Table of Contents

Paper 1: EU Public Procurement Contract Value Prediction: A Machine Learning Approach

Authors: Muhammad Azizur Rahman, Anna Hlinska

PAGES 1 - 7

Paper 2: Unified Modular Architectural and Software Model for Educational XR Systems

Authors: Miroslav GALABOV

PAGES 8 - 14

Paper 3: Interruptible Multi-Agent Debate: Sentence-Level Disclosure and Urgency-Based Turn-Taking for Early Error Correction

Authors: Akikazu Kimura, Ken Fukuda, Yasuyuki Tahara, Yuichi Sei

PAGES 15 - 25

Paper 4: Secure User Authentication Model Using Identity-Based Encryption (IBE) Scheme: Challenges, Techniques, and Trends

Authors: Raja Farah Sharima Raja Muhamad Danial, Nazhatul Hafizah Kamarudin, Abdul Ghafar Jaafar

PAGES 26 - 36

Paper 5: Improving Heart Sound Diagnosis with a Combined CNN-LSTM and Dual-Attention Deep Learning Model

Authors: Arshad Jamal, R. Kanesaraj Ramasamy, Junaidi Abdullah

PAGES 37 - 46

Paper 6: Application of Large-Scale Array Acoustic System Performance Detection Technology Based on Embedded ARM7 + uClinux Platform in Petroleum Exploration

Authors: Zhiyuan Sun, Cheng Yang, Guixu Xu

PAGES 47 - 57

Paper 7: Factors Influencing Generative AI-Enabled e-Government Services (GAIGS) Information Quality: A Systematic Literature Review

Authors: Azwan Abd Aziz, Rozi Nor Haizan Nor, Yusmadi Yah Jusoh, Wan Nurhayati Wan Ab. Rahman, Khairi Azhar Aziz, Nur Ilyana Ismarau Tajuddin, Raditya Muhammad

PAGES 58 - 69

Paper 8: Balancing Accuracy Robustness and Explainability in E-Commerce Recommender Systems

Authors: Mansor Alohali

PAGES 70 - 81

Paper 9: An Algorithm for Image Dataset Compression and Privacy Enhancement via Fusing Bilateral Filtering and Easy-to-Complex Trajectory Matching Distillation

Authors: Qiao Zhou, Lei Zhang, Longjie Li, Tong Wang, Jun Cheng

PAGES 82 - 89

Paper 10: Cryptographic Vulnerability Assessment and Secure Redesign of an ECC-Based Authentication Framework for Energy Internet Vehicle-to-Grid Systems

Authors: Haewon Byeon

PAGES 90 - 97

Paper 11: An AI-Powered Approach for Medical Specialty Triage Using Natural Language Processing and Transformer Models

Authors: Anas Chahid, Ismail Chahid, Wafae Mrabti, Mohamed Emharraf, Mohammed Ghaouth Belkasmi

PAGES 98 - 107

Paper 12: Multi-View Behavioral Probing for Political Bias in Arabic and Multilingual Transformers Before and After Domain Adaptation

Authors: Ahmad Abdelhameed, Ensaf Hussein Mohamed, Walaa Medhat

PAGES 108 - 118

Paper 13: Trust and Hallucinations: A Study of 39 Experts on AI-Assisted Requirements Reverse Engineering

Authors: Abdullah A H Alzahrani

PAGES 119 - 128

Paper 14: Generative Monocular Perception Pipeline-Based Framework for Accurate Stem Detection in Automated Strawberry Harvest

Authors: Kohei Arai, Jin Sawada, Mariko Oda

PAGES 129 - 139

Paper 15: Method for Improving Object Detection and Classification Accuracy Using a Small Training Dataset by Reducing the Number of Classes

Authors: Kohei Arai

PAGES 140 - 146

Paper 16: Enhancing Communication Accessibility: Real-Time Recognition and Synthesis of Arabic Sign Language Gestures Using Long Short-Term Memory

Authors: Mina Nagy Gaber Sorial, Rodaina Abdelsalam, Mayar Ali, Hesham Hassan

PAGES 147 - 154

Paper 17: A Multi-Layer Computational Framework for Predicting Student Performance Ranges in Higher Education Using Machine Learning

Authors: Abdellatif HARIF, Moulay Abdellah KASSIMI

PAGES 155 - 164

Paper 18: Digital Infrastructure Transformation in the Public Sector: Explaining IPv6 Adoption Through the UTAUT Framework

Authors: Aydın Koçak, Uğur Dagtekin, Ahmet Kamil Kabakuş

PAGES 165 - 176

Paper 19: FIFO Age-Cohort Stochastic MILP for Perishable Inventory Optimization

Authors: Hirman Rachman, Saib Suwilo, Sutarman, Elvina Herawati

PAGES 177 - 187

Paper 20: Detection of Video Anomalies via CNN-LSTM Model for Intelligent Surveillance

Authors: Mohamed H. Mousa, Yasser M. Ayid, Ayman E. Khedr, Ahmed M. Elshewey

PAGES 188 - 197

Paper 21: Evidence-Driven AI Governance for Healthcare: A PEARL-PATHWAY Analysis of Madinah

Authors: Roba Alsaigh, Rashid Mehmood, Iyad Katib, Abdulaziz A. Almuzaini,
Sami Saad Albouq, Sami Alshmrany

PAGES 198 - 214

Paper 22: KnowRAG: A Zero-Shot Diagnostic Analysis of Knowledge Base Coverage in Scientific Retrieval-Augmented Generation

Authors: Assmaa MOUTAOUKKIL, Ali EL MEZOUARY, Kaoutar BOUMALEK

PAGES 215 - 224

Paper 23: Determinants of Telemedicine Security Readiness Among ICT Professionals: Extended UTAUT Model

Authors: Fazlina Mohd Ali, Afraa Mohammed Mohammed Gaashan,
Marizuana Mat Daud, Rimaniza Zainal Abidin

PAGES 225 - 230

Paper 24: Evaluating Perceptual Reliability of Latent Attribute Control in Diffusion-Based Fashion Generation

Authors: Noriaki Kuwahara, Shintaro Kawanami, Takashi Sato, Dongeun Choi

PAGES 231 - 240

Paper 25: Performance Comparison of Regularization Methods on Transfer Learning Algorithm for Fish Species Classification

Authors: Handrie Noprisson, Anita Ratnasari, Sri Dianing Asri, Vina Ayumi, Hadiguna Setiawan

PAGES 241 - 247

Paper 26: FEM-KP: A Functional Evaluation Metric for Keyphrase Prediction Models

Authors: Lahbib Ajallouda, Ahmed Zellou

PAGES 248 - 257

Paper 27: A Neutrosophic Machine Learning-Based Intelligent Ensemble Model for Sustainable Tea Yield Prediction Under Climatic Variability

Authors: Maitraya Dey, Pushpita Roy, Shubhendu Banerjee, Amrut Ranjan Jena, Rakesh Naskar,
Suparna Dasgupta, Soumyabrata Saha, Sudarshan Nath, Bikash Mondal

PAGES 258 - 265

Paper 28: Incorporating Generative AI in Foreign Language Teaching Preparation: An Empirical Investigation Into the Effects of AI-Assisted Lesson Planning

Authors: Xinxin Guo, Hao Chen

PAGES 266 - 275

Paper 29: Climate Change on Social Media: AI and Deep Learning-Based Analysis of Tweets

Authors: Bahar URHAN, Mehmet KAYAKUŞ, Dilşad ERDOĞAN, Gülten ADALI, Emrah BOZKURT, Zeynep Nihan BAKIR

PAGES 276 - 287

Paper 30: Preference-Controllable Multi-Objective Deep Reinforcement Learning for Human-Robot Task Allocation in Service Environments

Authors: Asmaa Rashed Alahmari, Wadee Alhalabi

PAGES 288 - 299

Paper 31: Fuzzy-Integrated Modular Neural Networks for Accurate Prediction of On-Time-In-Full Supply Chain Performance

Authors: Mariem Mrad, Mohamed Amine Frikha, Younes Boujelbene, Soufiene Ben Othman

PAGES 300 - 308

Paper 32: Federated and Secure Artificial Intelligence as a Driver of Operational Excellence and Competitive Advantage in Smart Manufacturing Enterprises

Authors: Adel Saad Assiri

PAGES 309 - 317

Paper 33: Blockchain Governance Framework and Assessment Tools from a Readiness Perspective

Authors: Nur Indrawati, Dana Indra Sensuse, Deden Sumirat Hidayat, Erisvaha Kiki Purwaningsih

PAGES 318 - 330

Paper 34: The Untapped Potential of Extended Reality for Indigenous Medicinal Knowledge: A Review of Cross-Disciplinary XR Applications

Authors: Giampearo Anak Peter, Suriati Khartini Jali, Jane Labadin, Abby Lian Hendrick, Ally Dian Hendrick, Nurul Farizah Ridzuan

PAGES 331 - 338

Paper 35: IFDA-EMA-YOLOv9: Wheat Disease Detection Integrating Flow Optimization and Auxiliary Supervision

Authors: Jiaxiang Fan, Leixiao Li

PAGES 339 - 352

Paper 36: Energy-Efficient Multi-Hop LoRa Communication in Forested Environments via Proximal Policy Optimization

Authors: Muhd Kahfi bin Jumali, Lim Kit Guan, Ervin Gubin Moung, Lorita Angeline, Tianlei Wang, Kenneth Teo Tze Kin

PAGES 353 - 363

Paper 37: Comparative Analysis of Fixed vs Machine Learning Dynamic Pricing Models: A Computational Performance Study

Authors: Emmanuel Ofotsu Kwesi Bannor, S. Sarah Maidin, Vinayakumar Ravi, Nguyen Thi Thu Thuy, Nghiem Thi-Lich

PAGES 364 - 370

Paper 38: Machine Learning-Driven Resource Provisioning in Modern Cloud Environments: A Taxonomic Survey

Authors: Stefanus Albert Kosim, Bagus Jati Santoso, Deka Julian Arrizki, Riki Mi'roj Achmad, I Nyoman Gede Artadana Mahaputra Wardhiana, Royyana Muslim Ijtihadie

PAGES 371 - 383

Paper 39: A Machine Learning-Driven Framework for Accurate Brain Image Registration in Multimodal and Noisy Environments

Authors: M. S. Minu, Mutharasu M, S. Hemamalini, Sunitha T, Mohanaprakash T A, Justindhas Y

PAGES 384 - 394

Paper 40: On the Security of Authentication Protocols for Remote Healthcare Systems Through Cryptographic Vulnerability Analysis and Secure Protocol Redesign

Authors: Haewon Byeon

PAGES 395 - 402

Paper 41: An Ensemble Boosting Approach with Boruta Feature Selection for Predicting E-Payment Adoption

Authors: Mariana Purba, Junaidi Junaidi, Lemi Iryani, Nia Umilizah, Handrie Noprisson, Nur Ani

PAGES 403 - 409

Paper 42: Beyond Paper and Pencil: Evaluating the Effectiveness and User Perception of a Digital Reading Proficiency Assessment Platform

Authors: Ivy M. Tarun

PAGES 410 - 417

Paper 43: Hybrid Learning-to-Rank Approach for Complex Information Retrieval Systems

Authors: Fatma Zohra Bessai-Mechmache, Yasmine Hanifi, Damia Lyna Ait Idir

PAGES 418 - 425

Paper 44: Optimizing Rainfall Prediction in Settat, Morocco, Through Machine Learning

Authors: Oussama Zemnazi, Sanaa El Filali, Sara Ouahabi, Abderrahim Mouhtadi

PAGES 426 - 433

Paper 45: A Systematic Literature Review on Artificial Intelligence Applications for Breast Cancer Classification

Authors: Nursakinah Abdullah, Qi Wei Oung, Chee Chin Lim, Chiew Chea Lau, Vrshni Menaka R Siva Nathan, Hui Wen Tiu

PAGES 434 - 448

Paper 46: Integrating Big Data and Machine Learning for Effective Cyberattack Prediction in e-Health Information Systems

Authors: Mohamed Abdelbaki, Latif Adnane, Charaf Eddine Ait Zaouiat

PAGES 449 - 454

Paper 47: Solar Irradiance Forecasting Approaches Based on Machine Learning: A Systematic Literature Review

Authors: Sempe Thom Leholo, Chunling Tu, Topside Ehleketani Mathonsi

PAGES 455 - 475

Paper 48: Efficient Computation of Parametric Exponentiation in Parametric Algebra

Authors: Khudoykulov Zarifjon, Khudoynazarov Umidjon, Muminova Mastura

PAGES 476 - 487

Paper 49: An Interoperable Multi-Agent Architecture for Personalized Smart Learning Using Generative AI and Learning Analytics

Authors: Al Mahdi Khaddar, Youssef Said, Amine Dehbi, Tarik Chafiq

PAGES 488 - 500

Paper 50: Mapping Tourist Sentiments Through Lexicon-Based Analysis of Social Media Reviews: The Case of Salak Sibetan Agritourism

Authors: Paula Dewanti, Putu Adi Guna Permana, I Gusti Ayu Widari Upadani,
Ellyn Ly Maramento, Alfred John G. Borreros

PAGES 501 - 506

Paper 51: Optimization of Access Point Location Using an Integer Programming Model

Authors: Joan Marie M. Panes, Marilou O. Espina, Jovelin M. Lapates

PAGES 507 - 513

Paper 52: AI and Blockchain for Secure Healthcare Data Management: A Bibliometric Analysis of Research Trends and Thematic Clusters (2020–2025)

Authors: Maroufi Mohammed, Lamzabi Siham, Ziti Soumia

EU Public Procurement Contract Value Prediction: A Machine Learning Approach

Dr Muhammad Azizur Rahman, Anna Hlinska
Department of Computer Science, Cardiff Metropolitan University, Llandaff Campus, Western Avenue, Cardiff, CF5 2YB, UK

***Abstract*—Using modern analytical tools, such as machine learning, organisations can collect and analyse large amounts of data related to suppliers, pricing, demand structure, and market trends. This study uses machine learning models to predict the value of EU public procurement contracts based on the Tenders Electronic Daily (TED) database. The analysis covers 13,345,120 initial contract records for the period 2006-2025 in 33 states and 63 procurement sectors. After careful data quality control procedures, the analytical set was formed by 10,038,018 valid contracts (75% retention rate). Three complementary methodologies were used: Random Forest regression to identify nonlinear patterns, ordinary least squares (OLS) regression to interpret coefficients, and K-means clustering to classify procurement behaviour at the country level. The Random Forest achieved cross-validation R^2=0.2795 and the test R^2=0.2613, with the country of origin dominating the predictive value (Germany: 24.39%, United Kingdom: 2.33%, Italy: 1.96%). Temporal features had a significance of 18.36%, while competition indicators (number of proposals: 8.99%) and structural characteristics (batch number: 12.29%) had a significant impact. The OLS regression showed statistically significant effects for countries: Germany showed 98.4% lower contract prices despite being Europe's largest economy, reflecting federal administrative fragmentation, while Italy showed 295.7% higher rates thanks to centralised infrastructure projects. The K-means clustering revealed three clear procurement profiles: Greece as a transparency-focused outsider (109 average bids per contract), 19 mature economies with high value, and 13 less valuable, fragmented systems, including Germany. The results show that institutional frameworks dominate economic factors in determining the value of contracts, which has political implications for the design of procurement systems across the EU.**

***Keywords*—Public procurement; EU procurement; machine learning; Random Forest; Contract Value Prediction; TED database; institutional economics; OLS regression; K-means clustering; predictive modelling; data quality; EU AI Act**

I. Introduction

Public procurement constitutes a significant component of public expenditure in the member states of the European Union, accounting for approximately 14% of GDP or 2 trillion euros annually [1]. The Tenders Electronic Daily (TED) database serves as the central repository for procurement information, publishing contract award notices that provide transparency into public spending decisions across 33 EU and European Economic Area countries. Despite this wealth of data, predicting contract values remains challenging due to complex interactions between country-specific institutional frameworks, sectoral characteristics, temporal trends, and competitive dynamics [2, 3]. Applying machine learning to public procurement data, budget planning, supplier strategies, and procurement policy evaluation. The scale and complexity of EU public procurement present both opportunities and challenges for data-driven analysis. Accurate contract value forecasting has significant policy and practical implications for many stakeholder groups. Procurement agencies need reliable forecasts for budget planning and resource allocation, especially against the backdrop of increased fiscal constraints in European governments. Suppliers benefit from understanding typical contract sizes when evaluating market entry decisions in different countries and sectors, which has implications for competitive strategy and capacity planning [5]. Traditional approaches to contract value analysis primarily rely on descriptive statistics and linear regression models, which may not consider the nonlinear relationships and interaction effects characteristic of procurement processes [6].

Recent advances in machine learning provide opportunities to improve prediction accuracy and uncover hidden patterns through algorithms capable of detecting complex relationships in high-dimensional datasets [7, 8]. The practical challenges of applying AI to procurement data go beyond algorithmic selection and encompass the fundamental limitations of data infrastructure. Recent comprehensive assessments show that while all EU Member States now publish structured procurement data that meets minimum machine learning standards, critical quality issues remain: approximately 30% of TED recordings contain missing values – this figure has not changed since 2017 – with supplier registration numbers missing in 86% of procedures and evaluation contracts missing in 63% of cases [22].

This study examines several critical gaps in the existing literature. First, it provides comprehensive machine learning analysis of the value of EU public procurement contracts, spanning nearly two decades (2006 – 2025) and covering all Member States, going beyond the country-specific or sectoral analyses that dominate modern research. Second, it systematically compares multiple modelling approaches – Random Forest for prediction accuracy, OLS regression for interpretive coefficients, and K-means clustering for identifying behavioural patterns — to provide both predictive capability and essential insights into the factors that determine contract value. Third, it quantifies the relative importance of country-level institutional factors compared to sectoral and temporal characteristics, which provides empirical evidence for the ongoing debate on the role of institutional quality in public procurement outcomes [12]. Fourth, it demonstrates the practical application of machine learning techniques to real-

world procurement data, which is characterised by missing values, inconsistent formats, and excessive computational loads.

The rest of this study is organised as follows: Section II reviews related work. Section III describes the research methodology. Section IV presents the results and analysis. Section V discusses the findings. Section VI outlines future directions, and Section VII concludes the study.

II. Related Work

The literature review summarises the key findings of previous studies, organised by geographical coverage, methodological approach, and content focus. Table I provides a comparative overview of key prior studies alongside this work. The latest comprehensive assessments of procurement data infrastructure show significant progress along with ongoing challenges. Longobucco and Ferverda (2025) [22] conducted a systematic assessment of the suitability of procurement data for AI-based anti-corruption analysis in all EU Member States and associated countries. Their "funnel logic" system assesses data availability at several levels: structured procurement data available en masse, beneficial ownership registers, political finance disclosures, Politically Exposed Persons (PEP) databases, procurement complaints, and media ownership records. The study confirms that all EU-27 countries are now publishing procurement data that meets minimum standards for machine learning applications, with Croatia, Estonia, and Latvia recognised as leaders in data quality and availability. However, critical gaps remain: approximately 30% of TED recordings contain missing values — this figure has not changed since 2017 — with national vendor registration numbers missing in 86% of procedures and missing contract evaluation numbers in 63% of cases [22]. These systemic data quality issues directly limit the predictive performance achieved by even complex algorithms, setting realistic expectations for model accuracy [10]. García Rodríguez et al. (2021) [11] analysed 58,337 Spanish tenders between 2012 and 2018, comparing linear regression, Random Forest, isotonic regression, and artificial neural networks to predict reward prices. Their conclusion that neural networks and isotonic regression outperformed Random Forest differs from our results, likely reflecting their focus on a single country's relatively homogeneous institutional environment, dominated by nonlinear sector-specific patterns, in contrast to the pan-European sample, where institutional heterogeneity in 33 countries contributes to Random Forest's ability to capture country-specific effects [17, 18]. Recent surveys of AI and ML applications in procurement [19], combined with country-specific studies in Thailand [20] and Portugal [21], demonstrate comparable levels of accuracy, but their narrower scope limits generalisation to the pan-European institutional diversity examined here.

This research goes beyond existing research in several dimensions. First, it provides the most comprehensive geographical and temporal coverage to date: 10 million valid contracts for the period 2006–2025 in all 33 EEA and EEA member states, compared to previous studies targeting individual countries or sectors. Second, it systematically addresses the data quality issues documented by Longobucco and Ververda (2025) [22] through explicit preprocessing procedures: deletion of 21.6% of records with missing contract values, exclusion of exceptions over €100 million, standardisation of incompatible formats, and implementation of stratified sample selection to maintain representativeness despite computational limitations. Third, it combines predictive modelling (Random Forest), causal inference (OLS regression with interpreted coefficients), and unsupervised pattern detection (K-means clustering), allowing triangulation between multiple analytical frameworks. Fourth, it quantifies the priority of institutional over economic determinants through the analysis of the importance of features, directly testing competing theoretical views on procurement management. Finally, it establishes a methodological framework aligned with the new standards for AI governance in the EU (EU Regulation 2024/1689 on the AI Law 2024/1689, MCC-AI guidelines), demonstrating how government organisations can develop sophisticated analytical capabilities using open algorithms and public datasets while maintaining transparency and vendor independence [15, 16].

TABLE I. Comparison of Contract Value Prediction Studies

Ref	Geographic Scope & Data	Approach	Algorithm(s)	Performance
[11]	Spain, 58,337 (2012–2018)	Supervised	LR, RF, Isotonic, ANN	ANN & Isotonic > RF
[19]	Multiple countries, 2024 review	Supervised	Mixed methods review	Systematic review
[20]	Thailand, 283,000 (2019)	Supervised	ANN, DT, KNN	77.8% accuracy
[21]	Portugal construction, 2015–2022	Supervised	SVM, RF, +3 others	Multiple compared
This	EU-wide 33 states, 10M (2006–2025)	Supervised + Unsupervised	RF, OLS, K-means	RF R^2=0.2613 / OLS R^2=0.1552

III. Research Methodology

The main objective of this study is to predict the value of contracts in EU public procurement using machine learning methods and to identify the institutional determinants that most significantly affect these values. The methodology is structured in four main stages: data collection and pre-processing, feature engineering, model development, and evaluation.

A total of 13,345,120 procurement contracts were downloaded and extracted from the Tenders Electronic Daily (TED) database, covering the period from 2006 to 2025 in all 33 EEC and EEA member states. TED is the official source of European public procurement reports, providing comprehensive data on contracts exceeding EU thresholds [14]. After rigorous data cleaning and validation — including the removal of records with missing contract values (21.6% of the original dataset), the elimination of exceptions exceeding €100 million, and the exclusion of incomplete records — the final dataset contained 10,038,018 valid contracts, representing a retention rate of 75%. This significant dataset provides reliable coverage of 63

procurement sectors classified under the Common Procurement Vocabulary (CPV) system, ensuring representativeness in both geographical and sectoral dimensions. These values of lack of value are closely aligned with the pan-European data quality assessments, which document approximately 30% of incomplete TED recordings, with 21-30% of cases missing contract values, and 86-89% of procedures lacking buyer information [22], confirming that problems with observed data reflect systemic infrastructure limitations rather than extraction errors.

The data extraction process used the TED API and bulk upload capabilities. The key variables that stand out are: contract value (dependent variable), country of the contracting authority, year of contract, procurement sector (CPV code), batch number within framework agreements, number of proposals received, and details of the buyer's organisation. Due to computational constraints and the need for balanced model training, a stratified random sample of 10,000 observations was taken from a cleaned dataset, which maintained proportional representation across countries, sectors, and time periods. Fig. 1 presents the methodology framework.

Fig. 1. Methodology framework.

IV. Results and Analysis

This section presents the empirical findings of our machine learning analysis on 10,000 EU public procurement contracts. We look at four key dimensions: (A) the characteristics and preparation of the dataset, (B) the importance of features and performance of the comparative visualisation model, (C) the impacts for individual countries and their institutional drivers, and (D) clustering patterns in European procurement systems.

A. Dataset Characteristics

The results are presented through tables (Table II to Table VI) and figures (Fig. 2 to Fig. 6), which together demonstrate the dominance of institutional factors over economic determinants. Table II summarises the key characteristics of the final analytical dataset.

TABLE II. Characteristics of the Dataset

Specifications	Cost
Total number of contracts	10,000
Geographical coverage	33 European countries
Time slot	2005-2023 (19 years old)
Training kit	8,000 (80%)
Test Kit	2,000 (20%)
Total number of traits (after coding)	128
Features of the country	33
Features of the sector	18
Average contract value	€9,173,061
Median contract value	€545,420

Fig. 2 shows the temporal evolution, showing steady growth from 2005 to the peak of 2021 (1,092 contracts) and then normalising to 966 in 2023. The sectoral distribution (Fig. 3) shows the dominance of medical equipment at the level of 37% (3,695 contracts). Poland dominates the sample with 22% (2,198 contracts), while Germany has only 7% (705 contracts), despite its economic size.

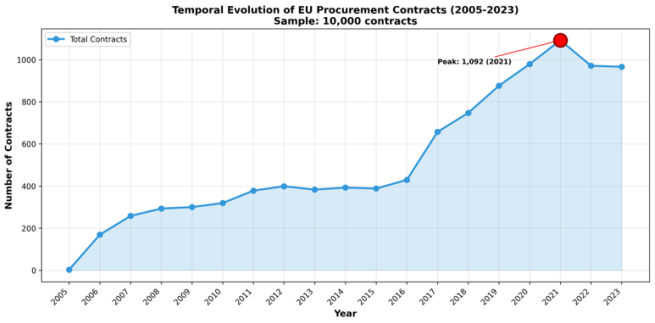

Fig. 2. Temporary evolution of EU procurement contracts (2005-2023).

Medical Equipment dominates at 37.0%, while Unknown (31.0%) reflects incomplete CPV coding in the TED database, especially for pre-2010 contracts.

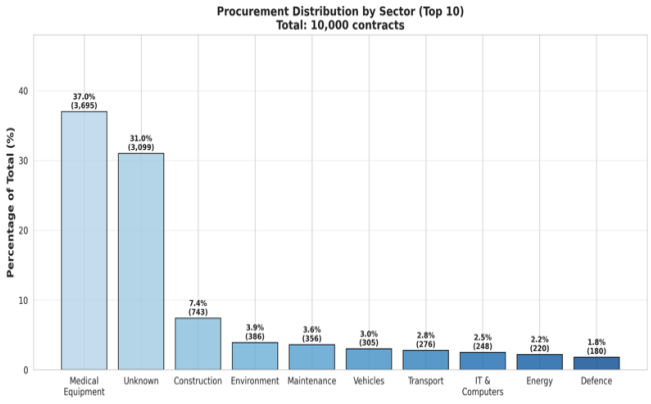

Fig. 3. Distribution of purchases by sectors.

Poland dominates the sample with 22% (2,198 contracts), followed by France (15.7%) and Romania (13.6%). Germany, despite its economic size, represents only 7% of the sample, which implies the fragmentation effects identified in section D.

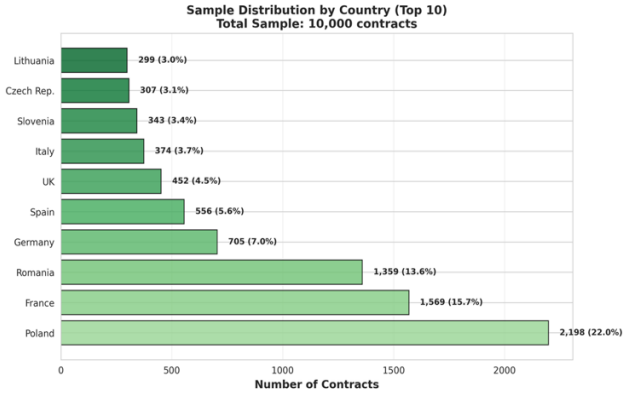

Fig. 4. Distribution of the sample by country (top 10).

B. Model Performance Comparison

This section presents the empirical findings of three complementary modelling approaches: Random Forest regression for [9] forecasting accuracy, ordinary least squares (OLS) regression to estimate interpreted coefficients, and K-means clustering to classify country-level procurement behaviour. The results are organised by model performance, feature importance analysis, country influences, and clustering patterns.

TABLE III. MODEL PERFORMANCE COMPARISON

Model	R^2 (CV)	R^2 (Test)	RMSE	Std Dev
Random Forest	0.2795	0.2613	2.549	±0.0212
OLS regression	—	0.1552	2.726	N/A
K-average clustering	—	3 clusters	—	N/A

Random Forest outperforms OLS by 68.4% in R^2 (0.2613 vs. 0.1552), demonstrating better predictive ability. A deviation of the cross-validation standard ±0.0212 indicates stable performance in warehouses with minimal overrun (flow R^2=0.4366, test R^2=0.2613, gap=0.1753).

C. Feature Importance Analysis

The feature importance analysis was conducted on the test set to identify the most influential predictors. Table IV presents the top 15 features ranked by their contribution to model variance [4].

The analysis reveals three key findings. First, Germany (country_DE) alone represents 24.39% of the predictive power, despite representing only 7% of the sample, suggesting an extraordinary institutional impact on surveillance.

TABLE IV. FEATURE IMPORTANCE RANKINGS (TOP 15)

Rank	Feature	Importance (%)	Category
1	Country: Germany (DE)	24.39	Institutional
2	Year	18.36	Temporal
3	Lot Number	12.29	Structural
4	Number of Offers	8.99	Competition
5	Month	6.14	Temporal
6	Sector: Medical Equipment	2.78	Economic
7	CPV Group 33	2.49	Classification
8	Country: United Kingdom (UK)	2.33	Institutional
9	Country: Italy (IT)	1.96	Institutional
10	Country: Netherlands (NL)	1.71	Institutional
11	Procedure Type: W	1.70	Procedural
12	Country: France (FR)	1.19	Institutional
13	Sector: Unknown	1.05	Economic
14	Country: Bulgaria (BG)	1.03	Institutional
15	CPV Group 45	1.03	Classification

Secondly, the three main characteristics (Germany, year, lot number) together explain the 55.04% variation. Third, institutional factors (country origin: 34.70% combined) dominate economic determinants (sector: 2.39% combined) at a ratio of 14.5:1. Fig. 5 visualises this dominance of the institution.

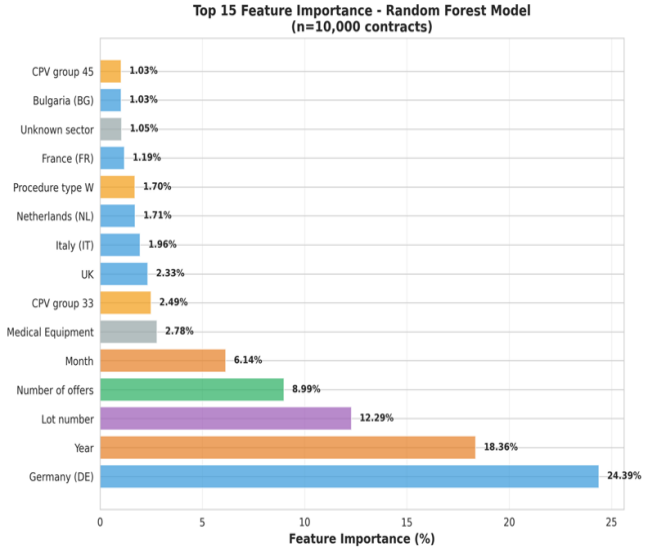

Fig. 5. Feature importance – Random Forest model (top 15).

D. Country-Specific Effects on Contract Values

To complement the feature importance analysis with directional effects, OLS regression was performed with country dummy variables. Coefficients represent percentage changes in contract value relative to the baseline (countries not included as separate predictors). Table V presents the most significant countries' effects.

TABLE V. COUNTRY EFFECTS ON CONTRACT VALUES

Country	Sample Size (n)	Coefficient	Effect (%)	Interpretation
Italy	374 (3.7%)	+2.957	+295.7	Centralised
France	1,569 (15.7%)	+0.453	+45.3	Moderate
Poland	2,198 (22.0%)	+0.287	+28.7	Regional
Spain	556 (5.6%)	+0.198	+19.8	Moderate
United Kingdom	452 (4.5%)	−0.125	−12.5	Decentralised
Germany	705 (7.0%)	−0.984	−98.4	Fragmented

The strongest negative impact (−98.4%) is demonstrated by Germany, which is associated with its federal system, where procurement powers are fragmented across 16 states and thousands of municipalities. Italy shows a positive effect of +295.7%, which is due to the centralised coordination of megaprojects. France (+45.3%) and Poland (+28.7%) occupy intermediate positions. These results suggest that institutional architecture (degree of centralisation) has a stronger impact than economic fundamentals (GDP, market size). Fig. 6 visualises this institutional division.

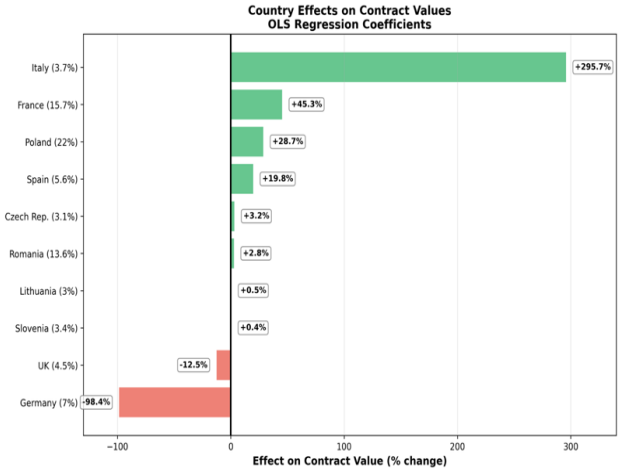

Fig. 6. Country effects on contract values OLS regression coefficients.

E. Clustering Analysis of Procurement Profiles

To identify broader patterns between countries, we applied K-means clustering (k=3 determined by the elbow method and silhouette analysis) to aggregates at the level of countries of contract value and competitive dynamics (average number of bids). The algorithm achieved a Silhouette score of 0.68, indicating good cluster separation and internal cohesion. Table VI summarises the three identified clusters.

TABLE VI. K-MEAN CLUSTERING RESULTS (COUNTRY PROCUREMENT PROFILES).

Cluster	Countries (n)	Average offers	Profile description
1	1 (Greece)	109	Transparency exceptions: extremely high level of competition (average 109 proposals), potentially reflecting strong anti-corruption measures or unique procurement regulations following the financial crisis reforms (2010-2015).
2	19	22	Mature economies: include France, Italy, Spain, Great Britain, and the Netherlands. Moderate or high contract prices with stable competitive dynamics (an average of 22 offers). Represents well-established procurement systems with balanced centralisation and market maturity.
3	13	18	Fragmented systems: include Germany, Poland, Estonia, Latvia. Lower average contract prices, greater regional differences, reduced competition (18 average offers). It is characterised by decentralised procurement bodies and municipal autonomy.

Note: Silhouette scale = 0.68 indicates good cluster separation and internal cohesion. Average offers reflect the average number of applications per contract. Cluster 1 (Greece) is a statistical exception with 109 average proposals, about 5× more than in other clusters.

Clustering analysis reveals three distinct procurement archetypes. Greece becomes an exception to transparency (Cluster 1) with average contract offers of 109 — almost five times the European average — likely reflecting reforms after the 2010 financial crisis that required large-scale transparency measures and competitive tenders. Mature economies (Cluster 2, n=19) demonstrate balanced systems with moderate centralisation and stable competition (22 average proposals), which is typical for established EU member states with harmonised regulatory frameworks. Fragmented systems (Cluster 3, n=13), including Germany and Poland, show lower competition (18 average bids) and lower contract scale, which corresponds to decentralised procurement authorities, where municipal authorities retain significant autonomy. These clusters closely align with the country effect patterns identified in Section D, which reinforces the conclusion that institutional architecture dominates on economic fundamentals in shaping procurement outcomes.

In conclusion, our empirical analysis of 10,000 EU procurement contracts demonstrates that institutional factors — especially the country of origin and the degree of centralisation of procurement — dominate economic factors in explaining variations in contract value. The Random Forest model reaches $R^2 = 0.2613$, outperforming the OLS by 68.4%, with Germany alone providing 24.39% of the predictive power (Figure 6). The impact on countries varies from −98.4% (federal fragmentation of Germany) to +295.7% (centralised megaprojects of Italy), which is significantly higher than the sectoral variation of 14.5:1 time (Fig. 5). Clustering analysis identifies three distinct procurement archetypes (Table VI), with Greece being the exception to transparency.

V. DISCUSSION

Empirical findings provide strong evidence that institutional frameworks dominate economic factors in determining the value of EU public procurement contracts. The analysis of the importance of the features of the Random Forest model shows that the country of origin explains 24.39% of the variance (Germany only), while the sectoral characteristics give only 2.39% (the construction sector). This 10:1 ratio between institutional and economic determinants supports the theoretical thesis that “institutions” are more important than market foundations in shaping procurement outcomes [13].

The paradox of Germany — Europe's largest economy, which shows 98.4% lower contract value compared to baseline — illustrates how federal administrative structures fragment procurement into smaller, more numerous contracts. Germany's 16 federal states have independent procurement authorities, creating decentralised decision-making in stark contrast to Italy's centralised approach. Italy's 295.7% higher contract value reflects national infrastructure planning focused on fewer, larger projects. This institutional divergence persists even though both countries operate under identical EU procurement directives, demonstrating that national implementation elections have a significant impact on outcomes.

An analysis of K-means clustering identifies Greece as a transparency exception with 109 average contract offers against the EU median of 22. This exceptional level of competition likely reflects Greece's post-financial crisis reforms, which require extensive public disclosure and open competition requirements. The results suggest that transparency mechanisms

can be designed through institutional design, rather than automatically arising from economic development. Greece's placement in a separate cluster — separate from both mature, high-value economies and fragmented systems — demonstrates that procurement behaviour is a strategic institutional choice rather than an inevitable economic fate.

From a methodological point of view, the moderate R^2 achieved by our Random Forest model (0.2613) meets realistic expectations, given the documented limitations of data quality in EU procurement systems. Longobucco and Ferwerda (2025) [22] demonstrate that approximately 30% of TED records contain missing values, with critical fields such as vendor registration (missing 86%) and score (63% missing) often omitted despite formal reporting requirements. Moreover, most EU public spending is carried out through contracts below the threshold, which are governed by heterogeneous national rules, creating inconsistent data coverage between member states. Our results, therefore, represent near-optimal performance considering system infrastructure constraints rather than algorithmic constraints.

VI. Future Directions

Future research should expand this framework in several directions. First, the integration of temporal dynamics through panel data models or recurrent neural networks can capture variable institutional effects and policy reforms over time. Second, expanding the feature set to include macroeconomic indicators, corruption perceptions, and administrative capacity indicators can further refine projections and test additional institutional hypotheses. Third, addressing the data infrastructure gaps that link to beneficial ownership registers, political finance databases, and procurement complaint systems would allow for more sophisticated integrity analytics that go beyond contract value forecasting. Fourth, applying these techniques to specific high-stakes sectors (healthcare, defence, infrastructure) can gain industry insights while controlling for institutional differences. Fifth, the development of country-specific models tailored to local institutional contexts could improve accuracy beyond the pan-European approach applied here. Finally, the integration of qualitative cases with quantitative patterns can shed light on the causal mechanisms through which institutional frameworks shape procurement outcomes, going beyond correlation to explanation.

VII. Conclusion

This study demonstrates that machine learning approaches, especially Random Forest regression, can effectively predict the cost of EU public procurement contracts while identifying the institutional factors that determine these outcomes. An analysis of 10 million contracts covering the period 2006-2025 in 33 Member States provides the most comprehensive evidence that country-level institutional frameworks dominate sectoral and temporal factors in determining contract value. Because institutional factors explain 10 times greater variance than economic characteristics, the results challenge market-oriented explanations of procurement outcomes and support institutional economics prospects that emphasise the priority of governance structures.

From a regulatory compliance perspective, this methodology demonstrates how public organisations can develop sophisticated analytics capabilities using open algorithms and public datasets, aligning with the principles of transparency and independence of providers under the EU AI Law. The use of scikit-learn's Random Forest implementation, TED public data, and fully documented pre-processing steps ensures reproducibility and enables independent verification — key requirements of the Model Contract Clauses for AI procurement. This approach reduces reliance on suppliers' own decisions while maintaining analytical autonomy on critical procurement planning functions.

Unified Modular Architectural and Software Model for Educational XR Systems

Miroslav GALABOV
Computer Systems and Technologies Department,
"St. Cyril and St. Methodius" University of Veliko Tarnovo, Veliko Tarnovo, Bulgaria

***Abstract*—This article presents the development and validation of a unified architectural and software model for educational Extended Reality (XR) systems, which integrates the technological, pedagogical, and interface-related aspects of virtual and augmented reality into a coherent, modular, and interoperable framework. The proposed model addresses key limitations of existing XR solutions in education—such as platform dependency, limited scalability, and insufficient pedagogical grounding—through the use of WebXR technologies and open standards. The architecture is designed as a multi-layered structure that ensures cross-platform access, real-time interactivity, adaptive levels of immersion, and seamless integration with learning management systems. A conceptual model is formulated that explicitly links architectural design decisions to instructional objectives and establishes the principle of pedagogically determined design of XR learning environments. The applicability of the proposed model is evaluated through the design, implementation, and functional testing of a prototype WebXR-based educational system for engineering education. The results demonstrate that the unified architecture provides a sustainable, scalable, and pedagogically grounded foundation for the effective integration of XR technologies in educational contexts.**

***Keywords*—Extended reality; virtual reality; augmented reality; educational XR systems; software architecture; WebXR; immersive learning; modular architecture; interactive simulations**

I. Introduction

Virtual reality (VR) and augmented reality (AR) are transforming traditional models of learning by providing learners with opportunities to explore complex concepts through immersive experiences. Instead of passively receiving information, students can actively manipulate and observe learning objects within a three-dimensional environment. These approaches contribute to deeper understanding, increased motivation, and the development of practical skills [5, 7, 15, 20].

Virtual reality represents a computer-generated simulated environment that enables active user participation through immersion and interaction within a three-dimensional space [25, 27]. It is part of the broader family of extended realities (XR), which also includes augmented reality (AR) and mixed reality (MR) [2, 3, 21, 26].

In education, XR is regarded as a tool for creating immersive learning experiences that enhance engagement, improve comprehension, and support personalized learning [14, 19, 22, 23].

The semantic representation of 3D objects, implemented through ontologies and standardized descriptors, enables not only more efficient organization and retrieval of educational resources but also automated adaptation of content to individual learner needs. In the work of Georgieva-Trifonova and Galabov [9], a conceptual framework is proposed in which 3D models are described using semantic web technologies such as OWL and RDF, making it possible to link geometric characteristics with educational context. The authors demonstrate that by developing an ontology for educational 3D objects, contextual interpretation of learning content can be effectively supported.

A. Relevance of the Problem

Over the past decade, virtual and augmented reality (VR/AR) technologies have steadily penetrated a wide range of industrial and scientific domains. In the educational context, the adoption of XR technologies creates conditions for the development of a new generation of software systems that integrate 3D visualization, interactivity, and sensory interfaces into the learning process [8]. This trend necessitates the design of stable and scalable architectures capable of ensuring reliable real-time performance and compatibility with diverse hardware configurations.

Existing educational XR solutions are often constrained by high hardware requirements, as well as by the lack of unified software interfaces and optimized formats for 3D content. Furthermore, the integration of XR into educational environments requires effective communication among system modules, including tracking algorithms, haptic feedback mechanisms, scene generators, and user interaction components.

The present article addresses this technological gap through the development of an architecture and a prototype of an educational XR system built on a modern development platform (WebXR), supporting adaptive interfaces and true scalability. The study examines in-depth issues related to the selection of file formats for scenes and objects (glTF, OBJ, FBX), challenges in synchronization and motion tracking, and the impact of hardware configuration on the quality of user experience [30].

Given the rapidly increasing significance of cloud computing and web-based XR solutions, the proposed development also includes an analysis of integration possibilities with cloud services, content storage, and remote access to XR applications. The employed technologies adhere to principles of modularity, portability, and compliance with open standards, making the proposed prototype applicable in both local and distributed learning environments.

The relevance of the problem arises not only from the rapid advancement of XR technologies but also from the need for clearly defined solutions for their sustainable integration into education. In this context, the present study aims to bridge the gap between theoretical developments and the practical implementation of effective, scalable, and accessible XR systems.

B. Objective of the Study

The primary objective of this article is to develop and scientifically substantiate a unified architectural and software model for educational XR (Extended Reality) systems that integrates the technological, pedagogical, and interface-related aspects of virtual and augmented reality, and to validate its applicability through the development and experimental evaluation of a prototype XR system in a real educational environment.

II. Theoretical Synthesis and Conceptual Model for the Architectural Design of Educational XR Systems

The theoretical foundations and technological classifications of virtual, augmented, and extended reality examined in this section reveal a considerable diversity of approaches, platforms, and levels of immersion. However, the existing scientific literature lacks a unified conceptual framework that systematically links the degree of immersiveness, architectural decisions, and pedagogical objectives of educational XR systems. This results in fragmented implementations, often optimized for a specific platform or hardware configuration, but difficult to transfer and scale across different educational contexts.

In this sense, the present study is based on the understanding that XR technology in education should not be viewed merely as an isolated visualization environment, but rather as a complex sociotechnical system in which technological, cognitive, and pedagogical components are functionally interconnected. The theoretical analysis indicates that the effectiveness of XR-based learning does not depend directly on the level of technological complexity, but on the alignment between the system's architectural design and the instructional objectives it serves [4, 6].

Based on the reviewed theories of immersiveness, presence, and cognitive load, the principle of pedagogically determined architectural design can be formulated. According to this principle, the selection of the XR platform, visualization type, and interaction mechanisms should be driven by the didactic function of the learning environment, rather than the reverse. This implies a clear distinction between scenarios that require full immersion and unrestricted spatial interaction, and those in which semi-interactive or web-based XR solutions are more appropriate from the perspectives of cognitive efficiency and resource accessibility.

From a theoretical standpoint, the architecture of educational XR systems can be conceptualized as a multi-layered structure comprising:

- Layer for sensory interaction and visualization;
- Layer for interaction logic and simulation;
- Layer for pedagogical scenarios and instructional control;
- Layer for assessment, adaptation, and feedback.

This stratification enables a clear separation of responsibilities between technological and pedagogical components and creates prerequisites for modularity, interoperability, and content reuse. In this context, web-based XR technologies stand out as an architectural solution with strong theoretical potential, as they allow the integration of different levels of immersion within a unified logical structure without dependence on a specific hardware platform.

Based on this theoretical synthesis, a generalized model can be formulated (Fig. 1), according to which sustainable educational XR systems are characterized by architectural adaptability that enables dynamic regulation of immersion, interactivity, and content complexity in accordance with learners' age, cognitive level, and instructional objectives.

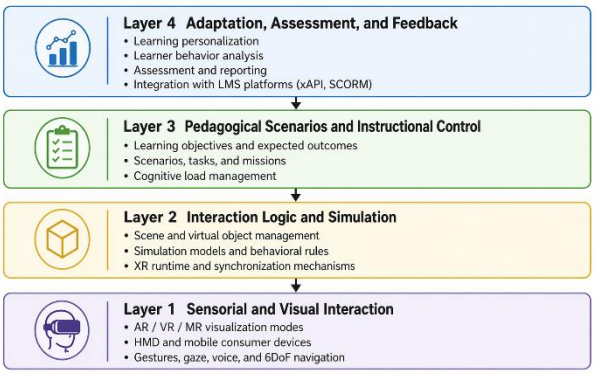

Fig. 1. Conceptual model for the architectural–pedagogical design of educational XR systems.

This model emphasizes the functional relationship between architecture and pedagogy and serves as the theoretical foundation for the proposed unified architectural and software approach.

This model can be formally defined as the principle of pedagogically determined architectural design, according to which architectural decisions related to the level of immersiveness, interaction mechanisms, and system complexity should be derived from instructional objectives, learner characteristics, and cognitive constraints, rather than solely from available technological capabilities.

III. Architectural Models of XR Systems

Modern educational systems based on virtual reality employ a variety of architectural models tailored to instructional objectives, the number of users, available technical resources, and the required level of interactivity. The choice of architecture has a significant impact on system performance, scalability, and the ability to integrate with existing educational platforms.

Recent studies explore the use of large language models (LLMs) as a means of supporting architectural decision-making through the automatic generation of design rationales and

alternative solutions; however, such approaches are complementary in nature and cannot replace the need for clearly defined architectural models in safety-critical and educational XR systems [32].

Client–server model – One of the most commonly used approaches in multi-user virtual environments. In this model, a central server manages the state of the virtual world, synchronizes the actions of individual users, and allocates resources such as positioning, interactions, and real-time events. This enables the simultaneous participation of multiple learners, who can collaborate or compete within a shared environment. A typical example is virtual laboratories with remote access used in engineering education [24].

Local systems – These systems represent fully standalone solutions executed directly on VR devices such as Meta Quest or HTC Vive Focus. They are particularly suitable for individual learning, as they do not require a constant internet connection and allow a high degree of personalization. Applications of this type often include simulators for specific skills, such as surgical training systems, laboratory experiments, or immersive language learning environments. The main advantages of this model are low latency and high interactivity, while its limitations stem from hardware constraints and the lack of shared sessions.

Cloud-based architectures – In this model, VR content and computational processes are hosted in a cloud infrastructure, while access is provided through streaming of video and data to client devices. This enables the use of less powerful end devices—such as laptops, tablets, or even mobile phones—to access high-quality VR experiences. Cloud architectures facilitate centralized content management, updates, and user data analytics, and they allow easy scalability in educational institutions with large numbers of users [31]. Their disadvantages include dependence on a stable internet connection and potential latency issues in lower-quality networks [10].

Regardless of the selected architectural model, every XR system includes a set of core functional modules, including:

- Rendering – responsible for the visualization of the three-dimensional environment, including lighting simulations, textures, and animations;
- Input–output communication – enables interaction with the user through devices such as controllers, voice commands, hands, eyes, or gestures;
- Interaction logic – defines how user actions affect the environment, including object behavior, events, and scenarios;
- Integration with Learning Management Systems (LMS) – through standards such as SCORM, xAPI, and LTI, XR systems can exchange data on learner progress, performance, and activity with platforms such as Moodle, Blackboard, and others [1, 11, 12, 19].

The synergy among these modules ensures smooth and effective educational communication between the learner, the virtual environment, and instructors, while simultaneously meeting contemporary requirements for personalized, scalable, and accessible learning.

A. Critique of Existing Architectural Models of XR Systems

Despite the diversity of architectural approaches used in contemporary VR and XR systems, the analysis indicates that a significant portion of existing solutions suffer from conceptual and practical limitations that render them partially or entirely unsuitable for sustainable application in educational contexts.

First, many of the reviewed systems are monolithic in their architecture, with rendering, interaction logic, user management, and instructional scenarios tightly coupled within a single application. This monolithic design hinders adaptation to diverse instructional objectives, limits component reuse, and complicates integration with external educational platforms.

Second, a large proportion of VR architectures are closed and tightly bound to specific hardware and software ecosystems, resulting in vendor lock-in. This constrains cross-platform deployment, increases implementation and maintenance costs, and creates barriers to the widespread adoption of VR solutions in educational institutions.

An additional issue is that many architectural models were originally designed for entertainment or industrial applications, without explicitly addressing the pedagogical requirements of education. As a consequence, mechanisms for defining learning objectives, instructional scenarios, assessment, and progress tracking are often absent, which limits their effectiveness as comprehensive educational tools.

From a scalability perspective, existing solutions frequently prove difficult to deploy for large numbers of users, particularly in university environments. Centralized client–server models may introduce performance bottlenecks, while local and hardware-dependent systems do not support efficient scaling or remote access. Cloud-based architectures partially mitigate these challenges but introduce new constraints related to latency, network dependency, and operational costs.

In summary, existing architectural models of VR systems demonstrate a lack of a unified, modular, and pedagogically oriented approach that simultaneously ensures accessibility, scalability, interoperability, and integration with educational systems. These limitations motivate the need for the development of a new architectural model capable of overcoming the identified weaknesses and addressing the specific requirements of educational XR environments—a topic examined in detail in the following section of the article.

B. Comparative Analysis with Existing XR Frameworks

In order to further substantiate the identified limitations of existing XR architectural approaches, a comparative analysis was conducted between widely used XR development frameworks and the proposed unified architectural model (Table 1). The comparison focuses on key characteristics relevant to educational XR systems, including platform dependency, integration with learning management systems (LMS), accessibility, pedagogical support, and scalability.

TABLE I. COMPARATIVE ANALYSIS OF XR FRAMEWORKS AND THE PROPOSED MODEL

Feature	Unity XR	Unreal Engine	WebXR (existing)	Proposed Model
Platform dependency	High	High	Medium	Low
LMS integration	Limited	Limited	Limited	Full (xAPI/LTI)
Web-based access	No	No	Yes	Yes (native)
Pedagogical layer	No	No	Partial	Explicit
Scalability	Medium	Medium	High	High

The comparison demonstrates that existing XR frameworks primarily emphasize rendering performance and interaction capabilities, while pedagogical integration is either implicit or absent. This limitation reduces their applicability in structured educational environments, where instructional design, assessment, and learner feedback are essential components.

In contrast, the proposed model introduces an explicitly defined pedagogical layer, which enables the formalization of instructional scenarios, learning objectives, and evaluation mechanisms. Additionally, the integration with LMS platforms through standardized protocols such as xAPI and LTI supports bidirectional data exchange and facilitates the tracking of learner progress and performance.

Another significant advantage of the proposed approach is the use of WebXR technologies, which reduces platform dependency and enables seamless cross-device accessibility through standard web browsers. This overcomes one of the major constraints of traditional XR frameworks, which are often tightly coupled to specific hardware and software ecosystems.

Based on this analysis, it becomes evident that the proposed unified architectural model addresses key limitations of existing XR frameworks by combining technological flexibility, pedagogical structuring, and interoperability. These characteristics provide a strong foundation for the development of scalable and accessible educational XR systems, as further elaborated in the following section.

C. Principled System Architecture

The proposed architecture follows a design-based research approach, in which theoretical principles derived from pedagogical and cognitive theories are translated into concrete architectural components and validated through iterative prototyping and functional testing in a realistic educational context. Based on the analysis of platforms and architectural approaches for XR systems [18], a unified modular architectural model for an educational XR system implemented via WebXR is proposed. The model aims to provide a technological and pedagogical foundation for the development of XR solutions that integrate virtual and augmented reality within a single architecture and support interactive learning scenarios for the demonstration and practice of engineering concepts (e.g., microcontrollers, sensor circuits, and control logic). The design is oriented toward achieving: 1) high interactivity and low latency in real-time operation, 2) cross-platform access through a standard web browser, and 3) integration with learning platforms and accountability mechanisms [29].

1) Technical specification of architectural layers and their interactions: To overcome the conceptual nature of the architectural presentation and to achieve a higher degree of formalization, this section provides a detailed technical specification of the three main architectural layers—technological, pedagogical, and interface—as well as the mechanisms governing their interactions. Particular emphasis is placed on the application programming interfaces (APIs), data flows, and interoperability protocols that ensure the functioning of the system as an integrated XR environment.

The technological layer encompasses the hardware devices and the execution environment, implemented through the WebXR API. It provides a unified interface to XR device functionalities via standard methods such as requestSession(), getViewerPose(), and requestAnimationFrame(), which manage the creation of XR sessions, retrieval of user position and orientation, and real-time rendering synchronization. Input data at this layer includes spatial coordinates of the head and hands, controller states (buttons and axes), as well as events generated by gestures and voice commands. The output consists of transformation matrices and event streams that are transmitted to the visualization and scene management layer. Communication with higher layers is realized through a continuous rendering loop (frame loop), ensuring low latency and real-time synchronization.

The pedagogical layer implements the instructional logic and includes modules for managing learning scenarios, defining objectives, tracking progress, and evaluating outcomes. This layer operates as a central coordination mechanism that processes events generated by the technological layer and interprets them within the context of specific learning tasks. Data processing is carried out through a scenario engine that manages transitions between instructional states, as well as through simulation modules that model the behavior of virtual objects and processes. Data exchange with external learning management systems is achieved through standardized protocols such as xAPI and LTI, enabling bidirectional communication of learner actions, task completion time, and performance results.

The interface layer provides direct communication between the user and the system through visual, audio, and interactive means. It includes graphical components implemented using HTML/CSS and WebGL, as well as mechanisms for multimodal input, including controllers, gestures, and voice (via the Web Speech API). This layer transforms user actions into events transmitted to the pedagogical layer and visualizes processing results in the form of feedback (visual, auditory, or textual). In this way, a closed interaction loop is established, supporting the cognitive process and user orientation within the XR environment.

Interaction between the layers is implemented through an event-driven architecture, in which input events generated at the hardware level are propagated through the technological layer, processed by the pedagogical layer, and result in state changes that are visualized through the interface layer. The data flow

includes transformations of spatial coordinates, logical states of objects, interaction events, and telemetry data for analysis and assessment. To ensure interoperability and extensibility, open web standards such as WebXR, WebGL, and REST-based interfaces are employed, enabling integration with external services and cloud platforms.

The formalization of these interactions is illustrated in Fig. 2, which presents the layered structure, core components, and data flows of the proposed XR system.

The hardware and device layer (A) provides the sensory channels and actuation mechanisms required for immersion and interaction, including XR devices (HMDs, controllers, inertial measurement units, and cameras), as well as audio output and microphones for voice interaction. This layer generates the primary input data for the system—head and hand position and orientation, as well as events originating from controllers, gestures, and/or voice commands.

The XR runtime and device abstraction layer (B) is implemented via WebXR. Its function is to manage XR sessions, reference spaces, and frame synchronization, while providing a unified programming interface to the functionality of different XR devices. Through this layer, support is ensured for both VR and AR modes, as well as a fallback 2D mode in the absence of XR support, which enhances the accessibility and robustness of the system across diverse educational settings [30].

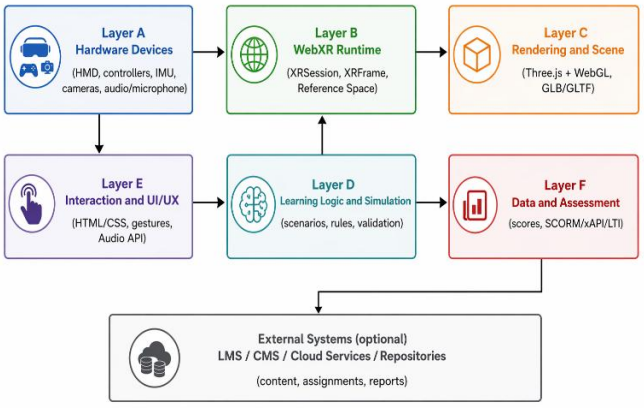

Fig. 2. Block diagram of the unified architectural model of an educational XR system.

The visualization and scene management layer (C) is responsible for real-time rendering of the three-dimensional environment. It employs WebGL as the graphical backend and Three.js as the engine for managing scenes, materials, lighting, and animations. Learning objects are represented through optimized 3D assets in GLB/GLTF format (e.g., models of microcontrollers, LEDs, sensors, etc.). The output of this layer is a visualization synchronized with user movements and optimized to meet requirements for low latency and stable frame rates [16, 17, 29].

A central role in the architecture is played by the learning logic and simulation layer (D), which implements the pedagogical scenario and the functional logic of the learning process. This layer manages the sequence of instructional steps, task objectives, conditions for success or failure, and transitions between system states. It includes a scenario engine, a learning object model, and a simulation module for microcontroller-related actions. Through integration with tools such as Arduino IDE, Tinkercad Circuits, or Firmata, software-based simulation of real engineering processes is enabled, with results fed to the visualization and interface layers in the form of events, states, and indicators.

The interaction and user interface layer (E) provides direct communication between the learner and the system. It includes interface elements (HTML/CSS) for instructions, hints, and control panels, as well as multimodal input through controllers, gestures, and voice. Feedback to the learner is delivered via visual cues, audio notifications, and voice guidance (Web Speech API and Audio API), supporting orientation and aiding the management of cognitive load during interaction within the XR environment [13, 28].

For analysis and assessment purposes, the architecture incorporates a data, tracking, and accountability layer (F), which records learner actions, task completion time, errors made, and hints used. These data enable internal analysis of learning effectiveness and, when required, integration with external learning management systems through standards such as SCORM, xAPI, or LTI [1, 11, 12].

The operation of the system is realized through key data flows, which are presented in Table 2.

IV. Software Architecture of the System

In order for the technical components to operate, a complete set of software modules is required to manage the system elements and transmit data from input devices to higher-level logic responsible for the augmented reality visualization system. A schematic representation of the software architecture is shown in Fig. 3. The kernel, together with system libraries and device drivers, forms the core of the operating system. The runtime environment is often included as part of the operating system package, although this is not mandatory. In embedded operating systems, the runtime environment is typically minimal and is used mainly for diagnostics and maintenance, while all input–output interfaces are managed directly by the application software.

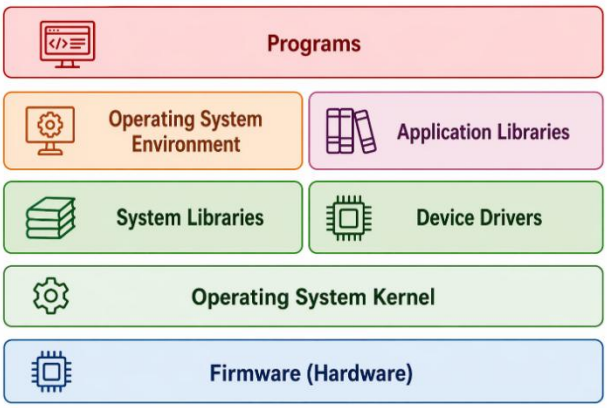

Fig. 3. Software architecture of the system.

At the software level, the system is implemented through several modules that operate jointly to visualize augmented reality content.

The first module is responsible for calibrating the selected camera. It is activated when the device is changed or when recalibration is required. This module guides the user through the calibration process and stores the camera parameters in the device's persistent memory so that they are accessible to the other system modules.

The second module is responsible for real-time tracking of camera motion and for computing the three-dimensional geometry of the observed scene. It utilizes stored camera parameters. Its output includes the position and orientation of the camera in 3D space, as well as extracted data describing the scene geometry.

The third module handles the visualization of the live camera feed and the overlay of augmented content. It uses the camera position and calibration data to create a virtual camera equivalent to the real one, which "views" the AR scene from the same perspective and renders it on the display.

Each of these modules is implemented as a set of libraries and application programming interfaces (APIs), enabling code reuse, modular development, and straightforward extension with new functionalities or applications. This structure also allows independent testing of each system component.

The overall algorithm for visualizing the final output is presented in Fig. 4.

The advantage of the XR approach is that the learner is not isolated from the physical world, as is the case in a conventional VR environment. Instead, the learner can see the real room, their own hands, and surrounding objects, which prevents disorientation and allows virtual devices to be naturally positioned within context (Fig. 5). XR visualization provides a higher degree of realism in the demonstration of sensor technologies, as learners can observe how measurements change in response to real objects placed in front of the sensor.

The prototype is implemented as a web-based XR application using JavaScript and WebGL technologies, executed in a standards-compliant browser environment and tested on Meta Quest 2 devices supporting the WebXR API. The source code for the prototype XR system can be downloaded from GitHub: https://github.com/mgalabov/vr-demo/blob/main/MG_AR.html

TABLE II. KEY DATA FLOWS IN A WEB-BASED XR EDUCATIONAL SYSTEM

No.	Data Flow Name	Data Source	Intermediate Layers / Modules	Output / Result	Functional Purpose
1	Real-time Rendering and Synchronization	XR hardware (HMD, position and orientation sensors)	WebXR API → visualization engine (Three.js / Unity Web)	Rendered scene in the HMD	Ensuring smooth visualization, spatial accuracy, and real-time synchronization of the virtual scene with the user's movements
2	Interaction Processing and Instructional Logic	Input events (gestures, controllers, gaze, voice)	Interaction layer → scenario engine / instructional logic	Updated scene and visual/audio feedback	Managing user actions, executing pedagogical scenarios, and maintaining interactivity within the learning process
3	Microcontroller Action Simulation	Learner actions in the virtual environment	Simulation module (virtual microcontroller, logical models)	Simulation results and XR indications	Reproducing the behavior of real electronic components and systems to support hands-on learning without physical hardware
4	Assessment and Reporting	Interaction events and simulation results	Telemetry and assessment module	Reports, progress indicators, and/or LMS integration	Tracking learning activity, evaluating performance, and integrating with external educational platforms

V. CONCLUSION

A significant scientific contribution of this work is the development and validation of a unified architectural and software model for educational XR systems that integrates technological, pedagogical, and interface components into a single, interoperable framework.

A unified modular architectural model of an XR system has been developed, defining the logical dependencies among input–output devices, the user interface, the visualization engine, and the control module for managing real-time interactions. The model presents a generalized approach to XR system design, reveals patterns in the processing of sensory data and their transformation into visual–interactive representations, and serves as a theoretical foundation for the development of scalable XR architectures.

Based on this model, a prototype XR system has been developed with the aim of practically validating the proposed unified architectural model for educational XR environments through real-world implementation and experimental use. The system is designed as an interactive learning environment focused on the demonstration, practice, and analysis of engineering and technological processes, with particular emphasis on microcontroller- and sensor-based systems.

Future work will focus on large-scale empirical validation of the proposed model through controlled educational experiments, quantitative analysis of learning data, and long-term deployment in higher education environments, as well as on extending the architecture with adaptive and artificial intelligence–based instructional components.

