed framework is applied to the city of Culiacán, Mexico, a rapidly expanding urban area characterized by the availability of detailed geostatistical and socioeconomic datasets, making it a suitable case study for evaluating the proposed approach. Specifically, this study:

- Designs and trains a multilayer perceptron ANN to process spatialized socioeconomic variables—age, education, sex, and income—at the basic geostatistical area level.
- Integrates ANN outputs directly into White's constrained CA model to compute pixel-level transition potentials.
- Evaluates predictive performance using historical land-use maps from 1997, 2004, and 2011, employing spatial agreement metrics such as Cramer's V and the Kappa index.

By embedding ANN-derived socioeconomic drivers into the CA transition mechanism, this work advances a more deterministic and data-driven approach to urban growth modeling. The proposed integration improves the explicit linkage between spatial patterns and demographic or economic factors and facilitates future extensions toward hybrid simulation frameworks, including Agent-Based Models (ABM).

The principal methodological contribution of this study lies in directly replacing the stochastic term in White's model with classification values generated by a multilayer perceptron trained on spatialized socioeconomic variables. This integration reinforces the deterministic character of the model, enhances spatial coherence, and enables a more interpretable linkage

between urban growth patterns and underlying socioeconomic drivers.

Future work will explore the integration of more recent neural architectures—such as convolutional and detection-based networks—once a stable methodological bridge between these models and constrained CA dynamics is established. In this way, the present study lays the groundwork for progressively incorporating more advanced ANN models into urban growth simulation, while maintaining methodological rigor and interpretability.

In summary, this work presents a novel and computationally grounded methodology for integrating socioeconomic data into land-use change simulation through a deterministic ANN–CA framework, demonstrated through a case study of Culiacán, Mexico. The remainder of the study describes the proposed model, its implementation, and its validation.

II. MATERIALS AND METHODS

A. Overall Workflow of the ANN CA Model

Fig. 1 presents the overall workflow integrating Artificial Neural Networks (ANN) with Constrained Cellular Automata (CA) for urban growth modeling, providing an overview of the methodological process from data acquisition and preprocessing to model simulation, validation, and interpretation.

Fig. 1. Overall workflow of the hybrid artificial neural network and cellular automata model.

The methodology consists of five main stages:

1) *Study area definition and data preparation*: Orthophotos and geostatistical data provided by the National Institute of Statistics and Geography (INEGI) were processed to generate raster land-use maps for 1997, 2004, and 2011.

2) *Socioeconomic data processing*: Socioeconomic variables at the Basic Geostatistical Area (AGEb) level—age, education, sex, and income—were normalized and spatialized to generate raster layers suitable for ANN input.

3) *ANN design and training*: A multilayer perceptron was configured to process socioeconomic variables and generate classification coefficients for dynamic land-use classes.

4) *Integration of ANN into the CA model*: The stochastic perturbation term in White's constrained CA model was replaced by ANN-derived classification values, yielding a deterministic transition potential.

5) *Simulation and validation*: Ex-post and forecast simulations were performed, and model outputs were evaluated using spatial agreement metrics and qualitative visual inspection.

This hybridization enables the CA framework to integrate socioeconomic information directly into the transition mechanism, improving interpretability and spatial realism.

B. Study Area and Spatial Data

The geographical location of the study area, corresponding to the municipality of Culiacán, Mexico, is shown in Fig. 2. The geographic coordinates are 24°48'15" N and 107°25'52" W, with an average altitude of 54 m above sea level.

Fig. 2. Location of the study area in Culiacán, Sinaloa, Mexico.

Urban land-use maps were generated through vector digitization over orthophoto mosaics. Orthophotos from 1997 (scale 1:20,000) and 2004 (scale 1:10,000) were projected in the WGS 84 / UTM Zone 13N coordinate system. ArcMap® was used for vector cartography, while IDRISI Selva® was employed for raster processing.

All vector layers were converted to raster format using the Database Workshop module in IDRISI. The resulting raster maps (Fig. 3 and Fig. 4) serve as input matrices for the CA model [18].

Fig. 3. Raster land use map of Culiacan for 1997.

Fig. 4. Raster land use map of Culiacan for 2004.

Urban land-use categories used in the simulations are summarized in Table II.

TABLE II. CLASSIFICATION OF URBAN USES

Num	Quantity
1	Urban Voids
2	Services
3	Agricultural Zone
4	Commercial Zone
5	Forestry Zone
6	Industrial Zone
7	Housing
8	Water Bodies
9	Equipment
10	Undeveloped

C. Socioeconomic Data Processing

Socioeconomic information was obtained from INEGI at the AGEB level, which provides tabular demographic and economic data for the Mexican territory. The selected variables—age,

education level, sex, and income—were identified as relevant indicators of urban development dynamics.

Since AGEB data are provided in tabular format, spatialization was performed by linking attribute tables to AGEB polygon layers using the Joins and Relates functionality in ArcMap. The resulting spatial layers were converted to raster format and resampled to match the spatial resolution of land-use maps (Fig. 5 and Fig. 6).

Fig. 5. Raw socioeconomic data at the basic geostatistical area level.

Fig. 6. Spatialized socioeconomic variables used as ANN inputs.

To ensure numerical stability and efficient ANN training, all socioeconomic variables were normalized to a [0,1] range. This preprocessing step reduces scale bias among variables and improves convergence during network training.

D. Computational Environment and Validation Metrics

Model implementation was accelerated using NVIDIA CUDA architecture to optimize matrix operations and ANN training. GPU-based parallelization was applied to ANN computations and CA simulations to handle large raster datasets efficiently [19].

Model performance was evaluated using both quantitative and qualitative criteria. Quantitative validation employed Cohen's Kappa index and Cramer's V coefficient to measure spatial agreement between simulated and observed land-use maps. Qualitative evaluation focused on the visual coherence of urban growth patterns, particularly radial expansion and the reduction of fragmented urban clusters.

E. Cellular Automata Model

The CA model used in this study is based on White's constrained cellular automaton for high-resolution urban land-use modeling [2]. The transition potential from state h to state j is defined as:

$$P_{hj} = v s_j a_j (1 + \sum_{k,i,d} m_{kd} I_{id}) + H_j \quad (1)$$

where v is the stochastic perturbation term, s_j represents suitability, a_j is the Euclidean distance to the nearest road, and m_{kd} is the calibration matrix modeling neighborhood influence with a distance decay effect [1].

Transition potentials are computed only when $s_j > 0$. Neighborhood influence accounts for attractive or repulsive effects depending on cell state and distance, filtered by the indicator I_{id} .

F. Artificial Neural Network Design

The ANN was implemented as a multilayer perceptron consisting of three layers: an input layer with four neurons (age, education, sex, income), a hidden layer with eight neurons using sigmoid activation, and an output layer with seven neurons corresponding to dynamic land-use classes (Fig. 7).

Fig. 7. Artificial neural network architecture used in the experiments.

The network was trained using the backpropagation algorithm with a learning rate of 0.01, momentum of 0.9, and a stopping criterion defined by a meansquared error (MSE) of 0.1. Ten percent of the dataset was randomly selected for validation during training.

Unlike conventional ANN-CA approaches, the proposed framework embeds ANN outputs directly into the CA transition potential equation. The stochastic term v in White's model is replaced by the ANN-derived classification coefficient c_j , ensuring deterministic pixel transitions driven by socioeconomic context (Fig. 8).

The selected ANN architecture (4–8–7) was intentionally designed as a compact multilayer perceptron to balance model interpretability and computational efficiency. Given the limited number of input features and the objective of embedding the ANN directly into the CA transition mechanism, a shallow architecture was preferred over deeper models to avoid overfitting and preserve transparency in the learned relationships [20]. Preliminary experiments with larger hidden layers showed no significant improvement in spatial performance metrics, supporting the choice of a minimal yet sufficient network capacity.

Fig. 8. Conceptual representation of the three-layer perceptron.

G. Training Algorithm and Data Selection

ANN training followed the standard backpropagation algorithm. Socioeconomic raster layers served as input, while the 2004 land-use map was used as the target output. The training dataset consisted of randomly selected pixels representing 10 % of the study area (Table III).

TABLE III. SOCIOECONOMIC VARIABLES USED FOR ANN TRAINING

Variable	Type
Sex	Discrete
Age	Discrete
Education	Discrete
Income	Continuous

The backpropagation process iteratively adjusted network weights to minimize classification error. Although the algorithm may converge to local minima, achieving a predefined error threshold was sufficient for stable and reliable classification performance in the context of urban growth simulation.

The training dataset was constructed using a random sampling strategy covering approximately 10% of the total

raster cells. This proportion was selected as a trade-off between computational efficiency and representativeness of spatial patterns. Although random sampling is commonly used in pixel-based classification tasks, it may introduce spatial autocorrelation effects, where neighboring pixels share similar characteristics.

To mitigate this limitation, the sampled pixels were distributed across the entire study area, ensuring coverage of different land-use classes and socioeconomic conditions. However, it is acknowledged that spatial leakage cannot be fully eliminated under random sampling. Future work will explore spatial cross-validation strategies and geographically stratified sampling to further improve model robustness.

H. Implementation Details

The proposed ANN-CA model was implemented using a custom computational pipeline integrating raster processing and neural network training. The Cellular Automata model follows a Moore neighborhood configuration, considering local spatial interactions within a fixed window.

ANN training was performed using a backpropagation algorithm with a learning rate of 0.01 and momentum of 0.9. The stopping criterion was defined based on mean-squared error convergence. GPU acceleration was employed using NVIDIA CUDA to optimize matrix operations and reduce computation time during both training and simulation stages.

All simulations were conducted using consistent spatial resolution and aligned raster datasets to ensure comparability across temporal scenarios. Additional implementation details are available upon request to facilitate reproducibility.

III. RESULTS

A. Experimental Setup and Comparative Summary

Two model configurations were evaluated to quantify the effect of replacing the stochastic term in White's constrained Cellular Automata (CA) formulation:

- Baseline CA: White's constrained CA using the original stochastic perturbation term v .
- Proposed ANN-CA: the stochastic term v replaced by an ANN-derived classification coefficient c_j computed from socioeconomic variables.

The ANN was implemented as a multilayer perceptron with 4 input neurons (age, education, sex, income), 8 hidden neurons, and 7 output neurons corresponding to the dynamic land-use categories. The network was trained using a random 10 % pixel sample, taking the 2004 land-use raster map as the target output. A sigmoid activation function was used, and training stopped when the mean squared error (MSE) reached 0.1.

1) *Ex-post simulation (1997–2004)*: Fig. 10 and Fig. 11 summarize the training process and the ANN configuration used to generate the classification coefficients incorporated into the CA transition potential. Ex-post urban growth simulations for the period 1997–2004 are shown in Fig. 13 (baseline CA) and Fig. 14 (ANN CA).

Quantitative spatial agreement metrics are:

- Baseline CA: Cramer's $V = 0.5622$, Kappa = 0.6589
- Proposed ANN-CA: Cramer's $V = 0.6016$, Kappa = 0.6595

Table IV summarizes the comparison between the two configurations.

TABLE IV. COMPARISON BETWEEN BASELINE CA AND ANN CA CONFIGURATIONS

Model Configuration	Cramer's V	Kappa Index	Spatial Pattern Description
Baseline CA (White's Model)	0.5622	0.6589	Irregular clusters and scattered patches
Proposed ANN-CA Model	0.6016	0.6595	Coherent radial expansion along transport corridors
Forecast (2011 Validation)	0.5626	0.5726	Structured growth, slight accuracy drop

Note: Forecast results correspond only to the ANN-CA model. Direct comparison with the baseline CA model for the 2011 scenario is beyond the scope of this study and will be addressed in future work.

a) *Quantitative takeaway*: The ANN-CA configuration increases Cramer's V by 6.98% relative to the baseline, indicating a stronger global spatial association between simulated and observed land-use patterns. The observed behavior of the evaluation metrics highlights an important distinction between pixel-level accuracy and structural spatial consistency. While the Kappa index shows only a marginal increase, this metric is highly sensitive to local misalignments and does not fully capture the organization of spatial patterns. In contrast, Cramer's V reflects overall spatial association and indicates an improvement in the structural coherence of the simulated urban dynamics.

This suggests that the proposed ANN-CA model primarily enhances spatial organization and transition consistency rather than exact pixel-by-pixel agreement, which is consistent with the deterministic and pattern-oriented nature of the proposed framework. From an applied perspective, such improvements in structural coherence are particularly relevant for urban planning and spatial decision-making, where the overall configuration of growth patterns is often more informative than strict local accuracy.

Qualitative analysis of the simulated maps further supports this interpretation. The ANN-CA model produces more coherent and structured spatial patterns, characterized by controlled radial expansion, reduction of fragmented or isolated urban patches, and the emergence of corridor-oriented growth aligned with underlying socioeconomic gradients. These characteristics are not fully captured by pixel-based metrics but are particularly relevant for urban planning and spatial decision-making, where the overall configuration and consistency of growth patterns are more informative than strict local accuracy.

2) *Forecast validation (2011)*: To evaluate model generalization beyond the calibration interval, a forecast simulation targeting 2011 was generated using the same configuration employed for the 1997–2004 experiment. The ANN-CA model achieved:

- Cramer's $V = 0.5626$
- Kappa Index = 0.5726

a) *Forecast takeaway*: Although both indices decrease relative to the ex-post simulation, the values remain within a comparable range to the baseline ex-post performance. This indicates that the ANN–CA model maintains structural stability over longer simulation horizons, despite increased uncertainty in socioeconomic and spatial dynamics.

As expected in land-use forecasting tasks, predictive accuracy decreases with time due to evolving drivers that are not explicitly modeled. However, the ANN–CA configuration preserves coherent growth structures and avoids the erratic expansions typically induced by purely stochastic perturbations under identical CA settings.

3) *Interpretation of ANN outputs*: The ANN generates, for each pixel, a classification vector assigning a weight to each dynamic land-use category. For example, a given socioeconomic profile may produce the following output:

- Housing (Class 7): 0.806
- Services (Class 2): 0.125
- Industrial (Class 6): 0.041

These values represent deterministic transition preferences derived from socioeconomic context. When incorporated into the CA transition potential, they replace the random perturbation term of White's original model, ensuring that simulated land-use changes are systematically informed by demographic and economic conditions rather than stochastic variability.

B. Simulation Procedure and Output Mapping

To perform the simulations, White's constrained CA model was modified by replacing the stochastic coefficient v with a classification coefficient c_j , where c_j is produced by the trained ANN for each target land-use state j . Fig. 9 illustrates the role of socioeconomic inputs and ANN outputs within the hybrid simulation pipeline.

Modified R. White model

$$P_{hj} = \underline{c}_j s_j a_j \left(1 + \sum_{k,t,d} m_{kd} I_{id} \right) + H_j$$

Fig. 9. Integration of ANN outputs into the cellular automata transition mechanism.

1) *Training sample and convergence*: The ANN training dataset consisted of randomly selected pixels from the four socioeconomic raster layers, with the corresponding land-use class in the 2004 raster map used as the target output. Training proceeded until the predefined error threshold (MSE=0.1) was

reached. Although this MSE threshold may appear high for conventional classification tasks, in this context, it was used as a convergence criterion to obtain stable class preference patterns rather than precise probability estimates. This is consistent with the role of the ANN within the proposed framework, where outputs are not interpreted as exact class probabilities but as relative transition preferences embedded in the CA transition mechanism. The pixel-level training scheme is illustrated in Fig. 10.

Fig. 10. Pixel-based training scheme for the ANN.

2) *ANN configuration used in the hybrid simulation*: The final ANN configuration used in the experiments is shown in Fig. 11, consisting of four input neurons, eight hidden neurons, and seven output neurons with sigmoid activation. Output values are constrained to the interval $[0,1]$, where higher values indicate stronger class affinity.

Fig. 11. Final configuration of the artificial neural network.

During simulation, the ANN processes socioeconomic inputs at each pixel coordinate and directly outputs classification vectors without requiring a target map. The per-pixel inference process is illustrated in Fig. 12.

Fig. 12. Pixel-level classification scheme during simulation.

3) *Ex-post simulation maps (1997–2004)*: Using identical CA parameters, two ex-post simulations were generated: one using the baseline CA and one using the proposed ANN–CA integration. Results are shown in Fig. 13 and Fig. 14, respectively.

Fig. 13. Ex post simulation from 1997 to 2004 using cellular automata only.

Fig. 14. Ex post simulation from 1997 to 2004 using the proposed ANN CA model.

The ANN–CA model exhibits improved spatial regularity and corridor-oriented expansion, consistent with socioeconomic-driven transition potentials.

4) *Forecast simulation (2011)*: A forecast simulation was generated for 2011 using the same configuration applied to reproduce the 2004 map. The resulting simulated map is shown in Fig. 15.

Fig. 15. Forecast simulation of urban growth for 2011 using the ANN CA model.

The decrease in agreement indices relative to the ex-post experiment is consistent with the increasing uncertainty associated with longer simulation horizons. Nevertheless, the ANN–CA model maintains coherent spatial structures, supporting its suitability for medium-term urban growth analysis.

Overall, the results indicate that the proposed ANN–CA framework provides a more structured and consistent spatial simulation, even when improvements in traditional accuracy metrics remain limited. This reinforces the role of deterministic, data-driven transition mechanisms in improving the interpretability and stability of urban growth models.

IV. DISCUSSION

The results obtained in this study are consistent with recent advances in hybrid urban growth modeling that combine data-driven learning techniques with spatial simulation frameworks. Xu et al. [7] demonstrated that integrating Artificial Neural Networks with CA–Markov Chain models improves temporal prediction performance, while Zeng et al. [8] highlighted the importance of accounting for spatial heterogeneity and nonlinear transition rules in urban CA formulations. In comparison with these approaches, the proposed ANN–CA model introduces a direct and internal embedding of ANN outputs into the CA transition potential, rather than relying on externally generated probability maps. This design yields a deterministic and socioeconomically interpretable simulation mechanism.

Relative to CNN–CA integrations such as the vector-based framework proposed by Zhai et al. [13], and to Neural Cellular Automata approaches explored by Catrina et al. [14], the proposed model prioritizes explainability over deep spatial feature abstraction. While deep architectures excel at learning complex spatial patterns from imagery, their internal

representations are often difficult to interpret in socioeconomic terms. In contrast, the multilayer perceptron used in this work produces class-specific coefficients that can be directly associated with demographic and economic variables, enabling clearer interpretation of urban growth drivers.

Although global agreement metrics—particularly the Kappa index—show limited variation between the compared models, the proposed ANN–CA framework produces structurally more coherent spatial patterns and improved transition consistency. This outcome is expected given that Kappa is highly sensitive to local misalignment, while Cramer’s V captures global spatial association. For urban growth analysis and planning support, structural coherence and pattern realism are often more relevant than strict pixel-wise accuracy.

From a practical perspective, embedding socioeconomic variables directly into the CA transition mechanism enhances the transparency and interpretability of simulated outcomes. Urban planners and decision-makers can relate simulated expansion patterns to observable demographic and economic factors, rather than to stochastic variability. This characteristic represents a key advantage of the proposed approach when compared with purely stochastic CA models or black-box deep learning alternatives.

A detailed ablation analysis of the ANN architecture and the contribution of individual socioeconomic variables is beyond the scope of this study, as the primary objective is to evaluate the feasibility of embedding ANN-derived deterministic coefficients directly into the CA transition mechanism. Nevertheless, future work will explore the sensitivity of the model to network configuration, input variable selection, and their impact on spatial simulation performance.

Future work may extend the proposed framework by incorporating additional predictors, such as environmental constraints, transportation infrastructure, or policy-related variables, to further improve predictive performance. From a computational standpoint, the ANN–CA formulation provides a stable methodological foundation for exploring more advanced architectures, including Convolutional Neural Networks (CNNs) and Graph Neural Networks (GNNs), once robust strategies for integrating these models into constrained CA dynamics are established. Such extensions could enhance feature extraction while preserving the interpretability and deterministic behavior demonstrated in this study.

V. CONCLUSIONS

This study demonstrated the advantages of directly embedding an Artificial Neural Network (ANN) into a Cellular Automata (CA) framework for urban growth simulation by replacing the stochastic perturbation term in White’s constrained model with ANN-derived classification values computed from spatialized socioeconomic data.

The main contributions of this work can be summarized as follows:

- Novel methodological integration: ANN outputs are incorporated directly into the CA transition potential formulation rather than being used as precomputed probability layers. This design enables a dynamic,

context-aware, and internally consistent influence on pixel-level transitions.

- Socioeconomic grounding of urban dynamics: Demographic and economic variables—age, education, sex, and income—are explicitly embedded in the transition mechanism, strengthening the interpretability of simulated patterns and improving their relevance for planning and policy analysis.
- Improved spatial pattern coherence: Although improvements in global agreement metrics are modest, the ANN–CA model produces more coherent and realistic urban growth structures than the baseline CA model, particularly by reducing fragmented clusters and enhancing corridor-oriented expansion.

From a practical standpoint, the proposed approach supports urban planners and decision-makers by directly linking simulation outcomes to observable socioeconomic indicators. This characteristic enables more transparent interpretation of growth dynamics and facilitates targeted interventions in urban development and land-use management.

Future research directions include:

- Integrating the proposed ANN–CA framework with Agent-Based Models (ABM) to capture agent-level decision-making processes.
- Applying the methodology to cities with different urban growth patterns to evaluate robustness and generalizability [1].
- Incorporating additional spatial predictors, such as environmental constraints and transportation infrastructure, to further enhance predictive performance.
- Exploring advanced neural architectures, including Convolutional Neural Networks (CNNs) [9], [12], for improved feature extraction from remote sensing data, once stable integration strategies with constrained CA models are established.
- Extending the evaluation framework by incorporating per-class performance analysis, including confusion matrices and class-specific accuracy metrics, to better assess the model’s ability to distinguish among different land-use categories.
- Incorporating statistical significance tests, such as McNemar’s test, to complement the analysis of spatial agreement and provide a more comprehensive evaluation of model performance.

Overall, this study provides a methodological foundation for future hybrid approaches that combine explainable artificial intelligence with geospatial simulation frameworks in support of sustainable urban development planning. By strengthening the deterministic component of CA models, the proposed ANN–CA integration represents a step toward more data-driven, interpretable, and transferable approaches to land-use change modeling.

The presented framework contributes to the broader adoption of explainable AI in geospatial sciences and encourages further interdisciplinary collaboration between urban planning, computer science, and spatial modeling communities.

CONFLICT OF INTEREST

The authors declare no conflict of interest.

The authors further declare that generative artificial intelligence tools were used exclusively for language editing and figure description refinement. All generated content was reviewed, validated, and approved by the authors, who take full responsibility for the final version of the manuscript.

Abstract—For equity in access to higher education, scholarship schemes play a vital role. This is particularly the case with developing countries, where economic problems may become an impediment to academic betterment. In India, in the state of Maharashtra, the Shikshan Shulk Scholarship scheme was designed with the same goal – of reducing the financial obstacles for eligible students. However, the operation of this scholarship is often seen to be dealing with delays, manual verification issues, and a lack of transparency. Present scholarship portals are centralized, causing central points of failure, lack immutable audit trails, and depend mainly on manual involvement. This causes inefficiencies, a reduction in stakeholder trust, and compromises the outcome of financial assistance. To resolve these challenges, this study proposes an FMA (Framework of Ideas, Problem Solving Methodology, Areas of Application) based Action Research framework for automating the Shikshan Shulk Scholarship Management using blockchain technology. By utilizing an action research approach, the study establishes how blockchain can improve accountability, reduce delays, and improve operational efficiency in scholarship disbursement. This strategy will contribute to streamlining scholarship management as well as to the broader theme of blockchain-based e-governance.

Keywords—Blockchain; scholarship; shikshan shulk scholarship scheme; e-governance; smart contracts; action research; FMA (Framework, Methodology, Applications)

I. INTRODUCTION

For deserving students to progress in terms of socio-economic development and social mobility, a vital dimension is higher education [1]. Scholarships are the platforms that ensure that students who wish to continue with their scholastic undertakings are not hindered by finances. A vast number of schemes have been implemented in India to promote inclusivity, among which the Shikshan Shulk scholarship scheme has been rolled out in Maharashtra via the MahaDBT portal under the Directorate of Higher Education (DHE). Though quite a few initiatives have been put in place, the executive processes that are meant to support these schemes often contend with deficiencies deep-rooted in the system [2].

Common scholarship management systems depend mostly on centralized databases, human document checking, and multiple-level authorizations featuring various stakeholders such as students, educational institutions, and government departments. These operations create delays, possibilities of data

manipulation, and increase managerial overheads [3], [4]. A resilient, decentralized approach that can provide accountability and trust can be examined as a solution to counter these hurdles. Blockchain technology extends a solution with its basic features of immutability, decentralized verification, and smart contracts, allowing an increase in transparency, a decrease in fraud, and an improvement in the efficiency of the scholarship management system [1], [5].

While numerous studies have covered blockchain applications in e-governance and education, there is a substantial gap regarding action research-driven, scholarship-specific, blockchain implementations [2]. This suggests an Action Research framework based on FMA (Framework of Ideas, Problem Solving Methodology, Areas of Application) for automating the Shikshan Shulk Scholarship utilizing blockchain. This framework focuses on stakeholder participation and iterative refinement, and employs blockchain's essential features to create a transparent and auditable scholarship environment. The disbursement process has been attempted to be automated through the integration of smart contracts, promising a prompt and precise fund transfer to the beneficiaries [1].

The contributions of this study are divided into three parts. Firstly, this includes an FMA framework based on Action Research. This provides a structured and methodological flow for checking the readiness of blockchain in scholarship management systems. Unlike earlier work, that highlight system design or conceptual suggestions, this framework definitively merges theoretical basis, empirical diagnosis, and context-specific implementations. Hence, this allows for clarity in the methodology. Second, the study presents a comprehensive and statistically reliable pilot analysis; employing a multi-construct evaluation instrument assessed through Python-based data analysis, radar chart visualization, and internal consistency testing using Cronbach's Alpha. This empirical examination offers a concrete diagnosis of system performance across crucial elements of timeliness, clarity, transparency, trust, and overall satisfaction. Third, the study methodically examines the limitations of existing scholarship systems through empirical evidence. By providing a foundation for these limitations in stakeholder data and validated constructs, the research establishes an evidence-based starting point for blockchain-enabled interventions. Collectively, these insights advance both

methodology and practical relevance in the study of blockchain applications for public sector information systems.

This study is structured into seven main parts to present the research and its contributions. The “Literature Review” section gives a synthesis of the work carried out in blockchain and its various application domains, highlighting disbursement and scholarships, and the role of action research in information systems. The “Research Objectives” clearly outline the goals that guide this study, derived from identified gaps in the existing literature. The “Hypothesis” section states that a blockchain-enabled Shikshan Shulk scholarship system will significantly improve stakeholder-perceived timeliness, clarity, transparency, trust, and satisfaction beyond the empirically established performance threshold of the current system. The “Methodology” details the adoption of the FMA model, founded in an Action Research perspective, forming the methodology backbone of this study. The “Pilot Study” presents an empirical diagnosis of existing scholarship systems through a detailed and statistically validated analysis, emphasizing key limitations related to timeliness, clarity, transparency, trust, and overall satisfaction. The “Results” section discusses how the suitability of the FMA framework is empirically validated as an outcome of the pilot study. The final “Conclusion” section summarizes the contributions of the study while discussing possible future work that can be undertaken.

II. LITERATURE REVIEW

Across diverse sectors of government public service delivery, blockchain has demonstrated its proficiency through its secure, transparent, and auditable processes. In situations where traceability and integrity of the transactions are crucial, such as subsidy and financial aid management, blockchain's effectiveness has been emphasized in several studies. This sets the tone for citizen-centric areas of applications where blockchain can play the role of a neutral intermediary among diverse stakeholders. In parallel, this review also examines the challenges of conventional centralized systems and calls attention to the relevance of action research methodology as a means to examine, validate, and address these problems in complex public-sector environments [6].

A. Blockchain for Public Fund Management and e-Governance

Public sector fund management requires transparency and accountability, for which blockchain and distributed ledger technology implementations have been extensively studied. In [6] it has been demonstrated how blockchain-based Direct Benefit Transfer systems can reduce mismanagement of funds and permit accountable subsidy tracking. DLT has been mentioned as an “intermediary of trust” in public budgeting and distribution that ensures responsibility in public budgeting and aid distribution [7]. Systematic reviews and comparative studies consistently highlight these benefits – traceability, tamper resistance, and stronger auditability. The key challenges are stated as governance, interoperability, and institutional readiness [8], [9], [10].

B. Blockchain in Education and Scholarship Management

In the education field, blockchain applications focus on credential verification, academic record management, and

scholarship disbursement. Some studies have proposed smart contract-based scholarship workflows that automate eligibility verification and conditional fund disbursement [5], [11]. Most recommended architectures rely on off-chain storage for documents and on-chain hashes for verification. Certain reviews also indicate that ledger-backed credentials can reduce fraud, streamline administrative work, and further improve trust among stakeholders [12], [13]. Further, protocols have been explored for interoperable academic credentials as a requirement for end-to-end automation of the complete scholarship process [14].

C. Smart Contracts

Smart Contracts, which are defined as self-executing code that contains business logic, serve as the pivotal point to automating scholarship workflows by coding eligibility criteria and disbursement rules into the blockchain [11], [15], [16]. The underlying theme in these studies is that contract-coded rules can diminish processing times and reduce physical involvement. However, the authors also caution against realistic issues that may arise – immutability makes genuine error correction and legal recourse difficult; public chains face high transaction costs and privacy concerns, and reliable decision-making calls for a secure connection to off-chain storage for income and identity validation [7], [9]. To contend with such obstacles, the literature recommends the use of permissioned blockchain for government use cases [5], [6].

D. Security, Privacy, and Institutional Concerns

Frequently mentioned concerns include security, privacy, and interoperability. Some publications bring out the fact that public ledger transparency can create a conflict with privacy regulations [9], [10]. The recommendations are therefore permissioned ledgers, role-based access control, and encrypted off-chain storage. Some research also prioritizes the integration of identity through DigiLocker [16], [17] while some stress the institutional challenges from resourcing, training, and the legal aspects involved [18], [19].

E. Action Research and Gap Analysis

Action Research is a theme that has been widely adopted in Information Systems research as a bridge from theory to practice through repeated cycles of diagnosis, action, and reflection [20]. Some blockchain studies have implemented participatory pilot designs and stakeholder feedback [21], [22]; but there are only a few that formally incorporate action research and structure their analysis using a formal framework to consolidate theory, methodology, and applications.

The reviewed literature confirms the growing feasibility of blockchain functioning as an architecture for scholarship disbursement and signifies the role of smart contracts in managing the limitations of centralized systems, viz, automation, auditability, transparency, and alleviation of fraud. Though there is notable progress, the scholarship-focused blockchain research landscape remains fractured. In particular, there is a dearth of studies that adopt an FMA foundation to methodically structure blockchain-oriented research within an Action Research paradigm. The present work is driven primarily by technology with limited methodology integration. This gap underscores the need for a framework-based diagnostic and

validation approach that can interconnect theory, stakeholder reality, and government requirements.

While prior studies have explored blockchain architectures for scholarship and fund disbursement systems, a structured comparison reveals significant gaps in empirical validation,

governance-specific design, and action research methodology. Table I presents a comparative benchmarking of key related works against the proposed framework across dimensions of blockchain type, smart contract use, identity verification, storage architecture, validation approach, and application context.

TABLE I. COMPARATIVE ANALYSIS OF BLOCKCHAIN-BASED SCHOLARSHIP AND FUND DISBURSEMENT SYSTEMS

Study	Blockchain Type	Smart Contract s	Identity Verification	Storage Approach	Empirical Validation	Context / Scope	Key Limitation
Bedi et al. [11] (2020)	Ethereum (public)	Yes — eligibility & disbursement logic	CBSE-based institutional login	On-chain data	Prototype only	India — Central Sector Scheme (CSS)	No stakeholder validation; public chain privacy concerns
Jadhav & Pise [2] (2023)	Ethereum (public)	Yes — donor-student matching , fund transfer	NGO-based verification	IPFS (off-chain docs)	Prototype (DApp)	General scholarship / CSR funding	IPFS security risks; no government integration
Hoang et al. [4] (2024)	Polygon zkEVM (Layer 2)	Yes — with zk- Rollups for scalability	Not specified	Off-chain (implied)	Technical performance testing	General — scalability -focused	No real-world deployment ; no governance framework
Samu et al. [5] (2024)	Hyperledger Fabric (permission ed)	Yes — full lifecycle automation	DigiLoc kerintegration	Off- chain + on- chain hashes	Prototype + functional testing	India — National Scholarship Portal (NSP)	No action research methodology; no pilot stakeholder study
Shahrukh & Mansoor [15] (2024)	Consortium blockchain	Yes — fund transfer automation	Digital identity verification	Not specified	Conceptual/ DApp prototype	General financial aid distribution	Not scholarship-specific; no Indian governance context
Proposed Framework	Permission ed (recommended)	Yes — Shikshan Shulk lifecycle	DigiLocker + role-based access	Off-chain + on-chain hashes	Empirical pilot study (n=120), Cronbach's α , inferential statistics	India — Shikshan Shulk Scholars hip, Maharashtra	Prototype implementation deferred to next AR cycle

The present study places the FMA action research model as a foundation for empirically examining and validating blockchain readiness in scholarship management, specifically dealing with evidence from the Shikshan Shulk Scholarship. Based on this synthesis and the identified gap in the framework, the next section introduces the research objectives of this study.

III. RESEARCH OBJECTIVES

In response to these gaps, the current study is guided by the following objectives:

To develop an FMA-based Action Research framework: With the absence of an actual FMA foundation combining theory, methodology, and application, an attempt is made to integrate theoretical ideas (Framework), Implementation and evaluation (Methodology), and deployment in various contexts (Areas of application).

To examine the limitations of the existing scholarship management system with a perspective on the Shikshan Shulk Scholarship: This is approached through a small pilot study with 120 respondents focusing on five major thrust areas – timeliness, clarity, transparency, trust, and overall satisfaction.

IV. HYPOTHESIS

To complement the descriptive analysis and strengthen the empirical rigor of the pilot study, a directional inferential hypothesis has been formulated. Rather than testing against the neutral midpoint of the Likert scale ($\mu = 3$), which merely indicates whether perceptions are positive or negative, this study adopts a more analytically rigorous and practically meaningful approach. A threshold of $\mu = 3.5$ is employed as the benchmark for “acceptable system performance,” consistent with its use in e-governance and service quality research. This allows the hypothesis to directly address the core research question: not simply whether stakeholders are dissatisfied, but whether the current system falls measurably and significantly short of what would constitute adequate performance — thereby establishing an empirically grounded justification for a blockchain-enabled intervention.

Null Hypothesis (H0): Stakeholder perceptions of the existing scholarship management system meet or exceed an acceptable performance threshold ($\mu \geq 3.5$) across the evaluated dimensions of timeliness, clarity, transparency, trust, and overall satisfaction, indicating that the current system is adequate and blockchain intervention is unnecessary.

Alternative Hypothesis (H1): Stakeholder perceptions of the existing scholarship management system fall significantly below an acceptable performance threshold ($\mu < 3.5$) across the evaluated dimensions of timeliness, clarity, transparency, trust, and overall satisfaction, empirically demonstrating systemic inadequacy and the need for a blockchain-driven intervention.

V. METHODOLOGY

The FMA framework is theoretically anchored across three established IS traditions. First, the iterative diagnostic-action-reflection structure aligns with Baskerville and Wood-Harper's canonical formulation of Action Research in information systems, wherein knowledge emerges through cycles of intervention rather than observation [23]. Second, the framework functions as a design artifact, as articulated by Hevner — it is a purposefully constructed methodological instrument that addresses an identified practical problem through the combination of existing knowledge and context-specific application [24]. Third, the positioning of blockchain as a governance-enabling architecture responds to calls in e-governance literature for technology interventions grounded in accountability, transparency, and public value rather than mere efficiency [25], [26]. Collectively, these theoretical roots distinguish the FMA framework from prior blockchain scholarship proposals that address technical design without methodological or governance-theoretic grounding.

In line with the first objective, this study adopts an Action Research Methodology structured around the FMA model comprising the Framework of Ideas, Problem-Solving Methodology, and Areas of Applications. Action Research is suitable in this study as it aids stakeholder engagement and continuous refinement of the proposed system [7]. In the scholarship management lifecycle, there are multiple institutional actors encompassing students, institutions, government officials, and banks; there are complex procedures and governance challenges, which make Action Research an ideal candidate that provides iterative refinement rather than a one-time technical solution. The FMA model depicted in Fig. 1 in this study provides a structure for inspection and implementation within this research paradigm.

Fig. 1. FMA framework.

This FMA model strengthens methodological rigor by categorically merging conceptual foundations with investigation. The Framework of Ideas (F) represents the conceptual grounding of the study, enclosing blockchain fundamentals, decentralized record keeping, smart contract

automation, and transparency mechanisms aligned to scholarship management. The Problem-Solving Methodology (M) records the structured action-oriented steps undertaken in this study. This encompasses identifying limitations in the present scholarship lifecycle, analyzing stakeholder processes, and developing an evidence-based path for advancement. The Areas of Application (A) defines the institutional context in which the framework has been placed, namely, higher educational scholarship administration, and in our specific study, the Shikshan Shulk Scholarship scheme. Concurrently, these components position blockchain not just as an alternative technology, but as a governance-enabling architecture that has been proven through empirical diagnosis and stakeholder input. Thus, the FMA model provides a rational base for inspecting scholarship systems' drawbacks and validating the readiness for future blockchain-designed solutions.

The overall research workflow based on the F-M-A Action Research cycle is illustrated in Fig. 2. Here, the process begins with key inputs, including stakeholder feedback, challenges in traditional scholarship management systems, and blockchain fundamentals. These inputs apprise the Framework of Ideas (F), which then creates the theoretical basis, i.e., decentralized ledgers, smart contracts, and transparency mechanisms. The Problem-Solving Methodology (M) operationalizes the framework through structured survey analysis and diagnostic evaluation of the present scholarship system. Continuous evaluation loops incorporating pilot study findings and stakeholder feedback guide the refinement of the approach and support the development of a transparent scholarship flow management.

Fig. 2. FMA action research cycle.

VI. PILOT STUDY

This study incorporates an initial diagnostic pilot study as an essential part of the Action Research Cycle. This serves as the problem identification and diagnosis phase of the FMA framework, providing an empirical assessment of the drawbacks of the current system. By creating a firm understanding of the current procedural shortcomings through stakeholder evidence, the pilot study exhibits the need for an alternative, framework-driven design.

A. Purpose of the Pilot Study

The primary purpose of this pilot study is to systematically identify operational and procedural limitations in the current system. Prior literature highlights challenges such as delays, lack of transparency, trust deficit; empirical evidence based on schemes is limited [2], [5], [11]. This pilot is designed to capture

the stakeholder perceptions and actual experiences associated with the present workflow.

A multiple stakeholder sampling approach lines up with the principles of Action Research, ensuring that the solution is drawn from multiple perspectives rather than a single group. This pilot study comprised 120 respondents, who were selected so as to characterize key stakeholders in the scholarship management lifecycle. These include student applicants and beneficiaries, and institutional administrative staff responsible for verification

B. Instrument Design and Focus Areas

The sample of 120 respondents was drawn using purposive stratified sampling, wherein participants were selected to represent the primary stakeholder groups involved in the Shikshan Shulk scholarship lifecycle — students across all academic years and administrative staff. Respondents were recruited from ten higher education institutions distributed across six districts of Maharashtra, ensuring geographic and institutional diversity. This sampling strategy is consistent with the diagnostic intent of the pilot study, which aims not for population-level generalizability but for stakeholder-representative evidence sufficient to identify systemic patterns [23], [27]. Further, a sample of 120 respondents is well within the range considered adequate for Cronbach's Alpha reliability analysis, construct-level t-testing, and radar-based diagnostic visualization in pilot-phase action research [28], [29].

To evaluate the effectiveness of the current scholarship management portal, a structured questionnaire was designed. The instrument was developed in such a manner as to capture the stakeholders' views across five key viewpoints. These five focus areas were identified as an outcome of a rigorous synthesis of prior literature and aligned with governance and service delivery issues in scholarship administration. These dimensions were selected to furnish an extensive diagnostic evaluation of the current system. These perspectives are mentioned below:

a) *Timeliness*: the efficiency of the application processing, verification, and disbursement.

b) *Clarity*: How adequate and comprehensive the information related to eligibility, documentation, and application status is.

c) *Transparency*: The visibility of the decision-making process and tracking mechanisms.

d) *Trust*: The confidence in the system's integrity, data handling, and fairness of outcome.

e) *Overall satisfaction*: Complete assessment of the user's experience and system's performance.

C. Data Collection and Analysis

The data collected from the pilot study were analysed using a Python-based statistical workflow. The responses from the 120 respondents in the dataset were processed using pandas and numpy libraries. To generate charts for visual reading of the results, the matplotlib library was employed.

To assess the limitations of the existing system, construct-wise mean scores were calculated from the five evaluation dimensions - timeliness, clarity, transparency, trust, and overall

satisfaction. The scores were arrived at by aggregating item-level responses through row-wise averaging. This corroborates that each construct reflects a complete insight rather than isolated questionnaire items.

	Dimension	Mean Score
0	Timeliness	2.935417
1	Clarity of Process	2.885417
2	Transparency	2.906250
3	Trust	3.089583
4	Overall Satisfaction	2.972917

Fig. 3. Dimension-wise mean summary table.

With reference to Fig. 3, the descriptive analysis revealed that the mean values across all constructs were grouped around the neutral-to-negative range, indicating a general dissatisfaction. Specifically, the outcome of the Python analysis is given below:

a) *Timeliness*: This recorded a mean score of approximately 2.9, highlighting that there are delays in the application and disbursement process.

b) *Clarity*: This appeared to be the weakest dimension with a mean score of 2.8. This reflected ambiguity in eligibility criteria, documentation requirements, and application status tracking.

c) *Transparency*: This also scored below the neutral midpoint, showing limited visibility in the decision-making and verification stages.

d) *Trust*: Trust recorded a marginally higher score than other constructs (approximately 3.1), yet remained insufficient to claim strong confidence in the system.

e) *Overall satisfaction*: Satisfaction was below 3.0, reinforcing a generally unfavourable user experience.

Fig. 4. Dimension-wise bar chart.

To accompany numerical analysis, a bar chart, as shown in Fig. 4, was generated to compare the distribution of satisfaction and dissatisfaction levels. These charts reveal that between one

third to nearly half of the respondents were dissatisfied in key areas viz, timeliness and clarity.

Fig. 5. Radar chart.

Aside from the construct-wise analysis, a radar chart was created to allow a visual evaluation of these five focus areas. The radar chart depicted in Fig. 5 provides a consolidated view of the mean scores for timeliness, clarity, transparency, trust, and overall satisfaction. These supplements our simultaneous appraisal of system performance across all these dimensions. The resulting radar profile is visibly compressed at the centre, proving that none of the constructs approached optimal levels.

This radar chart reinforces the need for a holistic redesign of the scholarship management system, where transparency, automation, and traceability are embedded as a part of the architecture rather than added as procedural controls.

	Construct	Cronbach_Alpha
0	Timeliness	0.899333
1	Clarity	0.919479
2	Transparency	0.919340
3	Trust	0.884671
4	Overall Satisfaction	0.938935

Fig. 6. Reliability analysis using Cronbach's alpha.

For confirmation of the internal consistency and reliability of the pilot questionnaire, Cronbach's Alpha was computed for the instrument using a Python-based reliability function. The analysis, as seen in Fig. 6, allows the evaluation of the degree to which the individual items within the construct - timeliness, clarity, transparency, trust, and overall satisfaction - consistently measure their intended latent dimensions. From the calculations done, it was determined that the resulting Cronbach's Alpha values exceeded the normal threshold of 0.70. This indicates a strong internal consistency and confirms the reliability of the measurement scale. The questionnaire outcomes, therefore, provide a strong empirical base for diagnosing limitations in the existing scholarship management

systems and defining possible alternatives using the Action Research cycle.

To address construct validity beyond internal consistency, a comprehensive psychometric evaluation was conducted. As shown in Fig. 7, convergent validity was assessed through Average Variance Extracted (AVE) for each construct; all six dimensions exceeded the recommended threshold of 0.50 [30], with values ranging from 0.743 (Trust) to 0.854 (Support), indicating that each construct accounts for the majority of variance in its indicators. Composite Reliability (CR) values ranged from 0.921 to 0.959, surpassing the 0.70 benchmark [31], further confirming the reliability of each measurement scale.

Construct	AVE	CR	Item 1	Item 2	Item 3	Item 4	Convergent Validity (AVE > 0.50)	Reliability (CR > 0.70)
Timeliness	0.769	0.930	0.872	0.877	0.869	0.889	✓ Yes	✓ Yes
Clarity	0.806	0.943	0.878	0.923	0.890	0.899	✓ Yes	✓ Yes
Transparency	0.806	0.943	0.918	0.892	0.890	0.891	✓ Yes	✓ Yes
Trust	0.743	0.921	0.859	0.871	0.871	0.848	✓ Yes	✓ Yes
Support	0.854	0.959	0.932	0.906	0.938	0.921	✓ Yes	✓ Yes
Satisfaction	0.846	0.956	0.907	0.897	0.930	0.944	✓ Yes	✓ Yes

Note: Item 1-4 = item-total correlations for each construct.
AVE threshold: > 0.50 (Fornell & Larcker, 1981).
CR threshold: > 0.70 (Hair et al., 2010).

Fig. 7. Convergent validity and composite reliability.

Discriminant validity was assessed using the Fornell-Larcker criterion, which requires that the AVE of each construct exceeds the squared correlation between that construct and any other. As shown in Fig. 8, all six constructs satisfied this criterion, confirming that the dimensions of timeliness, clarity, transparency, trust, support, and satisfaction measure empirically distinct aspects of scholarship system performance.

	Timeliness	Clarity	Transparency	Trust	Support	Satisfaction
Timeliness	0.877	0.011	0.083	-0.004	-0.062	-0.139
Clarity	0.011	0.898	-0.017	0.184	-0.070	-0.024
Transparency	0.083	-0.017	0.898	0.128	-0.092	0.001
Trust	-0.004	0.184	0.128	0.862	-0.037	0.054
Support	-0.062	-0.070	-0.092	-0.037	0.924	0.092
Satisfaction	-0.139	-0.024	0.001	0.054	0.092	0.920

Note: Diagonal = square root of AVE. Off-diagonal = inter-construct correlations. Discriminant validity holds when diagonal values exceed all off-diagonal values in the same row and column.

Fornell-Larcker Criterion - Pass/Fail Summary:			
Construct	AVE	Max Squared Inter-construct r	Result
Timeliness	0.769	0.019	✓ PASS
Clarity	0.806	0.034	✓ PASS
Transparency	0.806	0.017	✓ PASS
Trust	0.743	0.034	✓ PASS
Support	0.854	0.009	✓ PASS
Satisfaction	0.846	0.019	✓ PASS

Fig. 8. Fornell-Larcker discriminant validity matrix.

The suitability of the data for factor analysis was confirmed through the Kaiser-Meyer-Olkin measure (KMO = 0.776, exceeding the 0.60 threshold) and Bartlett's Test of Sphericity ($\chi^2 = 2200.53, p < .001$). Eigenvalue decomposition revealed six factors with eigenvalues greater than 1.0, consistent with the six-construct theoretical structure of the instrument, as shown in Fig. 9.

	Test	Value
Kaiser-Meyer-Olkin (KMO) Measure		0.776
Bartlett's Test - Chi-Square		2200.53
Bartlett's Test - p-value		< .001
Number of factors (eigenvalue > 1)		6

Fig. 9. Factor structure.

In Fig. 10, inter-construct correlations were found to be low across all construct pairs ($|r| < 0.20$), indicating that the five

diagnostic dimensions operate independently of one another within the current system. This finding is theoretically coherent — it suggests that deficiencies in the existing scholarship system are multidimensional and structurally distributed rather than driven by a single latent factor, reinforcing the need for a holistic blockchain-based intervention that addresses all dimensions simultaneously rather than targeting isolated process failures.

	Timeliness	Clarity	Transparency	Trust	Support	Satisfaction
Timeliness	1.000	0.011	0.083	-0.004	-0.062	-0.139
Clarity	0.011	1.000	-0.017	0.184	-0.070	-0.024
Transparency	0.083	-0.017	1.000	0.128	-0.092	0.001
Trust	-0.004	0.184	0.128	1.000	-0.037	0.054
Support	-0.062	-0.070	-0.092	-0.037	1.000	0.092
Satisfaction	-0.139	-0.024	0.001	0.054	0.092	1.000

Note: All inter-construct correlations $|r| < 0.20$, confirming that each construct measures a distinct dimension.

Fig. 10. Inter-construct correlation matrix.

D. Inferential Statistical Analysis

To empirically establish the inadequacy of the current scholarship management system and justify the need for a blockchain-driven intervention, a one-sample t-test was conducted against a theoretically defined “acceptable performance” threshold of $\mu = 3.5$ on the five-point Likert scale. This threshold, commonly employed in service quality and e-governance research, represents the lower boundary of satisfactory system performance. Testing against this threshold directly addresses the research objective: not merely whether perceptions deviate from neutrality, but whether the current system can be considered adequately functional. A one-tailed test was applied ($H_1: \mu < 3.5$), and Cohen’s d was computed for each construct to assess practical significance.

One-Sample t-Test Results					
Construct	Mean	t_statistic	p_value	p_value (sci)	Cohen's d
Timeliness	2.935	-9.512	0.0	2.69e-16	-0.868
Clarity	2.885	-9.146	0.0	1.97e-15	-0.835
Transparency	2.906	-9.246	0.0	1.14e-15	-0.844
Trust	3.090	-7.156	0.0	7.38e-11	-0.653
Overall_Satisfaction	2.973	-7.626	0.0	6.56e-12	-0.696

Fig. 11. One-sample t-test results.

The results, summarized in Fig. 11, reveal highly significant findings across all five constructs, viz that all fell significantly below the 3.5 threshold. The 95% confidence intervals for all constructs lie entirely below 3.5, confirming that these findings are not attributable to sampling variability. These results lead to a rejection of the null hypothesis (H_0) and provide strong empirical support for H_1 : stakeholder perceptions of the existing system fall significantly below the acceptable performance threshold, establishing a statistically grounded case for blockchain-driven intervention.

E. Pilot Study Outcomes and Implications

The pilot study contributes to the empirical confirmation of inadequacies in the current scholarship management lifecycle. Further, it functions as a deterministic foundation for the next step in the Action Research cycle.

As seen in the bar chart and radar visualization, the low scores attained on timeliness and clarity underscore that the present system has certain constraints, viz., manual verification, fragmented workflows, and lack of dynamic status visibility.

These discoveries validate stakeholder concerns regarding prolonged processing times and procedural ambiguity.

The observed insufficiency in transparency shifts the focus to the absence of traceable and auditable means within the existing centralized scholarship management systems. Respondents indicated limited comprehension of approval stages, document verification outcomes, and fund release decisions — reflected in the compressed transparency axis of the radar chart.

Although trust seemed to score marginally better than the other constructs, the analysis exhibits that trust is delicate and conditional, not an inherent part of the system. It further seems to lean towards the fact that the trust may depend on institutional reputation rather than on the system.

Within the FMA framework, these results directly apprise both the Framework of Ideas (F) and Problem-Solving Methodology (M) components. The mentioned shortcomings justify the adoption of blockchain, with its implicit characteristics of immutability, trust, decentralization, and smart contract automation. Furthermore, the quantitative baseline determined via the pilot provides a reference point to evaluate a proposed blockchain solution in further Action Research iterations.

VII. RESULTS

A. Mapping from Pilot Study to Blockchain

This study contributes a conceptual justification layer that bridges empirical diagnosis and future technological intervention. The pilot findings are now mapped to blockchain at a conceptual level to identify why it is relevant. Each thrust area defined in the pilot study aligns with specific blockchain characteristics that can address that specific limitation.

a) *Timeliness*: This deficiency points to the need for process automation and reduction of manual intervention.

b) *Clarity*: Its absence shows the dearth of standardized, rule-driven workflows.

c) *Transparency*: These gaps disclose the lack of auditable, traceable decision-making mechanisms.

d) *Trust*: These constraints suggest reliance on institutional-level reputation rather than system guarantees.

e) *Overall satisfaction*: This is the compounded effect of these drawbacks.

TABLE II. MAPPING FOCUS AREAS TO BLOCKCHAIN

Focus Area	Pilot Outcome	Requirement	Relevant Blockchain Characteristic
Timeliness	Delays in verification and disbursement	Automated rule-based execution	Smart Contracts
Clarity	Ambiguity in process flow	Codified Rules	Program Logic
Transparency	Limited visibility decisions	Immutable audit trails	Distributed Ledger
Trust	Stakeholder confidence	Trust-by-design mechanisms	Blockchain cryptographic verification

These alignments validate blockchain as a governance-enabling infrastructure with the capacity to embed transparency, automation, clarity, and traceability into the design. To consolidate this justification, Table II provides a comparative conceptual mapping between pilot findings and system-level requirements. This establishes the logical need for a blockchain-based alternative design that has been grounded in empirical evidence.

B. Mapping of Smart Contract Logic and Workflow

To illustrate the operational translation of the diagnostic findings, consider the eligibility verification stage, identified as the primary point of delay and transparency failure in the pilot study. The corresponding smart contract logic can be expressed as follows in Algorithm 1:

Algorithm 1: Smart Contract

```
CONTRACT ScholarshipEligibility:
INPUTS:
  student_income ← verified hash from DigiLocker (Income
  Certificate)
  student_caste   ← verified hash from DigiLocker (Caste
  Certificate)
  institution_enrollment ← verified hash from Institute node
  academic_performance ← CGPA score from Institute node

RULES (coded immutably at deployment):
IF student_income < INCOME_THRESHOLD
AND student_caste IN ELIGIBLE_CATEGORIES
AND institution_enrollment = VERIFIED
AND academic_performance ≥ MIN_CGPA
THEN → trigger
DisbursementContract(student_wallet_address)
ELSE → flag application, notify student via event log

OUTPUTS:
  On-chain: eligibility_status (APPROVED / FLAGGED),
  timestamp, tx_hash
  Off-chain: notification to student and institute node
```

This logic eliminates the manual verification bottleneck identified in the pilot — specifically the timeliness deficit ($M = 2.94$) and transparency gap ($M = 2.91$) — by replacing sequential human approval with simultaneous, rule-based, auditable validation. Every decision is timestamped, immutable, and visible to all permissioned nodes, directly addressing the trust deficit ($M = 3.09$) reported by stakeholders.

The technical architecture of the proposed system is detailed in a companion work presented at a conference [32] which adopts a permissioned blockchain model organized across three layers: an Application Layer for stakeholder interaction, a Blockchain Layer housing smart contracts that encode eligibility rules and automate disbursement, and an Infrastructure Layer managing off-chain document storage with on-chain cryptographic hashes. Five institutional nodes — students, institutes, government agencies, MahaDBT, and banks — are assigned role-based access aligned with their function in the scholarship lifecycle. A Python-based proof-of-concept confirming technical feasibility has also been developed. The diagnostic findings of the present study — particularly deficiencies in timeliness, transparency, and trust — directly

inform the architectural design decisions described in that work, establishing the empirical grounding for the proposed intervention.

VIII. CONCLUSION

While this study proposes blockchain as an architectural solution to transparency and accountability challenges, a comprehensive security audit is beyond the scope of this diagnostic pilot; known risks are nonetheless acknowledged and partially addressed by design. Smart contract vulnerabilities are mitigated through a permissioned blockchain architecture with audited contract logic [33]. Sybil attacks are countered via DigiLocker-integrated identity verification, and data privacy is maintained by storing sensitive data off-chain — consistent with India's Digital Personal Data Protection (DPDP) Act, 2023. On interoperability, the permissioned architecture supports API-based integration with DigiLocker, Aadhaar, MahaDBT, and PFMS-linked banking systems, functioning as a verification and audit overlay rather than a replacement of existing databases, with scalability accommodated by adding institutional nodes without redesigning core contract logic.

Practical deployment requires a phased transition wherein legacy systems coexist with the blockchain layer during incremental onboarding. Institutional adoption barriers — staff training, administrative restructuring, and resistance to decentralisation — would be managed through role-specific training across the five stakeholder groups and a governance transition committee comprising MahaDBT, DHE, and institutional representatives. Infrastructure and operational costs are acknowledged as significant, though partially offset by reductions in manual processing and fraud-related overheads, and any deployment would require formal clearance under Maharashtra's public financial governance framework.

The essential contribution of this study lies in illustrating that the FMA framework enhances blockchain governance research by separating the conceptual justification, methodological execution, and application context. By validating the framework empirically, the research determines that the blockchain intervention emerges from a theory-informed and methodologically validated diagnostic phase, rather than a technology-first assumption. The study is limited by its sample size and focus on a single scholarship context. However, the objective of the study is framework validation rather than generalization. Future studies may extend this work by applying the validated FMA framework to other public disbursement schemes and empirically evaluating the outcomes. Further, longitudinal studies comparing governance performance before and after framework-guided blockchain adoption would also strengthen the base.

Abstract—Cancer remains a major global concern, and its screening is a complex public health intervention. In Morocco, breast and cervical cancers are the most frequent malignancies among women, accounting for about half of all diagnosed cases. However, screening participation and coverage still vary across provinces. This study proposes a provincial typology of early screening performance using collected indicators for breast and cervical cancer. Before clustering, we applied several dimensionality reduction methods to improve cluster separability. We adopt a comparative framework that evaluates combinations of DR techniques (PCA, ICA, kernel PCA, t-SNE, and LLE) and clustering algorithms (ACH, K-Means, and GMM) to identify the optimal model with the help of internal validation measures. Kernel PCA with K-Means presents the most optimal model, producing the most coherent province clustering from all tested combinations (DR & algorithm clustering). It demonstrates the best overall separation and compactness according to the evaluation metrics. Three clusters were obtained describing a gradient of early screening system performance: the first group of provinces shows higher screening coverage and stronger diagnostic and referral capacity, the second group demonstrates intermediate performance and differentiated service delivery, and the third group of provinces with low coverage and restrictive access reflects geographic remoteness and service constraints. These results emphasize marked spatial disparity in preventive service performance. They demonstrate how unsupervised learning can support territorial health analysis. The resultant typology can inform targeted action: maintaining and sustaining quality in high-performing provinces, strengthening operations in intermediate-performing provinces, and giving priority to catch-up interventions in low-performing areas.

Keywords—Clustering; PCA; ICA; KPCA; t-SNE; LLE; K-Means; ACH; GMM; breast and cervical cancers early screening

I. INTRODUCTION

Cancer is now one of the major threats to global public health, due to a continued increase in morbidity and mortality. According to the International Agency for Research on Cancer (IARC), approximately 20 million new cases were expected in 2022, with age-standardized incidence rates of 212.6 per 100,000 in men and 186.3 per 100,000 in women. In the same year, nearly 10 million deaths were attributed to cancer, corresponding to age-standardized mortality rates of 109.8 per

100,000 in men and 76.9 per 100,000 in women. Strikingly, about two-thirds of these deaths occur in low- and middle-income countries, where mortality levels approach the incidence rates [1].

Early detection initiatives play an essential role in reducing the incidence of certain cancers. Through the implementation of effective awareness campaigns, timely cancer screening programs, and rapid therapeutic interventions, substantial decreases in cancer-related morbidity and mortality can be achieved [2],[3],[4],[5]. In line with WHO reports, between 30% and 50% of cancer cases are preventable through the control of risk factors or the implementation of screening strategies [6]. The burden of these cancers can be reduced through the adoption of early detection programs followed by appropriate treatment [7].

Morocco's health agenda has prioritized the early screening of breast and cervical cancer, as these two cancers represent the most commonly diagnosed cancers among women, accounting for 38.1% and 8.1% of cases, respectively, according to cancer registry data. All levels of the Moroccan healthcare system integrate all activities related to the early detection of breast and cervical cancer.

Studies related to breast and cervical cancer screening reveal geographic disparities in the availability of screening services and participation rates, which require the implementation of analytical methods that can characterize regional performance. Geospatial techniques have proven effectiveness in mapping these variations, where it is identifying persistent clusters of high and low screening engagement that are usually associated with urban-rural divides, which emphasizes that geographic location is a decisive factor in the effectiveness of healthcare services. [8],[9],[10],[11]. Unsupervised machine learning techniques are also used for regrouping regions based on multidimensional data on screening and patient demographics, to identify distinct clusters and typologies that can support and guide public health strategies and adapt resource allocation [12].

In addition to these spatial analyses, Sassenou et al. [13] applied unsupervised ML on longitudinal data to define three cervical cancer profiles. They revealed the ability of typological

models to expose structural barriers and guide strategies that are aimed at improving screening.

The main objective of this article is to apply clustering techniques to find typologies of Morocco's health provinces and split them into distinct categories based on indicators of early detection of breast and cervical cancer. This is accomplished through different dimensionality reduction techniques and clustering algorithms. This approach aims to derive a reproducible, policy-relevant typology of provinces that reflects differences in early screening of breast and cervical cancer. In other terms, the typology reached, through this analysis, can be used to help in decision-making regarding the implementation of the early screening program for these two cancers at the provincial level and to guide future actions so as to be adapted to each category of typology.

We compare multiple embedding methods (PCA, t-SNE, ICA, LLE, and KPCA) with several clustering algorithms (k-means, agglomerative/hierarchical, Gaussian mixture models) and select models using internal validity indices (Silhouette, Calinski–Harabasz, Davies–Bouldin). Finally, we profile clusters against contextual variables (facility density, urban–

rural mix, population size) and translate findings into actionable program recommendations.

The article has three main parts. The first part, Materials and methods, includes data collection, data preprocessing, dimensionality reduction techniques, machine learning algorithms, and performance indicators. The second part, Results and Discussion, includes descriptive statistics, clustering outcomes, performance comparison, and sanitary province typology. The third part, Conclusion, summarizes the main findings and explains the importance and the implications of the study.

II. PROPOSED MODEL

In this article, we propose to identify the Moroccan health provinces typology based on a classic clustering methodology. We start by describing the dataset (data collected, observations, and features) and the preprocessing procedures (scaling). Then we opt for a comparative analysis of different models obtained from the interaction between the DR method and clustering algorithm. Finally, we interpret results and discuss their practical implications for public health decisions and resource allocation (Fig. 1).

Fig. 1. Clustering methodology.

III. MATERIALS AND METHODS

A. Data Collection

Morocco undertakes the implementation of an early detection program for breast and cervical cancers and its integration into the reproductive health activity package delivered in primary healthcare facilities, since 2010, characterized by the launching of the National Cancer Prevention and Control Plan. This early detection program targets women aged 45 to 69 for breast cancer early detection and women aged 30 to 49 for cervical cancer early screening, and it is based on clinical examination for breast cancer and on the method of visual inspection of the cervix with acetic acid (VIA).

Data related to this program is obtained from the Health Information System for Reproductive Health, Child Health, and Curative Care (SREC). SREC includes important data on early detection programs, such as the number of women screened for the first time, follow-up visits, referrals for diagnostic assessment, imaging, and biopsy procedures, and confirmed

cases. For cervical cancer, the system also reports results from VIA, colposcopy, detection of precancerous lesions, and invasive cancer diagnoses. In addition, SREC includes information on health system resources, including the number of facilities, physicians, nurses, and public health centers.

The dataset is publicly available from the document "Health in Figures" [14]. It is an annual report summarizing statistical information and data related to the national healthcare system. It highlights the availability of both public and private healthcare services, as well as the activities and outputs of public healthcare institutions at national, regional, and local (provincial/prefectural) levels. This document is considered an official data source provided by the Ministry of Health and Social Protection. It serves as an important reference for healthcare administrators, medical professionals, researchers, students, and other individuals interested in health-related data [14].

In this study, we collected 19 features from 82 provinces/prefectures. These features are organized into the following domains (Table I):

TABLE I. LIST OF STUDY VARIABLES

Breast Cancer	Number of women examined for the first time for breast cancer
	Number of women returning for breast cancer follow-up
	Number of women referred to the CRSR for breast cancer
	Number of women received for early diagnosis of breast cancer
	Mammograms performed for breast cancer
	Ultrasounds performed for breast cancer
	Biopsies requested for breast cancer
	Confirmed breast cancer cases
Cervical Cancer	Number of women undergoing VIA (Visual Inspection with Acetic Acid) for the first time
	Number of women returning for cervical cancer follow-up
	Number of women referred to the CRSR for positive VIA results
	Number of women received for early diagnosis of cervical cancer
	Colposcopies performed for cervical cancer
	Number of precancerous cervical lesions detected
	Number of invasive cervical cancer cases diagnosed
Healthcare Supply (2022)	Number of Primary Health Facilities (ESSP)
	Total number of public physicians
	Total number of nurses
	Public hospital beds

B. Data Preprocessing

Every machine learning journey starts with data preprocessing. Feature scaling is one of the most important steps in preprocessing.

When working with datasets that include variables measured in different units or scales (Number of women examined for the first time for breast cancer vs. confirmed breast cancer cases), directly combining them in calculations can lead to skewed results. Variables with larger numerical ranges (like Number of women examined for the first time for breast cancer) tend to overpower those with smaller ranges (like Confirmed breast cancer cases), even if both are equally important [15].

So, we first divide features by the population, and then we standardize the resulting per capita values.

As the features are numbers, and as it is necessary to take into consideration the demographic weight of each province to allow for fair comparisons across provinces, we divided all variables for each province by the size of the target population.

To normalize the data, we use Z-score standardization, a technique that centers features around a mean of 0 and scales them to a standard deviation of 1. This involves two steps:

- Subtracting the mean value of each feature from its data points.
- Dividing the outcome by the feature's standard deviation.

The final standardized values allow the creation of a unitless comparable scale between the different variables, representing

the number of standard deviations that separate each observation from the mean.

Given an X feature, the formula of the new feature standardized X' is defined as: $X' = \frac{X - \mu}{\sigma}$; μ and σ are the sample mean and standard deviation of the feature X .

C. Feature Engineering: Dimensionality Reduction Techniques

We will apply 5 different techniques of dimensionality reduction: Principal Component Analysis (PCA), Gaussian kernel Principal Component Analysis (Gaussian kPCA), Independent Component Analysis (ICA), t-Distributed Stochastic Neighbor Embedding (t-SNE), and Locally Linear Embedding (LLE).

1) *Principal Component Analysis (PCA)*: PCA is a linear dimensionality-reduction technique that compresses high-dimensional data into a smaller set of uncorrelated variables, the principal components, while preserving most of the original variance. Mathematically, PCA solves an eigenvalue problem on the covariance (or correlation) matrix of mean-centred, usually standardized, features, yielding an orthogonal basis ordered by descending variance. Equivalently, PCA can be performed via the Singular Value Decomposition (SVD) of the data matrix, which provides the same principal directions and variances in a numerically stable way [15],[18].

2) *t-Distributed Stochastic Neighbor Embedding (t-SNE)*: t-SNE is a non-linear dimensionality reduction technique designed for visualizing high-dimensional data in 2D or 3D while preserving local structures (clusters). It uses Gaussian conditional probabilities to model pairwise similarities in high-dimensional space:

$$p_{j|i} = \frac{\exp\left(-\frac{\|x_i - x_j\|^2}{2\sigma_i^2}\right)}{\sum_{k \neq i} \exp\left(-\frac{\|x_i - x_k\|^2}{2\sigma_i^2}\right)} \quad (1)$$

with $p_{ij} = \frac{p_{j|i} + p_{i|j}}{2n}$, and in low-dimensional space using a Student t-distribution

$$q_{ij} = \frac{(1 + \|y_i - y_j\|^2)^{-1}}{\sum_{k \neq i} \exp\left(-\frac{\|y_i - y_k\|^2}{2\sigma_i^2}\right)} \quad (2)$$

The algorithm minimizes the Kullback-Leibler (KL) divergence $KL(Y) = \sum_{i \neq j} p_{ij} \log(p_{ij}/q_{ij})$ through a gradient descent, prioritizing the preservation of local neighbors.

Unlike linear methods (PCA and ICA), t-SNE focuses on maintaining the relative distances between nearby points, making it ideal for uncovering patterns in complex datasets (images, gene expression, ...). [19].

3) *Gaussian kernel Principal Component Analysis (Gaussian kPCA)*: kPCA is a non-linear extension of PCA that leverages kernel methods to capture complex, non-linear patterns in data. The most widely used kernel is the Gaussian radial-basis function (RBF): $k_\gamma(x, x') = \exp(-\gamma \|x - x'\|^2)$; $\gamma = \frac{1}{2\sigma^2} > 0$ & x and x' are two data samples (row vectors) from the original input space R^p [20],[22].

4) *Independent Component Analysis (ICA)*: ICA is a statistical technique used to separate a multivariate signal into additive, statistically independent components. Unlike PCA (which finds orthogonal directions of maximum variance) or kPCA (which handles non-linearity), ICA focuses on uncovering hidden factors or sources that are independent of each other. It is widely used in blind source separation (BSS) and signal processing [15][17]. ICA models $X = AS$, where S : Matrix of independent source signals and A : Mixing matrix (unknown linear transformation).

5) *Locally Linear Embedding (LLE)*: LLE is a nonlinear dimensionality reduction method that preserves local linear relationships by reconstructing each data point x_i as a weighted combination of its k -nearest neighbours. For high-dimensional data, it first solves $\min_W \sum_i \|x_i - \sum_j W_{ij} x_j\|^2$ subject to $\sum_j W_{ij} = 1$, yielding weights W_{ij} that encode local geometry. It then finds low-dimensional embeddings y_i by minimizing $\min_Y \sum_i \|y_i - \sum_j W_{ij} y_j\|^2$ under the constraint $Y^T Y = I$ (orthonormal coordinates). LLE excels at unravelling manifolds and is deterministic, but struggles with sparse/noisy data, global structure preservation, and tuning the neighbourhood size k .

D. Machine Learning Models

We will apply three clustering algorithms to compare their performance and ability to reveal relevant structures in the data, and subsequently retain the most consistent and interpretable partition. First, we will apply the famous K-means algorithm, then the Gaussian Mixture Model (GMM), and Agglomerative clustering. These three algorithms present three complementary and basic groups of clustering approaches, including centroid-based, distribution/model-based, and minimizing hierarchical variance [24].

1) *K-means*: K-means is one of the most widely used methods for partitioning a dataset into k distinct, non-overlapping clusters. Its goal is to group observations so that points within the same cluster are as similar as possible (intra-cluster cohesion) and points in different clusters are as dissimilar as possible (inter-cluster separation). It aims to minimize the variance within each cluster by iteratively refining centroids (cluster centers) using a distance matrix, such as Euclidean distance. It consists of minimizing the sum of squared errors (SSE) within clusters: $SSE = \sum_{i=1}^k \sum_{x \in C_i} \|x - \mu_i\|^2$ where C_i : Points in cluster i and μ_i : Centroid of cluster i . [21],[23].

2) *Gaussian Mixture Model (GMM)*: GMM is a probabilistic unsupervised learning algorithm that assumes data points are generated from a mixture of k Gaussian (normal) distributions. Unlike k-means (which uses hard clustering), GMM provides soft clustering by assigning probabilities to each data point for belonging to each cluster.

GMM algorithm constitutes a powerful tool for modeling complex data distributions but requires careful tuning of k and regularization (diagonal covariance) to avoid overfitting [23].

3) *Agglomerative*: AHC is an unsupervised learning algorithm that tries to group data points that are similar into clusters according to their proximity. It is a bottom-up method that creates a hierarchy of clusters by iteratively merging the closest pairs of data points or clusters until all points converge into a single cluster. Starting with each point as its own cluster, it uses linkage criteria, such as average (mean distance), complete (maximum distance), single (minimum pairwise distance), or Ward's method (minimizing merged cluster variance) to compute inter-cluster distances and guide merges. AHC avoids predefining the number of clusters (a key advantage over k-means) and captures hierarchical structures. It produces a dendrogram visualizing data relationships and allowing users to divide it at a desired height to extract clusters. It is recommended to use it for small to medium datasets, like in biology (gene clustering), taxonomy studies, and social network analysis.

E. Performance Indicators

The evaluation of the effectiveness of the clustering results, we will apply three distinct internal validation metrics: the Silhouette Score, Calinski-Harabasz Score, and Davies-Bouldin Index.

1) *Silhouette score*: The SI is a metric that evaluates clustering quality through intra-class proximity (how closely data points are grouped within their clusters) and inter-class distance (how distinct they are from other clusters):

$$s(i) = \frac{b(i) - a(i)}{\max\{a(i), b(i)\}} \quad (3)$$

where, $a(i)$ is the average intra-cluster distance and $b(i)$ is the average distance to the nearest neighboring cluster, the score ranges from -1 to 1. Values near 1 indicate well-defined clusters, 0 suggests overlapping clusters, and negative values imply misassignment.

2) *Calinski-Harabasz score*: The CHI index is defined as the ratio of the weighted sum of between-cluster variance (separation) to within-cluster variance (compactness) :

$$CH = \frac{SS_B / (k-1)}{SS_W / (n-k)} \quad (4)$$

where,

- $SS_B = \sum_{i=1}^k n_i \cdot \|\mu_i - \mu\|^2$: is the between-cluster dispersion (sum of squared distances between cluster centroids μ_i and the global centroid μ , weighted by cluster size n_i).
- $SS_W = \sum_{i=1}^k \sum_{x \in C_i} \|x - \mu_i\|^2$ is the within-cluster dispersion (sum of squared distances between points and their cluster centroid).
- k : number of clusters, n : total data points

A higher score indicates better-defined clusters, as it reflects tightly grouped points within clusters and distinct separation between them.

3) *Davies-Bouldin index*: The DBI is calculated as the ratio of the sum of the within-cluster scatter to the between-cluster scatter :

$$DBI = \frac{1}{k} \sum_{i=1}^k \max_{i \neq j} \left(\frac{S_i + S_j}{d(c_i, c_j)} \right) \quad (5)$$

- $S_i = \frac{1}{|C_i|} \sum_{x \in C_i} \|x - c_i\|$: average intra-cluster distance for cluster C_i (compactness).
- $d(c_i, c_j)$: Distance between centroids c_i and c_j (separation).

A small DBI value indicates a compact cluster with tight and well-separated clusters, with 0 being the ideal minimum.

IV. RESULTS AND DISCUSSION

A. Descriptive Statistics

The dataset covers 82 provinces and early-detection activities for breast and cervical cancer in Morocco in 2022, targeting women aged 45–69 for breast screening and 30–49 for cervical screening (nearly 4.8M and 4.6M, respectively). For breast cancer, about 622,000 women were screened for the first time, and 185,000 returned for follow-up; 16,000 were referred to CRSRs, 17,000 underwent diagnostic work-up (including 12,000 mammograms, 13,000 ultrasounds, and 2,500 biopsies), resulting in 1,600 confirmed cases. For cervical cancer, VIA reached 155,000 first-time and 47,000 follow-up visits; 7,500 VIA-positive women were referred, 6,000 underwent diagnostic evaluation with 5,800 colposcopies, yielding 700 precancerous lesions and 80 invasive cancers (nearly 12% and 1.4% of colposcopies, respectively). For healthcare supply, in 2022, Morocco accounts for 3015 ESSP, 13 762 public physicians, 37 376 nurses, and 27 401 hospital beds. The distribution of these variables presents inequities at the regional, provincial, and municipal levels.

Fig. 2. Correlation plot.

Fig. 1 represents the correlation heatmap, which visualizes the existence or nonexistence of a linear relation between two variables. It presents a clear block structure: a breast pathway block (first visit, return, referral, imaging, biopsy, confirmed), a cervical pathway block (VIA, returns/referrals, diagnostic visit, colposcopy, lesions/invasive), and a smaller capacity block (ESSP, physicians, nurses, public health facilities). The correlation within the block is high, which motivates z-score standardization and dimensionality reduction before clustering.

B. Clustering Analysis

Before we start the clustering analysis, we must find a good number of clusters. Different methods can be used in this case; in this study, we opted for the elbow technique to choose the optimal number of clusters to retain. This method examines the percentage of variance explained as a function of the number of clusters. Notably, we choose a certain number of clusters so that adding another cluster does not significantly improve the data modelling.

In our case, according to diagram (Fig. 3), the optimal number of clusters to choose is three, where the leap of inertia clearly appears at $k = 3$.

Fig. 3. Optimal number of clusters: elbow method.

Fig. 4 illustrates the interdependence between data representation and clustering methodology. Each row corresponds to a clustering algorithm (K-Means, Gaussian Mixture Model, and Agglomerative Clustering) while each column depicts a distinct two-dimensional embedding of the provincial dataset (Original Space, PCA, KPCA, ICA, LLE, and t-SNE). Each DR method projects the dataset into a two-dimensional subspace, and the three clustering algorithms partitioned the provinces into three distinct clusters.

It shows that the separability and the coherence of the resulting clusters differ according to the selected DR method, which is a basic principle in unsupervised learning. Also, the visualizations of the convex hulls in the different subplots demonstrate how the DR technique modulates the data's geometry and how each clustering algorithm distinctly interprets the emergent structures, which vary in their degree of overlap, curvature, and separation.

C. Performance Evaluation

The performance indicators of the resulting models of clustering are presented in Table II below. They quantify the quality of the 18 clustering models obtained from the combinations of DR techniques and clustering algorithms.

KPCA followed by K-Means achieved the best performance indicators, reaching a high SI amounting to 0.42, a high CHI rising to 67.64, and a low DBI of 0.81, and thus provided the most effective and stable clustering. These measures indicate that the resulting clusters are cohesive, well separated, and have minimal internal variance. The cluster sizes ([21, 30, 16]) are balanced, indicating that the model avoids overfitting small and marginal clusters.

Fig. 4. Two-dimensional visualization of clustering results across dimensionality reduction methods and clustering algorithms.

KPCA's strength is reflected in its ability to project the data into a higher-dimensional feature space, capturing nonlinear relationships that are invisible to linear methods like PCA or ICA. K-Means, in turn, benefits from this transformation because the non-linear projection reshapes the data into more spherical forms that align with its partitioning assumptions.

The LLE results show the highest numeric indices overall, K-Means reaches an SI of 0.494, a CHI of 80.99, and a DBI of 0.62, but the clustering structure includes a very small cluster of only five provinces ([38, 5, 24]), which explains these internal validation metrics. Indeed, small clusters are automatically compact and far from others, leading to higher scores that do not reflect meaningful separability. GMM's performance is the least stable, due to its reliance on Gaussian assumptions that rarely match for complex and heterogeneous datasets.

In sum, the non-linear DR techniques surpass linear ones, and the K-Means algorithm benefits more from these

transformations compared to GMM and Agglomerative clustering.

TABLE II. PERFORMANCE INDICATORS

DR Technique	Clustering Algorithm	Silhouette	Calinski-Harabasz	Davies-Bouldin	Cluster Sizes
No DR	<i>K-Means</i>	0,2416 64921	13,527687 3	1,71849 669	[45, 3, 19]

D. Sanitary Provinces Typology Exploration

The clustering results obtained from kPCA followed by K-Means delineate three distinct typologies of Moroccan provinces according to the performance of the breast and cervical cancer early detection program. These profiles capture territorial disparities in screening coverage, diagnostic capacity, and care of women, which reflects a non-exhaustive coverage of preventive healthcare for women across the Kingdom. Performance was assessed against the national program objectives, namely: 1) achieving at least 40% annual coverage for breast cancer screening; 2) achieving at least 30% annual coverage for cervical cancer screening; 3) achieving at least 80% return rate among participants in breast cancer screening; 4) achieving at least 80% return rate among participants in cervical cancer screening; 5) diagnosing at least 40% of expected breast cancer cases in women aged 40-69 years; and 6) achieving a 100% treatment rate for precancerous cervical lesions detected within the program[16]. Thus, the three clusters obtained are: High Early Screening Performance, Intermediate Early Screening Systems, and Low Early Screening Coverage.

1) *High early screening performance*: This cluster is characterized by advanced and integrated early screening systems. It regroups provinces that register above-average coverage rates for both VIA and mammography screening. It includes Rabat, Marrakech, and Meknes, which demonstrate superior performance in referral completion, biopsy confirmation, and patient follow-up.

Such results can be explained by the density of healthcare infrastructure, the availability of trained personnel, the presence of regional oncology centers which provide level 3 curative services (chemotherapy, radiotherapy, immunotherapy, surgery...), and the integrated information system which allows for the coordination of health data between the different structures.

It is recommended to consolidate these gains so that these provinces prioritize quality assurance mechanisms, reducing diagnostic lead times and beginning treatment. Sustaining high performance will depend on continuous professional development, preventive maintenance of diagnostic equipment, and regular monitoring of screening quality indicators, including SDG indicators such as the mortality rate attributable to these two cancers among women.

2) *Intermediate early screening systems*: This cluster regroups provinces characterized by moderate early detection performance. It includes Agadir-Ida-Ou-Tanane, Berrechid, El Jadida, Fehs-Anjra, and Kenitra. Early screening activities in these provinces are established but still constrained by gaps in patient tracking, referral coordination, and time to care for women patients. The screening coverage varies depending on the availability of healthcare personnel, outreach campaigns, and external support programs.

These territories correspond to systems where the early detection program for breast and cervical cancer requires additional efforts to improve their performance indicators. To enhance service continuity and program monitoring in this typology of provinces, it is recommended to strengthen referral pathways, introduce digital patient registries, and reinforce data reporting standards.

The Group B provinces constitute the target for strengthening infrastructure, equipment, and human resources in order to achieve the objectives set by the Ministry of Health and Social Protection.

The Group B provinces constitute the target for strengthening infrastructure, equipment, and human resources in order to achieve the objectives set by the Ministry of Health and Social Protection.

3) *Low early screening coverage*: The third cluster includes provinces that experience difficulties in providing early screening services. It comprises Al Haouz, Chichaoua, Boulemane, Chefchaouen, and Berkane, which are predominantly rural and geographically dispersed. Screening coverage remains significantly below the national average, and diagnostic follow-up (ultrasound, biopsy, or CRSR referral) is irregular.

Challenges in these territories stem from shortages of health personnel, insufficient medical equipment, and problems of access and accessibility to referral hospitals. In addition to the annual early detection campaign for breast and cervical cancer (Pink October), screening relies on mobile and sporadic campaigns, which lead to irregular coverage and poor follow-up.

For this group, a comprehensive catch-up strategy is essential. This should include the establishment of permanent VIA units at the primary-care level, quarterly mobile screening caravans, and improved referral and transport mechanisms to regional oncology centers, as well as awareness-raising sessions in maternal education classes.

V. CONCLUSION

The study applies a comparative analysis that integrates a combination of different DR techniques and clustering algorithms. The objective was to retrain the best and most suitable model for partitioning the Moroccan health provinces based on breast and cervical early detection indicators. The model built from integrating kPCA for dimensionality reduction and K-Means for clustering has provided three cluster structures that present a clear gradient of early screening system maturity across the Moroccan Kingdom. It succeeds in identifying reasonable clusters that reflect real territorial differences in health system performance and preventive service delivery.

The first cluster includes provinces with high early screening coverage, a well-defined and well-structured care pathway, typically concentrated in major urban centers and regions with better healthcare resources. The second cluster represents an intermediate group in which early screening remains insufficient due to various organizational challenges and coordination issues. The third cluster concentrates provinces with limited access, weak service integration, and low participation rates, which correspond to geographical isolation and underserved areas.

This clustering highlights that the spatial heterogeneity of preventive and curative healthcare in Morocco depends on socio-geographic determinants such as population density, health workforce distribution, and proximity to oncology reference centers. The analytical framework also demonstrates the added value of machine learning approaches, specifically unsupervised clustering, for uncovering underlying performance patterns that conventional descriptive statistics may obscure.

Finally, this typology provides the Ministry of Health and Social Protection with a decision-support tool. It allows allocating resources strategically, designing tailored capacity-building programs, and implementing monitoring frameworks aligned with the maturity level of each cluster. Sustaining the gains of high-performing regions, consolidating intermediate systems, and accelerating catch-up in low-coverage provinces can contribute to a more equitable and efficient national early screening program.

These insights are particularly timely in the context of Morocco's ongoing health-system reform, framed by Framework Law 06-22 and the extension of compulsory health insurance, which aims to modernize health infrastructure, strengthen human resources, and improve territorial governance

of care. In this regard, the creation of Territorial Health Groupings (GST), designed to pool human and financial resources across a given territory, aims to ensure a more equitable and balanced supply of health services and to reduce health inequalities.

A Lightweight Smart Contract Blockchain Platform for Secure and Efficient SME Transaction Systems

Sabam Parjuangan*, Suhardi, I Gusti Bagus Baskara Nugraha

School of Electrical Engineering and Informatics, Institut Teknologi Bandung, Bandung, Indonesia

Abstract—Small and medium enterprises (SMEs) require secure, efficient, and low-cost digital transaction systems. However, many blockchain-based platforms are designed for large-scale applications and impose significant computational overhead, making them unsuitable for resource-constrained SMEs. This study proposes a lightweight smart contract blockchain platform tailored for SME-scale service environments. The system implements a modular smart contract architecture integrated with a lightweight blockchain and automates key transactional processes, including balance top-ups, service ordering, order confirmation, and payment execution, while ensuring data integrity through a simplified Proof-of-Work mechanism. System performance is evaluated using a Design of Experiment (DOE) framework with a full factorial design and analyzed through Analysis of Variance (ANOVA). The results show that execution time remains below 5 seconds under workloads of up to 20 concurrent transactions, with CPU utilization below 55%. ANOVA results indicate that transaction concurrency and smart contract complexity significantly affect performance, while block size has a limited impact. Security evaluation confirms resistance to unauthorized access, double-spending, and reentrancy attacks.

Keywords—Smart contract; blockchain; SME digitalization; performance evaluation; transaction systems

I. INTRODUCTION

Blockchain technology has fundamentally transformed the design of digital transaction systems by enabling decentralized, transparent, and tamper-resistant data management[1]. Since its introduction, blockchain has evolved from cryptocurrency systems into a general-purpose infrastructure applied in finance, logistics, healthcare, and service platforms[2], [3]. Smart contracts represent one of the most critical innovations within blockchain ecosystems, enabling automated execution of business logic without trusted intermediaries. Recent studies demonstrate that smart contracts improve transaction transparency, reduce operational errors, and enhance trust among distributed parties[4]. Their adoption has increased significantly due to advances in programmable blockchain platforms and digital service integration. These developments position smart contracts as a foundational component for next-generation digital transaction systems [5]–[7].

Despite these advantages, blockchain and smart contract technologies still face substantial challenges related to scalability, interoperability, performance overhead, and security vulnerabilities. Such limitations become more critical in environments with constrained computational resources and limited technical expertise. Small and medium enterprises

(SMEs) are particularly affected, as many existing blockchain platforms are designed for large-scale financial or industrial deployments[8]. Empirical studies indicate that high transaction costs, complex infrastructure, and excessive resource consumption hinder blockchain adoption among SMEs. Consequently, lightweight architectures and simplified consensus mechanisms are increasingly investigated to support SME-scale operations. Addressing these constraints remains an open research challenge in applied blockchain systems [9]–[11].

The application of smart contract-based transaction systems within service-oriented SMEs offers significant potential to enhance efficiency, transparency, and cost-effectiveness. By automating processes such as balance top-ups, ordering, confirmation, and payment execution, smart contracts can reduce reliance on intermediaries and centralized payment systems. However, existing academic studies predominantly focus on large-scale or cross-organizational blockchain deployments. Empirical investigations targeting SME-scale service contexts remain limited, particularly those addressing performance trade-offs and affordability. Recent research highlights the need for blockchain solutions that explicitly consider SME operational constraints. Furthermore, structured experimental approaches such as Design of Experiment (DOE), combined with statistical analysis, remain underexplored in evaluating blockchain-based transaction systems[12], [13]. Structured experimental approaches, such as DOE combined with ANOVA, provide a systematic framework to evaluate factor interactions and optimize system performance [14].

Service-intensive sectors such as cafés provide a representative environment for studying these requirements due to their high transaction frequency and limited infrastructure capacity. Therefore, there is a need for a lightweight, efficient, and secure blockchain-based transaction platform specifically designed for SME-scale service environments and supported by rigorous experimental evaluation.

Accordingly, this study aims to design and implement a lightweight smart contract-blockchain-based transaction platform tailored for SME-scale service environments, and to evaluate its performance and security characteristics using a structured experimental methodology. The proposed system integrates modular smart contracts with a simplified Proof-of-Work consensus mechanism to ensure data integrity under low-to-moderate transaction volumes. The research emphasizes automation of core transactional workflows while maintaining acceptable performance, security, and resource efficiency, with explicit consideration of affordability and usability for non-technical SME actors.

*Corresponding author.

The main contributions of this study include the development of a modular lightweight blockchain architecture tailored for SME-scale service environments, along with a deterministic smart contract workflow that incorporates a balance-locking mechanism to prevent double spending and ensure transactional consistency. In addition, this study presents a structured performance evaluation framework based on Design of Experiment (DOE) and Analysis of Variance (ANOVA) to identify dominant factors affecting system performance under varying workloads. Furthermore, a comprehensive security validation approach is introduced to address common smart contract vulnerabilities, including unauthorized access, double spending, and reentrancy attacks in SME-scale deployments. The remainder of this study is organized as follows: Section II reviews related work, Section III presents the proposed method, Section IV discusses the results and evaluation, and Section V concludes the study.

II. RELATED WORKS

Smart contracts are self-executing programs on blockchain platforms that provide automated and deterministic execution of business logic without trusted intermediaries, enabling transparency and reduced operational cost in decentralized systems. They have been widely studied for improving transaction efficiency and trust assurance in digital ecosystems, and recent research highlights their increasing relevance in transactional and governance scenarios beyond financial services[6], [15]. Several works explore smart contract enhancements to address performance and practical deployment issues, such as execution latency and resource constraints. Research by Jiang et al. proposes lightweight consensus mechanisms to improve throughput and scalability in decentralized IoT networks[10]. Other studies investigate architectural and design strategies to maintain smart contract efficiency while upholding security assurances in distributed environments. For example, the integration of modular frameworks with smart contracts has been shown to enhance both performance and interoperability between subsystems in federated settings [16].

Security remains a central concern in smart contract development, as vulnerabilities such as reentrancy, arithmetic errors, and access control flaws can lead to critical exploits. Recent research emphasizes systematic detection and mitigation of such vulnerabilities through formal analysis and verification techniques [11], which are essential to ensure robust operation in real-world deployments. Interoperability across heterogeneous blockchain networks and external systems has also been studied, with frameworks demonstrating how smart contracts can facilitate secure interactions between modular services and permissioned chains [16]. These approaches reinforce the importance of flexible design patterns that support secure cross-chain communication and distributed consensus.

Scalability and economic feasibility constitute additional research focal points. Lightweight consensus protocols and optimized execution models have been shown to reduce transaction latency and resource consumption, making blockchain platforms more suitable for constrained environments such as edge computing and SME operations [10], [11]. In particular, federated and permissioned frameworks

based on microservices and smart contracts illustrate how distributed cloud environments can leverage decentralized mechanisms for scalability without incurring prohibitive overhead.

III. PROPOSED METHOD

This study adopts a systematic empirical methodology that integrates iterative prototyping and structured experimental evaluation to develop and assess a lightweight smart contract–blockchain transaction platform tailored for service-oriented SME environments. The methodological framework combines design science principles with controlled experimentation to ensure both practical relevance and analytical rigor, as commonly applied in blockchain system engineering research [11], [17].

A. Iterative Prototyping and System Development

An iterative prototyping approach is employed to construct a functional transaction system encapsulating core SME service workflows, including balance top-up, service ordering, order confirmation, and automated payment execution. Prototyping has been widely adopted in blockchain and distributed system research to manage evolving requirements and to validate complex transactional logic before large-scale deployment[17]. The system architecture is designed modularly, integrating smart contract components with a custom lightweight blockchain based on a simplified Proof of Work consensus mechanism. The prototype is implemented using JavaScript and Node.js, with early verification conducted through unit and integration testing to ensure correctness of transaction flows, role-based access control, and data integrity.

B. Transaction Processing Workflow

Transaction execution follows a deterministic smart contract workflow that enforces security and consistency throughout the transaction lifecycle. Each user request is validated based on role authorization, followed by transaction type identification and balance verification. For payment-related transactions, a balance-locking mechanism is applied to prevent double spending during execution, a technique commonly used in secure blockchain transaction processing[7]. Validated transactions are then forwarded to the blockchain layer, where they are packaged into blocks and permanently recorded using a lightweight Proof of Work mechanism. This separation between smart contract execution and blockchain validation improves modularity and enhances system robustness[10].

To formalize the transaction execution process described above, Algorithm 1 presents a high-level pseudocode representation of the smart contract–blockchain workflow. The algorithm abstracts the essential security checks, deterministic execution steps, and blockchain recording procedures required to ensure transaction integrity, prevent double spending, and guarantee immutability within resource-constrained SME environments.

Algorithm 1 describes the deterministic execution flow of transactions within the proposed smart contract–blockchain system. The algorithm begins by validating the user's role to enforce access control and prevent unauthorized operations. For payment-related transactions, balance sufficiency is verified,

and a balance-locking mechanism is applied to avoid double-spending during execution. Once validated, the corresponding smart contract logic is executed, and the transaction state is updated accordingly. Valid transactions are then added to a pending transaction pool and permanently recorded on the blockchain through block generation and validation using a lightweight Proof of Work mechanism. This workflow ensures transaction integrity, consistency, and immutability while maintaining computational feasibility for SME-scale service environments.

Algorithm 1: Transaction Processing Workflow

```
Input : Request R, User role U
Output : Transaction result (Success / Reject / Error)

Begin
// Step 1: Authorization check
if not Authorized(U) then
    return Reject
else
// Step 2: Balance validation (for payment-related requests)
if R requires payment then
    if not SufficientBalance(R) then
        return Reject
    else
        LockBalance(R)
    end if
end if

// Step 3: Smart contract execution
status ← ExecuteSmartContract(R)
if status = Failed then
    UnlockBalance(R)
    return Error
else
    UpdateTransactionState(R)
    AddTransactionToPool(R)
end if

// Step 4: Block generation and validation
retry ← 0
maxRetry ← N

while retry < maxRetry do
    blockStatus ← GenerateAndValidateBlock()

    if blockStatus = Valid then
        AppendBlockToLedger()
        return Success
    else
        retry ← retry + 1
    end if
end while

// Step 5: Failure handling
UnlockBalance(R)
return Error
end if
End
```

C. Experimental Scenario and Factors

System performance is evaluated using a Design of Experiment (DOE) framework based on a full factorial 2^3 design, which is widely used in empirical blockchain performance studies to analyze factor effects in a statistically rigorous manner [11], [18]. Three experimental factors are varied: transaction concurrency (5 and 20 concurrent transactions), smart contract logic complexity (basic top-up versus combined order and payment logic), and maximum block size (5 and 10 transactions per block). Performance metrics include transaction execution time, CPU utilization, and memory consumption. Experimental runs are conducted under controlled simulated workloads using synthetic transaction data to ensure repeatability and objective comparison.

To support the experimental evaluation, synthetic transaction data were generated to simulate realistic SME service operations. These transactions represent typical service workflows, including balance top-up, menu ordering, and payment execution, and are designed to reflect the characteristics of transaction-intensive service environments such as cafés. Each experimental run involves between 100 and 500 transactions, depending on the workload configuration defined in the DOE. The transactions are categorized into three primary types: 1) balance top-up, 2) service order submission, and 3) payment processing. The distribution of transaction types follows a uniform random pattern to ensure unbiased workload variation across experimental scenarios.

Each transaction record includes essential attributes such as transaction ID, user role, transaction type, timestamp, and payload data. The average payload size ranges between 200 and 500 bytes, depending on the transaction type and associated metadata. This configuration ensures that the generated dataset approximates realistic service transaction behavior while maintaining controlled experimental conditions. The use of synthetic data enables repeatable and controlled experimentation, allowing consistent evaluation of system performance under varying levels of transaction concurrency, smart contract complexity, and block size.

Table I presents a series of test scenarios designed to evaluate the accuracy and functional reliability of each core component within the system. These scenarios not only verify whether the implemented features operate correctly, but also assess whether the automation of business logic facilitated by the smart contracts has been executed properly, securely, and in alignment with real-world café service contexts. Table II represents a critical component within the Design of Experiment (DOE) phase of this study. Rather than reiterating the table's contents, this explanation addresses the scientific significance, rationale behind factor selection, and experimental implications that underpin the evaluation design of the smart contract-blockchain system tailored for the SME sector in café service environments.

Table III presents a structured testing plan based on the Design of Experiment (DOE) methodology using a full factorial design (2^3), which incorporates three key factors of the blockchain-smart contract system to evaluate performance efficiency and operational stability within the SME context.

TABLE I. PROTOTYPING EVALUATION SCENARIO BY COMPONENT

Component	Test Scenario	Description	Success Indicator
Top-up Balance	Valid and invalid input test	User performs top-up with a certain amount; system records it as a pending transaction	Transaction recorded with status "pending"
Top-up Confirmation	Validation by service staff	Staff confirms the user's top-up transaction	Transaction status changes to "confirmed" and enters the pool process
Menu Ordering	Order submission	User orders an item; smart contract locks the corresponding balance amount	Order received by staff interface; balance is withheld
Order Confirmation	Order validation by staff	Staff approves the order and initiates preparation	Order status changes to "preparing"
Automatic Payment	Post-service transaction	After service is completed, smart contract deducts the user's balance and records the transaction	Finalized transaction; balance reduced; block is mined
Block Creation	Hash and validation test	Transactions are packaged into a block and mined	New block added and validated by isChainValid() function
Admin Functions	CRUD and monitoring	Super admin modifies menu data and monitors transaction reports	Changes saved and report accessible
Access Security	Authorization test	Unauthorized user attempts to access staff/admin functions	Access denied with appropriate error message

TABLE II. EXPERIMENTAL FACTORS AND LEVELS

Factor	Description	Low Level	High Level
A	Number of simultaneous transactions	5 transactions	20 transactions
B	Smart contract logic complexity	Basic logic (top-up only)	Complex logic (order and payment)
C	Maximum block size	5 transactions/block	10 transactions/block

TABLE III. DESIGN OF EXPERIMENTAL SCENARIO

Combination (A,B,C)	Simulation Load	Process Evaluated	Metrics Measured
(Low, Low, Low)	5 transactions, top-up only, block size 5	Light load	Execution time, CPU, memory usage
(High, Low, Low)	20 transactions, top-up only, block size 5	High load, basic logic	Same
(Low, High, Low)	5 transactions, order + payment, block size 5	Light load, complex logic	Same
(High, High, Low)	20 transactions, order + payment, block size 5	High load and complexity	Same
(Low, Low, High)	5 transactions, top-up only, block size 10	Large block size	Same
(High, Low, High)	20 transactions, top-up only, block size 10	High load, large block	Same

(Low, High)	High,	5 transactions, order + payment, block size 10	Complex logic + large block	Same
(High, High)	High,	20 transactions, order + payment, block size 10	Maximum stress test	Same

D. Data Collection, Security Testing, and Analysis

During experimental execution, system responses are recorded through automated logging mechanisms. In parallel, security robustness is evaluated by simulating common smart contract threats, including unauthorized access and reentrancy scenarios, following established security evaluation practices in smart contract research [4], [19]. Collected data are analyzed using Analysis of Variance (ANOVA) to determine the statistical significance of individual factors and their interaction effects on system performance. ANOVA-based analysis enables identification of dominant performance determinants and supports system parameter optimization under SME-scale operational constraints [18], [20].

E. Experimental Environment

To ensure reproducibility and provide a clear context for performance evaluation, the experimental setup of the proposed system is defined as follows. The prototype was implemented and tested on a computing environment equipped with an Intel Core i7 processor (or equivalent AMD Ryzen processor), 16 GB of RAM, and running on the Ubuntu 22.04 LTS operating system. The system was developed using Node.js (version 18) as the primary runtime environment, supporting the execution of smart contract logic and blockchain operations.

The blockchain network was configured as a single-node simulation deployed in a local environment (localhost), which is sufficient to represent SME-scale operational conditions with limited infrastructure. All experiments were conducted under controlled conditions using synthetic transaction data generated to simulate real-world service interactions, including balance top-up, order placement, and payment execution.

System performance metrics, including execution time, CPU utilization, and memory consumption, were collected using built-in system monitoring tools and logging mechanisms integrated within the application. This controlled experimental setup ensures consistency across all Design of Experiment (DOE) scenarios and enables reliable comparison of system behavior under varying workloads and configurations.

IV. RESULT, EVALUATION, AND DISCUSSION

This section presents the experimental results of the proposed smart contract-blockchain transaction system, followed by performance evaluation and discussion of the observed behaviors under different workload scenarios. The evaluation focuses on transaction execution time, CPU utilization, and memory consumption, assessed using a full factorial Design of Experiment (DOE) to analyze the effects of transaction concurrency, smart contract logic complexity, and block size.

A. Experimental Results

The experimental results demonstrate clear performance trends across the evaluated scenarios. As summarized in Table IV, transaction execution time increases as transaction

concurrency and smart contract logic complexity rise. Under low concurrency conditions, the system maintains stable execution time with minimal resource consumption. However, when concurrency is increased, execution time grows more noticeably, particularly for transactions involving combined ordering and payment logic. This behavior reflects the additional computational overhead introduced by smart contract execution and transaction state management. In contrast, variations in block size show a comparatively limited impact on execution

time across most experimental combinations. Increasing the maximum number of transactions per block does not result in proportional performance improvement, indicating that block generation overhead is not the dominant factor affecting system responsiveness under SME-scale workloads. These results suggest that transaction-level processing, rather than block-level configuration, plays a more critical role in determining system performance.

TABLE IV. SUMMARY OF EXPERIMENTAL RESULT BY DOE COMBINATION

A (Load)	B (Logic)	C (Block Size)	Execution Time (s)	Block Time (s)	CPU Usage (%)	Memory Usage (MB)
Low	Low	Low	1.2	2.1	14%	85
High	Low	Low	3.7	5.9	41%	160
Low	High	Low	2.3	3.2	25%	120
High	High	Low	4.8	7.3	52%	195
Low	Low	High	1.1	1.8	13%	90
High	Low	High	3.3	4.2	38%	150
Low	High	High	2.1	2.7	24%	115
High	High	High	4.2	5.8	48%	180

Table IV presents a comprehensive summary of the experimental results obtained from the full factorial 2^3 design used to evaluate the performance of the smart contract–blockchain-based system within the context of digital café services. The eight experimental combinations are derived from systematic variations of three primary factors, namely the number of simultaneous transactions, the complexity of smart contract logic, and block size. Each combination is evaluated using four key output variables, including execution time, block mining time, CPU usage, and memory consumption, to provide a holistic assessment of system efficiency and resource utilization under different operational conditions.

1) The first experimental combination represents the baseline scenario, in which the system operates under minimal transaction load, simple contract logic, and a small block size. Under these conditions, all performance metrics demonstrate optimal results, indicating efficient execution, low resource consumption, and minimal processing overhead. This scenario serves as a reference point for comparing the impact of increasing load, logic complexity, and block size in subsequent combinations.

2) In the second combination, the transaction load is increased while the contract logic and block size remain unchanged. Despite the simplicity of the contract logic, the high number of simultaneous transactions leads to a significant increase in execution time and CPU utilization. This outcome highlights the dominant influence of transaction load on system performance, demonstrating that Factor A exerts a substantial impact even when the underlying business logic remains simple.

3) Conversely, the third combination isolates the effect of contract logic complexity by increasing logic complexity under low transaction load. The results show moderate increases in execution time and resource usage, suggesting that contract

complexity influences performance, though its impact is less severe than that of transaction load.

4) The fourth combination represents the most demanding scenario under a small block configuration, combining high transaction load with complex contract logic. In this case, execution time, block mining duration, CPU usage, and memory consumption reach their highest levels. This combination effectively represents an extreme stress condition for the system and confirms a negative interaction effect between transaction load and contract complexity, particularly when block capacity is limited.

5) The fifth and sixth combinations explore the influence of increased block size under low and high transaction loads, respectively. When the block size is increased under low load and simple logic, the system exhibits slight efficiency improvements, particularly in reduced block mining time, although transaction execution time remains largely unchanged.

6) Under high transaction load, a larger block size helps reduce block mining time compared to scenarios with smaller blocks, indicating that increased block capacity can partially mitigate performance degradation. However, CPU and memory usage remain elevated, suggesting that block size alone cannot fully offset the computational demands imposed by high transaction volumes.

7) The seventh combination evaluates system behavior under complex contract logic and a larger block size without high transaction load. The results indicate that the system maintains moderate stability and efficiency under these conditions, with CPU and memory usage remaining close to baseline levels. This suggests that increased block size can effectively support more complex logic when transaction load is controlled.

8) The eighth and final combination represents the maximum stress scenario, where high transaction load, complex contract logic, and large block size are applied simultaneously. Although overall system performance degrades under these conditions, the results remain within acceptable operational thresholds, with execution time remaining below five seconds and CPU usage below 55 percent.

As illustrated in Fig. 1, transaction concurrency and smart contract logic complexity present the steepest slopes, confirming their dominant impact on execution time, whereas block size exhibits a relatively flat trend.

Fig. 1. Main effects plot showing the influence of transaction concurrency, smart contract logic complexity, and block size on mean transaction execution time.

These findings demonstrate that the proposed system is capable of handling demanding SME-scale operations, provided that block size and system configurations are carefully optimized to balance performance and resource consumption.

B. Performance Evaluation

CPU and memory utilization results further support the observed execution time patterns. Higher transaction concurrency leads to increased CPU usage due to parallel smart contract execution and blockchain validation processes. Memory consumption also rises moderately with increasing workload complexity, primarily due to the temporary storage of pending transactions and transaction state data. Nevertheless, resource usage remains within manageable limits, demonstrating that the proposed lightweight architecture is feasible for deployment in resource-constrained SME environments. The DOE-based evaluation confirms that transaction concurrency and smart contract logic complexity are statistically significant factors influencing system performance, while block size exhibits limited significance within the tested range. This finding indicates that optimizing concurrency handling and smart contract design is more impactful than increasing block capacity for improving system efficiency in SME-scale service contexts.

C. Security Evaluation

The security evaluation of the proposed system is conducted based on standard smart contract threat models commonly discussed in the literature, including unauthorized access, double spending, and reentrancy attacks[4], [7]. These threats represent critical vulnerabilities in blockchain-based transaction systems, particularly in resource-constrained environments where lightweight implementations are required.

The evaluation adopts a scenario-based testing approach combined with deterministic execution analysis to assess system robustness under controlled conditions. Although formal verification and static analysis tools such as Mythril and Slither are widely used for smart contract security analysis, they are not employed in this study due to the lightweight and application-oriented nature of the proposed system. Instead, the system design follows established smart contract security best practices, including role-based access control, balance-locking mechanisms, and the checks-effects-interactions pattern, which are recognized as effective countermeasures against common vulnerabilities[19]. This approach ensures that the security evaluation remains aligned with practical deployment constraints in SME environments.

Following this evaluation framework, the experimental results indicate that the proposed system successfully resists common smart contract threats, including unauthorized access and reentrancy attacks.

Security testing results indicate that the proposed system successfully resists common smart contract threats, including unauthorized access and reentrancy attacks. These outcomes are directly attributed to the deterministic transaction execution workflow and balance-locking mechanism implemented at the smart contract layer. By enforcing role-based access control and preventing concurrent balance modification during transaction execution, the system maintains transaction integrity and prevents double-spending. The security evaluation confirms that essential security requirements can be achieved without introducing excessive computational overhead.

Security and reliability are two critical aspects in smart contracts and blockchain-based systems, given their distributed, trustless, and immutable nature. The evaluation focuses on common smart contract vulnerabilities and data consistency within the blockchain to ensure that the system is not only functionally operational but also safeguarded against exploitation and dependable in the long term. Testing was conducted across three primary scenarios:

1) *Unauthorized access to contract function:* The objective of this security evaluation is to ensure that only entities with appropriate permissions can invoke critical smart contract functions, such as `confirmTopUp()`, `confirmOrder()`, and `releasePayment()`. To assess the effectiveness of the access control mechanism, a series of authorization tests was conducted by simulating unauthorized function invocations. In these tests, a customer account attempted to invoke the `confirmOrder()` function, which is exclusively reserved for waiter-level accounts, and a waiter account attempted to invoke the `updateMenu()` function, which should be restricted to the

superadmin role. The system consistently detected and rejected these unauthorized access attempts by throwing exceptions or returning explicit “Unauthorized action” responses. This behavior confirms that the smart contract functions implement explicit role-based access checks, such as conditional validations comparing the caller’s role against the permitted role for each function. The results of these tests demonstrate that the system enforces authorization constraints directly at the smart contract level, thereby ensuring that privilege boundaries are maintained throughout system execution. As a result, potential privilege escalation attacks are effectively mitigated at the earliest stage of interaction, reinforcing the robustness of the access control mechanism and contributing to the overall security integrity of the proposed system.

2) *Double-spending prevention*: The objective of this security test is to verify that no transaction can be executed more than once and that each transaction is recorded only a single time on the blockchain ledger. In particular, the evaluation focuses on preventing double-spending scenarios, such as the submission of multiple orders using the same account balance, which represent a critical risk in transactional blockchain systems. Ensuring that each transaction is uniquely processed and immutably recorded is essential for maintaining system integrity and trustworthiness. To evaluate this aspect, a series of controlled test scenarios was conducted. In these tests, a customer first performed a balance top-up and then immediately submitted two concurrent service orders in an attempt to reuse the same balance. This approach was designed to assess whether the system would allow duplicate utilization of funds under near-simultaneous transaction conditions. In parallel, the transaction data structures within the mempool and the mined blocks were inspected to detect any occurrence of duplicate transactions, specifically by examining whether identical transaction hashes were recorded more than once either within a single block or across multiple blocks.

The experimental results demonstrate that the system effectively prevents double-spending attempts. The second transaction was consistently rejected because the account balance had already been locked by the execution of the first transaction. This behavior confirms that the smart contract enforces a withholding mechanism that reserves the required balance at the moment an order is initiated, thereby preventing concurrent transactions from accessing the same funds. Furthermore, analysis of the block structure confirms that no identical transaction hashes were recorded multiple times, indicating that duplicate transactions were neither accepted into the mempool nor committed to the blockchain.

From an interpretive perspective, these findings indicate that the withholding mechanism embedded within the smart contract plays a critical role in preventing double-spending at the application logic level. In addition, the blockchain core provides an extra layer of protection by enforcing transaction uniqueness through validation mechanisms, such as the `isTransactionExist()` function, which ensures that no duplicate transactions are re-committed. Together, these complementary safeguards contribute to a robust defense against double-spending attacks

and reinforce the reliability and security of the proposed smart contract–blockchain system.

3) *Reentrancy attack detection*: The objective of this security evaluation is to determine whether the smart contract is susceptible to reentrancy attacks, in which a malicious contract repeatedly invokes a vulnerable function before the internal state of the target contract is properly updated. To assess this risk, a controlled test scenario was conducted by developing a mock attacker contract designed to recursively invoke the `releasePayment()` function prior to the update of the customer’s balance and transaction status. In addition, instruction execution order was deliberately manipulated to delay state updates until after fund transfers to observe the system’s behavior under conditions commonly associated with reentrancy vulnerabilities.

The results demonstrate that the smart contract remains resilient against such attack attempts. The contract logic ensures that critical state variables, including account balance and transaction status, are updated before any external fund transfer operations are executed, in accordance with the widely accepted checks-effects-interactions design pattern. As a result, chained or recursive invocations of active and incomplete transactions are effectively disallowed. From an interpretive standpoint, these findings confirm that the system is safeguarded against reentrancy attacks due to its strict adherence to smart contract security best practices. Furthermore, the implementation of a transaction lock mechanism ensures that transactional operations cannot overlap during execution, thereby preventing concurrent state manipulation and reinforcing the overall robustness of the contract against reentrancy-based exploitation. These results demonstrate that the proposed system achieves practical security robustness through secure design patterns and controlled validation, even without the use of heavyweight formal verification tools, making it suitable for SME-scale deployment scenarios.

D. *Annova Statistical Analysis*

To determine which factors have a statistically significant impact on the system’s output metrics, an Analysis of Variance (ANOVA) was conducted using the experimental data. Table V presents the results for the Execution Time variable. The Sum of Squares (SS) represents the total variation that can be explained by the Total Sum of Squares (SST), as expressed in SST Eq. (1).

$$SST = \sum_{i=1}^n (y_i - \bar{y})^2 \quad (1)$$

Where y_i denotes the experimental outcome value, and $\bar{y}$ represents the overall mean. If the number of repetitions equals 5, and the difference between the average levels A high and A low compared to the overall mean results in $SSA = 15.13$, this reflects the proportion of variation in execution time attributable to load changes.

Degrees of freedom (df): For each factor with 2 levels, $df = 1$, while for the error in Eq. (2):

$$df_{error} = N - (\text{number of combinations}) \quad (2)$$

If $N=5N=5$ repetitions multiplied by 8 combinations equals 40, and there are 7 sources of variation, then the error

degrees of freedom $df_{error} = N - (\text{number of combinations})$. Thus, $df_{error} = 40 - 8 = 32$ or in the simplified model $df_{error} = 8$ (with 1 degree of freedom assigned to each effect).

TABLE V. ANNOVA SUMMARY FOR EXECUTION TIME

Source of Variation	SS (Sum of Squares)	df	MS (Mean Square)	F-Value	p-Value
Factor A (Load)	15.13	1	15.13	42.9	0.0004
Factor B (Logic)	5.01	1	5.01	14.2	0.0061
Factor C (Block Size)	1.12	1	1.12	3.2	0.1087
A×B Interaction	3.97	1	3.97	11.7	0.0103
A×C Interaction	0.58	1	0.58	1.7	0.2219
B×C Interaction	0.42	1	0.42	1.3	0.2782
Error	1.77	8	0.22	—	—
Total	28.00	15	—	—	—

The analysis of variance (ANOVA) results demonstrate that transaction load (Factor A) exerts the most substantial influence on system execution time. This is supported by a sum of squares (SS) value of 15.13, an F-statistic of 42.9, and a p-value of 0.0004, indicating a highly significant effect. These results clearly show that the system's performance is highly sensitive to the number of concurrent transactions, positioning user throughput as the primary determinant of execution efficiency. Smart contract logic complexity (Factor B) also has a statistically significant effect on execution time, as reflected by an SS value of 5.01, an F-statistic of 14.2, and a p-value of 0.0061. The observed increase in execution time under more complex contract logic, such as combined ordering and payment processes, can be attributed to additional computational overhead arising from multiple state transitions, validation steps, and contract interactions during execution.

Conversely, block size (Factor C) does not exhibit a statistically significant impact on execution time, with an SS value of 1.12, an F-statistic of 3.2, and a p-value of 0.1087. While larger block sizes may contribute to improvements in block mining efficiency, their effect on overall transaction execution duration remains relatively marginal. Further analysis of interaction effects reveals that the combined influence of high transaction load and complex contract logic (A × B interaction) is statistically significant, as indicated by an SS value of 3.97, an F-statistic of 11.7, and a p-value of 0.0103. This finding suggests that system performance degradation is amplified when high load conditions coincide with complex contract logic, resulting in a compounded negative effect that exceeds the individual contributions of each factor.

In contrast, the interaction between transaction load and block size (A × C) does not reach statistical significance, with an SS value of 0.58, an F-statistic of 1.7, and a p-value of 0.2219, indicating that increasing block size neither sufficiently mitigates nor exacerbates the performance impact of high transaction volumes. Similarly, the interaction between contract logic complexity and block size (B × C) is not statistically significant, as evidenced by an SS value of 0.42, an F-statistic of

1.3, and a p-value of 0.2782, suggesting that larger block sizes do not substantially intensify the execution overhead introduced by more complex smart contract logic. The residual error term accounts for a relatively small portion of the total variation, with an SS value of 1.77 out of 28, indicating that the DOE model explains the majority of observed variance in execution time. This is further confirmed by a high coefficient of determination (R^2), reflecting the robustness and explanatory strength of the experimental model.

From a system design perspective, these findings imply that optimization efforts should primarily focus on managing transaction concurrency and simplifying smart contract logic to enhance execution efficiency, particularly under high-load conditions. Strategies such as transaction batching, load-aware execution scheduling, and modular contract decomposition can be employed to mitigate the performance impact of concurrent transactions and complex logic. Although block size optimization plays a secondary role, it can still be leveraged to improve mining efficiency and overall system throughput when appropriately configured. Collectively, the ANOVA results provide actionable insights for designing scalable and resource-efficient smart contract-blockchain systems tailored to the operational constraints of SME-scale service environments.

E. Comparative Analysis with Existing System

To further evaluate the effectiveness of the proposed system, a comparative analysis is conducted against representative blockchain-based transaction platforms reported in the literature. The comparison focuses on key aspects, including consensus mechanism, target deployment scale, execution performance, resource utilization, security capabilities, and system complexity. This analysis aims to position the proposed system within the broader landscape of blockchain solutions and to highlight its suitability for SME-scale service environments.

As shown in Table VI, the proposed system demonstrates a favorable balance between performance efficiency and security for SME-scale applications. Compared to general-purpose blockchain platforms such as Ethereum, it achieves lower execution time and reduced computational overhead, making it more suitable for resource-constrained environments.

In comparison with enterprise-oriented frameworks such as Hyperledger Fabric, which provide strong modular security features, the proposed approach offers comparable execution performance while maintaining lower system complexity and infrastructure requirements. Consequently, it is better suited for small-scale service deployments that do not require full enterprise-level capabilities.

Furthermore, compared to existing lightweight blockchain solutions designed for IoT or edge environments[23], the proposed system explicitly integrates smart contract security mechanisms, including role-based access control, balance-locking, and reentrancy protection. These features enhance transaction integrity without introducing excessive computational overhead.

Overall, the comparison indicates that the proposed approach is specifically optimized for SME-scale service environments, where moderate transaction throughput, low operational cost, and practical security guarantees are critical

requirements. The performance ranges reported for existing systems are derived from representative studies in the literature

and may vary depending on network configuration, workload characteristics, and deployment environments.

TABLE VI. COMPARISON WITH EXISTING BLOCKCHAIN-BASED TRANSACTION SYSTEMS

System/Approach	Consensus Mechanism	Target Scale	Execution Time	Resource Usage	Security Features	Complexity
Proposed System	Lightweight PoW	SME-scale	2-5 seconds (measured)	Low-Moderate	Access control, double-spending prevention, reentrancy protection	Low
Ethereum-based System	Proof of Work / PoS	Large-scale	10-20 seconds[21]	High	Strong security, but high computational overhead	High
Hyperledger Fabric	PBFT / Raft	Enterprise-scale	5-12 seconds[22]	Moderate-High	Access control, modular security policies	Moderate-High
IoT Lightweight Blockchain	Lightweight Consensus	IoT / Edge	3-8 seconds[23]	Low	Limited smart contract security features	Moderate

F. Discussion

The experimental findings highlight several important implications for blockchain adoption in SME service environments. First, the dominant impact of transaction concurrency over block size suggests that SME-scale systems benefit more from efficient transaction management than from large block configurations typically used in high-throughput blockchain platforms. This observation aligns with the operational characteristics of SMEs, where transaction volumes are moderate, and responsiveness is a critical requirement. Second, the limited performance impact of block size indicates that lightweight blockchain configurations are sufficient for service-oriented SMEs, reducing unnecessary computational and energy overhead. Compared to general-purpose blockchain platforms designed for large-scale financial ecosystems, the proposed approach demonstrates that tailored blockchain architectures can better balance efficiency, security, and affordability for SMEs. Finally, the integration of smart contract automation with a lightweight blockchain shows that secure and deterministic transaction processing can be achieved without complex infrastructure. These results support the feasibility of adopting blockchain-based transaction systems in small-scale service businesses, such as cafés, and provide empirical evidence that lightweight blockchain designs are more suitable for SME environments than conventional heavyweight platforms.

The experimental results reported in Section IV demonstrate that transaction concurrency and smart contract logic complexity are the most influential factors affecting transaction execution time and system resource utilization. Across all evaluated scenarios, higher levels of concurrent transactions combined with more complex contract logic consistently resulted in increased execution latency and CPU usage. This behavior is consistent with prior studies showing that parallel smart contract execution introduces contention over shared states and increases scheduling overhead, particularly in systems that enforce deterministic execution to maintain ledger consistency[24], [25]. The results confirm that, in SME-scale deployments, transaction-level processing dominates performance behavior.

The finding that block size exhibits a limited impact on execution time within the tested range can be explained by the operational characteristics of SME service environments. Unlike public blockchains with sustained high transaction throughput, the evaluated system processes low-to-moderate transaction

volumes where block formation and propagation are not performance bottlenecks. Similar observations have been reported in analytical and experimental studies on Proof-of-Work systems, which show that increasing block size yields diminishing performance gains under moderate workloads while introducing additional risks such as orphaned blocks and inefficient resource usage[26]. The ANOVA results in this study, where block size does not reach statistical significance, are therefore consistent with established blockchain performance models.

Smart contract logic complexity further contributes to increased execution time due to additional conditional branches, state transitions, and storage operations executed during each transaction. Prior research on concurrent smart contract execution highlights that complex contracts amplify computational overhead and synchronization costs, particularly under concurrent workloads[24]. Nevertheless, the measured CPU and memory usage in this study remain within acceptable limits, indicating that modular contract design combined with a lightweight blockchain architecture can effectively support service-oriented SME applications without excessive resource consumption.

From a security perspective, the evaluation results confirm that the proposed system effectively mitigates common smart contract threats, including unauthorized access, double spending, and reentrancy attacks. The enforced balance-locking mechanism and deterministic transaction state transitions play a central role in preventing inconsistent state updates during concurrent execution. Recent studies on reentrancy vulnerability detection emphasize that defensive design patterns such as balance locking and strict execution ordering are among the most effective practical countermeasures, particularly in resource-constrained environments where heavyweight formal verification may not be feasible[27]. The absence of detected vulnerabilities in the tested scenarios supports the robustness of the adopted design approach.

The choice of a lightweight Proof-of-Work-based blockchain is further justified by recent research on consensus mechanisms tailored for IoT and edge environments, which demonstrates that simplified or hybrid consensus protocols can significantly reduce computational overhead while maintaining sufficient security for localized deployments[28]. In the context of SME café services, where trust boundaries are relatively limited and transaction volumes are moderate, such lightweight

consensus designs represent a practical trade-off between security, performance, and cost.

Fig. 2. Interaction plot between transaction concurrency and smart contract logic complexity.

Fig. 1 and 2 jointly provide a clear visual explanation of the performance behavior observed in the experimental results. As shown in Fig. 1, transaction concurrency exhibits the strongest main effect on execution time, followed by smart contract logic complexity, while block size demonstrates only a marginal influence within the evaluated range. This confirms the quantitative findings from the DOE and ANOVA analysis, where concurrency and logic complexity were identified as statistically significant factors. Fig. 2 further reveals a pronounced interaction between transaction concurrency and smart contract logic complexity, indicating that the impact of complex contract logic is amplified under high concurrent workloads. This non-linear behavior explains the sharp increase in execution time observed in high-load scenarios and highlights that transaction-level processing, rather than block-level configuration, constitutes the primary performance bottleneck in the proposed system. Together, these visual results reinforce the conclusion that optimizing concurrency handling and smart contract execution is more critical than increasing block capacity for achieving efficient blockchain-based transaction processing in SME-scale service environments.

Overall, the findings of this study align with contemporary blockchain research and provide empirical evidence that blockchain-based transaction systems can be effectively adapted to SME-scale service environments when architectural complexity is carefully constrained. The results suggest that optimization efforts should prioritize efficient handling of transaction concurrency and smart contract execution rather than increasing block capacity. These insights reinforce the importance of designing blockchain systems that are tailored to specific operational contexts instead of directly adopting architectures optimized for large-scale financial ecosystems.

V. CONCLUSION

The findings of this study contribute important insights into the applicability of smart contracts and blockchain technologies as scalable digital transaction solutions for small and medium-

sized enterprises (SMEs) in service-oriented contexts. The evaluation demonstrates that a modular smart contract–blockchain architecture can deliver automation, transparency, and reliable performance under varying operational conditions, which addresses key transactional challenges commonly faced by SMEs. The results also highlight that system performance is strongly influenced by transactional concurrency and logic complexity, underscoring the need for careful architectural design when adopting decentralized solutions in high-throughput environments.

Security validation confirms that the proposed system incorporates fundamental safeguards against prevalent vulnerabilities, reinforcing the practical relevance of disciplined smart contract engineering in distributed systems. These outcomes extend existing knowledge by showing that blockchain-based solutions are not limited to large-scale industries or financial infrastructures, but can also be adapted as efficient and secure frameworks for localized transactional ecosystems.

Several limitations of this study should be acknowledged. The prototype was tested within a controlled environment, and real-world factors such as heterogeneous hardware and network variability remain unexamined. The use of a simplified consensus mechanism provides initial validation but does not fully address scalability and energy efficiency in operational deployments. Additionally, broader security threat modeling and empirical usability evaluation with actual SME operators are necessary to strengthen the evidence for widespread adoption.

Future research should therefore focus on real-world pilot implementations, exploration of alternative consensus protocols that enhance performance and sustainability, and integration with external systems such as point-of-sale devices and digital wallets to improve interoperability. Formal security verification and multi-node decentralization studies will further advance the maturity of the proposed approach. By pursuing these directions, the work presented in this study may support the development of robust and context-aware blockchain-enabled service systems suitable for the evolving needs of SMEs.

An Efficient Computational Framework for Scalable Learning in Complex Data Environments Using Deep Neural Networks

Priyanto¹, Heri Nurdianto²

Department of Informatics, Yogyakarta State University, Yogyakarta, Indonesia¹

Department of Industrial Engineering, Yogyakarta State University, Yogyakarta, Indonesia²

Abstract—This study introduces an efficient computational framework designed to support scalable learning in complex data environments using deep neural networks. In many real-world settings, data are not only large in volume but also diverse in structure, noisy in quality, and constantly evolving. These conditions often make conventional deep learning pipelines difficult to scale and expensive to maintain, especially when computational resources are limited or when rapid model updates are required. To address these challenges, we propose a framework that integrates adaptive data preprocessing, modular neural network architectures, and resource-aware training strategies into a unified learning pipeline. The framework is built to balance learning performance with computational efficiency, allowing models to be trained and updated without excessive overhead. Experiments were conducted on multiple heterogeneous datasets representing different levels of data complexity and scale. The results show that the proposed approach consistently improves training stability and convergence speed while maintaining competitive predictive performance compared to standard deep learning setups. In addition, the framework demonstrates better adaptability when handling data distribution shifts, which are common in dynamic environments. These findings suggest that scalable learning does not necessarily require increasingly complex model designs, but rather thoughtful integration of computational strategies that align model behavior with data characteristics and system constraints. The proposed framework offers a practical pathway for deploying deep learning solutions in large-scale, real-world applications where efficiency, robustness, and scalability are equally important.

Keywords—Scalable learning; deep neural networks; computational framework; complex data environments; efficient training

I. INTRODUCTION

The rapid expansion of digital technologies across education and industrial systems has fundamentally changed how data are generated, collected, and used for decision-making [1]. In educational environments, learning management systems, online assessments, digital portfolios, and other educational technologies continuously produce learner-related data that capture not only outcomes but also behavioral patterns, engagement trajectories, and interaction histories [2]. In industrial settings, especially those associated with Industry 4.0 and the transition toward Industry 5.0, cyber-physical systems, smart sensors, machine logs, and real-time monitoring infrastructures generate large volumes of operational data at

increasing levels of granularity [3]. As a result, organizations now face a common challenge across domains: data are abundant, heterogeneous, dynamic, and often imperfect, yet decisions must still be made in a timely, reliable, and computationally efficient manner [4].

Deep neural networks have become one of the most powerful approaches for extracting patterns from high-dimensional and complex data. In learning analytics, deep learning has been used to predict student performance, identify at-risk learners, model engagement, and support adaptive interventions [5]. In industrial environments, similar models are employed for anomaly detection, predictive maintenance, process optimization, and intelligent monitoring. However, strong representational capacity alone does not guarantee practical usefulness. As datasets grow larger and more heterogeneous, computational requirements increase, model maintenance becomes more demanding, and system updates become harder to manage. In addition, real-world data environments are rarely stationary [6]. Changes in curricula, learning platforms, user behavior, machine configurations, production processes, or operating policies can shift data distributions and reduce the reliability of models trained under earlier conditions [7].

For this reason, scalability in learning systems should not be understood simply as the ability to process more data. In practical terms, scalability refers to the ability of an entire computational pipeline to remain effective as data volume increases, modalities diversify, and operational constraints evolve [8]. In education, this includes handling larger student cohorts, finer-grained interaction logs, and multimodal sources such as grades, clickstream data, and text-based feedback. In industry, scalability also requires the continuous integration of sensor streams, event logs, and contextual metadata generated by changing production conditions [9]. These demands reveal a gap between the theoretical success of deep learning methods and the practical requirements of maintaining deployable learning systems over time [10].

Existing studies have addressed this problem from several angles. Some focus on reducing model complexity or accelerating training, while others emphasize incremental learning, distributed optimization, multimodal fusion, or robust preprocessing for large-scale data [11]. Although these studies provide useful contributions, they are often presented as isolated technical solutions [12]. In many cases, the interaction between

preprocessing, model configuration, training strategy, and adaptation to data drift is not treated as a unified design problem. Consequently, prior work often resembles benchmarking or task-specific optimization rather than offering an integrated framework that organizations can adapt to complex and evolving real-world environments [13].

Another important limitation in the current literature is that performance is often evaluated primarily through predictive accuracy under controlled settings. Such evaluations are valuable, but they do not fully capture whether a learning system can remain stable, efficient, and maintainable in practice [14]. In complex domains such as educational analytics and industrial intelligence, organizations need models that not only perform well but also tolerate noise, missing values, changing data structures, and limited computational resources. Therefore, scalability should be considered an emergent property of the whole learning system rather than a property of a single model architecture [15].

This study addresses that gap by proposing an efficient computational framework for scalable learning in complex data environments using deep neural networks [16]. Instead of introducing a single specialized model, the proposed framework integrates three complementary design principles: adaptive preprocessing for heterogeneous data, modular neural network design for multimodal learning, and resource-aware training strategies for stable and efficient optimization. This integrated perspective is intended to bridge the gap between experimental deep learning performance and operationally viable deployment across domains [17].

The main contributions of this study are threefold. First, it proposes an integrated framework that coordinates preprocessing, model modularization, and training adaptation within a single pipeline for scalable deep learning. Second, it evaluates the framework across heterogeneous datasets representing educational and industrial contexts, thereby examining cross-domain applicability rather than a single isolated task. Third, it demonstrates that scalability can be

improved not only through model sophistication but also through coordinated pipeline design that enhances stability, efficiency, and adaptability under distributional change and resource constraints [18].

II. MATERIALS AND METHODS

This study employed a computational and empirical research design to develop and evaluate an efficient framework for scalable learning in complex data environments using deep neural networks. The proposed framework was designed for heterogeneous, evolving, and partially noisy data settings, with emphasis on balancing predictive performance and computational efficiency [19]. Rather than treating preprocessing, model design, training, and evaluation as separate stages, the framework integrates them into a unified pipeline that can be adapted across domains with limited reconfiguration.

A. Dataset Selection and Rationale

The study used datasets drawn from two representative domains: learning analytics and industrial manufacturing systems. These domains were selected because both exhibit core characteristics of complex data environments, including multimodality, temporal dependence, missingness, noise, and distribution shifts over time. The educational datasets consisted of structured learner records, semi-structured interaction logs, and unstructured textual data such as feedback and discussion content. The industrial datasets included time-series sensor sequences, categorical machine event logs, and contextual production metadata [20].

The selection of these datasets was based on three considerations. First, they reflect practical deployment scenarios in which data are generated continuously and require scalable model updating. Second, they contain heterogeneous input types that challenge conventional single-stream deep learning pipelines. Third, they allow evaluation of both predictive quality and operational efficiency under increasing data scales. Table I summarizes the datasets used in this study.

TABLE I. OVERVIEW OF DATASETS USED IN THE STUDY

Dataset Source	Data Characteristics	Scale and Description
Learning Analytics (Educational Platforms)	Multimodal data combining structured records (scores, completion rates), semi-structured interaction logs (clickstream, time-on-task), and unstructured text (student feedback, forum posts)	~120,000 learner records; ~3.5 million interaction events collected across multiple academic terms
Industrial Manufacturing Systems (Industry 4.0/5.0)	Time-series sensor readings (temperature, vibration, energy consumption), categorical event logs (machine states, maintenance events), and contextual metadata (production line configuration)	~2.1 million sensor sequences; data sampled at 1–5 second intervals from multiple production units
Integrated Multimodal Dataset (Cross-Domain Fusion)	Fused representation of educational and industrial data after preprocessing, normalization, embedding, and temporal segmentation for scalable deep learning experiments	~1.8 million aligned samples used for training, validation, and testing across experimental scenarios

B. Data Preprocessing

Adaptive preprocessing was used to ensure consistent data representation across heterogeneous inputs while limiting unnecessary computational overhead. Numerical variables were standardized using z-score normalization. Categorical variables were encoded using trainable embeddings rather than one-hot vectors in order to reduce dimensionality while preserving latent relationships. Textual inputs were processed through lightweight tokenization and dense embedding layers. For

industrial sensor data, sliding-window segmentation was applied to capture local temporal structure while maintaining manageable input lengths [21].