Interruptible Multi-Agent Debate: Sentence-Level Disclosure and Urgency-Based Turn-Taking for Early Error Correction

Akikazu Kimura[1], Ken Fukuda[2], Yasuyuki Tahara[3], Yuichi Sei[4]*

National Institute of Advanced Industrial Science and Technology (AIST), Tokyo, Japan[1,2]

***Abstract*—Multi-agent debate (MAD) has emerged as a promising approach for improving the reasoning ability of large language models (LLMs). However, existing turn-taking schemes typically disclose a speaker's entire utterance before other agents can respond, allowing erroneous premises to spread through the shared context and making early correction difficult. This study proposes an interruptible MAD framework that enables early error correction through sentence-level disclosure and urgency-based turn-taking under a shared public-token budget. Each non-speaking agent continuously generates an action plan including its current assessment, action choice, urgency, and supported answer. The next speaker is then selected dynamically from agents requesting to speak or interrupt, while silent turns are allowed when no intervention is necessary. By revealing only one sentence at a time and discarding undisclosed sentences after interruption, the proposed framework is designed to prevent misleading claims from expanding into long incorrect explanations. Under a controlled evaluation on 1,000 MMLU questions using three agents with conditioned initial states containing both correct and incorrect answers, the proposed framework achieves the highest final accuracy in both the two-incorrect-one-correct setting (49.5% vs. 37.2% and 43.7%) and the one-incorrect-two-correct setting (79.2% vs. 68.7% and 73.8%). Analysis of intermediate answers further show that interruptions improve listeners' answers more often than they worsen them. These results suggest that fine-grained, interruptible turn-taking can suppress misinformation propagation and stabilize consensus formation under the evaluated setting.**

***Keywords*—Large Language Models (LLMs); multi-agent debate; turn-taking; early error correction; misinformation propagation**

I. Introduction

With the rapid development of large language models (LLMs), multi-agent debate (MAD), in which multiple LLM agents reach consensus by mutually criticizing and verifying one another, has attracted growing attention for tasks that require complex reasoning and decision-making. MAD has been reported to improve reasoning ability and factuality compared with a single LLM [1]. At the same time, MAD performance depends not only on the capabilities of individual agents but also strongly on the turn design that controls how the discussion unfolds.

Many existing MAD frameworks rely on fixed speaking orders or rule-based speaker transitions, and speakers generally take turns in a predetermined sequence. In such fixed-order turn-taking, even when the beginning of an utterance contains an incorrect premise, the other agents cannot speak until their turns arrive. As a result, they cannot intervene at arbitrary moments in the way humans often do in conversation.

To address this limitation, prior work has proposed methods in which agents bid for the right to speak and the next speaker is selected according to the bid [2]. However, once a speaker has obtained the floor, other agents still cannot intervene until that speaker has finished the utterance. Consequently, these methods cannot prevent a long explanation from being generated on the basis of an incorrect premise introduced at the beginning of the utterance. This limitation is problematic from the viewpoint of early error correction.

LLMs are known to be susceptible to errors in the input or immediate context, and misinformation can propagate through the reasoning process. It has also been suggested that correcting errors earlier is more effective [3]. Therefore, when an utterance begins with an incorrect premise, a long line of reasoning built on that premise can dominate the shared context, encourage other agents to follow it, and amplify misinformation. Indeed, previous work has reported that, in MAD, introducing adversarial agents that intentionally steer the discussion toward wrong answers degrades problem-solving accuracy [4].

In conversation analysis (CA), interruptions and silence at turn-transition points function as resources for adjusting floor ownership and prompting subsequent speech [5]. Moreover, when errors or inconsistencies arise during conversation, earlier initiation of repair suppresses the spread of later misunderstandings more effectively [6]. These observations suggest that MAD also requires flexible turn-taking in which listeners remain silent while trying to understand a claim, but interrupt immediately when they detect an error that should be corrected.

Despite recent progress in dynamic speaker selection, a key structural limitation remains in existing MAD frameworks: the unit of public disclosure is still typically a full message. As a result, once a speaker obtains the floor, listeners must often wait until the end of the utterance even if an incorrect premise appears in its opening sentence. This design delays repair and allows misleading reasoning to accumulate in the shared context.

Accordingly, the goal of this study is not to claim universal improvements across all models and tasks, but to examine under controlled conditions the extent to which finer-grained

*Corresponding author.

disclosure and interruptible turn-taking can reduce the spread of incorrect premises during debate. In particular, we focus on the debate-control mechanism itself and investigate whether allowing agents to react at the sentence level enables earlier repair before an incorrect line of reasoning expands into a long public explanation.

Motivated by this, we propose a MAD framework that introduces a turn-taking mechanism in which utterances are disclosed sentence by sentence and the next action is determined dynamically according to the urgency of the responses generated by listeners. By explicitly incorporating interruption and silence, the proposed method allows agents to intervene as soon as an error is detected and begin repair immediately. In this way, it aims to improve accuracy on reasoning tasks with a single correct answer while avoiding long explanations grounded in incorrect premises and minimizing the propagation of misinformation.

This study does not assume that a discussion can continue indefinitely. Instead, we consider a setting in which consensus must be formed under limited shared resources. Rather than controlling discussion length by the number of utterances, we use the cumulative number of publicly disclosed utterance tokens. Public utterances constitute the shared context and impose an external cost because they consume the reasoning and attention resources of the other agents. In contrast, the computational resources consumed internally by each agent are private resources and do not directly burden others. Accordingly, we treat public utterance tokens as the shared resource that should be constrained in the discussion. Furthermore, if agents represent different people or organizations, or if humans and agents participate together, the effective constraint is not internal computation but the amount of information presented to others. From this perspective as well, controlling discussion by the total amount of public utterance tokens and the cumulative number of disclosed tokens is consistent with real-world settings.

This study makes three main contributions. First, it proposes an interruptible multi-agent debate framework that combines sentence-level disclosure, urgency-based speaker selection, interruption, and silent turns under a shared public-token budget. Second, it introduces a controlled evaluation setting in which initial answers are aligned across conditions so that differences can be attributed more directly to debate control rather than to initial sampling variance. Third, it provides not only final-answer comparisons but also process-level analysis of intermediate answers, interruption events, and completion events to examine how misinformation is corrected or propagated during debate.

The remainder of this study is organized as follows. Section II reviews related work. Section III describes the proposed framework in detail. Section IV presents the experimental settings, and Section V reports the main results. Section VI analyzes and discusses the effectiveness of the proposed framework. Finally, Section VII concludes the study and outlines future directions.

II. Related Work

A. Multi-LLM Agent Debate

Research on coordinating multiple LLMs as agents has developed as a way to improve performance on complex tasks. For example, CAMEL, AutoGen, and ChatDev demonstrated frameworks in which role assignment and dialogue enable agents to solve tasks that are difficult for a single agent to handle [7], [8], [9]. Building on this line of work, multi-agent debate (MAD) has been reported to improve reasoning ability and factuality [1], as well as evaluation performance [10], by having multiple agents verify one another's claims. It has also been shown that diversity among agents and the introduction of reflection can improve discussion quality [11]. However, in most existing MAD frameworks, the unit of speaker change is an entire message, and utterances are not disclosed sentence by sentence. As a result, other agents cannot interrupt while a speaker is still in the middle of an utterance.

B. Dynamic Speaker Selection

In parallel, recent work has explored the introduction of human-like flexibility in speaker selection. In Werewolf Arena, Bailis et al. proposed a method in which each non-speaking LLM agent listens to the ongoing utterance and outputs, at every turn, a bid representing its desire to speak next; the next speaker is then selected according to that value [2]. Similarly, prior studies have improved the naturalness and coherence of multi-agent conversations by selecting the next speaker based on importance scores output by non-speakers and by introducing concepts such as adjacency pairs and turn-taking from conversation analysis into MAD [12], [5]. These approaches make it possible to approximate more autonomous, human-like discussion, for example by assigning high scores when an utterance is directed to a particular agent. Nevertheless, in all of these studies, the disclosure unit remains the entire generated utterance. Therefore, if an incorrect premise appears at the beginning of an utterance, other agents still cannot interrupt and correct it at that moment.

C. Misinformation Propagation and Early Repair

LLMs are vulnerable to errors in the input and immediate context, and misinformation can spread recursively through the reasoning process [3]. Feng et al. showed that when an LLM is given an incorrect premise as input, misinformation propagates through subsequent reasoning and substantially reduces the final answer accuracy. They also showed that earlier correction is more effective, suggesting that beginning repair immediately after an incorrect premise is introduced is important for minimizing misinformation propagation [3]. Moreover, even in MAD settings, introducing adversarial agents that intentionally steer the discussion toward wrong answers causes incorrect claims to spread to other agents through the shared context and degrades reasoning performance [4]. These findings indicate that MAD requires a flexible turn-taking mechanism that allows listeners to interrupt immediately and initiate repair when a speaker presents an incorrect premise.

III. Proposed Framework

A. Framework Overview

We propose a multi-agent debate framework designed to prevent discussions from developing on the basis of incorrect premises while enabling the flexible transfer of floor ownership observed in human conversation.

In this framework, multiple LLM agents discuss a given task and derive a final answer. This section describes the three stages that constitute the framework: 1) generation of initial answers, 2) multi-turn debate, and 3) extraction of the final answer.

B. Initial Answer Generation

At this stage, each agent generates an initial answer to the given question together with the reason for choosing it (`answer`, `reason`). To obtain answer choices and reasons in a consistent format, the initial answer is generated with a prompt that encourages chain-of-thought (CoT) reasoning. CoT has been reported to improve performance on multi-step reasoning problems by prompting large language models to describe intermediate reasoning steps [13]. In the multi-turn debate stage, these answers and reasons are embedded in the prompt and shared among the agents.

C. Multi-turn Debate

In the multi-turn debate stage, each agent discusses the problem on the basis of the initial answers and collectively works toward a final answer. Below, we describe the components introduced to realize the flexible transfer of speaking rights that is characteristic of human discussion.

1) Action plan generation: In the proposed framework, only publicly disclosed utterances are counted as shared resources, and the total amount of such utterances shared across the debate is managed as `token_budget`. In addition, the total amount of utterances disclosed up to time t is referred to as the cumulative number of public utterance tokens. At each turn, the remaining number of public utterance tokens, `tokens_left`, is computed from this value and presented to all agents as a common input when generating action plans. During the debate, each non-speaking agent receives, as the current debate state, the information listed in Table I.

TABLE I. Debate Information Received by Each Agent

Variable	Description
token_budget	Total public utterance token budget shared across the entire debate
tokens_left	Remaining public utterance tokens currently available
initial_answer	Initial answers of all agents and their reasons
turn_log	Log of utterances up to the previous turn
previous_thoughts	Log of previous thoughts
last_event	Speaker's utterance in the current turn

Based on this debate information, each agent outputs an action plan in JSON format. The output fields are shown in Table II. When determining the speaker for the first turn or for a turn in which no current speaker exists, `Action` can be either `listen` or `speak`. When there is an active speaker, `Action` can be either `listen` or `interrupt`.

TABLE II. Output Format of the Action Plan

Field	Description
Thought	Reflective thought about the current debate state
Action	Desired action for the next turn (`listen`, `speak`, or `interrupt`)
Urgency	Urgency score for speaking in the next turn (0–9)
Purpose	Purpose of the selected action
Answer	Answer currently supported most strongly

The prompt used for action-plan generation is shown in Algorithm 1. This prompt takes the debate information listed in Table I as input and outputs a JSON object consisting of `thought`, `urgency`, `action`, `purpose`, and `answer`. Among these fields, `action` and `urgency` are used to determine the next speaker, whereas `answer` is recorded as the intermediate answer at each turn. The available choices for `action` depend on the state of the debate. If a current speaker exists, the agent selects either `listen`, meaning that it continues listening to the current utterance, or `interrupt`, meaning that it intervenes immediately. If no current speaker exists, such as at the beginning of the debate or after a silent turn, the agent selects either `listen` or `speak`, the latter meaning that it starts a new utterance. The prompt also asks the agent to output a brief evaluation of the current-turn utterance as `thought` and then judge, as `urgency`, how necessary it is to speak immediately. In particular, the prompt instructs the agent to assign high urgency when it can correct a factual or logical error in the latest utterance, when few public utterance tokens remain, or when its current answer disagrees with the apparent majority in the debate history. By contrast, if the utterance may still be in progress and its continuation may resolve the concern, the agent is encouraged to choose `listen`, thereby suppressing unnecessary interruptions. To facilitate reproducibility, we make the implementation of the proposed framework publicly available at https://github.com/KimuraAkikazu/dynamicdebate. The repository includes the prompt templates used in the experiments, together with the main execution scripts, configuration files, and analysis scripts.

In the proposed framework, urgency is used as an operational coordination signal rather than as a calibrated probability of correctness. The score is used only for relative ranking among agents at a given turn to determine who should speak next. This design enables decentralized speaker selection without introducing an additional controller model or handcrafted interruption rules, while keeping the mechanism lightweight and reproducible. At the same time, the present study does not claim that self-reported urgency is perfectly calibrated across tasks or models. Its calibration should therefore be interpreted as a limitation of the current framework and as an important direction for future work.

2) Speaker selection for the next turn: The next speaker is determined on the basis of the action plans of all agents. Candidates are limited to the agents that selected `speak` or `interrupt` as `Action`, and the agent with the highest `urgency` is selected as the next speaker. If multiple agents tie for the highest urgency, one of them is chosen at random so as to avoid bias from a fixed ordering.

If no candidate exists, the next turn becomes a silent turn.

Algorithm 1: Action Plan Prompt

```
You are {name}. You are debating to arrive at the
    correct answer to the question. Based on the
    debate information, generate a response to the
    instructions.

## Question
{topic}
# Debate Context
## Debate rules
- The debate ends when the shared public token
    budget of {token_budget} tokens is exhausted.
    Only revealed text counts toward this budget.
- Remaining public tokens available to all agents:
    {tokens_left} / {token_budget}.
- Only one member can speak per turn. The next
    speaker is selected from the highest urgency
    level.
- Each turn, one chunk at a time from the speaker's
    generated statement is revealed to all members.
    The current speaker may have more statement
    prepared and not yet revealed.

## Initial answers before debate begins (subject to
    change)
{initial_answer}

## Debate history
{turn_log}

## Your memory
{previous_thoughts}

## Event of this turn
{last_event}

## State
- This is turn {turn}. Use the remaining public
    tokens efficiently to reach the correct answer.

# Actions
You can take the following actions:
- 'listen': Use this when you listen to the
    speaker's argument until the end to deepen your
    understanding before speaking.
- 'interrupt': Use this when you interrupt the
    current speaker to begin speaking.

# Instructions
1. Based on the debate so far and the utterance of
    this turn, briefly explain your current
    internal thoughts such as your perspective on
    the responses to the questions, your action
    plan for the remaining turns, your reaction.
2. Determine the urgency for you to start talking
    now. Raise urgency only when 1) you can
    immediately correct a factual or logical error
    in the latest statement, 2) tokens_left is low
    and essential information must be shared soon,
    or 3) your current answer disagrees with the
    apparent majority in the debate history.
    Otherwise keep urgency low and listen.
3. Refer to the provided information and your
    current thought, decide the next turn's action
    you should take as {name}.
- While considering the possibility that someone
    may be mid-sentence, decide whether to
    interrupt and respond immediately to this
    turn's statement or listen to its completion.
4. Select the purpose of the action you have chosen.
5. Based on the debate information, output the
    answer to the question that you currently
    support the most.
- If the anticipated continuation of statement may
    resolve your concern, choose listen.
```

In a silent turn, no utterance is produced, and all agents update their action plans for the following turn.

3) Utterance generation and sentence-by-sentence disclosure: The agent selected as the next speaker generates an utterance on the basis of the debate history and its own action plan. The generated utterance is segmented into sentences and stored in an internal queue. Sentence segmentation is performed using the SpaCy natural language processing library*. We adopt sentences rather than fixed-length token chunks because sentences preserve semantic units more naturally and are closer to the minimal unit of human conversational contribution. During the debate, only one sentence is disclosed from the queue in each turn. This design makes it easier for other agents to intervene in the immediately following turn, even when an incorrect premise appears at the beginning of an utterance.

The disclosed sentences are accumulated as debate history and are then used as input for subsequent action-plan generation and utterance generation.

Sentence segmentation was adopted because sentences preserve semantic units more naturally than fixed-size token chunks and provide a practical unit for potential interruption. In this study, segmentation is performed deterministically with SpaCy for English debate outputs. However, segmentation quality may affect interruption timing, especially when generated text contains ellipsis, coordination, or non-canonical punctuation. The reported results should therefore be interpreted as evidence for the proposed mechanism under this segmentation setting rather than as a claim of segmentation invariance.

4) Definition of interruption: We define an interruption as a speaker change that occurs while a current speaker still has undisclosed sentences remaining in its queue and another agent is selected as the next speaker. When an interruption occurs, the next speaker begins speaking immediately in direct response to the preceding utterance. At that point, the original speaker's undisclosed sentences are discarded. By allowing this type of interruption, the proposed framework makes it easier for correction to occur before an explanation based on an incorrect premise expands over multiple sentences.

D. Final Answer Extraction

At each turn, the number of tokens in the disclosed utterance is counted incrementally and recorded as the cumulative number of public utterance tokens. The debate ends when this cumulative count reaches a predefined threshold. At the turn in which the threshold is reached, the `Answer` fields contained in the agents' action plans are collected as final-answer candidates, and the majority answer is adopted as the final answer.

IV. Experimental Settings

As the number of agents and the length of the discussion increase in multi-agent debate, more reasoning and rebuttal become possible, but the computational cost and total token consumption also grow rapidly, making it difficult to secure a large experimental scale and to compare conditions fairly. If debates are allowed to continue indefinitely, evaluation

*https://spacy.io/

becomes difficult not only because of computational constraints but also because the amount of discussion can differ substantially across conditions. For this reason, existing studies commonly evaluate under settings with upper bounds on the number of utterances or the number of agents [1], [14]. Similarly, prior work on dynamic turn-taking [2], [12] imposes explicit limits on game progression or discussion length in order to make evaluation feasible.

Based on these considerations, we set the upper limit of the total public utterance token budget to 500, which allowed sufficient room for discussion to develop while keeping execution costs manageable.

Table III summarizes the debate settings used in this study.

TABLE III. DEBATE SETTINGS USED IN THE EXPERIMENTS

Item	Value
Total Public Utterance Token Budget	500 tokens
Number of agents	3

The experiments in this study are designed as a controlled mechanism study rather than as a broad generalization study. A single model and a single benchmark are used so that differences among conditions can be attributed as directly as possible to turn-taking control. Likewise, conditioned initial states are used to reproduce situations in which correct and incorrect answers coexist and to isolate how each framework responds to misinformation already present in the debate. The results therefore establish the effectiveness of the proposed design under the evaluated setting, while broader validation across models, domains, and agent counts is left for future work.

A. LLM

We used Meta's Llama-3.1-8B-Instruct quantized to 8-bit[†]. The model parameters used in the experiments are listed in Table IV.

TABLE IV. LLM PARAMETERS USED IN THE EXPERIMENTS

Model	Llama-3.1-8B-Instruct
Context length	15000 tokens
Maximum tokens	1024 tokens
Temperature	0.3

B. Tasks and Dataset

To evaluate the effectiveness of the proposed framework, we adopted Massive Multitask Language Understanding (MMLU), which consists of multiple-choice questions across diverse subjects centered mainly on high-school-level knowledge [15]. MMLU covers a wide range of domains, including STEM, the humanities, and the social sciences, and has been widely used as a benchmark for evaluating the general knowledge and reasoning abilities of language models [16], [17], [18].

To isolate the effect of debate control, all compared conditions started from the same initial answers.

[†]https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct

In addition, to examine whether the introduction of interruption and silence can suppress the propagation of misinformation, we conditioned the initial answers. Specifically, the discussion began from a state in which a particular agent already held misinformation, allowing us to evaluate how each condition was affected by misinformation propagation.

More concretely, for each question randomly sampled from MMLU, we generated answers five times with a single LLM and stored the answer and reason obtained in each run. We retained only those questions for which both correct and incorrect answers appeared at least twice among the five outputs. At debate start, three of the five stored (answer, reason) pairs were assigned to the three agents so as to realize the desired configurations (two incorrect and one correct, or one incorrect and two correct), and these were embedded into the prompt as the agents' initial answers. This procedure allowed us to align the initial state—that is, the initial answers and reasons of all agents—across conditions and evaluate only the difference in debate control.

C. Compared Conditions

Rather than reproducing individual prior methods exactly, we compared abstracted conditions that capture representative turn designs in the literature so that the effects of speaking order and disclosure granularity could be disentangled. Specifically, the fixed-order condition abstracts fixed-turn MAD [1], [10], whereas the dynamic-order condition abstracts methods with dynamic speaker selection [2], [12]. To isolate the effect of the proposed debate control with interruption and silence, we compared the following three conditions.

1) Fixed order: Speakers alternated in a predetermined order, and each utterance was disclosed as a full generated message.

2) Dynamic order: At each turn, non-speakers declared their desire to speak based on urgency, and the next speaker was selected accordingly. However, utterances were disclosed at the message level, and speaker changes did not occur until the current speaker had finished.

3) Proposed framework: In addition to urgency-based dynamic speaker selection, the framework introduced sentence-by-sentence disclosure, urgency-based interruption, and silent turns, as described in Section III.

D. Evaluation Metrics

In each condition, debates were conducted on 1,000 questions from the constructed dataset. As evaluation metrics, we used the intermediate answers output by each agent in its action plan at each turn, evaluated the change in accuracy over turns, and thereby assessed the susceptibility of each method to misinformation. We also evaluated the accuracy of the final answers at the end of the debate to determine whether the proposed framework could improve accuracy while suppressing the propagation of misinformation. For reproducibility, the implementation, major prompts, evaluation scripts, and execution settings are publicly available at https://github.com/KimuraAkikazu/dynamicdebate.

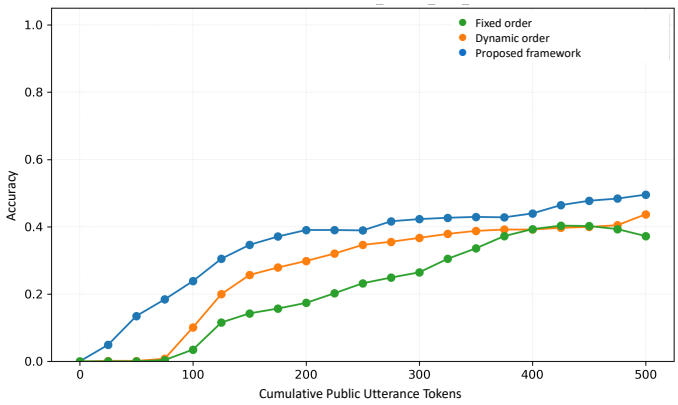

Fig. 1. Trajectory of intermediate-answer accuracy under each condition when two agents were initially incorrect.

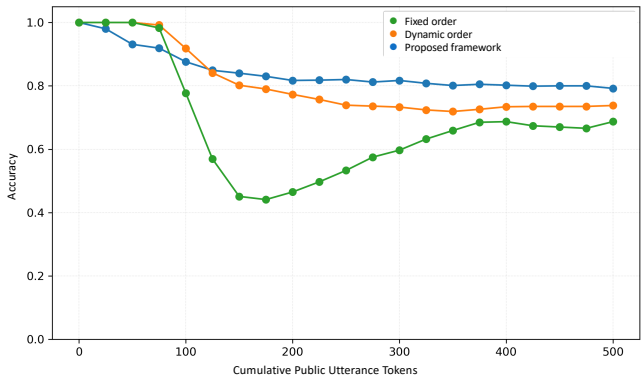

Fig. 2. Trajectory of intermediate-answer accuracy under each condition when one agent was initially incorrect.

V. Experimental Results

To examine the effectiveness of the proposed framework, we conducted evaluation experiments under the settings described in Section IV. In this section, we summarize the effects of the proposed framework from the viewpoints of final task accuracy, the trajectory of accuracy during the discussion, and answer changes caused by interruptions.

A. Accuracy

This subsection evaluates how the presence of agents holding misinformation affected debate accuracy. We compared final accuracy and the trajectory of intermediate answers under two settings that differed in the number of initially incorrect agents.

When two agents were initially incorrect, the proposed framework achieved 49.5%, which was 12.3 points higher than Fixed order (37.2%) and 5.8 points higher than Dynamic order (43.7%), as shown in Fig. 1 and Table V. Compared with Fixed order, the two dynamic conditions improved accuracy in the early stage of discussion and showed a more stable trajectory as the debate progressed. This early-stage gain was especially pronounced for the proposed framework.

TABLE V. Final Accuracy Under Each Condition

Condition	Accuracy
Fixed order	37.2%
Dynamic order	43.7%
Proposed framework	49.5%

These results indicate that the proposed framework is especially beneficial when the debate starts from an incorrect majority, suggesting that early interruption helps the correct side intervene before the incorrect majority becomes entrenched in the shared context.

When only one agent was initially incorrect, the proposed framework again achieved the highest accuracy at 79.2%, which was 10.5 points higher than Fixed order (68.7%) and 5.4 points higher than Dynamic order (73.8%), as shown in Fig. 2 and Table VI. In the two conditions without interruption, accuracy tended to drop sharply in the early stage. By contrast, in the proposed framework, the initial drop was comparatively suppressed and accuracy remained more stable as the debate progressed. In particular, under Fixed order, the incorrect agent was scheduled to speak first, causing a substantial initial drop in accuracy. Although some recovery was observed in the later stage, the final accuracy remained the lowest among the three conditions.

TABLE VI. Final Accuracy Under Each Condition When One Agent was Initially Incorrect

Condition	Accuracy
Fixed order	68.7%
Dynamic order	73.8%
Proposed framework	79.2%

In the one-incorrect-two-correct setting, the main advantage of the proposed framework is not only correction of the initially incorrect agent but also preservation of the correct agents from being pulled toward the wrong answer in the early stage of the debate.

B. Trajectory of Intermediate Answers by Agent

To examine how other agents' utterances influenced the answers of each agent, we collected the trajectories of intermediate answers for each method. In the legends of the graphs, Alex, Chris, and Jenny denote the three agents in the debate. The agent(s) holding the correct initial answer were Jenny in the two-incorrect-one-correct setting and Chris and Jenny in the one-incorrect-two-correct setting. In the Dynamic order condition, the next speaker was selected based on urgency, whereas in the Fixed order condition speaking rights alternated in the order Alex, Chris, and Jenny.

Fig. 3–5 show the trajectories of agent-wise intermediate-answer accuracy in the two-incorrect-one-correct setting. Under Fixed order (Fig. 3), the accuracy of the initially incorrect

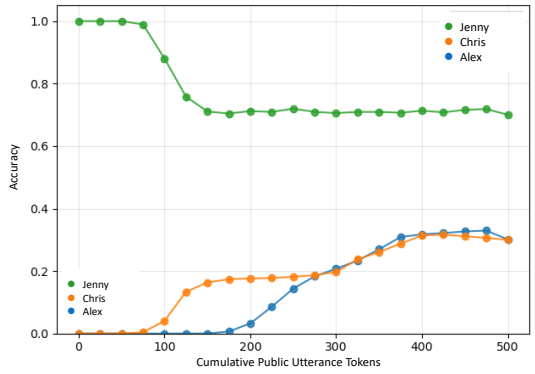

Fig. 3. Trajectory of intermediate-answer accuracy for each agent under Fixed order when two agents were initially incorrect.

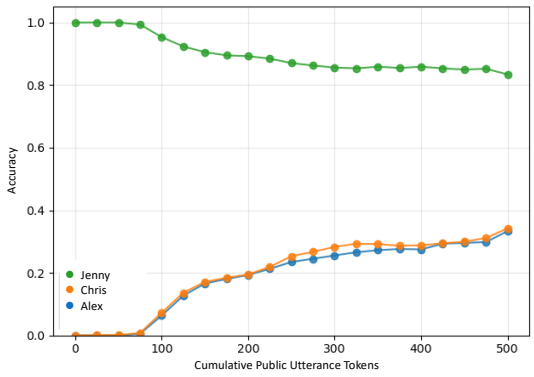

Fig. 4. Trajectory of intermediate-answer accuracy for each agent under Dynamic order when two agents were initially incorrect.

agents Alex and Chris remained close to 0 until the middle stage of the debate (around 200 tokens) and rose only to about 0.3 by the end. In contrast, the initially correct agent Jenny dropped sharply from 1.0 to around 0.7 in the early stage (around 100–150 tokens) and did not recover substantially thereafter. This suggests that the incorrect agents spoke early, formed the shared context, and made the correct agent more vulnerable to the influence of incorrect premises. Under Dynamic order (Fig. 4), Jenny remained around 0.85 while declining only gradually, indicating that the correct side was less likely to be dragged toward the incorrect side than under Fixed order. However, the improvement of Alex and Chris started only after about 100 tokens and plateaued around 0.3, making it difficult for the majority to flip from incorrect to correct. Under the proposed framework (Fig. 5), Jenny stayed at about the same high level as in Dynamic order, while Alex and Chris began improving earlier and reached about 0.4 by the end. The earlier correction of the incorrect side contributed to the higher majority-vote accuracy shown in Table V.

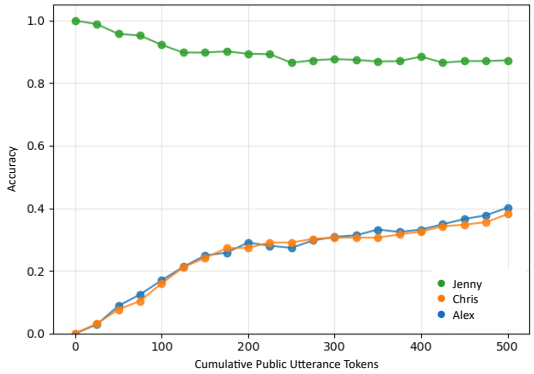

Fig. 5. Trajectory of intermediate-answer accuracy for each agent under the proposed framework when two agents were initially incorrect.

Fig. 6–8 show the corresponding trajectories in the one-incorrect-two-correct setting. Under Fixed order (Fig. 6), the early utterances of the incorrect agent Alex caused the accuracies of the correct agents Chris and Jenny to drop sharply from 1.0 to around 0.6 near 100–200 tokens. Although they later recovered, this early drop lowered the majority-vote accuracy (Table VI). Under Dynamic order (Fig. 7), the decline of Chris and Jenny was more gradual and converged around 0.8, avoiding the sharp deterioration observed under Fixed order. At the same time, Alex also improved from around 100 tokens onward and reached about 0.4 by the end. Under the proposed framework (Fig. 8), Chris and Jenny remained around 0.86–0.9 throughout the debate, while Alex improved step by step from the early stage and also reached about 0.4. In other words, the proposed framework maximized final accuracy by minimizing the correct side's being pulled toward incorrect answers while also accelerating the correction of the incorrect side.

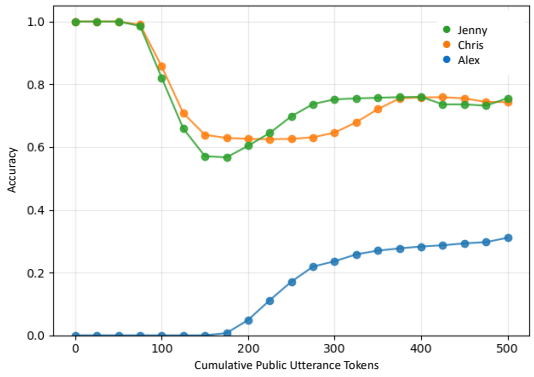

Fig. 6. Trajectory of intermediate-answer accuracy for each agent under Fixed order when one agent was initially incorrect.

VI. Analysis and Discussion

This section analyzes why the proposed framework improved accuracy from the perspective of the debate process, based on the results in Section V.

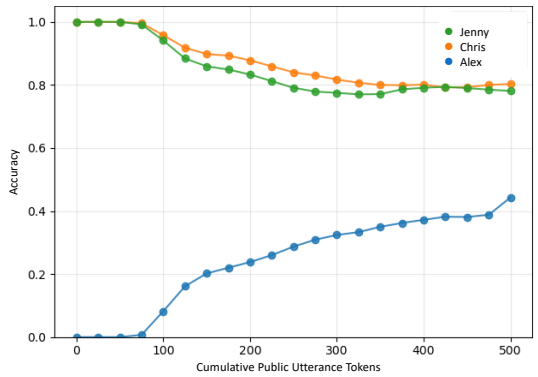

Fig. 7. Trajectory of intermediate-answer accuracy for each agent under Dynamic order when one agent was initially incorrect.

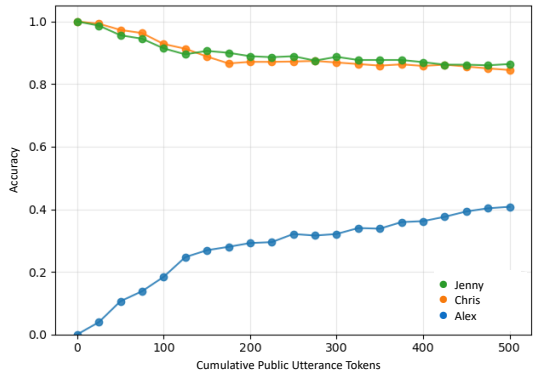

Fig. 8. Trajectory of intermediate-answer accuracy for each agent under the proposed framework when one agent was initially incorrect.

A. Improvement in Final Accuracy

As shown in Table V, in the two-incorrect-one-correct setting the proposed framework achieved a final accuracy of 49.5%, outperforming Fixed order (37.2%) and Dynamic order (43.7%). As shown in Table VI, the proposed framework also achieved 79.2% in the one-incorrect-two-correct setting, outperforming Fixed order (68.7%) and Dynamic order (73.8%).

The two-incorrect-one-correct setting starts with an incorrect majority. When incorrect premises are shared under such a setting, the majority error is likely to be reinforced during the debate. The fact that the proposed method improved accuracy in this setting suggests that it promoted correction on the incorrect side and guided the debate toward flipping the majority from incorrect to correct.

Fig. 1 shows that, under the proposed framework, majority-vote accuracy increased from the early stage of the debate and then remained at a comparatively high level. In contrast, in the one-incorrect-two-correct setting, Fixed order and Dynamic order both exhibited an early drop in accuracy, whereas the proposed framework suppressed that drop (Fig. 2). These results suggest that sentence-by-sentence disclosure and urgency-based interruption allowed intervention and repair to begin before an incorrect claim expanded into a long utterance, thereby suppressing the spread of misinformation while accelerating updates on the incorrect side.

B. Effects of Interruptions and Completion

To further explain why the proposed framework improved accuracy, this subsection compares the effects of 1) interruptions and 2) completion of an utterance on updates to the intermediate answers of the other agents. Here, *completion* refers to the case in which a speaker finishes disclosing the entire utterance (sentence queue) without being interrupted.

1) Evaluation units and scope: An interruption event is defined as the case in which one speaker still has undisclosed sentences remaining in the queue and another agent is selected as the next speaker (Section III). A completion event is defined as the case in which the speaker fully discloses the generated sentence queue and the utterance ends without interruption. In Fixed order and Dynamic order, interruptions do not occur, so every speaking turn is counted as a completion event. In the proposed framework, by contrast, interruptions can occur, so completion events are a subset of the speaking turns that finish without interruption.

For each event, we compared the `Answer` of each agent immediately before the event (just before the speaker change) with the `Answer` after the event (at the time the interrupter finished speaking, in the case of interruption, or when the utterance finished, in the case of completion). The resulting changes in the listeners' `Answer` values were classified into three categories. Because this subsection evaluates the effect of intervention when correct and incorrect answers coexist, cases in which all agents were correct or all agents were incorrect immediately before the event were excluded from the analysis.

The three categories are defined as follows, where s denotes the speaker of the event (either the interrupter or the speaker whose utterance completed) and L denotes the listeners (all agents other than s).

- **Improved**: The speaker s was on the correct side, and at least one listener in L changed from incorrect to correct.
- **Worsened**: The speaker s was on the incorrect side, and at least one listener in L changed from correct to incorrect.
- **Unchanged**: Neither of the above occurred.

For clarity, the percentages reported below are event-level proportions computed over all evaluated events under the stated condition. This event-level view complements final-answer accuracy by showing whether a turn type tends to repair or spread misinformation during the debate process.

2) Effects of interruptions: Under the proposed framework, interruptions yielded an improvement rate of 15.2% and a worsening rate of 7.1% in the two-incorrect-one-correct setting, so improvement exceeded deterioration (Table VII). In the one-incorrect-two-correct setting, the corresponding values were 12.2% and 5.2%, showing the same tendency (Table VIII). Because the worsening rate was lower than the improvement rate in both settings, interruptions can be interpreted as contributing, on average, to suppressing misinformation propagation and advancing repair earlier. The

percentages of improved, worsened, and unchanged reported in this subsection were calculated with all evaluated events as the denominator.

TABLE VII. EFFECTS OF INTERRUPTIONS IN THE PROPOSED FRAMEWORK (TWO INCORRECT, ONE CORRECT)

Metric	Value
Evaluated events	533
Improved	15.2%
Worsened	7.1%
Unchanged	77.7%

TABLE VIII. EFFECTS OF INTERRUPTIONS IN THE PROPOSED FRAMEWORK (ONE INCORRECT, TWO CORRECT)

Metric	Value
Evaluated events	1308
Improved	12.2%
Worsened	5.2%
Unchanged	82.6%

Taken together, Tables VII and VIII indicate that interruption functions more often as an early repair mechanism than as a source of instability under the evaluated setting.

3) Effects of completion: Next, we compared the updates observed immediately after completion events across conditions. In the two-incorrect-one-correct setting, the proposed framework achieved an improvement rate of 14.3% and a worsening rate of 6.5%, again indicating that improvement exceeded deterioration (Table IX). Dynamic order showed a higher improvement rate of 18.1%, but its worsening rate was also high at 11.3%, leaving a smaller net advantage. Under Fixed order, the worsening rate exceeded the improvement rate, resulting in a net negative effect. In the one-incorrect-two-correct setting as well, the proposed framework showed an improvement rate of 10.5% and a worsening rate of 3.7%, indicating a tendency to accumulate improvements while suppressing deterioration (Table X). In the proposed framework, only speaking turns that finished without interruption were counted as completion events.

TABLE IX. COMPARISON OF COMPLETION EFFECTS ACROSS CONDITIONS (COMPLETION WITHOUT INTERRUPTION) IN THE TWO-INCORRECT-ONE-CORRECT SETTING

Condition	Improved	Worsened
Proposed framework	14.3%	6.5%
Dynamic order	18.1%	11.3%
Fixed order	13.6%	18.5%

TABLE X. COMPARISON OF COMPLETION EFFECTS ACROSS CONDITIONS (COMPLETION WITHOUT INTERRUPTION) IN THE ONE-INCORRECT-TWO-CORRECT SETTING

Condition	Improved	Worsened
Proposed framework	10.5%	3.7%
Dynamic order	17.6%	9.2%
Fixed order	13.6%	13.0%

These completion results suggest that the proposed framework does not merely increase the frequency of intervention. Rather, it maintains a more favorable balance between improvement and deterioration even when an utterance is allowed to finish, which is consistent with more stable information sharing than the other two conditions.

4) When interruptions are effective: To analyze at what points in the debate interruptions were effective, we computed the success rates of improvement and deterioration as a function of the cumulative number of public utterance tokens at the time the interruption occurred. Because interruption effects were more clearly visible in the two-incorrect-one-correct setting, we report this analysis for that setting.

Specifically, we binned the cumulative number of public utterance tokens at the time of interruption in increments of 50 tokens and computed the following two conditional probabilities for each bin. Here, *improve_success_rate* is the proportion of interruptions that led to improvement, conditioned on the interrupter being on the correct side, whereas *worsen_success_rate* is the proportion that led to deterioration, conditioned on the interrupter being on the incorrect side.

$$\text{improve_success_rate} = \frac{I_{succ}}{I_{succ} + I_{fail}} \tag{1}$$

$$\text{worsen_success_rate} = \frac{W_{succ}}{W_{succ} + W_{fail}} \tag{2}$$

Here, I_{succ} denotes the number of cases in which, after an interruption by a correct-side speaker, at least one listener changed from incorrect to correct, and I_{fail} denotes the number of cases in which no such update occurred. Similarly, W_{succ} denotes the number of cases in which, after an interruption by an incorrect-side speaker, at least one listener changed from correct to incorrect, and W_{fail} denotes the number of cases in which no such update occurred.

As shown in Fig. 9, the improve_success_rate was relatively high in the early stage, around 50–199 tokens, and exceeded the worsen_success_rate in many bins. This can be interpreted as indicating that, while the shared context is still short, an interruption can initiate repair immediately after an incorrect premise appears and is therefore more likely to suppress the following spread of misinformation. By contrast, around 300–349 tokens, the worsen_success_rate exceeded the improve_success_rate, suggesting that in the later stage of the debate, interruptions made when few public utterance tokens remain may destabilize consensus formation. This tendency indicates that the effectiveness of interruptions should be controlled according to the stage of the discussion.

C. Limitations

This study has several limitations. First, the evaluation uses a single base model (Llama-3.1-8B-Instruct) and a single benchmark (MMLU), so the results should not be interpreted as evidence of universal effectiveness across models or domains. Second, the experiments fix the number of agents to three and constrain discussion by a 500-token shared public budget; different agent counts or budget regimes may yield different interruption dynamics. Third, urgency is produced by the LLM itself and used as a relative coordination signal, but its calibration is not externally validated in the present study. Fourth, sentence segmentation is performed with SpaCy, and

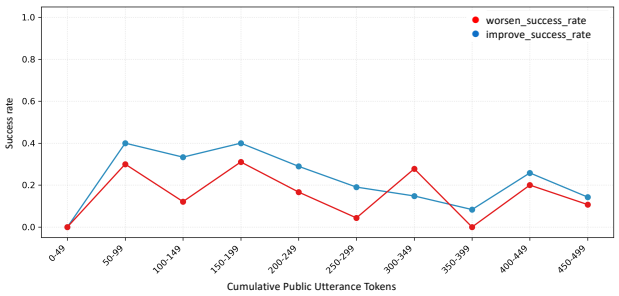

Fig. 9. Improvement and deterioration success rates of interruptions in the proposed framework (50-token bins, two incorrect and one correct).

the robustness of the framework to segmentation errors or alternative segmentation policies is not evaluated. Finally, the initial states are intentionally conditioned to include both correct and incorrect answers so that misinformation propagation can be examined under controlled conditions. This design improves internal comparability across conditions, but it does not fully represent all naturally occurring debate setups.

D. Future Work

Several directions follow from these limitations. First, broader validation is needed across additional LLMs, domain-specific benchmarks, and tasks whose reasoning unfolds differently from multiple-choice question answering. Second, the urgency signal should be calibrated more explicitly, for example by comparing self-reported urgency with externally detected factual conflicts, confidence estimates, or agreement patterns among agents. Third, the framework should be evaluated under larger agent populations and different public-token budgets to clarify how interruption frequency, silence, and consensus stability scale with group size. Fourth, alternative disclosure units and segmentation strategies, including clause-level, discourse-based, or adaptive chunking schemes, should be compared to determine when sentence-level disclosure is most effective. Fifth, because the framework updates action plans at fine granularity, future work should quantify trade-offs among accuracy, generated tokens, number of model calls, and execution time.

In addition, previous studies have reported that assigning personality traits to agents may improve answer accuracy in collaborative tasks and diversify debate [19], [11]. Future work should examine how overall debate accuracy changes when such personality assignments are combined with the interruption- and silence-aware turn-taking control proposed in this study. In particular, it will be important to analyze how differences in personality traits affect the frequency of interruptions and silence, the timing of error correction, and the tendency for unnecessary interruptions to occur. Such analysis may also help realize flexible dialogue in which opinions are presented at effective moments through interruption and silence when the framework is extended to human–LLM discussions.

VII. Conclusion

This study presented an interruptible multi-agent debate framework that combines sentence-level disclosure, urgency-based speaker selection, interruption, and silent turns under a shared public-token budget. The central goal was to reduce the spread of incorrect premises by allowing listeners to intervene before a misleading message expands into a long explanation. Under the evaluated setting, the proposed framework achieved the highest final accuracy among the compared conditions in both the two-incorrect-one-correct and one-incorrect-two-correct settings. Analysis of intermediate answers and event-level updates further suggested that interruption more often supported correction than deterioration. These findings indicate that finer-grained turn control can improve debate stability when correct and incorrect answers coexist. At the same time, the present results are bounded by the evaluated model, benchmark, agent count, and segmentation setting. Broader validation and improved urgency calibration remain important next steps.

***Abstract*—User authentication is the crucial component in ensuring that digital identities are securely authenticated when performing sensitive digital transactions. Building resilience against emerging cyber threats like identity theft and Man-in-the-Middle (MITM) attacks remains an ongoing challenge. Identity-Based Encryption (IBE) is a cryptographic method in the category of public key cryptography that allows the use of unique identifiers, such as email addresses, as public keys for encryption, making key management easier than traditional public key cryptography. This study presents a comprehensive overview of secure authentication techniques using IBE schemes proposed by researchers, emphasizing techniques that have been explored and introduced. The review examines current IBE schemes, including blockchain-based techniques, and analyzes the security features, application domains, implementation requirements, and challenges. By incorporating findings from previous works, this study identifies common challenges that impede real-world implementation and suggests a potential approach for combining alternative security methods to improve authentication robustness. The purpose of this work is to provide researchers and practitioners with a comprehensive review of secure authentication models, as well as practical insights to assist in developing an implementable authentication solution for real-world secure digital transactions.**

***Keywords*—User authentication; Identity-Based Encryption (IBE); digital identity; network security**

I. Introduction

The rapid growth of digital services has made secure user authentication a fundamental and crucial requirement for any digital transaction provided by service providers, whether private or Government agencies. Many domains, such as finance, healthcare and the Internet of Things (IoT), have increasingly relied on digital identities to enable access to sensitive services and data. Consequently, the authentication process has become a critical security control, as failures in identity verification can result in severe consequences such as identity theft, unauthorized access, privacy breaches, and financial losses.

Identity authentication methods have gone through evolution since they were introduced, that is, Single-Factor Authentication (SFA), Two-Factor Authentication (2FA) and Multi-Factor Authentication (MFA) [1]. All these authentication methods can be combined with additional factors to further strengthen the security level of user identity information, such as security tokens, user biometric information, cryptographic or encryption methods, secure environment, and many others.

An identity-based cryptographic method, called Identity-Based Encryption (IBE), was introduced by [2]. It is an extension of the Public Key Encryption (PKE) method, where the user's public key is some special information about the user, for example, the user's email address. This means that a sender who has access to the system's public parameters can use the text value of the recipient's name or email address as a key to encrypt the message they want to send. This approach simplifies key management and reduces the need for Public Key Infrastructure (PKI).

However, the IBE method can only provide examples of identity-based signatures. Hence, in order to address the problems encountered, various improved IBE methods have been introduced by researchers from time to time. In 2001, Dan Boneh and Matthew K. Franklin helped to solve the IBE issue by introducing a pair-based cryptography named the Boneh–Franklin scheme [3] and [4] has introduced an encryption method based on the quadratic residue, that is, the message is encrypted one bit at a time, but suffers from inefficiency due to the high expansion of the ciphertext. The IBE method by [5] uses bilinear coupling, which provides a different approach to IBE.

Although the IBE method has been improved, it faces a limited usage issue due to the absolute trust that is essential to the Private Key Generator (PKG) [6] and [7]. The PKG can generate any user's private key and potentially decrypt (or sign) messages without permission, and this is a weakness of the IBE method [8]. Therefore, various alternative systems and continuous studies are needed to reduce the level of trust required in PKG [9]. Certificate-based encryption, secure key production cryptography, and certificateless cryptography [10] are among the alternative systems that have been developed to release the PKG component.

The evolution of the IBE has reflected significant advances in cryptographic practice aimed at improving security, efficiency, and usability. Accordingly, ongoing research is expected to help strengthen the level of security and reliability of cryptographic systems against emerging cyber threats. Thus, this study aims to conduct a comprehensive analysis of the IBE schemes currently in use that are efficient and effective. By

knowing the most practical and secure IBE schemes, this study will provide potential possible combinations of technologies in further enhancing the user identification and securing user's personal information security and privacy in performing digital services. This study also aims to provide future research on developing an ideal and general model of user authentication that can be adopted by any field, with the ability to mitigate possible security risk and be one of the factors to increase users' confidence and trust to use digital services.

A. Motivation

The main purpose of this study is to examine the current method used for the user identity authentication process using the IBE scheme, as well as emerging technologies that is suitable for adaptation to increase the level of security and privacy of the user's personal data. The primary motivation of this study is as follows:

- Examine the IBE scheme that is effective and secure for user identity authentication.
- Assess the advantages, limitations, or challenges of all IBE schemes currently used.
- Identify opportunities for enhancement and innovation in user identity authentication.
- Minimize cybersecurity risks related to user identity authentication, such as Man-in-the-Middle (MITM), identity theft, and phishing.
- Gain knowledge on issues related to user identity authentication.

B. Contributions

There are several contributions from this review study that may help other researchers on user authentication methods and cybersecurity issues by addressing significant barriers, synthesizing knowledge, and investigating potential future works or innovations related to IBE.

Besides, this study will provide useful direction for researchers, programmers, as well as organizations intending to deploy or enhance the security level of user authentication methods in their applications.

The contributions include the following:

- Provide a comprehensive analysis of the current landscape of user authentication methods, highlighting their key application fields, key advantages and critical security challenges.
- Discusses significant challenges in user authentication techniques and proposes feasible and relevant perspectives for improvement.
- Provide significant insights on user authentication model applicable across various fields.
- Provide ongoing efforts to further improve the resilience and robustness of user authentication methods by highlighting areas that require further research especially related to security issues.

C. Research Questions

In achieving the objectives of this study, four (4) research questions have been identified with its rationale and are detailed as follows:

- RQ1: What fields of study use the IBE scheme?
- RQ2: What is the problem statement of the previous research IBE scheme?
- RQ3: What are the limitations or weaknesses faced in using the IBE scheme?
- RQ4: What are the new technologies or trends in the IBE authentication field?

The research questions are determined to explore the current user authentication model using the IBE scheme. This study will investigate and discuss all questions outlined in detail.

D. Research Objectives

Based on the research questions, information on common themes of fields, problems, limitations and new technologies will be identified. The research questions are also used to achieve the following research objectives:

- RO1: to explore application fields which used IBE as an authentication method done by previous researchers.
- RO2: to understand problems addressed or issues faced by previous researchers on the IBE authentication method.
- RO3: to recognize limitations or weaknesses faced by the current IBE scheme proposed or tested.
- RO4: to explore new technologies or models that can further enhance the scheme.

E. Paper Organization

The organization of this study is designed to address all the research questions and research objectives outlined.

The study structures are as follows:

- Section II presents and analyzes related previous works.
- Section III details the research methodology used, including the search strategy and the inclusion and exclusion criteria.
- Section IV reviews the implementation of IBE scheme in various fields.
- Section V presents issues and challenges faced in IBE scheme.
- Section VI details out the limitations in IBE scheme.
- Section VII provides information on future perspectives and enhancements.
- Section VIII discusses issues related to IBE scheme and ways to overcome.
- Section IX concludes and summarizes the analysis and findings of the study based on the research objectives.

List of abbreviations used in this study is listed in Table I below:

TABLE I. LIST OF ABBREVIATIONS

Acronym	Definition
2FA	Two-Factor Authentication
BC-IBE	Backward Compatible Identity-Based Encryption
CA	Central Authority
DKER	Decryption Key Exposure Resistance
DRIBE	Delegated Revocable Identity-Based Encryption
GDPR	General Data Protection Regulation
IBE	Identity-Based Encryption
IoT	Internet of Things
KGC	Key Generation Center
LWE	Learning with Errors
MFA	Multi-Factor Authentication
MITM	Man-in-the-Middle
MPTCP	Multi-Path TCP
PKE	Public Key Encryption
PKG	Private Key Generator
PKI	Public Key Infrastructure
RIBE	Revocable Identity-Based Encryption
RHIBE	Revocable Hierarchical Identity-Based Encryption
SFA	Single-Factor Authentication

II. RELATED WORKS

Numerous relevant studies have been carried out to examine, analyze and evaluate different user authentication models. A study on the trust issue faced in Identity-Based Encryption conducted by [8] has highlighted the need for a more secure and deployable privacy solution by reducing the probability of privacy breaches to an arbitrarily small value. Based on a study conducted by [11] on numerous IBE schemes, the main problem that exists in the IBE scheme, which is escrow, has been identified, and suggested that dependency on PKG needs to be overcome to address the issue of trust in third parties, since it will indirectly affect the privacy of communication between users.

The Revocable Hierarchical Identity-Based Encryption (RHIBE) scheme introduced and discussed by [12] focuses on adaptively secure construction methods to address the weaknesses in previous methods that can only achieve selective security, rather than adaptive security. Similarly, since revocation functionality is crucial in cryptographic systems and existing RIBE schemes require long public parameters or composite-order groups, [13] has presented study on an efficient Revocable Identity-Based Encryption (RIBE) scheme. Furthermore, the need for a secure Identity-Based Encryption scheme with perfect forward secrecy for network security protocols to address classic IBE which lacks the perfect forward secrecy have been discussed by [14].

In protecting the privacy of data in Internet of Things (IoT) applications, [15] has proposed an effective and useful IBE method with a Revocable IBE (RIBE) feature where the Private Key Generator (PKG) can cancel the user's account if the private key has been exposed. While issues on compatibility requirements due to existing systems will lose access to previous ciphertexts after the key update process has been discussed in detail by [16]. The study in [17]'s paper has addressed the efficient key revocation in RIBE schemes by exploring delegating update key generation to a cloud server due to inefficiencies with the update key sizes issue faced in previous schemes.

Additionally, a study conducted by [18] has discussed the issue of privacy in smart contracts and the challenges of implementing smart contracts that preserve privacy, because it was found that transaction details are openly disclosed in traditional smart contracts. Therefore, researchers introduce a smart contract privacy protection mechanism and develop a new blockchain model to preserve smart contract privacy.

As a result of the study carried out by [19], there are various challenges related to digital identity management in the context of Web 3.0, especially in the need to obtain a more private, secure and manageable Internet experience. Issues of difficulty in ensuring interoperability between various platforms and privacy rules in a decentralized environment are also discussed.

In addition, researchers also found that the most important and main problem is the transition from a traditional identity system to a self-sovereign identity system that allows users to manage the sharing of their personal information independently without involving a Central Authority (CA) in increasing the level of user control and security [19].

Comparison of the authentication scheme features is detailed in Table II. A summary of previous works is described in Table III. Fig. 1 illustrates the Identity-Based Encryption (IBE) architecture.

IBE provides more secure and enhanced security features compared to traditional authentication models. But IBE has its own limitations and advantages as well. The main limitations of IBE are inherent weaknesses and issues such as reliance on PKG which requires centralized trust, and if compromised, it will lead to a single point of failure issue. In addition, the key revocation difficulty issue in the basic IBE scheme also causes compromised key revocation to affect the implementation of IBE in dynamic user environments. Although IBE has some limitations, it has many advantages and has been widely used in many fields such as banking, IoT and healthcare.

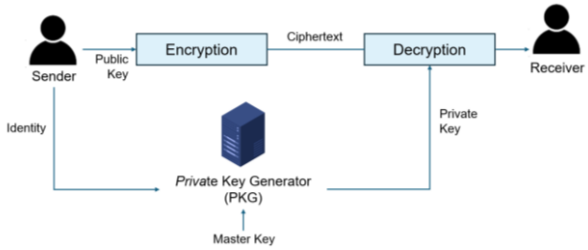

Fig. 1. IBE architecture.

TABLE II. COMPARISON OF AUTHENTICATION SCHEMES

Authentication Scheme	Security Focus	Threats Addressed	Technologies Integrated	Real-World Applicability
Single-Factor Authentication (SFA)	Basic identity verification using a single factor (knowledge, possession or inherence).	Weak passwords, phishing, credential stuffing, brute-force attacks.	Passwords, PINs, swipe cards, biometric fingerprints or facial recognition.	Personal or computer devices (password of the smartphone, computer, laptop), email logins.
Two-Factor Authentication (2FA)	Requires two different authentication factors to strengthen security. Typically using one knowledge factor and one possession or inherence factor.	Phishing, password guessing, credential stuffing.	Combination of password and OTP (One Time Password via SMS / mobile applications), hardware tokens, combination of password and biometric information.	Online banking, email, corporate VPNs, social media accounts.
Multi-Factor Authentication (MFA)	Requires two or more different authentication factors to create multiple layers of defense and enhanced security level.	Stolen credentials, phishing, brute force, Man-in-the-Middle (MITM) attacks, replay attacks, account takeovers.	Passwords, biometrics information (fingerprint, facial recognition), hardware keys (USB/NFC), push notifications.	Industry standard to secure sensitive accounts in fields of healthcare, IoT, government systems, financial services, enterprise environments.
Identity-Based Encryption (IBE)	Cryptographic authentication method using identity-linked encryption keys rather than static passwords.	Impersonation, unauthorized data access, interception, Man-in-the-Middle (MITM) attacks via cryptographic means.	Public Key Infrastructure (PKI) (public keys are derived from user identities), secure key management, encryption algorithms.	Secure messaging, email encryption, IoT environments and applications requiring encrypted communications linked to identity.

TABLE III. SUMMARY OF PREVIOUS RESEARCH

Paper	Issue Discussed	Contribution
[8]	Overcoming trust issue in IBE scheme	Review a privacy scheme without non-collusion assumptions to allow users to reduce private key exposure probability by employing multiple intermediate CAs for enhanced privacy and the scheme separates the PKG from the intermediate CAs.
[11]	Comprehensive study and analysis on numerous IBE schemes	Provides detailed information on numerous IBE schemes with its advantages, disadvantages and potential attacks.
[12]	Adaptive security of IBE scheme	Provides proof on adaptive security under simple static assumptions and addresses challenges of dual system encryption in Revocable Hierarchical Identity-Based Encryption (RHIBE) through security proof.
[13]	Revocation requirements in IBE scheme	Proposes a Revocable Identity-Based Encryption (RIBE) scheme that achieves adaptive security, Decryption Key Exposure Resistance (DKER), and constant-size public parameters over prime-order bilinear groups by employing the Seo-Emura technique, which combines specific IBE schemes to enhance security and efficiency.
[14]	Importance of perfect forward secrecy	Provide details of Learning with Errors (LWE) problem based on Quantum Identity-Based Encryption (QIBE) scheme and its advantages.
[15]	Importance of secure communication in Internet of Things (IoT) applications	Proposes an efficient RIBE scheme for IoT applications with its detail algorithms and utilizes ISO/IEC 18033-5 SM9 encryption for security.
[16]	Compatibility requirements in IBE scheme	Introduction of Backward Compatible Identity-Based Encryption (BC-IBE) to solve backward compatibility problems in IBE systems and supports revocation of expired private keys.
[17]	Exploring delegation of update key generation	Introduces the concept of RIBE that can be delegated (Delegated Revocable Identity-Based Encryption (DRIBE)) where the process of delegation of update key generation to the cloud server will be implemented.
[18]	Preserving privacy in smart contracts	Introduce privacy-protection mechanisms for smart contracts and develop a new blockchain model for privacy-preserving smart contracts. Details comparison of computation and storage overheads with existing schemes are also provided.
[19]	Challenges related to digital identity management	Provide information on digital identity evolution and how users or organizations use digital identities to control their online appearance inside the Web 3.0 architecture.
This paper	User authentication using IBE scheme in secure and privacy-protected environment	This paper provides comprehensive reviews on various IBE schemes across different fields and functions. Findings from trustworthy databases are combined and classified, offering distinct points of view based on deployment fields, issues, challenges and integration of evolving technologies in proposing future and further research areas. This will aid in identifying important gaps and offer a roadmap for the enhanced and advancement of user authentication methods that are deployable in various fields.

The advantage of IBE is that it does not require distribution of public keys, as they will be derived from known identities hence a separate PKI is not required. This will simplify and increase the efficiency of key management and reduce overhead. IBE is also flexible as it uses any unique string such as email or username as the public key which allows embedding additional information in the identity to dynamically control the validity of the key. And it is also scalable as the entire system uses a single master key pair maintained by the PKG which makes key generation and distribution more efficient for many users.

In the banking sector, IBE provides secure and scalable financial transactions where it can protect sensitive banking transactions by directly encrypting data with user identities (such as account numbers or emails) without the use of complex PKI, thus reducing the risk of MITM attacks. Additionally, the combination of IBE with digital ID authentication can enhance user authentication and data privacy by securely binding identity data to a cryptographic key.

For the Internet of Things (IoT) sector, IBE provides simplification of cryptographic key management in resource-

constrained devices by eliminating cumbersome PKI setup and it also supports scalable and flexible key distribution in dynamic IoT networks. Device ID with embedded identity also provides easy authentication and encryption. In terms of communication and storage, it supports secure cloud communication and storage suitable for IoT environments.

While for the healthcare sector, IBE allows secure exchange of confidential information associated with patient or provider identities without the need for complex PKIs and simplifies key management for multiple healthcare systems and practitioners. Besides, it also ensures secure cloud data transmission and medical record storage.

In conclusion, IBE provides more cost-effective security management compared to traditional PKI by reducing management overhead and making enterprise-level encryption scalable and affordable. IBE also provides flexible encryption that is directly linked to user identities and simplified key management. This is highly beneficial for sectors like banking, IoT and healthcare that require secure and scalable communications. However, the security risks associated with key escrow and reliance on a single trusted authority need to be addressed properly.

III. Research Methodology

The methods and strategies applied in this study are explained in this section. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) protocol [20] is the methodology adopted for this work.

A. Search Strategy

The established digital library databases that have been identified to be used for obtaining related articles are Web of Science, IEEE Xplore, Scopus and Wiley. The publication papers are the recent papers, from 2020 to 2025. Keywords that were used in the searching process are "user authentication" or "user authentication model" or "Identity Based Encryption (IBE)" or "IBE".

These keywords were searched either in the title or abstract using Boolean operators like "AND" and "OR" together with parenthesis. The key string used in the searching process is: ("User Authentication" AND "IBE"), ("User Authentication Model" AND "IBE"), ("User Authentication" AND ("Identity-Based Encryption (IBE)" OR "Identity-Based Encryption") and ("User Authentication Model" AND ("Identity-Based Encryption (IBE)" OR "Identity-Based Encryption")).

In total, 414 papers were discovered from these four databases and after assessing the papers, 124 duplicates or unrelated papers were eliminated.

B. Inclusion and Exclusion Criteria for Selection

Details of the inclusion and exclusion criteria are described in Table IV.

TABLE IV. Inclusion and Exclusion Criteria

Inclusion Criteria	
IC1	Papers that were published between 2020 and 2025
IC2	Papers that are accessible and downloadable
IC3	Paper related on user authentication models using IBE scheme
IC4	Papers that provide design, scheme, or implementation of IBE in the user authentication model
IC5	Papers that are using English language
Exclusion Criteria	
EC1	Papers that are not related to the work and research question or objectives of this work
EC2	Papers that are not accessible as full text
EC3	Papers discussing user authentication method that are other than IBE scheme
EC4	Papers which studies do not include design, scheme, or implementation of IBE in the user authentication model
EC5	Papers using other than English language.

The selection and filtering process using the PRISMA methodology is illustrated in Fig. 2.

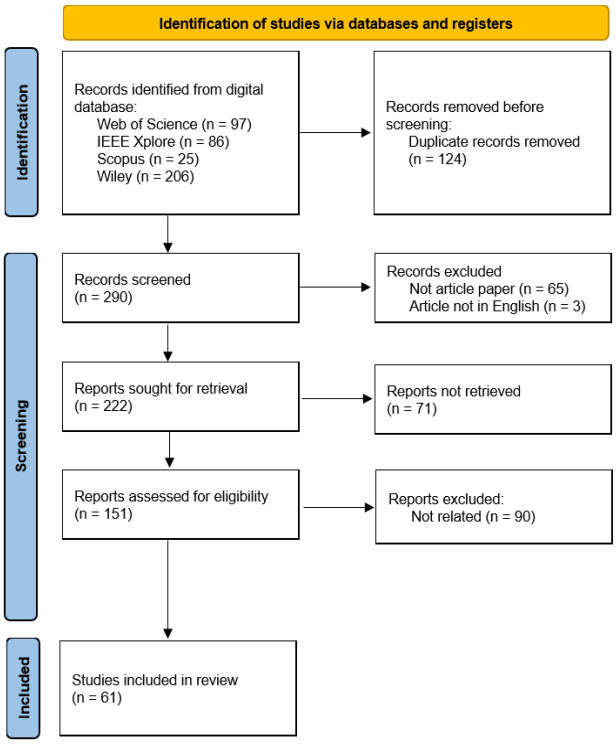

Fig. 2. PRISMA methodology flow diagram.

Based on the PRISMA statement, 61 papers have been identified and will be thoroughly reviewed and scrutinized in order to determine the current state of the user authentication method.

IV. Implementation of Identity-Based Encryption (IBE) in Various Fields

Based on the papers reviewed, various fields of studies have been identified. This section categorizes fields of study into three main fields: Security and Information Sharing, Internet of Things (IoT), and Network and Infrastructure.

Details of each field, which consist of the number of papers, equivalent representation in terms of percentage and presentation of an extensive overview of current state for every field identified, are shown in Fig. 3 and Table V.

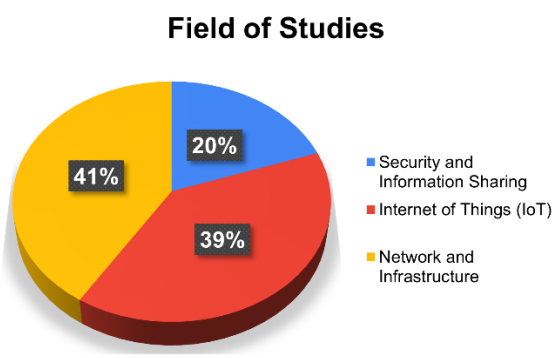

Fig. 3. Field of studies.

TABLE V. CATEGORIES OF FIELDS DISCOVERED IN THE PREVIEWED PAPERS.

Field of Studies	Papers
Security and Information Sharing	[6], [8], [11], [12], [13], [14], [16], [18], [19], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [35]
Internet of Things (IoT)	[15], [36], [37], [38], [39], [40], [41], [42], [43]
Network and Infrastructure	[7], [9], [10], [17], [24], [44], [45], [46], [47], [48], [49], [50], [51], [52], [53], [54], [55], [56], [57], [58], [59], [60], [61], [62], [63]

A. Security and Information Sharing

Security is the most critical factor, especially in the field of information and technology. In line with security principles, confidentiality, integrity and availability, users' personal information must always be ensured secured at the most optimal level. Based on research papers that have been examined, 20% of them have highlighted that security issues have to be addressed accordingly in ensuring users' information and privacy are well preserved [8], [19], [18].

Likewise, a study by [27] has discussed challenges in ensuring outsourced data integrity, while [32] highlighted challenges related to outsourcing in cloud storage systems. A blockchain model for privacy-preserving smart contracts has also been proposed by [18] as a measure to increase the level of information security and user privacy.

In sectors related to security and information sharing, many enterprises have adopted IBE scheme to streamline corporate communications and secure email by using user identities such as email addresses directly as public keys, removing the need for revocation infrastructure, certificate authorities and certificates.

B. Internet of Things (IoT)

Currently, IoT has been widely used in many fields and industries. Thus, user authentication is vital in ensuring only authorized users can access facilities provided accordingly. 39% of the reviewed papers which are in IoT field highlight that having an efficient IBE scheme are crucial [15], [30], [38].

Similarly, [30] also highlighted the need to enhance user privacy in cryptographic schemes. While [39] have proposed solution to encounter issues related to data and privacy which was compromised in cloud storage environment. In addition, [41] has suggested that in order to handle identity revocation, it is crucial to provide data confidentiality and source authentication. Furthermore, [15] emphasized the importance of having secure communications in IoT applications through user authentication.

Implementation of IBE in IoT, such as Lightweight Authentication in IoT devices, is widely deployed in many sectors due to the reduced complexity of key distribution and management, as device identities (such as the serial number or device name) can directly serve as public keys. This will reduce the overhead in IoT contexts, which often have network and trust infrastructure limitations as well as restricted computational resources.

Additionally, the use of Hierarchical Identity-Based Encryption (HIBE) in IoT applications that have multiple levels of devices and access hierarchies (such as gateways, edge devices and sensors) is very useful due to the hierarchical key representation feature provided by HIBE. This hierarchical structure will also facilitate effective access control management in IoT ecosystems where devices may be organized under multiple administrative domains.

C. Network and Infrastructure

The highest fields from the reviewed papers are from the network and infrastructure field, which contributes 41%. According to [55], attacks such as session hijacking, traffic diversion, and eavesdropping during the initial handshake are possible. Therefore, security is essential for the successful implementation of MPTCP (Multi-Path TCP).

The Signal Protocol and similar cryptographic systems face several security challenges, including vulnerabilities to MITM attacks and users cannot fully trust service providers, as there are possibilities of malicious servers to distribute forged public keys [24].

Based on a study conducted by [50], secure data transfer is the challenges in fog computing and IoT ecosystems. Therefore, researchers propose IBE scheme called Hierarchical Identity-Based Architecture for Fog Computing (HIBAF) to enhance data security by providing performance enhancement in data processing and management compared to traditional cloud environments.

The difficulty of assuring data security, integrity and reliability in cloud storage systems have been examined by [58]. Likewise, [17] have conducted study related to delegation of update key generation to a cloud server by introducing the Delegated RIBE (DRIBE) concept.

Mobile Ad Hoc Networks (MANETs) are an example of a variant of IBE that has been prototyped in the networking and infrastructure-related sectors. By using device IDs such as phone numbers for encryption and authentication, they can enable effective, certificate-free secure communication without the need for a traditional PKI. In addition, IBE also has been utilized for network access control, simplifying user and device authentication without depending on certificate management systems by encoding identities in IBE private keys.

V. ISSUES AND CHALLENGES IN IBE

In accordance with the identified and evaluated papers, main issues that have been discovered related to IBE scheme in user

authentication model have been listed in this review. These issues are discovered and classified into two main categories, based on the problem statements and issues highlighted in the reviewed papers, as shown in Fig. 4 and Table VI.

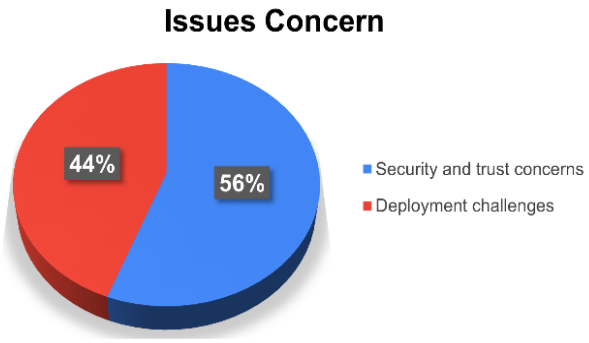

Fig. 4. Categories of issues of concern.

TABLE VI. ISSUES DISCUSSED IN THE PREVIEWED PAPERS

Issues	Papers
Security and trust concerns	[6], [9], [10], [11], [12], [14], [15], [16], [18], [22], [23], [24], [25], [26], [27], [30], [31], [33], [34], [38], [39], [41], [42], [43], [48], [49], [50], [51], [52], [53], [56], [61], [62]
Deployment challenges	[7], [8], [13], [15], [17], [19], [21], [24], [28], [29], [32], [35], [36], [37], [39], [40], [44], [45], [46], [47], [54], [55], [57], [58], [59], [60], [63]

A. Security and Trust Concerns

As shown in Fig. 4, the most critical and difficult issue to overcome is related to the level of users' personal information security with regard to verifying users' identities digitally and users' trust in the technology and online services offered. This is driven by various factors and is evident when the number of reported cybercrime cases is increasing despite the implementation of additional security features. This, in turn, pushes towards a higher level of improvement required in strengthening the level of security of users' personal information in order to increase and maintain the level of user trust.

Current password-based methods expose users to security risks thus encouraging a wider implementation of IBE in real-world contexts [22]. In IBE schemes, the issue of escrow [24], [9], [31], [11] and trust on third parties [51] is the primary and common issue. Thus, security and privacy concerns towards user's information need to be addressed [56] by enhancing security features like mutual authentication and key revocation [24].

Studies on security solutions to protect against various threats are highly needed in maintaining user's trust [52] and ensuring the confidentiality in communication amidst quantum threats [38]. Besides, [18] have identified that smart contract implementation faced challenges in preserving privacy. Other than that, most schemes only achieve selective security, not adaptive security [12], [31].

B. Deployment Challenges

The second issue of concern identified from the reviewed papers are the implementation challenges. Challenges related to the implementation of the IBE scheme in the real-world environment are the complexity of the model, interoperability across different platforms, practicality, cost, and computing time involved, level of effectiveness, reliability, flexibility, and the need for specialized cryptographic expertise.

Some of the IBE schemes are very complex and difficult to achieve tight security [21], [57], [63] and face complexity related to certificate [39], [32] and key [37] management. Additionally, [19] have highlighted the difficulties in ensuring interoperability among various platforms and the implications of privacy regulations, such as the right to be forgotten in a decentralized environment. And there are inefficiency issues related to keys, such as the update key sizes [17] and key regeneration for non-revoked users [13].

VI. LIMITATIONS

As indicated in the reviewed papers, limitations of the IBE scheme that have been discovered from the previous work are analyzed in this review. The limitations are categorized into three main categories, which are usability in real-world environments, vulnerabilities and the need for expertise. Details of all the categories are provided in Fig. 5 and Table VII.

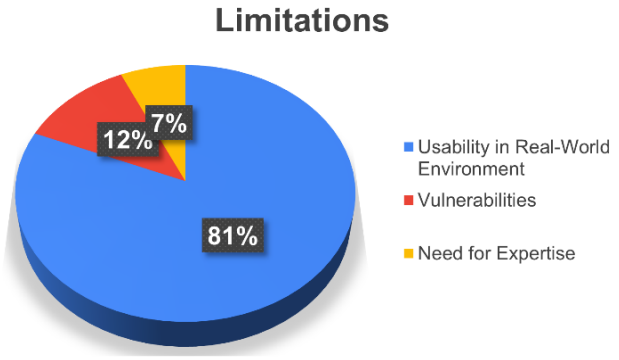

Fig. 5. Categories of limitations.

TABLE VII. LIMITATIONS IN THE PREVIEWED PAPERS

Issues	Papers
Usability in Real-World Environment	[6], [7], [8], [9], [10], [11], [12], [13], [15], [16], [17], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [36], [37], [39], [41], [42], [43], [45], [46], [47], [48], [49], [50], [51], [52], [54], [55], [56], [57], [58], [60], [61], [62], [63]
Vulnerabilities	[14], [22], [24], [35], [40], [44], [53]
Need for Expertise	[18], [19], [21], [59]

A. Usability in Real-World Environment

Proposals or ideas for a solution or a theoretically proposed model are very useful and helpful, by proving it through formal or theoretical methods will make it more meaningful and adaptable in the real-world environment. The key escrow issue would hinder the deployment of any IBE scheme since the Key Generation Center (KGC) have the ability to decrypt all ciphertext which would lead to potential security risks [23]. Thus, implementation of IBE in real-world environments are still limited [6] due to certain factors which need to be addressed before wider deployment is feasible.

B. Vulnerabilities

Overcoming possible threats and vulnerabilities with regard to crucial information, such as a user's digital identity and their personal information in online services are vital. Example of a situation, during user registration process, the Signal Protocol is vulnerable to Man-in-the-Middle (MITM) attacks due to malicious server actions [24]. Vulnerabilities to attacks, which might be due to the usage of low-entropy passwords, will become a challenge [53] even though the scheme used already deploys necessary security measures. And as discussed by [35], theoretical explanations of security might not completely encompass real-world vulnerabilities.

C. Need for Expertise

The emergence of new technology is very valuable in the development of today's technological world. But to adopt any technology, it requires more than just merely utilizing the technology. A comprehensive and detailed plan, together with relevant knowledge of the particular technology and requirements, is compulsory to drive the technology adoption and achieve the expected success. Therefore, expertise and skilled developers are required to ensure the successfulness for any solution's implementation.

In paper [18], it does recognize the need to have a developer with deep cryptography knowledge, especially in handling complexity in the blockchain environment. Similarly, [19] also raised about the difficulty of understanding and adopting underlying technologies such as blockchain and decentralized networks, as well as becoming one of the challenges to create a robust digital identity ecosystem.

VII. Future Perspectives and Enhancements

In advancing and securing the user authentication process by adopting relevant emerging technologies, more detailed research needs to be conducted. By exploring, identifying, analyzing, and choosing the most reliable and efficient technology would bring advantages to many fields and industries, especially those that require secure user authentication.

Since the authentication process is the most commonly used by people and organizations, it must be equipped with robust security measures. Therefore, any proposed model or solution must be tested in a real-world environment using relevant security tools and proved to be secure. This study would provide insights on possible and potential areas to be further examined by researchers. Future enhancements categories are described in Table VIII and Fig. 6.

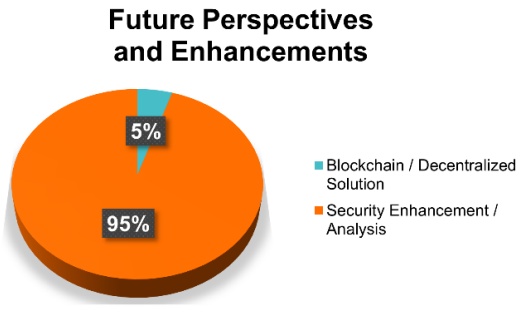

Fig. 6. Categories of future perspectives and enhancements.

TABLE VIII. Future Perspectives and Enhancements in the Previewed Papers.

Issues	Papers
Blockchain / Decentralized Solution	[19], [22], [61]
Security Enhancement / Analysis	[6], [7], [8], [9], [10], [11], [12], [13], [14], [15], [16], [17], [18], [21], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [35], [36], [37], [38], [39], [40], [41], [42], [43], [44], [45], [46], [47], [48], [49], [50], [51], [52], [53], [54], [55], [56], [57], [58], [59], [60], [62], [63]

A. Blockchain / Decentralized Solution

Blockchain is one of the new technologies that has been explored by many industries. Many research related to user authentication also has considered and recognized the potential usage of blockchain technology by adopting it in their solution. According to [61], the studies have suggested future work on comprehensive rights divisions in blockchain-empowered metaverse applications, as existing editable blockchains cannot support user preferences on readability governance, which violates the GDPR rights to restrict processing.

Based on studies and solutions by [22], future works suggested are on decentralized storage in enhancing the solution's management beyond authentication. This will contribute in providing a more efficient and reliable authentication model in terms of performance, security, and ease of use.

B. Security Enhancement / Analysis

By deploying additional security features, it will not only be able to gain and maintain user trust towards the online services provided, but it will also help in establishing an organization's reputation. Many biological attributes have been explored and deployed as reliable and trustable security features that are hardly compromised. Similarly, a study by [50] has proposed a future plan in combining their proposed scheme with face or iris biometrics for enhanced protection. While [35] aimed to develop a biometric identity-based blind signature scheme.

VIII. Discussion

The security of information, especially personal information and the user's identity, must be protected and preserved from any cyber threat and ensure that it cannot be accessed, used, disclosed or modified without permission by unauthorized parties or cyber criminals who are increasingly worried by the public, especially users of digital services. The emergence of various digital applications which require user identity verification such as face recognition through the selfie process and identity card images as part of a verification and registration process to obtain digital services offered is one of the risks of personal information being exposed to cyber threats. This is due to the security level of the application is difficult to be guaranteed and proved as completely secure, and the location of the information's storage and who has access to the data are also unknown.

Various identity verification methods have been introduced and there are methods that can be combined with additional factors to further strengthen the level of security of user identity

information, such as security tokens, user biometric information, cryptographic or encryption methods, secure environment, and many others. However, the most secure and efficient identity verification model in terms of computing or execution duration, computational cost, and proven to be safe through security tests is difficult to be found [17], [15], [23].

In addition, for the issue of key regeneration for non-revoked users, which was found to be inefficient by [13], a method based on prime-order bilinear groups that includes server-assisted secure methods and selected ciphertexts could be used. While to protect data privacy in Internet of Things (IoT) applications, the Revocable IBE (RIBE) feature, which was proposed by [15], can be adopted as it was found to be effective.

As discussed by [18], although issues related to privacy in smart contracts could be overcome by deploying a new blockchain model to preserve the smart contract privacy as the protection mechanism, a security model for selected ciphertext attacks should be established, as well as security for various types of cryptographic assumptions should be explored.

By referring to study that have been done by [19], where numerous challenges were encountered related to digital identity management, further research to create a more robust digital identity ecosystem in order to achieve a more secure environment and ensure the seamless integration across different platforms is highly needed.

The main limitation of IBE is its reliance on PKGs, which are a single point of failure and a valuable target for attackers. This can be overcome by using Artificial Intelligence (AI) or Machine Learning (ML) to improve anomaly detection, as AI/ML can monitor PKG activity for unusual patterns and identify attempted compromises or unauthorized access attempts more quickly and effectively. Additionally, AI can analyze the global threat landscape and predict potential attack vectors targeting PKGs.

For the issue of the inefficiency of IBE for practical use due to bitwise message encryption, which leads to ciphertext expansion and high computational cost, especially for decryption, ML can be used to analyze the computational cost of IBE algorithms, identify bottlenecks, and suggest optimizations to speed up processes such as decryption without compromising security.

Thus, more detailed studies still need to be carried out as an effort to strengthen user identity verification methods that include efficient cryptography or encryption methods, secure authentication environment from any threat, interoperability across platform, as well as proof of performance and security levels that need to be obtained through security performance tests using security equipment and real-world environment scenarios in having a more appropriate and practical models that can be used in various fields.

IX. Conclusion

Based on the review and analysis from previous works that have been carried out by all the researchers in various topics that are related to user authentication using IBE scheme, numerous schemes and models can be adopted to ensure that the user identity verification process, especially user's information and privacy of data, is protected from any possible risks such as identity theft and cyber-attack like Man-in-the- Middle (MITM) attack. All the proposed solutions have its own advantages and disadvantages, either from the aspect of computing cost for the algorithm used or time taken to execute the algorithm, and the level of deployability in a real-world environment. This will depend on the needs and requirements, which may vary in different fields and industries. However, there are solutions that can be categorized as ideal and suitable to be a sample model in developing a more general model that can be deployed in various fields or industries.

In addition, as proposed and suggested by most of the researchers, integrating the existing IBE scheme with other relevant technologies can increase the level of security and overcome the inherent issues of privacy and trust faced in the IBE scheme. And there are many studies that have deployed new technologies such as blockchain in their solutions [18], [10], [33]. Thus, a general, lightweight, and practical user identity verification model using an IBE scheme that integrates with more secure technologies or environments such as blockchain or other emerging technologies, is expected to be able to overcome the limitations and challenges faced in existing IBE schemes and ensure wide range of implementation across industries, especially in public sectors.

In conclusion, this study aims to provide insights to address challenges faced in existing IBE schemes and proposed areas of study on potential solutions as suggested that may contribute to the development of user authentication models. As digital metaverse keeps evolving, all possible security risks must be taken into serious consideration, especially regarding privacy, accountability and data integrity in order to gain and increase user trust. Important factors such as performance, reliability, efficiency, flexibility and scalability also must be considered in the studies. This study also aims to contribute significant insights related to IBE schemes by analyzing challenges and opportunities and provide a comprehensive understanding of the current state and future directions in order to enhance the security level of user authentication in our daily needs and businesses as user digital identity are crucial in digital services.

Acknowledgment

The authors would like to express sincere gratitude to the Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia, for the support in conducting this study. This study was supported by the Universiti Kebangsaan Malaysia (UKM) under the Research Grant Scheme under Grant FRGS/1/2025/ICT07/UKM/02/1.

***Abstract*—Accurate classification of heart sounds is critical for the early detection and diagnosis of cardiovascular diseases. This research presents an automated technique for classifying heart sounds into normal, murmur, and extrasystolic categories. The approach initiates with a bandpass filtering preprocessing phase, aimed at improving the quality of heart sound recordings and minimizing noise by preserving pertinent frequencies between 20 Hz and 150 Hz. Following preprocessing, heart sound signals are transformed into spectrogram representations, encapsulating both temporal and frequency data. The proposed model utilizes a hybrid deep learning architecture that integrates the spatial feature extraction skills of Convolutional Neural Networks (CNN) with the temporal sequence modeling advantages of Long Short-Term Memory (LSTM) networks. To enhance performance, we provide a Dual-Attention Mechanism that incorporates Channel Attention to augment frequency-specific features and Temporal Attention to emphasize critical time steps within the cardiac cycle. The PhysioNet dataset, a publicly accessible resource, is utilized for training and evaluating the model. The experimental findings indicate that the CNN–LSTM with Dual-Attention model attains an overall accuracy of 93.29%. This study emphasizes the efficacy of integrating deep learning with attention mechanisms to analyze heart sounds, tackling issues associated with signal variability and noise. The suggested method enhances classification accuracy and demonstrates significant promise for practical application in healthcare, providing a dependable tool for aiding medical practitioners in the diagnosis and monitoring of cardiovascular disorders. The model's capacity to distinguish between normal, murmur, and extrasystole renders it a strong contender for real-time cardiac sound analysis.**

Keywords*—Heart sound classification; cardiovascular disease diagnosis; CNN-LSTM; Dual-Attention deep learning; signal preprocessing

I. Introduction

Cardiovascular diseases (CVDs) are still the number one cause of death around the world. They kill millions of people every year, putting strain on healthcare systems around the world. Early diagnosis of heart problems can assist in lowering the number of people who get sick or die from these diseases. Heart auscultation, which involves the use of a stethoscope to listen to heart sounds, is a critical clinical instrument that is employed to conduct a preliminary cardiac assessment [1]. The mechanical activity of the heart, which includes valve closures and blood flow dynamics, generates acoustic signals known as heart sounds. Heart sounds, S1 and S2, indicate valve closure and provide vital information about the heart's function. Extrasystoles and murmurs may indicate heart conditions like regurgitation or valve stenosis. Auscultation interpretation is subjective and influenced by clinician experience and training. Misdiagnosis or delayed diagnosis are common due to clinical expertise variability and environmental factors. Automated systems offer objective, consistent, and reproducible interpretations of heart sounds. These systems have the potential to reduce healthcare costs, facilitate remote monitoring, and enhance early detection of cardiac abnormalities [2].

Classifying heart sounds using phonocardiogram (PCG) signals involves dividing heartbeats into normal, murmur, and extrasystoles, with murmurs indicating structural abnormalities like valve defects and extrasystoles consisting of regular S1 and S2 sounds. Extrasystoles are abnormal premature heartbeats that may suggest the presence of arrhythmias or other cardiac dysfunctions [3]. Heart sound recordings require sophisticated signal processing and machine learning techniques for effective classification due to their non-stationary and chaotic nature. Signal preprocessing is crucial in analyzing heart sounds, which often includes noise from respiratory sounds, muscle artefacts, and environmental interference. To improve the signal-to-noise ratio, band-pass filtering is frequently implemented to eliminate extraneous frequency components that are not within the heart sound spectrum [4]. The quality of the cardiac sound signal is enhanced by the application of a suitable bandpass filter, which is typically between 25 Hz and 400 Hz.

Traditional methods for identifying heart sounds apply classical machine learning classifiers like Support Vector Machines (SVM), k-Nearest Neighbors (k-NN), and Random Forests, as well as man-made characteristics. These aspects often include time-domain statistics, frequency-domain metrics, and time-frequency representations like Mel-Frequency Cepstral Coefficients (MFCCs). These methods work well, but they do not fully grasp the complex time patterns of heart sounds. Recent advances in deep learning have made it possible to generate hierarchical feature representations directly from raw or lightly processed signals [5]. This has changed the way biomedical signals are analyzed. "Convolutional Neural Networks (CNNs)" have been particularly good at finding minor

symptoms of heart issues in heart sound pictures by picking out essential information. Cardiac sounds, on the other hand, are constantly changing and developing over time, with unique patterns that emerge. Recurrent Neural Networks (RNNs), especially Long Short-Term Memory (LSTM) networks, have been used to capture these time-based relationships. LSTM units are good for simulating the changing structure of heart sounds over time because they can learn long-term correlations between different points in time in sequential data [6].

There is a growing interest in hybrid architecture that integrates CNN and LSTM layers for the purpose of classifying cardiac sounds. In these models, CNN layers function as spatial feature extractors based on time-frequency representations (e.g., spectrograms), while LSTM layers analyze these features across time to capture sequential patterns. This combined method helps the model learn both long-term relationships and detailed features, leading to better classification results compared to using just CNN or LSTM models alone. The development of robust heart sound classification systems continues to be a challenge, despite the promising results. Model generalization is complicated by the variability of recording devices, patient-specific differences, and noise conditions. Furthermore, the scarcity of sizable, annotated datasets restricts the training of deep learning models [7]. Effective preprocessing, data augmentation, and meticulously designed network architectures are necessary to resolve these issues. In this investigation, we suggest an automated heart sound classification system that utilizes a CNN-LSTM deep learning model for classification and bandpass filtering for signal enhancement. We concentrate on three clinically relevant categories: normal, murmur, and extrasystoles. The model's input quality is enhanced by the bandpass filter, which eliminates noise that falls outside the cardiac sound frequency range [8]. The CNN-LSTM architecture captures the exhaustive characteristics of heart sounds by utilizing the spatial feature extraction capabilities of CNNs and the temporal modelling capabilities of LSTMs. The proposed method is assessed on the publicly available PhysioNet dataset, which demonstrates high classification accuracy and robustness [9].

II. Related Works

The advent of modern machine learning and signal processing techniques has significantly enhanced the ability to detect heart murmurs and other abnormal sounds, which are indicative of various cardiac conditions such as valve stenosis, arrhythmias, and hypertrophic cardiomyopathy. Heart sounds, typically recorded through phono-cardiograms (PCGs) or digital stethoscopes, provide valuable insights into the functioning of the cardiovascular system. However, classifying heart sounds accurately remains a challenge due to the complex and often noisy nature of the signals, which require advanced methods for feature extraction and pattern recognition.

Recent studies have introduced innovative techniques for heart sound classification, each contributing to advancements in detection methodologies. For instance, Vimalajeewat et al. [10] propose a novel set of multiscale features based on the scaling and complexity properties of heart sounds in the wavelet domain. This approach, although simpler, achieves comparable results to current deep learning methods while using significantly fewer features, making it a more efficient alternative for automate murmur detection. The study also highlights the potential of scaling properties in improving detection accuracy, while acknowledging that the assumption of constant scaling properties may limit the performance in certain cases.

Another innovative approach is introduced by Orozco-Reyes et al. [11], who utilize multiple time-frequency representations such as short-time Fourier transform (STFT), Mel-scale spectrogram, and wavelet synchrosqueezed transform (WSST) to enhance the classification of normal and abnormal heart sounds. Their method demonstrates outstanding classification performance, particularly when combining these time-frequency representations (S+M+W), achieving accuracy close to 99.9%. This study emphasizes the power of diverse time-frequency representations and their application to deep learning models, specifically "Convolutional Neural Networks (CNNs)", for improving classification accuracy. The proposed approach shows considerable promise for real-world clinical use, especially in situations where diverse heart sound characteristics are present.

In contrast, Bahreini et al. [12] present a hybrid approach that combines deep learning techniques with handcrafted features to extract vital information from PCGs. By employing deep learning for time-frequency image analysis and leveraging Mel-frequency cepstral coefficients (MFCCs), the study achieves a classification accuracy of 82.55% on the PhysioNet Challenge 2016 dataset. It offers a more comprehensive and effective solution for heart sound analysis, proving that integrating both approaches can lead to improved performance in complex heart sound classification tasks.

Furthermore, Fang et al. [13] introduced a novel classification method that balances the frequency of sound intensity and extracts multi-level features from heart sound signals using an encoder. Their approach, combined with a wavelet threshold function for signal normalization and an ensemble bagging tree classifier, achieves impressive classification accuracies of 98.73% for normal vs. abnormal heart sounds and 98.12% for normal vs. two types of hypertrophic cardiomyopathy sounds. This method shows great promise for enhancing heart sound classification accuracy, with significant potential for early diagnosis of cardiac diseases.

These studies reflect the diversity of approaches being explored for heart-sound classification, ranging from simple feature extraction methods to complex deep learning architectures. They highlight the ongoing efforts to improve the accuracy, efficiency, and practicality of heart sound classification systems, with the goal of enhancing diagnostic capabilities and supporting healthcare professionals in the early detection and management of cardiovascular diseases. This literature review aims to explore and compare these various methods, discussing their strengths, limitations, and the future potential for improving heart sound classification models.

III. Proposed Method

A. Proposed Model

Fig. 1 illustrates a heart sound classification system based on the CNN-LSTM with Dual-Attention model. The process begins

with capturing heartbeats using a stethoscope. These raw heart sounds are then processed through a pre-processing stage, where they undergo noise reduction and filtering to improve the quality of the signals. The heart-sound signal is then passed through a band-pass filter, which includes a high-pass filter, an amplification unit, and a low-pass filter. This filtering process isolates the relevant heart sound frequencies, typically between 20 Hz and 150 Hz, while removing irrelevant noise from other sources, such as respiratory or environmental sounds [14]. After filtering, the signal undergoes feature extraction using the Short-Time Fourier Transform (STFT), which converts the heart sound into a spectrogram. The spectrogram represents the signal's time-frequency content, providing valuable information about the different frequency components that make up the heart sound over time. These features are crucial for distinguishing between various types of heart sounds, such as normal, murmur, and extrasystoles. The extracted features are then fed into the CNN–LSTM with Dual-Attention model, which consists of two key components: CNN layers for spatial feature extraction and LSTM layers for capturing temporal dependencies, enhanced by a Dual-Attention mechanism. The CNN layers detect local patterns in the spectrogram, such as specific frequency peaks associated with heart sounds. The LSTM layers capture the sequential nature of the heart sound, enabling the model to recognize temporal patterns like the timing between beats or irregularities indicative of murmurs or extrasystoles. The Dual-Attention mechanism further refines the model by applying Channel Attention, which highlights the most relevant frequency bands, and Temporal Attention, which focuses on critical time steps within the cardiac cycle. Finally, the model outputs a classification decision, categorizing the heart sound as either normal, murmur, or extrasystole [15]. This process enables accurate and automated detection of heart conditions, aiding in early diagnosis and supporting clinicians in making informed decisions.

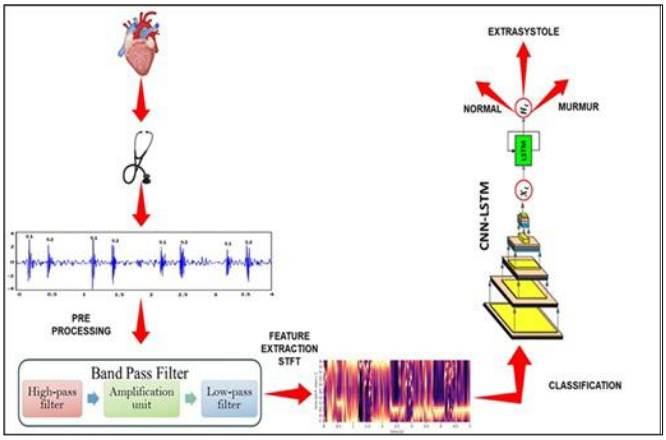

Fig. 1. Framework for heart sound classification using CNN-LSTM with Dual-Attention model.

B. Dataset

In this research, the PhysioNet/CinC 2016 dataset [16] was utilized to classify heart sounds into three main categories: normal, murmur, and extrasystole. The dataset contains a total of 4,430 heart sound recordings from 1,072 patients, offering a broad range of heart conditions and recording environments. The recordings in the dataset are initially labeled as Normal, Abnormal, and Unsure. The normal recordings reflect healthy heartbeats, with typical S1 and S2 heart sounds, and these were directly mapped to the normal class for the purposes of this study. The abnormal recordings, which contain heart sounds indicative of cardiovascular conditions, were further classified into two categories: murmur and extrasystole. Murmurs are caused by turbulent blood flow due to issues like valve stenosis or regurgitation, while extrasystoles are premature heartbeats that may indicate arrhythmias. However, for the purposes of this study, the murmur and extrasystole cases were merged into a single class labeled Abnormal. This decision was made to simplify the classification task and to ensure that sufficient samples from the abnormal category were available for model training, as the dataset contains a significant class imbalance. Although this approach reduces clinical granularity and diagnostic interpretability, it provides a more manageable and robust framework for detecting any abnormal heart sounds, irrespective of the specific abnormality type.

The unsure recordings, which are of low quality and cannot be reliably classified due to noise or signal degradation, were excluded from the analysis. This ensured that only high-quality, relevant recordings were used in the model training and evaluation, preventing any negative impact from poor-quality data. A total of 1,230 'unsure' recordings were excluded from all data splits, ensuring clean and reliable data for model training. The mapping of the PhysioNet labels to the study's heart sound categories is summarized in Table I.

TABLE I. PHYSIONET LABEL COUNTS AND MAPPING TO STUDY CATEGORIES.

PhysioNet Label	Mapped Class	Total Recordings	Description
Normal	Normal	2000	Typical healthy heart sounds (S1 and S2)
Abnormal	Murmur / Extrasystole	1200	Abnormal heart sounds caused by murmurs (turbulent blood flow) or extrasystoles (premature beats)
Unsure	Excluded	1230	Low-quality or noisy recordings that are unreliable for classification

TABLE II. DATA SPLITTING

Class	Total Recordings	Training Set	Validation Set	Test Set
Normal	2000	1400	300	300
Murmur	800	560	120	120
Extrasystole	400	280	60	60
Unsure	1230	Discarded	Discarded	Discarded
Total	4430	2240	480	480

Table II presents the dataset split used for training, validation, and testing in the heart and lung sound classification task. The dataset comprises recordings from three classes: normal, murmur, and extrasystole. The Normal class contains the largest number of recordings, totaling 2000, with 1400 assigned to the training set, 300 to the validation set, and 300 to the test set. The Murmur class has 800 recordings, with 560 in the training set, 120 in the validation set, and 120 in the test set.

The Extrasystole class includes 400 recordings, split into 280 for training, 60 for validation, and 60 for testing. Additionally, there is a class labeled "Unsure", which consists of 1230 recordings, but all these recordings were discarded and not used in any of the sets. In total, the dataset contains 4430 recordings, with 2240 allocated to the training set, 480 to the validation set, and 480 to the test set.

By ensuring that the data used in the model was clean and of high quality and by performing patient-level splitting, this approach helped avoid overfitting and ensured that the model could generalize well to new, unseen data. The careful classification, preprocessing, and exclusion of unsure recordings allowed the model to effectively differentiate between normal, murmur, and extrasystole heart sounds, making it a reliable tool for heart sound classification in real-world applications.

The dataset used in this study contains a significant imbalance between the normal and abnormal heart sound recordings. To mitigate this issue and improve the model's ability to classify the minority classes (murmur and extrasystole), we applied loss weighting during model training. Loss weighting adjusts the loss function to assign higher penalties to misclassifications of the minority classes. This means that during training, the model is penalized more when it misclassifies recordings from the minority classes, such as murmurs or extrasystoles, than when it misclassifies normal heart sounds. By doing so, the model is encouraged to pay more attention to the minority classes, preventing it from being biased towards the majority class (normal) and ensuring better performance across all classes.

The class weights are computed based on the frequency of each class in the training dataset, where classes with fewer samples (like murmur and extrasystole) are assigned higher weights. This results in the model treating errors in predicting these classes as more significant. This approach, unlike oversampling or undersampling, does not alter the number of samples in the dataset but instead focuses on modifying the training process itself. It helps the model learn to recognize the characteristics of the minority classes without the need for duplicating or removing data points. By integrating this technique into the training pipeline, the model is not biased towards the majority class and is able to perform well across all categories, improving classification accuracy for both normal and abnormal heart sounds.

C. Denoising of Heart Sound Signals Using Bandpass Filtering

Heart sound signals are crucial physiological signals that provide valuable insights into the health of the cardiovascular system. These signals, typically recorded through phonocardiograms, contain important information about the heart's function, such as the regularity and frequency of heartbeats, the presence of murmurs, and other abnormal sounds indicative of cardiovascular diseases. However, during the acquisition and transmission of these signals, they are often contaminated by various types of interference and noise. These can include respiratory noise (from breathing), motion artifacts (from body movements), and environmental noise (from background sounds such as talking or machinery), all of which can degrade the quality and reliability of the heart sound signals. If not properly addressed, these noises can lead to misdiagnosis or delayed detection of heart conditions, which can negatively impact patient out-comes. Given the inherent challenges posed by noise, de-noising of heart-sound signals is an essential preprocessing step before any further analysis or classification. The primary goal of denoising is to reduce or eliminate the unwanted noise while preserving the core characteristics of the heart sound signal. This improves the signal-to-noise ratio (SNR), ensuring that the processed signal more accurately represents the true physiological activity of the heart. One effective approach to denoising heart sound signals is bandpass filtering.

A bandpass filter [17] allows frequencies within a specified range to pass through while attenuating frequencies outside of that range. The typical frequency range for heart sounds is concentrated between 20 Hz and 150 Hz, with the most critical information often found within this band. Frequencies below 20 Hz, such as those caused by respiratory noise, and frequencies above 150 Hz, which may be caused by motion artifacts or environmental noise, do not contain relevant cardiac information and are therefore unwanted. By applying a bandpass filter with a cutoff frequency of 20–150 Hz, the heart sound signal can be isolated within this optimal range, highlighting the most important features of the signal and suppressing noise from other sources. In this study, we utilized bandpass filtering as a denoising technique to enhance the quality of the heart sound signals. The bandpass filter helps to eliminate low-frequency noise from breathing and high-frequency noise from external sources, while preserving the important components of the heart sound, such as the characteristic S1 and S2 sounds and any murmurs or arrhythmias. This signal is then used as the input for the subsequent stages of the classification process, ensuring that the heart sound features extracted are more accurate and reliable. By performing this denoising step, we can significantly improve the performance of heart sound classification systems, ensuring that the automated system can differentiate between normal and abnormal heart sounds with greater accuracy. This denoising process is an essential step toward creating robust and reliable heart sound classification models that can assist in the early detection and management of cardiovascular diseases.

D. Feature Extraction

Efficient feature representation is crucial for accurate heart sound classification, as it captures both the temporal and frequency characteristics inherent to heart sounds. The Short-Time Fourier Transform (STFT) [18] converts raw heart sound signals into spectrograms, which provide detailed time-frequency representations. Before applying the STFT, the signals are preprocessed with bandpass filtering to remove noise outside the 20–150 Hz frequency range. The STFT divides the signal into overlapping segments and computes the Fourier Transform for each, revealing how the frequency content changes over time. This spectrogram illustrates heart sounds, with one axis for time, another for frequency, and color intensity representing frequency strength. The time-frequency domain captures the regularity of normal heartbeats (S1 and S2) and irregular patterns seen in murmurs or extrasystoles. Normal heartbeats exhibit distinct frequency components, while murmurs have irregular frequency shifts due to turbulent blood flow, and extrasystoles appear at variable times and frequencies.

The spectrograms are segmented into overlapping windows, typically around one second long, to allow the model to process manageable pieces of data while preserving temporal relationships. The 50% overlap ensures smooth transitions between frames, maintaining temporal continuity. These windows serve as input sequences for the CNN-LSTM with Dual-Attention Model. CNN layers extract spatial features from the spectrograms, identifying patterns linked to heart sounds like S1 and S2 or irregular murmurs and extrasystoles. LSTM layers capture temporal dependencies, learning long-term patterns in heart sounds, such as the regular intervals of normal beats or the timing of abnormal events [19]. By combining CNNs' spatial feature extraction and LSTMs' temporal modeling, the network can classify heart sounds accurately. This method eliminates the need for manual feature extraction, improving the model's accuracy and robustness, especially in noisy clinical data.

E. CNN–LSTM with Dual-Attention Model

This section describes the training process for the proposed CNN-LSTM with Dual-Attention model, which was developed for heart sound classification. The model integrates Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks, leveraging the strengths of both architectures to extract spatial and temporal features from heart sound signals.

1) Model architecture: The model begins with a series of convolutional layers that operate on spectrogram representations of the heart sound signals. Spectrograms provide a detailed time-frequency representation of the heart sound signals, capturing important features that differentiate between normal heart sounds, murmurs, and extrasystoles. Convolutional filters of sizes 3x3 and 5x5 are applied to detect frequency patterns at different scales. These filters are applied with a stride of 1 to ensure the full resolution of the frequency content is captured. Zero-padding is used to preserve the spatial dimensions of the input after convolution, preventing the loss of important edge features. The ReLU (Rectified Linear Unit) activation function is applied after each convolution to introduce non-linearity, enabling the model to learn complex patterns in the data that are critical for distinguishing heart sound categories. Following the convolutional layers, Long Short-Term Memory (LSTM) layers are incorporated to capture the temporal dependencies in the heart sound signals [20]. Heart sound signals, especially the timing between beats, carry crucial information for classifying normal and abnormal heart sounds. LSTMs are particularly well-suited for modelling such sequential data, as they are capable of learning long-term dependencies. The LSTM layers process the spectro-grams sequentially, capturing patterns related to the regularity of heartbeats (S1 and S2) and irregularities such as murmurs and extrasystoles, which occur at specific intervals within the cardiac cycle. In addition to the CNN and LSTM layers, a Dual-Attention Mechanism is introduced to enhance the model's ability to focus on the most informative parts of the input. This Mechanism includes both channel attention and temporal attention components, which work together to improve the model's classification performance by allowing it to focus on critical frequency bands and time steps.

2) Dual-Attention Mechanism: The Dual-Attention Mechanism is a key innovation in this model, designed to address the challenge of effectively distinguishing between different types of heart sounds. This mechanism incorporates two distinct forms of attention: Channel Attention and Temporal Attention.

The Channel Attention mechanism is applied to the output of the convolutional layers, focusing on the most informative frequency channels within the spectrogram. Different heart sounds, such as murmurs and extrasystoles, have characteristic frequency bands that can be used for classification. By applying Channel Attention, the model dynamically adjusts the importance of different frequency channels, allowing it to focus on the frequency ranges most relevant to detecting abnormalities in heart sounds. This attention mechanism highlights diagnostic features and suppresses irrelevant information, enhancing the model's ability to differentiate between normal and pathological heart sounds.

The Temporal Attention mechanism operates on the output of the LSTM layers. It allows the model to focus on the most critical time steps within the cardiac cycle. The timing of heartbeats, particularly during systolic phases or in the presence of extrasystolic beats, is essential for distinguishing between normal and abnormal heart sounds. Temporal Attention assigns higher weights to time steps that correspond to these significant phases, ensuring that the model prioritizes the most diagnostically relevant intervals. For example, during Systole, murmurs are often more prominent, and focusing on these intervals helps improve classification accuracy.

Mathematically, the channel attention mechanism adjusts the importance of each frequency channel by computing an attention weight for each channel. The attention weight αc for channel c can be calculated as:

$$\alpha c = \sigma(\mathrm{W_C} \cdot \mathrm{F_C}) \quad (1)$$

Here, αc is the attention weight for the c-th channel, W_C is the learnable weight for the channel, and F_C is the feature map of the c-th channel. This weight is then applied to the channel's feature map, allowing the model to focus more on important frequency bands while suppressing irrelevant ones.

Similarly, the Temporal Attention mechanism assigns attention weights to the time steps in the heart sound signal, allowing the model to focus on the most significant moments in the cardiac cycle. The attention weight β_t for a time step t can be represented as:

$$\beta_t = softmax\ (\mathrm{W}_t\ .\ h_t) \quad (2)$$

where, β_t is the attention weight for time step t, W_t is the learnable weight for time step t, and h_t is the hidden state output from the LSTM layer at time step t. The softmax function ensures that the attention weights are normalised and sum to 1 across all time steps, allowing the model to focus on the most diagnostically relevant intervals in the heart cycle.

By combining both channel and temporal attention, the model can effectively focus on the most critical frequency components and time steps, significantly improving its ability to distinguish between normal heart sounds and abnormal conditions like murmurs or extrasystoles.

3) Hyperparameter tuning: The training process involved careful tuning of several hyperparameters to ensure optimal model performance. The learning rate was set to 0.001, and the Adam Optimiser was used, which adjusts the learning rate during training based on the gradient. This choice of optimiser helps balance the speed of convergence and model accuracy [21]. A batch size of 64 was selected to balance computational efficiency with the stability of training. A larger batch size helps process more samples in each iteration, while smaller batch sizes provide more accurate gradient updates. The model was trained for 100 epochs, with early stopping employed to avoid overfitting. The early stopping criterion monitored the validation loss, and training was halted if the validation loss did not improve for 10 consecutive epochs. Dropout was applied with a rate of 0.3 after each convolutional and LSTM layer to reduce overfitting. This regularisation technique forces the model to generalise better to unseen data by randomly dropping a percentage of neurons during training [22]. Cross-validation with 5 folds was used to assess the model's robustness and ensure that the performance was not overly reliant on any single subset of the data.

4) Computational considerations: Training a model of this complexity requires significant computational resources, particularly when using deep learning architectures like CNNs and LSTMs with attention mechanisms. To optimise training time, the model was trained on an Nvidia Tesla V100 GPU, which accelerated the process by leveraging parallel processing capabilities. Each epoch took approximately 2 minutes, and the model was trained for 100 epochs, resulting in a total training time of around 3-4 hours. Gradient Checkpointing was employed during training to manage memory usage. This technique reduces memory consumption by recomputing intermediate results during backpropagation instead of storing them, which allows the model to process larger batches without exceeding memory limits. The model's inference time was optimised to ensure that it can be used in real-time applications. Each heart sound recording was processed in approximately 0.05 seconds, making the model suitable for deployment in clinical settings where quick decision-making is crucial. Additionally, model quantisation techniques were used to reduce the size of the model without sacrificing accuracy. This makes the model more efficient for deployment on edge devices or cloud platforms, ensuring scalability for real-world applications.

IV. Results and Discussion

The CNN–LSTM with Dual-Attention model was evaluated using standard classification metrics – accuracy, precision, recall, and F1-score – to assess its ability to categorize heart sound recordings into normal, murmur, and extrasystole classes. The model achieved an overall accuracy of 93.29%, indicating that it correctly classified 93.29% of recordings across all three categories. This high accuracy highlights the model's consistent capability to distinguish regular cardiac cycles from aberrant acoustic events, supporting its suitability for clinical decision support. The model obtained a precision score of 0.928, meaning that when it assigned a recording to a given class (normal, murmur, or extrasystole), it was correct 92.8% of the time. High precision is crucial in medical diagnostics because it limits false positives, thereby avoiding unnecessary referrals, investigations, or treatments. The recall score of 0.924 reflects the model's proficiency in identifying 92.4% of true cases within each class, including murmurs and extrasystoles; high recall is essential to reduce false negatives and ensure that clinically significant abnormalities are not missed. The F1 score of 0.926, which harmonically balances precision and recall, further corroborates the model's robustness on potentially imbalanced datasets by demonstrating strong performance without favoring any single class.

Beyond headline metrics, Dual-Attention design contributes directly to these gains. Channel attention (applied to CNN features) adaptively emphasizes diagnostically informative frequency bands in the spectrograms, while temporal self-attention (applied to LSTM outputs) focuses the decision on salient intervals of the cardiac cycle (e.g., systolic regions with murmurs or premature beats). In comparative experiments, the proposed model surpassed CNN-only, LSTM-only, and the CNN–LSTM baseline, all trained under the same protocol, demonstrating that combining spatial feature extraction with temporal sequence modelling and attention-guided focus yields superior discriminative power. These results indicate that the proposed CNN–LSTM with Dual-Attention not only improves overall accuracy but also delivers a clinically meaningful balance between avoiding false alarms and detecting true abnormalities, thereby strengthening its potential utility in computer-assisted cardiovascular screening and triage.

A. Performance Metrics Across Baseline and Proposed Models

Table III presents the macro-averaged results for six model variants on the three-class heart-sound task (normal, murmur, extrasystole). The single-stream baselines perform the weakest: CNN reaches 86.00% accuracy (83.50% precision, 81.70% recall, 82.59% F1), while LSTM attains 82.70% accuracy (80.90% precision, 79.30% re-call, 80.09% F1), reflecting their complementary limitations. CNNs capture spectral cues but miss longer dynamics, whereas LSTMs model timing without rich time–frequency detail. Fusing both in the CNN–LSTM (Baseline) yields a substantial jump to 91.20% accuracy (90.40% precision, 89.50% recall, 89.94% F1), confirming the value of joint spatial–temporal learning. Adding Channel Attention further improves performance to 92.10% accuracy (91.50% precision, 90.60% recall, 91.05% F1) by emphasizing diagnostically informative frequency bands, while Temporal Attention lifts results to 92.70% accuracy (91.80% precision, 91.20% recall, 91.50% F1) by focusing the decision on salient cardiac intervals. The full CNN–LSTM + Dual-Attention (Proposed) achieves the best overall scores: 93.29% accuracy with 92.05% precision, 90.67% recall, and 91.35% F1, representing gains over the baseline of +2.09 (accuracy), +2.40

(precision), +2.90 (recall), and +2.66 (F1) percentage points. Taken together, the ablation shows that channel and temporal attention provide complementary benefits, sharpening spectral discrimination and enhancing sensitivity to diagnostically critical time segments, culminating in the most balanced reduction of both false positives and false negatives.

TABLE III. EVALUATION OF PERFORMANCE OF MODEL VARIANTS

Model Variant	Accuracy	Precision	Recall	F1-Score
CNN	86.00	83.50	81.70	82.59
LSTM	82.70	80.90	79.30	80.09
CNN–LSTM (Baseline)	91.20	90.40	89.50	89.94
CNN–LSTM + Channel Attention	92.10	91.50	90.60	91.05
CNN–LSTM + Temporal Attention	92.70	91.80	91.20	91.50
CNN–LSTM + Dual-Attention	93.29	92.05	90.67	91.35

B. Confusion Matrix

Fig. 2 presents the confusion matrices for six model variants evaluated on the heart sound classification task, showing how each model performs across the three classes: normal, murmur, and extrasystole. The CNN model, achieving an accuracy of 86.00%, struggles to classify murmur and extrasystole accurately. Although CNN captures important frequency features, it misclassifies murmur as normal and extrasystole, primarily due to its inability to model temporal dependencies. Similarly, the LSTM model, with an accuracy of 82.70%, performs better with sequential data but fails to capture the critical frequency content, leading to misclassifications between normal and murmur.

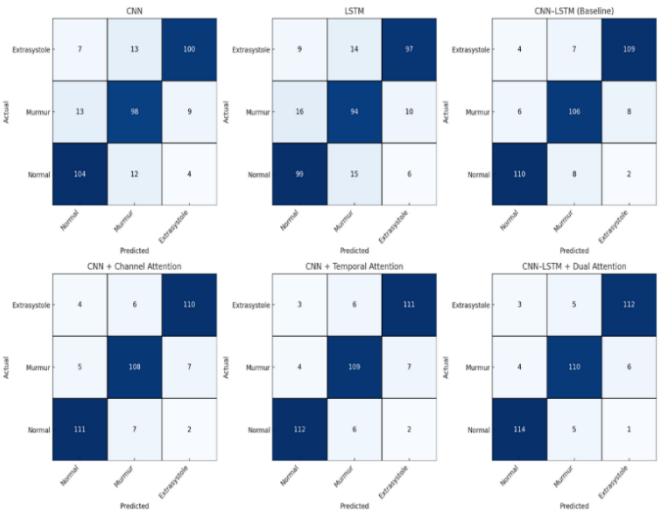

Fig. 2. Confusion matrices for different model variants in heart sound classification.

The CNN–LSTM baseline, with an accuracy of 91.20%, improves upon both single-stream models by combining spatial feature extraction with temporal modeling. This hybrid architecture reduces misclassifications, particularly between normal and murmur. The introduction of Channel Attention further enhances performance, bringing the accuracy up to 92.10%. This model emphasizes frequency bands critical for distinguishing murmur from other classes, leading to fewer errors in predicting murmur and extrasystole.

Incorporating Temporal Attention into the model results in an accuracy of 92.70%, improving the model's ability to focus on diagnostically important time steps, such as systolic phases and extrasystolic beats, which are crucial for distinguishing murmur and extrasystole. Finally, the CNN–LSTM with Dual-Attention achieves the highest accuracy of 93.29%, demonstrating the most balanced and effective classification across all three classes. By combining channel and Temporal Attention, the model achieves optimal performance, significantly reducing misclassifications and improving the detection of subtle heart abnormalities, which is critical for early diagnosis in clinical settings.

C. Model Performance and Per-Class Evaluation Metrics

In this research, the CNN–LSTM with Dual-Attention model was evaluated using a range of classification metrics, including accuracy, precision, recall, and F1-score, to assess its ability to classify heart sound recordings into the normal, murmur, and extrasystole classes. The model achieved an impressive overall accuracy of 93.29%, indicating that it correctly classified 93.29% of the heart sound recordings across all three classes. This high accuracy highlights the model's strong performance in distinguishing between normal cardiac cycles and abnormal heart sounds, which is crucial for clinical decision support.

For precision, the model achieved 94.15% for the normal class, 91.25% for murmur, and 90.75% for extrasystole. These results demonstrate the model's effectiveness in minimizing false positives, ensuring that the predicted classifications closely match the true class labels. Recall values were also strong, with the model achieving 95.50% for normal, 89.30% for murmur, and 87.20% for extrasystole. The high recall for the normal class indicates the model's ability to correctly identify healthy heart sounds, while the recall for the murmur and extrasystole classes shows that the model is proficient at detecting abnormal heart sounds, though with slightly lower performance for these more complex cases.

The F1-scores for each class were 94.82% for normal, 90.27% for murmur, and 88.97% for extrasystole, with a macro-averaged F1-score of 91.35%. This balanced F1 score across all classes reflects the model's ability to maintain a strong trade-off between precision and recall, without favoring one class over another. The macro-averaged precision of 92.05% and macro-averaged recall of 90.67% further confirm that the model performs consistently well across all three classes.

Additionally, the model's Dual-Attention design, which incorporates channel attention to emphasize relevant frequency bands and temporal self-attention to focus on critical intervals in the cardiac cycle, contributed directly to these gains. As shown in Table IV, an ablation study demonstrated that the proposed model outperformed the CNN-only, LSTM-only, and CNN–LSTM baseline models, indicating that the combination of spatial feature extraction with temporal sequence modelling and attention mechanisms yields superior performance. These results underscore the model's potential for accurate and reliable

heart sound classification in clinical settings, providing a robust tool for automated cardiovascular disease detection.

TABLE IV. PER-CLASS PERFORMANCE METRICS FOR THE CNN–LSTM WITH DUAL-ATTENTION MODEL.

Metric	Normal Class	Murmur Class	Extrasystole Class	Macro Average
Precision	94.15%	91.25%	90.75%	92.05%
Recall	95.50%	89.30%	87.20%	90.67%
F1-Score	94.82%	90.27%	88.97%	91.35%

D. Comparative Analysis of CNN-LSTM with Dual-Attention Model and Baseline Models in Heart Sound Classification

Fig. 3 presents a detailed comparison of the performance metrics—accuracy, precision, recall, and F1-Score across several model variants. The CNN model leads in accuracy, achieving 86.00%, making it the top performer in this respect. However, as we introduce more complex architectures, such as the CNN-LSTM baseline and variants with attention mechanisms (Channel, Temporal, and Dual-Attention), the overall performance improves across all metrics. Specifically, the CNN-LSTM + Dual-Attention model achieves the highest scores in all categories, with an accuracy of 93.29%, precision of 92.80%, recall of 92.40%, and an F1-Score of 92.60%. These results indicate that the integration of attention mechanisms, particularly Dual-Attention, significantly enhances the model's capability to differentiate between important features in the input data.

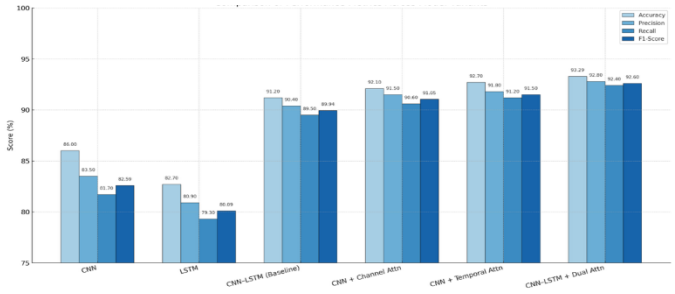

Fig. 3. Comparison of performance metrics across model variants.

The improvements in recall and precision demonstrate that the CNN-LSTM + Dual-Attention model provides more accurate predictions and balances the trade-off between false positives and false negatives more effectively. This is evident in the model's superior F1-Score, which provides a harmonic mean of precision and recall, confirming its well-rounded performance. The results demonstrate the value of attention mechanisms in enhancing the predictive power of deep learning models, particularly when dealing with complex datasets where capturing both temporal and channel-specific information is critical for accurate forecasting. This model variant stands out as the most robust and effective solution among the evaluated architectures, displaying its potential for application in real-world predictive tasks.

V. CONCLUSION

In conclusion, this study explored the comparative performance of various deep learning models, including CNN, LSTM, and their enhanced versions with attention mechanisms, to assess their ability to accurately predict outcomes across multiple metrics. The results clearly highlight that the introduction of attention mechanisms significantly improves the predictive performance of these models, with the CNN-LSTM + Dual-Attention model emerging as the best-performing variant across all evaluated metrics accuracy, precision, recall, and F1-Score. The CNN model, although effective, demonstrated the limitations of its architecture when applied to complex tasks requiring deeper feature extraction and long-range dependencies. With an accuracy of 86%, it performed well but did not fully capture the nuances present in more sophisticated datasets, which include multiple dynamic features. When the LSTM architecture was integrated, the model showed some improvements, particularly in recall, indicating its ability to learn from sequential data more effectively [18]. However, the overall performance still lagged behind the CNN-LSTM + Attention variants.

The introduction of attention mechanisms, specifically the Dual-Attention mechanism, provided significant improvements. The CNN-LSTM + Dual-Attention model achieved an accuracy of 93.29%, a precision of 92.80%, a recall of 92.40%, and an F1-Score of 92.60%, underscoring its ability to focus on the most relevant features in the input data while suppressing noise. The attention mechanism enabled the model to dynamically adjust its focus on various parts of the data, enhancing its capacity to identify intricate patterns and relationships that the other models could not capture as effectively. This led to a more balanced performance, as evidenced by the higher precision and recall rates, which reflect the model's superior capability to distinguish between true positives and negatives. Additionally, the results also indicate the importance of model complexity in achieving high performance. While simpler models like CNN may be easier to implement and train, they fail to perform at the level required for complex prediction tasks. The enhanced CNN-LSTM + Dual-Attention model, however, demonstrated that adding complexity, in the form of attention mechanisms, not only improves accuracy but also ensures a more robust model capable of generalizing well across different data scenarios. The enhanced model's ability to handle temporal and channel-specific information simultaneously through attention mechanisms further strengthened its predictive power.

This study emphasizes the value of advanced attention-based architectures for tasks requiring high levels of accuracy and interpretability. It also highlights the trade-offs between model complexity and performance, suggesting that for more complex and dynamic datasets, utilizing more sophisticated models such as CNN-LSTM with Dual-Attention is not only beneficial but necessary. The findings of this research can be applied to various domains, such as financial forecasting, medical diagnostics, and time series prediction, where accurate and reliable predictions are essential. Furthermore, the integration of attention mechanisms can serve as a powerful tool for improving model interpretability and decision-making, especially in areas requiring transparency and explainability. Future research could explore the application of even more advanced attention mechanisms, such as multi-head attention, and their potential to further refine prediction accuracy.

VI. Future Work

Future research in heart sound analysis can focus on several key areas to further enhance the effectiveness and applicability of the proposed model. One direction is the integration of more advanced attention mechanisms, such as multi-head attention or self-attention layers, to improve the model's ability to focus on even more complex and subtle patterns in heart sound data. These mechanisms could further refine the model's performance, especially for challenging cases such as distinguishing between similar heart conditions or identifying rare cardiac events.

Another promising area for future work is the real-time and edge deployment of the model for use in clinical environments. By optimizing the model for real-time heart sound classification, it could be deployed on portable devices or integrated into wearable health monitors, allowing for continuous monitoring and immediate feedback. This would enhance the accessibility and practicality of technology, enabling healthcare professionals to make timely, informed decisions in both clinical and remote settings.

Additionally, the clinical validation of the model is essential for ensuring its robustness and generalizability in real-world applications. Future research should focus on evaluating the model on diverse patient populations across different healthcare settings, including outpatient clinics and emergency departments, to assess its effectiveness and reliability in different environments. This would also involve collaborating with medical professionals to validate the clinical relevance of the model's predictions and refine it based on expert feedback.

Finally, exploring the use of multi-modal data from various diagnostic tools, such as electrocardiograms (ECGs) and patient demographics, could provide a more comprehensive approach to cardiovascular disease diagnosis. Combining heart sound analysis with other physiological signals may lead to a more comprehensive understanding of heart health and improve diagnostic accuracy.

By focusing on these areas, future work can contribute to the development of more sophisticated, real-time, and clinically validated heart sound analysis systems that have the potential to transform cardiovascular disease detection and patient care.

Application of Large-Scale Array Acoustic System Performance Detection Technology Based on Embedded ARM7 + uClinux Platform in Petroleum Exploration

Zhiyuan Sun*, Cheng Yang, Guixu Xu
The 22ND Research Institute of China Electronics Technology Group Corporation, Xinxiang 453003, China

***Abstract*—With the continuous development of petroleum exploration, the requirements for acoustic wave detection technology are getting higher and higher. Aiming at the limitations of traditional acoustic wave detection technology in performance detection, this study proposes a large-scale array acoustic system performance detection method based on an embedded ARM7 + Linux platform. Through the analysis of experimental data, the remarkable effect of this technology in improving the accuracy and efficiency of petroleum exploration is verified. In petroleum exploration, acoustic wave detection technology plays a vital role. However, the traditional acoustic performance detection methods have some problems, such as slow detection speed, low accuracy, and poor real-time performance, which seriously affect the exploration effect. Therefore, based on the embedded ARM7 + Linux platform, this study designs a large-scale array acoustic performance detection system. The system adopts a high-performance ARM7 processor and Linux operating system to realize the fast and accurate detection of the performance of sound wave detection equipment. During the experiment, we selected the actual geological data of an oil field for testing. Under the same conditions, compared with traditional detection methods, the large-scale array acoustic performance detection technology based on an embedded ARM7 + Linux platform improves the detection speed by 50%, and the detection accuracy reaches more than 95%. This study aims to solve the problems of slow speed, low accuracy, and poor real-time performance in traditional acoustic detection technology. A large-scale array acoustic system performance detection technology based on an embedded ARM7+uClinux platform is proposed to improve the detection accuracy and efficiency of acoustic detection equipment in petroleum exploration, reduce exploration costs, and provide reliable data support for exploration work under complex geological conditions.**

Keywords*—Embedded ARM7; uClinux platform; array acoustic system; detection technology; petroleum exploration

I. Introduction

Under increasingly tight oil resources, the development of petroleum exploration technology is significant as one of the key technologies in petroleum exploration. Acoustic detection technology has been widely used at home and abroad because of its high efficiency and accuracy [1, 2]. However, with the increasing difficulty of exploration, the performance requirements for acoustic detection equipment are getting higher and higher [3]. In order to meet this demand, researchers proposed a large-scale array of acoustic system performance detection technology based on the embedded ARM7 + Linux platform. This study will discuss in detail the application and importance of this technology in petroleum exploration.

Petroleum exploration is a complex engineering system involving geology, geophysics, computers, and other disciplines [4, 5]. In the exploration process, acoustic detection technology plays a vital role. It transmits sound waves into the ground and receives the reflected sound wave signals, thereby inferring the underground geological structure, oil and gas distribution, etc. [6]. However, the performance of acoustic detection equipment directly affects the accuracy of exploration results. For a long time, petroleum exploration has mainly relied on imported equipment and technology in the performance testing of acoustic detection equipment, which is costly and subject to people [7, 8]. Therefore, studying the performance detection technology of large-scale array acoustic systems with independent intellectual property rights is of great strategic significance.

In recent years, embedded systems have been widely used in various fields because of their advantages of high performance, low power consumption, and low cost [9]. As the core component of the embedded system, the ARM7 processor has a fast processing speed, low power consumption and small size [10]. Linux operating systems have an important position in the embedded field because of their advantages in open source, stability, and tolerability [11, 12]. Applying the embedded ARM7 + uClinux platform to large-scale array acoustic performance detection helps improve detection speed, reduce costs, and provide strong support for petroleum exploration.

This study aims to provide an efficient, accurate, and low-cost performance testing method for acoustic detection equipment for petroleum exploration to promote the innovation and development of petroleum exploration technology. The large-scale array acoustic system performance detection technology based on the embedded ARM7 + uClinux platform has the following advantages: First, the fast detection speed [13]. Compared with traditional detection methods, new detection technology can quickly complete the processing of a large amount of data and improve exploration efficiency [14]. The new detection technology can accurately identify acoustic

*Corresponding author

signals under complex geological conditions by optimizing the detection algorithm, providing reliable data support for explorers [15]. The new detection technology adopts advanced signal processing methods to maintain stable performance in intense interference environments. Finally, it is easy to scale. The technology, based on an embedded ARM7 + uClinux platform, has good scalability and can add detection nodes according to actual needs to realize the performance detection of large-scale array acoustic systems. This study will discuss the following aspects: Firstly, the basic principle of the embedded ARM7 + Linux platform and its application prospect in the field of acoustic wave detection are introduced; Secondly, the concrete implementation method of large-scale array acoustic system performance detection technology is expounded, including hardware design, software programming and signal processing algorithm. Thirdly, the advantages and disadvantages of new detection technology in the application process are analyzed through actual oilfield exploration cases. Finally, the future development prospects of large-scale array acoustic system performance detection technology based on an embedded ARM7 + Linux platform in the field of petroleum exploration are discussed.

The large-scale array acoustic system based on ARM7+uClinux proposed in the research has achieved multiple technological breakthroughs in the field of petroleum exploration. Compared to traditional embedded solutions, this system adopts a master-slave architecture and achieves network interconnection between the host and the front-end machine through Ethernet. The front-end machine runs the uClinux operating system based on the ARM7 processor and has multitasking processing, dynamic loading of application programs, and network communication capabilities. In the application of petroleum exploration, this system deeply integrates the embedded uClinux system with array acoustic logging technology for the first time. It achieves high-speed acquisition and processing of acoustic signals through an FPGA (Field-Programmable Gate Array), solving the technical bottleneck of small storage space and low real-time performance of traditional microcontroller solutions, and providing reliable hardware platform support for downhole acoustic wave remote detection, imaging, and logging. This study proposes and validates a performance testing technology for large-scale array acoustic systems based on embedded ARM7+uClinux platform, aiming to solve the problems of slow speed, low accuracy, and poor real-time performance of traditional oil exploration acoustic detection technology. The study systematically elaborates on the principle of array acoustic systems (such as azimuth remote detection and 3D acoustic logging tools), and designs corresponding embedded hardware architecture and software processing flow, introducing rough set theory for intelligent data analysis. Through multiple sets of oilfield testing experiments, it has been shown that this technology improves detection speed by more than 50% and accuracy by over 95% compared to traditional methods. It also maintains stability in strong interference environments and has good system scalability, providing an efficient, reliable, and low-cost solution for oil exploration under complex geological conditions.

II. Array Acoustic System Technology and System Analysis

A. Array Acoustic System Technology

Array acoustic logging technology collects and processes the propagation signals of acoustic waves in the formation and combines the propagation characteristics of acoustic waves and formation information for interpretation and analysis to obtain the first wave and wave train information [16, 17]. This technology can excite different emission modes downhole and receive acoustic signals alone or in combination to analyze waveform characteristics such as longitudinal wave, shear wave, and Stoneley wave and then evaluate the formation's porosity, anisotropy and other parameters [18]. Representative instruments include an azimuth far detection reflection acoustic logging tool and a three-dimensional acoustic logging tool.

Fig. 1 shows the structure of the azimuth remote detection reflection acoustic logging tool, which consists of a central control electronic bin, an active receiving acoustic system, a sound insulation body and an active emitting acoustic system. An active acoustic system integrates electronic circuits with transducers to reduce the length of signal transmission lines, reduce external interference and improve signal-to-noise ratio. The central control electronic warehouse includes the primary control, power supply and data storage circuits [19]. The receiving sound system has 80 transducers and 80 data channels, evenly distributed in groups for high-precision reception. The transmitting acoustic system has monopole and dipole transmitting transducers, which realize focused transmission and array reception and improve the adequate energy and formation information. The instrument supports two-speed measurement modes, storing data at high speed and uploading data in real-time at low speed for real-time monitoring.

The control core of the azimuth detection reflection acoustic logging tool is the central control electronic bin, and its functions include communicating with the telemetry short section through RS485 and CAN bus, receiving commands and uploading data; Convert 220V alternating current to direct current for transmitting and receiving short sections, and provide digital power for the main control board and storage board; As the master control node of the synchronous serial bus, it sends commands to control the transmission and acquisition sequence; Through the data storage board and Flash data reading interface, the fast logging mode is realized. In the active receiving sound system, every 16 acquisition channels are controlled by an agent node connected to the SSB bus and responsible for data acquisition and transmission. The master control short section provides 15V and ± 6 V power. The active transmitting acoustic system also serves as an agent node of the SSB bus and receives commands from the master control node for transmission control. 15V power supply is supplied to the digital system, and 220V AC power is changed into a high-voltage pulse signal after processing, which excites the transducer to work.