Missing values were handled through a combination of domain-aware imputation and masking. Mean or median imputation was applied to low-missing numerical fields, while missing categorical values were represented through dedicated embedding identifiers. For sequential data, masking vectors were passed to temporal modules so that the model could learn

informative absence patterns instead of treating missingness as random noise. This choice was motivated by the observation that, in complex real-world systems, data absence may itself carry operational meaning.

Dimensionality reduction techniques such as PCA were not adopted as the primary preprocessing strategy in the final framework because the data used in this study were multimodal and contained substantial nonlinear dependencies. Although PCA is effective for reducing redundancy in linearly correlated features, it may suppress discriminative structures when the target signal depends on nonlinear interactions or cross-modal relationships. For this reason, the framework prioritized feature standardization, embeddings, temporal segmentation, and modular representation learning over aggressive global projection methods.

C. Model Architecture

The proposed framework was implemented as a modular deep neural network composed of three main input branches, depending on data availability:

- A feedforward branch for structured numerical and categorical features.
- A temporal branch for sequential sensor or interaction-log inputs.
- A text branch for short textual feedback or unstructured language inputs.

For structured features, a multilayer perceptron with hidden layer sizes of 256, 128, and 64 neurons was used, with ReLU activation, batch normalization, and dropout of 0.30. For sequential inputs, either a bidirectional GRU or a temporal convolution block was used, depending on sequence length and task requirements. In the main experiments, the GRU configuration included two recurrent layers with 128 and 64 hidden units. For textual inputs, an embedding layer followed by global average pooling and a dense transformation layer was used to maintain computational efficiency.

Outputs from the active branches were concatenated and passed through an attention-based fusion layer, followed by two fully connected layers of 128 and 64 neurons. The output layer used softmax activation for classification tasks and a linear

activation for regression or forecasting tasks. Weight decay of $1e-5$ and dropout regularization were used to reduce overfitting. This modular design allowed the same framework to be reconfigured for structured-only, multimodal, and cross-domain settings without rewriting the entire pipeline.

D. Baseline Configuration

To support fair comparison, the baseline model used a conventional deep learning pipeline consisting of standard normalization or encoding, a single monolithic DNN architecture, and a fixed training schedule. The baseline did not include modality-specific branches, attention-based fusion, incremental updates, or resource-aware scheduling. This baseline was selected to reflect a commonly used deep learning setup in applied predictive tasks and to isolate the contribution of the proposed integrated framework.

E. Training Strategy

Models were trained using the Adam optimizer with an initial learning rate of 0.001. Batch sizes of 32, 64, and 128 were explored depending on the resource scenario, with 64 used as the default setting. Training was conducted for up to 100 epochs with an early stopping patience of 10 epochs based on validation loss [22]. A ReduceLROnPlateau schedule was used to decrease the learning rate when validation performance stagnated. To support scalability in dynamic environments, the framework included an incremental update procedure. After the initial training phase, new data batches were introduced using short update cycles of 5–10 mini-epochs rather than full retraining. This design was used in the concept drift and continuous deployment scenarios. In addition, curriculum-inspired sampling was applied in some large-scale experiments by introducing representative subsets of the data in early epochs and gradually increasing data diversity as training stabilized.

F. Experimental Scenarios

The proposed framework was evaluated through several experimental scenarios: baseline comparison, data-scale stress testing, heterogeneity and modality ablation, concept drift evaluation, incremental updating, resource-constrained training, and robustness to noise and missingness. These scenarios were chosen to reflect practical deployment conditions rather than only ideal benchmark settings. Table II presents the experimental scenarios in detail.

TABLE II. EXPERIMENTAL SCENARIOS FOR EVALUATING THE PROPOSED FRAMEWORK

Scenario	Experimental Setup	Evaluation Focus
S1 – Baseline Deep Learning Pipeline	Standard preprocessing (basic normalization/encoding), single-architecture DNN, fixed training schedule without incremental updates	Predictive performance as baseline (accuracy/F1 or RMSE), training time, convergence stability
S2 – Proposed Framework (Full Pipeline)	Adaptive preprocessing, modular DNN (structured + sequential + attention where needed), resource-aware training with early stopping and learning-rate scheduling	Performance vs. efficiency trade-off, stability across heterogeneous inputs, overall scalability
S3 – Data Scale Stress Test	Training on increasing data sizes (e.g., 25% → 50% → 75% → 100%) for both baseline and proposed framework	Scalability behavior: growth of training time/memory, convergence speed, performance degradation (if any)
S4 – Heterogeneity and Modality Ablation	Controlled experiments by removing/adding modalities (structured only; +logs; +text; +sensor sequences), keeping target tasks consistent	Contribution of each modality, robustness of multimodal fusion, sensitivity to input complexity
S5 – Concept Drift / Distribution Shift	Temporal split by term/period (education) and by production phase/configuration (industry); evaluate train-on-past, test-on-future	Adaptability under drift: performance retention, need for retraining, stability under changing patterns
S6 – Incremental Learning Update	Train initial model, then update with new batches (mini-epochs) without full retraining; compare with full retrain strategy	Update efficiency, performance recovery, computational savings, practicality for continuous deployment

S7 – Resource-Constrained Training	Run training under constrained settings (smaller batch, limited GPU/CPU, reduced memory), compare baseline vs. framework	Robustness under limited resources, feasibility for institutions with modest computing capacity
S8 – Robustness to Noise and Missingness	Inject controlled noise and missing values; compare masking/imputation strategies used in the framework vs. baseline handling	Training stability, error sensitivity, resilience to imperfect real-world data conditions

G. Evaluation Metrics and Validation Procedure

Evaluation focused on both predictive performance and computational efficiency. For classification tasks, accuracy, precision, recall, and F1-score were computed, along with confusion-matrix-based analysis. For regression or forecasting tasks, mean squared error and root mean squared error were used. Computational evaluation included relative training time, convergence stability, and memory usage.

To improve robustness, 5-fold cross-validation was used for the main predictive experiments. In temporal drift scenarios, train-on-past/test-on-future evaluation was applied to preserve chronological realism. Each experiment was repeated across multiple runs using fixed random seeds to reduce variance due to stochastic initialization. Results are reported as averaged outcomes across folds or runs where appropriate.

H. Implementation Environment

The framework was implemented using widely adopted deep learning libraries in Python. Experiments were executed under both single-GPU and constrained-resource settings in order to evaluate deployment feasibility across academic and industrial environments. Although hardware availability varied across scenarios, the same preprocessing logic, modular design principles, and evaluation protocol were maintained to preserve comparability across experiments.

Overall, the methodological design was intentionally iterative. Preliminary pilot runs were used to identify bottlenecks in preprocessing, model modularization, and update scheduling, and these observations informed refinement of the final framework. This iterative design reflects the practical reality of developing scalable learning systems for complex environments, where methodological usefulness depends not only on theoretical elegance but also on operational reliability.

The experimental setup was implemented using widely adopted deep learning libraries to ensure reproducibility and to facilitate potential transfer of the framework to other contexts. Hardware configurations varied across experimental runs to simulate different resource conditions, ranging from single-GPU environments typical of academic institutions to more scalable configurations available in industrial settings. This variation allowed the study to explore how the framework performs under different computational constraints and to identify trade-offs between model complexity and resource consumption. Where possible, model configurations and preprocessing routines were kept consistent across domains to highlight the generalizability of the framework, while allowing for domain-specific adjustments in feature selection and data representation.

III. RESULTS

The proposed framework was evaluated across educational learning analytics and industrial manufacturing datasets that differed in scale, modality, and temporal dynamics. The results are presented in terms of predictive performance, computational

efficiency, robustness under heterogeneous inputs, and adaptability under data drift.

A. Overall Predictive Performance and Efficiency

Across both domains, the proposed framework achieved predictive performance that was comparable to or better than the baseline while requiring less training time under increasing data scales. In learning analytics tasks, the framework produced smoother convergence behavior and lower validation instability, particularly when multimodal inputs were included. In industrial forecasting and anomaly detection tasks, the framework maintained stronger performance when the data contained noise, missing segments, and temporal variability. As shown in Table III, the gap between the baseline and the proposed framework became more pronounced as the data scale increased. At smaller scales, both approaches performed similarly; however, at 50% and 100% of the available data, the baseline required disproportionately longer training time and showed more unstable predictive behavior. In contrast, the proposed framework preserved stable performance while controlling the growth of computational cost.

TABLE III. PERFORMANCE AND EFFICIENCY ACROSS DATA SCALES

Setup	Predictive Performance (Avg.)	Training Time (Relative)
Baseline (25% data)	High (reference)	1.0×
Proposed Framework (25% data)	Comparable	0.85×
Baseline (50% data)	Slight decline	1.6×
Proposed Framework (50% data)	Stable	1.2×
Baseline (100% data)	Noticeable variance	2.9×
Proposed Framework (100% data)	Stable	2.0×

These results indicate that the proposed framework scaled more effectively than the conventional pipeline, particularly when the data volume increased beyond the level at which baseline hyperparameters remained stable.

B. Performance Across Modalities

The modality ablation experiments showed that structured features alone yielded moderate predictive performance but were insufficient for capturing more complex and longer-term patterns. In the educational domain, adding interaction logs improved performance by incorporating temporal and behavioral signals. Adding text-based features led to a further improvement, especially for tasks related to engagement and risk prediction. In the industrial domain, combining sensor streams with contextual metadata improved anomaly forecasting and condition-aware prediction.

As shown in Table IV, the proposed framework benefited more consistently from additional modalities than the baseline. The baseline became increasingly sensitive to feature imbalance and noise as new data streams were added, whereas the modular

framework produced more stable gains through branch-specific representation learning and fusion.

TABLE IV. MODALITY CONTRIBUTION ANALYSIS

Input Configuration	Performance Trend	Stability Under Noise
Structured only	Moderate	High
Structured + Logs	Improved	Moderate
Structured + Logs + Text	Further improved	Lower (baseline) / Higher (framework)

C. Robustness Under Resource-Constrained Training

The resource-constrained experiments revealed clear differences in convergence stability. Under smaller batch sizes, reduced memory conditions, and limited GPU availability, the baseline models showed unstable gradients and slower convergence. The proposed framework maintained smoother optimization trajectories and reached acceptable performance with fewer unstable oscillations (see Fig. 1).

Fig. 1. Illustrates the difference in convergence behavior between the baseline and the proposed framework under limited-resource training conditions.

The proposed approach demonstrated faster stabilization of training loss, indicating that the framework remained viable even when computational resources were restricted.

D. Adaptability Under Distribution Shift

Temporal evaluation showed that both domains were affected by a distribution shift. In educational data, models trained on earlier terms lost performance when tested on later terms with changing interaction patterns and assessment structures. In industrial settings, predictive performance also declined when production phases, machine configurations, or operational states changed over time. However, the proposed framework recovered more efficiently than the baseline through incremental updating. While the baseline required full retraining to restore performance, the proposed approach achieved moderate-to-high recovery with substantially lower computational cost. As shown in Table V, the incremental update strategy offered a practical compromise between predictive retention and retraining overhead.

These results confirm that Table V is central to the study because it shows how the framework behaves when learning

conditions evolve, which is one of the main practical challenges addressed in this study.

TABLE V. ADAPTABILITY UNDER DISTRIBUTION SHIFT

Approach	Performance Retention (%)	Recovery Cost (Relative)
Baseline (no update)	Low	0.0×
Baseline (full retrain)	High	1.0×
Proposed Framework (incremental update)	Moderate–High	0.4×

E. Additional Classification Metrics

To provide a more comprehensive evaluation, classification experiments were assessed not only using accuracy but also precision, recall, and F1-score. In general, the proposed framework produced more balanced performance across these metrics than the baseline, particularly under multimodal and noisy settings. Confusion matrix analysis further showed that the framework reduced false negatives in risk-sensitive scenarios and improved class discrimination under heterogeneous inputs.

The results consistently show that the proposed framework improves scalability not by maximizing a single metric, but by jointly improving predictive stability, multimodal integration, update efficiency, and feasibility under computational constraints.

IV. DISCUSSION

The results demonstrate that scalable learning in complex data environments is better achieved through coordinated pipeline design than through reliance on a single high-capacity model. The proposed framework consistently showed that adaptive preprocessing, modular representation learning, and resource-aware training can work together to improve practical scalability across both educational and industrial domains [23]. This finding is important because many existing studies emphasize isolated optimization techniques or benchmark-oriented model comparisons, whereas real-world deployment depends on the interaction of multiple design decisions throughout the full learning pipeline [24].

One of the most important findings of this study is that the framework became increasingly advantageous as data complexity and scale increased. At smaller scales, the baseline remained competitive, which suggests that conventional deep learning pipelines may still be sufficient for relatively simple settings [25]. However, when data volume increased, modalities were added, or temporal variation became stronger, the limitations of the baseline became more visible. This pattern supports the argument that scalability should be understood not only as computational throughput but also as the capacity to preserve learning stability under growing system complexity.

The modality ablation results further reinforce the value of the modular design. Heterogeneous data are common in both learning analytics and industrial intelligence, yet they are often difficult to integrate effectively within a monolithic architecture. In the proposed framework, branch-specific processing allowed each modality to contribute meaningful information without destabilizing the full system. This is a practical advantage because organizations rarely introduce all data types at once.

Instead, new data sources are often added gradually, and the framework's modularity makes such expansion more manageable [26].

The results under resource-constrained conditions are also noteworthy from an implementation perspective. Many educational institutions and small-to-medium industrial organizations operate with modest hardware resources and cannot sustain highly expensive model training workflows [27]. The smoother convergence and reduced computational burden observed in the proposed framework suggest that it is more suitable for environments where deployment practicality matters as much as predictive performance. This makes the framework particularly relevant for operational settings beyond well-funded research laboratories.

The concept drift experiments highlight another major practical implication. In both educational and industrial contexts, data environments evolve over time. A learning system that performs well only under static conditions will eventually become unreliable in deployment [28]. The proposed framework does not eliminate drift-related degradation, but it reduces the operational cost of adapting to change through incremental updates. This is a meaningful advantage because full retraining is often expensive, disruptive, and difficult to schedule in real-world systems. Therefore, the framework contributes not only to predictive performance but also to the long-term maintainability of learning infrastructures [29].

From a theoretical perspective, the findings also help explain why simpler dimensionality reduction approaches such as PCA may underperform in complex multimodal settings. PCA is useful for compressing linearly correlated features, but it is less effective when meaningful target patterns arise from nonlinear, temporal, and cross-modal interactions. In the present study, stronger performance was obtained by preserving modality-specific structure and learning distributed representations through embeddings, temporal modules, and fusion mechanisms. This suggests that, in heterogeneous environments, representation learning should be guided by data structure and task requirements rather than by global variance compression alone [30].

The study also has direct implications for organizational implementation. In educational systems, the proposed framework can support adaptive analytics pipelines that update models across academic terms without repeated end-to-end retraining. In industrial systems, it can be deployed to monitor machines, detect anomalies, and update predictive models as production conditions shift [31]. Because the framework emphasizes modularity and update efficiency, it can be integrated gradually into existing analytics infrastructures rather than requiring full architectural replacement. This makes the approach more feasible for institutions seeking incremental digital transformation.

Despite these strengths, several limitations should be acknowledged. First, the modular architecture introduces additional design decisions, and effective module selection still requires domain knowledge. Second, although the framework is more efficient than the baseline, it may not outperform highly specialized architectures designed for a single narrow task [32]. Third, while the present evaluation covers heterogeneous and

dynamic conditions, broader validation on additional real-world domains would strengthen claims of generalizability. These limitations indicate that the framework should be viewed as a flexible design strategy rather than a fixed universal solution. Future work can build on this study in several directions [33]. One promising extension is the integration of explainable AI mechanisms to improve transparency and user trust, especially in education and high-stakes industrial decision contexts. Another is the development of automated configuration strategies that recommend modules, hyperparameters, and update schedules based on observed data characteristics. Further studies may also compare the present framework with transformer-based architectures, continual learning models, and edge-deployable systems under stricter resource constraints [34].

V. CONCLUSION

This study proposed an efficient computational framework for scalable learning in complex data environments using deep neural networks. The framework integrates adaptive preprocessing, modular neural network design, and resource-aware training strategies into a unified pipeline intended for heterogeneous, evolving, and computationally constrained settings. The empirical results show that the proposed approach maintains competitive predictive performance while improving convergence stability, training efficiency, multimodal robustness, and adaptability under distribution shift. The findings indicate that scalability should not be interpreted only as the ability to process larger datasets. Instead, it should be understood as the ability of a learning system to remain reliable, efficient, and maintainable as data volume, modality diversity, and operational complexity increase. In this sense, the contribution of this work lies not in introducing a single specialized model but in demonstrating that coordinated pipeline design can substantially improve the practical deployment of deep learning systems across domains such as learning analytics and Industry 4.0/5.0 applications. From an applied perspective, the framework offers a realistic pathway for organizations that need to update models continuously, integrate new data sources gradually, and operate under non-ideal computational conditions. At the same time, the study acknowledges that no single framework can fully address every domain-specific challenge. Future research should, therefore, extend this work by incorporating explainability mechanisms, automated configuration support, broader cross-domain validation, and comparisons with newer continual-learning and transformer-based architectures. These directions will help further strengthen the operational and scientific value of scalable deep learning in real-world environments.

Abstract—The development of edge computing has facilitated the development of numerous applications with diverse characteristics and stringent quality of service (QoS) requirements; these applications demand significant computational power and have strict time-sensitive constraints. While cloud computing offers seemingly unlimited computational resources, it often fails to meet the real-time demands of certain applications because of the latency introduced by the distance between edge devices and cloud data centers. Edge computing enables computational services closer to edge devices, better fulfilling these time-sensitive demands. Task scheduling that tries to share tasks among diverse virtual machines in an optimum manner concerning overall system performance metrics, such as minimal execution time or reduced energy consumption, is one of the key challenges of this heterogeneous computing environment. Task scheduling is an NP-complete problem. Therefore, metaheuristic algorithms are usually applied to obtain near-optimal solutions. The study presents an enhanced grey wolf optimization hybridized by a dimension learning-based strategy, EGWODLB, for optimizing QoS objectives focusing on execution time and energy consumption. The experimental results reflect that EGWODLB outperforms the benchmark algorithms by achieving significant improvements in both execution time, energy consumption, and VM utilization.

Keywords—Edge computing; energy consumption; execution time; task Scheduling; grey wolf optimization dimension learning

I. INTRODUCTION

With the penetration of intelligent edge devices, the 21st century turns computationally intensive with several broad applications ranging from online gaming, video conferencing, and 3D modeling. Such resource-intensive computing applications are normally restricted in edge devices due to the limited battery life and processing power, resulting in poor user experiences for resource-intensive operations [1][2]. The concept of Edge Computing, therefore, came to alleviate this, offloading expensive computation into local EC servers, hence making performance great and saving energy and execution time, the important role of EC in building the spaces where the demands of modern applications and the limited abilities of edge devices have equipped it to become a key technological component for time-critical applications. For instance, autonomous vehicles, smart cities, and healthcare [3]. Despite the considerable advantages of Edge Computing (EC), the task scheduling problem in these contexts is far from trivial. Huge

search spaces can randomly generate satisfactory task assignments [4]. Scheduling algorithms take a considerable amount of time to converge, which can lead to the underutilization of virtual machines. This inefficiency circumscribes the maximum potential of edge computing systems and negatively affects the timely execution of tasks, especially in IoT and real-time data processing[5].

To address these challenges, EC operates within an environment that aims to optimize resource allocation and performance by distributing tasks between edge devices and EC servers. This distribution is based on various factors such as task requirements, network conditions, and resource availability. However, inefficiencies in scheduling algorithms continue to limit this potential, as they may not fully exploit the capabilities of available resources [6]. Effective task scheduling is pivotal in ensuring that EC systems can operate efficiently. This involves the intelligent allocation of tasks to appropriate resources, considering multiple optimization goals, such as minimizing energy consumption, execution time, and completion delay, while ensuring that the Quality of Service (QoS) standards are met [7]. However, the EC environment needs to manage resources efficiently, which requires effective task scheduling. It involves the intelligent allocation of resource tasks, taking into account various optimization objectives such as energy consumption, execution time, and completion delay, all to maintain the Quality of Service (QoS) requirement [8].

Many current algorithms, such as traditional heuristic and metaheuristic approaches, struggle with the flexibility needed to effectively manage the dynamic and constantly evolving conditions of edge environments. These algorithms have gained popularity for task scheduling in EC, particularly for NP-complete problems. The general idea of such algorithms is that they can reasonably perform in limited amounts of time to obtain near-optimal solutions for complex problems.[9]. These include (PSO, GA, FOA, and ACO); all these algorithms have their goal of reaching as near an optimal solution as possible to the complex problem at hand within reasonable time limits[10], [11]. However, these methods are suffering from shortcomings such as a slow convergence rate, inherent randomness tied to global search capability, and trapping in local optima that usually result in suboptimal solutions[12]. o far, the biggest challenge in applying such metaheuristic approaches to real-time edge computing is how to find a good balance between global exploration and local exploitation

[13],[14]. Recently, many challenges have been overcome by using the algorithm called Grey Wolf Optimizer. GWO has some special advantages in comparison with other metaheuristic algorithms. For example, memory is lower than that of PSO since only one position vector is used, and GWO avoids convergence to local optima because of the use of the top three solutions, while the PSO algorithm focuses on one best solution[15]. Besides, GWO has less complexity and fewer parameters than GA, implying faster computation time and lower energy consumption. It also shows better adaptation to the dynamic resource availability inherent in EC environments [16].

The GWO takes inspiration from grey wolves, always living in a structured social hierarchy, and their natural behavior and hunting strategy. More recently, the grey wolf optimizer has gained considerable attention over other metaheuristic algorithms due to efficient convergence performance, low complexity, minimum utilization of energy, and easy implementation converter [17]. The GWO has been widely used in many fields to solve a set of problems, such as optimization problems, classification problems, economic and power dispatch, and Capacitated Vehicle Routing problems [18]. Recently, with its attractive characteristics, this algorithm has gained specific attention from researchers in multi-objective problems of task scheduling, especially in edge computing, given the particular features of EC servers [19]. The major influencing factors include execution time and energy consumption, the most important among them all. Though scheduling tasks on EC servers reduces execution time through the exploitation of proximity to resources, it could lead to higher energy consumption. Overall, the rise in energy consumption can be attributed to several factors, including the added computational overhead required for efficient task management and mapping, frequent scheduling in dynamic environments, and the ongoing monitoring and adjustment of resource utilization to accommodate fluctuating demands.[20]. Moreover, most edge devices are limited in computation capability and power supply, and high energy consumption within an edge server increases not only operation costs but also shortens equipment life. Consequently, energy consumption reduction becomes critical to edge networks. Most of the work in improving energy efficiency in edge servers has focused either on developing energy-efficient hardware for edge computing or strategies of offloading jobs from the cloud to an edge server. Workload scheduling and task assignment to an appropriate virtual machine, though critical aspects that can significantly enhance EC server execution time and energy efficiency, have not yet been clearly addressed [21].

To address the identified limitations, this study proposes an enhanced version of the GWO, designed to improve its efficiency and effectiveness. The enhancement incorporates a novel search mechanism known as the dimension learning-based Hunting (DLH) strategy, inspired by the individual hunting behaviour of wolves in nature. The DLH strategy expands the global search capability by leveraging multi-neighbour learning, allowing the algorithm to explore the search space more thoroughly. In each iteration, the (EGWO) generates two potential solutions for each wolf: one based on the (DLH) strategy and another from the standard GWO

approach. The algorithm then applies a selection and update process to determine the best candidate solution, ensuring that the wolves move to more optimal positions in subsequent iterations. Furthermore, a network performance model is integrated to assess critical performance metrics. This model minimizes delays by effectively assigning tasks to the most suitable virtual machines, resulting in improved system performance and efficiency.

The main contributions of this study are as follows:

- The existing research and challenges related to task scheduling, particularly those related to energy consumption and execution time, are examined as multi-objective optimization problems.
- A mathematical framework optimizes energy consumption, execution time, and VM utilization by allocating tasks to virtual machines.
- Introducing an enhanced EGWODLB strategy to improve task scheduling, aiming to reduce both execution time and energy consumption in edge computing environments
- Through simulations, the proposed EGWODLB algorithm significantly outperforms other methods in minimizing energy consumption, execution time, VM utilization, and running time.

This study is organized as follows: The relevant research is reviewed in Section II. The system model is examined in Section III. Section IV describes the suggested approach in depth. Section V provides an explanation of the experimental setting, and Section VI discusses the findings. The study is finally concluded in Section VII with a review of the results and recommendations for additional research.

II. RELATED WORKS

Edge computing has emerged as a promising approach to complement cloud computing by improving resource management and enhancing performance[22]. However, the inherently dynamic and varied nature of edge environments creates significant challenges, particularly in areas such as task offloading, network performance monitoring, and the handling of task dependencies [23]. Task offloading within edge computing has become a critical concern, attracting considerable research interest. A range of metaheuristic algorithms has been investigated to tackle this issue, with each method offering distinct advantages and drawbacks. These algorithms play an essential role in optimizing task management decisions, whether on edge devices or EC servers, across various computing settings, due to their capacity to find near-optimal solutions in complex and evolving environments [21].

The Particle Swarm Optimization (PSO) algorithm has become a popular choice for task scheduling in edge computing environments due to its ability to efficiently find optimal solutions for complex problems [24]. Over time, various modifications and enhancements have been introduced to enhance the Particle Swarm Optimization (PSO) algorithm's effectiveness in task scheduling. Drawing inspiration from the

social behaviours of animals such as birds and fish, these advancements have enabled the algorithm to adapt to the dynamic and flexible demands of edge computing. As a result, PSO has become a cost-effective and energy-efficient solution that meets strict Quality of Service (QoS) requirements. Recently, a two-level scheduling framework has been developed to tackle optimization challenges in edge computing environments. At the upper level, the Inertia Weight Particle Swarm Optimization (IW-PSO) method addresses edge users' complex, non-convex, and nonlinear power allocation problem, focusing on minimizing transmission energy consumption. A binary PSO algorithm is utilized at the lower level to handle the joint task offloading and resource allocation problem, modelled as a Mixed-Integer Nonlinear Programming (MINP) problem. This hierarchical framework achieves an optimal scheduling solution, reducing energy consumption while enhancing response times and overall system efficiency [25]. This study introduces a hybrid method integrating Genetic Algorithms (GA) and Particle Swarm Optimization (PSO) to optimize multi-objective job scheduling in fog computing environments. Combining both algorithms' strengths, the hybrid approach outperforms traditional single-algorithm techniques. It optimises between exploring and exploiting the search space, resulting in more effective solutions. Experimental findings reveal that the proposed hybrid algorithm significantly enhances execution time and reduces energy consumption, demonstrating its efficiency and practicality [26]. This study proposes a Particle Swarm Optimization (PSO)-based approach aimed at reducing energy costs and minimizing the time required to identify viable solutions. Experimental results indicate that the energy-efficient PSO metaheuristic effectively leverages its capabilities to achieve significant performance improvements [27]. A centralized orchestrator layer is proposed to implement a two-tier cooperative scheduling mechanism. At the first level, tasks are scheduled locally on EC servers, ensuring efficient handling of resources at the edge. The second level operates within the orchestrator, where tasks are distributed to either the cloud or a nearby base station. Task prioritization is determined based on factors such as required throughput and acceptable delay, enabling the system to optimize resource allocation and performance [28]. This research presents a heuristic Particle Swarm Optimization (PSO) algorithm, termed LPSO, built upon the Lyapunov framework. The algorithm is designed to stabilize queues and complete tasks within defined timeframes while balancing computational energy usage at IoT nodes, transmission energy requirements, and energy consumption in the fog computing environment. By fine-tuning these parameters, the proposed LPSO algorithm effectively reduces total energy consumption and promotes efficient task execution. [29]. The main goal of scheduling is to minimize task completion time and lower energy consumption on edge devices. The study introduces two optimization techniques grounded in slow-motion particle swarm optimization to address this NP-hard challenge. Notably, a position-based mapping strategy is developed to convert particle positions into practical and efficient scheduling solutions [30]. The Particle Swarm Optimization (PSO) algorithm is highly effective for solving continuous optimization problems. It is renowned for its straightforward implementation and fast convergence speed.

However, it is prone to premature convergence, which can result in suboptimal solutions as it becomes trapped in local optima. Consequently, additional enhancements are required to improve its overall performance.

Genetic Algorithms (GAs) have demonstrated their effectiveness in addressing complex task scheduling problems across diverse computing environments, including cloud computing, Edge Computing (EC), and fog computing [31]. Their primary strength is their capacity to produce excellent results quickly, even for NP-complete problems like job scheduling, which makes them an invaluable tool in these situations [32]. In order to minimize the total energy consumption of fog nodes (FNs) while ensuring that the Quality of Service (QoS) requirements for Internet of Things tasks are met, the research presents a mathematical model for the task scheduling problem. [33]. This study introduces an enhanced task scheduling strategy, IGA-TSPA, based on an improved genetic algorithm. The approach refines the initialization and mutation processes of the genetic algorithm, effectively narrowing the initial solution space and accelerating convergence toward optimal solutions [34]. A scheduling system was created to break down applications into discrete jobs, which are then handled using a task queue. An auction-based bidding approach was used to find the most appropriate server for each application [35]. The Genetic Algorithm (GA) employs a weighted probabilistic crossover method to optimize work scheduling, considering the fitness of Virtual Machines (VMs).

The Fruit Fly Optimization Algorithm (FOA) has been widely used for job scheduling challenges in many fields, significantly improving efficiency and optimization. [36]. In recent research, an improved Fruit Fly Optimization (IFFO) algorithm was designed to optimize the scheduling of multiple workflows in a cloud computing environment by minimizing both makespan and associated costs [37]. A Fruit Fly-inspired Simulated Annealing Optimization System (FSAOS) was proposed as a potential solution. To address the issue of premature convergence in both global and local searches, the framework integrates simulated annealing into the optimization process. Additionally, a trade-off factor is introduced, allowing application owners to select the most suitable service quality that minimizes execution costs [38]. The Firefly Algorithm (FA) excels in solving multimodal optimization challenges and effectively avoids getting trapped in local optima. However, its effectiveness in dynamic environments largely relies on precise tuning of key parameters, such as the smell coefficient and attractiveness function, to ensure optimal performance.

The Ant Colony Optimization (ACO) algorithm has proven to be highly effective in addressing task offloading challenges across various fields, including edge computing and construction project management. Drawing inspiration from the natural behavior of ants, the algorithm mimics their method of leaving pheromone trails to guide others [39]. These pheromone trails enable ants to navigate the solution space, marking their routes and assessing the quality of potential solutions, to converge on the optimal one. Recently, there has been research based on an ant colony. For resource and task selection criteria in clusters, the ACO technique was

proposed in [40]. To attain the required quality for scheduling workflows, users define QoS restrictions. [41] presents a workflow scheduling method based on the ant colony system (ACS) that has been improved with new features. The idea of a knowledge matrix combined with the ACO algorithm is covered in [42]. Researchers employed the ACO technique to assess the historical attractiveness of distributing jobs to the same physical machine. An energy-efficient scheduling system based on ant colonies was invented. Pheromone systems have been revised and proven in [43] and [44]. Due to the balance between exploration and exploitation, it has demonstrated encouraging outcomes in several optimization situations. To evaluate its performance in dynamic situations like edge computing. However, more research is necessary as its applicability in these settings is yet mostly unexplored.

In the realm of task scheduling for edge computing, traditional optimization techniques and artificial ontologies have historically played a central role in research [45]. While these strategies have proven efficient in specific situations, their use is frequently limited by significant computational complexity, resulting in high resource usage and increased energy needs. These constraints represent important issues for EC systems, which operate under strict criteria for minimizing energy usage and execution time to support real-time applications. To address these constraints, researchers have increasingly adopted metaheuristic approaches such as Particle Swarm Optimization (PSO), Genetic Algorithms (GA), the Fruit Fly Optimization Algorithm (FOA), and Ant Colony

Optimization (ACO). These techniques stand out for their ability to deliver high-quality solutions with lower complexity than classical methods, enabling more energy-efficient task scheduling. However, their dependency on multiple parameters to achieve optimal results can offset these advantages by increasing computational overhead and energy usage. Consequently, such approaches often fall short of meeting the rigorous performance demands of EC applications, especially in Internet of Things (IoT)-driven environments where rapid response times and power efficiency are paramount. This work proposes the Enhanced Grey Wolf Optimization algorithm integrated with a Dimension Learning-Based strategy (EGWODLB) to overcome these challenges. This novel mechanism addresses the dual objectives of reducing energy consumption and minimizing task execution time in EC systems. By effectively balancing key parameters with minimal input requirements, EGWODLB demonstrates its ability to manage large-scale IoT workloads with remarkable efficiency. Moreover, the algorithm ensures optimized task scheduling, faster response times, and improved system performance, aligning seamlessly with modern EC applications' energy and latency demands. Table I provides a consolidated overview of recent studies on task scheduling in edge computing environments, highlighting both key findings and existing limitations. This summary captures the current state of research, offering insights into the strengths and gaps of various approaches used to address task scheduling challenges in dynamic and resource-constrained edge computing environments.

TABLE I. SUMMARY OF LITERATURE ON TASK SCHEDULING

Algorithm	Strategy Enhancement	Main Goals	Benefits	Limitation	Ref
PSO	Standard PSO	Efficient task scheduling in edge environments	Fast convergence, simple implementation, energy-efficient, but prone to premature convergence	Prone to local optima, lacks robustness in dynamic environments	[24]
IW-PSO + Binary PSO	Two-level scheduling: IW-PSO for power allocation, Binary PSO for offloading/resource allocation	Minimize transmission energy, improve system efficiency	Jointly reduces energy and enhances response time	Increased complexity due to dual-layer structure	[25]
GA-PSO Hybrid	Genetic Algorithm + PSO	Multi-objective job scheduling	Improves execution time and reduces energy compared to single algorithms	inherits the drawbacks of both GA and PSO	[26]
PSO-based Heuristic	Cost-oriented PSO variant	Reduce energy costs and decision time	Achieves significant performance improvements	limited handling of task dependencies or dynamics	[27]
Cooperative PSO + Orchestrator	Local edge scheduling + orchestrated cloud/Base Station tasks	Task prioritization by throughput and delay	Optimizes resource use in two-tier environments	Lacks fine-grained control of edge tasks	[28]
LPSO	PSO with Lyapunov framework	Stabilize queues, balance energy in IoT/Fog	Reduces energy while ensuring timely task completion	Requires accurate modeling of system dynamics	[29]
Slow-Motion PSO	Mapping particle positions to tasks	Handle NP-hard scheduling, minimize makespan	Converts abstract positions into feasible schedules	not scale with heterogeneous environments	[30]
GA	Classic GA with probabilistic crossover	General task scheduling in MEC/Fog/Cloud	Fast for NP-complete problems, highly adaptable	limited exploitation	[31]
IGA-TSPA	Improved GA with refined initialization and mutation	Speed convergence, improve job matching	Narrows the solution space, faster convergence	Still risks local optima in large task sets	[34]
GA + Auction Model	GA with task queue and bidding	Efficient job-server pairing	Dynamic and fair server assignment	Bidding-based methods may introduce latency	[35]
FOA	Standard Fruit Fly Optimization	Improve workflow scheduling in the cloud	Enhances efficiency and optimization	less efficient in constrained edge environments	[36]

IFFO	Improved FOA minimizes the makespan and cost	Multi-workflow scheduling	Achieves cost and time efficiency	Multiple objectives can reduce	[37]
FSAOS	FOA + Simulated Annealing	Avoid local optima	Enables balanced QoS and cost	Annealing can slow convergence	[38]
FA (Firefly Algorithm)	Tuning the smell coefficient and attractiveness	Solve multimodal problems	Avoids local optima, needs careful tuning		
ACO	Pheromone trail modeling	Workflow scheduling, resource matching	Balances exploration-exploitation, energy efficient	Scalability issues in large	[40]

A review of recent literature reveals substantial advancements in task scheduling strategies for edge computing, particularly through metaheuristic and hybrid optimization methods. Nevertheless, critical limitations persist. Many approaches, such as standard PSO and GA variants, exhibit premature convergence, limited scalability, and inadequate performance in handling dynamic and heterogeneous workloads, especially under real-time constraints. Others, including hybrid and cooperative algorithms, introduce high computational overheads and often lack effective mechanisms. Moreover, several studies fail to balance key objectives such as energy consumption, execution time, and VM utilization simultaneously, frequently sacrificing one to optimize another. The need for manual parameter tuning, inability to adapt to fluctuating edge environments, and poor convergence in multi-objective contexts further hinder practical deployment. These issues underscore the necessity for a more adaptive multi-objective scheduling solution. In response, this study proposes an Enhanced Grey Wolf Optimizer integrated with a Dimension Learning-Based strategy (EGWODLB) that is specifically designed to improve convergence speed, task scheduling accuracy, and optimization across diverse edge environments.

pursuit of optimality to optimise task assignments. This intelligent strategy can explore the huge solution space for finding the optimal task-to-VM assignments since there can be thousands of ways to configure them. It does the runtime monitoring of QoS metrics like execution time and energy consumption once the optimal task assignments are done to VMs. The system dynamically readjusts the resources and allocations to maintain peak performance under intensive resource utilization. QoS monitoring will offer real-time feedback, which permits adjustment and adaptations to variant conditions in line with the highest level of service quality. It encompasses integrating tasks generated from edge devices, EPTs calculation, optimization by EGWODLB, and task allocation to VMs for efficient task allocation for resource management in a multiuser, multiple-server edge computing environment.

III. PROBLEM DESCRIPTION

The section offers a thorough explanation of the mathematical model that was applied to solve the edge computing environment's task scheduling challenge. that includes multiple users and servers. The proposed model considers EC servers, each with unique specifications such as RAM, storage capacity, CPU cores, and network bandwidth. These servers are capable of scaling to meet different Quality of Service (QoS) requirements. Consider $V_{machine} = \{V_{machine1}, V_{machine2}, \dots, V_{machinev}\}$ as a set of virtual machines within an EC server. Each virtual machine's processing capacity is expressed in milliseconds (M). Let $T = (t_1, \dots, t_2, \dots, t_n)$ represent the set of tasks submitted by edge devices for execution on these virtual machines. Given the large number of tasks and virtual machines, the task scheduling problem becomes highly complex, involving a vast search space with numerous possible task-to-VM assignments. The task length LT_i of each task t_i is determined in millions of instructions. The Estimated Processing Time (EPT) is utilized to track the time needed to execute a specific task across different virtual machines.[46] EPT_{ij} refers to the EPT of t_i on $V_{machinej}$ computed as Eq. (1):

$$EPT_{(ij)} = \frac{LT_i}{V_{machinej}}, 1 \leq i \leq n, 1 \leq j \leq v \quad (1)$$

where, LT indicates the task's length i and where $V_{machinej}$ denotes the processing power of the virtual machine. We aim to reduce the execution time and energy consumption to increase the quality of service. To address the extensive search space, the method uses an enhanced GWO-integrated DLB strategy called the EGWODLB. This approach leverages dimension learning to explore the large combinatorial space efficiently, thus improving the effectiveness and efficiency of the scheduling process. Accurate task assignments are crucial for reducing execution time and energy consumption. The

Fig. 1. System model.

Fig. 1 shows a model of the system for a multiuser, multi-server context where computational tasks originate from various edge devices. These tasks are managed by a sophisticated scheduling system designed to allocate resources efficiently. The system calculates the estimated processing time (EPT) for every task running on each VM via the following equation $ETP_{ij} = \frac{LT_i}{PSV_{(machine)j}}$, where LT_i is the task length in millions of instructions (MI) and $PSV_{(machine)j}$ indicates the processing power of the VM. It leverages a more enhanced strategy known as EGWODLB for task-VM assignments in

execution time (ET) is defined as the maximum total duration required to complete all tasks as in Eq. (2).

$$ET = \max_{j \in \{1, 2, \dots, v\}} \sum_{i=1}^n x_{ij} \times ET_{ij} \quad (2)$$

Energy consumption is a key factor in the quality of service and includes both the active and idle states of virtual machines. Research indicates that a virtual machine typically consumes more of its total energy while idle. Therefore, the energy consumption $EV_{(machine)j}$ for a specific $V_{machinej}$ can be calculated as Eq. (3):

$$E_{vmj}^{total} = E_j^{total} \times a_j + (ET - ET_j^{total}) \times Cen_j g_j \quad (3)$$

where, E_{vmj}^{total} indicates the total time VM is actively executing the tasks of $Cen_j g_j$ energy consumption rate of VM during the idle state, and a_j indicates the energy consumed in its active state. Consequently, the following equation can be used to determine an edge system's overall energy consumption:

VM Utilization is a performance metric that quantifies the effective computational capacity of a virtual machine (VM) used over a given period. It is defined as the ratio of the time a VM is actively engaged in executing tasks to the total time it is available during a simulation. The overall VM Utilization across all VMs is formulated as Eq. (4):

$$U_j = \frac{\sum_{i=1}^n x_{ij} \times EPT_{ij}}{ET} \quad (4)$$

where, x_{ij} is a binary decision variable indicating whether the task t_i is assigned to a virtual machine j , EPT_{ij} is the estimated processing time of the task t_i on VM j , and ET denotes the overall execution time (makespan) of the system as defined in Eq. (2).

To evaluate the overall utilization of the edge computing system, the average VM utilization across all virtual machines is computed as Eq. (5):

$$U_{avg} = \frac{1}{m} \sum_{j=1}^m U_j \times 100 \quad (5)$$

where, m is the total number of virtual machines. Utilization is expressed as a percentage to reflect the efficiency of resource use across the system.

A. Network Model

The network connection model in edge computing is designed to optimize data flow and interaction between edge devices and edge servers [47]. This model plays a critical role in enhancing the performance of real-time applications by ensuring efficient data transmission while balancing local processing capabilities with the extensive resources available at the edge. In this model, edge devices such as smartphones and IoT sensors connect to edge computing through dedicated communication links. This setup enables low-latency data processing, which is essential for meeting the stringent Quality of Service (QoS) requirements of real-time applications. Tasks requiring higher computational power or additional storage are seamlessly transferred from edge devices to one or more edge servers, leveraging their superior processing capabilities. The hierarchical structure of the model ensures efficient task and

data flow between these devices and servers, optimizing local resource usage while taking full advantage of Edge Computing (EC) infrastructure [48]. Moreover, interconnections between edge servers allow tasks to be offloaded from one edge server and results retrieved from another. This collaborative mechanism enhances resource utilization, minimizes latency, and upholds QoS standards for a wide range of applications. As a result, this network connection model significantly improves the overall performance, efficiency, and reliability of the edge computing environment. Let $M = (MD_1, MD_2, \dots, MD_n)$ Consider the collection of edge devices and $S = (MS_1, MS_2, \dots, MS_p)$ represent the set of edge servers in the environment, the following guidelines are used to calculate the network model. Every edge device needs to be linked to a single edge server [Eq. (6)].

$$\sum_{j \in M} k_{ij} = 1 \quad \forall MD_i \in M \quad (6)$$

where, k_{ij} is a binary variable that indicates whether the edge server MS_j is linked to an edge device MD_i (1 if true, 0 otherwise). Multiple edge servers can be linked to each edge device [Eq. (7)].

$$\sum_{j \in S} h_{ij} = 0 \quad \forall MS_i \in S \quad (7)$$

where, the binary variable h_{ij} indicates if the edge server MS_i and order the edge server MS_j are connected (1 if true, 0 otherwise). From the source to the destination, the data flow needs to be preserved [Eq. (8)].

$$\sum_{z: (z,i) \in L} f_{zi} - \sum_{z: (z,i) \in L} f_{ij} = q_i, \forall i \in M \cup S \quad (8)$$

where, L is the set of network links, z is an index for servers from which data is flowing into the server i , q_i is the flow demand at the server i , and f_{ij} is the data flow from server i to server j .

B. Fitness Function

The Enhanced Grey Wolf Optimization (EGWO) is a metaheuristic algorithm that schedules tasks based on a fitness function to identify the most suitable computing resources. The fitness function plays a crucial role in evaluating solutions by aligning them with the objectives of minimizing energy consumption and execution time. In this study, the fitness function is specifically designed to prioritize solutions that achieve these goals effectively. The performance of the proposed algorithm is significantly influenced by the value of the fitness function. In the context of Multi-objective Optimization (MOP), it is essential to address various conflicting objectives simultaneously. However, the fitness function cannot directly compare the generated solutions against each other, highlighting the complexity of achieving a balanced optimization [Eq. (9)].

$$F(Y) = (1-\alpha) \times ET + \alpha \times E_{vmj}^{total} \quad (9)$$

where, ET represents the overall execution time (makespan), E_{vmj}^{total} denotes the total energy consumption of all virtual machines, and $\alpha \in [0,1]$ is a weighting parameter that controls the trade-off between the two objectives.

The parameter α plays a critical role in balancing the optimization priorities. When α approaches 0, the model

prioritizes minimizing execution time, which is suitable for latency-sensitive applications. Conversely, when α approaches 1, the model emphasizes energy efficiency, making it more appropriate for energy-constrained environments. Intermediate values of α provide a balanced trade-off between performance and energy consumption.

To evaluate the robustness of the proposed model, a sensitivity analysis was conducted by varying α across different values within the interval $[0, 1]$. The results indicate that moderate values of α (e.g., $\alpha = 0.4$ to 0.6) achieve a good balance between execution time and energy consumption, while extreme values tend to bias the optimization toward a single objective. Based on this observation, a balanced value of α is selected in this study to ensure effective multi-objective optimization.

IV. PROPOSED APPROACH

The enhanced grey wolf optimizer (EGWODLB) enhances the original GWO algorithm and integrates a dimension learning-based hunting (DLB) strategy to achieve numerous goals. This represents the first application of the EGWODLB method in the context of edge computing. GWO is inspired by the natural social hierarchy and hunting behavior of grey wolves. Starting locations for the remaining ω wolves are then nudged toward positions corresponding to the best three fitness values to locate the global optimum. The three top wolves are the best candidates in the GWO technique, known as α , β , and δ (Fig. 2). Wolf hunting consists of three major stages: circling, chasing, and attacking the prey.

Fig. 2. Grey wolf hierarchy (dominance diminishes from the top down).

Encircling: Provide a mathematical representation of the actions of grey wolves as they circle their prey via Eq. (10) and Eq. (11).

$$D_{\vec{O}} = C_{\text{vec}} \cdot M_p(t) - M(t) \quad (10)$$

$$M(t+1) = M_p(t) - D_{\text{(vec)}} \cdot A \quad (11)$$

where, $D_{\vec{O}}$ represents the computed distance between the grey wolf and its prey, whereas $C_{\vec{O}}$ is the coefficient vector. In this model, $m(t)$ denotes the position of the grey wolf at a specific time t , and M_p represents the prey's location at the

same time. The coefficient vectors C and A are determined via Eq. (12) and Eq. (13):

$$A = 2 \cdot a \cdot r_1 - a \quad (12)$$

$$C_{\vec{O}} = 2 \cdot (\text{rand } 0, 1) \quad (13)$$

Here, r_1 and r_2 are random vectors that appear in the range of $[0, 1]$, and according to Eq. (14), the components of the vector decrease linearly from 2 to 0 during the repetitions.

$$a = 2 - (2 \cdot \frac{t}{\text{maxiteration}}) \quad (14)$$

where, t indicates the iteration that is currently in use, whereas t_{max} represents the maximum number of iterations.

Hunting: To describe wolves' hunting behavior quantitatively, α , β , and δ require greater knowledge of the prey's position. As a result, the other wolves (ω) are driven to follow the three best solutions (α , β , and δ). Eq. (15)-(16) characterize the hunting behavior as follows:

$$\begin{aligned} D_{\alpha} &= \text{acs}(C_1 \cdot Y_{\alpha}(t) \cdot M(t)) \\ D_{\beta} &= \text{acs}(C_2 \cdot Y_{\beta}(t) \cdot M(t)) \\ D_{\delta} &= \text{acs}(C_3 \cdot Y_{\delta}(t) \cdot M(t)) \end{aligned} \quad (15)$$

$$\begin{aligned} Y_1(t) &= Y_{\alpha}(t) - A_1 \cdot D_{\alpha}(t), \\ Y_2(t) &= Y_{\beta}(t) - A_2 \cdot D_{\beta}(t), \\ Y_3(t) &= Y_{\delta}(t) - A_3 \cdot D_{\delta}(t) \end{aligned} \quad (16)$$

where, $Y_{\alpha}, Y_{\beta}, \wedge Y_{\delta}$ represents the top three solutions at iteration t . The coefficients A_1, A_2, A_3 are computed via Eq. (12), and $D_{\alpha}, D_{\beta}, D_{\delta}$ are defined via Eq. (15).

$$Y(t+1) = \frac{Y_1(t) + Y_2(t) + Y_3(t)}{3} \quad (17)$$

Attacking: the hunting phase ends when the wolves stop moving, and the wolves attack the prey. The whole procedure is controlled through a parameter a , which is linearly decreased from iteration to iteration to balance the exploration and exploitation. As can be seen from Eq. (14), a is updated in each iteration, decreasing from the value 2 to 0 according to [49]. As pointed out, during the first iterations the algorithm emphasizes exploration, while the latter ones belong to the exploitation. During this step, wolves move randomly to a position somewhere between their current position and the position of prey.

A. Enhanced Grey Wolf Optimizer (EGWO)

The leading wolves α , β , and δ in the grey wolf optimizer (GWO) algorithm direct the remaining wolves (ω) to investigate advantageous areas of the search space to identify the optimal solution. This strategy, however, may occasionally cause the algorithm to become trapped in local optima, reducing population diversity and ultimately causing premature convergence. We introduce an enhanced grey wolf optimizer (EGWO) to address these problems. This enhanced version incorporates a new search strategy, along with revised selection and updating processes. The EGWO algorithm progresses through three key stages: initialization, movement, selection, and updating, which are explained.

Initialization stage: N wolves are distributed at random over the search space in this phase, within the given range $[li, uj]$, via Eq. (18).

$$Y_{ij} = L_j + rand_j(0,1) \cdot (U_j - L_j), i \in (1, N), j \in (1, D) \quad (18)$$

The position of the i -th wolf in the t -th iteration is represented as a vector of real values, $Y_i(t) = \{Y_{i1}, Y_{i2}, \dots, Y_{iD}\}$, where D is the problem's dimensionality. The entire wolf population is organized in a matrix, Population, with N rows and D columns. The fitness value of $Y_i(t)$ is determined via the fitness function $f(Y_i(t))$.

Movement stage: In addition to individual and group hunting, another important habit observed in grey wolves has inspired further improvements to the GWO algorithm. The enhanced grey wolf optimizer (E-GWO) incorporates a novel movement technique called the dimension learning-based hunting (DLB) search strategy. This approach allows each wolf to learn from its peers to discover a new potential position $Y_i(t)$. Below is a comparison of how the traditional GWO and DLB search strategies generate different candidate positions.

Canonical GWO Search Strategy: Using the standard grey wolf optimizer (GWO) algorithm, the top three wolves in the population are identified and given the roles of α, β , and δ . Eq. (12)-(14) are used to compute the linearly decreasing coefficient a , as well as the coefficients A and C_{vec} . To determine how to encircle the prey, the positions Y_α, Y_β , and Y_δ are enumerated via Eq. (15) and (16). Finally, the initial candidate for the new position of wolf $Y_i(t)$ is computed via Eq. (17).

Dimension Learning-Based (DLB) Search Strategy: In the traditional GWO algorithm, the three leader wolves guide each wolf's new position. However, this approach can result in slow convergence, reduced population diversity, and local optima entrapment. The DLB strategy aims to address these issues by incorporating additional learning mechanisms. To address these issues, the proposed DLB search strategy incorporates individual hunting, where wolves learn from their neighbors. In the DLB search strategy, each component of the new position for wolf $Y_i(t)$ is calculated via Eq. (12). This strategy allows the wolf to learn from its various neighbors and a randomly selected wolf from the population. In addition to the candidate position $Y_{(i-gwo)}(t+1)$, the DLB search strategy produces another potential candidate for the wolf's new position, labeled $Y_{(i-dlb)}(t+1)$. The process begins by determining a radius $RS_i(t)$, which is calculated on the basis of the Euclidean distance between the current position of $Y_i(t)$ and the candidate position $Y_{(i-gwo)}(t+1)$, as specified in Eq. (19).

$$RS_i(t) = \|Y_i(t) - Y_{(i-gwo)}(t+1)\| \quad (19)$$

Next, the neighbors of $Y_i(t)$, denoted as $N_i(t)$, are determined via Eq. (20) on the basis of the radius $RS_i(t)$, where D_i represents the Euclidean distance between $Y_i(t) \wedge Y_j(t)$.

$$N_i(t) = \{Y_j(t) | D_i(Y_i(t), Y_j(t)) \leq RS_i(t), Y_j(t) \in population\} \quad (20)$$

After the neighborhood of $Y_i(t)$ is constructed, multineighbor learning is carried out via Eq. (20). In this process, the d -dimension of $Y_{(i-dlb)}(t+1)$ is computed via the d -th dimension of a randomly chosen neighbor $Y_{n,k}(t)$ from $N_i(t)$ and a randomly selected wolf $Y_{r,k}(t)$ from the population [Eq. (21)].

$$Y_{(i-dlb),k}(t+1) = Y_{(i-k)}(t+1) + rand(0,1) \cdot (Y_{(n,k)}(t+1) - Y_{(r,k)}(t+1)) \quad (21)$$

Selection and updating stage: During this stage, the fitness values of the two candidates are compared to determine whether one has a higher value, $Y_{(i-gwo)}(t+1)$ and $Y_{(i-dlb)}(t+1)$, via Eq. (22).

$$Y_i(t+1) = \begin{cases} Y_{(i-dlb)}(t+1), & \text{if } f(Y_{(i-gwo)}) < f(Y_{(i-dlb)}) \\ Y_{(i-dlb)}(t+1), & \text{otherwise} \end{cases} \quad (22)$$

Next, to update the position of $Y_i(t+1)$, if the fitness value of the chosen candidate is better than that of $Y_i(t+1)$, it is updated with the selected candidate. If not, $Y_i(t)$ remains unchanged in the population. Finally, after this process is completed, the search continues until the predetermined maximum number of iterations (Maxiter) is achieved, at which point the iteration counter (iter) is increased by one for everyone. The EGWODLB algorithm is shown in Algorithm 1

Algorithm 1: EGWODLB

Input: $N, D, Maxiter$
Output: $Y_{best} \wedge F_{best}$
Begin

1. Initializing population of N solution $i=(1,2, \dots, N)$ using Eq. (14)
2. Calculate the fitness value $F(Y)$ for each wolf using the objective function using Eq. (8)
3. Identify the top three wolf $\alpha, \beta, \wedge \delta$ on their fitness value
4. **For** $iter = 2$ to $Maxiter$ **do**
5. **For** each wolf in in the population **do**
6. Grey wolf optimizer strategy
7. Updated the position $Y(t+1)$ by following $\alpha, \beta \wedge \delta$ using Eq. (14), to (16)
8. Dimension learning Strategies
9. Generate and alternative candidate position $Y_{(i-dlb)}(t+1)$ using Eq. (20)
10. Selection and updating
11. Calculate the fitness $F(Y(t+1))$ and $F(Y_{(i-dlb)}(t+1))$
12. **If** $F(Y_{(i-dlb)}(t+1)) < F(Y(t+1))$ **then**
13. Update $Y(t+1) = Y_{(i-dlb)}(t+1)$
14. **End if**
15. **End for**
16. Update $\alpha, \beta, \wedge \delta$ if new better solution is found
17. **End for**
18. Set $Y_{(best)}$ = the best solution found in the population
19. Set $F_{(best)}$ = fitness value
24. **Return** $Y_{(best)}$ and $F_{(best)}$
25. **END**

The computational complexity of the proposed algorithm is $O(N \times \text{MaxIter} \times n)$, where n is the number of tasks.

V. EXPERIMENTAL SETUP

The experiments were performed using the same simulation settings as outlined in the baseline study. In the experiment scenario, several edge devices generate different applications. Every application consists of several tasks that are required to be executed by edge resources. The proposed method considers ten EC servers, each connected with several edge devices. In the simulated edge environment, the computing capability of the server VM is set to 100 and 1000MIPS. Every edge server can have one or more processors, and every task has a random length ranging from 10 to 510 MIPS. The simulations are based on four tasks with total workloads of 40, 80, 120, and 160, and the maximum iterations are 500, respectively. To make the length of each task have inherent unpredictability, the tasks are generated randomly. For the hardware setup, the experiments were conducted on a high-performance system equipped with an Intel Core i7 processor (2.80 GHz, 8 cores), 8 GB of RAM, and an NVIDIA GTX 1080 GPU, providing the necessary resources for parallel processing. Edge Computing (EC) servers and edge devices were emulated using virtual machines configured to reflect typical edge processor specifications. The software environment was based on Ubuntu 20.04 LTS, utilizing Python 3.12 and essential libraries for optimization and performance evaluation. Both synthetic and real-world datasets were employed to test the algorithm under various EC load conditions. The synthetic datasets generated task requests with diverse parameters, such as task size and computational requirements. Evaluation scenarios included varying network bandwidth, latency, and EC server loads to simulate various operational environments. The parameters used for the simulation are presented in Table II.

TABLE II. PARAMETERS AND THEIR DESCRIPTIONS

Parameters	Description
N	Number of wolves in the population during optimization.
D	Number of dimensions in the solution space.
VM	Set of VMs available for task execution.
$TL_{i,j}$	Length of task i , measured in millions of instructions (MI).
ET	Maximum duration required to complete all tasks
E_{total}	Total energy consumed by VM j during task execution.
EPT_{ij}	Estimated processing time for task i on VM j .
FY	Fitness function.
L	Set of network links between edge devices and servers.
$r_1 \wedge r_2$	Random values used in GWO to ensure diversity in the population.
Y_i	The current position of the i -th wolf in the solution space.
$PSV_{machine}$	Processing capability of the j -th virtual machine (VM).

Table III outlines the key simulation parameters employed to evaluate the performance of the proposed EGWODLB algorithm within a multi-user, multi-server edge computing environment. The experimental setup includes 10 heterogeneous edge servers with processing capacities ranging

from 1000 to 2800 MIPS, and tasks with lengths varying from 2000 to 5600 million instructions (MI). Task data sizes span 400 to 600 MB, and the total number of tasks ranges from 40 to 160 to reflect dynamic workload scenarios. The system bandwidth is fixed at 1 Gbps to simulate realistic network constraints. Additionally, a population size of 50 is adopted for the optimization process, and a weight coefficient parameter $a \in [0,1]$ is used to balance multiple objectives. These configurations are designed to simulate diverse edge conditions and workloads, enabling a comprehensive assessment of the EGWODLB algorithm execution efficiency and energy consumption performance under varying computational demands.

TABLE III. SIMULATION PARAMETERS

Parameters	Values
No of Server	10
CPU Power	1000-2800MS
Bandwidth capacity	1Gbs
Task length	2000-5600MI
Data Size	400-600mb
No of Task	[40,80,120,160]
a	[0,1]
Population size	50

VI. RESULT AND DISCUSSION

This section comprehensively analyses the findings obtained from the experimental evaluations, comparing the proposed EGWODLB algorithm against the benchmark algorithm using the evaluation metrics, which are presented in the following subsections

A. Execution Time Result Analysis

Execution time remains a critical performance indicator in task scheduling for edge computing environments, particularly in latency-sensitive applications. Fig. 3 and Table IV present a comparative evaluation of the proposed Enhanced Grey Wolf Optimization Integrated Dimension Learning-Based (EGWODLB) strategy against the benchmarks QPSO and EADFPSO algorithm across varying workloads of 40, 80, 120, and 160 tasks. The experimental findings demonstrate that the EGWODLB algorithm consistently outperforms EADFPSO by achieving significantly lower execution times across all task scenarios. For instance, under the highest workload of 160 tasks, EGWODLB recorded an execution time of 39.40 seconds, whereas QPSO and EADFPSO required 41.19 and 40.29 seconds. Although this margin may appear modest in absolute terms, it represents the execution time by average 4.71% reduction. More notably, the EGWODLB algorithm demonstrated robust stability in execution time as task load increased. While EADFPSO exhibited noticeable time degradation beyond 120 tasks, EGWODLB sustained relatively smoother performance. This is attributed to the integration of the Dimension Learning-Based (DLB) strategy, which enhances the search diversity of the population and mitigates the risk of premature convergence. By learning from neighboring solutions and generating diversified candidates,

the algorithm ensures that task-to-VM mappings are optimized even under high computational stress.

TABLE IV. EXECUTION TIME BASED ON INCREASING NUMBER OF TASKS

Number of Tasks	QPSO Execution time(S)	EADFPSO Execution time(S)	EGWODLB Execution time(S)	Improvement (%)
40	20.98	20.91	20.11	3.82
80	29.66	28.81	27.20	5.58
120	33.56	32.94	30.55	7.25
160	41.19	40.29	39.40	2.20

Fig. 3. Execution time based on increasing number of tasks.

As shown in Fig. 3 and Table IV, it proves that EGWODLB generally performs the lowest execution time throughout the various tasks evaluated. For example, at a workload of 160 tasks, the execution time recorded by EGWODLB was 39.40, while QPSO and EADFPSO had execution times of 41.19 and 40.29, respectively. Therefore, this large execution time reduction logically means that the algorithm is better in terms of capability regarding the scheduling of tasks, even when it comes to increasing the workloads.

B. Energy Consumption Result Analysis

Energy consumption is a crucial metric in the evaluation of task scheduling algorithms for edge computing, as it directly affects the overall QoS and the environmental sustainability of edge computing systems. In resource-constrained edge environments where power availability is often limited, minimizing energy consumption while maintaining

responsiveness is a complex yet essential objective. Table V and Fig. 4 illustrate the comparative energy consumption performance of the proposed EGWODLB algorithm and the benchmarks QPSO and EADFPSO across various task loads, 40, 80, 120, and 160 tasks. The experimental results clearly show that EGWODLB achieves consistently lower energy consumption than benchmarks under all evaluated scenarios. This is enabled by its integration of the Dimension Learning-Based (DLB) strategy, which enhances the task scheduling process by promoting more energy-efficient task-to-VM assignments. The strategy reduces redundant computations, thereby limiting energy waste due to underutilized and overburdened virtual machines. Most importantly, the total cumulative energy consumption achieved by EGWODLB across all workloads is 12.09%, which represents a significant reduction in overall energy consumption compared to the benchmark method.

TABLE V. ENERGY CONSUMPTION WITH DIFFERENT NUMBER OF TASKS

Number of Tasks	QPSO Energy (J)	EADFPSO Energy(J)	EGWODLB Energy(J)	Improvement (%)
40	3.44	3.26	2.80	14.11
80	4.60	4.58	3.99	12.88
120	4.97	4.89	4.20	14.11
160	5.77	5.50	5.10	7.27

Fig. 4. Energy consumption with different tasks.

As shown in Fig. 4 and Table IV, the energy consumption performance of the algorithms under varying workloads. It is obvious that the EGWODLB algorithm always has the lowest energy consumption in all scenarios. When faced with a maximum workload of 160 tasks, EGWODLB consumes 5.10 energy consumption (J), significantly less than QPSO and

EADFPSO, which consume 5.77 and 5.50 energy consumption (J), respectively. The result indicates a significant decrease in energy consumption, demonstrating the efficiency of the proposed EGWODLB in reducing energy consumption in the edge computing environment.

Fig. 5. VMs against execution time.

Fig. 5 illustrates the performance of the proposed EGWODLB scheduling algorithm. The evaluation involved executing a fixed set of 40 tasks across a varying number of Virtual Machines (VMs), which were incrementally increased from 10 to 30. The execution time was measured for each scenario. As depicted in Fig. 5, the execution time decreased significantly as the number of VMs increased, regardless of the algorithm used. This improvement is attributed to the enhanced

parallel processing capabilities provided by additional VM resources in the edge environment, which directly reduces task completion times. The results highlight that the proposed EGWODLB algorithm consistently achieved the shortest execution times, outperforming traditional methods. For instance, with 30 VMs, the EGWODLB algorithm completed all 40 tasks in just 4.22 seconds, while the benchmark algorithms required 12.35 seconds, more than double the time.

This superior performance is attributed to the iterative optimization of scheduling solutions using the EGWODLB method.

Fig. 6. Energy saving for EGWODLB with EADFPSO.

As shown in Fig. 6, the analysis evaluates task groups ranging from 40 to 160 tasks. The results reveal that the EGWODLB algorithm achieves substantial energy savings compared to the EADFPSO algorithm: 23.5% for 40 tasks, 5.4% for 80 tasks, 16.2% for 120 tasks, and 10.7% for 160 tasks. These findings highlight the superior energy efficiency of the EGWODLB algorithm across varying task loads.

C. Virtual Machine (VM) Utilization Results

Virtual Machine (VM) Utilization quantifies the efficiency of task allocation by measuring the percentage of computational resources actively engaged in task execution. It serves as a critical metric for evaluating how well an algorithm distributes workload. Higher VM utilization reflects better exploitation of system resources, reduced idle time, and more effective parallel processing. VM utilization is analyzed for both the EADFPSO and the proposed EGWODLB algorithms across varying task sizes. As shown in Table VI and Fig. 7, the EGWODLB algorithm consistently demonstrates superior VM utilization, indicating a more balanced and optimized task allocation strategy. The improvement in utilization, although modest, indicates that EGWODLB executes tasks with better efficiency, reflecting enhanced workload.

TABLE VI. SUMMARY OF VM UTILIZATION FOR BOTH EADFPSO AND EGWODLB

Number of Tasks	EADFPSO Execution Time (s)	EGWODLB Execution Time (s)	EADFPSO VM Utilization (%)	EGWODLB Utilization VM (%)
40	20.34	17.11	39.33	46.76
80	29.42	25.01	54.38	63.97
120	30.15	27.58	79.60	87.02
160	40.58	34.98	78.86	91.48

The results in Fig. 7 provide a clear comparative analysis of VM utilization achieved by the EADFPSO and EGWODLB algorithms across increasing workload sizes (40 to 160 tasks). The EGWODLB algorithm demonstrates significantly higher

VM utilization than the baseline EADFPSO in all scenarios. For instance, with a task load of 40, EGWODLB achieves a VM utilization of 46.76%, compared to 39.33% for EADFPSO. The efficiency gap widens as the task load increases. At 160 tasks, EGWODLB reaches a utilization level of 91.48%, while EADFPSO achieves only 78.86%. This performance difference is attributed to EGWODLB's superior task distribution strategy, which minimizes task queuing delays and ensures that more VMs remain actively engaged throughout the simulation period. By reducing idle time across the VM. Underutilized VMs not only waste energy but also lead to suboptimal task execution times. Therefore, the ability of EGWODLB to maintain utilization rates of 91.48% under peak loads makes it particularly suitable for real-time and large-scale edge-based applications.

Fig. 7. VM utilization for EADFPSO and EGWODLB.

VII. CONCLUSION

This work proposed an advanced EGWODLB approach to scheduling tasks in EC. The algorithm, in this work, outperforms the benchmark algorithms in execution time and energy consumption under various kinds of workloads. By incorporating the dimension learning-based hunting strategy, the algorithm will enormously improve its exploration and exploitation capability in the search space, leading to a more efficient scheduling of tasks. These results emphasize that, because of its notable features in execution time, energy consumption, VM utilization, and running time, EGWODLB can function as a highly effective mechanism for performance optimization concerning the edge computing model. To better reflect realistic edge computing scenarios, the experimental setup is extended to include larger and more diverse workloads. with a proportional increase in virtual machines to simulate heterogeneous environments. This allows evaluation of scalability in terms of execution time, energy consumption, and resource utilization. The results show that the proposed EGWODLB approach maintains stable performance and scales effectively with increasing workload size, demonstrating its suitability for dynamic real-world edge computing applications.

Feature work studies may be presented on how the EGWODLB algorithm may be utilized in dynamic and

heterogeneous edge computing scenarios, and/or the need to incorporate with machine learning to improve its adaptability and scalability.

A Leakage-Aware and Reproducible Evaluation Framework for Predictive Maintenance Classification

Abdulrahman M. Qahtani

Department of Computer Science-College of Computer Science and Information Technology, Taif University, Taif, KSA

Abstract—Predictive maintenance classification is widely used to support industrial maintenance planning; however, reported model performance is often influenced by evaluation practices that allow unintended information leakage between training and testing data, resulting in optimistic and difficult-to-reproduce estimates. This study examines predictive maintenance classification from the perspective of evaluation design, with a specific focus on quantifying the impact of leakage on performance assessment. A leakage-aware and fully reproducible evaluation protocol is implemented on the AI4I 2020 dataset, which exhibits severe class imbalance representative of practical industrial conditions. A comparative analysis between leakage-prone and leakage-aware evaluation settings shows that leakage-prone configurations can inflate AUC estimates by up to 8–9 percentage points, demonstrating the substantial influence of evaluation design on reported performance. Logistic Regression, Random Forest, and Gradient Boosting models are evaluated using stratified five-fold cross-validation with strictly fold-wise isolated preprocessing. While tree-based models achieved strong discriminative performance (mean AUC = 0.966 and 0.971), recall remained substantially lower than specificity, highlighting the persistent challenge of minority-class detection. The findings demonstrate that evaluation configuration, rather than model architecture alone, can significantly influence performance interpretation and lead to misleading conclusions when leakage is not controlled. This work provides a transparent and reproducible framework for reliable empirical evaluation in predictive maintenance research.

Keywords—Predictive maintenance; evaluation methodology; information leakage; reproducible machine learning; cross-validation; class imbalance; performance metrics

I. INTRODUCTION

Predictive maintenance has become a central application of machine learning in industrial environments, where data-driven models are deployed to anticipate equipment failures and support maintenance planning [1], [2]. While significant effort has been devoted to improving predictive performance through advanced modeling techniques, the practical value of these systems depends not only on model accuracy but also on the reliability and reproducibility of the reported evaluation results [3]. As predictive maintenance research continues to expand, evaluation methodology has emerged as a critical yet often underemphasized component of empirical validity [4].

A growing body of evidence in the broader machine learning literature highlights the impact of information leakage on reported model performance [5], [6]. Leakage can arise from improper data splitting, preprocessing performed outside

validation folds, or test-informed decision-making, leading to overly optimistic and difficult-to-reproduce results [7]. In predictive maintenance datasets, which typically exhibit severe class imbalance, such methodological inconsistencies can substantially distort the interpretation of classifier behavior [8].

Despite these concerns, many predictive maintenance studies continue to prioritize algorithmic innovation over evaluation rigor. Comparative analyses are frequently conducted under heterogeneous experimental protocols, limited metric reporting, or insufficient documentation of preprocessing and validation procedures [9], [10]. Consequently, it remains unclear whether observed performance differences across studies reflect genuine modeling advances or artifacts introduced by evaluation design.

From an operational perspective, evaluation integrity is often more consequential than marginal improvements in predictive accuracy. Maintenance decisions are sensitive to the balance between missed failures and false alarms, particularly in imbalanced classification settings. Reliance on single metrics such as accuracy can obscure critical trade-offs, whereas multi-metric reporting, including recall, specificity, F1-score, and AUC, provides a more reliable assessment of classifier behavior [11], [12]. Ensuring that such metrics are computed under strictly leakage-aware and reproducible protocols is therefore essential for defensible empirical comparison.

In this study, we propose a leakage-aware and reproducible evaluation framework for predictive maintenance classification. Using the publicly available AI4I 2020 dataset and a set of standard machine learning classifiers as controlled analytical instruments, we enforce strict fold-wise preprocessing isolation through pipeline-based cross-validation with fixed random seeds. All experimental configurations are predefined, deterministic, and free from test-driven optimization. The empirical findings demonstrate that evaluation design materially influences the interpretation of performance metrics under class imbalance, even when model architecture remains unchanged.

The main contributions of this work are as follows:

- A leakage-aware cross-validation framework that strictly isolates preprocessing and model fitting within each fold.
- A deterministic and fully reproducible evaluation protocol with frozen partitions and fixed experimental configurations.
- A comprehensive multi-metric assessment strategy tailored to imbalanced predictive maintenance datasets.

- An empirical analysis demonstrating how evaluation rigor affects performance interpretation across classical machine learning models.

Rather than introducing new predictive architectures, this work establishes a practical and reproducible evaluation framework for empirical predictive maintenance studies, providing a structured basis for transparent experimentation and defensible performance reporting.

II. RELATED WORK

Machine learning-based predictive maintenance (PdM) has been extensively studied in recent years, with numerous approaches proposed for fault detection, remaining useful life estimation, and prognostics using sensor and operational data across industrial domains such as rotating machinery, manufacturing systems, and smart factories. Early and contemporary research has explored both classical machine learning and deep learning architectures to model failure processes and optimize maintenance scheduling [2], [10]. Recent systematic reviews highlight the continued expansion of PdM research, noting the integration of artificial intelligence and big data strategies for PdM in Industry 4.0 environments [13] and broader application-wise analyses of machine learning-driven PdM techniques [14]. Additionally, recent systematic reviews synthesize PdM models, methods, and challenges within Industry 4.0, extending insights into data processing, modeling, and implementation barriers [15].

Alongside model development, prior research has examined performance assessment practices under class imbalance and asymmetric error costs, particularly in contexts where rare failure events carry high operational consequences. Widely reported evaluation metrics include accuracy, precision, recall, F1-score, and area under the ROC curve [11], [16]. However, contemporary analyses emphasize that metric selection critically shapes performance interpretation in imbalanced settings, where accuracy-dominated reporting may obscure failure detection behavior [8], [12]. A broad systematic review of time-series predictive maintenance algorithms also underscores the importance of rigorous evaluation practices when comparing diverse modeling approaches [17].

Beyond PdM specifically, the broader machine learning literature has increasingly highlighted evaluation design, reproducibility, and generalizability as central determinants of empirical validity. Methodological work has documented how information leakage due to improper data splitting, preprocessing outside fold isolation, or test-informed parameter optimization can lead to optimistic and difficult-to-reproduce performance estimates [5], [6]. Recent research on synthetic data techniques for PdM also notes that data generation and augmentation strategies have implications for evaluation integrity when models are evaluated on synthetic versus real distributions [18].

Despite increased awareness of reproducibility concerns, safeguards against leakage and transparent experimental reporting remain underdeveloped in many PdM studies. Evaluation protocols are not always described in sufficient detail to support exact replication, complicating efforts to disentangle genuine modeling advances from artifacts introduced by

evaluation configuration [7], [19], [20]. While recent systematic reviews summarize modeling approaches and industrial datasets in predictive maintenance [14], [17], detailed methodological comparisons focused specifically on evaluation design and reproducibility remain scarce.

In contrast to research centered on algorithmic innovation, the present study focuses explicitly on evaluation integrity and reproducibility in predictive maintenance classification. By introducing a leakage-aware and deterministic evaluation framework with strict fold isolation and multi-metric reporting, this work clarifies how evaluation design materially influences the interpretation and comparability of predictive maintenance results in a gap that remains underexplored in existing literature.

III. METHODOLOGY

A. Problem Formulation

The task addressed in this study is binary predictive maintenance classification, where the objective is to identify whether a machine operating instance corresponds to a failure event based on observed operational and sensor-derived features. Let $y \in \{0,1\}$ denote the target variable, where $y = 1$ indicates the occurrence of a machine failure and $y = 0$ represents normal operation. This formulation reflects common predictive maintenance scenarios in industrial systems, where failure events are inherently rare, and datasets exhibit pronounced class imbalance, posing challenges for reliable performance evaluation [2].

The primary methodological focus of this work is not on improving predictive accuracy through algorithmic innovation, but on ensuring evaluation correctness and reliability under realistic conditions. Prior studies have shown that predictive maintenance datasets are particularly vulnerable to evaluation bias due to improper data partitioning, inclusion of post-outcome indicators, and preprocessing performed outside validation folds, all of which can unintentionally introduce information leakage [9], [10]. Such leakage can result in overly optimistic performance estimates that fail to reflect true generalization behavior.

In this study, the binary classification problem is intentionally treated as a controlled analytical setting for examining the impact of evaluation design under severe class imbalance. All problem definitions, feature selections, and evaluation choices are fixed before experimentation and applied consistently across all models. This formulation enables the analysis to isolate the effects of evaluation methodology on reported performance, rather than conflating them with model-specific optimization strategies or architectural complexity, which aligns with best practices for reproducible and defensible empirical machine learning research [21].

B. Dataset and Feature Selection

All experiments are conducted using the AI4I 2020 Predictive Maintenance Dataset, obtained from the UCI Machine Learning Repository, which has been widely used as a benchmark for evaluating predictive maintenance classification methods under realistic industrial conditions [2], [22]. The dataset contains 10,000 operational instances and exhibits a severely imbalanced binary target, with machine failure events

accounting for approximately 3.39% of all samples. Such an imbalance reflects practical maintenance scenarios and places additional emphasis on careful evaluation design and metric selection.

To ensure evaluation correctness and causal validity, feature selection is performed before any modeling or data splitting. Attributes that do not represent information available at prediction time are explicitly excluded to prevent information leakage. These include identifier variables (UDI, Product ID), which carry no predictive meaning, as well as post-outcome failure-type indicators (TWF, HDF, PWF, OSF, RNF) that encode failure mechanisms observable only after an event has occurred. The exclusion of such variables follows established best practices in predictive maintenance research and applied machine learning evaluation, where post-event signals are recognized as a common source of optimistic bias if inadvertently included [9], [21].

The final feature set used throughout the study consists of five numerical operational variables: air temperature, process temperature, rotational speed, torque, and tool wear, along with one categorical variable representing machine type. This feature configuration is intentionally preserved across all models and experimental folds to maintain comparability and isolate the impact of evaluation methodology rather than feature engineering choices. Table I. summarizes the dataset composition, retained features, excluded attributes, and class distribution employed consistently in all experiments.

C. Leakage-Aware Evaluation Design

A leakage-aware evaluation protocol is adopted to ensure that all reported results reflect genuine out-of-sample behavior rather than artifacts of experimental design. Given the pronounced class imbalance in the target variable, stratified five-fold cross-validation is employed so that each fold preserves the original failure-to-non-failure ratio. This choice follows established evaluation practice in imbalanced classification settings, where stratification is necessary to obtain stable and interpretable performance estimates across folds [23], [24].

To prevent information leakage, data splitting is performed before any preprocessing, feature transformation, or model

fitting. A fixed random seed (42) is used to construct and freeze the cross-validation folds, ensuring full determinism and enabling exact reproduction of all reported results. Once defined, the same fold partitions are reused consistently across all models and metrics, eliminating variability arising from repeated resampling.

TABLE I. SUMMARY OF THE AI4I 2020 PREDICTIVE MAINTENANCE DATASET AND FEATURE SELECTION

Category	Description
Dataset name	AI4I 2020 Predictive Maintenance Dataset
Source	UCI Machine Learning Repository
Total samples	10,000
Target variable	Machine failure (binary)
Failure rate	$\approx 3.39\%$
Non-failure rate	$\approx 96.61\%$
Numerical features	Air temperature, Process temperature, Rotational speed, Torque, Tool wear
Categorical features	Machine type
Excluded identifier attributes	UDI, Product ID
Excluded post-outcome indicators	TWF, HDF, PWF, OSF, RNF
Feature selection timing	Before data splitting and model training
Purpose of exclusions	Prevention of information leakage and preservation of causal validity

All preprocessing operations, model training steps, and performance evaluations are executed strictly within the training portion of each fold using pipeline-based implementations. The held-out test fold is never accessed during preprocessing, parameter estimation, threshold selection, or any intermediate computation. Test data are used exclusively for final metric evaluation, in accordance with best practices for leakage prevention and reproducible empirical assessment in applied machine learning [25], [26]. Fig. 1 illustrates the overall leakage-aware cross-validation pipeline, emphasizing the strict isolation between training and test data at every stage of the evaluation process.

Fig. 1. Leakage-aware cross-validation pipeline used in this study, showing strict isolation between training and test data and aggregation of evaluation metrics across folds.

D. Preprocessing and Modeling Pipeline

To enforce strict separation between training and test data, all preprocessing and modeling operations are implemented using pipeline-based design through scikit-learn Pipelines and a ColumnTransformer. Pipeline-based implementations are widely recommended for preventing information leakage in empirical machine learning studies, as they ensure that feature transformations are learned exclusively from training data and then applied unchanged to held-out samples [25], [26]. In this study, numerical features are standardized using StandardScaler, while the categorical feature representing machine type is encoded using OneHotEncoder with explicit handling of unseen categories, which is essential for stable evaluation under cross-validation [27].

Three classical machine learning classifiers are evaluated: Logistic Regression, Random Forest, and Gradient Boosting. These models are selected deliberately as controlled analytical instruments rather than as competitors in a performance-driven comparison. Their established use in predictive maintenance and industrial condition monitoring makes them suitable for studying evaluation effects without confounding factors introduced by architectural complexity [2], [9]. By employing models with different inductive biases under a unified evaluation protocol, the analysis isolates the influence of evaluation design on reported metrics rather than attributing differences to model innovation.

All model hyperparameters are fixed a priori and applied consistently across all folds and experiments. No hyperparameter tuning, model selection, or threshold adjustment is performed, and no information from test data influences any preprocessing or modeling decision. This design choice follows best practices for avoiding test-driven bias and overly optimistic performance estimation in cross-validated studies [28]. Table II summarizes the evaluated models and their fixed hyperparameter configurations used throughout the experimental analysis.

TABLE II. EVALUATED MODELS AND FIXED HYPERPARAMETER SETTINGS

Model	Library	Fixed Hyperparameters
Logistic Regression	scikit-learn	max_iter = 1000, random_state = 42
Random Forest	scikit-learn	n_estimators = 200, random_state = 42, n_jobs = -1
Gradient Boosting	scikit-learn	Default parameters, random_state = 42

E. Performance Metrics

Model performance is evaluated using a predefined set of complementary metrics: accuracy, precision, recall (sensitivity), F1-score, specificity, and the area under the receiver operating characteristic curve (AUC). This multi-metric reporting strategy is adopted to capture different aspects of classifier behavior in highly imbalanced predictive maintenance settings, where aggregate measures such as accuracy alone may provide a misleading impression of performance by favoring the majority class [12], [24].

In predictive maintenance applications, different types of classification errors carry distinct operational implications,

making it essential to evaluate trade-offs between missed failure events and false alarms. Metrics such as recall and specificity provide complementary perspectives on these error types, while precision and F1-score reflect the reliability of positive predictions under imbalance. The inclusion of AUC further supports threshold-independent assessment of class separability, which is commonly recommended when comparing classifiers under varying decision thresholds [29].

All performance metrics are computed exclusively on the held-out test folds within the leakage-aware cross-validation protocol described earlier. Metric values are then aggregated across folds using mean and standard deviation to summarize central tendency and variability. No post hoc threshold adjustment, metric-driven model selection, or test-informed reporting is performed. This evaluation design ensures that reported results reflect stable and reproducible estimates of model behavior under consistent and leakage-free experimental conditions [25].

F. Reproducibility and Experimental Control

Reproducibility is treated as a first-class design requirement throughout this study. All sources of stochasticity, including cross-validation splitting and model initialization, are explicitly controlled using a fixed random seed (42). The resulting stratified cross-validation folds are frozen and stored, ensuring that identical train-test partitions can be reused for verification, extension, or independent auditing of the reported results. Controlling randomness at this level is widely recognized as a prerequisite for reliable empirical comparison in machine learning evaluation studies [29], [30].

In addition to deterministic data partitioning, comprehensive experiment records are maintained to support full reproducibility. These records include dataset hashes, library and dependency versions, model configurations, metric definitions, and evaluation protocol details. Such documentation practices are increasingly emphasized in applied machine learning research to reduce ambiguity, prevent irreproducible claims, and facilitate transparent validation of experimental findings [19].

By combining fixed experimental configurations with explicit artifact preservation, the evaluation protocol ensures that all reported results can be independently reproduced without reinterpretation or undocumented assumptions. These measures do not introduce additional performance constraints but instead define the methodological conditions under which the experimental conclusions are valid. As a result, reproducibility in this study is not treated as a post-hoc reporting concern but as an integral component of evaluation correctness and scientific rigor.

IV. RESULTS

A. Overall Cross-Validation Performance

Table III summarizes the mean and standard deviation of all evaluation metrics across five stratified cross-validation folds under the leakage-aware protocol. The results reveal consistently high accuracy values across models (≥ 0.97), primarily reflecting the dominance of the non-failure class in the dataset. However, accuracy alone does not adequately

characterize predictive performance under severe class imbalance.

More informative differences emerge when considering recall, F1-score, and AUC. Gradient Boosting achieved the highest overall discriminative performance ($AUC = 0.971 \pm 0.011$), followed closely by Random Forest ($AUC = 0.966 \pm 0.010$), while Logistic Regression exhibited comparatively lower recall and F1-score values. These findings indicate that while all models maintain strong separability, their ability to detect minority failure events varies substantially.

Importantly, all results were obtained without post hoc threshold tuning or test-informed optimization, ensuring that the reported performance reflects genuine out-of-sample behavior under a strictly controlled evaluation protocol.

B. Metric-Specific Behavior under Class Imbalance

Fig. 2 provides a direct comparison of precision, recall, F1-score, and specificity across models, highlighting pronounced metric-dependent behavior under severe class imbalance.

TABLE III. CROSS-VALIDATION PERFORMANCE SUMMARY (MEAN $\pm$ STANDARD DEVIATION)

Model	Accuracy	Precision	Recall	F1-score	Specificity	AUC
Logistic Regression	0.970 ± 0.002	0.725 ± 0.106	0.186 ± 0.053	0.292 ± 0.065	0.997 ± 0.001	0.896 ± 0.010
Random Forest	0.983 ± 0.001	0.916 ± 0.058	0.546 ± 0.035	0.682 ± 0.022	0.998 ± 0.001	0.966 ± 0.010
Gradient Boosting	0.985 ± 0.002	0.855 ± 0.042	0.617 ± 0.096	0.713 ± 0.068	0.996 ± 0.002	0.971 ± 0.011

Fig. 2. Bar chart comparison of precision, recall, F1-score, and specificity across models.

Precision values remain relatively high for tree-based models, indicating reliable identification of predicted failure cases. In contrast, recall values remain substantially lower than specificity across all classifiers, reflecting the inherent difficulty of detecting rare failure events under fixed decision thresholds. This imbalance-driven asymmetry underscores the limitation of accuracy-dominated evaluation and reinforces the need for multi-metric reporting.

Specificity values consistently exceed 0.99, demonstrating stable identification of non-failure instances across models. Meanwhile, the relatively low variance observed in AUC values confirms consistent ranking performance across folds, even when threshold-dependent metrics such as recall and F1-score exhibit variability.

Fig. 3 presents the aggregated mean ROC curves for each classifier, providing a threshold-independent view of separability. While all models demonstrate strong discriminative capacity, the differences in threshold-level behavior observed in Fig. 2 indicate that operational performance remains sensitive to decision threshold selection under class imbalance.

Fig. 3. Mean ROC curves for logistic regression, random forest, and gradient boosting under leakage-aware cross-validation.

C. Stability and Variability Across Cross-Validation Folds

Performance stability was assessed using fold-wise standard deviations. As summarized in Table IV, variability remains limited for accuracy, specificity, and AUC, indicating consistent generalization behavior under the fixed experimental configuration and leakage-aware protocol.

Higher variability is observed for recall and F1-score, reflecting sensitivity to fold-level class composition under severe class imbalance. This pattern is expected in minority-

class detection settings and further emphasizes the importance of reporting multiple complementary metrics rather than relying on a single aggregate indicator.

No degenerate folds, convergence failures, or numerical instabilities were observed. All models completed training and evaluation successfully on every fold. Given the fixed random seed and frozen fold definitions, the entire evaluation process is fully deterministic and reproducible, reinforcing the methodological integrity of the proposed framework.

TABLE IV. PER-FOLD PERFORMANCE METRICS ACROSS FIVE STRATIFIED CROSS-VALIDATION FOLDS

Model	Fold	Accuracy	Precision	Recall	F1-score	Specificity	AUC
Logistic Regression	Fold 1	0.9710	0.8462	0.1642	0.2750	0.9990	0.8887
Logistic Regression	Fold 2	0.9685	0.6667	0.1471	0.2410	0.9974	0.8914
Logistic Regression	Fold 3	0.9675	0.5789	0.1618	0.2529	0.9959	0.9075
Logistic Regression	Fold 4	0.9720	0.7308	0.2794	0.4043	0.9964	0.9057
Logistic Regression	Fold 5	0.9705	0.8000	0.1765	0.2892	0.9984	0.8856
Random Forest	Fold 1	0.9820	0.8780	0.5373	0.6667	0.9974	0.9783
Random Forest	Fold 2	0.9845	0.9512	0.5735	0.7156	0.9990	0.9503
Random Forest	Fold 3	0.9830	0.9474	0.5294	0.6792	0.9990	0.9702
Random Forest	Fold 4	0.9820	0.8333	0.5882	0.6897	0.9959	0.9647

To further highlight the impact of evaluation design, a comparison between leakage-prone and leakage-aware configurations was conducted. The results show that leakage-prone evaluation can inflate AUC estimates by up to 8–9 percentage points. This observation confirms that evaluation settings can substantially influence reported performance, even when the underlying models remain unchanged.

V. DISCUSSION

The findings of this study demonstrate that evaluation design is not a peripheral methodological detail but a central determinant of how predictive maintenance performance is interpreted. Under the strictly controlled and leakage-aware protocol adopted here, the evaluated classifiers exhibit stable behavior across folds while revealing clear metric-dependent differences. Rather than producing artificially inflated or unstable outcomes, the results indicate moderate and interpretable performance distinctions, reinforcing the need for cautious reporting in highly imbalanced failure prediction settings [25], [28].

A key empirical finding of this study is the quantification of performance inflation under leakage-prone evaluation. The comparative analysis revealed that AUC estimates can be inflated by up to 8–9 percentage points when preprocessing and validation are not strictly controlled. This result provides concrete evidence that evaluation design can substantially alter

reported performance, reinforcing that observed improvements may not solely reflect model capability but may instead be partially driven by methodological artifacts in evaluation design.

A prominent observation concerns the metric-dependent behavior induced by class imbalance. Although overall accuracy remains consistently high due to the predominance of non-failure instances, recall and F1-score provide a more operationally meaningful assessment of failure detection capability. The observed trade-offs between recall and specificity highlight the limitations of accuracy-dominated evaluation, as improvements in one dimension may correspond to conservative behavior in another. These results align with established findings in imbalanced classification research, which emphasize the necessity of multi-metric evaluation in skewed datasets [12], [24].

The leakage-aware evaluation protocol directly shapes the interpretation of these patterns, particularly when contrasted with leakage-prone configurations that introduce measurable performance inflation. By enforcing strict fold-wise isolation of preprocessing, model training, and metric computation, the reported results reflect genuine out-of-sample performance rather than optimistic estimates introduced by inadvertent information leakage. This controlled design clarifies that variability often attributed solely to model architecture may instead stem from evaluation configuration. The limited fold-

wise variability observed across most metrics further supports the reproducibility and stability of the adopted framework, consistent with broader recommendations in applied machine learning reproducibility research [19], [26].

When considered alongside prior predictive maintenance studies that primarily emphasize algorithmic performance gains [2], [10], the present findings provide complementary methodological insight. While challenges related to class imbalance and evaluation consistency are frequently acknowledged, they are often addressed implicitly. This study provides explicit empirical evidence that evaluation design materially influences reported outcomes within predictive maintenance classification, demonstrating the practical relevance of reproducibility and leakage safeguards in industrial AI applications [30].

The classical classifiers employed in this analysis serve as controlled analytical instruments rather than competitive performance benchmarks. Accordingly, the conclusions are methodological in scope, emphasizing how protocol design, metric selection, and reproducibility controls influence empirical interpretation. By situating predictive maintenance evaluation within a deterministic and leakage-aware framework, this study contributes to a clearer and more transparent basis for future comparative research without extending claims beyond the dataset and experimental configuration examined. This perspective is essential for ensuring that reported advances in predictive maintenance are both reliable and practically meaningful in real-world deployment settings.

VI. LIMITATIONS

This study is positioned as a methodological contribution focused on evaluation design rather than algorithmic optimization. Accordingly, the conclusions should be interpreted within the context of examining how leakage control, reproducibility, and metric selection influence performance interpretation in predictive maintenance classification.

The empirical analysis is conducted using a single publicly available dataset. While this enables full transparency and controlled comparison under a fixed evaluation protocol, results may vary across datasets with different operational characteristics or failure distributions. Future investigations may extend the proposed framework to additional industrial datasets to further assess generalizability.

In addition, the analysis employs classical machine learning models with fixed configurations to isolate evaluation effects under deterministic conditions. The absence of hyperparameter tuning or adaptive optimization is deliberate and supports reproducibility; however, alternative model families or cost-sensitive threshold adjustments may yield different operational trade-offs. These considerations define the scope of the present study without limiting its central methodological contribution.

VII. CONCLUSION

This study examined predictive maintenance classification from the perspective of evaluation integrity rather than algorithmic innovation. By adopting a leakage-aware experimental protocol, enforcing strict separation between training and testing procedures, and providing deterministic and

reproducible evaluation settings, the work demonstrates how reported model behavior is shaped by evaluation design choices. The analysis underscores the importance of multi-metric reporting under class imbalance, where reliance on single aggregate measures may obscure meaningful trade-offs between failure detection and false alarm control. Using classical machine learning models as controlled analytical instruments, the study isolates evaluation effects and establishes a transparent framework for interpreting predictive maintenance results in a reproducible and defensible manner.

The findings reinforce that methodological rigor and careful evaluation practice are essential for producing reliable and interpretable empirical evidence in applied machine learning. Rather than emphasizing marginal performance improvements, this work highlights clarity, reproducibility, and consistency as foundational elements for credible comparison. Within its defined scope, the proposed evaluation framework provides a practical reference for future predictive maintenance studies, supporting more transparent and methodologically sound empirical assessment across industrial AI applications.

Deep Learning-Based Model to Predict Personality Traits of Social Media Users

Faiza Abid, Mazni Binti Omar, Mohamad Sabri Bin Sinal

School of Computing-College of Arts and Sciences, Universiti Utara Malaysia. Kedah, Malaysia

Abstract—The rapid expansion of social media platforms has created enormous amounts of user-created content and behavioral information, providing the computational means to study human personality and psychology. This study creates a temporal deep learning model and Gated Recurrent Units (GRUs) to predict personality traits with behavioral and content-based features obtained from Facebook social media. The research fits the Big Five Personality Traits paradigm and aims at modelling temporal relationships in user activity patterns, including the frequency of posts, linguistic behavior, and social interaction relationships, to identify latent psychological aspects. A GRU-based framework was created to model sequential dependencies and contextual relationships among the activity timelines of the user. To evaluate the model performance and reliability, two comparison baselines: Long Short-Term Memory (LSTM) and Artificial Neural Network (ANN) were run within the same experimental conditions. Model evaluation also used regression (Mean Absolute Error, MAE; Coefficient of Determination, R^2) and classification (Accuracy, Precision, Recall, F1-score, and AUC-ROC) metrics, which were also validated using a 10-fold cross-validation process to ensure that they were stable and generalizable. The experimental findings indicated that the proposed GRU model was always better in all the evaluation metrics compared to the base models. It had the least MAE (0.00825) and the highest R^2 (0.9917) and showed outstanding predictive reliability. GRU had a high accuracy (96.8) and F1-score (0.96) and AUC-ROC (0.98), which were better than LSTM ($F1 = 0.95$) and ANN ($F1 = 0.84$), in classification performance. The analysis at the trait level showed that the predictive accuracy is high on all dimensions of personality, with Agreeableness ($R^2 = 0.9942$, $F1 = 0.97$) being the most accurately predicted and Extraversion ($R^2 = 0.9862$) having a high predictive consistency. The findings of the cross-validation also confirmed the strength and the external validity of the GRU framework.

Keywords—Personality trait prediction; deep learning; gated recurrent units; human psychology; social media analytics; digital behavior analysis

I. INTRODUCTION

Social media has taken a vital role in modern society, being a communication tool, a dissemination of information, and a socializing tool. According to the research, of the entire population of 5.35 billion or 66.2 percent of the global population, 5.24 billion or 64.9 percent were social media users and 41.2 percent internet users [1]. In the digital era, due to the convergence of psychology and Artificial Intelligence, the study and interpretation of human personality have changed. Through an examination of 40 million Twitter users and 100 million Weibo users, researchers found that percolation-like

spread occurs more frequently than current theoretical models would suggest [2].

Five Big Personality Traits (openness, extraversion, conscientiousness, agreeableness, neuroticism) have emerged as a general psychological paradigm of computation in personality modelling during the last decade [3].

According to statistics, Facebook is one of the most popular social network platforms [1]. Facebook profile information is relevant to scientists in relation to different decision-making processes [4]. The first is that the profile of a user shows the personality of that user, and the second is other features of the accounts, which enable a user to make assumptions about the character of the users. In the meantime, other unrelated details of the account and profile may be subjected to false evaluation [5]. The FB-OSN usage has grown tremendously in recent years. This new phenomenon leaves several opportunities in advertising, networking, as well as information acquisition and dissemination. Thus, it was discovered that Facebook could be reasonably applied in the determination of behavior studies [5],[6].

The researchers resorted to Facebook Automatic Scraping in order to test the personalities of users through an unsupervised prediction algorithm known as Pear. As Pearson r , which is a measure of the accuracy of personality predictions, indicates, the personalities of the believers of fake news are different concerning the ones who do not [5],[7]-[10].

The recent breakthrough in artificial intelligence and deep learning has provided new perspectives and possibilities in computing personality. Recurrent neural networks (RNNs), specifically Long Short-Term Memory (LSTM) networks and Gated Recurrent Units (GRUs), have shown great potential to capture temporal dependencies in sequence data of behavior [11]. These architectures are very adept at receiving time-series data, and as such, are well-suited to analyzing user behavior patterns, which develop over time on social media platforms. Many studies have been conducted on the use of deep learning to predict personality. Researchers managed to use GRU networks to recognize depression and anxiety based on text in social media, which proves that such networks are capable of detecting diverse psychological conditions based on temporal linguistic features [12]. On the same note, another study made use of GRU architectures to forecast psychological qualities on the basis of social media behavior, effectively capturing temporal dynamics within user posts indicative of underlying personality traits [13]. Although these studies have demonstrated potential, they have been largely based on text-based characteristics or periodic behavioral snapshots and do

not capture the dynamic nature of user interactions, which is harder to model. Although these achievements have been made, there are still major gaps in the literature. First, the vast majority of the current methods concentrate entirely on the study of linguistic content at the expense of the intense time dynamics of behavioral characteristics, including the frequency of posting, the time of interaction, and the dynamics of engagement. Second, there is limited comparative analysis between GRU structures and other deep learning networks (especially LSTM and classic ANNs) when applied to the issue of personality prediction. Third, the computational efficiency of GRUs-based learning, namely through simplified gating networks that use a reduced number of parameters than LSTM, is not well explored in terms of its practical benefits for personality modelling tasks [14]-[17].

This study fills these gaps by proposing a new GRU-based model that combines content-based and temporal behavioral features derived from Facebook interactions between users to determine the Big Five personality dimensions. Three major contributions are made by this approach, including: 1) a multi-layered GRU architecture is designed that particularly optimized to use sequential behavior modeling in personality prediction, 2) a detailed comparative analysis is executed in the architecture against LSTM and ANN baselines under the same conditions of experiment and evaluation metrics, and 3) it is shown that temporal modeling of behavioral patterns makes a great contribution to the accuracy of prediction as compared to the methods based on stationary features. This model offers more accurate and fine-tuned personality inferences than current approaches by offering the dynamic nature of social media behavior over time.

This research is intended to create a deep learning model based on GRU to predict personality traits using social media data through deep behavioral analytics and assess its performance. The proposed solution to the improvement of personality inference reliability and accuracy in social media contexts is to incorporate both temporal and contextual patterns into user interactions. The model is based on content-based and behavioral features that are derived from social media.

II. METHODOLOGY

The Gated Recurrent Unit (GRU) architecture employed in this study is designed to predict the Big Five personality traits from Facebook user interaction data. The model captures temporal dependencies in sequential data through its recurrent layers, which allow it to process data that is not independent but rather depends on previous inputs (such as prior posts, likes, and interactions).

Fig. 1. GRU model architecture.

Fig. 1 illustrates the proposed GRU (Gated Recurrent Unit) model developed to predict the Big Five personality traits: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism from social media behavioral attributes.

Below is a detailed explanation of each component in the GRU architecture:

A. Input Layer

The input vector $X = [x_0, x_1, x_2, \dots, x_n]$ represents the normalized behavioral attributes extracted from Facebook (e.g., likes, posts, friends, photos, tags, etc.).

Each input x_i corresponds to one behavioral feature.

These inputs are fed sequentially into the first GRU layer to capture temporal and contextual dependencies among user behaviors.

$$X_t = [x_{t1}, x_{t2}, \dots, x_{tn}] \quad (1)$$

B. GRU Layers (1, 2 & 3) – Hidden Units: 64

Three stacked GRU layers, each with 64 hidden units, capture long-term dependencies in sequential data.

The GRU unit functions as a simplified LSTM cell with fewer parameters, defined by the following update equations:

$$\begin{aligned} z_t &= \sigma(W_z \cdot [h_{t-1}, x_t]) && \text{(Update gate)} \\ r_t &= \sigma(W_r \cdot [h_{t-1}, x_t]) && \text{(Reset gate)} \\ \tilde{h}_t &= \tanh(W_h \cdot [r_t * h_{t-1}, x_t]) && \text{(Candidate activation)} \\ h_t &= (1 - z_t) * h_{t-1} + z_t * \tilde{h}_t && \text{(Hidden state update)} \end{aligned} \quad (2)$$

Where:

- h_t : hidden state at time t
- x_t : input vector at time t
- z_t : update gate controlling information flow
- r_t : reset gate controlling forgetfulness
- W_z, W_r, W_h : learnable weight matrices
- σ : sigmoid activation
- $*$: element-wise multiplication

These layers learn behavioral sequence patterns, e.g., how posting frequency relates to likes or group activity over time.

C. Dropout Layers (20%)

To prevent overfitting and improve generalization, dropout regularization is applied between major GRU blocks.

- Random activation and deactivation of neurons during training: Dropout randomly deactivates 20% of the neurons:

$$h'_t = \text{Dropout}(h_t, p = 0.2) \quad (3)$$

where $p = 0.2$ is the dropout probability.

D. GRU Layers (4 & 5) – Hidden Units: 32

The learned representations are further refined by 2 smaller GRU layers (with 32 units each), which pay attention to the most informative behavioral patterns. The layers eliminate the number of dimensions of the features and recreate latent psychological signals, which are associated with the personality dimensions.

E. Output Layer

The five output values are the continuous values, which correspond to each of the personality traits of the Big Five. A linear activation function was applied to the output layer to produce continuous personality trait scores.

F. Loss Function

With Mean Squared Error (MSE) as the loss function, which is suitable when performing continuous regression, the model was trained:

$$\text{MSE} = (1/n) \sum (y_i - \hat{y}_i)^2$$

y_i is the actual personality scores, $\hat{y}_i$ is the predicted personality scores, and n is the sample size.

Furthermore, the model in this research was trained with the Adam optimizer [18], which is a more popular optimization algorithm that unites the advantages of Momentum and RMSprop.

G. Training Time and Resources

All models were trained on a GPU (Graphics Processing Unit), and therefore, convoluted computation is particularly suited to the GRU and LSTM models, which are computationally intensive models. The training times of the models differed depending on the complexity of the architecture and the quantity of parameters. ANN is simpler, and it trains faster compared to GRU and LSTM. GRU and LSTM were, on average, taking about 2.5 minutes per epoch, and ANN took 1.5 minutes per epoch. The best estimates of the hyperparameters and all training settings are presented in Table I.

TABLE I. TRAINING PROCEDURE

Hyperparameter	GRU	LSTM	ANN
Optimizer	Adam (lr = 0.001)	Adam (lr = 0.001)	Adam (lr = 0.001)
Batch Size	32	32	32
Epochs	25	25	25
Early Stopping (Patience)	5	5	5
Dropout	20%	20%	20%
Activation Function	Linear	Linear	Linear
Training Time (per Epoch)	2.5 min	3.0 min	3.5 min

Here, Adam optimizer [18] was used (learning rate = 0.001) and early stopping was by means of validation loss (patience = 5). Linear output activations were used by all models, which guaranteed their compatibility with continuous personality scores.

H. Model Comparison

In order to measure the performance of the proposed Gated Recurrent Unit (GRU) architecture, two baseline models (LSTM and ANN) were run under the same experimental conditions. In this part, a thorough analysis of the GRU framework, Long Short-Term Memory (LSTM), and the Artificial Neural Network (ANN) in terms of their architecture features, their performance in personality traits prediction, and the efficiency of their computation is provided. The present comparison will assist in pointing out the reasons why GRU was selected as the main model to predict personality traits based on data about interaction with Facebook users. Table II represents a detailed comparative analysis across GRU, LSTM, and ANN.

TABLE II. MODEL ARCHITECTURE COMPARISON

Model	Layer Type	Units	Dropout	Total Parameters
GRU	Layer 1	64	0.2	14,400
	Layer 2	32	0.2	9,312
	Output Layer	5	N/A	165
LSTM	Layer 1	64	0.2	31,781
	Layer 2	32	0.2	20,992
	Output Layer	5	N/A	165
ANN	Dense Layer 1	128	0.2	12,549
	Dense Layer 2	64	0.2	6,496
	Output Layer	5	N/A	165

The data that was employed in this study is a set of Facebook user activity data that is complemented with demographic features and behaviour characteristics. Such data were obtained based on publicly available Facebook profiles and offered the overall view of user patterns of activity, likes, posts, tags, events, and other types of social interaction. All the members of the dataset are described as a combination of behavioural indicators and self-reported personality traits. The privacy of all users has been taken care of for this study.

The total number of participants in the dataset were 99,17 and aged 21-26 years; the mean age of the participants is 23.49 years, with a standard deviation of 1.67 years. The comparatively youthful sample population implies that the personality attributes get noticed at some stage of life when they might be in growth and transformation. Data cleaning methods were used to clean anomalous data (i.e. non-numeric tokens in the gender column) during preprocessing.

The scores in terms of personality traits lie between 0 and 1, and the characteristics of each trait are as follows:

- Openness: min = 0.031, max = 0.712, mean = 0.284, SD = 0.120.
- Conscientiousness: min = 0.000, max = 0.866, mean = 0.215, SD = 0.120.
- Extraversion: min = 0.032, max = 0.565, mean = 0.259, SD = 0.099.

- Agreeableness: min = 0.007, max = 0.745, mean = 0.263, SD = 0.131.
- Neuroticism: min = 0.011, max = 0.851, mean = 0.294, SD = 0.132.

It is important to note that this distribution demonstrates that some traits have a wide variance (e.g., Neuroticism), whereas other traits, such as Extraversion, have a more localized one. These continuous targets are limited and continuous targets, which are best suited to regression models and can be forecasted through linear activations in the output layer.

III. RESULTS

The dataset includes demographic characteristics and normalized session indicators based on Facebook user activity. The dataset was preprocessed and divided into training, validation, and testing partitions (80/20 with an in-training validation split).

A. GRU Architecture

Two stacked layers of GRU (64 and 32 units) with dropout (0.2) and a linear dense head to five output traits.

Adam optimizer was used (learning rate = 0.001), and early stopping was by means of validation loss (patience = 5). Linear output activations were used by all models, which guaranteed their compatibility with continuous personality scores.

B. Trait Distributions

The frequency distribution of normalized scores of the big five personality traits, Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism, is shown in Fig. 2. The histograms indicate the distribution of the scores on the traits in the data set, with the red dashed line indicating the mean and the green dashed line indicating the median. The fact that most of the characteristics follow the near-normal distribution reflects that the data gives a balanced sample between low, moderate, and high scores. The mean of neuroticism is a little higher, implying that a greater percentage of the respondents are predisposed to emotional variability. Simultaneously, other traits, like Conscientiousness and Extraversion, have lower means; that is, fewer people are highly rated on these scales.

Fig. 2. Distribution of personality traits.

C. Correlation Analysis

Fig. 3 shows the correlation between the input behavioral characteristics (session counts, likes, posts, and interactions) and the Big Five personality traits. The high positive correlations (dark green) show aspects that have a strong impact on traits. As an illustration, the one-scale number of posts (1S-NoP) demonstrates a substantial correlation with Openness ($r = 0.73$) and Conscientiousness ($r = 0.74$), which implies that the frequency of posting is a good behavior indicator of these characteristics. Meanwhile, the weaker correlations in such features as Gender and AGE imply that the prediction effect is insignificant. This value assists in determining the traits that add the most value in the correct prediction of traits.

Fig. 3. Feature-target correlation matrix.

D. Correlation Heatmap

Fig. 4. Correlation heatmap – features and personality traits.

Fig. 4 correlation heatmap builds on the former figure, demonstrating the relationship between all variables, both input

characteristics and output characteristics. The redder cells denote high positive correlations, whereas the bluer ones denote negative ones. The inter-feature correlations are high (e.g., between 1S-NoP, 1S-NoL, and 1S-NoI), indicating that the user activity measures are indeed interdependent, and this confirms the use of deep learning models such as GRU that can address multicollinearity. High levels of diagonal confirm that there is internal consistency within personality traits - especially between Openness, Conscientiousness, and Extraversion.

E. Model Training History

Fig. 5 represents the training and validation results of the GRU model in terms of epochs and shows both the mean squared error (MSE) loss and the mean absolute error (MAE). The fact that the downward trend of the two curves does not change indicates effective learning with no overfitting. The fact that the training and validation curves are close to each other shows that the model is stable and correctly regularized through dropouts and early stopping. This ascertains that the GRU extrapolates well to unseen data and the error rates are low overall during training.

F. Model Evaluation

Fig. 6 indicates the ROC (Receiver Operating Characteristic) plot of the five traits, indicating the trade-off between the rate of true positives and false positives. Each curve is drawn towards the upper-left side, with AUC values ranging between 0.996 and 0.999, which exhibits outstanding discriminative power. The GRU model has remarkably high scores in the AUC of Openness, Conscientiousness, and Neuroticism, which implies that personality traits are reliable to classify. These findings support the strength and the overall balance of the model in terms of categories.

G. Overall Model Performance

To be consistent, the three models were tested on the same pre-processed data. The measures of performance were based on regression metrics (MAE, R^2) and classification metrics (Accuracy, Precision, Recall, F1-score, and AUC-ROC). Table III demonstrates the general model performance using conventional evaluation measures.

Fig. 5. GRU training history.

TABLE III. OVERALL MODEL PERFORMANCE

Mode l	MAE	R2	Accurac y	Precisio n	Recal l	F1-scor e	AUC - ROC
GRU	0.00825	0.9917	96.8%	0.95	0.96	0.96	0.98
LSTM	0.01013	0.9870	95.2%	0.95	0.95	0.95	0.97
ANN	0.03624	0.8603	86.4%	0.84	0.84	0.84	0.88

Fig. 6. ROC curves – GRU model.

The GRU model always had the lowest error (MAE = 0.00825) and highest coefficient of determination ($R^2 = 0.9917$), which means it was very predictive. The metrics of classification also established that GRU is better than the other two, where the F1-score of 0.96 was higher than 0.95 and 0.83 of LSTM and ANN, respectively.

IV. DISCUSSIONS

The research has created and tested a deep learning model for the predictive ability of the Big Five personality traits based on Facebook behavioral data using GRU. The proposed model was shown to be better in performance with respect to LSTM and ANN baselines, with a higher R-square, 0.9917, and F1-score, 0.96, respectively. The findings in this section are interpreted, placed in the context of the existing literature, analyzed in terms of their theoretical and practical implications, and significant limitations are recognized.

There are a number of factors that could explain the better performance of the GRU architecture compared to LSTM and ANN models. First, the gating mechanism at GRU is simplified, using only two gates (update and reset) as opposed to the three gates of the LSTM, which has a lower number of parameters to be trained, yet has the ability to learn long-term dependencies. This architectural efficiency ensured that overfitting the dataset of 9,917 users, as the results of the training and validation curves are very close to each other (Fig. 5). This decreasing number of parameters (the model is almost three times fewer than LSTM) enabled it to extrapolate to unknown data with more success and had less computational waste.

Second, the stacked GRU network was useful in learning hierarchical behavioral sequences. The first layers (64 units) were educated on general timing trends, including posting frequency cycles and interaction rhythms, and the second layer (32 units) was discovering more abstract psychological signals. This hierarchical representation learning was especially useful with such traits as Agreeableness ($R^2 = 0.9942$, $F1 = 0.97$), which were viewed as consistent patterns of social engagement as good behavioral predictors.

Third, the combination of content-based (posts, likes) and interaction-based (tags, events, groups) features offered a multi-dimensional perspective of the personality expression. Fig. 3 correlation analysis indicated that posting frequency (1S-NoP) was significantly correlated with Openness ($r = 0.73$) and Conscientiousness ($r = 0.74$), and that interaction measures were more likely to predict Extraversion and Agreeableness. The capability of the GRU to describe temporal relationality among these features helped it to address the interactive nature of various dimensions of behavior.

This fact was demonstrated by the relatively poor results of the ANN baseline ($F1 = 0.84$, $R^2 = 0.9753$), which supports the role of a temporal model. The ANN could not reproduce patterns like the tendency to post more and more frequently or to change preference in interaction partners, patterns which would be more related to personality traits than snapshot portraits would be.

A. Theoretical Implications

Theoretically, these results could be used to comprehend the expression of personality in digital behavior. Temporal behavioral patterns have great predictive power and support the theory of trait-state personality, which assumes that persistent personality traits determine temporary behavioral states. GRU capacity to predict sequential dependencies implies that personality features were not only disclosed by the actions of individuals, but also by the sequence of actions through time—the rhythm and consistency of use of social media might be a better predictor of personality than the content itself.

B. Practical Applications

The accuracy of GRU-based personality prediction that was demonstrated has various practical uses, and each of them has significant ethical implications.

Psychological guesses might be used to recommend content by the system in the form of a better news feed, advertising, and connection recommendations. As an example, the users with the highest Openness tend to be recommended with various content and new experiences, whereas the users with high Conscientiousness may like organizational tools and productivity options. Inferred personality-based personalization should be visible, and users should be able to know how their personal information affects their experience. In the same way, the study may assist in the mental health screening and intervention, Human Resources and Organizational Psychology, Targeted Marketing, and Consumer Research.

V. CONCLUSION

The combination of psychology, artificial intelligence, and social media analytics has colossal potential to comprehend human behavior in large proportions. In order to fulfill this promise, it is necessary to continuously engage in the conversation between researchers, platforms, policymakers, and citizens, based on the principles of transparency, accountability, and the respect of human dignity.

The main aim of this research was to examine the efficacy of a deep learning framework, specifically Gated Recurrent Units (GRU), to forecast the Big Five personality traits on the basis of social media organized behavioral information. Whereas the textual analysis or a fixed set of features (e.g., a like) was the main tool in the traditional approaches, this research took a new path in its methodology, specifically, the use of normalized and temporalized behavioral attributes, which were fed into recurrent neural networks.

GRUs outperform other models as they are computationally efficient, they can capture long-term dependencies in time, and they do not overfit due to simplified gating. The relevant findings contribute to the body of computational social science, and this work can guide researchers to develop experimental inferences on personality through temporal modeling in the future.

The GRU model not only provides accuracy but also forms the possibility of structured behavioral modeling as an effective method of personality prediction by computation.

Finally, the work provides support for the role of the recurrent architectures in personality prediction and the name of GRU as the balanced model is offered, which combines accuracy, stability, and efficiency.

Department of Information Technology, Visayas State University Alangalang, Alangalang, Leyte, Philippines¹

Abstract—Injection attacks persist as dominant threats in modern web systems due to obfuscation, polymorphism, and multi-vector exploitation across SQLi, XSS, LDAP Injection, and Command Injection. Existing defenses often rely on static signatures or single-vector models, which limit generalization under adversarial payload mutation. This study addressed that limitation by designing and evaluating a unified multi-vector detection framework that integrated Natural Language Processing (NLP) and Deep Q-Network (DQN) Reinforcement Learning (RL) within a structured Design–Development–Research methodology. The study consolidated heterogeneous open-source datasets comprising 346,954 benign and 653,046 malicious XSS samples, 107,328 benign and 136,746 malicious SQLi samples, 1,591 benign and 515 malicious Command Injection samples, and 1,100 benign and 900 malicious LDAP Injection samples. The pipeline operationalized canonicalized payloads as inputs, hybrid lexical–semantic feature extraction and supervised classification as processes, and probabilistic attack decisions with calibrated thresholds as outputs. The NLP pipeline fused TF-IDF character n-grams with transformer embeddings to preserve structural and contextual signatures. Logistic Regression and One-vs-Rest Linear SVM achieved strong discrimination under group-aware splits, while the DQN agent optimized decision thresholds using reward-based calibration without modifying classifier parameters. Results demonstrated stable ROC and Precision–Recall performance, coherent embedding separation, and convergence of reinforcement learning rewards and loss. The deployed system was evaluated using ISO/IEC 25010 functional suitability criteria, including functional completeness, correctness, and appropriateness, to verify that the detection pipeline executed all required operations and produced reliable decision outputs and explainable, confidence-supported decisions. The framework strengthened secure digital infrastructure, contributing to resilient innovation ecosystems aligned with Sustainable Development Goals 9 and 16.

Keywords—Deep Q-network reinforcement learning; injection attack detection; machine learning for cybersecurity; multi-vector attack detection; Natural Language Processing; payload analysis; web application security

I. INTRODUCTION

Injection attacks continue to represent one of the most persistent [1] and damaging categories of vulnerabilities in modern web applications [2]. Since the early adoption of database-driven systems [3], attackers have exploited weaknesses in input validation mechanisms to manipulate application logic and execute unauthorized commands. Despite

continuous advancements in web security technologies [4], injection attacks remain prevalent across production environments because adversaries frequently adapt their payload structures through obfuscation, encoding manipulation, and contextual exploitation. These techniques [5] enable malicious inputs to bypass traditional detection mechanisms that rely primarily on rule-based filtering or static pattern matching.

The increasing complexity of web architectures has further amplified this challenge [6]. Modern applications operate within distributed environments composed of cloud services, microservice architectures, and API-driven communication layers. Within such ecosystems, a single injection vulnerability may propagate across interconnected services and compromise large portions of a system infrastructure. Security reports [7] and vulnerability disclosures consistently identify SQL Injection (SQLi) [8], Cross-Site Scripting (XSS) [9], Lightweight Directory Access Protocol (LDAP) Injection [10], and Command Injection [11] as recurring attack vectors in real-world deployments. Although numerous defensive solutions have been proposed, many existing detection systems still operate within narrowly defined boundaries that limit their ability to recognize heterogeneous injection behaviors.

Traditional detection techniques often rely on signature matching [12], rule enforcement [13], or heuristic filtering [14]. While these approaches remain effective against previously known payload patterns, they frequently fail when attackers introduce obfuscation layers such as encoding transformations [15], fragmented syntax [16], or dynamically generated payload structures [17]. Consequently, detection systems that depend solely on static rules struggle to maintain reliability when adversarial inputs evolve. This limitation [18] has motivated the adoption of data-driven approaches that apply machine learning techniques to model malicious input patterns.

Recent study [19] explored the use of machine learning and deep learning algorithms for detecting injection attacks. These approaches introduced statistical learning capabilities that improved detection accuracy compared with rule-based systems. However, several limitations [20] persist within existing models. Many solutions focus exclusively on a single attack vector [21], which restricts their ability to generalize across heterogeneous payload grammars. Furthermore, several studies rely on handcrafted feature engineering or static decision thresholds [22] that cannot easily adapt when attack distributions shift. In addition, experimental evaluations in prior

research have occasionally used naive data partitioning strategies [23] that allow duplicated or templated payloads to appear across training and testing sets, resulting in inflated performance estimates.

Natural Language Processing [24] has emerged as a promising direction for addressing these limitations because injection payloads can be interpreted as adversarial textual sequences rather than isolated anomalies. Character-level representations [25], lexical token analysis [26], and transformer-based embeddings [27] allow detection systems to capture both structural syntax and contextual semantics embedded within malicious inputs. Hybrid feature representations [28] that combine lexical and semantic signals have shown improved robustness against encoding manipulation and payload mutation. However, most NLP-based detectors remain static once deployed [29], relying on fixed classification thresholds that may become suboptimal when data distributions change.

Reinforcement learning [30] offers a complementary mechanism for addressing this limitation by enabling systems to optimize decision policies through reward-driven learning. Instead of retraining classification models repeatedly, reinforcement learning can refine decision thresholds [31] by observing the trade-off between false positives and false negatives across sequential prediction outcomes. Deep Q-Network architectures [32] provide a stable framework for learning such policies through experience replay and target network synchronization. Despite these advantages, existing reinforcement learning applications in cybersecurity primarily focus on network-level intrusion detection or anomaly detection tasks [33]. The integration of reinforcement learning with NLP-based payload representations for injection detection remains relatively underexplored.

This study addressed these research gaps by developing a unified detection framework that integrates Natural Language Processing representations with Deep Q-Network reinforcement learning for multi-vector injection attack detection. Rather than treating SQLi, XSS, LDAP Injection, and Command Injection as independent problems, the framework modeled them as manifestations of a shared adversarial input paradigm. The proposed architecture combined hybrid lexical–semantic feature extraction with supervised classification and reinforcement-based decision calibration. This design enabled the system to preserve interpretability while improving decision stability under class imbalance and evolving payload behavior.

Moreover, the researcher considers the technical contribution of the study, as this recognizes the broader societal importance of strengthening secure digital infrastructures. Reliable detection of injection-based attacks is essential for safeguarding information systems that support public services, digital governance, financial platforms, and data-driven innovation. By developing a framework capable of detecting multiple forms of malicious input across heterogeneous web environments, the present work contributes to the advancement of resilient technological systems and responsible digital transformation. Such efforts support the objectives of Sustainable Development Goal 9, which promotes innovation and resilient infrastructure, and Sustainable Development Goal

16, which emphasizes secure and accountable institutions in the digital era. Strengthening cybersecurity capabilities at the application level therefore represents not only a technical advancement but also an enabling component of trustworthy and sustainable digital ecosystems.

II. RELATED WORKS

A. Multi-Vector Injection Attack Detection

Web injection attacks have continued to represent a major security concern for web-based systems and distributed application environments [34]. Among the most reported attack vectors are SQLi and XSS, both of which enable attackers to manipulate application logic by inserting malicious input sequences into data processing pipelines. Additional attack vectors, such as LDAP Injection and Command Injection [35], also pose significant risks, particularly in environments where backend services execute system commands or directory queries. Although these attack types share the same fundamental principle of malicious input manipulation, many existing detection approaches have treated them as independent problems and developed specialized models for each attack family.

Previous research [36] demonstrated that traditional detection mechanisms based on signature matching [37] or rule-based filtering [38] performed adequately when payload structures followed known patterns. However, these approaches often degraded when attackers introduced payload obfuscation, encoding variations, or fragmented syntax structures. Studies on web intrusion detection reported that static filtering mechanisms frequently failed to detect payload variants that maintained the same malicious intent while modifying their surface representation. Consequently, rule-based detection systems struggled to maintain robustness in environments where payload mutation and adversarial manipulation occurred frequently.

Machine learning techniques [39] were later introduced to improve detection capability by learning statistical patterns from malicious inputs. Algorithms such as Naïve Bayes [40] [64], decision trees [41], and support vector machines [42] were applied to classify web requests based on extracted features from payload content. While these methods improved detection accuracy compared with static filtering, many implementations remained constrained by handcrafted feature representations or single-attack detection frameworks. As a result, models trained to detect one injection family often failed to generalize when encountering different payload grammars or attack contexts. This limitation motivated the exploration of unified detection approaches capable of learning shared structural patterns across multiple injection attack categories.

B. Natural Language Processing for Injection Payload Modeling

Recent advances in Natural Language Processing have enabled cybersecurity researchers [43] to treat malicious payloads as adversarial textual sequences [44] rather than isolated anomalies [45]. From this perspective, injection payloads can be analyzed using linguistic representation techniques that capture both structural syntax [46] and contextual semantics [39] embedded within malicious inputs. Character-level representations have been widely applied [47] in

injection detection tasks because they effectively capture operators, delimiters, encoded fragments, and other structural elements commonly present in attack payloads. Character n-gram models [48] have demonstrated resilience to obfuscation techniques since they preserve low-level token relationships even when payload structures are partially modified.

Transformer-based language models [49][50] have further improved the ability of detection systems to capture contextual relationships within textual data. These models generate dense semantic embeddings [51] that encode contextual dependencies between tokens, allowing systems to identify patterns that may not be visible through surface-level token statistics alone. Studies applying transformer embeddings to security tasks reported improved classification performance in scenarios where payload semantics extended beyond simple pattern matching.

Hybrid representation strategies [52] that combine lexical statistical features with semantic embeddings have been proposed to leverage the strengths of both approaches. Lexical features [53] preserve structural signatures that characterize injection payload syntax, while semantic embeddings capture contextual relationships [54] that may indicate malicious intent. Despite these advantages, most NLP-driven injection detection systems have operated as static classifiers once deployed. Their prediction behavior often relies on fixed decision thresholds that may become suboptimal when input distributions change or when adversaries introduce new payload variations.

C. Reinforcement Learning for Adaptive Decision Calibration

Reinforcement learning has emerged [55] as a promising technique for adaptive decision optimization in cybersecurity systems. Unlike conventional supervised learning models that rely solely on fixed prediction boundaries, reinforcement learning agents learn policies [56] by interacting with an environment and optimizing rewards based on the consequences of their actions. In intrusion detection contexts [57], reinforcement learning has been applied to tasks such as anomaly detection, resource allocation, and dynamic defense strategies.

Deep Q-Network architectures have proven particularly effective for solving complex decision-making problems through value-based learning [58]. By combining neural networks with Q-learning principles, these systems approximate optimal action policies while maintaining stability through mechanisms such as experience replay and target network synchronization. Several studies [55] demonstrated the effectiveness of reinforcement learning in adaptive cybersecurity systems where detection policies must balance conflicting objectives such as maximizing attack detection while minimizing false alarms.

However, existing reinforcement learning applications in intrusion detection [59] have primarily focused on network traffic analysis or anomaly detection in communication systems. Few studies have explored the use of reinforcement learning for calibrating classification decisions in text-based injection detection tasks. In many previous implementations [59], reinforcement learning agents directly modified classifier parameters or retrained models dynamically during operation,

which introduced instability and increased computational complexity.

D. Evaluation Integrity and Functional Suitability in Security Systems

Another important challenge identified in prior research concerns [60] the reliability of experimental evaluation in injection detection studies. Several investigations reported that performance metrics may be artificially inflated when datasets contain duplicated [61] payload templates that appear across training and testing partitions. In such cases [62], machine learning models may memorize payload structures rather than learning generalized attack patterns. To address this issue, group-aware data partitioning strategies have been proposed to ensure that similar payload templates remain within the same data partition, thereby preventing leakage between training and evaluation datasets. Beyond detection accuracy, operational cybersecurity systems must also satisfy broader software quality requirements to ensure reliable deployment. The ISO/IEC 25010 software quality model [63] defines functional suitability as a critical attribute that evaluates whether a system provides complete, correct, and appropriate functionality for its intended purpose. While many intrusion detection studies emphasize classification accuracy and related performance metrics, relatively few investigations assess whether detection systems meet these broader operational requirements.

These observations highlight the need for detection frameworks that not only achieve high classification performance but also maintain evaluation integrity and operational reliability. The present study responded to these challenges by integrating leakage-controlled evaluation procedures with functional suitability validation under ISO/IEC 25010. This approach ensured that the proposed framework was evaluated not only in terms of statistical performance but also in terms of its practical applicability in real-world security environments.

III. METHODOLOGY

This section describes the research framework and methodological procedures used to design, develop, and evaluate the proposed unified multi-vector injection attack detection system. It explains the research design, system architecture, dataset preparation, modeling techniques, and evaluation procedures that operationalized the objectives of the study.

This study adopted the Design–Development–Research (DDR) methodology [34] [72] to design, implement, validate, and deploy the study, a multi-vector injection attack detection framework. DDR was selected because it operationalized a problem-driven security need into an engineered solution through iterative development and empirical evaluation. The approach explicitly separated offline intelligence generation from online inference execution, ensuring reproducibility, deterministic runtime behavior, and reduced operational risk. All training, optimization, and calibration occurred offline, while the deployed system performed read-only inference using pre-validated artifacts. This methodological structure ensured that model learning, optimization, and policy calibration occurred in a controlled offline environment, while the deployed

system executed deterministic inference using validated artifacts.

A. Needs Analysis Phase

The needs analysis identified operational gaps in current web input defenses based on published security literature and observed characteristics of real attack payloads. The review indicated that many solutions: 1) targeted only one injection vector, 2) depended heavily on brittle signature rules, or 3) relied on adaptive online learning that introduced instability and non-deterministic behavior in production. Obfuscation techniques—encoding, symbol manipulation, whitespace variation, and syntactic distortion—reduced the reliability of purely rule-based detection.

Based on these findings, the study defined the following requirements for the proposed framework: 1) support multiple injection vectors (SQLi, XSS, LDAP Injection, and Command Injection) within a unified label space, 2) operate with offline training and no runtime model mutation, 3) produce deterministic and reproducible inference outputs; and 4) align with ISO/IEC 25010 functional suitability criteria, including functional completeness, correctness, and appropriateness.

These requirements guided architectural decisions of NLP features, classical linear classifiers for predictable behavior, and a reinforcement learning refinement mechanism operated on confidence signals rather than raw payloads.

B. Design and Development Phase

1) *System environment and design*: The system was developed under a controlled runtime environment to prevent configuration drift between offline development and online deployment. Table I defines the software environment requirements implemented in the study.

TABLE I. USER-DEFINED STUDY SOFTWARE REQUIREMENTS

Software/Version/Library	Usage/Purpose
Python 3.11	Python runtime environment (venv creation)
Pandas, Numpy & Scipy	Data & numeric stacks
Scikit-learn, joblib	Machine Learning Stacks
TF-IDF Vectorizer	NLP Features
Transformers, torch	Semantic Embeddings
TQDM, Logging	Progress/Logging tooling
Matplotlib/Wordcloud	Visualization
Imblearn	RandomOverSampler
Umap-learn	UMAP Projection
FastAPI	Online Deployment
Uvicorn	
Pydantic	
Requests/BeautifulSoup4	Web Extraction
Hostinger (AlmaLinux10)	Online Deployment (as Virtual Private Serve)

Table II lists the Python modules used to implement preprocessing, machine learning training, reinforcement learning calibration, and API deployment.

TABLE II. PYTHON IMPORTS SPECIFICATIONS

Imports/Package	Names/Specifications
Standard	os, re, json, time, logging, traceback, html, base64, urllib.parse, warnings, random, datetime, zoneinfo
Data/ML	numpy, pandas, scipy.sparse, sklearn.model_selection (GroupShuffleSplit/train_test_split), sklearn.feature_extraction.text, sklearn.linear_model, sklearn.svm, sklearn.multiclass, sklearn.preprocessing, sklearn.metrics
Deep Learning (DQN-RL)/NLP	torch, transformers (AutoTokenizer, AutoModel)
API Layer	fastapi, pydantic, uvicorn, fastapi.middleware.cors, fastapi.staticfiles

In Table III, the hardware requirements are also considered by the researchers as this allows to fully operate system development, as presented.

TABLE III. SYSTEM HARDWARE REQUIREMENTS

Purpose	Requirement
Model Testing & Running	Minimum of four (4) CPU cores; Eight (8) to sixteen (16) GB Random Access Memory (RAM); and Memory in Solid Storage Drive (SSD) with free storage of minimum of two hundred fifty-six (256) gigabytes (GB) storage.
Full Scale Training & Embeddings	Minimum of eight (8) CPU cores; Sixteen (16) to thirty-two (32) gigabytes (GB) Random Access Memory (RAM); and Memory in Solid Storage Drive (SSD) with free storage of minimum of three hundred (300) GB storage.

2) Offline development/intelligence generation

a) *Dataset collection, consolidation, label harmonization*: Prior to model training, the dataset underwent deduplication, canonicalization, and label verification procedures to eliminate redundant payload templates and minimize the risk of dataset contamination or unintended data leakage between training and evaluation partitions. Multiple labeled datasets containing benign and malicious web inputs were aggregated from curated repositories and controlled experimental logs. The datasets represented realistic attack conditions, including obfuscation, encoding variations, and syntactic manipulation, as presented in Table IV.

TABLE IV. DATASET DISTRIBUTION BY ATTACK VECTOR

Attack Vector	Safe Samples	Malicious Samples
XSS	346,954	653,046
SQLi	107,328	136,746
Command Injection	1,591	515
LDAP Injection	1,100	900

The datasets originated from publicly available cybersecurity repositories, including curated payload collections from IEEE DataPort, Kaggle repositories, and previously published experimental datasets. Prior to model training, the study applied deduplication, canonicalization, and label normalization procedures to ensure consistency across dataset sources. This step reduced the risk of mislabeled samples,

duplicate payload templates, and dataset contamination that could artificially inflate model performance. Moreover, all datasets were merged into a unified corpus to enforce consistent preprocessing, feature extraction, and labeling conventions across attack categories. The implementation consolidated sources into a unified dataframe with a standardized schema, payload text (raw); payload_canonical (canonicalized); attack_family (normalized multiclass label); is_attack (binary: benign vs attack) and source (dataset key).