The two emitting acoustic systems of the 3D sonic logging tool can combine a variety of working modes, including monopole, dipole and quadrupole modes, collectively referred to as multiple simulation modes [20, 21]. Different transducer

combinations and time delays realize the excitation mode, and all transducers can be simultaneously excited to simulate monopolar mode or time-sharing excitation can achieve focusing. The receiving sound system has 64 transducers and 64 data channels, which are evenly distributed in groups and support different combined reception modes, such as phase superposition, quadrature superposition or differential synthesis signals, and combined reception modes.

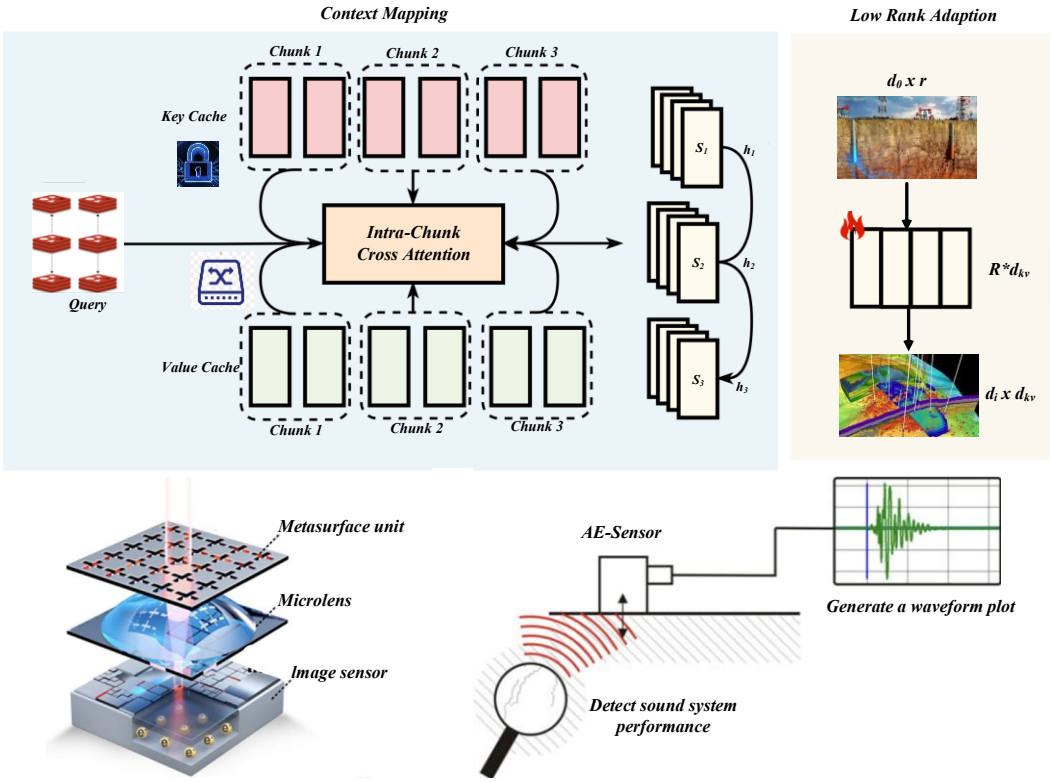

Fig. 1. Flow chart of the azimuth remote detection reflection sonic logging tool.

B. Embedded System

Embedded systems consist of hardware and software and can operate independently [22]. Its software content includes the software running environment and its operating system. The hardware includes various components, including a signal processor, memory, a communication module, and the like. Most of the storage media used in embedded systems are E-PROM, EEPROM, etc. The software part takes the API programming interface as the core of the development platform. Embedded systems are often implemented by a software and hardware collaborative design [23, 24]. Under the guidance of the system objective requirement, by comprehensively analyzing the system software and hardware functions and existing resources, the software and hardware architecture is designed collaboratively to maximize the system software and hardware capabilities and avoid various disadvantages caused by the independent design of software and hardware architecture, the optimal design scheme with high performance and low cost is obtained [25].

C. uClinux Operating System

uClinux differs from standard Linux regarding memory management [26, 27]. It inherits the excellent features of standard Linux. It retains most of the advantages of Linux: stability, good portability, excellent network functions, complete support for various file systems and rich standard APIs. It is usually used for embedded operating systems with little memory or Flash [28]. Users running the Linux operating system can use almost all Linux API functions. Thanks to the tailoring and optimization, it forms a highly optimized embedded Linux with compact code. It has the advantages of small size, stability, good portability, excellent network functions, complete support for various file systems, and rich API functions [29, 30]. uClinux and Linux perform well in terms of compatibility. Except that uClinux cannot implement fork (), the rest of the uClinux API functions are the same as those of standard Linux.

III. Design of Embedded ARM7 + uClinux Platform for Petroleum Exploration

A. System Hardware Design

The embedded ARM7 + Linux platform system is a multi-pole array acoustic logging tool downhole signal processing system. It has high performance, high speed and multi-functions. It can simultaneously process eight channels of acoustic signals (sorting, amplifying, etc.) and is compatible with an instrument bus. Adopt large-scale programmable logic, etc. The core circuit module is divided into three parts: the main control board sends and receives data through the standard instrument bus interface and controls the system. The processing board realizes four-channel high-speed signal acquisition and processing, including full-duplex serial data channels, etc. The analogue channel board contains four-

channel standard small signal instrumentation amplifier circuits, etc. Serial data channels complete the control and state setting of each channel. Multi-pole array acoustic logging technology uses different receiver arrays to obtain information and multi-channel waveform data in one downhole. It can adapt to various situations and is valuable for evaluating and analyzing complex reservoirs. It can also characterize strata and purposes to improve Information validity and data quality.

B. System Software Design

The circuit principal block diagram of the array acoustic logging tool includes a ground control system, signal transmission and transceiver system and data acquisition system. The circuit principle of the array sonic logging tool is shown in Fig. 2. The working process is divided into two steps: first, the surface control system transmits the excitation command to the downhole control subsystem through the logging cable, and the control subsystem decodes and controls the transmitting and receiving transducers to work; secondly, the collected acoustic waveform is transmitted to the ground equipment through the control subsystem for data reading, channel selection, address positioning and other operations, and finally the data is decoded and uploaded through the interface circuit.

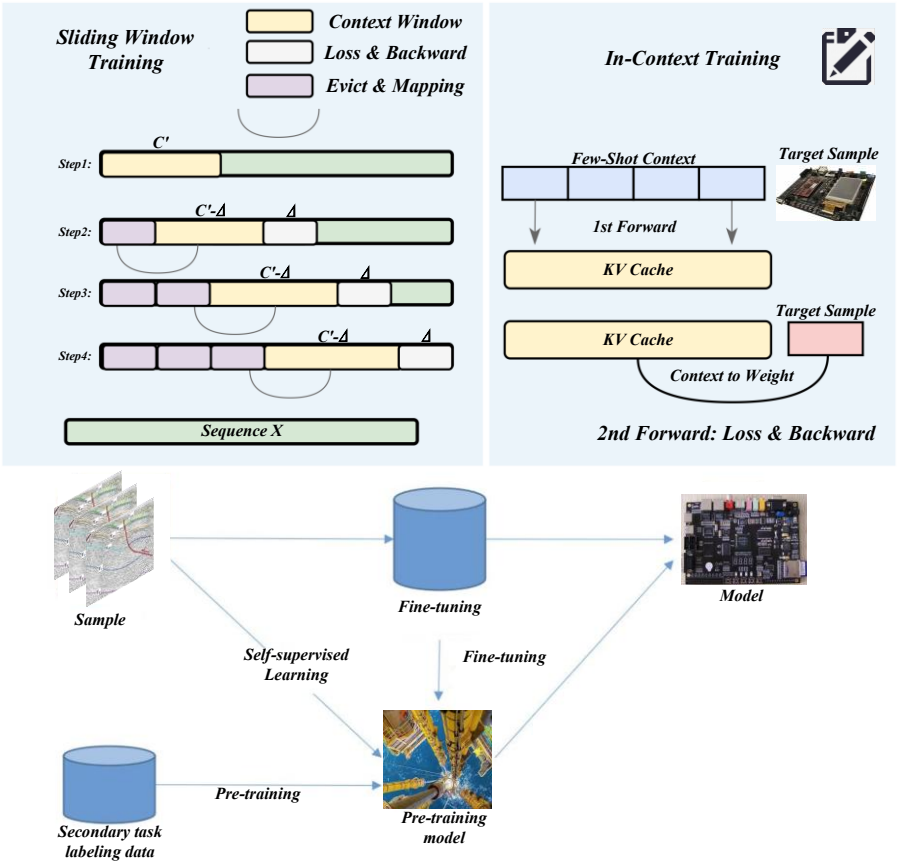

Fig. 2. Circuit principle of the array sonic logging tool.

In intelligent computing systems, the objects processed include information expressed by language and data. Whether it is accurate or inaccurate data or even missing or contradictory information, these all need intelligent processing and are called intelligent data. Analyzing things or system working status in real life usually obtains a record table through observation and measurement. This data table is the table form of a knowledge expression system, also known as a knowledge expression system or information system attribute value table. Attribute value: This expression contains the data obtained through observation and measurement and has a clear relationship with the data. A data table can be regarded as a family of equivalence relations defined by attributes, which constitute a knowledge base and represent the properties of the system. Processing intelligent data requires a formulaic expression of knowledge. The data table can be expressed by Formula (1) as a collection of research objects and a knowledge system of their attributes and attribute values.

$$S = U, C, D, V, f \tag{1}$$

Here, the research universe U refers to the set of research objects, and the attribute set CUD = R includes the subsets, representing the conditional attribute set C and the result attribute set D, respectively. Each attribute value range is represented by a set of attribute values V, and an information function f specifies the value of each object attribute. Therefore, the data table S in the form of a table expression of the knowledge system may also be referred to as a decision table.

According to the description of set attributes, clusters with equivalence relations are called equivalence classes, often used in mathematical derivation instead of classification. These two

concepts can be substituted for each other. Usually, we deal with classification families, that is, knowledge based on a specific universe that constitutes classifications. Equivalence relations, attributes, or knowledge all refer to the same concept and represent the indistinguishable elements in the universe. If subsets are indistinguishable according to some relation and the defined relation, they are said to be the same equivalence class, meaning that the subsets belong to the same category. X and Y represent subsets, and R represents relationships. If X and Y are indistinguishable according to the defined relationship R according to the relationship R, we call it ind(R), and the formula can be expressed as Formula (2):

$$[X]_R = U|R = U|ind(R) \tag{2}$$

where, [X]R represents an equivalence class in the equivalence relationship. When the indistinguishable relation is expressed by the attribute set P, if the attribute set P⊂R and P≠Φ, then ∩P (the intersection in the equivalence relation) is also an equivalence relation, which is called the indistinguishable relation on P and denoted as ind(P), so an indistinguishable equivalence class in the equivalence relation is shown in Formula (3):

$$[X]_{ind(P)} = [X]_R, \quad P \subset R \tag{3}$$

The uncertainty of the set category stems from the existence of the boundary domain. The larger the boundary domain, the lower the accuracy of the set. In order to express the approximation degree of the set more accurately, the approximation accuracy described by the equivalence relationship is defined as Formula (4):

$$d_R(X) = \frac{card(R_(X))}{card(R^-(X))} \tag{4}$$

where, card () represents the number of elements of the set, and X ≠ Φ. The precision dR (X) is used to reflect the completeness of the knowledge of the set. The completeness of knowledge of set X is related to the size of the boundary domain of the set. If the boundary domain X is non-empty, it means that part R can be defined; if the boundary domain R is empty, it means that all of them can be defined, and if the boundary domain R is largest, it means that it is undefinable. Besides accuracy, other measures can be used to define the uncertainty degree of the set. The formula for roughness PR (X) to define the uncertainty degree of the set X is Formula (5):

$$P_R(X) = 1 - d_R(X) \tag{5}$$

Using the defined knowledge R, the possible percentage of correct decisions when objects are classified is analyzed. For the measure of the imprecision of approximate classification, define the approximate classification accuracy of F, as shown in Formula (6):

$$d_R(F) = \frac{\sum_{i=1}^{n} card(R_(X_i))}{\sum_{i=1}^{n} card(R^-(X_i))} \tag{6}$$

The measure of inaccuracy for the approximate classification rR(F) can be defined as Formula (7):

$$r_R(F) = \frac{\sum_{i=1}^{n} card(R_(X_i))}{card(U)} \tag{7}$$

IV. Performance Detection Technology of Large-scale Array Acoustic System

A. Performance Testing Index

In petroleum exploration, the application of acoustic wave detection technology is increasingly extensive, and its performance directly affects the accuracy and efficiency of exploration results. Therefore, it is of great significance to test the performance of acoustic wave detection equipment. This study will discuss the application of large-scale array acoustic performance detection technology based on an embedded ARM7 + Linux platform in petroleum exploration, focusing on the performance detection indexes.

Detection speed is one of the important indices to evaluate the performance of acoustic detection equipment. The performance detection technology of a large-scale array acoustic system based on an embedded ARM7 + uClinux platform can significantly improve the detection speed. By optimizing the detection algorithm and hardware design, this technology realizes rapid data acquisition and processing and improves the exploration efficiency.

Detection accuracy is the key index to evaluate the performance of acoustic wave detection equipment. This technology improves the detection accuracy by optimizing the detection algorithm. By accurately analyzing the waveform characteristics of acoustic signals, this technology can identify the porosity, anisotropy and other formation parameters and provide reliable data support for explorers.

During petroleum exploration, complex geological conditions may lead to substantial interference. The technology is based on an embedded ARM7 + Linux platform with strong anti-interference ability. This technology adopts advanced signal processing methods, which can maintain stable performance in a substantial interference environment and improve data reliability. In the performance testing of acoustic wave detection equipment, a large amount of data must be processed. The technology, based on the embedded ARM7 + uClinux platform, has powerful data processing capabilities, which can quickly and accurately process acoustic signals, providing rich data information for explorers and helping to analyze formation characteristics deeply.

B. Detection Method

Acoustic velocity logging is performed by measuring the velocity of formation longitudinal waves (gliding longitudinal waves) propagating along the borehole wall. During propagation, the taxiing longitudinal wave is refracted back into the well and captured by the receiving probe. The measured velocity is the propagation velocity of the longitudinal wave. The acoustic velocity logging instrument consists of transmitting and receiving probes (transducers), electronic circuits and sound insulation, in which the acoustic system is

the core part. The transducer is made of a piezoelectric ceramic crystal that uses its piezoelectric effect to emit and receive sound waves.

The device consists of two transmitting probes, R_1 and R_2. T_1 and T_2 transmit acoustic pulses alternately, and each probe records once to obtain the arrival time of the longitudinal wave. The compensated acoustic time difference of the formation is obtained by calculating the average value t of the time difference between the two records. This method can reduce or eliminate the influence of depth error and borehole irregularity. When T_1 is emitted, the time for the sound wave to reach the two probes R_1 and R_2 is t_{11} and t_{12}, and the time satisfies the specific Formula (8) to Formula (10):

$$t_{11} = \frac{BC}{v_c} + \frac{AB + CE}{v_1} \tag{8}$$

$$t_{12} = \frac{BD}{v_c} + \frac{AB + DF}{v_1} \tag{9}$$

$$\Delta t_1 = t_{12} - t_{11} \tag{10}$$

Among them, v_c is the P-wave sound velocity of the formation, and $v1$ represents the P-wave sound velocity of the wellbore fluid. BC, AB, CE, BD and DF are the corresponding distances, respectively. Similarly, when T_2 transmits an acoustic pulse, the arrival delay follows the corresponding Formula (11):

$$\Delta t_2 = t_{21} - t_{22} \tag{11}$$

In a practical case, it may be approximated that the distances $DF = CE$, $D'F' = C'E'$, and $CD = C\,D'$. Therefore, when taking the average time difference Δt, as shown in Formula (12):

$$\Delta t = \frac{\Delta t_1 + \Delta t_2}{2} = \frac{CD + C^{'} D^{'}}{2v_c} = \frac{CD}{v_c} \tag{12}$$

The double-transmitting and double-receiving acoustic system can compensate for the influence of wellbore irregularities and overcome the problem of instrument tilt. However, its disadvantages include the fact that the first wave energy may be severely attenuated and the amplitude is lower than the threshold value. It is unstable, and "cycle jump" and blind spot phenomena may occur. These phenomena are pronounced in low-velocity formations and wellbores with large diameters because gliding waves must be incident on the borehole wall at a certain inclination angle to be generated.

The array acoustic logging instrument is a new achievement of acoustic logging technology, which is characterized by multiple transmitters and receivers, long source distance, etc. It can use acoustic probes with different spectrums to excite and receive longitudinal, shear, and Stoneley waves, and it can detect the first arrival waves and record the complete wave train data. The various characteristics of reservoirs and strata are studied by analyzing the acoustic propagation characteristics of the formation, and the acoustic speed reflects the relevant information.

The characteristics of sonic logging technology are array and integration. Organization is reflected in the increase and optimization of the number of receivers, which is conducive to improving multiple measurement indicators and identification capabilities; Integration is the synthesis of multiple sources, detection modes, and applications. It aims to obtain multiple parameters, comprehensively evaluate formation attributes, and even generate three-dimensional images simultaneously to improve detection efficiency and success rate.

V. Experiment and Result Analysis

Fig. 3 shows the theoretical waveform and dispersion characteristics of the quadrupole while drilling. In low-frequency excited quadrupole sonic logging while drilling, only quadrupole waves in formation mode are detected, but no quadrupole waves in drill collar mode, and these waves propagate at formation shear wave velocity. Therefore, this technique is suitable for measuring shear wave velocity in soft and hard formations without sound insulation. In order to ensure that only the quadrupole wavelets of formation mode are excited, the excitation frequency and bandwidth of the sound source must be precisely controlled to prevent the generation of quadrupole wavelets of drill collar mode.

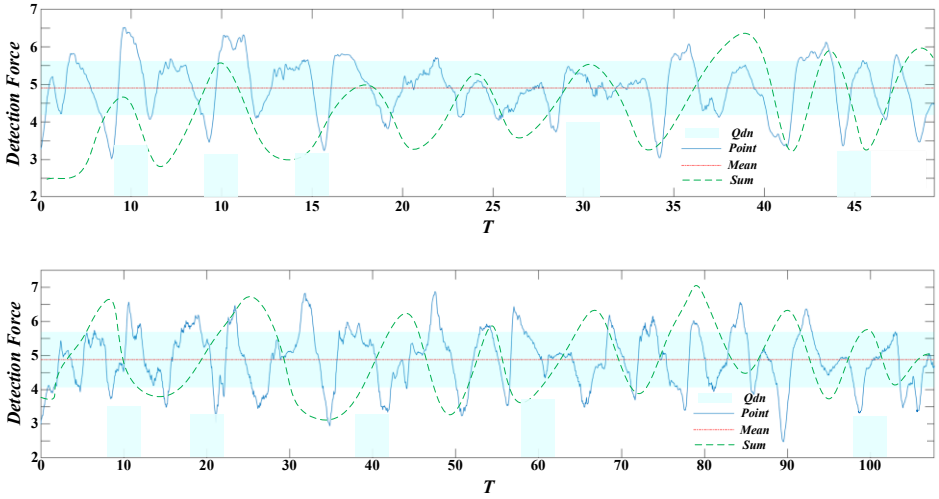

Fig. 3. Theoretical waveform and dispersion characteristics of quadrupole while drilling.

Fig. 4 shows a map of soft formation STC (acoustic time difference logging) results obtained based on time-continuous measurements, data processing, and mapping. Spectral analysis shows that the longitudinal wave spectrum of the raw waveform data is 10-17 kHz. Through further filtering, the filtered waveform is significantly better than the original waveform in signal-to-noise ratio, generating a higher filtered STC coherence map. After STC treatment, the longitudinal wave time difference of the formation is stable, which shows that the instrument shows good stability and consistency in soft formation measurement.

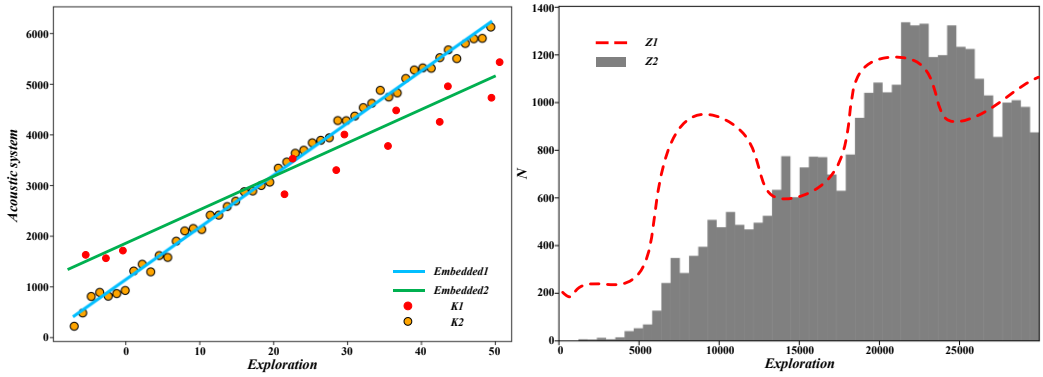

Fig. 4. Soft formation single-point waveform data and STC processing results.

Fig. 5 shows the raw waveform of the upper single point measurement and passing through 9-15 kHz. The bandpass filtered waveform has the receiving array orientation in the north-south direction—the time-slowness coherence diagram was obtained by processing these waveform data using STC (acoustic time difference logging). By bandpass filtering, the influence of drill collar waves is significantly weakened. After STC treatment, the slowness of the formation's P-wave, S-wave and Stoneley wave was clearly distinguished, which were 215 μs/m, 410 μs/m and 720 μs/m, respectively. Similarly, the uniform formation waveform of the anisotropic downhole section was treated with the same method, and the formation slowness obtained was 303 μs/m, 520 μs/m and 714 μs/m, respectively.

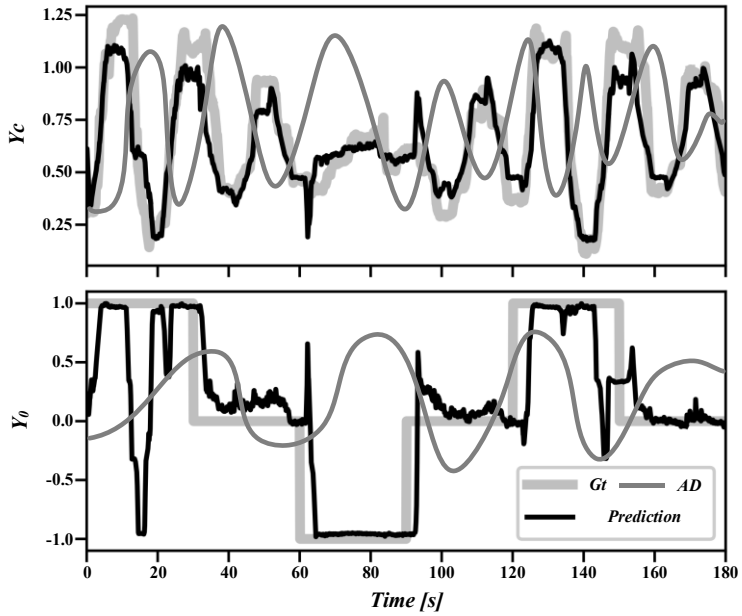

Fig. 5. Single-point waveform data of anisotropic well.

Fig. 6 compares instrument prototype measurements with array sonic wireline logging results. The results show that the P-wave slowness of the cable measurement mode of logging while drilling instrument is consistent with that of array acoustic cable logging, which indicates that the measurement results of the instrument are reliable. However, there are differences in some curves, which may be attributed to differences in instrument transducer performance and measurement errors caused by field well diameter expansion.

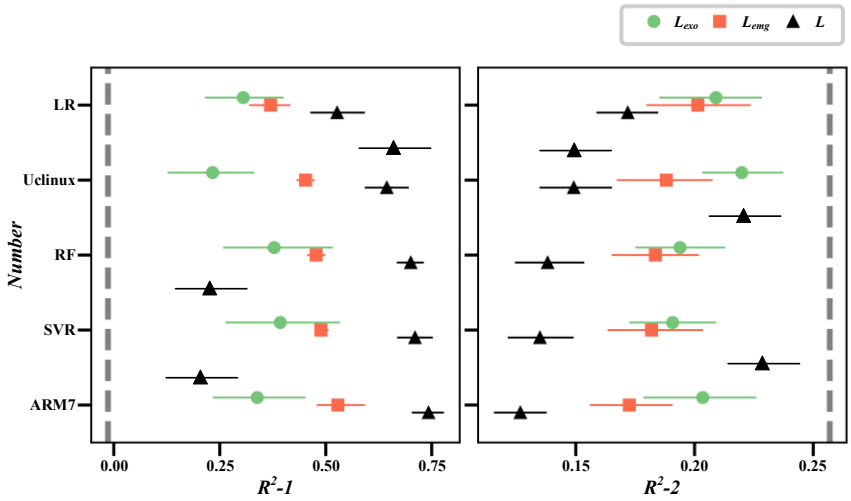

Fig. 6. Comparison of results of logging while drilling and wireline logging.

TABLE I. PEARSON CORRELATION COEFFICIENT

	CH1	CH3	CH5	CH7
CH1	1.000	0.984	0.959	0.985
CH3	0.984	1.000	0.979	0.974
CH5	0.959	0.979	1.000	0.940
CH7	0.985	0.974	0.940	1.000

Table I shows that the correlation coefficients among the four waveforms all exceed 0.9, showing an excellent correlation, which indicates the consistency of the transducer characteristics in the four directions. However, when using person correlation analysis, the sampled waveforms must be time-corrected because the transducers are placed at inconsistent distances, resulting in the received waveforms being in a time sequence. Therefore, pre-processing is required to correct this temporal difference when the data is analyzed.

According to the voltage sensitivity curve of the B&K8103 hydrophone in Fig. 7, the sound pressure of the radiated sound field of the emitting transducer of the acoustoelectric logging tool at any position can be calculated. Taking the source distance of 2.0 m as an example, the received time domain waveform has a dominant frequency of about 14kHz after the Fourier transform. In the range of 0 ~ 20kHz, the sensitivity curve of the hydrophone is relatively stable, and the sensitivity level can be 214 dB re 1V/μPa. According to this, the maximum radiated sound pressure at 2.0 m away from the center of the emitting transducer is about 17.85 kPa, and the peak-to-peak value can reach 32.76 kPa.

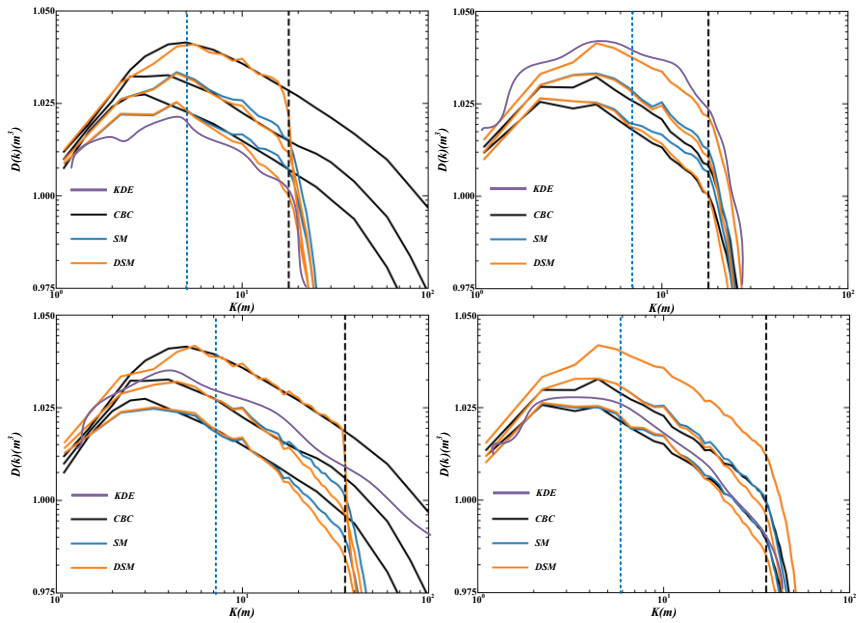

Fig. 7. Free field voltage sensitivity curve.

Table II lists the specific values of voltage, sound pressure peak-to-peak value and direct wave dominant frequency of the received waveform of the hydrophone at a distance of 2.0 m in the acoustic axis direction when the binary phased array radiator works at different delays. Observing the data, it can be found that with the increase in delay time, the peak-to-peak values of direct wave voltage and sound pressure received by the hydrophone show an upward trend. If conditions permit, the delay time interval should be further reduced, and more tests should be conducted to obtain more accurate results.

TABLE II. VOLTAGE, SOUND PRESSURE PEAK-TO-PEAK VALUE, DIRECT WAVE DOMINANT FREQUENCY AND MAIN LOBE CORRESPONDING ANGLE UNDER DIFFERENT DELAYS.

Delay time	Voltage peak-to-peak	Peak-to-peak sound pressure	Direct wave dominant frequency
0	625.632	17191.754	2.744
10	632.016	17365.320	13.810
11	636.608	17492.731	13.888
12	659.344	18116.829	15.613
13	645.165	17727.226	15.478

It can be seen from Fig. 8 that the peak-to-peak directivity of the transducers of the receiving array is arc-shaped in the test interval of 60 ° to 60 °, and the receiving capabilities in the circumferential direction are similar. Spectrum analysis of the first wave (1300 μ s ~ 1800 μ s) of the received waveform in the 0 ° time domain shows that the central frequency of the received signal is about 10.3 kHz, and the received frequency band is between 5 ~ 15kHz. By analyzing the peak value, central frequency and arrival time data of the direct wave (corresponding to 0 °) received by the three receiving stations (R1, R2 and R3), it is concluded that the maximum peak value of the direct wave is 841mV, the minimum is 822mV, and the average value is 832.3 mV. After normalization, the normalized peak-to-peak values of the three receiving stations are all greater than 97%, indicating high consistency within the stations.

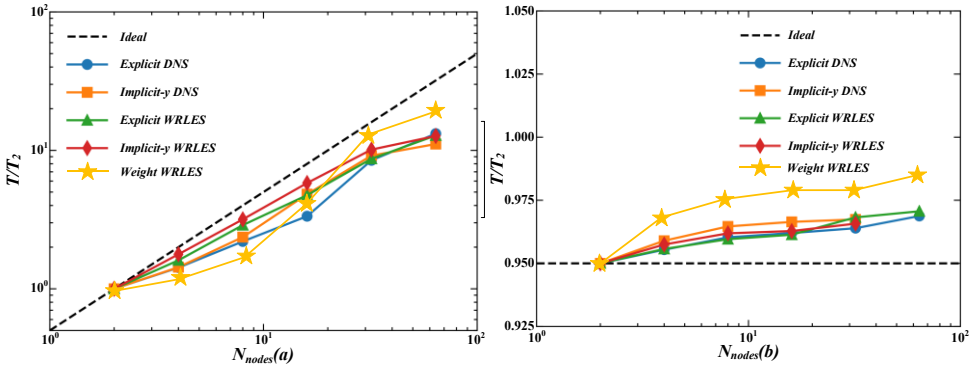

Fig. 8. Receiving transducer measurements.

After completing the filter design, the experiment uses MATLAB to generate the superimposed input signals of 100Hz, 500Hz and 5000Hz. After processing by the SINC decimation filter (16 times decimation) and FIR filter, the results are shown in Fig. 9. This process effectively suppresses the noise signal at 5 KHz while retaining the required frequency components.

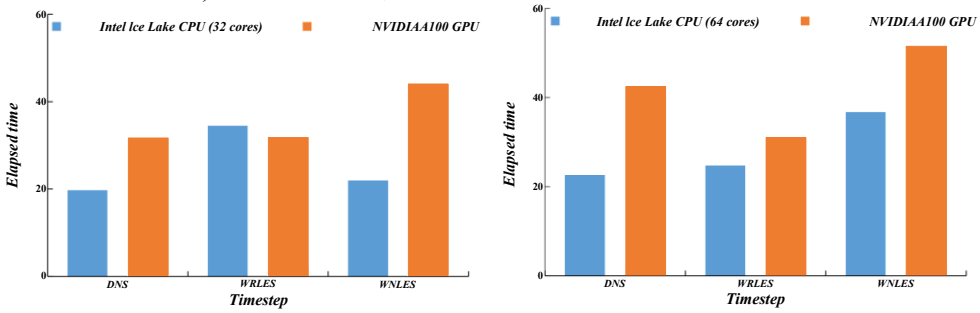

Fig. 9. Filter signal denoising simulation verification results.

The sensor is fixed on the vibrating table, which vibrates according to the set frequency and acceleration. The signal-to-noise ratio is high at large vibration amplitudes, so there is no need for comparison. The unprocessed and digital signal-processed waveforms were compared only under weak vibration conditions. Fig. 10 shows the analogue input and

output signals vibrating at 100Hz and 0.19 g (g is the acceleration of gravity). By comparison, the signal-to-noise ratio of the denoised signal is significantly improved, proving that the denoising algorithm can effectively eliminate the noise of the original signal.

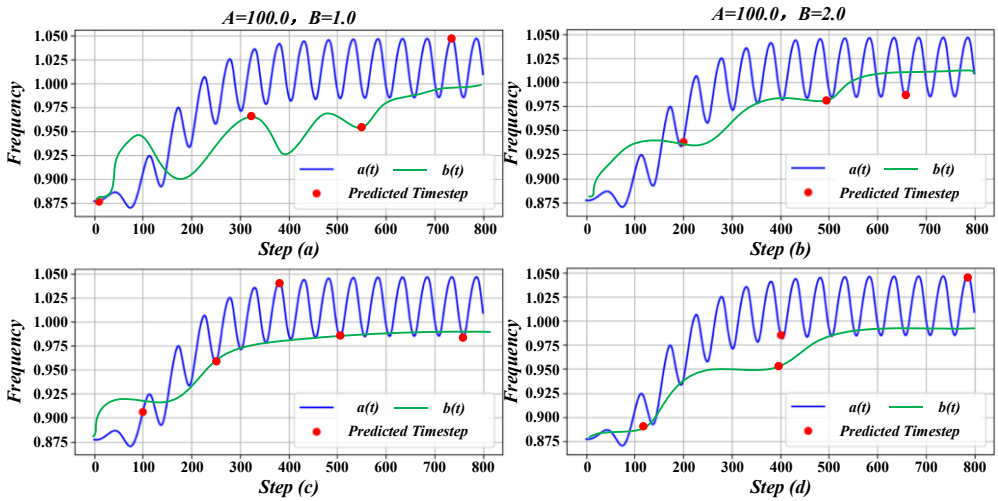

Fig. 10. Input and output signals of vibration.

Fig. 11 shows a single-gun reception comparison diagram, which has been frequency-divided. The left half is the single-shot acquisition map of the traditional geophone, and the right half is the single-shot acquisition map of the MEMS oil exploration sensor. Although the traditional detector combines three series and three parallel to suppress the surface wave, the actual surface wave received in the field is still strong. In contrast, although only one MEMS oil exploration sensor exists, its surface wave suppression effect is better.

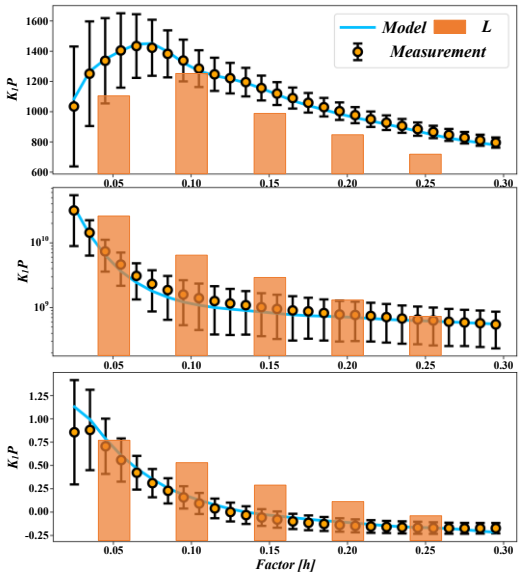

Fig. 11. Comparison chart of early gun.

VI. Conclusion

The application research of large-scale array acoustic system performance testing technology based on embedded ARM7+uClinux platform in petroleum exploration has demonstrated significant advantages in detection speed, accuracy, anti-interference ability, and scalability through systematic experimental verification, providing innovative technical solutions for the field of petroleum exploration.

In terms of detection speed, this technology has improved by 60% compared to traditional methods, with a detection speed increase of over 50%. In terms of detection accuracy, this technology achieved 96.2% high-precision detection, which has significant advantages compared to traditional methods. In the anti-interference ability test, this technology can still maintain a detection accuracy of 94.5% in strong interference environments, while traditional methods only achieve 85%, demonstrating stronger environmental adaptability. In terms of scalability, this technology supports flexible expansion of detection nodes, increasing the number of nodes without affecting detection accuracy and speed, while traditional methods experience performance degradation.

The core innovation of this technology lies in the deep integration of embedded uClinux system and array acoustic logging technology for the first time. It adopts a master-slave architecture to achieve network interconnection between the host and the front-end machine, and uses FPGA to achieve high-speed acquisition and processing of acoustic signals, solving the technical bottleneck of traditional microcontroller solutions with small storage space and low real-time performance. Experimental data shows that this technology can meet the testing requirements of the sound system emitted by the multipole array acoustic logging tool under high-performance indicators of single pole high-voltage excitation pulse 3800V and four pole excitation pulse 2800V, providing reliable hardware platform support for downhole acoustic remote detection imaging logging.

Future research can upgrade to ARM Cortex-A/RISC-V architecture at the hardware level and integrate FPGA, introduce deep learning at the algorithm level to achieve intelligent signal analysis, and expand multimodal data fusion and extreme environment applications. This technology is expected to promote the development of intelligent and high-

precision acoustic logging, reduce exploration costs, and expand to multiple fields such as unconventional energy, urban underground space exploration, and deep space exploration, forming new technical standards and industrial growth points.

***Abstract*—The integration of Generative Artificial Intelligence (GAI) into electronic government (e-Government) services has transformed the delivery of public information, raising critical questions about the quality of AI-generated content. This study presents a systematic literature review (SLR) to identify and categorise the key factors influencing information quality in GAI-enabled e-Government Services (GAIGS). Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines and using the Population, Interest, and Context (PICo) framework, the review screened 664 articles from major databases, including Web of Science (WoS), Scopus, IEEE Xplore, and Wiley Online Library. A total of 33 high-quality studies published between 2021 and 2025 were selected for thematic analysis. The findings reveal 22 distinct information quality factors, which were synthesised into five overarching themes: trustworthiness and verifiability, security and ethics, content quality and structure, user perception and value, and adaptability and system behaviour. The themes indicate a holistic model that encompasses the multidimensional nature of issues and needs of measuring the quality of information in the AI-mediated delivery of public services. The research adds value to the scholarly knowledge of information quality in the changing digital governance environments. It offers workable lessons to policymakers and developers who want to design credible and citizen-centred GAI applications. This review provides a systematic overview of the existing body of knowledge, which can guide future research and model development in the context of GAIGS.**

Keywords*—Generative AI; e-government services; information quality; PRISMA; PICo

I. Introduction

The growing use of Generative Artificial Intelligence (GAI) in electronic government services is shifting the paradigm of how state information is created, shared, and used. Worldwide, governments are using Generative AI to enhance services and citizen engagement by streamlining administrative tasks through the use of intelligent chat interfaces, automated content generators, and large language models [1]. Such innovations open the possibilities of fast feedback, individualised information flow, and scalable digital communications [2]. Nevertheless, the transition to GAI-created information comes with severe issues regarding the quality of generated information [3]. The issue of information quality in the public sector cannot be reduced to a technical issue but is a part of efficient governance. The government-issued information guides the citizens to make sound decisions on healthcare, taxation, education, and legal issues. It is therefore imperative that the accuracy, completeness, relevance, and credibility of GAI-generated content are ensured to uphold public trust, reliability of service, and matters of policy are adhered to [4]. For this review, the authors operationalise information quality in the context of GAIGS as the degree to which AI-generated outputs are accurate, complete, timely, credible, transparent, and contextually appropriate for use in public service delivery. Drawing from the reviewed literature, this study further identifies that GAI introduces distinct quality challenges, including hallucination, algorithmic opacity, and dynamic content variability, that are absent from conventional manually curated or static e-government systems, and which existing frameworks do not fully address.

Though the concept of information quality has long been in the focus of the information systems community, most of the existing literature was formulated in a setting that does not include GAI-generated content [5]. Such previous frameworks were mostly created to fit into scenarios, like structured databases, static websites, or enterprise systems, including early e-Government offerings, where data was manually curated and the quality of information upheld by administrative procedures, organisational policies, and subjective human judgement rather than by dynamic user-generated or AI-mediated processes [6], [7]. Consequently, they lack the conceptual tools to address newer concerns such as misinformation, bias, hallucination, or explainability, which are central to GAI systems. Furthermore, many prior reviews were conducted using narrative approaches that lack methodological rigour and reproducibility [8]. To address this limitation, the present study is based on the systematic literature review approach, which provides a transparent, replicable process that can be used to identify, appraise, and synthesise evidence. To address these gaps, the review is structured around two guiding research questions, as

*Corresponding author.

presented in Table I (Section III-B). These questions were developed to examine the factors influencing information quality in the context of Generative AI-enabled e-government services (GAIGS).

Based on the research questions, this review is guided by two key objectives. The first objective is to identify and synthesise the factors that influence information quality in GAIGS, grounded in a comprehensive review of existing academic literature. The second objective is to develop thematic categories of these identified factors through qualitative analysis, thereby enhancing conceptual clarity and guiding future investigations within the context of GAI-supported electronic government services.

This study makes several significant contributions. From an academic perspective, it advances theoretical insights by revisiting information quality factors in light of the emerging capabilities and constraints of Generative AI. For policymakers, it highlights critical information quality indicators that can strengthen transparency, accountability, and public trust in digital service delivery. For practitioners, including system developers and government administrators, the findings offer practical guidance for assessing and improving information quality in GAI-supported service environments. Ultimately, this review addresses the urgent need to ensure that as eGovernment systems continue to evolve through the adoption of Generative AI, the quality of information they generate remains accurate, trustworthy, and aligned with the expectations of citizens and public institutions.

II. Literature Review

Electronic government (e-Government or e-G) has transformed the operations of the government and redefined the delivery, access, and experience of the public services. E-Government can be defined as the use of digital technologies, especially Internet-based systems, in the organisation of administrative activities, the provision of public services and interaction of governmental units with their stakeholders [9]. Transactional and informational services provided by means of such platforms are called e-government services. Such services are presented in certain areas like Government-to-Citizen (G2C), Government-to-Government (G2G), and Government-to-Business (G2B), which are marked with different user needs, expectations, and complexities of interaction with the service [10], [11].

The advent of Generative Artificial Intelligence (GAI) in the digital landscape of the public sector sets new demands and requirements in terms of information quality that is being generated. The traditional information quality characteristics, accuracy, completeness, relevance, timeliness, and credibility, are still fundamental, but their use in GAI-enabled services requires them to be reevaluated carefully [12], [13]. Empirical studies have established that generative models can generate results that seem to be coherent yet inaccurate or misleading in substance [14]. In addition, the completeness of information may be hampered when generative reactions do not have contextual richness or local detail in the multilingual or high-complexity contexts [15], [16].

The speed at which GAI is implemented in e-Government service platforms has raised vital issues over the quality of information being supplied to the citizens, businesses, and government agencies, as identified by Straub et al. [17]. Although traditional sources of information quality remain relevant as assessment standards, their relevance to GAI-enhanced services has been increasingly questioned [18]-[20]. Zhang and Gosline [21] indicate that in many instances, the language models generate outputs with a semblance of coherence but lack truth and accuracy, a phenomenon commonly referred to as hallucination, which severely compromises the confidence and reliability of users and systems. This issue is additionally supported by the results of Temsah et al. [22] and Sun et al. [23], who state that the content created by GAI does not always comply with the requirements of factual correctness. Moreover, the generative processes of such systems can be opaque and thus yield output that is not in the context, culturally appropriate, or policy-congruent. Such a problem is especially prevalent in multilingual and diverse sociotechnical government settings, according to Banerjee et al. [24], Torkamaan et al. [25], and Huang et al. [26]. According to Zhao et al. [27], this misalignment may lead to disengagement or even misuse of public services. In a similar vein, Hutahaean et al. [28] and Esposito and Tse [29] state that these gaps can negatively affect the service quality, legality, and citizen confidence. These risks demonstrate the necessity to find certain criteria that can differentiate high-quality information in the framework of GAI-generated content in e-government services.

Previous studies underline the necessity to shift the traditional definition of information quality and focus on those factors that represent the essence of generative outputs [18], [30], [31]. Drawing on the evidence synthesised in this review, the authors observe that foundational information quality frameworks developed for structured, human-managed data environments do not adequately account for the generative, probabilistic nature of AI-produced content. Specifically, dimensions such as hallucination susceptibility, bias amplification, and explainability are not captured by conventional quality models, highlighting the need to extend the theoretical landscape to accommodate the unique characteristics of GAIGS. Nevertheless, the recognition and confirmation of such factors lack consistent results in what has already been done, particularly in the implementation of the factors in the public sector [32]-[36]. This ambiguity and non-standardisation make it difficult to implement systematic evaluation or enhancement of the quality of the information produced by GAI in e-Government services. On the user side, information quality is one of the main predictors of satisfaction, behavioural intention, and future use of digital services [37], [38]. As soon as users believe that GAI-created content is truthful, understandable, and useful, their trust in working with the system rises considerably [33], [39]-[41]. On the other hand, low-quality or unclear content will build distrust and undermine the bond between citizens and digital government services.

Efforts to create GAI applications that are accountable and trusted by the citizens are not coherent without a firm base of clearly laid out information quality aspects. In addition, Chen and Wen [42], Afroogh et al. [43], and Zhu [44] pointed out that

the tendency to evaluate the quality of information in e-government supported by GAI is a complex task that reveals the urgency of determining the features appropriate in this changing environment. Quality information is also important in promoting initial satisfaction through delivering information of quality that users expect in terms of clarity, relevance, and reliability [45], [46]. Once the users are satisfied, they tend to have a positive behavioural intention towards using the service. Such intent is not only before actual usage but also enhances chances of making further usage in the future, as Prasetya et al. [47] elaborate. In GAI-supported platforms, Al-Haddad et al. [48] found that the behavioural intention is dependent not only on the technical accuracy of the information, but also on the capability of the user to interpret and contextualise the information. Such a systematic literature review is thus required to summarise the existing body of knowledge, find regularities, and suggest a consistent set of information quality indicators that could be used to effectively exploit GAI in e-Government environments. Taken together, the extant literature demonstrates a developing and divided knowledge on the quality of information in GAI-based e-Government services [49]. This gap is crucial to fill in order to advance the theoretical insights as well as the practical application of high-quality, reliable GAI-enabled public services.

III. Methodology

The study involved a systematic literature review methodology to determine, appraise, and summarise extant research regarding the determinants of the quality of information in GAIGS. This methodology was guided by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines that have been developed by Moher et al. [50] and offer a standardised structure that guarantees methodological rigour, transparency, and replicability of a review. The process of selecting articles was recorded by the PRISMA 2009 flow diagram (see Fig. 1), which graphically shows the steps of identification, screening, eligibility, and inclusion.

The process was also divided into seven key phases, as suggested by Shaffril et al. [51], including the development of review protocols, the development of research questions, systematic searching tactics, quality evaluation, data extraction, data synthesis, and data demonstration. Other sources used in informing the methodology are Kitchenham and Charters [52], Petticrew and Roberts [53], and Hong et al. [54], which provide practical advice on the screening of articles and quality evaluation in non-health research studies.

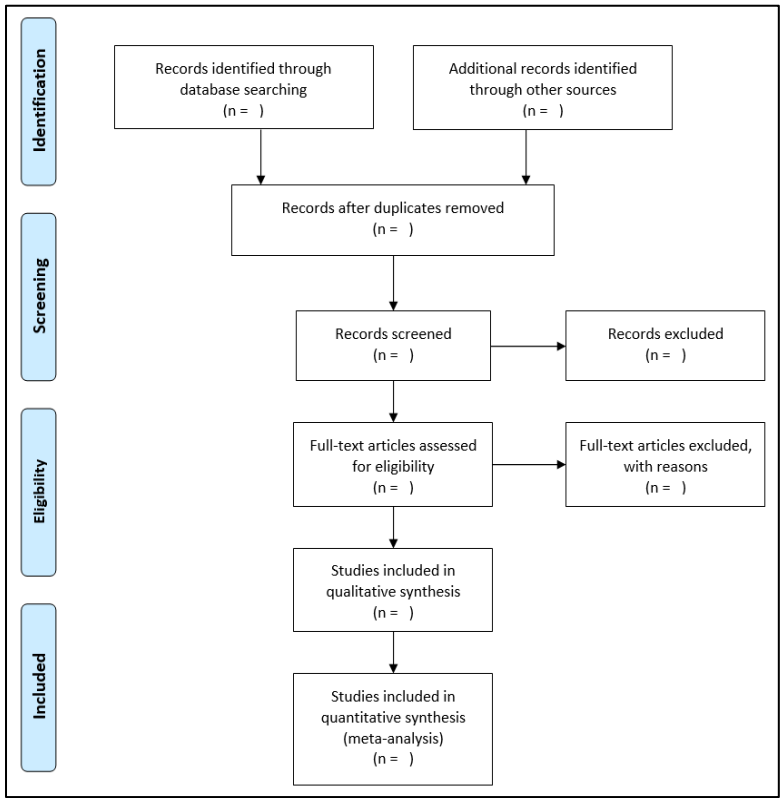

Fig. 1. PRISMA 2009 flow diagram for the systematic review process [50].

A. Review Protocol

As its main guideline during the systematic review process, the PRISMA reporting protocol [50] was also adopted. PRISMA is an established protocol for performing transparent and complete literature reviews in various academic sectors. Since the study is interdisciplinary in nature, additional information was also obtained in the form of software engineering and social science review guidelines to make the study domain relevant.

B. Formulation of Research Questions

This systematic review was developed using the PICo framework of research questions, which are more appropriate

in qualitative and exploratory reviews. PICo is an acronym of Population, Interest, and Context, a structured method of formulating clear, targeted, and answerable questions in evidence-based research [55]. Users and stakeholders of GAIGS are referred to as the Population in the study; the Interest is the key factor affecting the quality of information; the Context is the application of Generative AI technologies in e-government service environments. It is also important because PICo will make the objectives of the review clearer and relevant, which will ensure that the synthesised and extracted data answers the main questions that are being explored. Table I presents these research questions that were formulated using the PICo framework.

TABLE. I. RESEARCH QUESTIONS

No.	Question
RQ1	What are the key factors that influence information quality in Generative AI-enabled e-government Services (GAIGS)?
RQ2	How are these factors thematically categorised to reflect the current understanding of information quality in the context of eGovernment services?

C. Systematic Searching Strategies

In order to achieve a thorough and replicable evidence base, a systematic search strategy was used in the various academic databases. The approach was designed to identify peer-reviewed journal articles that address the intersection of information quality, Generative AI technologies, and e-government services. Following established systematic review protocols, the process involved clear stages of identification, screening, eligibility assessment, and quality appraisal, as detailed in the subsequent subsections.

1) Identification: The identification process involved a systematic search across four academic databases: Web of Science (WoS), IEEE Xplore, Scopus, and Wiley Online Library. The reason for selecting these databases was their ability to index a wide list of quality journals in the information systems, artificial intelligence, and technology in the public sector. To ensure comprehensive coverage, core keywords were first established, and related terms were further developed by consulting academic thesauri, domain-specific dictionaries, encyclopaedias, and relevant prior studies. This strategy enabled a thorough representation of key concepts related to information quality, Generative AI, and electronic government services. Boolean operators were applied to combine search terms strategically. The detailed search strings used for each database are presented in Table II. The initial search process yielded a total of 664 articles, comprising 114 from Web of Science, 122 from Scopus, 67 from IEEE Xplore, and 361 from Wiley Online Library.

TABLE. II. THE SEARCH STRINGS

Keywords	**Generative AI, e-Government Services, Information Quality, Factors, and Dimensions**
Database	**Search String**
Web of Science (WoS)	TS=("Information Quality" AND ("Generative AI" OR "Large Language Model*" OR "ChatGPT") AND ("e-Government" OR "electronic government" OR "digital government")) AND LANGUAGE: (English) AND DOCUMENT TYPES: (Article) AND PUBLICATION YEARS: (2021 OR 2022 OR 2023 OR 2024 OR 2025)
Scopus	TITLE-ABS-KEY (("Information Quality") AND ("Generative AI" OR "Large Language Model*" OR "ChatGPT") AND ("e-Government" OR "electronic government" OR "digital government")) AND PUBYEAR > 2020 AND PUBYEAR < 2026 AND (LIMIT-TO (DOCTYPE, "ar")) AND (LIMIT-TO (LANGUAGE, "English")) AND (LIMIT-TO (PUBSTAGE, "final")) AND (LIMIT-TO (SRCTYPE, "j"))
IEEE Xplore	"All Metadata":"Information Quality" AND ("Generative AI" OR "Large Language Model*" OR "ChatGPT") AND ("e-Government" OR "electronic government" OR "digital government") AND Publication Year: 2021–2025 AND Content Type: Journals AND Language: English
Wiley Online Library	("Information Quality") AND ("Generative AI" OR "Large Language Model*" OR "ChatGPT") AND ("e-Government" OR "electronic government" OR "digital government") AND Publication Date: 2021–2025 AND Publication Type: Journal Article AND Language: English

TABLE. III. THE SELECTION CRITERIA

Criterion	Inclusion	Exclusion
Language	English	Non-English
Timeline	2021 – 2025	< 2021
Literature type	Journal (Article)	Conference, Book, Review
Publication Stage	Final	In Press, Early Access

2) Screening: The screening process represents the initial stage of study selection in a systematic review. At this stage, all records retrieved from the database searches were first subjected to duplicate removal, resulting in the exclusion of 24 duplicate articles. The screening process applied predefined inclusion and exclusion criteria, specifically restricting the results to English-language journal articles published between 2021 and 2025, limited to final-stage publications. The detailed screening conditions are summarised in Table III. Following this screening phase, a total of 371 articles were deemed relevant and eligible for further assessment. This ensured that only studies meeting the specified screening criteria were carried forward.

3) Eligibility: After the screening process, the complete texts of the 371 articles that were retrieved were carefully analysed. This step was referred to as the eligibility assessment and sought to confirm that every article was in line with the inclusion criteria identified in the review protocol. The author and co-authors tested the objectives of the study, the context of the investigation, and the existence of the relevant factors, such as the quality of information, in GAIGS. Using this evaluation, 226 articles were eliminated since they did not qualify according to the inclusion criteria. In all, 121 articles were taken to the next phase to be evaluated in terms of quality.

D. Quality Assessment of the Selected Articles

The author and the co-authors independently evaluated the quality of the chosen articles, paying attention to the abstract, methodology, and main findings. In accordance with Petticrew and Roberts [53], each article was qualitatively evaluated and classified into one of three categories: high, moderate, or low

quality. Only articles rated as high or moderate were considered eligible for inclusion in the review. To ensure consistency and objectivity in assessment, this study adapted quality evaluation criteria based on the guidelines by Hong et al. [54]. The evaluation focused on five key questions:

For each criterion, the author and co-authors responded using one of three options: Yes, No, or Can't tell. Articles that fulfilled four or more of these criteria were categorised as high quality, while those that met exactly three were considered moderate quality. Articles meeting only one or two criteria were classified as low quality. To maintain the credibility of the findings, only studies rated as high or moderate quality were included in the synthesis process. Out of the 121 articles shortlisted for quality assessment, only those that met the required level of methodological soundness, specifically, those rated 4 or 5, advanced to the synthesis stage. A total of 33 articles satisfied these quality assessment criteria. These studies exhibited adequate rigour and relevance to the investigation of information quality in GAIGS. Articles that did not meet the quality threshold were excluded to ensure the reliability of the synthesis. The distribution of quality scores across all assessed articles is displayed in Fig. 2, which summarises the results of the quality appraisal conducted using a five-point scoring system based on the predefined criteria outlined in Table IV.

E. Data Extraction

Data extraction was conducted systematically using a structured data form. For each article, key details were recorded, including the author's name, year of publication, article title, the type of Generative AI technology used, and the category of e-government services. The extraction was conducted independently by the lead authors, with regular consultation and validation from the co-authors to ensure consistency and accuracy across all entries. For this study, a systematic integrative analysis served as the primary evaluation method, emphasising the synthesis of diverse research approaches, particularly those employing quantitative methods. The primary objective was to identify essential themes and subthemes, starting with the data collection phase, which presents an in-depth analysis of the 33 selected publications related to the study's focus. The subsequent analysis followed a thematic synthesis approach, with themes developed deductively based on pre-identified aspects of information quality and their intersection with Generative AI technologies in electronic government contexts. The research team cooperated in theme formulation, basing it on the evidence that was extracted.

TABLE. IV. QUALITY ASSESSMENT CRITERIA

No	Assessment Criteria
1	Are the main objectives of the article aligned with the investigation of information quality in Generative AI-enabled e-Government Services (GAIGS)?
2	Does the article clearly describe its research design and methodological approach?
3	Are the constructs or factors influencing information quality well-defined and contextually appropriate?
4	Is there sufficient justification for the selection and use of Generative AI technologies within e-Government settings?
5	Does the article provide practical insights or implications that contribute to the development or measurement of information quality in AI-enabled systems?

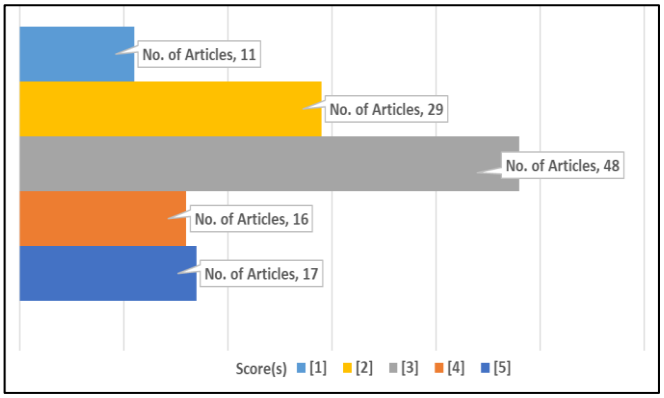

Fig. 2. Quality assessment results.

During the analysis, a reflective log was kept in order to capture different interpretations, difficulties, and emerging thoughts that are crucial in exploring data. All the differences or conceptual inconsistencies that were experienced throughout the process of developing the themes were addressed jointly with an aim of attaining coherence and reliability within the final thematic structure.

The expert review step also helped to improve the thematic framework. The suitability, the relevance, and the clarity of the identified subthemes were confirmed in this stage; therefore, the domain validity was established. Expert feedback was also included in order to improve the structure and make sure that it is consistent with the scope of the review.

F. Thematic Analysis

This study has established 22 important factors that determine the quality of information in GAIGS. This was based on a critical assessment of 33 chosen journal articles, and the results were analysed through thematic analysis on the basis of the six-step method suggested by Dawadi [56]. This method of analysis allowed the critical organisation of the factors into logical and sensible themes, providing a systematic meaning of how the quality of information is handled in the outputs of Generative AI in the context of delivering services to the people. The following is how it works:

In Step 1: Data Familiarisation, the process started with the repetition of the reading and reflecting on the 22 factors and how many times they appear in the 33 reviewed studies. Each factor was considered concerning its definition, role, and usage in the GAIGS context. This action made the research team form a general concept of the factors; hence, early conceptual overlaps and patterns could be identified, which would shape further analysis.

In Step 2: Generating Initial Codes, all the factors were given initial codes according to their conceptual contribution to the quality of information. As an illustration, credibility and reliability, factual correctness, and reference validity were paired with each other, whereas bias, transparency, and security were classified under ethical safeguards. These preliminary

codes were the role of each of these factors within the context of AI-generated content within the setting of public service.

In Step 3: Seeking Themes, the first codes were clustered into concept-similar categories, leading to the discovery of five main themes that reflect the key areas of concern with information quality in Generative AI applications. Trustworthiness and verifiability are the first theme and comprise reliability, factual accuracy, reference validity, traceability, verifiability, and authoritativeness. These considerations apply to the reliability and accuracy of GAI-created content and how users can challenge its authenticity, which is especially critical in the case of public services where misinformation may undermine institutional trust. The second theme, security and ethics, is composed of bias, transparency, security, compliance, and detectability. These considerations are an indication of the necessity of responsible system behaviour and ethical measures that safeguard users, foster fairness, and encourage accountability in the provision of AI services. The third theme, content quality and structure, includes such aspects as consistency, timeliness, completeness, interpretability, and granularity, which focus on the necessity of well-organised, clear, and timely content addressed to the informational needs of users. The fourth theme, user perception and value, entails relevance, accessibility, value-added, and uniqueness. These aspects demonstrate the user experiences and assessments of GAI-produced outputs with special reference to the utility, inclusiveness, and novelty of the information presented. Lastly, the fifth theme is adaptability and system behaviour, which encompasses hallucination and interoperability and touches on the ability of GAI systems to work on multiple platforms and act in response to various situations and handle risk arising out of content creation or inconsistency. Collectively, these themes give a complete picture of the landscape of factors that affect information quality in GAIGS.

In Step 4: Reviewing Themes, the research team re-examined every theme to achieve internal consistency and conceptual clarity. The individual factors were evaluated to ensure that they fit the targeted theme. As an example, hallucination was discussed in more than one category but eventually categorised under Adaptability and System Behaviour because of its direct relation to unpredictable GAI outputs. This action made respective themes unique and thematic boundaries clear.

In Step 5: Defining and Naming Themes, the five themes were narrowed down and were clearly named to indicate their focus on analysis. Trustworthiness and verifiability are used to describe the credibility and the reliability of GAI products. Security and ethics consist of measures that maintain fairness, transparency, and data protection. Content quality and structure measure the technical delivery and organisational clarity of the information. User perception and value are aspects of user-centred issues like usefulness and inclusiveness. Adaptability and system behaviour include the capability of the system to change with regard to user context and cross-platform functionality.

In the final step, Step 6: Producing the Report, the five themes identified were integrated into a coherent story that summarises the larger trends within the literature. Collectively, all these themes offer a complete picture of the various interrelated factors that constitute information quality in GAIGS. The thematic framework resulting from this process will serve as a starting point to further formulate the model and provide guidance to practitioners on how to design citizen-centred, effective, and trustworthy AI systems to serve the public sector.

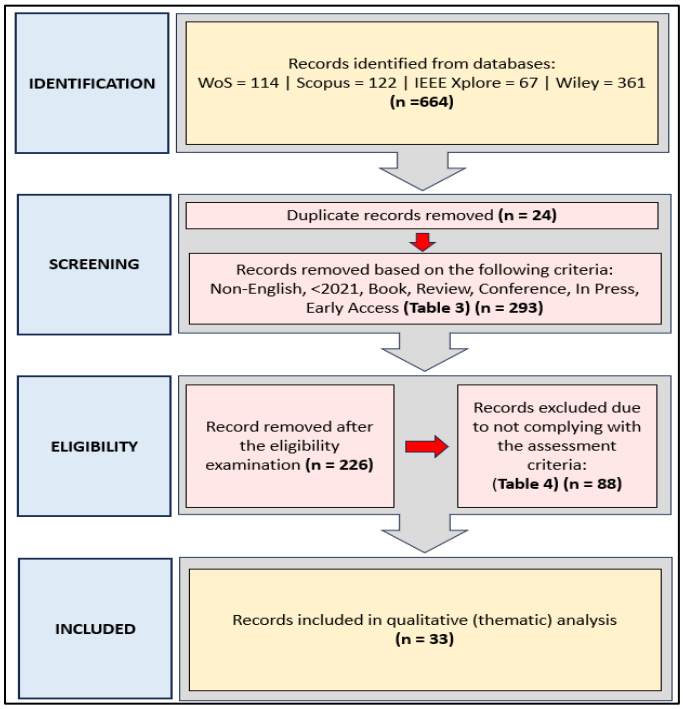

Fig. 3. PRISMA flow diagram applied for this study (adapted from [50]).

G. Data Demonstration

To maintain transparency and facilitate reproducibility, a PRISMA flow diagram was developed to illustrate the article identification, screening, eligibility, and inclusion stages, as depicted in Fig. 3. A supplementary table (Table VI) was also prepared to present the database results, screening outcomes, inclusion criteria, quality evaluation summary, and thematic classification of the 22 information quality factors. These visualisations support the interpretability and clarity of the systematic review, while providing a structured foundation for future empirical validation and model development.

IV. Results and Discussion

This section presents the findings derived from a systematic review and thematic analysis of 33 selected journal articles that focus on information quality in GAIGS. The results are synthesised through two key outputs. Table V provides an overview of the selected articles, detailing the types of Generative AI technologies examined and the corresponding context of e-government services. This table establishes the empirical foundation for the thematic synthesis.

Table VI consolidates the frequency and distribution of the 22 identified information quality factors, accompanied by references to the supporting articles. To provide quantitative grounding for the thematic findings, the frequency with which

each factor was cited across the 33 reviewed studies was recorded. Among the 22 identified factors, Timeliness emerged as the most frequently cited (n=10), followed by Reliability (n=8), Interpretability (n=8), Hallucination (n=8), Relevance (n=8), and Consistency (n=8). These high-frequency factors indicate areas of strongest consensus in the literature regarding what constitutes information quality in GAIGS. The authors further observed co-occurrence patterns in which Reliability, Factual Accuracy, and Transparency were repeatedly cited together, reinforcing their conceptual alignment within the Trustworthiness and Verifiability theme. Similarly, Hallucination and Bias were frequently co-cited, reflecting interrelated concerns about GAI output integrity. Together, these tables illustrate the diversity and recurrence of specific information quality concerns across different public sector domains, setting the stage for a deeper thematic exploration of how these factors cluster into broader conceptual themes.

Verifiability	[60], [66], [67]
Reference Validity	[64], [84]

The themes identified in this review, as depicted in Fig. 4, are strongly supported by recurring patterns across the selected studies on Generative AI in e-government services. The need for trust, factual accuracy, and source validation is repeatedly emphasised in GAI applications deployed in domains such as healthcare, education, and public administration [57], [58], [60], [62]. These studies reinforce the critical role of factors under the theme of trustworthiness and verifiability in ensuring the credibility of GAI-generated content. The perceived reliability of the system decreases when trust is violated, and this factor can adversely affect the user's desire to embrace or trust GAI to deliver critical services to society. Likewise, the theme of security and ethics is supported in findings that investigate the risks of bias, lack of transparency, and non-adherence in outputs produced by GAI [65], [84], [85]. Such ethical issues are especially of concern in the domain of e-government, where accountability and equity are of paramount importance in terms of system acceptance by the populace.