Label harmonization was enforced through dataset-specific overrides and mapping rules as follows: 1/Yes/Malicious/Attack → family label; and 0/No/Benign/Normal → benign.

For SQLi, additional heuristics detected SQL-like structures when explicit labels were missing.

b) *Dataset splitting with group-aware controls*: To prevent leakage from duplicate or templated payloads across splits, the offline pipeline used group-aware splitting: 1) the implementation formed a group key using the canonical payload and dataset source, 2) the system applied *GroupShuffleSplit* to produce: a) Train split, b) Temporary split c) Then Valid/Test split from the temporary set using group constraints again. This approach ensured that similar payload templates derived from the same attack generation scripts did not appear in both training and testing partitions, hence preventing information leakage moreover, this also ensured that near-identical payloads did not appear in both training and evaluation partitions, strengthening the validity of reported metrics and avoiding inflated performance. In addition, the pipeline performed deduplication on: i) *payload canonical*, ii) *attack family*, and iii) *source*, to further reduce redundancy and leakage risk.

c) *NLP pipeline*: The offline NLP design used two complementary feature channels:

- Canonicalization, it is where the input normalization while preserving malicious intent. The canonicalization routine performed:
 - URL decoding (iterative),
 - HTML entity unescaping,
 - Safe base64 decoding attempt,
 - Whitespace normalization,
 - Comment token normalization/removal (--, #, /* */).

This reduced superficial variability while keeping attack-relevant structure, also these preprocessing operations preserved the semantic structure of attack payloads while reducing superficial encoding variations that could otherwise introduce noise during feature extraction.

- Lexical Representation
 - TF-IDF Vectorizer (analyzer="char", ngram_range=(2,5), max_features=30000) this is for the offline training.

- Character n-grams captured obfuscation-resistant patterns (operators, quotes, brackets, encoded fragments) and generalized well for attack strings.
- Semantic representation via transformer embeddings
 - The system used a transformer encoder (distilroberta-base) with mean pooling over token embeddings.
 - Batch encoding was instrumented with progress and ETA logging to ensure tractable execution and auditable runtime behavior.
- Feature fusion using the hybrid vector space
 - The pipeline standardized transformer embeddings (StandardScaler) and fused them with TF-IDF sparse vectors using `hstack([X_tfidf, csr_matrix(E_scaled)])`

This produced a single hybrid representation that combined surface-form structure (*lexical*) with contextual semantics (*embedding*).

d) *Classical machine learning*

- Logistic Regression (probabilistic, multiclass)
 - Balanced class weights to address dataset imbalance.
 - High iteration cap to ensure convergence in high-dimensional spaces; and
 - Produced probabilistic outputs (predict_proba) used for ROC-AUC and confidence voting.
- One-vs-Rest Linear SVM (margin-based separation)
 - Implemented and classified as the `OneVsRestClassifier (LinearSVC(...))`
 - Produced decision scores (decision_function) used as confidence-like signals after normalization.

These models were selected because they behaved predictably in sparse, high-dimensional spaces, supported stable evaluation, and produced scores suitable for downstream decision refinement.

e) *RL decision refinement*

- RL Formulation: A reinforcement learning refinement layer was designed to adjust decision behavior around ambiguous regions by operating on classifier score distributions rather than raw payloads. RL component did not replace the supervised classifiers. Instead, it operated as a decision-level calibration mechanism that optimized the classification threshold based on prediction outcomes. The RL agent interacted with the classifier output scores and adjusted the decision boundary through discrete actions that increased or decreased the threshold. The researcher presented this formulation in Table V.

TABLE V. USER-DEFINED RL IMPLEMENTATION AND FORMULATION

RL Stages	Description	Components/Implementation
State	Compact telemetry including the current threshold and normalized confusion-related signals. In your RL environment implementation, the state was:	[th, fp/N, fn/N, tp/N, tn/N] This state summarized decision quality and threshold position, enabling reward-driven calibration.
Action Space	5 discrete actions controlling threshold adjustment	{-0.05, -0.02, 0, +0.02, +0.05}
Policy learning	DQN Single Agent	Q-network implemented in MLP with two hidden layers (128 units each, ReLU) Exploration strategy used the ϵ -greedy with decay: $eps_start=1.0 \rightarrow eps_end=0.05$ with multiplicative decay (eps_decay) Optimizer Adam was observed with consistent with stable optimization for value-based learning Experience replay is the replay buffer with minibatch updates to reduce correlation Target network synchronization with periodic synchronization to stabilize Q-learning
Reward Design	Reward	The reward penalized false positives and false negatives with explicit weights, emphasizing recall robustness: $reward = (TP - fp_weight \cdot FP - fn_weight \cdot FN) / N$

- Artifacts and Convergence Handling: RL training occurred offline and persisted a policy snapshot named `torch.save(agent.q.state_dict(), "dqn_policy.pt")`.

Convergence was operationally monitored through episode reward trends and stabilized threshold movement over epochs as the logs also computed epoch estimated time of accomplished (ETA) and heartbeat signals to confirm progress without silent stalls. This RL mechanism did not retrain classifiers online as this served as an offline-trained decision calibration policy, preserving deterministic runtime behavior.

After training, the learned policy remained fixed during deployment and did not update dynamically. The deployed system therefore applied a static threshold policy derived from offline training to preserve deterministic behavior.

f) *Offline-to-online artifact creation and file mapping:*

To enforce a strict boundary between learning and inference, the implementation serialized and transferred only the minimum set of artifacts required for deployment in tabular presentation in Table VI and Table VII.

TABLE VI. DEPLOYMENT ARTIFACTS USAGE

Artifacts	Usage
<code>tfidf_char_2_5.joblib</code>	Vectorizer
<code>label_encoder.joblib</code>	Class Mapping
<code>transformer_scaler.joblib</code>	Embeddi Scaler
<code>transformer_spec.json</code>	Model Name/Pooling Spec
<code>logreg_model.joblib</code>	probability engine and calibration backbone
<code>ovr_linearsvc_model.joblib</code>	Enhanced boundary enforcer
<code>viz_arrays.npz</code>	Evaluation Evidence

<code>src/sentinelguard/chunking.py</code>	
<code>src/sentinelguard/config.py</code>	
<code>src/sentinelguard/web_extract.py</code>	Startup script, launched Uvicom (Hosting/VPS)
<code>start_sentinelguard.command</code>	

C. *Evaluation Phase*

1) *Offline evaluation:* All trained models were evaluated offline using: a) Accuracy b) Precision, Recall, F1-score (per class and averaged) c) ROC-AUC (macro/micro using OvR where applicable) d) Confusion matrices and e) Confidence distribution plots and ROC/PR curves. Evaluation outputs were exported as immutable evidence file. Only models meeting predefined stability and performance expectations were promoted to deployment artifacts.

2) *Online evaluation and deployment validation:* Online inference was implemented using FastAPI served through Uvicorn, with artifacts loaded once at startup into memory by an inference engine. The deployed system executed: a) Payload intake (direct text, URL extraction, or pasted HTML source depending on endpoint). b) Canonicalization using the same preprocessing logic used offline. c) TF-IDF transformation using the fitted vectorizer artifact. d) Semantic embedding generation using the transformer specification. e) Feature fusion and scoring using loaded classifiers, and f) Deterministic prediction and confidence reporting.

Moreover, the deployment validation confirmed the following criteria as follows: a) Correct artifact loading and class mapping consistency, b) Stable API routing and response formatting, c) Consistent predictions across repeated requests, d) Persistence across service restarts (startup script behavior), and e) No runtime learning or artifact modification.

After completing the development and evaluation stages, the trained artifacts were integrated into the deployment environment to validate the operational behavior of the proposed framework.

D. Ethical Considerations

This study adhered to established ethical standards throughout the design, development, and research phases. The study handled injection payloads exclusively within a controlled research context. All datasets were obtained from publicly available open-source repositories such as the IEEE Dataport [65], Kaggle Repositories [66] and from existing studies. The study did not use proprietary data or personally identifiable information. The functions found harmonized datasets and filtered irrelevant or unknown entries to ensure that only necessary and ethically sourced data were retained. All injection payloads used for training and testing remained confined to offline research environments. Canonicalization and preprocessing routines implemented and sanitized inputs to prevent accidental misuse. This design then provided transparency and enabled analysts to critically evaluate system decisions rather than treating the framework as a black-box classifier. All trained models, encoders, and evaluation results were stored in serialized form using joblib artifacts and structured logs. This approach ensured reproducibility, verifiability, and auditability of results. Visualization and performance outputs generated further supported accountability and academic rigor. The study complied with institutional policies governing ethical conduct in computing research. Since the framework did not process personal or user-specific data, the study aligned with applicable data privacy regulations, including the Philippine Data Privacy Act and related international standards.

IV. RESULTS

This research aimed to design and develop a unified detection framework capable of identifying four major injection attack vectors: SQLi, XSS, LDAP Injection, and Command Injection.

Fig. 1 presents the class distribution of the consolidated dataset used in the study. The dataset comprised benign inputs and four injection attack classes, reflecting realistic imbalance patterns commonly observed in real-world web traffic. SQLi and XSS constituted the majority of malicious samples, while LDAP Injection and Command Injection appeared less frequently, consistent with trends reported in existing cybersecurity literature. This distribution ensured that the framework was evaluated under conditions that approximated operational environments rather than artificially balanced datasets.

Fig. 2 and Fig. 3 illustrates the confusion matrices produced by the Logistic Regression and One-vs-Rest Linear SVM classifiers on the test partition using group-aware splits. Both models demonstrated strong classification capability across all

injection vectors, correctly identifying the majority of malicious payloads while maintaining low misclassification rates for benign inputs. Importantly, correct predictions were observed even for underrepresented LDAP and Command Injection samples, indicating that the unified feature representation preserved discriminative characteristics across heterogeneous attack grammars.

Fig. 1. Distribution payloads after dataset consolidation.

Fig. 2. Logistic regression classifier evaluated using group-aware splits.

Fig. 3. One-vs-rest linear SVM classifier evaluated using group-aware splits.

To provide a consolidated quantitative overview of the classifier performance, Table VIII summarizes the overall

evaluation metrics obtained from the group-aware test partition. The table reports the Accuracy, Precision, Recall, F1-score, and ROC-AUC values derived from the confusion matrices and ROC-PR analyses presented in the subsequent figures.

TABLE VIII. CLASSIFICATION PERFORMANCE SUMMARY

Model	Accuracy	Precision	Recall	F1-score	ROC-AUC
Logistic Regression	0.96	0.95	0.95	0.95	0.99
One-vs-Rest Linear SVM	0.97	0.96	0.96	0.96	0.99
Logistic Regression + RL Calibration	0.97	0.96	0.96	0.96	0.99
Linear SVM + RL Calibration	0.98	0.97	0.97	0.97	0.99

Subsequently, this research focused on developing an NLP-based pipeline capable of normalizing heterogeneous injection

payloads and extracting meaningful lexical and semantic representations.

Fig. 4 shows the character-level n-gram salience patterns across injection classes. SQL Injection and Command Injection payloads exhibited high salience for operator-heavy and delimiter-based n-grams, while XSS payloads were dominated by script-related tokens. LDAP Injection samples displayed distinct directory query patterns, despite lower sample frequency. These findings confirmed that the canonicalization and TF-IDF processes preserved attack-specific structural signatures while reducing superficial encoding variability.

Fig. 5 presents the frequency distribution of critical operators following canonicalization. The normalization process reduced noise introduced by encoding schemes while maintaining symbols essential for attack discrimination. Fig. 6 illustrates the normalized payload length distribution, showing reduced variance across payload sources after preprocessing, which improved feature consistency across models.

Fig. 4. Character-level n-gram salience patterns across injection attack classes.

Fig. 5. Operator frequency distribution after payload canonicalization.

Fig. 6. Normalized payload length distribution following preprocessing.

Fig. 7. t-SNE visualization of hybrid lexical-semantic embeddings.

Fig. 7 displays the t-SNE projection of the hybrid embedding space derived from TF-IDF features and transformer-based semantic embeddings. The visualization revealed coherent clustering between benign and malicious inputs, with partial separation among injection families. This structure indicated that the hybrid representation effectively captured both lexical regularities and contextual semantics necessary for multi-vector detection.

Pertaining to the evaluation of the implementation of a Deep Q-Network (DQN) agent designed to adaptively calibrate detection thresholds in response to evolving payload behavior.

Fig. 8. Moving average of DQN episode rewards.

Fig. 8 shows the moving average of episode rewards during reinforcement learning training. The reward signal increased steadily before stabilizing, indicating that the agent converged toward a consistent decision policy.

Fig. 9. DQN loss curve during training.

Fig. 9 presents the DQN loss curve, which decreased and stabilized without oscillation, confirming training stability and effective value approximation.

Fig. 10. Q-value evolution across RL episodes.

Fig. 10 illustrates the evolution of Q-values across training episodes, further validating convergence and policy consistency. These results demonstrated that the reinforcement learning component enhanced decision calibration without modifying the underlying classification models.

This research assessed the detection performance of the framework using leakage-controlled group-aware splits and standard classification metrics.

Fig. 11. ROC curve for logistic regression (group-aware evaluation).

Fig. 11 and Fig. 12 present the ROC curves for the Logistic Regression and Linear SVM classifiers, respectively. Both models achieved strong discriminative performance, with curves consistently approaching the upper-left region of the ROC space.

Fig. 12. ROC curve for linear SVM (group-aware evaluation).

Fig. 13. Precision-recall curve for logistic regression.

Fig. 14. Precision-recall curve for linear SVM.

Precision-Recall curves shown in Fig. 13 and Fig. 14 further demonstrated balanced trade-offs between sensitivity and precision, particularly under class imbalance conditions.

As for the last objective of the study being evaluated and deployed, the system, using ISO/IEC 25010 functional suitability criteria, specifically completeness, correctness, and appropriateness.

Fig. 15. System interface and operational pipeline.

Fig. 15 illustrates the deployed system interface, demonstrating successful execution of the complete detection pipeline, including input ingestion, extraction, chunking, classification, aggregation, and export. The system consistently completed all stages without runtime failure, satisfying functional completeness.

Fig. 16. Page-level prediction and confidence aggregation during live analysis.

Fig. 16 presents the page-level prediction and confidence aggregation results obtained during live analysis. The system produced probabilistic outputs supported by chunk-level evidence, enabling stable and explainable decisions.

Fig. 17. Deployment-level page classification output.

V. DISCUSSION

The study demonstrated that the unified framework effectively addressed the problem of multi-vector injection attack detection by integrating lexical, semantic, and adaptive decision components within a unified framework. Results obtained from leakage-controlled, group-aware evaluation confirmed that the proposed approach maintained strong discriminative capability across SQLi, XSS, LDAP Injection, and Command Injection, even under realistic class imbalance conditions. The consistent performance observed across Logistic Regression and Linear SVM classifiers indicated that the hybrid feature representation preserved attack-specific structural and contextual characteristics rather than overfitting to dataset artifacts.

The character-level n-gram salience analysis and operator frequency distributions provided empirical evidence that payload canonicalization and TF-IDF processing retained semantically meaningful attack signatures while suppressing superficial encoding variability. Distinct operator patterns were observed across injection families, validating the design choice to employ character-level modeling for heterogeneous payload grammars. The normalized payload length distribution further demonstrated that preprocessing reduced variance across data sources, improving feature consistency and contributing to stable downstream classification.

The lexical–semantic embedding space revealed coherent clustering between benign and malicious inputs, with partial separation among attack families. This structure confirmed that transformer-based embeddings complemented statistical text features by capturing contextual semantics that were not expressible through surface-level token patterns alone. Importantly, misclassifications occurred primarily between syntactically adjacent attack classes rather than between benign and malicious inputs, indicating semantic proximity rather than systemic detection failure.

The reinforcement learning component enhanced the framework by adaptively calibrating decision thresholds without altering the underlying classification models. The steady convergence of episode rewards, stabilization of loss values, and monotonic Q-value evolution demonstrated that the Deep Q-Network agent learned a consistent policy for decision refinement. These results confirmed that reinforcement learning functioned as a decision-level optimizer rather than a replacement for supervised learning, preserving model interpretability while improving operational robustness.

To operationalize the proposed framework, deployed as a web-based inference system capable of analyzing live URLs, raw payloads, and page source content. Fig. 15 illustrated the deployed interface, which executed the complete detection pipeline, including extraction, chunking, classification, aggregation, and export without manual intervention. The system produced page-level decisions using majority voting and average confidence stabilization, ensuring consistent outcomes across heterogeneous input sources.

Fig. 16 and Fig. 17 presented the confidence distribution across attack classes, demonstrating that the system generated decision-ready probabilistic outputs rather than binary labels. Chunk-level evidence further exposed the contribution of individual text segments to the final decision, supporting transparency and analyst interpretability. This evidence-driven decision formation directly addressed limitations of prior black-box detection systems by enabling traceable and explainable outputs suitable for real-world security operations.

Functional suitability was evaluated in accordance with ISO/IEC 25010. The system achieved full functional completeness by successfully executing all pipeline stages from input ingestion to result export. Correctness and appropriateness were evidenced through stable predictions, confidence margins, explainability indicators, and exportable artifacts, as summarized in Fig. 19. Collectively, these findings confirmed that it did not merely achieve high detection accuracy but also satisfied operational requirements for reliability, transparency, and decision readiness in deployment environments.

Hence, the results demonstrated that the framework provided an explainable and deployment-ready solution for unified multi-vector injection attack detection. By combining NLP-driven feature normalization, representation learning, and reinforcement-based decision calibration, the framework advanced beyond isolated single-attack detectors and addressed practical challenges encountered in real-world web security monitoring.

VI. CONCLUSION

The results confirmed that unified framework successfully achieved its primary objective of unified multi-vector injection attack detection. The framework accurately detected SQLi, XSS, LDAP Injection, and Command Injection within a single operational pipeline, addressing the limitations of single-attack detection systems. The NLP representation preserved both lexical structure and contextual semantics, enabling reliable discrimination across heterogeneous attack grammars. Group-aware evaluation demonstrated that the observed performance reflected genuine generalization rather than dataset leakage. The reinforcement learning component functioned effectively as a decision-level optimizer. It improved threshold calibration and operational stability without compromising model interpretability or altering classifier behavior. Deployment-level validation confirmed that the system executed all detection stages reliably and produced explainable outputs suitable for real-world security analysis. Based on ISO/IEC 25010 criteria, the framework met functional completeness, correctness, and appropriateness requirements. Overall, the study established that it is an adaptive, self-learning, explainable, and deployment-ready solution for multi-vector web injection attack detection, advancing beyond isolated detection approaches and aligning with operational cybersecurity needs.

VII. RECOMMENDATIONS

Future work should extend the framework to include additional injection vectors, such as XML Injection and Server-Side Template Injection, to further enhance coverage. Longitudinal evaluation using continuously evolving real-world traffic is recommended to assess robustness under adversarial drift. Integration of online learning mechanisms may further improve adaptability without retraining the core classifiers. Deployment in production-scale environments is recommended to evaluate system performance under high-throughput conditions. The evaluation focused on classifier performance and reinforcement learning calibration under leakage-controlled data partitions. Additional experiments, such as adversarial payload mutation testing, cross-dataset generalization, and ablation analysis of feature components, remain potential directions for future investigation.

Future research may explore tighter coupling between reinforcement learning policies and confidence calibration strategies to optimize detection thresholds dynamically across different operational contexts. These extensions would strengthen the applicability of the system, while preserving its core principles of explainability, reliability, and functional suitability.

Abstract—Artificial intelligence is driving digital transformation across multiple sectors, including healthcare, pharmaceuticals, industrial production, and the automotive industry. In healthcare specifically, AI-powered predictive analytics offer significant potential for optimizing operational efficiency and resource allocation. To demonstrate this potential, we present a case study focused on hospital length of stay (LOS) prediction using 2,125,280 admission records from the New York SPARCS database. We implemented and compared four machine learning algorithms: Linear Regression, Random Forest, Gradient Boosting, and XGBoost. Following hyperparameter optimization, the XGBoost model achieved superior performance with $R^2=0.8686$, RMSE=3.24 days, and MAE=1.42 days, substantially outperforming Linear Regression ($R^2=0.5339$, RMSE=6.10 days, MAE=2.86 days). Prediction accuracy reached 63.34% within ± 1 day and 89.44% within ± 3 days of actual LOS. SHAP analysis identified Total Costs, Total Charges, Hospital Service Area, APR Medical Surgical Description, and APR DRG Code as the most impactful predictors. Performance varied across LOS categories, with MAE ranging from 0.66 days for short stays (1-3 days) to 11.81 days for extended hospitalizations (>30 days). These results demonstrate that ensemble machine learning methods, particularly XGBoost, provide clinically meaningful accuracy for healthcare operational planning, though challenges remain for extended stays and complex cases requiring specialized modeling approaches.

Keywords—Machine learning; XGBoost; healthcare operations; hospital resource management; ensemble methods; predictive analytics; SHAP analysis

I. INTRODUCTION

Nowadays, digital transformation is revolutionizing multiple sectors, including healthcare, pharmaceutical, industrial, and automotive industries, fundamentally reshaping operational processes, decision-making frameworks, and service delivery models [1], [2]. Artificial intelligence (AI) stands as one of the main enablers for this transformation, encompassing diverse technological paradigms, including computer vision for visual perception tasks, large language models (LLMs) for natural language understanding and

generation, machine learning (ML) for pattern recognition and prediction, and deep learning (DL) for hierarchical feature extraction from complex data [3,4]. Machine learning particularly enables critical analytical tasks spanning forecasting future trends, regression for continuous outcome prediction, classification for categorical decision-making, and clustering for pattern discovery [4-8]. These capabilities are realized through three primary learning paradigms: supervised learning, where models learn from labeled training data, unsupervised learning for discovering hidden patterns without explicit labels, and reinforcement learning for sequential decision-making through interaction with environments [4-8].

In the healthcare field, ML has demonstrated transformative potential across diverse applications, including medical image analysis, hospital readmission prediction, clinical decision support, and operational resource management [8-10]. These applications leverage ML's capacity to model complex, non-linear relationships in heterogeneous clinical data. Among ML algorithms, ensemble methods have proven particularly effective for healthcare tabular data [2,11], with XGBoost emerging as a leading approach due to its regularization mechanisms, efficient handling of missing values, computational scalability, and interpretability through SHAP-based feature importance analysis [12-16].

Hospital length of stay prediction represents a critical application where accurate forecasting enables proactive bed management, optimized discharge planning, evidence-based staffing, and financial forecasting [17,18]. While prior studies have applied various approaches to LOS prediction [11,19-22], most focus on specific clinical subpopulations or single institutional datasets, limiting understanding of model performance across diverse patient populations and healthcare settings. This study addresses this gap through a comprehensive evaluation of four machine learning algorithms on 2,125,280 admission records from New York's statewide hospital database [23], providing insights into algorithm selection, hyperparameter optimization value, prediction accuracy heterogeneity, and key drivers of length of stay. We address four primary objectives:

- Develop and validate predictive models for hospital LOS using four algorithms spanning traditional and modern machine learning approaches.
- Conduct rigorous performance comparison across these algorithms using multiple complementary evaluation metrics to identify optimal modeling approaches for operational deployment.
- Provide interpretable insights through SHAP analysis to identify key clinical, administrative, and financial drivers of length of stay, informing targeted interventions for LOS reduction and supporting clinical understanding of model predictions.
- Assess performance heterogeneity across patient subpopulations stratified by LOS duration to identify clinical scenarios where predictions are sufficiently accurate for operational use versus populations requiring alternative prediction strategies.

Our approach leverages 2,125,280 admission records from the New York Statewide Planning and Research Cooperative System (SPARCS), representing diverse patient populations, hospital types, and clinical conditions across an entire state healthcare system. This scale and diversity enable robust model development and evaluation that captures real-world complexity beyond single-institution studies. By comparing baseline and optimized XGBoost configurations, we quantify the value of hyperparameter tuning for healthcare prediction tasks. Through stratified performance analysis across LOS categories, we provide actionable guidance on appropriate model deployment strategies for different patient populations, conceding that uniform prediction accuracy across all cases is neither achievable nor necessary for operational value.

The remainder of this study is organized as follows: Section II reviews the state-of-the-art in machine learning applications for healthcare, with a focused analysis of prior work in hospital length of stay prediction. Section III describes the dataset, preprocessing procedures, feature engineering, and experimental setup, including model configurations and evaluation methodology. Section IV presents comprehensive results, including overall model performance comparison, train-test generalization analysis, feature importance rankings, stratified performance across LOS categories, clinical and operational implications of findings, and interprets feature importance patterns. Section V concludes with a summary of key findings and their implications for healthcare operations management and outlines future research directions.

II. RELATED WORK AND STATE-OF-THE-ART

In the healthcare field specifically, machine learning has emerged as a transformative technology for addressing longstanding challenges in clinical practice [8], operational management [9], and public health surveillance [10]. The ability of ML algorithms to process vast quantities of heterogeneous data, including electronic health records, medical imaging, laboratory results, genomic sequences, and administrative databases, enables the extraction of actionable insights that inform evidence-based decision-making at individual patient and population health levels [6,24]. Unlike

traditional rule-based systems or simple statistical models, ML approaches can automatically learn complex, non-linear relationships between hundreds or thousands of variables without requiring explicit programming of decision rules, adapting to new patterns as additional data becomes available [6,7].

The application of ML in healthcare has expanded dramatically over the past decade, encompassing diverse domains with demonstrated clinical value and operational impact [7]. In medical imaging, convolutional neural networks (CNNs) and ensemble methods have achieved expert-level performance in cancer detection from radiology and pathology images, with applications spanning breast cancer screening from mammography [25], lung nodule detection from CT scans [26], diabetic retinopathy identification from fundus photographs [27], and skin lesion classification from dermoscopic images [28]. These systems not only match or exceed human radiologist performance in controlled settings but also demonstrate potential for reducing diagnostic delays, improving screening accessibility in resource-limited settings, and providing decision support for less experienced clinicians.

Hospital readmission prediction represents another critical application domain where ML has shown substantial promise for reducing healthcare costs and improving patient outcomes [29,30]. Predictive models utilizing patient demographics, comorbidities, prior utilization history, laboratory values, and medication regimens can identify high-risk patients requiring intensive post-discharge interventions such as home health visits, telephonic follow-up, or expedited outpatient appointments [31]. By enabling proactive risk stratification, these models support transition care management programs that have demonstrated reductions in 30-day readmission rates, particularly for conditions with historically high readmission burdens, including heart failure, chronic obstructive pulmonary disease, and pneumonia [31].

In pharmaceutical operations and supply chain management, ML algorithms optimize inventory levels, predict drug demand fluctuations, identify counterfeit medications through pattern analysis, and forecast medication adherence patterns to enable targeted interventions [32-34]. These applications address critical challenges in medication availability, cost containment, and therapeutic effectiveness, with particular relevance for specialty pharmaceuticals with high costs and narrow therapeutic windows. Clinical decision support systems (CDSS) powered by ML provide real-time guidance to clinicians on diagnosis, treatment selection, medication dosing, and adverse event prediction [35,36]. Modern CDSS implementations leverage ML to personalize recommendations based on individual patient characteristics rather than applying one-size-fits-all clinical guidelines, accounting for factors such as genetic variations affecting drug metabolism, comorbidity interactions modifying treatment effectiveness, and patient preferences influencing adherence likelihood [36-38].

Additional healthcare ML applications include sepsis prediction from vital sign trends and laboratory trajectories enabling early intervention before clinical deterioration; mortality risk estimation supporting goals-of-care discussions

and resource allocation decisions; surgical complication forecasting informing preoperative risk stratification and patient counseling; disease progression modeling for chronic conditions enabling personalized monitoring schedules; and resource utilization prediction supporting capacity planning, staff scheduling, and financial forecasting [37,39]. Each of these applications demonstrates ML's capability to extract predictive signals from complex clinical data that traditional approaches struggle to model effectively.

Among machine learning algorithms, ensemble methods have demonstrated particular effectiveness for healthcare applications involving tabular data [2,6]. Within the ensemble learning paradigm, eXtreme Gradient Boosting (XGBoost) has emerged as a dominant algorithm for tabular data prediction, demonstrating superior performance across various healthcare applications, including disease risk prediction [40,41], operational outcome modeling [42], and cyberattack detection in the Internet of Medical Things (IoMT) for data privacy and confidentiality efficiency [43]. XGBoost extends traditional gradient boosting with several algorithmic innovations, regularization mechanisms that prevent overfitting by penalizing model complexity; a sparsity-aware algorithm for efficient handling of missing values by learning optimal default directions for tree splits; second-order gradient information in the objective function enabling more accurate optimization; parallel processing capabilities supporting scalability to large datasets; and tree pruning strategies that build trees to maximum depth then prune backward, identifying optimal tree structures more efficiently than traditional forward-stopping approaches [16].

These features make XGBoost particularly well-suited for clinical datasets characterized by heterogeneous features spanning continuous laboratory values, categorical diagnosis codes, binary indicators, and ordinal severity scores; missing observations due to selective test ordering based on clinical suspicion rather than systematic assessment; and complex non-linear relationships including feature interactions (e.g., age modifying disease severity impact) and threshold effects (e.g., laboratory values exhibiting different risk associations above versus below clinical cutoffs) [44]. The algorithm's built-in cross-validation, feature importance quantification, and interpretability through SHAP (SHapley Additive exPlanations) values further enhance its applicability to healthcare settings where model transparency and clinical interpretability are essential for adoption [16].

Hospital length of stay (LOS), the interval between admission and discharge, represents a critical outcome variable affecting both patient welfare and healthcare system efficiency [17,18]. Accurate LOS prediction enables multiple operational improvements, proactive bed management allowing anticipatory patient flow planning rather than reactive responses to capacity constraints; optimized discharge planning with early engagement of case managers and coordination of post-acute care services; evidence-based staffing decisions aligning nursing and ancillary service levels with anticipated patient volumes; improved patient and family communication through realistic expectation-setting regarding hospitalization duration; and financial forecasting supporting budget planning and resource allocation decisions [17].

Prior research on LOS prediction has employed diverse methodological approaches with varying degrees of success. Traditional statistical methods, including Bayesian belief networks (BBNs) [45], and Cox proportional hazards models treating discharge as a time-to-event outcome [46] provide interpretable coefficients, but struggle to capture non-linear relationships and complex feature interactions characteristic of clinical data.

More recent work has focused on ensemble methods and deep learning architectures. Random forest models for LOS prediction [11,21,22] have shown robust performance across multiple clinical domains, including cardiology, oncology, and general medicine, with feature importance analysis identifying key predictors such as admission diagnosis, comorbidity burden, and initial laboratory abnormalities. Gradient boosting approaches [19,20,47] have achieved competitive performance while offering computational efficiency advantages.

XGBoost specifically has been applied to LOS prediction in several clinical contexts. In a study by Chen et al. [15], the XGBoost algorithm was applied as a multi-classification model to predict ischemic stroke patients' length of hospital stay across three categories: 1–7, 8–14, or >14 days. The model utilized 28 clinical attributes and achieved a high-performance accuracy of 0.89 while identifying key predictors like NIHSS scores, coma indices, and surgical status [15]. Another study by Zeleke et al. [19], XGBoost was one of eight regression models used to predict the exact LoS for patients admitted through the emergency department. Thus, XGBoost and Ridge regressions showed the best performance by minimizing prediction error. A study by Hasan et al. [14] on ICU patients using the MIMIC-III database applied XGBoost for predicting patient length of stay, achieving an R^2 of 0.86 and an RMSE of 1.2, outperforming Random Forest and SVM models. XGBoost was applied as a classification model in a study of Chang et al. [13] to identify low-severity "triage level 3" patients predicted to have a discharge length of stay under 4 hours, using only information available at the triage stage. XGBoost demonstrated the best performance in external validation with an AUC of 0.761, suggesting its potential use for real-time patient streaming in emergency departments [13]. Furthermore, XGBoost was applied to predict postoperative hospital length of stay using 1,433 admission variables from Japan's DPC database, achieving a Mean Absolute Error of 2.82 days [12]. The model identified surgical procedure type and hospital volume as key predictors. However, comprehensive evaluation across large, diverse inpatient populations representing the full spectrum of medical and surgical conditions remains limited, with most studies focusing on specific clinical subpopulations or single institutional datasets.

III. MATERIALS AND METHODS

A. Dataset Description and Preprocessing

This study utilized the New York Statewide Planning and Research Cooperative System (SPARCS) inpatient de-identified dataset for the year 2023, publicly available through the New York State Department of Health [23]. The original dataset comprised 2,125,754 hospital admission records across 33 variables, encompassing patient demographics, clinical

characteristics, administrative information, and financial data from hospitals throughout New York State.

Data preprocessing involved systematic removal of records with missing values in critical clinical variables. Specifically, 474 records (0.02%) with missing values in APR (All Patient Refined) Severity of Illness Description and APR Risk of Mortality were excluded, resulting in a final analytical dataset of 2,125,280 records (99.98% retention rate).

The Length of Stay variable, originally stored as string format, was converted to integer type. Records with extreme outliers (LOS > 120 days, representing 0.01% of cases) were retained to preserve real-world distributional characteristics.

From the original 33 variables, 23 were retained based on clinical relevance, data completeness, and non-redundancy. Excluded variables included facility identifiers (Operating Certificate Number, Permanent Facility Id, Facility Name), redundant descriptive fields (CCSR Diagnosis/Procedure Descriptions, APR DRG/MDC Descriptions), and highly incomplete variables (Birth Weight, Payment Typologies 2 and 3, Zip Code).

Four derived features were created to enhance predictive capability. First, Cost_Per_Day was calculated as Total Costs divided by Length of Stay, representing daily resource intensity. Second, Charge_Cost_Ratio was computed as Total Charges divided by Total Costs, reflecting hospital pricing practices. Third, Is_Emergency as a Binary indicator derived from Emergency Department Indicator (Y=1, N=0). And, Is_Surgical is another Binary indicator extracted from the APR Medical Surgical Description (Surgical=1, Medical=0).

The Cost_Per_Day was subsequently excluded from modeling as it is outcome-derived and requires knowledge of LOS, leaving 21 final predictive features.

Categorical variables were encoded using scikit-learn's LabelEncoder to convert string categories into numerical representations. The following 15 categorical features underwent label encoding: Hospital Service Area, Hospital County, Age Group, Gender, Race, Ethnicity, Type of Admission, Patient Disposition, CCSR Diagnosis Code, APR DRG Code, APR MDC Code, APR Risk of Mortality, APR Medical Surgical Description, Payment Typology 1, and Emergency Department Indicator. This encoding strategy preserved ordinal relationships where present (e.g., Age Groups, Severity levels) while enabling tree-based algorithms to efficiently handle categorical splits.

No feature scaling was applied to the full feature set, as tree-based ensemble methods are scale-invariant. However, for Linear Regression, features were standardized using StandardScaler to prevent scale-dependent coefficient bias.

The final analytical dataset consisted of 2,125,280 records $\times$ 23 variables, with 21 predictive features and 1 target variable (Length of Stay). All features were numerical with zero missing values. The target variable exhibited right-skewed distribution with mean=5.78 days, median=3.00 days, standard deviation=8.78 days, and range=1-120 days. A summary of the preprocessing process on the dataset is provided in Table I.

TABLE I. DATASET CHARACTERISTICS AND PREPROCESSING SUMMARY

State	Characteristic	Value
Original Dataset	Total records	2,125,754
	Total variables	33
	Study period	2023
	Data source	NY SPARCS Inpatient Database
After Data Cleaning	Final records	2,125,280 (99.98% retention)
	Final variables	23
	Records excluded	474 (0.02%)
	Missing values	0
Target Variable (Length of Stay)	Mean $\pm$ SD	5.78 $\pm$ 8.78 days
	Median (IQR)	3.00 (2.00-6.00) days
	Range	1-120 days
	Mode	2 days (21.5%)
Feature Types	Categorical features	15
	Numerical features	6
	Engineered features	4
	Total predictive features	21

B. Experimental Setup

To balance computational efficiency with statistical robustness, a stratified sampling approach was employed. From the full dataset of 2,125,280 records, 500,000 records (23.5%) were randomly sampled while maintaining the original distribution of the target variable. This subset was partitioned into training (70%, $n=350,000$), validation (15%, $n=75,000$), and test (15%, $n=75,000$) sets using scikit-learn's train_test_split function. The validation set was used for hyperparameter optimization in the XGBoost (Optimized) model, while the test set remained completely held out for final performance evaluation. All splits used random_state=42 for reproducibility.

Model performance was assessed using multiple complementary metrics to capture different aspects of prediction quality, such as coefficient of determination (R^2), root mean square error (RMSE), mean absolute error (MAE), mean absolute percentage error (MAPE), and prediction accuracy bands. Overfitting was assessed by comparing training and test performance across R^2 and RMSE metrics, with train-test gaps quantifying model generalization.

C. Regression Models

1) *Linear Regression*: Ridge regression with L2 regularization served as the baseline model, implemented using scikit-learn with default regularization parameter ($\alpha=1.0$). Features were standardized prior to training using StandardScaler to ensure equal contribution scales. The model was fit using ordinary least squares with a ridge penalty to prevent overfitting in the presence of multicollinearity. Its parameter configuration is listed in Table II. The regression model for Length of Stay prediction can be expressed as:

$$\hat{Y} = \beta_0 + \sum_{i=1}^{21} \beta_i \cdot X_i + \varepsilon \quad i = 1, \dots, 21 \quad (1)$$

where, $\hat{Y}$ is the predicted length of stay (in days), β_0 is the intercept term, β_i is coefficient for feature I , X_i is the standardized value of feature i , and ϵ is the error term.

2) *Random Forest regressor*: Random Forest, an ensemble of decision trees trained on bootstrap samples with random feature subsets, was implemented using scikit-learn. Its parameter configuration is listed in Table II. The model aggregates predictions from multiple trees to reduce variance while maintaining low bias through the ensemble averaging mechanism.

3) *Gradient Boosting regressor*: Gradient Boosting builds an ensemble by sequentially adding trees that correct residual errors of preceding trees, implemented using scikit-learn with a squared error loss function. Each new tree is fit to the negative gradient of the loss function. Its parameter configuration is listed in Table II.

^c. Gradient Boosting

^d. XGBoost with default configuration

^e. XGBoost with optimized configuration

4) *XGBoost*: XGBoost (eXtreme Gradient Boosting) implements an optimized distributed gradient boosting framework with advanced regularization, parallel processing, and efficient handling of sparse data. The default configuration used standard hyperparameters (Table III), while the optimized configuration (Table II) used parameter selection focusing on balancing model complexity (tree depth, number of estimators), learning dynamics (learning rate), sampling strategies (subsample ratios), and regularization (gamma, L1/L2 penalties).

All models were trained on the 350,000 record training set with full convergence to specified iteration limits. Training time varied substantially across algorithms, Linear Regression

(Ridge) with 0.07 seconds, default XGBoost with 2.25 seconds, optimized XGBoost with 11.31 seconds, Random Forest with 59.49 seconds, and Gradient Boosting with 220.17 seconds.

Model predictions were generated for both training (n=350,000) and test (n=75,000) sets to assess overfitting through train-test performance comparison. All models were evaluated using identical test data to ensure fair comparison.

Feature importance for the best-performing model (XGBoost Optimized) was quantified using SHAP (SHapley Additive exPlanations) values, a unified framework for interpreting predictions based on cooperative game theory. SHAP values represent each feature's contribution to the prediction for individual instances, with positive values pushing predictions higher and negative values lower.

The analysis was conducted on a random sample of 5,000 test set instances (6.7% of the test set) to balance computational feasibility with statistical stability. Mean absolute SHAP values across all samples provided global feature importance rankings, identifying the primary drivers of length of stay predictions. This approach offers advantages over traditional feature importance metrics by accounting for feature interactions and providing locally faithful explanations.

IV. RESULTS AND DISCUSSION

A. ML Models' Performance

The comparative analysis of five machine learning algorithms applied to 2,125,280 hospital admission records from the New York SPARCS dataset revealed substantial differences in predictive performance for length of stay (LOS) estimation. As illustrated in Fig. 1 and summarized in Fig. 2 and Table III, the optimized version of the XGBoost model achieved superior performance across all evaluation metrics, with an R^2 of 0.8686, RMSE of 3.24 days, and MAE of 1.42 days. This represents a remarkable improvement over traditional linear regression ($R^2=0.5339$, RMSE=6.10 days, MAE=2.86 days), demonstrating that the complex, non-linear relationships inherent in hospital length of stay are better captured by ensemble tree-based methods.

Fig. 1. Actual vs. Predicted length of stay of selected models on test set.

Fig. 2. Comprehensive model comparison on the test set.

TABLE III. MODEL PERFORMANCE ON TRAINING VS. TEST SETS

Model	Train R ²	Test R ²	ΔR^2	Train RMSE	Test RMSE	$\Delta RMSE$
Linear Regression	0.5472	0.5339	0.0133	5.98	6.10	0.12
Gradient Boosting	0.8754	0.8472	0.0282	3.14	3.49	0.35
XGBoost (Default)	0.8649	0.8364	0.0285	3.27	3.61	0.34
Random Forest	0.9078	0.8434	0.0644	2.70	3.54	0.84
XGBoost (Optimized)	0.9503	0.8686	0.0817	1.98	3.24	1.26

The clinical significance of these results becomes apparent when examining the prediction accuracy bands shown in Fig. 2. The optimized version of the XGBoost model achieved 63.34% of predictions within ± 1 day of actual LOS, 82.01% within ± 2 days, and 89.44% within ± 3 days. In contrast, linear regression achieved only 31.47% accuracy within ± 1 day and 57.30% within ± 2 days. For a healthcare system with an average LOS of 5.78 days, the ability to predict within 1.42 days (MAE) represents approximately 24.6% relative error, which is operationally valuable for bed management, discharge planning, and resource allocation. This level of accuracy enables hospital administrators to make data-driven decisions with reasonable confidence intervals, potentially reducing bottlenecks in patient flow and improving overall throughput efficiency.

The three ensemble methods (Random Forest, Gradient Boosting, and XGBoost) clustered closely in performance, all achieving R² values above 0.84, while substantially outperforming linear regression. Random Forest achieved R²=0.8434 (RMSE=3.54 days, MAE=1.57 days), Gradient Boosting reached R²=0.8472 (RMSE=3.49 days, MAE=1.68 days), and the optimized version of XGBoost surpassed at R²=0.8686 (RMSE=3.24 days, MAE=1.42 days). The scatter plots in Fig. 1 reveal that all ensemble methods produce predictions that cluster tightly around the perfect prediction line (red dashed diagonal), whereas linear regression shows considerably more scatter, particularly for longer stays exceeding 20 days.

Interestingly, the default XGBoost configuration (R²=0.8364, RMSE=3.61 days, MAE=1.70 days) performed slightly below both Random Forest and Gradient Boosting, highlighting the critical importance of hyperparameter optimization in achieving optimal model performance. The improvement from default to optimized XGBoost ($\Delta R^2=0.0322$, $\Delta RMSE=0.37$ days, $\Delta MAE=0.28$ days) demonstrates that careful tuning of learning rate, max depth, min child weight, and regularization parameters can yield clinically meaningful improvements. This 0.28-day reduction in MAE, while seemingly modest, translates to approximately 20% improvement in prediction error and could impact thousands of patient flow decisions across a large hospital system annually.

The residual distributions presented in Fig. 3 provide critical insights into model behavior and potential biases. All ensemble methods exhibited nearly unbiased predictions with mean residuals close to zero (Random Forest: -0.000, Gradient Boosting: 0.003, XGBoost Optimized: 0.001, XGBoost Default: 0.006), while linear regression showed a slight positive bias (mean=0.021). The standard deviations of residuals followed the same performance hierarchy as RMSE values, with the optimized version of XGBoost showing the tightest distribution (std=3.238), followed by Gradient Boosting (std=3.492), Random Forest (std=3.535), XGBoost Default (std=3.613), and Linear Regression (std=6.099).

Fig. 3. Histograms of prediction residuals (actual LOS - predicted LOS, in days) for the studied models on the test set.

The nearly symmetric, approximately normal distribution of residuals for ensemble methods indicates that these models do not systematically over- or under-predict across the LOS spectrum. This is particularly important in healthcare applications where both types of errors carry consequences:

- Underpredicting LOS may result in premature discharge planning and resource shortages,
- While overpredicting unnecessarily occupies beds and resources.

The median residuals close to zero (XGBoost Optimized: -0.070, Gradient Boosting: 0.139, Random Forest: -0.100) further confirm the lack of systematic bias. Linear regression, however, shows a broader residual distribution with longer

tails, suggesting inconsistent prediction quality across different patient populations and clinical scenarios.

The train-test performance comparison, illustrated in Fig. 4, reveals important patterns regarding model generalization. Linear regression demonstrated minimal overfitting with nearly identical train and test R^2 values (0.547 vs. 0.534, gap=0.013), consistent with its fundamental simplicity and high bias. However, this stability comes at the cost of poor overall performance, making it unsuitable for practical deployment despite its generalization properties.

Fig. 4. Comparison of training and test set performance for the studied models using R^2 scores and RMSE values.

Among ensemble methods, Gradient Boosting showed the best generalization characteristics with a train-test R^2 gap of only 0.0282 (0.8754 train vs 0.8472 test) and RMSE difference of 0.35 days (3.14 train vs 3.49 test). Random Forest exhibited moderate overfitting (R^2 gap=0.0644, RMSE difference=0.84 days), while XGBoost configurations showed varying degrees. The default XGBoost demonstrated excellent generalization (R^2 gap=0.0285, RMSE difference=0.34 days), comparable to Gradient Boosting. Notably, the optimized XGBoost, despite achieving the best test performance, exhibited the largest overfitting signature (R^2 gap=0.0817, RMSE difference=1.26 days), with train R^2 =0.9503 versus test R^2 =0.8686.

This overfitting pattern in the optimized XGBoost model warrants careful interpretation in the healthcare context. While the train R^2 of 0.9503 suggests nearly perfect fit to training data, the test performance of R^2 =0.8686 still substantially exceeds all other models, including the less-overfitted Gradient Boosting (R^2 =0.8472). This indicates that the hyperparameter optimization process successfully identified genuine predictive patterns rather than merely fitting noise. However, from a clinical deployment perspective, this overfitting raises important considerations:

- The model may have learned hospital-specific patterns,
- Temporal trends specific to the training period,
- Or subtle interactions between features that may not generalize to future time periods or different healthcare settings.

Prospective validation on out-of-time test sets and external validation on data from other hospital systems would be essential before widespread deployment.

The analysis of prediction errors across different LOS groups, presented in Fig. 5, reveals critical insights about model performance heterogeneity. The optimized version of

XGBoost model demonstrated strongly differential performance across stay duration categories, with MAE systematically increasing from 0.66 days for 1-3 day stays to 11.81 days for stays exceeding 30 days. This more than 17-fold increase in absolute error highlights a fundamental challenge in healthcare predictive modeling: short stays are inherently more predictable than extended hospitalizations, which often involve complications, comorbidities, and unpredictable clinical trajectories.

The box plots of residuals in Fig. 5 illustrate this heterogeneity visually. For short stays (1-3 days and 4-7 days), predictions cluster tightly around zero error with narrow interquartile ranges and few outliers, indicating consistent, reliable predictions. The median residuals remain close to zero across all groups, confirming the absence of systematic bias. However, as LOS increases, the distribution widens dramatically, with the >30 days category showing extensive scatter and numerous extreme outliers extending beyond ± 50 days. This pattern reflects the clinical reality that patients with prolonged hospitalizations often experience complex, unpredictable courses involving multiple complications, ICU transfers, infections, or delayed discharge due to placement issues.

Fig. 5. Prediction error by the LOS Group of the optimized XGBoost model.

From a healthcare operations perspective, these findings suggest differentiated deployment strategies for LOS prediction models. For routine cases expected to have short stays, the model's high accuracy (MAE=0.66 days for 1-3 day group, 1.23 days for 4-7 day group) enables confident operational planning for bed turnover, same-day discharges, and routine resource allocation. For intermediate stays (8-14 days: MAE=2.20 days; 15-30 days: MAE=4.23 days), predictions provide useful guidance but should be accompanied by wider confidence intervals in planning tools. For extended stays beyond 30 days (MAE=11.81 days), the model's limited accuracy suggests it should serve as a baseline estimate rather than a precise planning tool, with frequent re-prediction as the hospitalization progresses and more clinical information becomes available. This adaptive prediction approach, updating forecasts daily as new clinical data emerges, could substantially improve accuracy for complex cases.

B. Feature Importance

Before interpreting the feature importance results, an important methodological caveat must be stated. The two highest-ranked predictors: Total Costs and Total Charges, are financial variables that accumulate during the hospital stay and are not available at the time of patient admission. Their prominence in the SHAP rankings, therefore, reflects the

model's ability to exploit outcome-correlated proxies rather than purely independent clinical signals. This constitutes a form of target leakage that limits the model's applicability to prospective, admission-time prediction. Readers should interpret all subsequent importance rankings with this constraint in mind, and the clinical implications discussed below should be understood in the context of retrospective or near-discharge prediction scenarios rather than early forecasting.

The feature importance analysis, presented in Fig. 6, provides interpretable insights into the clinical and administrative factors driving LOS predictions. The dominance of financial variables, Total Costs (mean |SHAP value| ≈ 2.6) and Total Charges (≈ 1.5), as top predictors is particularly noteworthy. While these variables are highly predictive, they represent outcome proxies rather than truly independent predictors, as costs accumulate over the course of hospitalization. This finding has important implications for real-time prediction systems; at admission, these values are unknown, limiting the model's utility for early LOS forecasting unless historical cost patterns or initial procedure costs are used as proxies.

Hospital Service Area emerged as the third most important feature (mean |SHAP value| ≈ 1.0), reflecting substantial variation in LOS across different clinical departments and specialties. This aligns with clinical intuition, as surgical units, medical wards, intensive care units, and specialty services have fundamentally different patient acuity levels and treatment protocols. The importance of this feature suggests that department-specific LOS prediction models might offer further accuracy improvements by capturing unit-specific workflows and patient populations. The APR Medical Surgical Description and APR DRG (Diagnosis Related Group) Code features (mean |SHAP values| ≈ 0.7 and 0.5 respectively) capture the primary reason for hospitalization and its severity, representing core clinical determinants of resource utilization and recovery time.

Geographic factors, represented by Hospital County (mean |SHAP value| ≈ 0.5), ranked as the sixth most important predictor, potentially reflecting regional variations in practice patterns, socioeconomic factors affecting patient populations, availability of post-acute care facilities, and hospital-specific policies. The Charge-to-Cost Ratio (≈ 0.4) and Patient Disposition (≈ 0.4) provide complementary information about hospital billing practices and discharge destinations (home, skilled nursing facility, rehabilitation, etc.), both of which correlate with case complexity and LOS.

Notably, demographic factors showed relatively modest importance, with Age Group ranking lowest among all features (mean |SHAP value| < 0.2). This suggests that once clinical condition, procedures, and severity are accounted for, age contributes minimally to LOS variability. Similarly, APR Risk of Mortality, Type of Admission, Emergency Department Indicator, surgical status (Is Surgical), and APR Severity of Illness Code all showed relatively small contributions (mean |SHAP values| 0.2 - 0.4). This ranking challenges some clinical assumptions about LOS drivers and suggests that while these factors influence outcomes and resource intensity, their

incremental predictive value beyond procedure codes and service area is limited. This insight could guide data collection priorities and inform which variables are most critical for accurate LOS prediction in resource-constrained settings.

Fig. 6. Global feature importance for the optimized XGBoost model using mean absolute SHAP values on test set predictions.

C. Results Synthesis

The practical implications of these findings for healthcare delivery are multifaceted and significant. First, the high accuracy achieved by the optimized version of the XGBoost model for the majority of cases (those with LOS < 15 days, representing the bulk of admissions) enables several operational improvements. Hospital bed management systems could integrate these predictions to forecast bed availability 24-72 hours in advance with reasonable accuracy, allowing proactive management of elective admissions and emergency department patient flow. Discharge planning coordinators could receive automated alerts identifying patients likely to require post-acute care placement, enabling earlier engagement of care coordination resources when placement is most feasible.

Second, the feature importance analysis suggests actionable insights for targeted interventions. The strong predictive signal from the Hospital Service Area indicates that department-specific initiatives to reduce LOS variation could be monitored and evaluated using these models. Departments with systematically longer-than-predicted stays could be flagged for process improvement initiatives. The prominence of diagnosis and procedure codes validates current payment systems based on DRGs but also suggests opportunities for risk adjustment in benchmarking and quality reporting.

Third, the model's differential performance across LOS categories has important implications for resource allocation. Hospitals could segment their prediction systems by expected stay duration, applying the highly accurate model for routine

cases to optimize daily operations, while implementing more conservative planning assumptions and clinical judgment for complex cases likely to exceed 30 days. This stratified approach acknowledges the fundamental differences in predictability across case types and avoids over-reliance on model predictions where uncertainty is high.

Fourth, the minimal contribution of age and other demographic factors to prediction accuracy, once clinical variables are included, suggests that concerns about age-based discrimination in algorithmic decision-making may be less salient for LOS prediction than for other healthcare AI applications. However, this finding should not be interpreted as evidence that demographic factors are clinically unimportant; rather, it indicates that their effects are largely mediated through clinical presentations and procedures, which the model captures through other variables.

Several methodological aspects of this study merit discussion. The large sample size (2,125,280 records after cleaning) provides robust statistical power and enables the detection of subtle patterns in LOS variation. The minimal missing data (only 0.25% missingness in Hospital Area/County, with no missing values after preprocessing) eliminates concerns about imputation bias affecting results. The 70/15/15 (train/validation/test) split follows standard practice, though the temporal ordering of data splits is not specified in the provided information. If data were split randomly without considering admission dates, the model may have inadvertently "learned" from future time periods to predict past cases, potentially inflating performance estimates. Ideally, temporal validation (training on earlier time periods, testing on later periods) would provide more rigorous evidence of prospective prediction capability.

The comparison of five distinct algorithms, ranging from simple linear regression to optimized gradient boosting, provides comprehensive evidence that ensemble tree-based methods substantially outperform traditional approaches for this application. The inclusion of both default and optimized XGBoost configurations demonstrates the value of hyperparameter tuning, while the residual analysis confirms that superior test metrics reflect genuine predictive improvement rather than distributional artifacts. The use of multiple complementary metrics (R^2 , RMSE, MAE, prediction accuracy bands) provides a comprehensive assessment of model performance from different perspectives relevant to clinical decision-making.

The SHAP feature importance analysis represents a methodological strength, providing interpretable insights into model predictions rather than treating the model as a black box. This interpretability is crucial for clinical acceptance and regulatory approval of AI systems in healthcare. However, the strong dependence on Total Costs and Total Charges raises questions about whether the model is learning causal relationships or merely detecting correlations with downstream outcomes. A more rigorous causal analysis, potentially using only admission-available variables or implementing a time-aware feature selection process, might reveal different importance rankings and could improve the model's utility for admission-time prediction.

V. CONCLUSION

This study demonstrates that ensemble machine learning methods, particularly optimized XGBoost, substantially outperform traditional approaches for hospital length of stay prediction. Analyzing 2,125,280 admission records, our best model achieved $R^2=0.8686$ and $MAE=1.42$ days, with 63.34% of predictions within ± 1 day of actual LOS. This accuracy level enables actionable operational planning, including proactive bed management, early discharge planning, and optimized resource allocation.

The performance hierarchy, with ensemble methods achieving $R^2>0.84$ versus 0.53 for Linear Regression, confirms that LOS prediction requires sophisticated algorithms to capture complex, non-linear relationships. Feature importance analysis revealed financial variables, Hospital Service Area, and clinical coding as top predictors, while demographic factors contributed minimally. Performance varied substantially across LOS categories (MAE : 0.66 days for 1-3 day stays versus 11.81 days for >30 days), indicating excellent accuracy for routine cases but limited predictive value for complex, extended hospitalizations.

Key limitations include geographic restriction to New York hospitals, reliance on outcome-derived financial variables limiting prospective forecasting utility, poor performance for extended stays (>30 days), and lack of external validation. Future work should prioritize external validation across diverse healthcare settings, development of specialized models for complex cases, and prospective implementation trials evaluating clinical impact. Despite these constraints, machine learning-based LOS prediction offers substantial potential for improving healthcare operational efficiency and resource management. A key constraint on the prospective deployment of the proposed model concerns the reliance on financial variables (specifically, Total Costs and Total Charges), which rank as the two most important predictors according to SHAP analysis. These variables are accumulated progressively over the course of hospitalization and are therefore unavailable at the time of admission. Consequently, the model in its current form is better suited for retrospective analysis and post-hoc resource planning than for real-time, admission-time LOS forecasting. Any operational deployment in a clinical setting would require either the exclusion of these variables or their replacement with admission-available proxies, such as estimated procedure costs derived from billing schedules or historical average costs per diagnosis-related group (DRG). Future work should evaluate a restricted model trained exclusively on admission-available features to quantify the performance trade-off and assess its practical utility for early-stage clinical decision-making.

ACKNOWLEDGMENT

The authors would like to acknowledge the New York State Department of Health for providing access to the Statewide Planning and Research Cooperative System (SPARCS) data through the Health Data NY open data platform. This study used the Hospital Inpatient Discharges (SPARCS De-Identified) dataset for calendar year 2023, which is publicly available at <https://health.data.ny.gov>

A Socio-Technical Analysis of Enterprise Architecture Misalignments

Dr. Ayed Alwadain

Department of Computer Science and Engineering, King Saud University, Riyadh, Saudi Arabia

Abstract—Modern organizations must adapt to competitive environments through the analysis of their current state and plan for a future state through the use of Enterprise Architecture (EA). EA is a management discipline to align business and IT strategies. However, many organizations face challenges in effectively implementing and using EA due to misalignments between EA parts, such as organizational support, documentation, and governance, leading to inefficiencies. Thus, this study employs the Punctuated Socio-Technical Information System Change model to examine EA misalignments through four interrelated components: structure, task, actor, and technology. It offers a comprehensive analytical lens for examining EA misalignments. This model is used to examine how EA misalignments emerge from disruptions or inconsistencies among various EA components that affect EA coherence and efficiency. Considering the purpose and nature of this research, a case study is a suitable research method. The research issue to be examined, EA misalignments, is contemporary and must be explored in its context. The findings reveal some EA misalignments that are categorized into four groups: organizational, governance, capabilities, and management, highlighting how disruptions among these components affect EA coherence and efficiency. The implications of this research are twofold: first, EA components must be aligned for optimal efficiency; second, any misalignment between these components results in EA operational inadequacies and practice failures.

Keywords—Enterprise Architecture; EA; EA issues; EA misalignments; socio-technical systems

I. INTRODUCTION

Modern organizations operate in dynamic and intensely competitive environments. To survive, they must adapt their processes and effectively use information systems [1]. In order to deal with complexity and plan a transformation journey, organizations adopt Enterprise Architecture (EA). EA is a managerial discipline guided by strategy to facilitate the design and evolution of an organization's business and IT landscapes in order to realize its strategic objectives [2, 3].

Despite its importance, many organizations face substantial challenges to establish and use EA effectively. These challenges span various aspects of EA such as EA support, modeling, documentation, planning, use, communication, and governance [1, 4-7]. For example, manual EA processes are often time-consuming, costly, and prone to errors which lead to outdated or inaccurate representations of both business and IT [8, 9]. Further, EA issues are often analyzed independently of each other, while in reality they are interconnected and impact each other.

In addition, despite the growing interest in EA research, most

of the publications are not based on solid theoretical foundations [10-12]. It is stated that most of EA research has been predominantly atheoretical [12]. In reality, EA research community has overlooked, or disregarded pertinent theoretical foundations that explain the various aspects of EA practice, which is a highly multifaceted organizational phenomenon [12].

Thus, this study aims at a deeper understanding of EA issues from a socio-technical theoretical perspective using a case study research method. It uses the Punctuated Socio-Technical Information System Change (PSIC) model [13] as an analytical lens for examining EA misalignments. The model perceives an organization as a system that consists of four interrelated components: structure, task, actor, and technology. These components interact dynamically within a socio-technical system, and influence each other [13]. This model is used to examine how EA misalignments emerge from disruptions or inconsistencies among various EA components that affect EA coherence and efficiency. The model highlights that these four components must be aligned for organizational systems to operate efficiently. On the other hand, misalignments between any of these components lead to inadequacies and failures in the system [13].

The research issue to be examined, EA misalignments, is a contemporary phenomenon that must be explored within its context. Thus, a case study research method is selected. The case study data is deductively analyzed using the PSIC's model four components to find EA misalignments.

The contributions of this study are threefold. First, certain misalignments were identified and grouped into four primary categories: organizational, governance, capabilities, and managerial misalignments. Through the use of the PSIC model, this study offers an empirically grounded taxonomy of EA misalignments that can serve as a reference for future theory development in EA research. Second, this study shows that the PSIC is applicable at a finer-grained level of analysis, specifically, the operational misalignments within an EA program. It constitutes a contextual adaptation of the PSIC model to the EA domain. Third, the study enriches the model by showing that EA misalignments frequently occur as multi-component rather than twofold misalignments. It reveals the causal interdependence among EA misalignments across four related components (structure, task, actor, and technology). For instance, the data shows that insufficient funding [structure] does not only cause a funding issue in isolation. It also influences EA team capabilities [actor], affects EA tools maintenance [technology], and interrupts EA activities [task], leading to multi-component misalignments.

EA elements impact one another and engage in dynamic interactions within a socio-technical system. That means any disruptions to one or some of these elements have a negative impact on EA practice as a whole. Thus, organizations have to make sure the EA elements are aligned and work in harmony to realize the promised value of EA.

This study is organized as follows: Section II reviews the literature and introduces the Punctuated Socio-Technical Information System Change (PSIC) model. Then, Section III outlines the research methodology. Section IV presents and discusses the findings. Finally, Section V concludes the study.

II. LITERATURE REVIEW

This section presents the literature review for this study, which is organized into three subsections: enterprise architecture, research problem, and theoretical foundations.

A. Enterprise Architecture

EA is a managerial discipline guided by strategy to facilitate the design and evolution of an organization's business and IT landscapes in order to realize its strategic objectives [2, 3]. It is a practice that provides a holistic view of an organization's business goals, processes, data, information systems, and technology [1, 14, 15]. It supports decision-making, improves business-IT alignment, and enhances responses to changes [5, 7, 16]. It provides methodologies and techniques for the analysis of a current state of the enterprise and planning for a future state, leading to risk mitigation, cost reduction, and operational efficiency [11, 16, 17].

EA enhances business and IT planning processes while ensuring business continuity, risk management and compliance [11, 18, 19]. A successful EA implementation necessitates incorporating diverse stakeholder perspectives, which empowers organizations to make informed decisions, optimize operations, and facilitate transformation [20].

B. Research Problem

The complexity of organizations makes EA implementation and management challenging, specifically when unplanned changes in business or technology happen [21]. In addition, stakeholders' resistance, a lack of expertise, and insufficient governance structures further complicate EA challenges, which obstruct the successful implementation of EA practices [4, 7]. EA implementation continues to be a challenging topic for organizations, despite the diversity of approaches that define EA processes, applications, and governance structures [7].

Organizations continue to encounter several problems in implementing EA, which reduce the return on substantial EA investments [9, 11]. The ambiguity in processes and procedures, together with insufficient collaboration with the EA department, leads to issues [22]. Organizations face challenges in maintaining documentation due to ambiguous responsibilities and a lack of knowledge regarding enterprise architecture and the relevant stakeholders, leading to outdated and inaccurate documentation [5, 9, 23]. The stakeholders and teams responsible for documenting EA encounter challenges related to the size and complexity of EA landscapes [5, 7, 9]. Thus, effective stakeholder management is essential for aligning the outcomes of EA with stakeholder preferences. Facilitating

participation in EA activities fosters trust and understanding [22].

Although several studies had investigated EA issues [24, 25], a comprehensive understanding of such issues remains elusive [4-6, 26]. This gap in the literature highlights the need for a wider understanding of EA issues that face organizations and the development of effective strategies to overcome them. In particular, by addressing these obstacles, organizations can realize the maximum potential of EA, enabling organizations to better navigate the complexities of both business and IT landscapes and achieve strategic objectives [10, 17, 19].

Further, the adoption of theories in EA research is notably minimal, despite the large number of EA publications [12, 16]. The absence of solid theoretical underpinnings may indicate that the EA practice is not adequately understood [12].

C. Theoretical Foundations

This study builds on previous research which explicitly considers information systems as socio-technical systems and analyzes diverse social and technological elements within them. For example, a socio-technical model is used to examine information systems change [13]. It is used to show how misalignments among social and technical components within information systems and their environments influence the system [13].

To deeply understand EA issues, this study explores key misalignments in EA practice using a socio-technical model following [13]. In particular, this study uses the Punctuated Socio-Technical Information System Change (PSIC), as shown in Fig. 1 [13]. Such a model demonstrates the attributes of a good classification. It is simple, comprehensive, and reasonably well defined [13]. It offers a comprehensive analytical lens for examining EA issues. The model perceives an organization as a multivariate system that consists of four interrelated components: structure, task, actor, and technology. These components interact dynamically within a socio-technical system and influence each other [13]. These components interact, impacting one another. Here's the details of these components:

Fig. 1. Socio-technical system [13].

- Task: It refers to the activities and processes that need to be accomplished.

- **Structure:** It refers to the organizational structure such as organizational hierarchy, support, governance and communication.
- **Actor:** It refers to people or roles engage or interact with a system.
- **Technology** includes tools and infrastructure used to complete tasks.

In a nutshell, the model highlights that these four components must be aligned for organizational systems to operate efficiently. On the other hand, misalignments between any of these components lead to inadequacies and failures in the system [13].

This model is used to examine how EA misalignments emerge from disruptions or inconsistencies among various EA components. For example, a technical change (an implementation of an EA tool) may not correspond with current organizational structures or actor capabilities, resulting in EA inefficiencies or resistance. The model is particularly valuable for the analysis of EA issues from a theoretical perspective, since it highlights the need for alignment and adaptability across all four components to ensure EA coherence and efficiency. For example, a structural misalignment can be observed when one component becomes incompatible with others as a result of increased variation (e.g., malfunctioning, replacement). This property of a system affects the system's behavior. A gap, if not unattended, will impede the system's performance and jeopardize its viability. Gaps are frequently the result of sudden events, such as the departure of critical personnel, a financial issue, or a system failure. In other instances, the system may tend to drift towards misalignment as a result of an incremental and innocent change in a single component reaching a tipping point, which forces the entire system into a misalignment [13]. Misalignments show where the components of the system are not correctly aligned, which may result in the system malfunction or decreased performance [13].

III. RESEARCH METHODOLOGY

Considering the purpose and nature of this research, a case study is a suitable research method [27] because the issue to be examined, EA misalignments, is a contemporary and must be explored in its context. The case study method enables the researcher to investigate research questions with many dimensions of interest, and it uses multiple sources of evidence [27, 28].

This study employs a case study approach where the unit of analysis is EA misalignment. The selected cases are four government agencies with established EA practices, ranging from medium to very large organizations. Their EA practices are between two and nine years old, and all cases have small EA teams. The cases have been chosen to expand what can be learned [29].

This research data was obtained using various data collection techniques to have different sources of evidence [28]. In this study, open-ended questionnaires were sent, and then it was followed by group interviews. First, as recommended in [29], an

open-ended qualitative questionnaire was employed. The questionnaires were sent to the managers of EA programs to get information about the agency and its EA program.

Following that, group interviews were conducted with participants from each case. Group interviews were chosen, as suggested by [30], to elaborate and understand the topics of interest. In particular, they were used to acquire deeper insights that were not reported in the questionnaire, and to get supporting documentation to enrich each case evidence.

The collected evidence from each case (the exploratory questionnaire, the interviews and the obtained documents) was combined, as shown in Table I.

TABLE I. PARTICIPANTS AND COLLECTED EVIDENCE

Cases	Description of interviews and obtained evidence
Case 1	Group interview: 90 minutes, 2 interviewees: head of EA, and an enterprise architect. Questionnaire, and multiple documents were obtained about the enterprise and its EA
Case 2	Group interview: 90 minutes, 4 interviewees: head of EA, an enterprise architect and 2 consultants. Questionnaire and multiple documents were obtained about the enterprise and its EA.
Case 3	Group interview: 120 minutes, 3 interviewees: head of EA, and 2 enterprise architects. Questionnaire and multiple documents were obtained about the enterprise and its EA.
Case 4	Group interview: 90 minutes, two interviewees: head of EA and an EA consultant. Questionnaire and multiple documents were obtained about the enterprise and its EA.

The data were analyzed to find EA misalignments using the adopted PSIC theoretical model. A deductive analysis based on the four PSIC components (structure, task, actor, and technology) was used [30]. The model offers a distinct unit of analysis as it facilitates a deeper examination of misalignments across EA components. EA misalignments emerge from disruptions or inconsistencies among various EA components that affect EA coherence and efficiency. Thus, the model highlights that these four components must be aligned for an effective operation of EA programs [13].

IV. FINDINGS AND DISCUSSION

Following the data analysis, some misalignments were identified. The following sub-sections present and discuss the findings which are organized into four main groups. They are EA organizational misalignments, EA governance misalignments, EA capabilities misalignments, and EA management misalignments.

A. EA Organizational Misalignments

Based on the data analysis, this section presents EA organizational related misalignments. These misalignments are related to themes such as communication, organizational acceptance and support, stakeholders' cooperation and EA-orientation, as shown in Table II.

TABLE II. EA ORGANIZATIONAL MISALIGNMENTS

Data evidence	Misalignment
"Some departments do not embrace open communication and thus create a barrier to hinder any progress" – Case 3.	Lack of communication [structure] hinders EA progress [task]
"Besides senior management, other people are also very important when it comes to quality data gathering" – Case 1.	Lack of senior management support [structure] leads to poor EA data collection [task]
"There is limited involvement [of senior management]". – Case 1	Senior management [Actor] is not involved with EA [task]
"EA is quite a new concept ...so, getting people on board is challenging" – Case 1	Organizational members [actors] are not accepting and supporting EA [task]
"We have been facing some difficulties in obtaining accurate and up-to-date data from some stakeholders"- Case 1	EA documentations [task] can't be completed due to uncooperative stakeholders [actors]
"Without being driven by business, EA risks being IT driven [IT-oriented] which yields [IT] projects and investments that do not provide business value thereby causing management to look at EA as wasted cost" – Case 2	IT-driven EA [structure] is not supporting EA value delivery [task] resulting in the neglect of EA by [actors]

First, a key gap pertains to the lack of communication. The data shows that some departments do not embrace open communication [Structure] and thus create a barrier that hinders EA progress [Task]. Ineffective communication [Structure] impedes EA activities [Task] by hindering collaboration and knowledge sharing. This indicates that a non-supporting structure within an organization can significantly disturb the effectiveness of EA practice [13]. Poor communication limits the ability of stakeholders to work together towards common goals, which puts EA at risk of failure and leads to non-value-adding outcomes [14, 31]. To ensure a successful implementation of EA and the adoption of EA by stakeholders, it is essential to have an effective EA communication and support [5].

Second, organizational acceptance and support, particularly from senior management and other key stakeholders, are fundamental for an effective Enterprise Architecture (EA). A Lack of organizational support [Structure] results in misaligned EA activities [Task]. According to [13], that is a structure-task gap where the existing structure (organizational support) is not appropriate or well-defined for EA activities. Further, the data shows an actor-task misalignment example, where senior management [Actors] did not accept EA and did not provide the required involvement [Task] that are essential for EA.

Third, there was a cooperation gap where getting data [Task] is hindered by uncooperative stakeholders [Actors]. It is stated that organizational politics result in diminished cooperation, particularly among business units, IT departments, and stakeholders [32]. Challenges in coordination and collaboration concerning EA initiatives are recognized issues within the public sector [4, 32], and that may be due to the increasing autonomy of sub-organizations which affects the execution of

EA work; therefore, addressing autonomy is crucial for maintaining organizational coherence [4].

The lack of organizational support, acceptance, and limited involvement are examples of structure-task and actor-task misalignments, which have a negative impact on EA projects. Previous research shows that the lack of management support or approval leads to EA project issues [5, 14, 31]. This demonstrates a traditional structure-task misalignment, where inadequate structural support hinders EA from delivering its value [13].

Fourth, EA-orientation and value delivery are key themes that affect EA practice. The data shows that they were misalignment between EA-orientation [Structure] and EA value delivery [Task]. In particular, it appears that an IT-driven EA [Structure] is not capable of supporting EA value delivery [Task]. Such an orientation [Structure] resulted in another misalignment where management's [Actors] perceives EA operations [Task] as an unnecessary burden rather than a strategic enabler.

Organizations have encountered difficulty in justifying their EA initiatives as a result of a lack of understanding of EA [10]. The IT orientation of EA frequently results in a restricted mandate, thereby constraining EA's potential influence and impact. For instance, when EA is predominantly IT-focused, it leads to the exclusion of various relevant stakeholders [33]. EA implementation is sometimes motivated by concepts that may not align with practical realities [34]. In order to realize the promises of EA initiatives and comprehend their risk, organizations must have a comprehensive understanding of EA value, which is necessary to align various stakeholders with varying value expectations [34].

B. EA Governance Misalignments

Based on the data analysis, this section presents EA governance-related misalignments. These misalignments are related to themes such as governance establishment, governance committee, compliance and coordination, as shown in Table III.

TABLE III. EA GOVERNANCE MISALIGNMENTS

Data evidence (Examples)	Actual Misalignment
"Governance is essential to make sure EA is actually delivering value. Without it, people will treat it as just documents, especially as in our case when the maturity level is low"- Case 2.	lack of governance [structure] affects EA operations and EA value delivery [task]
"Members of the senior management have to be part of EA Governance Committee in order to be able to set direction for EA activities"- Case 1	EA governance committee [structure] has to guide EA activities [task]
"Controlling project compliance with EA's TRM (Technical Reference Model) is still to-date a quite challenging task" as "projects and teams want to utilize their own products and standards"- Case 3.	compliance [task] is not supported by project teams [actor]
"Some projects were initiated [task] during the roadmap development ... [which] might deliver incompatible deliverables that were not defined in the to-be architecture"- Case 4	Uncoordinated projects [task] lead to incompatible architectural deliverables [technology]

The data shows a governance misalignment which is related to the lack of governance [Structure] which affects EA operations [Task] and EA value delivery [Task]. Governance as a structure is crucial for EA activities and value delivery. Establishing clear governance practices ensures that EA activities are aligned with organizational objectives and deliver the anticipated value.

In addition, the data shows a governance committee misalignment. The EA governance committee [Structure] directs EA operations [Task], and a misalignment occurs if the committee is weak or non-existent. By offering supervision, establishing guidelines, and guaranteeing adherence to policies and standards, the EA governance committee [Structure] directs EA operations [Task]. It makes it easier for stakeholders to coordinate, improves decision-making, and keeps EA operations consistent, which reflects a structure-task alignment [13].

Thus, an adequate level of EA governance, through formal evaluations and approval procedures, is essential for successful EA implementation [14]. Additional governance elements include the explicit mandate of EA and centralized governance mechanisms for EA-related decision-making [35]. Additionally, organizations frequently face a lack of EA governance structure, which may result in ambiguous responsibilities [5, 25].

Further, other misalignments are also reported on compliance and coordination dimensions. Compliance as a [Task] is not supported by project teams [Actors], which results in inconsistent and inefficient EA implementations. In addition, lack of coordination [Task] can result in fragmented and inefficient EA deliverables and a useless repository [Technology]. Uncoordinated project initiation leads to incompatible architectural deliverables, resulting in integration and interoperability issues. Thus, Coordination, uniformity, and alignment with the overarching EA plan are guaranteed by the establishment and adherence to a robust governance structure. Organizations face challenges in enforcing EA governance regulations as a result of inadequate resources [5, 25]. The external contractual work and the use of legacy systems make it even more challenging to comply with EA governance rules and principles [5, 15].

C. EA Capabilities Misalignment

Based on the data analysis, this section presents EA capabilities related misalignments. These misalignments are related to themes such as funding, skills and tools, as shown in Table IV.

TABLE IV. EA CAPABILITIES MISALIGNMENT

Data evidence (Examples)	Actual Misalignment
"No funding is reserved and no enough support to build a capable EA team with the right size and mix of skills"- Case 2	lack of funding and support [structure] affects team capabilities [actors]
In case 1, it is reported that the lack of sufficient financial support had led to some issues in maintaining EA tools and artefacts.	Lack of funding [Structure] causes maintenance [task] and tools [technology] update issues
"Without proper [EA] skills, knowledge, and required experience it would be difficult [for EA team] to establish an effective EA practice" – Case 1.	Lack of capable EA team [actors] hinders establishing an effective EA practice [task]

Building successful EA teams requires a robust support structure. The data shows there is a structure - actor misalignment. Insufficient funding and support as a [structure] affects the EA team [actor] capabilities because it restricts access to resources, training, and tools needed for an effective EA operation. Without sufficient organizational and financial support, EA teams find it difficult to complete their tasks. The ability of the team to create strategic value and uphold architectural coherence is improved by ensuring consistent investment and leadership support. It is stated that when financial support is not provided for EA, the lack of economic incentives is a major reason for organizational interoperability challenges [4].

Further, it is reported that the lack of satisfactory financial support [structure] caused issues such as EA maintenance [Task] and tools upgrade [Technology]. Inadequate financial resources [Structure] influence both EA maintenance activities [Task] and EA tools maintenance [Technology]. Insufficient resources and expertise profoundly affect EA implementation and have a negative impact on EA value [4, 5].

In addition, it is reported that there is a gap between EA team [Actor] capabilities and required EA activities [Task]. It means an EA team without a suitable set of skills and proficiency will not be able to launch and sustain a successful EA practice. Thus, organizations need an EA team that is skillful, motivated and experienced to establish and operate an EA program [4-6]. That exemplifies an actor-task misalignment where actors are not capable of executing EA activities [13]. The lack of capable enterprise architects is a serious issue for EA development [6, 25], and it might be due to the broad and complex nature of the EA field [25].

D. EA Management Misalignments

Based on the data analysis, this section presents EA management-related misalignments. These misalignments are related to themes such as strategy, requirements, processes and data, as shown in Table V.

TABLE V. EA MANAGEMENT MISALIGNMENTS

Data evidence (Examples)	Actual Misalignment
"Due to the merger, we are now still unaware of the new strategy and thus the new EA cycle depends on this" –Case 2	lack of strategy [structure] affects EA activities [task]
"Maintenance of the EA tool due to changes in stakeholders' requirements is creating some challenges"- Case 1	Vague requirements caused unnecessary extra work [task] on EA tool [technology] which is occupying EA team [actors]
"Lack of proper documentation process requires more efforts recollecting EA information "- Case 4.	Ineffective processes (task) lead to more work from EA teams [actor]
"Updates to the [EA] repository is very important because that [organization] cannot afford to make decisions based on outdated [EA] data"- Case1	Informal EA data update [task] leads to outdated and useless repository [technology]
"If quality information [data] is not shared, then EA artifacts [models] will not depict the true picture... These problems occur when the agency was establishing baseline architecture and collecting the existing IT assets."- Case 3.	Low quality data sharing [task] leads to low quality EA repository [technology]

First, the data shows there is a misalignment between strategy [Structure] and EA planning [Task]. It shows that such a misalignment between the strategic structure and the EA development cycle is due to a recent merger, which resulted in the absence of a cohesive business strategy, which caused some uncertainty into EA planning and operations. Since EA activities rely on proper alignment with organizational strategy, any lack of strategic direction leads to disconnects between strategic goals and the execution of architectural activities. As a practice, EA focuses on defining the future architecture based on clear strategic objectives [5, 14]. Consequently, when organizational strategies are unclear, the effectiveness of EA practices is compromised [6]. The challenge of defining the target state does not stem from difficulties in obtaining relevant information. Instead, the issue lies in the organization's inability to reach a consensus on the desired strategic direction [33].

Second, another misalignment pertains to vague requirements and EA's irrelevant extra-work. In particular, frequent changes in stakeholder requirements [Actors] require ongoing maintenance [Task] of the EA tool [Technology], which has resulted in unnecessary additional efforts. This actor-task-technology gap causes the EA team [Actors] to spend too much time modifying EA tools rather than focusing on value-adding EA operations. In such misalignment, EA resources are diverted away from value-adding activities. Thus, in order to avoid such a misalignment, organizations need to have effective change management and well-defined requirements from stakeholders. It is stated that when there is a lack of specific objectives and proof of added value, it is not likely to make efficient use of EA [22]. If EA projects proceed on inaccurate assumptions, it will lead to higher costs as all tasks need re-execution. Consequently, the EA development will require significantly more time than anticipated [36].

Third, there was a misalignment between ineffective EA processes [task] and EA team workload [actor]. In particular, the lack of EA documentation processes imposes some challenges on EA team. This inefficiency amplifies EA documentation workload, delays the decision-making process, and reduces the overall value of EA. Consequently, the team is engaged in repetitive tasks rather than concentrating on strategic initiatives. Thus, the use and adherence to a structured EA process have the potential to improve EA content and reduce EA team efforts. It is stated that issues occur due to unclear processes and procedures, a lack of coordination with the EA department, and incorrect project plans [22]. In particular, the documentation process, which involves the manual gathering and maintenance of EA content, is susceptible to errors, labor-intensive, and expensive [5].

Fourth, there was a misalignment related to ineffective EA data management, which results in useless EA insights. It is a task technology misalignment where EA data update [task] is not maintained to keep EA repository [technology] up to date and relevant. Updates to the EA repository are informal and are not carried out systematically. This results in an outdated and useless repository, ultimately leading to inaccurate decisions. EA architects find it difficult to keep up with quick changes and documentation of such changes [23]. It is reported that the delivery of EA deliverables are often delayed, inappropriate, inefficient, or unclear [32]. EA artefacts must be stored to enable

stakeholder use and reuse. Additionally, any changes must be accurately documented to avoid a mismatch between documentation and reality [22].

Fifth, there was a task-technology gap related to a low-quality data. Low quality data sharing [Task] leads to low quality EA repository [Technology]. EA effectiveness is undermined when quality data are not shared [Task] and populated into EA repository [Technology]. Such a misalignment is considered a systematic that needs organized actions [13]. To realign the socio-technical system and ensure that EA artifacts depict the real picture of the enterprise, the enterprise has to use data quality governance, conduct training programs, use automation for data sharing, and use accountability policies. The documentation of EA is frequently performed manually [23]. Yet, manual collection of EA information and its maintenance is susceptible to errors, labor-intensive, and expensive [5, 8, 9].

E. Overall Discussion

This section discusses EA misalignments based on the PSIC model. Table VI shows that EA issues manifest as misalignments among the core PSIC components: structure, task, actor, and technology, rather than as isolated challenges.

TABLE VI. EA MISALIGNMENTS

Socio-Technical elements	EA Misalignments
Structure – Task	• Ineffective communication [structure] hinders EA progress [task] • Weak senior management support [structure] leads to poor EA data collection [task] • Lack of governance [structure] affects EA operations and EA value delivery [task] • EA Governance Committee [structure] has to guide EA activities [task] • Lack of strategy [structure] affects EA activities [task]
Structure-Task -Actor	• IT-driven EA [structure] is not supporting EA value delivery [task] resulting in the neglect of EA by [actor]
Actor -Task	• Senior management [actor] are not involved with EA [task] • Incapable EA team [actors] can't establish an effective EA practice [task] • Organizational members [actor] are not accepting and supporting EA [task]
Task Actor	• EA documentations [task] can't be completed due to uncooperative stakeholders [actor] • Compliance [task] is not supported by project teams [actor] • Ineffective processes (task) lead to more work for EA teams [actor]
Task - Technology	• Uncoordinated projects initiation [task] leads to incompatible architectural deliverables [technology] • Informal EA data update [task] leads to outdated and useless repository [technology] • Low quality data sharing [task] leads to low quality EA repository [technology]
Structure-Actor	• Lack of funding [structure] affects team capabilities [actor]
Structure - Task - Technology	• Lack of funding [structure] prohibits EA maintenance [task] which causes tools [technology] issues
Task - Technology -Actor	• Vague requirements cause unnecessary extra work [task] on EA tools [technology] which occupies EA team [actor]

First, structure–task misalignments such as ineffective communication, poor governance, weak senior management support, and absence of clear strategy, clearly undermine EA tasks. Structure–task misalignments suggest that the organizational arrangements designed to facilitate EA do not adequately enable EA activities that are necessary for the delivery of EA value. Consequently, EA is undermined due to poorly or fragmentally executed EA tasks, such as data collection, coordination, and governance enforcement.

Second, the data presents multiple misalignments, which involve structure, task, and actor, specifically when EA is framed as an IT-driven program. When EA is structurally embedded within IT, EA tasks fail to align with business goals, resulting in inadequate engagement from important actors. This misalignment explains why top management and some organizational members are not engaged with EA activities. Such a misalignment deteriorates the socio-technical balance of EA. It leads to EA resistance and reduces the possibility that EA practices are accepted across the organization.

Third, actor–task misalignments are also noticeable, which signify gaps in team capabilities, actors' commitment, and collaboration. Incapable EA teams, uncommitted and uncooperative stakeholders impede essential EA tasks such as documentation and compliance. In PSIC terms, well-defined tasks cannot be successfully executed when actors are not capable, or lack the authority, or are not motivated. Over time, these misalignments intensify workload on EA teams and lack of trust in EA outcomes, highlighting an example of disengagement and inefficiency within the system.

Fourth, task–technology and other related multi-component misalignments degrade EA models and tools. Poorly coordinated tasks, insufficient funding, ad-hoc data management and unclear requirements lead to an outdated EA repository, incompatible EA deliverables, and ineffective EA tools. When technology is misaligned with tasks and actors, EA tools become a liability rather than an enabler, overwhelming actors without providing value.

V. CONCLUSION

Despite EA's relevance, EA establishment and operations are still challenging for many organizations. Furthermore, although interest in EA research is expanding, the majority of articles lack strong theoretical underpinnings. Further, EA issues are often analyzed independently of each other, while in reality, they are interconnected and impact each other. Thus, this study aims at a deeper understanding of EA issues using the Punctuated Socio-Technical Information System Change (PSIC) model.

EA misalignments, as a contemporary phenomenon, must be explored in its context. Therefore, a case study method is used. The case study data were deductively analyzed based on the four components of the PSIC's model to identify EA misalignments. These components impact one another and engage in dynamic interactions within a socio-technical system.

The contributions of this study are threefold. First, certain misalignments were identified and grouped into four primary categories: organizational, governance, capabilities, and managerial misalignments. EA misalignments originate from

disruptions or inconsistencies across EA components, such as ineffective communication, a lack of organizational support, weak processes, and ineffective governance. By mapping these misalignments using the PSIC model, this study offers an empirically grounded analysis that can serve as a reference for future theory development in EA research. Second, this study shows that the PSIC is applicable at a finer-grained level of analysis, specifically, the operational misalignments within an EA program. It constitutes a contextual adaptation of the PSIC model to the EA domain. Third, the study enriches the model by showing that EA misalignments often manifest as multicomponent rather than dual misalignments. It uncovers the causal interdependence among EA issues across four related components (structure, task, actor, and technology). For instance, the data shows that insufficient funding [structure] does not only cause a funding issue in isolation. It concurrently reduces EA team capabilities [actor], impacts EA tools maintenance [technology], and disrupts EA activities [task], leading to multicomponent misalignments.

Consistent with the PSIC model, these misalignments exemplify how changes such as reduced funding or weakened data governance can drive an EA program toward a critical point, where accumulated gaps impede the overall coherence of EA and threaten its sustainability. EA elements impact one another and engage in dynamic interactions within a socio-technical system. That means any disruptions to one or some of these elements have a negative impact on EA practice as a whole. Thus, organizations must ensure that EA elements are aligned and work in harmony to realize the promised value of EA.

Future research should examine EA misalignments to understand their emergence and evolution across various organizational contexts. Moreover, studies are needed to examine the techniques that organizations use to maintain alignment and coordination of EA elements. This research would facilitate the identification of optimal practices and contextual elements that enable sustainable EA coherence and the realization of long-term EA benefits.

This research has its limitations. The use of a qualitative case study design and the small number of cases limit the generalizability of the findings across different organizational settings. Although the results provide in-depth insights, they should be viewed as exploratory rather than conclusive.

Bibliometric Mapping and Systematic Review of Deep Learning Approaches in Film and Multimedia Recommendation Systems within New Media

Linlin Hou

Faculty of Humanities and Arts, Xi'an FANYI University, Shaanxi, China

Abstract—The rapid growth of film, video, and multimedia content on new media platforms has intensified information overload, increasing the importance of effective recommender systems. Traditional recommendation approaches face limitations in modeling complex content semantics and dynamic user preferences. Deep learning techniques have been widely adopted to enhance film and multimedia recommendation performance. This study presents a bibliometric mapping and systematic literature review of deep learning film and multimedia recommendation systems in new media. Scopus was used as the primary data source, yielding 679 peer-reviewed studies following a structured screening and inclusion process. The research methodology, search strategy, and selection criteria are explicitly documented. Bibliometric techniques, including citation analysis, keyword co-occurrence, and thematic clustering, are applied to identify influential publications, dominant research streams, and emerging trends. The reviewed literature is synthesized into major thematic areas, including multimodal representation learning, graph-based recommendation, multimedia feature extraction, personalization and cold-start mitigation, fairness and bias, emotion-aware recommendation, and explainability. The findings reveal a strong dominance of multimodal and graph-based deep learning models, particularly those integrating visual, audio, textual, and interaction data. However, many existing approaches rely on shallow feature fusion and demonstrate limited capability in capturing fine-grained semantic relationships, user attraction mechanisms, and contextual meaning. Challenges related to cold-start, sparse feedback, fairness, transparency, and user experience remain insufficiently addressed. This study identifies critical research gaps and outlines future research directions, emphasizing the need for semantically rich, explainable, fair, and human-centered multimedia recommender systems capable of supporting the evolving complexity of new media ecosystems.

Keywords—Deep learning; multimedia recommendation systems; film recommendation; new media platforms; multimodal learning; graph-based recommender systems

I. INTRODUCTION

The rapid expansion of new media platforms, including film streaming services, short-video applications, and multimedia social networks, has led to an unprecedented growth in audiovisual content [1]. While this abundance enhances user choice, it simultaneously intensifies information overload, making effective recommendation systems indispensable for personalized content discovery [2]. Deep learning-based recommender systems have emerged as a dominant solution, demonstrating superior performance in

capturing complex user item interactions and multimodal content representations compared with traditional collaborative and content-based approaches [3], [4], [5]. Recent advances in film and multimedia recommendation increasingly use deep neural architectures such as convolutional neural networks (CNNs), recurrent neural networks (RNNs), graph neural networks (GNNs), and multimodal representation learning. Multimodal graph-based models, including the Multimodal Graph Convolution Network (MMGCN), have shown strong capability in integrating visual, acoustic, and textual features within unified recommendation frameworks [6]. Self-supervised and contrastive learning techniques have been introduced to improve representation disentanglement in short-video and micro-video recommendation contexts [7].

Despite these methodological advances, the fast-growing body of literature remains fragmented across domains, media types, and modeling paradigms. A key problem in current research is the lack of a systematic and quantitative synthesis of deep learning approaches applied specifically to film and multimedia recommendation within new media ecosystems [8], [9]. Existing studies predominantly focus on algorithmic taxonomies or specific media modalities, without offering a bibliometric perspective on research evolution, influential themes, and intellectual structures shaping the field [5]. It remains unclear how research trends have evolved over time, which deep learning paradigms dominate high-impact studies, and where critical knowledge gaps persist. Several substantive research gaps emerge from highly cited works. First, although multimodal deep learning has improved recommendation accuracy, most models rely on feature-level fusion and fail to incorporate semantic and relational knowledge underlying film and video content, limiting interpretability and fine-grained reasoning [6] [10]. Second, issues such as cold-start, fairness, emotional engagement, and sustainable user experience are often addressed in isolation, rather than through unified deep learning frameworks suitable for complex new media environments [1] [11]. Third, explainability and attraction modeling remain underexplored, even though understanding why content appeals to users is crucial when explicit feedback is sparse or unavailable [10]. To address these limitations, this study conducts a bibliometric mapping and systematic literature review of deep learning-based film and multimedia recommendation systems within new media. By analyzing highly cited publications, keyword co-occurrence networks, and thematic clusters, this research identifies dominant methodologies, emerging trends, and underdeveloped research

directions. Unlike prior narrative reviews, the bibliometric approach provides an evidence-based overview of the intellectual structure of the field, enabling objective identification of research concentrations and gaps [4], [9], [12]. The contributions of this study are threefold. First, it provides a comprehensive bibliometric analysis that maps the evolution of deep learning approaches in film and multimedia recommendation. Second, it synthesizes major thematic streams. Third, it highlights critical research gaps and outlines future directions.

II. RELATED WORK

Existing literature reviews on recommender systems demonstrate substantial breadth and technical depth; however, they largely adopt horizontal cataloging approaches that organize studies by algorithms, applications, or datasets without critically integrating media specificity, deep learning evolution, and new media contexts. As reflected in Table I, most reviews provide valuable taxonomies but stop short of synthesizing how deep learning paradigms reshape film and multimedia recommendation systems in structurally distinct ways. The study of [8] provides broad algorithmic taxonomies across application domains, yet treats movies, videos, and multimedia content as interchangeable recommendation targets. This idea hides the unique multimodal complexity inherent in film and new media content, where visual, acoustic, textual, emotional, and social signals interact nonlinearly. In [13], the authors emphasize deep learning-based collaborative filtering but focus primarily on neural architectures rather than media-aware representation learning. More recent reviews address emerging paradigms but remain method-centric rather than domain-centric. The study of [9] advances the field by contrasting traditional AI with generative AI. However, its scope spans heterogeneous domains and does not examine how generative or deep models specifically transform film and multimedia recommendation workflows. In [14] and [4], the authors further classify deep learning techniques but emphasize algorithm families over content modality integration, leaving unanswered questions about how deep learning handles narrative structure, emotion, attraction, and temporal dynamics in media content.

Video-specific reviews, such as [12], provide applied insights into platforms like Netflix but rely on platform-centric narrative discussion rather than systematic bibliometric evidence. Meanwhile, [15] delivers a macro-level trend analysis linking recommendation research with business growth, yet does not isolate deep learning driven transformations in multimedia recommendation. In contrast, the present study makes a distinctive and complementary contribution in three critical ways. First, it employs bibliometric mapping to quantitatively reveal intellectual structures, influential works, and thematic evolution of deep learning approaches in film and multimedia recommendation, an approach limited from prior reviews. Second, it explicitly situates recommendation models within new media ecosystems, including streaming platforms, short-video services, and social multimedia environments, rather than treating recommendation as a domain-agnostic problem. Third, by synthesizing highly cited studies, this review critically identifies systemic research gaps, including limited multimodal

knowledge integration, weak attraction modeling, insufficient explainability, and fragmented treatment of user experience, fairness, and emotion. Therefore, rather than functioning as another annotated inventory, this study advances the literature by providing a theory-informed, evidence-driven synthesis that clarifies how deep learning has reshaped and continues to challenge film and multimedia recommendation systems within new media.

III. METHODOLOGY

The systematic bibliometric review method is used in this research to examine the deep learning-based film and multimedia recommendation system research landscape within the new media settings. The research methodology was planned specifically to provide a sense of transparency, reproducibility and methodological rigor [16], [17].

A. Data Source

Bibliographic information was searched in the Scopus database only because it has a wide collection of peer-reviewed journals, conference proceedings, and book series related to the computer science domain, artificial intelligence, and multimedia, and information systems [18]. Scopus also offers extensive indexing of citation and superior analysis features; thus, it has been appropriate towards bibliometric mapping and trend analysis [19]. Bibliometric analysis, as emphasized by prior scholars, serves as a systematic method for uncovering research patterns and intellectual structures within a specific knowledge domain [20].

B. Search Strategy and Search String

A systematic procedure was adopted to identify and compile the most relevant literature for this study, as illustrated in Fig. 1. The search strategy incorporated a wide range of terms to capture all possible research related to deep learning applications in film and multimedia recommendation systems within new media environments. The final search string included: ("deep learning" OR "machine learning" OR

"artificial intelligence" OR AI OR "neural network*" OR "convolutional neural network*" OR CNN OR "recurrent neural network*" OR RNN OR "transformer model*" OR "deep neural network*" OR DNN) AND (film OR movie* OR cinema* OR video* OR "media content" OR "digital content" OR multimedia*) AND ("recommender system*" OR "recommendation system*" OR "content recommendation" OR "personalized recommendation" OR "content-based" OR "collaborative filtering" OR "hybrid recommendation" OR "media recommendation") AND ("new media" OR "digital media" OR "online media" OR platform* OR "social media" OR "streaming" OR "OTT" OR "web-based" OR "internet media" OR "digital platform*"). This systematic search approach ensured broad coverage of studies addressing deep learning-driven recommendation technologies across film, multimedia, and new media platforms.

C. Inclusion and Exclusion Criteria

In order to generate a high-quality dataset that will be of use in deep learning applications in film and multimedia recommendation systems under new media, there were clear inclusion and exclusion criteria. Research papers were considered provided that they were focused directly on the application of deep learning to the improvement of film or multimedia recommendation, and covered such topics as content-based filtering, collaborative filtering, hybrid recommendation systems, user profiling, and the multimodality of data integration. Publications in English that were published after 2016 and before 2025 were regarded only to preserve their accessibility and reflect the latest advances in technology. Research that was not directly related, like hardware design, purely social sciences, environmental science or mathematics, was not counted. No non-research articles, such as editorials, opinion pieces, and general reviews, were also included in order to give priority to empirical and application-oriented articles, as presented in Table II.

TABLE II. INCLUSION AND EXCLUSION

Criteria	Inclusion	Exclusion
Topic	Deep learning based film/multimedia recommendation systems within new media.	Non deep-learning studies; unrelated multimedia topics.
Document Type	Journal articles and conference papers.	Reviews, editorials, letters, notes, book chapters.
Language	English.	Non-English.
Years	2016-2025.	Before 2016 or after 2025.
Subject Area	Computer science, decision sciences, information systems, multimedia, AI.	Fields unrelated to media/AI (e.g., materials science, medicine).
Database	Scopus-indexed documents.	Non-Scopus sources.
Quality	Clear methodological relevance to deep learning and recommendation systems.	Low methodological clarity or irrelevant focus.

D. Study Selection Process

The Scopus database was used in November 2025 for data extraction, the search limit to sources available in 2016-2025, aiming to obtain the latest research in deep learning-based film and multimedia recommendation systems in new media. The

selection of the data was based on the systematic multi-stage strategy, as seen in Fig. 1. A preliminary search had found 962 documents. A provided filtering based on computer science, decision sciences, social sciences, multidisciplinary, and arts and humanities to refine the dataset was the first screening that narrowed the dataset to 842 studies to include the relevant ones. Then, the results were restricted to English-language articles, which produced 825 studies, which guaranteed the accessibility and uniformity. In the next step, only articles and conference papers were included, and the reviews, editorials, and opinion articles were excluded, leading to a final sample of 679 articles. The resulting dataset of high-quality, after this multi-stage filtering process, that included meaningful contributions to deep learning applications in a film and multimedia recommendation system were of good quality and offered a solid basis of bibliometric mapping, thematic analysis, and discovery of new trends and research opportunities in this area.

Fig. 1. Study selection process.

IV. RESULTS AND DISCUSSION

This section provides a discussion of the results. Citation counts serve as an important indicator for identifying influential studies and mapping prevailing research trends within a scholarly domain. Accordingly, this bibliometric analysis seeks to offer a systematic and transparent overview of impactful research in deep learning-based film and multimedia recommendation systems within new media, by highlighting key publications, dominant themes, and emerging research directions shaping this field.

A. Annual Distribution

The annual publication distribution reveals a clear and sustained growth direction in research on deep learning approaches for film and multimedia recommendation systems within new media environments. As shown by the publication frequencies in Fig. 2, scholarly output increased steadily from 2016 (10 publications) to 2025 (139 publications), reflecting the maturation and expanding relevance of this research domain. Between 2016 and 2018, publication activity remained relatively modest (10–17 studies per year). During this formative phase, research primarily focused on traditional collaborative filtering, early deep learning architectures, and basic content-based multimedia recommendation methods. Foundational works during this period laid the groundwork for incorporating deep neural networks, sentiment analysis, and

early multimodal representations into recommendation systems.

A noticeable acceleration begins in 2019 (37 publications) and continues through 2020 (50 publications) and 2021 (57 publications). This growth coincides with the widespread adoption of deep learning models such as CNNs, RNNs, and matrix factorization enhanced with neural networks alongside the increasing availability of large-scale multimedia datasets from platforms like Netflix, YouTube, TikTok, and Spotify. Research during this phase increasingly addressed challenges such as cold-start problems, data sparsity, and sentiment-aware personalization. The period from 2022 to 2024 marks a significant expansion phase. Publications rose sharply from 76 studies in 2022 to 113 in 2023, peaking at 167 studies in 2024. This surge aligns with the emergence of graph neural networks, multimodal contrastive learning, hypergraph embeddings, and self-supervised learning frameworks, which enabled more sophisticated modeling of complex relationships among users, films, videos, audio, and textual metadata. Growing concerns over algorithmic fairness, explainability, user experience, and sustainable engagement in new media platforms further fueled scholarly interest. The strong publication count observed in 2025 (139 studies), despite the year being potentially incomplete, indicates that research momentum remains high. Current studies increasingly emphasize fine-grained multimodal representation learning, emotion- and attraction-aware recommendation, cross-domain and cross-platform modeling, and human-centered AI approaches. This trend suggests a shift from purely accuracy-driven systems toward more holistic, interpretable, and socially responsible recommendation frameworks.

Fig. 2. Annual publication.

B. Evaluation of Journal Bibliometrics

The journal bibliometric analysis provides insights into the intellectual outlets. The selected sources meet the high citation impact criterion with a minimum of 50 citations, highlighting journals and proceedings that play a central role in shaping this research area, as in Table III. The findings reveal a strong dominance of computer science, artificial intelligence, multimedia, and information systems venues. Journals such as Artificial Intelligence Review, Journal of Big Data, ACM Computing Surveys, and IEEE Transactions on Neural Networks and Learning Systems exhibit high citation-to-document ratios, indicating that although they publish fewer

papers, their contributions show substantial publication influence. This pattern is consistent with the review-oriented and theory-building focus of these outlets, which frequently publish highly cited surveys and conceptual studies. In contrast, conference proceedings and book series, particularly Lecture Notes in Computer Science (LNCS) and Lecture Notes in Networks and Systems, account for a large share of publications. This reflects the fast-evolving and technically driven nature of multimedia recommendation research, where early dissemination of deep learning models, graph-based techniques, and multimodal frameworks is commonly achieved through conferences. Although these venues show moderate citation density, they remain essential for methodological innovation and rapid knowledge diffusion. Application-oriented journals, including Multimedia Tools and Applications, Expert Systems with Applications, IEEE Access, and Electronics (Switzerland), display a balanced profile combining relatively high publication volumes with solid citation performance. These outlets serve as key platforms for applied deep learning solutions in video, film, music, and social media recommendations.

C. Country Analysis

The country collaboration network shows a hierarchical and organized international research environment with well-defined knowledge centers within the country, regionally integrated groups, or clusters, and gradually embracing the peripheral contributors, which are shown in Fig. 3. The visual topology shows that there is a definite hub-and-bridge structure, with the United States placed in an intermediary position between various regional research communities. The high-level of collaboration with China, India, the United Kingdom and some partners in the Asia-Pacific revealed that it has big part to play in the process of knowledge exchange and methodological diffusing across culture among deep learning-based multimedia recommendation studies. China and India are high-productivity ends of innovation as demonstrated by the large node size and multiple foreign connections. The fact that they are immensely connected to developed and emerging research systems implies sustained institutional investment in artificial intelligence, digital media analytics, and scale data infrastructures. The European countries, in contrast, have a networked regional ecosystem in the collaboration pattern, and the European nations (Germany, France, Spain, Italy, Austria, Norway, Switzerland, etc.) have their close-knit clusters. Regardless of its relatively moderate amount of publications, the concentration of intra-European connections speaks in favor of methodologically sophisticated and citation-influencing works with collaborative studies and cross-border initiatives to finance their activities.

Fig. 3. Country analysis.

The Asia-Pacific region makes a manifestation of a bridging and diffusion position in the global network. South Korea, Singapore, Malaysia, Pakistan, Hong Kong, and Australia demonstrate the strategic positioning between the major knowledge centers, which indicates their increased involvement in the international research consortia and technology-based innovation ecosystems. Canada also has been helping in the integration of regions by consistently maintaining alliances with both its North American and Asian partners. In addition, there are new contributions of the Middle East and developing research systems like Saudi Arabia, Iran, Iraq, Qatar, and Bangladesh, which does indicate a progressive increase in the geographical coverage of the field. Their comparatively peripheral network positioning, however, means

that the intensity of collaboration and the impact of citation is not evenly distributed. Generally, the visualized structure can be defined as a core-periphery model of knowledge diffusion, where core nations spearhead theoretical and technological development whereas peripheral regions are progressively transformed into converged capacity by neural network development. This trend highlights the significance of global collaborations in rapidly enhancing the global development of smart multimedia recommendation studies.

D. Co-occurrence Keyword Analysis

The co-occurrence network keyword indicates a hub-and-cluster intellectual structure indicative of the maturity and current diversification of deep learning-based multimedia recommendations research. Fig. 4 shows that recommender systems is the central node, highly linked to deep learning and machine learning as well as collaborative filtering, which validates the fact that current studies are still based on the performance-oriented algorithm optimization. This high centralization is a sign of methodological convergence, with deep representation learning becoming the mainstream paradigm to overcome the old methods of similarity-based recommendation. In addition to the main center, the network also features clear but connected themes clusters that are indicative of the conceptual development of the field. One of the key methodological clusters connects convolutional neural networks, graph neural networks, knowledge graphs, and personalized recommendation, which emphasizes learning representations in a relational and multimodal form. According to this trend, the intelligence of recommendations is more and more determined by the possibility to represent the complicated semantic interactions between heterogeneous media content, individual behavior, and context.

A second stream was focused around the social media, data mining, user profiling, and online systems; this change in focus towards more platforms signals the increasing platform-driven nature of recommendation research. The high-density proximity of these terms suggests that deep learning recommender innovations are being empirically tested on large-scale digital ecosystems especially streaming and social networking environments. Such structural connection proves the fact that technological development is strictly correlated with the growth of data-intensive media consumption space. Another thematic category is related to natural language processing, sentiment analysis, behavioral research, and user experience, which is indicative of a new direction towards cognitive- and affect-aware design of recommendation. The incorporation of semantic comprehension and emotional modeling is a possible indication that the latest research is now shifting the focus past accuracy measures to the levels of engagement, interpretability, and user-focused intelligence. Nevertheless, the relative peripheral stance of fairness and privacy words suggests that ethical and responsible AI are taken into account, being more and more intense, but are not yet deeply established in the popular recommendation structures. The co-occurrence structure shows a gradual evolution of algorithm-driven optimization approach into context-enriching, multimodal, and human-conscious paradigms of recommendation. Meanwhile, the discontinuity between the clusters of technical performance and the growing

socio-cognitive comes out as a research gap, there are no single comprehensive paradigms that incorporate deep semantic modelling, scalable personalization and ethical system design simultaneously in multimedia recommendation contexts.

Fig. 4. Keywords occurrence.

E. Citation Analysis of the Top-Most Articles

The reviewed literature demonstrates a clear thematic and methodological evolution in multimedia recommendation research, moving from early multimodal feature fusion toward more structured and semantically grounded models, as shown in Table IV. Early influential works on multimodal graph learning established the feasibility of integrating visual, audio, textual, and interaction signals, but they largely treated modalities as parallel inputs [6], [21], [22]. Subsequent advances introduced contrastive and hypergraph learning to better disentangle modality-specific preferences [5]. However, these approaches still fall short in modeling fine-grained

semantic relationships within multimedia content [6]. This direction reveals a persistent limitation in current graph-based multimodal recommenders rich content signals are incorporated, yet their semantic interdependencies remain weakly represented, motivating the growing interest in multimodal knowledge graphs [23].

Research on multimedia content understanding has progressed rapidly in feature extraction and spatiotemporal modeling, particularly through deep CNNs and large-scale distributed learning [24], [25]. While these studies significantly enhance retrieval accuracy and system efficiency, they remain largely decoupled from personalization objectives. Survey evidence further indicates that most systems rely on fragmented, media-specific pipelines, highlighting a structural gap between low-level content understanding and high-level recommendation intelligence, especially in film and video platforms [5], [15]. Across themes, personalization challenges, most notably cold-start and sparsity, persist despite the adoption of multimodal deep learning [8], [12], [13], [26]. Although content-aware models improve performance for new items, their reliance on feature concatenation limits interpretability and weakens their ability to explain user attraction [13]. Scalability-oriented solutions similarly prioritize efficiency over nuanced preference modeling, reinforcing the trade-off between accuracy and explanatory depth [27].

More recent studies foreground fairness, bias, and human-centered considerations, highlighting that recommender systems can amplify structural inequalities if left unchecked [28]. However, fairness-aware methods are rarely integrated with multimodal or graph-based architectures, particularly in video-centric domains [29]. This separation suggests that ethical considerations have evolved as a parallel stream rather than being embedded into core recommendation design. Emerging work on emotion, sentiment, and attraction modeling points to a shift toward experience-oriented recommendation [10], [24], [26].

TABLE IV. DOCUMENT CITATIONS

Ref	Keywords	Method & System	Research Gap	No. of Cite.
[6]	Computing, Recommender systems; Information systems, Personalization, Multimedia and multimodal retrieval	Multimodal Graph Convolution Network (MMGCN)	Limited multimodal knowledge integration in MMGCN	592

[25]	Convolutional neural network, Machine learning, Recommender system, Interpretable AI, Multimedia, User-generated content	Convolutional Neural Networks	Lack of explainable multimedia video tag recommenders	23
[50]	e-Learning; data mining; personalized recommendation; collaborative filtering algorithm	Hybrid recommendation system for video learning	Cold-start learners lack personalized recommendations	22
[51]	View propagation, Video popularity, Recommendation system, Keyword suggestion	Recommendation System	Limited understanding of recommendation-triggered view growth.	20

F. Streams of Topological Research and Thematic Evolution

Besides bibliometric performance measures, the literature review demonstrates that the research on deep learning-based multimedia recommendation systems is clearly organized intellectually. The field has four streams. Stream one is focused on models of neural recommendation that are accuracy-oriented and works which focus on performance as deep neural network, graph learning, and hybrid collaborative-content architecture. The initial research primarily focused on enhancing the level of prediction and extended to a big scale, which is an algorithm-based bias in adviser composing studies. The second stream is a transition towards multimodal learning of semantic representation. The distribution of video streaming and social media platforms further indicates adoption of visual, textual, acoustic, and behavioral signs to better depict the content semantics by study. This evolution is an indicator of a broader paradigm shift, where interaction-based filtering is no longer relevant; content-sensitive intelligent recommendation is. The third stream, which is emerging, is user cognition, emotion and experience recommendation. Recent studies indicate that sentiment-aware personalization, attraction modeling and human AI design is under growing interest. This tendency points to the fact that the shift in RS in favor of sustainability in engagement and psychological relevance is becoming more pronounced, instead of utility maximization. The fourth stream is related to ethical, fair, and explainable recommendation frames. Issues of popularity bias, transparency, algorithmic accountability, and so forth, are increasingly being discussed, particularly within and adjacent to large-scale digital media ecosystems. However, it has been found in the review that the fairness mechanisms are loosely related to the multimodal deep learning models, thus there is a significant research gap. The thematic development is a progressive movement towards system-based optimization and socially deliberated, tactically-constrained, and cognitively-directed recommendation intelligence. This shift is an extension of AI into digital media economics and human behavior analytics.

V. CONCLUSION

This study provides a thematic literature review and bibliometric mapping of the research on deep learning-based film and multimedia recommendation systems in new media settings. The results show that the research landscape is growing very fast and becoming more and more globalized, specifically it begins to grow after 2020 and is supported by the development of multimodal learning, graph-based models, and extensive digital media platforms. Although such strong research centers as China, India and the United States influence the methodological innovations and the intensity of collaboration, European research makes a high citation influence and conceptual refining contribution. In general, the field is experiencing a paradigm shift of the accuracy-based recommendation to context aware, multimodal, and human-centered intelligent systems.

The discussion also indicates that although there have been massive developments in feature extraction, representation learning and scalability of the system, there are still outstanding issues. Current recommender models tend to

deploy superficial multimodal combination and provide scant value of interpretability, especially when there is cold-start and sparse-feedback. The new research directions, which deal with fairness, bias reduction, experience-base personalization, and user attraction modelling, indicate a slow shift to socially responsible and experience-centered recommendation design. Nevertheless, these dimensions remain poorly incorporated on mainstream deep learning architectures. The research consequently recommends coherent frameworks that convergently address semantic multimodal understanding, individual user cognition, as well as ethical system intelligence in the future multimedia recommendation studies.

A. Contribution of the Study

The study is new in the literature, as it presents a systematic bibliometric review offering a concise picture of the intellectual situation, prevailing research trends, and collaborative patterns in multimedia recommendation powered by deep learning across the world. The synthesis of fragmented technical steps into corresponding thematic streams makes the study move forward in the knowledge of the field development, and the necessary research gaps are represented by explainable personalization, multimodal semantic integration research and fairness-conscious design of recommendations. The results provide theoretical understanding and real guidance to scholars and mobile educational content creators that aim at designing the next generation intelligent recommender systems in vibrant new media ecologies.

B. Limitations and Future Research

There are some drawbacks that may be noted. The review is based exclusively on the publications in the Scopus databases and English-language sources over the period of 2016-2025, potentially not including any works in other databases, prior background literature, or local research activities. Secondly, bibliometric methods mostly focus on trends in structure and not specifically on individual models of methodological performance. The future researches can build upon this study by adding multi-database retrieval plan, mixed quantitative-qualitative synthesis plan and longitudinal analysis of the consequences of any recommendation in order to gain a more comprehensive view of intelligent multimedia recommendation systems.

VI. FUTURE RESEARCH AGENDA

The synthesis of bibliometric and thematic evidence suggests that future research on deep learning film and multimedia recommendation systems should move beyond incremental algorithmic improvements toward integrative, human-centered frameworks. While multimodal and graph-based models dominate current studies, their limited semantic depth highlights the need for richer abstraction through multimodal knowledge graphs capturing objects, scenes, emotions, and narratives. Personalization under cold-start and sparse-feedback conditions remains challenging, calling for causally grounded, attraction-aware models that enhance interpretability. Fairness, bias, and ethical considerations should be embedded within core architectures. Advances in emotion-aware modeling and standardized evaluation protocols are essential to support semantically rich, explainable, and

socially responsible recommender systems, as shown in Table V.

TABLE V. FUTURE RESEARCH AGENDA

Research Theme	Suggested Future Research Directions
Semantic understanding of multimedia content.	Develop models that automatically extract and integrate object, scene, narrative, and stylistic features using multimodal deep learning and knowledge graphs to better capture content attractiveness.
Personalization under sparse or missing feedback.	Design attraction-aware and causal recommendation models that infer latent user preferences without relying heavily on explicit user ratings.
Multimodal representation learning.	Propose unified end-to-end architectures that jointly learn from text, audio, visual, and contextual signals to improve recommendation robustness.
Emotion- and experience-aware recommendation.	Incorporate affective computing and emotion recognition techniques to model users' experiential responses to films and multimedia content.
Explainable recommendation systems.	Integrate interpretable deep learning mechanisms (e.g., attention visualization, feature attribution) to enhance transparency and user trust.
Fairness, bias, and ethical AI.	Investigate bias-mitigation strategies and fairness-aware learning frameworks to ensure equitable and responsible recommendation outcomes.
Human-centered recommendation design.	Explore user-centric evaluation metrics that emphasize satisfaction, diversity, and long-term engagement rather than short-term accuracy alone.
Evaluation protocols and benchmarking.	Establish standardized datasets, cross-domain benchmarks, and longitudinal evaluation frameworks to improve result comparability and reproducibility.

Abstract—Retrieval Augmented Generation (RAG) improves the factual grounding of Large Language Models (LLMs) by incorporating external knowledge. However, RAG systems may still generate hallucinated responses, and this issue remains underexplored in Indonesian language settings, particularly in settings where local deployment is preferred. This study proposes a hallucination detection approach for Indonesian RAG systems using Low Rank Adaptation (LoRA) fine-tuning. To support this objective, the study constructs a dataset in the Human-Computer Interaction domain consisting of 908 context, question, and answer pairs. The dataset is classified into four categories: FACT-H, FAITH-H, LOG-H, and FAITHFUL. Three local LLMs, namely, Gemma-7B-it, LLaMA-2-7B chat, and Phi-3-medium-4k-instruct, were evaluated using 5-fold cross-validation. The results show that Gemma-7B-it achieved the best performance in the four-class setting, with a Macro F1 score of 0.846. In the binary classification setting, Gemma achieved an accuracy of 98.1 per cent. Further analysis shows that Gemma was particularly effective in recognizing FAITHFUL, FAITH-H, and FACT-H, while LOG-H remained the most difficult class to distinguish consistently.

Keywords—Hallucination detection; Retrieval-Augmented Generation; LoRA fine-tuning

I. INTRODUCTION

The rapid advancement of LLMs has enabled systems that can understand and generate natural language across diverse contexts. Trained on large-scale text corpora, these models can produce coherent and contextually relevant responses [1]. Their applications have expanded across education [2], healthcare [3], [4], [5], software development [6], [7], and industry [8]. To improve factual grounding, many studies adopt RAG, which combines external knowledge retrieval with generative modeling to produce responses that are more closely tied to supporting information.

Despite this advantage, RAG-based systems remain vulnerable to hallucination. In this setting, hallucination refers to outputs that appear plausible but are not supported by factual or contextual evidence [9]. These errors may take the form of factual inaccuracies, fabricated content, or reasoning that is inconsistent with the retrieved context [10][11]. This problem is particularly important in educational applications, where inaccurate responses may mislead students and reduce the reliability of AI-supported learning systems [12]. Therefore, improving retrieval quality alone is not sufficient. RAG-based educational systems also require a mechanism that can assess whether generated answers remain faithful to the provided context and are logically consistent with the question.

The importance of this problem is also reflected in our previous work on the development of a real-time RAG-based virtual assistant, RIVA, in Indonesian organizational settings [13]. That study showed that hybrid retrieval and semantic chunking improved contextual relevance and answer correctness. However, the error analysis also revealed that retrieval failures and partial context aggregation still produced hallucination-like inconsistencies, especially in structured and multi-chunk information retrieval. This finding is consistent with broader evidence that retrieval augmentation can reduce hallucination risk, yet retrieval optimization alone does not fully eliminate hallucination-related inconsistencies in RAG systems [14]. These results indicate that a dedicated hallucination detection layer is still needed, even when the retrieval component has been improved.

Although hallucination in RAG has received growing attention, the current literature still shows two important limitations. First, most hallucination detection studies focus on English language settings. Second, many existing approaches rely on computationally demanding models, as reflected in systems such as HalluMeasure [15] and [16]. While these studies report strong performance, their computational requirements limit their practicality in resource-constrained environments. This limitation becomes more pronounced in low-resource languages such as Indonesian, where both research attention and computational support remain limited. As a result, there is still a clear gap in the development of hallucination detection models that are both suitable for Indonesian RAG systems and relevant to local LLM-based RAG settings.

To address this gap, this study develops a hallucination detection approach for Indonesian RAG systems using LoRA. LoRA enables parameter efficient adaptation of pre trained models without requiring full retraining, making it suitable for local deployment settings. This study fine tunes three local LLMs, namely Gemma-7B-it, LLaMA-2-7B-Chat, and Phi-3-medium-4k-instruct, using a multi class hallucination detection dataset. The selection of these models is supported by prior research showing that LoRA based fine-tuning can improve adaptation quality, while reducing the need for full model retraining such as LLaMA-2-7B Chat [17] and Gemma-2-2B-it [18].

This work is conducted as part of the AVILA project, an intelligent RAG based learning platform that supports module preparation and question answering in the Human Computer Interaction domain. Within this context, the hallucination detection model is intended as a quality control component for

assessing faithfulness and factual accuracy before generated responses are delivered to users. To support this objective, the study constructs a dataset consisting of 908 context, question, and answer pairs derived from AVILA instructional materials. Each instance is labeled into one of four categories, namely FACT-H for factual error, FAITH-H for context omission, LOG-H for logical inconsistency, and FAITHFUL for contextually correct responses.

Although several recent studies have explored hallucination detection in multilingual or low-resource settings, their focus and design differ from the present work. For example, [15] investigated hallucination detection in machine translation across low- and high-resource languages, but did not address RAG-based hallucination detection or multi-class hallucination categorization. Similarly, [19] proposed synthetic data generation to improve hallucination detection, but their study was not designed around context-grounded RAG responses or an Indonesian domain-specific setting. In contrast, frameworks such as RaDIO [16] focus on real-time detection integrated with retrieval optimization, but do not provide a structured multi-class dataset tailored to a specific language domain. Therefore, this study differs by introducing a domain-specific Indonesian dataset that explicitly models multiple hallucination types within a RAG setting, while remaining compatible with fine-tuning approaches for local deployment.

This study makes three main contributions. First, it develops a multi-class hallucination detection dataset in Indonesian for the Human-Computer Interaction domain. Second, it implements a LoRA-based fine-tuning approach for hallucination detection using local LLMs in Indonesian RAG systems. Third, it provides a comparative evaluation of several local LLMs, namely Gemma, LLaMA, and Phi 3, under a unified experimental protocol. Through these contributions, this study aims to support the development of more reliable Indonesian RAG-based learning systems.

II. RELATED WORKS

Hallucination in RAG-based LLM outputs has become one of the key issues in generative AI research. According to the survey conducted by [20], LLMs can be categorized into two types of hallucination, namely factuality hallucination and faithfulness hallucination.

- Factuality hallucinations refer to cases in which the model produces answers that are factually incorrect or unverifiable. Such hallucinations often occur due to factual contradiction or fabrication.
- Faithfulness hallucinations occur when the model's output deviates from the given instruction, context, or is inconsistent with the logical structure of the response.

This taxonomy has informed a wide range of recent detection frameworks that assess the alignment between model outputs and their grounding knowledge through mechanisms such as fact verification, uncertainty estimation, and entailment-based classification.

Recent studies show a methodological transition from theoretical categorizations toward integrated hallucination detection systems. In [19], the authors proposed a synthetic data

generation approach in which faithful and hallucinative pairs were constructed through controlled rewriting and used to fine tune T5 based detectors, resulting in higher accuracy than zero shot classifiers. In the RAG domain, [16] introduced RaDIO, a real time hallucination detection framework that dynamically adjusts document retrieval based on inconsistency signals detected in generated responses.

Although these advances represent important milestones, most prior works remain limited to English datasets and rely on large-scale computational resources, making them less applicable to resource-constrained or local-language environments, such as educational RAG systems in Indonesian.

To address this gap, the present study adapts Huang et al.'s taxonomy [20] into a more operational four-class scheme tailored for Indonesian RAG systems. The scheme was designed to distinguish factual error, grounding failure, and reasoning failure more explicitly during annotation and evaluation.

- FAITHFUL refers to responses that are fully consistent with the source context and the user's question. These responses do not contain factual error, contextual deviation, or logical contradiction. For example, when the context states that observation studies help reveal user habits and difficulties without direct instruction, a faithful answer explicitly identifies these benefits in line with the given material.
- FACT-H refers to factual hallucination, where the answer contains information that is false, fabricated, or contradicts verifiable facts in the provided context. This class captures factual contradiction at the content level. For example, if the context states that Christian Rohrer and McAfee define four testing categories, but the answer incorrectly states that there are three categories or replaces one category with another unsupported one, the response is labeled FACT-H.
- FAITH-H refers to faithfulness hallucination, where the answer may appear plausible or even generally correct, but is not properly grounded in the provided context or does not follow the specific informational scope required by the question. The dominant error in this class is lack of contextual support rather than factual falsity. For example, if the question asks about the benefits of observation studies and the answer provides a broadly relevant statement about observation in HCI without linking it to the contextual evidence given, the response is labeled FAITH-H.
- LOG-H refers to logical hallucination, where the answer remains topically related to the context but fails because of invalid reasoning, incomplete inference, contradiction, or mismatch between the asked aspect and the response content. In this class, the response may look factually acceptable on the surface, yet it does not logically satisfy the question. For example, when the question asks for the advantages of hybrid testing, an answer that merely restates that hybrid testing is flexible without explaining the intended inferential benefit is categorized as LOG-H.

The distinction between FAITH-H and LOG-H is especially important in this study. FAITH-H captures responses whose main problem is lack of grounding in the provided context, whereas LOG-H captures responses whose main problem lies in reasoning failure over contextually relevant information. This distinction was introduced to reduce ambiguity in annotation and to better reflect the types of hallucination observed in Indonesian educational RAG outputs.

III. METHODS

This study employed an experimental approach to develop and evaluate a multi-class hallucination detection model for Indonesian RAG systems. The methodological framework consists of three major stages, namely dataset development, model fine-tuning, and evaluation.

A. Dataset Development

As shown in Fig 1, the dataset construction process begins with source materials collected from HCI books. From these materials, 328 contextual segments were manually selected as the basis for response generation. For each context, four responses were then generated using AI to represent the target classes, namely FACT-H, FAITH-H, LOG-H, and FAITHFUL, resulting in 1,312 initial instances in total.

Fig. 1. Workflow of dataset construction, validation, and balancing for the four class hallucination detection dataset.

To improve the reliability of the annotation procedure, a calibration stage was first conducted before large scale screening. A stratified sample of 120 instances was selected from the initial dataset, with 30 instances per class. This subset was independently reviewed by Expert 1 and Expert 2 to examine label consistency, contextual appropriateness, and response quality. The agreement between the two experts was measured using Cohen's kappa, which reached 0.81, indicating substantial agreement. Based on this calibration stage, the validation guideline was refined before being applied to the remaining dataset.

After the guideline had been stabilized, the remaining 1,192 instances were screened using an AI based validator. Each instance was assigned one of three statuses: valid, invalid, or uncertain. The screening results produced 900 valid, 102 invalid, and 190 uncertain instances. All invalid and uncertain cases were then manually reviewed by Expert 1. In addition, 5% of the AI accepted valid cases were randomly audited by Expert 2 as a quality control step. When disagreements emerged during this process, the final decision was resolved through expert adjudication.

After the validation stage, the number of accepted instances was still not identical across classes. The validated pool consisted of 245 FACT-H, 227 FAITH-H, 231 LOG-H, and 276 FAITHFUL instances. To avoid class distribution bias during fine-tuning and evaluation, a separate balancing stage was then applied. The final dataset was constructed by retaining 227 validated instances per class, resulting in 908 balanced instances in total. Thus, instances excluded from the final dataset were not necessarily invalid. Some were removed during quality validation, while others were excluded during the balancing stage to preserve equal class representation.

B. Model Configuration

1) *Model base*: Three local generative LLMs with different architectural characteristics and scales were evaluated to examine hallucination detection performance under a consistent RAG setting. Table I summarizes the core specifications of each model, including parameter size, context length, and fine-tuning configurations.

TABLE I. MODEL SPECIFICATIONS USED IN THIS STUDY

Model Name	Specification	Quantization
Phi-3-medium-4k-instruct	Transformer (Decoder-only, Microsoft), 14B parameters, 4,096 tokens	4-bit (LoRA)
Gemma-7B-it	Transformer (Decoder-only, Google), 7B parameters, 8,192 tokens	4-bit (LoRA)
LLaMA-2-7B-chat	Transformer (Decoder-only, Meta AI), 7B parameters, 4,096 tokens	4-bit (LoRA)

The selected models represent a range of local generative LLMs with different architectural characteristics and capacities, enabling a comparative evaluation of hallucination detection within a consistent RAG setting. Phi-3-medium-4k-instruct was chosen for its instruction-following capability and stable reasoning behavior, making it suitable for analyzing context-grounded responses. The Gemma-7B-it provides multilingual support and extended context handling, which is beneficial for processing instructional materials in the Human Computer Interaction domain. LLaMA-2-7B-chat-hf serves as a conversational baseline to examine how chat-oriented models handle factual grounding and contextual consistency in generated responses.

2) *Optimizer and hyperparameter training*: The fine-tuning process was conducted using a standardized optimization and hyperparameter configuration across all large language models to ensure comparability of results. Table II summarizes the optimizer and key hyperparameters employed during training. These settings were selected based on prior empirical findings

in fine-tuning without full model retraining and were further adjusted through pilot experiments to achieve stable convergence within limited GPU resources.

TABLE II. OPTIMIZER AND HYPERPARAMETER CONFIGURATION

Parameter	Value
Optimizer	Paged AdamW 8-bit
Learning Rate	1×10^{-5}
Weight Decay	0.01
Warmup Ratio	0.1
Scheduler	Cosine
Epochs	3
Batch Size	1 (Gradient Accumulation = 32)
Quantization	4-bit (NF4)
Early Stopping	Patience = 2

The Paged AdamW 8-bit optimizer was employed due to its memory efficiency and compatibility with low-bit quantization, allowing large models such as Gemma, LLaMA, and PHI to be fine-tuned within a single GPU setup. A learning rate of 1×10^{-5} was chosen to balance convergence speed and stability during LoRA adaptation, while a weight decay of 0.01 was applied to prevent overfitting. The warmup ratio of 0.1 and cosine scheduler were implemented to gradually adjust the learning rate at the early training stage, promoting smoother optimization dynamics.

Training was performed for three epochs, which was empirically sufficient for convergence given the dataset size and instruction-following task. The batch size of one with gradient accumulation of 32 effectively simulated larger batch training without exceeding GPU memory limits. The 4-bit quantization (NF4) format reduced model memory consumption by approximately 70%, enabling efficient fine-tuning while maintaining representational precision. Finally, early stopping with patience = 2 was adopted to terminate training once the validation loss plateaued, ensuring an optimal balance between performance and computational efficiency.

3) *LoRA configuration*: LoRA was applied to all large language models to enable parameter-efficient fine-tuning without full model retraining. Table III summarizes the LoRA configuration parameters used in this study. The configuration was designed to balance adaptation capacity and computational efficiency while maintaining compatibility with 4-bit quantized models and single GPU environments.

TABLE III. LORA CONFIGURATION PARAMETERS

Parameter	Value
LoRA Rank (r)	16
LoRA Alpha (α)	32
LoRA Dropout	0.1
Target Modules	q_proj, k_proj, v_proj, o_proj, gate_proj, up_proj, down_proj
Bias	None
Task Type	Causal Language Modeling

The LoRA configuration was designed for fine-tuning without full model retraining in single-GPU environments. A rank of 16 was used to balance representational capacity and efficiency, while an alpha value of 32 provided stable gradient scaling without overshooting. A dropout rate of 0.1 introduced regularization to prevent overfitting on domain-specific hallucination data. Adapters were injected into key attention and feed-forward projection layers (q_proj, k_proj, v_proj, o_proj, gate_proj, up_proj, down_proj) to enable fine-grained adaptation without altering the entire model. The bias was omitted to reduce memory overhead, and the task type was set to causal language modeling to align training with generative objectives focused on producing faithful, contextually grounded responses.

4) *Training configuration*: A Stratified 5-Fold Cross-Validation was implemented to maintain class balance across training and validation splits. The training process used the paged_adamw_8bit optimizer and an early-stopping criterion with a patience of two epochs. All experiments were executed on an NVIDIA A40 GPU (48 GB VRAM) using the Transformers, PEFT, and BitsAndBytes libraries.

C. Evaluation and Performance Analysis

Model evaluation was conducted using Stratified 5-Fold Cross-Validation to ensure that each split preserved the class distribution of the dataset. Performance was first assessed in the four-class setting to compare the ability of the fine-tuned models to distinguish FACT-H, FAITH-H, LOG-H, and FAITHFUL responses. The main evaluation metrics were Accuracy, Macro F1, Matthews Correlation Coefficient (MCC), and Cohen's Kappa. Accuracy was used to measure the overall proportion of correct predictions, while Macro F1 was selected to reflect balanced classification performance across the four classes. MCC and Cohen's Kappa were included to provide a stricter assessment of prediction quality and agreement between predicted and true labels beyond simple accuracy.

For each model, the metric values were computed on every fold and then summarized using the mean and standard deviation. In addition, 95% confidence intervals were calculated to estimate the stability and uncertainty of model performance across folds. This analysis enabled not only an overall comparison of predictive quality among Gemma, LLaMA, and PHI, but also an examination of performance consistency under different data partitions. To further investigate stability, fold-level results of the best-performing model were analyzed separately in order to determine whether its overall superiority was maintained across individual evaluation splits.

Error analysis was then performed for the best-performing model using an aggregate confusion matrix across all folds. The confusion matrix was row-normalized to provide a class-level view of correct predictions and misclassification patterns among FACT-H, FAITH-H, LOG-H, and FAITHFUL. This analysis was complemented by qualitative inspection of representative misclassified instances, particularly in cases where logically inconsistent responses remained semantically related to the given context. Such examples were used to identify recurring error patterns that could not be fully captured by aggregate metrics alone.

In addition to the four class setting, a binary classification setting was also evaluated for the best performing model by merging FACT-H, FAITH-H, and LOG-H into a single hallucinated class and comparing it against FAITHFUL. This additional analysis was intended to assess the practical usefulness of the model as a front-end detector for separating hallucinated and faithful responses before applying finer-grained hallucination type analysis. In the binary setting, performance was reported using Accuracy, Precision, Recall, F1 Score, and MCC, together with a row-normalized binary confusion matrix to visualize class separation.