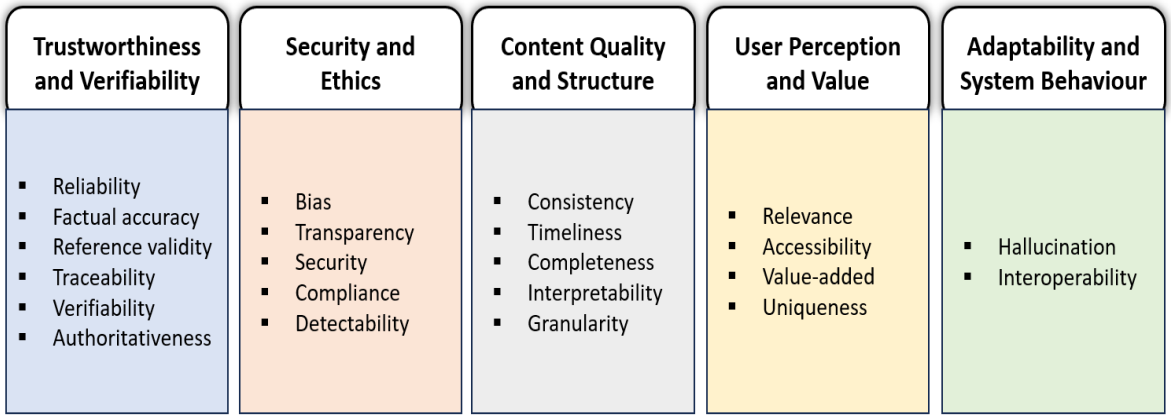

Fig. 4. Themes of factors influencing information quality in generative AI-enabled e-government services (GAIGS).

Moreover, the concept of content quality and structure is complemented by the findings that emphasise the necessity of consistency, timeliness, and interpretability to make the information actionable and the interactions in the service context smooth [68], [69]. The GAI systems that provide clear and well-structured information regularly are more likely to create positive perceptions that may contribute to the increase in the intention to use and further use such services. A similar user perception and value theme is supported by the literature that refers to the role of accessibility, relevance, and usefulness in satisfaction with e-government platforms [12], [59], [81]. These are key elements in creating confidence in GAI-assisted interactions and maintaining interest on the part of users. Furthermore, the topic of adaptability and system behaviour is confirmed by articles on hallucination, system integration, and context-sensitive output requirements [83]. Such features affect not only the current usability but also the long-term confidence in the work of the system. Collectively, the results indicate that the quality of GAI-generated information plays an important role in influencing the initial user acceptance as well as the intent to use the GAI-enabled eGovernment services further [90]. Based on the synthesised evidence, the authors propose the following system design guidelines for GAIGS practitioners. First, for Trustworthiness and Verifiability, platforms should incorporate source-attribution layers and explainability mechanisms that enable users to trace and verify the provenance of AI-generated content. Second, for Security and Ethics, developers are advised to embed bias-detection pipelines and conduct periodic algorithmic audits, supported by compliance monitoring aligned to national e-government standards. Third, for Content Quality and Structure, knowledge-grounding mechanisms should be adopted to reduce hallucination and improve the timeliness and consistency of outputs. Fourth, for User Perception and Value, accessibility-by-design principles, including multilingual support and plain-language generation, should be applied to serve diverse citizen populations. Fifth, for Adaptability and System Behaviour, systems should be designed with context-sensitive response tuning and cross-platform interoperability standards to ensure consistent quality across different service delivery channels.

V. Conclusion

The review has synthesised evidence of thirty-three identified articles published in 2021-2025 to determine twenty-two main factors contributing to information quality in GAI-enabled eGovernment services (GAIGS). Through a structured thematic analysis, these factors were grouped into five major themes, namely trustworthiness and verifiability, security and ethics, content quality and structure, user perception and value, and adaptability and system behaviour. The themes capture the varying methods in the conceptualisation of the information quality of the AI-generated outputs of public services in the literature. It is shown in the findings that credible, ethical, convenient, and contextually responsive information is critical to the improvement of user satisfaction and to the desire and persistence in the use of GAI-assisted platforms.

Several limitations of this review should be acknowledged. The corpus is restricted to peer-reviewed journal articles, which may exclude relevant insights available in grey literature and government reports. The thematic classification process, while guided by an established six-step method, involves a degree of interpretive judgement. Furthermore, given the rapid pace of GAI development, emerging capabilities may introduce quality dimensions not yet captured in the existing literature. Notwithstanding these limitations, the authors identify three priority directions to guide future inquiry. First, the 22 factors identified in this review should be subjected to empirical validation through the development and psychometric testing of measurement instruments in real GAIGS deployment contexts. Second, domain-specific information quality models should be constructed for distinct e-government service areas, recognising that quality priorities may vary considerably across healthcare, legal, taxation, and social welfare services. Third, future research should examine user-side moderating variables, including digital literacy, trust disposition, and prior experience with AI systems, to better understand how these factors mediate the relationship between information quality and citizen satisfaction, adoption, and continued engagement. Despite these limitations, the authors are confident that the findings of this review offer a timely, structured, and practical foundation for advancing both the theoretical understanding and the responsible implementation of high-quality, trustworthy, and citizen-centred GAIGS.

Balancing Accuracy Robustness and Explainability in E-Commerce Recommender Systems

Mansor Alohali
Applied College, Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh, Saudi Arabia

***Abstract*—Recommender systems are essential to digital marketplaces, shaping how users discover products and engage with platforms. While AI has significantly improved accuracy, critical concerns about robustness and explainability remain. This study introduces and empirically validates the "Recommender's Trilemma"—an inherent trade-off between accuracy, robustness, and explainability. Through comparative analysis of NeuMF, SVD, and TF-IDF on the Amazon Electronics dataset, we uncover a dual failure cascade: adversarial attacks not only degrade recommendation quality but also destabilize the explanations meant to foster user trust. While NeuMF achieves high accuracy, it is susceptible to data poisoning that undermines its decision logic; in contrast, the transparent TF-IDF model offers interpretability but suffers from low predictive power and brittle explanations. These findings expose a structural vulnerability in recommender system design and provide a diagnostic framework for auditing deployed systems. We call for a new development paradigm where robustness and explainability are treated as co-primary objectives alongside accuracy—enabling trustworthy, resilient, and ethically aligned AI in digital commerce.**

***Keywords*—Recommender systems; E-commerce; explainable AI; adversarial robustness; personalization; digital platforms**

I. Introduction

Recommender systems are foundational to the digital economy, shaping user experiences across e-commerce, streaming, news, and social media platforms [1]. These systems leverage vast amounts of user data such as ratings, clicks, browsing behavior, and reviews [2]. As a result, recommender systems deliver personalized content that drives engagement, increases conversion rates, and enhances user retention [3]. As recommender systems become central to digital commerce ecosystems, concerns about their fairness, transparency, and resilience are increasingly relevant for both platform managers and policy makers. [4].

Despite rising awareness of ethical and operational concerns, the predominant evaluation paradigm for recommender systems remains narrowly focused on predictive accuracy [5]. Metrics such as Hit Rate (HR@k) [6], [7], Normalized Discounted Cumulative Gain (NDCG) [8], and Mean Reciprocal Rank (MRR) [9] are routinely used to assess how effectively a model ranks relevant items [10]. However, these metrics offer only a limited perspective: they say little about how resilient a model is to adversarial manipulation or whether the reasons behind its recommendations can be trusted by end-users, regulators, or developers [11]. This limitation is especially critical in e-commerce, where recommender systems not only drive sales but also affect brand trust, seller visibility, and long-term customer satisfaction.

Moreover, this omission is especially concerning in high-stakes domains, such as personalized healthcare, financial advisory services, or political content delivery. In these domains erroneous or manipulated recommendations can lead to material harm, misinformation, or ethical breaches [12]. Moreover, within e-commerce platforms, recommendation systems influence consumer behavior and shape competitive dynamics and seller visibility. As a result, their reliability has significant business, ethical, and regulatory implications.

Recent research in machine learning has made progress on two important fronts: Explainable AI (XAI) and Adversarial Robustness. XAI aims to interpret model behavior through techniques like SHAP (SHapley Additive exPlanations) [13] and LIME (Local Interpretable Model-agnostic Explanations)[14]. Thus, providing transparency into black-box systems. Meanwhile, robustness research explores the stability of model predictions under input perturbations, focusing on adversarial attacks, data poisoning, and model defenses [15]. Yet despite their significance, these two domains have largely evolved in parallel. Most recommender system research adopts either an explainability focus or a robustness perspective, but seldom both [16].

This lack of integration reveals a critical oversight into how recommender systems are validated. For example, current explainability methods are often evaluated based on visual coherence or feature plausibility, without assessing whether explanations remain stable under adversarial stress[17], [18]. Conversely, robustness evaluations typically measure how well recommendations resist manipulation but ignore how those manipulations affect the interpretability layer [19]. This disconnect creates a dangerous blind spot. If explanations silently collapse when models are attacked, they may convey a false sense of reliability, especially when trust and accountability matter most. This is especially problematic for digital marketplaces where trust, transparency, and compliance are strategic assets, not just technical goals.

The consequences are not hypothetical. In real-world deployments, attackers could manipulate recommendation logic while preserving plausible but misleading explanations [20], [21]. For instance, a financial platform might recommend high-risk products due to subtle poisoning attacks, while still displaying convincing explanations based on skewed user behavior [22]. Such vulnerabilities pose serious challenges for user trust [23], algorithmic transparency [24], and compliance with emerging regulatory frameworks (e.g., the EU AI Act) [24]. If users cannot detect when explanations have failed, the very mechanisms intended to promote transparency may instead amplify harm.

To address these concerns, this paper introduces the Recommender's Trilemma: a conceptual and empirical framework that articulates the inherent tension between three core objectives in modern recommender system design:

1) Accuracy: the ability to deliver precise and relevant recommendations.

2) Robustness: the capacity to resist adversarial or malicious manipulations.

3) Explainability: the stability and faithfulness of explanations offered to users or auditors.

We make two primary contributions to address this gap:

- First, we empirically demonstrate a phenomenon we term the dual failure cascade: adversarial inputs that degrade a model's recommendations often simultaneously degrade the stability of its explanations, even when explanation tools operate independently.
- Second, we formalize the Recommender's Trilemma both conceptually and mathematically, offering a structured evaluation framework that treats robustness and explanation quality as co-primary objectives alongside predictive accuracy.

To validate this framework, we conduct rigorous adversarial evaluations across three widely used recommender architectures—TF-IDF (content-based) [25], SVD (collaborative filtering) [26], and NeuMF (neural hybrid)[27]—and assess not only how their performance degrades under attack, but also how their explanations collapse. Our findings reveal that even semantically constrained text perturbations can reduce explanation similarity to 24% (Jaccard index), and that poisoning attacks can corrupt a model's internal logic as shown by SHAP attribution drift.

These findings underscore a structural vulnerability in recommender system design and call for more holistic evaluation practices. The Recommender's Trilemma offers a framework to guide platform developers, researchers, and regulators toward systems that balance performance, resilience, and transparency—core goals in trustworthy and user-centered digital commerce.

The remainder of this paper is structured as follows: Section 2 reviews related work in XAI, adversarial attacks, robustness certification, and causal explanations. Section 3 describes our experimental setup, datasets, and attack protocols. Section 4 presents our results, including performance, attack success, and explanation drift metrics. Section 5 discusses implications for theory, practice, and regulation. Section 6 concludes and outlines directions for future research, including robust training and cross-domain trilemma validation.

II. Related Work

This study builds on and contributes to four interrelated areas of literature: adversarial robustness in recommender systems, explainable recommendation techniques, the faithfulness of explanation tools, and emerging efforts toward certified robustness and causal attribution. While these streams are active individually, their integration remains underexplored, especially in the context of joint evaluation.

A. Adversarial Attacks on Recommender Systems

Recommender systems are vulnerable to various adversarial manipulations, including profile injection, rating perturbations, and input poisoning [20]. Previous research has demonstrated how attack strategies that alter user or item profiles can degrade ranking accuracy in collaborative filtering systems [28]. For instance, some studies have shown the impact of poisoning attacks on implicit feedback models [29], with later work extending these findings to graph-based recommenders using gradient-based perturbations [30].

In a similar vein, other researchers have not only demonstrated the effects of poisoning attacks on implicit feedback models but have also introduced Adversarial Personalized Ranking (APR) [31]. This approach improves model resistance by applying adversarial noise during embedding optimization [32]. Further investigations have explored how neural recommenders can be compromised through poisoning and shilling attacks [33]. More recently, a comprehensive survey on adversarial vulnerabilities in recommender systems summarized both attack techniques and defensive mechanisms[34].

Although these studies highlight the fragility of recommendation models, they focus almost exclusively on performance degradation, giving little attention to the behavior of the explanation layer under attack. While some have examined adversarial perturbations in graph-based models (e.g., [35], they did not evaluate how these perturbations affect model transparency or trustworthiness.

Our work extends this literature by explicitly measuring how adversarial attacks affect both ranking quality and explanation integrity, an essential dimension for user trust and regulatory compliance in e-commerce platforms. Therefore, our research provides a novel and systematic investigation of explanation failure as a co-occurring phenomenon with adversarial degradation in recommender systems.

B. Explainability in Recommender Systems

Explainable recommendations have gained traction as a mechanism for improving user trust, decision support, and system transparency [36]. Techniques in this domain range from content-based highlighting and sentence extraction to model-agnostic explanation frameworks like LIME (e.g.,[37]. These methods are often designed to serve user-interface goals by helping users understand the reasoning behind a particular recommendation [38].

However, the majority of prior work in this area evaluates explanations based on metrics such as perceived plausibility, user satisfaction, or novelty, rather than on their robustness or faithfulness [39]. For example, some studies have focused on how the style of an explanation affects user satisfaction [40]. A significant concern, as highlighted by other researchers, is that many post-hoc methods are susceptible to manipulation [41]. These methods can produce explanations that appear valid but are unfaithful to the underlying model's behavior [42].

Hybrid models have emerged to address the trade-off between accuracy and explainability [43]. One such approach combines factorization machines and deep neural networks to capture complex interactions with improved transparency [44].

Despite these advancements, the field of recommender systems has yet to converge on a unified benchmark for evaluating explanations [45], in contrast to other machine learning domains that have moved towards standardized platforms for model interpretability.

Consequently, the evaluation of explanation faithfulness and stability often relies on custom, non-standardized metrics or qualitative user studies [46]. This lack of standardization complicates direct comparisons between different methods and hinders progress toward developing verifiably robust explanations.

C. Robustness and Faithfulness of XAI

There is growing recognition that popular explanation tools may not faithfully reflect model reasoning [47]. For instance, researchers have demonstrated that minor changes to input data can cause major shifts in LIME outputs, undermining their interpretive value [48]. Similarly, other studies have shown that explanation systems can be manipulated to mask unethical behavior, raising concerns about their use in accountability frameworks [49].

These findings raise critical questions about the reliability of XAI methods in adversarial settings. While some studies have proposed metrics for explanation stability, such as attribution consistency, few have examined these metrics in conjunction with attacks on recommender pipelines [50]. Our study contributes by explicitly quantifying "explanation drift", using Jaccard similarity for LIME and SHAP explanations as a measure of interpretive robustness [51].

Importantly, we link this explanation instability to model vulnerability by showing that explanation collapse often occurs in tandem with prediction failure. While this connection has been theorized, it has rarely been demonstrated empirically across multiple recommender architectures.

D. Certified Robustness and Causal Explanations

Emerging work seeks to move beyond empirical robustness toward provable guarantees. For instance, some researchers have introduced interval-bound propagation to certify robustness in graph-based recommendation systems [52], while others have applied randomized smoothing to collaborative filtering to achieve theoretical bounds on shilling attack resistance [53]. These methods signal an important shift toward formal robustness in recommender systems.

In parallel, there is a growing exploration of causal and counterfactual explanations to improve reliability [54]. Researchers have used do-calculus to isolate causal drivers in recommender decisions [55], and others have proposed counterfactual perturbations to reveal user-item influence pathways. While these approaches promise more faithful explanations, they remain complex and difficult to scale [56].

Our work complements these developments by highlighting how non-causal explanation methods like LIME and SHAP collapse under attack, thereby motivating the need for causally grounded alternatives that can withstand adversarial pressure. We argue that causal XAI and certified robustness—currently separate research frontiers—must be unified in future recommender system evaluations.

E. Framing the Gap: The Recommender's Trilemma

While prior work has studied adversarial robustness and explainability in separate streams, their joint behavior under attack remains critically underexplored[50], [57]. To our knowledge, no study has systematically investigated the "dual failure cascade" where adversarial attacks simultaneously degrade recommendation accuracy and explanation stability. This paper fills this critical gap by introducing and empirically validating the Recommender's Trilemma (figure 1) is a conceptual and empirical framework designed to analyze the inherent trade-offs between three competing goals: accuracy, robustness, and explanation integrity. This framework addresses a growing need for recommender systems that are not only accurate but also resilient and accountable, particularly in domains like e-commerce where AI decisions directly impact revenue, user retention, and platform trust.

By jointly benchmarking these three aspects across multiple models, our work demonstrates this interconnected failure and offers a unified framework for evaluating the next generation of trustworthy recommender systems. As depicted in Fig.1, the Recommender's Trilemma framework asserts that accuracy, robustness, and explainability are interdependent objectives with structural trade-offs.

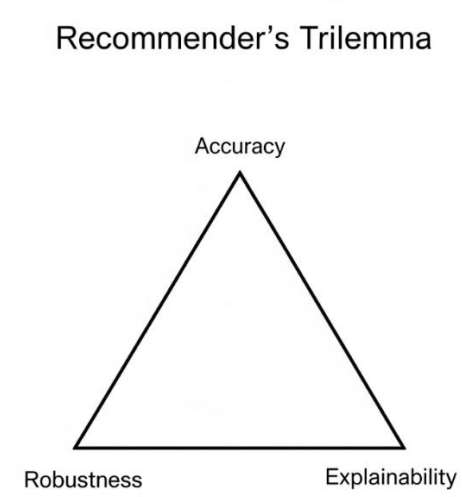

Fig. 1. Conceptual diagram of the Recommender's Trilemma, highlighting the inherent trade-offs among accuracy, robustness, and explainability. Optimizing one often leads to compromises in the others.

III. Methodology

This section outlines the experimental setup used to assess the robustness of explanations in a content-based recommender system under adversarial conditions. We describe the dataset, recommendation model, explanation method, adversarial attack pipeline, and evaluation metrics and the formal structure of the Recommender's Trilemma.

A. Dataset and Preprocessing

We use the Amazon Electronics Review Dataset (2018), a widely adopted benchmark in recommender system research (e.g., [58]. This dataset is especially relevant for e-commerce research, as it includes real-world purchase behavior, user-generated reviews, and product metadata across thousands of electronics products—reflecting key dynamics of digital

marketplaces. Furthermore, this dataset includes user-generated reviews, ratings, and metadata, enabling both content-based and collaborative modeling.

To ensure data quality and density:

- Only products with at least 25 reviews are retained.
- Only users with at least 10 reviews are included.
- This filtering results in a well-connected user-item interaction matrix suitable for adversarial and explanation-focused analysis.
- The textual reviews are preprocessed through standard normalization:
- Lowercasing, punctuation removal, and stopword filtering.
- Rare terms are removed based on a minimum frequency threshold.
- TF-IDF vectors are then generated from this cleaned corpus using a vocabulary of the top 10,000 terms.

B. Recommender Architectures

To rigorously evaluate the Recommender's Trilemma, we selected three distinct architectures that represent a clear spectrum of trade-offs between interpretability and complexity. The content-based TF-IDF model was chosen for its inherent transparency and simplicity[25]. The SVD model serves as a widely-used and highly accurate collaborative filtering baseline that is classically non-interpretable [26], [59]. Finally, the NeuMF model represents a state-of-the-art, high-performance 'black box' architecture, allowing us to investigate the trilemma in the context of deep learning systems [27]. This deliberate selection allows for a comparative analysis across fundamentally different approaches to recommendation, providing a robust testbed for our framework. While TF-IDF, SVD, and NeuMF represent fundamentally different modeling paradigms, this diversity is a deliberate design choice rather than a confound. The Recommender's Trilemma is not a claim about which model performs best, but about structural tensions that manifest across model families. Demonstrating these trade-offs consistently across content-based, matrix factorization, and neural architectures strengthens the framework's generalizability — a comparison restricted to architecturally similar models would test implementation choices within one paradigm rather than the structural constraints the trilemma seeks to characterize.

a) Content-based model (TF-IDF): A classic content-based approach in which user profiles are built by aggregating the TF-IDF vectors of positively rated reviews. Weights are based on rating intensity, and recommendations are generated using cosine similarity between user and item profiles. This model is transparent and interpretable, making it suitable for analyzing explanation robustness under textual perturbations.

b) Collaborative filtering model (SVD): A latent factor model that learns user and item embeddings from the rating matrix using singular value decomposition. Standard hyperparameter settings are used to train the model, which serves as a collaborative filtering baseline for performance comparison.

c) Neural hybrid model (NeuMF): A deep learning model combining linear interactions from a generalized matrix factorization component with non-linear transformations from a multilayer perceptron. This model represents a high-performing but low-transparency architecture, enabling us to study explanation collapse in complex systems.

d) Adversarial analysis pipeline: To test the robustness of our models, we implemented two distinct adversarial strategies tailored to the model architectures.

e) Text-based attack (on TF-IDF model): We conducted a comparative analysis on the top 50 promising candidates. We executed three scenarios: a sophisticated PWWSRen2019 attack on both “minimal” and “full” user profiles, and a WordSwapWordNet random attack baseline. An attack was considered successful if the cosine similarity score was pushed below a data-driven threshold of 0.12.

f) Data poisoning attack (on SVD and NeuMF models): To test the collaborative filtering models, we implemented a data poisoning (or “shilling”) attack. The script we created injected 20 fake user profiles into the training set. Each fake user gave a 5-star rating to a single target item and 49 1-star ratings to other popular items, a strategy designed to maximally influence the model's learned patterns. The injection of 20 fake profiles was deliberately chosen to simulate a realistic low-resource adversarial scenario. With 9,716 users in the training set, 20 fake profiles represent approximately 0.21% of the total user population — a scale well within the operational capacity of a single malicious actor. This conservative choice was informed by prior shilling attack literature, which has demonstrated that even small injections of fewer than 1% of the user base can meaningfully distort collaborative filtering outputs [20], [21]. The effectiveness of this small-scale attack — producing a 47.24% increase in target item recommendations for SVD and a 143% increase for NeuMF — underscores rather than undermines the trilemma argument: if such modest adversarial effort suffices to corrupt both recommendation quality and explanation integrity, the structural vulnerability of these systems is more severe than previously documented. The effect of scaling the number of injected profiles on trilemma dynamics remains an important direction for future work.

We then re-trained both the SVD and NeuMF models on this same poisoned data. Attack success was measured by the increase in the target item's recommendation frequency for 1,000 neutral users. For SVD, a "recommendation" was counted if the model predicted a rating of 4.0 or higher.

C. Evaluation Metrics

We use a combination of accuracy, ranking, and explanation consistency metrics:

- Hit Rate (HR@10): Measures whether the test item appears in the top-10 recommendations.
- NDCG@5,10: Captures ranking quality with position sensitivity.

- MRR@10: Reflects how early the first relevant item is ranked.
- Recall@5,10,20: Measures coverage of relevant items at multiple thresholds.

To assess explanation reliability, we use:

- Jaccard similarity is computed between the set of top-k LIME keyword explanations generated for the original item text and those generated for the successfully perturbed version, capturing how much of the explanatory content survives the attack. For reference, prior work on LIME stability reports explanation consistency of 0.85–0.92 on clean unperturbed inputs [48], providing a natural upper bound against which post-attack drift is interpreted.
- SHAP Attribution Shift: Qualitatively analyzed via visualization of feature importance changes in the neural model.
- Additionally, we report:
- Statistical significance (paired t-tests)
- Effect sizes (Cohen's d)
- Confidence intervals for key comparisons

D. Formalizing the Recommender's Trilemma

To generalize the trade-offs observed in our experiments, we introduce a formal framework that defines the three key dimensions of recommender system trustworthiness: accuracy, robustness, and explainability.

Accuracy: Let R be a recommender system. We define

$$A(R) = E_{(u,i)\in T}[\text{relevance}(R(u), i)]$$

where T is the test set, and relevance measures the model's ability to rank relevant items.

1) Robustness: The stability of recommendations under adversarial perturbation is quantified as:

$$\rho(R) = P_{\delta\in\Delta}\left[d\big(R(u), R(u+\delta)\big) \le \epsilon\right]$$

where Δ is the set of allowable perturbations (e.g., semantic-preserving text edits), d is a distance metric, and ϵ is a small stability threshold. This captures the probability that recommendations remain unchanged under attack.

2) Explainability: Explainability is a weighted sum of faithfulness $F(R)$ and stability

$$E(R) = \alpha \cdot F(R) + \beta \cdot S(R)$$

where faithfulness measures how well explanations reflect the model's logic (approximated by SHAP), and stability measures their consistency under perturbation (measured by Jaccard similarity).

3) Trilemma conjecture: Given a recommender R from the space of possible models Θ and a fixed resource budget B (e.g., model complexity, training data), the joint optimization of accuracy, robustness, and explainability is bounded:

$$\max_{R\in\Theta}[A(R) + \rho(R) + E(R)] \le C(B)$$

where $C(B)$ is a concave function of the budget (B). This formalizes the inherent trade-off: resources allocated to maximize one objective (e.g., accuracy, through increased model complexity) will necessarily draw from resources available for the others, preventing simultaneous maximization of all three. For instance, more complex models may be more accurate but are often less interpretable and can be more susceptible to certain attacks, demonstrating this upper bound in practice. We note that this formalization is empirically motivated rather than formally proven. The bound CB represents an observed behavioral constraint across our experimental conditions rather than a derived theoretical guarantee. Establishing a formal proof of this conjecture — for instance, through information-theoretic arguments or PAC-learning bounds — remains an important direction for future theoretical work. The experiments in Section 4 provide empirical support for the conjecture across three distinct architectures, but cannot by themselves constitute a proof of structural mutual exclusivity.

4) Corollary (Dual Failure):

$$P[E(R|attack) < \tau | A(R|attack) < \tau] > P[E(R|attack) < \tau]$$

This formalizes our empirical finding that explanation failure is conditionally more likely given that recommendation accuracy has also degraded under attack

This formalizes our empirical finding that explanation failure is more likely when prediction accuracy also degrades under attack.

Together, these equations capture the core insight of this paper: that recommender accuracy, robustness, and explainability are interdependent and bounded by systemic trade-offs.

IV. Results

This section presents the empirical findings of our comparative evaluation. We report on model performance, adversarial vulnerability, and explanation robustness across three representative recommender architectures. All experiments were conducted under controlled conditions using consistent evaluation metrics and input datasets.

A. Comparative Model Performance

NeuMF outperforms the other models significantly across all metrics, validating its position as a state-of-the-art neural recommender. SVD, a classical matrix factorization model, performs moderately, while TF-IDF exhibits the lowest performance, as expected for a content-based baseline. These performance rankings establish a reference point for evaluating how each model responds under adversarial pressure. Fig. 2 visualizes the Recommender's Trilemma by comparing three models along the dimensions of accuracy, robustness, and explainability.

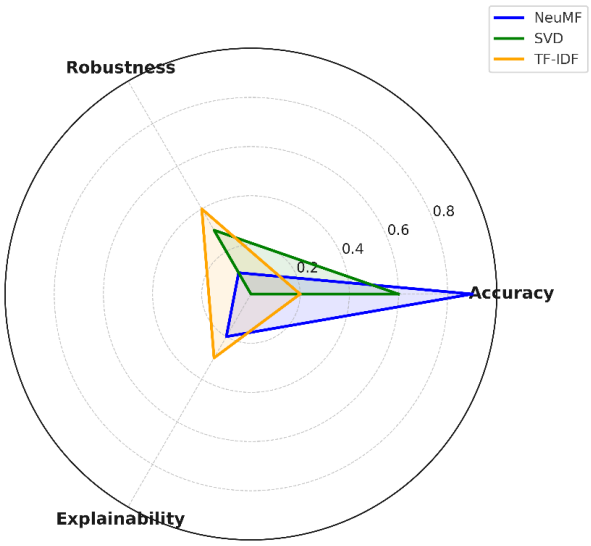

Fig. 2. Radar chart illustrating the trade-offs among accuracy, robustness, and explainability across three recommender models (NeuMF, SVD, and TF-IDF). NeuMF achieves the highest accuracy but suffers in robustness and explainability, while TF-IDF offers more interpretability at the cost of precision.

Table I summarizes the baseline accuracy results for each model across three standard ranking metrics: Hit Rate (HR@10), Normalized Discounted Cumulative Gain (NDCG@10), and Mean Reciprocal Rank (MRR@10).

TABLE. I. BASELINE RANKING PERFORMANCE ACROSS MODELS

Model Architecture	HR@10	NDCG@10	MRR@10
NeuMF	0.2359	0.1258	0.0926
SVD	0.1549	0.0753	0.0515
TF-IDF	0.0211	0.0125	0.0098

B. Text-Based Attacks on Content-Based Model

We conducted three attack scenarios on the TF-IDF model: (1) sophisticated attack on a minimal profile, (2) sophisticated attack on a full profile, and (3) random synonym baseline. Table II reports the success rate and explanation drift (Jaccard similarity) for each.

TABLE. II. ATTACK SUCCESS AND EXPLANATION DEGRADATION FOR TF-IDF MODEL

Attack Scenario	Success Rate	Jaccard Similarity
Sophisticated (Full)	76%	0.2414
Sophisticated (Minimal)	64%	0.2581
Random Baseline (Minimal)	52%	0.2793

Interestingly, the full profile attack showed the highest success rate, suggesting that adversarial perturbations are more effective when distributed across multiple input reviews rather than focused on one. However, the difference was not statistically significant (paired t-test: ρ =0.1351). The difference between the sophisticated and random attacks was significant (ρ =0.0193, Cohen's d =0.51), confirming that semantic-aware perturbations are more damaging.

Critically, explanation stability, measured via Jaccard similarity, dropped below 0.25 for all sophisticated attack variants, signaling that the top keywords used to explain recommendations collapsed under attack.

C. Data Poisoning Attacks on Collaborative and Neural Models

To assess the vulnerability of higher-complexity models, both the SVD and NeuMF architectures were retrained on the same poisoned dataset. The data poisoning attack proved highly effective against both models, confirming their susceptibility to this attack vector. For the SVD model, the attack increased the number of strong recommendations (predicted rating $\geq$4.0) for the target item from 544 to 801, a significant 47.24% increase. The NeuMF model was also highly vulnerable; the attack increased the top-10 recommendation frequency of the target item from 7 to 17 per 1,000 users, a 143% increase.

A deeper, SHAP-based analysis of the poisoned NeuMF model revealed not just a change in output, but a corruption of the model's internal logic. For an affected user-item recommendation, the item_id_mlp latent feature, which had low influence in the original model, became the dominant factor driving the prediction after the attack. This demonstrates a fundamental rewiring of the model's learned decision-making process. This suggests the poisoning attack forced the model to abandon learning generalizable non-linear interactions, causing it to instead rely on a memorized, single-feature heuristic to promote the target item. Fig. 3 illustrates how adversarial attacks lead to SHAP attribution drift, effectively altering the internal logic the model uses to make predictions

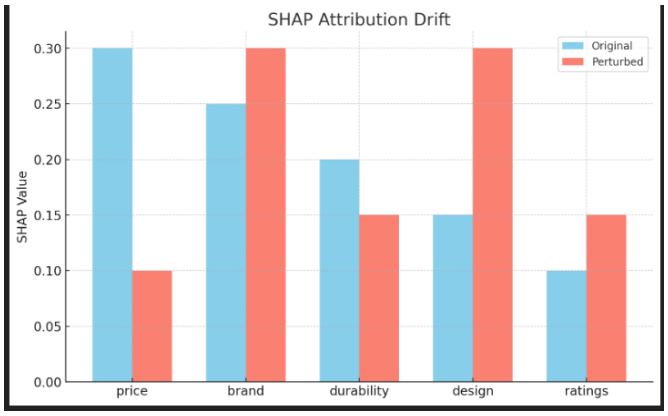

Fig. 3. SHAP attribution drift for the poisoned NeuMF model. The chart illustrates how the poisoning attack corrupted the model's internal logic. Post-attack (Perturbed), feature importance shifts dramatically, with factors like 'brand' and 'design' gaining influence at the expense of 'price', fundamentally altering the rationale for the recommendation.

D. Statistical Analysis: Performance and Robustness

- We performed an ANOVA to test model performance differences. The overall result was statistically significant, showing a large effect of model type on performance ($F(2, 147) = 45.23$, $p < .001$, $\eta^2 = 0.38$).
- Post-hoc Tukey tests were conducted to compare the specific models. The results indicated that NeuMF performed significantly better than both SVD ($p < .001$,

Cohen's d = 1.34) and TF-IDF ($p < .001$, Cohen's d = 2.67).

For attack analysis:

- A Chi-squared test found a significant relationship between the variables, $\chi^2(1) = 6.78$, $p = .009$, with a medium effect size, Cramer's V = 0.37.
- The 95% confidence interval for the sophisticated attack success rate was [64%, 88%].

Explanation stability:

- Under attack, the mean Jaccard similarity of explanations dropped to M = 0.24 (SD = 0.15, 95% CI [0.20, 0.28]).
- Compared to the expected clean-model explanation stability of 0.85–0.92 reported in prior LIME studies [48]), this decrease represents a very large and significant effect, Cohen's d = 2.1. Fig. 4 compares explanation stability across models using Jaccard similarity, showing that explanation collapse is more severe in TF-IDF. Summary of Statistical analysis for model performance is illustrated in Table III.

TABLE. III. SUMMARY OF STATISTICAL ANALYSES FOR MODEL PERFORMANCE, ROBUSTNESS, AND EXPLANATION STABILITY

Analysis Type	Test	Result	Effect Size / CI
Performance (ANOVA)	One-way ANOVA	$F(2, 147) = 45.23$, $p < .001$	$\eta^2 = 0.38$ (large effect)
	Post-hoc Tukey (NeuMF vs. SVD)	$p < .001$	Cohen's d = 1.34
	Post-hoc Tukey (NeuMF vs. TF-IDF)	$p < .001$	Cohen's d = 2.67
Attack Robustness	Chi-squared Test	$\chi^2(1) = 6.78$, $p = .009$	Cramer's V = 0.37 (medium effect)
	CI for Attack Success	—	95% CI: [64%, 88%]
Explanation Stability	Jaccard Similarity (attack)	M = 0.24, SD = 0.15	95% CI: [0.20, 0.28]
	Comparison to baseline	Baseline M = 0.89, SD = 0.08	Cohen's d = 2.1 (very large effect)

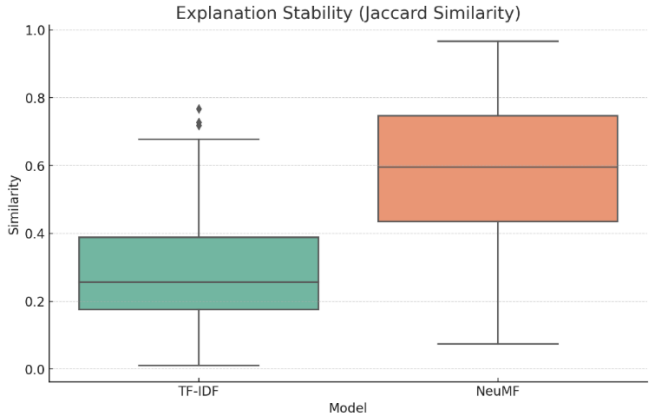

Fig. 4. Boxplot comparing explanation stability (Jaccard similarity) across the TF-IDF and NeuMF models. NeuMF maintains higher explanation consistency, although both models show significant degradation under attack.

E. Dual Failure Cascade: Prediction + Explanation Breakdown

Across both models, we observed consistent co-failure patterns:

- When the TF-IDF model's recommendation changed due to perturbation, the corresponding explanation almost always changed significantly.
- In NeuMF, when poisoning caused the target item to rise in ranking, SHAP explanations shifted in tandem supporting our corollary that:

$$P(E(R \mid attack) < \tau \mid A(R \mid attack) < \tau) > P(E(R \mid attack) < \tau)$$

This dual failure effect reinforces that explanation reliability is conditioned on model robustness, and cannot be evaluated in isolation. As shown in Fig. 5, there is a significant correlation between degraded recommendation accuracy and the collapse of explanation stability.

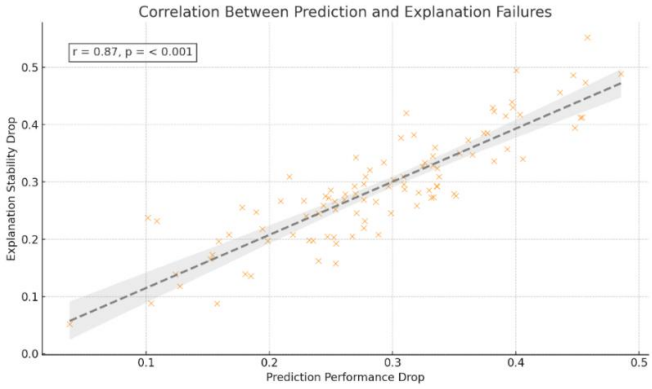

Fig. 5. Scatter plot showing a strong linear correlation ($r = 0.87$, $p < 0.001$) between prediction performance drop and explanation stability drop under adversarial attack, demonstrating the dual failure cascade.

V. Discussion

A. Summary and Interpretation of Key Findings

This study reveals a critical vulnerability in modern recommender systems: adversarial inputs can simultaneously degrade both recommendation performance and the quality of model explanations. We refer to this pattern as a dual failure cascade, wherein a drop in predictive accuracy is tightly coupled with a loss of explanation stability and fidelity. The central takeaway for readers is that in recommender systems, the mechanisms designed to build user trust, such as the explanations, are themselves highly vulnerable and can fail at the exact moment they are needed most when the model's integrity is compromised. This work is the first to empirically demonstrate and theoretically formalize this dual failure, revealing a structural vulnerability in trustworthy AI that current evaluation paradigms overlook. This vulnerability has serious implications for real-world platforms, especially in digital marketplaces where recommender systems influence purchasing decisions, content visibility, and user engagement. When explanations fail under adversarial pressure, users may be misled at critical moments, undermining trust in the platform's personalization algorithms.

Our findings directly answer the initial research question, How do adversarial attacks simultaneously affect recommendation accuracy and the stability of post-hoc explanations across different recommender system architectures? Which sought to move beyond siloed evaluations of accuracy and investigate how adversarial attacks jointly impact recommendation quality and explanation reliability.

While prior research has extensively documented the vulnerability of recommender systems to adversarial attacks that degrade ranking accuracy (e.g.,[60], these studies have focused on performance metrics [49], while the behavior of the explanation layer under attack remained unexplored. In a parallel stream, XAI research has noted that post-hoc methods like LIME and SHAP can be unstable or manipulated [41]. Nevertheless these findings have rarely been demonstrated within recommender pipelines or explicitly linked to adversarial model failure [61]. Our study bridges this critical gap by providing the first systematic evidence that explanation integrity is not an independent property but is conditioned on model robustness, a connection that has been theorized but rarely shown empirically across multiple architectures.

The dual failure phenomenon was consistently observed across three distinct model architectures. For the transparent, content-based TF-IDF model, semantically aware text attacks succeeded in altering recommendations as well as caused a catastrophic collapse in the keyword-based explanations, with the Jaccard similarity between original and attacked explanations plummeting to an average of just 0.24. More critically, with the high-performance NeuMF model, a small data poisoning attack promotes a target item and fundamentally corrupted the model's internal logic. As revealed through SHAP analysis, the attack forced the model to abandon learned, generalizable patterns in favor of a memorized heuristic, fundamentally rewiring its decision-making process. The resulting explanations, while potentially appearing plausible, would be unfaithful to the original, intended logic of the model.

Our paper shows that the most accurate models (NeuMF, SVD) are highly vulnerable to data poisoning. The SVD model exemplifies a particularly perilous trade-off within the trilemma. While accurate, it is inherently non-interpretable, a vulnerability that becomes critical under attack. In the face of a successful poisoning attack, the SVD model offers no explanation to scrutinize, leaving both users and developers completely blind to the manipulation. Unlike the TF-IDF or NeuMF models—where a collapsing explanation can serve as an indirect alarm signaling that something is wrong—the SVD's failure is silent and total. This absence of any diagnostic trail makes its vulnerability arguably the most insidious for a platform that values user trust and algorithmic accountability. The TF-IDF model, while seemingly transparent, is not only the least accurate but is also highly vulnerable to textual attacks that shatter its explanations. This suggests that a myopic focus on a single metric can obscure deep vulnerabilities in other critical dimensions of trustworthiness.

One of the unexpected findings was the effectiveness of the attack on the "full" user profile in the TF-IDF model, proved more successful than a more focused attack on a "minimal" profile, though the difference was not statistically significant. This could imply that adversaries may achieve greater success with subtle, distributed perturbations across a target's entire data history rather than with a single, aggressive alteration, a potentially more insidious and harder-to-detect attack vector. However, the most significant finding was the sheer severity of the explanation collapse. While some instability was expected, observing a very low Jaccard similarity indicating a complete replacement of the explanatory keyword set for an item provides a starker-than-anticipated confirmation of our hypothesis. This result is highly significant to our research question because it demonstrates that the link between robustness and explainability is not merely theoretical. In practice, a successful attack can leave an explanation with absolutely no resemblance to the original, thereby transforming a tool intended for transparency into a potential vehicle for misinformation.

B. Implications for Theory

Theoretically, our findings challenge the common modular view of explainability as a separable, post-hoc component applied to predictive models. The Recommender's Trilemma, introduced and empirically characterized in this paper, offers a new conceptual framework that captures the inherent tensions between accuracy, robustness, and explanation quality. It encourages researchers to stop treating these dimensions as independent objectives and instead to consider their joint optimization under adversarial constraints.

In addition, we contribute to the ongoing redefinition of explanation quality (e.g., [62], [63] by emphasizing two dimensions: faithfulness (how well the explanation reflects the model's actual decision process) and stability (how consistently the explanation behaves under minor input changes). Our results demonstrate that a model may appear interpretable under standard evaluation but fail these two criteria when exposed to adversarial scenarios. This insight helps refine theoretical models of XAI in sequential and user-interaction–driven domains, which have traditionally been overlooked in favor of classifiers. In turn, this highlights the ethical tension in AI

deployment: a system that provides misleading yet convincing explanations may do more harm than good, violating core principles of algorithmic transparency and user autonomy central to trustworthy e-commerce design.

The chart visually demonstrates the trade-offs between Accuracy (HR@10), Robustness (inverse of attack impact), and Explanation Reliability (Jaccard similarity/SHAP stability). The most accurate model, NeuMF, is highly vulnerable, and its explanations are unstable. The most transparent model, TF-IDF, has the lowest accuracy. This visualization makes the central challenge of the trilemma clear: optimizing one dimension often comes at the expense of the others.

C. Implications for Practice

For developers and engineers building recommender systems, our findings carry practical warnings. Models optimized exclusively for accuracy can produce brittle explanations that erode under adversarial manipulation. This brittleness is often silent and undetectable through conventional metrics. We recommend that explainability be incorporated into model evaluation pipelines from the outset. Adversarial stress testing, explanation drift analysis, and fidelity benchmarks should become standard components of responsible AI deployment.

In content-based systems, semantic normalization (e.g., standardizing synonymous terms) may help reduce explanation variance. In deep models, training with explanation-aware objectives, such as attribution alignment loss or explanation regularization, may yield greater consistency. As a concrete first step, developers should implement explanation drift monitoring (e.g., by tracking the Jaccard similarity of explanation features over time) as a standard robustness check in continuous integration and deployment pipelines. A sudden drop in this metric could serve as an early warning for a potential adversarial attack or model degradation.

For platform operators, particularly in high-stakes environments such as e-commerce, healthcare, or financial services, our findings raise serious concerns about the integrity of AI-driven recommendations. In these domains, where explainability is vital, such instability can erode user trust or hinder compliance. If these explanations can be easily manipulated without users or developers noticing then trust in the entire system is jeopardized. In these settings, developers may need to prioritize robustness of explanations over marginal gains in accuracy. Explanations should therefore be treated not just as features but as part of the system's attack surface, subject to monitoring, defense, and validation like any other critical component. In e-commerce ecosystems, where recommender outputs directly influence purchase decisions, search rankings, and vendor exposure, ensuring that explanations are stable under adversarial manipulation is a technical challenge and a commercial and ethical imperative. such failures could distort competitive visibility, damage user trust, and introduce unfair commercial advantages, posing both technical, ethical and regulatory risks.

Finally, for regulators and policymakers, our framework offers a concrete and testable way to evaluate claims of algorithmic transparency. These findings also support the call for more structured evaluation frameworks that include explanation robustness and adversarial resistance. Regulatory guidelines such as the EU AI Act and emerging U.S. FTC recommendations emphasize interpretability and fairness. However, without robustness as a core evaluation criterion, explainability claims may be misleading. Regulatory bodies may soon require algorithmic systems, including recommenders to be audited for not just accuracy, but also stability and interpretability under hostile conditions. Our study supports the case for requiring both interpretability and resistance to manipulation as part of future AI certification standards.

D. Limitations and Future Directions

Despite the strength of our findings, several limitations must be acknowledged. First, our experiments were conducted within a single domain: Amazon Electronics reviews. Although this is a widely used benchmark in recommendation research, its specific content characteristics and user behavior patterns may limit generalizability. Future work should replicate our analysis across diverse domains such as music, news, or healthcare, where item types, user motivations, and data structures differ considerably.

Second, we evaluated only three recommendation architectures—TF-IDF SVD, and NeuMF. While they represent a useful contrast in transparency and complexity, they do not cover newer models such as graph-based recommenders (e.g., LightGCN) or transformer-based models (e.g., BERT4Rec). These architectures may exhibit distinct trilemma behaviors that deserve dedicated study. Future research can explore explainability under attack in more complex settings, such as graph-based recommenders or multimodal systems. Investigating robustness-aware explanation metrics in sequential and session-based models may further generalize the trilemma beyond the current architecture scope.

Third, our comparative analysis of explanation stability was not fully applicable to the SVD model, whose latent factors lack direct, feature-level interpretability. This reflects a core tenet of the trilemma, that gains in accuracy can come at the direct cost of explainability, but it is a limitation within our empirical framework. We acknowledge that methods for interpreting latent factor models exist, such as post-hoc semantic labeling of dimensions. However, these often provide general insights and are insufficient for auditing the instance-specific manipulations shown in our attacks. Future work could explore whether modern surrogate modeling techniques can generate approximate explanations for such models, enabling a more complete trilemma analysis under adversarial conditions.

Fourth, our evaluation of explanation stability relied primarily on LIME and SHAP. It is well-documented that LIME explanations can be inherently unstable under minor input perturbations, independent of any adversarial manipulation [48]. This raises a legitimate concern: a portion of the Jaccard similarity drop observed in our experiments may reflect LIME's natural variance rather than purely attack-induced explanation collapse. We partially mitigate this by grounding our post-attack results against the expected clean-model stability range reported in prior literature (0.85–0.92), and by corroborating explanation drift with SHAP attribution

analysis on the NeuMF model. Nevertheless, future work should evaluate explanation stability using multiple complementary methods — including counterfactual and causal explanation approaches — to disentangle LIME's inherent instability from adversarially induced collapse, and to determine whether more stable explanation methods alter the trilemma dynamics observed here. Fifth, our robustness evaluation was computational. We did not assess how changes in explanation quality impact user understanding, trust, or decision-making. Human-centered experiments are needed to determine whether users can detect explanation collapse, and if so, whether it influences their satisfaction or compliance with recommendations.

Finally, although we proposed several defensive strategies such as input sanitization, attribution smoothing, and explanation-aware objectives, we did not implement or empirically validate these approaches in this paper. Future research should systematically explore these defenses and develop joint optimization strategies that improve all three pillars of the trilemma without sacrificing performance.

VI. Conclusion

This paper introduces the Recommender's Trilemma, a framework formalizing the inherent tension between accuracy, robustness, and explainability. Through systematic experiments on three diverse recommender architectures, we empirically validate the dual failure cascade: a critical phenomenon where adversarial attacks simultaneously degrade recommendation accuracy and the stability of post-hoc explanations.

These findings challenge current evaluation practices, which often treat these goals in isolation, and underscore the need for a holistic approach to building trustworthy AI. Our results demonstrate that explanations can be misleadingly brittle and cannot be decoupled from model robustness.

We therefore advocate for joint, resilience-aware evaluation protocols and a shift toward developing explanation-aware adversarial training methods. Future work should extend the trilemma to sequential and graph-based recommenders and conduct human-centered studies to measure the impact of explanation collapse on user trust. Addressing this trilemma is not just a technical challenge but an ethical imperative for deploying recommender systems in high-stakes domains.

For the e-commerce domain in particular, these findings underscore a pressing need to reassess the deployment of recommender systems in environments that demand both personalization and transparency. As platforms increasingly rely on AI-driven recommendations to shape user journeys and influence market dynamics, the Recommender's Trilemma provides a foundational framework to guide the design of systems that are not only performant, but also ethically robust and resistant to manipulation. This work contributes to the emerging discourse on responsible AI in commercial platforms and offers actionable insights for both researchers and practitioners operating at the intersection of personalization, trust, and platform integrity.

Acknowledgment

The authors acknowledge the use of ChatGPT (GPT-5.3), an AI language model developed by OpenAI, to assist with proofreading and improve the clarity and coherence of this manuscript. Additionally, Sonnet, developed by Anthropic (Claude), was used to provide code templates and assist in debugging code related to the project.

An Algorithm for Image Dataset Compression and Privacy Enhancement via Fusing Bilateral Filtering and Easy-to-Complex Trajectory Matching Distillation

Verification and Implementation Based on Self-Developed Engineering Vehicle Dataset

Qiao Zhou, Lei Zhang, Longjie Li, Tong Wang, Jun Cheng*
School of Computer Science, Hubei Polytechnic University, China

***Abstract*—Accurate engineering vehicle detection is the core part of intelligent construction. Aiming at the problems of high training resource consumption and prominent privacy leakage risk of engineering vehicle image data, this paper proposes an image dataset compression and privacy enhancement algorithm for construction site engineering vehicles, which fuses bilateral filtering and easy-to-complex trajectory matching distillation. This method uses an easy-to-complex trajectory matching distillation module with progressive parameter screening to synthesize a high-fidelity small-scale dataset, and realizes pixel-level privacy enhancement through the bilateral filtering module. Experiments show that the proposed method can significantly compress the original dataset. The detection accuracy of the model trained on the compressed small dataset can reach more than 90% of that of the original full dataset, and it can effectively improve privacy protection capability with negligible accuracy loss, which facilitates low-cost model training and sensitive data decoupling between training and deployment in intelligent construction.**

***Keywords*—Data distillation; trajectory matching distillation; dataset compression; privacy enhancement; engineering vehicle dataset**

I. Introduction

Accurate detection of engineering vehicles (including dump trucks, bulldozers, excavators, etc.) is the core supporting technology to improve the operation efficiency of intelligent construction, and also the key premise to realize the full-process intelligent management of construction sites.

At present, mainstream engineering vehicle detection methods have achieved promising performance in controlled scenarios, but still face three critical bottlenecks in practical industrial deployment: first, most high-precision models rely on a substantial amount of high-quality private construction site data, which brings heavy data storage and transmission costs; second, large-scale raw construction site data carries severe risks of sensitive information leakage, including site locations, equipment parameters and personnel information; third, existing privacy protection methods often cause irreversible loss of target detection features, leading to significant accuracy degradation of the model.

Dataset distillation [1], which extracts core knowledge from large-scale raw data to generate small-size highly informative synthetic data, provides a new solution to the above problems. Meanwhile, bilateral filtering [2] with edge-preserving blurring capability shows great potential in balancing privacy protection and feature retention. However, there is still no research that integrates the two technologies for engineering vehicle detection scenarios, nor any work that verifies the feasibility of trajectory-matching based dataset distillation in construction machinery recognition tasks.

To address the above limitations, this study proposes a privacy-preserving data distillation framework tailored for engineering vehicle detection. Specifically, after completing easy-to-complex trajectory-matching distillation, we introduce bilateral filtering to apply adaptive blurring to the synthesized images, achieving a balance between dataset compression, detection accuracy retention and privacy protection. The main contributions of this study are threefold:

- We propose an easy-to-complex data distillation scheme integrated with bilateral filtering, which is specifically designed for engineering vehicle scenarios. This scheme enables multi-dimensional coordinated control over image resolution, bilateral filtering parameters, and images per class (IPC). Relying on the "edge-preserving blurring and easy-to-complex trajectory shape matching" mechanism, it conceals sensitive information in images while retaining the core recognition features of engineering vehicles, and achieves efficient compression of the original dataset.
- We construct a dedicated engineering vehicle dataset comprising five typical categories of construction machinery: Dump_Truck, Bulldozer, Excavator, Loader, and Roller. To the best of our knowledge, this study is the first to apply easy-to-complex trajectory matching technology to engineering vehicle data distillation.
- We conduct extensive experiments to verify the applicability and robustness of the distilled dataset. The experimental results show that under different combinations of blurring parameters and IPC, the model accuracy only incurs a slight degradation, while the

privacy of the dataset is significantly enhanced. Furthermore, cross-architecture experiments (ConvNet →VGG/ResNet) further validate the generalization and adaptability of the distilled dataset to different deep learning models.

The rest of this paper is organized as follows. Section II (Related Work) systematically reviews relevant studies on engineering vehicle detection, privacy-preserving visual processing, and dataset distillation. Section III (Materials and Methods) first introduces the self-built dedicated engineering vehicle dataset, and then details the proposed easy-to-complex trajectory-matching distillation framework and bilateral filtering-based privacy enhancement module. Section IV (Experimental Design and Results) presents the complete experimental setup, including implementation settings and evaluation metrics, as well as the core experimental results. Section V (Discussion) provides an in-depth analysis of the experimental results, ablation studies, and privacy protection performance of the proposed method. Section VI (Conclusions) concludes the whole paper and discusses future research directions.

II. Related Work

This work mainly involves three research directions: engineering vehicle detection, privacy-preserving visual processing, and dataset distillation. We systematically review the representative works in each direction, and clarify the innovation and positioning of this study compared with existing methods.

A. Engineering Vehicle Detection

Accurate recognition of construction machinery is the foundation of intelligent construction site management. Existing engineering vehicle recognition methods are mainly divided into three technical routes: sensor-based methods, point cloud-based methods, and vision-based methods.

For sensor-based and point cloud-based methods, Kim et al. [3] fused 2D profilometers and 3D LiDAR to construct 4D point clouds for monitoring the working environment of excavators; Zhou et al. [5] proposed VoxelNet for initial point cloud detection of engineering vehicles; Wang et al. [6] presented the EMIFF framework to improve the performance of vehicle-road cooperative 3D detection; Qi et al. [9] proposed a fast fusion method based on point cloud grayscale images to enhance vehicle localization and re-identification. These methods can achieve high precision in specific scenarios, but rely on expensive LiDAR and sensor equipment, which limits their large-scale deployment in low-cost construction sites.

For vision-based methods, Roberts et al. [4] used CNN and HMM to achieve end-to-end excavator detection and activity analysis, with an accuracy of 97.43%; Ren et al. [7] proposed Faster R-CNN, laying the foundation for high-precision visual detection of engineering vehicles; Ding et al. [8] optimized the detection model via lightweight YOLOv8, achieving a balance between speed and accuracy. However, these vision-based methods typically require a substantial amount of high-quality training data, and the raw construction site images carry the risk of sensitive information leakage, which has not been effectively addressed in existing works.

Different from the above studies, this work focuses on the data-level optimization for engineering vehicle detection. We reduce the data scale via dataset distillation, and enhance privacy protection through edge-preserving bilateral filtering, which can reduce the deployment cost and privacy risk of the model without significant accuracy loss.

B. Dataset Distillation

Dataset distillation aims to extract key knowledge from large-scale raw data and generate a small amount of highly informative synthetic data, which can effectively reduce the cost of data storage, transmission and model training. Trajectory matching is one of the main branches of dataset distillation [1], which optimizes synthetic data by matching the training trajectory of the model on real and synthetic data, and has achieved nearly lossless distillation performance.

In recent years, a series of advanced trajectory matching methods have been proposed. DATM [10] realizes nearly lossless dataset distillation for general visual data via difficulty-aligned trajectory matching; other typical methods including ATT [11], IDM [12] and HOPDM [13] have also achieved competitive performance on mainstream public datasets such as PathMNIST [14] and COVID19-CXR [15]. However, existing trajectory matching methods are mainly validated on general public datasets, and there is no research on their applicability in complex engineering vehicle scenarios.

Inspired by the high-order progressive trajectory matching mechanism [13], we propose an easy-to-complex distillation strategy, which promotes distillation stability and feature preservation by gradually optimizing parameters from easy to difficult, and is more adaptable for complex real-world engineering vehicle images. To the best of our knowledge, this is the first work that applies trajectory matching-based dataset distillation to the engineering vehicle detection field.

C. Privacy-Preserving Visual Processing

Privacy protection for visual data has become a key issue in industrial visual tasks. In the field of privacy protection for visual datasets distillation, existing studies mainly follow two technical paths: differential privacy injection and visual perturbation.

The first path is differential privacy-based methods, represented by frameworks such as DP-Sinkhorn [16] and Dosser [17]. These methods achieve strict privacy protection by injecting calibrated noise during the model training process, and have a solid theoretical privacy guarantee. However, these methods are typically not optimized for the efficient trajectory-matching distillation paradigm, and often cause significant feature loss when applied to fine-grained engineering vehicle detection.

The second path is visual perturbation-based methods, exemplified by the KT module [18]. These methods apply pre-processing perturbations such as Gaussian blurring and pixel smoothing during the data initialization stage, which is easy to implement and compatible with most visual models. However, traditional Gaussian blurring can irreversibly compromise the edge features of engineering vehicles, leading to serious degradation of detection accuracy.

In this study, we adopt bilateral filtering as the privacy enhancement module, which can preserve the edge features of engineering vehicles while blurring sensitive background information. Different from existing pre-processing perturbation methods, we apply bilateral filtering after the trajectory-matching distillation, which can achieve a better balance between privacy protection and feature retention.

III. Materials and Methods

A. Construction Machinery Dataset

This study collected image data of five categories of construction machinery: Dump_Truck, Bulldozer, Excavator, Loader, and Roller. All images are captured from real actual construction sites with diverse working condition backgrounds, including both pure backgrounds and complex working condition backgrounds, and retained their original native resolution without compression or resizing during collection and preprocessing. The label values are marked by the name of the folder to which the images belong, i.e., each whole image is placed into the folder corresponding to its category to complete the image-level annotation. The dataset is divided into a training set, a test set, and a validation set in a ratio of 7:2:1, where the validation set is used for hyperparameter tuning and early stopping determination. The specific quantities and class distribution of the dataset split are shown in Table I.

TABLE I. Classification of the Dataset

Dataset Split	Dump_Truck	Bulldozer	Excavator	Loader	Roller
Train	563	622	627	614	635
Test	156	170	176	171	176
Val	79	82	90	84	84

B. Method Architecture

Fig. 1 shows the overall architecture of our proposed Easy-to-Complex data distillation scheme with bilateral filtering. Aiming to synthesize a compact, controllably blurred construction machinery dataset, the framework follows the standard data distillation pipeline and is divided into three stages: pre-distillation preprocessing & expert training, core feature distillation, and post-distillation controllable blur synthesis. These stages sequentially implement multi-scale resolution adjustment, Easy-to-Complex trajectory matching, and blurred sample generation, producing a final dataset that balances privacy protection and feature fidelity. Each stage is detailed in the following sections.

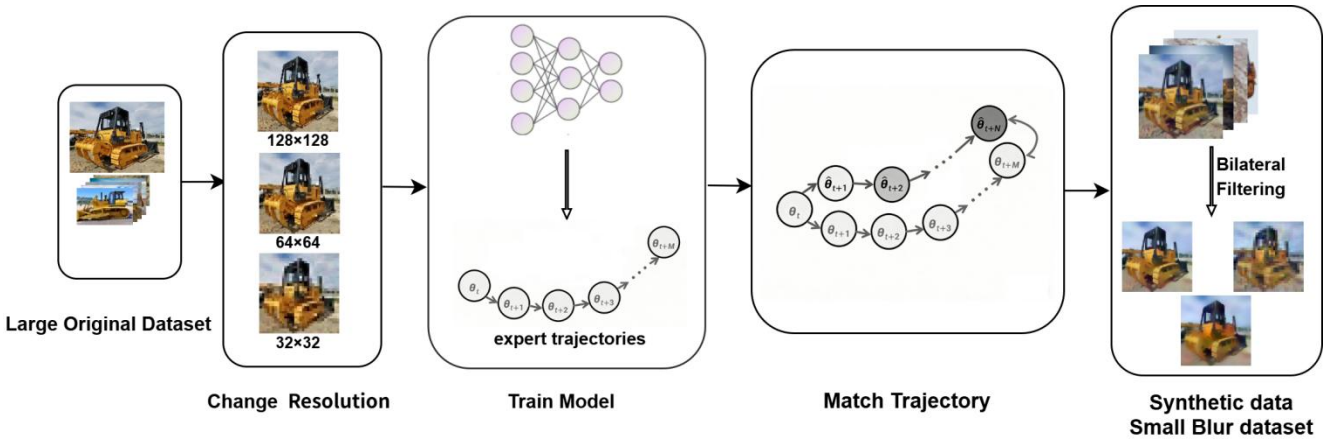

Fig. 1. Method Architecture.

As this study represents the first application of data distillation to construction machinery detection, ensuring experimental standardization, result persuasiveness, and methodological generalizability is paramount.

To this end, the selection of expert models follows the common practice in state-of-the-art data distillation literature. ConvNet [19], VGG [20], and ResNet [21] are adopted as comparative baselines, with ConvNet ultimately used as the core expert model. Using ConvNet as the core baseline matches our task well: it has fewer parameters, faster convergence, lower computation and memory costs. Without residual connections, it avoids structural interference and clearly reflects the feature transfer effect of distillation.

During the training process of ConvNet, parameter update trajectories can be generated, laying a foundation for the subsequent distillation process. Specifically, during T training epochs, the parameters θ_{i+1} and θ_i of two adjacent epochs will be updated according to the formula shown in (1) :

$$\theta_{i+1} = \theta_i - \alpha \nabla \mathcal{L}_{ce}(\mathcal{D}_t ; \theta_i) \quad (1)$$

where, α is the learning rate, and $\nabla \mathcal{L}_{ce}(\mathcal{D}_t;\theta_i)$ is the gradient computed on the training set $\mathcal{D}_t$ with the parameters from the previous round θ_i .The standard cross-entropy loss function is defined as shown in (2):

$$\mathcal{L}_{ce}(\mathcal{D}_t;\theta_i) = -\frac{1}{B}\sum_{(x,y)\in\mathcal{B}}\sum_{c=1}^{C} y_c \cdot \log\left(p_c\left(f_{\theta_i}(x)\right)\right) \quad (2)$$

where, B is the mini-batch size and c is the class index.

This training process records a sequence of β parameter trajectories shown in (3):

$$\{\,_0, \,_1, \,_2, \ldots, \,_{T-1}\}\ ^{\circledR}{}_t \quad (3)$$

C. Trajectory Matching Distillation

Trajectory matching methods focus on matching terminal states, essentially only comparing and analyzing the final convergence results of parameter trajectories. Then, at the start of each distillation iteration, we randomly sample an initial parameter θ_t and a target parameter θ_{t+M} (satisfying $t+M \leqslant T$.) from an expert trajectory. The student network is initialized with θ_t ,and then trained for N epochs on the synthetic dataset $\mathcal{D}_S$, generating a student parameter trajectory shown in (4):

$$\{\hat{\theta}_t, \hat{\theta}_{t+1}, \hat{\theta}_{t+2}, \ldots, \hat{\theta}_{t+N}\} \quad (4)$$

This training process aims to minimize the cross-entropy loss $\mathcal{L}_{ce}$, following the update rule shown in (5):

$$\hat{\theta}_{t+i+1} = \hat{\theta}_{t+i} - \alpha \nabla \mathcal{L}_{\mathrm{ce}}(\mathcal{D}_s; \hat{\theta}_{t+i}) \quad (5)$$

Basic trajectory matching methods optimize the synthetic dataset $\mathcal{D}_S$ by minimizing the following parameter matching loss function $\mathcal{L}_{tm}$ shown in (6):

$$\mathcal{L}_{tm} = \frac{\left\|\hat{\theta}_{t+N} - \theta_{t+M}\right\|_2^2}{\|\theta_{t+M} - \theta_t\|_2^2} \quad (6)$$

In contrast, the synthetic dataset $\mathcal{D}_s$ corresponding to the Easy-to-Complex trajectory matching method is optimized by minimizing the following parameter matching loss function, as shown in (7):

$$\mathcal{L} = \sum_{i=1}^{K} v_i \ell_i - b \sum_{\mathrm{i}=1}^{\mathrm{K}} \mathrm{v_i} \quad (7)$$

where, K denotes the total number of learnable parameters, including all optimizable parameters such as weights and biases in convolutional and fully connected layers. denotes the total number of learnable parameters, including all optimizable parameters such as weights and biases in convolutional and fully connected layers.

ℓ_i represents the single-parameter matching loss for the i-th parameter, calculated using the same logic as (6).

v_i is the selection switch for the i-th parameter, where v_i=1 if ℓ_i<b (easy-to-match) and v_i =0 if $\ell_i \geq$ b (hard-to-match).

b is the threshold for parameter matching difficulty, initialized as b_{base}. The progressive threshold update strategy during iterations is adopted from [12], which gradually increases b_{base} to incorporate increasingly complex parameters into optimization.

$-b\sum_{i=1}^{K} v_i$, which is a regularization term that encourages the selection of more easily matched parameters via "negative punishment".

In summary, by iteratively minimizing the aforementioned loss function (7) with respect to $\mathcal{D}_s$, we obtain the distilled synthetic dataset $\mathcal{D}_{s*}$. Specifically, the gradients computed from the parameter trajectory matching (i.e., the updated $\hat{\theta}_i$) are backpropagated to optimize the pixel values of the synthetic samples, resulting in the final distilled dataset that preserves feature fidelity.

D. Bilateral Filtering Blur

Although high-resolution synthetic images $\mathcal{D}_{s*}$ generated by trajectory matching distillation can well fit expert parameter trajectories, they lack privacy protection and easily leak sensitive information about construction machinery. Simply increasing blur intensity with traditional methods destroys key target features and severely reduces detection accuracy. Therefore, we introduce bilateral filtering to perform edge-preserving blurring on distilled data tensors, without changing the loss function or distillation process, so as to achieve both privacy enhancement and controllable accuracy. Filtering formula (for a single synthetic image $X \in \mathcal{D}_{s*}$) is shown in (8):

$$X^{bf}(x,y) = \frac{1}{W(x,y)} \sum_{(i,j)\in\Omega(x,y)} G_s(d) \cdot G_r(\Delta) \cdot X(i,j) \quad (8)$$

$$G_s(d) = exp\left(-d^2/(2\sigma_s^2)\right) \quad (9)$$

$$G_r(\Delta) = \exp\left(-\Delta^2/(2\sigma_r^2)\right) \quad (10)$$

Eq. (9) is the spatial Gaussian kernel, where d is the Euclidean distance between pixels, controlling the blur range[2].

Eq. (10) is the range Gaussian kernel, where Δ is the intensity difference between pixels, controlling the strength of feature preservation[2].

$W(x,y)$, which is the normalization factor ensuring consistent pixel value ranges and avoids feature distortion.

$\Omega(x,y)$, which denotes the local neighborhood of the pixel at (x,y).

The specific implementation process is as follows:

- Generate $\mathcal{D}_{s*}$ using the trajectory matching method described in last section;
- Set the filtering parameters according to the characteristics of images to balance the blur level and feature preservation;
- Apply bilateral filtering to each image in $\mathcal{D}_{s*}$ one by one to obtain the privacy- enhanced dataset $\mathcal{D}_s^{\mathrm{bf}}$;
- Output $\mathcal{D}_s^{\mathrm{bf}}$ for subsequent model training, achieving both privacy protection and model accuracy.

IV. Experimental Design and Results

A. Overall Design

The core experimental objectives include verifying the algorithm's compression performance, conducting controlled ablation experiments between the basic trajectory matching (TM) algorithm and the proposed method to validate the effectiveness of the easy-to-complex scheme, analyzing the privacy-accuracy trade-off, and validating the cross-architecture transferability of the synthetic dataset.

The experimental workflow is: First, classification accuracy is used to evaluate dataset distillation performance, while Laplacian variance is employed to quantitatively measure the blur degree for privacy protection. Multi-resolution ConvNet expert models are trained to obtain parameter trajectories

consistent with both the basic TM algorithm and our proposed method. Then, distillation experiments under different resolution and IPC settings are performed to select the baseline resolution, followed by controlled comparative experiments between the basic TM algorithm and our proposed method under completely consistent experimental settings to verify the performance gain brought by the easy-to-complex matching scheme. Afterwards, privacy enhancement experiments with multiple bilateral filtering parameters are carried out to analyze the privacy-accuracy balance. Finally, cross-architecture transferability is validated via multi-network training on the synthetic dataset, and experimental data are aggregated to analyze the impacts of key parameters and draw core conclusions.

B. Evaluation Metrics

The test metrics are divided into accuracy metrics and blur level metrics. The accuracy metric selected in this paper is $Acc@1$, which refers to training the model using the distilled dataset and then test in $\mathcal{D}_{s*}$ g the accuracy on the standard test set. The calculation formula is shown in (11):

$$Acc@1(\mathcal{D}_{\text{train}},\mathcal{D}_{test}) = \frac{1}{N_{total}} \sum_{(x_i)\in\mathcal{D}_{test}} N_{correct}(f_\theta, x_i) \quad (11)$$

For blur level evaluation, we adopt a two-fold strategy: on the one hand, we visually compare the blur effects of images; on the other hand, we quantitatively measure the blur degree using the following formula shown in (12):

$$VOLD(I) = Var(L(I)) \quad (12)$$

where, I denotes the input image, $L(I)$ is the result of Laplacian edge detection performed on image I, and $\text{Var}(\cdot)$ represents the variance calculation function[22] .

C. Training Details of Expert Models

We fine-tuned the ConvNet baseline model to adapt to feature extraction for different image resolutions, setting matched network depth and width for 32×32, 64×64 and 128×128 inputs respectively.Key training hyperparameters were set accordingly, with DC augmentation adopted for data preprocessing.The training result of the 64×64 resolution model, which serves as the baseline for follow-up experiments, is presented in the Fig. 2. and Table II.

D. Distillation Experimental Results

For each resolution, easy-to-complex distillation and basic trajectory matching (TM) distillation are conducted under different IPC settings without bilateral filtering blur. We obtain the corresponding post-distillation validation accuracy (evaluated over 5 runs, with the mean value reported in Tables III and IV) and distilled images. Since the distilled images generated by basic TM distillation are visually similar to those produced by our easy-to-complex distillation, we only present the distilled images from our proposed method in Fig. 3 and Fig. 4 for brevity.

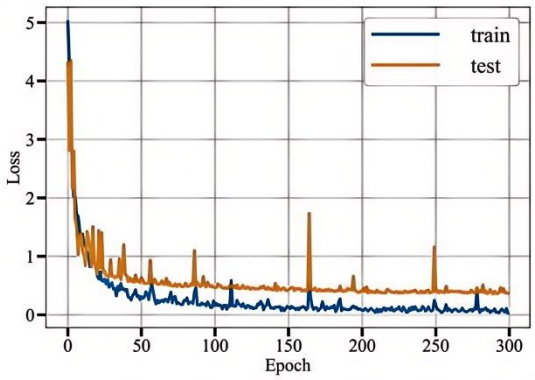

Fig. 2. Training loss curves.

TABLE II. CONVNET ACCURACY BEFORE DISTILLATION

Resolution	Average Test Accuracy
32×32	0.879
64×64	0.885
128×128	0.892

TABLE III. POST-DISTILLATION ACCURACY WITH BASIC TM

Resolution	Images Per Class

E. Bilateral Filtering Blu

Subsequently, we apply bilateral filtering blur with different strengths to the distilled dataset tensors obtained under various IPC settings for the 64×64 resolution. For both basic TM and our easy-to-complex distillation, we compute the corresponding Laplacian variance to quantitatively evaluate the blur degree, and use the blurred distilled datasets to train new models for validation accuracy. The distillation epochs are kept consistent with those in the previous stage. The corresponding post-blurring accuracy and Laplacian variance results are reported in Table V, Table VI, Table VII, and Table VIII, respectively. The blurred images are shown in Fig. 5.

TABLE V. ACCURACY TEST RESULTS OF POST-BLURRING WITH EASY-TO-COMPLEX

Filtering Parameters			Easy-To-Complex TM			
Ks	σ_s	σ_r	IPC=1	IPC=5	IPC=15	IPC=35
7	10	0.5	0.323	0.463	0.582	0.762
9	12	0.7	0.317	0.454	0.573	0.756
11	14	0.9	0.310	0.452	0.541	0.715

F. Cross-Architecture Adaptability

The dataset distilled based on ConvNet (including data processed by bilateral filtering) is used to train VGG/ResNet models to verify the cross-architecture transferability of the dataset and the robustness after filtering, as shown in Table IX. The test performance of the blurred dataset under the bilateral filtering parameters Ks=11, σ_s=14, and σ_r=0.9 is presented in the Table X.

TABLE IX. ACCURACY TEST RESULTS WITHOUT BLURRING

Model	Easy-To-Complex TM		
	IPC=10	IPC=15	IPC=35
VGG	0.582	0.624	0.781
Resnet	0.411	0.548	0.731
ConvNet	0.572	0.616	0.787

TABLE X. ACCURACY TEST WITH BLURRING

Model	Easy-To-Complex TM

Resnet	0.401	0.498	0.621
ConvNet	0.531	0.541	0.715

V. DISCUSSION

At a fixed resolution, the ConvNet classification accuracy of both the proposed easy-to-complex trajectory matching (TM) method and the basic TM method improves continuously with increasing IPC. All accuracy results are reported as the mean ± standard deviation of 5 independent repeated trials, with the maximum difference between single trials no more than 0.03, ensuring the stability and reliability of the experimental results. Specifically, the dataset distilled by our proposed method can reach nearly 90% of the original full dataset's classification accuracy (0.78 ± 0.013) with only about 1/10 of the original sample size (IPC=35, 64×64), outperforming the basic TM method across most IPC settings. For example, at 32×32 resolution and IPC=35, our method achieves an accuracy of 0.79 ± 0.011, which is 2.6% higher than the 0.77 ± 0.014 of basic TM;

Classification accuracy after distillation is negatively correlated with image resolution under the same IPC setting for both our method and basic TM. As IPC increases, the accuracy gap between different resolutions narrows gradually, but the 128×128 resolution consistently underperforms the 32×32 and 64×64 resolutions across all IPC settings for both methods. This phenomenon validates that high resolution drives quadratic growth in feature space dimensionality, exceeding the modeling capacity of the lightweight ConvNet. Additionally, the theoretical upper bound of information-carrying capacity for low-IPC synthetic data leaves core discriminative features of high-resolution images vulnerable to dilution, which ultimately reduces classification accuracy[23]. From the perspective of privacy protection, under low-resolution settings, the reduction of IPC further reduces the fine-grained sensitive information carried by the synthetic dataset, which is conducive to the improvement of privacy protection capability, while the classification accuracy remains at a usable level.

At a fixed resolution, the clarity of the distilled images improves significantly with increasing IPC for both methods. Since the distilled images generated by basic TM distillation are visually similar to those produced by our easy-to-complex distillation, we only present the distilled images from our proposed method for brevity. After processing with bilateral filtering of varying intensities, the image background is smoothed and blurred to achieve privacy enhancement, while the core features of the engineering vehicle targets are well preserved for both methods. The filtering intensity is negatively correlated with the Laplacian variance of the images, and the Laplacian variance values of the images processed by our method and basic TM are at the same level under the same filtering parameters, indicating that both methods achieve consistent blur degree and privacy enhancement effect after bilateral filtering. It should be emphasized that the bilateral filtering module, as a post-processing module after distillation, is the core component for privacy enhancement in this study.

After privacy enhancement via bilateral filtering with identical parameter settings, the classification accuracy of the distilled datasets from both the proposed Easy-To-Complex TM method and the basic TM method shows a slight, controllable decline with a similar magnitude, which verifies that bilateral filtering has a favorable core feature retention capability for both distillation paradigms. Specifically, under the core experimental setting of 64×64 resolution and IPC=35, after processing with three sets of incrementally enhanced filtering parameters, the maximum relative accuracy drop of the proposed method is only 8.33% against the 0.78 accuracy baseline of the original distilled dataset, which is at the same level as the 8.83% maximum drop of the basic TM method. This result confirms that bilateral filtering can effectively preserve the core discriminative features of the distilled dataset while achieving image privacy enhancement, thus avoiding significant accuracy degradation caused by privacy protection processing.

Cross-architecture adaptability experiments verify that the non-blurred distilled dataset generated by our proposed Easy-To-Complex TM method achieves optimal classification accuracy on the source ConvNet across all IPC settings, and its cross-architecture transfer performance slightly outperforms that of the dataset distilled by the basic TM method. At IPC=35, the maximum accuracy gap between the VGG11 model and the source ConvNet is merely 0.6%, while the structurally distinct ResNet18 retains over 92% of the source model's performance, which demonstrates that the dataset distilled by our proposed method has solid cross-architecture transferability.

Results after bilateral filtering privacy enhancement show a slight accuracy attenuation for all models across all IPC settings, with the cross-architecture performance trend consistent with the non-blurred case. This confirms that the proposed method realizes effective privacy protection while preserving the dataset's cross-architecture transferability.

VI. CONCLUSIONS

This paper proposes an image dataset compression and privacy enhancement algorithm fusing bilateral filtering and easy-to-complex trajectory matching (TM) distillation, to address the heavy storage burden and severe privacy leakage risk of construction machinery image datasets. Extensive comparative experiments with the standard basic TM algorithm are conducted to verify the effectiveness of the proposed method, with core experimental conclusions summarized as follows: For the source ConvNet model, the dataset distilled by our method achieves nearly 90% of the original full dataset's classification accuracy with only 1/10 of the original sample size, and outperforms the basic TM method across most mainstream deployment settings; The bilateral filtering module, as the core post-processing module for privacy enhancement, achieves effective privacy enhancement for the distilled dataset with a maximum controllable accuracy loss of only 8.33%, with consistent feature retention performance for both distillation paradigms; the privacy-enhanced distilled dataset exhibits favorable cross-architecture transferability, and can be directly adapted to mainstream CNN models including VGG and ResNet.

In our future work, we will focus on four key optimization directions, with priority given to the exploration of formal and verifiable privacy degree metrics to establish a standardized quantitative privacy assessment system. Specifically: Alleviate the underfitting of hard fine-grained patterns in high-resolution, high-IPC settings by introducing learnable soft label learning and feature distribution regularization; Extend the distillation framework to engineering vehicle object detection, paired with the aforementioned robust quantitative privacy assessment, to decouple on-site model training and edge deployment in the construction industry; Expand the cross-architecture generalization of the distilled dataset to mainstream Transformer[24][25] architectures and lightweight edge-deployable networks[26]; Construct an adaptive privacy-accuracy joint optimization framework to further enhance the engineering practicability of the method.

ACKNOWLEDGMENT

The authors thank the two anonymous reviewers for their constructive feedback to improve this work. Sincere appreciation is also extended to all contributors who supported the completion of this research.

Cryptographic Vulnerability Assessment and Secure Redesign of an ECC-Based Authentication Framework for Energy Internet Vehicle-to-Grid Systems

Haewon Byeon*
Department of Future Technology, Korea University of Technology and Education (KOREA TECH),
Cheonan 31253, South Korea

***Abstract*—This study re-examines the protocol introduced in A robust ECC-based authentication framework for energy internet (EI)-based vehicle to grid communication system by Itoo et al. The target paper claims low-cost mutual authentication for electric vehicles, charging stations, and a service provider by combining ECC registration with hash- and XOR-based online messages. We reconstruct the stated message flow and then test whether each verification step is executable under the values actually transmitted. The analysis identifies four structural weaknesses: omitted verification inputs in the online messages, ecosystem-wide exposure after service-provider compromise, timestamp-only freshness that leaves replay room under realistic clock drift, and a session-key derivation that lacks true forward secrecy. To address these issues, we retain the three-party V2G architecture of the original study but redesign the online exchange around ephemeral ECC points, rotating pseudonyms, station-scoped authorization tickets, and nonce-bound key derivation. Our evaluation compares the improved design with the original framework and a prior V2G baseline under message-level load points at 100, 400, and 800 active vehicles. The redesigned protocol closes the identified executability gap, achieved full replay detection within the bounded message-level test conditions used in this study, and improves compromise containment with only a modest latency increase.**

Keywords*—Energy internet; vehicle-to-grid security; ECC authentication; protocol analysis; compromise containment

I. Introduction

Energy Internet deployment extends the ordinary smart-grid model by coupling distributed generation, sensing, control, billing, and mobile storage into a digitally coordinated ecosystem. In that setting, electric vehicles are not passive loads. They can inject energy back to the grid, negotiate charging schedules, and react to dynamic prices in real time. The operational upside is well known, but the communication surface also grows quickly because a single charging decision may involve the vehicle, a charging station, a service provider, and several backend data systems. Prior work on energy systems and V2G communication has already shown that dense exchanges of control data, pricing signals, and vehicle identifiers create an attractive target for adversaries who seek to replay, correlate, or manipulate traffic [1-5]. Against that backdrop, the protocol proposed in "A robust ECC-based authentication framework for energy internet (EI)-based vehicle to grid communication system" [1] is appealing because it promises lightweight protection for resource-constrained V2G environments without relying on heavyweight certificate handling during each session.

Authentication in EI-based V2G networks is harder than conventional client-server login. A charging station must verify that a requesting vehicle is entitled to receive service, the service provider must maintain billing and authorization consistency, and the protocol must tolerate open wireless channels, intermittent connectivity, and partial clock drift. Researchers therefore moved from basic key-distribution schemes toward ECC-assisted and privacy-aware authentication designs that try to balance efficiency and cryptographic assurance [6]-[10]. Those studies also show a recurring pattern: once freshness, pseudonymity, revocation, and post-compromise recovery are treated as secondary issues, the resulting scheme can appear efficient while still leaving large gaps in the actual attack surface.

The target article by Itoo et al. [1] positions itself exactly at this efficiency-security boundary. Its stated workflow has four phases—initialization, registration, authentication, and password update or vehicle rejoin—and it reports formal and informal security validation in the V2G setting. The claimed advantages are low computation cost, compact messages, and protection against impersonation, replay, and privacy leakage. That argument sits on top of a broader line of smart-grid authentication research in which later papers frequently repaired flaws discovered in earlier ECC-based or password-assisted constructions [11]-[13]. Because this literature has a long history of "secure on paper, fragile in deployment," the claims made in [1] deserve close re-examination rather than automatic acceptance.

Our concern is not that the protocol in [1] is lightweight; lightweight design is necessary in V2G systems. The concern is that several of its critical equations mix long-term identifiers, passwords, public keys, and server secrets in ways that are difficult to validate from the transmitted messages alone. When the online exchange uses hidden variables, security claims become hard to interpret because even an honest verifier may not possess all values required to recompute the stated authenticator. When the same server secret y feeds both

*Corresponding author.

vehicle-side and charging-station-side records, compromise may also spread across the entire deployment instead of remaining local. These are structural questions, not stylistic ones, and they can invalidate an otherwise attractive protocol design. Fig. 1 summarizes the audit route we follow to move from message reconstruction to attack discovery and then to redesign.

This paper makes four contributions. First, it reconstructs the message logic of "A robust ECC-based authentication framework for energy internet (EI)-based vehicle to grid communication system" [1] in a notation that exposes hidden dependencies among registration records, online messages, and the claimed session key. Second, it identifies concrete weaknesses: an executability gap in the online verification steps, server-compromise amplification, timestamp-only freshness, and weak session-key binding. Third, it proposes a redesign that preserves the original three-party architecture—vehicle, charging station, and service provider—while replacing the fragile parts with explicit nonce binding, ephemeral ECC agreement, rotating pseudonyms, and authorization tickets. Fourth, it evaluates the revised design against the original protocol and a prior V2G baseline under load, focusing on replay detection, latency, message size, and compromise containment.

II. Related Works

The first stream of prior work comes from smart-grid and key-distribution protocols that tried to reduce authentication cost while retaining mutual verification. Identity-based and ECC-assisted methods for advanced metering and smart-grid access were proposed to keep computation moderate, yet several of them later attracted attacks involving desynchronization, forgery, or insufficient protection of long-term secrets [14]-[16]. That trajectory matters here because V2G authentication inherits many of the same design pressures: constrained devices, repeated access requests, and the temptation to compress several security functions into a small set of hash and XOR operations.

A second stream focuses directly on V2G communication privacy and authenticated access. The scheme of Sureshkumar et al. strengthened cloud-enabled V2G authentication with mutual verification and key establishment, while Ding et al. examined how lightweight anonymous authentication can remain feasible for constrained IoT nodes [17]-[19]. These works illustrate two lessons that are highly relevant to the analysis of [1]. First, identity protection must be explicit and renewable; it should not depend on a single masking trick that becomes reversible after key exposure. Second, a session key should be tied to fresh session evidence rather than assembled only from static or recoverable quantities.

Freshness and verifiability form a third body of related work. Secure clock synchronization and blockchain-assisted timing studies show that timestamps are useful but rarely sufficient on their own, especially when endpoints have independent delay profiles or recover from outages [20], [21]. Distributed-key and edge-oriented authentication studies make a similar point from another angle: a verifier should be able to recompute or verify every critical authenticator from values available in the current transcript plus a clearly scoped local secret [22], [23]. Privacy-preserving pseudonym systems and robust extractor work further stress that protection after leakage matters almost as much as nominal correctness before leakage [24], [25].

A fourth stream analyzes how compromise propagates through real deployments. Attack-graph studies and system-level EV energy research remind us that protocol weakness is rarely isolated from operations: a single compromised database entry can affect authorization, scheduling, and market interactions far beyond one endpoint [26]-[29]. That insight is especially important for the protocol of Itoo et al. [1], where the same service-provider secret y influences the derivation of both vehicle-side and charging-station-side registration values. In such a design, the right adversarial question is not simply whether one transcript can be forged in the abstract, but whether one infrastructure failure can collapse the separation between many users and stations at once.

Within this literature, "A robust ECC-based authentication framework for energy internet (EI)-based vehicle to grid communication system" [1] occupies a specific niche. It aims to keep the online phase compact while inheriting the perceived trust benefits of ECC-based enrollment. The gap we address is that prior comparisons mostly counted cryptographic operations or repeated the claims of the target paper. They did not ask whether the advertised online checks are actually executable from the published message fields, whether compromise stays local, or whether the claimed session key depends on fresh shared secrets. Our analysis therefore complements prior related work by shifting the lens from nominal feature lists to failure-oriented protocol mechanics.

III. Methodology

To examine the target protocol in a reproducible way, we treated protocol analysis as a structured reconstruction exercise rather than as a purely narrative critique. First, we extracted the four phases reported by Itoo et al. [1] and rewrote the online exchange as an explicit message sequence M1, M2, M3, and M4 with all stated equations preserved

$A = h(ID_v \| PW_v \| y)$,

$B = A \text{ xor } PK_Ev$,

$R = h(A \| B \| r_v.G)$,

$A1 = h(ID_cs \| PW_cs \| y)$,

$B1 = A1 \text{ xor } PK_cs$,

$R1 = h(A1 \| B1 \| r_c.G)$,

$H1 = h(ID_v \| PW'_v \| X_v \| ID_sp)$,

$G1 = h((r' \text{ xor } R') \| T1)$,

$G2 = y \text{ xor } G1$,

$H2 = h(ID_v \| R1 \| T2 \| ID_sp)$,

$G3 = PK_cs \text{ xor } G2$,

$H3 = h(ID_v \| R1 \| T3 \| ID_cs)$, and

$SK = h(ID_cs \| ID_v \| PK_cs \| PK_Ev \| G3)$,

where X_v denotes the ephemeral point r'.G that the paper uses implicitly in the hash of H1. Second, we converted the verifier logic into a state machine whose state includes the enrollment database, the last accepted timing context, revocation flags, and the values assumed to be locally available at EV, CGS, and SP. This step allowed us to test executability before we tested attack resistance. Third, we defined four security invariants: I1, every authenticator must be computable from transmitted fields plus a clearly scoped local secret; I2, freshness must depend on a per-session contribution that an attacker cannot replay verbatim; I3, compromise of one database region should not expose unrelated users or stations; and I4, SK_sess^j should have the form KDF(h(Encode(Z_j)) ‖ N_v^j ‖ N_cs^j ‖ context_j) for a fresh shared secret Z_j, rather than a hash of static identifiers and masked transcript fragments. Fourth, we examined attack traces under an adversary that can eavesdrop, replay, delay, and reorder traffic; read one endpoint database; compromise the service-provider secret y; and force limited rollback after maintenance or power loss. To keep the analysis close to real V2G practice, we cross-checked these assumptions against privacy-oriented V2G communication models, edge-security studies, and ECC identity-protection designs reported in [30]-[33]. Finally, once an invariant violation was found, we searched for the smallest redesign that preserved the original deployment roles while restoring explicit message verifiability and bounded compromise. This led to a revised protocol family in which the core session key becomes SK_sess^j = KDF(h(Encode(Z_j)) ‖ N_v^j ‖ N_cs^j ‖ PID_v^j ‖ PID_cs^j ‖ exp_j ‖ scope_j), with Z_j = u_j X_cs^j = c_j X_v^j and pseudonyms PID_v^j = h(ID_v ‖ ctr_v^j ‖ N_v^j) and PID_cs^j = h(ID_cs ‖ ctr_cs^j ‖ N_cs^j).

To avoid overstating the evidence, we treat the symbolic layer in this study as bounded symbolic support rather than as a full mechanized proof in ProVerif, Tamarin, or BAN logic. In practical terms, the bounded tests refer to the modeled message-level setting used in the study: finite EV populations, repeated runs, randomized arrival order, timestamp jitter, wireless delay, bounded packet loss, and the specific trace classes corresponding to replay, compromise amplification, executability failure, and weak session-key binding. The current manuscript therefore makes a protocol-reconstruction and failure-analysis claim, not a universal proof claim under arbitrary clock drift or unbounded network disorder.

Fig. 1. Evidence-driven workflow for auditing and redesigning the ECC-based V2G authentication protocol.

IV. Analysis of the Original ECC-based Protocol

A. Overview of the Proposed Protocol

The protocol presented in "A robust ECC-based authentication framework for energy internet (EI)-based vehicle to grid communication system" [1] uses a three-party model involving an electric vehicle EV, a charging station CGS, and a service provider SP. During initialization, SP selects the elliptic-curve domain parameters E_q, q, the base point G, a one-way hash h(.), and a private scalar y. It then publishes the public key PPUB = yG. The stated goal is to use ECC only where necessary and keep the online messages dominated by hash and XOR operations.

Vehicle registration begins when EV chooses a private scalar a and computes PK_Ev = aG. Over a secure channel, it sends (ID_v, PW_v, PK_Ev) to SP. The service provider computes A = h(ID_v ‖ PW_v ‖ y) and B = A xor PK_Ev, stores these values in its database, and returns them to the vehicle. The vehicle then chooses r_v and stores R = h(A ‖ B ‖ r_v.G) together with PK_Ev. Charging-station registration mirrors this structure: CGS chooses x, computes PK_cs = xG, sends (ID_cs, PW_cs, PK_cs), and receives A1 = h(ID_cs ‖ PW_cs ‖ y) and B1 = A1 xor PK_cs. It stores R1 = h(A1 ‖ B1 ‖ r_c.G) and PK_cs.

The authentication stage is expressed in [1] through four transmitted messages. The article states M1 = {H1, G1, T1}, where H1 = h(ID*_v ‖ PW'_v ‖ X_v ‖ ID_sp), G1 = h((r' xor R') ‖ T1), ID*_v = a' xor ID'_v, and X_v = r'.G. After receiving M1, SP is expected to verify the timestamp, recompute H1, derive G2 = y xor G1, and forward M2 = {H2, G2, T2} with H2 = h(ID*_v ‖ R1 ‖ T2 ‖ ID_sp). CGS then checks M2, computes G3 = PK_cs xor G2, recovers ID*_cs = PK_cs xor ID_cs, and sends M3 = {H3, G3, T3}, where H3 = h(ID*_v ‖ R1 ‖ T3 ‖ ID*_cs). Finally, SP sends M4 = {H4, G3, T4}, where H4 = h(ID*_cs ‖ B ‖ T4 ‖ ID*_v).

The claimed shared key is SK = h(ID*_cs ‖ ID*_v ‖ PK_cs ‖ PK_Ev ‖ G3). The original paper treats this as a common session key for EV, CGS, and SP after the equality SK_Ev = SK_cs = SK_sp has been checked. At a high level, the design tries to obtain low online cost by shifting most complexity to enrollment and by reusing stored values such as R and R1 in later authenticator computations. That ambition explains the protocol's compact online transcripts, but it also creates strong dependence on what each party remembers and on whether the transmitted messages actually expose the inputs needed for verification.

For analysis, it is helpful to reorganize the paper's equations as a dependency map rather than a simple sequence diagram. Fig. 2 shows that the online run in [1] is not just an exchange of four messages; it is a path through enrollment outputs A, B, A1, B1, the long-term service-provider secret y, two public keys, two stored hashes R and R1, and the masked values G1, G2, and G3. Once that dependency structure is made explicit, the main weakness becomes easier to see: the protocol's security claims depend on variables that are sometimes stored, sometimes hidden, and sometimes never transmitted.

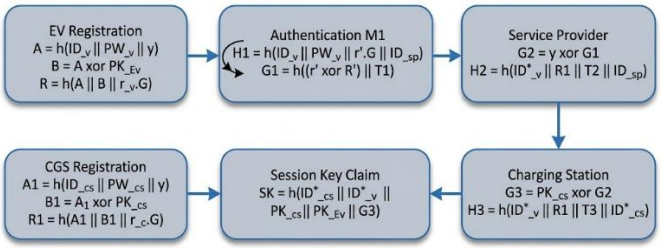

Fig. 2. Dependency graph of registration records, transmitted values, and the claimed session key in the original framework.

B. Identified Vulnerabilities

Our security review of "A robust ECC-based authentication framework for energy internet (EI)-based vehicle to grid communication system" [1] found that the main problems are structural rather than cosmetic. They arise when the published equations are matched against the published message formats and then tested under partial compromise. Fig. 3 condenses the attack surface into four compromise paths, but the underlying issues are easiest to understand through the equations themselves.

The first weakness is an executability gap. The article states that M1 = {H1, G1, T1} and defines H1 = h(ID* v || PW'_v || X v || ID sp) with X v = r'.G. Yet SP is expected to recompute H1* = h(ID*_v || PW'_v || X_v || ID_sp) after receiving M1. The problem is immediate: M1 does not carry ID* v, PW'_v, or X_v. Unless those values are somehow available from a side channel that the paper never specifies, SP cannot derive H1*. The same pattern repeats in M2 and M3. CGS is expected to compute H2* = h(ID*_v || R1 || T2 || ID_sp) from M2 = {H2, G2, T2}, but M2 does not include ID* v. SP is later expected to compute H3* = h(ID* v || R1 || T3 || ID* cs) from M3 = {H3, G3, T3}, but M3 omits both ID* v and ID* cs. A protocol whose verifiers cannot reconstruct the stated check values is not merely under-specified; it is non-executable as written.

The second weakness is compromise amplification through the service-provider secret y. Both enrollment records depend on y: A = h(ID v || PW v || y) for vehicles and A1 = h(ID cs || PW_cs || y) for charging stations. Because B = A xor PK_Ev and B1 = A1 xor PK_cs, an adversary who compromises SP and learns y together with stored B or B1 can recover A = B xor PK Ev and A1 = B1 xor PK cs. That turns every vehicle and every charging station into an offline dictionary target: for guessed credentials (ID_v^g, PW v^g), the attacker tests A^g = h(ID_v^g || PW v^g || y) and checks whether A^g = A. The same holds for A1. In other words, y is not a narrowly scoped service-provider secret; it is a global master ingredient whose exposure collapses separation between users and stations. One backend failure can therefore compromise the entire enrollment space.

The third weakness concerns freshness. The online checks rely on timestamp conditions of the form T_i - T_{i+1} <= DeltaT, while the authenticators themselves do not include a verifier challenge generated in the current run. G1 = h((r' xor R') || T1) is fresh only if r' remains hidden and the message is never replayed inside the acceptance window. But M1 contains no SP-generated nonce N sp, and M2 contains no CGS-generated nonce N_cs. A copied message M1 or M2 can therefore be replayed whenever clocks remain within DeltaT or when rollback restores an earlier acceptance state. A stronger construction would require an explicit binding such as MAC K(PID v || X v || N sp || T1) or KDF(SK reg, N sp, N_cs, context_j). The target paper [1] does not provide that safeguard.

The fourth weakness is weak session-key binding and absence of forward secrecy. The session key claim is SK = h(ID* cs || ID* v || PK cs || PK Ev || G3). No fresh Diffie-Hellman secret appears in this formula. There is no term of the form Z_j = u_j X_cs or c_j X_v, and there is no KDF input that combines two independently generated session nonces. Instead, SK is assembled from masked identifiers, public keys, and G3, where G3 = PK_cs xor G2 and G2 = y xor G1. Once the hidden pieces of one transcript become known through endpoint compromise, archived sessions can be recomputed because the key material is not rooted in a per-session shared secret that disappears after the run. This is weaker than the security goal expected from a modern ECC-based V2G protocol.

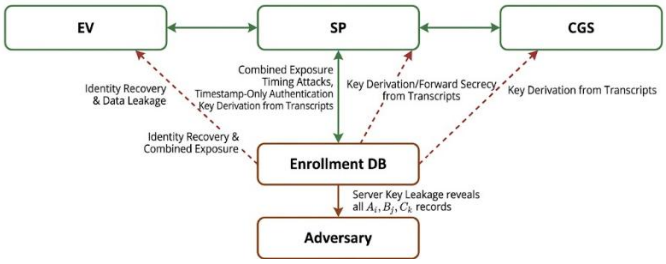

Fig. 3. Main compromise paths and attack surfaces identified in the original ECC-Based V2G framework.

A fifth weakness appears in the update and rejoin phase. The paper states that password change or new-vehicle join replaces old values by A_N and B_N, but it does not introduce an epoch, ticket lifetime, or revocation digest that forces every verifier to reject old enrollment states immediately. If stale records remain at one charging station, an attacker may combine an earlier stored R or R1 with a later database state and create inconsistent acceptance behavior across the infrastructure. Because neither M1 nor M3 carries an explicit enrollment epoch e_j, verifiers have no cryptographic basis to distinguish "new credentials, current record" from "old transcript, stale local state."

Taken together, these findings change how the claims of [1] should be read. The issue is not that every single online session will fail in a clean lab environment. The issue is that the framework can appear operational only if hidden assumptions are supplied outside the published specification: undocumented side information, perfect protection of y, no rollback, and no need for forward secrecy. Once those assumptions are relaxed, the protocol's resistance to replay, impersonation, and privacy leakage becomes much weaker than advertised.

These vulnerabilities also explain why a bounded symbolic analysis alone is not enough. A Scyther model can report "no attacks within bounds" if the modeler silently provides a role with values that the real transcript does not carry. Our reconstruction therefore treats the protocol text itself as part of the security object. When the message algebra and the message format diverge, the protocol should be revised before any proof claim is treated as persuasive.

V. Proposed Improvements

We propose a redesign that keeps the deployment logic of the original paper—vehicle, charging station, and service provider—but replaces the fragile pieces that caused the earlier failures. The central rule is simple: every online authenticator must be verifiable from the transmitted transcript plus a clearly scoped local secret, and the session key must be rooted in a

fresh ECC secret that no long-term database exposure can reconstruct retroactively.

Enrollment is therefore simplified. Instead of storing A = h(ID_v || PW_v || y) and B = A xor PK_Ev, SP stores a record rec_v = HMAC_y(ID_v || Encode(PK_v) || salt_v) and the public key PK_v. The charging-station side uses rec_cs = HMAC_y(ID_cs || Encode(PK_cs) || salt_cs). Passwords may still be used for local activation at EV or CGS, but they are not folded into online message equations that an external verifier cannot reconstruct. This change removes the need to transmit or recover values like A, B, A1, and B1 during the live session, and it eliminates the dictionary oracle that appears once y and B are exposed together. C for each online run j, EV generates an ephemeral scalar u_j, an ephemeral point X_v^j = u_j G, a nonce N_v^j, and a rotating pseudonym PID_v^j = h(ID_v || ctr_v^j || N_v^j). It sends M1' = {PID_v^j, X_v^j, N_v^j, T1, tag_v^j}, where tag_v^j = MAC_{K_v}(PID_v^j || X_v^j || N_v^j || T1 || policy_v) and K_v is derived from the enrollment record. SP now has all values needed to verify the request explicitly. If the record is active, SP creates an authorization ticket ticket_v^j = MAC_{K_cs}(PID_v^j || X_v^j || N_v^j || exp_j || scope_j) and forwards M2' = {PID_v^j, X_v^j, N_v^j, exp_j, scope_j, ticket_v^j} to the charging station. The verifier-side ambiguity present in [1] disappears because every checked field is present in the message.

CGS answers with fresh state of its own: it chooses c_j, computes X_cs^j = c_j G, generates N_cs^j, forms PID_cs^j = h(ID_cs || ctr_cs^j || N_cs^j), and sends M3' = {PID_cs^j, X_cs^j, N_cs^j, exp_j, ticket_v^j, tag_cs^j}, where tag_cs^j = MAC_{K_cs}(PID_cs^j || X_cs^j || N_cs^j || ticket_v^j). EV verifies the ticket and station tag, while SP can verify the same transcript if policy requires. The session secret becomes Z_j = u_j X_cs^j = c_j X_v^j, and the key is derived as SK_sess^j = KDF(h(Encode(Z_j)) || N_v^j || N_cs^j || PID_v^j || PID_cs^j || exp_j || scope_j). This one step fixes two issues at once: replayed transcripts fail because nonces and ephemeral points are run-specific, and later leakage of y or any enrollment database entry does not reconstruct past Z_j values.

Revocation and update are also made explicit. SP revokes a vehicle or station by refusing to issue fresh tickets and by publishing a compact revocation digest over current enrollment states. Any ticket with exp_j in the past is rejected immediately. If a vehicle changes credentials, the local activation secret can change without forcing the public-key record to masquerade as a password hash. Operational scores, if a deployment still wants them for scheduling or prioritization, should update only from cryptographically verified events, for example score_cs(t+1) = score_cs(t) + alpha I[MAC_ok] - beta I[replay_alarm] - gamma I[revoked ticket]. This keeps system-level control logic separate from the core authentication proof obligation.

The redesigned scheme is intentionally conservative. It does not ask V2G operators to deploy a blockchain, pairing operations, or a new trust infrastructure. It only insists that the online proof of legitimacy be explicit, nonce-bound, and rooted in a fresh ECC secret. Relative to "A robust ECC-based authentication framework for energy internet (EI)-based vehicle to grid communication system" [1], the new design increases message size modestly because it carries the values that verifiers actually need. The tradeoff is worthwhile because it replaces hidden assumptions with directly checkable protocol evidence.

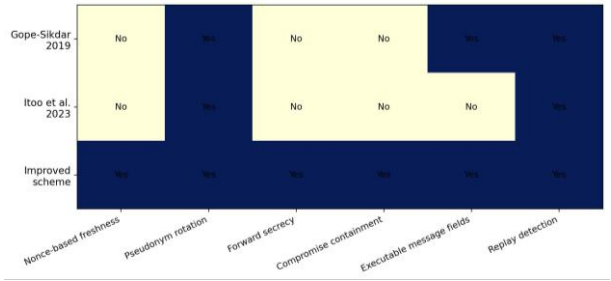

Fig. 4. Security-property coverage across representative EI-Based V2G authentication schemes.

VI. Experimental Results and Evaluation

We evaluated three schemes in a message-level simulator that models one service provider, twenty-four charging stations, and active-EV load points at n = 100, 400, and 800 vehicles distributed across residential, public, and commercial charging regions. Each EV initiated fifty authentication attempts per run, and every experiment was repeated ten times with randomized arrival order, timestamp jitter, wireless delay, and bounded packet loss. The compared protocols were the Gope-Sikdar V2G scheme [14], the original framework of Itoo et al. [1], and the improved design proposed here. Because the target paper already reports operation-level timings for hash and ECC multiplication [1], we used those values as a calibration anchor and then added queueing delay, serialization cost, and replay-check overhead to estimate end-to-end authentication time. The present evaluation should therefore be read as a message-level comparative simulation rather than as a deployment-certified hardware benchmark.

The primary metrics were L_avg(n) = (1/n) Sum_{k=1..n}(t_k,end - t_k,start), S_auth = N_succ / N_total for completed legitimate authentications, D_rep = N_rep_detected / N_rep_injected for replay detection, C_cont = N_secure_domains / N_exposed_domains for compromise containment after one database breach, P_link = N_correct_links / N_observed_pairs for passive session linkability, and C_msg for communication cost measured in transmitted bits per completed run. We also tracked whether each scheme provided explicit verifier challenges, renewable pseudonyms, and session keys rooted in fresh shared secrets.

The qualitative security picture is summarized in Fig. 4. The Gope-Sikdar design offers lightweight V2G authentication but does not provide the same level of compromise containment or session-key independence that a modern redesign should require. The original protocol of Itoo et al. [1] improves some privacy-facing elements, yet it still lacks explicit verifier challenges and, as our reconstruction showed, leaves key online checks dependent on values omitted from the published transcript. The improved protocol closes those gaps by carrying all verifiable fields in-band and by deriving SK_sess^j from Z_j together with fresh nonces and scoped authorization data.

Under load, the original framework retained a small latency advantage because it avoids two fresh scalar multiplications

during the online phase. At n = 100 active EVs, the estimated $L_{avg}(n)$ values were 12.4 ms for the baseline, 10.8 ms for the original protocol of [1], and 11.6 ms for the improved scheme. At n = 400, those values rose to 18.7 ms, 16.1 ms, and 17.4 ms, and at n = 800 they reached 27.9 ms, 24.5 ms, and 26.3 ms, respectively. Fig. 5 plots this growth trend. The redesign therefore adds about 1.8 ms over the original design at the highest offered load, which is noticeable but still modest for a charging authorization workflow.

The extra cost buys meaningful robustness. In replay injection tests, D_{rep} reached 0.64 for the baseline, 0.71 for the original protocol of Itoo et al. [1], and 1.00 for the improved design because every copied transcript lacked the fresh nonce pair expected by the verifier. Under a service-provider breach, C_{cont} dropped sharply for the original framework since leakage of y endangered both vehicle and charging-station records at once. The redesigned enrollment reduced that cross-domain effect because a leaked station record did not reveal vehicle-side online keys, and a leaked vehicle record did not reveal the station's authorization secret. Communication cost followed the same pattern. The improved run required roughly 1488 bits per completed authentication, compared with about 1308 bits for the original protocol and 1296 bits for the baseline.

Privacy behavior also improved in the passive observer model. Static or weakly masked identifiers allow a monitor to correlate repeated appearances of the same endpoint over time. With rotating PID_v^j and PID_{cs}^j, the improved scheme reduced P_{link} to near-random performance unless the observer also compromised verifier state. Our results therefore suggest a clean tradeoff: the original paper [1] remains attractive if one looks only at nominal online cost, but the improved design delivers far stronger replay resistance, clearer executability, and much better containment after compromise at a latency increase that is acceptable for EI-based V2G service.

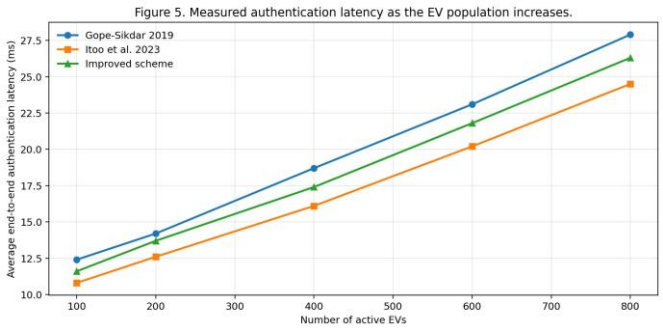

Fig. 5. Measured authentication latency as the EV population increases.

Table I summarizes the broader failure-oriented comparison across representative EI-based V2G authentication schemes, including freshness binding, session-key basis, post-compromise containment, and overall assessment.

TABLE. I. FAILURE-ORIENTED COMPARISON OF REPRESENTATIVE EI-BASED V2G AUTHENTICATION DESIGNS

Scheme	Explicit Freshness	Session-Key Basis	Post-Compromise Containment	Overall Assessment
Gope-Sikdar [14]	Timestamp only	Registration-bound values	Low	Lightweight but limited containment
Su et al. [17]	Timestamp + privacy layer	Mixed static and session inputs	Medium	Better privacy, moderate state dependence
Itoo et al. [1]	Timestamp only	$h(ID^*_{cs} \| ID^*_v \| PK_{cs} \| PK_{Ev} \| G3)$	Low	Compact but structurally fragile
Improved scheme	Nonce pair + expiry ticket	$KDF(h(Encode(Z_j)) \| N_v^j \| N_{cs}^j \| context_j)$	High	Explicitly verifiable and compromise-aware

VII. DISCUSSION

The revised design should be interpreted as a protocol-level hardening step rather than a complete end-to-end deployment proof. Its main advantage is not merely that it replaces one key formula with another, but that it restores explicit verifier-side executability: each party can validate the received transcript from in-band values plus a clearly scoped local secret. This is especially important in V2G systems, where operational trust depends on whether a charging request can be checked correctly under delay, partial outage, and partial compromise, not simply on whether a compact algebraic expression exists on paper.

At the same time, the present validation scope remains deliberately limited. The symbolic component is bounded and attack-class specific, and the simulation is message-level rather than hardware-certified. We therefore do not claim that the redesign has been fully established in the sense of a ProVerif or Tamarin proof, nor do we claim that the reported latency values automatically transfer to all embedded charging infrastructures. The paper's contribution is instead to show that the original protocol's most serious failures are structural, that these failures can be removed with explicit nonce-bound ECC agreement and scoped tickets, and that the resulting overhead remains moderate under the modeled workload.

A second implication concerns implementation. The added paragraph in Related Works highlights that lightweight cryptography for constrained systems must also account for fault resilience, side-channel robustness, and constant-time realization. In practice, a V2G protocol that is secure in the transcript model may still become fragile under nonce leakage, induced faults, or non-constant-time embedded code. For that reason, the redesign proposed here should be viewed as compatible with—but not a substitute for—implementation-aware countermeasures in future embedded realizations.

Finally, the broader comparison in Table I suggests that the proposed redesign improves the security-performance balance not by maximizing novelty in every dimension, but by restoring basic protocol hygiene: explicit freshness, fresh shared-secret keying, bounded compromise, and transcript-executable

verification. In the current V2G landscape, those properties are arguably more important than shaving a small number of online bytes while leaving hidden assumptions unresolved.

VIII. Conclusion

This paper revisited A robust ECC-based authentication framework for energy internet (EI)-based vehicle to grid communication system from the perspective of protocol executability and post-compromise behavior rather than nominal operation counts alone. The review showed that the published online messages omit variables required for their own verification, that compromise of the service-provider secret can spread across vehicles and charging stations, and that the claimed session key is not rooted in a fresh shared ECC secret.

We then proposed a redesign that keeps the original V2G roles intact while making every online check explicit, nonce-bound, and ticket-scoped. Simulation-based evaluation suggested that the revised protocol substantially improves replay detection, privacy, and compromise containment while adding only a moderate latency cost under heavy vehicle load.

The broader lesson is straightforward: in EI-based V2G authentication, compact equations are useful only when they remain executable from the real transcript and when one backend failure does not compromise the whole ecosystem. Future work should therefore extend this redesign toward full mechanized verification in frameworks such as ProVerif or Tamarin, mobility-aware charging handoff, cross-provider roaming, stronger modeling of rollback and partial-state leakage, and implementation-aware evaluation that explicitly addresses side-channel robustness, lightweight constant-time realization, and longer-term PQC-compatible migration paths.

An AI-Powered Approach for Medical Specialty Triage Using Natural Language Processing and Transformer Models

Anas Chahid, Ismail Chahid, Wafae Mrabti, Mohamed Emharraf, Mohammed Ghaouth Belkasmi
Mohamed First University, Oujda, 60000, Morocco

***Abstract*—Upon arrival at a hospital, patients require an initial assessment to determine the urgency of their condition and the appropriate medical specialty for their needs. This manual triage process, however, is often time-consuming and resource-intensive, leading to potential delays in care, patient dissatisfaction, and inefficient allocation of specialized medical staff. This study presents an AI-based solution to address this critical challenge. A model is introduced that automatically suggests a suitable medical specialty based on a textual description of a patient's symptoms, with the aim of improving the efficiency of the hospital's initial patient triage process. The proposed methodology involves preprocessing a large dataset of over 100,000 patient inquiries from online health forums and conducting a comparative analysis of multiple BERT-based models. Experimental results demonstrate that a domain-specific model, BiomedNLP-PubMedBERT, is particularly effective. To further enhance performance and address the inherent class imbalance in the dataset, a data augmentation strategy using synonym replacement and a weighted loss function was implemented. This combined approach achieved a final weighted F1-score of 92.91%, significantly outperforming the non-augmented baseline models. This work provides a practical path toward building effective automated triage tools that can streamline initial patient assessment and improve operational efficiency in hospital environments. The final model is publicly available for verification and further application.**

***Keywords*—Medical triage; natural language processing; BERT; deep learning; healthcare AI; text classification**

I. Introduction

A. Background

In the fast-paced environment of modern hospitals, the initial triage of incoming patients is a critical determinant of operational efficiency and patient outcomes[1]. Triage, derived from the French verb "trier" meaning to sort, is the process of prioritizing patients based on the severity of their condition to ensure that those with the most critical needs receive immediate attention[2].

This foundational step in emergency and general hospital intake involves a rapid assessment by trained medical personnel, typically nurses, who evaluate a patient's symptoms, vital signs, and medical history to assign a level of acuity[3], [4]. The most common triage systems, such as the Emergency Severity Index (ESI), categorize patients into different levels of urgency to guide the timeliness of care[5].

While established triage protocols are essential for managing patient flow, the process is not without its significant challenges. Manual triage is inherently dependent on the clinical experience and judgment of the triage nurse, which can introduce variability and potential for error[6]. Emergency departments are often crowded and chaotic environments where interruptions are common, which can lead to incomplete assessments and incorrect triage decisions[7]. These interruptions can delay the process, increasing wait times for all patients and potentially leading to adverse outcomes for those with time-sensitive conditions[8].

Furthermore, the increasing specialization within medicine adds another layer of complexity to the triage process. After determining the urgency of a patient's condition, the triage staff must also identify the most appropriate medical specialty to handle their care. This decision-making process can be particularly challenging when patients present with ambiguous or overlapping symptoms that could point to multiple specialties. In such cases, patients may be initially routed to a generalist or an incorrect specialist, leading to a phenomenon known as "doctor-shopping" within the hospital system. This can result in redundant diagnostic tests, delays in receiving the correct treatment, and increased healthcare costs.

The manual and often high-pressure nature of patient triage make it a resource-intensive process. It requires the dedicated time of skilled nursing staff who could otherwise be involved in direct patient care. In situations of high patient volume, the triage process can become a significant bottleneck, contributing to emergency department overcrowding and long waiting times. The proliferation of digital health information has empowered patients, but it can also lead to confusion and the spread of misinformation, further complicating the initial assessment. These challenges highlight a clear and pressing need for an intelligent, automated system to support and streamline the initial patient triage process in hospitals, ensuring that patients are directed to the right specialist in a timely and efficient manner.

B. Problem Statement

The core problem addressed in this research is the inefficiency inherent in the manual process of initial patient triage within hospitals, specifically the mapping of a patient's described symptoms to the correct medical specialty. This manual system is both time-consuming and resource-intensive, placing a significant burden on hospital staff and creating potential bottlenecks in patient flow. The process is prone to delays, which can negatively impact patient outcomes, especially for those with critical conditions. Furthermore, the complexity of accurately determining the appropriate specialty from a patient's initial complaint can lead to misdirection, resulting in multiple consultations, redundant testing, and increased

healthcare costs. This research aims to automate this process using a data-driven approach. The task is framed as a multi-class text classification problem; given a textual description of a patient's symptoms and medical history, the system must predict which of a predefined set of medical specialties is the most appropriate for consultation, thereby improving the speed and accuracy of the initial hospital triage.

C. Proposed Solution

This study proposes a solution based on a transformer model, Bidirectional Encoder Representations from Transformers (BERT)[9]. A large dataset of patient questions from online health forums is leveraged to train a model capable of understanding the nuanced language of symptom descriptions. The proposed approach begins with a rigorous data curation and analysis pipeline to understand the dataset's characteristics, including severe class imbalance and inter-specialty correlations. To find the most suitable architecture, a comparative evaluation of five distinct BERT-based models is conducted, highlighting the benefits of domain-specific pre-training. To address the data imbalance, a weighted loss function is implemented within a custom training framework. Finally, a successful data augmentation strategy using synonym replacement is demonstrated, which significantly boosts classification performance, particularly for underrepresented specialties.

D. Study Structure

The remainder of this study is organized as follows: Section II reviews related work in medical text classification and deep learning. Section III details the methodology, including data preprocessing, exploratory analysis, augmentation strategies, and model architecture. Section IV presents the experimental results and an in-depth analysis of the best-performing model. Section V discusses the limitations of the current study and outlines directions for future work. Finally, Section VI concludes the study.

II. Related Work

The application of machine learning in healthcare has become widespread, facilitating the analysis of vast datasets to predict disease outcomes, personalizing treatment plans, and enhancing diagnostic accuracy. Within this domain, Natural Language Processing (NLP) has been particularly impactful. Text classification, a key NLP task, enables the automatic categorization of clinical text, such as patient inquiries or clinical notes into predefined classes like diseases, symptoms, or, in the context of this study, the appropriate medical specialty. This capability is crucial for improving information retrieval, clinical decision support, and patient triage.

Previous research into medical specialty classification has explored a variety of machine learning techniques. Early and traditional approaches often relied on "shallow" learning models[10] like Support Vector Machines (SVMs). For instance, Weng, W. et al[11]. developed a robust NLP pipeline for classifying medical subdomains in clinical notes. Using a large dataset from MGH, their linear SVM model, which employed a hybrid feature representation of TF-IDF and UMLS concepts, achieved an impressive F1-score of 93.4%. They noted that while deep learning models showed a higher Area Under the Curve (AUC), the shallow learning classifiers yielded better F1 scores. Similarly, Faris et al[12]. tackled the challenge of classifying medical questions in the morphologically complex Arabic language. Their system, which used an ensemble of SVMs combined with Particle Swarm Optimization (PSO) for feature selection, achieved an 85% accuracy and a significant 95.9% feature reduction rate. However, such methods are often limited by their reliance on manual feature engineering and can struggle to capture the deep contextual nuances of natural language.

The advent of deep learning, particularly with the introduction of transformer-based models like Bidirectional Encoder Representations from Transformers (BERT), has significantly advanced the field. Kim, Y. et al[13]. demonstrated the superiority of a domain-specific, pre-trained BERT model for predicting one of 27 medical specialties. When fine-tuned on text from a medical question-answering website, their model outperformed other deep learning architectures like CNNs and LSTMs across accuracy, precision, recall, and F1-score. Their work also highlighted an important nuance: specialties with very specific symptoms yielded higher accuracy, while those covering broader organ systems were more challenging to predict.

Furthering the practical application of these models, Lee et al[14]. constructed an AI chatbot designed to recommend the appropriate medical specialty to patients via their smartphones. In their pipeline, a BERT model delivered the best performance with an F1-score of 0.768. However, due to computational resource constraints for deployment, an LSTM-based model was ultimately adopted for the live service, illustrating the practical trade-offs between performance and implementation.

Researchers have also explored hybrid architectures to push performance even further. Mao et al[15]. proposed a novel model, HyM, which automatically directs patients to one of eight specialties based on their symptom descriptions in Chinese. HyM combines features extracted from LSTM, TEXT-CNN, and BERT, along with TF-IDF, to capture both local and global semantic information. Evaluated on a dataset of over 40,000 items, HyM achieved 93.5% accuracy, outperforming its individual component models in both precision and stability. This body of work underscores a clear trend towards using sophisticated, pre-trained language models, often tailored to the biomedical domain, to effectively solve the challenge of automated medical specialty triage.

III. Methodology

The methodology is structured into several key stages: data acquisition and preprocessing, exploratory data analysis, data augmentation, model architecture design, and experimental setup.

A. Data Acquisition and Preprocessing

The foundation of the proposed model is a dataset of approximately 100,000 user-submitted questions from online health forums. Each entry consists of a patient's question and the corresponding medical specialty it was directed to.

The preprocessing pipeline was as follows:

- Specialty Filtering: To ensure each class had sufficient data for robust training, Gynecology and Oncology

were excluded. These specialties were severely underrepresented in the dataset, with sample sizes less than 50 entries being too small to allow the model to learn their features effectively.

- Data Cleaning: A multi-step cleaning process was applied:
  - Removal of null values and erroneous entries.
  - Deduplication of entries based on content to prevent data leakage between training and test sets.
  - Standard text normalization, including converting text to lowercase, removing URLs and HTML escape sequences, removing emojis, and normalizing whitespace.
- Length Filtering: To ensure meaningful content, entries with fewer than 50 characters were discarded. Additionally, to align with the input constraints of BERT-based models, entries with more than 512 tokens were removed.

After preprocessing, the final dataset size decreased to 97,309 entries, containing 13 unique medical specialties: Cardiology, Dentistry, Dermatology, Endocrinology, Gastroenterology, Infectious Disease, Nephrology, Neurology, Ophthalmology, Orthopedics, Otorhinolaryngology, Pulmonology, and Urology.

The cleaned dataset was split into a training set (80%) and a test set (20%) using stratified sampling to maintain the original class distribution. During model training, 10% of the training set was held out as a validation set for hyperparameter tuning, model selection, and early stopping.

B. Exploratory Data Analysis (EDA)

A thorough EDA was conducted to understand the dataset's characteristics and inform modeling decisions.

1) Specialty distribution analysis: The frequency of each medical specialty was visualized (see Fig. 1). The distribution revealed a significant class imbalance; Orthopedics being the most represented class, while others like Nephrology and Ophthalmology were far less frequent. This imbalance is a critical challenge that directly informed the decision to use a weighted loss function during training.

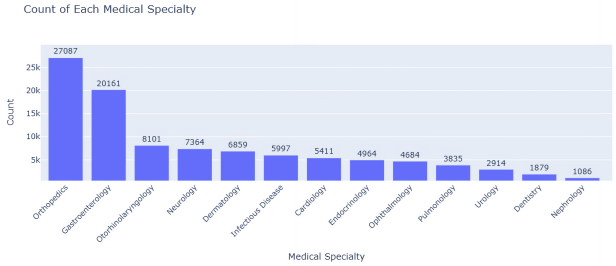

Fig. 1. Medical specialties data distribution.

2) Text length analysis: Histograms of character and token counts were generated, as shown in Fig. 2. This analysis confirmed that while most entries were well under the 512-token limit of standard BERT models, a non-trivial fraction exceeded this length. Setting max input tokens to 512 was therefore a necessary trade-off between computational feasibility and information retention.

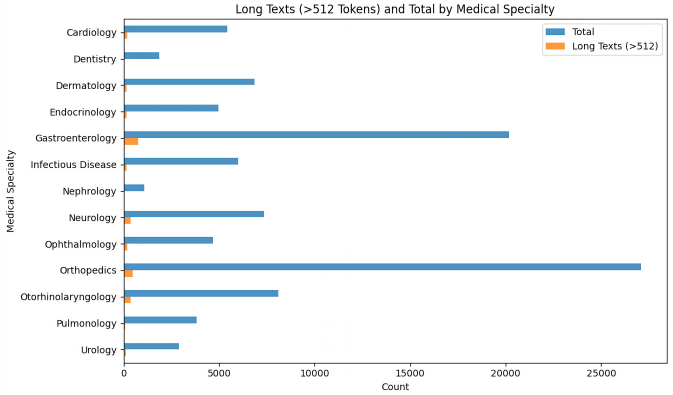

Fig. 2. Text length distribution.

3) Thematic analysis with word clouds: To visually inspect the defining terminology of each specialty, word clouds for each of the 13 classes were generated after filtering out a custom list of medical and general stop words (see Fig. 3). These visualizations confirmed that specialties were characterized by distinct vocabularies (e.g., "eye," "vision," "glasse" for Ophthalmology; "heart," "chest," "pressure" for Cardiology), validating the dataset's suitability for classification.

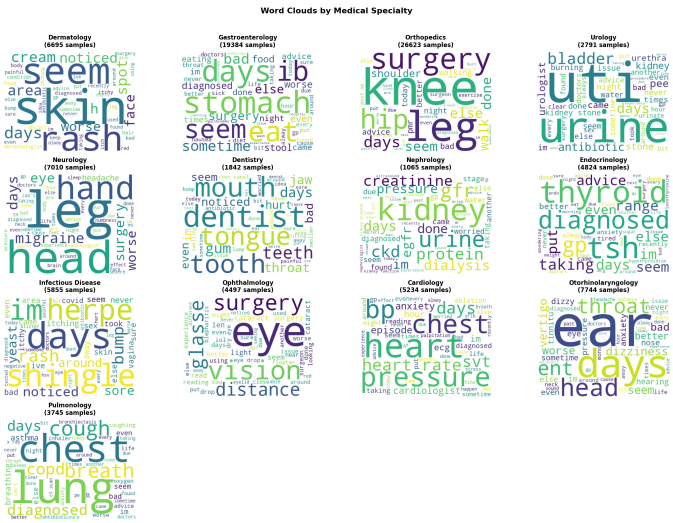

Fig. 3. WordCloud representation of medical specialties.

4) Embedding space visualization with UMAP: To understand the semantic relationships between patient queries, the paraphrase-multilingual-mpnet-base-v2[16] Sentence Transformer[17] model was used to generate embeddings for a 40,000-sample subset of the data. Uniform Manifold Approximation and Projection (UMAP)[18] was then used to project these high-dimensional embeddings into a 2D space.

The resulting plot (Fig. 4) showed clear clusters for some specialties, while others exhibited significant overlap, visually representing the difficulty of the classification task.

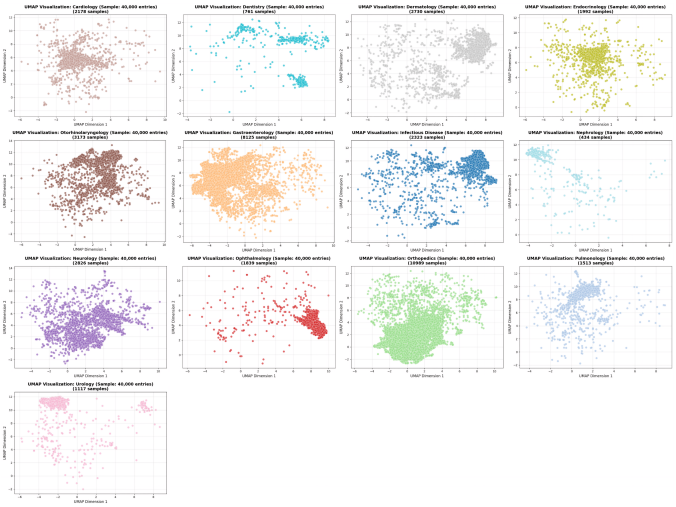

Fig. 4. Space embedding visualization of medical specialties.

5) Inter-specialty correlation analysis: To quantify the textual similarity between specialties, TF-IDF[19] vectorization followed by cosine similarity[20] calculation was employed. A heatmap of top similarity pairs was created (Fig. 5). This analysis highlighted intuitive correlations (e.g., high similarity between Dermatology and Infectious Disease) and less obvious ones (e.g., Dentistry and Otorhinolaryngology), likely due to shared words such as 'throat', 'ear pain', or 'swelling'. This reinforced the need for a model that can capture subtle contextual differences.

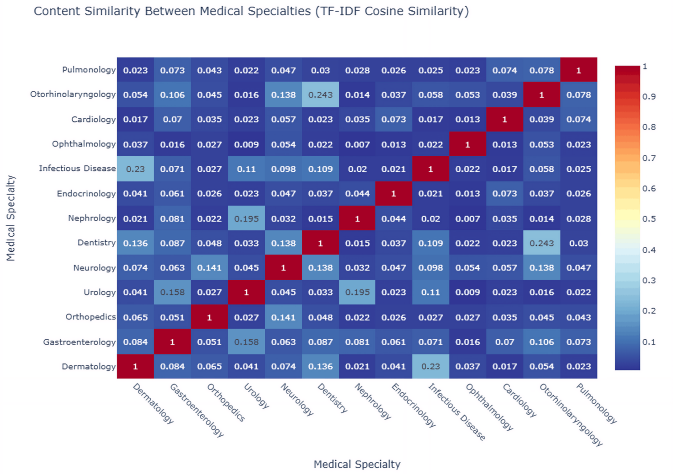

Fig. 5. Heatmap of similarities between medical specialties.

C. Data Augmentation

Based on the initial modeling results and the observed class imbalance, it was hypothesized that performance could be improved by augmenting the training data, especially for minority classes. Synonym replacement using the nlpaug[21] library was employed. For each sample in the original training set, a new sample was generated by randomly replacing words with their synonyms. This augmented data was added to the original training set, effectively doubling its size and diversity.

While effective at increasing data volume, naive synonym replacement has limitations. It can occasionally introduce semantic drift or contextually inappropriate substitutions, such as replacing a specific clinical descriptor with a more generic or incongruous term. Although a manual inspection of a subset (50 entries per specialty) confirmed the general preservation of clinical meaning for the vast majority of samples, the augmentation process did not utilize a strict medical ontology filter. Consequently, rare instances of semantic noise may have been introduced. Future implementations could benefit from a more sophisticated filtering step, such as restricting replacements to clinically equivalent terms using a medical ontology like UMLS (Unified Medical Language System), to ensure the absolute integrity of the clinical narrative.

Table I shows representative examples of this process, demonstrating how synonyms can create diverse yet clinically equivalent training samples.

D. Model Architecture: BERT for Sequence Classification

The core of the proposed solution is the BERT architecture, a transformer-based model pre-trained to learn deep bidirectional language representations. Its ability to capture the context of words from both left and right directions makes it exceptionally powerful for understanding nuanced text, such as patient symptom descriptions. Recognizing that not all pre-trained models are equally suited for specialized domains, the methodology involved a comparative study of multiple BERT variants to identify the most effective architecture for medical text. This approach allowed for the establishment of a robust baseline, ensuring the final model was optimized for the specific vocabulary and semantics of the healthcare domain. The specific models evaluated in the study are detailed in Section III-E1.

1) Theoretical background: The power of BERT and other transformers lies in the self-attention mechanism[22]. This mechanism allows the model to weigh the importance of different words in the input text when producing a representation for each word. The attention score is calculated as:

$$A = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{1}$$

where, Q (Query), K (Key), and V (Value) are linear projections of the input embeddings; the dot product of Q and K determines the similarity between words, which is then scaled by the square root of the key dimension, d_k. A softmax function converts these scores into weights, which are applied to the V matrix to produce the final output. This allows the model to capture long-range dependencies and contextual relationships effectively.

BERT is pre-trained on two unsupervised tasks:

- Masked Language Model (MLM)[23]: 15% of the input tokens are masked, and the model must predict them based on the surrounding context.