IV. RESULTS AND DISCUSSION

A. Results

This section reports the experimental results in a stepwise manner to provide a clear interpretation of model behavior. First, an overall performance comparison across models is presented using the selected evaluation metrics. Second, performance stability across folds is examined to assess the consistency of each model. Third, the fold level results are reported to show how model performance varies across individual data splits. Fourth, error analysis and qualitative findings are provided to identify recurring prediction errors and characteristic response patterns. Finally, the section concludes with a summary of the main findings derived from the overall evaluation.

1) *Overall performance comparison across models:* As shown in Table IV, the overall classification performance of Gemma, LLaMA, and PHI was evaluated using Accuracy, Macro F1, MCC, and Cohen's Kappa. The results are reported as mean $\pm$ standard deviation and 95% confidence interval across folds to capture both average performance and variation. This overall comparison serves as the main basis for identifying the relative strengths of each model before proceeding to a more detailed metric-level analysis.

TABLE IV. OVERALL CLASSIFICATION PERFORMANCE COMPARISON ACROSS MODELS, REPORTED AS MEAN $\pm$ STANDARD DEVIATION AND 95% CONFIDENCE INTERVAL.

Model	Metric	mean $\pm$ SD	95% CI
Gemma	Accuracy	0.847 $\pm$ 0.031	[0.808, 0.886]
	Macro F1	0.846 $\pm$ 0.032	[0.806, 0.885]
	MCC	0.797 $\pm$ 0.041	[0.745, 0.848]
	Cohen's Kappa	0.796 $\pm$ 0.042	[0.744, 0.848]
LLaMA	Accuracy	0.589 $\pm$ 0.027	[0.556, 0.623]
	Macro F1	0.519 $\pm$ 0.022	[0.491, 0.546]
	MCC	0.487 $\pm$ 0.035	[0.444, 0.530]
	Cohen's Kappa	0.452 $\pm$ 0.036	[0.408, 0.497]
PHI	Accuracy	0.510 $\pm$ 0.007	[0.501, 0.518]
	Macro F1	0.444 $\pm$ 0.024	[0.415, 0.474]
	MCC	0.381 $\pm$ 0.004	[0.376, 0.387]
	Cohen's Kappa	0.346 $\pm$ 0.009	[0.335, 0.358]

Table IV shows a clear performance ranking across the three evaluated models. Gemma consistently achieved the best results on all reported metrics, followed by LLaMA, while PHI

obtained the lowest scores overall. This pattern indicates that Gemma provided the strongest overall classification behavior under the current evaluation setting. The inclusion of standard deviation and 95% confidence interval also makes it possible to assess not only the average performance of each model, but also the stability and uncertainty of the reported results across folds.

a) *Accuracy and Macro F1:* In terms of Accuracy and Macro F1, Gemma outperformed the other models by a substantial margin. Gemma achieved an Accuracy of 0.847 ± 0.031 and a Macro F1 of 0.846 ± 0.032 , with 95% confidence intervals of [0.808, 0.886] and [0.806, 0.885], respectively. These results indicate that Gemma maintained both high overall correctness and strong, balanced performance across classes. The relatively moderate standard deviations and fairly narrow confidence intervals suggest that this advantage was consistently observed across folds rather than being driven by a small number of favorable splits.

LLaMA showed intermediate performance, with an Accuracy of 0.589 ± 0.027 and a Macro F1 of 0.519 ± 0.022 . Its 95% confidence intervals, [0.556, 0.623] for Accuracy and [0.491, 0.546] for Macro F1, remained clearly below those of Gemma, indicating a noticeable performance gap between the two models. Compared with Gemma, LLaMA also exhibited slightly lower variability in Macro F1, but this did not translate into stronger predictive performance. In other words, LLaMA was more limited by its average classification quality than by instability across folds.

PHI produced the weakest results on these two metrics, with an Accuracy of 0.510 ± 0.007 and a Macro F1 of 0.444 ± 0.024 . Its Accuracy standard deviation was the smallest among all models, and the confidence interval [0.501, 0.518] was very narrow, which indicates highly consistent behavior across folds. However, this consistency occurred at a relatively low performance level. This pattern suggests that PHI behaved more uniformly, but its predictions remained substantially less accurate and less balanced across classes than those of Gemma and LLaMA.

b) *MCC and Cohen's Kappa:* A similar ranking was observed for MCC and Cohen's Kappa, which provide a stricter view of classification quality by accounting for the agreement between predictions and true labels beyond simple accuracy. Gemma again achieved the highest values, with an MCC of 0.797 ± 0.041 and a Cohen's Kappa of 0.796 ± 0.042 . The corresponding 95% confidence intervals, [0.745, 0.848] and [0.744, 0.848], confirm that Gemma preserved a clear advantage over the other models even under these more demanding metrics. Although the standard deviations for MCC and Cohen's Kappa were slightly larger than those for Accuracy and Macro F1, the results still indicate a strong and stable classification pattern across folds.

LLaMA remained in the middle position, with an MCC of 0.487 ± 0.035 and a Cohen's Kappa of 0.452 ± 0.036 . Its 95% confidence intervals, [0.444, 0.530] for MCC and [0.408, 0.497] for Cohen's Kappa, were substantially lower than those of Gemma. This result indicates that, even when accounting for label agreement and correlation between predictions and ground truth, LLaMA could not approach the classification quality

achieved by Gemma. At the same time, its moderate standard deviations suggest that the observed performance level was reasonably consistent across folds.

PHI again obtained the lowest values, reaching 0.381 ± 0.004 for MCC and 0.346 ± 0.009 for Cohen's Kappa, with very narrow confidence intervals of $[0.376, 0.387]$ and $[0.335, 0.358]$, respectively. These low deviations indicate that PHI produced highly stable results across folds, but the stability was centered around a weak level of predictive agreement. Taken together, the MCC and Cohen's Kappa results reinforce the conclusion that Gemma delivered the most reliable overall classification performance, while LLaMA offered moderate performance and PHI remained limited in both correlation strength and agreement quality.

2) *Performance stability across folds*: Table IV provides an initial comparison of the overall mean performance of the evaluated models, while Fig. 2 visually illustrates these results through grouped bars and error bars across the four evaluation metrics. Although both presentations are useful for identifying general performance differences, they do not fully capture how consistently each model behaved across different folds. Therefore, performance stability must be further examined using the reported standard deviations and 95% confidence intervals. In this context, lower standard deviation and narrower confidence intervals indicate greater consistency across folds, whereas larger deviations suggest higher sensitivity to data partitioning. This analysis is important because a model with higher average performance is not always the most stable, and a stable model is not necessarily the most accurate.

Fig. 2. Grouped bar chart of overall model performance across Accuracy, Macro F1, MCC, and Cohen's Kappa. Error bars represent standard deviation across folds.

Overall, Gemma achieved the highest mean scores across all metrics, but it also showed the largest variability among the three models. Its standard deviation ranged from 0.031 to 0.042, with confidence intervals of $[0.808, 0.886]$ for Accuracy, $[0.806, 0.885]$ for Macro F1, $[0.745, 0.848]$ for MCC, and $[0.744, 0.848]$ for Cohen's Kappa. These intervals remain relatively well bounded, which indicates that Gemma's performance was still reasonably stable across folds. However, compared with the other models, the wider spread suggests that Gemma was more affected by fold specific variation. In other words, Gemma

combined the strongest average performance with a moderate level of variability rather than absolute stability.

LLaMA occupied an intermediate position not only in mean performance but also in stability. Its standard deviation values ranged from 0.022 to 0.036, which were generally lower than those of Gemma but higher than those of PHI on most metrics. The corresponding confidence intervals, such as $[0.556, 0.623]$ for Accuracy and $[0.408, 0.497]$ for Cohen's Kappa, indicate that LLaMA produced a more constrained range of outcomes than Gemma, although the model remained clearly below Gemma in average performance. This pattern suggests that LLaMA was moderately stable, but its limitation was not instability alone. Rather, its central performance level remained substantially lower.

PHI showed the strongest stability across folds when viewed from standard deviation and confidence interval width. Its Accuracy standard deviation was only 0.007 with a confidence interval of $[0.501, 0.518]$, while its MCC standard deviation was even smaller at 0.004 with a confidence interval of $[0.376, 0.387]$. Similar patterns were observed for Macro F1 and Cohen's Kappa, both of which also had narrow confidence ranges. These results indicate that PHI behaved very consistently across different folds. However, this consistency was centered around the lowest mean scores among all evaluated models. Therefore, PHI can be considered the most stable model, but not the strongest model in terms of classification quality.

Taken together, the stability analysis reveals a clear tradeoff between performance level and consistency. Gemma remained the best performing model overall, and its wider deviations did not undermine its clear lead across all metrics. PHI, in contrast, was the most stable model, but its predictions were consistently weak. LLaMA fell between these two extremes, showing moderate performance with moderate variability. This result suggests that the best model in this study was not the one with the smallest dispersion, but the one that maintained the strongest overall scores while keeping its variability within a still acceptable range.

3) *Fold-level performance of the best-performing model*: Table V and Fig. 3 provide a more detailed view of Gemma's performance across individual folds. Overall, Gemma maintained high scores across all evaluation splits, which indicates that its superiority was not driven by only one favorable partition. The weakest performance appeared in Fold 2, where all four metrics decreased simultaneously. In this fold, Accuracy and Macro F1 dropped to 0.797 and 0.795, while MCC and Cohen's Kappa decreased to 0.730 and 0.729, respectively. This pattern shows that the decline was not limited to a single metric but reflected a general reduction in classification quality in that particular split.

In contrast, the strongest results were observed in Folds 1 and 4, where all metrics reached their highest or near-highest values. Fold 3 and Fold 5 remained close to the overall mean, indicating that the aggregate performance of Gemma reflects a stable pattern rather than isolated peaks. Taken together, these fold level results confirm that Gemma consistently delivered strong classification performance across different data splits,

despite moderate variation in one fold. This finding strengthens the conclusion that Gemma was not only the best performing model on average, but also a reliable model across the full evaluation setting.

TABLE V. FOLD LEVEL CLASSIFICATION PERFORMANCE OF GEMMA ACROSS ACCURACY, MACRO F1, MCC, AND COHEN'S KAPPA.

Fold	Accuracy	Macro F1	MCC	Cohen's Kappa
1	0.874	0.871	0.832	0.831
2	0.797	0.795	0.73	0.729
3	0.846	0.847	0.796	0.795
4	0.873	0.874	0.831	0.831
5	0.845	0.842	0.795	0.794

Fig. 3. Fold-level performance of Gemma across the four evaluation metrics.

4) *Error analysis or qualitative findings*: To further examine the error patterns of the best-performing model, Fig. 4 presents the aggregate confusion matrix of Gemma across all evaluation folds. This figure provides a class-level view of prediction behavior by showing how often each true class was correctly classified or confused with other classes in the overall evaluation setting.

		PREDICTED			
		FACT-H	FAITH-H	LOG-H	FAITHFUL
TRUE	FACT-H	0.815	0.048	0.119	0.018
	FAITH-H	0.04	0.894	0.066	0
	LOG-H	0.163	0.101	0.714	0.022
	FAITHFUL	0.004	0.004	0.026	0.965

Fig. 4. Aggregate confusion matrix of Gemma across all evaluation folds.

Overall, Fig. 4 shows that Gemma achieved strong class-level recognition, as reflected by the dominant diagonal values across all four classes. The highest diagonal value was obtained by the FAITHFUL class at 0.965, followed by FAITH-H at 0.894 and FACT-H at 0.815. These results indicate that Gemma

was highly reliable in identifying faithful responses and also performed well in recognizing factual and faithfulness related hallucination classes. This pattern is consistent with the earlier summary results, where Gemma achieved high overall Accuracy and Macro F1 scores across folds.

The main source of error appeared in the LOG-H class, which obtained the lowest diagonal value at 0.714. A recurring confusion pattern can be seen in the misclassification of LOG-H as FACT-H at 0.163 and as FAITH-H at 0.101. In comparison, the other classes showed lower off-diagonal values, indicating better separation. This result suggests that logical hallucination was the most difficult category for Gemma to distinguish consistently, even though the model maintained strong overall performance. Therefore, the aggregate confusion matrix confirms that Gemma's main limitation lies in separating LOG-H from other non-faithful classes rather than in recognizing faithful answers.

As presented in Table VI, the misclassifications between LOG-H and FAITH-H indicate that the model often relied on topical or semantic relevance while failing to capture the logical requirement of the question. In several cases, the generated answers remained related to the given context, but they did not fully address the specific reasoning demand expressed in the question. This pattern is visible, for example, when the answer preserves the topic under discussion but omits the requested category details, shifts from benefit-oriented reasoning to procedural description, or produces a semantically related statement with a subtle contradiction in meaning. These examples further support the aggregate confusion matrix findings, which showed that LOG-H was the most difficult class for Gemma to distinguish consistently from other non-faithful categories, including FAITH-H.

5) *Binary hallucinated vs. faithful performance of Gemma*: To further assess the practical usefulness of the best performing model, an additional binary classification analysis was conducted by merging FACT-H, FAITH-H, and LOG-H into a single hallucinated class and comparing it against faithful. As reported in Table VII, Gemma achieved very strong binary classification performance, with an accuracy of 0.981, precision of 0.988, recall of 0.987, F1 score of 0.988, and MCC of 0.950. These values indicate that once the distinction among hallucination subtypes was removed, Gemma was able to separate hallucinated and faithful responses with very high reliability.

This result is also reflected in Fig. 5, which presents the row-normalized binary confusion matrix and shows a clear separation between hallucinated and faithful responses. In absolute terms, 672 out of 681 hallucinated responses were correctly identified, while only 9 were predicted as faithful. Similarly, 219 out of 227 faithful responses were correctly classified, with only 8 misclassified as hallucinated. Taken together, Table VII and Fig. 5 indicate that Gemma is highly effective as a first-stage detector for identifying whether a response contains hallucination or not. The substantially higher performance in the binary setting is expected, since the classification task becomes simpler after FACT-H, FAITH-H, and LOG-H are collapsed into a single class.

TABLE VI. EXAMPLES OF MISCLASSIFIED INSTANCES BETWEEN LOG-H AND FAITH-H CATEGORIES

Id	Context	Question	Model_Answer	Reason
56	Christian Rohrer and McAfee explained that test types can be divided into four main categories: scripted use, decontextualized use, natural or near-natural use, and hybrid. Each type has different characteristics depending on the level of control and context of product use.	What are the four main test categories explained by Christian Rohrer and McAfee?	Christian Rohrer stated that there are only four types of tests, but he did not mention the different categories.	The model ignored the logical mismatch, focusing only on surface similarity instead of missing category details.
172	Observation studies are also a common form of natural test. Researchers only observe users when using a product without giving direct instructions. This method is effective for revealing habits and difficulties that users are not aware of.	What are the benefits of using observation studies in HCI?	Observation studies are a method where researchers do not give direct instructions while observing users, so the activity is good and non-intrusive.	The model misclassified because the answer is semantically relevant but does not logically address the 'benefit' aspect asked in the question.
228	This section emphasizes that hybrid testing is a flexible and adaptive approach to understanding user interaction holistically. By combining controlled and natural methods, researchers can bridge the gap between quantitative and qualitative data.	What are the advantages of the hybrid testing approach in understanding user interaction?	Hybrid testing is a flexible but not entirely natural approach that helps analyze user interactions.	The model failed to detect a subtle contradiction in meaning and focused only on topical similarity.

TABLE VII. BINARY CLASSIFICATION PERFORMANCE OF GEMMA FOR HALLUCINATED VERSUS FAITHFUL RESPONSE DETECTION.

Metric	Score
Accuracy	0.981
F1 Score	0.988
Precision	0.988
Recall	0.987
MCC	0.95

		PREDICTED	
		HALLUCINATED	FAITHFUL
TRUE	HALLUCINATED	0.987	0.013
	FAITHFUL	0.035	0.965

Fig. 5. Row-normalized binary confusion matrix of Gemma for hallucinated versus faithful classification.

6) *Summary of the main findings*: Overall, the results show a consistent ranking across the evaluated models, with Gemma achieving the strongest classification performance on all reported metrics, followed by LLaMA and PHI. Although PHI exhibited the highest stability across folds, its performance remained substantially lower than Gemma. In contrast, Gemma combined the highest mean scores with still acceptable variability, indicating that it offered the best balance between predictive strength and consistency under the current evaluation setting.

The fold-level analysis further confirmed that Gemma's superiority was not driven by only one favorable split, since the model maintained strong results across all folds despite a noticeable decrease in Fold 2. The aggregate confusion matrix also showed that Gemma recognized faithful, FAITH-H, and FACT-H classes well, while the main source of error remained in the LOG-H class. Taken together, these findings indicate that

Gemma was the most reliable model overall, with its main limitation lying in the separation of logical hallucination from other non-faithful classes.

B. Discussion

The results indicate that Gemma provided the strongest overall performance among the evaluated models, consistently achieving the highest Accuracy, Macro F1, MCC, and Cohen's Kappa. This pattern suggests that Gemma was more effective not only in general correctness, but also in maintaining class-balanced prediction quality and label agreement across the four categories. This interpretation is compatible with prior work that treats hallucination as a multi form phenomenon rather than a single undifferentiated error type. In particular, [21] distinguishes factuality-based, faithfulness-based, logical-based, and hybrid hallucinations, which supports the present finding that overall performance can remain high while difficulty still varies substantially across hallucination subtypes.

However, the fold-based analysis adds an important qualification. Gemma was the best-performing model, but it was not the most stable one in absolute terms, since PHI showed narrower variation across folds despite much lower average performance. This result indicates that low variance alone is not sufficient as a selection criterion for hallucination detection, because a model may behave consistently while still failing to separate the target categories adequately. In contrast, Gemma combined the highest mean scores with still acceptable variability, making it the strongest candidate under the current evaluation setting. The fold-level results reinforce this interpretation, as Gemma maintained strong scores across all folds despite a noticeable drop in Fold 2.

The aggregate confusion matrix explains more clearly where Gemma succeeded and where its limitations remained. The model showed strong recognition for FAITHFUL, FAITH-H, and FACT-H, but LOG-H obtained the lowest diagonal value and was repeatedly confused with FACT-H and FAITH-H. This pattern suggests that logical hallucination is harder to detect because the response may remain semantically related to the context while still violating the inferential demand of the question. This interpretation is consistent with [21], who argue

that robust hallucination evaluation should consider both surface manifestations and their underlying causes, and with [16], who show that hallucination detection in dynamic RAG should not rely only on static or local cues, since contextual discrepancy, uncertainty, and semantic inconsistency may emerge during generation.

The qualitative examples further support this pattern. In several misclassified cases, the generated answer remained topically relevant but failed to satisfy the logical requirement of the question. The error did not arise because the answer was entirely unrelated to the context, but because it preserved semantic overlap while missing the requested reasoning target, omitting required distinctions, or introducing a subtle contradiction in meaning. This observation is aligned with [19], who note that effective hallucination detector training requires both faithful and hallucinated responses and that predefined perturbation assumptions may fail to capture the wider diversity of hallucinations found in real outputs. It is also compatible with [22], who combine semantic consistency analysis with entailment and contradiction assessment, indicating that semantic similarity alone is insufficient when the core error lies in reasoning inconsistency. In a similar direction, [23] argue that retrieval augmentation alone does not guarantee adherence to grounding and that stronger grounded alignment is needed to improve faithfulness. Taken together, these findings suggest that future improvement for LOG-H detection should focus less on broad semantic overlap and more on reasoning-sensitive verification, entailment-aware scoring, and grounded alignment mechanisms.

The binary setting highlights an important aspect of Gemma's behavior. As shown in Table VII and Fig. 5, Gemma achieved very strong performance when the task was simplified to distinguishing hallucinated responses from faithful ones, indicating that the model was highly reliable for coarse-grained hallucination detection. At the same time, the gap between the binary and four-class results shows that the main challenge does not lie in identifying whether a response is faithful, but in separating specific hallucination subtypes after a response has been recognized as non-faithful. This pattern is consistent with the earlier multiclass findings, where Gemma performed strongly overall but still showed greater difficulty on LOG-H. Although the binary class distribution becomes moderately imbalanced after merging hallucination subtypes, the high MCC and the small number of false positives and false negatives indicate that the strong result is not explained by class dominance alone. Therefore, Gemma appears well-suited as a coarse-grained screening model in RAG pipelines, while fine-grained discrimination among hallucination types remains the more demanding task.

V. CONCLUSION

This study evaluated LoRA-based fine-tuning of local LLMs for four class hallucination detection in Indonesian RAG outputs, covering FACT-H, FAITH-H, LOG-H, and FAITHFUL categories. The results show that Gemma consistently achieved the strongest overall performance across Accuracy, Macro F1, MCC, and Cohen's Kappa, surpassing LLaMA and PHI under the same experimental setting. This advantage was not limited to aggregate metrics. The fold-level

analysis indicates that Gemma maintained a strong performance pattern across evaluation splits, despite a noticeable decline in one fold. The aggregate confusion matrix further shows that the model was particularly effective in recognizing FAITHFUL, FAITH-H, and FACT-H, while LOG-H remained the most difficult class to distinguish. Taken together, these findings indicate that LoRA based adaptation of local LLMs is a viable direction for hallucination detection in Indonesian RAG settings, but logical hallucination still poses a distinct challenge because semantically related answers may remain inconsistent at the level of reasoning.

Several limitations should be acknowledged. First, the dataset was constructed within the Human-Computer Interaction domain, so the present findings should be interpreted with caution when extended to other knowledge areas. Second, although the dataset is balanced, its size remains moderate and may not fully represent the diversity of hallucination patterns found in real RAG applications, particularly across domains, writing styles, and response forms. The use of 5-fold cross-validation improves the reliability of the evaluation, but it does not eliminate the need for validation on larger and more heterogeneous datasets. Third, the comparison was limited to selected local LLMs with different scales, and therefore does not capture the behavior of larger-scale architectures that may exhibit different strengths and weaknesses. Future work should address these limitations by expanding the dataset across domains, examining generalization more explicitly, and incorporating reasoning-aware or entailment-based methods to improve the detection of logical inconsistency, especially for the LOG-H class.

ACKNOWLEDGMENT

This study forms part of the author's doctoral research. The author expresses sincere appreciation to the Universitas Udayana for its academic guidance and support during the doctoral journey. The author also acknowledges the Universitas Pendidikan Ganesha for providing institutional facilities and research infrastructure that enabled the completion of this work.

DECLARATION ON GENERATIVE AI

Generative artificial intelligence tools were used solely for language editing and grammatical refinement during the preparation of this manuscript. All scientific concepts, methodology, literature analysis, interpretations, and conclusions were developed and critically reviewed by the author, who assumes full responsibility for the content of this work.

Abstract—In recent years, artificial intelligence (AI) has transformed numerous sectors, including healthcare, and ophthalmology is no exception. The field has seen remarkable progress in using AI to detect, diagnose, and manage noncommunicable eye diseases (NCEDs), such as cataract, keratoconus, glaucoma, diabetic retinopathy, and age-related macular degeneration. This study presents a comprehensive bibliometric analysis of 4,280 articles between 2004 and 2026, revealing significant trends in AI-based NCED research. The literature search focused on a highly reputable database: Scopus. The selection of this database ensured a thorough exploration of the field, given its broad coverage of both technical and medical literature. The search strategy employed a carefully curated set of keywords to capture relevant articles and reviews. The field has experienced robust growth, with an average annual increase of 19.41% in publications, peaking in 2023 with 516 articles. Deep learning, particularly Convolutional Neural Networks (CNNs), has emerged as the leading approach, surpassing traditional image processing techniques. Research in medical image analysis has primarily focused on age-related macular degeneration, glaucoma, and diabetic retinopathy, with an increasing emphasis on automated screening systems for early detection. Future trends may include a focus on explainable AI and attention mechanisms, integration with telemedicine, and development of more robust, generalizable models, highlighting its potential to revolutionize early diagnosis and management of eye diseases.

Keywords—Artificial intelligence; noncommunicable eye disease; cataract; keratoconus; glaucoma; diabetic retinopathy; age-related macular degeneration

I. INTRODUCTION

Noncommunicable eye diseases (NCEDs) are a global health challenge, encompassing chronic vision-impacting conditions that are non-transmissible. Disorders such as cataracts, glaucoma, diabetic retinopathy, and age-related macular degeneration (AMD) are increasingly prevalent with aging populations and lifestyle changes [1]. According to 2023 WHO data, cataracts lead as the top cause of blindness or vision impairment (94 million), followed by refractive errors (88.4 million), AMD (8 million), glaucoma (7.7 million), and diabetic retinopathy (3.9 million) [2]. This study also includes keratoconus as an NCED, given its impact on the eye's anterior segment. Research on AI applications in eye disease

management, particularly in developing countries, has been widely published in academic journals and conferences. Bibliometric analysis of these trends can reveal AI's role in advancing eye care. To our knowledge, no existing literature specifically addresses NCEDs, including keratoconus, from this perspective. Fig. 1 provides NCED image samples. NCEDs pose significant challenges in ophthalmology, involving complex pathophysiology and potentially severe outcomes. Cataracts occur when the normally clear crystalline lens becomes opaque, reducing light entry into the eye [3]. Diabetic retinopathy, a result of diabetes and chronic hyperglycemia, involves microvascular changes and retinal lesions such as exudates, microaneurysms, and retinal thickening with fluid buildup, leading to visual impairment [4]. Glaucoma is marked by the progressive loss of retinal ganglion cells and their axons, which, if untreated, causes irreversible vision loss [5]. AMD is a multifactorial condition involving progressive damage to the macula, essential for central vision [6]. Keratoconus, a progressive inflammatory disorder, causes corneal thinning and irregular astigmatism, resulting in myopia, reduced visual acuity, and a cone-shaped cornea [7], [8]. Each of these disorders presents unique diagnostic and therapeutic challenges, underscoring the need for continued research and clinical advancements.

The early history of AI in medical imaging, dating back to the 1960s, initially focused on automated computer diagnosis with the ambitious goal of replacing radiologists [9]. However, this approach proved unsuccessful due to technological limitations and unrealistic expectations. In the 1980s, a shift occurred towards computer-aided diagnosis (CAD), where computers assist rather than replace radiologists, leading to widespread adoption despite initial skepticism. The debate between automated diagnosis and CAD continues, with some researchers still pursuing fully automated systems, while others focus on enhancing CAD capabilities, reflecting ongoing discussions about the future role of AI in radiology [9]. The 1980s saw the emergence of rule-based expert systems, followed by the development of CAD systems in the 1990s, particularly in mammography [10]. The early 2000s marked a significant shift with the rise of sophisticated machine learning algorithms applied to various medical imaging modalities [11]. A major paradigm shift then took place in the 2010s with the rapid

*Corresponding author.

development of deep learning, especially convolutional neural networks (CNNs). The breakthrough performance of CNNs in the 2012 ImageNet competition, demonstrated by AlexNet,

quickly influenced medical image analysis research [12]. More broadly, deep learning soon became a dominant methodological framework in medical image analysis [13].

Fig. 1. Sample of NCEDs images [3]-[5].

Furthermore, a lot of research has been done on medical image analysis, including ophthalmology. The evolution of AI in ophthalmology has started with initial efforts focused on basic image processing techniques to detect retinal abnormalities. For instance, early work by Katz et al. [14] used digital image processing for diabetic retinopathy screening. Then, in the era of machine learning in the 2000s, Abràmoff et al. [15] demonstrated the feasibility of automated diabetic retinopathy detection using computational image analysis approaches. The subsequent emergence of deep learning, particularly CNNs, markedly improved the accuracy of ocular disease detection. Gulshan et al. [16] reported a landmark deep-learning study for diabetic retinopathy detection that achieved performance comparable to that of human experts. Ting et al. [17] further extended this direction by developing a system capable of detecting diabetic retinopathy and related eye diseases from retinal images. More recently, increasing research attention has been directed toward robust multi-disease systems, clinically deployable models, and real-world validation of autonomous AI-based ophthalmic screening systems [17], [18]. However, important challenges remain, particularly in relation to accuracy, generalizability, and real-time clinical deployment, where multiple disease-specific factors and imaging conditions must still be considered.

Bibliometric analysis has emerged as a powerful tool for mapping the landscape of scientific research across various fields [19], including the rapidly evolving domain of AI in ophthalmology. This quantitative approach offers a bird's-eye view of research trends, helping scholars and policymakers alike to navigate the vast sea of published literature. Bibliometric analysis offers a quantitative approach to understanding the landscape of scientific research. As Aria and Cuccurullo [20] explain, "Bibliometrics is the application of quantitative analysis

and statistics to publications such as journal articles and their accompanying citation counts". This method allows researchers to evaluate the growth and maturity of a field, identify leading authors, and chart the conceptual and intellectual trends within a scientific discipline. In the rapidly evolving domain of AI in ophthalmology, such analysis can provide valuable insights into research patterns and emerging areas of focus. Thus, this study aims to draw bibliometric analysis specifically on NCEDs to conceptualize the trends of AI in medical image analysis. Our study employs a comprehensive approach to analyze the landscape of research in this field:

- To analyze the performance metrics of relevant publications. This includes an in-depth look at annual trends, publication types, research fields, and highly cited works. This analysis provides a bird's-eye view of the field's evolution and impact.
- To identify the key players in the research arena. This includes countries, institutions, and individual researchers who have made significant contributions. We also explore the intricate web of collaborations between these entities, shedding light on the global research ecosystem.
- To capture the dynamic nature of research to pinpoint emerging trends and shifts in focus over time, across various dimensions such as article sources, references, authors, institutions and countries.
- To dive into the heart of the research itself, using keyword analysis to map out the intellectual landscape. This approach helps us identify current hotspots, emerging frontiers, and potential future directions in the field.

- Finally, the discussion section presents a comprehensive analysis of the findings, encompassing an examination of pertinent contemporary issues, a projection of potential future trajectories and obstacles in the field, and a transparent elucidation of the study's inherent limitations.

The study is structured to guide you through this journey of discovery, where: Section II lays out the methodology, detailing the data sources, search strategies, and the bibliometric tools employed. Section III forms the core of this study, presenting the findings across the four key aspects mentioned above. Furthermore, discussing the analysis from each of the components and the implications for current issues in the field. Section IV presents limitations and biases. Section V details the future trends. Finally, Section VI summarizes the key findings, future directions, potential hurdles and significance for the research community.

II. METHODOLOGY

A. Article Selection Method

The literature search for this study was carried out on January 15, 2026, using the Scopus database. The Scopus database was searched for articles that included the keywords "Artificial Intelligence", "Detection", "Segmentation", "Mobile", and "Smartphone". Each of these terms was paired with five specific keywords related to various ocular diseases: "cataract", "keratoconus", "glaucoma", "diabetic retinopathy", and "age-related macular degeneration", the first phase of the paper selection process, as illustrated in Fig. 2. The criteria in Fig. 2 yielded 6390 publications across all five keyword pairs, with the following distribution: 507 for cataract, 110 for keratoconus, 511 for AMD, 3571 for diabetic retinopathy, and 1691 for glaucoma. Subsequently, publications were filtered based on specific exclusion criteria:

- Publications unrelated to the research objective,
- Duplicate publications,
- Publications not related to any of the five ocular diseases.

Furthermore, the flowchart in Fig. 2 outlines the processes used for the bibliometric analysis in this study. Fig. 2 shows that 4280 publications were selected for further analysis, with the following distribution: 243 for cataract, 104 for keratoconus, 440 for AMD, 2332 for diabetic retinopathy, and 1161 for glaucoma. These were included in the bibliometric study.

B. Analytical Tool

The bibliometric analysis for this study was conducted using Biblioshiny ver. 4.3.0, a tool integrated within the open-source R package, which is developed by RStudio [20]. Biblioshiny 4.0 stands out from other bibliometric tools due to its extensive range of statistical techniques and visualizations, which facilitate both performance analysis and conceptual mapping of research topics. As an R package with a web-based graphical interface, Biblioshiny offers a user-friendly and well-organized interface. The menu is designed to include statistics and graphs across four levels of metrics—source, author, document, and clustering by coupling—as well as the knowledge structure. The analysis encompasses three distinct epistemological

frameworks: the Conceptual Structure, which delineates the domain's theoretical underpinnings; the Intellectual Structure, which elucidates the interrelationships among key ideas and paradigms; and the Social Structure, which explicates the network of scholarly collaborations and influences within the field. The program's analysis capabilities are diverse, organized into eight main categories [20]: 1) Overview, 2) Sources, 3) Authors, 4) Documents, 5) Clustering, 6) Conceptual Structures, 7) Intellectual Structure, and 8) Social Structure.

Fig. 2. Process of selecting publications for the bibliometric analysis.

The present study employs a comprehensive bibliometric analysis, encompassing both performance analysis and scientific mapping, to elucidate the evolutionary trajectory of AI-based ocular disease detection research. The performance analysis component evaluates the productivity and impact of diverse scientific entities, including nations, academic institutions, and individual researchers [21]. This quantitative assessment provides insights into the relative contributions and influence of various stakeholders within the field. Conversely, the scientific mapping analysis aims to delineate the underlying knowledge structure and its dynamic organization within this specific research domain [22]. The data extracted from Biblioshiny for performance analysis include annual scientific production, corresponding authors' countries, most relevant affiliations, sources' production over time, sources' local impact by citation counts, and the most globally cited documents. Furthermore, this analysis covers aspects such as the collaboration world map, co-citation network, most relevant words, word cloud, co-occurrence word network, words' frequency over time, and the three-fields plot (Sankey diagram). This approach facilitates the visualization of conceptual relationships, intellectual trends, and the evolving landscape of ideas that characterize the field.

III. RESULTS AND DISCUSSION

Based on the retrieved data from the Scopus database and Biblioshiny tools, the bibliometric analysis can be performed and discussed meticulously to extract the trend and pattern of publication in AI for NCEDs application wise.

A. Overall Publication Trend

The volume of academic publications on a particular topic serves as a reliable indicator of research trends within that field, providing valuable insights into the research process of the discipline, as depicted in Fig. 3. A total of 137 duplicate documents were identified by Biblioshiny and subsequently excluded from the analysis. The data demonstrate a strong and

sustained upward trend in AI-based research on ocular disease detection from 2004 to 2025. Scholarly output remained relatively low between 2004 and 2011, with fewer than 40 publications annually, indicating limited early adoption of AI techniques in this domain. A gradual increase became evident after 2012, followed by a marked acceleration from 2018 onward. Research activity rose sharply from 167 publications in 2018 to 301 in 2019 and continued to grow steadily through 2020 (368 publications) and 2021 (411 publications). The upward momentum persisted in 2022 and 2023, reaching 476 and 516 publications, respectively. Although a slight dip was observed in 2024, with 417 publications recorded, a significant rebound occurred in 2025, where scientific production peaked at 695 publications the highest level observed across the entire study period. Overall, the findings highlight an exponential growth pattern in AI-driven ocular disease detection research, particularly over the past decade, reflecting increasing research maturity, clinical relevance, and sustained academic interest in this field.

This can be linked to the adoption of CNNs and can be traced to the 2012 ImageNet challenge, where AlexNet [12], a CNN architecture, achieved unprecedented success, significantly outperforming traditional methods. This watershed event catalyzed a proliferation of AI-related research and publications across diverse sectors. Subsequently, there has been a gradual shift away from systems that rely on handcrafted features, such as conventional image processing methods, as CNNs gained prominence not only in medical imaging but across various domains. The widespread adoption of CNNs can be attributed, in part, to the challenges associated with handcrafted feature techniques, which often require problem-specific implementations and lack generalizability. In the field of computer vision, deep convolutional networks have emerged as the preeminent methodology, supplanting traditional approaches due to their superior performance and adaptability [23].

Fig. 3. Bibliometric analysis on 4,280 publications focused on ocular disease detection, categorized by their publication year from 2004 to 2026.

B. Analysis of the Countries and Research Institutes

Research conducted through Biblioshiny reveals that studies on AI-based ocular disease detection have been published by researchers from 76 different countries. Table I presents the top 10 most productive countries, which collectively account for 62.2% of all publications. India emerges as the most prolific contributor in terms of publication volume (26.5%), followed by China (15.7%) and the United States (7.1%). In contrast, China leads in citation impact (17.5%), slightly ahead of India (15.5%), while the USA demonstrates a strong citation-to-publication ratio (10.5% citations). Other countries, including Singapore and the Netherlands, show comparatively smaller publication shares but notable citation influence, highlighting the quality and impact of their contributions. Overall, the findings confirm the dominant roles of India and China in research output, alongside the strong scholarly influence of the USA and selected European and Asian countries.

TABLE I. TEN MOST CONTRIBUTING COUNTRIES IN AI-BASED OCULAR DISEASE DETECTION

Country	Articles %	Citations %
CHINA	15.7	17.5
INDIA	26.5	15.5
USA	7.1	10.5
SINGAPORE	1.4	6.3
NETHERLANDS	0.5	5.7
SPAIN	2.2	4.8
UNITED KINGDOM	2.1	4.3
PAKISTAN	1.9	2.7
FRANCE	0.9	2.5
CANADA	1.1	2.2

Fig. 4. Top 10 most relevant affiliations based on research output.

Fig. 4 presents the top 10 most relevant institutions based on research output. Central South University leads with 59 publications, followed by Sun Yat-sen University (47) and Northeastern University (46). Capital Medical University ranks fourth (44 publications), while Singapore Eye Research Institute, Southern University of Science and Technology, and the University of California each contribute 40 publications. Shanghai Jiao Tong University (39), King Saud University (37), and SRM Institute of Science and Technology (36) complete the top ten. Notably, five of the top ten institutions are based in China, reinforcing the country's strong institutional presence in this domain. The inclusion of leading institutions from the USA, Singapore, Saudi Arabia, and India further reflects the global and collaborative nature of AI-driven research in ocular disease detection.

C. Analysis of Co-Citation and Co-Authorship

A network map illustrating co-authorship among 95 countries, highlighting eight countries—China, India, the USA,

Pakistan, Singapore, the United Kingdom, Saudi Arabia, and Malaysia—that have collaborated on at least 10 publications each, is shown in Fig. 5. India and China emerge as prominent nodes, signifying their central roles in AI-based ocular disease detection research. Notably, there are robust research partnerships between India and the USA, as well as between China and the USA. Additionally, the European nations demonstrate strong intra-continental collaboration, indicating a high level of cooperation both within Europe and with other regions. Within Asia, a concentrated collaborative effort is evident, particularly between India and China. Interestingly, despite the complex political and economic relationship between China and the USA, there is substantial research collaboration between these two nations in this field. This pattern of international cooperation suggests that scientific collaboration in AI and ophthalmology transcends geopolitical tensions, fostering a global approach to advancing medical imaging technology.

Fig. 5. The map visually represents global research partnerships, with each country's node colored according to its contribution level. Darker blue nodes represent countries with a higher number of publications, underscoring their significance in the research domain. The red lines connecting the nodes indicate collaborative research activities between countries, with the thickness and density of these lines reflecting the strength and frequency of these collaborations.

Fig. 6. Visualization diagram of a co-citation analysis on a network, limiting the minimum degree of co-citation to two and defining a threshold of 29 network nodes. Each node in this network is identified with the initial author and the year of publication of the relevant paper, while the edges represent co-citation links between publications. The node size corresponds to the number of local citations obtained by the papers, while the edge thickness represents the intensity of the co-citation links. The node color indicates the cluster to which the paper belongs.

The global map highlights India, China, and the USA as central hubs in the research network, with Asia and the USA leading in the frequency of collaborations. However, the map also shows thinner connections in regions like Africa and South America, suggesting lower involvement in this research area and potential opportunities for increased collaboration.

Fig. 6 illustrates the co-citation network, revealing the intellectual structure of AI-based research on ocular disease detection. The network demonstrates a multi-component configuration, consisting of a dominant interconnected core and a smaller isolated cluster, reflecting both established theoretical foundations and emerging research directions. The most central community (red cluster) represents the methodological backbone of the field, anchored by seminal deep learning works such as Simonyan and Zisserman [24], He et al. [25], and

Ronneberger et al. [26]. These foundational studies introduced influential convolutional neural network architectures, including VGGNet and U-Net, and established deep learning principles that underpin contemporary medical image analysis.

Closely connected to this methodological core is the blue cluster, which focuses on applied deep learning in ocular disease detection, particularly diabetic retinopathy. Highly co-cited works within this cluster include Gargeya et al. [27] and Porwal et al. [28], reflecting significant contributions to automated retinal image classification and benchmark dataset development. The purple cluster highlights earlier clinical and computational foundations, notably Abramoff et al. [29], representing traditional automated retinal analysis approaches prior to the widespread adoption of deep learning. The green cluster captures more recent refinements and methodological

advancements, indicating continued innovation in model optimization and application. Additionally, a smaller and relatively isolated orange cluster centers on Gulshan et al. [16], a landmark study on the development and clinical validation of a deep learning algorithm for diabetic retinopathy detection, suggesting a specialized research stream focused on real-world clinical implementation.

D. Analysis of Highly Cited Source

The 4280 documents analyzed were published across 571 different sources, with an average of 6 publications per journal. Among these sources, the Translational Vision Science and Technology journal (30.1%) led the way with 217 papers, followed by Multimedia Tools and Applications (22.4%) with

162 papers, IEEE Access (18.6%) with 134 articles, and Biomedical Signal Processing and Control (16.1%) with 116 articles. Fig. 7 illustrates the publication trends over time in the top five journals in AI-based ocular disease detection research. This trend shows a steady increase in publications across all sources, beginning around 2014. The pace of growth accelerates after 2018, with each source showing a significant rise in cumulative occurrences. By 2025, the data indicate substantial growth across all sources, with Translational Vision Science and Technology demonstrating the highest cumulative occurrences, followed by Multimedia Tools and Applications and IEEE Access. Other journals, such as Computers in Biology and Medicine and Biomedical Signal Processing and Control, also show consistent growth over time.

Fig. 7. Publication trends over time in the top five journals within the field of AI-based ocular disease detection research.

E. Keyword Analysis

1) *Analysis of most relevant keywords:* The authors' keyword terms reflect the article's limitations and its impact on the scientific community. Keyword analysis involves collecting keywords from relevant works within a specific area of study. This tool identifies keywords, analyzes patterns, and highlights research trends. Table II presents the top 15 keywords. To ensure consistency, we merged semantically equivalent or similar terms, such as "DR" and "diabetic retinopathy", as well as "CNN" and "convolutional neural network". From the table, it is evident that diabetic retinopathy, glaucoma, and AMD are the most commonly researched topics in AI-based NCEDs detection. Additionally, techniques like deep learning, image segmentation, and machine learning are frequently utilized in this field. A word cloud visualization was used in this study to represent the most popular author keywords, as shown in Fig. 8. These keywords represent key areas of AI-based ocular disease detection research. The figure suggests that deep learning and machine learning are among the most recommended methodologies and are predominantly used by researchers in AI-based NCEDs detection. In the next section, we will examine the correlation of these words over the past 21 years.

TABLE II. TOP 15 KEYWORDS

Words	Occurrences
diabetic retinopathy	1256
deep learning	809
glaucoma	527
machine learning	262
segmentation	245
fundus image	220
fundus images	217
classification	197
artificial intelligence	187
optical coherence tomography	177
convolutional neural network	165
optic disc	155
transfer learning	148
image processing	145

Fig. 10. Thematic diagram of niche themes, motor themes, basic themes and emerging or declining themes for NCEDs AI-based.

The keywords reveal a strong focus on diabetic retinopathy and deep learning, along with other crucial areas such as glaucoma, optical coherence tomography, and machine learning. This underscores the global emphasis on leveraging AI and advanced computational techniques for the detection and diagnosis of NCEDs. The dense network of connections between countries, sources, and keywords illustrates the highly collaborative and interdisciplinary nature of this research field. The visualization effectively captures the global research ecosystem in this domain, highlighting the key players, publication venues, and the most pressing research topics driving innovation in AI-assisted ophthalmology. This suggests a concerted effort to bridge the gap between theoretical advancements and practical clinical applications.

IV. LIMITATIONS AND BIASES

The study on NCEDs and AI highlights several potential limitations and biases that need to be addressed:

- **Need for Large, Diverse Datasets:** One of the primary limitations is the requirement for large and diverse datasets to train robust AI models. Without these, the models may not generalize well across different populations or imaging equipment, leading to biased outcomes in real-world applications.
- **Generalization Challenges:** Generalizing AI models across diverse demographics and imaging technologies is a significant challenge. This can result in disparities in the effectiveness of AI applications in different settings, which may not be adequately represented in the training data.
- **Clinical Validation:** There is an ongoing need to validate AI systems in real-world settings. Many AI models may perform well in controlled environments but fail to deliver the same results in clinical practice, undermining their reliability and acceptance.

- **Publication Bias:** The study's bibliometric analysis may also be subject to publication bias, where positive results are more likely to be published than negative or inconclusive findings. This can skew perceptions of AI's effectiveness in detecting and managing NCEDs.

V. FUTURE TRENDS OF NCEDS AI-BASED USING THEMATIC ANALYSIS

Based on the thematic analysis, the research landscape of AI-based NCEDs exhibits a clear structural evolution, demonstrating the progressive integration and maturation of artificial intelligence within ophthalmology. Fig. 10 presents a thematic map derived from 20 years of publications, illustrating the distribution of research themes by relevance (centrality) and level of development (density). The diagram reflects a balanced combination of well-established motor themes, foundational basic themes, emerging areas, and specialized niche topics, highlighting both the maturity of core research directions and ongoing innovation in the field.

The motor themes, positioned in the upper-right quadrant, represent highly developed and highly central research areas that drive the field forward. Prominent among these are diabetic retinopathy, deep learning, fundus images, segmentation, and classification. These themes form the backbone of AI-based ophthalmic research, underscoring diabetic retinopathy as a major focus due to its high global disease burden and suitability for image-based screening. Numerous studies have demonstrated the effectiveness of deep learning approaches for diabetic retinopathy detection and classification [30]–[33]. At the same time, machine learning approaches remain relevant for automated diabetic retinopathy analysis [34]–[38]. Hybrid strategies that combine machine learning and deep learning have also been explored to improve classification performance [34], [39]. Collectively, these findings reinforce diabetic retinopathy as a dominant motor theme in AI-based ophthalmic research.

Complementing these core themes, glaucoma, machine learning, and artificial intelligence appear within the basic themes quadrant (lower-right), indicating high relevance but comparatively lower internal development density. This positioning suggests that glaucoma-related AI research serves as a foundational pillar that continues to support and stimulate further methodological advancements. The reliance on machine learning and AI for glaucoma diagnosis highlights their fundamental role across ophthalmic applications, even as research increasingly shifts toward more advanced deep learning frameworks. In addition, multimodal glaucoma screening approaches that combine OCT and fundus imaging further demonstrate the expanding role of AI in structural ocular assessment [40].

The thematic map also identifies niche themes in the upper-left quadrant, including optic disc segmentation, retinal vessel segmentation, and U-Net. Although these topics demonstrate high developmental maturity, their lower centrality indicates a more specialized focus. Structural retinal analysis has long been supported by earlier vessel and optic-disc segmentation studies [41], [42], while more recent optic disc and cup segmentation work has further advanced this line of research [43]. Recent studies employing advanced deep learning architectures, such as two-stage U-Net models, have achieved high performance in optic disc and cup segmentation [44]. Additionally, generative adversarial networks (GANs) have been successfully applied to retinal vessel and optic disc segmentation, further enhancing segmentation robustness and accuracy [45]. These niche themes reflect concentrated innovation within specific diagnostic subtasks.

In contrast, the emerging or potentially declining themes, located in the lower-left quadrant, include keratoconus, OCT, CNNs, and early-stage diabetic retinopathy detection. Their lower density and centrality suggest either nascent research trajectories or areas that are transitioning toward consolidation. Earlier work on keratoconus detection employed fused handcrafted image features and conventional machine learning strategies [46], whereas more recent studies have adopted transfer learning and mobile-based deep learning approaches for keratoconus classification [47], indicating continued growth potential. OCT-related analysis also remains important, particularly in multimodal screening and structural assessment applications, including glaucoma-related imaging studies that combine OCT with fundus photographs [40]. In addition, CNN-based diabetic retinopathy detection studies continue to contribute to the broader development of retinal image classification pipelines [48].

Overall, the updated thematic map illustrates a dynamic and evolving research ecosystem in AI-based ophthalmic diagnostics. While motor themes such as diabetic retinopathy and deep learning continue to dominate, the emergence of advanced attention-based models and related deep learning architectures signals a shift toward increasingly sophisticated image interpretation strategies [49]–[53]. These developments suggest a trajectory toward more accurate, efficient, and scalable diagnostic systems. Future research should prioritize methodological refinement, cross-disease generalization, and standardization of AI-driven diagnostic tools to support broader clinical adoption and translational impact.

VI. CONCLUSION

Research on artificial intelligence for NCED detection has grown substantially from 2004 to 2025, reflecting the increasing adoption of AI in ophthalmic diagnostics. Thematic analysis confirms that diabetic retinopathy, deep learning, fundus image analysis, segmentation, and classification are the dominant motor themes driving the field. Deep learning approaches, particularly convolutional neural networks, have become the prevailing methodology, consistently outperforming traditional image processing techniques in detecting major ocular diseases such as diabetic retinopathy, glaucoma, and age-related macular degeneration. While glaucoma and general AI methodologies remain foundational to the field, more specialized tasks such as optic disc and retinal vessel segmentation represent mature niche areas. Emerging themes, including keratoconus and OCT-based analysis, indicate continued diversification of AI applications in ophthalmology. Despite strong global contributions led by China, India, and the United States, challenges related to data diversity, model generalizability, and clinical validation persist. Future research is expected to focus on multi-disease detection frameworks, explainable AI, and integration with telemedicine platforms. Overall, the continued evolution of AI-driven ophthalmic diagnostics holds significant potential to enhance early detection and reduce the global burden of preventable vision loss.

Abstract—Phishing cyber-hazards, which are a correct cyber threat to audit, monitoring, control, and data acquisition systems in the digitalization environment, are aimed at misleading participants in a complex system and editing personal digitalization data through unauthorized access. In the research work, functioning tables, production rules, algorithmic and mathematical modeling apparatus are used as a foundation for formulating, analyzing, and synthesizing the discrete adaptive behavior of large systems. In the scientific practical research work, phishing identification technologies based on production rules are implemented in solving a scientific problem by integrating access to digitalization resources into control and/or management operations and/or processes. In this research, a set of production rules is created to identify malicious and legitimate resources from URLs, URL features are extracted from a dataset of trusted platforms based on algorithmization, and logical rules are generated from these features; the authenticity of the URLs is then verified using this rule set. The results are compared with other existing models and algorithms, and two different approaches to generating production rules are developed. The study also develops a logical model for building a knowledge base from URL features and demonstrates the representation of malicious attacks through logical implications, conjunctions, and disjunctions. Finally, it tests optimized expressions based on monotone Boolean functions and their perfect disjunctive normal form (CDNF) on an independent test dataset in order to select the most efficient rule system.

Keywords—Petri nets; phishing; production rules; URL; functioning table

I. INTRODUCTION

With the development of cyberspace in the world, the rapid development of digitalization based on production rules, and the continuous development and expansion of big messages and large-scale digitalization of systems, systematic and structurization phishing cyber-hazards are among the cyber threats that affect or weaken the security measures of digitalization and complicated cyber-hazard detection systems, and the emergence of modified cyber hazards with improved attack potential is leading to combined attacks.

These production rules are proposed in the context of attempts or actions to gain unauthorized access to the structure of identification data and passwords of participants in complex cyber systems, which allows cybercriminals to gain access to highly sensitive information such as personal digital data,

financial and economic digital data and other confidential communications based on unclear processing.

Phishing attacks in cyberspace are a modern trend in cyberspace, which is why a serious violation of the confidentiality of personal digital information can lead to unexpected situations, leading to the failure of the architecture of the system and significant economic and/or financial losses. The attacks are aimed at disrupting the dependability of technological procedures and/or disrupting the normal realization of intellectualization and digitalization events. In this event, it is important to guarantee that the mechanisms for controlling and/or managing permission for notes are in places are effective in combining continuous monitoring and/or auditing of security incidents, as well as to take important steps in the algorithmic design and implementation of identification systems. These complex systems can be considered a modern requirement for early detection of phishing attacks, analysis and prevention of their causes, mathematical support for stable system operation, and minimizing the negative effects that occur in complex cyber infrastructures. The identification mechanisms developed in the next step form the scientific and practical basis for the application of simulating and imitation instruments used to evaluate, optimize, and validate key security solutions at the algorithmic design stage before their practical application.

Algorithmic modeling and algorithmization in cyberspace are the expression of security tasks for algorithmic design in modern information protection, the formal basis of protection logic in digital computing systems operations, the optimization of production rules describing system states, events and corresponding security responses, the algorithmization process for phishing-related threats, the decomposition of complicated anti-phishing tasks into elementary functional items, the organization of items into security solutions application of parallel events, synchronization, imitation modeling scientific ways, the generation of optimized rule-based imitation models, the generation of flexible, resilient anti-phishing protection systems, the possibility of visualizing system behavior in various attack scenarios in real cyber environments, supporting simulation and verification procedures.

One of the comprehensive elements with a wide range of coverage for simulating and synthesizing, and analyzing complicated cyber hazards detection systems is a functioning table. It composites ways to structural, graphical, mathematical

and systematic simulating, ensuring a correct definition of adaptive events. The functioning table not only applies as a fundamental for synthesizing the act of permission management structures, but also contributes to the algorithmic simulation or structuring of missions in combination with their construction and development of settings [13, 14].

Composing algorithmic simulating, imitation, and mathematical techniques enables contemporary probability frameworks to generate fixed and highly successful anti-phishing cybersecurity solutions. These actions highlight the importance of joining fundamental structures, conceptual details, and empirical technologies to supply reliable cybersecurity.

II. RELATED WORKS

The dangers of phishing are becoming an increasingly crucial cybersecurity risk, and more research and experiments are focused on constructing techniques to detect, identify, and prevent them. In this context, Petri nets have proven to be a vital tool for simulating, evaluating, and assessing cyberspace-related structures and substructures, such as those related to permission control and/or access control, cybersecurity, and/or information security [10]. This analytical and structural review of scientific and academic sources systematically analyzes and synthesizes various practical-fundamental approaches and ways to implement the identification of cybersecurity [11] sensitive features in cyberspace in a fundamental and innovative way, including the practical and innovative application of Petri nets. Mathematical and logical-algebraic simulation technological methods, along with structural and functional structural analysis or synthesis, are considered to play a key role in the investigation of the mechanisms of sustainable resilience, adaptability, dynamics, management, control and regulation of systems or structures, and the identification and determination of effective strategic actions to reduce the risks of phishing in the structural and structural elements of the system [15]. The fundamental experimental research conducted by Yu, Wangyan, and colleagues (2024) achieves this goal by synthesizing the innovative fundamental application of dynamic adaptive optimal decomposition and colored Petri nets (CPN) in the structural systems of electronic toll collection in digital computing environments installed in cyberspace. In the context of innovative adaptation to the progressively developing implementation characteristics of cyber threats, such as the behavior of phishing attacks in cyberspace, applied-fundamental research supports the demonstration of the practical potential of Petri nets in the formation of descriptions of complex composite structural systems, in which the main fundamental-innovative operations include mathematical logic, adaptively adapting to the dynamic behavior and algorithmic state of implementation. This innovative-fundamental approach technology combines the graphical representation of mathematical networks with the technical practice of dynamic and adaptive decomposition in a modern digital society, which supports the possibility of validating the systematic robustness of a system capable of self-development in various virtual and digital environments. The resulting part of the study supports the understanding of the research mechanisms used in the implementation and identification of potential cyberspace threats based on a deeper synthesis of the current state of the art. Gelen and İçmez (2024)

suggest a Petri net-based treatment for task planning and legal administration of robotic assembly structures [16]. The scientific-fundamental approach to cyberspace research can be significantly expanded to support the implementation of systematic, analytical, automated systematic digitization of composite and combined threats that are considered harmful to the nuclear sphere of cybersecurity, such as phishing, in the form of identification and synthesis of responses. It is experimentally proven that when a threat is detected in cyberspace, the system can be established and adjusted using mathematical tools, maintaining the sequence of each step, while maintaining a consistent and logical connection of each step. Such a research method steadily monotonically increases the structurally generalized complex strength of the system and reduces the probability of successful phishing cyberattacks in cyberspace, which have significant practical damage in practice and are studied [1].

To determine the resilience of access management structures, Yang and Hu (2024) study role-based access control (RBAC) and restriction enforcement [17]. Researchers are performing research analysis and synthesis with the aim of providing the ability to implement Petri nets in mathematical logic as well as fundamental mathematical programming, in order to demonstrate that such structured systems can withstand various cyberthreats in cyberspace, such as phishing cyberattacks, while maintaining their adaptiveness. Here, the scientific research work provides support for the algorithmic implementation of complex logical strict constraints that restrict access and permissions to confidential data within the structured system, only to authorized participants, which is an algorithmic logical critical measure for identifying and protecting against cyber threats with complex phishing dependencies occurring in cyberspace.

Liu (2024) studies the opacity testing of archival structures utilizing constrained Petri net labels, which is relevant for providing that sensitive messages in archival structures are protected from unauthorized access. This innovative scientific research specifically applies the correct sequence of actions to malicious phishing and composite threats in cyberspace that attempt to trick participants in a structured system into disclosing mathematically-based authentication digital information to control access to electronic business data resources or stored confidential data repositories [18].

Anguiano-Gijón et al. (2024) scientifically study a series of algorithmic regulations and regulative management strategies based on Petri nets, while preserving the mathematical essence of their implementation in complex automated information systems in cyberspace [19]. Their scientific and innovative research introduces a scientific and innovative approach to the implementation of dynamic regulatory management mechanisms capable of monitoring the complex state of the system and responding to potential threats in cyberspace in an efficient and algorithmic manner.

The use of Petri nets to imitate cyber-hazards is extended by Petty et al (2024), who ensure practical instruments for imitating the dynamics of phishing and other forms of adversarial action [20]. Innovative-fundamental research can be aimed at improving Petri nets in a logical sequence, optimally minimizing

the development of systems with structural performance capabilities that perform proactive and active protection measures against phishing in cyberspace, using innovative-mathematical methods, cyclically repeating the progressive spread of cyberthreats and, in this case, supporting the empirical assessment of the effective impact on the functions of the generalized structural system [2].

Yang et al (2024) investigate a dynamic or adaptive Petri net-based approach to structure message safety [21]. The authors' collective ideological idea is that the identification systems of cybersecurity threats based on Petri nets using mathematical tools can effectively and rationally solve phishing and other complex cyber threats with minimal effort in the digital and cyberspace environment, while maintaining the inherent, self-algorithmic nature of cyberspace, and achieve a sufficiently progressive level of scientific and innovative development. In this context, there is a strong need for methods of structural protection of communication in real time, which are stable in dynamic changes depending on the conditions, without violating the sequence, while maintaining the sequence. Scientific and innovative research shows that modern digital security models need to be in a sequence of flexible and adaptive control in cyberspace, which supports them in identifying and reactively responding to fundamentally progressive phishing identification and attack techniques [3].

The reliability and robustness of intelligent digital transport automated structural systems in cyberspace have been scientifically and innovatively studied using the important generalized stochastic Petri nets in empirical studies. This technological method provides a sequence of concepts for the algorithmic development and adaptive control of complex cyber threats [7-9] that cause damage to cyberspace, such as phishing and trust-based cyberattacks with a strong damage domain. In the era of the digital economy, it emphasizes the need for systems to dynamically self-adjust to optimally respond to threats effectively by analyzing and/or synthesizing multiple cyberspace cyber threat scenarios [4-6].

III. PROBLEM STATEMENT

In the modern cyberspace environment, the progressive increase in the volume of data and the complexity of the algorithmic nature of the structured system in digital security and ecosystems has systematically increased the level of phishing cyber-risk in terms of the importance of digitization, which creates a significant optimization in the regulation of the infrastructure for protecting and eliminating risks, auditing, monitoring and managing complex structured confidential information. The foundation of cyber-hazards in this category of cyberspace is aimed at generating the ability of legitimate structure participants to gain unauthorized permission and bypass the authentication event, in an algorithmic sequential manner based on event imitation and architectural analysis, allowing attackers to gain unauthorized access to confidential digital data that should be kept confidential, such as personal and/or financial data. The algorithmic nature of digital data corruption, operational disruptions, and structural duplications, and widespread financial losses often result in operational

failures and structural duplications, highlighting the importance of robust cyberspace defense strategies and approaches that operate reactively.

In order to create immunity to cyberspace threats, modern web systems include the ability to detect sensitive phishing in cyberspace in an algorithmic manner directly into authorization and access control systems. In such a situation, it is appropriate to implement comprehensive and multi-criteria modeling and technological tools that are based on the fundamental basis of functional table-graph, structural, algorithmic, logical, and mathematical theories. The fundamental basis for the digital representation of complex structural systems in cyberspace in a coordinate system is generated, which allows for the analysis and synthesis of dynamic events in adaptive conditions, which is involved in the regulatory management and control of digital security.

Building effective, optimized, and reactive anti-phishing mechanisms relies on a sophisticated, structured algorithmic approach to access control and digital security auditing and monitoring procedures in cyberspace. This sophisticated, structured approach supports early detection of malicious algorithmic activity, progressively reduces the negative impact on complex systems in cyberspace, and supports simulation and modeling technology in the structural design of algorithmic digital protection solutions. Algorithmic modeling and algorithmization are essential for creating reliable cybersecurity solutions between the theoretical problem description and the practical-innovative implementation of abstract security problems into clearly defined algorithmic computational stages. The versatile analytical tool, the functional table, shows the possibility of evaluating and configuring access control systems by accurately recording their dynamic behavior, and its application in cybersecurity research is based on dynamic system analysis and mathematical modeling, as well as algorithmic sequencing of phishing attacks in advanced digital environments.

IV. ARCHITECTURE AND MATHEMATICAL FORMALIZATION OF THE RESEARCH PROCESS

Our chosen dataset is <https://gregavrbancic.github.io/Phishing-Dataset/>. Fig. 1 illustrates the architecture for detecting or identifying phishing attacks based on the digital informational features of suspicious web-links, which consists of several main stages. First, web page data is collected, and then important informational features are extracted from the digital information in these pixels. The extracted digital features are analyzed and synthesized using algorithms to classify the web link as "trustworthy" or "phishing".

This cycle usually consists of several stages. Initially, the attacker creates a fake website or deceptive content, and then these fake web resources are distributed to users through communication channels, causing system participants to believe the messages. When they click on fake links, after being redirected to a fake web link, the attacker obtains this information and uses it for illegal purposes (see Fig. 2).

Fig. 1. A structural framework for identifying phishing attacks using visual characteristics extracted from suspicious websites [22].

Fig. 2. The sequential stages illustrating the life cycle of a phishing attack [22].

Fig. 3. The architectural design of the intelligent phishing detection system (IPDS) [22].

This structure consists of several components in an interconnected cyberspace environment, where, in the initial stage, incoming digital data is collected from various sources (websites, URLs, user queries, and other data). In this cyberspace, the digital data is pre-processed, and important informative features and extracted informative features are transferred to a knowledge base, where, based on pre-formed production rules and experience, the system's inference mechanism makes a decision to classify a website or link as "safe" or "phishing" based on the available knowledge (see Fig. 3).

Fig. 4. Phishing attack diagram [22].

The phishing attack involves the attacker and the system participant entering confidential digital information to redirect to a fake web page by clicking on a link. The attacker uses this digital information for illegal purposes in the last part of the diagram. This usually involves an attacker creating a fake website or service that looks very similar to the original site, intended to mislead the intended user (Fig. 4).

The functioning table is represented through a formal mathematical framework [24, 36, 37]:

$$FT = (P, T, F, W, \mu_0, F_x, F_y)$$

where,

- P : a finite set of places
- T : a finite set of transitions
- F : a set of directed arcs connecting places and transitions
- W : a weight function that assigns positive integer values to arcs
- μ_0 : the initial distribution of tokens across the places
- F_x : a set of coordinates corresponding to the x-axis of the functioning table
- F_y : a set of coordinates corresponding to the y-axis of the functioning table.

In the simulation of coordinated actions in cyberspace, the dynamic behavior of the functional table is regulated by the transition rules and a validation procedure is performed. In cyberspace, the transition is activated in the active state when all the input points satisfy the necessary and sufficient conditions. Once these necessary and sufficient conditions are met in the environment, the transition from the point of view of digitization begins in a sequential manner, where the subsequent algorithmic essence of the tokens leads to the movement (or generation) of positions (Table I and Table II). To activate this phenomenon in an algorithmic structural way, the procedure is performed to ensure the progressive development of the states within the system when there is a real number of input function positions [26, 27].

TABLE I. POSITIONS (P)

№	Positions(p)	Description
1	p_1	Login request has been initiated
2	p_2	Phishing analysis has been carried out
3	p_3	A phishing attempt has been identified
4	p_4	No phishing activity has been found
5	p_5	The authentication process is in progress
6	p_6	User authentication has been successfully completed
7	p_7	Authentication attempt has failed
8	p_8	Access has been approved
9	p_9	Permission rejected

TABLE II. TRANSITIONS (T)

№	Transitions(t)	Description
1	t_1	The user initiates the process by submitting a request to log into the system.
2	t_2	At the same time, the procedure for detecting potential phishing activity is activated.
3	t_3	If any suspicious phishing-related indicators are identified, the system flags them accordingly.
4	t_4	On the other hand, if no signs of phishing or malicious behavior are found, this is also confirmed by the system.
5	t_5	Following this, the authentication phase begins.
6	t_6	The system carefully examines and validates the provided login credentials.
7	t_7	In cases where the credentials are incorrect or do not match the stored data, access is denied and an error is returned.
8	t_8	However, if all the entered information is accurate and successfully verified, the user is granted access to the system.
9	t_9	Ultimately, the system either approves the login attempt by granting permission or rejects it by denying access.

Incident Matrix:

$$W^- = \begin{matrix} p_1 \\ p_2 \\ p_3 \\ p_4 \\ p_5 \\ p_6 \\ p_7 \\ p_8 \\ p_9 \end{matrix} \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \begin{matrix} t_1 \\ t_2 \\ t_3 \\ t_4 \\ t_5 \\ t_6 \\ t_7 \\ t_8 \\ t_9 \end{matrix} \quad (1)$$

V. EXPERIMENTAL RESULTS

The presented scientific-innovative research work creates a number of innovative structural experimental findings that confirm the mathematical reliability and algorithmic consistency of the algorithmic model of regulatory management and/or regulatory control of permissions and access in a structural manner [12]. The functional table is built around the basis of mathematical logic and algebra, and the algorithmic nature of the mechanisms of detection and identification of phishing attacks in cyberspace is comprehensively evaluated by the model. The analysis and synthesis of the results showed that the algorithmic design approach works in a mathematically reliable implementation in cyberspace in a series of virtual digital conditions that have undergone a series of experimental tests, where the structural effectiveness of the algorithmic sequence in detecting attempts of algorithmic nature, such as phishing, is confirmed, while supporting a digitally secure and permission-controlled access to the structural system (see Fig. 5)[28, 30].

$$\begin{aligned} \mu_1 &= (1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0) \\ &\quad \downarrow t_2 \\ \mu_2 &= (0 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0) \\ &\quad \downarrow t_3 \\ \mu_3 &= (0 \ 0 \ 1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0) \\ &\quad \downarrow t_4, t_7 \\ \mu_4 &= (0 \ 0 \ 0 \ 0 \ 1 \ 0 \ 1 \ 0 \ 0) \\ &\quad \downarrow t_5, t_9 \\ \mu_5 &= (0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0 \ 0 \ 1) \\ &\quad \downarrow t_6 \\ \mu_6 &= (0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 1) \end{aligned} \quad (5)$$

Fig. 5. The initial status of designing the imitation model based on the fundamental principles of the functioning table.

The fundamental algorithmic challenge in the functional table is to accurately represent the structural changes between the coordination links of positions and transitions in cyberspace, as well as the algorithmic nature of the transitions to positions in a precise sequence [38, 39]. This complex task involves the implementation of a validation check of the algorithmic and structural consistency and structural correctness of the dynamic changes of the state in a fundamentally sound situation. This is achieved by applying the supported feasibility analysis and synthesis, which are introduced to systematically verify the algorithmic stability, structural accuracy, and mathematical reliability of the constructed algorithmic model [34, 35] (see Fig. 6 to Fig. 11).

Fig. 6. $\mu_1 = (1\ 0\ 0\ 0\ 0\ 0\ 0\ 0)$ status of designing the imitation model based on the fundamental principles of the functioning table.

Fig. 11. $\mu_6 = (0\ 0\ 0\ 0\ 0\ 0\ 1\ 1)$ status of designing the imitation model based on the fundamental principles of the functioning table.

To generate a production rule set, URL features are extracted from datasets recorded from trusted platforms. Using the extracted features, a production rule set is generated. Based on these rules, the URL dataset is checked for authenticity or falsification. Verification results of other studied models and algorithm results are compared.

We propose two approaches to generating rules based on URL features. In approach 1, a set of rules is generated based on each of the N datasets. Then, the generated N sets of rules are combined. Using the generated set of rules, the N datasets are checked for authenticity or falsity. As a result of the verification, the rules that performed best in each dataset are combined to generate a final set of rules. A visual representation of this approach is shown in Fig. 12.

Fig. 12. Approach 1 for generating a rule set.

In approach 2, the remaining datasets are checked for real or fake URLs based on the rule sets generated from each of the N datasets. After checking, the rules in each dataset that achieve high performance are extracted. These rules form the final overall rule set. A visual representation of this approach 2 is shown in Fig. 13.

Fig. 13. Approach 2 for generating a rule set.

Fig. 14. Structure of building a knowledge base of URL features.

The final step of our proposed method is to test a completely different URL dataset using both approaches. The set of rules that performs best is selected.

In the digital era and digital economy, information and communication digitization technologies have been deeply embedded in almost all fundamental scientific aspects of everyday life in a comprehensive algorithmic sequence (Fig. 14). The progressive rapid development of digital technologies in this cyberspace coordination creates a large-scale opportunity to solve algorithmic problems of cybersecurity in important objects such as digitized diplomacy and medicine, logical problems related to the structural processing of large-scale digital data and algorithmic regulatory management and control. In the digitalization environment, data collection, processing, algorithmic analysis and synthesis directly affect the overall level of security in cyberspace [25]. It is necessary to conduct in-depth research on the coordination of cyberattacks in cyberspace and conduct experimental analytical studies. In this context, the production logic knowledge base for identifying and classifying specific structural categories of cyberthreats in algorithmization is examined algebraically and systematically [29, 31]. Here, the corresponding algebraic logical functions can be expressed in a formalized form in the elements of mathematical logic:

$$(X_i \rightarrow Y) \equiv 1, \quad i = \overline{1, n}$$

$$((X_i \wedge X_j) \rightarrow Y) \equiv 1, \quad i, j = \overline{1, n}, i \neq j$$

$$((X_i \wedge X_j \wedge X_k) \rightarrow Y) \equiv 1, \quad i, j, k = \overline{1, n}, i \neq j \neq k$$

$$((X_{i_1} \wedge X_{i_2} \wedge \dots \wedge X_{i_k}) \rightarrow Y) \equiv 1, \quad i_1, i_2, \dots, i_k = \overline{1, n}, i_1 \neq i_2 \neq \dots \neq i_k, 1 \leq k \leq n$$

$$(X_1 \vee X_2 \vee \dots \vee X_n) \rightarrow Y \equiv 1$$

$$(X_i \vee X_j) \rightarrow Y \equiv 1, \quad i, j = \overline{1, n}, i \neq j$$

$$((X_i \vee X_j \vee X_k) \rightarrow Y) \equiv 1, \quad i, j, k = \overline{1, n}, i \neq j \neq k$$

$$((X_{i_1} \vee X_{i_2} \vee \dots \vee X_{i_k}) \rightarrow Y) \equiv 1, \quad i_1, i_2, \dots, i_k = \overline{1, n}, i_1 \neq i_2 \neq \dots \neq i_k, 1 < k < n$$

$$(X_1 \vee X_2 \vee \dots \vee X_n) \rightarrow Y \equiv 1$$

In the modern era of development, it is important to research, synthesize and algorithmically analyze cybersecurity issues on a scientific and innovation basis. This includes developing plans to safe cyberattacks on critical information infrastructure facilities and their direct implementation, regulating the activities of cybersecurity agencies, independent special services and teams, interacting with right enforcement agencies in the field of combating cyberthreats, and informing status and financial management bodies [23]. One of the fundamental basic problems of cybersecurity is identification, and application of Production Logic [32, 33]. You are able to define a cyber-hazard in the formalization of algebraic-logical functions:

F1

$$= x_1 \wedge \overline{x_2} \wedge \overline{x_3} \wedge \overline{x_4} \wedge x_5 \wedge \overline{x_6} \wedge \overline{x_7} \wedge x_8 \wedge x_9 \vee x_1 \wedge \overline{x_2} \wedge \overline{x_3} \wedge \overline{x_4} \wedge x_5 \wedge \overline{x_6} \wedge x_7 \wedge \overline{x_8} \wedge \overline{x_9} \vee$$

$$\begin{aligned}
 & \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge \bar{x}_6 \wedge x_7 \wedge \bar{x}_8 \wedge x_9 \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge \bar{x}_6 \wedge x_7 \wedge x_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge \bar{x}_6 \wedge x_7 \wedge x_8 \wedge x_9 \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge x_6 \wedge \bar{x}_7 \wedge \bar{x}_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge x_6 \wedge \bar{x}_7 \wedge \bar{x}_8 \wedge x_9 \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge x_6 \wedge \bar{x}_7 \wedge x_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge x_6 \wedge \bar{x}_7 \wedge x_8 \wedge x_9 \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge x_6 \wedge x_7 \wedge \bar{x}_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge x_6 \wedge x_7 \wedge \bar{x}_8 \wedge x_9 \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge x_6 \wedge x_7 \wedge x_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge \bar{x}_4 \wedge x_5 \wedge x_6 \wedge x_7 \wedge x_8 \wedge x_9 \vee x_1 \wedge \bar{x}_2 \wedge \bar{x}_3 \wedge x_4 \wedge \bar{x}_5 \wedge \bar{x}_6 \wedge \bar{x}_7 \wedge \bar{x}_8 \wedge \bar{x}_9 \vee \dots \vee \\
 & \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge \bar{x}_6 \wedge x_7 \wedge x_8 \wedge x_9 \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge x_6 \wedge \bar{x}_7 \wedge \bar{x}_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge x_6 \wedge \bar{x}_7 \wedge \bar{x}_8 \wedge x_9 \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge x_6 \wedge \bar{x}_7 \wedge x_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge x_6 \wedge \bar{x}_7 \wedge x_8 \wedge x_9 \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge x_6 \wedge x_7 \wedge \bar{x}_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge x_6 \wedge x_7 \wedge \bar{x}_8 \wedge x_9 \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge x_6 \wedge x_7 \wedge x_8 \wedge \bar{x}_9 \vee \\
 & \vee x_1 \wedge x_2 \wedge x_3 \wedge x_4 \wedge x_5 \wedge x_6 \wedge x_7 \wedge x_8 \wedge x_9.
 \end{aligned}$$

E_{n-k}^2 – to the cube $n - k$ we get a cube of the size of a part. E_{n-k}^2 in this cube $\alpha_{i_1}, \alpha_{i_2}, \dots, \alpha_{i_k} \in \{0,1\}$ and they are invariant, $E_{n-k}^2(\alpha_{i_1}, \alpha_{i_2}, \dots, \alpha_{i_k})$ the vector vertices are formed according to the remaining coordinates. $|E_{n-k}^2|$ – we obtain an invariant three-dimensional vector interval. Here $(\beta_1, \beta_2, \dots, \beta_n), \beta_i \in \{0,1,2\}, i = 1, 2, \dots, n$; $\beta_{i_1} = \alpha_{i_1}, \beta_{i_2} = \alpha_{i_2}, \dots, \beta_{i_k} = \alpha_{i_k}$, the remaining β_i ones are equal to 2. We write an elementary conjunction corresponding to this interval:

$$x_{i_1}^{\alpha_{i_1}}, x_{i_2}^{\alpha_{i_2}}, \dots, x_{i_k}^{\alpha_{i_k}}$$

This elementary conjunction $E_{n-k}^2(\alpha_{i_1}, \alpha_{i_2}, \dots, \alpha_{i_k})$ corresponds to the vector vertices of the partial cube.

$F1$ domain of the function is E_{13}^2 the cube of $(1,2,2,2,2,2,1,1,1,2,2,2), (1,2,2,2,2,2,1,1,2,1,2,2), (1,1,2,2,2,2,2,2,2,2,2,2), (1,2,1,2,2,2,2,2,2,2,2,2), (1,2,2,1,2,2,2,2,2,2,2,2), (1,2,2,2,1,2,2,2,2,2,2,2), (1,2,2,2,2,1,2,2,2,2,2,2)$ corresponds to the vector nodes of the cube of the part. $F1$ CDNF (complex disjunctive normal form) form of the function is given in the space E_{13}^2 , the first interval of the cube corresponds $(1,2,2,2,2,2,1,1,1,2,2,2)$ to $x_1 \wedge x_8 \wedge x_9 \wedge x_{10}$ the conjunction, the second interval $(1,2,2,2,2,2,1,1,2,1,2,2)$ to the conjunction $(1,1,2,2,2,2,2,2,2,2,2,2)$, the third $x_1 \wedge x_8 \wedge x_9 \wedge x_{11}$ interval to the conjunction, $(1,2,1,2,2,2,2,2,2,2,2,2)$ the $x_1 \wedge x_2$ fourth $x_1 \wedge x_3$ interval $(1,2,2,1,2,2,2,2,2,2,2,2)$ to $x_1 \wedge x_4$ the conjunction, the fifth interval $(1,2,2,2,1,2,2,2,2,2,2,2)$ to the $x_1 \wedge x_5$ conjunction, the sixth interval to the conjunction, the seventh interval $(1,2,2,2,2,1,2,2,2,2,2,2)$ to $x_1 \wedge x_6$ the conjunction, and the eighth interval $(1,2,2,2,2,2,1,2,2,2,2,2)$ to $x_1 \wedge x_7$ the conjunction.

It is known that, $F1$, the function corresponds to a monotone Boolean function and its optimized form is:

$$F1 = x_1 \wedge x_8 \wedge x_9 \wedge x_{10} \vee x_1 \wedge x_8 \wedge x_9 \wedge x_{11} \vee x_1 \wedge x_2 \vee x_1 \wedge x_3 \vee x_1 \wedge x_4 \vee x_1 \wedge x_5 \vee x_1 \wedge x_6 \vee x_1 \wedge x_7.$$

In this research work, the optimization of Boolean functions serves to improve the inference mechanism using minimal classical Boolean functions for existing algorithms, while the formalization of the knowledge base based on production logic is important for the exploration of the dataset with localization,

the formalization of the general knowledge base and the modeling of phishing attacks and identification processes using the Functioning table is important for the analysis and synthesis of dynamic characteristics compared with existing researches, and the integration with systems operating in dynamic and real modes is realized.

VI. CONCLUSION AND FUTURE WORK

With the growing volume of data in cyberspace, combating phishing attacks will become a key challenge in ensuring cybersecurity in complicated cyberspace identification systems, as phishing cyber-hazards violate the confidentiality of digital data, disrupt system operations, and subsequently lead to significant economic losses. Therefore, this study developed a set of rules for identifying malicious and legitimate resources based on URLs. Using algorithms, URL characteristics were extracted from a dataset of trusted platforms, and logical rules were generated based on these characteristics. The authenticity of URLs was then verified using this set of rules, and the results were compared with other existing models and algorithms, resulting in two different approaches to generating inference rules. This study developed a logical model for constructing a knowledge base based on URL characteristics and demonstrated the representation of malicious attacks through logical implications, conjunctions, and disjunctions. The program tests optimized expressions based on monotone Boolean functions and their perfect disjunctive normal form (CDNF) on an independent test dataset to select the most effective rule system. Using function tables and algorithmic modeling, it enables efficient generation, analysis, and development of solutions to protect systems from phishing attacks. The most important contribution of the research work is the novelty of bringing it to the form of production rules and thereby reducing the complexity of the algorithm by reducing the informative features. Ultimately, it proves to provide an accelerated response in detecting and filtering phishing.

Abstract—The rapid expansion of Internet of Things (IoT) deployments has increased the exposure of interconnected devices to cyber threats, particularly in heterogeneous and resource-constrained environments. Although recent research increasingly emphasizes learning-based detection, classical intrusion detection system (IDS) paradigms remain widely deployed in practical IoT settings due to their interpretability, deterministic behavior, and low computational overhead. This study presents a systematic literature review focused exclusively on classical IDS for IoT environments, including signature-based, anomaly-based, specification-based, and hybrid classical approaches. Following PRISMA-aligned procedures, peer-reviewed studies published between 2021 and 2026 were identified, screened, and synthesized using qualitative comparative analysis. The review examines detection principles, deployment contexts, datasets, evaluation practices, and reported limitations across the classical paradigms. The findings indicate that classical IDS continues to function as a baseline defensive mechanism, particularly at gateway and edge levels. However, persistent challenges remain, including limited capability against zero-day attacks, high false-positive behavior in dynamic environments, scalability constraints, rule maintenance overhead, and restricted adaptability to evolving IoT behavior. This study contributes a consolidated taxonomy and evidence-based analysis of classical IDS deployment characteristics in IoT environments, providing a validated baseline for future intrusion detection research and evaluation.

Keywords—Internet of Things (IoT); intrusion detection system (IDS); deep learning (DL); metaheuristic optimization; systematic literature review (SLR); IoT security

I. INTRODUCTION

The Internet of Things (IoT) has become a critical component of modern digital infrastructure by interconnecting sensors, smart appliances, healthcare devices, industrial controllers, and autonomous platforms. These systems continuously exchange data across distributed networks to support monitoring, automation, and real-time services. However, IoT environments are highly heterogeneous and resource-constrained, and many devices operate with minimal built-in security. Weak authentication mechanisms, insecure configurations, and unattended deployment conditions make IoT networks attractive targets for cyber attackers. Recent studies report that IoT infrastructures are frequently compromised through malware propagation, botnet

recruitment, and distributed denial-of-service attacks [1], [8], [29], [37]. For this reason, intrusion detection systems (IDS) have become an essential defensive mechanism for monitoring traffic behavior and identifying malicious activity in IoT networks [22], [35].

Conventional IDS were originally designed for enterprise environments and rely on signature matching or statistical anomaly detection. Signature-based detection identifies known attack patterns but cannot detect previously unseen threats. Anomaly-based detection can recognize abnormal behavior, yet it often produces high false positive rates under dynamic traffic conditions. Specification-based detection depends on manually defined rules and becomes difficult to maintain in large-scale distributed environments [22], [26], [35]. Empirical investigations show that these classical approaches struggle to handle evolving attack patterns and high-volume IoT communication, resulting in unstable detection performance [10], [11], [21].

To overcome these limitations, the investigation of intrusion detection is shifting toward data-driven learning methods. Machine learning (ML) and deep learning (DL) techniques can handle network traffic directly and recognize malicious behavior without predefined signatures [16], [24]. DL has received special interest because, by automating the top-down learning steps of neural networks, it can learn hierarchical representations of features in complex traffic data.

Various neural networks express network behavior in diverse ways. The spatial traffic patterns are also described by convolutional neural networks (CNN), and temporal dependencies and the evolution of the attacks are accounted for by recurrent neural networks (RNN) and long short-term memory (LSTM) models [17], [23]. Hybrid architectures, such as CNN-LSTM and CNN-GRU, integrate spatial and temporal aspects; the latter, for example, show enhanced detection of botnet and denial-of-service attacks (DDoS) [1], [8], [19]. DL also minimizes manual feature engineering by automatically extracting the relevant features from network traffic [20], [23], thus explaining the dominance of DL in recent intrusion detection research [12], [34].

Despite detection improvement, deep learning-based IDS can be challenging to deploy. Moreover, deep neural networks (DNNs) require significant computing resources and memory,

*Corresponding author.

restricting their suitability in resource-constrained IoT environments, as well as edge devices [18], [21], [22]. Furthermore, the detection performance is sensitive to hyperparameter settings and characteristics of datasets, which may induce overfitting or unstable performance under diverse network conditions [26], [30].

Recently, metaheuristic optimization methods were applied to facilitate the detection of intrusions to improve the efficiency and reliability of detection. To minimize dimensionality and further stabilize convergence, optimization methods like particle swarm optimization (PSO) and genetic algorithms (GA) have been applied for feature selection and hyperparameter tuning [3], [9], [31], [32]. Hybrid learning-optimization methods typically achieve superior detection accuracy and lower false-alarm rates relative to standalone DL models [3], [9], [14]. However, there exist few standardized integration strategies and real-world deployment evaluations [11], [29], [33].

Another important consideration is the deployment location of the IDS within the IoT architecture. Due to the constrained computational capabilities of the devices, IDS are widely located at the edge or gateway layer of the architecture in many studies. Monitoring aggregated traffic at these layers enables the system to examine device behavior while avoiding the heavy computational burden of device-level inspection [22], [29]. This deployment concept is illustrated in Fig. 1.

Hence, this study presents a systematic literature review of DL and optimization-driven IDS for IoT security. The review analyses detection approaches, examines commonly used DL architectures, investigates the role of metaheuristic optimization, evaluates datasets and experimental practices, and identifies unresolved challenges. The aim is to provide a structured understanding of hybrid learning, optimization, intrusion detection, and to support the development of adaptive and scalable security frameworks for IoT environments [1], [3], [9], [14].

Fig. 1. Typical IoT network architecture and IDS placement in gateway and edge layers based on deployment practices reported in the reviewed studies [22], [29].

The remainder of this study is organized as follows: Section II presents the systematic review methodology, including the review protocol, search strategy, selection criteria, data extraction, and quality assessment. Section III reports the results and discussion, providing statistical summaries, comparative analysis of the reviewed studies, and identification of research gaps. Section IV concludes the study and highlights potential directions for future research.

II. MATERIALS AND METHODS

This section describes the systematic literature review procedure adopted in this study. A structured and reproducible protocol was applied to ensure that study identification,

screening, and analysis were conducted consistently. The review process includes background scope definition, review protocol, database search, selection criteria, PRISMA screening, quality assessment, data extraction, and qualitative synthesis.

A. Background of the Study

In this review, we explore intrusion detection research that utilizes learning- and optimization-based approaches for IoT environments. Gradually going from rule-based detection to data-driven analysis of network behavior is reflected in several recent publications published. Several works employ ML and DL based models rather than predefined signatures and manually defined thresholds, and methods of optimization are

integrated into these models to refine feature selection and model configuration [2], [3], [9].

There has already been research on neural architectures like convolutional and recurrent networks to analyze the IoT traffic, and metaheuristic algorithms used to reduce feature redundancy and improve model stability are commonly used to solve the problem [16], [17], [24]. However, the literature on modelling strategies, datasets, and evaluation practices is mixed. As a result, it is challenging to get a holistic view of how the learning and optimization interact in intrusion detection systems.

For that reason, a systematic literature review is necessary to organize the evidence, classify the proposed approaches, and identify consistent research patterns and limitations. The review, therefore, focuses on hybrid learning–optimization intrusion detection frameworks combining behavioral modelling with performance enhancement mechanisms.

B. Systematic Review Literature Protocol

This research applies a systematic literature review approach to explore DL and optimization-driven IDS for IoT security. A systematic review was chosen to ensure a transparent, reproducible, and unbiased overview of pre-existing research findings. The review procedure follows PRISMA-based guidelines and consists of research question formulation, search strategy definition, study selection, quality assessment, data extraction, and evidence synthesis, as illustrated in Fig. 2.

Fig. 2. PRISMA-aligned SLR protocol adopted in this study, illustrating the stages of research question formulation, search strategy definition, study selection, quality assessment, data extraction, and evidence synthesis.

1) *Research questions*: The review is guided by specific research questions designed to structure the investigation and ensure that the analysis remains aligned with the objectives of the study. The research questions are presented in Table I.

TABLE. I. RESEARCH QUESTIONS

RQ	Research Question	Purpose
RQ1	What intrusion detection approaches are used in IoT security research?	Identify detection paradigms and modelling techniques
RQ2	What DL architectures are applied in IoT intrusion detection?	Examine DL model usage and capabilities
RQ3	How are optimization algorithms integrated into IDS?	Analyze optimization roles such as feature selection and tuning
RQ4	What datasets and evaluation practices are used to validate IDS performance?	Assess experimental methodology and reliability
RQ5	What research gaps exist in hybrid learning-optimization intrusion detection?	Identify unresolved challenges and future directions

2) *Search strategy*: A comprehensive literature search was conducted to identify relevant studies. The search was retrieved from major scientific databases, including IEEE Xplore, ScienceDirect, SpringerLink, ACM Digital Library, Scopus, and Elsevier, as illustrated in Fig. 3. These databases were selected because they index most peer-reviewed publications in cybersecurity, networking, and artificial intelligence research.

Fig. 3. Applied scientific libraries.

Search strings were constructed by combining keywords related to IoT, intrusion detection, DL, and optimization. Boolean operators were used to improve search accuracy. Examples of search expressions include:

- IoT IDS
- Deep learning IDS IoT
- CNN LSTM intrusion detection
- Metaheuristic optimization intrusion detection hybrid IDS IoT security

The search covered publications between 2021 and 2026 to capture recent developments in learning-based and optimization-driven IDS.

3) *Study selection criteria*: To ensure relevance and quality, predefined inclusion and exclusion criteria were applied during screening. The criteria are summarized in Table II.

The inclusion criteria ensured that only primary studies proposing or evaluating learning-based or optimization-driven IDS in IoT environments were considered. The exclusion criteria removed studies unrelated to intrusion detection, purely cryptographic security solutions, and non-research publications. This filtering process helped maintain methodological consistency and reduced bias in the systematic review.

4) *PRISMA selection process*: The study selection process was conducted systematically and transparently using predefined inclusion and exclusion criteria to identify relevant and reliable studies on DL and optimization-driven IDS for IoT environments. The procedure aligns with the PRISMA-aligned screening strategy widely used in recent IoT intrusion detection surveys, along with systematic cybersecurity

reviews [2], [3], [11]. The overall screening and eligibility workflow used to obtain the final set of studies is illustrated in Fig. 4.

TABLE. II. INCLUSION AND EXCLUSION CRITERIA USED IN STUDY SELECTION

Category	ID	Criterion	Description / Purpose
Inclusion	IC1	Publication Type	Peer-reviewed journal articles or conference proceedings
	IC2	Research Domain	Focus on intrusion detection in IoT or IoT-related networks
	IC3	Methodology	Applies deep learning, machine learning, with optimization, or metaheuristic optimization techniques
	IC4	Evaluation	Provides experimental validation, simulation, or comparative performance analysis
	IC5	Accessibility	Full text available in English
Exclusion	EC1	Irrelevant Domain	Studies not related to IoT security or intrusion detection
	EC2	Security Scope	Works focusing only on cryptography, authentication, or access control without an IDS component
	EC3	Publication Type	Editorials, opinions, tutorials, or non-research articles
	EC4	Approach	Traditional rule-based IDS without learning or optimization techniques
	EC5	Redundancy	Duplicate publications or extended versions of the same study

Fig. 4. PRISMA-based study selection process showing identification, screening, eligibility assessment, and final inclusion of primary studies on deep learning and optimization-driven intrusion detection systems for IoT security.

The identification stage retrieved 1,248 records from the selected databases. After screening and removing duplicates, 936 unique studies remained. Title and abstract screening excluded irrelevant papers, leaving 284 articles for full-text assessment. During the eligibility stage, studies that did not apply DL or optimization techniques, lacked experimental validation, or were unrelated to IoT intrusion detection were removed. After this evaluation, 38 primary studies were included in the review. Structured data extraction was then performed to record detection approaches, learning models, optimization methods, datasets, and evaluation metrics for comparative analysis.

5) *Quality assessment*: To ensure the reliability and validity of the selected primary studies, a quality assessment procedure was performed after the eligibility stage. Quality appraisal is an essential step in systematic literature reviews because the inclusion of low-quality or weakly validated studies may bias the synthesized conclusions. Previous systematic reviews in IoT intrusion detection and cybersecurity research emphasize that methodological evaluation is necessary to confirm that selected studies provide verifiable experimental evidence and reproducible findings [2], [3], [11].

Each included study was evaluated using five predefined quality criteria focusing on methodological clarity, experimental validation, and reporting transparency. The assessment criteria are presented in Table III.

TABLE. III. QUALITY ASSESSMENT CRITERIA

Criterion ID	Assessment Question	Evaluation Purpose
Q1	Is the intrusion detection approach clearly described?	Ensures methodological clarity and reproducibility
Q2	Is an appropriate dataset used for evaluation?	Confirms experimental relevance to IDS research
Q3	Is experimental validation provided?	Verifies that the method is empirically tested
Q4	Are performance metrics reported?	Allows objective performance comparison
Q5	Are limitations or future work discussed?	Indicates research transparency and critical analysis

Each study was evaluated using a binary scoring approach. A value of 1 was assigned when a criterion was satisfied and 0 otherwise, resulting in a total quality score ranging from 0 to 5. Studies lacking a clear methodological description, experimental validation, or reported performance evaluation were excluded to maintain review reliability. The results of their quality assessments were subsequently used to aid in data extraction and comparative analysis, so that the findings concluded from this process were based upon well-documented and experimentally validated research [3], [11].

6) *Data extraction*: After completing the quality appraisal, information from each selected study was retrieved systematically and consistently. In systematic reviews, data extraction is essential to make sure that every paper is examined using the same criteria so that the comparison between studies remains fair and reproducible. In fact, several recent studies on intrusion detection and cybersecurity highlight that structured extraction reduces the risk of subjective interpretations and promotes fair synthesis of existing literature [2], [3], [11].

In each included article, bibliographic, technical, and experimental descriptions were recorded. All attributes collected included year of publication, detection approach, DL model, optimization method, dataset, evaluation metrics, contributions, and reported limitations, as summarized in Table IV.

TABLE. IV. EXTRACTED DATA ATTRIBUTES

Attribute	Description	Purpose of Extraction
Publication Year	Year the study was published	Observe research development trends
Detection Approach	Type of IDS implemented	Categorize research direction
DL Model	CNN, LSTM, GRU, Autoencoder, or hybrid models	Identify commonly used architectures
Optimization Method	Metaheuristic algorithms such as PSO, GA, or GWO	Analyze optimization roles
Dataset Used	Benchmark or IoT datasets	Assess evaluation reliability
Evaluation Metrics	Accuracy, precision, recall, F1-score, FAR	Compare reported performance
Main Contribution	Proposed technique or improvement	Determine research focus
Identified Limitations	Reported weaknesses or future work	Support research gap identification

The attributes were selected because they represent the core components of learning-based IDS. Prior studies indicate that detection performance depends strongly on dataset selection, model architecture, and parameter optimization strategy [3], [9], [16]. In addition, the reporting of evaluation metrics and limitations allows the reliability and applicability of each proposed method to be assessed [11].

All extracted information was then organized into comparative tables. These tables enabled cross-study analysis of detection approaches, learning models, optimization strategies, and evaluation practices. Using a consistent extraction format ensured that the conclusions presented in this review were derived from comparable evidence across all 38 primary studies.

The compiled dataset was subsequently used to construct the taxonomy of approaches and to identify research trends and unresolved challenges in DL and optimization-driven intrusion detection for IoT security.

7) *Data synthesis and analysis*: After data extraction, the collected studies were examined using qualitative comparative analysis. This approach was adopted because the studied papers have diverse datasets, model structures, and evaluation methodologies, and hence statistical aggregation is not appropriate [2], [3], [11]. The objective of the synthesis was to identify common patterns and overall research trends rather than to evaluate individual studies separately.

Detection approaches, DL architectures, optimization techniques, and evaluation practices were analyzed. Based on their technical characteristics, the studies were grouped into three categories: deep learning-based IDS, optimization-assisted IDS, and hybrid learning-optimization IDS [3], [9]. This categorization enabled structured comparison across the selected papers.

The synthesis was also used to analyze the evolution of intrusion detection research on the trends toward integrated learning and optimization, as well as to identify common disadvantages concerning efficiency, real-time deployment,

and generalization [18], [21], [22]. The obtained observations can be summarized in the Results and Discussion section through comparative tables and research gap analysis, which provide the basis for identifying future research directions in IoT intrusion research.

III. RESULTS AND DISCUSSION

This section describes the findings obtained from 38 selected primary studies and interprets their implications for intrusion detection in IoT environments. The discussion begins with publication trends and research categorization, followed by findings related to DL, optimization-driven, and hybrid intrusion detection approaches. A comparative synthesis is then conducted to reveal consistent patterns across studies and to identify unresolved research gaps and challenges.

A. Overview of Included Studies

Descriptive evidence drawn from 38 primary studies included in the review is presented in this subsection. The aim is to provide an overview of research output and methodological orientation before the comparative analysis.

The reviewed studies were published between 2021 and 2026. A noticeable increase in publication frequency is observed after 2023. Earlier publications predominantly investigated deep learning-based IDS, whereas more recent studies increasingly integrate optimization mechanisms and hybrid learning frameworks. Several studies explicitly report that standalone deep learning models face computational overhead and configuration sensitivity when applied to IoT environments [3], [9], [21].

The temporal distribution of the studies is illustrated in Fig. 5 and summarized in Table V. Most of the selected publications appeared from 2023 onward, indicating rapid research growth in learning oriented IoT intrusion detection. This increase corresponds with the expansion of connected devices and the rising number of IoT-targeted cyber-attacks reported in recent works [1], [29].

NUMBER OF PUBLICATIONS PER YEAR

Fig. 5. Distribution of the included primary studies by publication year (2021–2026).

TABLE. V. DISTRIBUTION OF INCLUDED STUDIES BY PUBLICATION YEAR

Year	Number of Studies	Corresponding References
2021	2	[26], [27]
2022	7	[16], [17], [18], [19], [20], [24], [35]
2023	8	[21], [22], [28], [30], [31], [33], [34], [36]
2024	7	[8], [9], [10], [11], [12], [13], [15]
2025	7	[1], [2], [3], [5], [6], [7], [37]
2026	7	[4], [14], [23], [25], [29], [32], [38]
Total	38	—

Beyond publication trends, the reviewed papers were categorized according to their detection methodology. Three research categories were identified: deep learning-based intrusion detection, optimization-assisted intrusion detection, and hybrid learning-optimization intrusion detection. The classification was based on the implementation strategy reported in the respective papers.

Some studies in the DL category demonstrate using neural network architectures such as CNN, RNN, LSTM networks, and autoencoders. Optimization-assisted approaches apply metaheuristic algorithms mainly for feature selection or parameter tuning. Hybrid systems integrate both mechanisms within a single detection framework.

Recent studies demonstrate that DL models effectively recognize complex attacks on the IoT [16], [17]. More recent works combine optimization algorithms to improve reliability and computational efficiency [3], [9]. Hybrid frameworks represent a more recent direction and are intended for practical use in resource-constrained environments [22]. Fig. 6 and Table VI present its distribution across categories.

PERCENTAGE OF STUDIES PER CATEGORY

■ Deep Learning Based IDS ■ Optimization Assisted IDS
■ Hybrid Learning-Optimization IDS

Fig. 6. Classification of reviewed studies according to detection methodology.

TABLE. VI. DISTRIBUTION OF STUDIES BY DETECTION METHODOLOGY

Category	Number of Studies	Percentage (%)	Corresponding References
Deep Learning Based IDS	16	42.1%	[1], [8], [13], [16], [17], [18], [19], [20], [21], [23], [26], [27], [28], [34], [36], [38]
Optimization Assisted IDS	9	23.7%	[3], [5], [9], [24], [30], [31], [32], [33], [37]
Hybrid Learning-Optimization IDS	13	34.2%	[2], [4], [6], [7], [10], [11], [12], [14], [15], [22], [25], [29], [35]
Total	38	100%	—

Results indicate that DL is the most investigated approach, while in recent years, there has been an increase in hybrid learning-optimization systems. This shift suggests that the research community is moving beyond accuracy improvement toward achieving deployable and efficient intrusion detection suitable for real IoT environments.

1) *Deep learning based intrusion detection*: The literature review consistently indicates that the large majority of IoT intrusion detection research focuses on DL architectures. CNNs and recurrent architectures, particularly LSTM networks, are the most used models. CNN models effectively learn structural relationships among traffic features, while recurrent networks capture temporal communication behaviour and evolving attack patterns [16], [17].

Several studies combine both mechanisms. CNN-LSTM architectures first extract statistical traffic features and then analyze behavioral sequences, resulting in higher detection performance than standalone models [1], [19]. Autoencoder models are frequently applied for anomaly detection because they learn normal network behavior and identify deviations, enabling the detection of unknown attacks [20], [38]. Table VII provides a summary of the architectural usage patterns extracted from the studies reviewed.

Based on many studies, DL models are generally more accurate and lower in false alarms than traditional and shallow learning methods [16], [17], [24]. Nevertheless, the study of the data also shows some critical constraints. Deep neural networks require significant computational resources and memory, which restricts deployment on IoT devices and embedded systems [21], [22]. Model performance is also sensitive to hyperparameter configuration and dataset characteristics, which may lead to unstable performance across environments [18], [26].

Furthermore, most studies validate their models only in offline experimental settings, leaving real-time feasibility uncertain [22]. These findings indicate that DL improves detection capability but does not, by itself, ensure practical implementation in real IoT networks.

TABLE. VII. DEEP LEARNING ARCHITECTURES AND THEIR ROLES IN IOT INTRUSION DETECTION

DL Architect ure	Main Detectio n Role	Typical Attack Types Detected	Strength Observe d in Studies	Key Limitatio ns Reported	Examl e Referen ces
CNN	Spatial feature pattern extraction from traffic flows	DoS, DDoS, malware traffic	High classifica tion accuracy and stable feature learning	Cannot model temporal behavior	[17], [18], [21], [23]
RNN / LSTM / GRU	Sequentia l behavior analysis	Botnet communica tion, multi-stage attacks	Captures evolving attack behavior	Training complexi ty and long processing time	[16], [17], [28]
CNN–LSTM Hybrid	Combine d spatial and temporal modellin g	Botnet and coordinated attacks	Higher detection rate than standalon e models	Increased computati onal overhead	[1], [19], [22]
Autoenco der (AE)	Anomaly detection and unknown attack identifica tion	Zero-day and unknown intrusions	Detects unseen behavior without labelled data	Sensitive to threshold selection	[20], [38]
Ensemble Deep Learning	Multi-model classificat ion	Mixed attack environmen ts	Improved robustnes s and reduced false alarms	High training complexi ty	[13], [34]

Table VII shows that most studies rely on CNN and LSTM-based models, confirming their dominance in IoT intrusion detection research. However, the same studies consistently report computational overhead, configuration sensitivity, and limited real-time validation. These recurring limitations explain why subsequent research integrates optimization mechanisms to improve efficiency and deployment feasibility.

2) *Optimization-driven intrusion detection*: The reviewed studies show that optimization techniques are mostly applied to address the limitations of learning-based models. Metaheuristic algorithms have been applied to feature selection [3], [9] and parameter tuning.

Feature selection identifies relevant traffic attributes and removes redundant information, reducing dimensionality and improving classification performance [24]. Parameter tuning improves convergence behavior and stabilizes training, resulting in lower false alarm rates and improved reliability [3]. Across several studies, optimized models consistently outperform non-optimized models in both accuracy and stability [3], [9]. Table VIII lists the roles and observed contributions of metaheuristic optimization techniques across the studies.

Despite these benefits, optimization does not function as a standalone detection solution. As optimization methods are

predominantly performed offline during the training stage and may increase computational overhead due to iterative search processes [22]. As a result, optimization enhances performance efficiency but does not independently address deployment constraints or adaptability.

TABLE. VIII. ROLES AND CONTRIBUTIONS OF METAHEURISTIC OPTIMIZATION IN IOT INTRUSION DETECTION

Optimiza tion Algorith m	Integratio n Stage in IDS	Main Purpose	Reported Improve ment	Limitatio n Observed	Examl e Referen ces
Particle Swarm Optimizat ion (PSO)	Feature selection and parameter tuning	Select informativ e traffic features and adjust learning parameters	Higher detection accuracy and faster convergen ce	Additiona l training time due to iterative search	[3], [9], [31]
Genetic Algorith m (GA)	Feature subset optimizatio n	Remove redundant and irrelevant attributes	Reduced false alarm rate and improved stability	Computati onal overhead during search	[3], [24], [32]
Grey Wolf Optimizat ion (GWO)	Hyperpara meter tuning	Optimize network configurat ion	Improved classificat ion performan ce	Sensitive to populatio n size settings	[3], [9]
Whale Optimizat ion Algorith m (WOA)	Model parameter adjustment	Improve training behavior	Better convergen ce and detection reliability	Offline execution requireme nt	[9], [33]
Other Swarm-based Methods	Pre-processing optimizatio n	Reduce dimension ality	Lower computati onal load during inference	Not adaptive after deployme nt	[3], [22]

Table VIII shows that metaheuristic algorithms are primarily used as supporting mechanisms rather than as independent detection models. Most studies apply optimization before or during model training to refine input features or configuration parameters. It is primarily reported that the accuracy of the proposed detection increases, the false alarms decrease, and the convergence behavior improves as compared to the previous methods. However, the table also indicates a consistent limitation. Optimization is generally executed offline and introduces additional processing and some extra cost during training. Thus, optimization improves the model performance but does not independently solve real-time deployment and adaptability challenges.

These observations explain the emergence of hybrid learning–optimization IDS, where optimization improves efficiency while DL performs behavioral detection.

3) *Hybrid learning–optimization intrusion detection*: The reviewed literature shows a clear methodological shift from standalone learning models toward integrated learning optimization frameworks. Hybrid IDS integrates DL models with metaheuristic optimization techniques within a single

detection pipeline. Across the selected studies, this integration consistently produces more balanced performance than using DL or optimization independently.

In these systems, optimization is typically applied before or during model training, while DL performs the behavioral classification. Feature selection reduces input dimensionality and removes irrelevant traffic attributes, whereas the learning component captures nonlinear behavioral relationships within network communication. As a result, hybrid approaches improve both detection capability and computational efficiency [3], [9], [14].

Another observed advantage is deployment feasibility. Several studies report that reducing the number of input features significantly lowers processing requirements, making gateway or edge monitoring nodes more practical in IoT environments [21], [22]. Instead of analyzing traffic at individual devices, the IDS can operate at aggregation points where computational resources are moderately available but still limited.

Most hybrid systems employ combined neural architectures. Most authors rely on the CNN–LSTM model, where convolutional layers extract statistical traffic data, and recurrent layers analyze communication sequences and evolution of behavior [1], [19]. Other studies use autoencoder–LSTM architectures where autoencoders can learn normal behavior patterns and recurrent layers can detect temporal anomalies, thereby enhancing stealth and previously unseen attacks detection [20], [38]. Optimization algorithms then develop feature relevance or hyperparameters that lead to lower false alarm rates as well as stabilize training behavior [3], [9].

Despite these improvements, important limitations persist. Adaptive optimization is rarely implemented. In most cases, optimization is performed during training only, and the selected parameters remain fixed during operation [11]. Most of the time, the system is unable to adapt as attack behavior and concept drift evolve on real networks. Furthermore, many hybrid systems are validated only in controlled laboratory environments and do not demonstrate real-time operational performance [22].

The methodological evolution discovered in the studies reviewed is presented in Fig. 7, which outlines the taxonomy and development of the IoT intrusion detection research. The extracted evidence from 38 primary studies is summarized in Table IX to support cross-study comparison.

Fig. 7. Synthesized evolution and taxonomy of intrusion detection approaches for Internet of Things security derived from the reviewed studies [3], [9], [16], [17], [35].

TABLE. IX. COMPARATIVE SUMMARY OF EXTRACTED CHARACTERISTICS FROM THE REVIEWED STUDIES

Aspect	Observed Pattern	Supporting References
Detection approaches	Three categories: DL-based, optimization-assisted, and hybrid IDS	[1], [3], [14], [16], [22]
Learning models	CNN and LSTM are the most frequently used architectures	[16], [17], [20], [38]
Hybrid architectures	CNN–LSTM is the most common configuration	[1], [19], [22]
Optimization role	Feature selection and hyperparameter tuning	[3], [9], [24]
Optimization algorithms	PSO, GA, and GWO dominate	[3], [9]
Datasets	Both benchmark and IoT datasets are used	[21], [24], [30]
Evaluation metrics	Accuracy, precision, recall, F1-score, FAR	[11], [24]
Deployment setting	Mostly offline experimental evaluation	[21], [22]

B. Comparative Synthesis

Comparison of the three classes shows similar progression in research. DL improves behavioral modelling and enables recognition of complex attack patterns. Optimization enhances efficiency by refining feature quality and stabilizing model training. All these mechanisms are integrated in hybrid approaches, resulting in the most balanced performance.

However, none of the proposed strategies is accurate, real-time, adaptable, and has a low deployment cost integrated within the same package. DL models have demonstrated strong detection performance but require considerable computational resources. Optimization enhances efficiency, but it still relies on the base classifier. Hybrid systems offer improved overall performance but still lack adaptive real-time capability.

Consequently, the accumulation of evidence indicates an evolutionary path with respect to intrusion detection research. Learning methods address detection capability, optimization addresses efficiency, and hybridization addresses practicality. Nevertheless, practical IoT deployment requirements remain unmet because adaptability and real-time responsiveness are still insufficiently addressed.

Thus, as discussed by this synthesis, future research on intrusion detection should focus on an integrated, adaptive, and lightweight security mechanism that can perform continuously in dynamic IoT environments. The following subsection outlines the research gaps identified by this analysis.

C. Research Gaps and Open Challenges

The comparative synthesis of the 38 reviewed studies demonstrates that significant progress has been achieved in applying DL and optimization techniques to intrusion detection in IoT environments. The DL models enhance the attack detection capability, the optimization techniques improve the training stability and efficiency, and the hybrid frameworks combine both advantages. However, the cumulative evidence

also shows that existing IDS solutions are insufficient for practical IoT deployment. Several consistent research gaps appear across the reviewed literature.

1) *Lack of lightweight and deployable intrusion detection*: Deployment feasibility remains one of the most cited limitations. Deep neural networks (DNNs) require considerable computational resources and memory, which restricts their implementation on resource-constrained IoT devices and embedded platforms [21], [22]. Although hybrid systems can be optimized to reduce the dimensionality of feature space, many studies still consider offline simulations rather than real-world operation for most of their models.

IoT environments are constrained by energy, memory, and processing constraints, especially at the device and edge level. Currently, IDS implementations are therefore commonly centralized or tested on high-performance hardware. As a result, the literature shows a high detection performance but limited evidence for real-world deployment scale. Yet there is no proposed lightweight intrusion detection framework directly built for edge-based IoT monitoring.

2) *Static optimization and limited adaptability*: Optimization algorithms are widely used for feature selection and hyperparameter tuning, but the reviewed studies consistently apply them only during the training phase [3], [11]. After deployment, the optimized configuration remains fixed even though IoT network behaviour changes continuously.

IoT environments are highly dynamic. Device communication patterns change, new malware infections are introduced, and traffic loads evolve. Existing models are based on static configurations created on past datasets, which can decrease their performance when network conditions change. The absence of adaptive or continuous optimization mechanisms in present IDS designs shows that current designs do not adequately address concept drift and evolving attack behavior.

3) *Reactive detection instead of predictive security*: Most existing IDS solutions generally work as reactive mechanisms. They detect malicious behaviour only after abnormal traffic has already occurred [16], [17]. Although DL models can detect complex patterns, they rarely attempt to forecast future attacks or analyze pre-attack behavior.

Active defence mechanisms that can proactively predict threats and mitigate potential damage would be beneficial on IoT networks. However, predictive intrusion detection and forecasting-type security models are still rarely thoroughly examined in the data surveyed. This shows a research gap between the observation of patterns and the anticipation of problems.

4) *Incomplete evaluation practices and dataset limitations*: Another recurring issue concerns experimental validation. Most references to experimental studies heavily depend on benchmark datasets such as NSL-KDD or UNSW-NB15. Although the above datasets are valuable for

comparison, they are not representative of the heterogeneous communication of IoT devices [30]. Even the IoT-specific datasets contain only part of the actual operational behaviours.

Furthermore, evaluation often focuses on accuracy, precision, and recall, but underreports deployment-oriented metrics such as latency, scalability, and energy consumption [11]. High classification accuracy does not necessarily indicate practical effectiveness in real networks, especially under imbalanced traffic conditions. The lack of standardized evaluation metrics, therefore, limits the reliability of performance comparisons across studies.

5) *Overall implication of the study*: The commonality across the reviewed evidence is that DL enhances the detection capability; however, optimization and hybrid strategies lead to good performance. However, no existing method has all these features simultaneously by enabling lightweight deployment, adaptive operation, predictive capabilities, and realistic evaluation. As a result, there is a lack of an adaptive and optimized DL IDS dedicated exclusively to edge-based IoT scenarios in the existing literature. Hence, addressing this open issue leads to the motivation of the work in designing a modern hybrid and adaptive intrusion detection model on top of which is the proposed research founded.

IV. CONCLUSION

This study presented a systematic literature review of DL and optimization-driven IDS for IoT security. A systematic review protocol was followed to screen and review relevant studies published between 2021 and 2026. A total of 38 primary studies were selected using the PRISMA-based and quality-assessed approach and qualitatively compared and synthesized.

The findings show that intrusion detection research in IoT environments has evolved from standalone learning approaches toward integrated learning and optimization frameworks. In fact, DL-based IDS is the most explored approach. Both CNN and recurrent architectures, particularly LSTM-based models, dominated the research domain due to their ability to learn the spatial and temporal structures of network traffic. Hybrid neural architectures such as CNN-LSTM further improve attack recognition performance and are frequently reported to achieve higher detection rates than individual models.

The review also demonstrates that optimization techniques play an important supporting role. Feature selection and hyperparameter tuning are mainly performed with metaheuristic algorithms. These mechanisms reduce redundant attributes, improve convergence stability, and lower false alarm rates. However, optimization alone does not function as a detection mechanism and is typically applied only during training.

The hybrid learning-optimization IDS provides the most balanced performance among the reviewed approaches. By integrating behavioral modelling, which is performed in DL, and the improvement of efficiency because of the optimization, hybrid models offer superior detection performance by

reducing computational efforts. However, most research continues to be offline-based and in static settings, which restricts the practicality of actual IoT networks.

The comparative synthesis reveals several unresolved issues. Current systems are rarely lightweight enough for edge deployment, optimization is usually non-adaptive, detection remains reactive rather than predictive, and evaluation practices often rely on limited datasets and accuracy-oriented metrics. Consequently, no existing approach meets all aspects of accuracy, efficiency, flexibility, and operation as required in real time.

Overall, the review indicates that future intrusion detection research should focus on adaptive and lightweight hybrid architectures aiming to solve edge IoT problems. Integrating continuous optimization with DL and incorporating deployment-oriented evaluation metrics may enable practical and scalable security solutions. Hence, these observations provide the foundation and justification for developing an adaptive optimization-enhanced DL intrusion detection model capable of operating effectively in dynamic IoT networks.

ProGem: A Hybrid AI Framework for Task Effort Estimation

Shahid Islam^{1*}, Shazia Arshad², Natasha Nigar³, Jose Lukose⁴

Department of Computer Science, University of Engineering and Technology, Lahore, Pakistan^{1,2}

Department of Computer Science, Walter Sisulu University, South Africa^{3,4}

Abstract—Accurate effort estimation at the task level is essential for effective project planning, resource allocation, and meeting delivery timelines in software development. Traditional approaches have focused primarily on project-level estimation, leaving a critical gap in predicting the duration of individual tasks. This study presents ProGem, a novel hybrid framework that combines Google’s Gemini API with Facebook’s Prophet time-series forecasting model to estimate task effort at fine granularity. ProGem encodes contextual task features — including sentiment, priority, and urgency; and integrates temporal dynamics with semantic task understanding to produce robust duration predictions. The proposed approach is validated on 1,197 real-world tasks collected from software development environments spanning 2019 to 2025. Experimental results demonstrate that ProGem consistently outperforms both traditional models (Decision Tree, Random Forest, XGBoost) and other proposed hybrid models (RF-KNN, XGBERT), achieving the lowest MAE of 63.75, MSE of 9,987.54, RMSE of 100.45, and the highest coefficient of determination ($R^2 = 0.4750$). On individual real-world tasks, ProGem produced estimates of 9.16, 3.00, 6.08, 4.10, and 2.25 days against actual durations of approximately 7, 3, 5–6, 4, and 2 days, respectively, reflecting a prediction accuracy in the range of 90–95%. This work bridges the gap between high-level project estimation and fine-grained task-level forecasting, offering a data-driven solution to support dynamic planning in agile and DevOps development environments.

Keywords—Task effort estimation; software project management; time-series forecasting; real-time task insights

TABLE I. LIST OF ABBREVIATIONS

Abbreviation	Full Form
API	Application Programming Interface
BERT	Bidirectional Encoder Representations from Transformers
CBR	Case-Based Reasoning
COCOMO	Constructive Cost Model
DNN	Deep Neural Network
GLM	Generalized Linear Model
KNN	K-Nearest Neighbors
LGBM	Light Gradient Boosting Machine
MAE	Mean Absolute Error
ML	Machine Learning
MLP	Multilayer Perceptron
MMRE	Mean Magnitude of Relative Error
MSE	Mean Squared Error
NLP	Natural Language Processing
ProGem	Prophet + Gemini (Proposed Hybrid Model)
RBFN	Radial Basis Function Network
RF	Random Forest
RF-KNN	Random Forest – K-Nearest Neighbors (Proposed Hybrid Model)
RMSE	Root Mean Squared Error
SLR	Systematic Literature Review
SVM	Support Vector Machine
SVR	Support Vector Regression
TF-IDF	Term Frequency – Inverse Document Frequency

Abbreviation	Full Form
XGB	XGBoost (Extreme Gradient Boosting)
XGBERT	XGBoost + BERT (Proposed Hybrid Model)

I. INTRODUCTION

In the rapidly evolving landscape of software development, intelligent project management tools have become essential to ensure efficiency and adaptability. However, traditional dashboards often fail, focusing primarily on task assignment and progress tracking, while real-world development environments are characterized by dynamic factors such as delays, shifting priorities, and concurrent task execution. These complexities significantly hinder effective project planning. Previous research indicates [1] that inaccurate effort estimation is a major contributor to software project failures and cost overruns.

Research increasingly points to ML as a solution to this core problem of estimation accuracy. For example, Menzies et al. [2] demonstrated that ML techniques could significantly outperform traditional expert-based estimation methods. Building on this, the concept of context-specific models gained traction, as evidenced by Kocaguneli et al. [3], who argued for “transfer learning” in effort estimation to adapt models to different project environments. Further advancing the field, Fernández-Diego et al. [4] provided a comprehensive review of how modern ML algorithms, including deep learning, are being successfully applied to data from issue tracking systems to improve prediction accuracy.

Recent advances in the field further highlights both the potential and the persistent challenges of intelligent effort estimation. A comprehensive SLR by Pasuksmit et al. [5] examined agile estimation practices across industry and found that development teams continue to rely overwhelmingly on subjective manual techniques such as planning poker, which are well-documented to produce inconsistent and biased estimates, highlighting a critical gap between research maturity and practical tool adoption. This observation is reinforced by Uc-Cetina [6], whose recent survey confirmed that ML methods consistently outperform classical parametric models, such as COCOMO II when sufficient quality data is available, yet mainstream project management platforms have not incorporated these capabilities into their workflows. At the methodological frontier, Chen et al. [7] demonstrated that reinforcement learning-based dynamic feature selection can reduce prediction error (MMRE) by 20-30% compared to static ML baselines by adaptively identifying the most informative project attributes at estimation time, highlighting that feature engineering is as critical as model architecture. Complementing this, Maiga et al. [8] showed that pre-trained

BERT embeddings applied to issue titles and task descriptions significantly outperform traditional models that rely on numerical or categorical data alone, establishing that the semantic richness embedded in unstructured task text carries substantial predictive signal for effort estimation. Collectively, these studies confirm that while ML-driven estimation is technically mature, no existing solution integrates temporal dynamics, semantic task understanding, and real-time project metadata into a unified, task-level prediction framework. Table I presents the list of abbreviations.

Despite this proven potential, popular project management tools like Jira and Trello have not yet integrated these intelligent capabilities. They lack built-in recommendation engines and do not take advantage of historical performance data for automated insight generation, often leading to sub-optimal planning decisions. This reliance on manual input exacerbates the weaknesses of existing estimation practices. For instance, the inherent subjectivity and inconsistency of informal expert-based methods such as planning poker are well documented [9]. Similarly, traditional algorithmic models such as COCOMO [10] and Function Point Analysis [11] exhibit limitations, particularly in their inability to adequately address contemporary, human-centric factors like team dynamics and cognitive load, a gap critically examined by Jorgensen [12].

To address the limitations of existing studies, this work proposes a novel ML-driven system that integrates with Jira, processes historical task data, and predicts task completion times. A key innovation of the proposed system lies in its ability to generate accurate effort estimates even in the absence of story points, thereby addressing a critical limitation in existing project management tools by leveraging state-of-the-art techniques in software effort prediction. In summary, the key contributions are as follows:

- **New System Design:** An intelligent system is designed capable of predicting task effort estimations based on historical project data without relying on predefined story points.
- **Novel Hybrid Models:** We introduce three novel hybrid models that combine: 1) Random Forest [13] and KNN [14], named RF-KNN, 2) XGBoost [15] and BERT [16], named XGBERT, 3) Facebook's Prophet time series forecasting [17], and Google's Gemini API [18], named ProGem, achieving better prediction accuracy compared to traditional ML models.
- **Web Application:** A fully functional web-based platform is developed that seamlessly connects to Jira, applies ML predictions, and displays results through an interactive and user-friendly dashboard.
- **Real-world Dataset:** We collected a real-world task dataset from different software houses and published at Mendeley. (<https://data.mendeley.com/datasets/249h53865h/4>).

This study is organized into six sections: Section II reviews related work, followed by the proposed methodology detailed in Section III. Section IV presents the experimental design and analysis, while threats to validity are discussed in Section V. Finally, Section VI concludes the study with possible future research.

II. RELATED WORK

Effort estimation at the task and project levels has been extensively studied, with a variety of models and methodologies proposed over the years. The early foundational work by Boehm [10] introduced the COCOMO model, which estimates project-level effort based on attributes such as project size, complexity, and developer experience. Although effective for high-level estimation, traditional models like COCOMO and Function Point Analysis [11], [27] often lack the granularity and adaptability required for individual task-level predictions. Complementing this, Jorgensen [12] emphasized the importance of contextual factors and expert judgment to improve the precision of the estimation. However, expert-based approaches remain inherently subjective and difficult to scale consistently across diverse teams and projects.

With the rise of ML, various studies have leveraged historical project and issue tracking data to predict effort more accurately. The research [28] used the COCOMO dataset to predict software development effort using ML methods such as Regression, and Random Forest. Overall, the results showed that ML techniques can significantly improve software effort estimation accuracy. The Random Forest achieved the highest accuracy 86%, outperforming traditional COCOMO estimates. Also, Meharunnisa et al. [20] demonstrates that combining machine-learning regression models, particularly Linear Regression and Random Forest, with correlation-based feature selection can achieve extremely high predictive accuracy (R^2 near 1.0) for effort estimation. The authors found these models outperformed others like Gradient Boosting, especially when feature selection was applied. Using this method significantly improved performance, yielding higher R^2 and lower RMSE across several classic datasets like NASA93, COCOMO, Maxwell. However, the near-perfect R^2 values suggest possible overfitting to well-structured public benchmarks, and the approach has not been evaluated on the noisier, heterogeneous task data typical of real-world agile projects.

Sousa et al. [21] applied regression algorithms along with ensemble methods to estimate effort and duration for individual software tasks using industry data from project management tools like JIRA. Results showed that ensemble methods best perform across datasets. Further, prediction accuracy depended heavily on dataset characteristics. The reported MMRE ranged from 0.11 to 9.45 across datasets, indicating strong potential for ML models in project effort estimation. Similarly, another study [22] demonstrates that combining SVM, MLP and GLM via ensemble averaging can yield significantly improved predictions for software project effort and duration compared to stand-alone models or conventional estimation methods like COCOMO. While this confirms the strong potential of ML for task-level estimation, the wide MMRE range reveals high sensitivity to dataset characteristics, indicating that no single model generalizes robustly across different project contexts without further adaptation. The key limitation, however, is that this ensemble approach does not incorporate semantic features from task descriptions, leaving the rich information embedded in natural language task text unexploited.

Recent advancements in reinforcement learning and hybrid AI frameworks have further pushed the boundaries of estimation accuracy. Chen et al. [7] employed reinforcement learning for dynamic feature selection to train the standard models like

TABLE II. COMPARISON OF EXISTING STUDIES FOR TASK-LEVEL EFFORT ESTIMATION

Study	Dataset		Methodology	Results	Advantages	Limitations/Gaps
Boehm (1981) [10]	Software attributes	project	COCOMO for project-level effort estimation	Traditional measure of effort estimates based on project size, complexity etc.	Well-established; interpretable; widely adopted	Coarse granularity; ignores team dynamics and cognitive load; not suitable for task-level prediction
Jorgensen et al. (2007) [12]	Historical data	project/task	Review of estimation approaches	Emphasized both context and expert judgment for effort estimation	Highlights importance of contextual factors	Expert-based; subjective; difficult to scale consistently across diverse teams
Ahmed (2018) [19]	COCOMO Project		ML modes like Random Forest (RF) to predict effort	Reported 86% accuracy outperforming traditional COCOMO estimates	Demonstrates ML superiority over parametric models	Confined to project-level data; not validated on real task-level agile data
Meharunnisa et al. (2023) [20]	COCOMO, Maxwell	NASA93,	Linear Regression, RF	Simple models outperform Gradient Boosting when combined with feature selection	High R ² on benchmark datasets	Possible overfitting to structured benchmarks; not tested on noisy real-world agile task data
Sousa et al. (2023) [21]	JIRA, SCRAIM		Regression algorithms, RF, XGBoost	Ensemble models outperform non-ensemble methods	Uses real Jira data; task-level estimation	Wide MMRE range (0.11–9.45); high sensitivity to dataset characteristics; limited generalisability
Pospieszny (2018) [22]	COCOMO81, ISBG		SVM, MLP, GLM	Ensemble models perform better than classical parametric models	Ensemble averaging reduces variance	No semantic features from task descriptions; natural language task text unexploited
Chen et al. (2025) [7]	ISBSG, COSCOM		RF, SVR, Reinforcement learning	Improved estimation accuracy through dynamic feature adaptation	20–30% MMRE reduction; adaptive feature selection	No natural language integration; added training complexity; high data requirements
Uc-Cetina et al. (2023) [6]	Agile and projects	Non-agile	Systematic Literature Review (SLR)	ML approaches improve effort estimation accuracy when combined with project management data	Comprehensive survey of ML methods	No new model proposed; does not address task-level granularity
Pasukmit et al. (2024) [5]	Historic data		SLR	Agile effort estimation often depends on traditional approaches like planning poker	Highlights industry adoption gap	No predictive model; confirms problem but offers no automated solution
Resmi (2019) [23]	COCOMO81, Desharnais	NASA93,	Analogy-based Probabilistic models	Model performed better than multivariate linear regression	Low MMRE on benchmark datasets	Degrades when historical cases are dissimilar; less robust than ensemble methods
Shah et al. (2020) [24]	COCOMO, Desharnais	ISBSG,	Analogy-based Optimization model	Reported low MMRE values	Optimization improves analogy search	Dependent on closely matching historical cases; limited scalability
Nassif et al. (2016) [25]	COCOMO, Desharnais	ISBSG,	MLP	MLP achieved better results compared to regression trees and CBR	Consistent MMRE improvements	Requires large training data; low interpretability for project managers
Varshini et al. (2021) [26]	Public datasets		RF, MLP	Random Forest performed better than deep learning models	Robust on large complex datasets	No textual/semantic features; restricted to structured numerical inputs
Maiga et al. (2025) [8]	Public datasets		BERT embeddings, SVR	Leveraging semantic richness of unstructured project requirements improves accuracy	Strong NLP integration; outperforms numerical models	High computational cost; no temporal dynamics; no time-series integration
Proposed Work	Task dataset from software houses in Pakistan		Hybrid models (RF-KNN, XGBERT, ProGem)	Achieved better generalization and accuracy up to 90%–95%	Integrates semantic, temporal, and metadata features; story-point-free; Jira-connected	Single-organization dataset; days-level granularity; no developer-level features yet

RF and SVM. It achieved a substantial reduction in prediction error (MMRE), often 20-30%. Although this adaptive feature selection strategy is a significant advance, the framework does not incorporate natural language task descriptions, and its dependency on reinforcement learning introduces additional training complexity and data requirements that may limit adoption in smaller organizations.

Resmi [23] proposed a fuzzy analogy-based effort estimation model. The approach was evaluated on different public datasets, including COCOMO81, NASA93, and Desharnais. The proposed model achieved notable improvements compared to multivariate linear regression, with prediction ranging from

55 to 97.8% and MMRE values as low as 0.01. While the model outperforms multivariate linear regression, analogy-based probabilistic fuzzy approaches are generally less accurate and robust across diverse datasets compared to ensemble learning methods, which benefit from model diversity and error averaging. A similar study by Shah et al. [24] reported the effectiveness of an analogy-based optimization algorithm for software effort prediction when tested on COCOMO, ISBSG, and Desharnais datasets. However, analogy-based probabilistic fuzzy approaches are generally less accurate and robust across diverse datasets compared to ensemble learning methods, which benefit from model diversity and error averaging. The limitation shared by analogy-based methods is their depen-

dence on the availability of closely matching historical cases; when project characteristics diverge from the historical base, prediction quality degrades significantly.

Recently, deep learning models have gained attention of researchers for software effort estimation. Nassif et al. [25] trained MLP and RBFN on public datasets like COCOMO, NASA, and Desharnais. They compared the models with traditional ones such as CBR, regression trees, and linear regression. Results showed that the MLP consistently achieved the lowest MMRE values, demonstrating strong and reliable performance across datasets. Despite strong performance on benchmark datasets, these models require large volumes of training data and lack interpretability, making it difficult for project managers to understand or trust individual predictions. Varshini et al. [26] also evaluated various ML (random forest, SVM) and deep learning models (Neural Network, DNN) for predicting software development effort using multiple publicly available datasets. The results showed that while deep learning models performed competitively, the Random Forest algorithm achieved the highest accuracy and robustness, demonstrating superior performance in handling large and complex datasets for effort estimation. The study, however, did not incorporate task-level textual features, restricting its applicability to structured numerical inputs only.

Maiga et al. [8] employed pre-trained BERT embeddings (specifically BERT-Base and BERT-Large) on software project textual data such as issue titles, descriptions to estimate effort. The results indicate that the NLP-driven method combined with SVR significantly outperformed traditional estimation models that rely on non-semantic numerical or categorical data. However, the approach incurs high computational cost, requires substantial fine-tuning data, and does not incorporate temporal dynamics such as time-series patterns in historical task completion - a critical dimension for task scheduling in agile sprints.

Despite these advances, existing project management tools such as Jira and Trello lack integrated intelligent recommendation systems that leverage historical data, often leading to suboptimal planning. Pasuksmit et al. [5] also criticized agile estimation techniques like planning poker for subjectivity and inconsistency. These challenges highlight the need for data-driven adaptive estimation models that integrate task characteristics and team dynamics. As noted by Uc-Cetina [6] that ML methods improve software effort estimation accuracy compared to traditional parametric models like COCOMO II, especially when ample high-quality data are available. In agile settings, the availability of story-point histories, developer specific data, and task logs provides new opportunities for more precise development effort predictions.

These collective limitations highlight four key gaps that existing approaches fail to address simultaneously:

- The lack of task-level granularity in most estimation models,
- The failure to integrate semantic understanding of task descriptions with temporal forecasting,
- The absence of story-point-free estimation in practical tools, and

Algorithm 1: HybridXGBoostBERT

Input : T : textual input features, N : numeric features

Output: Y : final predicted duration and estimated completion date

```
1  $E_T \leftarrow \text{BERT}(T)$ ;           // generate BERT
   embeddings from text
2  $E_N \leftarrow \text{XGBoostEncode}(N)$ ;       // encode
   numeric features
3  $F \leftarrow \text{Concatenate}(E_T, E_N)$ ;    // combine all
   features
4  $Y \leftarrow \text{XGBoost.predictDate}(F)$ ;    // predict
   using XGBoost
5 return  $Y$ 
```

- The disconnect between research advances and deployed project management software.

Our proposed approach introduces three hybrid models — RF-KNN, XGBERT, and ProGem — that combine complementary ML paradigms to achieve robust, fine-grained task-level effort estimation without reliance on predefined story points. These studies are summarised in the updated Table II, which now includes the advantages and key limitations of each approach.

III. PROPOSED METHODOLOGY

In this section, we present three novel hybrid approaches.

A. XGBERT

This method (Algorithm III-A) merges the predictive strength of XGBoost with the contextual understanding of BERT. The BERT processes textual inputs, such as task names or descriptions, extracting semantic features that XGBoost uses for the final prediction. This fusion is particularly powerful for tasks involving natural language data.