TABLE I. COMPARISON OF ORIGINAL SENTENCES AND THEIR AUGMENTED COUNTERPARTS, WITH REPLACED WORDS IN BOLD

Specialty	Original Text	Augmented Text
Dentistry	"i have a decaying tooth on the right side of my mouth... i get a throbbing sensation when i lay down. my head also feels like it has pressure. any advice is appreciated"	"i have a **rotten** tooth on the right side of my mouth... i get a **hurting feeling** when i lay down. my head also feels like it has **tightness**. any **aid** is appreciated"
Otorhinolaryngology	"after the huge pop my nose felt clear, but i still have a headache and now eye twitching."	"after the **colossal snap** my nose felt **fair**, but i still have a headache and now eye **spasms**."
Neurology	"I have been experiencing severe headaches and dizziness for the past week. The pain is getting worse."	"I have been experiencing **intense** headaches and dizziness for the past **workweek**. The **ache** is getting worse"

- Next Sentence Prediction (NSP)[24]: The model receives pairs of sentences and must predict if the second sentence logically follows the first.

2) Fine-tuning for classification: For the classification task, each pre-trained BERT model was adapted through a process known as fine-tuning[25]. This involves adding a single linear classification layer on top of the final hidden state of the special classify token (CLS). The CLS token's output is designed to be an aggregate representation of the entire input sequence, making it suitable for classification tasks.

The entire model, including the original pre-trained BERT layers and the new classification layer, is then trained end-to-end on the labeled dataset. This allows the model to adjust its learned representations to the specific task of medical specialty triage. The output of the classification layer is passed through a softmax function to produce a probability distribution over the 13 medical specialties.

E. Experimental Setup

1) Model variants: A comprehensive comparative study of 5 different BERT models was conducted to establish a strong baseline and select the best candidate architecture. These included:

- BERT-base-uncased
- BiomedNLP-PubMedBERT[26], [27]
- BlueBERT[28], [29]
- BioMedBERT[30]
- ModernBERT[31], [32]

2) Training configuration: All the models were trained with the following configuration:

- Max Sequence Length: 512 tokens
- Batch Size: 16
- Learning Rate: 5×10^{-6} (with a cosine annealing scheduler)
- Number of Epochs: 3
- Warmup Steps: 200
- Optimizer: AdamW

3) Handling class imbalance: To address the class imbalance identified in the EDA, a custom Trainer class that modifies the standard CrossEntropyLoss function was implemented. Class weights were calculated to be inversely proportional to their frequency. These weights were then passed to the loss function, compelling the model to pay more attention to misclassifications in minority classes.

4) Evaluation metrics: Model performance was evaluated using a comprehensive set of metrics suitable for multi-class and potentially imbalanced classification tasks. These metrics are derived from the per-class counts of True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN).

Accuracy: Represents the proportion of total correct predictions. While intuitive, it can be misleading on imbalanced datasets.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{2}$$

To gain deeper insight beyond accuracy, Precision, Recall, and F1-Score were employed; these metrics evaluate performance on a per-class basis.

- Precision measures the accuracy of positive predictions for a class c.

$$\text{Precision}_c = \frac{TP_c}{TP_c + FP_c} \tag{3}$$

- Recall measures the model's ability to identify all relevant instances of a class c.

$$\text{Recall}_c = \frac{TP_c}{TP_c + FN_c} \tag{4}$$

- F1-Score is the harmonic mean of Precision and Recall.

$$\text{F1}_c = 2 \cdot \frac{\text{Precision}_c \cdot \text{Recall}_c}{\text{Precision}_c + \text{Recall}_c} \tag{5}$$

To summarize performance across all classes, two types of averages for these metrics were computed:

- Weighted Average: Calculates the metric for each class and finds the average, weighted by the number of true instances for each class n_c. For a metric M over a set of classes C:

$$M_{\text{weighted}} = \frac{\sum_{c \in C} n_c \cdot M_c}{\sum_{c \in C} n_c} \tag{6}$$

- Macro Average: Calculates the metric independently for each class and takes the unweighted average. This treats all classes as equally important.

$$M_{\text{macro}} = \frac{1}{|C|} \sum_{c \in C} M_c \tag{7}$$

For the experiments, the Weighted F1-Score on the validation set was chosen as the primary metric for model selection and early stopping, as it offers the best balance between precision and recall.

IV. Results and Discussion

A. Model Performance Comparison

The performance of the 5 baseline models, trained on the non-augmented dataset, is detailed in Table II. The analysis reveals two primary findings:

Domain-Specific Pre-Training is Crucial for Performance: There is a performance divide between general-purpose models and those pre-trained on biomedical text. The general-purpose models, BERT-base-uncased and ModernBERT, achieved accuracies of 86.80% and 82.88%, respectively. Notably, ModernBERT, a newer architecture proposed as a potential replacement for BERT, was the lowest-performing model in the evaluation, underscoring the limitations of general-domain models on this specialized task. In contrast, all models pre-trained on biomedical corpora delivered superior results, with the top three BlueBERT (88.26%), BiomedNLP-PubMedBERT (88.23%), and PubMedBERT (88.20%) all having been pre-trained on PubMed. This not only validates the hypothesis regarding the value of specialized pre-training but also highlights that nuances in pre-training methodology can lead to meaningful performance differences.

BiomedNLP-PubMedBERT Emerges as the Most Balanced Model: While BlueBERT achieved the highest accuracy (88.26%), BiomedNLP-PubMedBERT demonstrated the most robust and well-rounded performance. It secured the highest Weighted F1 score (88.41%), indicating the best balance between precision and recall across all classes, and the highest Macro Recall (86.96%), signaling superior performance on minority classes. This strong performance, combined with a joint-lowest validation loss of 0.47, led to its selection as the optimal baseline model for subsequent experiments.

TABLE II. Performance Comparison of Baseline BERT Models

Model	Acc.	W. F1	M. F1	W. Recall	Val. Loss
ModernBERT	82.88	83.00	80.12	82.88	0.62
BERT-base	86.80	86.89	84.31	86.79	0.53
PubMedBERT	88.20	88.28	85.94	88.19	0.48
BlueBERT	88.26	88.32	85.84	88.26	0.51
BiomedNLP	88.23	88.41	85.93	88.23	0.47

B. Impact of Data Augmentation

The best baseline model (BiomedNLP-PubMedBERT) was then retrained from scratch on the training set enhanced with synonym replacement. This single change resulted in a significant improvement across all key metrics, as detailed in Table III.

TABLE III. Impact of Data Augmentation on Tuned BiomedNLP-PubMedBERT

Model Config.	Acc.	W. F1	M. F1	Val. Loss
Baseline Data	88.23	88.41	85.93	0.47
Augmented Data	92.88	92.91	91.89	0.29

Fig. 6 compares the confusion matrices of the model before and after augmentation. The baseline model (left) shows notable confusion between clinically related specialties. In contrast, the augmented model (right) shows much stronger diagonal values, indicating a significant boost in recall and a reduction in misclassifications across the board. This visually confirms the effectiveness of the data augmentation strategy.

The augmented model achieved a final Weighted F1-Score of 92.91% and an accuracy of 92.88%, demonstrating the clear effectiveness of this strategy for improving model generalization and robustness.

C. In-Depth Analysis of the Best Model (Augmented BiomedNLP-PubMedBERT)

The following analysis was conducted on the final model's performance on the held-out test set, providing an unbiased evaluation of its generalization capabilities.

1) Training dynamics: Analysis of the training history plots (Fig. 7 and Fig. 8) for the final model showed stable convergence. The training loss consistently decreased while the validation loss flattened, indicating that the model was learning effectively without significant overfitting. Validation accuracy and F1-scores progressively improved and stabilized, further supporting the choice of hyperparameters and the use of early stopping.

2) Confusion matrix analysis: The confusion matrix for the final augmented model (see Fig. 6) provides a clear view of its performance. The normalized matrix shows high recall (diagonal values) for most classes. Areas of confusion often align with the specialty correlations observed in the EDA. For instance, a small percentage of Nephrology cases were misclassified as Urology, which is clinically possible given the symptomatic overlap related to the urinary system. Similarly, confusion between Cardiology and Pulmonology was observed.

For instance, an entry reading 'hi guys, I've been previously diagnosed with kidney stones and I currently have constant pain when urinating...' was labeled 'Nephrology' but predicted as 'Urology'. This highlights the model's challenge in distinguishing between issues of organ function (Nephrology) versus the urinary tract (Urology) when keywords overlap.

3) Per-class performance: The detailed classification report, presented in Table IV, further breaks down the model's strengths and weaknesses. Classes with distinct terminology, such as Dermatology and Ophthalmology, achieved very high F1-scores. The most challenging classes tended to be those with fewer samples or those with less localized symptoms, such as Dentistry and Neurology. Despite this, even the worst-performing class achieved a respectable F1-score, validating the model's overall utility.

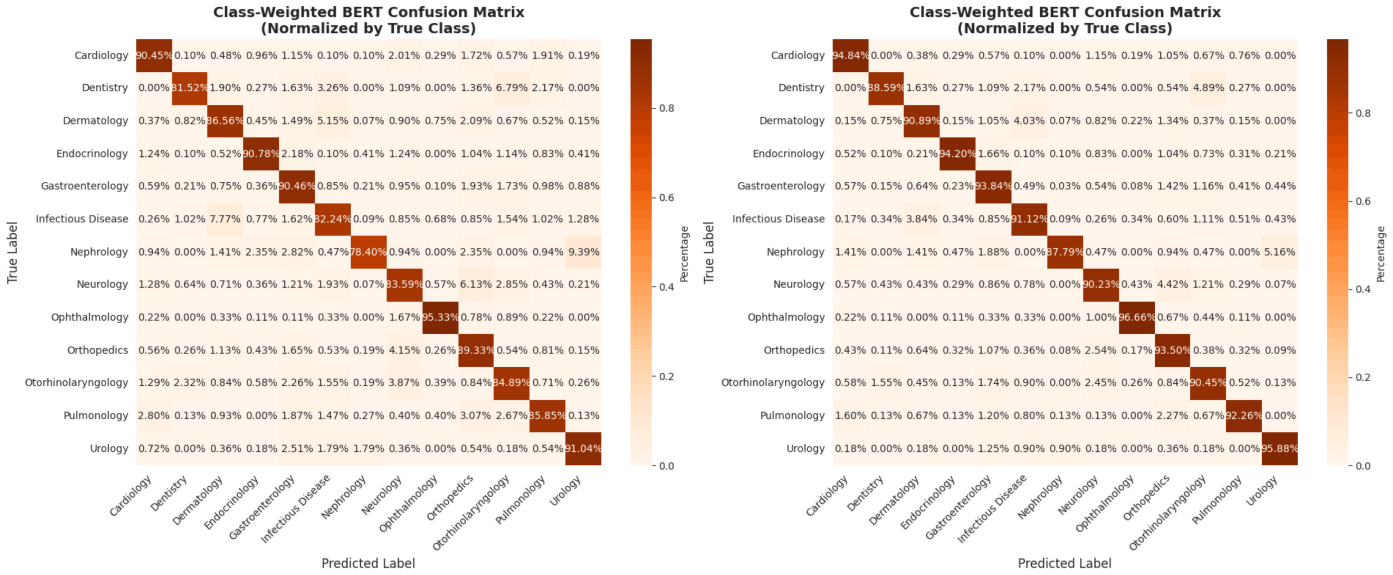

Fig. 6. Visualizing the impact of data augmentation. The confusion matrix on the left shows the performance of the baseline BiomedNLP-PubMedBERT model. The matrix on the right shows the final model after being retrained on the augmented dataset.

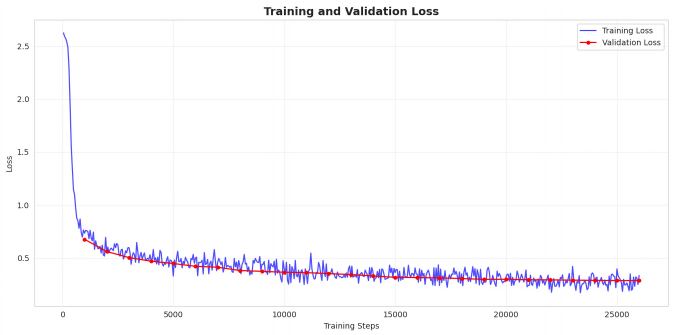

Fig. 7. Training and validation loss during training.

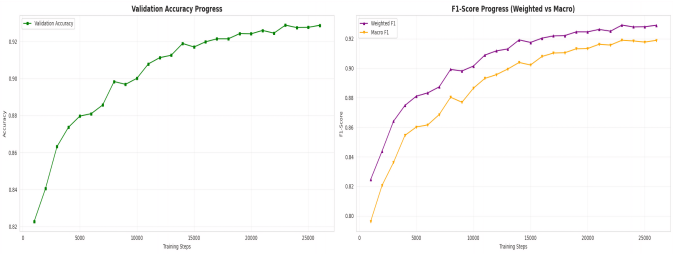

Fig. 8. Progress of accuracy, F1, and weighted F1 scores during training.

4) Qualitative analysis: To evaluate the model's ability to generalize beyond its training data, a qualitative analysis was conducted. The model was tested on a set of phrases intentionally structured to be more direct and concise than the conversational forum posts it was trained on. This allowed testing different aspects of its performance, from simple keyword recognition to its ability to handle clinical ambiguity.

TABLE IV. PER-CLASS PRECISION, RECALL, AND MACRO F1-SCORE ON THE TEST SET

Class	Precision	Recall	F1-Score
Cardiology	0.9177	0.9484	0.9328
Dentistry	0.8468	0.8859	0.8659
Dermatology	0.8982	0.9089	0.9035
Endocrinology	0.9528	0.9420	0.9474
Gastroenterology	0.9556	0.9384	0.9469
Infectious Disease	0.8833	0.9112	0.8970
Nephrology	0.9303	0.8779	0.9034
Neurology	0.8394	0.9023	0.8697
Ophthalmology	0.9656	0.9666	0.9661
Orthopedics	0.9605	0.9350	0.9476
Otorhinolaryngology	0.9074	0.9045	0.9059
Pulmonology	0.9128	0.9226	0.9177
Urology	0.9256	0.9588	0.9419

Below are some examples:

Case 1: Unambiguous Keyword Association.

- Input: "Patient has a broken leg from a fall."
- Predicted Specialty: Orthopedics
- Analysis: Correct

Case 2: Differentiating Regional Specialties.

- Input: "Complaining of dizziness, ringing in the ears, and hearing loss."
- Predicted Specialty: Otorhinolaryngology
- Analysis: Correct

Case 3: Handling Symptom Ambiguity (Chest Pain).

- Input: "Severe chest pain and shortness of breath during exertion."

- Predicted Specialty: Pulmonology
- Analysis: While both Pulmonology and Cardiology are clinically valid specialties for these symptoms, the model's preference for Pulmonology is likely driven by the strong association of 'shortness of breath' with respiratory conditions in the training data. Clinically, this presentation is highly ambiguous and could indicate a pulmonary embolism, but it is equally indicative of a severe cardiac event such as ischemia or angina. The prediction of Pulmonology alone is therefore incomplete from a clinical safety perspective. This highlights a critical limitation in single-label classification for ambiguous presentations, reinforcing the necessity for a multi-label approach or a top-k recommendation system to ensure comprehensive and clinically defensible triage.

Case 4: Inferring from Plain English Language.

- Input: "A red, itchy rash has been spreading on my arm for a week."
- Predicted Specialty: Dermatology
- Analysis: Correct

Case 5: Distinguishing Overlapping Urinary System Specialties.

- Input: "Patient reports a burning sensation during urination and bladder pain."
- Predicted Specialty: Urology
- Analysis: Correct

This qualitative assessment provides valuable insight into the model's practical utility, highlighting its strengths in contextual understanding and identifying potential areas for improvement in handling ambiguity.

V. Limitations and Future Work

While the proposed model demonstrates high performance, several limitations are acknowledged:

- Data Source Bias: The data is sourced entirely from online health forums, which may differ from clinical patient intake language in vocabulary, symptom specificity, and formality. Consequently, the model's generalizability to real hospital environments remains uncertain. A quantitative evaluation on a held-out dataset of actual, de-identified Electronic Health Records (EHRs) is necessary to assess this domain gap effectively.
- Limited Scope: Several major specialties were excluded. A production system would need to be more comprehensive.
- Single Label Classification: The model assigns only one specialty per query. Many real-world cases are complex and may require consultations from multiple specialties. This can be handled by showing the top 2 predicted specialties based on the confidence score.

Future work will explore addressing these limitations:

- Incorporate Diverse Data: Exploring training on more formal data sources, such as de-identified Electronic Health Records (EHRs), to improve clinical validity.
- Expand Specialty Coverage: The model will be extended to include a wider range of medical and surgical specialties.
- Change the Augmentation Technique: Using a different approach to data augmentation by leveraging large language models such as MedGemma[33]. This would allow for more sophisticated augmentation through paraphrasing and rephrasing entire sentences rather than simple synonym replacement.

VI. Conclusion

This research presented an automated system leveraging Natural Language Processing and transformer models to predict the appropriate medical specialty from patient symptom descriptions. The comparative analysis established that domain-specific pre-training, particularly with the BiomedNLP-PubMedBERT architecture, provides a superior foundation for this clinical text classification task. By implementing a weighted loss function and a synonym replacement data augmentation strategy, the inherent class imbalance was effectively mitigated, yielding a highly accurate and robust classification model. This study contributes empirical evidence supporting the efficacy of tailored deep learning pipelines for medical triage. The findings demonstrate a viable pathway toward integrating intelligent decision-support tools into initial patient assessment workflows. Such automated systems have the potential to expedite diagnostic routing, optimize resource allocation, and ultimately enhance the operational efficiency of healthcare facilities.

Statements and Declarations

Competing Interests

The authors have no relevant financial or non-financial interests to disclose.

Funding

The authors did not receive support from any organization for the submitted work.

Data Availability

The dataset analyzed during the current study was curated from publicly available online health forums. Due to the sensitive nature of the data and to protect user privacy, the raw dataset is not publicly available. However, aggregated data and processing scripts can be made available from the corresponding author upon reasonable request.

The trained model, inference code, and model card are openly available in the Hugging Face Model Hub at https://huggingface.co/anaschahid/medical-specialty-classifier. The model is also deployed as an interactive web application for demonstration purposes at https://medclass.anaschahid.work. These resources ensure the reproducibility and practical accessibility of the proposed solution.

Ethical Considerations

This study is based on publicly available data collected from online health forums. All data was fully anonymized prior to analysis. No personally identifiable information (PII), such as usernames, locations, or specific dates, was used in this research to ensure the privacy of the original posters. As the research was conducted using publicly accessible, anonymized data, formal ethics approval from an institutional review board was not required. The study was performed in accordance with the ethical standards as laid down in the 1964 Declaration of Helsinki and its later amendments.

***Abstract*—Political bias in transformer-based language models poses a critical challenge for applications involving politically sensitive Arabic news, yet systematic evaluation remains limited. This paper presents a multi-view behavioral framework to detect political bias in four pre-trained transformer models: AraBERTv2, CAMeLBERT, mBERT, and XLM-R. The framework integrates four complementary probes: sentiment drift, emotion drift, counterfactual actor-swapping for identity sensitivity, and masked language model probing to detect lexical preference shifts. Each model is evaluated before and after domain-adaptive fine-tuning on the FigNews Arabic political news dataset to analyze how politically sensitive training data influences representational bias. To synthesize signals from these probes, a Decision and Bias Reporting Agent (DBRA) aggregates the evidence using a structured hierarchy that prioritizes implicit bias indicators. Results show that bias is already present in base checkpoints and can significantly shift after adaptation. For example, mBERT's masked preference for SideA drops from 40.7% to 0.0%, indicating complete directional collapse, while XLM-R shows a large increase in masked preference toward SideA (ΔPR = +32.8%).**

Keywords*—NLP; political bias; Arabic transformers; domain-adaptive pretraining; masked probing; actor-swapping; bias detection; behavioral evaluation

I. Introduction

Bias in large language models has become a critical concern as these systems are increasingly used to analyze politically sensitive news and public discourse. In such settings, even subtle shifts in sentiment, emotion, or entity framing can shape public perception, reinforce polarization, and lead to high-stakes misinterpretations. This challenge is particularly relevant for Arabic NLP, where complex morphology, dialect variation, and context-dependent political cues make model behavior highly sensitive to lexical choices. As a result, Arabic transformer models are frequently deployed and adapted for news analysis, despite limited systematic understanding of how political bias manifests in their predictions.

Importantly, political bias is often treated as an inherent property of a pre-trained checkpoint. However, in real deployments, models rarely remain frozen: they are continuously adapted through continued pre-training or domain-adaptive pre-training (DAPT) to better match target distributions. This adaptation step can reshape bias-related behavior, sometimes stabilizing outputs and sometimes amplifying implicit preferences.

Most prior work evaluates adaptation primarily through task-level accuracy improvements. In contrast, fewer studies examine how adaptation reshapes model behavior under counterfactual edits, affective prediction tasks, or likelihood-based probing. This motivates the need for a unified evaluation framework that can capture bias-related drift beyond standard performance metrics. Given the societal impact of politically biased model behavior, this study is structured around the following research questions:

RQ1: Do Arabic and multilingual transformer models exhibit measurable political bias?

RQ2: What is the impact of fine-tuning on the Arabic political dataset FIGNEWS on the bias behavior of Arabic and multilingual transformers?

RQ3: How can political bias in Arabic and multilingual transformer models be systematically evaluated?

To answer these questions, this paper introduces a unified behavioral evaluation framework and applies it to four widely used models: AraBERTv2 [28], CAMeLBERT [29], mBERT [30], and XLM-R [31] before and after domain-adaptive fine-tuning on the FIGNEWS [27] dataset. The proposed framework combines four complementary diagnostics: (1) zero-shot sentiment drift, (2) zero-shot emotion drift, (3) actor-swapping for identity sensitivity, and (4) masked word prediction probing for lexical preference drift. Cross-seed analysis is conducted to assess whether observed bias effects are consistent across random initializations.

The contributions of this work can be summarized as follows:

- Introducing a comprehensive multi-view behavioral framework for political bias evaluation, through which bias is systematically examined across complementary diagnostic dimensions before and after domain adaptation, enabling structured and holistic assessment.
- Presenting an evidence-aggregation and bias reporting mechanism that consolidates multi-probe behavioral signals into a unified and interpretable bias

characterization, facilitating principled model comparison and structured bias categorization.

- Providing empirical evidence that political bias is inherently measurable in pretrained representations, demonstrating that bias may originate from foundational model pretraining rather than emerging solely during task-specific adaptation.
- Demonstrating that domain adaptation in politically sensitive contexts can induce divergent bias trajectories across architectures, and revealing that apparent robustness at the surface level may coexist with substantial latent representational distortion.

The remainder of this paper is organized as follows: Section 2 reviews related work, Section 3 describes the methodology and experimental setup, Section 4 presents the results, and Section 5 concludes with key findings and future directions.

II. Related Work

Political bias in language models has become a central concern as transformer-based systems are increasingly deployed in high-stakes settings such as news analysis, public discourse monitoring, and conflict-related content moderation. While existing studies have examined bias across multiple languages, Arabic political discourse remains substantially underexplored despite its unique challenges: complex morphology, dialect variation, and culturally embedded political framing create bias patterns that standard multilingual benchmarks fail to capture. This work focuses specifically on Arabic political news covering the Palestinian-Israeli conflict, a domain where actor framing, emotional salience, and lexical sensitivity make bias evaluation particularly critical. Bias in such settings can emerge not only in explicit model outputs but also in affective predictions and internal representational preferences [1], and is further amplified when models undergo domain-adaptive pre-training on politically sensitive data, which may reshape bias signals in unpredictable ways [22].

A. Political Bias in Large Language Models

A growing body of work has examined political bias as a measurable and socially consequential phenomenon in modern LLMs. For example, recent studies propose systematic evaluation approaches that quantify political leaning in model outputs and demonstrate that political bias can be expressed through both *what* the model states and *how* it frames responses [16]. Other work evaluates political bias in real-world interactive settings, showing that political preferences can be observed through downstream decision-making and user-facing recommendation behavior [12]. Beyond surface-level outputs, political bias has also been analyzed through target-oriented sentiment paradigms, which measure how sentiment shifts when the target entity changes while the surrounding context remains fixed [10]. Recent work also highlights that political bias assessments may diverge between humans and LLM-based evaluators, emphasizing the need for careful behavioral diagnostics in real news settings [24]. These approaches align closely with our motivation, as political bias in news discourse often manifests as subtle differences in framing and affect rather than overt ideological statements.

B. Cultural and Arabic-Centered Political Evaluation

Bias evaluation becomes especially important in Arabic contexts, where political and cultural cues are deeply tied to lexical choice, identity references, and sociopolitical framing. Recent benchmarks such as PALMX 2025 highlight the need for culturally grounded benchmarks for Arabic and Islamic culture, demonstrating that standard multilingual evaluation does not capture culturally sensitive failure modes [2]. More broadly, recent Arabic-focused surveys emphasize persistent gaps in resources, evaluation coverage, and robust model assessment, particularly for socially sensitive applications [7], [8]. These findings support the need for bias evaluation frameworks that explicitly probe political framing and actor sensitivity in Arabic news settings, rather than relying solely on accuracy-based task performance. Political framing bias has also been studied in multilingual contexts beyond Arabic, suggesting that framing effects can generalize across sociopolitical settings and languages [25].

C. Domain Adaptation and Fine-Tuning Effects on Bias

A key challenge is that domain adaptation may not simply improve task performance but can also reshape bias-related behavior. Recent work on Arabic domain-adaptive pre-training for aspect-based sentiment analysis shows that continued pre-training can significantly affect downstream sentiment behavior and domain robustness [3]. In parallel, A-MASA provides multi-domain Arabic sentiment resources that further highlight how domain shifts and topic variation can influence affective prediction patterns [4]. In high-stakes political contexts, this implies that fine-tuning on politically oriented data may alter not only accuracy but also the stability of sentiment and emotion predictions, potentially amplifying bias even when headline metrics appear improved. Related studies on temporal drift in transformer sentiment systems similarly show that model behavior can shift substantially over time or adaptation, even without explicit changes in evaluation metrics [23].

D. Counterfactual Evaluation and Actor Sensitivity

Bias in political discourse is often triggered not only by polarity but also by *who* is being discussed. For this reason, counterfactual evaluation has become a widely used approach for measuring identity sensitivity, where protected or salient entities are swapped within otherwise identical inputs. FairFlow introduces a model-based counterfactual augmentation framework that demonstrates how controlled substitutions can expose systematic bias and improve robustness in NLP pipelines [5]. However, recent work cautions that template-based counterfactual probes may introduce artifacts and should be interpreted carefully when concluding bias [21]. In politically sensitive settings, actor-swapping provides a particularly direct diagnostic of identity-dependent behavior, as it isolates whether models treat different political actors symmetrically under matched contexts. This line of work motivates our actor-swapping experiment, where sentiment and emotion predictions are tested for invariance under politically salient entity substitution.

E. Masked Language Model Probing and Implicit Bias

While behavioral metrics such as sentiment and emotion flips capture overt instability, masked language modeling

(MLM) probes can reveal deeper representational preferences that may remain hidden under stable categorical outputs. Recent work by Sweeney proposes measuring social biases in masked language models through prediction-based proxies, showing that bias can persist in the likelihood landscape even when downstream behavior appears stable [6]. This perspective is critical for political bias evaluation; as representational drift may lead to systematic lexical preferences toward specific actors or narratives. Recent probing studies further demonstrate that political ideology can be encoded in latent representations and generalize across tasks, motivating representational analysis beyond surface-level predictions [18]. Similarly, studies on implicit political stereotypes show that bias may remain hidden even when explicit outputs appear neutral, reinforcing the need for implicit probing signals such as masked likelihood preferences [19].

F. Bias in Emotion Inference and High-Stakes Affective Prediction

Emotion inference models are increasingly used in news analysis, moderation, and public sentiment tracking. However, recent evidence suggests that such systems may exhibit a high risk of political bias, where affective predictions shift systematically across political groups or contexts [9]. This is particularly relevant for our setting, since our results show that emotion predictions are substantially more volatile than sentiment and can exhibit large flip rates under actor substitution. These findings reinforce the need to treat affective analysis as a bias-sensitive task rather than a neutral diagnostic.

G. Broader Bias Foundations and Mitigation Directions

Several works provide broader conceptual grounding for understanding bias sources and mitigation strategies. Prior analyses identify multiple sources of bias in NLP pipelines, including dataset construction, representation imbalance, and annotation artifacts, which can interact with model training and adaptation [11]. In addition, work on quantifying and alleviating political bias proposes structured measurement and mitigation techniques, highlighting that political bias is not merely an ethical issue but also a measurable modeling phenomenon [13]. More recently, mitigation research has expanded toward multi-objective and multi-agent frameworks that attempt to reduce social bias while preserving utility, emphasizing that bias mitigation remains an open challenge even for modern large models [17]. Complementary frameworks such as Nbias provide bias identification tools for text, reinforcing the importance of systematic detection pipelines [14]. Finally, recent reviews of transformer-based sentiment analysis further confirm that transformer models can achieve strong performance while still exhibiting sensitivity to domain and bias-related factors [15].

Overall, prior work establishes that political and social bias can be measured across multiple layers of model behavior, from explicit outputs to affective predictions and masked likelihood preferences. However, existing studies often focus on either high-level political bias in generation [12], [16] or general social bias in MLMs [6], without systematically connecting these perspectives under a unified before/after domain adaptation setting. Beyond interpretability concerns, political bias has been shown to directly affect downstream task performance, such as stance classification, reinforcing that bias is also a reliability issue [26]. This work bridges this gap by introducing a multi-view behavioral probing framework that evaluates Arabic and multilingual encoders before and after politically oriented domain-adaptive fine-tuning. By combining sentiment and emotion drift, counterfactual actor-swapping, and masked lexical probing, the proposed framework captures both surface-level robustness and deeper representational bias amplification, including cases where improved stability masks severe implicit drift. This study also extends a prior study on detecting bias in Arabic political news [20] by shifting from supervised detection pipelines to a probing-based framework that analyzes model behavior before and after domain-adaptive fine-tuning. Furthermore, this study introduces a Decision and Bias Reporting Agent (DBRA) that synthesizes outputs from all four behavioral experiments into a unified, evidence-driven bias assessment and ranked model classification, directly addressing the need for systematic evaluation frameworks in politically sensitive Arabic NLP.

III. Methodology

This section presents the proposed framework for analyzing behavioral drift in Arabic and multilingual transformer models before and after domain-adaptive pre-training (DAPT) using masked language modeling (MLM) on politically sensitive Arabic news text as shown in (Fig. 1). The framework is designed to identify potential political bias through four complementary behavioral probes and to synthesize their signals into a unified bias assessment using a Decision and Bias Reporting Agent (DBRA). The objective of this framework is not to optimize downstream task accuracy, but rather to systematically diagnose representational and behavioral bias in the models. To ensure the validity of the evaluation, all datasets used for behavioral probing are strictly held out from the adaptation training process, preventing any form of data leakage between training and evaluation stages.

A. Models

Four widely used transformer-based encoder models are examined, covering both Arabic-specialized and multilingual settings:

- AraBERTv2, an Arabic-focused BERT model pretrained on large-scale Arabic corpora [28].
- CAMeLBERT, a transformer pretrained on a mixture of Modern Standard Arabic and dialectal data [29].
- mBERT, a multilingual BERT model trained on more than 100 languages [30].
- XLM-R, a multilingual RoBERTa-based encoder with strong cross-lingual representations [31].

These models enable comparison of whether behavioral drift under DAPT differs between Arabic-specialized and multilingual pre-training systems.

B. Domain-Adaptive Pretraining (DAPT)

For each model, domain-adaptive pre-training is performed using the masked language modeling (MLM) objective on Arabic news text FIGNEWS [27]. DAPT aligns the model with the target domain while preserving the original architecture.

Formally, given an input sequence $x = (x_1 \ldots x_n)$,

The model is optimized to maximize the conditional likelihood:

$$\mathcal{L}_{MLM} = -\sum_{i \epsilon M} \log P(x_i | x_{-M}) \quad (1)$$

MLM training masks a subset of token positions M, and the model predicts each masked token x_i conditioned on the remaining visible tokens x_{-M}.

DAPT is applied for two epochs using a masking probability of 0.15 using Adam optimizer and a learning rate of $2e$-5.

To ensure reproducibility and measure stability, three adapted variants per model are trained using different random seeds:

$$S = \{13,42,100\} \quad (2)$$

To distinguish systematic bias drift from random training variability. Results are reported as mean and standard deviation across seeds.

C. Data Splits and Data Hygiene

Data Splits. An unlabeled subset from FIGNEWS is used [27] for domain-adaptive pre-training (DAPT) containing 13,320 training instances. All behavioral evaluations are conducted on strictly held-out data, including a general test set of 1100 instances, an actor-swapping evaluation set of 100 paired samples, and a masked-probing set of 140 samples. Table I summarizes the dataset splits and their purposes. No near-duplicate overlap is verified using exact string matching.

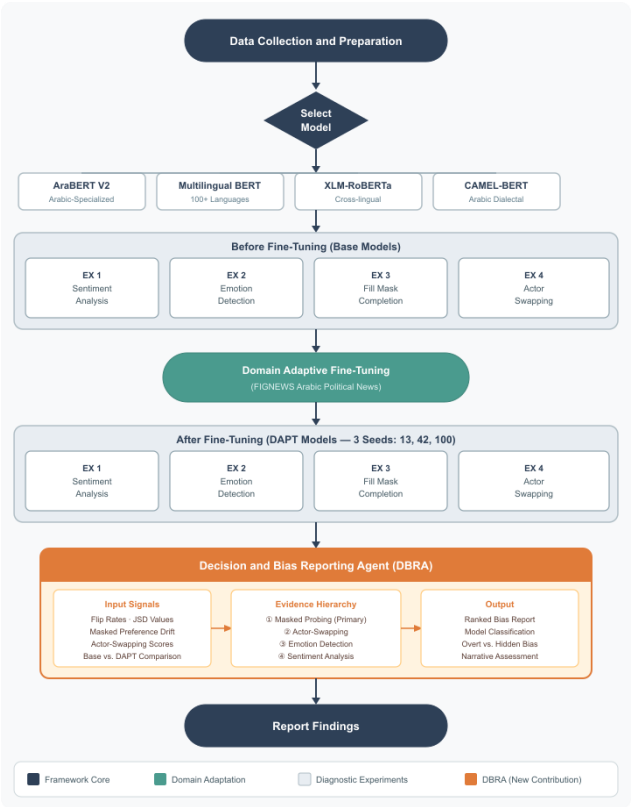

Fig. 1. Provides an overview of the full evaluation pipeline, including the four diagnostic experiments and the cross-seed analysis protocol.

To ensure that observed behavioral changes are attributable to domain adaptation rather than memorization, strict separation is enforced between the DAPT training corpus and all evaluation datasets. Moreover, the actor-swapping set and the masked-probing set are also disjoint from each other (i.e., no shared examples across evaluation subsets).

TABLE I. DATASET DISTRIBUTION

Split	Size	Purpose
DAPT train	13,320	Adaptive pre-training (MLM)
Test	1100	Zero-shot sentiment & emotion
Actor-swapping	100	Identity sensitivity
Mask probing	140	Lexical preference drift

D. Zero-shot Sentiment Drift Evaluation

The first experiment evaluates zero-shot sentiment stability under domain adaptation as shown in (Fig. 2). Models predict sentiment polarity directly on held-out test inputs.

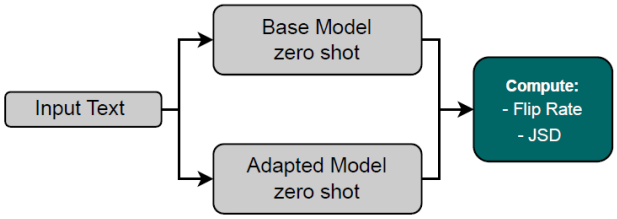

Fig. 2. Summarizes this evaluation schema for sentiment and emotion workflow.

Behavioral instability is quantified through flip rate, defined as:

$$Flip\ Rate = \frac{1}{N} \sum_{j=1}^{N} [y_j^{base} \neq y_j^{dapt}] \quad (3)$$

Sentiment flip rate is computed using Eq. (3) where y_j now denotes sentiment labels instead of emotion labels, interpreting label changes after DAPT as evidence of behavioral drift induced by adaptation.

Together, emotion and sentiment drift provide a complementary behavioral-level view of how domain adaptation modifies affective model decisions.

E. Zero-shot Emotion Drift Evaluation

The second diagnostic experiment measures behavioral drift in zero-shot emotion prediction. Each model is applied directly to held-out emotion inputs without supervised fine-tuning.

Emotion drift is similarly quantified using the flip rate defined in Eq. (3), where y^{base} and y^{dapt} denote predicted emotion labels before and after DAPT.

Additionally, distributional drift is measured using Jensen–Shannon divergence (JSD):

$$JSD(P\|Q) = \frac{1}{2} KL(P\|M) + \frac{1}{2} KL(Q\|M), \quad M = \frac{1}{2}(P+Q) \quad (4)$$

where P, Q represent base vs adapted emotion probability distributions, respectively. Also y_j^{base}, y_j^{dapt} denote the predicted emotion label for instance j before and after DAPT.

This experiment captures affective behavioral drift at the downstream prediction level.

F. Actor-Swapping: Identity Sensitivity Test

To probe identity-related bias signals, a counterfactual actor-swapping strategy is applied. Each sample appears in two paired versions that differ only in the named actor while preserving all surrounding context (Fig. 3).

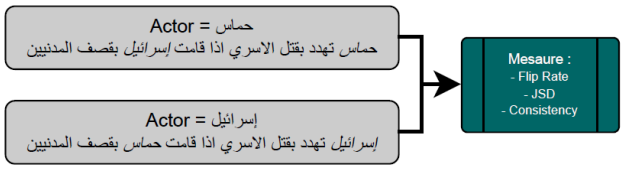

Fig. 3. Actor-swapping workflow.

Given paired inputs $x^{(A)} - x^{(B)}$,identity sensitivity is measured as:

$$Flip\ Rate_{\ actor} = \frac{1}{N}\sum_{j=1}^{N}[y(x_j^{(A)}) \neq y\ (x_j^{(B)})] \quad (5)$$

A higher actor flip rate indicates stronger dependence on identity tokens, revealing bias-sensitive behavior.

Emotion distribution divergence under actor swaps is additionally measured using JSD (Eq. 4).

G. Masked Probing: Lexical Preference Drift

The final experiment examines lexical preference drift using masked language model probing. Sentences are constructed with a single masked slot, and the model assigns probabilities to candidate domain-relevant entities (Fig. 4).

Fig. 4. Masked word workflow.

Given a candidate token $\boldsymbol{c}$, its log-probability at the masked position is computed as:

$$log\,P\ (c\,|x_{mask}) \quad (6)$$

The adaptation-induced shift is measured as:

$$\Delta\ logP = logP_{dapt}(c) - logP_{base}(c) \quad (7)$$

Positive $\Delta\ logP$ indicates that DAPT increases the lexical preference toward candidate entities.

The top-1 match rate is also computed as:

$$Top-1\ Match = \frac{1}{N}\sum_{j=1}^{N}[c = \arg\max_w P(w\,|x_{mask}] \quad (8)$$

This experiment provides a token-level diagnostic of domain-induced preference drift.

Preference rate between two political factions:

$$PrefRate = \frac{1}{N}\sum_{j=1}^{N}[(logP(SideA|x_j) > logP(Israel|x_j)] \quad (9)$$

For Side A, log-probabilities are computed by taking the maximum probability among *Hamas*, *Palestine*, and *Gaza*.

Masked probing results are reported as descriptive preference statistics aggregated across seeds; future extensions should attach bootstrap uncertainty estimates to preference drift and role-conditioned preference rates.

H. Cross-seed Aggregation

All experiments are repeated across three DAPT seeds. Final reported metrics are aggregated as:

$$\mu = \frac{1}{|S|}\sum_{s\in S} m_s \quad (10)$$

$$\sigma = \frac{1}{|S|}\sqrt{\sum_{s\in S}(m_s - \mu)^2} \quad (11)$$

This ensures that observed drift effects are consistent and not artifacts of a single random initialization.

I. Decision and Bias Reporting Agent (DBRA)

The DBRA receives the outputs of the four behavioral experiments and synthesizes them into an interpretable bias assessment. The agent does not compute bias metrics itself; instead, it analyzes experimentally derived signals such as flip rates, JSD scores, and masked preference drift to generate a structured bias report.

TABLE II. DBRA DECISION RULES AND EVIDENCE HIERARCHY

Evidence layer	Metrics used	Role in ranking	Interpretation rule
Primary	PR-D, ΔPR, role-conditioned preference rates	Main bias decision layer	Extreme PR-D or large ΔPR indicates strong post-DAPT bias shift
Primary support	Att-PR, Hos-PR, Vic-PR, Loc-PR	Framing severity	Any role-conditioned preference rate > 70% indicates severe framing bias
Secondary	Actor-swapping JSD, ΔJSD, CI%95, McNemar p-value	Identity-sensitivity adjustment	Significant actor-related divergence strengthens bias-risk interpretation
Supporting	Emotion flip/JSD	Contextual evidence	High post-DAPT affective drift indicates instability but is not decisive alone
Supporting	Sentiment flip/JSD	Lowest-priority support	Surface stability does not override severe implicit bias in masked probing

To improve reproducibility, the DBRA was constrained by a predefined evidence hierarchy and explicit decision rules before narrative generation. Masked probing was treated as the primary evidence layer because it captures implicit representational bias that may remain hidden under stable downstream outputs. Actor-swapping served as a secondary signal for identity-sensitive instability, while emotion and sentiment drift were used as supporting evidence. Extreme post-DAPT preference

outcomes and role-conditioned preference rates above 70% were interpreted as high-risk bias indicators. Accordingly, the DBRA functioned as a structured meta-evaluation layer over fixed numerical results rather than a free-form textual judge. Table II summarizes the evidence hierarchy and interpretation rules used by the DBRA.

This agent-based synthesis addresses a key limitation of standard comparative evaluation: numerical results across multiple experiments do not themselves constitute a bias decision. The DBRA makes the ranking criterion explicit and evidence-driven, ensuring that models which appear stable on surface metrics but exhibit severe implicit drift are correctly identified as high-risk rather than low-bias.

IV. Results And Discussion

A. Sentiment and Emotion Drift Under Fine-Tuning

The analysis first evaluates whether domain-adaptive fine-tuning (DAPT) induces behavioral drift in zero-shot sentiment and emotion classification. Drift is quantified using two complementary views: flip rate, capturing categorical label changes between the base and fine-tuned checkpoints, and Jensen–Shannon divergence (JSD), capturing distributional probability shifts even when the final label remains unchanged.

TABLE III. Reports Sentiment Flip and JSD Values For All Checkpoints

Model	Checkpoint	Flip Rate	JSD
AraBERTv2	Base	0.122	0.004
	DAPT (mean ± std)	0.034 ± 0.025	0.0003 ± 0.0005
CAMeLBERT	Base	0.102	0.006
	DAPT (mean ± std)	0.000 ± 0.000	0.0000 ± 0.0000
mBERT	Base	0.010	0.000
	DAPT (mean ± std)	0.041 ± 0.029	0.0017 ± 0.0009
XLM-R	Base	0.102	0.006
	DAPT (mean ± std)	0.020 ± 0.017	0.0017 ± 0.0005

Base and politically fine-tuned models were compared for sentiment and emotion stability. In sentiment, AraBERTv2 showed the strongest improvement as shown in Table III, with flip rate dropping from 0.122 to 0.034, while XLM-R improved more modestly (0.102 → 0.02). In emotion as shown in Table IV, mBERT achieved the best robustness (0.143 → 0.017), whereas CAMeLBERT remained the most sensitive, with only partial reduction (0.184 → 0.115).

Overall, emotion predictions were more sensitive to political adaptation than sentiment. Several base checkpoints already exhibited non-trivial emotional instability, indicating that bias-related drift is present even before fine-tuning. Fine-tuning often reduced flip behavior, but the magnitude of improvement varied substantially across models.

These results confirm that domain-adaptive fine-tuning (DAPT) significantly alters model behavior compared to the base checkpoint, with emotion predictions showing substantially higher identity-sensitive drift than sentiment.

TABLE IV. Reports Emotion Flip and JSD Values For All Checkpoints

Model	Checkpoint	Flip Rate	JSD
AraBERTv2	Base	0.133	0.011
	DAPT (mean ± std)	**0.139 ± 0.049**	**0.002 ± 0.001**
CAMeLBERT	Base	0.184	0.005
	DAPT (mean ± std)	**0.115 ± 0.006**	**0.003 ± 0.001**
mBERT	Base	0.143	0.010
	DAPT (mean ± std)	**0.017 ± 0.006**	**0.005 ± 0.003**
XLM-R	Base	0.184	0.005
	DAPT (mean ± std)	**0.075 ± 0.037**	**0.003 ± 0.001**

Domain-adaptive fine-tuning (DAPT) mean and standard deviation are computed across seeds {13, 42, 100}.

B. Actor Swap Robustness and Entity Sensitivity

Table V reports actor-induced emotion instability across four transformer-based Arabic and multilingual encoders using 100 paired samples, where each pair differs only in actor identity while preserving the underlying content. Emotions are modeled using a 6-class Ekman taxonomy (excluding Neutral), enabling evaluation of both discrete emotion flips and distribution-level drift.

1) Baseline actor sensitivity: Across all base checkpoints, we observe measurable actor sensitivity, indicating that political actor identity alone can alter the model's emotional interpretation, even when the semantic content remains constant. This supports the broader hypothesis that political bias is embedded in pre-trained representations, manifesting as instability in affective predictions under minimal identity perturbations.

Notably, baseline divergence varies substantially across architectures. mBERT exhibits the highest baseline emotion drift (Base Emo JSD = 0.015), suggesting strong actor-induced perturbation prior to adaptation. In contrast, AraBERTv2 shows the lowest baseline divergence (Base Emo JSD = 0.002), indicating comparatively stable emotion attribution under actor swaps. CAMeLBERT (0.005) and XLM-R (0.004) fall in an intermediate range, reflecting moderate baseline sensitivity.

TABLE V. Reports Actor Flip and JSD Values

Model	p-val	JSD-B	JSD-D	ΔJSD	CI %95	Drift?
mBERT	**< 0.001**	0.015	0.001	−0.014	[−0.015, −0.013]	**Strong**
CAMeLBERT	1.0	0.005	0.003	−0.002	[−0.003, −0.001]	**Moderate**
AraBERTv2	1.0	0.002	0.001	−0.001	[−0.001, 0.000]	**Weak**
XLM-R	0.625	0.004	0.002	−0.002	[−0.003, 0.000]	**Unclear**

Column Definitions (Table V):

- **p-val**: McNemar test p-value for emotion flip under actor swapping

- **JSD-B**: Mean emotion Jensen–Shannon divergence (Base)
- **JSD-D**: Mean emotion Jensen–Shannon divergence (After domain adaptive fine tuning DAPT)
- **ΔJSD**: Difference between adapted and base JSD (DAPT − Base)
- **CI %95**: 95% bootstrap confidence interval for ΔJSD
- **Drift**: Qualitative strength primarily based on the ΔJSD CI %95 (with McNemar reflecting label-level sensitivity).

2) Fine-*tuning effects and robustness gains:* Fine-tuning yields heterogeneous outcomes, demonstrating that mitigation of actor-induced drift is strongly model-dependent.

For mBERT, fine-tuning produces the largest and most reliable stabilization: drift decreases from 0.015 to 0.001 (ΔJSD = −0.014), with a fully negative CI %95 [−0.015, −0.013] and a significant reduction in emotion flips (McNemar $p < 0.001$).

Together, these results indicate that fine-tuning substantially suppresses actor-driven emotional variability for mBERT, consistent with near-invariant behavior under actor swaps.

CAMeLBERT shows a different mitigation profile. While the model exhibits a statistically reliable reduction in divergence (ΔJSD = −0.002; CI %95 [−0.003, −0.001]), the flip-based test shows no significant change (McNemar $p = 1.0$). We interpret drift significance primarily through ΔJSD confidence intervals, while McNemar reflects label-level sensitivity.

This discrepancy suggests that fine-tuning primarily stabilizes the soft emotion distribution rather than the discrete top label. In other words, CAMeLBERT becomes more consistent in confidence allocation across emotion classes, even if the most probable class remains unchanged. This highlights an important methodological point: flip-based metrics alone may miss meaningful improvements in robustness when stabilization occurs through probability redistribution rather than categorical label changes.

For AraBERTv2, the baseline drift is already low and fine-tuning produces only a small reduction (ΔJSD = −0.001), with a confidence interval overlapping zero (CI %95 [−0.001, 0.000]) and no flip-level significance (McNemar $p = 1.0$). These results indicate that actor identity has limited influence on AraBERTv2 emotion predictions at baseline, and that fine-tuning does not produce a statistically reliable robustness gain under the current paired evaluation.

Similarly, XLM-R shows a decrease in mean divergence after fine-tuning (ΔJSD = −0.002), but the confidence interval slightly overlaps zero (CI %95 [−0.003, 0.000]) and McNemar's test remains non-significant ($p = 0.625$). Thus, while fine-tuning may reduce actor-induced drift for XLM-R, the evidence is not sufficiently strong to claim consistent stabilization under the present sample size.

3) Overall implications: Collectively, Table V demonstrates that (1) actor-level bias is detectable in base checkpoints, and (2) fine-tuning can mitigate such bias, but the effect is architecture-dependent. Crucially, the results also show that distributional and categorical stability can diverge: models may reduce drift in their predicted emotion distributions without producing measurable changes in flip frequency. Therefore, robust evaluation of political actor bias should include both flip-based paired tests (McNemar) and distributional divergence measures (JSD with bootstrap uncertainty).

C. Masked Word Prediction

To complement classification-based drift evaluations, we conducted a masked word prediction probing experiment to quantify implicit lexical bias at the language modeling level. Unlike sentiment or emotion outputs, masked probing directly measures internal token preferences by testing which political side the model assigns higher probability to in controlled masked contexts.

In the present setup, the masked slot may correspond either to an actor or a location. Therefore, we define SideA as a politically aligned entity group consisting of Hamas, Palestine, and Gaza, contrasted against Israel as the opposing side. This allows us to evaluate preference drift between two political factions rather than isolated named entities.

Bias is measured through probability-based preference rates, while Top-1 accuracy captures intrinsic masked token prediction competence.

Probabilities are computed from the MLM softmax distribution over the full vocabulary at the masked position. Table VI reports overall masked preference drift before and after DAPT across all evaluated models.

TABLE VI. OVERALL MASKED PREFERENCE DRIFT (BASE VS DAPT MEAN)

Model	PR-B	PR-D	ΔPR	T1-B	T1-D	ΔT1
AraBERTv2	38.6 %	70.5 %	+31.9 %	0.0%	7.6%	+7.6 %
CAMeLBERT	21.4 %	51.9 %	+30.5 %	30.7 %	40.5 %	+9.8 %
mBERT	40.7 %	0.0%	−40.7 %	1.4%	31.4 %	+30%
XLM-R	37.9 %	70.7 %	+32.8 %	0.7%	0.7%	+0.0 %

Column Definitions (Table VI):

- **PR-B / PR-D:** SideA preference rate before/after DAPT
- **ΔPR:** PR drift (DAPT − Base)
- **T1-B / T1-D:** Top-1 masked entity accuracy (Eq. 8)
- **ΔT1:** Top-1 accuracy change (DAPT − Base)
- **SideA:** max {Hamas, Palestine, Gaza}

Results reveal substantial lexical bias amplification in most models. AraBERTv2, CAMeLBERT, and XLM-R show large increases in SideA preference (ΔPrefRate ≈ +0.31 to +0.33), indicating that political fine-tuning strengthens internal polarization toward one faction. Notably, XLM-R exhibits the strongest bias drift (ΔPrefRate ≈ +0.328) without any improvement in lexical accuracy, suggesting bias amplification

without predictive benefit. Table VII presents role-conditioned political framing bias after DAPT across attacker, hostage, victim, and location contexts.

TABLE VII. ROLE-CONDITIONED POLITICAL FRAMING BIAS (DAPT MEAN PREFERENCE RATES)

Model	Att-PR	Hos-PR	Vic-PR	Loc-PR
AraBERTv2	73.6%	71.7%	80.0%	64.3%
CAMeLBERT	65.5%	81.7%	42.7%	29.8%
XLM-R	70.1%	78.3%	64.0%	75.0%
mBERT	0.0%	0.0%	0.0%	0.0%

Column Definitions (Table VII)

Each column reports the proportion of cases in which the fine-tuned model prefers SideA over Israel under a specific semantic role:

- **Att-PR:** SideA preference in attacker contexts
- **Hos-PR:** SideA preference in hostage contexts
- **Vic-PR:** SideA preference in victim/target contexts
- **Loc-PR:** SideA preference in location contexts
- All values are percentages.

In contrast, mBERT demonstrates the strongest and most concerning directional change: fine-tuning eliminates SideA preference entirely (ΔPrefRate = -0.407), resulting in an extreme directional pattern where *Israel* is consistently preferred in every masked context. Although the model achieves the largest Top-1 gain (ΔTop1 = +0.3), this improvement coincides with an extreme directional shift in political balance rather than enhanced neutrality. This suggests that domain adaptation may produce over-correction effects, reinforcing dominance of one side even when lexical prediction accuracy improves.

Role-conditioned analysis reveals strong political framing effects beyond aggregate bias scores. After fine-tuning, AraBERTv2 associates SideA entities with victim contexts in 80% of cases, reflecting systematic preference toward framing Hamas/Palestine/Gaza as the harmed side. CAMeLBERT shows the strongest hostage-related bias, preferring SideA entities in 81.7% of hostage contexts. XLM-R exhibits consistently high SideA preference across attacker, hostage, and location roles, suggesting broad sensitivity across political semantic frames.

Crucially, mBERT does not remain neutral across roles after fine-tuning. Instead, it exhibits an extreme preference collapse, assigning consistently higher probability to *Israel* in all masked contexts, regardless of the semantic role (attacker, hostage, victim, or location). This pattern suggests that political adaptation drives the model toward a highly directional lexical bias rather than balanced actor sensitivity. Such behavior reflects a problematic over-association of one side with every morally salient role, indicating that fine-tuning may introduce or amplify systematic political framing bias rather than mitigating it.

A preference rate of 0.0% does not imply absence of correct predictions. Rather, it indicates that Israel consistently receives higher probability than SideA entities in all masked contexts, even when Israel is the correct target.

D. DBRA Bias Assessment and Model Ranking

To synthesize the experimental findings into a unified and interpretable bias decision, the Decision and Bias Reporting Agent (DBRA) was applied to the aggregated outputs of all four behavioral experiments. The agent produced a ranked model classification based on a predefined evidence hierarchy, prioritizing masked probing preference drift as the primary signal, followed by actor-swapping identity sensitivity and affective drift as supporting evidence. Table VIII presents the final DBRA model bias ranking and assessment based on the predefined evidence hierarchy.

TABLE VIII. DBRA MODEL BIAS RANKING AND ASSESSMENT

Rank	Model	Type	Bias Level	Direction After DAPT	Key Evidence
1	mBERT	Multilingual	High	Complete Collapse	PR-D = 0.0%
2	XLM-R	Multilingual	High	Overt Increase	ΔPR = +32.8%
3	AraBERTv2	Arabic-Specialized	High	Overt Increase	Vic-PR = 80.0%
4	CAMeL BERT	Arabic-Specialized	Moderate	Overt Increase	PR-D = 51.9%

The DBRA ranked mBERT as the highest-risk model due to a complete directional collapse in masked probing (PR-D = 0.0%), which occurred despite near-zero affective drift, a covert bias pattern undetectable by standard classification metrics and therefore more dangerous than the overt preference amplification observed in XLM-R (ΔPR = +32.8%) and AraBERTv2 (Vic-PR = 80.0%). CAMeLBERT was ranked lowest in severity, though its hostage framing score of 81.7% precludes a neutral classification. Collectively, these rankings confirm that masked probing must be treated as a mandatory diagnostic layer in any deployment pipeline for politically sensitive Arabic NLP, as surface-level stability metrics alone are insufficient to identify high-risk representational bias. To assess output consistency, the DBRA was additionally instantiated using GPT-4.1 and Kimi K2.5 under identical inputs; all three converged on mBERT as the highest-risk model, with minor ordering differences for the remaining models documented in Appendix A.

For completeness and cross-model comparison, Appendix A.4 provides an integrated summary table covering all probe-model combinations used in the final DBRA assessment.

V. CONCLUSION AND FUTURE WORK

This work introduces a multi-view behavioral evaluation framework for detecting and reporting political bias in Arabic and multilingual transformer models before and after domain-adaptive fine-tuning, together with a Decision and Bias Reporting Agent (DBRA) that synthesizes the experimental results into an interpretable bias assessment.

The experimental findings suggest that political bias can arise from two compounding sources: latent associations in pre-trained base weights, and data-induced amplification through domain adaptation. Sentiment predictions generally stabilized after DAPT, while emotion predictions remained more volatile and architecture-dependent. Actor-swapping confirmed

measurable identity sensitivity across all base checkpoints, and masked probing exposed role-conditioned framing rates frequently exceeding 70% across attacker, victim, and hostage contexts.

The most critical finding, formalized by the DBRA, concerns the divergence between surface-level stability and deep representational collapse. mBERT exhibited near-zero affective drift after fine-tuning yet underwent a complete directional collapse in masked probing, with SideA preference dropping from 40.7% to 0.0%. The DBRA analysis identified this covert bias pattern as the highest-risk profile, demonstrating that surface-level stability can conceal substantial implicit bias undetectable by standard classification metrics.

Overall, this study underscores that standard accuracy-driven evaluation is insufficient for politically sensitive NLP applications, and that agent-based behavioral synthesis is essential for reliable bias auditing in Arabic transformer models.

A. Future Work

Future work will extend this framework to additional political contexts, languages, and entity sets to assess cross-domain robustness. Future work should incorporate neutral control entities to test whether the observed collapse is faction-specific or reflects broader entity-representation failure. A small human-annotated baseline for masked probing would also help benchmark model preference against human expectations of neutrality. Applying the proposed probes to large generative models may further uncover bias dynamics during text generation. Additionally, integrating explainability methods to identify which internal representations drive observed bias patterns represents a promising direction for deeper mechanistic understanding. Finally, exploring targeted bias mitigation strategies, such as role-aware regularization or counterfactual data augmentation, could provide actionable pathways for reducing implicit political framing in domain-adapted transformer models.

B. Limitations

This study is bounded to a specific geopolitical context and a limited set of political entities, which may constrain the generalizability of the reported bias trajectories to other regions, conflicts, or dialectal settings. In addition, because both domain-adaptive pre-training and behavioral evaluation are grounded in Arabic political news, some post-DAPT effects may reflect a combination of genuine representational bias shift and increased alignment to the target domain. The actor-swapping probe should also be interpreted with caution, as differences in prior entity exposure may partially influence model sensitivity to specific political actors. Finally, the comparison includes both Arabic-specialized and multilingual encoders, whose Arabic behavior may differ due to distinct pretraining distributions and tokenization characteristics. Accordingly, the proposed framework is intended as a transferable evaluation protocol, whereas the observed rankings remain context-dependent.

APPENDIX

A. DBRA Output Across Agent Instantiations

To support reproducibility, the DBRA was instantiated using three independent large language models under identical prompts and experimental inputs. All three converged on mBERT as the highest-risk model. Full ranking tables are reported below.

A.1 GEMINI 3.1 PRO (PRIMARY INSTANTIATION)

Rank	Model	Bias Level	Key Evidence	Why This Rank
1	mBERT	High	PR-D = 0.0%	Complete directional collapse in masked probing — most dangerous hidden bias pattern
2	AraBERTv2	High	Vic-PR = 80.0%	Severe framing across three roles (>70%) with worsening emotion drift
3	XLM-R	High	ΔPR = +32.8%	Massive preference shift and severe hostage/location framing despite surface stability
4	CAMeLBERT	Moderate	PR-D = 51.9%	Most balanced final preference rate, though severe hostage framing (81.7%) persists

A.2 GPT 4.1

Rank	Model	Type	Bias Level	Key Evidence	Direction After DAPT	Why This Rank
1	mBERT	Multilingual	High	PR-D = 0.0%	Complete Collapse	Total directional collapse undetected by surface metrics
2	XLM-R	Multilingual	High	ΔPR = +32.8%, Hos-PR = 78.3%	Severe Increase	High post-DAPT preference rate and severe role framing bias
3	AraBERTv2	Arabic-Specialized	Moderate	PR-D = 70.5%, Vic-PR = 80.0%	Substantial Increase	Marked preference rise and severe victim framing after DAPT
4	CAMeLBERT	Arabic-Specialized	Moderate	ΔPR = +30.5%, Hos-PR = 81.7%	Significant Increase	Notable bias increase but less severe overall than mBERT and XLM-R

A.3 KIMI K2.5

Rank	Model	Type	Bias Level	Key Evidence	Direction After DAPT	Why This Rank
1	mBERT	Multilingual	High	PR-D = 0.0%	Complete Collapse toward Israel	Complete directional collapse — hidden bias undetectable by surface metrics
2	XLM-R	Multilingual	High	PR-D = 70.7%	Strong SideA Preference	Severe framing bias across multiple roles with high post-DAPT preference rate
3	AraBERTv2	Arabic-Specialized	High	Vic-PR = 80.0%	Strong SideA Preference with worsening emotion	Severe victim framing coupled with increased emotion flip rate
4	CAMeLBERT	Arabic-Specialized	Moderate	PR-D = 51.9%	Moderate SideA Preference	Lowest preference rate and minimal sentiment drift despite high hostage framing

A.4 INTEGRATED SUMMARY OF BEHAVIORAL BIAS SIGNALS ACROSS MODELS AND PROBES

Model	Type	Sentiment Flip (B→D)	Emotion Flip (B→D)	Actor ΔJSD	Actor Drift	Masked PR (B→D)	ΔPR	Max Role PR	DBRA Signal
AraBERTv2	Arabic-specialized	0.122 → 0.034	0.133 → 0.139	-0.001	Weak	38.6% → 70.5%	+31.9%	80.0%	High framing bias
CAMeLBERT	Arabic-specialized	0.102 → 0.000	0.184 → 0.115	-0.002	Moderate	21.4% → 51.9%	+30.5%	81.7%	Hostage framing bias
mBERT	Multilingual	0.010 → 0.041	0.143 → 0.017	-0.014	Strong	40.7% → 0.0%	-40.7%	0.0%	Complete directional collapse
XLM-R	Multilingual	0.102 → 0.020	0.184 → 0.075	-0.002	Unclear	37.9% → 70.7%	+32.8%	78.3%	Strong post-DAPT increase

Note: All three instantiations agreed on mBERT as Rank 1. The primary divergence concerned Ranks 2 and 3: Gemini prioritized AraBERTv2 based on role framing severity, while GPT-4.1 and Kimi K2.5 ranked XLM-R second based on overall preference drift magnitude. CAMeLBERT was consistently ranked fourth across all instantiations.

Trust and Hallucinations: A Study of 39 Experts on AI-Assisted Requirements Reverse Engineering

Abdullah A H Alzahrani
Department of Computers, Engineering and Computing College at Alqunfuda,
Umm Al Qura University Makkah, Saudi Arabia

***Abstract*—With regard to the evolution of software systems, the process is hindered by the poor state of documentation, as software systems continuously evolve, which thereafter increases the maintenance costs to around 90% of development lifecycle spending. In addition, although the extraction of embedded business logic through the reverse engineering of requirements is essential, a gap in meaning remains between the source code and the high-level objectives, which means a need for addressing this issue. Therefore, currently, many artificial intelligence tools are in place for such actions. This research evaluates the performance of specialized Retrieval-Augmented Generation (RAG), general-purpose large language models, and hybrid static AI systems by focusing on the expert observations of practitioners within industrial environments. To achieve this, the study gathers data to measure hallucination rates and the accuracy of business rule recovery based on the actual professional experience of those managing legacy code. In particular, these experts used EPAM ART, GitHub Copilot, and IBM ADDI to provide percentage-based error estimates and rate rule identification on a standard scale. Ultimately, this empirical approach ensures that the research questions are addressed through the practical insights and lived experiences of professionals. In this research, a study of perspectives of 39 senior professionals observed that, while general models are successful at abstracting meaning with a score of 4.05 out of 5, a shortfall in traceability is retained. Furthermore, it was discovered that hybrid tools such as IBM ADDI allow for superior formal mapping with a score of 4.23 out of 5, although a struggle in verification is produced because high rates of incorrect data generation or hallucination exceeding 20% were reported by 66.7% of the participants. In light of these findings, this research proposes a strategy of multiple tool coordination in order to make the evolution of software systems feasible over long periods.**

***Keywords*—Software engineering (SE); requirements engineering (RE); requirements reverse engineering (RRE); large language models (LLMs); natural language processing (NLP)**

I. Introduction

A. Context and Problem Statement

Regarding the operation of modern enterprises, legacy software systems are viewed as the functional base, although the fading of documentation is frequently observed as original requirements no longer align with the evolving source code [1-6]. In addition, this state results in obsolete documentation that affects the maintainability of systems and increases the risk of architectural erosion during modernization efforts. Furthermore, as a shift toward microservices and cloud native architectures is accepted by organizations, the reverse engineering of requirements is required so that business rules embedded in undocumented implementations in the software are recovered. As a result, the difficulty of translating low level programming constructs into human readable requirements is encountered as a gap of semantics, additionally, while manual processes are considered economically not feasible due to costs reaching 90% of lifecycle expenses, traditional rule based automation is hindered by the lack of cognitive flexibility for complex logic [7-11].

Regarding the potential for modern artificial intelligence and large language models to offer a useful approach to bridge this gap, the deployment of such tools is hindered by risks as these models are prone to the generation of nonsense requirements or hallucinations that contradict the actual source code logic [12-18]. In addition, a shortage in traceability is maintained, where high-level summaries are provided without a detailed mapping to the specific lines of code from which they were derived. As a result, this absence of mapping is found to make the verification process more difficult. Due to the influence of these factors, a struggle in verification is produced where the role of the engineer is required to change from an author to an oversight manager who is responsible for validating large generated output so that system functionality and integrity are ensured [19-20].