The Hybrid XGBoost-BERT (Fig. 1) workflow begins with the initialization phase, setting up the system and loading data. Task text is then processed by BERT, which generates embeddings representing the semantic meaning of the text. These embeddings are combined with structured features, which are numerical or categorical data related to the task. The combined data is then fed into XGBoost for prediction. The outputs from both BERT and XGBoost are merged, and cross-validation is performed to assess the model stability and performance across different subsets of the data. Finally, the average performance metrics, such as accuracy or F1-score, are calculated to evaluate the model's effectiveness.

B. RF-KNN

This hybrid approach (Algorithm III-B) uses Random Forest for the selection of features or initial prediction and KNN to refine the results based on similar past instances. It combines the strength of ensemble learning with instance-based reasoning, with the aim of improving the accuracy of the prediction of the duration of the task.

Fig. 1. Novel hybrid model 1: XGBERT.

Fig. 2. Novel hybrid model 2: RF-KNN.

The Hybrid RF-KNN (Fig. 2) workflow starts with data preprocessing to prepare features for modeling. Random Forest is applied first for initial predictions or feature importance, followed by KNN to refine results based on similar instances. The predictions of both models are then merged, and the ensemble logic is used to generate the final output. The process

ends with an evaluation using metrics such as accuracy or RMSE to assess performance.

Algorithm 2: Hybrid Random Forest – KNN Ensemble Model

Input : T : textual input features (Summary, Description),
 N : categorical metadata features (Issue Type, Status, Priority, Labels),
 D : date features (Created, Resolved)
Output: Predicted task completion date

- 1 $E_T \leftarrow \text{TFIDF}(T)$; // extract text features using TF-IDF
- 2 $E_N \leftarrow \text{OneHotEncode}(N)$; // one-hot encode metadata features
- 3 $Y \leftarrow (\text{Resolved} - \text{Created}).\text{days}$; // calculate numeric completion durations
- 4 Train KNN regression on E_T to predict Y ; // text-based regression
- 5 Train Random Forest regression on E_N to predict Y ; // metadata-based regression
- 6 $Y_{\text{pred}} \leftarrow \text{Average}(\text{KNN.predict}(E_T), \text{RF.predict}(E_N))$; // combine model predictions
- 7 $\text{Predicted_Date} \leftarrow \text{Created} + \text{timedelta}(Y_{\text{pred}})$; // convert predicted duration to date
- 8 **return** Predicted_Date

C. ProGem

Prophet is a time-series forecasting tool developed by Facebook that handles seasonality and trend changes well. When combined with Google's Gemini API, which provides contextual understanding of task names and features, this approach allows for intelligent time-aware predictions of task duration. It effectively integrates semantic and temporal data for effort estimation, as shown in Algorithm III-C1.

1) *Encoding schemes*: The Prophet model, by default, is designed for time-series forecasting and does not natively handle categorical variables. To incorporate features such as *Sentiment*, *Priority*, and *Urgency*, a manual encoding scheme is applied during data preprocessing. Specifically, *SentimentEncoded* is defined as 0 for Negative, 1 for Neutral, and 2 for Positive sentiments. Similarly, *PriorityEncoded* and *UrgencyEncoded* follow the scheme of 0 for Low, 1 for Medium, and 2 for High. These encoded features are then added to the Prophet model using the `add_regressor()` function, allowing the model to learn the effect of these categorical variables on the predicted duration. This enables the Prophet model to incorporate contextual task metadata into its forecasting pipeline effectively.

SentimentEncoded: 0 (Negative), 1 (Neutral), 2 (Positive)

PriorityEncoded: 0 (Low), 1 (Medium), 2 (High)

UrgencyEncoded: 0 (Low), 1 (Medium), 2 (High)

The process starts with task details, which are analyzed by the Gemini-2.0-Flash model (Fig. 3). The key information from the analysis is converted into features suitable for prediction models. These features are used by two separate models,

Algorithm 3: Hybrid Prophet–Gemini API

Input : G : Google Gemini API,
 $S = \{\text{summary}, \text{priority}, \text{labels}\}$: feature set,
CreatedDate: task creation date
Output: d_{final} : predicted duration,
CompletionDate: estimated completion date

- 1 Load trained Prophet model with regressors
Sentiment_Encoded, Priority_Encoded, Urgency_Encoded; // load forecasting model
- 2 $f_s \leftarrow G(S) \rightarrow \{\text{Sentiment}, \text{Priority}, \text{Urgency} (\text{encoded})\}$; // extract encoded features via Gemini
- 3 $\hat{y} \leftarrow \text{Prophet.predict}(f_s)$; // predict log-duration
- 4 $d_p \leftarrow \exp(\hat{y}) - 1$; // inverse log-transform to get duration
- 5 $d_g \leftarrow G.\text{predictDuration}(S)$; // direct duration prediction from Gemini
- 6 **if** d_g is valid **then**
- 7 $d_{\text{final}} \leftarrow \frac{d_p + d_g}{2}$; // average both predictions
- 8 **else**
- 9 $d_{\text{final}} \leftarrow d_p$; // fallback to Prophet prediction
- 10 CompletionDate $\leftarrow$ CreatedDate + d_{final} ; // compute final completion date
- 11 **return** $d_{\text{final}}, \text{CompletionDate}$

Prophet and Gemini-2.0-Flash, to predict the task's duration. The duration estimates from both models are averaged together. This average duration is used to calculate the final predicted completion date, which is then returned as the output.

IV. EXPERIMENTAL ANALYSIS

A. Performance Measures

The following regression metrics are used to assess the outcomes of the prediction:

1) *Mean Absolute Error (MAE)*: The MAE is one of the most intuitive and widely used regression evaluation metrics due to its simplicity and interpretability. It calculates the average of the absolute differences between the predicted values y'_i and the actual values y_i , effectively quantifying the average magnitude of the prediction errors without considering their direction. This ensures that all errors contribute proportionally to the final metric, with the larger errors not disproportionately penalized. Unlike squared error metrics, MAE is robust to outliers to a certain extent and is measured in the same unit as the target variable, making interpretation more straightforward. The mathematical expression for MAE is:

$$\text{MAE} = \frac{1}{N} \sum_{i=1}^N |y_i - y'_i| \quad (1)$$

where, N is the total number of predictions, y_i is the actual value, and y'_i is the predicted value. In practice, a

Fig. 3. Novel hybrid model 3: ProGem.

lower MAE value indicates a model with better generalization performance, especially in scenarios where all errors should be treated equally.

2) *Mean Squared Error (MSE)*: The MSE is another fundamental metric used to evaluate the performance of regression models. It measures the average of the squared differences between actual values y_i and predicted values y'_i , emphasizing larger errors more than smaller ones due to the squaring operation. This characteristic makes MSE highly sensitive to outliers—large individual deviations can significantly impact the overall score.

$$MSE = \frac{1}{N} \sum_{i=1}^N (y_i - y'_i)^2 \quad (2)$$

In this equation, N is the total number of data points, and $(y_i - y'_i)$ is the residual (or prediction error) for the i^{th} data point. Since the errors are squared before being averaged, MSE tends to magnify the effect of large errors, potentially skewing the evaluation in datasets with outliers.

3) *Root Mean Squared Error (RMSE)*: The RMSE is the square root of the MSE. It measures the average magnitude of the errors in a set of predictions. RMSE provides insight into how spread out the errors are, with larger values indicating higher variance in the errors. The equation for RMSE is:

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^N (y_i - y'_i)^2} \quad (3)$$

Here, N is the total number of observations, y_i represents the actual output value, and y'_i represents the predicted output value. The equation computes the square of the residuals (the differences between actual and predicted values), averages them, and then takes the square root to return the RMSE.

4) R^2 (*R-squared*): R^2 , or the coefficient of determination, measures the proportion of variance in the dependent variable explained by the independent variables in the model. It ranges from 0 to 1, where 0 indicates no explanatory power and 1 indicates perfect fit. The equation for R^2 is:

$$R^2 = 1 - \frac{\sum_{i=1}^N (y_i - y'_i)^2}{\sum_{i=1}^N (y_i - \bar{y})^2} \quad (4)$$

Here, N is the number of observations, y_i is the actual value, y'_i is the predicted value, and $\bar{y}$ is the mean of the actual values. The numerator represents the sum of squared residuals, and the denominator is the total sum of squares. R^2 indicates how well the model explains the variance in the data, with higher values signifying a better fit.

B. The Dataset

This study analyzes a dataset of 1,197 work items of type Task, extracted from the Jira account of a software organization. Initially, the dataset was comprised over 5,000 tasks, but after applying filtering criteria relevant to task type and completeness, we retained 1,197 records covering the period from 2019 to 2025. The dataset specifications are in Table III.

TABLE III. TASK DURATION PREDICTION DATASET SPECIFICATIONS

Subject	ML based estimation of software development effort using hybrid and traditional models
Specific Subject Area	Development of predictive models for estimating task durations using historical data from Agile project management tools
Type of Data	CSV file
How Data Were Acquired	Data collected from real-world project tracking platforms (e.g., Jira, Trello) and cleaned manually to include task duration, complexity, priority, and tags
Data Format	Raw and analyzed numeric/categorical fields including task ID, description, labels, predicted and actual duration
Parameters for Data Collection	Tasks labeled with metadata such as priority, labels, and timestamps; effort in days computed or annotated; each task associated with model predictions
Description of Data Collection	Dataset includes 1,000+ software development tasks with manually verified actual durations and automated predictions from various ML models (e.g., RF, XGB, Prophet). Aimed at evaluating and comparing models for time estimation.
Data Source Location	Institution: Department of Computer Science, University of Engineering and Technology (UET) Lahore, Pakistan
Dataset Availability	Dataset is available at: https://data.mendeley.com/datasets/249h53865h/4

The data was collected by accessing Jira projects as a developer, followed by an export of task-level details. To ensure the dataset is suitable for analysis, a systematic preprocessing pipeline was applied. Missing entries were observed in some fields. For categorical attributes (e.g., priority), missing values were imputed with the most frequent category. Duplicate records were detected using a combination of summary and creation date. Date fields (created and resolved) are standardized to ISO format for consistency, while textual fields (summary and description) were normalized to lowercase and cleaned by removing stop words to facilitate NLP.

C. The Attributes

The attributes listed in Table IV are used for the training of ML models.

D. Hyperparameter Setting

To optimize the performance of our predictive models, we selected and tuned a range of hyperparameters specific to each algorithm, as summarized in Table V. The selection of hyperparameters significantly impacts the model's ability to learn complex patterns while avoiding overfitting. For traditional ML models like Decision Trees, Random Forests, and XGBoost, parameters such as tree depth and number of estimators were calibrated using grid search and cross-validation. In hybrid models, such as RF-KNN and XGBERT, component-specific tuning ensures optimal integration between architectures. Prophet and Gemini-based models required minimal hyperparameterization, relying instead on robust defaults and external API intelligence.

Additionally, regularization techniques such as pruning and early stopping were employed to prevent over-complexity in tree-based models. For neural components like BERT, fine-tuning was limited to key transformer layers to maintain generalizability across varied inputs. These comprehensive tuning strategies were essential for ensuring each model not only achieved high predictive accuracy but also maintained robustness across different project scenarios.

For traditional ML models like Decision Trees, Random Forests, and XGBoost, parameters such as tree depth and number of estimators were calibrated using grid search and cross-validation. In hybrid models, such as RF-KNN and XGBERT, component-specific tuning ensures optimal integration between architectures. Prophet and Gemini-based models

required minimal hyperparameterization, relying instead on robust defaults and external API intelligence.

E. Results and Discussion

To comprehensively evaluate the effectiveness and predictive accuracy of the proposed task-level effort estimation model, a set of representative example tasks were selected. These tasks reflect common software development activities and vary in complexity, scope, and required effort. To evaluate the performance of different traditional approaches and proposed novel hybrid approaches, we compared several models using standard regression metrics, including MAE, MSE, R^2 , and RMSE, as summarized in Table VI and Fig. 4.

The experimental results demonstrate that hybrid models significantly outperform traditional ML approaches in real-world forecasting tasks. Among all the models evaluated, the hybrid model 'ProGem' consistently achieved the best performance across multiple evaluation metrics, including MAE, MSE, R^2 , and RMSE. Not only did ProGem exhibited lowest prediction errors, but it also produced estimations remarkably close to actual task durations in real-life scenarios. These findings validate the effectiveness of combining Prophet's robust time-series forecasting capabilities with Gemini's powerful deep learning architecture. The synergy between these models enhances predictive accuracy and generalization, making the ProGem a promising solution for demand-side energy management and other time-sensitive predictive applications.

Table VIII summarizes the comparative performance of various models on real-life software development tasks selected randomly (as shown in Table VII). This reveals substantial differences in estimation accuracy across models. The traditional approaches like Random Forest (RF), XGBoost (XGB), LGBM, and SVR tend to overestimate durations. For example, *Task 1* (actual: ~7 days) is predicted at **200** (RF) and **240** (SVR) days—exceeding the real value by over **28 times**. Likewise, *Task 4* sees a prediction of **90 days** from SVR, far beyond the actual ~4 days, indicating poor real-world generalization. In contrast, hybrid models offer significantly improved accuracy. The hybrid approach XGBERT leverages semantic understanding to refine predictions, while RF-KNN incorporates local context. Most notably, the ProGem model demonstrates superior alignment with actual durations: **9.16** days for *Task 1*, **3.00** days for *Task 2*, and **2.25** days for *Task*

TABLE IV. FEATURES AND THEIR VALUE RANGES

5	~2 days	40	42	38	55	25	27	2.25

concern is dataset representativeness. Although the dataset used in this study contains real-world tasks from software development environments, it may not fully reflect the variability of tasks across different organizations, domains, or development methodologies. This limitation can affect the external validity and generalizability of the findings to other contexts. Another threat lies in the simplification of task duration—modeled as the time span between task creation and completion. This approach does not account for temporal factors such as non-working days, holidays, or organizational shifts (e.g., team restructuring or workload fluctuations), which may influence task completion times. Ignoring such dynamics may introduce bias and reduce the model's predictive accuracy. Data quality poses an additional concern. Despite preprocessing and cleaning, the presence of missing values, outdated records, or inconsistent labeling could affect model training and evaluation. Any residual noise in the data may lead to internal validity threats by skewing the model's learning patterns. Moreover, the limited feature space in the current implementation constrains the model's ability to capture complex interdependencies. Factors such as developer expertise, task interdependencies, or sprint planning dynamics are not yet incorporated, potentially limiting the explanatory power and construct validity of the model.

Another limitation lies in the use of days as the unit of effort measurement and prediction. While consistent with the resolution typically available in Jira exports, this coarse granularity inflates errors for short-duration tasks (e.g., a few hours) and reduces the sensitivity of evaluation metrics such as MAE and RMSE. As a result, small deviations in actual effort may be exaggerated, particularly for lightweight tasks. Future

work should incorporate finer-grained effort logs (e.g., hours or developer activity records) to improve precision and interpretability. The reliability of measured effort is a limitation, as task duration based on Created–Resolved timestamps may include logging delays, non-working days, or task reopenings. Despite preprocessing to remove incomplete and erroneous records, residual noise may still bias predictions. Future work should incorporate finer-grained measures (e.g., work logs or calendars) to improve accuracy and validity.

To mitigate these threats, future research should prioritize the use of larger and more diverse datasets, integrate richer contextual features (e.g., team composition, workload, dependencies), and adopt more advanced modeling techniques, including deep learning or ensemble-based architectures. These improvements can enhance model robustness, adaptability, and applicability across varied project settings.

VI. CONCLUSION AND FUTURE WORK

In this work, we have presented a novel hybrid approach for task effort estimation by predicting the duration of individual tasks based on a combination of the task name, complexity, and starting date. Leveraging the Prophet model for time-series forecasting and the Gemini API for enriched task-related metadata, our proposed method shows strong potential for accurate predictions. The model is validated using real-world data, demonstrating promising results in both accuracy and applicability within fast-paced, agile environments. The key contribution of this study lies in its emphasis on task-level estimation, an often overlooked area compared to project-level prediction. Traditional models usually focus on broader project

Fig. 6. Illustration of ML models' predictions on real-life tasks.

estimates, whereas our approach provides fine-grained predictions, which are more actionable for teams working under agile or iterative frameworks. This study supports improved planning, resource allocation, and deadline management.

The future work on this task-level effort estimation model includes several directions for improvement and expansion. Future versions can improve accuracy by integrating additional features like task dependencies, team skillsets, past performance of assignees, and communication data. Elements such as comments or priority changes may offer deeper insights into task behavior. In real-world settings, tasks often change due to shifting priorities or scope updates. Future versions should explore real-time adaptability using reinforcement learning or other adaptive learning methods to refine predictions as new data emerges. While Prophet performs well for time-series forecasting, combining it with ML models (e.g., Random Forest, SVM) may capture non-linear relationships between metadata and task duration, boosting overall accuracy. As task datasets grow, ensuring scalability will be vital. Future research can explore parallel processing and distributed computing to handle large-scale enterprise projects efficiently.

Trend-Based Encoding of Exogenous Time-Series for Interpretable Financial Prediction

Khudran M. Alzhrani[✉]

Department of Computers-College of Engineering and Computing in Al-Qunfudhah
Umm Al-Qura University, Makkah, Saudi Arabia

Abstract—Integrating heterogeneous exogenous data into financial prediction models is challenging due to scale mismatches and semantic ambiguity. We propose a trend-encoding framework that transforms raw exogenous time-series into directional binary representations, improving predictive robustness while preserving interpretability. Using Saudi stock market data with COVID-19 indicators, we evaluate predictive models under baseline and trend-enhanced configurations. Results show that trend encoding consistently enhances predictive stability over raw inputs. Interpretable models benefit disproportionately, achieving performance comparable to black-box methods. Sectoral analysis reveals heterogeneous sensitivities: Banking responds strongly to case and mortality trends, Energy to recovery indicators, while Food & Beverages shows weaker alignment. These findings show that trend-based encoding of exogenous signals can improve cross-domain financial prediction, particularly for interpretable models.

Keywords—Trend-based encoding; exogenous time-series; interpretable machine learning; financial prediction forecasting

I. INTRODUCTION

Financial markets are increasingly influenced by a wide range of exogenous signals, from public health trends and policy shifts to environmental and geopolitical events. These signals, when integrated into predictive models, have the potential to enhance forecasting accuracy by capturing real-world context that pure market metrics often miss [1], [2]. However, the raw form of such exogenous data — often noisy, scale-dependent, and temporally misaligned with financial time series — presents a significant barrier to effective and interpretable modeling. Representation of external signals thus emerges as a critical, yet underexplored, challenge in financial machine learning [3].

Traditional stock prediction models have predominantly relied on historical price and volume data. More recent approaches incorporate external datasets — such as sentiment from news and social media, government announcements, or macroeconomic indicators — to improve robustness, especially during volatile periods [4]. However, these methods often feed raw or minimally processed values directly into complex, non-interpretable models, obscuring the relationship between the external signal and the predicted outcome. This practice limits transparency and makes it difficult for financial decision-makers to understand why a model makes a particular prediction, which is crucial for risk assessment and regulatory compliance [5].

The core challenge lies in transforming heterogeneous, real-world exogenous data into a format that is both informative for prediction and amenable to interpretation. Raw

indicators like daily case counts, policy severity indices, or emission levels have different scales, reporting frequencies, and noise profiles. When used directly, they can degrade model performance, introduce overfitting, and render the contributions of individual features inscrutable, particularly in inherently interpretable models like decision trees.

This study addresses this representation gap by proposing a trend-based encoding framework for exogenous time-series data. Instead of modeling raw values, we convert external indicators into directional, binary trend signals that capture whether the underlying metric is increasing or decreasing relative to the previous period. This transformation offers several advantages: it normalizes scale, reduces noise from magnitude fluctuations, provides a consistent semantic meaning (upward/downward pressure), and aligns naturally with the decision logic of interpretable models. We demonstrate this framework using COVID-19 epidemiological data — a prominent, publicly available, and high-frequency exogenous signal — as a case study to validate our approach. The pandemic serves not as the primary subject of analysis, but as an ideal real-world data source to test the encoding methodology under conditions of significant market disruption.

The contributions of this work are as follows:

- We propose a trend-based encoding approach that transforms raw exogenous time-series into directional features suitable for interpretable financial models.
- We design a causally valid data integration pipeline that aligns exogenous indicators with financial time-series while preventing look-ahead bias.
- Through comparative experiments, we show that interpretable models benefit more consistently from trend-encoded exogenous signals than non-interpretable models.
- We provide a sector-level analysis demonstrating that the impact of exogenous trends varies across Banking, Energy, Food & Beverages, and Health Care sectors.

The rest of the study is organized as follows: Section II reviews related work on exogenous data integration in financial prediction and highlights the gap in data representation strategies. Section III describes the datasets used and the construction of the trend-encoded financial-exogenous dataset. Section IV details the trend-encoding framework and the predictive modeling approach. Section V presents the experimental setup, results, and analysis. Finally, Section VI summarizes the findings and suggests directions for future work.

II. RELATED WORK

This section reviews literature relevant to our proposed trend-encoding framework, organized into three interconnected themes: the integration of exogenous data into financial prediction models, the representation and modeling of trends in time-series data, and the pursuit of interpretability in financial machine learning. A critical observation across these themes is the relative under-exploration of simple, transparent data transformations for aligning heterogeneous external signals with financial time-series.

A. Exogenous Data in Financial Prediction

The use of non-market data to augment financial forecasting has grown substantially, particularly during periods of high market volatility driven by external shocks. Early works focused on macroeconomic indicators, news sentiment, and social media data [6]. The COVID-19 pandemic served as a catalyst, highlighting the predictive value of high-frequency, real-world exogenous signals. Several studies directly incorporated pandemic metrics: [7] used daily case and death counts with LSTM models to forecast stock prices; [8] integrated case counts and sentiment indices within a multi-task deep learning architecture; and [9] combined infection data with Twitter sentiment in a system using SVM and tree-based models. Other works employed related proxies, such as government mobility indices [10] or predicted mortality peaks [2]. A common thread is the treatment of these exogenous indicators as raw numerical inputs or as features for complex embedding layers within deep neural networks. While effective for predictive accuracy in specific contexts, this approach often obscures the direct, interpretable relationship between the external signal and the market response, especially when scale differences and noise are not explicitly addressed through the data representation itself.

B. Trend and Directional Encoding in Time-Series

The concept of simplifying complex time-series into directional or trend-based representations has precedent in both finance and signal processing. In technical analysis, metrics like moving average convergence divergence (MACD) or the directional movement index (DMI) distill price action into momentum and trend signals [11]. In broader time-series analysis, change-point detection and regime-switching models aim to identify shifts in the underlying data-generating process [12]. However, the application of such concepts specifically to preprocess and encode *exogenous* signals for integration with a separate financial target series remains relatively limited. Existing studies in nowcasting and leading indicator analysis typically rely on scale-preserving transformations, including year-over-year changes, differencing, and Z-score normalization to align heterogeneous indicators [13], [14], [6]. While effective for capturing magnitude-driven dynamics, these approaches retain scale sensitivity and do not explicitly abstract directional information. The work of [15], which applied stationary wavelet transform to COVID-19 case data before feeding it into a BDLSTM, represents a form of multi-resolution filtering but remains within a complex, non-interpretable modeling framework. Our proposed method distinguishes itself by advocating for a minimal, scale-invariant binary encoding (up/down trend) as a generic preprocessing

step, deliberately sacrificing magnitude information to gain robustness, alignment simplicity, and, crucially, interpretability.

C. Interpretability in Financial Machine Learning

The demand for explainable AI in finance is driven by regulatory requirements, risk management needs, and the practical value of actionable insights [16]. Interpretable models, such as decision trees (CART, C5.0), rule-based systems, and linear models with constraints, offer transparency by design [17]. Post-hoc explanation techniques like SHAP [10] and LIME can be applied to black-box models but provide approximations rather than faithful representations of the underlying logic. A key challenge in employing inherently interpretable models is feature engineering: these models perform best when inputs are semantically clear, have manageable ranges, and exhibit logical relationships to the target [18]. Raw exogenous data—with erratic scales, missing values, and complex temporal dynamics—often violates these conditions, pushing practitioners toward black-box models that can learn complex embeddings automatically [19]. Consequently, while many studies compare model performance [20], [21], few systematically investigate how different *data representations* specifically affect the performance gap between interpretable and non-interpretable models. Our work posits that a tailored encoding strategy, such as trend-based transformation, can bridge this gap by creating features that are inherently compatible with the logical splitting mechanisms of interpretable models, thereby unlocking their potential without sacrificing predictive utility.

Prior research establishes the value of exogenous data and highlights the importance of interpretability but leaves a gap regarding systematic, transparent methods for converting raw external signals into features optimized for interpretable financial prediction. This study addresses that gap by proposing and evaluating a trend-based encoding framework.

III. DATA DESCRIPTION

This study integrates two heterogeneous, real-world time-series datasets to develop and validate a trend-encoding framework for cross-domain prediction. The core challenge is their inherent mismatch: the financial data (daily stock market activity) and exogenous public health data differ in temporal resolution, scale, reporting conventions, and semantic meaning. Specifically, the financial dataset consists of daily trading records from the Saudi Stock Exchange (Tadawul) [22], while the exogenous dataset comprises daily COVID-19 epidemiological reports published by the KAPSARC Data Portal [23]. This section details each dataset's characteristics and the preprocessing steps required to create a causally aligned, prediction-ready integrated dataset.

A. Exogenous Public Health Signal Dataset

We utilize a publicly available epidemiological dataset as a representative high-frequency exogenous signal. The dataset consists of daily reports released by a national public health authority and is structured around four primary numerical indicators: Cases, Mortalities, Recoveries, and Tested. Each record includes a *Report_Type* attribute (Cumulative or Daily), a reporting *Date*, and geographic descriptors at the city and region levels.

TABLE I. COVID-19 DATASET STATISTICS

Report Type	Indicator	Records
Cumulative	Cases	193,121
Cumulative	Active	185,467 (excluded)
Cumulative	Critical	1,090 (excluded)
Cumulative	Mortalities	93,827
Cumulative	Recoveries	189,891
Daily	Cases	72,542 (retained)
Daily	Recoveries	70,444 (retained)
Daily	Mortalities	6,811 (retained)
Daily	Tested	1,151 (excluded)

The raw dataset exhibits several characteristics commonly observed in real-world exogenous signals, necessitating careful preprocessing and motivating the adoption of a trend-encoding strategy, as summarized in Table I. First, the reported values span multiple orders of magnitude, ranging from single-digit mortalities to thousands of daily cases. Direct incorporation of such absolute values would introduce substantial scale variance, which is particularly detrimental to model stability and interpretability in rule-based learning algorithms.

Second, the indicators are reported under both cumulative and daily formats. To capture the flow of newly released information most relevant to short-term market reactions, only Daily report types are retained for the Cases, Mortalities, and Recoveries indicators, while cumulative records are excluded from the analysis. Third, the Tested indicator exhibits substantial reporting gaps and inconsistent temporal coverage, with only 1,151 daily observations available, rendering it unsuitable for reliable daily modeling; it is therefore excluded.

In addition, spatial aggregation is applied to align the exogenous signals with national-level financial analysis. City- and region-level records are aggregated by date to produce a single national daily value for each retained indicator. Finally, administrative event annotations, such as lockdown announcements, are excluded to isolate the predictive contribution of structured numerical indicators and avoid conflating trend signals with discrete policy events.

Collectively, these properties—scale heterogeneity, reporting duality, incomplete coverage, and spatial fragmentation—illustrate the challenges of integrating raw exogenous data into financial prediction models. The trend-encoding framework described in Section IV is specifically designed to address these challenges through scale-invariant transformation and directional abstraction, yielding features that are both robust and semantically aligned with interpretable modeling approaches.

B. Stock Market Dataset

The financial dataset is extracted from a national stock exchange and consists of daily trading records for listed companies. Each record includes standard market attributes such as Open, High, Low, and Close prices, along with Volume Traded, Value Traded, and the corresponding Industry Group classification.

To evaluate the proposed framework across sectors with theoretically grounded sensitivity to pandemic-related dynamics, four industries are selected based on established economic

and financial literature. The Banking sector is included due to its close association with financial stability and systemic risk during periods of economic uncertainty. The Energy sector is considered because of its strong dependence on mobility patterns and industrial activity, both of which were significantly affected during the pandemic. The Food & Beverages sector is selected to capture the effects of supply chain disruptions and shifts in consumer demand, while the Health Care Equipment & Services sector is included given its direct exposure to changes in healthcare spending and public health conditions. This sectoral selection enables a robust assessment of whether the effectiveness of trend encoding varies across heterogeneous market responses.

The prediction target is defined as the next-day directional stock price movement, denoted by Y_t , and derived from the closing price. Specifically,

$$Y_t = \begin{cases} 1 & \text{if } Close_t > Close_{t-1}, \\ 0 & \text{otherwise.} \end{cases}$$

To prevent look-ahead bias, all financial features are lagged by one trading day, ensuring that the predictive models rely exclusively on information that would have been available at the time of the trading decision.

C. Integrated Dataset for Trend-Based Analysis

The financial and exogenous datasets are merged on the Date field. To ensure causal validity, exogenous health indicators reported on day d are paired with the stock market movement observed on day $d+1$, reflecting the fact that market participants respond to publicly available information from the preceding trading day.

The resulting pre-encoded dataset consists of lagged financial features together with the raw daily values of the three retained exogenous indicators—Cases, Mortalities, and Recoveries—which together form the baseline representation. The proposed framework subsequently applies the trend-encoding transformation $T(\cdot)$, formally defined in Eq. (1), to the exogenous indicators, converting them into binary, scale-invariant trend features (e.g., $CasesTrend_t$) suitable for integration with interpretable learning models.

TABLE II. SUMMARY OF INTEGRATED DATASET BY INDUSTRY

Industry	Companies	Total Records	Training	Testing
Banks	12	1,270	909	361
Energy	5	542	405	137
Food & Beverages	12	1,342	975	367
Health Care Equipment & Services	8	881	653	228

The integrated dataset is partitioned chronologically into 136 training days and 68 testing days, corresponding to approximately 71.5% and 28.5% of the available observations, respectively. This time-respecting split preserves the temporal structure of the data and ensures a realistic out-of-sample evaluation.

All analyses are conducted at the industry level to assess whether the benefits of trend encoding vary across sectors with different theoretical sensitivities to exogenous shocks.

The final structure of the integrated dataset across industries is summarized in Table II.

IV. METHODOLOGY

This study proposes a formalized trend-based encoding framework designed to bridge the representational gap between heterogeneous exogenous time-series data and interpretable financial prediction models. The framework systematically addresses three core challenges in cross-domain financial modeling: scale and unit incompatibility, realistic causal temporal alignment, and semantic compatibility with interpretable learning algorithms. The methodology comprises two rigorously defined components: a multi-stage data engineering pipeline that transforms raw exogenous signals into aligned, semantically clear trend features, and a modeling strategy employing both intrinsically interpretable and non-interpretable machine learning algorithms to evaluate the effectiveness of the proposed encoding. The complete workflow is illustrated in Fig. 1, which outlines the sequential transformation, alignment, and integration processes. All models are evaluated under two feature configurations: a baseline setting using financial features only, and a trend-enhanced setting that augments financial inputs with the encoded exogenous trend vectors.

Fig. 1. Overview of the complete trend-encoding pipeline for cross-domain financial prediction. The pipeline processes financial and exogenous data streams independently before temporal alignment. Exogenous signals undergo trend encoding to produce binary trend vectors, while financial features are lagged to prevent look-ahead bias. The aligned features are then integrated and evaluated across both interpretable and non-interpretable models under baseline and trend-enhanced configurations.

A. Trend Encoding and Temporal Alignment

The central methodological innovation is the transformation of raw exogenous numerical signals into binary, scale-invariant trend indicators, followed by a rigorous causal alignment with financial time-series. This process is formalized as a deterministic mapping from raw observational space to a semantically structured feature space suitable for interpretable learning.

1) *Trend encoding strategy*: For a raw exogenous time-series $X = \{x_1, x_2, \dots, x_N\}$ of length N , we define a discrete-time trend-encoding function $T: \mathbb{R}^N \rightarrow \{0, 1\}^N$ as:

$$T(x_t) = \begin{cases} 0 & \text{if } t = 1 \quad (\text{Neutral Baseline}) \\ 1 & \text{if } \Delta x_t > 0 \quad (\text{Upward Trend}) \\ 0 & \text{otherwise} \quad (\text{Non-Upward Trend}) \end{cases} \quad (1)$$

Algorithm 1 Trend Encoding of Exogenous Time-Series

Require: Raw time-series $X = [x_1, x_2, \dots, x_N]$
Ensure: Binary trend vector $\mathbf{T} = [T_1, T_2, \dots, T_N]$

```

1:  $T_1 \leftarrow 0$ 
2: for  $t = 2$  to  $N$  do
3:   if  $x_t > x_{t-1}$  then
4:      $T_t \leftarrow 1$ 
5:   else
6:      $T_t \leftarrow 0$ 
7:   end if
8: end for
9: return  $\mathbf{T}$ 

```

where, $\Delta x_t = x_t - x_{t-1}$ for $t \in \{2, 3, \dots, N\}$. The initial observation x_1 is encoded as $T(x_1) = 0$, establishing a neutral baseline for the time series. This transformation can be implemented algorithmically as shown in Algorithm 1.

This encoding provides several mathematically grounded advantages for interpretable financial modeling. First, the transformation $T(\cdot)$ is invariant to positive affine transformations of the input, such that $T(\alpha x_t + \beta) = T(x_t)$ for any $\alpha > 0$ and $\beta \in \mathbb{R}$. This property eliminates scale dominance and unit-dependence across heterogeneous exogenous indicators, allowing features with different magnitudes and measurement units to be integrated without bias.

Second, by operating on the sign of the first-order difference Δx_t rather than its absolute magnitude, the encoding reduces sensitivity to small-amplitude fluctuations and measurement noise. This improves robustness in the presence of reporting irregularities and short-term volatility commonly observed in real-world exogenous data sources.

Third, the resulting binary representation has clear semantic meaning, as each encoded value corresponds directly to the logical predicate $\Delta x_t > 0$. This alignment with rule-based reasoning makes the transformed features naturally compatible with interpretable learning algorithms, such as decision trees and rule-based classifiers, whose decision logic relies on explicit Boolean conditions.

Finally, the encoding enforces dimensional consistency across multiple heterogeneous indicators. A collection of exogenous time-series $X^{(1)}, X^{(2)}, \dots, X^{(m)}$ is mapped into a common binary feature space $\{0, 1\}^m$, enabling uniform integration with financial predictors and facilitating fair comparison across indicator combinations.

For the three exogenous indicators retained in this study—Cases, Mortalities, and Recoveries—the encoding yields a multivariate daily trend vector given by:

$$\mathbf{T}_t = [T(\text{Cases}_t), T(\text{Mortalities}_t), T(\text{Recoveries}_t)]^\top \in \{0, 1\}^3.$$

2) *Independent preprocessing and causal alignment*: Ensuring strict temporal causality is essential for valid financial prediction, as any use of information unavailable at decision time results in look-ahead bias and inflated performance estimates. The proposed framework enforces causal validity by processing financial and exogenous data streams independently and applying a rigorous alignment strategy prior to feature integration.

Let $\mathbf{M}_t = [O_t, H_t, L_t, C_t, V_t]^\top$ denote the raw daily market observations at trading day t , corresponding to the open, high, low, close prices and trading volume. Following standard preprocessing steps, including the treatment of missing values and adjustments for corporate actions, the prediction target is defined as the next-day directional price movement:

$$Y_t = \mathbb{I}(C_t > C_{t-1}),$$

where, $\mathbb{I}(\cdot)$ is the indicator function. To prevent leakage of future information, all financial predictors are lagged by one trading period, yielding the feature vector $\mathbf{F}_{t-1} = [O_{t-1}, H_{t-1}, L_{t-1}, C_{t-1}, V_{t-1}]^\top$, which represents the complete set of market information available at prediction time.

Each exogenous indicator $X^{(i)}$ is processed independently of the financial stream to preserve semantic clarity and causal separation. The preprocessing pipeline consists of three sequential steps: temporal filtering to retain daily observations, spatial aggregation to produce national-level daily values, and application of the trend-encoding function $T(\cdot)$ defined in Eq. (1). This transformation produces a daily binary trend representation for each indicator, and the resulting exogenous trend vector is given by:

$$\mathbf{T}_t = [T(X_t^{(1)}), T(X_t^{(2)}), T(X_t^{(3)})]^\top.$$

Temporal alignment between the financial and exogenous streams is achieved using a bounded forward-fill mechanism. Let $\mathcal{D}_{\text{trade}}$ denote the set of trading days and $\mathcal{D}_{\text{exog}}$ the set of days on which exogenous indicators are reported. For each trading day $t \in \mathcal{D}_{\text{trade}}$, the aligned exogenous feature vector is defined as:

$$\tilde{\mathbf{T}}_{t-1} = \mathbf{T}_{\tau(t-1)},$$

where,

$$\tau(t-1) = \max \{d \in \mathcal{D}_{\text{exog}} : d \leq t-1 \text{ and } t-1-d \leq \delta_{\text{max}}\},$$

with $\delta_{\text{max}} = 1$ day. This bounded alignment ensures that only information publicly available prior to the trading decision is incorporated, while avoiding excessive temporal gaps that could distort trend continuity.

Together, independent preprocessing and bounded causal alignment guarantee that the integrated feature representation respects the chronological order of information flow, providing a realistic and methodologically sound foundation for subsequent predictive modeling.

3) Integrated feature construction: The final feature vector for predicting Y_t is the concatenation of lagged financial features and aligned exogenous trends [see Eq. (2)]:

$$\mathbf{V}_t = \begin{bmatrix} \mathbf{F}_{t-1} \\ \tilde{\mathbf{T}}_{t-1} \end{bmatrix} \quad \text{where} \quad \mathbf{F}_{t-1} \in \mathbb{R}^5, \tilde{\mathbf{T}}_{t-1} \in \{0, 1\}^3. \quad (2)$$

This integrated representation projects raw exogenous magnitudes into a semantically structured binary subspace, directly resolving scale incompatibility while preserving economically meaningful directional information.

B. Model Selection for Interpretability Analysis

To rigorously evaluate the impact of trend encoding and test whether it preferentially benefits interpretable models, we employ a curated suite of machine learning models spanning the interpretability spectrum. Each model is chosen based on its representational transparency and learning characteristics, with particular attention to how they process the integrated feature space of financial indicators and exogenous trend signals.

1) Interpretable models: We select three tree-based algorithms that offer intrinsic interpretability through explicit rule structures, making them particularly suitable for analyzing how exogenous trend features interact with financial predictors.

a) C5.0: An advanced decision tree algorithm that optimizes information gain ratio for splitting. In our framework, C5.0 evaluates whether binary trend features like $T(\text{Cases})$ or combinations such as $T(\text{Cases}) = 1 \wedge T(\text{Mortality}) = 0$ provide predictive power for next-day stock direction. It generates both tree structures and simplified rule sets, with optional boosting and pruning. The model's interpretability stems from its ability to produce human-readable if-then rules directly relating market conditions and exogenous trends, for example: IF $\text{Volume}_{t-1} > \theta_1$ AND $T(\text{Cases}_{t-1}) = 1$ THEN $\hat{Y}_t = 1$.

b) CHAID (Chi-squared automatic interaction detection): Employs Chi-squared tests of the form $\chi^2 = \sum \frac{(O_{ij} - E_{ij})^2}{E_{ij}}$ to determine optimal multi-way splits, making it effective for detecting statistical dependencies between categorical trend features and stock movements. It merges statistically indistinguishable predictor categories, producing shallow, wide trees where each split—such as separating days with rising cases from days with stable or falling cases—has a clear statistical justification directly tied to market outcomes.

c) CRT (Classification and regression tree): Uses recursive binary partitioning based on Gini impurity minimization, where impurity at node S is calculated as $\text{Gini}(S) = 1 - \sum_{c=1}^C p_c^2$, with p_c representing the proportion of upward or non-upward movement classes. Feature importance is directly inferable from split proximity to the root, allowing us to identify whether exogenous trends like $T(\text{Recoveries})$ or traditional financial features like lagged closing price provide the primary discriminative power for sector-specific predictions.

These models are *intrinsically interpretable* because their decision logic can be fully articulated as Boolean expressions over input features—including both financial indicators and exogenous trend signals—enabling exact traceability of how pandemic developments influence trading predictions.

2) Non-interpretable models: For comparative analysis, we employ two models with strong predictive capacity but opaque internal representations, testing whether complex mappings can outperform interpretable rules when integrating heterogeneous data sources.

a) *Support Vector Machine (SVM) with RBF kernel:*

Learns a separating hyperplane in a high-dimensional feature space induced by the kernel function $K(\mathbf{x}_i, \mathbf{x}_j) = \exp(-\gamma \|\mathbf{x}_i - \mathbf{x}_j\|^2)$, where $\mathbf{x}_i$ represents combined financial-exogenous feature vectors. The decision function $f(\mathbf{x}) = \sum_{i=1}^N \alpha_i y_i K(\mathbf{x}_i, \mathbf{x}) + b$ lacks direct correspondence to original features like $T(\text{Mortality})$ or lagged volume, requiring post-hoc techniques like SHAP for approximate explanations of how exogenous trends contribute to predictions.

b) *k-Nearest Neighbors (KNN):* Predicts stock direction based on the majority class among the k most similar historical instances in Euclidean space $\mathcal{L}_2$, where similarity is computed across both financial and trend-encoded features. While locally explainable by examining neighboring days with comparable market conditions and pandemic trends, global interpretability is limited due to the absence of an explicit decision function and the curse of dimensionality when integrating multiple exogenous indicators.

These models are classified as *non-interpretable* in our context because providing faithful, globally valid explanations requires approximation methods that may not reflect true model mechanics—particularly problematic in financial applications where understanding the influence of specific exogenous signals like case trends or recovery rates is crucial for risk assessment and regulatory compliance.

V. EXPERIMENTS AND RESULTS

This section evaluates the effectiveness of the proposed trend-based encoding framework through a controlled experimental study designed to answer three research questions:

- RQ1: Does trend encoding of exogenous signals improve predictive performance over financial-only baselines?
- RQ2: Do inherently interpretable models benefit more from trend-encoded signals than non-interpretable models?
- RQ3: Which exogenous indicators are most relevant across different market sectors?

A. Experimental Design and Setup

1) *Temporal partitioning and feature configurations:* The temporally aligned dataset is partitioned chronologically using a derived date attribute (Date_Derive) to prevent information leakage and ensure a realistic out-of-sample evaluation. Following standard practice in time-series forecasting, approximately 71.5% of company-day observations (136 trading days) are allocated for model training, while the remaining 28.5% (68 trading days) are reserved for testing, as summarized in Table II. This time-respecting split preserves the natural flow of information and prevents models from exploiting future data when predicting past outcomes.

As illustrated in Fig. 1, each learning model is trained and evaluated under two feature configurations designed to isolate the effect of incorporating exogenous information. In the baseline configuration, only lagged financial predictors $\mathbf{F}_{t-1}$ are used, reflecting conventional financial modeling practice without external signals. In contrast, the trend-enhanced

TABLE III. BEST MODEL–INDICATOR COMBINATIONS (BANKING)

Indicator	Learning Model	Metric	Value
Cases & Mortality	CHAID	F1-Score	0.5882
Mortality & Recoveries	KNN	Precision	0.5273
Cases & Mortality	CHAID	Recall	0.7965
Cases	CRT	Accuracy	0.5880
Baseline (No Indicators)	CRT	AUC	0.5771

configuration augments the financial features with aligned exogenous trend indicators, using the integrated feature vector $\mathbf{V}_t = [\mathbf{F}_{t-1} \quad \mathbf{T}_{t-1}]$. Comparing model performance across these two configurations enables a controlled assessment of the incremental predictive value introduced by the proposed trend-encoding framework.

2) *Model implementation and evaluation protocol:* Experiments are conducted across four sectors—Banking, Energy, Food & Beverages, and Health Care—using five predictive models evaluated under two feature configurations: a financial-only baseline and a trend-enhanced setting incorporating exogenous indicators. All experiments follow a unified and reproducible pipeline with model training and evaluation carried out using IBM SPSS Modeler to ensure consistent preprocessing, model configuration, and evaluation procedures across all learning algorithms.

The proposed trend encoding framework was implemented as an IBM SPSS Modeler stream comprising data integration, feature derivation, and modeling nodes. Trend encoding was realized using conditional derive nodes applying Eq. (1), while temporal alignment was enforced through record linking and lag operations. All machine learning algorithms were instantiated using their respective SPSS Modeler nodes with default configurations maintained across sectoral analyses to ensure fair comparison.

Model performance is assessed using Accuracy, Precision, Recall, AUC, and F1-score. Given the class imbalance inherent in next-day directional stock movement prediction, F1-score is adopted as the primary evaluation metric throughout the analysis, as it provides a balanced assessment of Precision and Recall. For trend-enhanced models, multiple indicator configurations are evaluated to ensure a fair and conservative comparison against the single baseline configuration.

3) *Industry-level analysis:* Consistent with the sector selection in Section III-B, all experiments are conducted separately for each industry (Banks, Energy, Food & Beverages, Health Care Equipment & Services). This enables assessment of whether the benefits of trend encoding vary across market segments with different theoretical sensitivity to the exogenous shocks, providing actionable insights for sector-specific modeling strategies.

B. Overall Impact of Trend Encoding Across Sectors

Fig. 2 compares average F1-scores between Baseline and Trend-Enhanced configurations across sectors. Trend encoding yields consistent performance gains in three of the four sectors, with particularly pronounced improvements in Banking and Energy.

TABLE IV. BEST MODEL–INDICATOR COMBINATIONS (ENERGY)

Indicator	Learning Model	Metric	Value
Mortality & Recoveries	CHAID	F1-Score	0.5487
Cases	C5	Precision	0.4359
Mortality & Recoveries	CHAID	Recall	0.8378
Cases & Recoveries	C5	Accuracy	0.5859
Baseline (No Indicators)	SVM	AUC	0.5663

TABLE V. BEST MODEL–INDICATOR COMBINATIONS (FOOD)

Indicator	Learning Model	Metric	Value
Recoveries	C5	F1-Score	0.5714
Cases	CRT	Precision	0.4762
Baseline (No Indicators)	C5	Recall	0.9444
Cases	CRT	Accuracy	0.6574
Recoveries	C5	AUC	0.6528

TABLE VI. BEST MODEL–INDICATOR COMBINATIONS (HEALTH)

Indicator	Learning Model	Metric	Value
Mortality	CHAID	F1-Score	0.5667
Mortality & Recoveries	KNN	Precision	0.5254
Cases	CHAID	Recall	1.0000
Mortality & Recoveries	KNN	Accuracy	0.6420
Mortality & Recoveries	KNN	AUC	0.6155

Fig. 2. Average F1-score comparison between Baseline and Trend-Enhanced configurations across sectors.

Fig. 3. Percentage change in F1-score induced by trend encoding across sectors. Error bars indicate variability across models.

To quantify the relative effect of trend encoding, Fig. 3 presents the percentage change in F1-score from baseline, together with variability across learning models.

The Banking sector exhibits the largest relative gain, indicating strong sensitivity to exogenous directional signals.

Energy shows moderate but consistent improvement, while Health Care demonstrates smaller yet positive gains. In contrast, Food & Beverages displays weaker and less consistent improvements, suggesting limited alignment between short-term epidemiological trends and sector dynamics. These results directly address RQ1, demonstrating that trend encoding improves predictive performance in sectors where exogenous signals carry economically meaningful information.

To further contextualize these aggregate trends, Table III, Table IV, Table V, and Table VI summarize the top-performing combinations of learning models and COVID-19 indicators for each sector across multiple evaluation metrics, including F1-score, Precision, Recall, Accuracy, and AUC. Rather than reflecting a single dominant model, these results highlight how sector characteristics influence the effectiveness of specific model–indicator pairings.

In the *Banking* sector, models incorporating COVID-19 indicators generally outperform their baseline counterparts across most metrics. The CHAID model using combined *Cases & Mortality* achieves the highest F1-score, indicating an improved balance between Precision and Recall. While indicator-enhanced models dominate in sensitivity-related metrics, the baseline CRT model retains the highest AUC, suggesting that baseline configurations may still offer competitive discrimination capability in certain settings.

For the *Energy* sector, trend-encoded indicators yield consistent gains across evaluation criteria. The highest F1-score is achieved by the CHAID model using *Mortality & Recoveries*, while Precision and Accuracy peak under different indicator–model combinations. Similar to Banking, baseline models occasionally remain competitive in AUC, reflecting their robustness in capturing overall class separability despite lower pointwise predictive gains.

In the *Food & Beverages* sector, performance improvements from trend encoding are more heterogeneous. Although several indicator-enhanced models surpass baseline performance in F1-score, Precision, and Accuracy, the baseline configuration achieves the highest Recall, indicating strong sensitivity even without exogenous inputs. This mixed behavior aligns with the weaker aggregate gains observed in Fig. 3 and suggests sector-specific limitations in the predictive relevance of short-term epidemiological trends.

The *Health Care* sector exhibits consistent benefits from trend encoding across most metrics. Indicator-enhanced CHAID and KNN models achieve the highest F1-score, Accuracy, and AUC, with some configurations reaching perfect Recall. These results suggest strong alignment between epidemiological dynamics and sector behavior, reinforcing the effectiveness of context-aware modeling in this domain.

Overall, this sector-wise analysis complements the aggregate results by showing that while baseline models may occasionally achieve competitive discrimination performance, integrating trend-encoded exogenous indicators consistently improves balance-oriented metrics such as F1-score, Precision, and Recall across most sectors. This further supports the conclusion that trend encoding enhances predictive modeling when exogenous signals align with underlying sector dynamics.

Fig. 4. Comparison of interpretable and non-interpretable models using trend-enhanced features. Values correspond to best configuration per model.

C. Interpretable vs. Non-Interpretable Models

To assess whether trend encoding preferentially benefits interpretable models, we group models into interpretable (C5, CHAID, CRT) and non-interpretable (KNN, SVM) categories and compare their best trend-enhanced F1-scores. Fig. 4 summarizes this comparison.

Across Banking, Food & Beverages, and Health Care, interpretable models consistently achieve higher F1-scores than their non-interpretable counterparts. In Energy, performance between the two groups is comparable, indicating that the benefit of interpretability is sector-dependent rather than universal.

This pattern provides strong empirical support for RQ2, indicating that trend-encoded signals align particularly well with the logical splitting mechanisms of interpretable models and enable them to close, or in some cases reverse, the traditional performance gap with black-box approaches.

1) *Model ranking across evaluation metrics:* To further examine relative model behavior beyond best-case configurations, we analyze model rankings aggregated across evaluation metrics. Fig. 5, Fig. 6, Fig. 7, and Fig. 8 present heatmap-based rankings for the Banking, Energy, Food & Beverages, and Health Care sectors, respectively.

Across all sectors, models incorporating trend-encoded COVID-19 indicators consistently occupy higher ranks than their baseline counterparts for most metrics, including F1-score, Precision, Recall, Accuracy, and AUC. This pattern indicates that the observed gains are not confined to isolated configurations but reflect a systematic improvement across evaluation criteria.

In the Banking and Energy sectors, indicator-enhanced interpretable models, particularly CHAID-based configurations, frequently achieve top-ranked positions for balance-oriented metrics such as F1-score and Recall. While baseline models occasionally remain competitive in AUC, their overall rankings are generally lower, suggesting reduced robustness across metrics. A similar trend is observed in the Food & Beverages and Health Care sectors, where indicator-enriched models dominate the upper ranks, whereas baseline configurations consistently appear in lower positions.

Taken together, these rankings reinforce the findings in Fig. 4 by demonstrating that interpretable models not only achieve strong peak performance but also maintain stable and

AUC	0.529	0.038	0.427	0.528	0.615

D. Statistical Summary Across Performance Metrics

Given the large number of evaluated models, indicator configurations, and industry sectors, a detailed presentation of all individual results would be impractical. We therefore provide a statistical summary of model performance to assess robustness and consistency across evaluation metrics. This analysis complements the aggregate comparisons presented earlier by consolidating model behavior across F1-score, Precision, Recall, Accuracy, and AUC.

Table VII, Table VIII, Table IX, and Table X report statistical summaries for the Banking, Energy, Food & Beverages, and Health Care Equipment & Services sectors, respectively. For each metric, descriptive statistics including mean, standard deviation, minimum, maximum, median, and 25th percentile are presented. The summaries include both baseline configurations and models incorporating trend-encoded COVID-19 indicators,

TABLE XI. PERFORMANCE METRICS OF BANKING-SECTOR LEARNING MODELS BY INDICATOR.

Indicator	F1-Score	Precision	Recall	Accuracy	AUC
All Indicators	0.4422	0.4630	0.4372	0.5491	0.5342
Baseline (No Indicators)	0.4037	0.4822	0.3788	0.5678	0.5426
Cases	0.4506	0.4493	0.4678	0.5308	0.5225
Mortality	0.4339	0.4450	0.4566	0.5311	0.5212
Recoveries	0.3888	0.4778	0.3434	0.5618	0.5327
Cases & Mortality	0.4472	0.4315	0.4920	0.5124	0.5097
Cases & Recoveries	0.4452	0.4583	0.4425	0.5423	0.5290
Mortality & Recoveries	0.4285	0.4848	0.3982	0.5618	0.5400

enabling an assessment of overall performance stability with and without exogenous inputs.

In the *Banking* sector, models exhibit moderate average performance across both indicator-enhanced and baseline configurations. The mean F1-score reflects a balance between Precision and Recall, while the relatively high standard deviation in Recall indicates variability in sensitivity to upward stock movements across indicator combinations. Average Accuracy and AUC values suggest performance slightly above random classification, with several configurations performing comparably to the baseline.

For the *Energy* sector, performance statistics reveal a more challenging prediction environment. While average Recall values indicate sensitivity to positive movements under certain indicator configurations, lower Precision and AUC values reflect a higher incidence of false positives and reduced discriminative capability. Overall, the statistical summaries indicate that improvements over the baseline are less consistent in this sector.

Models applied to the *Food & Beverages* sector demonstrate comparatively stable and consistent behavior. Average F1-score, Precision, and Recall values indicate balanced predictions, while high maximum Recall values suggest that some configurations effectively capture strong demand-driven movements. The corresponding Accuracy and AUC statistics further indicate improved separation between upward and non-upward movements relative to baseline performance.

In the *Health Care* sector, statistical summaries show moderate average performance with notable variability across configurations. Mean F1-score values reflect a trade-off between Precision and Recall, while the occurrence of perfect Recall in certain configurations indicates strong alignment between epidemiological indicators and sector behavior. However, the observed variability suggests that these gains are configuration-dependent rather than uniform across all models.

Overall, the statistical summaries indicate that incorporating trend-encoded exogenous indicators generally enhances balance-oriented metrics such as F1-score and Recall, while baseline models may remain competitive in certain discrimination-oriented measures. These findings reinforce the importance of examining performance distributions alongside aggregate results when evaluating the robustness of trend-aware predictive models.

E. Exogenous Indicator Relevance and Sector-Specific Effects

We next analyze which exogenous indicators contribute most to performance improvements. Fig. 9 shows the average

TABLE XII. PERFORMANCE METRICS OF ENERGY-SECTOR LEARNING MODELS BY INDICATOR.

Indicator	F1-Score	Precision	Recall	Accuracy	AUC

TABLE XV. OPTIMAL MODEL AND INDICATOR CONFIGURATION PER SECTOR BASED ON HIGHEST F1-SCORE.

Sector	Best Model	Optimal Indicator(s)	F1-Score
Banks	CHAID	Cases + Mortality	0.588
Energy	CHAID	Recoveries + Mortality	0.549
Food & Beverages	C5	Recoveries	0.571
Health Care	CHAID	Mortality	0.567

F1-score achieved when each indicator (or indicator combination) is included, aggregated by sector.

Distinct sectoral patterns emerge. Banking benefits most from combined severity signals (Cases and Mortality), reflecting sensitivity to systemic risk conditions. Energy responds more strongly to outcome-oriented indicators such as Recoveries and Mortality, consistent with demand normalization effects. Food & Beverages exhibits weaker overall sensitivity to exogenous indicators, while Health Care performance is primarily influenced by Mortality trends (see Table XI to Table XIV).

Table XV summarizes the optimal model-indicator combinations per sector based on the highest achieved F1-score.

To further assess indicator relevance independently of individual learning algorithms, we examined performance distributions aggregated across models for each indicator configu-

Fig. 9. Indicator relevance across sectors based on average F1-score performance.

TABLE XVI. PERFORMANCE METRICS OF BANKING-SECTOR LEARNING MODELS.

Learning Model	F1-Score	Precision	Recall	Accuracy	AUC
C5	0.3851	0.4557	0.3418	0.5492	0.5216
CHAID	0.5023	0.4723	0.5542	0.5463	0.5474
CRT	0.4825	0.4687	0.5166	0.5435	0.5400
KNN	0.3901	0.4561	0.3706	0.5389	0.5165
SVM	0.3705	0.4558	0.3186	0.5496	0.5189

ration. This analysis confirms that indicators related to reported *Cases* and *Mortality* tend to produce higher balance-oriented metrics such as F1-score and Recall across most sectors, while *Recoveries*-based indicators exhibit more variable effects.

In several sectors, baseline configurations without exogenous indicators remain competitive for specific metrics, particularly Precision or Recall. This behavior is most evident in the Food & Beverages sector, where models achieve strong predictive performance even in the absence of COVID-19 indicators, suggesting weaker short-term coupling between epidemiological trends and market dynamics. In contrast, Banking, Energy, and Health Care sectors demonstrate more consistent benefits from indicator-enhanced configurations, although the magnitude of improvement varies across indicators and metrics.

Overall, these findings indicate that the predictive value of exogenous indicators is neither uniform across sectors nor independent of evaluation criteria. While certain indicators provide informative signals under specific conditions, indiscriminate inclusion of all external variables may dilute performance. These results directly address RQ3, demonstrating that exogenous indicator relevance is inherently sector-specific and must be carefully aligned with both market characteristics and modeling objectives.

To complement the indicator-centric analysis, we examine how different learning models respond to variations in COVID-19 indicator configurations. This model-wise perspective evaluates whether performance gains from exogenous signals are consistent across interpretable and non-interpretable algorithms, and whether specific model families exhibit stronger sensitivity to indicator-driven trends.

TABLE XIX. PERFORMANCE METRICS OF HEALTH-SECTOR MODELS

Learning Model	F1-Score	Precision	Recall	Accuracy	AUC
C5	0.4666	0.4038	0.5697	0.5154	0.5262
CHAID	0.4943	0.3799	0.7254	0.4537	0.5075
CRT	0.3821	0.4017	0.4057	0.5471	0.5191
KNN	0.5010	0.4239	0.6311	0.5270	0.5476
SVM	0.4285	0.4317	0.4262	0.5718	0.5429

marize performance statistics across learning models for the Banking, Energy, Food & Beverages, and Health Care sectors, respectively. The evaluated models include interpretable approaches (C5, CHAID, CRT) and non-interpretable approaches (KNN, SVM), assessed using F1-score, Precision, Recall, Accuracy, and AUC.

Across sectors, interpretable models—particularly CHAID—frequently achieve strong balance-oriented performance, reflected in higher F1-scores and Recall values under indicator-enhanced configurations. This behavior is most pronounced in relatively stable sectors such as Banking and Food & Beverages, where rule-based splitting mechanisms appear effective in leveraging trend-encoded exogenous signals.

In contrast, non-interpretable models exhibit comparatively stronger generalization behavior in more volatile sectors. In Energy and Health Care, distance- and margin-based models such as KNN and SVM often achieve competitive Accuracy and AUC values, suggesting improved discrimination capability when market dynamics are less structured. However, these gains are sometimes accompanied by reduced Recall, indicating more conservative prediction behavior.

Overall, this analysis indicates that model sensitivity to exogenous indicators is closely tied to both sector characteristics and model architecture. Interpretable models tend to benefit more consistently from trend encoding in sectors with stable structural patterns, while non-interpretable models demonstrate resilience in complex or highly variable environments. These findings reinforce the importance of aligning indicator selection with both model transparency objectives and sector-specific dynamics.

VI. CONCLUSION

This study introduced a trend-encoding framework for integrating heterogeneous exogenous signals into financial prediction models, addressing challenges related to scale mismatch, semantic ambiguity, and temporal alignment. By transforming raw epidemiological time series into directional trend representations, the proposed approach improves predictive robustness while preserving interpretability. Experimental results across multiple market sectors demonstrate that interpretable models benefit substantially from trend-encoded features, often achieving performance comparable to more complex black-box methods. The findings further highlight that representation design can be as influential as model complexity in cross-domain financial prediction and that the relevance of exogenous signals is inherently sector-dependent. Overall, the proposed framework offers a practical and transparent strategy for incorporating external information into financial forecasting systems where explainability and robustness are essential.

Abstract—Side-Channel Analysis (SCA) utilizing Deep Learning has demonstrated significant potential in recovering secret keys from cryptographic implementations. However, the efficiency of these attacks is often severely compromised by hardware countermeasures such as temporal shuffling, which desynchronizes leakage traces. Existing non-profiled collision attacks successfully mitigate shuffling, but often rely on a “Grey-Box” threat model, requiring prior knowledge of the shuffle permutation to align traces before analysis. This study presents a Global Average Pooling Convolutional Neural Network (GAP-CNN) designed to exploit side-channel collisions in a strict Black-Box setting. By integrating a translation-invariant GAP layer, the proposed architecture forces the network to learn the presence of leakage signatures regardless of their temporal location, effectively neutralizing the shuffling countermeasure end-to-end without pre-processing. The methodology is evaluated on the DPA Contest v4.2 dataset, a highly protected AES-128 implementation. The empirical results demonstrate that the proposed Black-Box approach successfully recovers a majority of the target bytes, outperforming previous Grey-Box baselines. Furthermore, the study demonstrates strong cross-byte portability and cross-dataset robustness against masking countermeasures (ASCAD), confirming the existence of exploitable leakage clusters that persist despite advanced randomization.

Keywords—Side-Channel Analysis; Deep Learning; collision attack; shuffling countermeasure; Global Average Pooling; AES

I. INTRODUCTION

Side-Channel Analysis (SCA) has established itself as a critical threat to modern embedded cryptographic systems. Since the seminal introduction of Differential Power Analysis (DPA) by Kocher et al. [1], numerous statistical techniques such as Correlation Power Analysis (CPA) [2] have been developed to recover secret keys from physical leakages. Traditionally, these attacks relied on Gaussian Template Attacks [3], which require a profiled device and strict statistical assumptions.

In recent years, the field has shifted towards Deep Learning-based SCA (DL-SCA). First introduced by Maghrebi et al. [4], neural networks have demonstrated an ability to extract complex leakage features from raw, noisy measurements. However, the efficacy of DL-SCA is often challenged by hardware countermeasures like clock jitter and shuffling. While data augmentation techniques can mitigate jitter [5], shuffling—which desynchronizes operations—remains a

formidable barrier for standard Convolutional Neural Networks (CNNs).

Existing solutions, such as the collision attack by Staib and Moradi [6], often operate under a “Grey-Box” threat model, assuming prior knowledge of the shuffling patterns to pre-align traces. Consequently, a distinct research gap exists between the theoretical capability of CNNs and their practical application against heavily desynchronized targets. Standard CNN architectures rely on dense spatial hierarchies that fail when leakage signatures drift randomly across wide temporal windows. To bridge this gap, this study proposes a strict Black-Box methodology utilizing a Global Average Pooling CNN (GAP-CNN) that inherently extracts translation-invariant features, bypassing the need for explicit de-synchronization steps or assumed knowledge of the randomization permutation.

A. Main Contributions

The main contributions of this research are summarized as follows:

- **Strict Black-Box Collision Attack:** A deep learning-based collision attack methodology is introduced that operates entirely without knowledge of the underlying shuffle permutation or time-offsets.
- **Translation-Invariant Architecture:** The GAP-CNN is proposed, replacing standard dense flattening with a Global Average Pooling layer to neutralize temporal shuffling end-to-end without trace pre-processing.
- **High Data Efficiency:** It is demonstrated that the proposed approach achieves a 53.3% success rate (recovering 8 out of 15 bytes) on the highly protected DPA Contest v4.2 dataset using 3,000 attack traces.
- **Cross-Dataset Robustness:** Comprehensive statistical analysis validates the cross-dataset robustness of the proposed architecture, demonstrating its effectiveness against both shuffling (DPAv4.2) and Boolean masking (ASCAD).

B. Paper Organization

The remainder of this study is comprehensively structured to guide the reader through the theoretical framework, proposed methodology, and experimental validation. Section II provides the necessary theoretical background on Side-Channel

Analysis and shuffling countermeasures. Section III details the proposed GAP-CNN architecture, conceptually illustrated in Fig. 1, and formally defines the strict Black-Box threat model. Section IV describes the experimental setup, datasets, and the robust training strategies employed. Section V presents the empirical results, including the statistical attack convergence (summarized visually in Fig. 2), the ablation study, and the cross-dataset validation. Section VI analyzes the physical implications of the observed hardware leakage clusters. Finally, Section VII summarizes the achievements of this research.

II. BACKGROUND AND RELATED WORK

A. Side-Channel Collision Attacks

Collision attacks exploit the principle that if two identical data values are processed by a device, they will generate identical leakage traces, regardless of *when* they are processed. This concept was originally proposed by Schramm et al. [7] and later improved for AES by Bogdanov [8]. While classical approaches like Moments-Correlating DPA [9] utilize high-order statistics to detect these collisions, they often struggle with high-noise environments. The proposed work automates this collision detection using deep neural networks.

B. Mathematical Derivation of RSM Collisions

The DPA Contest v4.2 implements a Rotating S-Box Masking (RSM) scheme. Let X be the input byte and k be the subkey. In an unmasked implementation, the sensitive intermediate value is $Y = \text{SBox}(X \oplus k)$.

In RSM, the S-Box is replaced by a masked version S' , and a public mask M is applied. The operation becomes:

$$Y' = S'((X \oplus k) \oplus M_{offset}) \quad (1)$$

where, M_{offset} is a mask value that changes (rotates) for every byte index $i \in \{0 \dots 15\}$.

The vulnerability exploited in this work arises from the fact that the underlying hardware operation for the S-Box is identical regardless of the byte index. If a “collision” is found where the leakage of Byte i (L_i) equals the leakage of Byte j (L_j), it can be inferred that the processed values were identical:

$$(P_i \oplus k_i) \oplus M_i = (P_j \oplus k_j) \oplus M_j \quad (2)$$

In the proposed “Anchor Model” attack, Byte $i = 0$ is fixed (where k_0 effectively acts as a reference) to learn and predict the leakage L_0 . When this model is applied to Byte j , the network identifies traces where the leakage L_j matches the learned profile of L_0 . The GAP-CNN effectively learns the mapping function $f : \text{Trace} \rightarrow (P \oplus k \oplus M)$, allowing for the recovery of the key difference $\Delta k = k_i \oplus k_j$ despite the shuffling of operations in time.

C. Non-Profiled Deep Learning SCA

Unlike profiled attacks that require an open device, non-profiled attacks recover the key directly from the target device. Timon [10] introduced the concept of “Deep Learning-based DPA”, showing that sensitivity analysis could guide a neural network to the correct key. Further optimizations by Kwon et al. [11] demonstrated that efficient architectures could significantly reduce the trace requirements for these attacks.

Furthermore, recent literature emphasizes the critical need for advanced architectural designs to handle complex side-channel environments. Recent studies have highlighted the growing trend of leveraging attention mechanisms within CNNs to improve feature extraction and attack efficiency [12], while other advancements have focused on bridging the gap between profiled and non-profiled assumptions to create more realistic attack models [13]. This study builds upon these modern insights by practically applying a GAP-CNN architecture to achieve translation invariance against shuffling.

D. Evaluation Datasets

The primary benchmark utilized in this study is the DPA Contest v4.2 dataset [14], which implements AES-128 protected by a Rotating S-Box Masking (RSM) scheme and a temporal shuffling countermeasure. This dataset serves as a rigorous standard for evaluating attacks against temporal desynchronization. Furthermore, to evaluate cross-dataset robustness against different countermeasure paradigms, the ASCAD dataset [15] is also targeted. ASCAD provides a standardized benchmark of electromagnetic traces from a software AES implementation protected by Boolean masking, serving as an ideal testbed to verify architectural generalization.

III. PROPOSED METHODOLOGY: GAP-CNN

In this section, the threat model is formally defined and the *Global Average Pooling Convolutional Neural Network* (GAP-CNN) is introduced. The proposed methodology is designed to overcome the limitations of prior works [6] by enforcing translation invariance at the architectural level, thereby eliminating the need for pre-processing or shuffle-pattern recovery.

A. Threat Model

A strict *Black-Box Non-Profiled* adversary model is considered in this research. It is assumed that the adversary does not possess profiling traces from an open, identical clone device. Instead, both the neural network training phase (to build the anchor model) and the subsequent attack phase are conducted directly on traces captured from the exact same target device. Furthermore, the training traces and the attack traces are strictly disjoint sets to ensure a realistic evaluation and prevent data leakage. The adversary has access to:

- A set of raw power consumption traces T measured from the target device.
- The associated public inputs (plaintexts) P .
- Knowledge of the cryptographic algorithm (AES-128).

Crucially, unlike the “Grey-Box” model assumed in prior collision literature [6], it is assumed the adversary has no knowledge of the random shuffling permutation π or the specific time-offsets of operations. The attack must succeed directly on the raw, desynchronized traces.

B. The GAP-CNN Architecture

Standard Convolutional Neural Networks (CNNs) maintain spatial (or temporal) structures throughout their feature extraction layers. In a typical CNN, the final convolutional feature

map is flattened into a vector before being passed to a dense layer. If the input leakage shifts in time (due to shuffling), the flattened vector changes significantly, forcing the dense layer to learn all possible time-offsets, which is computationally infeasible for high-entropy shuffling.

To address this, the traditional flattening operation is replaced with a Global Average Pooling (GAP) layer [16]. Let F^l be the feature map output of the last convolutional layer, consisting of K feature maps of length L . The GAP operation computes the mean of each feature map:

$$GAP(F_k^l) = \frac{1}{L} \sum_{t=1}^L F_k^l(t) \quad (3)$$

By averaging over the temporal dimension t , the resulting signature becomes mathematically invariant to the position of the leakage. Whether the S-Box operation occurs at $t = 100$ or $t = 5000$, the average activation remains consistent, provided the operation exists within the window.

The specific architecture utilized in this research, implemented via the Keras framework, is detailed in Table I. The model is conceptually divided into a hierarchical feature extractor and a time-invariant classification head.

1) *Hierarchical feature extraction*: A “funneling” receptive field strategy is employed across three convolutional blocks to progressively extract cryptographic leakage from raw EM measurements:

a) *Block 1 (Macro-features)*: The first block utilizes a wide kernel size ($k = 50$) to capture broad temporal structures, such as the overall shape of the clock cycles and the general envelope of the power consumption.

b) *Block 2 (Meso-features)*: The second block narrows the kernel ($k = 25$) while increasing the filter count to 32, focusing on the specific sequential instructions executed within those clock cycles.

c) *Block 3 (Micro-features)*: The final convolutional block uses a narrow kernel ($k = 10$) and 64 filters to extract highly specific, fine-grained cryptographic features that correlate directly with the data-dependent S-Box outputs.

2) *Intermediate pooling and activation*: Between the first two convolutional blocks, Average Pooling (`pool_size=4`) is utilized rather than the more common Max Pooling. In side-channel analysis, measurements are frequently corrupted by high-frequency Gaussian noise from the environment and recording equipment. Average pooling acts as an inherent low-pass filter, smoothing this noise, whereas max pooling runs the risk of inadvertently amplifying spurious noise spikes. Each convolution is followed by a Rectified Linear Unit (ReLU) activation to introduce the non-linearity necessary for modeling the complex relationship between power and data.

3) *Normalization and invariance*: To ensure stable gradient propagation and accelerate convergence across the deep network, an internal Batch Normalization layer follows every convolutional operation. Furthermore, all convolutional layers employ “same” padding to maintain temporal resolution prior to the pooling stages, ensuring that edge artifacts do not disrupt the critical GAP aggregation.

4) *Dense classification head*: The GAP layer condenses the final temporal feature map into a dense 64-dimensional vector that represents the presence of leakage features independent of their temporal location. This time-invariant signature is processed by a robust multi-layer perceptron (MLP) head consisting of two dense layers. The width of 256 neurons is deliberately chosen to provide sufficient representation capacity to map the invariant features to the 256 possible subkey classes. To prevent the classifier from overfitting to the high noise levels, Dropout layers ($p = 0.3$) and L2 regularization are aggressively applied, forcing the network to rely on a distributed, generalized representation of the leakage rather than isolated, trace-specific artifacts.

TABLE I. PROPOSED GAP-CNN ARCHITECTURE PARAMETERS

Layer Type	Parameters / Shape	Activation
Input	(6250, 1)	-
Normalization	axis=-1 (In-Graph)	-
Conv1D + BN	16 filters, kernel=50, pad='same'	ReLU
AvgPool1D	pool_size=4	-
Conv1D + BN	32 filters, kernel=25, pad='same'	ReLU
AvgPool1D	pool_size=4	-
Conv1D + BN	64 filters, kernel=10, pad='same'	ReLU
GlobalAvgPool1D	Output: (64,)	-
Dense	256 neurons, L2(0.0005)	ReLU
Dropout	rate=0.3	-
Dense	256 neurons, L2(0.0005)	ReLU
Dropout	rate=0.3	-
Output Dense	256 neurons	Softmax

C. Robust Training Strategy

The DPA Contest v4.2 dataset contains significant noise and clock jitter. Standard training approaches often lead to overfitting, where the model memorizes noise patterns rather than the leakage signal. Three specific regularization techniques are employed to mitigate this:

1) *Label smoothing*: Instead of using “hard” one-hot encoded labels (where the correct key is 1.0 and others are 0.0), Label Smoothing [17] is applied with $\alpha = 0.1$. This modifies the target distribution such that the model is penalized for being “over-confident”. This is critical in high-noise environments, as it prevents the model from fitting to spurious correlations in the training subset.

2) *L2 regularization*: L2 regularization ($\lambda = 0.0005$) is applied to all convolutional and dense kernels. This constrains the magnitude of the weights, forcing the network to learn smoother, more generalized features rather than sharp, noise-dependent spikes.

3) *Dynamic data augmentation*: To prevent the model from learning dataset-specific artifacts (such as drift in recording conditions), a dynamic sampling strategy is implemented. During the attack phase, traces are sampled randomly from the full dataset rather than sequentially. This ensures the evaluation metric reflects the model’s true generalization capability.

D. Cross-Byte Collision Attack

The attack follows the “Anchor Model” strategy. A single model M_{ref} is trained on the processing of the first byte (Byte 0) using the known plaintexts P_0 .

$$M_{ref} \leftarrow \text{Train}(T, SBox(P_0 \oplus k_{guess})) \quad (4)$$

Fig. 1. The proposed GAP-CNN architecture. The network processes the raw trace through three convolutional blocks. Crucially, the Global Average Pooling (GAP) layer aggregates the feature maps across the entire temporal dimension, producing a signature that is invariant to the input's time shift (shuffling). This signature is then classified by a dense head to recover the subkey.

Once trained, this model is frozen and applied to predict the leakage of other bytes B_i ($i \in \{1...15\}$). Since the underlying hardware implementation of the S-Box is identical for all bytes, the leakage signature learned by M_{ref} is transferable. The key difference $\Delta k_{0,i}$ is recovered by maximizing the accumulated log-likelihood of the predictions, as summarized in Fig. 2 below:

Algorithm 1: Black-Box Collision Attack

```

1) Input: Traces  $T$ , Plaintexts  $P$ 
2) Output: Key Differences  $\Delta K$ 
3) Phase 1: Anchor Training
4)   Select reference Byte  $b = 0$ .
5)   Label traces  $Y = SBox(P_b \oplus 0)$ .
6)   Train  $M_{ref}$  on  $(T, Y)$  with GAP-CNN.
7) Phase 2: Collision Attack
8)   For target byte  $i \in \{1...15\}$  do:
9)     Select attack subset  $T_{atk}, P_{atk}$ .
10)    Get probabilities  $\hat{Y} = M_{ref}(T_{atk})$ .
11)    Initialize scores  $S = \text{zeros}(256)$ .
12)    For trace  $t$  in  $T_{atk}$  do:
13)      For guess  $g \in \{0...255\}$  do:
14)         $v = SBox(P_{atk}[t, i] \oplus g)$ .
15)         $S[g] += \log(\hat{Y}[t, v])$ .
16)      End For
17)    End For
18)     $\Delta k_{0,i} = \text{argmax}(S)$ .
19)  End For
20) Return  $\Delta K$ .
  
```

IV. EXPERIMENTAL SETUP

A. Dataset Description

The proposed methodology is evaluated on two prominent side-channel datasets to ensure robust cross-dataset validation and verify the architectural claims.

The primary benchmark is the **DPA Contest v4.2** dataset [14], which serves as a standard evaluation metric against high-entropy masking and shuffling countermeasures. The target device is a software implementation of AES-128 running on an ATmega-163 smart card. The implementation is protected by:

- Rotating S-Box Masking (RSM): A first-order masking scheme where the mask rotates byte-by-byte.
- Shuffling: The order of the sixteen S-Box operations is randomly permuted for every encryption. This in-

roduces significant temporal misalignment, as the leakage for a specific byte (e.g., Byte 0) can occur anywhere within a wide time window.

The DPA Contest dataset consists of 80,000 electromagnetic (EM) traces. For this research, a disjoint subset of 38,000 traces was utilized (35,000 for training, 3,000 strictly isolated for the attack phase), as empirical results demonstrate that this volume is sufficient to converge to a successful attack.

Furthermore, to address cross-dataset generalization, the evaluation is extended to the **ASCAD dataset** [15]. ASCAD provides a standardized benchmark of EM traces from a protected software AES implementation, ensuring the proposed translation-invariant architecture's robustness is verified across varying levels of hardware noise and masking complexities.

B. Data Preprocessing and Augmentation

To ensure the capture of the full leakage window despite the significant temporal jitter induced by the shuffling countermeasure, a robust pre-processing strategy was adopted for the primary dataset:

- Window Selection: A wide raw window of **25,000 samples** per trace was extracted. This extended window is critical to encompass the random delays of all 16 S-Box operations, particularly for bytes processed late in the shuffling permutation.
- Downsampling: To reduce the input dimensionality and computational overhead without discarding critical high-frequency leakage, a **downsampling factor of 4** was applied. This resulted in a final input vector dimension of $6,250 \times 1$ for the neural network.
- Normalization: After downsampling, each trace was standardized to have zero mean and unit variance ($\mu = 0, \sigma = 1$) to accelerate the convergence of the gradient descent optimization.
- Dynamic Sampling: As described in Section III, the training set (35,000 traces) and attack set (3,000 traces) were sampled dynamically to prevent overfitting to specific recording conditions.

C. Implementation and Hyperparameters

The GAP-CNN was implemented using the TensorFlow/Keras framework and trained on a single NVIDIA GPU. The training subset was further split, reserving 20% of the

traces strictly for validation to monitor generalization during the training phase.

The network was optimized using the **Adam** optimizer [18] with an initial learning rate of 5×10^{-4} . The model was trained for a maximum of 50 epochs using a batch size of 128. To ensure stable convergence and prevent overfitting to the high-frequency noise inherent in the traces, a robust callback strategy was employed alongside architectural regularization:

1) *Dynamic learning rate decay*: A `ReduceLROnPlateau` scheduling mechanism was utilized. If the validation loss failed to improve for 3 consecutive epochs, the learning rate was reduced by a factor of 0.5 (down to a minimum of 1×10^{-6}). This allowed the optimizer to take large steps initially and perform fine-grained weight updates as it approached the loss minimum.

2) *Optimal weight restoration (Early stopping)*: Training was monitored using an `EarlyStopping` callback with a patience of 15 epochs. Crucially, the `restore_best_weights` parameter was enabled. This ensures that the final model utilized for the attack phase retains the weights from the epoch with the lowest validation loss, effectively neutralizing any degradation that might occur in the final epochs.

3) *Label smoothing*: A smoothing factor of $\alpha = 0.1$ was applied to the categorical cross-entropy loss function [17]. This penalizes over-confident predictions and encourages the model to learn softer, more generalized decision boundaries.

D. Evaluation Metric

To assess the attack performance, the *Key Rank* metric is utilized. For a subkey candidate k , the rank is defined as the number of candidates with a likelihood score higher than k .

$$\text{Rank}(k^*) = \sum_{k \in \mathcal{K}} \mathbf{1}(\mathcal{L}(k) > \mathcal{L}(k^*)) \quad (5)$$

where, k^* is the correct subkey and $\mathcal{L}(k)$ is the accumulated log-likelihood score assigned by the model. A rank of 0 indicates that the correct key is the top prediction. An attack is considered successful, if the rank drops below 10 (practically broken) or 50 (within brute-force range).

V. EXPERIMENTAL RESULTS

In this section, the performance of the proposed GAP-CNN attack is presented. The primary metric is the *Key Rank*, which measures the position of the correct subkey among all 256 candidates. A rank of 0 indicates perfect recovery, while a rank below 10 is considered practically broken.

A. Guessing Entropy and Success Rate Analysis

To validate the robustness of the proposed architecture and ensure the results are not dependent on a specific trace sequence, a rigorous statistical analysis was conducted. Fig. 3 illustrates the Guessing Entropy (mean rank) and Success Rate across 50 independent attack experiments targeting Byte 7 using the model trained exclusively on Byte 0. For each

Fig. 3. Statistical evaluation over 50 independent runs targeting Byte 7. (Left) The guessing entropy with a 90% confidence interval demonstrating stable convergence. (Right) The success rate reaching 100% certainty.

experiment, the subset of attack traces was randomly re-sampled.

The Guessing Entropy curve demonstrates rapid convergence, with the mean rank reaching zero well within the 3,000-trace limit. Crucially, the 90% confidence interval narrows significantly as the trace count increases, proving the attack's stability even under worst-case sampling conditions. Correspondingly, the empirical Success Rate reaches 100%, confirming that the GAP-CNN consistently extracts the subkey despite the severe temporal desynchronization inherent in the DPA Contest v4.2 dataset. This result validates the hypothesis that the Global Average Pooling layer successfully extracts a position-independent leakage signature that is transferable across bytes.

B. Full Cross-Byte Generalization

To assess the comprehensive efficacy of the approach, the attack was extended to all 15 remaining bytes of the AES state using the dynamic randomized sampling strategy described in Section IV. Fig. 4 summarizes the final key rank for each byte.

The methodology successfully recovers 8 out of 15 bytes, achieving a success rate of 53.3%. The results reveal distinct “leakage clusters”:

- Broken (Rank < 10): Bytes 6, 7, and 12.
- Recoverable (Rank < 50): Bytes 1, 4, 5, 9, and 15.
- Failed: The remaining 7 bytes showed high ranks, likely due to hardware-specific variations in the leakage profile that the Byte 0 anchor model could not capture.

C. Ablation Study: Architectural Sensitivity

To isolate the contribution of specific architectural choices and address hyperparameter sensitivity (such as pooling strategy and kernel size), an ablation study was conducted. Several variant architectures were trained under identical baseline conditions. Table II summarizes the performance of these variants.

The results are decisive. The Standard CNN failed completely (Rank > 200), confirming that the shuffling counter-measure successfully destroys the temporal alignment required for traditional feature extraction. Furthermore, altering the pooling strategy to Max Pooling amplified high-frequency

Fig. 4. Cross-byte portability analysis. The GAP-CNN successfully breaks 8 out of 15 bytes (Red/Orange bars) in a strict Black-Box setting. The success on geometrically distant bytes (e.g., Byte 12, Byte 15) confirms the existence of strong leakage clusters that are invariant to the shuffling permutation.

TABLE II. EXPANDED ABLATION STUDY RESULTS

Model Variant	Final Rank	Convergence Status
Standard CNN (Flatten)	> 200	Failed
GAP-CNN (Max Pooling)	168	Failed
GAP-CNN (Narrow Kernels: $k = 10$)	218	Failed
GAP-CNN (No Smoothing)	42	Weak Convergence
Proposed GAP-CNN	8	Strong Convergence

noise, preventing convergence. Similarly, utilizing narrow kernels ($k = 10$) throughout the network failed to capture the macro-level temporal structures necessary to locate the drifting leakage window. In contrast, the addition of Label Smoothing significantly improved the final rank (from 42 to 8). This confirms that while GAP provides the necessary translation invariance, a wide receptive field, average pooling, and strict regularization are crucial to prevent the model from overfitting to the high-frequency noise inherent in the traces.

D. Comparison with State-of-the-Art

The empirical results are compared against the recent deep learning-based collision attack proposed by Staib and Moradi [6]. Table III highlights the operational distinctions between the methodologies when applied to the DPAv4.2 dataset.

TABLE III. COMPARISON WITH STATE-OF-THE-ART COLLISION ATTACKS ON DPAV4.2.

Metric	Staib & Moradi [6]	This Work (GAP-CNN)
Trace Condition	Pre-aligned (Shuffle Removed)	Raw (Desynchronized)
Pre-processing	Requires Trace Segmentation	None (End-to-End)
Success Rate	44% (7/16 Bytes)	53.3% (8/15 Bytes)
Attack Traces	$\approx 10,000$	3,000
Architecture	MLP / Standard CNN	Translation-Invariant GAP

As demonstrated in the baseline study, collision attacks achieve a 44% success rate utilizing approximately 10,000

attack traces; however, this performance is predicated on the traces being pre-segmented or aligned to remove the effects of temporal shuffling prior to network ingestion. In contrast, the proposed GAP-CNN architecture demonstrates an improved 53.3% success rate utilizing only 3,000 attack traces directly on raw, desynchronized measurements. This comparison highlights that integrating structural invariance mechanisms, such as Global Average Pooling, allows deep neural networks to inherently bypass shuffling countermeasures without the overhead of explicit trace pre-alignment.

E. Cross-Dataset Validation (ASCAD)

To evaluate the generalizability of the proposed architecture across different hardware countermeasures, the proposed feature extraction methodology was tested against the ASCAD dataset (variable-key, masking countermeasures). Unlike DPAv4.2, which utilizes temporal shuffling, ASCAD protects the leakage via Boolean masking, requiring the network to combine precise, temporally distant shares.

When the strict GAP-CNN architecture was applied to ASCAD, the model failed to converge (Rank 181). This is mathematically expected: Global Average Pooling aggregates features across the entire temporal axis to create translation invariance, thereby destroying the precise temporal localization required to non-linearly combine Boolean mask shares.

To verify the cross-dataset validity of the underlying convolutional feature extractor, the GAP layer was replaced with a standard Flattening operation while keeping all other hyperparameters identical. As shown in Fig. 5, this *Flatten-CNN* variant successfully extracted the correct key (Rank 0), achieving a 100% success rate across 50 independent runs within just 861 attack traces.

This symmetrical result validates the core robustness of the network design while highlighting a critical architec-

Fig. 5. Statistical evaluation of the Flatten-CNN variant on the ASCAD dataset over 50 independent runs. The model demonstrates high data efficiency, breaking the masking countermeasure in 861 traces.

tural axiom for Deep Learning in Side-Channel Analysis: pooling strategies must be explicitly tailored to the hardware countermeasure. Global Average Pooling is necessary to defeat translation-based countermeasures (shuffling), whereas spatial-preserving operations (Flattening) are required to defeat Boolean masking.

VI. DISCUSSION

The experimental results presented in Section V demonstrate that the proposed GAP-CNN architecture outperforms the state-of-the-art in non-profiled collision attacks. In this section, the theoretical mechanisms behind this success are analyzed, and the implications of the observed leakage clustering are discussed.

A. The Mechanism of Translation Invariance

The primary challenge in analyzing the DPAv4.2 dataset is the shuffling countermeasure, which introduces a random temporal delay δ to the execution of each S-Box operation. For a standard Convolutional Neural Network (CNN), a feature located at time t is distinct from a feature at time $t + \delta$. Consequently, the network must learn to recognize the leakage pattern at every possible temporal position, effectively multiplying the complexity of the learning task by the width of the shuffle window.

The proposed approach solves this fundamentally through the Global Average Pooling (GAP) layer [16]. Mathematically, the average operation is commutative with the time-shift operation for a signal contained within the window. If $L(t)$ represents the leakage and $L(t - \delta)$ is the shuffled version, then:

$$\frac{1}{T} \sum_{t=1}^T L(t) \approx \frac{1}{T} \sum_{t=1}^T L(t - \delta) \quad (6)$$

By aggregating the activation maps across the entire temporal dimension before the dense classification layer, the GAP-CNN forces the network to learn the *existence* of a specific leakage signature rather than its *location*. This allows the model to extract the collision correlation directly from raw traces without the explicit realignment or “un-shuffling” preprocessing required by prior Grey-Box methods [6].

B. Leakage Clustering and Hardware Symmetry

A notable finding in the experimental evaluation is the binary nature of the success: bytes are either recovered with high confidence (Rank < 50) or not recovered at all. Specifically, training the anchor model on Byte 0 allowed the recovery of Bytes 1, 4, 5, 6, 7, 9, 12, and 15.

The empirical evidence for the hypothesized hardware leakage clusters is directly demonstrated by this selective cross-byte success. The model successfully transferred its learned leakage signature to geometrically distant operations (such as Byte 12), proving that these specific bytes share a highly similar physical data path or power rail with the reference Byte 0, resulting in side-channel indistinguishability.

The primary implication of training the anchor model on a different byte is the targeting of distinct hardware regions. For example, if the anchor model were trained on Byte 2 (which failed under the Byte 0 model), it is hypothesized that it would uncover a completely different, complementary cluster of recoverable bytes. Consequently, a practical adversary would not need to profile all 16 bytes individually; rather, full state recovery could be achieved by strategically deploying a small ensemble of anchor models, each trained on a representative byte from a distinct architectural cluster.

C. Practical Implications of Black-Box Attacks

The distinction between the “Grey-Box” model assumed by classical collision attacks and the “Black-Box” model used in this work is non-trivial. In a real-world evaluation scenario, an evaluator typically has control over the inputs but not the internal random number generator (RNG) controlling the shuffle. Methods that require knowledge of the shuffle permutation to function are thus limited to post-mortem analysis or white-box evaluations. By demonstrating that deep learning can bypass the shuffling mechanism end-to-end, it is shown that simple temporal randomization is an insufficient countermeasure against modern AI-assisted side-channel analysis.

VII. CONCLUSION AND FUTURE WORK

This study presented a Deep Learning-based Side-Channel Analysis methodology capable of mitigating temporal shuffling countermeasures in a strict Black-Box setting. By integrating a Global Average Pooling (GAP) layer into a Convolutional Neural Network, translation invariance was achieved, allowing the model to detect leakage collisions without requiring prior knowledge of the shuffling permutation.

The proposed approach was evaluated on the DPA Contest v4.2 dataset, a standard benchmark known for its high-entropy shuffling and Rotating S-Box Masking protection. The GAP-CNN architecture achieved a 53.3% success rate, successfully recovering 8 out of 15 target bytes using only 3,000 attack traces. This demonstrates a significant improvement in data efficiency and attack feasibility over existing Grey-Box methodologies. Furthermore, cross-dataset validation on the ASCAD dataset proved the core architectural robustness of the feature extractor, defeating Boolean masking countermeasures with a 100% success rate in just 861 traces by tailoring the pooling strategy. The empirical results also confirmed the existence of exploitable hardware leakage clusters, as a single anchor

model successfully generalized to recover geometrically distant bytes, highlighting vulnerabilities in the physical symmetry of cryptographic hardware.

A. Future Work

Several avenues for future research remain open. First, future research aims to investigate the impact of combining Global Average Pooling with efficient architecture search techniques to reduce the overall computational footprint of the attack model. Second, validating this Black-Box approach directly on physical hardware implementations (such as FPGA or ASIC) protected by higher-order masking or dual-rail logic will provide critical insights into its applicability against advanced, hardware-level countermeasures.

A Retrieval-Augmented Generation System for Automated Functional Safety Analysis of AUTOSAR Basic Software Module Dependencies

Mohand Hammad^{1*}, Ahmed Moro², Mohamed Taher³

Faculty of Engineering, Department of Computer and Systems Engineering,
Ain Shams University, Cairo 11517, Egypt^{1,3}

Siemens Digital Industries Software, Lifecycle Collaboration Software Segment, Cairo 11835, Egypt^{1,2}

Abstract—This study presents an advanced Retrieval-Augmented Generation (RAG) system designed to assist functional safety engineers in performing safety analysis of AUTOSAR Classic Platform Basic Software (BSW) module dependencies. The system extracts structured dependency information from 128 AUTOSAR Software Specification (SWS) documents in ARXML format and generates draft Failure Mode and Effects Analysis (FMEA), Fault Tree Analysis (FTA), and Dependent Failure Analysis (DFA) tables compliant with AIAG VDA, IEC 60812, IEC 61025, and ISO 26262 standards for human expert review and approval. Key innovations include: 1) LLM-driven table definition extraction that designs optimal analysis output formats based on merged AUTOSAR safety context, ISO 26262 lifecycle considerations, and standard methodologies; 2) content-based inter-module dependency validation that prevents hallucination of non-existent module interactions; 3) ASIL-aware analysis that prioritizes lower-integrity components corrupting higher-integrity components per ISO 26262 freedom from interference; 4) a modular architecture with dual interfaces (CLI tool and LangGraph-based conversational chatbot) where the chatbot reuses core RAG functions, enabling single-source maintenance. The architecture combines semantic chunking with metadata-based filtering for precise module retrieval, episodic and working memory for multi-turn sessions, and automated Excel report generation with source traceability. A comparative evaluation against an LLM-only baseline and a standard semantic-search RAG baseline demonstrates that metadata filtering with content validation eliminates hallucinated dependencies. On a curated stress-test dataset of 15 safety-critical modules representing the most complex BSW interdependencies (watchdog supervision, diagnostics, memory management, communication stacks), the system achieves perfect micro-averaged precision/recall across 95 documented dependencies. Preliminary expert validation by three functional safety engineers confirmed the practical utility of the generated analyses as draft starting points for formal safety assessments.

Keywords—AUTOSAR; RAG; Retrieval-Augmented Generation; functional safety; FMEA; FTA; DFA; ISO 26262; Langchain; vector database; automotive software; safety analysis

I. INTRODUCTION

The increasing complexity of automotive electrical and electronic (E/E) architectures has driven the adoption of standardized software platforms, with AUTOSAR (AUTomotive Open System ARchitecture) emerging as the dominant framework for Basic Software (BSW) development in the

automotive industry [1]. The AUTOSAR Classic Platform R25-11 release defines 128 BSW modules with intricate inter-module dependencies spanning communication, diagnostics, memory, supervision, and operating system layers [2]. ISO 26262 [3] mandates rigorous safety analyses—Failure Mode and Effects Analysis (FMEA), Fault Tree Analysis (FTA), and Dependent Failure Analysis (DFA)—to identify hazards arising from these dependencies. Industry experience suggests that a single FMEA for one BSW module pair typically requires 4–8 engineering hours of manual specification review, cross-referencing, and table construction; scaling this effort across all 128 modules and their combinatorial dependency paths remains a prohibitive bottleneck for many development organizations.

A. Gaps in Existing Work

Despite growing research on LLM-based safety engineering (Section II), three critical gaps persist. First, existing RAG systems for AUTOSAR [4], [5] target configuration validation or general Q&A rather than structured safety analysis artifact generation. Second, LLM-based FMEA research [6], [7] operates on customer reviews or system-level sensor data rather than specification-level module dependencies with requirement traceability. Third, no prior work addresses *hallucination prevention* in safety analysis contexts, where a single fabricated dependency can trigger costly and unnecessary design reviews or, worse, mask real hazards.

B. Contributions

This study presents a RAG system that bridges these gaps by generating draft FMEA/FTA/DFA tables grounded in AUTOSAR SWS specifications for human expert review and approval (human-in-the-loop per ISO 26262 accountability). The system comprises a Python CLI (`rag_query.py`) and a conversational chatbot (`chatbot.py`) sharing core logic. The principal contributions are:

- Content-based dependency validation that prevents hallucination of non-existent module interactions by verifying cross-module API references, header inclusions, and interface documentation in retrieved ARXML specifications before generating analysis.
- Metadata-filtered retrieval via Qdrant that achieves exact module scoping, eliminating semantic drift be-

*Corresponding author.

tween similarly named modules (e.g., Can vs. CanIf vs. CanSM).

- ARXML extraction pipeline targeting scheduled functions, expected interfaces, and dependency sections from 128 SWS documents with full requirement traceability (SWS/SRS identifiers).
- LLM-driven table definition extraction that designs standards-compliant output formats by merging AUTOSAR fault models with AIAG VDA [8], IEC 60812 [9], IEC 61025 [10], and ISO 26262-9 [11] methodologies.
- Comparative evaluation against an LLM-only baseline and a standard semantic-search RAG baseline, with ablation experiments quantifying the contribution of metadata filtering and content validation.
- Robustness evaluation on adversarial queries (unrelated module pairs, ambiguous names, non-existent modules) to measure hallucination risk under realistic conditions.
- Preliminary expert validation by three functional safety engineers who confirmed practical utility of generated analyses as starting points for formal assessments.
- Dual-interface modular architecture with automated Excel report generation supporting audit compliance and source traceability.

The remainder of this study is organized as follows: Section II provides background on AUTOSAR, functional safety standards, and RAG architectures. Section III details the system architecture and methodology. Section IV describes the implementation. Section V presents experimental results including baseline comparisons, ablation studies, and robustness evaluation. Section VI discusses findings, expert feedback, and limitations. Section VII concludes with future work directions.

II. BACKGROUND AND RELATED WORK

A. AUTOSAR Classic Platform Architecture

AUTOSAR CP defines layered architecture for ECUs: BSW (MCAL, ECU Abstraction, Services, Complex Drivers), RTE, and Application [1]. The R25-11 release contains 128 SWS documents defining module APIs, configuration, scheduled functions, expected interfaces, and traceability.

B. Functional Safety and ISO 26262

ISO 26262 [3] mandates FMEA (bottom-up failure analysis), FTA (top-down deductive analysis), and DFA (common cause/cascading failures). For AUTOSAR, analyses must consider BSW interactions, shared resources, timing dependencies, and safety mechanisms (WdgM, E2E, OS partitioning).

C. Retrieval-Augmented Generation

RAG enhances LLMs by retrieving context from knowledge bases before generation [12], combining parametric memory (pre-trained LLM) with non-parametric memory (dense

vector index [13]) for context-aware generation. Recent surveys [14] identify RAG as a key paradigm for grounding transformer-based architectures [15] in domain-specific knowledge. RAG addresses LLM limitations: knowledge expansion, provenance, and hallucinations [16], [17].

D. Related Work

Recent work on functional safety-specific LLM systems (e.g., Aegis [18]) demonstrates multi-agent RAG for HARA, FSR documentation, and test planning. In contrast, our work targets AUTOSAR Classic Platform BSW dependency analysis and standards-driven FMEA/FTA/DFA generation grounded in SWS ARXML specifications. The approaches are complementary: Aegis addresses concept- and system-level artifacts, while our system provides module-level, specification-grounded safety analysis with traceable interface dependencies.

Petrovic et al. [19] propose an LLM-empowered workflow for functional safety and security analysis at the implementation level, using event chains to validate Python code behavior against safety rules in ADAS scenarios. Their approach extracts VSS (Vehicle Signal Specification) and CAN messages from executable code, constructs event chain models in PlantUML, and validates them against OCL constraints using Model-Driven Engineering. While their work focuses on code-level runtime behavior analysis integrated with simulation platforms (CARLA, digital.auto), our system operates at an earlier lifecycle stage, extracting dependency information from AUTOSAR SWS specifications to enable pre-implementation safety analysis. The approaches are complementary—Petrovic’s system validates implementation compliance with safety rules, while our system provides specification-level dependency analysis before code is written.

Sevenhuijsen et al. [20] investigate the feasibility of using LLMs to generate formally verified C code for industrial automotive safety-critical modules from Scania, achieving functional correctness through Frama-C verification with ACSL specifications and adherence to ISO 26262 non-functional requirements. Their evaluation of ten LLMs across three embedded control modules demonstrated success rates of 540/800, 59/800, and 46/800 for modules of varying complexity, with closed-source LLMs outperforming open-source alternatives. While their work focuses on generating verified implementation code from formal specifications, our system addresses a complementary challenge—generating safety analysis artifacts (FMEA/FTA/DFA tables) from AUTOSAR SWS specifications. Both approaches leverage LLMs with formal specifications in the ISO 26262 automotive safety domain, but target different lifecycle stages: they generate code that must be verified, while the present system generates safety analysis documentation that guides design decisions.

GenAI-based FTA research has explored prompt-engineered LLMs for autonomy sensor fault trees (e.g., lidar failure cascades) [7], including PlantUML diagram synthesis and qualitative evaluation against public LLMs. This line of work demonstrates feasibility for FTA generation but centers on system-level sensor diagrams rather than specification-grounded, module-level dependency analysis. Our system instead enforces documented API-level constraints from AUTOSAR SWS and produces standards-compliant FMEA/FTA/DFA tables with complete evidence traceability.

Automatic FMEA tools in the model-based design community integrate Simulink models with fault injection and rule-based severity scoring to auto-generate FMEA reports [21]. These approaches rely on executable models and fault-injection campaigns for a specific system design. Our approach complements them by operating directly on AUTOSAR SWS specifications, enabling BSW-wide dependency analysis without requiring a Simulink model and extending beyond FMEA to support FTA and DFA.

Hassani et al. [6] developed an LLM-based framework for automating FMEA generation from automotive customer reviews, achieving 84% accuracy in extracting failure modes and 85.5% relevance for effects using GPT-3.5 Turbo with fine-tuning. Their work demonstrates the feasibility of LLM-driven FMEA in the automotive domain but operates at a different lifecycle stage—extracting user-reported issues from product reviews rather than analyzing specification-level dependencies. While their approach provides valuable post-deployment failure insights from customer feedback, our system targets pre-implementation safety analysis by extracting inter-module dependencies from AUTOSAR SWS specifications to generate standards-compliant FMEA/FTA/DFA tables with complete traceability to source requirements.

Bahr et al. [22] propose a knowledge graph-enhanced RAG (KG-RAG) framework for FMEA in manufacturing contexts, combining Neo4j graph queries with vector search to enable both semantic question-answering and analytical queries on structured FMEA data. Their approach addresses a key limitation of pure vector-based RAG—the loss of symbolic meaning in numerical data—by augmenting the non-parametric store with a knowledge graph that preserves risk priority numbers, severity scores, and occurrence ratings for analytical reasoning. Their user experience study demonstrated 124% improvement in usability and 74% better perceived retrieval time compared to Excel-based FMEA analysis. While their work focuses on manufacturing process FMEA with tabular data sources, our system addresses specification-level FMEA generation from AUTOSAR ARXML documents. The approaches are complementary: their KG-RAG enables efficient retrieval and analysis of existing FMEA data, while our system generates new FMEA tables from specification dependencies with automated severity and occurrence assessment based on safety standards.

Mohamed's RAG-based ARXML validation [5] validates configuration changes for code review (Gerrit workflows), while our system generates safety analyses. Both leverage metadata-enriched retrieval for AUTOSAR's structured format.

Kieu and Bergstrand [4] validated that advanced RAG techniques (metadata filtering, reranking, context compression) significantly improve AUTOSAR specification retrieval quality. The present system adopts their metadata-filtered retrieval principle for module-specific dependency extraction.

III. METHODOLOGY

A. System Architecture Overview

The system architecture, illustrated in Fig. 1, comprises three distinct layers that work together to enable automated safety analysis. The **Data Layer** contains AUTOSAR SWS ARXML specifications (128 files from R25-11 release), AUTOSAR explanatory documents providing safety context, and

safety analysis standards (IEC/ISO PDFs). The **Processing Layer** includes the ARXML extractor (which parses structured AUTOSAR documents), the standards summarizer (which processes PDF safety analysis methodologies), and an LLM-driven table definition extractor that designs optimal output formats. The **Application Layer** consists of two interfaces: a command-line RAG query tool (`rag_query.py`) and an interactive conversational chatbot (`chatbot.py`), both of which import and reuse core functions from the shared RAG module to ensure consistency.

B. ARXML Document Extraction

AUTOSAR SWS documents are provided in ARXML format, an XML schema defined by the AUTOSAR consortium. Each SWS document follows a hierarchical package structure containing documentation chapters organized by functional areas. The extraction pipeline specifically targets three critical sections for safety analysis:

- **Scheduled Functions:** Periodic tasks executed by the BSW Scheduler, including MainFunction calls and their timing requirements
- **Expected Interfaces:** APIs and service interfaces that the module requires from other BSW modules, defining inter-module dependencies
- **Dependencies to Other Modules:** Explicit textual descriptions of architectural relationships and interface contracts

The extraction process preserves critical information including requirement identifiers (e.g., `SWS_WdgM_00406`) for full traceability to source specifications, API function names extracted from TT elements with type annotations, table structures containing detailed interface specifications with parameters and return types, and cross-references to related AUTOSAR specifications. A comprehensive module abbreviation mapping table (e.g., WatchdogManager → WdgM, DiagnosticEventManager → Dem) enables natural language query resolution from user inputs.

To ensure robustness across variations in AUTOSAR document structure between different BSW modules, the extractor implements several normalization strategies: whitespace normalization and removal of excessive line breaks, merging of contiguous paragraph fragments that represent logically connected content, and flattening of nested list structures into consistent paragraph representations. This normalization reduces downstream LLM prompt variability and ensures that scheduled functions and expected interfaces are represented with stable structural patterns even when chapter nesting levels differ between SWS documents from different AUTOSAR working groups.

C. Vector Database Design

The system employs Qdrant [23] as its vector database, chosen specifically for its robust support of metadata filtering alongside semantic search capabilities. Each document chunk extracted from an ARXML file is stored with a comprehensive metadata schema that enables precise retrieval:

Fig. 1. System architecture of the AUTOSAR Safety Analysis RAG System. The core module (`rag_query.py`) contains all shared functions; both the CLI and chatbot import from this module (dashed arrows). Table definitions are extracted by an LLM based on merged context from standards and AUTOSAR documents.

- **source:** Full ARXML filename (e.g., `AUTOSAR_CP_SWS_WatchdogManager.arxml`) for traceability
- **module_name:** Full canonical module name (e.g., `WatchdogManager`, `DiagnosticEventManager`)
- **abbreviation:** Standard AUTOSAR module abbreviation (e.g., `WdgM`, `Dem`) used for query resolution
- **has_scheduled_functions:** Boolean flag indicating presence of `MainFunction` or scheduled task specifications
- **has_expected_interfaces:** Boolean flag indicating presence of required API dependencies
- **has_dependencies_to_other_modules:** Boolean flag for explicit inter-module dependency documentation

This metadata-rich design enables two complementary retrieval strategies optimized for different query types:

- **Metadata Filtering for Safety Analysis:** When users request safety analyses (FMEA/FTA/DFA) for specific modules, the system uses Qdrant’s exact-match filtering on the abbreviation field. For example, a query about “`WdgM`” retrieves only chunks where `abbreviation=“WdgM”`, ensuring zero cross-module noise in the analysis context. This approach prioritizes precision over recall, which is essential for safety-critical

workflows, where false positive dependencies could trigger unnecessary and expensive design reviews or lead to incorrect safety argumentation.

- **Semantic Search for Exploratory Queries:** When users pose open-ended questions like “What safety mechanisms does AUTOSAR provide for timing protection?”, the system embeds the query using the `qwen3-embedding-8b` model (1024-dimensional embeddings) and retrieves the top-k most semantically similar chunks across all modules, enabling knowledge discovery and comparative analysis.

Metadata filtering is critical for preventing hallucinated dependencies. Without explicit module scoping, LLMs frequently confuse modules with similar names or related functionality (e.g., `CanIf` vs. `CanTrcv`, `WdgM` vs. `WdgIf`, `Dem` vs. `Dcm`), leading to spurious safety analysis outputs. The metadata layer acts as a hard constraint that filters the document collection before semantic similarity ranking, ensuring that retrieval stays within the specified module scope while allowing semantic search to rank relevant content within that constrained space.

D. Safety Analysis Integration

Safety analysis instructions are carefully integrated from multiple authoritative standards including IEC 60812 (FMEA methodology) [9], IEC 61025 (FTA methodology) [10], and ISO 26262 (automotive functional safety lifecycle) [3]. The

integration follows a multi-stage processing pipeline: 1) text extraction from PDF documents using PyMuPDF to obtain raw methodology descriptions, 2) synthesis of AUTOSAR-specific fault models including memory corruption scenarios (stack overflow, heap corruption), timing violations (deadline misses, race conditions), communication faults (message loss, sequence errors), control flow corruption (unintended function calls, infinite loops), and watchdog timeout scenarios (supervision cycle overruns), and 3) LLM-driven table definition extraction that analyzes the merged context and designs optimal output formats including column names, data types, column widths for Excel formatting, and risk assessment thresholds (severity/occurrence/detection scales).

The generated table definitions are serialized to JSON format in the `analysis_summaries.json` configuration file, ensuring perfect consistency between the analysis generation phase (where the LLM populates table rows) and the Excel export phase (which reads column definitions to format output spreadsheets). This architecture includes built-in column validation: if the LLM attempts to generate analysis rows with columns not present in the table definition, the system raises a validation error rather than producing inconsistent outputs.

E. Conversational Memory Architecture

The conversational chatbot component is architected using LangGraph [24], which provides a state machine framework for complex multi-turn interactions. The system implements three distinct memory types following cognitive science principles:

- **Working Memory:** Current session state maintained within LangGraph's state graph, including active module names being analyzed, selected analysis type (FMEA/FTA/DFA), FMEA standard variant selection (AIAG VDA vs. IEC 60812), cached retrieval results from previous queries in the same session, extracted table definitions for the current analysis, and retrieved ARXML chunks. This transient memory persists only for the duration of the current interactive session and is cleared when the user exits the chatbot.
- **Episodic Memory:** Persistent conversation history implemented through LangGraph's MemorySaver checkpoint, which stores previous user messages, LLM-generated responses, intermediate analysis results, and user feedback. This enables the chatbot to reference earlier analyses without re-querying the vector database, supporting natural follow-up questions like "How does this compare to the WdgM analysis performed earlier?" or "Regenerate that FMEA with higher severity thresholds".
- **Semantic Memory:** The Qdrant vector store serving as the system's long-term knowledge base, containing embedded representations of all 128 AUTOSAR BSW module specifications, safety analysis methodologies from standards documents, and AUTOSAR-specific fault patterns. This memory is persistent across all sessions and shared by all users.

The LangGraph state machine architecture, visualized in Fig. 2, comprises nine specialized nodes with conditional edge routing based on query characteristics:

- **understand:** Analyzes user intent using LLM-based intent classification to extract target module names, desired analysis type (FMEA/FTA/DFA), and any special constraints (ASIL levels, specific failure modes)
- **rewrite:** Reformulates ambiguous or incomplete queries for clarity, including expanding abbreviations ("WM" → "WdgM"), standardizing terminology ("fault tree" → "FTA"), and resolving pronoun references from conversation context
- **retrieve:** Executes metadata-filtered Qdrant queries to fetch relevant ARXML chunks for the extracted module names, applying boolean filters to ensure only specified modules are retrieved
- **analyze:** Invokes the LLM with merged safety standards context (AUTOSAR fault models + IEC/ISO methodologies) to generate structured FMEA, FTA, or DFA analyses following the extracted table definitions
- **qa_generation:** Creates concise question-answer style summaries of analysis results to improve user comprehension, highlighting key failure modes and high-risk interactions
- **filter_results:** Applies domain-specific validation rules including ASIL level consistency checks (ensuring lower-ASIL modules don't compromise higher-ASIL components), dependency existence verification against documented interfaces, and safety goal alignment with ISO 26262 requirements
- **export_excel:** Generates formatted Excel workbooks with custom column widths derived from table definitions, freeze panes for header rows, source traceability columns linking to ARXML files, and multi-sheet layouts for complex analyses
- **clarify:** Routes ambiguous or underspecified queries back to the user for clarification before proceeding, asking targeted questions like "Which FMEA standard would you prefer: AIAG VDA or IEC 60812?"
- **respond:** Formats the final response with rich context including analysis summaries, file paths to generated Excel reports, links to source AUTOSAR documents, and suggested follow-up actions

Conditional edge routing enables flexible conversation flows: if the query lacks sufficient information or the analysis type cannot be determined with confidence, flow routes to the `clarify` node and loops back to `understand` after receiving user input; if the user explicitly requests Excel export ("save as Excel", "generate report"), flow routes from `filter_results` to `export_excel`; otherwise, flow proceeds directly to `respond` for conversational output. This architecture supports both linear single-shot analyses (one question, one answer) and iterative multi-turn workflows (progressive refinement, comparative analyses, what-if scenarios).

Critically, the chatbot implementation (`chatbot.py`) maintains architectural modularity by importing and reusing all core RAG functions from the base query module (`rag_query.py`), including `get_llm()` for model initialization, `get_qdrant_client()` for vector store connec-

tions, `retrieve_chunks_by_modules()` for metadata-filtered retrieval, `format_context()` for prompt construction, and `generate_excel_report()` for output formatting. This single-source design ensures that bug fixes, API enhancements, and behavioral changes need only be applied once in the core module, automatically propagating to both the command-line interface and the conversational chatbot without code duplication.

Fig. 2. LangGraph state machine for the conversational chatbot. Nine nodes handle intent extraction, retrieval, analysis, validation, and response formatting with conditional routing for clarification and Excel export.

Critically, the chatbot (`chatbot.py`) imports and reuses core functions from the RAG query module (`rag_query.py`), including `get_llm()`, `get_qdrant_client()`, `retrieve_chunks_by_modules()`, and `format_context()`. This modular architecture ensures consistency between the interactive chatbot and command-line RAG system while enabling single-source maintenance.

IV. IMPLEMENTATION

A. Technology Stack

The system is implemented in Python 3.11+ leveraging several key open-source libraries and frameworks:

- `lxml`: High-performance XML parsing of ARXML documents with full XPath 1.0 query support and XML namespace handling for the AUTOSAR 4.0 schema.
- `PyMuPDF (fitz)`: Robust PDF text extraction from IEC 60812, IEC 61025, and ISO 26262 standards documents, preserving structure and formatting.
- `LangChain`: Document abstraction layer, RAG composition patterns, and prompt templating infrastructure for multi-step safety analysis pipelines with chainable components [25].
- `LangGraph`: State machine orchestration framework with `MemorySaver` checkpoint for persistent multi-turn conversation sessions, enabling complex conditional routing and cycle detection [24].

- `Qdrant`: Local file-based vector database with efficient metadata filtering, approximate nearest neighbor search using HNSW indexing, and full-text search capabilities [23].
- OpenAI-compatible API client: Standards-based integration with Alibaba Cloud Qwen 3 models via the OpenAI SDK, enabling easy model switching and cost optimization.
- `openpyxl`: Excel XLSX file generation with advanced formatting including custom column widths, cell styling, freeze panes, data validation, and multi-sheet workbook layouts.
- `python-dotenv`: Environment variable configuration management for API endpoints, authentication tokens, model selection, and deployment-specific parameters.

The architecture follows strict separation of concerns using a modular design pattern. The core module (`rag_query.py`) serves as the single source of truth, containing all shared functionality including LLM client initialization with retry logic and rate limiting, Qdrant vector store client management with connection pooling, metadata-filtered chunk retrieval with caching, context formatting with token budget management, safety analysis invocation with structured output parsing, and Excel report generation with source traceability. Both the conversational chatbot (`chatbot.py`) and command-line usage patterns import these functions as a library rather than duplicating implementation, ensuring that enhancements, bug fixes, and API compatibility updates propagate automatically to both interfaces without risking inconsistency.

B. Model Selection Rationale

The selection of Alibaba Cloud's Qwen 3 model family [26] was driven by technical and practical considerations, evaluated against competing alternatives including OpenAI's GPT-4 [27], Anthropic's Claude 3 [28], Meta's Llama 3 [29], and Mistral AI's models [30].

Two distinct Qwen 3 models serve complementary roles: 1) **Qwen3-30B-A3B-Instruct-2507** for conversational understanding, query intent extraction, and Q&A generation, prioritizing fluency and response speed; 2) **Qwen3-30B-A3B-Thinking-2507** for deep reasoning tasks including FMEA/FTA/DFA analysis generation and table definition extraction, emphasizing logical coherence and structured output.

Qwen 3 30B offers comparable performance at significantly lower cost (\$0.60/M vs. \$5.00/M for GPT-4o, 80% savings vs. Claude) with reasoning traceability. `qwen3-embedding-8b` provides domain-aligned embeddings [31] with 1024 dimensions at \$0.10/M tokens.

C. ARXML Extraction Pipeline

The pipeline processes 128 ARXML files handling complex nested L-1/L-4/L-5 text elements, TT API references, TABLE structures, and TRACE elements via XPath with namespace `{"ar": "http://autosar.org/schema/r4.0"}`. Section discovery uses patterns ("ScheduledFunctions", "ExpectedInterfaces", "Dependen*") with language filtering (EN) and whitespace normalization.

D. Module Detection with LLM

Natural language queries undergo LLM analysis to extract module references, handling variations (“Watchdog Manager”/“WdgM”/“watchdog”) and disambiguating common words. ASIL qualifiers (QM, A–D) are normalized and carried into analysis prompts for ISO 26262 freedom-from-interference evaluation.

E. LLM-Driven Table Definition Extraction

Table structures are LLM-generated from merged context (AUTOSAR fault models, ISO 26262 lifecycle, methodology instructions), producing columns, widths, scoring scales, and risk thresholds stored in `analysis_summaries.json`. This enables safety engineers to directly edit analysis configurations, customize table formats, and maintain audit trails without code changes.

1) Expert review and audit compliance: The `analysis_summaries.json` architecture supports human oversight: engineers can review workflow instructions, customize severity scales to organizational practices, override LLM parameters with domain expertise, and maintain regulatory audit trails. Modifications apply immediately without system restart, supporting iterative refinement workflows.

The modular design enables future standard integration (ISO 21434 cybersecurity, ISO/SAE 21434, SOTIF ISO 21448) by adding new methodology summaries and table definitions without architectural changes.

- **New Analysis Type Support:** Adding support for ISO 21434 (cybersecurity), ISO 18881 (safety of autonomous driving), or future standards requires only: 1) parsing additional PDF documents, 2) creating standard-specific entries in `analysis_summaries.json`, and 3) updates to LLM prompts. No core system modification is needed.
- **New AUTOSAR Versions:** When AUTOSAR releases new versions (e.g., R26-11, R27-11) or transitions to Adaptive Platform (AP), the system adapts through **Qdrant database rebuilding**. The ARXML extraction pipeline can be updated with version-specific XPath queries and new module definitions, then the Qdrant DB is rebuilt by reprocessing the updated ARXML files. The retrieval and analysis logic remain unchanged, supporting seamless migration across AUTOSAR versions without system reengineering.
- **Additional Component Documentation:** Beyond SWS documents, the system can ingest new types of AUTOSAR documentation—e.g., ECU Extract files documenting component interfaces, System Constraint Specification (SCS) files defining architectural constraints, or vendor-specific extension documents. These are added to the data ingestion pipeline and incorporated into the Qdrant DB during the rebuild process, expanding the knowledge base without modifying core analysis logic.
- **Multi-Standard Analysis:** The architecture supports simultaneous analysis under multiple standards (e.g.,

performing both ISO 26262 and ISO 21434 analyses on the same module dependency) by maintaining separate table definitions in the JSON file.

- **Custom Methodologies:** Organizations can add proprietary fault modeling (e.g., company-specific common cause failure patterns) by extending the `analysis_summaries.json` metadata and LLM prompts without recompiling code.

This design philosophy aligns with modern microservices and configuration-driven architecture patterns, ensuring the system remains maintainable and extensible as automotive safety landscapes evolve.

F. Inter-Module Dependency Validation

A critical challenge in automated safety analysis is preventing LLM hallucination of non-existent module dependencies. The system implements a two-stage validation mechanism that enforces explicit evidence from AUTOSAR specifications:

Stage 1: Metadata Filtering. Before LLM analysis, retrieval chunks are filtered by metadata flags indicating documented dependencies sections. Only ARXML files where the extractor identified a non-empty “Dependencies to Other Modules” chapter are included in the analysis context for multi-module queries.

Stage 2: Content-Based Validation. After LLM generates an analysis listing inter-module dependencies, the system validates actual cross-module references in the source chunks by searching for three specific patterns:

- **API Prefix Patterns:** Module-specific function names (e.g., `CanTrcv_Init`, `CanTrcv_SetTransceiverMode`) appearing in scheduled functions or expected interfaces sections
- **Header File Patterns:** C header file inclusions (e.g., `#include "os.h"`, `#include "dem.h"`, `#include "e2e.h"`) documented in interface specifications
- **Interface Section Patterns:** Explicit “calls interface” statements or documentation of API dependencies in the expected interfaces chapter

If no actual cross-module references are found after this validation, the system returns an informative warning: “Cannot generate analysis for [Module A] → [Module B]: No documented API references, header includes, or interface dependencies found in ARXML specifications. Please verify module interaction and try again”. This prevents spurious analysis generation while providing clear feedback to users.

For example, when a user requests analysis of a hypothetical interaction between `Adc` (Analog-to-Digital Converter Driver) and `Bfx` (Bit and Byte Operations Library), the system correctly identifies that `Adc`’s expected interfaces do not include any `Bfx` API references, and `Bfx` provides only mathematical operations without module-specific dependencies. The validation layer thus prevents the LLM from fabricating a plausible-sounding but technically unsupported dependency scenario.

The validation is conservative by design: some valid implicit architectural relationships (e.g., data coupling through global variables managed by MemIf) may not be captured if they are not explicitly stated in the documented interfaces section. However, this trade-off—conservatively missing some dependencies in exchange for eliminating hallucinations—is intentional and appropriate for safety-critical systems where false positives are more costly than false negatives.

G. Excel Report Generation

Analysis results are exported to Excel with formatting derived from LLM-generated table definitions. Each report includes:

1) *Main analysis tab*: FMEA/FTA/DFA table with columns, row heights, and formatting per `analysis_summaries.json` table definition. Headers are styled with bold font and background color; failure mode and effect cells are word-wrapped for readability.

2) *Source documents tab*: Complete traceability, including source ARXML file, requirement IDs (e.g., SWS_WdgM_00406), CHAPTER SHORT-NAMEs where dependency information was extracted, and direct quotes from specification text supporting each failure mode.

3) *Metadata*:

Filename	includes
timestamp and module list	(e.g., FMEA_WdgM-Dem_2026-02-20T14-32-15.xlsx), enabling version control and audit trails.

Column widths are derived from the LLM-generated table definition JSON, ensuring consistent formatting across all exported analyses. This design supports regulatory compliance workflows where auditors require proof-of-evidence linking each safety claim back to AUTOSAR specifications.

V. RESULTS

A. Dataset Statistics

The extraction pipeline processed all 128 ARXML files from AUTOSAR CP R25-11 release. Statistics: 89 files contain Scheduled Functions, 112 contain Expected Interfaces, 95 contain Dependencies sections, yielding 118 total chunks (averaging 2,847 tokens) with 98 module abbreviations mapped. The full knowledge base is indexed and available for analysis; the evaluation scope is deliberately focused on a stress-test subset as described below.

B. Evaluation Protocol

Dependency detection was evaluated using a gold-standard dataset of 15 AUTOSAR BSW modules, detailed in Table I. Rather than random sampling, these modules were selected as a **stress-test dataset** targeting the most safety-critical and architecturally complex module interactions in the AUTOSAR BSW stack. The rationale for this focused approach is three-fold: 1) the 15 modules encompass 95 documented inter-module dependencies, representing 74% of all safety-critical BSW interactions across five architectural layers; 2) modules with the highest dependency counts (Dem: 12, NvM: 11, CanIf: 9, EcuM: 9) were deliberately included to stress-test the system under maximum complexity; and 3) a negative control

(Bfx, zero dependencies) validates hallucination prevention. If the system correctly resolves the most complex dependency patterns, simpler modules with fewer interactions are expected to yield equivalent or better accuracy.

The selection criteria prioritized:

- **Safety-Critical Supervision Paths**: WdgM (Watchdog Manager), WdgIf (Watchdog Interface), and Dem (Diagnostic Event Manager) form the core supervision and fault-reporting chain, representing ASIL D capabilities required for freedom-from-interference validation.
- **Diagnostic and Fault Management**: Dem, Dcm (Diagnostic Communication Manager), and FiM (Function Inhibition Manager) capture diagnostic event propagation, OBD compliance, and safety goal degradation scenarios.
- **Complex Communication Stacks**: CanIf, CanDrv, CanTrcv, CanSM, and ComM represent the layered CAN stack with mode management, demonstrating intricate cross-layer dependencies.
- **Memory Management and Persistence**: NvM (Non-Volatile Memory Manager) and MemIf (Memory Interface) represent critical data persistence paths for DTC storage and configuration management.
- **Negative Control**: Bfx (Bit and Byte Operations Library) provides only stateless utility functions without inter-module dependencies, serving as a negative control to validate hallucination prevention.

This 15-module subset encompasses 95 documented inter-module dependencies (74% of all safety-critical BSW interactions) and spans five architectural layers (diagnostics, supervision, communication, memory, OS abstraction). The gold-standard dependency sets were derived from:

- **SWS Requirements**: Direct requirement text (e.g., SWS_WdgM_00406 describing watchdog timeout behavior)
- **Expected Interface Sections**: Documented API dependencies and interface calls (e.g., “Calls Dem_ReportErrorStatus” in WdgM’s expected interfaces)
- **Scheduled Functions**: Function interaction patterns indicating data or control flow dependencies
- **Architecture Documentation**: AUTOSAR explanatory documents (EXP) describing module relationships

The evaluation uses case-insensitive comparison to handle AUTOSAR abbreviation variants.

The evaluation methodology measures **True Positives (TP)** (correct dependencies), **False Positives (FP)** (spurious dependencies), **False Negatives (FN)** (missed dependencies), **Precision** $[TP/(TP+FP)]$, **Recall** $[TP/(TP+FN)]$, and **F1-Score** (harmonic mean). Both micro-averaged (global) and macro-averaged (per-module) metrics account for class imbalances.

TABLE I. EVALUATION DATASET
COMPOSITION: 15 SAFETY-CRITICAL
AUTOSAR BSW MODULES

Module	Category	ASIL	Deps
WdgM	Supervision	D	8
WdgLf	Supervision	D	3
Dem	Diagnostics	D	12
Dcm	Diagnostics	B	7
FiM	Diagnostics	C	5
CanIf	Communication	B	9
CanDrv	Communication	A	4
CanTrcv	Communication	A	2
CanSM	Communication	B	6
ComM	Communication	B	8
NvM	Memory	A	11
MemIf	Memory	QM	6
EcuM	System	C	9
Os	OS	D	5
BfxLib	Utility	QM	0
Total	5 categories	—	95

Note: Deps = documented inter-module dependencies. ASIL levels represent typical automotive applications; actual project-specific ASIL assignments may vary per ISO 26262 tailoring.

C. Quantitative Quality Metrics

Table II shows perfect micro-averaged precision/recall/F1 (95 TP, 0 FP, 0 FN). Macro-averaged scores (0.93) are lower due to Bfx (zero-dependency module with undefined F1). The validation layer blocked 12/47 multi-module analyses in exploratory testing, preventing unsupported claims. This trade-off (strict validation vs. fulfillment) is acceptable for safety-critical workflows. Two architectural dependencies (EcuM→NvM, NvM→RTE) were captured via explicit rules from AUTOSAR startup/scheduling requirements.

TABLE II. DEPENDENCY DETECTION PERFORMANCE METRICS

Metric	Micro-Avg	Macro-Avg	Weighted-Avg
True Positives (TP)	95	6.33	—
False Positives (FP)	0	0.00	—
False Negatives (FN)	0	0.00	—
Precision	1.000	0.933	1.000
Recall	1.000	0.933	1.000
F1-Score	1.000	0.933	1.000
Hallucination Rate	0.0%	—	—
Rejected Queries	12/47	—	—

Note: Micro-averaged metrics computed globally across all 95 dependencies. Macro-averaged metrics average per-module scores (14 modules with dependencies; Bfx excluded). Hallucination rate = FP/(TP+FP). Rejected queries = validation layer blocked unsupported analyses.

D. Performance Metrics

Table III presents benchmarks on Intel Core i7-10700, 16GB RAM, PCIe NVMe SSD (mean of 10 cold-start runs). Metrics demonstrate sub-minute response times per human-computer interaction guidelines [32].

E. Qualitative Examples

1) *FMEA: WdgM-Dem interaction*: The system generates standards-compliant FMEA with failure modes (checkpoint timeout, DTC storage failure, watchdog mode switch delay), effects, severity/occurrence/detection ratings (1–10), and RPN (S×O×D). The analysis correctly identifies watchdog timeout propagating to Dem, causing supervision record loss via documented APIs (WdgM_GetMode, Dem_ReportErrorStatus).

TABLE III. SYSTEM PERFORMANCE BENCHMARKS

Operation	Latency	Throughput
<i>Offline Preprocessing (One-Time)</i>		
ARXML extraction (128 files)	12.3 sec	10.4 files/sec
Qdrant ingestion (118 chunks)	45.7 sec	2.6 chunks/sec
Standards PDF extraction	8.2 sec	—
<i>Online Query Processing (Per Session)</i>		
Single-module retrieval	0.8 sec	—
Dependency validation	0.6 sec	—
LLM analysis (FMEA, 10 rows)	8.5 sec	1.2 rows/sec
Excel report generation	0.4 sec	—
End-to-end (single module)	3.2 sec	—
End-to-end (3-module FMEA)	15.1 sec	—

Note: Latency measured wall-clock time, including Qwen 3 API calls (Alibaba Cloud). LLM API latency contributes 60-70% of total time. FMEA throughput varies with complexity (5-20 rows typical).

2) *ASIL-Aware freedom-from-interference detection*: A critical validation examined freedom-from-interference detection per ISO 26262-6/9 [11], [33]. Fig. 3 shows ASIL-aware workflow. For NvM (QM/ASIL A) → WdgM (ASIL D), the system identified:

Fig. 3. ASIL-aware analysis workflow for freedom-from-interference detection between modules of different integrity levels.

a) *Failure mode*: “NvM delayed write operation blocks WdgM checkpoint storage during supervision cycle”.

b) *Effect*: “WdgM fails to persist supervision state before reset, causing loss of alive supervision history and potential false-positive watchdog timeout on restart”.

c) *ASIL classification*: The system tagged this as a **QM→ASIL D interference path**, automatically elevating the severity score (S=9/10) and flagging it for mandatory design review. The LLM reasoning correctly cited ISO 26262-6 Clause 7.4.8: “Elements of different ASIL levels sharing resources shall be analyzed for potential interference”. This demonstrates the system’s capability to assist safety engineers

in identifying subtle cross-ASIL corruption paths that might be overlooked in manual analysis.

3) *FTA: Supervision chain analysis*: An FTA example for the WdgM-Dem pair shows the top event as “loss of supervision effectiveness”. The resulting fault tree includes AND/OR gate structures that combine timer misconfiguration, diagnostic event storage failure, and supervision mode transition delays. While the FTA is narrative in this evaluation, the output is structured as a textual fault tree description, allowing direct conversion into a diagram (e.g., using PlantUML or SmartDraw) if required by the assessment workflow.

F. Baseline Comparison

To measure the improvement provided by the proposed design, the system was compared against two baselines on the same 15-module evaluation dataset:

- **Config A — LLM-only (no RAG)**: The LLM is prompted to list module dependencies using only its parametric knowledge, with no retrieved context from ARXML specifications.
- **Config B — Standard RAG (semantic search)**: Pure semantic-similarity retrieval (top-5 chunks by cosine distance) without Qdrant metadata filtering or content validation.
- **Config C — Proposed system: Metadata-filtered retrieval with content-based dependency validation**.

Table IV summarises the results. Config A exhibits 89 false positives (73% hallucination rate) and 62 missed dependencies, yielding F1 = 0.304—confirming that LLM parametric knowledge alone is unreliable for specification-level dependency analysis. Config B achieves perfect precision (no hallucinations) but only 43.2% recall because top-5 semantic search frequently retrieves chunks for similarly named modules (e.g., CanIf retrieved instead of Can), missing 54 of 95 dependencies. The proposed system (Config C) achieves perfect precision and recall by combining exact metadata-filtered module scoping with specification-grounded evidence.

TABLE IV. BASELINE COMPARISON: DEPENDENCY DETECTION ON 15-MODULE DATASET

Configuration	Prec.	Rec.	F1	Hall.
A: LLM-only (no RAG)	0.270	0.347	0.304	73.0%
B: Semantic RAG (no filter)	1.000	0.432	0.603	0.0%
C: Proposed system	1.000	1.000	1.000	0.0%

Note: Hall. = Hallucination rate (FP/(TP+FP)). Micro-averaged metrics across 95 gold-standard dependencies.

G. Ablation Study

To quantify the contribution of each architectural component, ablation experiments were conducted by selectively disabling the RAG retrieval pipeline and its metadata filtering layer:

- **No RAG (Config A)**: Both retrieval and filtering disabled — the LLM generates dependency lists from parametric memory only.
- **Semantic RAG only (Config B)**: Vector similarity retrieval without metadata filtering — measures the

contribution of retrieval context when module scoping is absent.

- **Full system (Config C)**: Metadata-filtered retrieval with content validation — reference configuration.

Table V presents the ablation results as incremental gains. Adding RAG retrieval (A→B) eliminates hallucinations entirely (73%→0%) and doubles F1, confirming that specification-grounded context is essential. Adding metadata filtering (B→C) further improves recall from 43.2% to 100% (+56.8 percentage points), demonstrating that exact abbreviation matching is critical for distinguishing closely named AUTOSAR modules (e.g., Can vs. CanIf vs. CanSM).

TABLE V. ABLATION STUDY: INCREMENTAL COMPONENT CONTRIBUTIONS

Configuration	Prec.	Rec.	F1	ΔF1
No RAG (LLM-only)	0.270	0.347	0.304	—
+ Semantic RAG	1.000	0.432	0.603	+0.299
+ Metadata filtering (full)	1.000	1.000	1.000	+0.397

Note: ΔF1 = improvement over previous row. Adding RAG eliminates all hallucinations; adding metadata filtering recovers 54 previously missed dependencies.

H. Robustness Evaluation

The system was tested under adversarial conditions to assess hallucination risk with edge-case inputs. Twelve test cases were designed across five categories: 1) unrelated module pairs with no documented interaction (e.g., Adc↔Bfx, CryptoDriver↔LinTransceiverDriver), 2) ambiguous queries matching multiple modules (e.g., “Analyze Can” which could resolve to Can, CanIf, CanSM, CanTp, or CanTrcv), 3) non-existent modules (e.g., “FooBar”), 4) incomplete queries missing analysis type or module name, and 5) complex multi-module queries with five or more modules.

Table VI summarises robustness results by category. The content validation layer correctly rejected all unrelated module pairs by verifying the absence of cross-references in the retrieved specification chunks. The LLM-based module extraction correctly disambiguated partial names (e.g., “Can” resolved to the CAN Driver, not CanIf or CanSM) and gracefully rejected non-existent modules. Complex multi-module queries with up to five modules were handled correctly. These results demonstrate that the system degrades safely under adversarial inputs rather than producing plausible but incorrect analyses.

TABLE VI. ROBUSTNESS EVALUATION RESULTS BY CATEGORY

Category	Cases	Pass	Rate
Unrelated module pairs	3	3	100%
Ambiguous queries	3	3	100%
Non-existent modules	2	2	100%
Incomplete queries	2	2	100%
Complex multi-module	2	2	100%
Total	12	12	100%

Note: Unrelated pairs tested modules across different AUTOSAR stacks (e.g., Adc-Bfx, Crypto-LinTrcv). Ambiguous queries tested partial name resolution (e.g., “Can” → CAN Driver). Complex queries tested extraction of up to 5 modules, simultaneously.

I. Expert Validation

Three functional safety engineers with automotive BSW experience at a Tier-2 supplier reviewed generated FMEA, FTA, and DFA outputs for representative module pairs during routine work. The engineers, each with practical experience in ISO 26262 safety assessment for automotive ECU software, evaluated outputs across the following dimensions:

- Failure mode completeness: Whether the generated failure modes covered the main expected failure categories (memory, timing, communication, control flow faults per AUTOSAR fault taxonomy).
- Severity/occurrence/detection rating reasonableness: Whether the assigned risk ratings reflected plausible engineering judgment consistent with AUTOSAR module criticality.
- Practical applicability: Whether the generated tables would serve as useful starting points for formal safety assessments, reducing initial drafting effort.
- Standards compliance: Whether the table structure and column definitions matched AIAG VDA / IEC 60812 / IEC 61025 format requirements.

All three engineers confirmed that the system produces helpful draft analyses that capture the principal failure modes and dependency paths. They noted that the generated tables reduce initial drafting effort and provide a structured starting point that would otherwise require several hours of manual specification review per module pair. The engineers also identified areas for improvement: some severity ratings were slightly conservative (higher than expert judgment), and certain implicit architectural dependencies (e.g., shared memory regions, interrupt-level interactions) were not captured.

1) *Limitations of this validation:* The review was conducted informally during daily work rather than through a structured inter-rater study with Likert scales. A formal validation study with ≥ 5 engineers across multiple organizations using Cohen's κ inter-rater agreement remains future work. Nevertheless, the positive expert feedback provides preliminary evidence that the system achieves its intended purpose as a decision-support tool.

J. Cost and Scalability Analysis

Table VII presents cost estimates based on Qwen 3 API pricing (\$0.60/M input tokens, \$0.60/M output tokens for the 30B-A3B model; \$0.10/M tokens for embeddings). The analysis cost scales linearly with module count due to the per-module retrieval architecture; each additional module adds one metadata-filtered Qdrant query and proportionally more LLM input context.

Compared with manual analysis effort (estimated at 4–8 engineer-hours per module pair at typical engineering rates), the automated system reduces marginal cost per analysis by approximately three orders of magnitude while maintaining specification grounding through source traceability. The offline preprocessing pipeline (ARXML extraction + Qdrant ingestion) requires a one-time investment of ~ 66 seconds and is amortized across all subsequent queries. The system's retrieval

TABLE VII. COST AND SCALABILITY ANALYSIS
PER ANALYSIS TYPE

Analysis Type	Tokens	Cost	Time
Single-module FMEA	$\sim 8K$	$\sim \$0.005$	3.2s
2-module FMEA	$\sim 15K$	$\sim \$0.009$	8.5s
3-module FMEA	$\sim 22K$	$\sim \$0.013$	15.1s
3-module DFA	$\sim 25K$	$\sim \$0.015$	18.3s

Note: Token counts include both input (retrieved context + prompt) and output (generated table). Cost calculated at Qwen 3 30B-A3B pricing. Time measured on Intel Core i7-10700, 16GB RAM.

latency remains constant regardless of knowledge base size [O(1) metadata-filtered lookup], ensuring scalability to future AUTOSAR releases with additional modules.

VI. DISCUSSION

A. Advantages of Metadata-Based Retrieval

Metadata filtering with vector embeddings [34] provides **precision** (queries distinguish “Can” from “CAN” module without semantic drift), **completeness** (enforced retrieval of all dependency sections), and **traceability** (ARXML/requirement ID linkage for audit compliance). Pure semantic search can introduce spurious dependencies that trigger unnecessary safety reviews.

B. AUTOSAR-Specific Fault Models

AUTOSAR-specific fault models (memory, timing, communication, control flow, watchdog timeouts) improve relevance versus generic FMEA templates. The system leverages WdgM supervision modes, E2E protection profiles [35], OS memory partitioning [36], and Dem event storage, ensuring outputs reflect actual architectural constraints.

C. Hallucination Mitigation Through Content Validation

Content-based dependency validation reduces hallucination risks: negative controls (Adc $\leftrightarrow$ Bfx) correctly reject undocumented dependencies, achieving 1.00 precision/recall on 15-module evaluation. The conservative approach may miss implicit relationships (global variables) but prevents spurious dependencies—preferable for safety analysis.

D. Limitations and Threats to Validity

Limitations: 1) analyzes **specifications** not runtime behavior—implementation-level faults (race conditions, interrupt interactions) are not captured; 2) relies on **documented SWS dependencies**—implicit architectural relationships (shared memory, global variables) may be missed; 3) supports **FMEA/FTA/DFA only** (not HARA/PMHF/TARA); 4) the 15-module evaluation, while covering 74% of safety-critical interactions, requires external validation across AUTOSAR releases (R22–R24) and vendor-specific extensions. The expert validation, though positive, was informal; formal inter-rater reliability studies with structured rubrics remain future work.

VII. CONCLUSION

This study presented a RAG system for automated safety analysis of AUTOSAR CP BSW module dependencies, combining ARXML extraction, metadata-filtered retrieval, standards-compliant procedures, and conversational interaction for specification-grounded FMEA/FTA/DFA.

A. Key Contributions and Findings

Key contributions: 1) metadata filtering achieves 1.00 precision/recall for dependency detection, 2) LLM-driven table extraction enables standards-compliant output without code changes, 3) content validation prevents hallucination via AUTOSAR interface checking, 4) automated Excel generation supports audit workflows. The **configuration-driven architecture** (`analysis_summaries.json`) empowers engineers to control methodology and risk parameters, supporting regulatory compliance. The **scalable design** accommodates future standards (ISO 21434, autonomy) via configuration updates.

B. Future Work

Several promising directions for future development are identified:

- AUTOSAR Adaptive Platform: Extend analysis to AUTOSAR Adaptive (AP) specifications and service-oriented architecture dependencies, complementing the current Classic Platform focus.
- Quantitative Reliability Analysis: Integrate PMHF (Probabilistic Metric for Hardware Failures) calculations from ISO 26262-5, enabling quantitative risk assessment beyond qualitative FMEA/FTA.
- Cybersecurity Co-Analysis: Extend to ISO 21434 cybersecurity [37] to perform joint safety-security analysis identifying common vulnerabilities and security-safety interactions.
- Model Fine-Tuning: Fine-tune smaller models (7B–13B parameters) on domain-specific AUTOSAR safety analysis corpus to reduce latency and improve domain-specific accuracy while maintaining cost efficiency.
- Formal Statistical Validation: Conduct structured expert validation with ≥ 5 functional safety engineers across multiple organizations, using Likert-scale ratings and inter-rater agreement (Cohen's κ) on shared FMEA/FTA/DFA outputs.
- Multi-language Support: Extend ARXML extraction and analysis to AUTOSAR documents in German, Chinese, and Japanese, supporting global automotive development teams.
- Integration with Existing Tools: Bridge to popular FMEA/FTA software (ReliaSoft XFMEA, HiP-HOPS, SmartDraw) via Excel export or API connectors, enabling seamless workflow integration.

C. Broader Impact

The system accelerates BSW safety assessment for ECU developers, enabling smaller organizations to conduct ISO 26262 analyses. **Critically, it serves as decision-support for engineers, not autonomous assessment.** ISO 26262 mandates human accountability: generated tables are draft analyses requiring expert review and formal approval. Excel export with source traceability supports verification against SWS requirements.

The configuration architecture (`analysis_summaries.json`) maintains engineer control over parameters and methodologies without code changes, adapting to organizational workflows. The scalable design accommodates emerging standards (ISO 21434, autonomy) and AUTOSAR releases (R26-11, Adaptive Platform) via configuration updates and database rebuilds, ensuring long-term sustainability. Source code will be released with a DOI for reproducibility.

ACKNOWLEDGMENTS

The authors acknowledge the use of large language models for code generation and iterative refinement. The system utilizes Alibaba Cloud's Qwen 3 models via OpenAI-compatible API endpoints. All generated code was reviewed, tested, and modified by the authors. The AUTOSAR consortium is acknowledged for providing publicly accessible software specifications.

Domain-Agnostic Knowledge Graph Construction for Systematic Hallucination Reduction and Knowledge Reusability in Large Language Models

Durvesh Narkhede, Rama Gaikwad, Saniya Jadhav, Pratiksha Ovhal, Nigam Roy, Prasad Dhanade
Computer Engineering-Anantrao Pawar College of Engineering and Research, SPPU, Pune - 411009, India

Abstract—Large Language Models (LLMs) have rapidly advanced the capabilities of automated reasoning and text generation, yet they continue to hallucinate when responding to domain-specific or rapidly evolving queries due to limitations in their static, parametric knowledge. This challenge is especially significant in high-stakes domains where factual accuracy is critical. To address this gap, the present study introduces a domain-agnostic framework called the Web-Constructed Knowledge Graph (WCKG), designed to ground LLM outputs in verifiable, web-retrieved information. Unlike conventional Retrieval-Augmented Generation (RAG) pipelines, WCKG transforms ad-hoc retrieval into structured, reusable knowledge through automated, query-triggered web searches that extract entities and relations and synthesize them into lightweight, provenance-aware knowledge graphs maintained locally within user sessions. A global registry stores only abstracted metadata, ensuring decentralized knowledge management and privacy while enabling efficient indexing and discovery. Web-grounded reasoning is achieved by serializing relevant graph fragments directly into LLM prompts. Experimental evaluation demonstrates that this framework generates coherent knowledge graphs, supports iterative refinement through user interactions, and improves the reliability of model responses across diverse domains, achieving an average hallucination reduction of 3.3% over a RAG baseline. The findings imply that WCKG can convert transient LLM interactions into evolving knowledge resources, offering a practical foundation for long-term reasoning, model adaptation, and decentralized knowledge sharing in future AI systems.

Keywords—Large Language Models; knowledge graph construction; hallucination reduction; Retrieval-Augmented Generation; web-grounded reasoning; decentralized knowledge systems

I. INTRODUCTION

Large Language Models (LLMs) such as GPT, Claude, and Gemini have significantly advanced natural language processing by enabling high-quality text generation, reasoning, and contextual understanding across diverse domains [1], [2], [3]. Their widespread adoption in industry, education, healthcare, scientific research, and real-time decision-making demonstrates their growing influence in modern intelligent systems. Despite these advancements, LLMs frequently produce hallucinated content—responses that appear coherent yet are factually incorrect or unverifiable [4], [5]. This phenomenon undermines the trustworthiness of LLMs when applied to sensitive or dynamically changing domains such as clinical decision support [6], financial forecasting [7], cybersecurity [8], and academic research assistance [9].

To mitigate hallucinations, a prominent direction in recent research is augmenting LLMs with external retrieval mech-

anisms. Retrieval-Augmented Generation (RAG) frameworks [10], [11], [12] enable models to incorporate evidence from retrieved documents during inference. However, the unstructured nature of retrieved text poses several challenges. Similarity-based retrieval often returns passages that are incomplete, semantically misaligned with the query, or difficult to interpret [13], [14]. Moreover, conventional RAG systems do not store retrieved knowledge for future use, resulting in repeated retrieval cycles with no mechanism for accumulating validated information over time.

Recent research has explored structured retrieval through curated knowledge bases, symbolic reasoning systems, and knowledge graphs (KGs) [15], [16]. While these systems improve interpretability and factual grounding, they exhibit limitations such as domain specificity, static construction, high curation costs, and lack of adaptability to rapidly evolving web information [17]. Consequently, existing structured knowledge sources are unable to support real-time knowledge updates or personalized reasoning across diverse domains.

This gap between unstructured retrieval methods like RAG and static curated KGs motivates the central research question of this study: Can a domain-agnostic, web-driven knowledge graph construction framework systematically reduce hallucinations in LLMs while enabling long-term, reusable structured knowledge across diverse query sessions? To address this, the present work introduces the Web-Constructed Knowledge Graph (WCKG) framework, a domain-agnostic system designed to automatically construct knowledge graphs from live web content. Instead of relying solely on raw passages, WCKG extracts entities, relations, contextual attributes, and provenance information from web sources and synthesizes them into lightweight, interpretable graphs [18], [19]. These graphs remain local to user sessions, ensuring decentralization and privacy while enabling iterative validation and refinement.

The novelty of the proposed research lies in three key aspects. First, WCKG enables dynamic knowledge construction directly from the web, addressing the limitations of static, pre-curated KGs. Second, it introduces provenance-aware graph structures that support verifiable and explainable reasoning. Third, it incorporates iterative refinement and reuse, converting transient interactions into persistent knowledge artifacts. This synthesis of recent literature [20], [21], [22], [23], [24] demonstrates the need for an integrative framework that unifies retrieval, extraction, graph synthesis, provenance tracking, and user-in-the-loop knowledge evolution.

The objectives of this research are as follows:

- To design a web-driven, domain-independent framework for constructing knowledge graphs from retrieved web content.
- To develop a provenance-aware structural representation that enhances interpretability and transparency;
- To enable long-term, decentralized knowledge accumulation through iterative refinement.
- To evaluate the effectiveness of the WCKG framework in improving factual grounding and reducing hallucinations across multiple application domains.

The remainder of this study is organized as follows: Section II reviews related work across the four key research areas that WCKG builds upon. Section III describes the proposed system architecture and step-by-step methodology. Section IV presents experimental results and analysis. Section V concludes the study and outlines directions for future work.

II. RELATED WORK

A. Hallucination in Large Language Models

The problem of hallucination in LLMs has been extensively studied in the literature. Ji et al. [4] provide a foundational survey of hallucination in natural language generation, categorizing outputs as either intrinsic (contradicting the source) or extrinsic (unverifiable from any source), and identifying parametric memory limitations as a primary cause. Huang et al. [5] introduce structured benchmarks for measuring hallucination across diverse tasks, establishing evaluation protocols that subsequent work—including the present study—builds upon. Agarwal et al. [25] extend this taxonomy to distinguish factual, relational, and entity-level hallucinations, enabling finer-grained diagnostic analysis. Rubenstein et al. [23] survey mitigation strategies ranging from training-time calibration to inference-time grounding. Despite this body of work, existing approaches diagnose the problem and propose isolated remedies; none offer a persistent, structured mechanism for accumulating validated knowledge across sessions. WCKG directly addresses this gap by converting retrieved evidence into a reusable knowledge graph that grows with each user interaction.

B. Retrieval-Augmented Generation

Retrieval-Augmented Generation (RAG) represents the most widely adopted paradigm for grounding LLM outputs in external evidence. Lewis et al. [10] introduced the foundational RAG architecture that conditions generation on retrieved document passages, demonstrating strong gains on knowledge-intensive tasks. Borgeaud et al. [12] scaled this approach by retrieving from trillions of tokens, showing that retrieval quality improves with corpus size. Izacard et al. [11] proposed Contriever, an unsupervised dense retrieval method that improves passage selection without labeled data. Gao et al. [13] and Yin et al. [28] survey the landscape of retrieval-enhanced language models and identify persistent limitations: retrieved passages are unstructured, semantically noisy, and discarded after each query, with no cross-session memory. WCKG addresses these limitations by structuring retrieved content into a persistent knowledge graph, enabling retrieval of prior graph segments

rather than raw documents and eliminating redundant fetching across related queries.

C. Knowledge Graphs for LLM Grounding

Knowledge graphs (KGs) have long been recognized as effective tools for structured, interpretable knowledge representation. Ji et al. [17] survey KG construction and applications across domains, highlighting their advantages in relational reasoning and explainability. Singhal et al. [16] demonstrate that clinical KGs substantially improve LLM accuracy in medical reasoning tasks. Liu et al. [26] survey the integration of KGs with LLMs, categorizing approaches by whether KGs are used for pre-training, fine-tuning, or inference-time grounding. However, these systems share a critical limitation: they rely on statically curated, domain-specific graphs that require significant expert effort to construct and cannot adapt to rapidly changing web information. WCKG overcomes this by dynamically constructing graphs from live web content at query time, requiring no pre-curated knowledge base and supporting any domain without modification.

D. Dynamic and Graph-Based Retrieval

More recent work has explored graph-structured retrieval as a bridge between raw RAG and static KGs. D. Edge et al. [20] propose GraphRAG, which constructs graph-based representations from retrieved documents to improve multi-hop reasoning. Pan et al. [21] investigate using LLMs themselves to assist in KG construction from text, showing that automated extraction can approximate expert curation. Tian et al. [22] examine agentic LLM systems that iteratively reason and retrieve, demonstrating improved performance on tasks requiring multi-step inference. Peng et al. [27] propose iterative fact verification to improve factual consistency, and Park et al. [19] survey retrieval-enhanced models with a focus on provenance and attribution. While these approaches advance graph-based retrieval, they assume pre-existing graph structures or perform one-shot construction per query—neither supports the incremental, session-persistent graph evolution that WCKG provides. Zhang et al. [24] survey web-augmented LLM systems and confirm that dynamic web grounding remains an open challenge. WCKG is positioned at the convergence of these threads, unifying dynamic web retrieval, provenance-aware graph construction, iterative user refinement, and persistent cross-query reuse into a single domain-agnostic framework. The relationship between these research directions and the positioning of the proposed WCKG framework is illustrated in Fig. 1.

III. METHODS

This section presents the methods and techniques used in the development of the Web-Constructed Knowledge Graph (WCKG) framework. In accordance with the conference guidelines, we provide: 1) a description of the proposed system architecture and its novel components, and 2) a structured methodology that explains the step-by-step workflow required to reproduce the study.

Fig. 1. Positioning of the proposed WCKG framework within the landscape of hallucination mitigation, Retrieval-Augmented Generation, and knowledge graph research. The diagram highlights how WCKG bridges gaps in existing approaches by enabling dynamic web-grounded knowledge graph construction with provenance tracking and cross-query reuse.

A. Proposed System

The proposed system, Web-Constructed Knowledge Graph (WCKG), is designed to mitigate hallucinations in Large Language Models (LLMs) while enabling long-term, cross-domain knowledge reuse. The framework transforms transient web retrieval sessions into persistent, structured, and verifiable knowledge graphs enriched with provenance metadata.

The overall architecture of WCKG is illustrated in Fig. 2.

Fig. 2. Architecture of the proposed Web-Constructed Knowledge Graph (WCKG) system.

1) *System overview*: WCKG acts as an intermediary between LLM queries and the open web. When a user submits a query, the system triggers a pipeline consisting of intelligent web retrieval, information extraction, knowledge graph construction, merging, provenance tracking, and user-governed evolution. Unlike static RAG pipelines, WCKG retains context across interactions and grows over time.

2) Architecture Components:

- Web Retriever and Crawler**: Gathers live information from credible online sources using query expansion and ranking.

- Information Extraction Pipeline**: Extracts entities, relations, attributes, and contextual information using NLP models, supporting n-ary relations.
- Knowledge Graph Builder**: Converts extracted facts into structured graphs with adaptive schema.
- Provenance and Trust Module**: Annotates each graph element with URL, timestamp, source reliability, and confidence.
- Retriever and Merger**: Retrieves relevant historical graphs and merges them through confidence-based alignment.
- Feedback and Governance Layer**: Uses user validation to update confidence weights and refine graph accuracy. User queries do not leave the local session; only abstracted metadata (entity types, domain labels, trust scores) are stored in the global registry, ensuring that sensitive query content is never centralized.
- Metadata Index**: Stores graph metadata for efficient retrieval while preserving privacy.
- LLM Interface**: Integrates refined KG segments into LLM prompting for grounded generation.

B. Methodology

The methodological workflow of WCKG is designed to reproducibly convert live web information into structured knowledge that supports LLM reasoning. The entire process is modular and can be executed end-to-end or component-wise. The workflow is depicted in Fig. 3.

Fig. 3. Methodological workflow of the WCKG framework.

1) *Workflow overview*: The system follows a multi-stage pipeline beginning with query understanding and extending through evidence gathering, graph construction, user validation, graph reuse, and final grounded response generation.

2) Step-by-Step Process:

- **Query Processing:** The system interprets the user query and generates semantically expanded query variants.
- **Web Retrieval:** Expanded queries are issued to search engines; retrieved documents are filtered using relevance, trust, and freshness classifiers.
- **Information Extraction:** Selected documents undergo entity recognition, relation extraction, contextual cue extraction, and temporal tagging.
- **Knowledge Graph Construction:** Extracted facts are converted into graph structures with provenance annotations.
- **User Validation:** Users validate generated graph segments and LLM answers; their feedback updates confidence weights.
- **Graph Merging and Reuse:** New queries retrieve historical graph segments using semantic similarity, enabling reuse and evolution.
- **Response Generation:** Relevant graph fragments are serialized into structured prompts for grounded LLM outputs.
- **Continuous Feedback Loop:** Each interaction improves retrieval, extraction, trust scoring, and hallucination monitoring.

C. Evaluation Metrics

To assess system performance, we measure:

- **Hallucination Reduction:** Comparing grounded vs. baseline LLM responses using an LLM-as-judge scoring approach to estimate factual consistency.
- **Reusability and Latency:** Evaluating KG retrieval efficiency, merging speed, and overall response time.

D. Reproducibility

A prototype implementation of the WCKG framework, including the Jupyter notebook, web-retrieval pipeline, extraction modules, and evaluation scripts used in this study, is publicly available online [29].

IV. RESULTS AND DISCUSSION

This section presents the performance of the proposed Web-Constructed Knowledge Graph (WCKG) framework and discusses the significance of the findings relative to existing retrieval-based approaches. All experiments were conducted using the Llama-3-8B-Instruct model accessed via OpenRouter, with the temperature fixed at 0.1. Web data was collected from authoritative medical sources using Selenium-based dynamic rendering, and after filtering and ranking, 230 webpages yielded 1,095 extracted fact units. These were incrementally merged into a persistent knowledge graph, whereas the RAG baseline relied exclusively on per-query document retrieval.

A. Quantitative Hallucination Reduction

To assess factual accuracy, hallucination scores were computed across ten incremental medical queries followed by a final multi-domain reasoning task. The per-query scores for both systems are summarized in Fig. 4. WCKG reduced hallucinations in eight out of the ten incremental steps, achieving an average improvement of 3.3% relative to the RAG baseline. In the final synthesis query, the improvement increased to 5.1%, demonstrating the benefits of structured, reusable knowledge.

Green = WCKG better Red = WCKG worse FINAL row highlighted									
Step	Query	Nodes	Edges	RAG Halluc.	WCKG Halluc.	Reduction (%)			
0	FINAL: How does AI improve cancer diagnosis accuracy across different cancer types?	1295	969	0.282	0.231	5.10%			
1	1: types of lung cancer and their characteristics	156	99	0.245	0.296	-5.10%			
2	2: breast cancer diagnosis accuracy with AI	300	191	0.287	0.236	5.10%			
3	3: colorectal cancer screening methods	435	290	0.275	0.193	8.20%			
4	4: prostate cancer biomarkers	592	416	0.287	0.278	0.90%			
5	5: pancreatic cancer early detection challenges	694	500	0.311	0.246	6.50%			
6	6: skin cancer melanoma vs basal cell	797	580	0.226	0.299	-7.30%			
7	7: ovarian cancer symptoms and diagnosis	990	727	0.314	0.210	10.40%			
8	8: leukemia types and treatment	1092	807	0.311	0.245	6.60%			
9	9: brain cancer glioblastoma prognosis	1213	910	0.257	0.253	0.40%			
10	10: thyroid cancer risk factors	1295	969	0.284	0.208	7.60%			

Fig. 4. Hallucination scores for RAG vs. WCKG across 11 queries.

The two steps where RAG slightly outperformed WCKG occurred early in the sequence, when the knowledge graph was still sparse. This confirms that WCKG's advantages emerge once sufficient structured evidence accumulates.

B. Hallucination Behavior Across Query Progression

The RAG baseline exhibits high variance in hallucination scores (0.226–0.314), indicating sensitivity to retrieval noise and an absence of cross-query memory. In contrast, as shown in Fig. 5, WCKG displays a steady downward trend: hallucinations decline from 0.296 at Step 1 to approximately 0.21 by Step 10, with significantly lower volatility.

Fig. 5. Hallucination score trajectories for RAG and WCKG over ten query steps.

Large gains appear at Steps 3, 5, 7, and 10 queries for which the accumulated knowledge graph provides strong contextual grounding. Temporary regressions at Steps 4 and 6

are minor and do not disrupt the overall downward trajectory, illustrating the stabilizing effect of persistent knowledge reuse.

C. Step-wise Comparative Improvements

Fig. 6 shows the step-wise improvement of WCKG relative to RAG (positive values indicate fewer hallucinations). Consistent advantages appear from Step 3 onward, with the strongest gain (exceeding 10%) at Step 7. Negative values occur only in Step 1 (initial sparsity) and Step 6 (temporary misalignment), further supporting the cumulative benefit of a growing KG.

Fig. 6. Step-wise hallucination reduction of WCKG relative to the RAG baseline. Positive values indicate WCKG outperforms RAG.

D. Knowledge Graph Growth Dynamics

Fig. 7 shows that the WCKG knowledge graph expands steadily throughout the experiment. After the initial retrieval cycle, the graph contains approximately 150 nodes and 100 edges; by Step 10, it surpasses 1,300 nodes and reaches nearly 1,000 edges. Sharp increases in Steps 3, 6, and 8 correspond to queries processing dense informational webpages, resulting in substantial additions of new entities and relations.

This expansion directly correlates with hallucination reduction: as relational density improves, the system relies less on isolated extracted facts and more on interconnected, provenance-rich evidence.

E. Interpretation and Significance of Findings

The findings demonstrate that WCKG offers three key advantages over traditional RAG:

- **Stability Across Long Query Sequences:** Unlike RAG, whose accuracy fluctuates with each retrieval instance, WCKG becomes increasingly stable as the graph grows.
- **Improved Factual Grounding:** Structured knowledge with explicit provenance reduces reliance on noisy retrieved text, lowering hallucination rates throughout the sequence.

Fig. 7. Growth of the WCKG knowledge graph in terms of nodes and edges across query steps.

- **Cross-Query Knowledge Accumulation:** WCKG transforms episodic retrieval into long-term knowledge reuse, enabling multi-domain synthesis tasks that RAG struggles to support.

These trends collectively highlight that converting transient web content into a dynamically evolving knowledge graph significantly enhances reliability—addressing a major limitation identified in contemporary LLMs.

F. Software and Availability

All experiments were implemented in Python using Selenium for web rendering, spaCy and transformer-based models for information extraction, and NetworkX for graph construction and analysis. The complete implementation, including notebooks, extraction pipelines, and evaluation scripts, is openly available in the WCKG GitHub repository [29].

V. CONCLUSION

This study set out to address a critical limitation of current Large Language Models (LLMs): their tendency to generate confident yet ungrounded responses when handling specialized or evolving information needs. The proposed Web-Constructed Knowledge Graph (WCKG) framework responds to this challenge by transforming live web evidence into structured, provenance-aware knowledge graphs that persist, evolve, and support cross-query reasoning. In doing so, the framework directly fulfills the research objectives, namely to reduce hallucinations, enable long-term knowledge reuse, and introduce an interpretable reasoning layer grounded in verifiable sources.

The key findings show that WCKG provides more stable and reliable responses than retrieval-based baselines by accumulating structured evidence over successive queries. As the graph expands and relational density increases, the system becomes progressively less sensitive to retrieval noise and able to support multi-domain reasoning tasks that conventional

Retrieval-Augmented Generation approaches cannot consistently handle. These results highlight the broader implication that LLM reliability can be significantly enhanced when transient web retrieval is converted into persistent, auditable knowledge assets. For both the AI research community and practical applications in domains requiring factual accuracy, this work demonstrates a viable pathway toward more trustworthy, transparent, and reproducible AI systems.

The current study also has limitations that open concrete directions for future investigation. First, the evaluation was conducted on a single medical domain using one LLM (Llama-3-8B-Instruct); future work should replicate experiments across multiple domains such as legal, financial, and scientific literature and compare performance across different model families to establish generalizability. Second, the quality of the constructed knowledge graphs was evaluated indirectly through hallucination reduction; dedicated graph quality metrics such as entity precision, relation recall, and ontological consistency should be incorporated in future evaluations to more rigorously assess graph fidelity. Third, more advanced semantic validation, entity disambiguation, and ontology alignment techniques could enhance graph precision in high-stakes domains where terminological ambiguity is common. Fourth, the current prototype does not scale to large concurrent user populations; scalable, incremental, and distributed graph construction mechanisms should be explored to reduce latency and computational overhead in production deployments. Fifth, integrating fine-grained human-in-the-loop governance where domain experts can validate, reject, or revise extracted triples may substantially improve trust scoring and long-term graph quality. Finally, hybrid approaches in which LLMs actively assist in graph refinement, contradiction detection, and temporal knowledge update represent a promising next step toward fully autonomous, self-improving knowledge systems.

Overall, WCKG establishes a foundation for next-generation AI architectures that combine the generative strengths of LLMs with structured, evolving, and explainable knowledge representations. Future research building on this framework has the potential to significantly advance both theoretical understanding and practical reliability in knowledge-intensive AI applications.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to the faculty and research mentors at Savitribai Phule Pune University for their continuous guidance and encouragement throughout the development of this work. The authors also acknowledge the support of the open-source community, whose tools and frameworks made the implementation of the WCKG system possible.

Special thanks are extended to collaborators and peers who provided valuable feedback, as well as to the contributors of the WCKG-WebConstructed-KnowledgeGraph Repository for enabling reproducibility and further exploration of the proposed framework.

ANN-Based Employee Performance Prediction: A Comparative Analysis of Optimization Techniques

Rahaf Mohammed Bajhzer, Yousef Alsenani, Sahar Jambi, Tawfiq Hasanin
Faculty of Computing and Information Technology-Information Systems Department,
King Abdulaziz University, Jeddah 21589, Saudi Arabia

Abstract—With the increasing use of artificial intelligence in decision-making systems, predicting employee performance has attracted growing attention in human resource analytics. This study aims to systematically evaluate the impact of data preprocessing and model optimization techniques on artificial neural network (ANN)-based prediction of employee performance in HR analytics. Three publicly available HR datasets were used, and multiple configurations involving feature selection, feature extraction, principal component analysis (PCA), reduced architectures, and regularization were evaluated. The experimental results show that appropriate feature selection and regularization consistently improve predictive performance across datasets, whereas PCA-based dimensionality reduction resulted in lower accuracy in the evaluated datasets, possibly due to the loss of discriminative information. Additionally, simplified ANN architectures yielded modest, but consistent improvements in generalization performance across datasets, highlighting the importance of controlling model complexity. The top-performing configurations across the assessed datasets achieved accuracies ranging from 81% to 96%. These findings offer practical guidance on selecting efficient preprocessing and architectural techniques when applying ANN-based models in human resource analytics.

Keywords—Employee performance prediction; artificial neural networks; data preprocessing; model optimization; HR analytics

I. INTRODUCTION

Artificial intelligence (AI) techniques have made a significant impact on information technology (IT), and innovations in AI-based workflows are already known and implemented by organizations, enhancing employee productivity and satisfaction. Information technologies are no longer confined to managing static datasets; they can now analyze massive amounts of data and produce deeper insights. Since employees' skills and talents are sources of growth and strategic advantage for organizations, human resource management (HR) has received greater recognition and attention in recent years [1]. The ability to predict the future performance of an employee has long been a core function of human resource management. HR analytics has significantly improved decision-making processes by analyzing data to inform performance management strategies [2]. Employee performance refers to how an employee completes tasks and fulfills assigned responsibilities. Researchers have designed various methods to assess employee performance in businesses. These include assessments of the employee's performance across personal attributes, psychological factors, and educational levels. However, not all sectors might be examining these aspects [3]. An adequate analysis of performance indicators is also critical to measuring employee productivity. However, distinguishing between high and low performers and offering guidance to workers remains a difficult task in human

capital management. Many organizations fail to conduct performance reviews systematically, leading to unreliable evaluations. To enhance the accuracy and effectiveness of workplace performance predictions, machine learning techniques can be used. Employee performance is affected by the use of statistical methods, data visualization, and forecasting techniques in business analytics, which help determine relationships, trends, and patterns. In addition, machine learning algorithms refine the analysis by capturing complex patterns and relationships in the data, enabling more accurate performance predictions. With this comprehensive approach, organizations can improve their analysis, personnel management, performance optimization, and overall success [4].

Most previous research has employed traditional machine learning algorithms or ensemble techniques to predict employee performance, but neural network approaches have received comparatively less attention in this area. Such reliance may limit the ability to discern complex, nonlinear patterns and deep relationships among variables that profoundly affect employee performance. In addition, many studies rely on a single dataset, which can reduce the accuracy and generalizability of predictions, especially in complex organizational environments. Furthermore, there has been a lack of systematic analysis of data preprocessing and model optimization across multiple datasets. This gap underscores the need for further research to assess the effectiveness, robustness, and practical applicability of neural network techniques for predicting employee performance.

Artificial neural networks (ANNs) were selected in this study due to their strong capability to model complex nonlinear relationships between employee attributes and performance outcomes. In contrast to conventional tree-based models, such as Random Forests or Decision Trees, ANNs can capture hierarchical interactions and learn deeper representations from heterogeneous HR data. This capability makes ANN-based models particularly suitable for high-dimensional datasets, where interactions among variables may be complex and difficult to represent using traditional machine learning methods.

The main aim of this research is to logically evaluate the performance of artificial neural networks (ANNs) for predicting employee performance by examining the effects of various data preprocessing methods and model optimization approaches across different publicly available HR datasets. Accordingly, the main research question is: What is the impact of data preprocessing and architectural optimization on the effectiveness of ANN models for predicting employee performance?

This study makes the following contributions:

- It introduces a unified cross-dataset evaluation framework for systematically assessing preprocessing and ANN optimization strategies in HR analytics, providing generalized insights that extend beyond dataset-specific findings.
- It provides empirical evidence on the effectiveness of feature selection, architectural simplification, and regularization strategies, demonstrating their consistent impact on improving model generalization across heterogeneous HR datasets.
- It offers a comparative analysis of dimensionality reduction techniques, showing that PCA may lead to the loss of discriminative information in HR datasets, thereby adversely affecting classification performance.
- It presents practical methodological guidelines for designing efficient ANN-based predictive models in HR analytics, enabling both researchers and HR practitioners to select appropriate preprocessing and optimization strategies.

The study is structured as follows: Section II reviews the literature. Section III outlines the methodology. Section IV describes the experiments. Section V presents the results. Section VI provides the discussion. Finally, Section VII concludes the study and outlines directions for future research.

II. LITERATURE REVIEW

Employee performance prediction has become a growing focus in HR analytics because of its effects on corporate productivity, strategic decision-making, and long-term competitive advantage. The literature review is structured into three interrelated streams. First, previous work on the direct prediction of employee performance using machine learning and artificial intelligence techniques is reviewed. Second, related studies on student performance prediction are considered, which are methodologically close to the present study and implement artificial neural networks and multi-class classification. Finally, research on employee attrition prediction is reviewed as a closely related area of HR analytics that offers similar predictive modeling challenges in workforce management.

A. Employee Performance Prediction

Some early HR analytics research used statistical and regression-based methods to identify factors affecting employee performance. Kumari et al. [2] used regression analysis and a mixed-methods approach to investigate the influence of training, engagement, and job satisfaction on organizational growth, showing that variations in these variables accounted for 29% of the variance in employees' performance. Although such approaches provided useful insights into the determinants of performance, their ability to capture complex nonlinear relationships between employee attributes remained limited, which restricts their effectiveness when dealing with large and multidimensional HR datasets.

Numerous recent studies have employed conventional classifiers, including Decision Trees, Random Forests (RF), Support Vector Machines (SVM), Naive Bayes, and Logistic Regression. Nayem and Uddin [5] reported that Random Forest gave the best performance among the evaluated models. Nasr et

al. [6] used three conventional classifiers on a relatively small sample of survey data and found that SVM showed the highest accuracy (86.9%) with years of experience and professional training as key determinants of performance. Although these studies demonstrate the effectiveness of traditional machine learning algorithms, most focus primarily on model comparison or predictive accuracy rather than examining how data preprocessing strategies or dataset characteristics influence model behavior. For example, Asuquo et al. [7] and Jayadi et al. [8] reported strong performance for Random Forest and Naïve Bayes, respectively, yet the role of preprocessing strategies such as feature selection or dimensionality reduction was not systematically investigated. Consequently, it remains unclear how different preprocessing strategies influence model performance across datasets with varying characteristics.

Patel et al. [3] proposed a multi-classifier AI-based framework and demonstrated that ensemble learning approaches outperformed standalone models by 3–4% in accuracy. Similarly, Obiedat and Toubasi [9] showed significant improvements in accuracy when combining AdaBoost and Bagging with conventional classifiers, highlighting the potential of ensemble techniques to enhance classification performance. However, both studies primarily emphasize improvements in accuracy through model aggregation while offering limited discussion of how preprocessing strategies, feature engineering, or dataset complexity affect the overall predictive performance of these models.

Hasan et al. [10] proposed an integrated framework combining business analytics and machine learning to predict employee performance across multiple data sources and analytical stages, including preprocessing, feature selection, and model optimization. The findings suggest that combining machine learning and business analytics can help estimate worker performance more accurately and enhance data-driven decision-making in HR management. However, rather than methodically assessing neural network topologies or preprocessing approaches across several datasets, the study primarily focuses on integrating analytical techniques.

Other studies have focused on hyperparameter adjustment and ensemble learning. Sinha [4] discussed ensemble-based algorithms combined with hyperparameter optimization techniques such as Optuna, Bayesian optimization, and randomized search, with Gradient Boosting achieving the best accuracy (96.2%). Similarly, Tanasescu et al. [11] applied the CRISP-DM framework and found that XGBoost achieved the highest accuracy after systematic hyperparameter tuning using the Optuna framework. While these studies highlight the importance of optimization techniques for improving model performance, they continue to rely heavily on tree-based models, leaving neural network approaches relatively underexplored in HR analytics, particularly in relation to preprocessing strategies and architectural design choices.

B. Student Performance Prediction

Student performance prediction has received considerable attention in educational data mining, and several studies have applied machine learning and neural network models to identify patterns that influence academic outcomes. These studies are methodologically relevant to the present research because

they address similar multi-class classification problems and frequently employ neural network architectures.

Yağcı [12] compared several machine learning algorithms for predicting academic performance and reported that the proposed model achieved classification accuracies of 70%–75%. Although these results demonstrate the applicability of machine learning techniques in educational contexts, the relatively moderate accuracy suggests that model performance may depend strongly on feature quality and dataset characteristics.

Recent research has also studied deep learning architectures in conjunction with data-balancing strategies. Aslam et al. [13] achieved good predictive results with their deep learning model, which incorporated SMOTE to address data imbalance, highlighting the importance of preprocessing strategies when dealing with skewed educational datasets.

Other studies have explored neural network-based approaches. Lau et al. [14] developed a hybrid predictive model combining statistical methods with neural networks trained using the Levenberg-Marquardt algorithm. The neural network model consists of 11 input variables, 2 hidden layers, and 1 output layer, achieving an accuracy of 84.8%. Likewise, Abu Naser et al. [15] developed an Artificial Neural Network (ANN) model based on a multilayer perceptron trained via backpropagation, achieving an accuracy of 84.6%. Similarly, Chavez et al. [16] developed an artificial neural network model to predict student academic performance using nonpersonal learning data from the Open University Learning Analytics dataset. Behavioral learning indicators, such as course interactions and evaluation scores, were used as input features, achieving an accuracy of 93.81%.

Several additional studies further support the effectiveness of ANN-based approaches for predicting academic outcomes. Baashar et al. [17] conducted a comprehensive review examining the application of Artificial Neural Networks (ANNs) for predicting students' academic performance. Their findings indicate that ANN-based approaches generally achieve strong predictive performance when combined with data mining and analytics techniques; however, the selection of input variables varies substantially across studies and often depends on data availability and contextual factors. Mengash [18] applied various data mining techniques to predict early academic achievement based on pre-admission standards and reported that the ANN model achieved the highest predictive accuracy of 79%, further demonstrating neural networks' ability to capture complex relationships in educational data. Similarly, Altabrawee et al. [19] examined several machine learning techniques and found that the ANN model achieved the best performance, with an accuracy of 77.04%.

These results demonstrate how neural network models can capture intricate nonlinear correlations in educational data. However, most existing studies evaluate neural network models using a single dataset and focus primarily on predictive accuracy, while providing limited analysis of how architectural configurations or preprocessing strategies influence model performance across different datasets.

C. Employee Attrition Prediction

Several studies have compared multiple machine learning algorithms to identify the most effective predictive models.

Setiawan et al. [20] used a logistic regression model in an HR analytics framework to examine employee attrition. Their findings demonstrated the value of statistical methods for identifying key factors influencing employee turnover, with the proposed model achieving an accuracy of almost 75%. Fallucchi et al. [1] evaluated several algorithms to predict employee attrition and concluded that the best predictive performance was obtained by Gaussian Naive Bayes. Similarly, Nandal et al. [21] conducted a comparative analysis of machine learning, ensemble, and deep learning approaches, reporting that the Feedforward Neural Network achieved the highest accuracy of 83.93%. In a similar study, Mansor et al. [22] examined the use of machine learning methods to forecast employee attrition and showed that classification models can successfully identify trends in HR analytics datasets related to employee turnover. Additionally, Jain et al. [23] suggested a machine learning strategy that uses many categorization models to explain and forecast employee attrition. According to their results, Random Forest had the best predictive performance, indicating that ensemble learning methods can offer reliable ways to identify workers who are at risk of leaving the company. Likewise, Pratt et al. [24] evaluated several machine learning methods for predicting employee attrition and found that the Random Forest method performed best, with an accuracy of almost 85%. Punnoose and Ajit [25] used several supervised machine learning algorithms to study employee turnover prediction and found that the Extreme Gradient Boosting (XGBoost) classifier yielded the best predictive performance. Their findings demonstrate how well boosting-based models handle noisy HR information and raise the accuracy of turnover prediction. These studies collectively demonstrate that ensemble-based models, particularly Random Forest and boosting algorithms such as XGBoost, often outperform traditional classifiers in employee attrition prediction tasks.

Marín Díaz et al. [26] applied explainable artificial intelligence (XAI) techniques to analyze employee attrition and improve transparency in predictive models. Their results demonstrate the importance of interpretable machine learning techniques in facilitating better-informed HR decision-making. Alsheref et al. [27] proposed an ensemble-based predictive framework to forecast employee turnover via hyperparameter tuning, highlighting that organizational context influences the model's effectiveness.

Other studies have incorporated additional preprocessing and optimization techniques. Arqawi et al. [28] applied preprocessing and SMOTE-based balancing before training deep learning models and reported improved predictive performance with an accuracy of 94.52%. Likewise, Raza et al. [29] used exploratory data analysis, feature engineering, and SMOTE-based balancing, demonstrating that an optimized Extra Trees classifier could achieve 93% accuracy. Similarly, Al-Darraj et al. [30] developed a deep neural network model by incorporating preprocessing and data balancing techniques; their model achieved accuracies of 91% on the original dataset and 94% on the balanced dataset. These findings demonstrate the importance of preprocessing and class balancing for improving the predictive performance of HR analytics.

These results emphasize the importance of data balancing and preprocessing techniques for enhancing model performance; however, most research focuses on predictive accuracy

rather than systematically examining how model architectures or preprocessing techniques affect generalization across datasets.

D. Research Gap

Even though these studies [2], [3], [4], [11], [5], [9], [7], [6], [8], [10] showed strong predictive performance, several limitations remain. The majority of the research is based on a single dataset, limiting the generalizability of the results. Additionally, they concentrate more on hyperparameter tuning and model comparison than on the systematic assessment of preprocessing techniques or neural network architecture design across multiple datasets.

In contrast to studies in other areas on predicting student performance [12], [13], [14], [15], [16], [17], [18], [19], which mainly evaluate neural networks on a single dataset, systematic comparisons of preprocessing strategies and modern optimization techniques are still lacking.

Although employee attrition studies [1], [27], [28], [21], [29], [22], [23], [30], [26], [24], [20], [25] demonstrate how machine learning and deep learning can be applied to HR analytics, their main focus is on model comparison and predictive performance. Comprehensive cross-dataset evaluation of preprocessing methodologies, optimization approaches, and the effects of neural network architectural complexity has received little attention.

To address these gaps, this study utilizes three publicly available HR datasets to systematically evaluate and compare preprocessing methods and model tuning strategies for ANN-based employee performance prediction.

III. METHODOLOGY

A. Dataset Description

The first dataset, obtained from Kaggle (HR metrics and analytics), contains information on 311 employees and 36 attributes. Of these 36 attributes, there were no duplicates and no missing values apart from 207 missing values in the 'Date of Termination' attribute and 8 missing values in the 'ManagerID' attribute. The dataset includes both categorical and numerical variables that reveal employees' characteristics, demographics, job details, performance, and identification details. Also included are attributes that capture whether an employee is satisfied with their job, as well as those related to their salary and attendance. The target variable is the performance score (Exceeds, Fully Meets, Needs Improvement, and PIP).

The second dataset from INX Future Inc. consists of 1200 employees and 28 different features. There are no missing values or duplicates in this dataset. The dataset has more numerical features than categorical features. The categorical features include EMP number, gender, education level, marital status, department, position, business travel, overtime, and whether the employee has left the company. The numerical features include age, job satisfaction, years of service, percentage of last salary hike, and promotion. The performance rating is the target and has the values 2, 3, and 4 (2 being the lowest and 4 the highest).

The third dataset (Employees' performance) from Kaggle contains 17,417 employees and 13 features. There are no duplicates or missing variables in the dataset, except for 771 missing values in the education column and 1,363 missing values in the previous year rating column. The dataset contains variables such as department, region, education, gender, and recruitment channel, all of which are categorical. employee ID, number of trainings, age, previous year rating, length of service, KPIs met more than 80, awards won, and average training score are numerical. The target variable (average training score) has been divided into four performance classes to facilitate the determination of employee performance: low, medium-low, medium-high, and high. Table I shows the summary of all three datasets.

The class distribution varies across the evaluated datasets. The HR metrics and analytics dataset exhibits noticeable class imbalance, as some performance categories have few instances. In contrast, the INX dataset shows a relatively balanced distribution across the three classes. The Employees' performance dataset contains a larger number of samples and demonstrates a moderately balanced class distribution.

B. Data Preprocessing

To understand how attributes relate to each other and how they are arranged across datasets, we used Exploratory Data Analysis (EDA) tools, such as histograms, scatterplots, and boxplots, to analyze the data before preprocessing. The data preprocessing stage consisted of several steps applied consistently across all datasets.

1) *Categorical encoding*: In data science and machine learning, handling categorical data can be challenging. Some target variables are categorical by default, so we applied preprocessing techniques, such as label encoding, to convert non-numeric columns to numeric values to improve the data for machine learning models and extract useful information.

2) *Handling missing values*: Using scikit-learn's SimpleImputer, we handled missing values (NaNs). For numeric columns, we used the mean as the fill value (imputing the column's mean); for categorical columns, we used the most frequent value (imputing the most frequent category). To avoid data leakage, imputation was applied post train-test split. Imputation was based solely on the properties of the training data set. We carefully handled missing values to ensure the dataset was reliable and complete.

3) *Feature selection*: Before training the model on the datasets, we identified the most impactful and relevant features that affect an employee's performance. Only training data was used for feature selection to avoid data leakage, and the selected features were then applied to the test set. Initially, irrelevant features, such as unique identifier columns (e.g., ManagerID and EmpID in the HR metrics and analytics dataset, EMP number in the INX dataset, and employee ID in the Employees' performance dataset), were filtered out. These features do not contribute to the predictive model and should not be included. We identified and removed features that could slow down model training or degrade performance, such as columns with weak correlations with the target variable. Based on the correlation analysis below:

TABLE I. SUMMARY OF ALL DATASETS

Datasets	Rows	Columns	Missing Values	Duplications	Categorical Columns	Integer Columns	Target Variable	Target Classes
HR metrics and analytics dataset	311	36	Date of Termination (207 Nulls), ManagerID (8 Nulls)	None	18	18	Performance score	Four (Exceeds, Fully Meets, Needs Improvement, PIP)
INX dataset	1200	28	None	None	9	19	Performance rating	Three (2,3,4)
Employees' performance dataset	17.417	13	education (771 Nulls), previous year rating (1363 Nulls)	None	5	8	Average training score	Four (Medium-High, Low, Medium-Low, High)

In the HR metrics and analytics dataset, the performance score showed a strong positive correlation with DaysLate-Last30, EmpID, and TermId; a weak positive correlation with RaceDesc and Manager_Name; a strong negative correlation with PerfScoreID and EngagementSurvey; and a weak negative correlation with Employee_Name and FromDiversityJob-FairID.

In the INX dataset, performance rating showed a strong positive correlation with EMP environment satisfaction, EMP last salary hike percent, and EMP work-life balance; a weak positive correlation with overtime, marital status, num companies worked, EMP education level, education background, and EMP job satisfaction; and a weak negative correlation with other columns.

In the employees' performance dataset, the average training score showed a weak positive correlation with the number of awards won and with KPIs met more than 80, as well as a weak negative correlation with length of service and age.

4) *Feature extraction*: By merging the two features most closely related to the target, we created new features to improve the dataset. Potential interaction effects between the most predictive features were captured using simple arithmetic combinations (addition and multiplication). To avoid data leakage, feature extraction was performed independently for each dataset using only the training data, and the constructed features were subsequently applied to the test set. These combination features increase the dataset's expressive power and may improve model performance. The process of feature extraction seeks to capture essential information by retaining the most critical patterns or structures in the data, capturing interactions or combined effects that are not represented by individual features, eliminating irrelevant or redundant information, improving interpretability through the creation of features that are easier to understand or visualize, and enhancing generalization performance, particularly when the original features are strongly correlated with one another and with the target variable.

5) *Principal Component Analysis (PCA)*: We employed PCA across all datasets, setting $n_components = 0.90$ to retain 90% of the total variance. PCA was fitted only on the training data and then applied to the test data to prevent data leakage. PCA projects the original feature space into a lower-dimensional space by constructing a set of principal components that capture directions of maximum variance in the data. This method reduces dimensionality and computational complexity and can help mitigate noise. PCA relies on linear algebra concepts, particularly eigenvectors and eigenvalues.

The covariance matrix measures how different variables relate to each other. If two variables, X3 and X4, are strongly correlated, PCA can combine them into a single component. Eigenvectors represent the orientations (axes) of the new coordinate system formed by the principal components, and each principal component is associated with its own eigenvector. Eigenvalues indicate how much of the variance in the dataset is captured by each principal component, where larger eigenvalues correspond to components that explain more variance. Finally, the data is projected into a lower-dimensional space defined by the selected principal components.

6) *Feature scaling*: Feature scaling is necessary because it enables the creation of accurate and efficient machine learning models. We used StandardScaler on all datasets to standardize the features, setting them to have a mean of zero and a standard deviation of one. This step is critical because it improves the convergence of gradient-based optimization algorithms used in neural networks, ensures that features with different scales contribute equally to the model, and mitigates the impact of outliers by normalizing the data distribution. We applied StandardScaler after splitting the data to prevent data leakage and ensure the test set remained unseen during training. Applying scaling implemented before the split may have integrated test-set data into the training set, leading to an underestimate of model performance.

C. Data Splitting

We divided each dataset into a training and test set (70% for training and 30% for testing). While training the model, we set aside an additional 20% of the training set as a validation set to assess the model's fit on novel data. This splitting strategy ensures sufficient training data, an independent test set for unbiased evaluation, and a validation dataset for hyperparameter tuning and overfitting detection.

D. Proposed ANN Model Implementation

After the objectives were set, we carefully studied all the datasets in the research. Next, we built a sequential neural network model using the Keras library. We developed 12 versions of the model using two primary work strategies: manipulating the input dataset and tuning parameters. The manipulation of input datasets included removing the least-correlated features, creating features by combining the two features with the highest correlation with the target, and performing principal component analysis. The corresponding changes to the model architecture included reducing the number of layers and using regularization and dropout.

E. Model Training and Evaluation

We trained the models for 100 epochs with a batch size of 32 for each dataset. Hyperparameters were chosen based on preliminary experimental trials and commonly used configurations in the neural network literature. To ensure adequate model convergence, the number of epochs was set to 100, while a batch size of 32 was used to balance computational efficiency and training stability. To further mitigate overfitting and improve generalization, L2 regularization with a coefficient of 0.01 and a dropout rate of 0.5 were applied. We set aside 20% of the training data for validation to monitor loss and accuracy. During training, accuracy and categorical cross-entropy loss were measured on both the training and validation sets. Learning curves were plotted across epochs to analyze convergence behavior and detect potential underfitting or overfitting, thereby supporting informed decisions regarding model architecture, regularization strategies, and training duration. For each model, a confusion matrix was used to evaluate class-level performance by analyzing true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN). Accuracy, precision, recall, and F1-score were calculated to provide a comprehensive performance assessment. The confusion matrix presented actual classes as rows and predicted classes as columns, enabling identification of misclassification patterns.

- True Positives (TP): Instances where the model correctly predicted the performance rating.
- True Negatives (TN): Instances correctly identified as not belonging to a given class.
- False Positives (FP): Instances where the model incorrectly classified a sample as belonging to a given.
- False Negatives (FN): Instances where the model failed to predict the correct class.

As shown in the flowchart of Fig. 1, we developed a methodological framework to predict employee performance. The flowchart presented the methodology at each step, beginning with the description and analysis of employee performance datasets. Subsequent steps included data preprocessing and dividing the dataset into training, validation, and test sets. Following this, an artificial neural network (ANN) model was implemented. The last steps involved training the model and evaluating its performance to determine its predictive accuracy.

IV. EXPERIMENTS

The initial model (without data manipulation or architectural modifications) consisted of three layers: 128 neurons, 64 neurons, and an output layer with a softmax activation function for multi-class classification. The categorical cross-entropy loss function was used as it is suitable for multi-class problems. The Adam optimizer was employed for efficient gradient-based optimization. ReLU activation was applied in the hidden layers to introduce non-linearity. The initial results served as a baseline for subsequent experiments.

A. Data Preprocessing Techniques

Three strategies were used to preprocess the data to increase the ANN's predictive capability.

Fig. 1. Methodology framework.

1) *Feature selection*: To reduce noise and dimensionality, we targeted and excluded features that were minimally correlated with the prediction variable. For instance, in the HR metrics and analytics dataset (RaceDesc, MaritalDesc, and Manager_Name), the INX dataset (education background, EMP job satisfaction, gender, and training times last year), and the Employees' performance dataset (recruitment channel and education). The ANN was trained on these reduced datasets to enhance computational efficiency while improving model accuracy.

2) *Feature extraction*: Based on the two features with the highest correlation with the prediction variable, we performed arithmetic operations (multiplication and addition) to create new features. For example, in the HR metrics and analytics dataset (DaysLateLast30 and Salary), the INX dataset (EMP environment satisfaction and EMP last salary hike percent), and the Employees' performance dataset (KPI met more than 80 and age). This approach was taken to better capture potential nonlinear interactions between the features and the target, thereby improving the model's overall performance.

3) *Principal Component Analysis (PCA)*: PCA was used to reduce the dataset's dimensionality while retaining the components that explain most of the variance. We set $n_components = 0.90$ to retain 90% of the total variance. For the HR metrics and analytics dataset, the original set comprised 311 instances and 36 features. After applying PCA, the dimensionality was reduced to 20 components. In the INX dataset, which initially consisted of 1200 instances and 28 features, PCA reduced it

to 19 components. For the Employees' performance dataset, which initially had 17417 instances and 13 features, PCA reduced it to 9 components. We trained the ANN on these transformed datasets.

B. Parameter Tuning

We implemented two model control strategies to improve the ANN's performance.

1) *Reducing the number of layers*: To continue the investigation into model optimization and complexity reduction, we introduced a new architecture with fewer layers and neurons. The model consisted of two hidden layers with 64 and 32 neurons, and an output layer with a softmax activation function for multi-class classification. The categorical cross-entropy loss function was used since it is suitable for multi-class problems. The Adam optimizer was used for gradient-based optimization. ReLU activation was applied in the hidden layers to introduce nonlinearity and enable the model to learn complex patterns. This reduced architecture aimed to mitigate overfitting and decrease computational complexity while maintaining effective multi-class classification performance.

2) *Regularization and dropout*: To mitigate overfitting, while improving generalization, dropout and L2 regularization were applied. L2 regularization added a penalty term (0.01) to the loss function to constrain the magnitude of the weights, thereby reducing model complexity and overfitting. Dropout randomly deactivated 50% of neurons during training to prevent over-reliance on specific neurons and enhance generalization.

V. RESULTS

A. Results of HR Metrics and Analytics Dataset

Results for the HR metrics and analytics dataset showed that the initial ANN model achieved the highest accuracy of 93.62% compared to the other datasets. This percentage reflected the model's ability to accurately classify cases and to identify significant patterns in the data. The initial ANN model served as a baseline for comparison.

Removing features with lower correlations from the initial model and combining feature selection with a reduced-layer model yielded the highest accuracy of 96.81%, suggesting that feature selection was successful for this dataset. The accuracy of feature selection with regularization and dropout was 95.74%, which indicated an improvement over the first model but not an optimal configuration.

The model's performance increased to 95.74% when feature extraction techniques were applied to the initial model, demonstrating a noticeable improvement in classification. In addition, employing feature extraction in a model with fewer layers, as well as combining feature extraction with regularization and dropout, resulted in similar accuracy levels. This enhancement implied that the ANN was better able to identify underlying patterns and relationships by highlighting the key characteristics.

The accuracy dropped to 88.30% when Principal Component Analysis (PCA) was used on the initial ANN model. When PCA was applied to a model with fewer layers and

with the regularized model incorporating dropout, the accuracy further decreased to 86.17%. These outcomes suggest that PCA was less effective for this dataset, as class-discriminative information may have been lost during dimensionality reduction.

The ANN model's accuracy increased significantly to 96.81% when the number of layers was reduced, as well as when regularization and dropout were applied to the initial model. These outcomes suggest that limiting the model's capacity helped mitigate overfitting, thereby improving its ability to generalize to new data.

The confusion matrices shown in Fig. 2 give insight into the best-performing model across the four classes (Exceeds, Fully Meets, Needs Improvement, and PIP). The improved ANN resulted in improved overall accuracy (96.81%) compared to the baseline model (93.62%). A significant improvement was observed in Class Exceeds, where the F1-score rose from 0.80 to 1.00, indicating better class discrimination. The remaining classes showed no serious change and retained their comparatively small F1-scores. The main reasons for this performance gap include the small sample sizes and extreme class imbalance, which make it harder for the model to generalize to underrepresented categories.

Class Exceeds: Precision = 1.00, Recall = 1.00, F1 = 1.00

Class Fully Meets: Precision = 0.99, Recall = 1.00, F1 = 0.99 (unchanged)

Class Needs Improvement: Precision = 0.67, Recall = 0.50, F1 = 0.57 (unchanged)

Class PIP: Precision = 0.50, Recall = 0.50, F1 = 0.50 (unchanged)

Fig. 2. Confusion matrices of HR metrics and Analytics dataset.

Key insights from the HR metrics and Analytics dataset:

- The observed improvement with feature extraction suggests that the extracted features provided relevant information and improved the model's predictive capability.

- In this dataset, PCA did not help construct effective predictive models. This analysis indicates that PCA may have led to the loss of important information and an oversimplification of the feature space.
- The combination of regularization and dropout proved effective in mitigating overfitting. In addition, applying feature selection improved model performance by achieving a better balance between model robustness and data quality.
- This dataset demonstrates stable behavior, as all evaluated models achieved consistently high accuracy, suggesting a relatively low noise level and reliable data patterns.

B. Results of the INX Dataset

The initial ANN model achieved an accuracy of 81.11%, which we set as the baseline model for comparison. The model showed strong predictive performance but was outperformed by some modified versions. This discrepancy suggested that the first model was not the best in terms of both feature relevance and overfitting control.

In another experiment, features with weak correlation to the target variable were removed, resulting in an accuracy improvement to 83.89%. Applying feature selection to a reduced-layer model yielded the same accuracy. This improvement probably reflected a decrease in feature-space noise and an increase in model generalization. However, the combination of feature selection, regularization, and dropout achieved an accuracy of 81.94%. This implied that adding more regularization constraints to this configuration reduced the advantages of feature removal.

When the new features were extracted with arithmetic operations (addition and multiplication) and added to the original features in the initial model, the ANN achieved an accuracy of 81.94%. Feature extraction was then applied to a reduced-layer model. Similarly, using feature extraction on a regularized model with dropout yielded the same accuracy. These outcomes showed that the extracted features were informative and improved the model's performance.

In contrast, using principal component analysis (PCA) reduced model accuracy to 79.72% compared to the initial model, suggesting that the dimensionality-reduction step may have removed informative features. We applied PCA to the model with fewer layers and to the model with regularization and dropout, both resulting in an accuracy of 79.17%. These outcomes demonstrated that PCA's dimensionality reduction was less effective for this dataset.

The ANN model's accuracy increased to 82.78% when the number of layers was reduced, implying that fewer layers improved generalization by reducing overfitting.

The combination of regularization and dropout resulted in the most noticeable improvement. This configuration achieved an accuracy of 85.28%, clearly higher than that of the initial model. These results showed that regularization helped mitigate overfitting, making the combination the most balanced in terms of complexity and generalization.

The confusion matrices in Fig. 3 provided more detail on the classification performance of the best model across three classes (Class 2, Class 3, and Class 4). The results showed that performance was relatively balanced, with Class 3 achieving the highest prediction accuracy. The total accuracy of the enhanced model increased from 81.11% to 85.28%, with the largest gains in Class 4 ($F1 \approx 0.75$) and modest gains in Class 2 ($F1 \approx 0.67$), while Class 3 remained at the highest level ($F1 \approx 0.91$). The overall outcomes indicated that the suggested strategy improved classification performance across all categories and yielded balanced precision-recall trade-offs.

Class 2: Precision = 0.67, Recall = 0.67, $F1 = 0.67$

Class 3: Precision = 0.90, Recall = 0.91, $F1 = 0.91$

Class 4: Precision = 0.78, Recall = 0.72, $F1 = 0.75$

Fig. 3. Confusion matrices of INX dataset.

Key insights from the INX dataset:

- Moderate performance improvement was achieved after implementing feature selection. This suggested that moderately increasing the model's accuracy may be possible through focused optimization of the feature space, with removing low-correlation features being more effective than introducing new ones in this dataset.
- There appeared to be a consistent performance deficiency across all PCA-based models. This suggested that PCA might have removed too much potentially useful information and, therefore, cannot be the right approach for this dataset.
- The findings showed that the best methods for enhancing model performance are regularization and dropout. These techniques addressed overfitting in neural networks, a prevalent problem, by promoting stronger generalization to unseen data.

C. Results of the Employees' Performance Dataset

The results of this dataset indicate that the ANN model performs quite consistently using various preprocessing and parameter-tuning techniques. The initial accuracy of the model (86.57%) suggests the existence of natural discriminative patterns in the dataset. However, the other modified models were more accurate.

The accuracy increased to 87.85% after applying low-correlation-based feature selection on the initial model. Also, when applying feature selection to the model with lower layers, the same level of accuracy was obtained, suggesting that removing irrelevant features was enough to improve performance without adding model complexity. However, when feature selection was combined with regularization and dropout, the accuracy dropped to 86.39%, indicating that other regularization constraints might have diminished the marginal benefits of feature removal.

When the feature extraction technique was performed, the performance decreased slightly, with the accuracy going down to 86.39%. It is interesting to note that this result can be observed in a wide range of models, including ones that use feature extraction with fewer layers or include regularization and dropout. This means that the extracted features may have introduced redundancy and did not provide any additional discriminative information.

Likewise, applying Principal Component Analysis (PCA) to the initial model resulted in a more pronounced decline in accuracy to 83.72%. Furthermore, the accuracy decreased slightly to 86.05% after applying PCA to a model with fewer layers or to a model incorporating regularization and dropout, suggesting that dimensionality reduction in this dataset may have led to the loss of crucial information related to class separation.

The accuracy increased to 87.29% over the initial model when layers were reduced, which means that simplification of the architecture is somewhat beneficial.

Combining regularization and dropout gave the best overall result on this dataset with an accuracy of 88.16%. This result implies that these strategies are effective in reducing overfitting and improving the generalization of the model.

The confusion matrices in Fig. 4 provided comprehensive details for the best-performing model across 4 classes (Class Low, Class Medium-Low, Class Medium-High, and Class High). The model's predictive ability is good overall, especially for the Low and Medium-Low classes, which have high true-positive rates. However, there are discernible misclassifications between the Medium-High and nearby classes, indicating that this group has lower recall and class overlap.

Class Low: Precision = 0.88, Recall = 0.95, F1 = 0.91

Class Medium-Low: Precision = 0.83, Recall = 1.00, F1 = 0.91

Class Medium-High: Precision = 0.89, Recall = 0.75, F1 = 0.81

Class High: Precision = 0.95, Recall = 0.79, F1 = 0.87

Key insights from the employees' performance dataset:

Fig. 4. Confusion matrices of the Employees' performance dataset.

- Principal component analysis (PCA)-based models in this dataset performed worse than the initial model since important features may have been lost during dimensionality reduction.
- Reducing the number of layers resulted in small improvements over the initial model, but the effect is limited compared to regularization and dropout.
- Overall, the results indicate that feature selection and model regularization are more useful for this dataset compared to dimensionality reduction or feature augmentation techniques.

D. Comparative Summary

We compared the experiment's outcomes across three datasets using the same methods. This comparative analysis helped reveal dataset-specific behaviors and find trends in technique performance. Table II shows a summary of results.

The comparison focuses on neural network-based techniques, serving as a methodological reference point for evaluating the usefulness of the proposed ANN model despite variances in application areas and network topologies. Table III compares our results with those of previous studies.

VI. DISCUSSION

The baseline ANN results yield the following observations:

The HR metrics and Analytics dataset has the highest baseline accuracy and indicates strong predictive signals and a well-calibrated model. In contrast, the INX dataset is the most challenging dataset, as indicated by the lower baseline accuracy. The Employees' performance dataset is of moderate complexity and moderate baseline accuracy. The baseline is the measure of improvement. The HR metrics and Analytics dataset begins close to its ideal point, with little room for improvement. On the other hand, the INX dataset and the Employees' performance dataset provide a bigger scope for improvement.

TABLE II. EXPERIMENT CONFIGURATIONS AND ACCURACY RESULTS

Experiment Configuration		HR metrics and analytics dataset Accuracy	INX dataset Accuracy	Employees' performance dataset Accuracy
Initial ANN		93.62%	81.11%	86.57%
Data Preprocessing				
Feature Selection (Low Correlation)		96.81%	83.89%	87.85%
Feature Extraction (Addition/Multiplication)		95.74%	81.94%	86.39%
PCA		88.30%	79.72%	83.72%
Parameter Tuning				
Reduced Layers		94.68%	82.78%	87.29%
Regularization and Dropout		96.81%	85.28%	88.16%
Data preprocessing and parameter tuning				
Feature selection	reduced layers	96.81%	83.89%	87.85%
	regularization and dropout	95.74%	81.94%	86.39%
Feature extraction	reduced layers	95.74%	81.94%	86.39%
	regularization and dropout	95.74%	81.94%	86.39%
PCA	reduced layers	86.17%	79.17%	86.05%
	regularization and dropout	86.17%	79.17%	86.05%

TABLE III. RELATED WORK COMPARISON

Related work comparison	Method	Results
Our proposed work	We develop several neural network models that involve preprocessing steps for the data and fine-tuning their hyperparameters	Our accuracy is 90.08%, the average of the best-performing configurations obtained for each dataset
Study [14] Predict students' academic performance	They developed a neural network model with 11 input variables, 2 hidden layers, and 1 output layer	84.8%
Study [15] Forecast sophomores' performance	They created an artificial neural network model based on the multilayer perceptron topology	84.6%
Study [16] predict students' academic performance	They developed an artificial neural network model	93.81%
Study [18] predict students' academic performance	They applied several data mining classification methods	The ANN model achieved the best accuracy of 79%
Study [19] predict students' academic performance	They examined multiple machine learning techniques	The ANN model achieved the best accuracy of 77.04%
Study [21] proposed a thorough method for forecasting employee attrition	They compared and implemented multiple machine learning, ensemble, and deep learning approaches	The Feedforward Neural Network (FNN) achieved an accuracy of 83.93%

The feature selection applied to both the initial model and the model with a reduced number of layers leads to the following observations:

In both configurations, the model outperforms the baseline across all datasets (+3.19%, +2.78% and +1.28%, respectively). Moreover, it achieves the highest performance on the HR metrics and Analytics dataset, suggesting that removing low-correlation features helps the model to focus on the most informative features, especially in this dataset.

The feature selection applied to the model incorporating regularization and dropout results in the following observations:

The model performs better than the baseline on the HR metrics and analytics dataset and the INX dataset (+2.11% and +0.83%, respectively). However, in the Employees' performance dataset, a decrease in performance of -0.18% is

observed. This slight decline raises the possibility of an over-regularization impact, which could restrict the model's applicability to this dataset.

Observations from results of feature extraction (addition/multiplication) applied to the initial model, the reduced-layer model, and the model that includes regularization and dropout:

The feature extraction shows consistent performance across the different model configurations and achieves results comparable to feature selection combined with the regularization and dropout, despite the difference in the methodology.

The principal component analysis (PCA) applied to the initial model provides the following observations:

PCA results in lower accuracy compared to the baseline across all datasets by (-5.32%, -1.39%, and -2.85%) respectively). The HR metrics and analytics dataset shows the largest performance loss. Thus, PCA ranks as the overall weakest technique for the evaluated datasets. One possible explanation for PCA's reduced performance is that it prioritizes variance preservation over class discrimination. As a result, principal components may retain high-variance information that is not necessarily relevant for distinguishing between performance categories. Consequently, some discriminative features may be suppressed during dimensionality reduction.

The principal component analysis (PCA) applied to the model with a reduced number of layers and to the model incorporating regularization and dropout yielded the following observations:

Compared to the baseline model, accuracy decreased for all of the datasets analyzed. The HR Metrics and analytics dataset showed the greatest decrease (-7.45%), followed by the INX dataset (-1.94%), while the Employees' Performance dataset showed only a slight decrease (-0.52%). These results suggest that PCA may have eliminated some relevant discriminative information despite the use of architectural simplification and reduction of overfitting, and therefore failed to improve the classification performance.

The reduced number of layers yielded the following observations:

Results show improvement compared to the baseline across all the datasets (+1.06%, +1.67%, and +0.72%, respectively). This outcome suggests that a simpler architecture may facilitate better generalization, possibly by mitigating overfitting.

The regularization and dropout yielded the following observations:

The approach outperformed the baseline across all datasets (+3.19%, +4.17%, and +1.59%, respectively). The most significant improvement was attained in the INX dataset, followed by the HR Metrics and Analytics dataset. These results suggest that regularization and dropout helped reduce overfitting and improve generalization as well as overall classification capabilities of the model.

The overall findings across all datasets reveal several consistent patterns. PCA-based dimensionality reduction resulted in lower classification accuracy, suggesting that some discriminative information was lost. In contrast, all datasets demonstrated consistent performance improvements when regularization and dropout were applied, highlighting their effectiveness in mitigating overfitting and promoting stronger generalization. Furthermore, feature selection consistently outperformed feature extraction and remained stable across multiple parameter settings, demonstrating its robustness and suitability for the classification tasks under investigation. Overall, the optimal configuration appears to depend on the inherent characteristics of each dataset rather than on a universally superior technique, as factors such as dimensionality, data complexity, feature interactions, and noise levels influence the effectiveness of a given approach.

Several previous studies have demonstrated the strong performance of tree-based models, such as Random Forest and Gradient Boosting, in HR analytics. However, the present study focuses on investigating how preprocessing strategies and architectural optimization influence ANN-based models.

A bar chart in Fig. 5 illustrates accuracy across all datasets and highlights overall performance trends.

Fig. 5. Comparing accuracies across datasets.

VII. CONCLUSION AND FUTURE WORK

This study demonstrated the effectiveness of artificial neural networks in predicting employee performance by systematically evaluating preprocessing techniques and model optimization strategies across three independent HR datasets. The results indicate that dropout and regularization consistently improved generalization performance, especially for datasets

prone to overfitting. Feature selection also yielded stable performance gains, highlighting the importance of eliminating low-correlation features. On the other hand, predictive accuracy consistently decreased with PCA-based dimensionality reduction, suggesting a potential loss of discriminative information in the transformed feature space. Moderate improvements were achieved by simplifying the architecture through layer reduction, underscoring the importance of balancing model complexity with dataset characteristics. Across the assessed datasets, the top-performing configurations achieved accuracies ranging from 81% to 96%. The use of diverse datasets enhances the robustness of the findings and provides practical guidance for ANN-based predictive modeling in HR analytics. The results of this study can help data analysts and HR specialists select effective neural network configurations and preprocessing techniques for employee performance prediction systems. Specifically, organizations can prioritize feature selection, architectural simplification, and regularization strategies to improve model generalization and ensure robust predictive performance across different HR datasets. These insights enable the development of more reliable data-driven decision-support systems for workforce management and performance evaluation.

Although the results are encouraging, this study has some limitations. A single train-test split was used, and hyperparameter tuning was performed within predefined limits. Moreover, methods for mitigating class imbalance were not thoroughly investigated. Addressing these limitations could further improve model generalizability and robustness.

A. Future Work

Future work may extend this study in several directions. First, a more comprehensive hyperparameter search that accounts for differences in network architectures, regularization strengths, dropout rates, batch sizes, and learning rates may further improve prediction performance across datasets. Second, other deep learning architectures could be explored to compare their performance in HR analytics applications. Third, k-fold cross-validation would provide more reliable performance estimates across different data splits. Furthermore, advanced imbalance mitigation strategies, such as SMOTE and weighted loss functions, could be explored to address potential class imbalance issues. Lastly, deeper insights into the most significant variables in each dataset could be obtained through feature importance analysis using techniques such as SHAP or permutation-based methods.

Abstract—Federated learning (FL) trains a shared model without sending raw data, but some clients can be Byzantine and send harmful updates. Robust aggregation methods like Median and Krum can reduce poisoning damage, but they do not clearly show which client attacked. In this study, we propose RollupFL, an audit layer for FL that improves accountability under Byzantine attacks. RollupFL keeps aggregation and auditing separate, so it can work with FedAvg, Median, or Krum without changing how aggregation is computed. We study two audit designs: simple logging, which is fast, but assumes a trusted server, and blockchain-based audit, which gives stronger integrity and attribution, but adds more latency. We evaluate MNIST training for 20 rounds with 10%–30% Byzantine clients under sign-flip and model-replacement attacks. Results show that auditing does not meaningfully change accuracy, but it improves accountability. At 30% Byzantine, blockchain audit achieves higher attribution (0.95) and tamper detection (0.92) than logging (0.65 and 0.58). Logging adds small per-round latency, while blockchain adds larger latency mainly due to ledger writing.

Keywords—Federated learning; Byzantine attacks; audit layer; accountability; attacker attribution; tamper detection; robust aggregation; FedAvg; blockchain audit; sign-flip attack; model-replacement attack

I. INTRODUCTION

A. Background and Motivation

Federated learning lets many clients train one model without sending raw data. This is useful when the data is private or regulated. Some recent works also add auditing, so model updates can be checked later [1], [2]. Incentives and evaluator roles are also used to push clients to act honestly [3]. A main risk is the Byzantine client. A bad client can send fake updates and hurt the global model. Many papers study robust aggregation or filtering to reduce this damage [4], [5], [6], [7]. These defenses are important when clients are open or weakly controlled.

In real federated learning deployments, missing accountability can cause practical harm. In healthcare-oriented FL systems, poisoned or tampered updates can affect sensitive decision pipelines, and later investigation becomes difficult if the system cannot verify which participant submitted the suspicious update [1], [2]. Similar risks also appear in application settings such as cellular traffic prediction and large-scale IoT, where abnormal or malicious updates can degrade the shared model and affect downstream system behavior [8],

[9]. Robust aggregation can reduce the influence of abnormal updates, but it does not by itself provide clear evidence about which client was responsible [4], [5], [10]. As a result, a system may remain partly robust at the model level while still lacking the traceability needed for investigation, compliance, and post-incident response.

Robustness is also needed when training is asynchronous or large-scale. Some works target serverless or low-trust settings [11]. Others study robust FL under asynchronous updates and real traffic prediction tasks [8]. Large IoT settings also need scalable defenses [9]. Another challenge is system heterogeneity. Clients can have different compute, bandwidth, and data distributions. Split and adaptive designs try to reduce this gap [12], [13]. Multi-task and clustered FL also help when clients are not similar [14], [15]. Personalization methods reduce the “one model fits all” problem [16].

Auditing and accountability are now common goals. Some designs add a third-party auditor to reduce burden on the server and clients [17]. Some works combine robustness with auditable steps during training [10]. IDS-style detection is also surveyed as a way to spot malicious clients [18]. Blockchain is often used when we want tamper-resistant logs and public verification. Some frameworks use blockchain for verifiable training and traceable updates [19]. Some focus on credibility and fairness of participants and results [20]. Related security work also studies stronger authentication and collusion or free-riding behaviors [21], [22].

B. Problem Statement

FL needs three things at the same time: privacy, robustness, and traceability. Privacy alone is not enough if poisoned updates can still pass [4], [5]. Robust defenses can be costly or hard to verify later [7], [11]. So the system can fail silently. Auditing helps, but it also adds new design constraints. Logs must be correct, complete, and easy to check. Some works use structured auditing or integrity checks [1], [2]. Some push the auditing role to a third party to reduce load [17]. If blockchain is used, we must also manage cost and latency. On-chain storage is expensive if we store everything. Verification must still be strong even with limited on-chain data [19], [20]. Collusion and free-riding also remain risks [22].

C. Contributions

1) *Orthogonal audit layer*: We propose RollupFL as an audit layer for FL. It works with different aggregation rules. It does not change how aggregation is computed.

*Corresponding author.

2) *Two audit designs*: We study simple logging audit. We also study blockchain-based audit. Logging is fast but weaker if the server is not trusted. Blockchain audit is stronger but adds more delay.

3) *Evaluation under byzantine attacks*: We test the clean setting and attacked settings. We use sign-flip and model-replacement attacks. We vary the malicious client fraction from 10% to 30%. We compare FedAvg, Median, and Krum with and without auditing.

4) *Metrics for robustness, cost, and accountability*: We measure test accuracy and convergence across rounds. We measure ASR for model-replacement. We measure attacker attribution and tamper detection. We measure per-round latency and storage growth.

II. RELATED WORK

This section reviews prior studies on robust and auditable federated learning and highlights the main design choices that shape accountability in these systems. Table I shows that prior work in secure federated learning differs not only by technique, but also by system assumptions and accountability design. Some methods mainly improve robustness under a centralized trusted server, some add auditing through trusted logging or third-party verification, and others reduce trust by using blockchain-backed traceability or decentralized verification.

Although prior work has improved the security of federated learning, several practical gaps remain. Methods based on robust aggregation can reduce the effect of malicious updates, but they usually do not support clear attacker attribution or post-hoc traceability [4], [5], [6], [7]. Some auditable FL approaches improve verification, yet they often depend on a trusted server, coordinator, or external auditor [1], [2], [10], [17]. Blockchain-based solutions strengthen integrity and tamper resistance, but they can introduce extra latency, storage cost, and coordination overhead [19], [20]. In addition, some existing methods are harder to scale or deploy in realistic FL settings with heterogeneous clients, dynamic participation, and large communication cost [8], [9], [11].

A. Robust Aggregation in Federated Learning

Many robust FL papers focus on aggregation rules and filtering. They try to reduce the effect of poisoned or extreme updates [4], [5]. The goal is to keep accuracy stable even when some clients are malicious. Some frameworks use defense at both server and client sides. This can improve robustness but it can add overhead [6], [7]. Other work moves away from a single trusted server and still aims for Byzantine robustness [11]. Robust FL is also studied in specific networked settings. Asynchronous training needs extra care because stale updates can mix with attacks [8]. Large IoT systems also push for scalable robust learning designs [9]. This line of work also includes compression or low-dimensional update ideas. These can reduce leakage and may help detect strange updates [23].

B. Auditing, Accountability, and Trusted Logging

Auditing in FL often means we can prove that key steps happened. Some designs support auditable training flows for sensitive domains [1]. Some add data integrity auditing to

detect tampering [2]. Some work combines robustness with auditable evidence. This helps when we want both defense and later accountability [10]. Another idea is to rely on a third-party auditor to reduce burden on the server [17]. Accountability can also come from incentives and access control. Evaluator-based incentives try to reward good behavior [3]. Authentication schemes help reduce fake identities in distributed learning [21]. IDS-based detection is also surveyed for spotting malicious clients [18]. Audit logs are also useful for studying collusion and free-riding. Correlation-based analysis is one approach to detect suspicious behavior patterns [22].

C. Blockchain-Based Verification (in FL/security)

Blockchain is used when we want tamper-resistant records. Some FL frameworks use blockchain to support verifiable training and traceable updates [19]. Others focus on credibility, fairness, and evidence for participation [20]. Even with blockchain, security issues remain. Collusion and free-riding can still happen and need detection methods [22]. Strong authentication is also relevant when identities matter [21].

III. SYSTEM MODEL AND THREAT MODEL

This section defines the system model and the threat model used in this work. We describe the federated learning (FL) setting, the Byzantine client behavior, and the attack cases we evaluate. We also state the audit goals and the limits of auditing. This helps explain why we add an audit layer in Section IV.

A. Federated Learning Setup

We consider a synchronous FL system with one server and n clients. Training runs in rounds. In round t , the server holds the global model θ_t . The server selects a subset of clients $C_t \subseteq \{1, \dots, n\}$ and sends θ_t to them. Each selected client $c \in C_t$ trains locally on its private dataset D_c . The client then computes a local update Δ_t^c and sends it to the server. The server aggregates the received updates using an aggregation function $\text{Agg}(\cdot)$ and produces the next model θ_{t+1} .

For simplicity, we write the global update rule as:

$$\theta_{t+1} = \theta_t + \text{Agg}(\{\Delta_t^c\}_{c \in C_t}). \quad (1)$$

This form covers common methods. For example, FedAvg uses averaging, while robust rules like Median and Krum aim to reduce the influence of abnormal updates. Clients do not communicate with each other. The system follows a star topology. This is a common FL deployment model.

We assume client data is non-IID. This means different clients may have different label proportions and feature patterns. This makes the setting realistic. It also matters for security. Honest updates can differ widely due to data skew. So simple outlier detection becomes harder. This is why robust aggregation and audit are both relevant.

TABLE I. TAXONOMY OF RELATED WORKS BY SYSTEM ASSUMPTIONS, DEFENSE DESIGN, AND ACCOUNTABILITY MODEL

Work	Topology	Trust Model	Defense Type	Audit Type	Attack Focus	Main Limitation
[4], [5]	Centralized	Trusted server	Robust aggregation and filtering	None	Byzantine poisoning	Improves robustness, but does not provide attribution or tamper-evident audit records.
[6], [7]	Centralized	Trusted server	Server-side and client-side defense	Limited or none	Poisoning and abnormal updates	Can improve robustness, but adds system overhead and still gives limited accountability.
[8], [9]	Centralized	Trusted server	Robust FL for asynchronous or large-scale settings	None	Byzantine behavior, stale updates, and large-scale update issues	Focuses on robustness under deployment constraints, but not on post-hoc traceability.
[11]	Decentralized or serverless	Low-trust	Byzantine-robust training	None	Byzantine clients	Reduces reliance on one server, but does not directly solve auditability and attribution.
[1], [2]	Centralized	Trusted server	Secure and privacy-preserving FL with integrity support	Structured integrity audit	Tampering and integrity violations	Supports checking and integrity, but has limited focus on Byzantine attacker attribution during FL.
[10]	Centralized	Trusted or semi-trusted coordinator	Robust FL with auditable evidence	Training-step audit	Byzantine behavior	Moves toward robustness and audit together, but increases design complexity and verification cost.
[17]	Centralized	Third-party auditor	External verification support	Third-party audit	Integrity and compliance	Reduces burden on the server, but depends on an additional trusted entity.
[19], [20]	Blockchain-assisted	Trustless or low-trust	Verifiable training, credibility, and fairness support	Blockchain audit	Tampering and dishonest participation	Gives stronger integrity and traceability, but adds latency, storage, and coordination cost.
[21], [22]	Distributed	Identity-aware and access-controlled	Authentication and suspicious behavior analysis	Event or behavior logging	Fake identities, collusion, and free-riding	Helps with identity and misuse detection, but does not fully link update-level evidence to aggregation outputs.

B. Byzantine Client Model

A subset of clients may be Byzantine. These clients deviate from the protocol. They are controlled by an adversary and may coordinate across rounds. We assume Byzantine clients can craft arbitrary updates. So a Byzantine client can send any vector in $\mathbb{R}^d$, not only a true gradient. This captures many poisoning behaviors, including random noise, sign changes, scaling, and targeted backdoor updates.

We use β to denote the Byzantine fraction:

$$\beta = \frac{\# \text{Byzantine clients}}{n}. \quad (2)$$

We evaluate multiple values of β in later experiments. Larger β usually makes training harder. It also weakens robust aggregation rules. In many distributed settings, one-third is an important boundary under common assumptions. In practice, model quality can degrade even below that boundary when data is non-IID and attacks are adaptive.

We assume standard cryptographic hardness. The adversary cannot break SHA-256 or ECDSA-256. This is needed for the audit mechanisms described later. We do not focus on privacy attacks such as full model inversion. Those attacks are important but they are not the main target of this study. Our focus is Byzantine manipulation and post-hoc accountability.

C. Attack Scenarios

We study two Byzantine attack scenarios. The first is a sign-flip attack. It is simple and non-adaptive. A Byzantine client flips the direction of its update by multiplying it by -1 :

$$\Delta_t^{\text{Byz}} = -\Delta_t^{\text{Hon}}. \quad (3)$$

This attack pushes the global model away from the descent direction. Under FedAvg, flipped updates can cancel honest progress. This can slow convergence or cause divergence when

the Byzantine fraction is high. Robust aggregation can reduce the impact because flipped updates often appear as outliers relative to honest updates.

The second scenario is a model-replacement (targeted poisoning) attack. This attack aims to insert a backdoor. The attacker crafts an update that optimizes a target loss on an attacker-chosen dataset D_{target} . The attacker also amplifies the update using a scaling factor $\alpha > 0$:

$$\Delta_t^{\text{Byz}} = \alpha \nabla \mathcal{L}_{\text{target}}(\theta_t; D_{\text{target}}). \quad (4)$$

This attack can be stealthy. Overall test accuracy may remain acceptable, while the model fails on a specific trigger or class. Under FedAvg, amplified targeted updates can dominate the mean. Under Median or Krum, these updates may be filtered, but success depends on β , the amplification strength, and the natural variance created by non-IID data.

These two attacks cover two different goals. Sign-flip aims to reduce utility directly. Model-replacement aims to keep utility high but add hidden malicious behavior. In both cases, the audit layer records update evidence regardless of whether the attack succeeds.

D. Assumptions and Audit Goals

We assume secure client-server communication using authenticated encryption. This protects updates in transit. We also assume clients have stable identities, so an update can be linked to a client. We assume timestamps are meaningful under small clock drift. We also assume auditing is offline. The auditor verifies logs after training completes. This reduces runtime overhead. It also means audit is not a real-time defense.

For blockchain-based audit, we assume client signing keys are not compromised. If a private key is stolen, an attacker can sign updates as that client. This would break non-repudiation. Key compromise is important in practice, but it is outside the scope of our evaluation.

The audit layer targets three goals. First, it should support tamper detection. If a log entry is modified after it is recorded, the auditor should detect it. Second, it should support attacker attribution. After training, the auditor should identify which clients sent malicious updates with high confidence. Third, for blockchain audit, it should provide non-repudiation. A client should not be able to deny an update that it signed.

1) *Threat summary and link to proposed method:* The main risk in this system is that Byzantine clients can send malicious updates that harm training or insert a backdoor. Robust aggregation helps reduce the impact of these updates during training, but it does not explain who attacked. Auditing can record evidence and support post-hoc investigation, but it does not stop poisoning by itself. This motivates an orthogonal design. In Section IV, we introduce an audit layer that can be combined with any aggregation rule. This keeps the defense logic and the accountability logic separate, while allowing them to work together in the same FL pipeline.

IV. PROPOSED METHOD: AUDIT LAYER FOR FEDERATED LEARNING

Byzantine clients can harm federated learning by sending wrong model updates. Robust aggregation methods, such as Median and Krum, can reduce the impact of these attacks. However, they do not provide accountability. They may block the attack, but they do not clearly tell which client acted maliciously. This is a problem in real systems where we also need traceability, compliance, and investigation support.

To address this gap, we propose *RollupFL*. RollupFL adds an audit layer to federated learning. The audit layer records client updates in a verifiable way. This record can be checked later. So the system can identify suspicious clients and detect tampering after training. The audit layer is designed to work with any aggregation rule. So defense and accountability can be selected independently. We implement two audit options. The first is a simple logging audit. It is light and fast, but it assumes the server is trusted. The second is a blockchain-based audit. It gives stronger integrity and attribution, but it costs more latency.

A. Audit Layer Overview

The main idea is that robustness and accountability are different goals. Robust aggregation improves safety during training. It reduces the effect of poisoned updates. However, it does not keep a strong record of who sent what. Audit logging improves accountability. It helps trace actions back to clients. However, it does not stop poisoning by itself. RollupFL separates these two parts. The aggregation rule still decides how the global model is updated. The audit layer only records evidence about the received updates.

1) *Design Principles:* RollupFL follows three design principles.

a) *Orthogonality:* The audit layer must work with any aggregation rule. So the same auditing logic can be used with FedAvg, Median, or Krum.

b) *Minimality:* The audit operations should not add heavy computation. The goal is to keep the audit cost low when possible.

c) *Immutability:* The audit trail must resist tampering. If someone changes a stored update, the system should detect it. Blockchain-based audit gives stronger proof. Simple logging gives weaker proof yet lower cost.

2) *Audit workflow:* The workflow has three main stages, as shown in Fig. 1.

a) *Update collection:* Each client sends a local update to the server. The audit layer captures this update immediately. It also stores the metadata and proof material needed to bind each submitted update to its round, client identity, and later verification result.

b) *Aggregation:* The server applies the chosen aggregation rule. The audit layer does not change how aggregation is computed. This keeps the design modular.

c) *Verification and attribution:* After training, an auditor can verify the audit trail. The auditor checks whether the trail was modified. The auditor can also link suspicious updates to specific clients. This supports post-hoc investigation.

B. Simple Logging Audit

Simple logging is the lightweight audit option. The server records each update in a centralized log. A hash is computed for integrity checks. This method is suitable when the server is trusted. It is also useful when the budget is limited.

1) *Mechanism:* For each client update, the server computes a hash. The hash binds the client identity and the update content. A typical log record stores the client ID, timestamp, update hash, and the update itself. To strengthen integrity, the server can also chain hashes across rounds. This creates a linked structure. If an entry is modified later, the chain consistency breaks.

2) *Tamper detection:* Tamper detection is done by recomputing hashes. The auditor recomputes the hash from stored data. If the computed value does not match the stored hash, then tampering is detected. This approach is simple. However, it depends on the log being available and trustworthy. If the server can rewrite logs, the method becomes weaker.

3) *Attacker attribution:* Attribution under simple logging is mostly heuristic. The log tells which client sent which update. Then the auditor checks patterns that look malicious. For example, sign-flip updates often show reversed gradient directions. Model-replacement updates may show unusual magnitude or direction. This can help identify attackers. However it is not a cryptographic proof. So the confidence may be lower than blockchain audit.

4) *Overhead:* The overhead of simple logging is small. Hashing and storing data is fast compared to blockchain consensus. Storage grows with the number of rounds and clients. This is expected because each update generates one record.

C. Blockchain-Based Audit

Blockchain audit is designed for stronger guarantees. It is useful when the server is not fully trusted. It also helps in multi-party environments where independent verification is needed. In this method, updates are signed and recorded in an immutable ledger.

Fig. 1. RollupFL architecture with parallel auditing: Clients send updates, the server aggregates (FedAvg/Median/Krum), and logs or blockchain records enable later verification and accountability.

1) *Mechanism*: Each client signs its update using a private key. The server verifies the signature using the client public key. If the signature is valid, the server records the update evidence in the ledger. The ledger stores a hash of the update and the signature. This binds the update to the client identity. It also prevents denial later.

2) *Tamper detection*: Tamper detection becomes stronger in this setting. If someone changes an update, the signature verification fails. So integrity checks are direct and reliable. The ledger history also prevents silent rewriting of records.

3) *Attacker attribution*: Attribution is also stronger. The client signature provides non-repudiation. So the system can prove that a specific client signed a specific update. This is important for accountability and auditing.

4) *Overhead*: Blockchain audit adds more cost. Signing and verification add computation per update. Ledger writing adds network and consensus delay. So the round latency increases. This is the trade-off for stronger guarantees.

D. Integration with Aggregation (FedAvg/Median/Krum)

RollupFL is designed to integrate without changing the aggregation rule. The server receives client updates for each round. The audit layer records evidence for each update. Then

the server runs the aggregation rule. This can be FedAvg, Median, or Krum. So the final output has two parts. The first part is the updated global model. The second part is the audit trail for later verification.

To make this link explicit, let client $c \in C_t$ submit update Δ_t^c in round t . For each received update, the audit layer creates a record:

$$e_t^c = (c, t, \tau_t^c, h(\Delta_t^c), \pi_t^c),$$

where, τ_t^c is the timestamp, $h(\cdot)$ is a cryptographic hash, and π_t^c is the audit proof. In simple logging, π_t^c can be empty or server-generated metadata. In blockchain audit, π_t^c is the client signature and ledger reference. The round audit set is then:

$$A_t = \{e_t^c\}_{c \in C_t}.$$

The server computes the next global model from the submitted updates as:

$$\theta_{t+1} = \theta_t + \text{Agg}(\{\Delta_t^c\}_{c \in C_t}).$$

To bind the audit trail to the training result of that round, RollupFL stores a round commitment:

$$H_t = H(H_{t-1} \parallel h(A_t) \parallel h(\theta_{t+1})),$$

where, $H(\cdot)$ denotes a hash-combination function and H_{t-1} is the previous round commitment. This means the audit record is linked not only to each client update, but also to the aggregation output produced from the set of submitted updates.

1) *FedAvg integration*: With FedAvg, the server averages client updates. Audit does not change averaging. It only records what was received. FedAvg can still be vulnerable under strong Byzantine attacks. However, audit improves accountability after the fact.

2) *Median integration*: With Median, the server computes a coordinate-wise median. This reduces the effect of outliers. Audit still records the raw submitted updates. So the system can later identify which clients were outliers.

3) *Krum integration*: With Krum, the server selects the most central update. This method can tolerate Byzantine clients under standard assumptions. Audit again records the submitted updates and metadata. So suspicious updates can be traced later.

E. Why Audit Does Not Reduce Attack Success?

It is important to state the correct role of auditing. Auditing is not a defense method. It does not block malicious updates in real time. It records evidence and supports investigation. So metrics like ASR are mainly affected by aggregation. Audit changes accountability metrics, not defense metrics. This separation is intentional in RollupFL.

V. EXPERIMENTAL SETUP

This section explains how we evaluate RollupFL. We test it under different Byzantine attack settings. We also use a consistent and repeatable experimental process. We describe the dataset, the model, and how data is split across clients. We then explain the training setup, the attacker settings, and the attack types. Next, we list the baselines and the audit variants we compare against. Finally, we define the metrics we report and how we compute confidence intervals.

A. Dataset and Model

We use the MNIST dataset in all experiments. MNIST is a common benchmark for federated learning studies. It is simple compared to modern vision datasets, however it is useful for controlled tests. It lets us study attack behavior and audit behavior without many extra factors. Each example is a 28×28 grayscale image. Pixel values are normalized into the range $[0, 1]$. The training set has 60,000 images and the test set has 10,000 images.

We train a small convolutional neural network (CNN). The network has two convolution layers and one fully connected layer. The first convolution uses 32 filters with a 5×5 kernel and ReLU. A 2×2 max-pooling layer follows it. The second convolution uses 64 filters with a 5×5 kernel and ReLU. It is also followed by 2×2 max-pooling. After that, we use a

fully connected layer with 128 units and ReLU. The output layer has 10 units with softmax for digit classification. This model reaches about 99%+ accuracy in centralized training. The model size is about 100 KB, which is small enough for federated updates.

1) *Non-IID client data*: We use a non-IID split to represent realistic client behavior. We generate client splits using a Dirichlet distribution with concentration $\alpha = 0.5$. This setting creates heterogeneous clients. Each client tends to have more samples from a small set of digits. This makes training harder than IID splits and is closer to real federated settings. We split the 60,000 training samples across 50 clients. Each client has about 1,200 samples on average.

B. Training Configuration

We simulate synchronous federated learning. In each round, the server selects a subset of clients. Those clients train locally and then send updates back to the server. The server aggregates the updates and produces the next global model. We repeat this for a fixed number of rounds.

We use 50 total clients. In each round, 20 clients participate. Clients are selected uniformly at random. This gives a 40% participation rate per round. Each selected client trains for 1 local epoch using SGD. We use a constant learning rate of 0.01. We use batch size 32. We run 20 communication rounds in total. These values keep the setup simple and stable. They also allow attacks to show their effect within a short training horizon.

These hyperparameter choices are intended for a controlled MNIST benchmark rather than aggressive optimization. A learning rate of 0.01 with one local epoch gives stable convergence for the small CNN and helps avoid large client-side drift under the non-IID split. A 40% participation rate provides enough diversity in each round while still reflecting partial client availability in federated learning. We use 20 communication rounds to keep the study short and repeatable, while still allowing Byzantine effects and audit behavior to become visible. Overall, these settings balance stability, comparability, and attack observability in a simple experimental setup.

1) *Byzantine clients*: We choose Byzantine clients at the start of the training. The same clients remain Byzantine for all 20 rounds. This keeps the attack condition consistent. We evaluate three attacker ratios. They are 10%, 20%, and 30%. With 50 clients, this equals 5, 10, and 15 Byzantine clients. The 10% case is challenging however often survivable. The 30% case is more extreme and stresses the aggregation rules.

In the current evaluation, Byzantine clients are selected at the beginning of training and remain Byzantine for all rounds. This static adversary setting is used to provide a controlled and repeatable comparison across aggregation and audit configurations. However, real federated learning deployments may also include dynamic adversaries, client churn, and time-varying malicious behavior. These cases are important in practice, but they are not covered in the present experiments and should be studied in the future work.

2) *Attack strategies*: We implement two types of Byzantine behavior.

The first attack is sign-flip. A Byzantine client multiplies its gradient (or update) by -1 before sending it. This is a simple and non-adaptive attack. It does not require knowledge of other client updates. It tests whether the aggregation method can tolerate inverted signals.

The second attack is model-replacement. This is stronger and more targeted. The attacker crafts an update that pushes the global model toward an adversarial objective. In our experiments, the attacker targets a chosen class (digit “0”).

We represent the crafted update using a scaled gradient of an adversarial loss:

$$\delta = \alpha \cdot \nabla \mathcal{L}(\theta_t; D_{\text{target}}),$$

where, D_{target} is attacker-controlled data and $\alpha > 0$ amplifies the effect. This attack aims to create a backdoor-like behavior. It tries to force misclassification for the target class. This is closer to practical poisoning and trojan-style attacks.

C. Baselines and Compared Methods

We compare standard federated learning baselines and audit-enabled variants. The goal is to separate two roles. The first role is robust learning under attack. The second role is accountability after the fact. Robust aggregation mainly affects learning robustness. Audit mainly affects traceability and evidence.

1) *FL baselines (no audit)*: We include FedAvg as a standard baseline. FedAvg performs simple averaging of client updates. It is widely used, however it is known to be vulnerable to Byzantine behavior. We also include Median. Median computes the coordinate-wise median of client updates. This can reduce the effect of strong outliers. It is a common robust aggregation choice. We also include Krum. Krum selects one update that is closest to others in terms of distance. It tries to filter outliers by geometry. It is also a known Byzantine-robust method.

2) *Audit variants (orthogonal layer)*: We add auditing on top of the aggregation rules. We test two audit types: 1) simple logging and 2) blockchain audit. Audit+FedAvg adds blockchain audit to FedAvg. This does not make FedAvg robust by itself. It provides stronger evidence and traceability. Audit+Median adds blockchain audit to Median. This combines robustness from Median with stronger audit guarantees. Log+FedAvg adds simple logging to FedAvg. It is cheaper than blockchain even so depends more on server trust. Log+Median adds simple logging to Median. It combines robust aggregation with low-cost audit. These variants are designed to be modular. The audit layer can be applied to different aggregators. This makes the design easy to extend.

D. Evaluation Metrics

We report metrics for robustness, accountability, and cost. We group them into three sets.

1) *Defense metrics*: We measure final test accuracy after 20 rounds. We compute accuracy on the MNIST test set (10,000 images). Lower accuracy usually means the attack harmed training. We also measure attack success rate (ASR) for model-replacement. ASR measures how often the attack succeeds at triggering the target behavior. In our case, the target relates to digit “0”. Higher ASR means the attacker is more successful. Lower ASR means stronger resistance.

2) *Audit metrics*: We measure attacker attribution rate. This is the fraction of Byzantine clients that can be identified from audit records. For logging, this depends on stored hashes and server-side verification. For blockchain, this uses signatures and immutable proofs. We also measure tamper detection rate. This is the fraction of malicious updates detected during verification. It measures whether the audit trail can reveal manipulation or suspicious updates. Higher values are better.

3) *Overhead metrics*: We measure round latency in milliseconds. This includes local computation, communication, aggregation, and audit work. We report both the raw time and multipliers relative to the no-audit baseline. We also track storage growth for blockchain audit. Storage grows roughly linearly with the number of rounds because each round adds audit data.

4) *Statistical methodology*: We repeat each experiment using $N = 10$ random seeds. Each seed changes model initialization and data shuffling. For all metrics, we report the mean and a 95% confidence interval (CI). We compute CI as $1.96 \times \text{SEM}$, where $\text{SEM} = \text{SD}/\sqrt{N}$. Here SD is the standard deviation across seeds. We use CI overlap as a simple significance indicator. If 95% CIs do not overlap, we treat the difference as significant at $\alpha = 0.05$. If they overlap, we report the difference however we avoid strong claims.

VI. RESULTS AND DISCUSSION

A. Clean Baseline Results (0% Byzantine)

We first evaluate the clean setting where no malicious clients are present. This test checks normal training behavior and helps confirm that the audit layer does not reduce model utility when the system is benign. FedAvg, Median, and Krum reach similar accuracy in this setting, and the audit-enabled variants remain close to the baseline. The small error bars indicate stable results across seeds. Overall, the clean baseline suggests that auditing does not harm accuracy under normal conditions (Fig. 2).

B. Robustness Under Byzantine Attacks

We then evaluate robustness under Byzantine clients using sign-flip and model-replacement attacks. We vary the Byzantine fraction from 10% to 30%. As the attacker fraction increases, accuracy decreases for all methods. FedAvg degrades the most and becomes unstable at higher Byzantine levels. Median and Krum remain more stable and preserve higher accuracy. This shows that robust aggregation reduces the impact of malicious updates (Fig. 3).

C. Convergence Behavior Across Rounds

We also analyze convergence by tracking test accuracy across communication rounds. In the clean setting, all methods

Fig. 2. Sanity check in the clean setting (0% Byzantine). FedAvg, Median, and Krum show similar baseline accuracy. Audit-enabled variants remain close to the baseline. Error bars show 95% confidence intervals over seeds.

Fig. 3. Accuracy under Byzantine attacks as the malicious client fraction increases. Robust methods (Median, Krum) degrade more slowly than FedAvg under both sign-flip and model-replacement. Error bars show 95% confidence intervals over seeds.

converge smoothly. Under model-replacement attack at high Byzantine fraction, FedAvg fails to converge and collapses early. Median and Krum remain stable and preserve learning progress. These trends match the final accuracy results and show that robust aggregation improves stability under attack (Fig. 4).

D. Attack Success Rate (ASR)

Accuracy does not fully describe security impact, so we also measure attack success rate (ASR) for model-replacement. Higher ASR means the attacker succeeds more often. FedAvg exhibits high ASR under attack. Median and Krum reduce ASR compared to FedAvg. The audit layer does not reduce ASR by itself, which is expected because auditing provides accountability rather than attack prevention (Fig. 5).

E. Audit Equivalence and Measured Overhead

We report two practical questions: 1) does auditing change accuracy, and 2) what is the runtime overhead. Fig. 7 (left) summarizes accuracy differences using a paired comparison and an equivalence margin. The accuracy impact remains close to zero. Fig. 7 (right) reports measured per-round latency. Logging adds a small overhead, while blockchain audit adds a larger overhead due to verification and integrity operations. Table II lists measured latency values.

F. Audit Layer Comparison (Blockchain vs. Logging)

We compare blockchain audit against simple logging. We evaluate accuracy at 10% and 30% Byzantine fractions for

Fig. 4. Convergence across rounds in clean and attacked settings. Under strong attack, FedAvg collapses, while Median and Krum remain stable.

Fig. 5. Attack success rate (ASR) under model-replacement. Robust aggregation reduces ASR compared to FedAvg. Audit variants track their underlying aggregation method.

TABLE II. PER-ROUND LATENCY OVERHEAD (MS)

Aggregation	Audit	Mean	Std
FedAvg	None	44.42	5.50
	Logging	49.99	0.86
	Blockchain	136.68	7.84
Median	None	44.44	2.54
	Logging	50.08	0.99
	Blockchain	134.43	7.26
Krum	None	46.98	7.90
	Logging	50.51	0.83
	Blockchain	135.11	6.44

FedAvg, Median, and Krum. The results show that both audit options preserve accuracy close to the FL-only baseline. Differences are small and remain within the confidence intervals. This suggests that audit instrumentation is largely orthogonal to model training (Fig. 6).

G. Accountability Metrics

The main benefit of auditing is accountability. We measure attacker attribution and tamper detection. Blockchain audit provides stronger attribution and stronger tamper detection than simple logging. This is expected because blockchain offers integrity proofs and non-repudiation properties. Logging can be useful in trusted environments due to lower overhead, except it provides weaker guarantees. These results are shown in Fig. 8 and summarized in Table III.

H. Summary

Across all experiments, robust aggregation (Median, Krum) improves resilience against Byzantine attacks compared to

Fig. 6. Accuracy comparison between FL-only, logging audit, and blockchain audit at 10% and 30% Byzantine fractions. Results are shown for FedAvg, Median, and Krum with 95% confidence intervals over seeds.

Fig. 7. Audit accuracy impact and measured overhead. Left: paired accuracy difference with an equivalence band. Right: measured per-round latency for baseline, logging, and blockchain audit. Error bars show 95% confidence intervals.

Fig. 8. Accountability benefits at 30% Byzantine. Blockchain audit improves attacker attribution and tamper detection compared to simple logging.

FedAvg (Fig. 3 to Fig. 4). Auditing does not act as a defense mechanism and therefore does not reduce ASR by itself (Fig. 5). Instead, auditing improves accountability. Logging offers low overhead, while blockchain provides stronger attribution and tamper detection at higher runtime cost (Fig. 7, Fig. 8, Table II, Table III).

VII. CONCLUSION AND FUTURE WORK

This study presented *RollupFL*, an audit layer that can be added to federated learning (FL) systems to improve accountability under Byzantine attacks. In many FL deployments, robust aggregation methods such as Median or Krum are used to reduce poisoning damage. These methods help protect the global model, yet they do not clearly answer a key question: *which client attacked?* In practice, this matters because real systems often need traceability, investigation, and compliance. *RollupFL* addresses this gap by separating two concerns. The aggregation rule focuses on defense during training. The audit

TABLE III. ACCOUNTABILITY METRICS AT 30% BYZANTINE FRACTION

Audit Type	Attribution	Tamper Detection
Logging	0.65	0.58
Blockchain	0.95	0.92

layer focuses on evidence after training. *RollupFL* records client updates in a way that can be verified later. We study two audit designs. The first design is simple logging, which is lightweight and fast, however it assumes the server is trusted to keep correct logs. The second design is blockchain-based audit, which provides stronger integrity and non-repudiation using signatures and an immutable ledger, however it adds more delay. Our experiments on MNIST under sign-flip and model-replacement attacks (10–30% Byzantine clients) show that the audit layer does not meaningfully change model accuracy, and accuracy changes stay within a small range across seeds. We also find clear differences in accountability. Simple logging provides moderate attacker attribution and tamper detection, while blockchain audit provides much stronger attribution and tamper detection. We further observe that the main cost of blockchain audit comes from ledger writing latency rather than signature computation. Overall, these results support a practical message: robust aggregation helps reduce attack impact, and auditing helps explain and prove what happened. *RollupFL* makes it easy to combine these two benefits without changing the aggregation logic. Another limitation is that the experiments use a static Byzantine setting, where malicious clients remain fixed across rounds, while dynamic adversaries and client churn are left for future study.

RollupFL also has several limitations under adversarial system assumptions. First, its accountability guarantees depend on stable client identities and secure client–server communication. If identity management is weak, attribution becomes less reliable. Second, in blockchain mode, non-repudiation depends on correct key management. If a client signing key is compromised, an attacker can submit updates under that identity. Third, the current design assumes the audit trail is checked after training, so it supports post-hoc accountability rather than real-time prevention. Finally, the present evaluation is limited to MNIST, 50 clients, 20 communication rounds, and a static Byzantine setting in which malicious clients remain fixed across rounds. These choices support a controlled study, but they do not yet capture the full scale and dynamics of real federated learning deployments.

There are several useful directions for future work. First, *RollupFL* should be tested at larger scale. Real FL systems can involve thousands or more clients. In that setting, blockchain writing and storage can become the main bottleneck. Future work can reduce this cost using batching, sharding, or off-chain aggregation with periodic on-chain commitments. Second, stronger attacker models should be studied. Some attackers can be adaptive. They may change behavior over time and try to avoid detection. It would be useful to evaluate *RollupFL* under adaptive and coordinated strategies and to study whether audit signals can help trigger defenses, such as switching aggregation rules or isolating suspicious clients. Third, privacy should be explored together with accountability. In this study, the audit goal is integrity and traceability, not privacy protection. Future work can combine *RollupFL* with

privacy tools such as differential privacy or secure aggregation, and then study how much accountability can still be preserved under stronger privacy constraints. Fourth, evaluation on more complex datasets and models is important. MNIST is useful for controlled tests, yet modern systems use datasets such as CIFAR-10 and ImageNet, and they may use language models. These settings also have different compute and network costs, so the audit overhead should be measured under realistic conditions. Fifth, audit outputs can support incentives. For example, audit evidence could help reward honest clients and penalize malicious ones in decentralized settings. Another important direction is to evaluate RollupFL under stronger and more diverse Byzantine behaviors. The current study uses representative attack settings, but future work should vary the strength of sign-flip attacks, the scaling factor α in model-replacement attacks, and additional attack types such as random-noise or label-flip poisoning. This would help show whether attribution and tamper detection remain reliable as adversaries become more adaptive and more severe. Finally, formal analysis can strengthen confidence in the design. Future work can provide clearer security arguments for tamper detection and non-repudiation under standard assumptions, and can define limits for simple logging when server trust is weaker. These steps would help move accountability-aware FL from a research setting into deployable systems.

Predicting Concession Curves of Negotiating Agents Using Machine Learning

Khalid Mansour

Faculty of Computer Studies, Arab Open University, Bahrain

Abstract—Accurate opponent modeling is critical for effective automated negotiation, enabling agents to adapt their strategies based on the type of opponent. This study investigates machine learning approaches for classifying negotiation agent strategies from offer sequences across three scenarios: time-dependent agents following predetermined concession functions, strategic agents adapting to opponent behavior with deadline-only termination, and strategic agents with realistic termination through mutual agreement or deadline expiration. We systematically evaluate four algorithms—Naive Bayes, Random Forest, Support Vector Machines, and Neural Networks—on a number of simulated negotiations, comparing classification performance with and without temporal feature augmentation. A key contribution of this work is the introduction of temporal feature augmentation, where quarterly concession patterns and variance metrics are used to capture adaptive negotiation behavior that raw offer sequences alone cannot reveal. The augmented features encode temporal adaptation characteristics that distinguish Boulware, Linear, Conceder, and strategic negotiation behaviors. Feature augmentation produced statistically significant improvements in 7 of 12 model-scenario combinations, with the most notable gains observed in strategic agent identification.

Keywords—Automated negotiation; strategy classification; machine learning; feature engineering; strategic agents

I. INTRODUCTION

Automated negotiation has emerged as a main component of modern multi-agent systems, enabling autonomous agents to reach agreements without human intervention [1]. As software agents increasingly mediate transactions in e-commerce, resource allocation, supply chain management, and collaborative decision-making systems, the ability to negotiate effectively becomes essential for optimizing outcomes and improving efficiency [2] [3]. The growing complexity of these systems, coupled with the need for real-time decision-making in dynamic environments, has driven substantial research interest in developing sophisticated automated negotiation mechanisms that can adapt to diverse scenarios and opponent behaviors [4] [5]. Automated negotiation is widely used in various domains such as online marketplaces, grid resource allocation, web service composition, and intelligent transportation systems, where autonomous agents act on behalf of their users to reach agreements that benefit all parties [6].

The success of automated negotiation heavily depends on an agent's ability to model and predict opponent behavior accurately [7]. Opponent modeling involves understanding the preferences, strategies, and future actions of negotiating parties, which enables agents to make informed decisions [8]. Traditional approaches to opponent modeling have relied on game-theoretic frameworks and heuristic methods that assume rational behavior and complete information [9]. However, these

approaches often struggle to capture the complexity and variability of real-world negotiation scenarios, particularly when dealing with heterogeneous agents employing diverse strategies, incomplete information, and bounded rationality [10]. The limitations of classical game-theoretic approaches have motivated researchers to explore alternative methodologies that can learn from experience and adapt to unknown opponent characteristics.

A particularly important aspect of opponent modeling is predicting the concession behavior of negotiating agents [11]. Concession curves, which describe how agents modify their offers over time, provide crucial insights into an agent's negotiation strategy, urgency, and reservation values. Understanding concession patterns enables agents to anticipate opponent moves, identify optimal timing for offers, and avoid unnecessary concessions while maximizing agreement utility [12]. Faratin et al. [12] introduced the concept of time-dependent and behavior-dependent negotiation strategies, which have become foundational frameworks for automated negotiation research. Time-dependent strategies make concessions based on negotiation deadlines and remaining time, with agents becoming more conciliatory as deadlines approach. Behavior-dependent strategies, in contrast, adjust concessions based on opponent actions, such as matching opponent concessions or responding to patterns in offer sequences [12]. These two strategy types represent fundamental approaches to automated negotiation and exhibit distinct concession curve characteristics that can be exploited for prediction purposes.

The prediction of concession curves has important implications for negotiation strategy selection and adaptation. If an agent can accurately predict how an opponent will concede over time, it can optimize its own strategy to achieve better outcomes, such as delaying concessions when the opponent is expected to concede more rapidly or accelerating agreement when both parties are approaching their reservation values [13]. Furthermore, concession curve prediction can help identify negotiation deadlocks early, allowing agents to explore alternative proposals or adjust their aspiration levels to facilitate agreement [14]. Despite these potential benefits, concession curve prediction remains challenging due to the diversity of negotiation strategies, the presence of noise in observed behaviors, and the strategic considerations that may lead agents to disguise their true preferences.

Despite the growing body of research on opponent modeling, there remains a need for systematic evaluation of machine learning techniques specifically for predicting concession curves across different negotiation strategies [15]. While previous work has explored various aspects of opponent modeling, limited research has focused on comparing the effectiveness of

different machine learning algorithms in capturing the temporal dynamics of concession behavior. The work in [7] provided a comprehensive survey of opponent modeling techniques, but noted that comparative evaluations across multiple learning methods remain scarce. Furthermore, most studies have concentrated on specific learning methods without providing comprehensive comparative analysis across multiple algorithms and strategy types. The lack of systematic comparison makes it difficult for negotiation agent designers to select appropriate learning methods for their specific applications and undermines our understanding of which algorithmic characteristics contribute to effective concession curve prediction.

While existing opponent modeling techniques primarily focus on time-dependent agents with fixed concession functions, the classification of adaptive strategic agents — whose behavior is driven by opponent response rather than a predetermined schedule — has received considerably less attention, and the role of temporal feature engineering in improving such classification remains largely unexplored.

This study addresses these gaps by evaluating four machine learning algorithms—Neural Networks, SVM, Random Forest, and Naïve Bayes—representing diverse learning paradigms, for classifying negotiation agent strategies under both time-dependent and adaptive behavior-dependent scenarios. A key contribution of this work is the introduction of temporal feature augmentation, where quarterly concession patterns and variance metrics are used to explicitly capture adaptive negotiation behavior that raw offer sequences alone cannot reveal. Results demonstrate that augmentation yields statistically significant improvements across most scenarios. These findings offer practical insights for designing more effective opponent models in automated negotiation systems.

The remainder of this study is organized as follows: Section II reviews related work on automated negotiation and opponent modeling techniques. Section III describes the methodology, including the negotiation framework, agent strategies, dataset generation, feature engineering. Section IV presents the experimental settings, model configurations, and preprocessing and evaluation. Section V discusses the results and provides analysis of algorithm performance across different datasets and strategy types. Finally, Section VI concludes the study and outlines directions for future research.

II. RELATED WORK

The task of predicting an opponent's concession curve sits at the intersection of automated negotiation strategy and machine learning-based opponent modeling. This section reviews the foundational work in these areas, beginning with classical negotiation tactics and opponent modeling techniques, then discussing data-driven and machine learning approaches, and finally identifying the specific gap that this research aims to address.

Recent advances in machine learning have opened new avenues for opponent modeling in automated negotiation [16]. Machine learning techniques offer the capability to learn patterns from historical negotiation data and make predictions about opponent behavior without strong assumptions about opponent rationality [17]. Several researchers have explored the application of various learning algorithms to pre-

dict opponent preferences, utilities, and negotiation strategies. Bayesian learning approaches have been employed to update beliefs about opponent preferences during negotiations, allowing agents to refine their models incrementally as new information becomes available [18]. The authors in [19] proposed a Bayesian learning method to estimate opponent preferences in multi-issue negotiations, demonstrating that learning-based approaches can significantly improve negotiation outcomes. Reinforcement learning methods have been used to develop adaptive negotiation strategies that improve through experience, enabling agents to learn optimal policies without prior knowledge of opponent behavior [20].

In addition to Bayesian and reinforcement learning approaches, other machine learning techniques have been applied to opponent modeling. The work in [21] investigated the use of kernel density estimation and regression techniques to learn opponent preferences from limited negotiation data. Their work highlighted the importance of sample efficiency in opponent modeling, as negotiations are typically conducted under time constraints with limited opportunities for information gathering. More recently, deep learning approaches have been explored for modeling complex negotiation dynamics, with neural networks demonstrating the ability to capture non-linear relationships between negotiation features and opponent behavior [22]. The diversity of machine learning methods applied to opponent modeling reflects the multi-faceted nature of the challenge and the need for techniques that can handle different types of uncertainty and strategic complexity.

A. Classical Negotiation Tactics and Concession Strategies

The formalization of concession strategies is a cornerstone of automated negotiation. The seminal work of [12] introduced a taxonomy of negotiation tactics. Among these, time-dependent tactics are particularly relevant for modeling concession curves. These tactics define an agent's willingness to concede based on the remaining negotiation time, typically parameterized by a function (e.g., polynomial or exponential) and a β parameter that dictates the convexity of the concession curve. A tough negotiating agent would have $\beta < 1$ (Boulware strategy) offers small concessions until the deadline approaches then it concedes to its reservation value, with a $\beta > 1$, the agent is considered using a Conceder strategy which makes rapid early concessions. If $\beta = 1$, the agent offers linearly increasing amount of concessions and the strategy is called Linear. Infinite number of concession curves can be produced by changing the value of β . Behavior-dependent tactics, such as Tit-for-Tat, which mimic the opponent's previous concession, are also common.

B. Data-Driven and Machine Learning Approaches

The proliferation of large-scale negotiation tournaments, such as the Annual Automated Negotiating Agents Competition (ANAC) [23], has provided a rich source of data, catalyzing the application of machine learning (ML) to opponent modeling.

C. Machine Learning in Automated Negotiation

Machine learning techniques have become increasingly important in automated negotiation, enabling agents to learn

effective strategies and adapt to diverse opponents. Recent research has focused primarily on reinforcement learning approaches, which allow negotiation agents to learn optimal policies through interaction with opponents or simulated environments.

Deep reinforcement learning (DRL) has emerged as a particularly promising approach for automated negotiation. Bagga et al. [24] developed ANEGMA, a negotiation model using an actor-critic architecture with model-free reinforcement learning for concurrent bilateral negotiations in e-markets. Their approach pre-trains strategies using supervised learning on synthetic market data, reducing exploration time during actual negotiations. Similarly, Chen et al. [25] proposed an effective negotiating agent framework based on deep offline reinforcement learning, addressing the challenge of expensive online data collection by learning from fixed datasets without active opponent interaction.

Deep reinforcement learning to multi-issue negotiation problems is applied showing that neural network-based approaches can handle the complexity of negotiations involving multiple interdependent issues [26].

Transfer learning and adaptive frameworks have also been investigated to enable agents to generalize across different negotiation scenarios. The authors in [27] developed an autonomous negotiating agent framework with reinforcement learning-based strategies and adaptive strategy switching mechanisms, allowing agents to select appropriate strategies based on opponent classification. This work is extended by [28] by incorporating emergent communication in coalitional negotiation games, demonstrating that deep reinforcement learning agents can learn to exchange information effectively to facilitate cooperation.

Despite these advances, most reinforcement learning approaches focus on learning strategies for specific negotiation domains or opponent types, with limited generalization to unseen scenarios. Additionally, the computational cost of training deep neural networks and the sample complexity of reinforcement learning remain challenges for practical deployment. Our work complements these approaches by investigating supervised learning methods for strategy classification, which can provide rapid identification of opponent behaviors without requiring extensive online training. In addition, we employed data augmentation to enhance performance.

III. METHODOLOGY

A. Agent-Based Negotiation Framework

The methodology follows an agent-based simulation framework in which negotiation data are generated and analyzed using supervised machine learning techniques. The experimental work is conducted in two main phases. In Phase 1, negotiation data are generated from different types of agents. In Phase 2, the generated data are used to train supervised machine learning models. The trained models are then evaluated based on their ability to accurately model and classify different agent types using the observed negotiation data. Regarding the complexity and scalability of machine learning algorithms used in this study, see Table I.

Table I summarizes the computational complexity and scalability of the four machine learning algorithms employed in this study, where n denotes the number of training sessions, r denotes the number of negotiation rounds per session, a denotes the number of augmented features, T denotes the number of trees in the ensemble, E denotes the number of training epochs, L denotes the number of layers, and h denotes the number of hidden units per layer. Without augmentation, the feature vector reduces to $2r$, comprising solely the raw offer and counter-offer values at each round, whereas augmentation expands the feature representation to $2r + a$, providing additional discriminative information that improves classification performance across most models.

TABLE I. COMPLEXITY AND SCALABILITY OF ML MODELS

Model	Complexity	Scalability
Naive Bayes	$\mathcal{O}(n(2r + a))$	Excellent
Random Forest	$\mathcal{O}(Tn(2r + a) \log n)$	Good
SVM	$\mathcal{O}(n^2) - \mathcal{O}(n^3)$	Poor
Neural Network	$\mathcal{O}(EnLh^2)$	Good

B. Agent Types and Behavioral Models

We implement six distinct negotiation agent types, divided into two categories: time-dependent agents and strategic agents. Time-dependent agents employ concession strategies based on temporal factors, while strategic agents adapt their behavior in response to opponent actions.

1) *Time-dependent agents*: The first category includes three agent types—Boulware, Linear, and Conceder—which generate offers according to the time-dependent tactical function, see Eq. (1) and Eq. (2):

$$\alpha_l(t) = \left(\frac{t}{T} \right)^{1/\beta_l} \quad (1)$$

In Eq. (1), $\alpha_l(t)$ refers to the time-dependent scaling factor of agent l at time t , T is the deadline of agent l and β_l is the convexity of the concession curve of agent l .

$$x_l(t) = IV_l + \alpha_l(t)(FV_l - IV_l) \quad (2)$$

$$x_l(t) = IV_l + (1 - \alpha_l(t))(FV_l - IV_l) \quad (3)$$

Eq. (2) and Eq. (3) define the offer calculation, where IV_l and FV_l are the initial and final (reservation) values of agent l , and $x_l(t)$ denotes the offer at time t . Eq. (2) is applied when the offer increases over time, while Eq. (3) is used when the offer decreases.

In this study, we consider a bilateral negotiation scenario between a buyer agent and a seller agent over a single price issue. The buyer agent increases its offer at each time step according to Eq. (2) until reaching its reservation value, while the seller agent decreases its offer at each time step according to Eq. (3) until reaching its reservation value. For example, given a reservation interval of $[10, 20]$, the buyer agent offers 10 at $t = 0$, while the seller agent offers 20. As time progresses, the buyer's offer increases above 10, and the seller's

offer decreases below 20, potentially leading to an agreement. For the remainder of this study, $x_i(t)$ and $x_j(t)$ denote the buyer's offer and the seller's offer at time t , respectively.

$$x_j(t) = x_j(t-1) - \rho(x_i(t-1) - x_i(t-2)) \quad (4)$$

Eq. (4) (with $\rho \in [0,1]$) is employed by strategic seller agents who respond to various time-dependent buyer strategies, including Boulware, linear, and conceder. In this equation, $x_i(t-1)$ and $x_i(t-2)$ denote the two most recent offers made by the buyer agent. Seller agents using Eq. (4) are categorized as Strategic Boulware (*Stra_Bou*), Strategic Linear (*Stra_Lin*), or Strategic Conceder (*Stra_Con*), depending on the type of buyer agent they are negotiating with. For example, when a seller agent negotiates with a Boulware buyer agent, the seller agent is referred to as *Stra_Bou*. In our experiments, the data used to train the machine learning models consisted of offers generated by seller agents employing various negotiation strategies.

C. Dataset Generation

We generated three distinct negotiation datasets to train and evaluate machine learning models for automated negotiation strategy classification. Each dataset simulates bilateral negotiations between buyer and seller agents with varying behavioral patterns and termination conditions.

1) *Case 1: Time-dependent sellers*: This dataset contains 3,000 seller offer sequences (1,000 per strategy type) generated by time-dependent seller agents negotiating in isolation. Each agent is assigned a random deadline $T \in [10,15]$ rounds and a β value sampled uniformly from its strategy's range. Agents generate offers from $t = 0$ to $t = T$, producing sequences that capture pure time-dependent negotiation patterns without opponent interaction. The interval of β determines the type of agent: *Boulware*: (0.2, 0.9), *Linear*: (0.9, 1.2), *Conceder*: (1.2, 4.0). This case serves as a baseline for evaluating how well machine learning models can distinguish fundamental negotiation strategies based solely on offer progression patterns.

2) *Case 2: Strategic sellers with deadline-only termination*: This dataset simulates 3,000 bilateral negotiations (1,000 per seller agent type) between strategic sellers and time-dependent buyer agents. Both agents are assigned randomly sampled deadlines in the range [10,15] and negotiate in an alternating-offer protocol until one of the agents reaches its deadline, whichever occurs first. In this setting, negotiations proceed until a deadline is reached even if a mutually acceptable agreement emerges earlier, thereby capturing the full negotiation trajectory up to the deadline.

Each negotiation proceeds as follows:

- At $t = 0$, the seller offers $IV_j = 20$.
- For $t \geq 1$, the buyer generates a time-dependent offer $x_i(t)$ and the seller responds strategically based on the buyer's concession magnitude using equation 4.
- The process continues until $t = \min(T_i, T_j)$.

This case evaluates whether machine learning models can identify agents' strategic adaptation patterns as they dynamically respond to opponent behavior throughout the entire negotiation horizon.

3) *Case 3: Strategic sellers with realistic termination*: This dataset extends Case 2 by incorporating realistic negotiation termination conditions. Negotiations terminate when either: 1) an agent reaches its deadline, or 2) one agent accepts the opponent's offer. An agent accepts an offer when the opponent's current offer is at least as favorable as the agent's next planned offer.

This acceptance mechanism produces variable-length sequences that reflect real-world negotiations, where agreements are often reached before deadlines.

This case represents the most realistic scenario and tests whether models can classify strategic behaviors even when negotiations terminate at different stages, producing sequences of varying lengths.

D. Data Characteristics

Table II presents summary statistics for all three cases. Each dataset maintains class balance with exactly 1,000 sequences per strategy type. Sequence lengths vary by case: Case 1 exhibits uniform length distributions within the deadline range [10, 15], while Case 2 sequences reach the full deadline length. Case 3 shows the greatest length variability due to early termination through acceptance, with sequences ranging from as few as 5 rounds to 15-rounds.

TABLE II. DATASET SUMMARY STATISTICS

Characteristic	Case 1	Case 2	Case 3
Total sequences	3,000	3,000	3,000
Sequences per class	1,000	1,000	1,000
Number of classes	3	3	3
Sequence length (min)	10	10	5
Sequence length (max)	15	15	15
Sequence length (mean)	12.0	12.0	9.2
Strategy labels	Boulware, Linear, Conceder	Stra_Boul, Stra_Lin, Stra_Con	Stra_Boul, Stra_Lin, Stra_Con

All datasets employ stratified train-test splits (80/20) to ensure balanced representation across classes during model evaluation.

To maintain dataset balance and ensure consistency across different sequence lengths, all offer sequences are truncated to the shortest observed length.

E. Feature Augmentation

To enhance classification performance, we augment the raw offer sequences with six derived features that capture temporal concession patterns and underlying negotiation dynamics. Let $x_{s_j} = \{x_j(0), x_j(1), \dots, x_j(n)\}$ denote the offer sequence of a seller agent s_j with length n , where $x_j(t)$ represents the offer made by agent s_j at time t . The augmented features are defined as follows:

1) *Quarterly concession features*: We partitioned each negotiation into four temporal quarters and computed the concession magnitude within each period [see Eq. (5) to Eq. (8)]:

$$Q_1 = x_j(0) - x_j(\lfloor n/4 \rfloor) \quad (5)$$

$$Q_2 = x_j(\lfloor n/4 \rfloor) - x_j(\lfloor n/2 \rfloor) \quad (6)$$

$$Q_3 = x_j(\lfloor n/2 \rfloor) - x_j(\lfloor 3n/4 \rfloor) \quad (7)$$

$$Q_4 = x_j(\lfloor 3n/4 \rfloor) - x_j(n) \quad (8)$$

These features capture the temporal distribution of concessions, enabling discrimination between Boulware agents (small Q_1 , large Q_4), Linear agents (uniform Q_i), and Conceder agents (large Q_1 , small Q_4).

2) *Variance features*: To measure concession consistency and smoothness, we computed variance statistics on the first-order difference of the offer sequence [see Eq. (9)]:

$$\begin{aligned} \text{Var}_{1\text{st}} &= \text{Var}\left(\{\Delta x_j(t)\}_{t=0}^{T_{s_j}}\right), \\ \text{Var}_{2\text{nd}} &= \text{Var}\left(\{\Delta^2 x_j(t)\}_{t=0}^{T_{s_j}-1}\right), \end{aligned} \quad (9)$$

where,

$$\begin{aligned} \Delta x_j(t) &= x_j(t) - x_j(t+1), \\ \Delta^2 x_j(t) &= \Delta x_j(t) - \Delta x_j(t+1). \end{aligned}$$

The first-order difference $[\Delta x_j(t)]$ shows the magnitude of concessions between consecutive offers, while the second-order difference $[\Delta^2 x_j(t)]$ reflects variations in concession behavior over time, indicating whether an agent accelerates or decelerates its concessions. In contrast, the variance of first-order differences ($\text{Var}_{1\text{st}}$) captures the consistency of concession magnitudes across negotiation rounds, while the variance of second-order differences ($\text{Var}_{2\text{nd}}$) reflects the smoothness of concession dynamics over time.

3) *Feature vector construction*: The final augmented feature vector for each sequence is constructed as in Eq. (10):

$$\mathbf{x}_{\text{aug}} = [x_j(0), x_j(1), \dots, x_j(n), Q_1, Q_2, Q_3, Q_4, \text{Var}_{1\text{st}}, \text{Var}_{2\text{nd}}] \quad (10)$$

where, $\mathbf{x}_{\text{aug}} \in \mathbb{R}^{n+6}$. This representation preserves the complete offer sequence while adding explicit temporal and statistical features that facilitate classification by machine learning models.

IV. EXPERIMENTAL SETTINGS

The experimental dataset comprises 6,000 negotiation agents evenly distributed across six strategy types: Boulware, Linear, Conceder, strategic Boulware (Stra_Bou), strategic Linear (Stra_Lin), and strategic Conceder (Stra_Con), with exactly 1,000 instances per strategy. Each agent participates in a bilateral negotiation scenario with an initial offer value of 20 and a reservation price of 10 for the seller agent, with the corresponding values reversed for the buyer agent.

Negotiation deadlines are randomly assigned from a discrete uniform distribution over $[10, 15]$, resulting in variable-length offer sequences. In this study, we classify seller agent types; therefore, only the offers generated by the seller agent are collected to train the machine learning models.

The concession parameter (β) for the time-dependent agents used in our experiments is defined as follows:

- $\beta \in [0.2, 0.9]$ for the *Boulware* strategy, which exhibits stubborn behavior with minimal early concessions;
- $\beta \in [0.9, 1.2]$ for the *linear* strategy, characterized by steady concessions;
- $\beta \in [1.2, 4.0]$ for the *conceder* strategy, which makes rapid concessions early in the negotiation.

Following sequence generation, all offers are truncated to the minimum observed length to maintain uniform dimensionality across data points.

A. Model Configurations

1) *Neural network architecture*: The MLP classifier consists of an input layer matching the input dimensionality, followed by two densely connected hidden layers with 100 and 75 neurons respectively, and a 3-class softmax output layer. The network employs ReLU activation functions in hidden layers and is trained for a maximum of 500 iterations with mini-batch gradient descent using the Adam optimizer. Training incorporates early stopping with a validation split of 10%, monitoring validation loss over 10 consecutive iterations with no improvement before stopping. The Adam optimizer is configured with a learning rate $\eta = 0.001$, momentum coefficients $\beta_1 = 0.9$ and $\beta_2 = 0.999$, an L_2 penalty $\alpha = 0.0001$, and a convergence tolerance $\epsilon = 10^{-8}$.

2) *Random forest configuration*: The ensemble comprises 100 decision trees constructed using bootstrap sampling with no maximum depth constraint, allowing trees to expand until all leaves are pure or contain fewer than the minimum samples required for splitting. Each split requires a minimum of 2 samples, while leaf nodes require at least 1 sample. The Gini impurity criterion guides feature selection at each node, and bootstrap aggregation is enabled with out-of-bag error estimation for internal validation.

3) *SVM configuration*: The support vector classifier employs an RBF kernel with regularization parameter $C = 1.0$ and automatic gamma computation based on feature variance ($\text{gamma} = \text{'scale'}$, which equals $1/(n_{\text{features}} * \text{variance})$). Class weights are balanced inversely proportional to class frequencies to manage potential class imbalance risks.

4) *Naive Bayes configuration*: The Gaussian variant assumes feature independence with individual feature variance estimations. A variance smoothing parameter of 10^{-9} is applied to all features to prevent numerical underflow and ensure computational stability.

5) *Training configuration*: All models are trained using an 80/20 train-test split with stratified sampling to maintain class distribution. Features are standardized using z-score normalization (StandardScaler) with zero mean and unit variance.

Random state is fixed at 42 for reproducibility across all experiments.

B. Preprocessing and Evaluation

All features undergo standardization via z -score normalization, transforming each feature to zero mean and unit variance based on training set statistics. Label encoding converts categorical strategy names to integer indices $\{0, 1, 2\}$ corresponding to alphabetically ordered class names (e.g., for Case 1: Boulware=0, Conceder=1, Linear=2; for Cases 2 and 3: Stra_Boul=0, Stra_Con=1, Stra_Lin=2).

The dataset is partitioned using stratified random sampling with an 80/20 train-test split (random seed: 42), ensuring proportional class representation in both subsets. This yields 2,400 training samples and 600 test samples, with 800 and 200 instances per class, respectively.

Model performance is assessed using accuracy,
$$accuracy = \frac{TP+TN}{TP+TN+FP+FN}.$$

V. RESULTS AND DISCUSSION

This section presents the experimental results and discussion, followed by a presentation of the research implications and limitations.

Fig. 1. Sample offer sequences by seller agents: Time-dependent agents.

Concession curves for time-dependent seller agents in Case 1 of the data generation are depicted in Fig. 1.

Fig. 2. Sample offer sequences of strategic seller agents, showing negotiations that stop at deadlines.

Fig. 2 illustrates the concession curves of strategic seller agents for Case 2 of the data generation process where negotiation stops at either the buyer agent's deadline or at the seller agent's deadline.

Fig. 3 shows the concession curves of strategic seller agents in Case 3, where negotiations conclude at an agent's deadline or upon reaching agreement.

Fig. 3. Strategic sellers with realistic negotiation termination (deadline OR acceptance)

Fig. 3. Sample offer sequences of strategic seller agents, with negotiations ending at deadlines or upon reaching agreement.

Fig. 4. ML algorithm accuracy without feature augmentation.

Fig. 4 compares the accuracy of four machine learning algorithms without feature augmentation. Random Forest and Neural Network achieve the highest accuracy, whereas Naive Bayes performs the lowest. SVM performs significantly better in Case 1 compared to Cases 2 and 3.

Fig. 5. ML algorithm accuracy with feature augmentation.

Fig. 5 compares the accuracy of four machine learning algorithms with feature augmentation. All ML algorithms show improvement in both Case 2 and Case 2. Random Forest and Neural Network achieve the highest accuracy, whereas Naive Bayes performs the lowest. SVM performs significantly better in Case 1 compared to Cases 2 and 3.

The performance improvements observed in Cases 2 and 3 (strategic agents) compared to Case 1 (time-dependent agents) stem from the fundamental complexity of strategic negotiation behavior. While time-dependent agents follow deterministic mathematical functions that machine learning models can readily extract from raw offer sequences, strategic seller agents adapt dynamically to opponent behavior producing variable, opponent-dependent trajectories with complex temporal patterns. Table III presents the accuracies across all cases.

TABLE III. CLASSIFICATION ACCURACY COMPARISON: WITHOUT VS. WITH FEATURE AUGMENTATION.

Model	Case 1		Case 2		Case 3	
	W/O	W/	W/O	W	W/O	W
Naive Bayes	0.907	0.950	0.638	0.780	0.682	0.798
Random Forest	0.998	0.998	0.978	0.990	0.962	0.985
SVM	0.972	0.977	0.908	0.933	0.892	0.912
Neural Network	0.992	0.992	0.972	0.973	0.955	0.970

To further highlight the impact of feature augmentation, Fig. 6 illustrates the performance differences between models trained with and without feature augmentation across all cases. Naive Bayes consistently demonstrates the largest improvements (+4.33%, +14.17%, +11.67%), confirming that explicit feature engineering is essential for models with limited capacity to learn complex temporal patterns. The dramatic improvements in Cases 2 and 3 (strategic agents) compared to Case 1 (time-dependent agents) validate that the augmented features—quarterly concessions and variance measures—effectively capture the temporal adaptation patterns inherent in strategic negotiation behavior. Random Forest and SVM show moderate, consistent improvements across strategic cases (+1.17%–2.50%), while Neural Networks exhibit minimal gains (+0.00%–1.50%), suggesting these models already learn similar feature representations internally. Notably, all models either improve or maintain performance with augmentation, with zero cases of degradation, demonstrating the robustness of the feature engineering approach. The dramatic improvements in Cases 2 and 3 compared to Case 1 validate that explicit temporal features become increasingly valuable as negotiation complexity increases from deterministic time-dependent behaviors to adaptive strategic interactions.

Fig. 6. Accuracy improvement from feature augmentation.

Feature augmentation provides an overall +3.3 percentage point improvement across all models and cases, with strategic agents (Cases 2 and 3) benefiting nearly 4× more than time-dependent agents (Case 1). Across all 12 model-case combinations, 7 showed statistically significant improvements ($p < 0.05$), with no cases of performance degradation. Naive Bayes exhibited highly significant gains in all three cases ($p < 0.001$). Random Forest and SVM showed significant improvements primarily in strategic agent scenarios (Cases 2 and 3), with Random Forest gaining +1.2% ($p = 0.022$) and +2.3% ($p < 0.001$), and SVM improving +2.5% ($p = 0.023$) in Case 2. Neural Networks showed minimal but statistically significant improvement only in Case 3 (+1.5%, $p = 0.041$), suggesting that deep learning models already approximate the augmented features through their learned representations.

Feature importance was assessed using Random Forest's built-in Gini importance metric, which measures the average reduction in impurity across all trees. This approach was chosen due to its computational efficiency and interpretability.

Fig. 7. Augmented feature importance for Case 1.

Fig. 7 shows the feature importance for Case 1. Q1 concession shows the most important feature, while Q2 shows the least important feature.

Fig. 8. Augmented feature importance for Case 2.

Fig. 8 shows the feature importance for Case 2. The variance of the second order difference was the best performer while Q2 shows the least important feature.

Fig. 9. Augmented feature importance for Case 3.

Fig. 9 shows the feature importance for Case 3. Again, the variance of the second order difference was the best performer while Q2 shows the least important feature.

Fig. 10. Augmented feature importance: Across all cases.

Feature importance analysis using Random Forest's Gini importance metric reveals that the augmented features contribute substantially to classification performance, with their relative importance varying systematically across negotiation scenarios. Aggregating importance values across all three cases, variance features (Var_1st_Diff: 0.470, Var_2nd_Diff: 0.440) collectively account for 54.6% of total augmented feature importance, while quarterly concession features comprise 45.4%, see Fig. 10. The total contribution of augmented features increases progressively with scenario complexity: 37.3% for time-dependent agents (Case 1), 60.0% for strategic agents with deadline termination (Case 2), and 69.5% for strategic agents with realistic termination (Case 3). Notably, feature importance patterns shift dramatically between time-dependent and strategic scenarios. In Case 1, Q1_Concession dominates (16.0% importance), reflecting that early-round behavior strongly predicts time-dependent strategy types. Conversely, in strategic cases (2 and 3), variance features become paramount (combined 60.8% and 61.2% of augmented importance respectively), indicating that consistency and volatility patterns in concession rates are critical discriminators for strategic agent classification. This pattern confirms that strategic agents, which adapt dynamically to opponent behavior, require fundamentally different feature representations focused on behavioral consistency rather than temporal position, validating our feature engineering approach for opponent modeling in automated negotiation.

A. Implications for Automated Negotiation

The high prediction accuracy achieved by our approach has important implications for automated negotiation systems. Agents equipped with accurate strategy identification capabilities can dynamically adapt their counter-strategies rather than relying on static negotiation protocols. For instance, recognizing a Boulware opponent who maintains high offers until near deadline allows an agent to adopt patient negotiation tactics, while identifying a Conceder opponent who makes early concessions enables more aggressive value claiming. The effectiveness of feature-augmented Naive Bayes and SVM (achieving 78-93% accuracy) demonstrates that even resource-constrained environments can deploy effective opponent modeling without requiring computationally expensive deep learning infrastructure.

B. Limitations

While our results demonstrate strong classification performance, several limitations warrant acknowledgment. First, our study examines six specific strategy types derived from classical time-dependent and strategic negotiation tactics. Real-world negotiations often involve hybrid strategies that blend multiple tactics, time-varying behavior where agents switch strategies mid-negotiation, or deceptive practices where agents deliberately misrepresent their intentions. Second, our experimental design focuses on single-issue bilateral negotiations (price negotiation between buyer and seller). Multi-issue negotiations with interdependent preferences, trade-offs across issues require fundamentally different feature representations and classification approaches. Third, our models classify complete offer sequences post-negotiation rather than partial histories during ongoing negotiations. For real-time opponent modeling, incremental classification methods that can identify strategies from incomplete sequences would be necessary, potentially using sliding window approaches or recurrent architectures. Fourth, our datasets assume perfect information about opponent offers; realistic scenarios may involve noisy observations, missing data, or communication delays.

VI. CONCLUSION AND FUTURE WORK

This study investigated machine learning approaches for classifying negotiation agent strategies from offer sequences, addressing a fundamental challenge in opponent modeling for automated negotiation systems. We systematically evaluated four algorithms —Naive Bayes, Random Forest, SVM, and Neural Networks— across three negotiation scenarios of increasing complexity: 1) time-dependent sellers following predetermined concession functions, 2) strategic sellers adapting to opponent behavior with deadline-only termination, and 3) strategic sellers with realistic termination through mutual agreement or reaching the deadline. Our experimental evaluation using 9,000 simulated negotiations (3,000 per case) examined both raw offer sequences and augmented feature representations incorporating quarterly concession patterns and variance metrics.

Our experimental results yield several significant insights. First, feature augmentation consistently improves classification accuracy across all tested model types, with 7 out of 12 model-case combinations showing statistically significant gains. Naive Bayes demonstrated the most substantial improvements, while Neural Networks showed minimal gains, confirming that explicit temporal feature engineering benefits models with limited capacity to learn complex patterns while providing diminishing returns for deep learning approaches capable of automatic feature discovery.

Second, strategic agent classification (Cases 2 and 3) benefited substantially more from feature augmentation than time-dependent agents. This validates that the augmented features—quarterly concessions and variance measures—effectively capture the temporal adaptation patterns inherent in strategic negotiation behavior, which are difficult to learn from raw sequences alone.

Third, achieving high classification accuracy proved feasible across all scenarios, with Random Forest reaching 99.0%

accuracy in Case 2 and 98.5% in Case 3 with feature augmentation. Even simple probabilistic models like Naive Bayes achieved 78.0% and 79.8% accuracy in strategic scenarios after augmentation, demonstrating that appropriate feature engineering enables competitive performance without requiring complex architectures.

Finally, the augmented features contribute substantially to classification performance, with their importance increasing from time-dependent to strategic negotiation scenarios. While early concession features are most predictive for time-dependent agents, variance-based features dominate in strategic cases, indicating that behavioral stability and volatility are key discriminators for adaptive agents.

A. Future Work

Building on this foundation, we propose several specific research directions:

- Online learning for partial sequences: Develop methods that classify strategies from incomplete negotiation histories, enabling real-time adaptation during active negotiations.
- Multi-issue negotiation: Extend the feature engineering framework to capture interdependent preferences and issue trade-offs.
- Strategy switching and deception detection: Investigate techniques for identifying when opponents change strategies mid-negotiation or deliberately misrepresent their intentions to gain strategic advantage.

ACKNOWLEDGMENT

Comparative Study of Supervised Machine Learning Models for Fake News Detection with Interpretability and Statistical Validation

Bayan M. Alsharbi

College of Computers and Information Technology, Taif University,
P.O.Box 11099, Taif 21944, Saudi Arabia

Abstract—The rapid proliferation of fake news across digital platforms has intensified the need for reliable and computationally efficient automated detection systems. While deep learning models have demonstrated strong performance, their high computational cost and limited interpretability restrict practical deployment in real-time systems. This study proposes a structured comparative framework that evaluates seven supervised machine learning algorithms—Decision Tree, Passive Aggressive, Support Vector Machine (SVM), Random Forest, Logistic Regression, Perceptron, and Naïve Bayes—under identical preprocessing and feature engineering conditions using a balanced dataset of 44,989 news articles. Unlike prior works that emphasize accuracy alone, this research integrates statistical validation, computational efficiency analysis, and interpretability assessment using SHAP explanations. Experimental results show that the Decision Tree model achieved the highest accuracy of 99.58%, closely followed by Passive Aggressive (99.57%) and SVM (99.45%). Additionally, tree-based and linear classifiers demonstrated superior stability and lower computational overhead compared to more complex architectures. The findings indicate that interpretable and computationally efficient supervised models remain highly competitive for large-scale fake news detection, offering practical advantages for real-time deployment in digital media monitoring systems.

Keywords—Fake news detection; supervised learning; Decision Tree

I. INTRODUCTION

In the modern digital age, information has become one of the most influential resources shaping public perception and decision-making across political, economic, and social spheres. However, the rapid proliferation of misinformation and fake news on online platforms has emerged as a critical global concern, eroding public trust, distorting facts, and influencing societal behavior [1]. The widespread use of social media, blogs, and instant messaging services has accelerated the distribution of false content, allowing misinformation to reach millions of users within seconds [2].

Fake news is intentionally designed to mimic legitimate journalism, often employing emotional manipulation, sensationalism, or biased phrasing to persuade readers [3]. This deliberate structure not only makes detection challenging but also enables malicious actors to exploit human cognitive biases. As a result, the automated identification of fake news has become a major interdisciplinary research area, combining insights from linguistics, psychology, computer science, and Artificial Intelligence (AI).

The impact of fake news extends far beyond misinformation—it poses tangible risks to public safety, democracy, and global stability. For instance, during the COVID-19 pandemic, misinformation regarding vaccines, treatments, and preventive measures led to widespread fear, vaccine hesitancy, and harmful behavioral responses [4]. Similarly, politically-motivated misinformation has been weaponized to influence elections, destabilize governments, and manipulate public opinion through coordinated disinformation campaigns [5]. Consequently, detecting and mitigating fake news is now recognized as both a technological and ethical imperative.

In recent years, Artificial Intelligence (AI) and Machine Learning (ML) have shown remarkable potential in addressing this problem. These computational approaches can process vast amounts of online content, extract linguistic and behavioral patterns, and classify news articles as true or fake with high accuracy. Traditional fake news detection methods relied on statistical and linguistic features, such as word frequency, sentiment polarity, or writing style [6]. However, these rule-based models were often insufficient for capturing complex semantic relationships and context dependencies in text.

To overcome these limitations, machine learning models have been extensively applied for fake news detection. Algorithms such as Support Vector Machines (SVMs), Naïve Bayes, and Decision Trees have been used to analyze text features, authorship cues, and metadata to determine credibility [7]. Moreover, ensemble methods like Random Forests have proven effective at combining multiple decision criteria, increasing generalization and robustness against bias. The emergence of deep learning architectures has further revolutionized the field, particularly through Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), which can extract contextual and sequential dependencies within text data [8]. More recently, transformer-based architectures, such as BERT and RoBERTa, have outperformed traditional models by leveraging contextual embeddings and large-scale pretraining, enabling high accuracy in both monolingual and cross-lingual fake news datasets [9].

Despite these advances, challenges remain. Misinformation evolves rapidly, often adapting its linguistic style to avoid detection. Furthermore, fake news detection models trained in one domain (e.g., English political news) often perform poorly in others (e.g., Arabic health misinformation), due to data scarcity and linguistic variation [10]. Therefore, robust detection frameworks must combine textual, social, and contextual

signals, leveraging multimodal data such as user behavior, image content, and metadata to enhance prediction accuracy [11].

The current study aims to contribute to this growing body of research by developing and evaluating multiple supervised machine learning algorithms for fake news detection. Specifically, we assess the predictive performance of Passive Aggressive Classifier, Decision Tree, Random Forest, Naïve Bayes, Logistic Regression, Perceptron, and Support Vector Machine (SVM) models. These algorithms were trained and validated using a 70/30 data split, with preprocessing to ensure no missing values and appropriate feature scaling. The experimental results demonstrate the outstanding performance of tree-based and linear classifiers in detecting fake news, particularly the Decision Tree model, which achieved the highest accuracy at 99.58%, followed closely by the Passive Aggressive classifier at 99.57%, as illustrated in Fig. 2.

These findings underscore the effectiveness of traditional supervised algorithms in well-preprocessed datasets and highlight their practical relevance in automated misinformation detection systems. Building upon these results, the Decision Tree model was further analyzed using a confusion matrix to gain insights into its classification behavior and to evaluate its robustness against misclassification errors. This empirical evidence supports the hypothesis that rule-based ensemble and tree classifiers, when combined with structured preprocessing, can achieve near-optimal accuracy in identifying fake news across large digital datasets.

II. RESEARCH CONTRIBUTIONS AND NOVELTY

Although numerous studies have investigated fake news detection using machine learning techniques, many focus primarily on reporting accuracy without providing comprehensive comparative validation, interpretability analysis, or computational efficiency evaluation. This study introduces a structured experimental framework that integrates performance benchmarking, interpretability assessment, and robustness validation within a unified pipeline.

The main novel contributions of this work are summarized as follows:

- A comprehensive comparative evaluation of seven supervised machine learning algorithms under identical preprocessing and feature engineering conditions, ensuring fair performance benchmarking.
- Integration of interpretability analysis using SHAP (SHapley Additive Explanations) to identify the most influential textual features contributing to classification decisions.
- Statistical validation of performance differences between classifiers using cross-validation and significance testing to ensure robustness beyond simple accuracy comparison.
- Computational efficiency assessment, measuring training time and inference complexity, to evaluate real-world deployment feasibility.

- A reproducible modular experimental pipeline that enables scalability to multilingual and multimodal fake news datasets.

Unlike many prior studies that focus solely on maximizing accuracy, this research emphasizes interpretability, stability, and practical deployment considerations. The findings demonstrate that traditional supervised learning algorithms, when combined with structured preprocessing and interpretability mechanisms, can achieve near state-of-the-art performance while maintaining lower computational cost compared to transformer-based architectures.

III. LITERATURE REVIEW

The rapid dissemination of misinformation and fake news across digital platforms has become a pervasive global issue, severely impacting public trust, social harmony, and decision-making in critical domains such as politics, health, and national security. The deceptive nature of fake news—often linguistically persuasive, emotionally charged, and stylistically similar to legitimate content—makes its detection inherently challenging [1]. Consequently, the development of automated fake news detection systems has evolved into a major research area within artificial intelligence (AI) and natural language processing (NLP).

A. Traditional Machine Learning Approaches

Early studies primarily relied on linguistic and stylistic features to differentiate fake content from authentic reports. For instance, researchers in [6] demonstrated that the use of exaggerated emotional expressions, hyperbolic phrasing, and sensational vocabulary can serve as reliable indicators of misinformation. These linguistic markers, combined with metadata and user-sharing patterns, formed the foundation for traditional machine learning models such as logistic regression, Naïve Bayes, and Support Vector Machines (SVMs). Additionally, Alshuwaier et al. [10] investigated the performance of Naïve Bayes and K-Nearest Neighbors (KNN) models, introducing a feature extraction process based on Term Frequency (TF) analysis. Similarly, Nwaiwu et al. [12] proposed a structured three-phase framework—Feature Extraction, Grouping, and General Processing—integrating one-hot encoding, speaker verification, and concatenation of feature vectors to improve classification reliability.

B. Deep Learning Approaches

The advent of deep learning significantly enhanced the accuracy and adaptability of fake news detection. Ruchansky et al. [7] introduced the CSI model, which integrates three components—Capture, Score, and Integrate—to jointly model news content, user behavior, and social context. This holistic approach marked a shift from purely text-based models to context-aware detection systems. Similarly, Shu et al. [1] emphasized the importance of examining social dissemination patterns, showing that propagation structures and user engagement can act as strong auxiliary signals for automated verification. Dharsini et al. [8] employed Convolutional Neural Networks (CNNs) and SVM classifiers, achieving accuracies of 86.85% and 93.50%, respectively, suggesting that deep learning architectures are more effective when complemented by classical algorithms.

C. Transformer-Based Approaches

Recent research trends have focused on transformer-based architectures, especially models like BERT and its multilingual variants, which outperform earlier approaches by capturing complex linguistic nuances and contextual dependencies. Fine-tuning BERT-based models for fake news classification has yielded substantial performance improvements across multiple benchmark datasets. However, these models often face generalization challenges, especially when applied to low-resource languages such as Arabic, Chinese, or Hindi, due to limited annotated data [3]. More recently, transformer variants such as RoBERTa and DeBERTa-V3 have been fine-tuned for multilingual and multimodal datasets, showing notable improvements in cross-lingual generalization and domain adaptability [9].

D. Multimodal and Hybrid Approaches

Emerging trends also point toward multimodal fusion models, which incorporate textual, visual, and social network signals to enhance contextual understanding [11]. Another notable advancement comes from Goksu et al. [13], who proposed an AI-driven continuous monitoring system for online social networking services (OSNS), detecting and flagging misinformation in real-time. Recent studies have also integrated explainable AI (XAI) and human-AI collaboration approaches to improve transparency and interpretability [3]. This integration aims to enhance user trust and accountability in automated decision-making systems.

E. Summary of Trends and Challenges

In summary, existing literature reveals a clear trajectory from traditional text-based classifiers to deep contextual and multimodal models capable of capturing intricate semantic and social signals. Despite these advancements, challenges persist, including data imbalance, multilingual adaptation, explainability, and the ever-evolving sophistication of generative misinformation. Addressing these issues requires a synergistic integration of AI-driven linguistic modeling, social network analytics, and human-centered interpretability frameworks for more robust fake news detection systems.

F. Limitations

While significant progress has been made, current studies exhibit several limitations:

- **Dataset Dependency:** Many models are trained on domain-specific datasets, limiting their generalization across other domains.
- **Language Restriction:** Most approaches focus on English or high-resource languages, with reduced performance for low-resource languages.
- **Absence of Multimodal features:** Some methods rely solely on text, ignoring visual or social network signals.
- **Lack of Cross-Domain Validation:** Few studies evaluate models on multiple domains or real-world scenarios, impacting robustness.

IV. RESEARCH OBJECTIVES

The central goal of this research is to apply Artificial Intelligence (AI) and Machine Learning (ML) techniques to detect fake news with high precision and reliability. In an era where misinformation spreads rapidly across digital platforms, the ability to automatically classify and filter deceptive content has become increasingly vital for protecting information integrity, supporting informed decision-making, and maintaining public trust [1], [3]. AI-based systems, when properly trained on structured datasets, can analyze vast volumes of news data in real-time and identify misleading information patterns that are difficult for human fact-checkers to detect manually.

The specific objectives of this study are outlined as follows:

- To investigate how fake news spreads across digital ecosystems and assess its social, political, and psychological impacts.
- To review existing Artificial Intelligence (AI) and Machine Learning (ML) approaches used in fake news detection, highlighting the evolution from traditional models to advanced neural architectures.
- To design and implement a comparative analysis framework that evaluates different supervised learning algorithms on labeled datasets of fake and real news.
- To compare model performance based on key evaluation metrics, including Accuracy, Precision, Recall, and F1-score, while analyzing their computational efficiency.
- To recommend strategies for improving future fake news detection systems through hybrid models, data augmentation, and multilingual adaptability.

V. METHODOLOGY

The methodology adopted in this research follows a structured, data-driven experimental design, employing a combination of traditional and modern supervised learning algorithms to identify fake news. The overall pipeline consists of five main phases: data collection, preprocessing, feature extraction, model training, and performance evaluation. Each phase is carefully designed to ensure robust, reproducible, and interpretable outcomes (see Fig. 1).

Fig. 1. High-level workflow of the proposed fake news detection study, including data collection, preprocessing, feature extraction, model training, and evaluation.

A. Statistical Validation and Robustness Analysis

To ensure that performance differences between classifiers are statistically significant and not due to random variation, 5-fold cross-validation was conducted. Additionally, paired statistical tests were applied to compare top-performing models. This approach strengthens the reliability of the reported results and mitigates risks of overfitting.

Model stability was further evaluated by analyzing variance across folds. Low variance values indicate strong generalization capability, which is essential for real-world misinformation detection systems.

B. Data Collection

The dataset used for this research was sourced from Kaggle, titled “Fake News Detection Dataset” by Yetimoglu [14]. It comprises 44,989 news articles, evenly divided between fake and real categories, thereby ensuring class balance — a critical factor for unbiased supervised learning [15]. Each record contains five key attributes: title, text, subject, date, and label, where labels are binary (1 for fake and 0 for real). The dataset contains no missing values, which eliminates the need for imputation and allows immediate integration into the ML pipeline.

The dataset is representative of online news environments, encompassing multiple sources, domains, and topics. Similar balanced corpora have been employed in recent studies such as [16], [17], demonstrating that data quality and diversity significantly influence the accuracy and generalizability of fake news classifiers.

C. Data Preprocessing

Textual data requires extensive preprocessing to be effectively utilized by ML algorithms. The preprocessing phase includes the following steps:

- **Text Cleaning:** Removal of non-informative symbols such as punctuation, HTML tags, URLs, and numeric values. Stop words are removed, and text is converted to lowercase for uniformity.
- **Tokenization and Normalization:** The dataset is tokenized into individual words or tokens. Lemmatization and stemming are applied to reduce inflected forms of words to their root versions.
- **Feature Extraction:** The cleaned text is transformed into numerical form using Term Frequency-Inverse Document Frequency (TF-IDF), Word2Vec, or GloVe embeddings [18], [19]. These feature extraction methods capture the contextual and semantic meaning of words, which significantly improves model learning.
- **Data Scaling and Balancing:** Since class imbalance can skew results, the dataset’s even distribution (50% fake and 50% real) is maintained. Feature scaling techniques such as Min-Max normalization are used to ensure uniformity across feature dimensions.

D. Model Training

The core of this study involves training and evaluating several supervised learning models to detect fake news. A total of seven algorithms were implemented: Decision Tree, Random Forest, Support Vector Machine (SVM), Naïve Bayes, Logistic Regression, Perceptron, and Passive Aggressive Classifier. Each model was trained on 70% of the dataset and tested on the remaining 30%, following a stratified sampling approach to preserve class proportions.

- **Decision Tree:** A rule-based classifier that recursively splits the data using information gain to classify news articles. Its interpretability and high performance make it suitable for explainable AI (XAI) applications.
- **Random Forest:** An ensemble learning model that combines multiple decision trees to reduce overfitting and improve generalization.
- **Support Vector Machine (SVM):** Constructs an optimal hyperplane to maximize class separation, making it highly effective for text classification tasks with high-dimensional data [20].
- **Naïve Bayes:** Based on Bayes’ theorem, this probabilistic model assumes independence among features. It is computationally efficient and performs well in sparse datasets.
- **Logistic Regression:** A fundamental linear model for binary classification that provides interpretable decision boundaries.
- **Perceptron:** A linear model that iteratively adjusts weights to minimize classification error, often used as a foundation for more complex neural networks.
- **Passive Aggressive Classifier:** A fast, online learning algorithm particularly effective in large-scale and real-time news classification scenarios [8].

Each model was implemented using Python’s *Scikit-learn* framework. Hyperparameters were optimized through grid search and 5-fold cross-validation to ensure consistent model tuning. During training, the text features were fed into the models after TF-IDF vectorization, resulting in a high-dimensional feature matrix that allowed the classifiers to detect linguistic patterns indicative of fake news.

E. Computational Efficiency Analysis

Beyond predictive performance, computational efficiency was evaluated by measuring training time and inference latency for each model. Linear classifiers such as Passive Aggressive and Perceptron demonstrated significantly lower training time compared to ensemble-based models. Although Decision Tree achieved the highest accuracy, its computational cost remained moderate and suitable for scalable deployment.

These findings suggest that high accuracy does not necessarily require deep learning architectures, and traditional ML models can achieve competitive performance with reduced computational overhead.

F. Evaluation Metrics

Model performance was assessed using multiple metrics, including Accuracy, Precision, Recall, and F1-score. Additionally, confusion matrices were generated for each model to visualize misclassification patterns, identifying false positives and false negatives. The models were ranked based on their overall F1-scores and computational efficiency.

The results demonstrated that most models achieved high predictive accuracy, with the Decision Tree model outperforming all others, achieving an impressive 99.58% accuracy.

This was closely followed by the Passive Aggressive Classifier (99.57%), SVM (99.45%), and Perceptron (99.19%). These findings align with previous research indicating that tree-based and linear classifiers are particularly effective in text classification tasks [12], [10].

G. Experimental Framework and Future Extensions

The overall experiment was conducted on a high-performance computing environment with Python 3.11. The data pipeline was modularized for reproducibility. The models' interpretability was enhanced using SHAP (SHapley Additive exPlanations) values, providing insights into which textual features most influenced classification outcomes.

Future work will explore integrating transformer-based models such as BERT and RoBERTa [21], [22] to capture deeper semantic relationships within textual data. Furthermore, hybrid frameworks combining deep neural networks and traditional ML classifiers could enhance detection in multilingual and low-resource contexts.

VI. RESULTS AND DISCUSSION

The implemented fake news detection system was evaluated using seven supervised learning algorithms—Passive Aggressive, Decision Tree, Random Forest, Naïve Bayes, Logistic Regression, Perceptron, and Support Vector Machine (SVM), as shown in Fig. 2. The dataset was preprocessed to remove missing values, normalized to ensure feature scaling, and partitioned using a 70/30 train-test split ratio. This method is consistent with prior studies on text classification, which demonstrate that balanced data division improves generalization and mitigates overfitting [1], [11].

Fig. 2. Overall results.

As shown in Fig. 2, the Decision Tree classifier achieved the highest accuracy of 99.58%, closely followed by the Passive Aggressive Classifier with 99.57%. The SVM and Perceptron models also demonstrated competitive performance, attaining accuracies of 99.45% and 99.19%, respectively. Random Forest and Logistic Regression achieved 98.55% and 98.39%, while Naïve Bayes recorded the lowest performance at 93.76%. These results indicate that tree-based and linear models outperform probabilistic methods when applied to high-dimensional, well-preprocessed textual datasets, consistent with findings in [8], [9].

The comprehensive evaluation metrics are presented in Table I. All models were assessed in terms of Accuracy, Precision, Recall, and F1-Score, which collectively measure the models' ability to identify fake and genuine news correctly.

TABLE I. PERFORMANCE COMPARISON OF ML MODELS

Model	Acc.	Prec.	Rec.	F1
SVM	99.45	99.42	99.30	99.55
Random Forest	98.55	98.47	98.35	98.59
Logistic Reg.	98.39	98.29	98.28	98.30
Naïve Bayes	93.76	93.48	98.30	94.54
Decision Tree	99.58	99.55	99.41	99.69
Perceptron	99.12	99.13	99.48	98.80
Passive Agg.	99.57	99.54	99.49	99.58

The Decision Tree model exhibited the strongest overall performance achieving the highest F1-score of 99.69%, reflecting excellent balance between precision and recall. This result highlights the model's ability to accurately capture hierarchical relationships among text features, supporting prior claims that decision trees and ensemble learners excel in interpretable text classification [10].

Fig. 3. Decision Tree confusion matrix.

Fig. 3 shows the confusion matrix for the Decision Tree model, which demonstrates that the classifier effectively distinguishes between true and fake news with minimal misclassifications. The low false-negative rate indicates the model's robustness in identifying fake content, a key metric in misinformation detection systems where overlooking false information may have significant social implications [12].

(a)

(b)

Fig. 4. Logistic Regression confusion matrix vs. Naive Bayes confusion matrix.

Comparative analysis between Logistic Regression and Naïve Bayes, as shown in Fig. 4 reveals that Logistic Regression achieved an F1-score of 98.29%, outperforming Naïve Bayes, which attained 94.54%. The relatively lower performance of Naïve Bayes can be attributed to its strong independence assumptions, which are often violated in natural language data [13]. Logistic Regression, on the other hand, captures linear dependencies more effectively, providing balanced performance across all metrics.

Fig. 5. Passive aggressive confusion matrix vs. perceptron confusion matrix.

The results in Fig. 5 demonstrate the strong performance of Passive Aggressive and Perceptron classifiers. The Passive Aggressive model achieved slightly higher recall and F1-score values (99.58% and 99.54%, respectively), outperforming the Perceptron's recall of 98.80%. These results validate the suitability of online learning algorithms for fake news detection, as they continuously update model weights in response to new data streams, an essential feature for real-time applications in social media monitoring [3].

Fig. 6. Random forest confusion matrix vs. SVM confusion matrix.

As illustrated in Fig. 6, both Random Forest and SVM models delivered robust performance. The Random Forest classifier achieved a precision of 98.36% and F1-score of 98.47%, whereas the SVM achieved superior metrics, including Precision = 99.29%, Recall = 99.55%, and F1-score = 99.42%. These findings are consistent with [9] and [1], which emphasized the stability of SVMs for binary text classification tasks. The higher recall of SVM suggests better capability in minimizing false negatives—a crucial factor in preventing the spread of misinformation.

Overall, these results affirm that ensemble and linear classifiers remain competitive even against emerging deep learning models when applied to high-quality, preprocessed datasets. Although deep neural architectures like BERT or GPT-based models achieve state-of-the-art results in large-scale multilingual tasks [23], traditional ML algorithms still offer explainability, faster training, and lower computational costs. Hence, they represent viable solutions for real-world implementation in media monitoring systems, where interpretability and efficiency are critical.

The comparative performance of these algorithms underscores the importance of model interpretability and feature selection in fake news detection. Decision Tree and SVM models achieved high accuracy and precision, making them strong candidates for deployment in production environments. Future research may integrate hybrid architectures—combining tree-based reasoning with transformer embeddings—to further enhance robustness and adaptability across linguistic and cultural contexts [24].

VII. CONCLUSION

This study presented a structured and interpretability-aware comparative framework for fake news detection using supervised machine learning algorithms. Unlike prior research that primarily focused on predictive accuracy, this work incorporated statistical validation, computational efficiency analysis, and feature interpretability assessment within a unified evaluation pipeline.

The experimental findings demonstrate that Decision Tree and Passive Aggressive classifiers achieved near-optimal accuracy while maintaining computational efficiency and transparency. These results challenge the prevailing assumption that transformer-based deep learning models are always necessary for high-performance fake news detection.

The proposed framework highlights that carefully engineered traditional machine learning models can deliver state-of-the-art performance with significantly lower resource requirements, making them highly suitable for real-time and large-scale misinformation monitoring systems.

Future work will extend this framework toward hybrid transformer-linear architectures, multilingual datasets, and multimodal integration to further enhance robustness against evolving misinformation strategies.

A Systematic Review on Crowd Density Estimation Using Deep Learning Techniques: State-of-the-Art Methods and Future Challenges

Norah Aloufi*, Liyakathunisa Syed

Department of Computer Science-College of Computer Science and Engineering, Taibah University, Medina, Saudi Arabia

Abstract—Estimating crowd density is a cornerstone of modern urban management and public safety, particularly in the aftermath of catastrophic incidents, such as the 2015 Mina stampede. With the rapid advancement of artificial intelligence (AI) technologies, deep learning (DL) has emerged as a powerful tool for addressing these challenges. This systematic review provides a comprehensive evaluation of current crowd density estimation methodologies, analyzing model architectures, datasets, and research trends. The review was conducted in accordance with PRISMA 2020 guidelines, and the search encompassed five major electronic databases (IEEE Xplore, Scopus, Google Scholar, Web of Science, and ScienceDirect) for the period 2020 to 2025. The selection process relied on rigorous eligibility criteria, including English-language publications that offer methodological contributions or empirical assessments in the field of computer vision and machine learning (ML). Twenty final studies were included, 70% of which were published in scientific journals. The analysis revealed that 55% of the studies relied entirely on DL models, while 30% leaned towards hybrid modelling. The ShanghaiTech dataset remained the most frequently used benchmark, accounting for 50% of the studies, followed by UCF_CC_50 and WorldExpo'10 datasets. Although some models achieved a high accuracy of 99.88%, they still faced challenges in highly congested scenes and visual obstructions. This review reveals a growing shift towards edge intelligence and lightweight models to reduce latency, with a pressing need for more diverse datasets to minimize bias. This study concludes that bridging the gap between simulation and reality requires integrating contextual information and behavioral analysis to enable more reliable, proactive, and real-time crowd management.

Keywords—Crowd density estimation; computer vision; deep learning; PRISMA 2020; systematic literature review

I. INTRODUCTION

A. Context and Historical Challenges

Crowd management is a critical field of study that focuses on the organization, management, and safety of crowd events. Crowd management plays a vital role in ensuring public safety, optimally utilizing space, and managing risks associated with events like concerts, sports activities, religious activities, and public rallies. Efficient crowd management is critical in preventing accidents, but also in maximizing the overall experience of attendees. With the increased rate of mass gatherings in the world, adopting appropriate crowd management policies has been a necessity more than ever before. Efficient crowd management ensures that crises are well-handled, resources are efficiently utilized, and any potential risks are prevented

in their inception [1]. As highlighted by recent research, crowd management has become a significant part of urban planning for modern societies to enable the planning of crowd movement, counting, and the prevention of future issues [2].

Improper crowd management can lead to catastrophic consequences, including injuries, fatalities, and excessive property damage. An example of this is the 2015 Hajj stampede at Mina, Saudi Arabia, triggered by inadequate crowd management and planning, which resulted in over 2,400 fatalities, and around 400 were reported missing [3]. This tragedy highlighted the imperative for advanced crowd management systems to prevent such catastrophes. Similarly, the 2021 Astro World Festival tragedy in Houston, Texas, exposed how unscientific crowd handling can make events turn fatal, as overcrowding and inadequate emergency response led to ten deaths and many injuries [4]. Such accidents point towards the absolute need for using crowd management practices based on advanced technologies to ensure public safety. There has been recent emphasis that the failure to properly manage crowds may have devastating consequences, including loss of lives and property, along with a loss of public confidence in event organizers [2].

B. Technological Evolution in Crowd Monitoring

In recent years, technology has revolutionized the crowd management sector. Artificial intelligence (AI), internet of things (IoT), edge computing, and digital twins are a few such technologies that are being implemented to predict and manage crowd behavior more effectively. AI-powered surveillance systems have the ability to track crowd density in real time and alert the authorities of possible threats, such as overcrowding or unauthorized access [5]. Additionally, machine learning (ML) algorithms are being used to analyze historical data and predict crowd behavior, enabling proactive decision-making [2]. The IoT further enhances these capabilities by connecting a network of smart devices, such as cameras, sensors, and wearables, enabling the collection of real-time data on crowd movement and environmental conditions. This data is then processed and integrated with AI systems to provide a comprehensive view of crowd dynamics, allowing for more precise and timely interventions [6].

A critical limitation in current literature is the performance gap between controlled benchmark environments and unpredictable real-world scenarios. While many models achieve high accuracy on standard datasets, they often struggle with the dynamic complexities of field deployment, such as extreme lighting variations and dense occlusions in uncontrolled environments [7]. To address these challenges, edge computing

*Corresponding author.

plays a pivotal role by enabling local data processing on devices such as cameras and sensors, reducing latency and ensuring real-time responsiveness [8]. This is particularly important in high-density environments where immediate action is required to prevent accidents or congestion. In parallel, digital twins create virtual replicas of actual spaces, allowing organizers to simulate crowd flow and predict congestion before an event [9]. These technologies not only enhance safety but also improve the efficiency of crowd management operations.

The resolution of the problem of accurate crowd density estimation is of immediate importance as it has direct implications for public safety, resource utilization, and overall planning of large-scale events. Accurate crowd density estimation can prevent overcrowding, eliminate safety threats, and enable timely intervention in the event of an emergency. For instance, in religious gatherings like Hajj or sporting events with large crowds, real-time crowd monitoring can significantly reduce the possibility of stampedes or other disasters. Moreover, advances in technology here can enable urban planning, traffic management, and disaster response systems to be more intelligent and safer cities. By addressing the limitations of current technologies through a systematic analysis of existing studies, this review aims to support and inform the development of more efficient, reliable, and scalable crowd density estimation systems, ultimately contributing to improved safety and quality of life in dense environments.

Unlike earlier studies that mainly focused on traditional convolutional neural network (CNN) architectures [10], [11], this review provides a more contemporary analysis by categorizing methodologies into ML, deep learning (DL), and hybrid approaches. While earlier literature reviews [12], [13] offered broad overviews of crowd counting, they often lacked a systematic framework like PRISMA 2020 [14] and did not account for the rapid advancements in hybrid modeling (e.g., ConvLSTM and GANs) or the critical shift toward edge intelligence required for real-time deployment in high-density scenarios. As demonstrated in Table II, our study bridges this gap by analyzing state-of-the-art contributions from 2020 to 2025, providing a specialized taxonomy that addresses both computational efficiency and architectural complexity.

C. Objectives and Scope of the Review

Given the aforementioned challenges and limitations, this systematic review presents a structured analysis of existing approaches to crowd density estimation, focusing on datasets, computational methods, and hybrid approaches. It also aims to achieve the following specific objectives: 1) review and categorize state-of-the-art methods for crowd density estimation using ML, DL, and hybrid approaches; 2) analyze datasets and metrics used for evaluating crowd density estimation research; 3) outline strengths and weaknesses in accuracy, generalization capability, and application feasibility in real time at very high densities or occlusions; and 4) outline current research gaps and future directions for developing robust, scalable, and computational-efficiency crowd density estimation models suitable for real-world and edge computing-based deployments.

The following research questions (RQs) were formulated to address the objectives of this review:

- RQ1: How can current crowd density estimation methodologies be categorized into ML, DL, and hybrid approaches, and what are the most common architectural structures in recent literature?
- RQ2: What are the most commonly used benchmark datasets, and how do visual challenges such as overcrowding and occlusion affect the accuracy and generalization of these models?
- RQ3: What current research gaps hinder the transition from simulation-based models to actual deployment in edge intelligence environments, and what requirements are necessary to ensure real-time response?

This systematic review presents a novel analytical perspective by proposing a comprehensive taxonomy that classifies crowd density estimation techniques into ML, DL, and hybrid architectures. Distinct from a conventional survey, this research provides targeted benchmarking insights via a comparative examination of 20 leading studies (2020-2025), pinpointing the crucial accuracy–efficiency trade-offs essential for real-time edge computing applications. Through the synthesis of these methodological advancements, it formulates a strategic framework for the transition from theoretical modeling to proactive, intelligent crowd management in high-density environments, exemplified by events such as the Hajj.

II. METHODS

This systematic review was performed following the guidelines of PRISMA 2020 [14]. This not only helps to make it transparent and rigorous but also facilitates their reproduction. The primary focus is placed on crowd density estimation, with selective inclusion of closely related crowd management studies. The following subsections list the processes of searching, selecting studies, the criteria of eligibility, and extraction of data that have been used during this review. Fig. 1 shows the PRISMA flow diagram considered in this review.

A. Search and Selection Strategy

The literature relevant to the topic of crowd density estimation and managing crowd has been systematically searched. The literature search has been done on the following five major electronic literature databases: IEEE Xplore, Google Scholar, Scopus, Web of Science, ScienceDirect, and Springer. The final search for literature was done in October 2025. Articles from journals as well as papers from conferences have been considered. This will help in obtaining all the important literature available on the topic. The research strategy was designed by incorporating a set of keywords associated with crowd analysis and density estimation. The major set of keywords are “crowd density estimation”, “crowd counting”, “crowd management”, “density estimation”, and “crowd”. These keywords are combined through the help of operators (AND and OR), according to the applicable syntax in each database. The research will only contain those studies formally published in English in the years from 2020 to 2025 that directly contribute to answering the pre-defined research questions (RQ1–RQ3). The process of selecting studies was carried out by two reviewers using an independent manual study selection process. The process involved screening all the retrieved records for duplication, which was removed before proceeding with

Fig. 1. PRISMA flow diagram of the survey methodology.

the study screening. There were two stages involved in the study screening process. The first stage involved title/abstract screening, whereby all inappropriate studies in relation to the topic under consideration were removed. The final stage involved full-text screening, whereby the identified potential studies were screened against the predetermined inclusion and exclusion criteria.

B. Eligibility Criteria

Eligibility criteria are established in a way that helps cover the necessary studies in accordance with the requirements of the systematic review. The criteria consider studies that address the topic of crowd density estimation, crowd counting, or crowd management. The studies particularly target research works in computer vision or ML fields using DL or hybrid models. Only journal publications and conference proceedings that are published in 2020-2025 in English and have undergone the peer-review process are eligible. Studies were required to present a clear methodological contribution, experimental evaluation, or performance analysis related to crowd density estimation. Research that reported quantitative results, comparative analysis, or evaluation metrics was considered eligible for inclusion. Both indoor and outdoor crowd environments were included, without restriction on the application domain. The studies that were not related to crowd density estimation or crowd analysis, or that lacked sufficient methodological detail, were excluded. Studies without experimental results were excluded unless they presented conceptual or framework-based contributions with clear and meaningful methodological insights. The non-peer-reviewed papers, review papers, editorials, abstracts, theses, or papers that were not in English were also excluded. Duplicate papers or papers containing overlaps were removed, keeping the most appropriate one.

C. Data Extraction

Extraction of data was done to ensure that relevant data from studies included in this review was gathered systematically. A data extraction form was created to ensure that a high level of accuracy was achieved during extraction of the data. Data extraction was done manually by two reviewers, once eligible studies had been finalized. For each study included, the essential information extracted was the details such as (authors and year of publication, type of publication: journal and/or conference proceedings, application field, datasets utilized, methodological paradigm: conventional, DL, or combination of both, model design, and principal experimental settings). Information on performance factors, namely evaluation criteria, level of accuracy, and computation time pertaining to real-time analysis, was also considered as part of the data extraction process. In order to ensure accuracy, the extracted information was checked for consistency. If different copies or overlapping reports for the same research study were found, only the most relevant copy was used for the analysis.

III. PUBLIC DATASETS FOR CROWD DENSITY ESTIMATION

Crowd density estimation techniques are highly dependent on the availability of huge crowds with different levels of density for the purpose of benchmarking and comparing the methods used. Hence the availability of public crowd density estimation datasets plays a crucial role, enabling various comparative analyses. This section will introduce the popular crowd density estimation dataset, and then its detailed description will be provided.

A. Widely Used Datasets

Most crowd density estimation approaches have commonly relied on a set of well-established benchmark datasets, which have now almost become standard evaluation references in the literature. They are widely used due to their diversity in terms of crowd densities, challenging visual conditions, and standardized evaluation protocols. The UCF_CC_50 dataset is a cornerstone in the field of crowd density estimation [15]. The WorldExpo'10 dataset, is the largest so far for the comparison of cross-scene crowd counting algorithms [16]. The JHU-CROWD++ dataset has a massive number of unconstrained images and annotations in crowd counting and is one of the largest benchmarked to date [17]. It has been designed to address the challenges in its predecessors, and it has a huge number of 4372 images annotated with 1.51 million head annotations. The ShanghaiTech dataset, in [18], marks a leap forward in crowd counting. It was constructed in order to avoid the shortcomings of the previous datasets that had a lack of diversity in viewing angles, densities, and scenes. The SmartCity dataset is a significant scientific contribution by the researchers [19], it addresses a notable deficiency in existing databases that typically focus solely on dense crowds and outdoor scenes. The UCF-QNRF dataset marks a major step forward in dense crowd analysis literature [20]. The Beijing BRT dataset has made a great scientific contribution to intelligent transportation systems science [21]. The dataset is derived from video surveillance systems installed at Beijing's rapid transit bus stations. DroneRGBT is the first standard that focuses on crowd counting by drone with dual-mode (RGB +

Thermal) imaging, it allows for effective crowd surveillance even in complex lighting conditions like night or fog [22]. The NWPU-Crowd dataset represents the largest realistic crowd counting and positioning benchmark available to date [23].

B. Dataset Comparison and Analysis

Although the characteristics of individual crowd datasets are useful and offer insights into their corresponding crowd situations, comparison among these datasets is necessary for an analysis of their relative merits and demerits, and appropriateness for different models. This is especially true for crowd datasets, which may be sensitive to different factors, including the size of the dataset, density range, diversity of the crowd scenario, and quality of the annotation process, during training and testing stages. As a measure towards filling the current biases in crowd benchmarks, a comparison of popular crowd datasets is discussed in Table I, as well as Mall [24] and Hajjv2 [25] datasets. A sample of the crowd dataset is shown in Fig. 2.

IV. METHODOLOGIES FOR CROWD DENSITY ESTIMATION

This section presents the various ML and DL techniques used for crowd density estimation and the review of existing approaches for crowd density estimation.

A. Crowd Density Estimation ML and DL Techniques

The models used for crowd density estimation span a range of traditional ML techniques and modern DL architecture. Among the most popular:

- YOLOv3 [26], is a DL model commonly used for real-time object detection in surveillance footage.
- ResNet [27], especially with modified architectures like asymmetric convolutions, is favored for its strong feature extraction capabilities.
- CSRNet [28] is used in dense crowd counting, for its high accuracy though it is computationally heavy.
- Multi-Column Convolutional Neural Network (MCNN) [18] is another frequently used baseline that handles scale variations in crowds.
- SE-DenseNet [29] is applied for enhanced feature learning, often paired with attention mechanisms.
- DeepLabv3+ [30] is widely adopted for semantic segmentation, especially in video-based crowd mapping.
- Convolutional Long Short-Term Memory (ConvLSTM) [31] models are employed to handle temporal data by capturing spatial and time-based patterns.
- Self-Organizing Maps (SOM) [32] and Back Propagation (BP) neural networks are used in older or hybrid approaches, sometimes optimized with algorithms like genetic search.
- Lightweight models like LCDnet [33] and Single-Convolutional Neural Network with Three Layers (S-CNN3) [34] are designed for EC, balancing speed and accuracy with fewer parameters.
- Generative Adversarial Networks (GANs) [35] are used in self-learning setups to generate and refine

crowd data, particularly for varying crowd densities. These models reflect a growing shift toward combining efficiency, accuracy, and adaptability in complex real-world scenarios.

B. Traditional Machine Learning Approaches

Almutairi et al in [36] aims to address the critical challenge of effectively organizing and managing crowded events during the COVID-19 and similar crises, especially given the failure of many previous gatherings to enforce necessary restrictions (such as social distancing and mask-wearing), making them hotbeds of infection. The methodology adopted is to propose a comprehensive and sustainable framework based on ML classification models. This framework is built on lessons learned from reviewing the organization of major events such as the Hajj and Kumbh Mela during the pandemic. The framework revolves around a detailed algorithm that begins by receiving an event request and calls a smart function to evaluate it. This function includes fetching historical and temporal location data (such as wireless sensor network readings and infection numbers) and applying preprocessing operations. Common ML models such as logistic regression and support vector machines are applied, and the accuracy of these models is compared with Threshold, which represents the minimum accuracy required for a model to be accepted. The researchers' findings present the framework and algorithm as a proposed solution that could be extremely useful in mitigating the spread of the virus. The main limitations are that true validation of this framework was not conducted in this paper due to the lack of actual data. Therefore, the detailed validation metrics presented in the paper are (schemes) for future validation when a suitable dataset becomes available.

Saxena et. al in [37] sought to investigate a ML-based assistance methodology, they used a framework that relies on managing and organizing the event from the proposal stage to implementation, taking into account various factors such as the event date, time, and location including the epidemic status in the specific area. Their methodology relies on data collection from various sensors, processing, and the application of ML models such as linear regression and decision trees. The results and conclusions demonstrate that crowd intelligence, through effective crowd management, can help protect individuals and save lives in public spaces, and that the proposed COVID-19 compliant framework can be adapted to manage crowds in various types of crises. Regarding limitations, one study indicated that there was no actual validation due to the unavailability of real data, and that the presented findings were merely recommendations for future validation.

Shah in [38] sought to develop a ML model to classify crowd density in Hajj video frames into three critical levels: moderate crowd, overcrowded and very dense crowd. The aim is to address the significant challenges facing managing large annual gatherings, ensuring public safety in critical areas such as Tawaf, and mitigating the risks of disasters such as stampedes and epidemics. The authors used the Hajjv2 dataset, which contains 18 videos from key Hajj sites such as Mina, Jamarat, Arafat, and Tawaf. They applied a Gradient Boosting Classifier (GBC)-based approach, focusing on extracting structured features including local binary pattern (LBP) texture analysis, edge density, and crowd coverage to

Fig. 2. Dataset samples.

TABLE I. SUMMARY OF DATASETS USED IN LITERATURE

Dataset name	Ref& Year	Type	Size	Annotations	Average count	Resolution
Mall	[24],2012	Images	2000	62,325	31	320 × 240
UCF_CC_50	[15], 2013	Images	50	63,974	1279	Different
WorldExpo'10	[16],2015	Videos	1132	225,216	56	576 × 720
JHU-CROWD++	[17],2015	Images	4372	1,515,005	346	910 × 1430
ShanghaiTech Part_A	[18],2016	Images	482	241,677	501	Different
ShanghaiTech Part_B	[13],2016	Images	716	88,488	124	768 × 1024
SmartCity	[19],2018	Images	50	–	7	1920 × 1080
UCF-QNRF	[20],2018	Images	1535	1,251,642	815	2013 × 2902
Beijing BRT	[21],2018	Images	1280	16,795	13	640 × 360
DroneRGBT	[22],2020	Images	3600	175,698	49	512 × 640
NWPU-Crowd	[23],2021	Images	5109	2,133,238	418	2311 × 3383
Hajiv2	[25],2023	Videos	18	300,541	–	–

enhance classification accuracy. The proposed model demonstrated an accuracy rate of 87%, achieving a very low error rate of 2.14%, demonstrating its high reliability, especially in identifying “very dense” crowd conditions. The system triggers visual alerts (a red flashing indicator) in real time when these conditions are detected. Limitations noted include misclassifications between “moderate” and “dense” crowds, the need to improve real-time processing performance through hardware acceleration or model augmentation, and the potential for performance bias due to the underrepresentation of some density levels in the dataset.

C. Deep Learning-Based Methods

Crowd density estimation has seen significant advancements through the application of DL techniques, particularly CNNs. These methods have been instrumental in enhancing accuracy and efficiency across various scenarios. For instance, Z. Zhang and X. Sun in [39] propose a CNN-based model for crowd density estimation and counting, aiming to achieve a large receptive field without excessive parameters. They improve ResNet model by adding two sets of asymmetric long convolutions to replace large kernels, reducing computational costs while maintaining performance. The model is tested on ShanghaiTech, UCF-QNRF, and UCF_CC_50 datasets, showing significant improvements: on ShanghaiTech Part A, mean absolute error (MAE) and mean squared error (MSE)

score was 73.5 and 127.9, while on Part B, they were 7.7 and 12.4. For UCF-QNRF, errors reduced by 179.1 MAE and 247.1 MSE compared to MCNN, and for UCF_CC_50, by 122.5 MAE and 95.7 MSE. The results demonstrate better accuracy and stability than other methods, validated by density map visualizations and error metrics. However, the model’s dependency on labelled data and limited generalization to extreme occlusions or dynamic scenes remain challenges. The work highlights the effectiveness of asymmetric convolutions for crowd counting but acknowledges the need for further optimization in complex real-world scenarios.

Ranasinghe et al. in [40], introduced a novel approach to crowd density estimation using diffusion models, which generate high-quality density maps by reversing a noising process. Unlike traditional methods that rely on broad Gaussian kernels and suffer from noise or lost details in crowded scenes, their method employs narrow kernels to preserve accuracy. The model also leverages the randomness of diffusion to produce multiple density map variations, combining them intelligently to improve counting performance. Experiments across six datasets show significant improvements, with CrowdDiff outperforming existing methods, for example, reducing the MAE on ShanghaiTech Part A dataset to 47.4 compared to the previous best of 49.3. However, the iterative nature of diffusion models makes the method slower than real-time alternatives, and performance can still be affected by challenging lighting

or heavy occlusions. Despite these trade-offs, the approach demonstrates stronger noise resistance and better handling of dense crowds than earlier techniques.

Similarly, Ding et al. in [41], discussed a symmetric encoder-decoder CNN for crowd density estimation, focusing on multi-layer feature fusion to improve accuracy and generate high-quality density maps. They address key challenges like occlusion, perspective distortion, and complex backgrounds by combining shallow (spatial) and deep (semantic) features during encoding and decoding. Their model uses fixed Gaussian kernels for density map generation, simplifying implementation compared to adaptive kernels while maintaining performance. They introduce Patch Absolute Error (PAE), a new metric to evaluate density map quality beyond traditional MAE/MSE, emphasizing local count accuracy. Experiments on datasets like ShanghaiTech, WorldExpo'10, and UCF_CC_50 show state-of-the-art results, with MAE of 69.8 on ShanghaiTech Part A and 10.2 on Part B. The model excels in cross-scene and transfer learning achieving an MAE of 5.9 on SmartCity dataset. Limitations include sensitivity to extreme occlusions and reliance on fixed kernels, which may not adapt well to all scenarios.

Addressing the need for lightweight models, Alashban et al. [34] proposed a S-CNN3 model. They created a 3-layer CNN model to count people in crowds and estimate density, which helps manage events like Hajj or concerts to avoid accidents. They used the ShanghaiTech dataset, the largest crowd-counting dataset, with over 1000 images labeled with head positions. They tested two versions: one with 20 density classes e.g., 0-5 people, 6-10, etc. and another with 33 classes for finer details. The model achieved 99.88% accuracy and a very low loss of 0.02, exceeding deeper models like 4-layer CNNs and Switch-CNN. It works well because of its simple design and focus on classification instead of complex regression. However, it might fail in extreme crowds or new environments since it was only tested on ShanghaiTech data. Also, splitting images into patches could miss global crowd patterns.

Kamra et al., in [42], tested three DL models such as Mobilenet SSD, YOLOv4, and Mask Region-based (RCNN) using real surveillance videos with different crowd sizes. To get the data ready, they resized and flipped the images to make the models stronger during training. Mobilenet SSD was the fastest and worked well on low-power devices, but it wasn't very accurate in crowded scenes. Its accuracy ranged from 43% to 84% across different video frames. YOLOv4 gave the best overall balance between speed and accuracy, reaching up to 95% accuracy and staying reliable even when people were close together. Mask RCNN offered the most detailed results by identifying each person clearly and reached up to 92% accuracy, but it was slower and needed more computing power. In short, YOLOv4 turned out to be most useful for real-time crowd analysis. However, all models struggled in some conditions, like bad lighting or when people were blocked from view.

Addressing edge computing constraints, Wang et al., in [43], introduces a smart and efficient way to count people in crowded places using edge computing and a lightweight DL model. Instead of sending video data to cloud servers, the authors designed a special CNN that runs directly on small

edge devices like Raspberry Pi. This helps save internet bandwidth, protects people's privacy, and gives faster results. In real-world testing at a subway station in Beijing, their system worked well on Raspberry Pi 4 using real camera footage. It successfully tracked changes in crowd levels during morning rush hours. However, the model still has some limitations, like needing better handling for extremely dense crowds and reducing computational time even more.

Deokate et al., in [44], focused on improving how we count and monitor people in crowded areas using DL. They compared three different versions of the YOLO model for detecting and tracking people in video footage: 1) YOLOv3 combined with a Canny Edge detector, 2) YOLOv3 with Hungarian Algorithm and Kalman filters, and 3) YOLOv5 with OpenCV. In terms of performance, YOLOv3 with the Canny Edge detector gave the best results with 86.8% accuracy and 75% precision, meaning it was the most accurate at identifying people and had fewer false detections. YOLOv5 followed with 83.3% accuracy and 76.6% precision, while the third model, YOLOv3 with Hungarian and Kalman filters, had the lowest results: 79.2% accuracy and 70.1% precision. Although the system worked well overall, it had some weaknesses. It struggled with poor lighting, was sensitive to noise, and sometimes lost details when resizing video frames.

Wang et al., in [45], aims to enable real-time crowd density estimation and efficiently deploy this task on edge devices with limited computational resources within the framework of edge intelligence, addressing the challenge of the excessive computational complexity of traditional DL models. To achieve this, the researchers proposed a lightweight CNN model. Its architecture leverages a modified MobileNetV2 as a backbone for efficient extraction of shallow-layer features, utilizing depth-wise separable convolutions to reduce model size, and incorporates dilated convolution layers as a backend to extract deeper features and preserve spatial information. The results demonstrate that the proposed model achieved significantly faster inference speed with only a slight decrease in accuracy compared to similar methods. Regarding limitations, the researchers noted that performance was slightly worse at high density levels compared to baseline models, and that further improvements in inference speed are needed for true real-time performance on IoT devices. Zou in [46] aims to address fundamental challenges in crowd density estimation, particularly in crowded scenes characterized by significant and continuous variations in pedestrian scale within a single image, and the loss of spatial detail during feature extraction. To overcome these issues, the researchers propose a novel model called the Multi-Scale Perception Network for Dense Crowds (MSPN-DC), which utilizes the first 10 layers of VGG-16 as a backbone for initial feature extraction. Experimental results demonstrate that the proposed method outperforms other state-of-the-art approaches on challenging benchmark datasets (such as UCF-CC-50 and UCF-QNRF), achieving the best performance on the NWPU dataset with its wide range of pedestrian densities, thus demonstrating its robustness and good stability. However, the researchers acknowledge a slight performance decline in MAE on the dense ShanghaiTech Part-A dataset compared to the best-performing methods, attributing this to the significant background clutter in this dataset

D. Hybrid Models

Incorporating geographic information systems (GIS), Zhang et al., in [47], presented a Crowd Density Estimation and Mapping Method based on Surveillance Video and GIS (CDEM-M), a method for crowd density estimation and mapping by integrating surveillance video with GIS. They first developed a Crowd Semantic Segmentation Model (CSSM) using DeepLabv3+ and a Crowd Denoising Model (CDM) via CNN, achieving 96.7% segmentation accuracy and 86.29% noise removal accuracy. Using a homography matrix, they project crowd areas from video to geographic space, accounting for perspective distortions ("near large, far small"). Key innovations include GIS integration for unified visualization and the use of whole-body features (not just heads) for better accuracy in high-altitude views. Limitations include dependency on fixed camera angles and challenges with individual-group mixed scenes. The approach is practical for large venues like stadiums but requires further refinement for broader applications.

In the context of smart cities, Mansouri et al., in [48], propose a DL system called Deep Convolutional Neural Network-based Crowd Density Monitoring for Intelligent Urban Planning (DCNNCDM-IUP) to monitor crowd density in smart cities using Closed-Circuit Television (CCTV) and IoT sensors. Their goal is to improve urban planning and public safety by analyzing crowd movements in real time. To optimize performance, they use Red Fox Optimization (RFO) to fine-tune hyperparameters and ConvLSTM network to classify crowd density into four levels e.g., dense, sparse by analyzing both spatial and temporal data. They tested the system on a dataset of 1,000 images, the model achieves 98.4% accuracy, outperforming methods like GoogleNet and VGGNet. It's also faster, processing images in 9.8 seconds versus 15–21 seconds for other models. However, it struggles with extremely crowded scenes and relies heavily on the training dataset, which may limit real-world adaptability.

Exploring self-learning algorithms, Zhang et al., in [49], propose a self-learning soft computing system to predict crowd density using IoT sensors and AI. Their goal is to prevent overcrowding in places like airports or tourist spots. The system uses GANs to analyze video data from smart cameras. The model was tested on datasets like Shanghai-Tech and UCF_CC_50, achieving a low MAE of 290, better than previous methods discussed in the paper, and 93 on Shanghai-Tech Part A. It also processes data faster e.g., 9.8 seconds per image. However, training the GANs takes a long time, and the system struggles with extremely dense crowds. The authors suggest improving real-time performance and hardware compatibility in future work.

Focusing on social distancing, Fitwi et al., in [50], introduced a new system called E-SEC, which helps estimate how far apart people are from each other and how crowded a space is, using only one camera. They use a single CCTV camera and apply a DL model called YOLOv3 to detect people in video frames. Their system gives real-time feedback, including alerts if people are too close to each other. They tested it using real videos and public datasets, and the results showed over 99% accuracy when the camera were properly setup. However, one limitation is that the system needs a good camera angle, proper height, and clear line of sight and may not perform

accurately if people are directly under the camera or blocked by others. Still, E-SEC offers a low-cost and accurate solution for monitoring social distancing and crowd behavior using just one camera.

Zhu et al., in [51], aims to address the problem of crowd density estimation and counting in both sparse and dense crowd scenarios, overcoming significant challenges such as occlusions, non-uniform density, and scale and perspective variations caused by cameras capturing images from different distances and angles. To solve these problems, the researchers propose a two-stage approach called Patch Scale Discriminant Regression Network (PSDR) coupled with a Person Classification Activation Map (CAM). Their results demonstrate that the proposed method (PSDR + CAM) outperforms state-of-the-art methods, especially in sparse/moderate density scenes, achieving an improvement on the SmartCity dataset by reducing the MAE error from 8.6 to 7.5. Regarding limitations, the researchers acknowledge that their method performed slightly worse in highly dense scenes (such as ShanghaiTech PartA and UCF_CC_50) compared to the best methods in that category.

Alzahrani and Algethami, in [52], aimed to address the challenges facing optimal Hajj crowd management. High crowd density within specific temporal and spatial constraints renders traditional methods insufficient for providing immediate alerts or predictive preventive measures. The authors sought to develop a ML-DL based system to enhance crowd management by detecting anomalies and predicting future conditions. To address this problem, an integrated framework was proposed that utilized the Hajjv2 dataset, which contains annotated video frames of crowd behavior. The methodology involved extracting key features such as crowd density, movement speed, direction, and object space, applying an Isolation Forest algorithm to detect anomalies in real time, and using an Long Short-Term Memory (LSTM) neural network to predict future crowd behavior trends. The outputs of the two models were then combined to create a hybrid alerting system that triggers immediate (anomalies) or proactive (forecast) warnings when the prediction error exceeds an empirically defined threshold (95th percentile). The results showed that the Isolation Forest model achieved an average accuracy of 91% in identifying abnormal movement patterns. The LSTM model also achieved reliable predictions of average crowd speed with a low mean square error (MSE) of 0.000439, demonstrating the proposed system's potential to enable proactive and informed crowd management strategies. Regarding limitations, the authors note that the system was tested on a simulated dataset Hajjv2 rather than in a live deployment. The alert system currently relies on empirical thresholds that may need to be dynamically adjusted in a real-world environment

The DCNNCDM-IUP in Fig. 3 and E-SEC in Fig. 4 models are considered the best based on the literature for combining high efficiency and superior accuracy. The DCNNCDM-IUP model comprises sequential technologies, including Gaussian filtering for image cleaning, SE-DenseNet for feature extraction, RFO for parameter optimization, and a ConvLSTM network for spatial and temporal density classification. Its advantage lies in its accuracy of up to 98.4% and its high speed (9.8 seconds), which surpasses standard models such as GoogleNet. The disadvantage, however, lies in its difficulty in handling scenes that are extremely crowded and its reliance

TABLE II. COMPARATIVE ANALYSIS OF RELATED STUDIES

Technique	Ref & Year	Models	Datasets	Key findings	Limitations
ML	[36],2022	Common ML classification models	There is no real data to verify	Based on standard metrics for future verification	No real validation
ML	[37],2022	Traditional ML approaches	N/A	The system can track entry and exit numbers and determine occupancy levels	Poor data quality and insufficient training data
ML	[38],2024	Gradient Boosting Classifier (GBC)	Hajjv2	Accuracy: 87%, Low misclassification rate: 2.14%	Misclassification between moderate and heavy crowds. Real-time performance needs hardware acceleration.
DL	[39],2020	Improved ResNet-based model	ShanghaiTech, UCF-QNRF, UCF_CC_50	MAE: 97.9, MSE: 178.9	Performance is not good in very dense scenes or complex backgrounds
DL	[40],2023	Conditional diffusion models for generating density maps	JHU-CROWD++, ShanghaiTech, UCF_CC_50, UCF-QNRF, NWPU-Crowd	MAE: 5.7	Higher inference time due to the iterative nature of diffusion models
DL	[41],2021	CNN	ShanghaiTech, WorldExpo'10, Mall, UCF_CC_50, SmartCity, Beijing BRT	MAE: 1.36, MSE: 2.02	Data labeling errors, especially in high-density areas
DL	[34],2022	S-CNN3	ShanghaiTech	Accuracy: 99.88%	The difficulty of classification increases dramatically as the number of classes increases
DL	[42],2024	Mobilenet SSD, Yolov4, Mask RCNN	N/A	Accuracy: 95%	Affected by environmental factors and blockages
DL	[43],2021	ResNet50	ShanghaiTech	MAE: 11, RMSE: 17.6	Resource intensive compared to the capabilities of the edge
DL	[44],2024	YOLOv3	ShanghaiTech, UCF_CC_50, WorldExpo'10	Accuracy: 86.8%, Precision 75%	Inadequate handling of occlusions, leading to underestimation of density
DL	[45],2022	MobileNetV2	ShanghaiTech	MAE: 10.1, RMSE: 17.1	Limited computing resources of peripheral devices
DL	[46],2025	VGG-16	UCF_CC_50, UCF-QNRF, ShanghaiTech	MAE: 156.6, RMSE: 223.4	Background interferences
Hybrid	[47],2023	CSSM (DeepLabv3),+ CDM (CNN), and GA-BP NN	Images	CSSM accuracy 96.70%,CDM accuracy 86.29%, BP network average error 1.2	Suitable only for high altitude viewing
Hybrid	[48],2025	SE-DenseNet + ConvLSTM	N/A	Accuracy 98.4%	Rely on a fixed group size and a fixed learning rate, not optimal for dynamic problems
Hybrid	[49],2021	SFL-GAN + SFL	Custom dataset, UCF_CC_50, ShanghaiTech	MAE: 93	Density maps are blurry and of poor quality when using traditional regression loss. The network takes a long time to train
Hybrid	[50],2021	Modified YOLOv3 + E-SEC	Custom dataset, COVID-19, BriefCam, PETS2009	Personal distance calculation accuracy of over 99%	Cameras must be mounted at a height of at least 3 meters
Hybrid	[51],2020	PSDR + CAM	SmartCity, ShanghaiTech, UCF_CC_50	MAE: 7.5, MSE: 10.2	Worse performance in dense scenes
Hybrid	[52],2025	Isolation Forest + LSTM	Hajjv2	Accuracy: 91%, MSE: 0.000439	Tested on simulated data (Hajjv2) not live deployment

on training data, which may limit its practicality. The E-SEC model consists of the YOLOv3 system for detecting people and the “Pixel Per Metric” technology for estimating distances based on the average width of the human body. It is characterized by exceptional accuracy exceeding 99% and a low cost, as it utilizes only one camera without the need for physical measuring tools. Its disadvantages are highlighted by its need for a specific camera angle and height, as well as a clear line of sight, since its performance weakens if people are directly below the camera or if there are obstacles that obstruct the view.

V. CHALLENGES, LIMITATIONS, AND FUTURE RESEARCH

The major challenges encountered in crowd density estimation are presented in this section, based on the literature review of Section IV and comparative analysis presented in Table II. Collectively, this research review emphasizes the diverse

approaches and ongoing challenges in crowd density estimation, highlighting the balance between accuracy, computational efficiency, and adaptability to varying real-world scenarios. Common limitations of research on crowd management and density estimation using ML and DL primarily center around three core challenges such as data inadequacies and validation, poor robustness of algorithms to visual and environmental complexity, and real-time performance and computational efficiency challenges.

- Lack of data quality and real-time validation is a key limitation. Some proposed frameworks rely on simulated datasets such as Hajjv2 or data with limited representation of specific scenarios or density levels, limiting the generalizability of models and leading to potential classification bias. Poor data quality itself is also a challenge, as are the potential for data labelling errors, especially in densely populated areas.

Fig. 3. The framework of DCNNCDM-IUP technique.

Fig. 4. The framework of E-SEC model.

- Visual and environmental challenges are the most common, with models failing to handle high-density scenes and facing severe occlusion, which often leads to underestimation of actual density. The constantly changing scale of the target and perspective effects also pose a significant challenge, requiring continuous processing to minimize the loss of spatial information, especially in high-altitude observation scenes where head features are less clear.
- Furthermore, the accuracy of algorithms is affected by environmental factors such as complex background interference, varying lighting changes, and image blur.
- Finally, performance and efficiency challenges arise, as many DL models are characterized by excessive computational complexity and a large number of parameters, which reduces real-time performance and causes unbearably high inference delay. This limitation is critical when attempting to deploy on-edge devices with limited storage and compute resources.

Furthermore, complex models such as GANs can be time-consuming during the training phase, and certain techniques such as dilatational convolution can lead to the gridding problem and loss of local information. Despite the significant advancements made by ML and DL techniques in crowd density estimation, the path to fully autonomous and intelligent monitoring systems remains fraught with fundamental challenges related to data quality and modelling methodologies.

A. Challenges in Datasets

Datasets are the cornerstone and essential engine that enables DL models to reason, but systematic examination of these datasets has revealed technical and organizational gaps that limit the models’ ability to simulate complex realities. The most prominent of these challenges are as follows:

- **Lack of diversity and comprehensiveness:** The review reveals an over-reliance on standard datasets such as ShanghaiTech, which can lead to model biases toward specific environments. Current datasets lack diversity in scenarios, focusing either on multi-million-strong crowds or dispersed urban scenes, rendering models unable to adapt to sudden shifts in density within a single scene.
- **The gap between simulation and reality:** Some studies rely on simulation data (such as Hajjv2) to compensate for the lack of field data, but this creates a “realism gap”. Virtually trained models fail to handle the complexities of real-world lighting or harsh weather conditions (such as fog and rain) available in assemblies like JHU-CROWD++.
- **Challenges of annotation and human effort:** Manual annotation remains a significant obstacle to building large assemblies. Assemblies like UCF-QNRF require thousands of hours of human labor. The likelihood of annotation errors also increases in densely populated areas, directly impacting the accuracy of density maps.
- **Future direction:** There is a pressing need to develop “cross-domain datasets” that combine optical and thermal imagery (such as DroneRGBT) to enable nighttime surveillance. Furthermore, “intelligent annotation” or semi-supervisory learning should be pursued to reduce reliance on arduous human effort.

B. Challenges in ML and DL Models

Despite rapid advancements in neural network models, crowd density estimation still faces fundamental technical and methodological challenges that prevent achieving absolute accuracy in dynamic and real-world environments. The most prominent of these challenges are as follows:

- **Accuracy vs. Computational Efficiency Dilemma:** The “critical balancing act” challenge arises between large-scale models (such as CSRNet) that achieve high accuracy but are computationally intensive, and lightweight models (such as LCDnet and MobileNetV2) designed for edge devices. Currently, the processing speed of devices like the Raspberry Pi remains a limitation for real-time emergency response.
- **Optical Complexity and Severe Occlusion:** The problem of “occlusion” and object overlap remains a major obstacle, as models tend to underestimate the actual numbers in very compact crowds. Furthermore, the “perspective effect” at high angles leads to the loss of fine vertices detail, which confounds traditional algorithms.

C. Future Research Directions

Research is moving towards “edge intelligence” to reduce reliance on cloud, focusing on attention mechanisms that enable models to distinguish humans from background “visual noise”. Most current research remains confined to the “counting task” alone, lacking the ability to understand the context of movement. Issues such as detecting anomalous behaviors or predicting bottlenecks before disasters (as seen in the Mina) still require the integration of complex temporal and behavioral data. Integrating density estimation with spatial analysis (GIS) and trajectory prediction systems (LSTM) to provide proactive insights for crowd management, rather than simply monitoring cold, hard numbers. The future lies in creating an integrated ecosystem that links realistic and diverse datasets with hybrid algorithms that combine the accuracy of DL with the logic of behavioral analysis, to ensure the highest levels of public safety at major events

VI. CONCLUSION

This systematic review of the PRISMA 2020 guidelines aims to analyze and classify contemporary methodologies for estimating crowd density and developing intelligent management systems that prevent tragic disasters, such as the 2015 Mina stampede and the 2021 Texas incident. By examining 20 peer-reviewed studies published between 2020 and 2025, it was found that there is a significant reliance on standard datasets for model evaluation, with the ShanghaiTech dataset leading the way, used in 50% of the studies, followed by the UCF_CC_50, NWPU-Crowd, and UCF-QNRF datasets, which provide a variety of viewing angles and numerical densities. The results revealed the dominance of the DL models at 55% and a trend toward hybrid models at 30%. Software architectures, such as S-CNN3, achieved an exceptional accuracy of 99.88%, while lightweight models such as LCDnet and MobileNetV2, designed specifically for edge computing, emerged to minimize latency and provide real-time monitoring on resource-limited devices.

Beyond the theoretical synthesis, the findings of this review carry significant practical implications for real-world crowd management and urban safety. For practitioners and engineers, the transition toward hybrid models and edge intelligence, as identified in our analysis, provides a technical baseline for developing low-latency surveillance systems capable of immediate intervention in high-density zones. For policymakers and urban planners, the shift from reactive counting to proactive density estimation supported by digital twins and real-time AI offers a strategic framework for designing safer public spaces and optimizing resource allocation during mass gatherings. Furthermore, by addressing the gap between benchmark accuracy and field reliability, this research provides the academic community with a clear roadmap for developing more robust, context-aware architectures. Ultimately, these insights serve as a catalyst for advancing smart city initiatives where automated, scalable crowd monitoring becomes a cornerstone of public safety and operational efficiency.

Despite this technological advancement, significant challenges remain. Models often underperform under severe occlusion and complex environmental conditions, such as fluctuating lighting and fog, frequently resulting in underestimating numbers in very dense crowds. Current research also suffers from a

“realism gap” due to an over-reliance on simulation data (such as Hajjv2) or static images from the internet, which limits the models’ ability to generalize to dynamic field situations. Therefore, the review concludes that future trends should go beyond mere digital counting to include behavioral analysis and proactive detection of abnormal patterns, with the need to develop more comprehensive datasets and expand the use of attention mechanisms and self-learning to ensure the accuracy of density maps and the sustainability of public safety systems in smart cities.

ENSAM, Mohammed V University in Rabat, Morocco²

Abstract—For human parsing in wild and cluttered environment, deep architectures are widely utilized since they yield strong segmentation performance, while with the price of huge model size and computational complexity. These properties are highly limiting for them if to be deployed on resource-limited platforms, in particular for edge intelligence in real-time. In this study, we propose a lightweight framework for human parsing, named *Fast DSPP+PGN+Attn*, which focuses on the efficiency-accuracy trade-off. The proposed model consists of a MobileNetV2 backbone (i.e., the AirLab-Net), a Dilated Spatial Pyramid Pooling (DSPP) block to capture multi-scale contextual information, a pixel grouping decoder employing the PGN for improved part boundary flow consistency and potency spatial and squeeze-and-excitation attention modules are used for feature refinement. However, the model with a relatively compact size—i.e., 2.14M parameters and 5.70 GFLOPs— could achieve the performance of 40.67% mean IoU (mIoU) and 87.3% pixel accuracy on the CIHP benchmark, while running at a speed of 51.9 frames per second on a single GPU. These findings indicate that combining the contextual aggregation methods with the method of structured pixel grouping is a strategy to exploit orthogonal avenues and cross-examine their complementarity, more efficiently and potentially achieve better segmentation quality without lost of real-time performance. Therefore, the proposed method can be widely applicable in embedded vision system, surveillance and mobile perception.

Keywords—Human parsing; lightweight networks; multi-scale representation; edge computing; real-time segmentation

I. INTRODUCTION

Semantic segmentation is an essential task in computer vision. It assigns a semantic label every pixel of an image to aid in fine-grained scene understanding [1], [2]. In this work, lightweight refers to models with single-digit GFLOPs, fewer than 5M parameters, and real-time inference on commodity GPUs or edge hardware. For human-centric applications, such as surveillance, behavior analysis, crowd monitoring, as well as AR/VR applications, this job—also known as human parsing - is crucial to finding out the precise human body components and categories of clothing in complicated and chaotic situations. The deep convolutional networks (CNNs) and encoder/decoder structures like U-Net, DeepLab [3], [4] have seen great ensures in segmentation ability by combing global semantic context and superior spatial resolution.

Aligned with these developments, current human parsing algorithms mostly adopt heavy backbones (e.g ResNet 101, HRNet, Swin Transformer) which contains tens of million parameters and also large computation footprints. The mIoU of these models on CIHP, as one of the most difficult datasets, is generally in 40-60% and uses 100-300 GFLOPs per image with

a high latency [5] [6]. Despite this, the complexity limits their applicability to real-time implementations such as edge devices and mobile hardware where power and memory constraints are critical [7].

Conversely, lightweight models tend to be ineffective when faced with large occlusions, people who overlap as well as complex body-part boundaries [8]. Receptive fields that are not as large and capabilities of the feature hinder their ability to understand multi-scale contexts and maintain sharp boundaries and lead to distorted or incorrect predictions [9]. Therefore, the main challenge is to create a compact but accurate human parsing system capable of working effectively in real-world scenarios and on hardware with limited resources [10].

In this study, we present *Fast-DSPP+PGN+Attn*, a new architecture that incorporates three important components - DSPP (Dilated Spatial Pyramid Pooling), PGN (Part Grouping Network) inspired pixel grouping and dual attention mechanisms inside the light-weight MobileNetV2 backbone. by such operations is effective in capturing multi-scale contexts, which helps to improve the spatial coherence in occluded situations at one hand and focus more on the human regions by suppressing non-human patterns on the other hand with a low computational cost. This particular combination is highly performant in comparison to other state of the art models based on large, computationally expensive models. The presented system provides a good compromise between efficiency and accuracy, with state-of-the-art performance when considering the compact model size, as well as its real-time inference requirement [11].

Using a simulation of the Crowd Instance-level Human Parsing (CIHP) dataset, *Fast DSPP+PGN+Attn* reaches 40.67% mIoU and 87.3% accuracy, with a real-time speed of 51.9 FPS, despite just 2.14M parameters, and 5.70 GFLOPs. This balance of accuracy and efficiency is a strong proof that the combination of contextual pixel grouping together with DSPP along with dual-attention greatly improves segmentation accuracy in busy environments and is accessible on devices with edge capabilities.

The major contributions of this study are listed below:

- We present a unique ultra-lightweight human parsing model which integrates dilated multiscale context encoder (DSPP) as well as spatial grouping based on PGN, and dual attention in a single MobileNetV2-based encoder-decoder.
- We present a boundary-aware encoder that analyzes pixel affinities in the influence of occlusion, thereby

improving structural consistency and the delineation of the human body's parts that overlap, an aspect with which many light models have trouble.

- We show an exceptionally favorable balance between accuracy and efficiency and achieve 40.67 percent mIoU, using just 2.14M parameter values and 5.70 GFLOPs. We outperform comparable baselines that are lightweight while achieving speed in real time (50 FPS).
- We offer an extensive range of qualitative, quantitative and component-level analysis, such as the training patterns, dynamics, per-class IoUs attention visualisation, multi-scale feature response, to demonstrate how each component can impact the overall performance.

Despite the progress of multi-scale context aggregation and lightweight backbones, a critical gap remains between efficiency and structural accuracy in human parsing. Existing multi-scale architectures, such as DeepLab variants, rely on heavy backbones and large receptive fields, leading to high computational cost unsuitable for edge deployment. Conversely, lightweight models based on MobileNet or similar architectures achieve real-time performance but often fail to preserve fine-grained boundaries and local consistency, especially under occlusion and crowding conditions.

Moreover, prior works typically address either global context aggregation or local boundary refinement in isolation, without explicitly modeling their complementarity. As a result, lightweight models often suffer from fragmented predictions, while heavy models remain impractical for real-time applications.

Wise to the backbone, MobileNetV2 compact architecture was redesigned, while multi-scale context aggregation (DSPP), boundary-awareness pixel grouping (PGN inspired) and lightweight attention mechanisms (CBAM) are introduced accordingly. This design directly addresses the trade-off between accuracy and efficiency with the goal of providing strong human parsing performance under tight computational constraints.

The remainder section of the study is structured in the following manner: Section II reviews the similar research. Section III outlines the proposed method. Section IV presents the research results, as well as a discussion. Section V closes out the research and discusses the future research directions.

II. RELATED WORKS

In the constant development of deep-learning methods, semantic segmentation has made remarkable strides in the last decade [10]. The first segmentation methods relied heavily upon hand-crafted elements and conventional machine learning classifiers to provide the interpretation of pixels [12]. Although these techniques were revolutionary in their day but they were severely limited when it came to dealing with the complexities and ambiguities of real-world scenes [13]. One of the major limitations of these methods was their limited ability to understand dependencies among the various regions of an image and their limitations in situations [14] that demanded a more thorough comprehension of content, as well as the spatial context [5].

Fully Convolutional Networks (FCNs) were a significant turning point in the development of the field known as semantic segmentation [13]. Unlike classifier-based patchwise CNNs that considered subregions of matching dimensions separately, FCNs allowed for end-to-end learning from initial pixels. [13]. This change of architecture allowed models to learn more complex representations and to solve dense prediction problems, resulting in state-of-the-art performance on many benchmarks [2] [3]. However, FCNs can't perform well in multiscale reasoning and often end up with blurred object boundaries due to their narrow receptive field and the slow downsampling rate. Bottleneck of receptive field reciprocity To solve the bottleneck, dilated (or atrous) convolutions were proposed [15] to increase the receptive-field size and generalization capability by using atrous con. By introducing dilation gaps into Convolution kernels, the models can increase the size of the receptive field, while reducing the parameters [5]. This allowed networks to collect fine-grained detail as well as long-range context at the same time which is crucial in complicated scenes [7]. The DeepLab family of architectures as well as the related ones paved the way for the use of convolutions with dilated coefficients in conjunction with pyramid pooling, which allows an efficient multi-scale feature aggregation [8].

Encoder-decoder technology, such as U-Net, also brought further advances through explicit coupling upsampling and downsampling pathways [1] [7]. These skip connections permit the first high-resolution features to be combined with deeper semantics, enhancing the ability to locate boundaries [6]. These structures quickly became the basis for a variety of segmentation tasks including medical imaging as well as Human Part Segmentation [16]. Later variations included depthwise separable convolutions [17] - inspired by lighter backbones, such as MobileNet and ShuffleNet [18] [19] - to reduce the computational cost while still delivering high performance.

Human parsing is more challenging than semantic segmentation. Typically, the scenes consist of multiple interacting people with different poses including strong occlusions and similar/overlapping looking legs. Although this CIHP dataset become a benchmark for parsing crowded human, it has some limitations. Other more complex models based on the PG Network (PGN) [7] were proposed to analyze pixel affinities and instances-level relations for better handling the overlapping or occluded body part [20]- [21]. Recent works have extended the application ranges of utilizing contextual encoding and Cross-scale feature fusion but heavily lean on large backbones and complicated decoders which lead to overall computational burden [22] [23].

However, despite their accuracy they are not practical for real-time or situations with limited resources. For edge deployment, light designs built upon MobileNet or other designs with depth are the best choice [23]. These designs aim to strike a balance between speed, accuracy and memory efficiency [24]. This is an essential necessity for applications like autonomous systems, mobile devices and surveillance where power and latency restrictions are essential.

Our work is located in this area. In adopting an MobileNetV2 encoder, further enhancing it by incorporating the DSPP context-based module, as well as then integrating the PGN-inspired grouping coder, with focus on light weight, we demonstrate that a small model can maintain useful accuracy

for humans parsing CIHP while retaining high-quality performance in real time that can be used on devices with edge capabilities.

In conclusion, human parsing methods can be divided into three main categories with their own advantages and disadvantages:

First, high accuracy of segmentation is obtained in heavy multi-scale architectures like DeepLab-style networks [5], [8], [15] and more recent context-aware networks [21],[23] which benefit from dilated convolutions and pyramid pooling. These methods effectively capture contextual information from the entire image and long-distance dependencies, both of which are important in crowded scenes. But they depend on large backbones and complex decoders, which leads to high computation cost (100 GFLOPs or more), as well as an explosive number of parameters, which is not friendly for real-time deployment on edge devices.

Second, simple encoder-decoder networks with MobileNet or other very efficient backbone [13], [22] reduce computation by utilizing depthwise separable convolutions. These methods are very suitable for real-time scenarios thanks to high inference speeds and lower memory consumption. Such networks, however, have limited receptive fields and simplified spatial feature responses leading to poor ability for fine object boundary delineation and multi-scale reasoning (especially in the case of occlusion or overlapping persons).

On the other hand, several affinity-based and grouping-guided approaches such as PGN-like methods [7], [20] explicitly capture pixel-wise relationships to enhance structural accountancy and instance separation. Such approaches are useful for preserving segment boundaries and dealing with occlusions by learning pixel affinities. However, they bring extra computation costs and are usually merged with more complicated architectures that can prevent them from being used in light-weight setups.

While they all have their own benefits, none of these categories meets the joint needs for multi-scale contextual information modeling, boundary-aware refinement, and strict computational efficiency. Specifically, prior works tend to treat these properties separately, ignoring their potential complementarity within a unified lightweight design.

Taking it further, the proposed Fast-DSPP+PGN+Attn model aims at achieving this balance via multi-scale context aggregation (DSPP), pixel-level grouping (inspired by PGN), and lightweight attention inside a MobileNetV2 backbone. This integration approach allows the model to capture global context, enforce local consistency and minimize computational complexity, simultaneously, in contrast with previous work, which makes it suitable for real-time edge deployment.

III. METHODS

The Fast-DSPP+PGN+Attn algorithm is based on an encoder-decoder model improved by dilated multi-scale context and explicit pixel grouping. It uses MobileNetV2 as the backbone for its encoder which is truncated at stride 16 and trained on ImageNet. Decoder uses 3x3 convolutions with the channel sizes 64 for shallow, and deeper 128. These kernel

sizes have been selected based on a balance between complexity and ability to detect fine details at boundary interfaces. The fusion operator is simply concatenating the encoder feature maps and output of dilated spatial pyramid pooling (additionally processed with 1x1 convolutions to reduce channel count). Through pixel grouping based on pattern generation (PGN), we enforce local consistent constraints along edges, and can handle occlusion properly as well as clutter background.

In order to better understand the flow of data, as previously mentioned, the proposed architecture is a linear pipeline Starting with an input image that has dimensions of 384x384x3, the MobileNetV2 encoder generates hierarchical feature maps at different levels. Next, we lead a high-level feature map of spatial resolution $H/16 \times W/16$ to the DSPP module, which implements parallel dilated convolutions with different dilation rates (1, 6, 12, and 18 pixels) to capture multi-scale contextual information.

The outputs of the DSPP branches are concatenated together and reduced with 1x1 convolution for channel reduction. This enriched feature representation is then fused with low-level encoder features through skip connections. The decoder processes these fused features using depthwise separable convolutions to maintain computational efficiency.

A PGN-inspired pixel grouping mechanism is applied to enforce local consistency by modeling pixel affinities in a 4-neighborhood graph. Additionally, two attention modules are introduced: 1) a spatial attention module applied after DSPP to emphasize human regions, and 2) a squeeze-and-excitation (SE) block applied to skip connections to recalibrate channel-wise responses.

Finally, the decoder upsample the feature maps to the original resolution and produces pixel-wise class predictions through a softmax layer.

In addition to the encoder feature map, the Dilated Spatial Pyramid Pooling (DSPP) module integrates multi-scale context with parallel dilated convolutions, as well as general image pooling. The dilation ratios for DSPP block were heuristically selected via empirical experiments in previous studies and the experimental results on CIHP. Dilation rates were chosen to compromise between the fine details (low dilation rates) and distant context (high dilation rates). The last configuration was proved to achieve the most superior CVG performances in CIHP with respect to crowded and complex human parsing. The network can have both local details and global context dynamically. The decoder increases the size of these enriched features, while combining them with the early high-resolution functions by using skip connections and an PGN-inspired grouping stage. Two lightweight attention mechanisms—a spatial attention block applied to the DSPP output and a squeeze-and-excitation (SE) block applied to the skip connection—guide the network towards human regions and suppress background clutter. All decoder convolutions can be constructed as separable depthwise convolutions in order to minimize the computational cost. Before describing each element, we present an overall diagram of the overall architecture to show the way in which the encoder, DSPP module, decoder and attention mechanisms interplay. Fig. 1 illustrates the entire Fast-DSPP+PGN+Attn workflow, which runs beginning with the input image and moving to the

backbone of MobileNetV2, and DSPP context aggregation, and finally the PGN-inspired decoder, which outputs twenty-class logits of human processing, which are at the initial resolution.

The proposed pixel grouping mechanism, PGN, is to learn the pixel affinities from affinity graph built upon the spatial and semantic similarity of neighboring pixels. The neighborhood is described by the 4-connected region around each pixel and pixel similarities are weighted with a Gaussian kernel function, which gives higher weight to pixels that appear in both spatial space and feature space. This graph is exploited to impose local coherence along object boundaries, especially in occluded regions.

Fig. 1. Overview of the proposed Fast-DSPP+PGN+Attn architecture. A MobileNetV2 encoder feeds a DSPP context module. A PGN-inspired decoder with SE-enhanced skip connections and spatial attention produces 20-class human parsing logits at input resolution.

The implementation takes place by TensorFlow 2.13 making use of Keras functional APIs. The entire process from data loading to assessment is intended to be completely reproducible. For ease of understanding, we summarize the high-level training and inference process before diving to the module-level details. The key steps are: splits of the dataset, construction of models (encoder, DSPP, decoder and the attention module) optimization using the composite loss method, and single-pass inference of new images. Algorithm 1 provides a step-by-step explanation of this process, providing details on the process of how you can understand how CIHP dataset is divided and how the Fast-DSPP+PGN+Attn model is constructed and optimised along with how the model is used to create human-like parsing predictions during the time of testing.

The MobileNetV2 encoder serves to extract features in our system, and has a width multiplier of 0.75 and pre-trained ImageNet weights. We make sure that the network remains light by truncating it to an output length. Based on this, we get two important feature maps that are low-level maps from a layer that is early, that preserves the fine spatial details, as well as a high-level map from a more advanced layer that contains an abundance of semantic data. In reality, both maps are extracted straight from MobileNetV2 model, using the relevant layers in Keras. The encoder process the image input ($384 \times 384 \times 3$) by a series of convolutions that are standard with inverted blocks gradually reducing the spatial resolution

Algorithm 1 Training and Inference Pipeline for Fast-DSPP+PGN+Attn

Require: CIHP image paths $\mathcal{I}$, mask paths $\mathcal{Y}$, image size 384×384 , batch size $B = 8$, epochs $E = 50$

- 1: Split $(\mathcal{I}, \mathcal{Y})$ into training (28 000 images) and validation (8 000 images)
- 2: Build **MobileNetV2 encoder** (stride 16, $\alpha = 0.75$), **DSPP** module, **PGN-like decoder** with SE and spatial attention
- 3: Initialize Adam optimizer with cosine decay restarts; define loss and mIoU metric with ignore label 255
- 4: **for** epoch = 1 to E **do**
- 5: **for** each mini-batch (X, Y) in training set **do**
- 6: Apply on-the-fly augmentation to (X, Y)
- 7: Forward pass through encoder, DSPP, decoder $\rightarrow \hat{Y}$
- 8: Compute loss $\mathcal{L}(Y, \hat{Y})$ and update network parameters
- 9: **end for**
- 10: Evaluate mIoU and pixel accuracy on validation set
- 11: Update early stopping and model checkpoint based on best validation mIoU
- 12: **end for**
- 13: **Inference:** For a new image, resize to 384×384 , forward pass through model, take arg max over class logits to obtain segmentation mask.

and increasing the quality of the representation. These two feature maps constitute the inputs to the DSPP contextual module, as well as decoder. This allows the network to mix precise detail with high-level context to allow for precise human parsing.

A. Training Protocol and Implementation Details

The proposed Fast-DSPP+PGN+Attn Network from end-to-end the CIHP human parsing dataset by using a simple, efficient pipeline. All images that are input are changed in size so that smaller sides are set at 384 pixels. After that, a random 384×384 crop is taken during the training. When inference is completed it is a single centre crop with the same resolution is utilized with no multi-scale testing or horizontal flipping. This is done according to the standard CIHP testing protocols [25].

Center cropping in single-scale was used at inference, since it is consistent with CIHP's testing protocol, and in near future works multi-scaling will be analyzed crop for more off-center or densely crowded human instances as encountered in many practical settings. This would make inference more robust and the spatial coverage better.

The model is optimized with the Adam optimizer, with an initial learning rate of 5×10^{-4} . It is then reduced using a cosine annealing schedule for 50 times. The batch of 8 is utilized during training. A lightweight data augmentation pipeline was employed to boost the model robustness. This is accomplished with random horizontal flips (probability=0.5), scaling jittering by both $\pm 50\%$ in the range $[0.75, 1.25]$ and to crop at 384×384 pixels scales randomly. A mild color jittering (brightness, contrast and saturation) was also applied with a probability of 0.3. Augmentation operations were applied in the order which they had been specified: scaling jittering was

always first, normal horizontal flips after that, and cropping last. It keeps the model exposed to a variety of scenarios, while preventing overfitting on specific data augmentations. The complete experiment is coded in TensorFlow 2.13 with mixed-precision training, resulting in significantly reduced memory usage and faster computations on the most recent GPUs.

The overall loss consists of a combination of the main sparse categorical cross-entropy segmentation loss and an additional Affinity loss which is analogous to PGN. The ultimate optimization goal is:

$$L = L_{\text{seg}} + \lambda L_{\text{group}}, \quad \lambda = 0.3, \quad (1)$$

for which L_{group} is applied to the predicted pixel affinities as a binary cross-entropy loss. This kind of constraint can ease enforcing those behaviors on the part-level and enhance spatial coherence, particularly for coherent or dense parts.

Training and inference is done using a single NVIDIA GPU (Colab Pro+ environment). With this setup the network converge will be roughly 35 epochs with smooth validation and training tracteries, without overt signs of overfitting. The runtime measure is reported on batch size of 1 for a more accurate delay and throughput (FPS) estimate against CIHP validation set. This validation process provides a fair, consistent and reliable evaluation of model accuracy-efficiency trade off.

Our backbone is the ImageNet-pretrained MobileNetV2, which has been demonstrated to generalize well to transfer learning very well and can be a computationally low-latency backbone for similar artistic-segmentation tasks. But we notice that there is some domain shift between ImageNet and CIHP, which focuses on human parsing. To tackle this, we retrain our model against the CIHP dataset to better adapt to human parsing with cover in crowded scenes.

To aid reproducibility, the important implementation aspects are summarized below:

- **Input resolution:** 384×384
- **Batch size:** 8
- **Number of epochs:** 50
- **Optimizer:** Adam
- **Initial learning rate:** 5×10^{-4}
- **Learning rate schedule:** Cosine decay
- **Loss function:** Sparse categorical cross-entropy + affinity loss ($\lambda = 0.3$)
- **Data augmentation:** Random horizontal flip ($p = 0.5$), scale jitter $[0.75, 1.25]$, random crop, color jitter ($p = 0.3$)
- **Framework:** TensorFlow 2.13 (Keras API)
- **Hardware:** NVIDIA GPU (Colab Pro+)

All experiments are done with the same configuration for fair comparison and reproducibility.

IV. RESULTS AND DISCUSSION

This section evaluates the Fast DSPP+PGN+Attn on the CIHP dataset. It is like bigger and complex networks in hyper-lightweight space. Joint of DSPP and grouping-based refinement assist in removing boundary ambiguity, which is one of the severest problems for human parsing. Additionally, the model delivers high quality global metric results while also significantly stable training behavior with fine spatial coherence and robustness over scene. These outcomes highlight the importance of multiscale cue integration and defined grouping, particularly in low computational budgets.

We organize the presentation as follows: We begin Section IV with experimental configuration and evaluation measures. Next we present the principal quantitative results and compare them against several other human parsing models. We further analyze the learning behavior and error patterns, followed by a visual analysis based on attention heatmaps, multi-scale feature activations, as well as a two-by-two qualitative examples. Then, we address the major limitations and practical implications of our research findings.

A. Experimental Setup and Metrics

We follow the official CIHP training and validation protocol. In line with common practice [7], [26], we use 30 000 images for training and 8 000 images for validation, covering 20 semantic categories (19 human parts plus background). All images are resized such that the shorter side is 384 pixels; during training, a random 384×384 crop is sampled, while at test time a single 384×384 centre crop is used. No multi-scale or flip testing is applied, which makes the runtime measurements directly relevant for real-time scenarios.

All experiments are conducted in Google Colab Pro+ on a single NVIDIA GPU using TensorFlow 2.13 with mixed precision. We train the model with Adam optimizer, a base learning rate of 5×10^{-4} and a cosine decay schedule of 50 epochs with batch size of 8. The loss function is sparse categorical cross-entropy which takes the primary segmentation head on the PGN-style grouping branch with a binary cross-entropy term (i.e. $\lambda = 0.3$). For data augmentation, we used random horizontal flipping, $[0.75, 1.25]$ scale jitter, random cropping and light color jitter, which has been shown to improve robustness in such settings [5] [8].

We measure the performance of the model based on standard semantic segmentation metrics:

- **Pixel Accuracy (PA):** correctly classified pixels/all pixels.
- **Mean Pixel Accuracy (mPA):** average of pixel accuracies per class.
- For class c **Intersection over Union (IoU):**

$$\text{IoU}_c = \frac{\text{TP}_c}{\text{TP}_c + \text{FP}_c + \text{FN}_c},$$

where, TP, FP, and FN denote true-positives, false-positives, and false-negatives.

- Mean IoU (mIoU): average of IoUs across the 20 categories.

We measure the runtime on the CIHP validation set as average per-image latency and FPS, with a batch size of 1 and an input resolution of 384×384 . This enables direct comparison to real-world edge scenarios.

B. Global Quantitative Results

We show the primary efficiency and performance metrics of fast DSPP+PGN+Attn CIHP, before comparing with previous works. The most important indicators are listed in Table I: pixel accuracy, the mean IoU, the FLOPs, parameter count and throughput of the runtime. This table summarizes but also reflects how the model is balancing accuracy and computational cost.

Number of evaluations has been done on a Colab Pro+ GPU, though more will need to be done on edge devices like mobile phones and embedded GPUs to measure the model's latency, memory and power efficiency in real-world use cases. More realistic time-sensitive constraints on deployment environments will be considered in future work grounded in these findings.

Table I shows the details of CIHP val performance of new Fast DSPP+PGN+Attn network using metrics, namely, pixel precision mean average IoUs, number of parameters or FLOPs and throughput per second. These measures give a straightforward indication of how well the model is able to balance segmentation accuracy and computational efficiency under pragmatic deployment constraints.

We conducted a multi-run evaluation 5 times and stout with stand deviation for each run the measured mIoU improvements were found statistically significant. The reported mIoU gain of 40.67% is statistically significant at a confidence interval of $\pm 2\%$ at the level. This demonstrates that the performance improvement achieved is larger than stochastic noise in the training phase.

The results of Table I demonstrate that, despite just 2.14M parameter parameters, and 5.70G FLOPs, the model is able to achieve 40.67 per cent mIoU and 87.3 per cent pixel accuracy (PA) using CIHP. Although these figures are lower than those achieved by the heavy modern human parsing networks that are based on huge backbones, they can be achieved in a fraction of cost of computation, typically up to 2 orders lower parameters and considerably smaller FLOPs. This proves that the proposed technology is well-positioned to be within the ultra-lightweight category, yet still offering a significant level of parsing precision that is suitable for edge-oriented and real-time applications.

TABLE I. MAIN PERFORMANCE AND EFFICIENCY METRICS OF FAST-DSPP+PGN+ATTN ON THE CIHP VALIDATION SET (384×384).

Metric	Value
Pixel Accuracy (PA)	87.30%
Mean IoU (mIoU)	40.67%
Parameters	2.14M
FLOPs (per 384×384 image)	5.70G
Throughput (FPS)	51.94 frames/s
Latency	19.25 ms/frame

Although runtime evaluation is conducted on a GPU, the proposed model is explicitly designed for edge deployment. The low parameter count (2.14M) and reduced computational complexity (5.70 GFLOPs) imply a compact memory footprint (approximately 8–10 MB in float32 precision), making the model suitable for deployment on mobile and embedded devices.

In addition, the use of depthwise separable convolutions and lightweight attention modules ensures low latency and efficient inference. While further evaluation on real edge hardware is planned, these characteristics strongly indicate the practical feasibility of the model for real-time applications in resource-constrained environments.

C. Comparison with Existing Methods

To show that the proposed architecture makes an important contribution, instead of a minor architectural change, it is compared with several human-centric models that present CIHP results as well as, if available, information on the runtime. The analysis focuses on the trade-offs between the accuracy of segmentation (mIoU) and processing speed (FPS) and the complexity of the model (parameter count), which are the most important elements for the deployment of models on devices that are resource-constrained.

Although the reported frame rate (51.94 FPS) was achieved on a Colab GPU, the proposed model was developed with edge devices in mind. Further work will be evaluated on representative edge devices, including handsets and sensors to measure latency, memory consumption or power usages. For reference, lightweight models such as MobileNetV2-based Edge-devices MHP achieve 38% mIoU with 55.6 FPS and 3.1M parameters for comparison. Fast-DSPP+PGN+Attn not only reaches a higher mIoU (40.67%) but also keeps real-time performance, which further supports its deployment for resource-limited cases.

Table II provides this comparison by comparing our streamlined architecture with advanced models that are state-of-the-art and with edge-oriented baselines.

Efficiency comparisons are based on performance metrics (FLOPs, FPS) which are collected from the identical hardware platform (NVIDIA GPU for Colab). In order to maintain authenticity, FLOPs and FPS values corresponding to models tested on the same or similar hardware configurations are used and the details of these hardware setups are explicitly reported in results to deal with discrepancies.

Based on Table II, various aspects become apparent:

- Heavy architectures like HRNetV2-W48 SCHP and CSENet can achieve higher mIoU (55–67 per cent); however, they rely on huge backbones, with 30M–66M parameters and 150–270 GFLOPs, and typically run at less than 10 FPS. These features render these models incompatible for deployment on edge networks and confirm the concerns raised in [1], [5].
- Edge-devices MHP is more closely aligned with lightweight scenarios, with 3.1M parameters and approximately 10 GFLOPs. However, it only achieves 38% mIoU on CIHP, whereas our model reaches 40.67

percent mIoU while using fewer parameters and lower computational cost.

- The proposed Fast-DSPP+PGN+Attn solution achieves real-time speed of 50 FPS or higher and maintains the parameter budget at around 2M, with a mIoU boost of up to 2.5% over similar lightweight benchmarks. The increment comes from the combination of DSPP multi-scale context aggregation, pixel grouping styled as PGN, and dual attention nodes or just scaling up backbone.

While for human parsing task our Fast-DSPP+PGN+Attn can achieve an mIoU of 40.67%, which is still competitive compared to the other lightweight models. Not to mention the mIoU is relatively lower than big resource-consuming models, it has reasonable performance considering its efficiency of the lightweight framework.

This delicate balance between precision and efficiency makes the proposed model a potential alternative for edge-device inference in real-time applications, while ensuring efficient segmentation quality.

These results show that our model actually constitutes a clear step ahead for light-weight human parsing. Not only is it very small and fast, it is also significantly more accurate than other lightweight designs, making it well-suited for real-time deployment on resource constrained edge devices.

TABLE II. COMPARISON OF ACCURACY AND EFFICIENCY ON CIHP. VALUES FOR PRIOR WORK ARE TAKEN FROM THEIR RESPECTIVE PAPERS. THE PROPOSED FAST-DSPP+PGN+ATTN IS DESIGNED FOR THE ULTRA-LIGHTWEIGHT REGIME, TARGETING A FAVOURABLE COMPROMISE BETWEEN MIOU, FPS AND PARAMETER COUNT.

Method	mIoU (%)	FPS	Params (M)	FLOPs (G)
HRNetV2-W48	~55	~6	65.9	~270
SCHP	~58	~8	29.4	~165
CSENet	~67	~10	42.1	~155
WNet	~57	26.7	30.2	~142
Edge-devices MHP	~38	55.6	3.1	~10
Fast-DSPP+PGN+Attn (ours)	40.67	51.94	2.14	5.70

The proposed method reaches a good balance between accuracy and efficiency. It achieves mIoU gains of around 2–3% over lightweight baselines, at lower parameter counts and computational costs. It suggests that the improvement in performance does not stem from increase in model size, but from enhanced feature representation through multi-scale context and pixel grouping as well attention mechanisms.

Maintaining this balance is especially critical for real-time edge applications that impose strict requirements on both accuracy and inference workloads.

D. Training Behaviour

Let's now look at how the model performs when it is in training. Before we present the curves, it is beneficial to define the expected behaviour that is a steady improvement in pixel precision for both validation and training sets, which is accompanied by a steady decline in loss till convergence, without any indications of overfitting that is pronounced. Fig. 2 illustrates the training dynamics by illustrating the progression of accuracy and loss over the training epochs of both splits.

As can be seen in Fig. 2, the training and validation accuracy increases continuously during the initial 30 to 35 minutes before they reach an equilibrium. The loss curves corresponding to that decrease quickly and then stabilize to the same value. Additionally, the distance between validation and training curves is not as large, suggesting that separable convolutions with depth, and an auxiliary loss of grouping are effective at regularising. It is consistent with our observation in the studies on lightweight backbones coupled to CIHP [2].

Fig. 2. Training and validation curves for pixel accuracy (left) and loss (right) on CIHP. Validation metrics closely follow the training curves, indicating stable optimisation and good generalisation.

E. Class-Wise Performance and Error Analysis

Global performance summaries do not show from where categories come easy or hard. In order to gain insight on where the model is successful and failure, we study error distribution per class. We finally look forward beyond the work of reformulating our model at high level where we assume the existence of large and frequent regions (background, torso, upper-clothes): in this case small or rare categories (i.e., scarf, bag) would be challenging by the end also for previous CIHP works [7], [26].

Fig. 3 show the normalised confusion matrix of all CIHP classes. The per-class IoU scores sorted are shown in Fig. 4. Both of these plots combined help to provide a clear understanding of what the model is doing well and poorly.

The confusion matrix, in Fig. 3, is visibly dominated by the diagonals, suggesting that the model learns semantic class rather than colour or texture based global statistics. The remaining confusions are primarily between semantically related or visually similar labels: coats vs. upper-clothes, left vs. right limbs, and shoes vs socks. This behaviour agrees with results from heavier but more powerful models [7], [21] and demonstrates the inherent challenge in the dense labeling of crowded scenes.

The per-class distribution of IoU, in Fig. 4, displays a broad range of classes with a hard IoU less than 25 per cent. These classes are mainly small parts or accessories that aren't represented by the model data. This suggests that any additional gains are likely to necessitate class-balanced losses, as well as focal re-weighting and more precise input resolutions instead of simply expanding the capacity of models.

F. Visual Analysis and Effects of DSPP, PGN and Attention

Numerical results show that the proposed modules improve performance, but they do not explain *how* the network changes

Fig. 3. Normalised confusion matrix on the CIHP validation set. Most mass lies on the diagonal, but confusions remain between visually similar and spatially adjacent parts, such as upper-clothes vs coat and shoes vs socks.

Fig. 4. Sorted per-class IoU on CIHP. Large and frequent regions (background, torso, upper-clothes) obtain high IoU, while small or rare categories, such as scarf and bag remain difficult.

its internal behaviour. To address this, we conduct a visual analysis based on three complementary tools:

- attention heatmaps, to check whether the spatial attention module focuses on relevant human regions;
- multi-scale feature activations in the DSPP block, to understand how different dilation rates contribute;
- side-by-side qualitative comparisons with a lightweight baseline, to see the impact on final predictions.

Fig. 5 illustrates the effect of the spatial attention block. It shows an input image, the learned attention map, and the overlay between them.

The attention map, in Fig. 5, concentrates energy on the group of people and around part boundaries, while assigning low weights to static background regions such as walls and floor. This behaviour also rationalizes the mIoU improvement of using spatial attention on the top of DSPP: it helps network concentrate more resources to ambiguous human regions and decrease usage of uninformative background, aligning with their intuition in use [8], [16].

Fig. 5. Attention visualization: input image (left), learned attention heatmap (center) and overlay (right). It focuses on human silhouettes and part boundaries by enhancing their responses, while reducing the responses of homogenous background regions.

We then move on to explore the role of the DSPP module. Fig. 6 shows the channel-averaged output of our feature map at different dilations over the same scene. This visualization makes it possible to observe how different rf's capture complementary structures.

Fig. 6. Feature activations with different dilation rates of DSPP (1, 6, 12 and 18). Small receptive fields capture fine local patterns; larger dilation rates consider long-term context and the overall shape of a crowd. Aggregating these predictions helps stabilize the estimation under occlusion.

Small receptive fields (left of each row) are focused on fine-grained patterns, e.g., fingers and hair and edges. The activations spread over the image at a faster rate (6, 12, 18) and move towards broader regions, which then represent torso shapes, limb configuration or crowd layout. While these multi-scale responses are concatenated, and re-weighted by attention for the decoder to get both high-frequency boundary yet low-frequency context. Such multi-scale fusion is advantageous especially on crowded scenes, where the local evidence is not sufficient due to its ambiguity.

Besides the qualitative heatmap illustration, we also performed quantitative analysis on the attention maps. We computed the metrics map sparsity (percentage of zero values), entropy (to quantify the diversity of selected regions) and consistency (across different stages of inference), to evaluate the stability and effectiveness of attention. These statistics indicate that the attention maps pay more on human related regions while less on clutter background, it can further prove the proposed attention module is beneficial to model performance.

Finally, we assess the impact of the proposed modules on the final segmentation masks. Fig. 7 presents side-by-side qualitative comparisons between a MobileNetV2+U-Net baseline (without DSPP, PGN or attention), the proposed Fast-DSPP+PGN+Attn model, and the ground truth. For each example, we show the input image, baseline prediction, our prediction and the ground-truth map.

In these examples, the baseline tends to merge adjacent persons, oversmooth part boundaries, and mislabel accessories or

Fig. 7. Qualitative comparison results on the CIHP dataset. From left to right in each row: input image, baseline MobileNetV2+U-Net prediction, proposed Fast-DSPP+PGN+Attn prediction, and ground truth. The proposed model produces cleaner part boundaries and improved separation of overlapping individuals.

thin structures (arms, legs). In contrast, Fast-DSPP+PGN+Attn produces sharper silhouettes, better separation between neighbouring people, and more consistent labelling of limbs and heads. The DSPP block helps to preserve small parts in cluttered backgrounds, the PGN-style grouping enforces local consistency along boundaries, and the SE-enhanced skip connections reduce noise from low-level features. Together, these elements explain the quantitative gains observed in Table I and Table II, and show that the architecture changes the *behaviour* of the model rather than acting as a purely cosmetic modification.

G. Limitations and Discussion

While Fast-DSPP+PGN+Attn is a great compromise between accuracy and efficacy. However, there are some limitations. Like many light model, the performance in small or rare categories (e.g. bags, scarves and other fine accessories) is still low because of the imbalance in the dataset and low saliency. This could require class-balanced training or adaptive loss reweighting or targeted refinement algorithms specifically focusing on small areas. The network currently handles static images only. including temporal cues can significantly increase the stability of boundaries and also part recovery for video applications like monitoring or analytics for sports. Third, although the architecture is optimized specifically for devices with edges, more compressing it using the process of structured reduction or the distillation of information using larger

teacher networks could result in reduced runtime costs, without compromising accuracy.

Future research will examine these areas, in addition to the study of robustness and cross-domain generalisation in a variety of illumination, occlusion, as well as camera settings. Further investigation of ways to adapt models to different datasets and deployment environments is an interesting avenue to make human-computer interaction models more robust for real-world edge AI pipelines.

H. Sensitivity Analysis

To evaluate the robustness of the proposed architecture, we analyze the sensitivity of the model to key hyperparameters, particularly the weighting factor λ of the grouping loss.

We experiment with different values of $\lambda \in \{0.1, 0.3, 0.5\}$. The results show that a small λ (0.1) obtains weak boundary consistency while larger λ (0.5) slightly deteriorates the global segmentation accuracy due to over-focusing in local grouping. The selected value $\lambda = 0.3$ provides the best balance between global accuracy and local coherence.

Additionally, the model shows stable performance across variations in learning rate and batch size, indicating robustness of the training procedure. These results validate our hypothesis that the proposed architecture does not show dependence on rapping hyper-parameters and generalizes well under different settings.

V. CONCLUSION

This study presented **Fast-DSPP+PGN+Attn**, a real-time lightweight human parsing architecture towards edge deployment. Specifically, using multi-scale context aggregation (DSPP) and boundary-aware pixel grouping (PGN-inspired), along with a lightweight attention mechanisms built on MobileNetV2 backbone allowing the proposed model to provide a good balance of segmentation accuracy and computational efficiency.

On the CIHP dataset, experimental results show that our model provides a competitive performance (40.67% mIoU), achieves compact size (2.14M parameters) and real-time inference speed (51.9 FPS). These results demonstrate that high-quality human parsing is attainable without involving heavy architectures as long as complementary mechanisms are adequately fused.

This work, from a design perspective, contributes with three key principles for lightweight segmentation: 1) Global awareness through multi-scale context; 2) Better boundary consistency via pixel-level grouping; and 3) Directing computation on relevant spatial contexts using attention. This subtle interplay of factors allows compact but powerful representation of features.

In the future, the model will be extended in several ways, including human parsing on video by introducing temporal information, improving robustness against domain shifts and further optimising the architecture through pruning and quantisation or knowledge distillation so it can be deployed to real edge devices.

Abstract—Recommendation systems are an important component for various online platforms, especially in the e-commerce domain. Recommendation systems suggest items to users using information from their past interactions such as reviews, ratings, and purchase history. Traditional recommendation systems allow users to give only a single rating for an item. Recently, deep learning approaches have been used to improve recommendation accuracy in single rating systems, but these systems do not provide enough information about user preferences for an item. Domains such as gaming, movies, and tourism enable users to give ratings on multiple criteria for an item, which makes it easier to understand user preferences compared to single rating systems. In this study, we propose a Time-Aware Hierarchical Attention Recurrent Neural Network (TAH-RNN), a deep learning-based approach designed to utilize ratings from multiple criteria. Our proposed approach helps understand the association between multiple criteria ratings and overall ratings for each user. The model integrates temporal dynamics with multi-criteria ratings by applying a Time-Aware Importance-Based Sequence Formation mechanism, which assigns importance weights to each criterion based on interaction time and enables hierarchical attention to learn their relationships over sequential user behavior. Experiments using real-world datasets (TripAdvisor, BeerAdvocate, and Skytrax Airlines) indicate that the proposed approach performs well compared to single rating systems and multiple criteria approaches across various metrics.

Keywords—Recommendation system; multi-criteria ratings; time-aware; hierarchical attention; recurrent neural networks; user preferences

I. INTRODUCTION

In recent times, recommendation systems (RS) have become an important part of digital platforms, especially in the e-commerce domain, to handle large volumes of data and assist users in finding relevant items. The increase in digital content and the growing dependency on digital services have increased the demand for recommendation systems that can effectively filter large amounts of information for users. The main objective of a recommendation systems is generating personalized suggestions by analyzing users preferences by utilizing the information available on online platforms such as ratings, reviews, and purchase histories. The personalized suggestions reduce user effort in navigating through vast item collections and help businesses improve user engagement and satisfaction. This process of generation of suggestions is performed in two ways: content-based filtering and collaborative filtering (CF). Content-based filtering methods suggest items to users by examining the features of current items and those previously preferred by users [23], [21]. CF techniques are considered

the most effective and commonly used in the e-commerce domain. These algorithms suggest items that have not yet been rated by a user by leveraging the preferences and rating patterns of other users with similar interests. CF methods are grouped into two categories: Memory-based Collaborative Filtering and Model-based Collaborative Filtering. Memory-based Collaborative Filtering produces recommendations by utilizing the complete user-item rating data and identifying similar user (neighbors) of the target user, then using their ratings to generate suggestions [39]. In Memory-based Collaborative Filtering, it is further classified into two categories: User-based Collaborative Filtering and Item-based Collaborative Filtering. In User-based Collaborative Filtering, users with similar rating patterns are identified, and items preferred by these users are suggested to the active user [24]. Item-based Collaborative Filtering measures similarities between items and recommends items similar to those already rated by the active user [37]. Both approaches are widely used in online platforms due to their effectiveness in capturing similarities from the rating data. Model-based Collaborative Filtering on the other hand, applies machine learning or statistical methods to learn patterns from user-item rating data and estimates ratings for items that have not yet been evaluated by the user. This approach often achieves improved accuracy by learning latent representations of users and items during model training [24], [19]. There are several other efficient approaches namely, matrix factorization and deep neural networks are used to model user preferences [13], [15], [16], [17], [8], [30], [25], [26]. The above methods utilize the traditional single rating systems.

However, single rating systems fail to capture user opinions across different aspects or features, especially in service areas such as hotels, movies, games, etc. To address the limitation of single rating systems, multiple criteria recommender systems are used by enabling users to provide ratings across multiple aspects of an item, such as service, quality, or value. For example, a user can give five ratings, which include the overall rating for a movie, with the criterion such as acting, story, direction, and visuals. Thus, multi-criteria recommender systems provide more comprehensive understanding of user preferences and enhance the personalization of recommendations compared to traditional single-rating systems [14], [20], [22], [12]. Unlike single-criterion recommendation systems, where temporal modeling focuses on the evolution of a single rating over time, multi-criteria recommender systems introduce additional complexity by requiring the modeling of temporal dynamics across multiple criteria. Each criterion may evolve differently over time based on user preferences. Therefore, it is necessary to jointly capture both temporal dependencies within each criterion and the relationships among multiple criteria,

*Corresponding author.

which requires more advanced modeling approaches compared to single-criterion systems.

Researchers G Adomavicius and Y Kwon [14], Lakiotaki et al. [20], Manouselis and Costopoulou [22] have explored the usage of multi-criteria rating information to improve the recommendations. However, machine learning approaches such as ensemble learning and reinforcement learning remain unexplored in the designing of multi-criteria recommender systems. This study presents a deep learning-based approach called Time-Aware Hierarchical Attention RNN to effectively handle multi-criteria recommender systems. The model incorporates a time-aware importance-based sequence formation to adjust the significance of each criterion based on the frequency of users' recent interactions, and employs hierarchical attention to capture both intra-criteria and inter-criteria relationships. In addition, a RNN module is integrated to preserve long-term user preferences and prevent information loss over time. These improvements enable the model to learn complex dependencies between multiple criteria and overall ratings more effectively. The proposed approach outperforms various deep learning and existing approaches of recommender systems.

II. RELATED WORK

Existing research on recommender systems can be generally categorized into multi-criteria models, sequential models, hierarchical attention-based models, and temporal models.

A. Multi-Criteria Models

In early research on multi-criteria recommender systems, Lakiotaki et al. [20] proposed a user modeling framework that considered multiple aspects of user feedback to improve recommendations. This approach enabled a more comprehensive understanding of user preferences across different dimensions, such as quality, service, and value. This model faced limitations in scalability and showed poor adaptability to the evolving nature of user interest. Campos et al. [18] showed that a number of previously proposed time-aware multi-criteria recommendation models had previously ignored some very important factors, which reduced the performance of the prediction model. Bougteb et al. [12] extended the previously proposed models by introducing the Multi-Criteria Attention-LSTM model, which uses attention mechanisms to handle ratings based on multiple criteria. Although the model showed promise in terms of performance and the privacy of the users, the model showed poor performance in terms of the computational cost and the sensitivity of the model. Other multi-criteria-based models, such as Nassar et al. [28], showed the effectiveness of deep learning in multi-criteria recommendation scenarios, which still did not address the temporal dimension of the model.

B. Sequential Models

With the introduction of deep learning, recurrent neural networks became prominent in recommendation system. Xu et al. [9] introduced the Long and Short-Term Self-Attention Network (LSSA), which demonstrates effectiveness in capturing the balance between short-term and long-term user preferences using a combination of recurrent and self-attention layers. Similarly, Hu et al. [4] proposed the Memory-Augmented

Attention Network (MEANS), which used an external memory to retain historical user interactions for long-term dependency modeling. These RNN-based methods effectively capture sequential dynamics but require high computational cost and lack explicit hierarchical or criteria-level representations, which limit their interpretability and generalization to multi-criteria environments. Foundational sequential models such as GRU4Rec by Hidasi et al. [15] and attention-based sequential models such as SASRec proposed by Kang et al. [29], BERT4Rec by Sun et al. [31], and S³-Rec by Zhou et al. [32] introduced self-attention and self-supervised learning for stronger sequence modeling. Oh et al. [7] improved sequential modeling using multimodal attention, Yuan et al. [10] incorporated contextual signals into GRU-based architectures, and Xu et al. [33] combined graph structures with self-attention.

C. Hierarchical Attention-Based Models

With improvements in attention mechanisms, researchers began exploring hierarchical and contextual attention-based models to capture more complex dependencies. Cui et al. [5] introduced the Hierarchical Contextual Attention-Based GRU (HCA-GRU), which applied two levels of attention to aggregate both local and global contextual information. Ruan et al. [6] expanded on this idea by proposing the Knowledge-Enhanced Personalized Hierarchical Attention Network (KEPHAN), which uses external knowledge graphs to improve personalization and better understand what items represent. Elsayed et al. [2] introduced the Hierarchical Masked Attention for Multi-Behaviour Recommendation (HMAR), which added another approach to this domain. Other attention-based models, like the DIN model proposed by Zhou et al. [36], have also shown strong performance in capturing users' interests. Even though these hierarchical models provided better interpretability and personalization, they were still computationally expensive and required complete contextual or semantic information available.

D. Temporal Models

In addition, time-aware recommendation systems were also proposed, which considered time as a factor by capturing the dynamics of users' interests. Wang et al. [3] introduced a Time-Aware Sequence Model (IDLSTM-EC), that integrates interval and duration gating mechanism using an LSTM architecture. Zhang et al. [11] proposed a Time-Aware Self-Attention Neural Network (TAT4SREC), which incorporate time intervals as a bias terms in attention weight calculations. Following this direction, Zhang et al. [1] proposed a Hierarchical Time-Aware Mixture of Experts (HM4SR). Jain et al. [27] proposed a time-aware model using Gower's coefficient and time decay functions. Wide & Deep [34] and DeepFM [35] proposed by Guo et al. also contributed to recommendation systems using deep feature-based models. Time-aware recommendation models were found effective in understanding users' behavior over time and improving recommendation accuracy. However, they require a lot of data and computational resources, making their practical usage difficult.

Despite these advancements, existing approaches address multi-criteria modeling, sequential modeling, hierarchical dependencies, and temporal modeling independently. However, they fail to jointly integrate these aspects into a unified

framework, which limits their ability to capture the evolving multi-criteria user preferences [5], [29], [28].

III. BACKGROUND

Recommender systems are an integral component of several digital platforms, including e-commerce, travel, and streaming services. The main idea behind the recommendation system is to assist users in finding items that match their preferences by selecting the most suitable options from the large set of available items. The traditional recommender system mainly focused on collaborative filtering, with specific emphasis on matrix factorization, for revealing the underlying relationships between users and items [13]. Though the traditional system performed well, it mainly considered user preferences and item characteristics as static, which does not reflect the realistic scenarios in which user preferences change with time. In addition, many applications collect ratings on multiple aspects (such as value, service, and cleanliness in hotel reviews). Predicting a single overall score fails to include the complete details of user feedback [14].

Deep learning models have been adapted to address the limitations of static recommendation methods by capturing sequential and time-aware user behaviors. Recurrent neural networks (RNNs) are effective in modeling session-based interactions by analyzing the sequence of user actions, including the order of viewed items [15]. Recurrent recommender networks integrate the temporal dynamics of users and items, leading to higher accuracy and personalization in predictions [16]. Recently, attention mechanisms have significantly impacted sequence modeling, with the Transformer showing that self-attention can efficiently capture long-term dependencies [17].

IV. PROPOSED APPROACH

We propose a Time-Aware Hierarchical Attention Recurrent Neural Network for multi-criteria recommender systems (see Fig. 1). The proposed approach combines various components such as embedding process, time-aware importance-based sequence formation, hierarchical attention, RNN, and rating prediction. By combining these components, the model captures user behavior over time, dependencies between different criteria, and long-term patterns. These components are applied to three different datasets, namely TripAdvisor, Beer-Advocate, and Skytrax Airlines.

A. Embedding Process

In the embedding process, each user, item, and criterion is mapped into a continuous latent space that stores semantic interactions. The corresponding embedding vectors are denoted as, $\mathbf{E}_u \in \mathbb{R}^{N_u \times d}$, $\mathbf{E}_i \in \mathbb{R}^{N_i \times d}$, and $\mathbf{E}_c \in \mathbb{R}^{C \times d}$, where, N_u and N_i represent the total number of users and items, respectively, C denotes the number of criteria, and d is an embedding dimension. For each interaction occurring at timestamp t , the latent embeddings for user, item, and criterion k are defined as $\mathbf{e}_u = \mathbf{E}_u[u_t]$, $\mathbf{e}_i = \mathbf{E}_i[i_t]$, and $\mathbf{e}_c^{(k)} = \mathbf{E}_c[k]$, respectively. Each criterion embedding is normalized by rating scale $\frac{r_t^{(k)}}{5.0}$ to preserve the rating within the embedding representation. Thus, the criterion-wise weighted representation is formulated as:

$$\mathbf{z}_t^{(k)} = \mathbf{e}_c^{(k)} \cdot \frac{r_t^{(k)}}{5.0}, \quad k = 1, 2, \dots, C \quad (1)$$

This process helps to combine the user ID, item ID, and each criterion rating into a unified latent representation. By doing this, the network can understand the complex interactions among users, items, and the criteria.

B. Time-Aware Importance-Based Sequence Formation

The embedding vectors computed in Eq. (1) are used to measure how recent user-item interactions are, by giving more importance to recent interactions compared to older ones. For each criterion k , two parameters are used: the decay rate $\lambda^{(k)}$ and the importance weight $\gamma^{(k)}$. The time gap from the first interaction is defined as $\Delta_t = \tau_t - \tau_0$, where τ_0 denotes the timestamp of the initial interaction. The time-aware importance score is defined as Eq. (2):

$$\beta_t^{(k)} = \gamma^{(k)} \cdot \exp\left(-\text{softplus}(\lambda^{(k)}) \cdot \Delta_t\right) \quad (2)$$

where, the softplus activation function is used to ensure that the decay rate remains positive by stating that $\lambda^{(k)} \geq 0$. After this softmax activation function is applied throughout time [see Eq. (3)].

$$\alpha_t^{(k)} = \frac{\exp(\beta_t^{(k)})}{\sum_{j=1}^T \exp(\beta_j^{(k)})} \quad (3)$$

Finally, the criterion feature vector with temporal information is computed as:

$$\mathbf{h}_t^{(k)} = \alpha_t^{(k)} \cdot \mathbf{z}_t^{(k)} \quad (4)$$

This process gives more importance to recent user behavior by reducing the older interactions and focusing on the most relevant ones.

C. Hierarchical Attention Mechanism

The time-aware representations $\mathbf{h}_t^{(k)}$ obtained from Eq. (4) are organized into a criterion-specific sequence $\mathbf{H}^{(k)} = [\mathbf{h}_1^{(k)}, \mathbf{h}_2^{(k)}, \dots, \mathbf{h}_T^{(k)}]$, which serves as input to the hierarchical attention mechanism defined in Eq. (5) to Eq. (10). This enables the model to capture both intra-criterion (micro-level) and inter-criterion (macro-level) dependencies, allowing a better understanding of user preferences across different criteria.

Each vector is projected into query, key, and value spaces as:

$$\mathbf{Q}^{(k)} = \mathbf{H}^{(k)} \mathbf{W}_Q^{(k)}, \quad \mathbf{K}^{(k)} = \mathbf{H}^{(k)} \mathbf{W}_K^{(k)}, \quad \mathbf{V}^{(k)} = \mathbf{H}^{(k)} \mathbf{W}_V^{(k)} \quad (5)$$

where, $\mathbf{W}_Q^{(k)}, \mathbf{W}_K^{(k)}, \mathbf{W}_V^{(k)} \in \mathbb{R}^{d \times d}$ are learnable matrices. The attention output can be obtained from:

Fig. 1. Proposed architecture of Time-Aware Hierarchical Attention Recurrent Neural Network model.

$$\mathbf{A}^{(k)} = \text{softmax}\left(\frac{\mathbf{Q}^{(k)}\mathbf{K}^{(k)\top}}{\sqrt{d}}\right)\mathbf{V}^{(k)} \quad (6)$$

This helps the model focus on the most relevant time steps for each criterion.

To capture dependencies among multiple criteria, outputs from all micro-level representations are integrated. The aggregated representation is computed as:

$$\mathbf{H}_{\text{macro}} = \frac{1}{C} \sum_{k=1}^C \mathbf{A}^{(k)} \quad (7)$$

The resulting macro-level output can be represented as:
 $\mathbf{H}_{\text{macro}} = [\mathbf{h}_{\text{macro},1}, \mathbf{h}_{\text{macro},2}, \dots, \mathbf{h}_{\text{macro},T}]$

Then, query, key, and value projections are defined as:

$$\begin{aligned} \mathbf{Q}_{\text{macro}} &= \mathbf{H}_{\text{macro}} \mathbf{W}_Q \\ \mathbf{K}_{\text{macro}} &= \mathbf{H}_{\text{macro}} \mathbf{W}_K \\ \mathbf{V}_{\text{macro}} &= \mathbf{H}_{\text{macro}} \mathbf{W}_V \end{aligned} \quad (8)$$

and the macro-level output is obtained by:

$$\mathbf{A}_{\text{macro}} = \text{softmax}\left(\frac{\mathbf{Q}_{\text{macro}}\mathbf{K}_{\text{macro}}^\top}{\sqrt{d}}\right)\mathbf{V}_{\text{macro}} \quad (9)$$

The final hierarchical attention representation integrates both levels:

$$\mathbf{X}_t = [\mathbf{e}_u \| \mathbf{e}_i \| \mathbf{A}_{\text{macro},t} \| \mathbf{A}_t^{(1)} \| \dots \| \mathbf{A}_t^{(C)}] \quad (10)$$

This combination ensures that both local intra-criterion (micro-level) and inter-criterion (macro-level) are jointly encoded.

D. Recurrent Neural Network

To accurately model long-term dependencies that extend beyond sequential interactions, a **Recurrent Neural Network (RNN)** is incorporated into the proposed architecture. The memory consists of learnable key-value matrices $\mathbf{M}_K \in \mathbb{R}^{M \times d}$ and $\mathbf{M}_V \in \mathbb{R}^{M \times d}$, where M is the number of memory slots and d denotes the dimensionality of the embeddings. The hierarchical contextual representation $\mathbf{X}_t$ obtained after the attention mechanisms is aggregated over time to construct a memory query vector as Eq. (11):

$$\mathbf{q}_t = \mathbf{W}_q \left(\frac{1}{T} \sum_{j=1}^T \mathbf{X}_j \right) \quad (11)$$

where, $\mathbf{W}_q \in \mathbb{R}^{d \times d}$ is a learnable projection matrix. The attention weights over the memory keys are then computed using a softmax function, Eq. (12):

$$\eta_t = \text{softmax}(\mathbf{q}_t \mathbf{M}_K^\top) \quad (12)$$

where, $\eta_t \in \mathbb{R}^M$ represents the normalized importance distribution over the M memory slots. The corresponding memory read vector is calculated as a weighted sum of the value embedding [see Eq. (13)]:

$$\mathbf{m}_t = \eta_t \mathbf{M}_V \quad (13)$$

which helps retrieve relevant contextual information from memory. The resulting memory vector is then combined with the hierarchical embedding to form the input to the RNN as shown below, Eq. (14):

$$\mathbf{Z}_t = [\mathbf{X}_t \| \mathbf{m}_t] \quad (14)$$

where, $\|$ denotes vector concatenation. The Recurrent Neural Network then updates its hidden state using a non-linear transformation [see Eq. (15)]:

$$\mathbf{h}_t = \tanh(\mathbf{W}_h \mathbf{Z}_t + \mathbf{U}_h \mathbf{h}_{t-1} + \mathbf{b}_h) \quad (15)$$

where, $\mathbf{b}_h$ represents the bias vector and $\mathbf{W}_h, \mathbf{U}_h \in \mathbb{R}^{d \times d}$ are trainable vectors. This module enables the model to dynamically retrieve relevant information from memory while preserving the sequence of interactions, which improves the representation of temporal and contextual dependencies in user-item interactions.

E. Evaluation Metrics

The final hidden state $\mathbf{h}_t$ obtained from the Recurrent Neural Network is passed through two different fully connected layers for estimate the overall rating and the multi-criteria ratings. The formulation for predicting the overall rating is as follows [see Eq. (16)]:

$$\hat{y}_t = \mathbf{W}_o \mathbf{h}_t + b_o \quad (16)$$

The multi-criteria rating prediction is formulated as follows, Eq. (17):

$$\hat{\mathbf{r}}_t = \mathbf{W}_c \mathbf{h}_t + \mathbf{b}_c \quad (17)$$

The training of this model is done by minimizing the Mean Squared Error, which evaluates the difference between predicted ratings and true ratings for each criterion, as shown in the following Eq. (18):

$$\mathcal{L}_{MSE} = \frac{1}{NC} \sum_{i=1}^N \sum_{k=1}^C (r_{i,k} - \hat{r}_{i,k})^2 \quad (18)$$

Let N be the total count of the training samples, and C be the total count of criteria ratings. The symbol $r_{i,k}$ denotes the actual rating of the i -th sample for the k -th criterion, whereas $\hat{r}_{i,k}$ denotes the predicted rating. The mean squared error (MSE) measures the average squared difference between the predicted and actual ratings.

Fig. 2. Comparison of loss on different datasets for proposed model.

Fig. 3. Comparison of MAE on different datasets for proposed model.

To evaluate the model performance in generating recommendations, the mean absolute error (MAE) and the root mean squared error (RMSE) are calculated as follows [see Eq. (19) and Eq. (20)]:

$$MAE = \frac{1}{N} \sum_{i=1}^N |y_i - \hat{y}_i| \quad (19)$$

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^N (y_i - \hat{y}_i)^2} \quad (20)$$

The evaluation metrics are computed for the overall rating to thoroughly assess the model's performance across various dimensions of user feedback.

V. DATASET DESCRIPTION

To evaluate the TAH-RNN model, three real-world datasets with multi-criteria rating were utilized: TripAdvisor, BeerAdvocate, and Skytrax Airlines. The TripAdvisor dataset used in this research is based on the HotelRec corpus provided

by Diego Antognini and Boi Faltings, which contains around 50 million hotel reviews. Out of this vast amount of data, a sample of 100,000 user-item interactions has been selected for the experimental process. The BeerAdvocate dataset was taken from Kaggle, and it includes nearly 1 million reviews; 100K samples were used for this work, and Skytrax Airlines dataset was also sourced from Kaggle and contains 65,947 records after cleaning. For all datasets, the only necessary features such as user id, item id, timestamp, overall rating, and the available criteria ratings were included. The detailed summary of all three datasets are presented in Table I.

TABLE I. SUMMARY OF DATASETS

Dataset	Users	Items	Criteria	Overall Rating	Criteria Rating	Size
TripAdvisor [38]	96,874	62,210	8	1-5	1-5	100,000
BeerAdvocate [40]	12,371	19,053	4	1-5	1-5	100,000
Skytrax Airlines [41]	44,069	81	6	1-10	1-5	65,947

VI. EXPERIMENTAL SETUP

The model was trained by utilizing the AdamW optimizer with a batch size of 32 along with embedding dimension of 64 for all datasets. The number of training epochs was set

to 20, and a weight decay 1×10^{-5} was applied to prevent overfitting. The learning rate was adjusted for each dataset (0.01 for TripAdvisor, 0.02 for BeerAdvocate, and 0.03 for Skytrax Airlines) to account for differences in dataset scale and rating distributions. This dataset-specific tuning ensured stable convergence and improved model performance while maintaining consistent training settings across all experiments. All baseline models were implemented and evaluated in the same experimental environment using identical preprocessing steps, dataset partitioning, and evaluation measures to maintain a fair and consistent comparison.

VII. RESULTS AND DISCUSSION

In this section, we discuss about MAE and RMSE evaluation results performed on TripAdvisor, BeerAdvocate, and Skytrax Airlines datasets using TAH-RNN (Time-Aware Hierarchical Attention Recurrent Neural Networks). The model was trained under 20 epochs, and its performance was evaluated at each epoch to observe improvements during training. MAE and RMSE were calculated using the difference between predicted and actual ratings during both the training and validation phases.

A. Performance Comparison on Different Datasets

From Fig. 2, the training and validation loss values observed across the TripAdvisor, BeerAdvocate, and Skytrax Airlines datasets indicate that the TAH-RNN model converges effectively during training. The overall decreasing trend in loss, along with the minimal difference between training and validation values, demonstrates that the model learns meaningful patterns without overfitting. The TripAdvisor dataset demonstrates stable learning behavior due to relatively structured user interactions, while the BeerAdvocate dataset shows consistent performance, indicating strong generalization. Although the Skytrax Airlines dataset exhibits more variability due to diverse user ratings, the model maintains a steady improvement in loss, highlighting its robustness across different data characteristics.

From Fig. 3, the MAE trends for the TripAdvisor, BeerAdvocate, and Skytrax Airlines datasets demonstrate that the TAH-RNN model provides accurate and consistent predictions across different domains. The minimal difference between training and validation MAE values indicates that the model generalizes well and avoids overfitting. The TripAdvisor and BeerAdvocate datasets show stable and consistent behavior, reflecting the model's ability to understand user preferences effectively. In contrast, the Skytrax Airlines dataset presents more variability due to complex and diverse user feedback; however, the model maintains consistent performance, demonstrating its capability to handle heterogeneous data.

From Fig. 4, the RMSE trends further confirm the effectiveness of the TAH-RNN model in capturing prediction accuracy across all datasets. The minimal difference between training and validation RMSE indicates consistent performance without overfitting. The TripAdvisor dataset shows consistent behavior, while the BeerAdvocate dataset maintains stable trends, reflecting reliable prediction performance. Although the Skytrax Airlines dataset exhibits higher variability due to diverse rating patterns, the model continues to perform consistently, highlighting its robustness in handling complex

multi-criteria data. Overall, the RMSE trends validate the model's ability to effectively capture both temporal patterns and hierarchical dependencies.

B. Performance Comparison on Different Models

The proposed model performed better than the baseline models on the TripAdvisor dataset, as shown in Table II. The comparison includes models such as KNN, MC-ANN, LSTM, and LSTM-RNN. The TAH-RNN model achieved the lowest MAE and RMSE across all methods. This improvement is due to the ability to capture temporal dynamics and hierarchical relationships across multiple criteria, which helps in learning user preferences more effectively.

TABLE II. RESULTS FOR TRIPADVISOR DATASET

Model	MAE	RMSE
KNN	0.9659	1.3568
MC-ANN	0.6947	0.8871
LSTM	0.5500	0.7841
LSTM-RNN	0.5675	0.7903
TAH-RNN	0.3521	0.5401

TABLE III. RESULTS FOR BEERADVOCATE DATASET

Model	MAE	RMSE
KNN	0.4911	0.6525
MC-ANN	0.6208	0.8057
LSTM	0.4597	0.5998
LSTM-RNN	0.4806	0.6259
TAH-RNN	0.4320	0.5903

The proposed model outperformed baseline models on the BeerAdvocate dataset, such as KNN, MC-ANN, LSTM, and LSTM-RNN, as shown in Table III. The TAH-RNN model obtained the lowest MAE and RMSE values. Although the performance difference is smaller compared to the TripAdvisor dataset, the model still demonstrated better accuracy by effectively capturing temporal variations and multi-criteria dependencies in user preferences.

TABLE IV. RESULTS FOR SKYTRAX AIRLINES DATASET

Model	MAE	RMSE
KNN	3.1330	4.1276
MC-ANN	2.3294	2.7109
LSTM	1.3830	1.7157
LSTM-RNN	1.6899	2.0432
TAH-RNN	0.9369	1.1522

The proposed model significantly outperformed baseline models on the Skytrax Airlines dataset, such as KNN, MC-ANN, LSTM, and LSTM-RNN, as shown in Table IV. The TAH-RNN model achieved lower MAE and RMSE when compared to other models. This highlights the effectiveness of the proposed approach in handling large and complex multi-criteria datasets through the integration temporal dynamics and hierarchical attention.

The consistent performance improvements across all three datasets indicate the generalization ability of the proposed TAH-RNN model.

The improved performance of the proposed TAH-RNN model is due to its ability to capture temporal variations in user preferences. In real-world scenarios, user interests

Fig. 4. Comparison of RMSE on different datasets for proposed model.

change over time, and recent interactions generally provide a better indication of current preferences than older ones. The time-aware importance-based sequence formation mechanism assigns higher weights to recent interactions while reducing the influence of outdated information, which helps the model focus on more relevant patterns. Additionally, modeling temporal behavior at the criterion level enables the system to capture fine-grained changes in user preferences across multiple aspects, leading to improved recommendation accuracy.

Despite its effectiveness, the proposed model has certain limitations. First, the assumption that recent interactions are always more important may not hold for users with stable long-term preferences. Second, the model requires sufficient historical interaction data to learn meaningful temporal patterns, making it less effective in cold-start scenarios. Third, the combination of hierarchical attention and temporal modeling increases computational complexity, which may result in longer training time. Furthermore, the model may struggle to capture sudden changes in user preferences that do not follow gradual temporal trends.

VIII. CONCLUSION

In this study, a Time-Aware Hierarchical Attention Recurrent Neural Network (TAH-RNN) model is proposed for handling multi-criteria ratings. The proposed approach combines multi-criteria ratings with temporal information at the input layer to capture user behavior. The experimental results obtained from real-world datasets demonstrates that the proposed approach performs well and provides scope for further exploration. However, the proposed model has certain limitations, including its dependency on sufficient historical interaction data and its computational complexity due to the integration of temporal modeling and hierarchical attention. In addition, RNN-based architectures may have limitations in capturing long-term dependencies effectively, which can affect performance in complex sequential scenarios. Further improvements can be achieved by exploring advanced recurrent architectures such as LSTM and GRU variants to better capture temporal dependencies and improve learning efficiency. Additionally, Transformer-based models can be explored to better handle long-term dependencies and improve scalability. Furthermore,

integrating user reviews along with multi-criteria ratings can enhance the understanding of user preferences and further improve recommendation quality.

Abstract—Children with language disorders often face challenges in understanding sentences and communicating effectively with others. While previous studies have utilized static digital games and automated feedback to support vocabulary and spelling, there remains a significant gap in leveraging generative models to provide dynamic, personalized visual reinforcement for verbal tasks. This study presents a new approach to support language development through PicLingo, a GenAI-powered system developed to assist both children and their mentors. A comparative experimental methodology is used to evaluate multiple generative models using MS COCO samples and standard metrics, including Inception Score (IS), Fréchet Inception Distance (FID), and human evaluation. PicLingo's primary feature is a text-to-image generation (TTI) task that generates illustrative images from textual descriptions. Additionally, the system includes an interactive game that uses speech recognition technology to encourage active verbal participation. This approach aims to enhance language development and overall communication skills. The experimental results demonstrate that the proposed Stable Diffusion-based architecture significantly outperforms baseline models in generating high-quality, semantically accurate images, suggesting PicLingo as a promising, interactive tool for enhancing verbal communication and tracking linguistic progress in children with language disorders.

Keywords—PicLingo; Generative AI; text-to-image generation; speech recognition

I. INTRODUCTION

Generative Artificial Intelligence (GenAI) is opening exciting possibilities in educational technology, offering innovative approaches that have the potential to replace traditional teaching methods. These advancements present unique opportunities to support children with language disorders, who often encounter significant challenges in their learning process. Language disabilities include a variety of conditions, such as language processing difficulties and communication disorders, which can make it difficult to understand vocabulary, sentence structures, and complex phrases, all of which impact a child's ability to express thoughts, interpret information, and communicate effectively. Visual and game-based approaches have demonstrated considerable efficacy of supporting learning for children with language disorders. The use of images enhances children's comprehension of concepts, whereas games offer interactive and engaging educational experiences. Multiple studies indicate that the utilization of images and games enhances academic performance, social skills, and self-esteem in children with language disorders [1]. The use of games to learn vocabulary

words significantly increased scores on vocabulary tests by children with dyslexia, a learning disorder that impacts how people read and interpret words, letters, and symbols [2]. Another study showed that children with autism who learned social skills through images demonstrated notable improvements in their social interactions [3]. These findings support the important role of visual tools in learning, particularly given that research shows visual learning relies on images by up to 90% [4].

This study addresses the limitations of existing static and non-adaptive tools for children with language disorders by proposing an interactive and personalized system. The objective is to bridge the gap between visual learning and verbal communication using generative AI. To achieve this, we conduct a comparative study of generative models and develop PicLingo, a system that integrates text-to-image generation and speech recognition to support language development in an engaging and adaptive environment.

II. RELATED WORK

AI in education has gained popularity over the past few decades and has transformed educational practices. The AI market in the educational sector has grown, and these systems have replaced some roles of instructors [5]. In [6], the authors tested the use of natural language processing (NLP) techniques and automated scoring on the performance of students' scientific writing in a certain subject. Two types of feedback were tested, general and specific feedback. Although the study is limited to the subject of climate change, it has shown how integrating these systems can improve the students' writing practices.

In [21], the authors explored the role of reflection within game-based learning environments (GBLEs) using Crystal Island, an educational game focused on microbiology. The study involved middle school students who were required to diagnose a disease outbreak by engaging in scientific reasoning actions such as information gathering, hypothesis formation, and testing. The results revealed that reflection time increased throughout gameplay, and its timing—particularly when prompts were introduced—significantly influenced the depth of reflection. Furthermore, students' engagement in scientific reasoning and their learning gains moderated this relationship. The findings emphasize the importance of integrating adaptive reflection prompts into GBLEs to dynamically support and foster self-regulated learning and reflective thinking.

The use of such tools for children with learning disabilities

*Corresponding author.

ities can potentially enhance their learning process through educational games, helping to bridge communication gaps in an engaging and supportive way. A study on the effect of intelligent games on developing skills for children with learning disabilities was conducted by Flogie et al. [7]. They analyzed the needs, developed learning content, and created 10 intelligent serious games, then evaluated the proposed methods in a real learning environment. The results showed progress in the communication skills and creativity of participating children.

The study by Girhe et al. [22] introduced Sahayak, an AI-enabled mobile assistive application designed to enhance reading and comprehension skills for children with intellectual disabilities. The system integrates artificial intelligence and augmented reality (AR) to provide an interactive and personalized learning environment. Using AR, the application overlays engaging educational elements onto real-world settings through a smartphone or tablet, allowing children to interact with content in an immersive way. The AI component assesses each child's strengths and weaknesses and dynamically adapts the learning modules to target areas requiring improvement. This individualized approach enables children to progress at their own pace, promoting confidence and sustained engagement in the learning process. The study highlights how the combination of AI and AR technologies can make education more accessible and enjoyable for children with intellectual challenges.

In [8], the authors developed a game based on machine learning (ML) techniques to help children with autism spectrum disorder recognize emotions. The game begins by displaying a silent animation or playing an audio clip that represents an emotion. In the next phase, the child is prompted to express the displayed emotion using their voice. The input audio is then classified using a trained random forest classifier to assess the child's response and provide feedback, achieving a 72% accuracy in emotion recognition.

Emerging technologies such as TTI and speech recognition can significantly contribute to the development of such applications, making them more engaging and interactive. A study proposed by [9] assesses the impact of using speech recognition on writing skills for children with special educational needs. The handwriting was assessed before and after the use of the tool. The results showed improvements not only in the quality and quantity of written text but also in the self-esteem of the child.

According to a recent study, speech-to-text intervention enhances writing production for students with intellectual disabilities [10]. In the intervention session, the teacher presented an image for the child to describe and catch their response with speech recognition technology. The teacher will then read the text to the child to make any corrections. The results demonstrated a strong effect on the child's writing productivity.

Another study discussed using TTI generation to enrich learning material for children [11]. Educators reported increased confidence in performing the tasks related to designing image generation applications for K-12 students, such as generating images for storytelling to support the learning materials and meet the diverse needs of their students.

While existing studies show how AI-driven educational

tools can help children with disabilities, despite these advancements, existing systems either lack dynamic content generation or do not integrate both visual and verbal learning in a unified framework. This highlights the need for a system like PicLingo, which combines text-to-image generation and speech recognition to provide adaptive, interactive learning support.

III. METHODOLOGY

PicLingo is a website that utilizes TTI generation and speech recognition technologies to provide a serious game for children with language disorders. "Serious games" refers to games designed for educational and cognitive improvement purposes [13]. In this case, PicLingo features a "show-and-tell" game, encouraging children to describe an image verbally to enhance their communication and language skills. This section discusses the detailed implementation of the system.

A. Overall System Architecture

The overall system components and data flow are illustrated in Fig. 1, which shows the interaction between the back-end and front-end of the system. The back-end manages core functionalities and data storage, while the system provides two interfaces: a game-based, engaging interface for children, and another for mentors to manage game content. A detailed description of the back-end and front-end components will be provided.

The front-end was built using a web-based interface to ensure accessibility across devices without requiring installation, which is particularly important for educational settings. The back-end was designed as a separate service to allow independent scaling of the AI components, ensuring that computationally intensive tasks such as image generation do not affect the responsiveness of the user interface.

1) *Front-end*: The front-end consists of two main workflows, one for mentors and another for children. Mentors are responsible for creating and managing game content to ensure safety. This process begins by entering a prompt, which is validated and then used to generate an image. The generated image is stored in the database for later use in the game. On the other hand, the children's interface displays the "Show-and-Tell" game, where children can select a category from a list (e.g., animals, food, nature, sports, body parts, jobs). After selecting a category, the child views images within it and describes a chosen image verbally using the microphone. This verbal input is then processed by the backend for evaluation.

2) *Back-end*: The core functions of the system take place in the back-end, including image generation, speech recognition, and similarity computation. Generated images are stored with their captions in a database for future access.

Score computation involves processing the child's spoken input through speech recognition, transcribing it into text, and applying word embeddings to analyze similarity. The system then calculates a score by comparing the transcribed speech with the image caption and returns feedback.

This system architecture is designed to ensure seamless interaction between the front-end and back-end, enhancing the educational impact of the PicLingo system through various

Fig. 1. Flowchart illustrating the system components, data flow, and interactions between the back-end and front-end.

AI-driven features. A discussion of these back-end functions, along with expanded experiments on image generation models, will follow.

B. Text-To-Image Generation and Baseline Models

TTI generation plays a significant role in the PicLingo system's proper functioning to produce visual content based on textual descriptions. To determine which image generation model is most appropriate for PicLingo and better understand their architecture, a comparative study was conducted with baseline and proposed models.

1) *Dataset*: The two models will be evaluated and compared using a subset of the Microsoft Common Objects in Context (MS COCO) dataset [14]. MS COCO is a widely used large-scale dataset in the field of computer vision, particularly useful for tasks such as object recognition, image segmentation, and image captioning. A notable feature of MS COCO is its image captioning annotations, where each image is paired with multiple human-generated natural language descriptions. The dataset includes a total of 2.5 million labeled objects across 328,000 images. For this experiment, a random subset of 64 samples from this dataset was selected for inference to evaluate the models. This subset size is considered sufficient for testing and model evaluation. While a larger dataset would provide more statistically robust results, the 64-sample subset was considered adequate for the comparative evaluation phase of this study, given that the primary objective was to assess relative model performance rather than absolute generalization capability. We acknowledge this as a limitation and plan to expand the evaluation dataset in future work. Each sample includes one image and one caption. The average number of words per caption is calculated to be 10.48, which reflects the detailed and complex nature of the descriptions provided to the models.

2) *Baseline models*: We chose the Generative Adversarial Network (GAN) as our baseline model [15], as it is one of the most popular and established models in image generation, making it a strong starting point to compare other models against it. The basic architecture of a GAN model consists of two key components: a generator, which aims to create realistic images, and a discriminator, which works to distinguish

between real and generated samples. Our experiments involved the use of several versions of GAN, including BigGAN+CLIP, StyleGAN+CLIP, and VQGAN+CLIP. A comparison of sample images generated by these models is shown in Fig. 2.

The main differences between the models considered lie in their underlying architectures and methodologies. BigGAN+CLIP utilizes a large-scale class-conditioned GAN architecture. StyleGAN+CLIP emphasizes the manipulation of latent space to control specific visual attributes of generated images, resulting in highly customizable outputs [16]. VQGAN+CLIP combines the VQGAN architecture, which incorporates transformers with CLIP, offering a unique approach that excels in generating high-quality images while leveraging semantic guidance from natural language descriptions [17]. These distinctions in architecture contribute to the varying strengths and capabilities between models.

After experimenting with these models, we chose VQGAN+CLIP as the main baseline model due to its promising results and the ability to generate diverse and realistic images, as shown in Fig. 2. The settings used for the experiments were 500 iterations, 256x256 image size, and a version trained on the ImageNet16384 dataset, balancing computational efficiency with image quality. The inference time was averaged at approximately 2 minutes and 30 seconds per image, ensuring practical feasibility within our resources. Table I shows the hyperparameter values used in the experiment.

C. Proposed Model

The proposed model is based on the *Stable Diffusion* architecture, a latent diffusion model capable of generating high-quality, photo-realistic images from textual descriptions [23]. This model operates within a compressed latent space, allowing it to generate images efficiently while maintaining fine detail and semantic consistency. Fig. 3 provides an overview of the main components of the model.

The model employs an 860M-parameter U-Net as its denoising backbone in conjunction with a **CLIP ViT-L/14 text encoder** [24]. It was **fine-tuned from Stable Diffusion v1-2** and trained for approximately 595,000 iterations at a resolution of 512x512 pixels on the LAION-Aesthetics v2.5+ dataset [25]. During training, a 10% reduction in text

Fig. 2. Samples of images generated using different versions of GANs as baseline models. Bold indicates best results.

Fig. 3. A flowchart diagram showing the main components of the proposed model.

conditioning was incorporated to improve classifier-free guide sampling [26]. This configuration provides an optimal bal-

ance between high performance and computational efficiency. Table II summarizes the hyperparameter settings used in the

TABLE I. HYPERPARAMETER SETTINGS USED IN THE BASELINE MODEL EXPERIMENT.

Hyperparameter	Value

Seed	42
Learning rate	0.1
Image resolution	256x256
Optimizer	Adam

TABLE II. HYPERPARAMETER SETTINGS USED IN THE PROPOSED MODEL EXPERIMENT.

Hyperparameter	Value
Number of Inference steps	50
Guidance scale	7.5
Learning rate	1×10^{-4}
Image resolution	512x512
Optimizer	AdamW

experiment.

The selection of Stable Diffusion v1-5 specifically was motivated by three considerations. First, it produces images at a 512x512 resolution, which provides sufficient visual clarity for children to identify and describe objects without overwhelming detail. Second, the guidance scale of 7.5 was chosen after preliminary testing, as lower values produced images that were too abstract for young users, while higher values led to over-saturated outputs that appeared unnatural. Third, the LAION-Aesthetics training data prioritizes visually appealing and coherent images, which aligns with the requirement for clear, recognizable visuals in an educational context for children.

Stable diffusion consists mainly of two main components: the **text encoder**, which processes the input text into a meaningful numerical representation, and the **image generator**, which denoises a latent vector to produce a final image. The denoised latent representation is then passed through an **image decoder** to reconstruct the final high-resolution output.

1) *Text encoder*: The text encoder is responsible for transforming the input prompt into an embedding that captures its semantic meaning. In this work, the **CLIP (Contrastive Language-Image Pretraining)** model is used as the text encoder. CLIP, developed by OpenAI, was trained on millions of image-text pairs to learn a joint embedding space where both textual and visual concepts are aligned.

The input text is first tokenized and embedded through CLIP's **ViT-L/14 (Vision Transformer-Large, Patch 14)** architecture, which models contextual relationships between words using a transformer-based approach. Each token embedding captures the word's meaning relative to its context, allowing semantically similar concepts to occupy nearby regions in the latent space.

By using CLIP as the text encoder, the diffusion model effectively captures the intent and nuances of the prompt, enabling precise conditioning during the image generation process. This integration of language and vision features allows for more coherent and semantically aligned image synthesis compared to earlier word embedding techniques such as Word2Vec [27], GloVe [28], or BERT [29].

2) *Image generator and decoder*: The image generator operates within the latent space of the diffusion model. It begins with a random noise vector and iteratively denoises it under the guidance of the text embedding produced by the CLIP encoder. At each diffusion step, the neural network predicts and removes a portion of the noise, gradually refining the latent representation into a semantically coherent visual form aligned with the input text.

An 860M-parameter U-Net serves as the backbone of the denoising network. The U-Net's encoder-decoder structure and skip connections enable it to capture fine-grained details as well as broader spatial structures, making it particularly suitable for diffusion-based image synthesis.

Once the denoising process is complete, the latent vector is passed through a **Variational Autoencoder (VAE) decoder** [28], which reconstructs the latent representation into the pixel space, producing the final image. The VAE decoder ensures that the generated image maintains both high visual fidelity and semantic consistency with the textual prompt.

D. Speech Recognition

Speech recognition technology converts spoken language into text. In the PicLingo system, we use the Google Cloud Speech-to-Text API, renowned for its robust performance as a cloud-based speech recognition tool. The Google Cloud Speech-to-Text API was selected for several reasons specific to this application. First, it supports real-time transcription with low latency, which is essential for maintaining a child's engagement during interactive tasks. Second, it demonstrates robust performance with children's speech patterns, which tend to differ significantly from adult speech in terms of pronunciation and pacing. Third, its cloud-based architecture eliminates the need for local processing resources, making the system more accessible in low-resource educational environments.

E. Cosine Similarity

A text similarity metric calculates the degradation and contextual relevance. In the interactive game, cosine similarity is applied to measure the similarity between two texts, evaluating their semantic meaning, structural competence between the child's description, generated by speech recognition, and the stored image caption.

To implement this metric, the two texts must initially be represented as vectors [12], [30], [31], after which this metric determines the cosine of the angle formed between two vectors, thereby producing a similarity index that ranges from -1 to 1, where a value of 1 indicates complete similarity, a value of 0 indicates the absence of similarity, and a value of -1 indicates complete dissimilarity [see Eq. (1)].

$$\text{Cosine Similarity}(A, B) = \frac{\mathbf{A} \cdot \mathbf{B}}{\|\mathbf{A}\| \|\mathbf{B}\|} \quad (1)$$

Cosine similarity was selected over alternative metrics such as Euclidean distance or Jaccard similarity because it measures the angle between two vectors rather than their magnitude, making it more robust to differences in description length. This is particularly appropriate in this context, as children

with language disorders may produce shorter or less complete descriptions than expected, and penalizing response length would introduce unfair scoring.

IV. EVALUATION AND RESULTS

This section presents a comparative analysis between the baseline VQGAN model and the proposed Stable-diffusion-v1-5 model, evaluated using the mentioned dataset. To evaluate the performance of both models, three primary metrics were used: Inception Score (IS), Fréchet Inception Distance (FID), and Fleiss' Kappa for human evaluation.

A. Inception Score (IS)

The Inception Score is used to assess both the quality and diversity of generated images [18]. It measures the distance between the distributions of features extracted from these images using a pre-trained image classification model, where lower IS scores indicate better alignment of the generated images with real-world images in the feature space. Before applying IS calculation, images should be preprocessed by converting them to a common RGB format, resizing them to 299x299 pixels to match the expected size for the Inception model, and normalizing pixel values for consistent evaluation conditions. The IS can be calculated using the following Eq. (2):

$$IS(G) = \exp \left(\mathbb{E}_{x \sim p_g} [D_{KL}(p(y|x) \| p(y))] \right), \quad (2)$$

where,

- G : generative model being evaluated,
- p_g : distribution of generated images,
- x : generated images,
- y : class labels predicted by an Inception model,
- $p(y|x)$: conditional class distribution given the generated images,
- $p(y)$: marginal class distribution (often assumed to be uniform),
- D_{KL} : Kullback-Leibler divergence.

B. Fréchet Inception Distance (FID)

The FID metric measures the similarity between the feature distributions of real and generated images, with lower scores indicating a closer alignment between these distributions [19]. It takes both the mean and covariance of the distributions into account, making it a robust metric for generative models. This allows FID to capture even small differences between images. FID is calculated using the following Eq. (3):

$$FID = \|\mu_r - \mu_g\|^2 + \text{Tr}(\Sigma_r + \Sigma_g - 2(\Sigma_r \Sigma_g)^{1/2}) \quad (3)$$

where,

- μ_r : mean feature vector of real images,
- μ_g : mean feature vector of generated images,
- Σ_r : covariance matrix of real image feature vectors,
- Σ_g : covariance matrix of generated image feature vectors,
- $\|\cdot\|$: Euclidean distance,
- Tr : trace of a matrix.

C. Fleiss' Kappa for Human Evaluation

To complement the quantitative metrics, a human evaluation was conducted using Fleiss' Kappa, which measures the level of agreement among multiple raters beyond chance. Three raters with backgrounds in computer science were tasked with assessing the relevance of generated images to their respective text prompts, assigning a score of 0 for no match and 1 for a match.

Fleiss' Kappa is calculated based on the observed agreement among raters (P_o) and the expected agreement by chance (P_e) using the Eq. (4) [20]:

$$\kappa_{\text{score}} = \frac{P_o - P_e}{1 - P_e} \times 100, \quad (4)$$

Interpretation of Fleiss' Kappa scores indicates the level of inter-rater reliability, with higher scores representing stronger agreement.

Using these three metrics should provide a solid foundation to evaluate the models both qualitatively and quantitatively.

It is important to note that the evaluation was conducted on a relatively small subset of 64 samples due to computational constraints. While this size is sufficient for preliminary comparison, it may limit the statistical strength of the results. Future work will include larger datasets and more comprehensive statistical analysis, including variance reporting, to improve the robustness of the evaluation.

D. Results

The results listed in Table III demonstrated that the proposed model outperformed the baseline model in both IS and FID scores, reflecting the high quality of the generated images. Specifically, the proposed model achieved an IS of 4.26 and an FID of 1.83, while the baseline scored an IS of 4.06 and an FID of 6.44. To support these quantitative results, a human evaluation was conducted as detailed in Section IV-C. The proposed model achieved a kappa of 67%, indicating good agreement on the alignment between generated images and the prompt, whereas the baseline model scored a kappa of 17%, reflecting poor inter-rater agreement. To provide further insights into qualitative outcomes, Fig. 4 presents samples of images generated by both models. These results reveal that the images produced by the proposed model are of higher quality and are more realistic compared to those generated by the baseline. This visual comparison underscores the superior performance of the proposed model in generating visually appealing images, making it a more suitable choice for integration into the system.

Fig. 4. Samples of images generated using the baseline model versus the proposed model.

TABLE III. IS AND FID SCORES FOR VQGAN AND STABLE-DIFFUSION-V1-5.

Model	IS $\uparrow$	FID $\downarrow$
Stable-diffusion-v1-5	4.26	1.83
VQGAN+CLIP	4.06	6.44

V. DISCUSSION

The improvement in image quality and semantic alignment is particularly important for the target application. High-quality and contextually accurate images help children better understand visual concepts and support their ability to describe them verbally, which directly contributes to improving language development and engagement during the learning process.

The results demonstrated that the proposed Stable Diffusion model consistently outperformed the baseline in both quantitative and qualitative evaluations. One key observation is that diffusion-based models better capture semantic alignment between text and image, which is essential for educational applications like PicLingo. This improvement in semantic alignment enables the generation of clearer and more contextually accurate images, which can help children better understand visual concepts and support their ability to describe them verbally. Additionally, the integration of speech recognition with visual feedback created a multimodal learning experience that may enhance engagement and retention in children with language disorders. However, the improvement in performance comes at the cost of higher computational requirements.

From a practical perspective, the system shows promising potential for real-world educational use, particularly in personalized learning environments. However, further validation through real-world user studies is required. Future improvements could focus on optimizing performance and extending support to multilingual settings.

VI. CONCLUSION

This study highlights the potential of Generative Artificial Intelligence (GenAI) in transforming the learning experience of children with language disorders. We, therefore, present a novel pedagogical approach, PicLingo, powered by GenAI to provide a personalized learning environment for both the mentor and the child. Since image generation is one of the important features of this system, we conducted a comparative analysis of prominent generative models in the field to find the most effective model. Our analysis shows that the proposed Stable-diffusion-v1-5 model has superior performance over the baseline model, VQGAN+CLIP, with an IS of 4.26 and an FID of 1.83. Fleiss' Kappa results were 67%. It indicates that The proposed model can generate high-quality and diverse images containing semantic information according to the textual description provided by the mentor. Furthermore, PicLingo includes an interactive game through speech recognition technology that engages children by allowing them to determine whether their descriptions are accurate, making it an effective tool for improving communication skills and tracking a child's language development. Our findings indicate that PicLingo shows promising potential as an assistive educational tool;

however, further validation through real-world user studies is required to confirm its effectiveness in supporting children with language disorders. This highlights the potential of GenAI to enhance learning and contribute to the development of more adaptive educational tools.

A. Limitations and Future Directions

While the results are promising, this study is limited to a controlled environment and a relatively small dataset. Future work will focus on expanding the dataset to include a larger and more diverse set of samples (e.g., over 1,000 images) to improve evaluation reliability and generalizability. Additionally, user studies will be conducted with children and educators to assess the system's impact on language development using pre- and post-assessment methods.

Further improvements will include supporting multilingual capabilities (e.g., Arabic and English) and optimizing system performance to reduce response time in interactive environments. Moreover, integrating multimodal feedback—such as emotional tone recognition and adaptive difficulty adjustment—could further enhance the personalized learning experience.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to the College of Computer Science and Engineering at Taibah University for their continuous support and encouragement throughout this research.

An Evidence-Aware and Risk-Sensitive Retrieval-Augmented Generation Framework for Internal Auditing

Tareq Fahad Aljabri, Mariam Abdulaziz Alnajim
Saudi Telecom Company, Riyadh, Saudi Arabia

Abstract—Large Language Models (LLMs) that are enhanced with Retrieval-Augmented Generation (RAG) can aid in internal auditing, particularly in search and analysis of documents. However, in general, most RAG-based audit tools focus more on quick document access and being easy to use, then about deeper auditing reasons. They don't do much to help with significant audit procedures, such as maintenance of clear evidence, calculating risk, and making intelligent decisions. Because of this, they are yet to find a place in ongoing internal auditing, which needs serious evidence and must adhere to recommended auditing standards. This study introduces an *Evidence-Aware and Risk-Sensitive Retrieval-Augmented Generation (ER²-RAG)* to help in internal auditing. The framework doesn't just see how well documents can be retrieved, but also manages audit evidence and considers risk. It connects audit conclusions to supporting documents with confidence levels, modifies the information retrieval based on the audit risk and materiality, and restricts the process of generation to the standard audit reasoning practices. These design choices make AI assistance more transparent, reliable, and defensible in audit judgments. ER²-RAG has been developed and evaluated using the normal audit situations. These situations are related to the analysis of exceptions, evaluation of control efficiency, and control over procedural adherence. The research uses design science methodology. Compared to the older methods of RAG, ER²-RAG is efficient and presents a higher scope of evidence, references the sources much better, and the argument is clearer. The results indicate that risk sensitivity must be taken into account, and evidence should be used when adopting AI systems to perform continuous internal audits. The given research transforms RAG into not only aiding in information retrieval but also as a powerful reasoning foundation of professional assurance. It strives to enhance audit reliability and guide future development of evidence-aware AI systems.

Keywords—LLM; RAG; Audit; digitalization; automation

I. INTRODUCTION

Transformer-based Large Language Models (LLMs) have begun a new period in AI applications in many professional fields [1], [2]. This has changed the way we comprehend natural language [3]. More researchers and practitioners are using models like GPT3 and GPT4 to perform financial and audit procedures such as the analysis of documents, authoring planning, and doing analytical processes [4]. Due to this, there is an increasing interest to solve problem in internal auditing using LLMs. This includes handling more and more information, complex regulations, and necessity of constant assurance [5].

In spite of the current developments, not all of the LLM application is suitable for internal auditing [6]. The majority

of general conversation tools are only able to maintain limited context when chatting and require users to post documents individually. They are not very clear regarding the data that was provided to them with the answers. This is a significant weakness of internal audits, since the conclusions reached in the audit should be backed by traceable evidence, and should conform to specified standards [7]. The previous research has attempted to address this issue through Retrieval-Augmented Generation (RAG) with AI agents. This enabled them to gain access to confidential sources of audit knowledge and generate more accurate responses [8].

The latest studies have revealed that RAG-based AI agents are more successful than standalone LLMs at tasks such as searching documents, table processing data, and automation of audit workflows [9]. Nonetheless, such systems are more concerned with the data that they access rather than the way that auditors make inferences based on that data [10]. Internal auditors need to collect the appropriate data, evaluate its reliability, take audit risks into account, and report the findings to further review and regulation [11]. Current RAG frameworks do not clearly explain the reasoning and evidence needed [12].

A continuous auditing model, in which controls, transactions, and risks are continuously assessed rather than through recurring engagements, is becoming increasingly popular in internal auditing [13]. This change alters the expectations for supporting technologies. AI systems must be able to gather evidence over time, reevaluate risk when circumstances change, and support expert decisions that can be convincingly defended in such circumstances [14]. Because they lack explicit mechanisms for risk-aware reasoning and evidence attribution, current RAG-based agents fall short in meeting these needs. Their suitability for this new internal auditing method is therefore still limited [15].

This study presents an Evidence-Aware and Risk-Sensitive RAG (ER²-RAG) framework to address these problems and improve intelligent internal auditing. ER²-RAG integrates audit-specific reasoning constraints, explicit evidence traceability, and risk-weighted knowledge retrieval within an AI agent architecture, in contrast to earlier methods that prioritize retrieval efficiency. From basic information assistants to sophisticated audit reasoning systems that can support continuous internal auditing procedures, the framework seeks to develop RAG-enhanced agents.

Three major contributions are made by this study. It first presents a system that links verifiable source documents and confidence indicators to audit conclusions produced by arti-

cial intelligence. Second, it proposes a risk-sensitive retrieval approach that aligns information access with materiality and audit risk considerations. Third, it demonstrates how AI-assisted audit decisions can be made more transparent and consistent by using reasoning-limited generation. When taken as a whole, these contributions improve RAG-based auditing systems and set the stage for further studies on reliable AI in assurance services.

The rest of the study is organized as follows: Section II discusses the related work. Section III discusses the proposed methodology. Section IV discusses the detailed experiment results, and Section V concludes the findings of the proposed work.

II. RELATED WORK

According to recent research, the procedural, multi-step, and document-intensive nature of auditing makes it a good fit for LLM-based agents [16]. Accordingly, auditors gain more from a structured agent workflow that can: 1) direct a query to the appropriate subtask, 2) apply standardized audit methods via fixed prompts, and 3) connect to private audit repositories through retrieval mechanisms than from a single chatbot interaction. In order to minimize manual document handling while maintaining methodological consistency, Xiong et al. [17] describe an audit-agent design that revolves around these concepts and combines retrieval-augmented generation, customizable workflows (such as sequential/parallel agents), and prompt orchestration.

Retrieval-Augmented Generation is commonly used to address two persistent limitations of foundation LLMs in professional applications, namely knowledge cutoff and hallucinated outputs. In enterprise settings, RAG research has focused on building complete pipelines that span document ingestion, text chunking, embedding generation, vector database indexing, reranking strategies, and security and privacy controls. This work is typically accompanied by evaluation methods that assess retrieval quality and the faithfulness of generated answers [18], [19], [20], [21], [22]. In auditing contexts, the requirement for grounded responses becomes more critical, since audit conclusions must be directly traceable to authoritative evidence. Within audit-agent designs, RAG is therefore used as the primary mechanism for linking auditors to internal procedure manuals, workpapers, and regulatory guidance, without relying on repeated manual document uploads [17], [23], [24].

Audit procedures routinely require auditors to work with evidence that appears in different formats. Structured tables, including trial balances, accounts payable aging reports, and revenue listings, must often be analyzed together with narrative policy documents and prior audit workpapers [25], [26], [27]. This combination creates practical challenges for automated systems. Prior research shows that general-purpose LLMs perform poorly in such contexts, particularly when numerical consistency must be preserved, when information is spread across multiple documents, or when tabular evidence needs to be accurately reflected in generated responses [24], [28], [29], [30], [31]. These shortcomings have increased interest in RAG-enhanced agents for tabular processing and have driven the development of architectures that enable retrieval from both unstructured text and table-aware representations, ensuring that

responses are grounded in retrieved evidence and adhere to a predefined audit response schema [32], [33].

Baseline vector RAG can work well for local, pinpoint questions, but audit repositories contain dense cross-document dependencies (policies $\rightarrow$ procedures $\rightarrow$ templates $\rightarrow$ exceptions), where the “best” evidence may be distributed across multiple files. Graph-based RAG approaches address this by building an entity-relationship index and generating community summaries that support corpus-level (global) questions and sensemaking [34]. In parallel, blended/hybrid retrieval methods combine dense and sparse retrievers, or integrate knowledge graphs with vector retrieval to improve recall and robustness under terminology variation [35], [36]. Audit-agent work explicitly discusses evaluating baseline RAG against GraphRAG to better handle interconnected audit documentation [17].

“Helpful” responses are insufficient for audit use unless they are consistent with the engagement context, verifiable, and permission-aware. Evaluation beyond fluency, such as retrieval metrics (e.g., precision/recall, MRR) and generation metrics related to faithfulness and correctness, is becoming more and more important in the RAG literature [22], [19], [21]. Layered controls and validation gates are frequently motivated by governance concerns (confidentiality, scoped access, and evidence-only claims) in applied internal audit contexts. The need for careful design and monitoring is reinforced by related work in internal-auditing education, which also highlights privacy, ethical use, and reliability issues when implementing generative systems [37], [38], [39].

III. METHODS

The ER²-RAG framework, shown in Fig. 1, accepts a straightforward natural language question from an auditor, which can be supplemented with basic audit context like the business process being examined and the time frame of the audit. The query can be stated in simple terms and does not need to employ technical auditing terminology or established query formats.

The framework creates a structured, evidence-based audit response that includes a clear conclusion, clear references to the audit evidence that supports it, an assessment of the evidence’s strength, and a confidence level that is suitable for professional evaluation and documentation.

This framework aims to provide structure and clarity to an investigation that is usually informal. There are several steps involved in the process. These involve the breaking down of tasks, collecting evidence while also minding the potential risks, plainly displaying the source of evidence, and employing normal audit procedures rather than simply answering the question. Each step adds context and organization. It gradually introduces risk factors, audit-related issues, and supporting evidence. As a result, a simple question such as “Does the company check invoices before paying them?”, is converted into a structured audit evaluation that links findings with evidence-based data and is displayed to the auditor in a form suitable for professional review and documentation.

A. Layer-Wise Explanation of the ER²-RAG Framework

This subsection explains how an input query is progressively transformed as it passes through each layer of the pro-

Fig. 1. Flowchart representation of the ER²-RAG methodology for internal auditing.

posed ER²-RAG framework. For demonstration let's consider a simple, layman-level query: “Are invoices checked properly before payments are made?”

1) *Layer 1: Intake and task routing*: The auditor submits a raw natural-language query to the layer. The query is currently unstructured and might not include specific audit-related terms. Understanding the purpose of the query and classifying it into the proper audit task type are the goals of the intake and task routing layer. The system identifies that the query is about checking how effective the controls are for verifying invoices in the accounts payable process. It uses intent recognition and contextual clues to do this. The system also assesses an initial risk level based on the features of the process and any potential financial impacts. This step creates a clear task outline that directs all further actions by specifying the audit goal, the type of task, and the response format needed.

2) *Layer 2: Policy guardrails*: The structured task definition of the last layer is the input to the policy guardrails layer. This layer is not altering the meaning of the query. Rather, it establishes explicit guidelines on how one will access it. The system maintains access control as well as confidentiality, which ensures that only authorized audit documents are utilized. An important purpose of this layer is to abide by the principle that if there is no evidence, there should be no claim. This is a rule that prevents the system from making conclusions without evidence to support that conclusion. This layer provides a safe layer that enables the query to be processed safely whilst adhering to the audit regulations.

3) *Layer 3: Risk-Sensitive Retrieval (ER layer)*: The retrieval layer is risk-sensitive and utilizes initial query and task parameters to locate the relevant audit evidence in the private knowledge base. First, it broadens the query to fit certain terms of the process, and auditing of it is useful in improving retrieval. The system then does a hybrid search, which involves searching by semantic similarity and by keyword matching. The retrieved documents are then ranked with the help of a scoring system that concentrates on risk. Such a system places emphasis on the most recent versions, documents about the high-risk areas, and documents by trusted sources. The result of this layer is a ranked list of evidence items in decreasing order of their significance. The information in each piece comprises the type of the source, version, and relevance score.

4) *Layer 4: Evidence Attribution Engine (E² layer)*: The evidence attribution layer processes the ranked evidence chunks that have been retrieved previously. In this layer documents are retrieved and assessed according to the contribution

each has had to a particular auditing task rather than being considered as an unstructured collection. The query is divided into the explicit audit claims, i.e. whether invoices are inspected and whether the inspections take place regularly. The documents are then linked to every claim and classified as either direct, indirect, or inferred evidence. The confidence levels are based on the reliability and the consistency of evidence available. Propositions which are not supported enough are removed out of reasoning. Consequently, this layer generates organized claim-evidence mapping, which can be revised and traced to references.

5) *Layer 5: Reasoning-constrained generation*: This is where the emphasis is placed on putting together an audit response that will be based on the previous claims. This response is grounded on fundamental auditing principles and is dependent upon the already gathered evidence. In the example of verifying invoices, an answer is provided on whether there is a review process, where it might not be complete enough, and what risks are associated with that. The result of this is an early audit report that adheres to regular audit reasoning and can be traced to supporting documentation.

6) *Layer 6: Validation and quality gates*: Here, the draft audit response is verified, after which it is finalized. This is to ensure that nothing significant is left out and that the response is sensible. Simple checks are made to determine whether the format intended is correct, whether evidence supports the claims, and whether it brings any contradiction. In case an issue is discovered, additional information may be entered, or the confidence level may be re-established. Once this check is made, the audit reply will be available to be checked.

7) *Layer 7: Audit trail and continuous monitoring*: In the final stage, final audit response and supporting information are stored. This involves the original question, the documents involved, the findings that have been made, and the confidence level. Maintaining these records simplifies the reviewing of the work in the future and allows the audits to be tracked over time. In case the same questions crop up, these records can be reexamined to determine whether there has been any change of risk or controls. A brief summary of the layers and their functions is provided in Table I.

IV. EXPERIMENTAL RESULTS

A. Audit Query Set

In order to test the ER²-RAG model, we applied a series of real-life audit questions. The questions were provided in

TABLE I. STEP-BY-STEP PROCESSING OF AN AUDIT QUERY IN THE PROPOSED ER²-RAG FRAMEWORK

Stage	Component	Input	Processing Function	Output	Role of RAG
0	Auditor / User	Natural-language query + audit context	User submits a question in everyday language (e.g., “Are invoices checked properly before payments are made?”)	Raw audit query	–
1	Intake & Task Router	Raw query + context	Classifies the query type (e.g., control evaluation), detects risk and materiality, and selects the appropriate audit response template	Structured audit task definition	RAG not yet applied
2	Policy Guardrails	Task definition	Enforces audit scope, access permissions, confidentiality constraints, and the <i>no-evidence-no-claim</i> rule	Constrained execution environment	RAG constrained by governance
3	Risk-Sensitive Retrieval (ER Layer)	Structured task + expanded query	Performs query expansion and hybrid retrieval (vector, keyword, and graph-based search). Ranks documents based on risk relevance, authority, and recency	Ranked evidence chunks with metadata	Primary RAG retrieval stage
4	Evidence Attribution Engine (E ² Layer)	Retrieved evidence chunks	Maps retrieved documents to explicit audit claims, classifies evidence strength (direct, indirect, inferred), and assigns confidence scores	Evidence-backed claim structure	Transforms RAG output into grounded evidence
5	Reasoning-Constrained Generation	Evidence-backed claims + templates	Generates audit responses using structured audit reasoning (criteria, condition, cause, effect, and recommendation)	Draft audit conclusion with citations	RAG constrains generation to evidence only
6	Validation & Quality Gates	Draft response + evidence	Verifies citation coverage, detects contradictions, validates numerical consistency, and enforces output schema compliance	Validated audit response	RAG feedback loop (retrieve or regenerate if needed)
7	Audit Trail & Continuous Monitoring	Final response + metadata	Logs the query, supporting evidence, confidence scores, and version changes to support reviewability and continuous auditing	Versioned audit record	RAG supports future comparisons
–	Final Output	Validated response	Presents the final answer with explicit citations, confidence level, and evidence summary	Review-ready audit response	Fully RAG-grounded output

the same format that auditors typically pose when they are doing their planning, field work, and review. Technical or other fixed formats were not used. We kept the language simple and focused on common audit concerns, such as risk, compliance, and whether controls are actually working.

Twenty five de-identified audit questions covering multiple internal audit domains, such as accounts payable, payroll, access control, procurement, and policy compliance, made up the final query set. Instead of just requiring factual retrieval, each query was intended to require evaluative reasoning backed by documentary evidence. This design decision made sure that the evaluation assessed the framework’s capacity to convert unstructured inquiries into organized, fact-based audit conclusions.

Common audit task categories, including control operation assessment, compliance verification, exception identification, and monitoring activities, were used to classify the queries. A subset of representative queries used in the experiments is shown in Table II, along with the audit focus and task type that correspond to each query.

For both the proposed ER²-RAG framework and the baseline RAG system, each query was run independently under the same conditions. This made sure that variations in performance could be linked to the design of the framework rather than the creation of the queries. The evaluation was also able to determine how well the framework enriches minimal user input with audit-specific context, risk awareness, and evidence grounding thanks to the use of straightforward, intuitive queries.

All things considered, the audit query set provides a useful standard for evaluating the framework’s capacity to close the gap between unofficial auditor questions and audit outputs that can be professionally defended.

B. Evaluation Metrics

In order to measure the system applied in internal auditing, our measures need to be more than the soundness of the responses. When evaluating an automated response in professional audit practice, we evaluate its relevance or clarity, the effectiveness with which it is supported by data, its potential fit to risk factors, and its relevance to audit working papers. As a result, both technical performance and audit-specific quality dimensions are evaluated using the evaluation metrics employed in this study.

1) *Evidence coverage rate*: The percentage of material statements in the generated response that are specifically backed up by cited audit evidence is known as the evidence coverage rate. For an audit to be defensible, conclusions must have a stronger foundation in verifiable documents, which is indicated by a higher coverage rate.

2) *Citation correctness*: Citation correctness assesses whether the referenced materials actually bolster the assertions they are linked to. In order to make sure that citations are not only pertinent but also significantly support the corresponding audit statements, this metric was evaluated manually.

3) *Unsupported claim rate*: The percentage of statements in the output that are not supported by direct or indirect evidence is known as the “unsupported claim rate”. Since unsubstantiated claims erode professional skepticism and raise audit risk, lower values are preferred.

4) *Response consistency*: The variability of results when the same query is run repeatedly under the same circumstances is measured by response consistency. In audit contexts where reproducibility is crucial, high variability may be a sign of unstable reasoning, which is undesirable.

5) *Audit readiness*: The qualitative indicator of whether a generated response can be added to audit documentation with little change is called audit readiness. The answers received the

TABLE II. EXAMPLES FROM THE AUDIT QUERY SET USED IN EXPERIMENTAL EVALUATION

ID	Audit Query (Example)	Audit Area	Task Type
Q1	Are invoices checked properly before payments are made?	Accounts Payable	Control effectiveness
Q2	Are purchase orders approved before goods are received?	Procurement	Compliance verification
Q3	Is access to the payroll system reviewed regularly?	Payroll	Control monitoring
Q4	Are terminated employees removed from systems on time?	Access Control	Risk identification
Q5	Are changes to vendor master data properly authorized?	Vendor Management	Fraud risk assessment
Q6	Are manual overrides of system controls reviewed and approved?	IT Controls	Exception analysis
Q7	Are financial policies updated and communicated to staff?	Policy Governance	Compliance monitoring

TABLE III. COMPARISON OF BASELINE RAG AND ER²-RAG USING AUDIT-ORIENTED EVALUATION METRICS

Metric	Baseline RAG	ER ² -RAG
Evidence Coverage Rate (%)	68.4	92.1
Citation Correctness (%)	71.2	94.5
Unsupported Claim Rate (%)	18.7	4.3
Response Consistency (Std. Dev.)	0.21	0.08
Audit Readiness	Medium	High

TABLE IV. ABLATION STUDY RESULTS FOR THE ER²-RAG FRAMEWORK

Configuration	Evidence Coverage (%)	Citation Correctness (%)	Unsupported Claims (%)	Audit Readiness
Full ER ² -RAG	92.1	94.5	4.3	High
Without Risk-Sensitive Retrieval	84.7	88.9	8.6	Medium-High
Without Evidence Attribution	76.2	79.5	15.8	Medium
Without Validation Gates	81.4	83.1	11.2	Medium

rating Low, Medium, or High depending on the professional tone, clarity, structure, and evidence utilization.

All in all, these ratings give a clear picture of the extent to which the framework is capable of supporting practical internal auditing assignments.

As indicated by the outcome in Table III, ER²-RAG has always demonstrated better performance than the base RAG strategy in all the considered dimensions. The high performance of the evidence attribution and Risk-sensitive retrieval layers is indicated by the marked increase in the accuracy of citation and evidence coverage. Reasoning constraints and validation gates also help produce audit output that is more stable and defensible as demonstrated by the reduction of unsupported claims and the rise in the consistency of responses. All these findings indicate that ER²-RAG is more compliant with professional internal auditing demands, compared to the traditional systems that rely on RAG.

C. Ablation Study

To test the contribution of each of the components of the proposed ER²-RAG framework, an ablation study was conducted. This analysis was conducted to know the influence of key elements on the overall performance of the system with special attention to audit critical areas such as support of evidence, reasonableness, and audit preparation.

We started with the entire ER²-RAG system and switched off each of the elements one by one to observe the difference. We did not use the risk-based retrieval in certain tests. In other cases, we omitted the stage of evidence attribution or omitted the last checks of validation. All other factors were retained in order to make the comparison fair.

All versions were tested with the same audit questions as well as evaluation measures. By doing this, any variation in the outcome is a result of the part that was eliminated and not the variations in the data or the system configuration.

Table IV demonstrates the impact of the different elements of the ER²-RAG framework on system performance. When the risk-sensitive retrieval mechanism is eliminated, we observe a vast decrease in the coverage of evidence and accuracy of citations. This demonstrates that the ranking of sources according to risk is essential in obtaining reliable audit sources. The unsupported claims are significantly higher with the evidence attribution layer turned off, and the performance decreases the most. This highlights the significance of definite claim-evidence mapping towards auditing defensibility. Equally, the absence of quality and validation gates lets statements that have minimal or no support, which lessens reliability.

All things considered, the ablation study confirms that the recommended components function together rather than separately. The full ER²-RAG configuration consistently outperforms all ablated variations, validating the architectural

design choices and confirming the framework's suitability for professional internal auditing applications.

V. CONCLUSION

This research study has proposed ER2-RAG, an evidence-conscious and risk-sensitive RAG model of internal audit. The primary theoretical contribution is the design of audit-oriented RAG as a multi-layered architecture, which combines retrieval, evidence attribution, structured reasoning, validation, and audit trail generation into one structure. In this respect, the study adds new knowledge, demonstrating how generative AI may be customized to address the traceability, reliability and compliance requirements of internal audit.

The findings indicate that ER2-RAG has a significant positive impact on evidence coverage, citation correctness, response consistency, and audit readiness and fewer unsupported claims than usual RAG. The ablation experiment also supports the fact that risk-sensitive retrieval, evidence attribution, and validation gates have all effects on the overall performance. These results indicate the significance of evidence-based and audit-focused controls of credible AI-assisted auditing.

There are certain limitations in this study. It was tested on a small sample of de-identified audit queries and was not aimed at benchmarking at scale or more diverse corpus or security hardening. Future directions can build on the framework by assessing the framework on larger sets of auditors, more comparison to baseline, and more defense against an adversarial or misleading retrieved content. All in all, this study offers a conceptual and practical basis of reliable and audit compliant internal auditing generative AI systems.

Abstract—This study proposes a hybrid modeling and control framework for intelligent wheelchair systems that integrates formal methods with adaptive artificial intelligence to ensure safety, robustness, and real-time performance. The approach combines Timed and Colored Petri Nets for formal safety enforcement with machine learning techniques, including a Multi-Layer Perceptron, Q-learning, and fuzzy logic. The system is validated through simulation and FPGA-based implementation, demonstrating improved command accuracy, safety compliance, and response time compared to baseline approaches. The main contribution lies in the integration of formal verification with adaptive intelligence within a real-time embedded system for assistive mobility.

Keywords—Timed Petri Nets; assistive robotics; adaptive control; neural networks; fuzzy logic FPGA; human-machine interaction

I. INTRODUCTION

Recent advances in assistive robotics have significantly improved the autonomy of individuals with severe motor impairments, particularly through the development of intelligent electric wheelchairs. These systems increasingly rely on multimodal human-machine interfaces, such as joysticks, breath sensors, EEG signals, or voice commands, combined with embedded intelligence to provide safe and intuitive mobility. Despite these advances, designing wheelchair control systems that are simultaneously safe, adaptive, and compliant with strict real-time constraints remains a major challenge.

One of the key difficulties arises from the nature of human control signals. User inputs are often noisy, unstable, or incomplete due to tremors, fatigue, weak biosignals, or disease progression. Directly mapping such signals to motion commands may lead to unintended or unsafe movements. In parallel, intelligent wheelchairs operate in dynamic environments where collision avoidance and emergency reactions must be guaranteed within tight latency bounds, typically below 100 ms.

Existing approaches address these challenges only partially. Machine learning and deep learning techniques have demonstrated strong performance in filtering noisy inputs and inferring user intent, especially in EEG- or vision-based interfaces [6], [8]. Reinforcement learning methods further enable adaptive navigation and assisted driving by learning cooperative policies between the user and the autonomous

system [4], [9], [5]. However, such data-driven approaches generally lack formal guarantees of safety, correctness, and temporal behavior.

Conversely, formal models such as Petri Nets provide a rigorous framework for specifying, analyzing, and verifying concurrent and time-critical systems. Timed and stochastic extensions allow performance evaluation and safety analysis under temporal constraints [1], [2], while Colored Petri Nets support the modeling of complex, data-driven interactions [3], [7]. Nevertheless, purely formal approaches offer limited adaptability to individual users and evolving conditions.

This study addresses the following research question: How can an intelligent wheelchair control system be designed to be: 1) formally safe, 2) robust to noisy and uncertain input signals, 3) adaptive to individual and evolving user profiles, and 4) executable in real-time with minimal latency?

To answer this question, we propose a hybrid modeling and control framework that integrates formal methods with artificial intelligence. Timed and Colored Petri Nets are employed as a formal backbone to enforce safety constraints and real-time behavior. On top of this structure, a Multi-Layer Perceptron compensates noisy user commands, a Q-learning module adapts control sensitivity according to user state, and a fuzzy inference layer interprets ambiguous multimodal inputs. Finally, the proposed architecture is implemented on FPGA hardware to guarantee deterministic execution and low latency. This work builds upon our previous research [17], where we investigated the integration of Petri Nets with machine learning and decision-making models for healthcare robotics. In contrast to that work, which focused on high-level resource allocation, the present study addresses real-time control, user interaction, and safety-critical execution in intelligent wheelchair systems.

The main scientific contributions of this work are summarized as follows:

- A formally verified hybrid control architecture integrating Timed and Colored Petri Nets with adaptive artificial intelligence, ensuring mutual exclusion between motion and emergency states while maintaining learning-based adaptability.
- A mathematically formalized hybrid control model integrating Petri Nets with learning-based adaptation,

ensuring both formal correctness and adaptive intelligence.

- A neural-based command stabilization mechanism that reduces input noise variance by 37% under high disturbance conditions, significantly improving trajectory smoothness.
- A reinforcement learning strategy enabling online personalization of control sensitivity, achieving convergence within 30 training episodes.
- A complete formal analysis of liveness, boundedness, reachability, and safety properties through Petri Net modeling and reachability graph verification.
- A real-time FPGA implementation demonstrating deterministic execution with a 2.4× speedup compared to CPU-based software execution.

This work bridges the gap between formal verification and adaptive intelligence in safety-critical assistive mobility systems.

II. RELATED WORK

A. Petri Net-Based Formal Modeling

Petri Nets are a well-established formalism for modeling, analysis, and verification of concurrent and time-critical systems [11]. Timed Petri Nets extend the classical model by associating firing delays with transitions, enabling performance evaluation and latency analysis in real-time applications [1]. Stochastic Petri Nets further incorporate probabilistic behavior and have been applied to reliability and performance analysis of complex systems [2].

Colored Petri Nets increase modeling expressiveness by allowing tokens to carry data values, which is particularly useful for representing multimodal human-machine interactions. Recent works demonstrate the effectiveness of combining timed and colored extensions for specifying and verifying robotic systems with safety constraints [3], [7]. However, most Petri Net-based approaches focus primarily on formal verification and lack mechanisms for online adaptation to user-specific behavior.

B. Artificial Intelligence in Assistive Wheelchairs

Machine learning techniques are widely used to interpret noisy or incomplete user inputs in assistive systems. Neural networks, including CNNs and MLPs, have been applied to EEG-based wheelchair control and personalized assistive interfaces [6], [8]. These methods significantly improve intention recognition but do not provide formal safety guarantees.

Reinforcement learning approaches have shown promising results in adaptive wheelchair navigation and obstacle avoidance. Recent studies report improved robustness and user comfort by learning cooperative control strategies between the human user and the autonomous system [4], [9], [5]. Nevertheless, most of these approaches rely on CPU-based execution and are validated mainly in simulation environments.

Fuzzy logic remains relevant for handling uncertainty in multimodal interfaces by translating continuous signals into

linguistic variables [14]. Fuzzy controllers have been successfully applied in smart assistive devices to achieve smooth and human-like behavior [10]. However, fuzzy systems alone cannot ensure formal correctness or optimal adaptation.

C. Gap Analysis and Motivation

Despite significant progress, existing studies largely treat formal modeling and adaptive intelligence as separate concerns. Formal Petri Net models provide strong safety and verification capabilities but limited adaptability, while AI-based controllers offer adaptability without formal guarantees. Moreover, few works demonstrate a complete integration including formal modeling, adaptive learning, and real-time embedded implementation.

Motivated by these gaps, this work proposes a unified framework that combines Timed and Colored Petri Nets with machine learning, fuzzy logic, and FPGA-based execution to jointly address safety, adaptability, and real-time constraints in intelligent wheelchair control systems. In our previous work [17], we explored the integration of Petri Nets with Markov Decision Processes and machine learning techniques for optimizing resource allocation in healthcare robotic systems under crisis conditions. While that study focused on system-level decision-making and resource optimization, it did not address real-time human-machine interaction or adaptive control of assistive mobility devices.

The present work extends this line of research by introducing a hybrid control framework specifically designed for intelligent wheelchair systems, combining formal safety modeling with adaptive signal interpretation and real-time embedded implementation.

III. PROBLEM STATEMENT

The design of intelligent electric wheelchairs for people with reduced mobility remains a highly challenging research area, as it combines issues of safety, reliability, adaptability, and real-time performance. Despite recent advances in assistive robotics, several key challenges remain unresolved:

- Noisy and unstable control signals: User commands, whether from joysticks, breath sensors, EEG, or voice interfaces, are often affected by *tremors, fatigue, or signal artifacts*. These noise factors may result in unintended movements, reducing system reliability and even compromising user safety.
- Safety and risk of collision: In real-world environments, unexpected obstacles, delays in sensor-actuator loops, and user reaction times can cause accidents. Guaranteeing a *formal level of safety*, such as the prioritization of emergency stops, is a critical requirement.
- Lack of personalization and adaptability: Each user presents unique abilities and limitations, which evolve over time due to fatigue or progression of motor impairment. Static control strategies are insufficient; systems must *adapt dynamically* to individual conditions in order to maintain usability and comfort.

- Handling uncertainty in multimodal inputs: Multimodal interfaces (e.g., joystick + breath + EEG) produce *heterogeneous and uncertain data*. Traditional binary decision-making cannot effectively manage this uncertainty, leading to a higher error rate in command interpretation.
- Real-time execution constraints: Assistive devices must operate under strict real-time requirements. Latency above *100 ms* in command interpretation or obstacle avoidance can compromise user safety. CPU-based implementations often struggle to meet these constraints under heavy computational loads.

Problem Reformulation: The central research question can be expressed as follows:

How can we design an *intelligent wheelchair control system* that is simultaneously:

- formally safe, with guaranteed emergency reactions,
- robust to noisy and uncertain input signals,
- adaptive to individual user profiles and evolving conditions,
- and executable in real-time with minimal latency?

IV. METHODS

This section presents the proposed hybrid control methodology for intelligent wheelchair systems. The approach combines formal modeling with learning-based adaptation to ensure safety, robustness to noisy user inputs, personalization, and real-time execution. The overall architecture relies on four complementary components: 1) Timed and Colored Petri Nets for formal control and safety enforcement, 2) a Multi-Layer Perceptron (MLP) for command correction, 3) a reinforcement learning module for long-term adaptive control, and 4) a fuzzy inference system for managing uncertainty in multimodal inputs.

A. Timed and Colored Petri Nets

Petri Nets constitute the formal backbone of the proposed control architecture. A Petri Net is defined as a tuple:

$$N = (P, T, Pre, Post, M_0),$$

where, P is a finite set of places, T is a finite set of transitions, Pre and $Post$ are incidence functions, and M_0 denotes the initial marking. A transition is enabled when all its input places contain a sufficient number of tokens. Once fired, the marking is updated according to:

$$M' = M + (Post - Pre).$$

Timed Petri Nets extend this formalism by associating delays with transitions, allowing explicit modeling of sensor latency, processing time, and actuator response. Colored Petri Nets further enhance expressiveness by allowing tokens to carry data values, such as input type, intensity, or confidence level. These extensions are particularly suitable for modeling

multimodal human-machine interaction in assistive wheelchair systems.

Within the proposed framework, Petri Nets are responsible for sequencing control actions, enforcing priority rules, and guaranteeing safety properties such as emergency-stop precedence and mutual exclusion between motion and emergency states.

B. Command Correction Using Multi-Layer Perceptron

User control signals, such as joystick movement, breath pressure, or EEG input are often affected by noise, tremors, fatigue, and signal instability. Direct use of these raw signals may result in unintended or unsafe wheelchair motion. To improve robustness and reliability, a Multi-Layer Perceptron (MLP) is integrated to correct and stabilize user input commands before execution.

The MLP is a feed-forward neural network composed of an input layer, two hidden layers, and an output layer. Let the input vector be defined as:

$$x \in \mathbb{R}^m \quad (1)$$

The hidden layer activations are computed as:

$$h^{(l)} = f(W^{(l)}h^{(l-1)} + b^{(l)}) \quad (2)$$

where,

- $W^{(l)}$ is the weight matrix,
- $b^{(l)}$ is the bias vector,
- $f(\cdot)$ is the activation function (ReLU).

The corrected output command is computed as:

$$y = W^{(L)}h^{(L-1)} + b^{(L)} \quad (3)$$

The network is trained using cross-entropy loss [13]:

$$L = - \sum_{i=1}^K y_i^{true} \log(y_i^{pred}) \quad (4)$$

The architecture used in this work consists of:

- Input layer: 4 neurons (joystick X, joystick Y, breath signal, EEG confidence)
- Hidden layer 1: 16 neurons
- Hidden layer 2: 8 neurons
- Output layer: 2 neurons representing corrected motion commands

Fig. 1 illustrates the simplified architecture of the MLP used for signal correction.

The corrected output is then transmitted to the Petri Net control system, as shown in Fig. 2.

Fig. 1. Simplified multi-layer perceptron architecture used for correcting noisy user input signals.

Fig. 2. MLP-based signal correction pipeline integrated with the Petri Net control system.

An example of signal correction is illustrated in Fig. 3, where noisy input signals are transformed into stable control commands.

This neural correction layer significantly improves signal reliability, reduces command fluctuation, and enhances overall system safety while maintaining real-time performance suitable for FPGA implementation.

C. Q-Learning

Q-learning is used to adapt control decisions through interaction. The wheelchair is modeled as a Markov Decision Process (MDP) with states $s \in S$, actions $a \in A$, and

Fig. 3. Example of noisy input signal correction using the MLP, showing improved stability after neural processing.

Fig. 4. Q-learning structure, where each state is associated with multiple actions. The optimal policy is learned through reward-based updates of the global $Q(s, a)$ function.

reward function $R(s, a)$ [12]. The value of a state-action pair is updated as:

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha \left[r_{t+1} + \gamma \max_{a'} Q(s_{t+1}, a') - Q(s_t, a_t) \right] \quad (5)$$

where, α is the learning rate and γ is the discount factor. Rewards encourage safe navigation and penalize collisions. For example, a safe move could reward $+1$, while a collision gives -10 . This ensures the system learns policies that improve safety and efficiency over time.

Unlike deterministic control strategies, each state is associated with multiple possible actions, and the optimal action is selected based on the learned Q-values. This allows the system to dynamically adapt its behavior according to the user condition (e.g., stable, shaky, or fatigued), rather than relying on fixed state-action mappings.

The reward signal does not update a single state independently, but contributes to the global update of the Q-function. As a result, all state-action pairs are progressively optimized through interaction, leading to a learned control policy that improves over time.

The Q-learning module influences the decision layer by dynamically adjusting control sensitivity based on the learned policy, as illustrated in Fig. 4.

The learning performance of the Q-learning module is illustrated in Fig. 5, which shows the evolution of the accumulated reward over training episodes and demonstrates convergence toward an optimal policy.

Safety Consideration: It is important to note that the Q-learning module is trained exclusively in a simulated environment. During real-world deployment, the Petri Net supervisory layer enforces strict safety constraints and prevents unsafe actions such as collisions. Therefore, learning does not occur through real-world trial-and-error but is transferred from simulation to deployment, ensuring user safety at all times.

Fig. 5. Training performance of the Q-learning module showing reward convergence over episodes, indicating progressive improvement of the learned control policy.

D. Fuzzy Logic

Fuzzy logic manages uncertain or imprecise inputs, mapping continuous values to linguistic categories. For a variable x (e.g., breath pressure), fuzzy membership functions define degrees of belonging to sets:

$$\mu_{Weak}(x), \mu_{Medium}(x), \mu_{Strong}(x) \in [0, 1]. \quad (6)$$

A common choice is the sigmoid function:

$$\mu(x) = \frac{1}{1 + e^{-\beta(x-c)}}. \quad (7)$$

Rules then combine fuzzy sets, e.g.:

IF (breath intensity is Strong) AND (direction = Left)
THEN turn Left with High speed.

Defuzzification transforms the fuzzy output back into a crisp value using the centroid method:

$$y = \frac{\int_{\Omega} x \cdot \mu(x) dx}{\int_{\Omega} \mu(x) dx}. \quad (8)$$

This produces smooth, human-like decisions that are robust to noise.

Overall, Petri Nets ensure logical correctness and timing, MLPs normalize and classify user signals, Q-learning adapts strategies dynamically, and fuzzy logic handles ambiguity. Together, they provide a hybrid framework for safe and personalized wheelchair navigation.

V. SYSTEM MODELING USING PETRI NETS

A. Formal Description

The model is based on a **Colored and Timed Petri Net** formally defined as:

$\mathcal{N} = (P, T, F, \Sigma, C, G, D, M_0)$, where:

- P is the set of places;
- T is the set of transitions, with $P \cap T = \emptyset$;
- $F \subseteq (P \times T) \cup (T \times P)$ is the set of directed arcs;
- Σ is the set of colors (token types), such as $\{joystick, breath, voice, eeg\}$;
- $C : P \rightarrow 2^{\Sigma}$ associates each place with its allowed token colors;
- $G : T \rightarrow \text{Guards}$ defines logical guard conditions for transitions;
- $D : T \rightarrow \mathbb{R}_{\geq 0} \cup \{\text{stoch}(\lambda)\}$ assigns each transition a deterministic or stochastic delay;
- $M_0 : P \rightarrow \mathcal{M}(\Sigma)$ defines the initial marking.

A transition t is said to be *enabled* if, for each input place p , there exists a sufficient number of compatible tokens and if the guard $G(t)$ evaluates to true. Once fired, t consumes the input tokens and produces new output tokens after the delay $D(t)$ expires. Fig. 6 details the overall hybrid system architecture of the intelligent wheelchair.

VI. ANALYSIS OF THE PETRI NET MODEL AND REACHABILITY GRAPH

A. Interpretation of the Petri Net Structure

The Petri Net, presented in Fig. 7, models the decision and control flow of the intelligent wheelchair. Each place and transition represents a distinct phase of the control pipeline, ensuring modularity and traceability of system behavior.

The net begins with P_{cmd_in} , which stores raw user commands (joystick, EEG, or sip-and-puff). These inputs are preprocessed through the transition T_{mlp} , where a Multi-Layer Perceptron (MLP) filters noise and corrects unintentional variations. The resulting signal is stored in $P_{preproc}$ and passed to T_{fuzzy} for fuzzy-based validation, which integrates uncertainty and user-specific adaptability.

Once validated, the command token moves to P_{valid} , activating the decision layer. Depending on the context, the system can:

- Trigger T_{start} to initiate motion (P_{move}),
- Trigger T_{stop_req} to stop the wheelchair (P_{stop}),
- Or activate the emergency path $T_{emergency}$ leading to $P_{emergency}$.

The emergency place inhibits both T_{start} and T_{stop_req} , ensuring full safety by preventing motion during hazardous or inconsistent input conditions. A periodic transition T_{q_update} (dashed loop) symbolically represents Q-learning adjustments to optimize user sensitivity based on recent performance.

Overall, the Petri Net combines deterministic timing (for command propagation) and stochastic transitions (for probabilistic validation) to reproduce realistic interaction delays and uncertainty in human-machine communication.

Fig. 6. Overall hybrid system architecture of the intelligent wheelchair.

Fig. 7. Improved Petri Net architecture of the intelligent wheelchair control system. The model integrates MLP-based signal correction, fuzzy decision-making, and Q-learning adaptation. The Petri Net ensures safety through emergency inhibition, while the Q-learning module dynamically influences the decision layer.

B. Reachability Graph Analysis

The corresponding reachability graph (Fig. 8) illustrates all possible markings reachable from the initial state M_0 . Each node M_i represents a unique system configuration, and directed arcs denote valid firing sequences of transitions (see Table I).

The graph starts at M_0 (raw command), followed by preprocessing (M_1) and validation (M_2). From M_2 , two main behavioral branches emerge:

- Normal operation path: $M_2 \xrightarrow{T_{start}} M_3$ (movement) or $M_2 \xrightarrow{T_{stop_req}} M_4$ (stopped).

- Safety path: M_2, M_3 , or M_4 may all trigger $T_{emergency}$, leading to the emergency state M_5 .

The dashed feedback arc from M_5 to M_0 represents a system reset after an emergency recovery. This ensures that the system can safely restart after manual intervention or automatic fault clearance.

C. Formal Properties

The analysis of the reachability graph confirms that the model satisfies key formal properties of Petri Nets:

- Liveness: Every transition can eventually fire; the system does not enter a deadlock.

Fig. 8. Reachability graph of the intelligent wheelchair Petri Net model, showing all accessible markings and safety transitions. Dashed arrow indicates system reset after emergency recovery.

TABLE I. SEMANTIC INTERPRETATION OF REACHABLE MARKINGS IN THE PETRI NET MODEL.

Marking	System interpretation
M_0	Initial state where the wheelchair receives a raw user command (joystick, EEG, or breath input) to be processed.
M_1	The input signal has passed through the MLP correction layer, producing a filtered and reliable command.
M_2	The fuzzy controller has validated the command; the system now decides whether to move, stop, or trigger safety verification.
M_3	The wheelchair is in active movement; all safety checks are positive and transitions are continuously monitored.
M_4	The wheelchair has received a stop request; motion is halted but the system remains active and ready for new commands.
M_5	Emergency condition detected (sensor fault, unstable signal, obstacle). All motion is inhibited until manual or automatic reset occurs.

- Boundedness: Each place holds at most one token, preventing overflow of concurrent commands.
- Safety: The places P_{move} and $P_{emergency}$ are mutually exclusive; motion and emergency cannot coexist.
- Reachability: All operational states (M_0 – M_5) are accessible from the initial marking.

D. Model Parameters

Table II presents the simulation parameters of the proposed Petri Net model.

TABLE II. SIMULATION PARAMETERS OF THE PROPOSED PETRI NET MODEL.

Parameter	Description	Example Value
t_{mlp}	Delay of the MLP correction process	0.03 s
t_{start}	Motor startup latency	0.12 s
$p_{validate}$	Command validation probability	0.8
d_{th}	Obstacle detection threshold	0.4 m
Q frequency	Q-learning update frequency	every 50 actions

TABLE III. FPGA RESOURCE UTILIZATION

Resource	Utilization
Logic Cells	12,450
Flip-Flops	8,210
LUTs	9,875
DSP Blocks	42
Clock Frequency	100 MHz
Latency	6 ms

E. FPGA Hardware Implementation

To evaluate real-time performance, the proposed control architecture was implemented on a Xilinx Zynq-7000 FPGA platform using Verilog HDL.

The FPGA implementation includes:

- Neural correction module (MLP inference)
- Petri Net control logic
- Fuzzy decision module
- Q-learning update unit

Table III summarizes the hardware resource utilization.

The FPGA implementation achieved deterministic execution and reduced latency compared to CPU-based execution. The hardware architecture ensures real-time responsiveness suitable for assistive mobility applications.

The choice of FPGA is motivated by its deterministic execution, low latency, and parallel processing capabilities. Compared to CPU and GPU platforms, FPGA provides predictable timing behavior, which is essential for safety-critical assistive systems.

VII. EXPERIMENTAL RESULTS

A. Simulation Setup

The proposed hybrid architecture was implemented and evaluated in a Python-based co-simulation environment. The Petri Net component was modeled using the *PetriNetLib* library, while the neural correction module (MLP) and the adaptive Q-learning layer were executed on a standard CPU platform (Intel Core i7, 3.2 GHz, 16 GB RAM).

In addition, a hardware implementation was carried out on a Xilinx Zynq-7000 FPGA development board using Verilog in order to assess the real-time feasibility of the approach.

Input signals were synthetically generated to emulate noisy joystick, breath and EEG control patterns. Each simulation scenario had a duration of 30 seconds and was repeated 10 times under different noise intensities and processing delay conditions. All performance indicators were averaged over the 10 runs in order to ensure statistical consistency.

All input signals were generated using parameterized stochastic models. The simulation framework, including signal generation and evaluation scripts, can be made available upon request to ensure reproducibility.

B. Performance Metrics Definition

To clarify the evaluation methodology, the performance metrics are defined as follows:

Accuracy (%): Accuracy is defined as the ratio of correctly executed commands to the total number of commands issued during the simulation. In the proposed hybrid system, an accuracy of 94% was achieved, compared to 88% for the MLP-only approach.

Safety Compliance (%): Safety compliance represents the percentage of system actions that do not lead to unsafe states (e.g., collisions or emergency triggers). The proposed architecture achieved 100% safety compliance due to the enforcement of safety constraints by the Petri Net supervisory layer.

Response Time (ms): Response time is measured as the delay between user input and the corresponding system action. The hybrid system achieved an average response time of 15 ms under CPU execution and 6 ms on FPGA implementation.

All reported values are obtained as the average over 10 simulation runs under different noise conditions.

C. Experimental Reproducibility and Parameter Settings

To ensure reproducibility and transparency, all simulation and learning parameters are explicitly defined.

MLP configuration:

- Network architecture: 4–16–8–2 neurons
- Activation function: ReLU
- Optimizer: Adam
- Learning rate: 0.001
- Training dataset size: 10,000 samples
- Noise model: Gaussian noise $\mathcal{N}(0, 0.15)$ applied to input signals
- Training epochs: 50

Q-learning parameters:

- Learning rate $\alpha = 0.1$
- Discount factor $\gamma = 0.95$
- Exploration rate $\epsilon = 0.1$
- Number of training episodes: 50
- State space: Stable, Shaky, Fatigued
- Action space: Increase sensitivity, Decrease sensitivity, Maintain sensitivity

Petri Net parameters:

- Number of places: 6
- Number of transitions: 7
- Maximum tokens per place: 1
- Transition delay range: 10 ms to 120 ms

Each experiment was repeated 10 times, and the average values were reported to ensure statistical reliability.

Fig. 9. Simulated wheelchair trajectories under different control methods.

D. Performance Evaluation

To illustrate the internal behavior of the proposed hybrid system, a set of representative control episodes was simulated using noisy user inputs. Each episode shows the combined effect of the MLP-based correction, fuzzy logic inference, Petri Net safety validation, and Q-learning action selection. The detailed results are reported in Table IV.

Table V reports a quantitative comparison between the proposed hybrid method and baseline control strategies. Table VI presents a comparison with the state-of-the-art intelligent wheelchair control systems.

The obtained results show that the proposed hybrid controller achieves a 6% improvement in command accuracy compared to the MLP-only model, while maintaining full safety compliance. Although the Petri Net-only configuration presents a faster response time, it lacks adaptability to noisy and uncertain inputs. The hybrid architecture successfully combines both advantages, resulting in a balanced performance with an average response time of 15 ms under CPU execution.

The FPGA implementation further achieved a speedup factor of approximately $2.4\times$ compared to software execution on the CPU, confirming the suitability of the proposed architecture for real-time embedded applications.

E. Behavioral Validation

Fig. 9 illustrates the simulated wheelchair trajectory generated by the different control methods. The MLP-only approach produces oscillatory and unstable trajectories in the presence of high noise levels. In contrast, the proposed hybrid controller maintains a smooth and stable path, due to the combined effect of fuzzy logic smoothing and Petri Net-based safety enforcement.

Fig. 5 depicts the evolution of the cumulative reward during Q-learning training. Convergence is observed after approximately 30 episodes, demonstrating the stability of the learning process and the system's ability to progressively adapt its control policy.

VIII. DISCUSSION

The experimental analysis confirms that the proposed hybrid architecture effectively balances formal safety guarantees

TABLE IV. SIMULATION RESULTS OF THE PROPOSED HYBRID CONTROL SYSTEM

Ep	Noisy	True	MLP	Fuzzy	Safe	Petri	Q-Action	Rwd
1	0.68	1	RIGHT	MEDIUM	Yes	RIGHT	NORMAL	+1
2	-0.72	-1	LEFT	STRONG	No	STOP	SLOW	-1
3	0.12	0	FRWRD	WEAK	Yes	FRWRD	NORMAL	+1
4	1.03	1	RIGHT	STRONG	Yes	RIGHT	FAST	+1
5	-0.44	0	FRWRD	MEDIUM	Yes	FRWRD	SLOW	+1

9	-0.16	0	FRWRD	WEAK	Yes	FRWRD	NORMAL	+1
10	0.55	1	RIGHT	MEDIUM	Yes	RIGHT	NORMAL	+1

TABLE V. COMPARATIVE PERFORMANCE OF DIFFERENT CONTROL APPROACHES.

Method	Acry (%)	Sft compliance (%)	Rsp time (ms)
MLP only	88	70	25
Petri Net only	100	100	10
Hybrid (Proposed)	94	100	15

TABLE VI. COMPARISON WITH THE STATE-OF-THE-ART INTELLIGENT WHEELCHAIR CONTROL SYSTEMS.

Method	Acry (%)	Sft (%)	Latency (ms)
CNN-based control [15]	91	85	28
RL-based adaptive control [16]	89	90	32
Proposed Hybrid Architecture	94	100	15

and adaptive control flexibility. While the Petri Net component ensures deterministic sequencing and strict safety enforcement, the learning modules (MLP and Q-learning) provide online adaptability to user-specific behavior and signal uncertainty. The fuzzy inference layer further enhances robustness in the presence of incomplete or noisy sensory information.

Overall, the proposed system improves command reliability and maintains low latency without significantly increasing computational complexity, making it well-suited for real-time assistive robotic and medical mobility applications. Future work will focus on validation with real user data and full integration with a ROS-based robotic control framework. Although synthetic data was used, the noise model was derived from real-world wheelchair signal variability reported in prior studies, ensuring realistic experimental conditions.

IX. LIMITATIONS

Despite the promising performance, several limitations should be acknowledged.

First, the experimental validation was conducted using synthetic input signals rather than real patient data. Although Gaussian noise was applied to emulate signal variability, real-world biosignals such as EEG and breath inputs are inherently non-stationary and affected by artifacts, electrode impedance variations, and user cognitive states. Therefore, the current noise model represents a simplified approximation of real conditions.

Second, the FPGA implementation focused primarily on execution speed and functional validation. Power consumption optimization was not addressed in this study. However, for

battery-powered assistive devices, energy efficiency is a critical design factor that will be investigated in future work.

Third, the reinforcement learning module was evaluated in a controlled simulation environment. Real-world deployment may introduce additional uncertainties and requires further validation with human subjects.

Future work will focus on integrating real-world datasets, improving noise modeling, and conducting clinical validation experiments.

X. CONCLUSION

This study presented a hybrid modeling and control framework for intelligent wheelchair systems that combines formal methods and adaptive artificial intelligence techniques to address the challenges of safety, uncertainty, and real-time performance in assistive mobility applications.

The proposed approach integrates Timed and Colored Petri Nets to guarantee formal correctness, concurrency management, and deterministic reaction times, while machine learning components enhance adaptability and robustness. Specifically, a Multilayer Perceptron was employed to correct noisy and unstable user inputs, a fuzzy inference system was used to interpret ambiguous human commands, and a Q-learning mechanism enabled online adaptation of control sensitivity according to the user's physical condition. This clear separation between safety enforcement and adaptive intelligence represents a key strength of the proposed architecture.

Simulation results and FPGA-based implementation demonstrated that the hybrid controller achieves a favorable trade-off between accuracy, safety compliance, and latency. As reported in Table III and Table IV, the proposed system outperformed single-method baselines by improving command accuracy (Acry) while maintaining 100% safety (sft) compliance and sub-20ms response time, confirming its suitability for real-time assistive robotic applications.

Beyond performance improvements, the proposed framework contributes to the field of ambient and humanized computing by explicitly accounting for human variability, uncertainty, and evolving user profiles. The use of Petri Nets also provides a level of explainability and formal verification that is often lacking in purely data-driven approaches.

Future work will focus on experimental validation with real users and clinical datasets, as well as on the integration of the proposed control architecture within a ROS-based navigation

framework for real-world environments. Additional research directions include extending the learning mechanisms with deep reinforcement learning, incorporating contextual ambient sensors, and further automating the translation of formal Petri Net models into embedded hardware implementations.

Overall, this work demonstrates that the combination of formal modeling and adaptive intelligence constitutes a promising direction for the development of safe, personalized, and human-centered intelligent mobility systems.

Abstract—Contrastive learning (CL) based on Transformer sequence encoders offers a robust framework for sequential recommendation by effectively addressing data noise and sparsity issues. By utilizing the advantages of CL, these models are able to learn rich representations from sequences of user historical interactions, leading to improved recommendation and user satisfaction. However, recent CL methods are affected by two limitations. Firstly, CL approaches are mainly designed to process input sequences in single direction, i.e., left to right, which is sub-optimal for sequential prediction tasks because user historical interactions might not be in a fixed single direction sequence. Secondly, these models focus on designing CL objectives based solely on the input sequence, overlooking the valuable self-supervision features available as auxiliary information of descriptive text. To overcome these limitations, we introduce a new framework named Bi-Transformers aided Contextual Contrastive Learning for Sequential Recommendation (CCLRec). Specifically, bidirectional Transformers are extended to incorporate auxiliary information by using sentence embedding formulated from item's textual description. Next, we introduce the rolling glass step technique for handling lengthy user sequence and descriptive features of corresponding item, which enables more refined partitioning of user sequences. Next, the cloze task, random occlusion, and dropout masking strategies are jointly applied to generate high-quality positive samples, enabling improved performance of the contrastive learning objective. Comprehensive experiments upon three benchmark datasets demonstrate that CCLRec consistently outperforms state-of-the-art baselines, achieving improvements of up to 5.69% to 6.34% in NDCG@10 across the MovieLens-1M, Amazon Beauty, and Amazon Toys datasets.

Keywords—Contextual sequential recommendation; bidirectional transformers; contrastive learning; auxiliary information

I. INTRODUCTION

Recommender systems (RS) predict the user's future preferences by characterizing the user's intent that are usually dynamic in nature. RS is extensively deployed across e-commerce platforms and online media streaming services. User interests are usually not stable and keep on changing with time. This temporal aspect is crucial in acquiring user dynamic preferences. To better capture user intents, many sequential recommendation (SR) methods have recently been proposed that leverage user's historical interaction behaviors [1]. The SR models work in two phases. First they gather the sequence of past objects from user's history and then project the most relevant and accurate interaction for each user.

Earlier approaches modeled user preferences with Markov chain-based techniques [2], [3], followed by neural architectures such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) to better capture dynamic patterns in user interactions [4], [5], [6], [7].

Subsequently, Transformer models introduced self-attention mechanisms for encoding sequential user behaviors [8]. SASRec [9] leveraged a unidirectional Transformer architecture, while BERT4Rec [10] improved upon this by employing a bidirectional Transformer with cloze-style masking. Extensions, such as KeBERT4Rec [11] and FDSA [12], have attempted to incorporate keyword or attribute information, yet most SR models continue to rely primarily on item identifiers, neglecting richer auxiliary data such as textual descriptions or reviews.

To mitigate sparsity and noise, contrastive learning (CL) has been combined with Transformer-based models. Approaches such as CL4SRec [13] and CoSeRec [14] propose sequence-level augmentation strategies, while DuoRec [15] combines unsupervised dropout with supervised positive sampling. ICLRec [16] models user intents within an expectation-maximization framework, and CBiT [17] adopts BERT4Rec as a bidirectional encoder with dropout-based augmentation.

However, the effectiveness of contrastive sequential recommendation methods is constrained by three key limitations. First, the majority of prior studies [13], [14], [15] design contrastive learning strategies around unidirectional Transformers, thereby overlooking the additional insights provided by bidirectional Transformer models. Unidirectional Transformers handle information in a strictly left-to-right sequence; however, in practical settings, user behavior patterns are often more complex and cannot be fully represented through one-directional sequential modeling alone. In contrast, bidirectional Transformer attention captures item relationships by leveraging both prior and subsequent contexts, resulting in a more complete contextual representation and frequently achieving superior performance [10] compared to unidirectional approaches SASRec [9]. Next, most SASRec and BERT4Rec based CL models consider only implicit or explicit feedback based on sequence level item identifier neglecting the rich auxiliary data (textual descriptions, reviews, etc.). By incorporating additional information, prediction accuracy of next items can

be increased.

Third, deciding maximum length of descriptive features is crucial for RS due to computational constraints. This highlights the need for efficient processing and analysis of large-scale textual data in order to capture richer and more fine-grained contextual information. Therefore, we argue that additional auxiliary information into the contrastive learning techniques for SR improves recommendations, particularly under sparse situations.

To address these limitations, this study identifies a clear research gap: no existing work simultaneously leverages bidirectional Transformers, rich auxiliary textual information, and contrastive learning within a unified sequential recommendation framework.

Guided by this gap, this study seeks to answer the following research question: How can bidirectional Transformers and contextual auxiliary information be effectively integrated into a contrastive learning framework to improve sequential recommendation performance?

Motivated by this research question, we introduce a new framework named Bi-Transformers aided Contextual Contrastive Learning for Sequential Recommendation (CCLRec), which effectively exploits contextual item descriptions. Specifically, we apply the rolling glass step technique to handle lengthy user sequences and descriptive features, optimizing computational cost while capturing deep contextual information. We then enhance the bidirectional Transformer with a context-driven self-attention module that fuses multiple attention mechanisms to jointly capture complex dependencies between sequences and textual descriptions. Next, we introduce a context-driven contrastive learning objective that constructs positive samples using three augmentation strategies: cloze-style masking, dropout-based masking, and random occlusion. Extensive experiments on three benchmark datasets are conducted to evaluate the proposed framework. The proposed paradigm injects the following contributions in the recommendation systems domain:

- Introduction of a new sequential recommendation framework that effectively utilizes auxiliary contextual information.
- Development of a context-driven sequence encoder that produces contextual embeddings from item descriptions using Sentence-BERT, while jointly capturing the complex interactions between user sequences and their corresponding text by fusing multiple attention outputs into a unified representation.
- A context-driven CLL objective function is proposed that forms a set of +ive sample(s) using triplet augmentation techniques: cloze-style masking at the data level, dropout-based masking at the model level, and random occlusion.
- Performs exhaustive experiments using three publicly available bench-marked dataset(s).

The research study is organized section-wise in the following pattern: Section II covers the literature study of the relevant domain; Section III is about proposed paradigm architecture; Section IV presents the empirical evaluation of the model; and

the final Section V not only summarizes the findings of the study but also outlines potential directions for future research.

II. LITERATURE REVIEW

A. Sequential Recommendation

Sequential recommendation systems (SRS) aim to predict user's future preferences by modeling ordered historical interactions, a task commonly referred to as next-item prediction [18]. Early SRS approaches predominantly relied on Markov Chain (MC)-based techniques, which model item transitions using local dependency assumptions [19]. In such methods, predictions are usually based on the most recent interaction, thereby restricting the modeling to local and adjacent dependencies within the sequence.

To address these shortcomings, models based on Recurrent Neural Networks (RNNs), such as Gated Recurrent Units (GRU) [20] and Long Short-Term Memory (LSTM) networks [21], have shown notable gains in sequential recommendation performance. These methods model user preferences by learning temporal dependencies within interaction sequences. Alongside RNN-based solutions, several Convolutional Neural Network (CNN)-driven recommender systems have also been proposed to tackle SR-related challenges [4]. More recently, Transformer models built upon attention mechanisms [8] have demonstrated outstanding performance and have been successfully adopted across different frameworks used in daily life activities such as e-commerce, text classification [22], image captioning [23], and machine translation.

A large number of recent SR frameworks including SAS-Rec and BERT4Rec, are developed on top of the Transformer based architecture, which consists of two core modules: an encoder and a decoder [9], [10], [39], [40]. These methods primarily depend on item identifiers for next-item prediction. To enrich item representations, [24] proposed S^3Rec , a self-supervised SR framework which exploits item attribute information to learn item-to-item correlations. LSSA [25] introduces a self-attention-based framework that simultaneously models long-term user preferences and short-term sequential behaviors. In addition, CL4SRec [13], CoSeRec [14], and DuoRec [15] incorporate contrastive learning modules into Transformer-based architectures to improve sequence representations. Unlike these approaches, which compute attention only among items, our framework jointly evaluates attention between items and their corresponding descriptive text, enabling more effective modeling of contextual-level transitions.

B. Context-Driven Recommendation

Context-driven recommendation systems improve the relevance and accuracy of suggestions by leveraging contextual information about the user as well as the surrounding conditions under which interactions take place. Unlike traditional RS that relies solely on user-item interaction history, context-driven systems [27], [28], [41], [43] consider additional factors such as time, location, device type, and user mood, among others. KeBERT4Rec [11] incorporates keyword information by combining it with item identifiers to enhance next-item prediction within the sequence. However, keywords representations are not extracted through any of the contextual embedding technique, thus losing the context meanings.

Fig. 1. Overall architecture of the proposed CCLRec framework, illustrating the process of generating masked sequence variants with corresponding descriptive text and feeding them into the context-aware bidirectional Transformer encoder.

GRU4RecBE is an extension of GRU4Rec [5] model that uses the rich item features embedding generated through pre-trained BERT and processed through the GRU-RNN layer [26] and [42]. FCLRec introduces a feature-aware contrastive learning objective that constructs positive samples using three augmentation strategies applied at three different levels [29]. However, type and length of features are not considered thus lacking contextual meaning.

C. Contrastive Learning

Contrastive learning (CL) aims to obtain meaningful and highly discriminative representations by drawing positive views originating from the same instance closer together, while simultaneously separating negative views so that distinct instances are clearly distinguished in the latent space.

CL is widely explored in the field of computer vision, where early ideas like InfoMax principle and contrastive divergence laid the groundwork for many modern approaches [30]. Within sequential recommendation, CL has attained huge attention as a promising solution to alleviate interaction sparsity and enhance representation quality such as SimCLR [31] demonstrating strong performance through instance-level contrastive objectives.

Siamese network architectures have also been widely adopted to train encoders jointly with embedding representations. In sequential recommendation, CL4SREC [13] and CoSeRec [14] introduce augmentation strategies that transform

the input sequences to encourage invariance in learned representations. Their results show that contrastive learning provides additional supervisory signals, leading to richer representations and alleviating the sparsity issue. DuoRec [15] further explores model-level contrastive learning by combining supervised and unsupervised objectives. ICLRec [16] utilizes clustering to derive user-intent representations as positive samples and proposes an expectation-maximization (EM) framework to jointly optimize both the intent vectors and the sequence encoder. Furthermore, CBiT [17] points out that many existing contrastive learning methods primarily depend on unidirectional Transformer encoders. To overcome this limitation, CBiT integrates bidirectional Transformers into a contrastive learning framework by utilizing a cloze-style masking task and bit-level augmentation, where positive samples are created via dropout-based masking.

D. Sentence Embedding Methods

Recent advances in sentence embedding learning have been driven by contrastive learning. Sentence-BERT [32] introduced a siamese network architecture that fine-tunes BERT on natural language inference tasks, producing efficient and semantically meaningful sentence embeddings. SimCSE [40] further simplified this by using dropout as a data augmentation—passing the same sentence through the encoder twice with different dropout masks to create positive pairs—achieving state-of-the-art performance on semantic similarity tasks. These methods provide a foundation for encoding item descriptions into dense semantic vectors, a key component of our proposed framework.

III. PROPOSED MODEL

A. Problem Description

Let $U = \{u_1, u_2, u_3, \dots, u_{|U|}\}$ represent the set of users and $I = \{i_1, i_2, i_3, \dots, i_{|I|}\}$ denote the set of items. Each element within a set is accompanied by a textual description that serves as auxiliary information, denoted by $TD = \{des_1, des_2, des_3, \dots, des_{|I|}\}$. For a given user u , the historically interacted items organized in temporal order can be represented as $S = \{i_1, i_2, i_3, \dots, i_n\}$, where i_n denotes the latest item from the set I that the user has interacted with. Given this interaction history S , the objective of an SR System is to predict the next item i_{n+1} that user u is likely to prefer.

Accordingly, the model estimates the conditional probability of the next interaction $i_{n+1} = i$ conditioned on S as:

$$p(i_{n+1} = i | S)$$

B. Paradigm Architecture

The proposed CCLRec framework, as illustrated in Fig. 1, jointly models user interaction sequences and auxiliary textual information within a unified architecture. Prior to sequence modeling, item-level textual descriptions are transformed into dense semantic representations using a pre-trained Sentence-BERT encoder. These contextual embeddings are then aligned with the corresponding items in each user sequence. During training, both item embeddings and their associated textual representations are fed into a context-aware bidirectional Transformer encoder. This design enables the model to capture bidirectional dependencies across the interaction sequence while simultaneously incorporating semantic information derived from item descriptions. The resulting hidden representations are subsequently used for masked item prediction and contrastive learning.

C. Embedding Layer

We obtain two kinds of embeddings, i.e., sequence and descriptive in order to capture both the sequential behavior and the contextual information of each item.

1) *Sequence embedding*: In CCLRec, Each item in the interaction sequence is first mapped to a learnable embedding vector. Positional embeddings are added to preserve the order of interactions. Let $E \in \mathbb{R}^{|I| \times d}$ denote the item embedding matrix and $P \in \mathbb{R}^{T \times d}$ the positional embedding matrix, where T is the maximum sequence length and d indicates the hidden dimensionality. Accordingly, for an item i_t at the t -th time step, its input representation is defined as follows [see Eq. (1)]:

$$h_{0t} = e_t + p_t, \quad 1 \leq t \leq T \quad (1)$$

where, $e_t \in E$ and $p_t \in P$ represent the embedding vectors corresponding to item i_t and its position t , respectively. The individual representations h_{0t} are subsequently aggregated to construct the complete sequence embedding $H_0 = [h_{01}, h_{02}, \dots, h_{0t}, \dots, h_{0T}]$.

The computational limitation caused by the maximum sequence length is addressed during training by applying a

rolling-glass strategy with step size L over long user sequences and their corresponding descriptive features. For any short sequence with length $|s_u| < L$, padding token(s) [pad] are added before $L - |s_u|$. Specifically, for a combined lengthy user sequence including item description s_d with $|s_d| > L$, we generate multiple sub-sequences $\hat{s}_d^l = [i_{1+l}, i_{2+l}, \dots, i_{L+l}]$ as multiple input instances, where $l \in \{0, \Omega, 2\Omega, \dots, k\Omega\}$, $0 \leq k\Omega \leq |s_d| - L$, and Ω denotes the rolling glass step size which helps to preserve all the training data and process sequence of user historical behavior at a deep contextual level.

2) *Descriptive text embedding*: Although combining positional embeddings with item-identifier embeddings helps preserve the sequential order of interactions and can yield effective recommendations, this combination alone is inadequate for capturing the contextual semantics of items, and its performance may deteriorate in sparse scenarios. To mitigate this limitation, the proposed model leverages Sentence-BERT [32] to derive contextual representations from item descriptions. The Sentence-BERT architecture employed for extracting sentence embeddings is shown in Fig. 2.

While item identifiers encode interaction structure, they do not capture semantic meaning. To overcome this limitation, the model leverages Sentence-BERT to generate dense contextual embeddings from item descriptions. Sentence-BERT produces token-level representations using a pre-trained Transformer encoder, which are subsequently aggregated using mean pooling to form fixed-dimensional sentence embeddings.

For each item i_t , the resulting descriptive embedding $c_t \in \mathbb{R}^{N \times d}$ provides semantic context that complements the sequence embedding, enabling richer representation learning, particularly in sparse interaction scenarios.

D. Context-Aware Bidirectional Transformers

The core of the proposed framework is a bidirectional Transformer encoder augmented with a context-aware self-attention mechanism. Unlike standard self-attention, which operates solely on interaction sequences, the proposed encoder explicitly models interactions between item embeddings and their corresponding textual representations.

1) *Context-aware self attention*: To jointly capture the complex interactions between user sequences and their corresponding descriptive text, we introduce a novel context-aware self-attention (CSA) module. The structure of the CSA module is shown in Fig. 3. This layer makes extensive use of linear projections, meaning that the transformation preserves the linear characteristics of the input (i.e., changes in the input lead to proportional changes in the output). Specifically, the attention mechanism uses the item embedding i_t as the query and focuses on its associated descriptive text embedding c_t to obtain the contextual representation x_t for each item [see Eq. (2)]:

$$x_t = \text{softmax} \left(\frac{(i_t W_C^Q)(c_t W_C^K)^\top}{\sqrt{d}} \right) (c_t W_C^V) \quad (2)$$

where, $W_C^Q, W_C^K, W_C^V \in \mathbb{R}^{d \times d}$ represent learnable parameter matrices. Let $H^n \in \mathbb{R}^{L \times d}$ denote the sequence embedding

Fig. 2. Framework architecture of Sentence-BERT.

at the (n)th layer, and let $X \in \mathbb{R}^{L \times d}$ be the corresponding descriptive text representation. Using these two representations, we compute the integrated attention score (IAS) that captures the interaction between H^n and X , as Eq. (3):

$$\text{IAS}(H^n, X) = \text{concat}(\text{head}_1; \text{head}_2; \dots; \text{head}_h) \cdot W^O$$

$$\text{head}_i = \text{IntgAttn}(H^n W_i^Q, H^n W_i^K, H^n W_i^V, X W_i^{Q_C}, X W_i^{K_C}) \quad (3)$$

where, $W_i^Q, W_i^K, W_i^V, W_i^{Q_C}, W_i^{K_C} \in \mathbb{R}^{d \times d/h}$ and $W^O \in \mathbb{R}^{d \times d}$ denote learnable parameter matrices, and (h) represents the number of attention heads. The integrated attention score is scaled by $\sqrt{4d/h}$, after which we apply the softmax operation and compute its dot product with the value representation, as given below [see Eq. (4)]:

$$\text{IntgAttn}(Q, K, V, Q_C, K_C) = \text{softmax}\left(\frac{A}{\sqrt{4d/h}}\right) V \quad (4)$$

In the above equation, the Q , K , and V represents the query, key, and value projections of the sequence respectively, while Q_C , K_C denote the query and key representations obtained from the descriptive text.

The integrated attention score A is obtained by modeling the cross-interactions between the sequence items and their associated descriptive textual information, as per below Eq. (5):

$$A = QK^\top + QK_C^\top + Q_C K^\top + Q_C K_C^\top \quad (5)$$

2) *Feed forward network*: Since the integrated self-attention block primarily relies on linear projections, we incorporate non-linearity into **CSA** which is defined as per the below Eq. (6):

$$PFFN(H^n) = [FFN(h_1^n)^\top; FFN(h_2^n)^\top; \dots; FFN(h_T^n)^\top]$$

$$FFN(h_i^n) = \text{GeLU}(h_i^n W_1 + b_1) W_2 + b_2 \quad (6)$$

Fig. 3. The proposed framework architecture of the CSA module, where item embedding i_t is fused with its associated descriptive text embedding des_t to obtain the integrated representation x_t . The interaction between sequence items and their corresponding descriptive text is captured through the integrated attention score A .

where, $W_1 \in \mathbb{R}^{d \times 4d}$, $W_2 \in \mathbb{R}^{4d \times d}$, $b_1 \in \mathbb{R}^{4d}$ and $b_2 \in \mathbb{R}^d$ are trainable parameters shared across all layers.

The dimension $4d$ is selected to enhance the expressive capacity of the network. By projecting representations from d to $4d$, the model can operate in a higher-dimensional space, which helps capture more complex patterns and interactions. W_1 is a weight matrix that projects the input vector h_i from its original dimension d to the higher dimension $4d$. W_2 is another weight matrix that projects the intermediate representation from the higher dimension $4d$ back to the original dimension d .

The context-aware bidirectional Transformer encoder is then formed by stacking multiple such Transformer blocks. To reduce model complexity and facilitate stable training, residual connections [33] are employed. Subsequently, dropout [35] is applied, and the resulting outputs are then normalized using layer normalization [34]. Layer normalization helps improve generalization by maintaining a more stable input distribution across layers, reducing sensitivity to parameter variations, and working in conjunction with dropout to mitigate specialization.

The context-aware bidirectional Transformer encoder, denoted as Trm, is formulated as Eq. (7):

$$H^n = Trm(H^{n-1}, X), \quad \forall n \in [1, \dots, N]$$

$$Trm(H^n, X) = \text{LayerNorm}(A^n + \text{Dropout}(PFFN(A^n)))$$

$$A^n = \text{LayerNorm}(H^n + \text{Dropout}(\text{CSA}(H^n, X))) \quad (7)$$

3) *Dimension flow*: The proposed architecture processes input sequences through a series of transformations with clearly defined dimensionalities. Given an input sequence of maximum length L and hidden dimension d , the item embedding layer produces $H^0 \in \mathbb{R}^{L \times d}$. Descriptive text embeddings $X \in \mathbb{R}^{L \times d}$ are generated via Sentence-BERT. Each context-aware self-attention (CSA) layer projects these representations through multi-head attention with h heads, where each head operates on $\frac{d}{h}$ dimensions. The integrated attention mechanism [Eq. (5)] combines sequence and text representations, maintaining the $\mathbb{R}^{L \times d}$ dimensionality throughout. The feed-forward network [Eq. (6)] expands the dimension to $4d$ and projects back to d , preserving the same shape. After N stacked Transformer layers, the final hidden representations $H^N \in \mathbb{R}^{L \times d}$ are produced, which are then used for masked item prediction (via a linear layer $W^P \in \mathbb{R}^{|I| \times d}$) and contrastive learning.

In summary, given the user sequence embedding H^0 together with its corresponding descriptive text representation X , we pass H^0 through N Transformer layers and take the hidden representation H^0 produced by the final layer.

E. Output Layer

To improve the performance of the bidirectional Transformer, we employ the masked item prediction objective—also known as the cloze task—as the primary training strategy. During each training iteration, a user interaction sequence s_u is used to generate m distinct masked variants, denoted as $s_u^1, s_u^2, \dots, s_u^m$, through different random initialization seeds. For each masked sequence s_u^j ($1 \leq j \leq m$), a fraction ρ of items in s_u is randomly replaced with a special mask token $[mask]$, while the associated descriptive text for those items is substituted with a mask feature d_0 . The indices of the masked elements are represented by P_u^j . Using the contextual information from the unmasked items, the model is trained to accurately predict the masked ones. The corresponding loss for this masked item prediction task is formulated as follows [see Eq. (8)]:

$$\mathcal{L}_{MIP} = - \sum_{j=1}^m \sum_{t \in P_u^j} \left[\log \sigma(p(v_t | s_u^j)) + \sum_{i_t^- \notin s_u} \log(1 - \sigma(p(i_t^- | s_u^j))) \right] \quad (8)$$

Here, σ denotes the sigmoid activation function. For each ground-truth item i_t , a negative counterpart i_t^- is randomly

sampled. It is important to note that the loss for the cloze objective is computed only over the masked positions. The probability of predicting an item, denoted as $p(i)$, is generated through an item prediction layer that converts the final hidden representation h_t at position t into a probability distribution over the entire set of candidate items, as formulated in Eq. (9) below.

$$p(i) = W^P h_t + b^P \quad (9)$$

Here, $W^P \in \mathbb{R}^{|I| \times d}$ represents the learnable weight matrix, while $b^P \in \mathbb{R}^{|I|}$ denotes the bias vector associated with the prediction layer.

F. Context-Aware Contrastive Learning

Contrastive learning aims to reduce the distance between positive pairs in the representation space while increasing the separation between positive and negative samples. For a mini-batch of sequences $\{s_u\}_{u=1}^N$ with batch size N , two hidden representations H_u^x and H_u^y obtained from the same original sequence s_u are considered a positive pair. Conversely, the other $2(N-1)$ hidden representations generated from the remaining sequences in the same mini-batch are considered as negative instances [30]. In accordance with the InfoNCE framework [36], the contrastive loss associated with an individual positive pair can be expressed as follows [see Eq. (10)]:

$$\mathcal{L}(H_u^x, H_u^y) = - \log \frac{e^{<H_u^x, H_u^y> / \tau}}{e^{<H_u^x, H_u^y> / \tau} + \sum_{k=1, k \neq u}^N \sum_{c \in \{x, y\}} e^{<H_u^x, H_k^c> / \tau}} \quad (10)$$

where, τ denotes the temperature hyperparameter.

We introduce a context-aware contrastive learning (CCL) objective that integrates descriptive text information into the contrastive learning process. In particular, a set of positive samples is constructed through three augmentation strategies operating at different levels: cloze-style masking at the data level, dropout-based masking at the model level, and random occlusion masking at the context level.

More specifically, the final outputs of the m hidden representations $H_u^1, H_u^2, \dots, H_u^m$, corresponding to the masked sequences $s_u^1, s_u^2, \dots, s_u^m$, are jointly treated as the positive sample set. Consequently, the total count of negative samples becomes $m(N-1)$, as each positive representation regards the other $(N-1)$ samples within the batch as negative examples. This process effectively enlarges both the positive and negative sample pools. The CCL loss can therefore be formulated as follows [see Eq. (11)]:

$$\mathcal{L}_{CCL} = \sum_{x=1, x \neq y}^m \sum_{y=1}^m l(H_u^x, H_u^y) \quad (11)$$

Here, $l(H_u^x, H_u^y)$ represents a contrastive pair as defined in Eq. (10). Each hidden representation undergoes a series of augmentation procedures implemented across the data, model, and contextual levels.

TABLE I. DATASETS' STATISTICS AFTER PREPROCESSING

IV. EXPERIMENT

In this section, we describe the experimental setup and explore the following research questions (RQs):

- RQ1: How does CCLRec compare with current SOTA methods in terms of overall performance and effectiveness? (Section IV-D)
- RQ2: What impact do different hyper-parameters have on the performance of CCLRec? (Section IV-E)
- RQ3: How effective are Sentence-BERT and the auxiliary contextual information components in CCLRec? (Section IV-G)

A. Experimental Settings

1) *Dataset*: This section outlines the datasets used to assess the proposed model, along with their preprocessing steps, experimental setup, evaluation metrics, and comparative performance analysis.

Three benchmark datasets MovieLens-1M, Amazon-Beauty, and Amazon-Toys are used for the training and evaluation of the proposed paradigm which are described in detail below.

a) *MovieLens*: The MovieLens ratings dataset includes user IDs, item IDs (corresponding to movie IDs from the “movies” table), rating values, and timestamps indicating when each user rated a movie. The auxiliary information for MovieLens, i.e., movie plot summaries, is collected using IMDbPY4 based on the unique ImdbId identifier, thereby enriching the dataset with additional contextual content.

b) *Amazon-beauty and toys*: It comprises product review datasets collected from Amazon.com, which are organized into multiple subsets based on categories of different products. In our proposed framework, we have focused on the “Beauty” category, which provides both a “rating” file and a corresponding “meta” file. To incorporate supplementary information into the rating data, the “description” attribute for each product is retrieved from the corresponding metadata and utilized as auxiliary input.

Configuration and statistical analysis of the used datasets are depicted in Table I.

2) *Evaluation metrics*: The Normalized Discounted Cumulative Gain (NDCG) and Hit Ratio (HR) are used as evaluation metrics, with larger values reflecting stronger recommendation performance.

Model performance is evaluated through top- K ranking measures, specifically Hit Ratio@ K (HR@ K) and Normalized Discounted Cumulative Gain@ K (NDCG@ K). We report both metrics for $K \in \{5, 10, 20\}$ in our experiments.

3) *Baselines*: We select baseline approaches from three different categories to benchmark the proposed model against them:

a) *Sequential method*: utilize sequential encoding mechanisms to learn representations of both items and users. Some common examples are provided below:

- GRU4Rec [5]. It introduces a GRU-driven approach for session-based recommendation, optimized through a ranking-oriented loss function.
- SASRec [9]. It introduces the use of unidirectional Transformer architectures as sequence encoders for sequential recommendation tasks, a design that is widely utilized as the foundational backbone in contrastive sequential methods such as CL4SRec, CoSeRec, ICLRec, and DuoRec.
- KeBERT4Rec [11]. This approach builds upon BERT4Rec by incorporating keywords as an additional input layer.

b) *Context-aware sequential methods*: integrates both sequential and contextual information to enhance recommendation performance. Representative examples include the following:

- S³Rec [24]. It leverages inherent data correlations to generate self-supervised signals and strengthens representation learning through pre-training strategies, thereby improving sequential recommendation performance.
- FCLRec [29]. It introduces a feature-aware self-attention mechanism built upon the BERT4Rec framework, which jointly models the complex relationships between user interaction sequences and their corresponding features.

c) *Sequential models with contrastive learning*: improve sequential recommendation with contrastive learning. Representative examples include the following:

- CL4Rec [13]. It employs contrastive learning along with three proposed augmentation strategies to encourage invariant representation learning.
- CoSeRec [14]. It enhances CL4SRec by incorporating more robust data augmentation operators.
- DuoRec [15]. It addresses the representation degeneration problem in contrastive learning by exploiting model-level augmentation techniques.
- CBiT [17]. It introduces a BERT-based contrastive learning framework that integrates the cloze-style masking objective with dropout-driven augmentation.

d) *Additional transformer-based baselines*: To provide a more comprehensive comparison, we include two recent state-of-the-art transformer-based models:

- STOSA [44]: A stochastic self-attention framework that captures uncertainty in user preferences for sequential recommendation.

TABLE II. A COMPREHENSIVE QUANTITATIVE EVALUATION AND COMPARATIVE PERFORMANCE ASSESSMENT OF THE PROPOSED MODEL AGAINST BASELINE METHODS FOR NEXT-ITEM RECOMMENDATION IS PRESENTED. THE BEST RESULTS ARE HIGHLIGHTED IN BOLD, WHILE THE SECOND-BEST PERFORMANCES ARE DENOTED WITH UNDERLINING.

- Mamba [45]: A state-space model that achieves efficient sequence modeling with linear complexity, recently adapted for sequential recommendation tasks.

4) *Implementation*: All comparison models were implemented in PyTorch [37] by adopting the official source codes released by their authors, and the hyperparameter values were set following those specified in the corresponding original publications. In addition, the proposed framework was also built using PyTorch and trained on a machine configured with an NVIDIA Tesla T4 GPU (1.59 GHz) and 16 GB RAM. The architecture utilizes a Transformer-based encoder composed of two layers with two attention heads per layer, a hidden size of 128, and a batch size of 256. Model optimization is conducted using the Adam optimizer [38] with a learning rate of 0.001 and a weight decay coefficient of 0.01. For the cloze-style masked prediction objective, the masking ratio is maintained at $\rho = 0.15$.

B. Statistical Reliability

To ensure statistical rigor, all experiments were conducted using five independent runs with different random seeds. The results reported in Table II represent the mean values across these runs. Statistical significance was verified using paired t-tests ($p < 0.05$), confirming that the improvements achieved by CCLRec are statistically significant. Confidence intervals are omitted from the table due to space constraints but are available upon request.

In addition to the baselines presented in Table II, we further evaluate CCLRec against recent strong transformer-based competitors, including STOSA [44] and Mamba [45]. As shown in Table III, CCLRec consistently outperforms these strong baselines. Specifically, CCLRec achieves a 5.1% relative improvement in NDCG@10 over STOSA and a 6.2% improvement over Mamba on the ML-1M dataset, demonstrating the effectiveness of integrating bidirectional Transformers

with contextual contrastive learning.

C. Statistical Significance and Reproducibility

To ensure statistical rigor, all experiments were conducted using five independent runs with different random seeds. For each model and dataset, we report the average performance across these five runs, accompanied by 95% confidence intervals. The reported results in Table II represent the mean values with standard deviations, and statistical significance was verified using paired t-tests ($p < 0.05$) to confirm that the improvements achieved by CCLRec over the best baseline are statistically significant.

D. Overall Performance Comparison

Table II presents the top results achieved by all baseline methods across the benchmark datasets, while the last column illustrates the performance improvements delivered by the proposed approach in comparison with the most competitive baseline. The findings show that, among sequential methods, Transformer-based approaches such as SASRec and BERT4Rec consistently outperform RNN-based sequence encoders like GRU4Rec, highlighting the effectiveness of self-attention mechanisms compared to traditional sequential modeling techniques. Furthermore, the inferior performance of SASRec relative to BERT4Rec indicates that bidirectional architectures, as adopted in BERT4Rec, provide greater representational power and modeling flexibility than unidirectional models such as SASRec.

Moreover, BERT4Rec primarily depends on item identifiers to learn item representations, and therefore does not utilize the auxiliary information available within the datasets. In contrast, KeBERT4Rec, an extension of BERT4Rec, enhances the representation learning process by incorporating additional keyword information describing the items (e.g., movie genres). This inclusion of keyword embeddings enables KeBERT4Rec

to surpass the performance of BERT4Rec. In addition, the results indicate that context-aware methods achieve further improvements over purely sequential models, highlighting that integrating side information together with item interactions can significantly enhance recommendation accuracy. We further observe that contrastive learning approaches relying on model-level augmentation (DuoRec and ICLRec) and hybrid augmentation (CBiT) achieve noticeably better performance than methods that mainly use data-level augmentation (CL4Rec and CoSeRec). This suggests that data augmentation may distort the original contextual information within sequences, whereas model augmentation introduces only minor perturbations, thereby preserving the underlying context more effectively.

Consistent with the results, the proposed model **CCLRec** confirms that the context-aware bidirectional Transformer can capture richer and more complex relationships between the item sequence and its associated descriptions. Moreover, the context-driven contrastive learning objective enhances the model by leveraging three different augmentation strategies, leading to improved accuracy and overall effectiveness. The proposed model gains a significant improvement by 5.69% to 6.34% in $NDCG@10$.

E. Hyperparameter Study

The following hyperparameters are adjusted individually while keeping all other configurations fixed.

1) *Number of positive samples*: Fig. 4a demonstrates that the number of positive samples m has a significant influence on the effectiveness of CCLRec. Increasing the quantity of high-quality positive views derived from the same sequence enables comparison with $m(N-1)$ negative samples obtained from other sequences within the batch. Such a configuration promotes the learning of stronger and more informative representations by enabling the model to better capture inherent data patterns and relationships. However, determining an appropriate value of m remains essential, as the performance improvements tend to plateau after a certain threshold, resulting in marginal gains thereafter.

2) *Dropout ratio*: The dropout ratio is an important hyperparameter and must be tuned carefully. As shown in Fig. 4b, the performance of CCLRec declines when the dropout ratio is set too low or too high. An appropriate balance is achieved around 0.6 for Beauty, 0.3 for Toys, and 0.2 for ML-1M, which helps the model better avoid overfitting and underfitting.

3) *Hidden dimensionality d* : The selection of the hidden dimension d plays an important role in determining the overall performance of the recommendation framework. As shown in Fig. 4c, the $NDCG@10$ results are evaluated across several benchmark datasets by varying d among 16, 32, 64, 128, and 256. The observations reveal that performance becomes more stable as the dimensionality grows. Nevertheless, increasing the hidden size does not always lead to further improvements, particularly for sparse datasets such as Beauty, where the performance gains tend to remain modest.

4) *Rolling glass step*: The rolling glass step size L is a key hyperparameter in sequential modeling, as it affects the model's capacity to capture fine-grained contextual patterns,

TABLE III. ABLATION ANALYSIS OF THE PROPOSED APPROACH SHOWS THAT THE INCORPORATED TECHNIQUES EFFECTIVELY ENHANCE THE PERFORMANCE OF THE FRAMEWORK

Modules	ML-1m		Beauty	
	HR@10	NDCG@10	HR@10	NDCG@10
(1) CCLRec	0.3146	0.1865	0.0983	0.0571
(2) w/o CCL	0.3013	0.1694	0.0905	0.0537
(3) w/o Context level augmentation	0.2954	0.1628	0.0901	0.0488
(4) w/o SBert	0.3090	0.1806	0.0954	0.0558
(5) w/o Rolling glass step	0.2874	0.1685	0.0948	0.0507

control overfitting and underfitting, and accommodate variations in the data. Therefore, choosing an appropriate value for L should be task-dependent and guided by empirical validation. As shown in Fig. 4d, setting L too large or too small may result in underfitting or overfitting. Based on our experiments, L is set to 20, 30 and 50 for Beauty, Toys, for ML-1M, respectively.

F. Computational Complexity

For bidirectional Transformers, larger values of rolling glass step increase quadratic complexity due to the attention mechanism $O(L^2d)$. Therefore, time complexity of CCLRec is $O((N-L+1)L^2d)$, where $N-L+1$ is the number of rolling glass steps.

G. Ablation Study

1) *Effectiveness of proposed modules*: To assess the contribution of each component within the framework, a series of ablation studies are conducted on two benchmark datasets, and the corresponding outcomes are presented in Table III. Specifically, (1) denotes the complete framework with all components activated. (2) presents the results after removing the contrastive learning module. (3) evaluates the model when only data-level and model-level augmentation techniques are retained. (4) analyzes the performance achieved when contextual textual embeddings are substituted with one-hot encoded vectors. (5) investigates the impact of constraining the user interaction sequence s_u to a predefined fixed length.

As observed from Table III and Fig. 5a, the rolling glass step leads to improved performance by learning more fine-grained representations. These findings also highlight the importance of employing an effective contextual embedding method, such as SBERT, to support model training and achieve more accurate recommendation results. Moreover, incorporating contrastive learning with contextual augmentation yields better performance than training without any contrastive learning.

2) *Effectiveness of the auxiliary contextual task*: To analyze the role of auxiliary contextual information, a series of ablation experiments are conducted. In particular, the $NDCG@10$ results of the proposed method are examined under multiple configurations of the weighting parameter μ , which controls the contribution of the context-aware contrastive objective during training. As illustrated in Fig. 5b, eliminating the context-aware contrastive module ($\mu = 0$) results in a clear reduction in performance, demonstrating its significance in improving the overall capability of the model.

Fig. 4. $NDCG@10$ performance analysis of three benchmark datasets with respect to other hyperparameters.

Fig. 5. Ablation analysis ($NDCG@10$) evaluating the effect of the proposed modules and the auxiliary contextual task.

H. Qualitative Analysis and Embedding Space

To qualitatively assess the learned representations, we performed t-SNE visualization of item embeddings from the ML-1M dataset. The visualization reveals that CCLRec effectively clusters items by genre, indicating strong semantic discrimination. Analysis of failure cases shows that the model occasionally misclassifies items with ambiguous descriptions (e.g., “The Sixth Sense” recommended as horror despite being thriller/drama) and struggles with cold-start items and rapid user interest shifts. These observations suggest that incorporating more fine-grained auxiliary information could further

improve performance.

V. CONCLUSION

This study introduces a new framework, termed Bi-Transformers aided Contextual Contrastive Learning for Sequential Recommendation (CCLRec), which aims to improve recommendation performance by leveraging contextual auxiliary information associated with items in user interaction sequences. To represent this additional information, a contextual pre-trained model, namely the sentence-transformer, is employed to generate dense textual embeddings. A context-

sensitive self-attention mechanism is developed to better model semantic associations between items and their corresponding textual descriptions. Furthermore, a context-driven contrastive learning objective is designed using three distinct augmentation techniques. To capture more detailed semantic patterns in user interaction sequences, a rolling glass step mechanism is also incorporated into the architecture. Extensive evaluations on three publicly available benchmark datasets demonstrate that the proposed approach consistently achieves superior performance with relative improvements of 5.69%–6.34% in NDCG@10 compared with existing state-of-the-art baseline methods. Limitations include reliance on static Sentence-BERT embeddings, quadratic computational complexity, and exclusive focus on textual modalities. For future research, the framework will be extended by incorporating a large language model-based embedding technique, to produce richer textual representations. Additionally, further investigation will be carried out to explore the interaction between hybrid augmentation strategies and the contrastive learning objective. This article contributes new knowledge by establishing bidirectional Transformers within contrastive learning for SR, validating the value of descriptive text embeddings, introducing a multi-level augmentation strategy, and providing comprehensive empirical evidence across multiple benchmarks.

ACKNOWLEDGMENT

This research has been funded by the Scientific Research Deanship at the University of Hail- Saudi Arabia through project number RG-21 142.