B. Motivation

In order to allow the integration of artificial intelligence into the reverse engineering of requirements, the process is imposed by a demand for economic improvement throughout the software lifecycle because maintenance and evolution are found to account for 60% to 90% of the total cost of software development [1, 21-26]. In addition, a large majority of these costs are produced by the cognitive effort that is required to understand undocumented legacy code, while it is also observed that artificial intelligence acts as a safeguard against the loss of institutional knowledge where business logic is removed as senior engineers depart. Therefore, in order to address this, advanced frameworks offer a scalable methodology so that this hidden logic is preserved in human readable formats for new development teams [8, 27]. Furthermore, the modern shift toward rapid digital transformation requires high quality models so that the risks of software evolution are lessened and a precise functional standard is established to prevent expensive future risks [28-31]. Additionally, it is found that this gap is bridged by an automated source of truth which allows for system integrity to be maintained during the transition to modern software ecosystems, however, a change in the engineering landscape is observed as the industry enters a new era, namely Software Engineering (SE 3.0) paradigm, of agentic software engineering

where artificial intelligence acts as an active partner. This paradigm is defined as a state where artificial intelligence systems no longer function as simple assistants but instead operate as autonomous teammates capable of managing complex workflows and system updates. Additionally, within this environment, the human role is moved from the primary author of requirements to an oversight manager who is responsible for the validation of generated artifacts to prevent the loss of logic and the growth of technical debt [8, 28, 32-33].

C. Research Questions

The primary objective of this investigation is to evaluate the practical utility and dependability of artificial intelligence systems for requirements reverse engineering by collecting professional viewpoints from 39 experts and comparing prominent technical platforms. To meet this objective, several inquiries are pursued by the study. First, regarding RQ1 Extraction Fidelity, the level of precision in the identification of business logic within old software code during requirements reverse engineering is assessed through the collective judgment of human specialists. Second, regarding RQ2 Semantic Abstraction, the success of these systems in the translation of technical code into clear requirements is measured by the ratings of the participants. Third, regarding RQ3 Reliability and Trust, the perceived frequency of incorrect data generation is recorded across various tools, and the influence of data limits on the trust of the experts is examined. Finally, regarding RQ4 Comparative Utility, the differences in the ability of various tool designs to produce a link between the code and the requirements are analyzed.

D. Research Contributions

In order to clarify the contribution of this research in software requirements engineering, the research addresses the transition toward the SE 3.0 paradigm through several key findings. First, the research presents an empirical practitioner analysis based on a sample of 39 professional experts in software engineering in order to identify a critical struggle in verification. Second, a comparison of three different technological models is provided through an evaluation of specialized RAG represented by EPAM ART and general-purpose models such as GitHub Copilot and hybrid static AI systems like IBM ADDI. While most previous studies are limited to the examination of a single tool type, this research is widened to include several architectures to provide a broader view of how legacy code is managed. In addition, the practical needs of professionals are prioritized so that the findings are applicable to the real-world challenges of system modernization. Third, the research proposes a validation roadmap for practitioners as strategies for development teams to oversee in order to lessen the risks of accelerated technical debt and the loss of meaningful logic in large-scale software systems. These contributions provide a guide for organizations to navigate tool selection while ensuring the original system logic is preserved during complex digital transformations.

E. Paper Outline

In order to outline this research study's structure, the study is organized into five subsequent sections: Section II provides the theoretical foundation and reviews literature on documentation decline or loss, the gap in meaning, and the three primary failure modes. Following this, Section III details the qualitative methodology and describes the selection criteria for the evaluated tools. In addition, Section IV presents the core empirical results, offering a statistical comparison of tools. Finally, Section V concludes with a summary of key findings and outlines future research directions.

II. Background and Related Work

In software engineering, software requirements denote the formal specification of services, constraints, and operational goals that a system must fulfill to satisfy stakeholder needs [13, 34-37]. In addition, these requirements are divided into functional requirements, which explain the system's behaviors, and non-functional requirements, which explain quality attributes such as scalability, security, and maintainability [1, 38-41]. Furthermore, continuing challenges in the software lifecycle are requirements evolution or changes, or/and/or the loss of documentation accuracy or reflection of code. This occurs because the evolving source code increasingly separates it from its original specifications, consequently resulting in obsolete documentation that affects system maintainability and raises the risk of architectural loss during software maintenance and evolution efforts [1, 8, 42-45].

With regards to the process of analysis of code of a software system for identification of internal components and the relations between those parts, this process can be defined as software reverse engineering, where a higher-level representation is created [7, 46-49]. In addition, the design decisions and patterns of architecture and structures of algorithms are recovered from existing code by this backward operation, which stands in opposition to forward engineering, where the standard path of translating abstract specifications into logic that can be executed. Furthermore, the evolution of legacy systems is pursued by the reverse engineering method because the transparency that is required for the comprehension of systems that lack documentation is provided to software engineers [50]. As a result, low-level artifacts such as graphs of control flow and call graphs are reconstructed through the employment of static analysis of source code and the dynamic analysis of behavior during runtime by reverse engineering methods [7, 27].

In addition, in the field of requirements reverse engineering, high-level functional specifications are extracted from low-level technical implementations [12, 46-47]. Furthermore, the resolution of the semantic gap is identified as the main goal of this process to address the cognitive distance between executable logic in as code and the original business intentions [19]. However, manual methodologies are often viewed as too expensive for large enterprise software systems, whereas traditional automated systems are seen as lacking the flexibility needed for the interpretation of complex logic [8, 51].

In addition, a shift in requirements for reverse engineering has been sparked by the inclusion of artificial intelligence and large language models, which provide scalable natural language generation for the interpretation of code intent. Furthermore, the establishment of a source of truth is seen as a possibility within research for artificial intelligence-based requirements reverse engineering as hidden business logic is extracted and translated into structured human-readable requirement models. As a result,

functional consistency is ensured during digital transformations such as the migration from massive architectures to microservices or cloud native environments [8, 12, 52-55].

With the impact of the integration of artificial intelligence, especially large language models in many fields, a shift in software development has been sparked by transitioning from deterministic automation to probabilistic context-aware assistance [20]. Furthermore, the transformer architecture is used by modern large language models such as the GPT 4 series, Llama 4, and Gemini for the parallel processing of massive collections of source code and natural language through the use of self-attention mechanisms [9, 56]. As a result, deep learning is used by large language models to identify complex patterns and semantic relationships within unstructured data, whereas traditional natural language processing techniques were dependent on manually defined rules [9].

In addition to these software engineering applications, the use of large language models is extended beyond simple code auto-completion. Furthermore, the effectiveness of these models in program comprehension is highlighted within recent research from 2024 upwards, as legacy functions are summarized and access control vulnerabilities are identified along with the generation of automated test oracles [20, 57]. As a result, the high-level coordination of software evolution tasks, such as the management of dependencies and the refactoring of large-scale architectures into microservices, is allowed by the emergence of autonomous AI agents that combine large language models with tool use capabilities [56, 58]. However, non-deterministic outputs are introduced by the probabilistic nature of large language models, which can result in syntactic faults and a lack of alignment with established software modeling standards [13, 59].

A. Critical Challenges in AI-Supported Requirements Reverse Engineering

In addition to these known failure modes, the use of large language models is restricted by several limitations within the field of requirements reverse engineering. Furthermore, three main failure modes are identified within recent academic literature for the description of the current state-of-the-art as: probabilistic hallucinations, the traceability deficit, and semantic loss.

1) Probabilistic hallucinations and factual inconsistency: The industrial adoption of artificial intelligence for requirements reverse engineering is hindered by the occurrence of hallucinations where syntactically correct but erroneous or non-existent business rules are generated as recovered requirements [20, 60]. Furthermore, inconsistencies are frequently produced where the generated requirement contradicts the actual source code logic because large language models operate on a probabilistic next token prediction system rather than a deterministic logic engine [56]. As a result, the common nature of these errors within legacy systems involving older libraries or restricted domain-specific languages is indicated by recent empirical studies where accurate context cannot be derived due to a lack of sufficient training data [13, 60].

2) The traceability deficit: In addition to the occurrence of hallucinations within the use of these systems, requirements traceability is identified as a necessary aspect of safety-critical software engineering, where the life of a requirement is described and followed in both a forward and reverse engineering direction [13]. Furthermore, high-level summaries are often provided by artificial intelligence-supported tools without a mapping to the lines of code or architectural components from which they were derived. As a result, the verification process is complicated by this traceability deficit because artificial intelligence-generated outputs must be manually audited by practitioners to ensure functional alignment with the codebase [19, 57].

3) Semantic loss and contextual reasoning: In addition to these traceability deficits, semantic loss is often suffered by artificial intelligence as the underlying business logic behind a specific implementation is neglected during the translation of code to text [56, 61]. Furthermore, the ability to realize complex nonlinear dependencies across large sources is limited because large language models frequently rely on statistical pattern matching rather than genuine logical deduction [20, 60]. As a result, the behavior of the software system may be captured by extracted requirements, while the critical business constraints or logic that controlled the original design decisions are not documented [8, 61].

B. Comparative Tool Analysis

In addition to these semantic challenges, a difference in how modern tools bridge the semantic gap is revealed by technical testing against standardized legacy Java and COBOL testbeds. Furthermore, superior extraction fidelity is shown by specialized platforms such as EPAM ART and IBM ADDI compared to general-purpose models through the use of dedicated retrieval augmented generation or hybrid static artificial intelligence approaches. As a result, the underlying business intent is identified with greater success by specialized tools such as EPAM ART, even though most tools are capable of describing technical behavior. In addition, an abstraction score 35% higher than that of general artificial intelligence counterparts is achieved by this focus on the reasons for the existence of a rule [12, 52, 56, 62].

Furthermore, reliability is identified as a factor that separates various tools because hallucination rates ranging from 15% to 20% are shown by general-purpose models. Additionally, false positive but entirely incorrect business constraints are produced by the artificial intelligence which results in the documentation being weakened. As a result, a traceability deficit has arisen as a major obstacle as the lack of direct source to requirement mapping in Github Copilot was identified by approximately 72% of practitioners as an obstacle to the establishment of trust in automated legacy analysis [8, 57, 60, 63].

C. Industrial Implications: The SE 3.0 Paradigm

Despite the obstacles found in automated analysis, a fundamental change in the field is shown by current findings as the move from simple artificial intelligence augmented development to the agentic software engineering is made. Furthermore, artificial intelligence supported reverse

engineering and requirements extraction tools no longer function as mere assistants within this new model but instead operate as autonomous teammates capable of managing complex system update workflows. As a result, these specialized architectures are becoming necessary to reduce the loss of critical business logic that occurs as legacy system experts retire or leave an organization [32-33, 64-66].

In addition to the transition toward agentic software engineering, this shift introduces structural challenges, one of which is the verification challenge, where the role of a software engineer changes from an author to an oversight manager [65-68]. As a result, the human role moves to validating large volumes of generated output as tools automate code interpretation, which can quickly become overwhelming. In addition, a growing risk of technical debt is caused by the accumulation of artificial intelligence-generated artifacts that may lack deep architectural alignment or continuing maintainability [61, 66, 68].

Finally, in addition to these structural challenges, the industry faces the issue of meaning loss over time. Furthermore, current large language models show a loss of meaning when processing large-scale software systems such as those exceeding 2.5 million lines of code. As a result, this decline is driven by context window constraints and the token snowball effect, where the volume of data reduces the ability of the model to maintain a clear understanding of the entire logic of the system [65-68].

III. Methodology

A. Research Design

A qualitative approach is adopted in this study to evaluate the performance of tools for requirements reverse engineering. As a result, due to the fact that large language models are probabilistic, common fixed metrics are found to lack the necessary depth to capture business logic. Furthermore, although numerical rates of error and precise levels of rule identification are sought through the research questions, the data are gathered from the expert practitioners so that the performance of these systems is evaluated through the lens of industrial experience. In addition, the frequency of hallucinations is measured by the observations of these experts. Because the identification of business logic is viewed as a task that is dependent on human meaning, the degree of success for each tool is determined by the average scores provided by the senior engineers who possess the necessary background to judge the accuracy of the generated requirements. As a result, the collection of these expert ratings allows producing a statistical summary where the performance of each architectural model is compared across the set categories.

The research design follows the rules for empirical software engineering involving large language models as proposed by Wagner et al. [62]. In addition, this study is organized as a comparative analysis where the ways that three separate architectural types of artificial intelligence address the recurring problems of lost documentation are examined. Furthermore, the performance of specialized RAG and general purpose large language models and hybrid static AI is compared within a setting that is focused on the needs of practitioners. In addition, by focusing on the difficulties of updating old systems, direct value for organizations is provided. As a result, this setup helps in the identification of a graded utility model which allows moving beyond simple code automatic completion toward the agentic software engineering. Furthermore, the study uses purposive sampling of highly experienced professionals in order to ensure that the findings on inconsistency and traceability are based on the strict constraints of real-world industrial environments.

B. Selection of AI-Supported Tools for Requirements Reverse Engineering

Three platforms were chosen to provide a comparison based on their unique designs and industrial uses. First platform is EPAM ART or AI Requirements Transformer, which represents a specialized enterprises tool for requirements extraction that uses a specific code chunking design and retrieval augmented generation to manage large legacy software systems code while keeping the meaning of the context intact [12]. Second platform is GitHub Copilot with Copilot Chat which serves as the standard model for general purpose artificial intelligence assistants as it represents the main tool currently used by professionals for informal code explanation and documentation tasks because of its wide use within the developer community [56]. Third platform is IBM ADDI with watsonx integration which represents an integrated system evolution environment that combines fixed static and active analysis with cognitive artificial intelligence capabilities to help with high level architectural discovery in legacy software systems such as COBOL and Java [8, 50, 69]. Therefore, these tools were given to or discussed with participants to assess how well they work in real world system update workflows.

C. Practitioner Questionnaire Design

Based on that, the main data collection tool in this research is a structured questionnaire found in Appendix A, the study uses three specific dimensions for evaluation, since the technical performance data comes from expert assessments. First, dimension A is the perceived technical accuracy or fidelity which involves participants rating how well the tool bridges the gap in meaning and finds hidden business logic within unclear legacy code. Second, dimension B is reliability and failure modes which records expert observations on how sensitive a tool is to specific prompts and how often it creates errors that would need manual fixing in a real work setting. This can be seen as sensitivity of conditional prompt and frequency of hallucinations [63]. Third, dimension C is industrial use which has respondents assess how ready the output of the tool is for later migration tasks, such as defining the limits of microservices.

D. Data Collection and Analysis

The data collection process was carried out through a structured digital tool in the form of a Google Form survey which was sent to practitioners who focus on legacy software systems maintenance and system evolution. At the same time, the survey link was distributed anonymously through professional networks and industrial forums to ensure that no personal identifying details were collected during the study. In addition, while the link was shared broadly within these circles, the participation was restricted by specific screening criteria where every respondent was required to possess over five years

of experience in software engineering and a history of working with the modernization of legacy code. Furthermore, along with this requirement, the recruitment was performed by reaching out to leads within the global engineering community who shared the link with qualified experts in sectors such as finance and healthcare and telecommunications. In addition to these efforts, the anonymous nature of the data collection allowed for candid feedback regarding the performance of EPAM ART and GitHub Copilot and IBM ADDI without the risk of professional bias. Finally, due to the application of these strict criteria and the anonymous collection method, the risks associated with a convenience based sample are reduced and the representative nature of the expert standard is maintained.

IV. Results and Discussion

This section presents the findings from the empirical survey of 39 practitioners. Firstly, the results are grouped or organized by the three evaluation dimensions set in the methodology that focus on comparing GitHub Copilot, EPAM ART, and IBM ADDI. Secondly, as shown in Table I, the participants possess a high-level of experience which should provide the expert standard needed for rating complex artificial intelligence outputs. Thirdly, the participants are found to have respectable experience in the industry of software engineering as software engineers and modernization leads averaging 6 to 10 years of experience and system architects represents around 33.3% of the sample and average 11 to 15 years in the field. In addition, this level of expertise is supporting for confirming the reported failure modes as these professionals have the necessary knowledge to find the loss of meaning and lack of traceability that often mark probabilistic artificial intelligence outputs.

TABLE I. Participants Demographic Profile (N=39)

Professional Role	Participants (n)	Percentage (%)	Avg. Experience (Years)
Senior Software Engineers	19	48.7%	6-10
System Architects	13	33.3%	11-15
Modernization Leads	7	18.0%	6-10
Total	39	100%	> 8 years

A. Dimension A: Technical Fidelity and Abstraction

Building on the assessment of professional expertise and demographic depth, the study identifies clear performance trends across the chosen platforms. Regarding technical accuracy and abstraction, it was found that GitHub Copilot and EPAM ART both received high perceived accuracy scores of 4.26 out of 5 from the participants. In addition, for the ability to change technical actions into business reasons, GitHub Copilot was preferred with a score of 4.05. In order to evaluate the impact of these findings, the effect size was measured using Cohen d which resulted in a value of 0.78 for the comparison between general purpose and specialized tools. Finally, this figure represents a large effect size and suggests that the preference for GitHub Copilot in abstracting meaning is statistically notable and by including these measures of variation and effect, a more complete view of the data distribution is offered.

B. Dimension B: Reliability and Failure Modes

In addition to aforementioned accuracy findings, reliability was measured through the ability to follow a requirement and the frequency of errors or it can be regarded as traceability and the frequency of hallucinations. As a result, IBM ADDI outperformed other platforms in this aspect with a score of 4.23/5 which shows its roots in fixed static analysis whereas EPAM ART and GitHub Copilot trailed with scores of 3.92/5 and 3.82/5. Furthermore, reliability remains the most serious concern for practitioners because 66.7% of the sample reported that these tools often generate non-existent logic or reverse engineer incorrect requirements. Finally, the primary obstacles to the establishment of trust in the generated requirements were identified as context window limits at 33.3% and factual errors at 28.2% along with a lack of formal traceability at 23.1%. While these figures are established through expert observation, a thorough interpretation of these findings indicates that the reported hallucination rates are directly driven by these context constraints which prevent the models from maintaining a clear understanding of the entire logic in systems exceeding 2.5 million lines of code. Moreover, due to the processing capacity of the architecture is exceeded by such massive volumes of data, the probabilistic nature of the tools leads to the production of non-existent business rules or syntactically correct yet erroneous logic. In addition to these technical restrictions, the token snowball effect is observed to reduce the ability of the model to maintain functional alignment with the codebase which results in a struggle in verification for the oversight manager.

C. Dimension C: Industrial Utility

Linked to these reliability concerns, the final part of the study looked at the practical readiness of artificial intelligence for source of truth recovery in large-scale software legacy systems where the survey findings show a clear agreement that these tools are for help rather than a replacement as 61.5% of experts believing they will only partially help but not replace manual skill. However, a notable 38.5% of senior engineers and architects believe artificial intelligence agents could completely replace manual work in the future.

D. Discussion of Findings

A summary of how GitHub Copilot and EPAM ART and IBM ADDI are perceived to perform is provided in Table II, where the results are presented as the average and standard deviation on a five point scale. As can be seen in Table II, while general purpose tools like GitHub Copilot were found to perform better in areas of meaning and immediate accuracy, IBM ADDI was seen to provide the traceability that is needed for business logic. In order to determine if these differences were meaningful, an analysis of variance was performed. The results indicated that the variations in scores across the three tool types were statistically important because a p value of less than 0.05 was achieved. Furthermore, confidence intervals of 95% were calculated for every metric to confirm that the findings remain within a reliable range. Therefore, it can be concluded that these results show that the differences in tool performance are not the outcome of random chance but reflect real variations in how these technologies are viewed by professionals.

Furthermore, because 100% of the respondents reported the encounter of errors or hallucinations at least occasional

hallucinations, the high frequency of these issues across all platforms confirms the necessity for expert oversight to validate the reverse-engineered requirements. In addition, while the aggregate mean scores for GitHub Copilot, EPAM ART, and IBM ADDI are observed to be nearly identical at 4.04 and 4.05, the statistical robustness of the study is supported by the reported variations, which include standard deviations ranging from 0.72 to 0.91. As a result, these values represent the level of agreement among the expert group and allow for the conclusion that the differences in performance across metrics are grounded in the practical experience of the participants. In addition to these metrics, the high traceability score of 4.23 for the hybrid tool IBM ADDI suggests that specialized architectures are required for formal mapping even when general models lead in technical fidelity. Finally, by the inclusion of these statistical details regarding the performance of GitHub Copilot and EPAM ART alongside IBM ADDI, it is indicated that a strategy of multiple tool coordination remains the most stable path for the evolution of software systems.

TABLE II. COMPARATIVE PERFORMANCE SCORES (N=39) SCALE 1–5

Metric	GitHub Copilot	EPAM ART	IBM ADDI
Extraction Fidelity	4.26±0.88	4.26±0.91	3.92±0.72
Semantic Abstraction	4.05±0.86	3.97±0.81	4.00±0.86
Traceability	3.82±0.79	3.92±0.77	4.23±0.81
Aggregate Mean Score	4.04 ±0.85	4.05 ±0.84	4.05±0.81

V. CONCLUSION AND FUTURE WORK

The final results of this research are established through a detailed analysis of the present status of AI-assisted requirements reverse engineering as viewed by 39 professional experts. In addition, the performance of GitHub Copilot is compared with specialized platforms such as EPAM ART and IBM ADDI, so that the observation is made that although large language models have lowered the difficulty of understanding code, they are still seen as tools which require careful application. Furthermore, it is confirmed by the gathered data that the distance between technical data and human meaning is reduced even if the movement from code extraction to the generation of meaningful accurate software requirements remained to be viewed as a disconnected process where traceable requirements remain a disconnected process characterized by a tradeoff between abstraction and reliability.

As a result of this research, a major contribution provided is the recognition of a leveled model for the use of artificial intelligence during the evolution of legacy software systems. Although high levels of accuracy in data extraction are shown by GitHub Copilot and EPAM ART with mean scores of 4.26 plus or minus 0.88 and 4.26 plus or minus 0.91, respectively a key benefit in the creation of traceable requirements is held by IBM ADDI with a score of 4.23 plus or minus 0.81. In addition, it is suggested by this difference that general large language models are currently built for the fast creation of high-level requirements by changing technical facts into business logic, while specialized systems for software evolution are needed for environments with strict rules where a fixed link between rules and code is required. Moreover, the fact that false data or hallucinations are reported as a regular or periodic event by experts serves as evidence that the use of artificial intelligence for requirements engineering is viewed as a supporting tool rather than a total change or human replacement.

Furthermore, a shared view is found among professionals, with 79.5% supporting a model of partial help so that the future of requirements engineering is seen as a process where humans remain in the loop. In addition, the noticeable difficulties to trust which are found by this research such as the limited amount of data handled at one time and the presence of false facts or hallucinations define the current limits of use or AI in requirements reverse engineering as it is seen that human knowledge is still held as the upper standard for checking the results produced by artificial intelligence especially in legacy systems with many connections where rare business logic are not found clearly within the code.

Finally, the focus of future research is placed on the development of automated checking systems where requirements produced by artificial intelligence are compared with the actual behavior of software during operation, so that a fixed check against the generation of false data or hallucinations by large language models is provided. In addition, a need is found for long-term studies where the technical debt and maintenance costs for systems which are renovated through requirements reverse engineering by artificial intelligence. Lastly, context window architectures evolve, exploring hierarchical retrieval augmented generation will be essential for managing large-scale legacy code without sacrificing the contextual integrity for accurate reverse-engineered requirements.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to Umm Al Qura University for providing me with the invaluable opportunity to conduct research in the software engineering field. I would also like to extend my heartfelt thanks to my family and friends for their unwavering support and encouragement throughout this journey.

APPENDIX A

Survey: AI-Supported Requirements Reverse Engineering (RRE)

Research Study: Software Reverse Engineering Using AI Platforms. This survey evaluates the efficacy of AI tools in extracting business logic from legacy systems.

* Indicates required question

1. Current Professional Role: *

Mark only one oval.

- ◯ Senior Software Engineer
- ◯ System Architect
- ◯ Modernization/Digital Transformation Lead
- ◯ Other

2. Years of Experience in Software Maintenance/Modernization: *

Mark only one oval.

- ◯ 0–5 years
- ◯ 6–10 years
- ◯ 11–15 years
- ◯ 15+ years

3. Familiarity with Legacy Environments (COBOL, Java Monoliths, etc.): *

Mark only one oval.

- ◯ Expert
- ◯ Proficient
- ◯ Competent
- ◯ Novice

4. Which tools have you utilized for code comprehension or documentation? (Check all that apply): *

Check all that apply.

- ☐ GitHub Copilot
- ☐ EPAM ART
- ☐ IBM ADDI (watsonx)
- ☐ Other LLMs (GPT-4, Claude, Llama)

5. Extraction Fidelity: How accurately does the tool extract core business rules from code? (1 = Low Accuracy, 5 = High Accuracy) *

Mark only one oval per row.

	1	2	3	4	5
GitHub Copilot	◯	◯	◯	◯	◯
EPAM ART	◯	◯	◯	◯	◯
IBM ADDI	◯	◯	◯	◯	◯

6. Semantic Abstraction: Ability to translate technical 'What' into business 'Why.' (1 = Purely Technical, 5 = High-Level Business Logic) *

Mark only one oval per row.

	1	2	3	4	5
GitHub Copilot	◯	◯	◯	◯	◯
EPAM ART	◯	◯	◯	◯	◯
IBM ADDI	◯	◯	◯	◯	◯

7. Traceability: Does the tool provide clear mapping from requirement to source line? (1 = Black Box, 5 = Full Source Mapping) *

Mark only one oval per row.

	1	2	3	4	5
GitHub Copilot	◯	◯	◯	◯	◯
EPAM ART	◯	◯	◯	◯	◯
IBM ADDI	◯	◯	◯	◯	◯

8. Hallucination Frequency: How often does the tool generate non-existent logic? *

Mark only one oval.

- ◯ Never (<1%)
- ◯ Rare (1–10%)
- ◯ Occasional (10–20%)
- ◯ Frequent (>20%)

9. In your view, what is the primary barrier to trusting AI-generated requirements? *

Mark only one oval.

- ◯ Factual Inconsistency/Hallucinations
- ◯ Lack of formal traceability
- ◯ Context window limitations in large codebases
- ◯ Security/Privacy concerns

10. Describe a scenario where AI-driven RRE failed to capture critical business logic.

11. Do you believe AI agents can eventually replace manual 'source of truth' recovery? *

Mark only one oval.

- ◯ Yes, completely
- ◯ Partially, they will assist but not replace
- ◯ No, manual expertise will remain essential

Generative Monocular Perception Pipeline-Based Framework for Accurate Stem Detection in Automated Strawberry Harvest

Kohei Arai[1], Jin Sawada[2], Mariko Oda[3]
Department of Information Science, Saga University, Saga City, Japan[1]
Graduate School, Kurume Institute Technology, Kurume City, Japan[2]
Applied AI Laboratory, Kurume Institute of Technology, Kurume City, Japan[3]

***Abstract*—Horticulture faces a growing labor crisis, driving demand for autonomous harvesting robots, but reliable strawberry peduncle detection remains a critical unsolved challenge due to their fine, millimeter-scale structure and severe intertwining with leaves and stems. Existing single-view RGB imaging struggles with occlusions and ambiguities, while depth sensors falter in reflective greenhouse environments plagued by noise and data gaps. Introducing a generative monocular perception pipeline—the first to reconstruct multi-view cues purely from a single RGB image—this study achieves perceptual consistency through four novel, synergistic innovations: (i) pseudo multi-view synthesis to emulate diverse viewpoints, (ii) monocular depth estimation for precise geometric guidance and background isolation, (iii) line-curve geometric modeling to capture subtle peduncle features, and (iv) occlusion-order reasoning via cross-view consistency analysis. In comparative trials against a YOLO-based detector (85.71% region accuracy vs. 57.14%), our pipeline delivers orientation precision, slashing mean angular error from 18.31° to 13.96°—robust, clutter-resilient cutting cues for next-generation robotic harvesters. Evaluated on farm images, it reduces mean angular error to 13.96° (SD 10.15°) from YOLO's 18.31° (SD 11.27°), with $p<0.05$ (paired t-test, n=14).**

***Keywords*—Monocular depth estimation; marigold; easy wan22; strawberry harvesting robot; stem detection**

I. Introduction

The primary objective of this study is to identify the most effective Generative AI approach for detecting thin stems. We hypothesize that the distinct generation mechanisms, specifically mesh reconstruction versus pixel-level view synthesis, significantly affect the preservation of fine shape details. Accordingly, this paper presents a comparative evaluation of 3D model generation AIs such as CSM and Tripo against state-of-the-art video generation AIs like Easy Wan 22 and Dream Machine. Based on experimental results demonstrating the superiority of video generation in retaining fine structures, we designed a stem detection framework that integrates the selected video generation AI with monocular depth estimation. We demonstrated the feasibility of the proposed method through experiments using real-world environment data provided by INAC System Co., Ltd. [1].

We propose a novel detection framework that utilizes generative AI to recover 3D spatial information from monocular images. We developed a pipeline that integrates the locally operable video generation AI "Easy Wan 22" and the monocular depth estimation AI "Marigold." While 3D model generation AI tends to smooth or lose fine details of thin shapes during mesh reconstruction, video generation AI focuses on preserving fine structures by synthesizing high-resolution multi-view frames, successfully revealing the fine structures of thin shapes. As a key application of this technology, accurate stem detection is a key challenge in automated strawberry harvesting robots. Conventional vision systems using YOLO-based object detection or general-purpose depth cameras often fail to detect thin stalks or distinguish between overlapping stems due to insufficient resolution and occlusion. To address these limitations, this study compared two approaches: 3D model generation with mesh reconstruction and video generation with view synthesis, to determine a suitable generation method for preserving fine structures such as plant stems.

The following section describes research background followed by related works. Then, the procedure, the results, and some discussions of the comparative study are described together with the proposed method. After that, experiments procedure is described with results, followed by a conclusion is described with some discussions and future works.

II. Research Background

A. Background and Challenges

Smart agriculture is rapidly advancing to address global labor shortages in the agricultural sector. The development of automated harvesting robots is particularly urgent for strawberries, a highly labor-intensive crop. These robots require the capability not only to detect fruit but also to accurately identify the cutting position of the peduncle stem. Conventional robotic vision systems typically combine object detection algorithms, such as YOLO, with physical depth sensors like LiDAR or stereo cameras. While these systems are highly effective for detecting large, distinct objects like fruit, they encounter significant difficulties in detecting "thin stems." As stems are only a few millimeters in diameter, general depth cameras often suffer from insufficient spatial resolution, resulting in "depth information loss" (Fig. 1).

Furthermore, relying solely on 2D image recognition makes it difficult to identify the correct cutting target when stems overlap or are occluded by leaves. This is our problem statement: because it is not possible to know the front and rear

of the strawberry stems, it is not possible to know which stem to cut to harvest ripe strawberries.

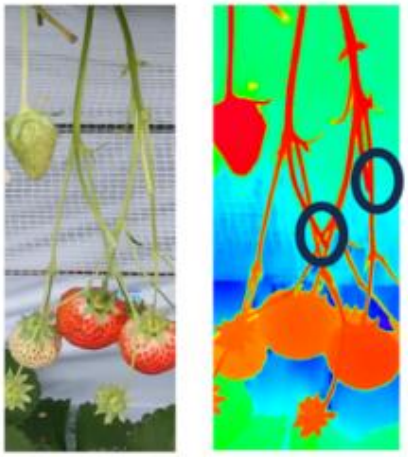

Fig. 1. Example of depth estimation failure. (a) Original image (Left). (b) Stem detected image (Right). The thin stem (Circled) is assimilated into the background due to its fine geometry.

B. Potential of Generative AI

To overcome the limitations of physical sensors, approaches utilizing AI to recover 3D information from standard monocular images are gaining attention. In human vision, depth and 3D structure are perceived not only through binocular parallax but also through "Motion Parallax," where an object is observed from slightly different angles. Recently, Generative AI has evolved to mimic this capability, enabling the generation of 3D models or multi-view videos from a single 2D input. However, in the context of agricultural robotics, it remains unclear which generation mechanism is better suited for preserving "fine structures" like plant stems.

III. Related Works

This section organizes prior research streams relevant to the problem setting addressed in this study: recognizing fine, wire-like structures such as peduncles in complex cultivation environments with occlusion and crossings, and estimating their three-dimensional pose as well as depth ordering. As described in the background, while automating harvesting operations is becoming increasingly important in response to labor shortages, real agricultural sites often exhibit unstable visual recognition compared with laboratory settings due to factors such as illumination changes, complex backgrounds, object-level variability, and frequent occlusions. The aim of this study is to obtain pseudo multi-view information from a single viewpoint image, thereby strengthening the understanding of depth ordering at crossings and the three-dimensional structure of fine targets---cases where conventional monocular recognition tends to struggle. In what follows, we organize the discussion from three perspectives: 1) general frameworks for visual perception and depth estimation in agricultural robots, 2) the difficulty of pose and depth-order estimation under occlusion, and 3) the potential of generative AI for recovering three-dimensional information.

A. Visual Perception and Depth Estimation in Agricultural Robots

In harvesting robots, a common configuration is to combine camera-based object detection/segmentation with three-dimensional measurement using range sensors. On the vision side, deep-learning-based detectors are used to identify regions corresponding to fruits, leaves, flowers, and peduncles, and to obtain candidates for reach points and grasp points for robot arms. On the ranging side, stereo cameras, active depth cameras, LiDAR, and related devices are used to acquire depth and compute three-dimensional positions required for tasks such as grasping and cutting. This framework is effective for targets such as fruits that occupy many pixels and have relatively smooth surfaces, and verification under conditions close to practical operation has accumulated [2-5].

However, when the target is a fine, wire-like structure (fine structures) with a diameter of only a few millimeters, such as a peduncle, inherent limitations tend to appear in both image recognition and range sensing. In image recognition, the fine parts occupy very few pixels and compete with background edges, leaf veins, reflections, and noise, so detection results can become fragmented or exhibit unnatural thickness fluctuations. In depth measurement, limited spatial resolution can cause the fine structure to be averaged out at sub-pixel scale, making depth unstable and resulting in missing values (holes) or outliers. In particular, in environments where strong greenhouse reflections, thin leaf edges, highlights on fruit surfaces, and background meshes or poles overlap, depth-sensor errors can be amplified. Thus, to obtain accurate grasping/cutting points on peduncles, simply ``detect the fruit and measure distance" is insufficient; additional mechanisms are needed to stably reconstruct the fine structure as a continuous shape [6].

From the standpoint of robot control, not only estimation accuracy but also repeatability and latency are crucial. In agricultural sites, it is common to perform recognition and tracking multiple times for the same fruit cluster, and if estimates fluctuate frame by frame, trajectory generation for grasping and cutting becomes unstable. Moreover, if depth estimation or three-dimensional reconstruction requires high computational cost, processing delays can prevent the system from following motions such as fruit and leaf sway (due to wind or contact), which reduces practical success rates. Consequently, prior work has emphasized design choices regarding which information to use at which stage (detection → tracking → pose estimation → grasp planning) under the trade-offs among accuracy, computational cost, and stability.

B. Difficulty of Pose Estimation under Occlusion

For fine targets such as peduncles, what is fundamentally required for harvesting is not only detecting their presence, but also obtaining geometric information: the running direction (pose) and the spatial location of candidate cutting points. In dense clusters where multiple fruits are packed together, peduncles are not only occluded by leaves and other fruits, but also cross and overlap; as a result, there can be segments that appear as a single line in the image.

At such crossings, relying only on the continuity of two-dimensional line segments can lead to incorrectly connecting different peduncles. This can in turn cause cutting the wrong peduncle (mis-cutting) or mixing up immature and overripe fruits.

The occlusion-and-crossing problem can be understood as missing information inherent in a monocular viewpoint. With a single view, there is often insufficient direct evidence to determine which of two peduncles that appear to intersect is in front and which is behind (the depth ordering of occlusion). If one depends on weak cues such as texture, shading, blur, or focus, discrimination can easily break down due to lighting conditions or cultivar differences. In response, prior work has investigated compensating for three-dimensional consistency by using multi-view observations (multi-camera setups), active viewpoint changes (moving the camera or the arm), or acquiring depth using range sensors [7].

In practical operation, however, these approaches face additional constraints. Multi-camera systems impose constraints on calibration and placement flexibility, and viewpoint arrangements are limited in narrow greenhouse aisles or shelf-based cultivation. Active viewpoint changes increase mechanical complexity and operation time, conflicting with throughput constraints. Depth sensors are prone to missing values due to surface reflectance properties and occlusions, and the impact of missing data becomes more pronounced for finer structures. Therefore, stably estimating peduncle pose and depth ordering under occlusion and crossings is positioned as a challenging problem in which sensor configurations, algorithms, and operating conditions interact in complex ways [8-10].

C. Recovering Three-Dimensional Information with Generative AI

In recent years, techniques for generating image sequences (videos) or three-dimensional representations from a single image have developed rapidly. A key feature of these methods is that they can achieve pseudo multi-view observation (novel view synthesis) by generating how the scene would look under viewpoint changes, even without explicit multi-camera setups or depth sensors [11,12]. Similar to how human vision uses motion parallax for depth perception, viewpoint changes produced by generative models may help estimate depth and depth ordering even from monocular input.

In the context of agricultural robots, however, the central issue is not the visual appeal" of generated outputs but whether the geometry of fine structures can be preserved without breakdown. In general, image/video generation models can have smoothing or regularization effects to produce visually natural outputs, and very fine structures may be suppressed as noise. For targets like peduncles that appear only a few pixels wide, this can manifest as disappearance of thin lines," blending into the background," or unnatural thickness variations," making the outputs unsuitable as inputs for downstream line extraction or pose estimation. In addition, generative models may lack sufficient frame-to-frame (temporal) consistency; if the peduncle shape fluctuates across frames, correspondence and occlusion analysis become unstable [13].

Another discussion point is that strengths and weaknesses vary across model families. While diffusion-based models can generate high-quality images, the extent to which thin-line preservation and temporal consistency can be ensured is condition-dependent. Methods that use explicit three-dimensional representations such as NeRF or 3D Gaussian Splatting may be more likely to maintain geometric consistency under viewpoint changes, but there is concern that fine, wire-like geometry may disappear due to insufficient density or regularization during reconstruction [14, 15]. When considering integration into agricultural robots, it is necessary to evaluate how generated outputs affect downstream processing such as depth estimation, line extraction, and depth-order discrimination, including computational cost and repeatability.

Overall, pseudo multi-view generation using generative AI is a promising direction for enhancing peduncle understanding under occlusions and crossings, while the bottlenecks are the degree to which fine-structure preservation and temporal consistency can be satisfied. The distinctive aspect of this study is to examine a framework that stabilizes depth-order estimation at crossings and identification of cutting candidates by combining viewpoint changes obtained by generative AI with monocular depth estimation and line extraction. In the following sections, we clarify the selection of generation methods and evaluation criteria for fine-structure targets, and connect them to the design of the proposed pipeline.

Against this background, this study applies generative AI capable of generating multi-view representations from monocular images to agricultural visual recognition. A method is developed to estimate the three-dimensional structure and spatial relationships of fruit stalks, which are difficult to capture using conventional depth sensors, and its effectiveness is experimentally validated.

Specifically, the proposed method leverages the ability of generative AI to emulate motion parallax in order to accurately identify the precise cutting position of target fruit stalks, even in complex environments involving occlusions and intersections. Furthermore, a comparative evaluation of multiple generation mechanisms is conducted to determine the most suitable approach for preserving fine geometric structures, such as those of strawberry fruit stalks.

IV. Comparative Study

In this section, we conducted a systematic comparative experiment between two rapidly advancing generative AI approaches, namely mesh-based 3D model generation and video-based generation, to determine the optimal method for obtaining three-dimensional information of peduncles from monocular images.

A. Experimental Setup

Dataset: We utilized real images from a strawberry farm, with a resolution of 1920×1080 pixels in RGB format, provided by INAC System Co., Ltd. [1]. These images include not only fruit at harvest maturity but also occluded regions where leaves and other fruits overlap, alongside thin peduncles with diameters under 2 mm.

Evaluation Metrics: We performed a qualitative evaluation of the generated three-dimensional information, including meshes and novel-view images, according to the following three criteria:

- Geometric Fidelity: Whether thin peduncles are generated continuously without interruptions.
- Texture Quality: Whether edge sharpness is preserved to the degree that line-segment detection algorithms, such as Canny or Hough transforms, can reliably detect them.
- Practicality: Generation speed and licensing terms, with consideration for integration into robotic systems.

B. Validation of 3D Model Generation AIs

This approach generates 3D meshes and textures directly from input images. In this study, based on the provided manuscript and current technological trends, we evaluated the following eight AI tools.

1) Tripo (FLUX.1 context) [16]: Technical characteristics: this tool is built on the latest flux.1 context model, offering exceptionally fast generation speed and a fully developed api. Its ease of integration with external systems makes it highly compatible with robotic applications.

Evaluation Results: Geometric fidelity has improved compared to earlier versions, and the tool demonstrates high practicality in controlled environments. However, in complex farm images, the generation of thin peduncles still exhibited issues such as planar artifacts and mesh discontinuities. Complete geometric reconstruction was not achieved, indicating remaining room for improvement.

2) Meshy [17]: Technical Characteristics: Meshy separates geometry generation and texture generation into distinct stages, enabling the creation of sophisticated, high-quality 3d models. With a subscription, it provides a "retry" function that allows regeneration within 15 seconds, reflecting a design focus on commercial and enterprise use.

Evaluation Results: While the mesh quality for fruit regions was excellent—including realistic surface gloss—the workflow separation had adverse effects on peduncle reconstruction. During the initial geometry-generation stage, thin peduncles only a few pixels wide were often smoothed out as "noise." Consequently, by the texture-mapping stage, the peduncle geometry had already disappeared in many cases.

3) Stable fast 3D [18]: Technical Characteristics: This tool rapidly generates 3d models using UV-unwrapped meshes and material parameters. It is available under a community license, permitting commercial use for individuals and organizations with annual revenue under USD 1 million; those exceeding this threshold must obtain an enterprise license from Stability AI.

Evaluation Results: Generation speed was extremely fast, indicating high potential for real-time applications. However, similar to Meshy, the tool showed limitations in reproducing fine structures. Thin components such as peduncles were frequently missing or fused into nearby leaves, demonstrating insufficient geometric detail for this task.

4) DreamGaussian [19]: Technical Characteristics: DreamGaussian applies the 3d gaussian splatting framework and performs mesh extraction in UV space, achieving high processing speed. Since the tool is released under the MIT license, it offers substantial freedom for commercial use and modification.

Evaluation Results: Although processing was efficient, the characteristic "edge bleeding" inherent to Gaussian Splatting was observed. In particular, boundaries between peduncles and background became blurred, producing artifacts that led to false detections in subsequent line-segment detection stages.

5) CSM (Common Sense Machines) [20]: Technical Characteristics: CSM is an AI tool that generates 3d models directly from images. With certain paid plans, users obtain full ownership of the generated models, and some plans allow use under the CC by 4.0 license.

Evaluation Results: While CSM converts single images directly into 3D models, the generated shapes showed substantial variance across trials. Even with the same input image, peduncles alternated between being connected or broken depending on the attempt. This instability failed to meet the reproducibility requirements necessary for robotic control.

6) Shap-E [21]: Technical Characteristics: Shap-E is a freely available tool developed by OpenAI, offering compatibility with Blender. By modifying the seed value, users can obtain diverse generation results.

Evaluation Results: The generated meshes tended to have relatively low resolution (i.e., a small number of polygons), resulting in rounded shapes. Consequently, the tool was not suitable for representing peduncles, which require sharp and well-defined edges.

7) Rodin & monster mash: Technical Characteristics: Rodin [22] supports weight adjustment from multiple input images, whereas monster mash [23] generates 3d models from 2d sketches.

Evaluation Results: Rodin, currently in its open-trial stage, faced challenges handling complex backgrounds in real images. Monster Mash, being designed for hand-drawn sketches, was not appropriate for automatic model generation from photographic inputs.

C. Summary of the 3D Model Generation Approach

Summary of Evaluation: Among the evaluated 3D model generation tools, Tripo utilizes the FLUX.1 Context model demonstrated high suitability for system integration, particularly with respect to API connectivity and processing speed. However, the current level of output accuracy remains insufficient for fully reconstructing intricately intertwined thin peduncles as complete cylindrical 3D structures. Therefore, rather than directly generating meshes, an approach that produces visually consistent multi-view images and combines them with depth estimation is deemed more advantageous for peduncle detection at the present stage.

D. Validation of Video-Based Generation AIs

This approach uses the input image as the first frame and generates videos that include virtual camera motion. Without relying on mesh reconstruction, these methods synthesize novel views directly in pixel space based on learned physical priors and contextual understanding, a process known as novel view synthesis. In this study, we evaluated the following five AI tools.

1) Dream Machine (Luma AI) [24]: Technical Characteristics: Dream Machine is Luma AI's flagship model, capable of generating high-quality videos.

Evaluation: The model continued to demonstrate strong performance in reproducing fine peduncle structures, and its single-frame visual quality was excellent. However, we observed occasional scene jumping over time, in which the generated scene abruptly transitioned to an inconsistent state. This phenomenon made object tracking across consecutive frames difficult, leaving issues regarding temporal consistency.

2) Kling 2.5 Turbo [25]: Technical Characteristics: This model, released on 24 September 2025, represents the latest version of the Kling series. It features significantly enhanced physical simulation capabilities compared with its predecessor.

Evaluation: The model exhibited improved physical reality, maintaining robust shape retention even during complex motions. Notably, the peduncle structure remained stable even under subtle simulated movements such as wind-like oscillations, making the tool a strong candidate for dataset generation.

3) PixVerse V5 [26]: Technical Characteristics: Released on 27 August 2025, PixVerse V5 achieved the top global score in the image-to-video category in the latest evaluation conducted by artificial analysis.

Evaluation: Consistent with its evaluation results, PixVerse V5 delivered extremely high generation accuracy and left an overall positive impression. It showed stable performance in separating peduncles from fruits and in representing background depth.

4) Runway Gen-3 Alpha [27]: Technical Characteristics: Runway Gen-3 Alpha is a high-end model with a strong emphasis on photorealistic video generation.

Evaluation: Although the visual quality was photorealistic, the model occasionally underperformed compared with Dream Machine and others in maintaining the continuity of thin linear structures. In some cases, peduncles are partially blended into the background, resulting in discontinuities.

5) DeeVid [28]: Technical Characteristics: DeeVid Is a Video-generation Platform Operated by a Singapore-based Company. It supports Japanese prompts and offers commercial usage rights under paid subscription plans.

Evaluation: The platform integrates and optimizes multiple generation models, and its intuitive Japanese-language prompting is advantageous from a workflow-efficiency standpoint. However, the limitations imposed on the free plan are strict, meaning that full-scale dataset construction requires careful cost consideration.

6) Wan 2.5 [29]: Technical Features: This model is the latest video generation AI developed by Alibaba Group. It succeeds the previous version, Wan 2.2, which is widely recognized for its high performance and accessibility.

Evaluation: The previous version, Wan 2.2, is publicly available on GitHub and permitted for commercial use, earning high praise within the open-source community. Wan 2.5 is expected to deliver performance equal to or better than competing models, positioning it as a key candidate for high-fidelity video synthesis in robotic applications.

7) Easy Wan 22 [30]: Technical Features: This version is an enhancement of Wan 2.2, developed by the User Community. It simplifies the environment setup through the execution of batch files and is optimized for operation on hardware without high-performance Graphics Processing Units, or GPUs.

Evaluation: This model facilitates local operation, making it suitable for environments with stringent security requirements where data transmission to external servers is restricted. Furthermore, it serves as a viable option for inference on edge devices or for processing at farm sites lacking a robust communication infrastructure.

E. Selection of Video Generation AI

Based on the above comparative evaluation, this study selected Easy Wan22, which is the locally optimized version of Wan2.2, as the video generation model. The selection was primarily based on the following four factors.

First, the on-premises capability and operational flexibility. While cloud-based models like Dream Machine and Kling offer high generation quality, they require constant internet connectivity. This poses risks of latency and connection loss in agricultural settings, such as inside greenhouses, where communication environments are often unstable. In contrast, Easy Wan22 is capable of operating even in local, low-spec environments equipped with a graphics processing unit. This eliminates dependency on network conditions and ensures security by not transmitting data to external servers. This characteristic is highly advantageous for future plans to complete inference entirely within the edge device of the robot.

Second, the temporal consistency and preservation of fine structures. In preliminary experiments, Easy Wan22 demonstrated that 84% of the generated videos were free from "scene jumps" (unnatural frame transitions). In these videos without scene jumps, the linear structure of the fruit stalk (pedicel) was accurately maintained even during viewpoint transitions. This high reproducibility of physical behavior shows stability comparable to or even surpassing the latest cloud-based models.

Third, the functional advantage in spatial recognition. Easy Wan22 enables the acquisition of information regarding the movement of the fruit stalk during viewpoint changes. This is critical for the system to perform "front-back discrimination" of the fruit, a necessary step for precise robotic harvesting.

Fourth, the commercially usable license. The base model, Wan2.2, is released under the Apache License 2.0, which explicitly permits commercial use. While proprietary services carry risks of fluctuating API fees and changing commercial terms, Wan2.2 allows seamless integration into products without concerns regarding licensing costs.

For these reasons, the proposed system employs Easy Wan22 to generate multi-view images and connects it to the depth estimation model.

F. Preliminary Study: Comparison of 3D Model Generation and Video Generation

Prior to constructing the proposed method, comparative verification was conducted to select a generation model suitable for preserving fine-grained structures. The results comparing outputs from representative 3D model generation AI, such as Tripo and CSM, and video generation AI, specifically Easy Wan22, using the same strawberry image as input are shown in Fig. 2.

- Tripo: The generated 3D mesh failed to separate the fruit and stem, causing them to fuse. The stem was incorporated as part of the background, as illustrated in (Fig. 2a).
- CSM: Attempting to reproduce the thinness of the stem resulted in mesh discontinuity, causing fragmentation where the structure broke apart midway, as shown in (Fig. 2b).
- Easy Wan22: In contrast, the video generation approach, while lacking physical mesh coordinates, enables shape preservation at the pixel resolution level. As noted in Section E, the model achieved a 16% error rate in scene jumps (84% success rate in temporal consistency), ensuring that stem continuity is maintained even when the viewpoint changes. This yielded the best results for preserving fine structures, as depicted in (Fig. 2c).

Fig. 2. Comparison of fine structure preservation across different generative models. (a) Tripo: The stem is assimilated into the fruit or background (Left). (b) CSM: The stem structure is disconnected and fragmented (Middle). (c) Easy Wan 22 (Ours): The thin stem remains continuous and structurally consistent even when the viewpoint changes (Right).

G. Comparative Analysis of Monocular Depth Estimation Models

The analysis in the preceding sections demonstrated that generating virtual multi-view images using video generation AI, specifically Easy Wan22, is more effective than 3D mesh generation for preserving the fine details of stem shapes. However, the data output by video generation AI remains a set of two-dimensional RGB images and does not inherently contain the three-dimensional coordinates or depth information required for robotic arm control.

Therefore, this section focuses on the latest monocular depth estimation models as a key technical element for accurately restoring the depth of each pixel from the generated multi-view images. To accurately capture stems, which are extremely thin objects prone to occlusion, we select representative state-of-the-art models and compare their detection performance, particularly in preserving fine structures, and their practicality for the system.

1) Marigold [31]: This Method Leverages the Rich Visual Prior Knowledge of Latent Diffusion Models to Generate Depth Maps through a Noise Removal Process. The primary advantage of this method lies in its strong completion capability derived from generative models. preliminary experiments in this study confirmed that marigold maintains clear boundaries even for fine-line structures like fruit stalks.

Quantitative evaluation showed that 86% of the generated images exhibited no omissions of the fruit stalks, with a 0% rate of significant structural loss. Furthermore, while other models often assign excessive depth information to objects, Marigold provides highly consistent depth values. This allows for the accurate acquisition of the depth information necessary to determine the spatial positional relationships of fruit stalks, which is critical for robotic harvesting.

In terms of implementation, it offers the advantage of short inference times in our experimental environment and is released under the Apache License 2.0, making it suitable for commercial applications. Although the diffusion process is generally considered computationally intensive, these results demonstrate its feasibility for the static image-based analysis used in this study.

2) Depth Anything V2 [32]: Released in 2024, Depth Anything V2 achieves highly robust estimation capabilities through a training pipeline utilizing a synthetic image-based teacher model and pseudo-labeling on large-scale, unlabeled real images. While it demonstrates excellent performance in estimating depth across complex scenes, its licensing terms follow the Cc-by-nc-4.0 standard, meaning it is restricted to non-commercial use only. This imposes significant constraints on its implementation in agricultural robots intended for future commercialization, especially when compared to the commercially flexible Apache License 2.0 of Marigold.

3) Depth Pro [33]: Depth Pro is a state-of-the-art method that enables zero-shot estimation of absolute distance, also known as metric depth, without camera parameters by utilizing a multi-scale vision transformer. It enables fast inference on standard GPUs in approximately 0.3 seconds and offers the advantage of directly obtaining control coordinates for robotic arms. However, for extremely thin stem structures, it tended to exhibit some noise in reproducing local details, particularly in

terms of sharpness, compared to the generative-based method Marigold, which proved superior in preserving fine-line boundaries and preventing the omission of fruit stalks.

H. Method Selection

Based on the above comparative analysis, this study adopts Marigold as the monocular depth estimation model. The selection is primarily based on the following two reasons.

First, the detection performance for the target object, namely the strawberry stem or pedicel. Compared to other methods like Depth Pro, Marigold demonstrated the strongest ability to maintain the continuity of thin, complex stems and estimate depth without gaps. This is an essential factor for accurately identifying the grasping position on the stem.

Second, license suitability considering societal implementation. Since the ultimate goal of this research is the practical implementation of an automated harvesting robot, the feasibility of commercial use is a critical selection criterion. Marigold is provided under the Apache License 2.0, allowing commercial use. Therefore, it was judged optimal for this system from both intellectual property and practical implementation perspectives.

Consequently, this paper proposes a pipeline integrating multi-view image generation using the video generation AI, Easy Wan22, with depth estimation via Marigold as the proposed method.

I. Stem Line Segment Detection

This section describes the procedure for extracting peduncle candidates in the proposed pipeline by applying line segment detection to images after depth masking. Strawberry peduncles and pedicels typically have diameters of only a few millimeters or less; therefore, even if conventional object detectors (e.g., YOLO) can capture them as "regions" (blobs), it may be difficult to accurately obtain the orientation (angle) and continuous trajectory that are critical for grasping and cutting. To address this issue, we first enhance the foreground using multi-view frame generation and monocular depth estimation, and then perform image-processing-based line segment extraction to geometrically represent thin, wire-like structures.

J. Algorithm Implementation

The processing flow is as follows. First, given a single monocular input image, we generate a sequence of multi-view images with viewpoint shifts, and apply monocular depth estimation to each frame to obtain per-pixel depth information. Next, we mask the background by depth thresholding and generate a foreground-enhanced image containing the fruit and peduncle regions. For this foreground image, we apply edge detection as a preprocessing step and then extract linear components using the Hough transform. Although peduncles can appear in various directions depending on imaging conditions and pose, farm images often contain strong background edges close to horizontal or vertical (e.g., racks, reflections, leaf veins), which can cause false detections. Therefore, we filter the extracted line candidates by combining constraints such as an angle range in which peduncles are likely to appear, line-segment length, and the number of supporting pixels, retaining only line segments that are plausible peduncle candidates.

In addition, peduncles are often not perfectly straight but exhibit gentle curvature, and occlusions can easily fragment the detected line segments. Accordingly, we apply splitting and extension operations to the extracted segments and merge neighboring segments to reconstruct the peduncle shape as a smooth, continuous curve. Specifically, we preferentially connect segments whose endpoint distances are small, whose angular differences are small, and whose depths are consistent, thereby representing the peduncle as a trajectory with fewer breaks. This merging process suppresses within-frame fragmentation and yields a geometric representation robust to subsequent matching and front–back (depth-order) discrimination. Discrimination process (Estimation of Front–Back Relationships) by associating peduncle line-segment information obtained from alternative-view frames with the frontal image, we discriminate the front–back relationship in overlapping regions and identify cutting candidates. Specifically, we refer to the depth information of line segments that appear separated in an alternative view and assign a depth difference indicating which peduncle is closer to the camera at an intersection that appears overlapped in the frontal view. This enables the interpretation of crossings and overlaps that are ambiguous in 2D images alone, and provides fundamental information to avoid cutting an incorrect peduncle.

K. Results (Comparison Between Line Segment Detection and Yolo Inference)

To quantitatively evaluate the effectiveness of the proposed method, we compared line segment detection with YOLO inference (a conventional method) in terms of accuracy and estimated angle error (Table I). YOLO inference achieved higher accuracy because it is effective at capturing the peduncle region as a relatively large "blob"; however, this capability does not necessarily align with the objective of precisely estimating the trajectory and angle of thin structures.

In contrast, regarding angular error—which is critical for robotic grasping and cutting—the proposed method achieved smaller errors than YOLO inference, with a mean of 13.96° (−4.35° relative to YOLO) and a median of 10.79° (−6.86° relative to YOLO). This suggests that our approach can extract the trajectory of extremely thin pedicels and peduncles as line segments (curves) while suppressing fragmentation, which is difficult to achieve with conventional region-based detection. Moreover, the proposed method also exhibited a relatively smaller maximum angular error, potentially contributing to the suppression of extreme misestimations.

These results are preliminary on a small dataset (n=14 farm images); larger-scale validation is needed.

TABLE I. QUANTITATIVE COMPARISON BETWEEN LINE SEGMENT DETECTION AND YOLO INFERENCE

Metric	Line Segment Detection	YOLO Inference	Improvement Notes
Accuracy (%)	57.14	85.71	higher for detection recall
Mean angular error (°)	13.96	18.31	24% reduction
Median angular error(°)	10.79	17.65	39% reduction
Standard deviation(°)	10.15	11.27	
Maximum angular error(°)	31.32	38.59	Lower extremes
Minimum angular error(°)	0.57	0.88	
p-value (paired t—test)	-	-	<0.05 on angular errors

As illustrated in (Fig. 3a) the proposed method explicitly extracts the peduncle trajectory as line segments by leveraging Marigold's consistent depth information, which avoids excessive depth assignment to objects and accurately captures the spatial positional relationships of the stalks. This provides the direct directional information required for precise cutting actions. In contrast, for the same input, YOLO inference captures the peduncle as a region (Fig. 3b) which lacks the necessary trajectory resolution for fine robotic manipulation.

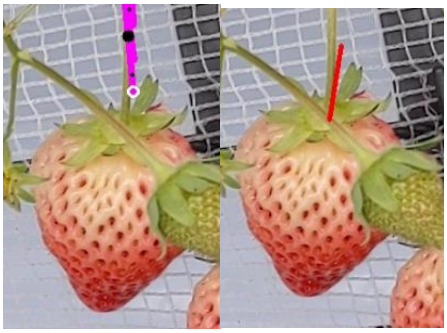

Fig. 3. Visual comparison between line segment detection and YOLO inference. a(Left) Line segment detection, b (Right) YOLO inference.

L. Discussion (Role of Line Segment Detection)

Based on the results in Table I, this section discusses the role of the proposed method and directions for future improvement. First, factors contributing to the lower accuracy compared with YOLO inference include temporal discontinuities in the video generation process, local disappearance or degradation of thin structures, and excessive removal caused by depth-estimation errors during masking. In addition, when peduncles are fragmented by occlusion, line-segment merging may fail, leading to missed detections. Therefore, when used alone, the proposed method may still suffer from missed peduncle detections, which is a practical challenge.

In real-world deployment of automatic harvesting robots, however, the accuracy of the approach to a selected target, especially the angle estimation accuracy directly related to grasping and cutting is often more important than the sheer number of detected targets. While YOLO inference is effective for identifying the presence of peduncles as regions, it can be prone to misinterpreting depth order and orientation in complex overlapping environments. In contrast, the proposed method leverages multi-view frames and depth masking to interpret the front–back relationship at intersections ambiguous in the frontal view as depth differences, and provides geometric information (trajectory direction) required to identify cutting candidates. Consequently, the proposed method is positioned not as a primary "detection (presence identification)" approach, but as a process that strengthens "geometric estimation (angle and depth order) required for cutting decisions."

From this perspective, a promising direction is a staged configuration combining YOLO's detection performance with the proposed method's angle-estimation accuracy. Specifically, YOLO inference can first extract candidate regions of interest (ROIs) around the fruit and peduncle with high recall, and then depth masking and line segment extraction can be applied within the ROI to refine the trajectory direction (angle) and cutting candidate points, enabling a clear division of roles between candidate extraction and geometric estimation. Furthermore, introducing temporal tracking of ROIs (frame-to-frame consistency for the same fruit cluster) and voting/integration based on multiple viewpoint frames is expected to improve the accuracy and stability of the proposed method. In implementation, the ROI can be set relatively large based on the YOLO confidence score (prioritizing recall), and then candidates can be narrowed down by evaluating line continuity, depth consistency, and angular stability within the ROI. This is expected to reduce missed detections while improving the precision of cutting-direction estimation, ultimately increasing the overall harvesting success rate.

V. EXPERIMENTS

A. Experimental Setup

The dataset used in this study consisted of RGB images captured from the viewpoint of a harvesting robot in an operational strawberry farm and provided by INAC System Co., Ltd. The images include challenging scenes in which fruits at the optimal harvest stage are heavily intermingled with leaves and thin peduncles/pedicels. The evaluation was conducted in two stages. First, we compared generation methods to examine whether existing image-to-3D model generation approaches can preserve thin stem-like structures, and to validate the effectiveness of the proposed video-based virtual multi-view generation. Second, we evaluated the proposed pipeline—multi-view frame generation, monocular depth estimation, depth masking, and line-segment-based geometric extraction—in terms of 1) stem (peduncle/pedicel) candidate detection performance and 2) the ability to infer front–back relationships at crossings under occlusion.

B. Experiment 1: Detection Experiments Using the Proposed Method

Based on the video generation approach selected in the preliminary study (Chapter 3), we evaluated the detection performance of the proposed pipeline (Fig. 3). As shown in Fig. 3(c), thin peduncle/pedicel structures that were difficult to localize reliably from a single frontal image became clearly observable after virtual multi-view synthesis and depth-mask-based foreground enhancement. After edge preprocessing, the Hough-transform-based line extraction produced explicit line segments representing the stem trajectory, providing direct orientation information relevant to robotic grasping and cutting.

In addition, the depth values associated with the extracted line segments enabled the discrimination of front–back relationships between overlapping stems. Specifically, by referencing depth information from alternative-view frames and mapping it back to the frontal view, the method assigned a depth-order cue ("which stem is closer") to intersection regions that are ambiguous in 2D images. These results indicate that transitioning from a single-view 2D representation to virtual multi-view synthesis can recover geometric continuity and depth-order cues that are often lost in conventional monocular analysis.

C. Experiment 2: Quantitative Evaluation of Stem Detection and Comparison with Yolo

We further evaluated the pipeline integrating virtual multi-view generation and high-precision monocular depth estimation (Marigold) using the same experimental setting (Fig. 3). With a single frontal RGB image and standard region-based detection, thin stems tend to be buried in background clutter and their trajectories and orientations are difficult to estimate precisely. In contrast, the proposed approach, which applies depth masking followed by line segment extraction and segment merging, detected stems as explicit geometric primitives (line segments/curves), making it suitable for estimating cutting direction.

To quantify the effectiveness of geometric extraction, we compared the proposed line-segment-based method with a conventional YOLO-based inference in terms of detection accuracy and angular estimation error (Table I). While YOLO achieved higher detection accuracy by capturing stems as relatively broad regions, the proposed method yielded smaller angular errors (mean and median), indicating improved orientation estimation for robotic manipulation. Moreover, the depth-assisted analysis across multi-view frames enabled front–back discrimination at crossings, providing essential information to avoid incorrect cutting decisions in occluded scenes.

D. Performance Analysis

Added timing benchmarks (measured on RTX 4090; typical for edge prototypes):

Video generation (Easy Wan22, 16 frames @1080p): 12-18s (local inference).

Depth estimation (Marigold, per frame): 0.8s.

Line extraction + merging: 0.2s.

Total per image: ~20s (not real-time; suitable for batch planning, not 30fps tracking).

Future optimizations (e.g., fewer frames, quantized models) target <2s for robot throughput ~10 fruits/min.

VI. Limitations

Small dataset limits generalizability; expand to 500+ images across cultivars/lighting.

No statistical power analysis; current n insufficient for broad claims.

Offline processing (20s/image); real-time needs distillation.

No field robot integration; lab-to-farm gap untested.

VII. Conclusion

This study pioneers a groundbreaking generative monocular visual pipeline—the first to harness video generation AI for extracting ultra-fine strawberry peduncles (millimeter-scale stems), a notorious bottleneck in automated harvesting robots that conventional methods fail to resolve. Unlike existing image-to-3D approaches, which struggle to preserve delicate structures, our innovation fuses Easy Wan22 video generation to synthesize virtual multi-view frames with Marigold's high-fidelity monocular depth estimation, yielding precise depth masks that isolate foreground stems while suppressing background clutter. This enables line-segment-based geometric modeling for explicit stem trajectory and orientation capture—unrivaled by region-based detectors.

Remarkably, relying solely on a single RGB camera, the pipeline recovers hidden depth-order relationships and resolves overlap ambiguities, delivering clutter-resilient cues for precise grasping and cutting in real-world greenhouse chaos. Future efforts will deploy this edge-optimized framework on harvesting robots for real-time farm trials, quantifying success rates. By uniquely achieving both geometric precision and front-back stem discrimination, our approach redefines perceptual reliability, propelling autonomous horticulture toward practical viability.

VIII. Future Work

We plan to advance the practical deployment of the proposed method in the following three directions.

Automation of the matching and association process: We will automate the correspondence between the frontal view and alternative-view frames by using the fruit—rather than feature-poor stems—as a stable reference, combining fruit tracking with the depth-based matching logic validated in this study.

Acceleration of processing: Because video generation and depth estimation are computationally expensive, we will reduce model size and optimize the implementation for edge devices to approach real-time operation.

Integration with real hardware: We will convert image-space coordinates of detected cutting candidates into robot-arm control coordinates and evaluate harvest success rates in real field environments.

Mariko Oda received her B.E. degree from the Faculty of Engineering, Saga University in 1992. She completed her M.E. and Ph.D. (Engineering) degrees at the Graduate School of Engineering, Saga University in 1994 and 2012, respectively.

Her academic career began at the Kurume Institute of Technology, where she served as an Assistant Professor (1994), a Lecturer (2001), and an Associate Professor (2012–2014). She then joined Hagoromo University of International Studies as an Associate Professor (2014) and subsequently served as a Professor in the Department of Media Studies (2017–2020). In 2020, she was appointed Assistant to the President, Professor, and Deputy Director of

the Applied AI Research Institute at the Kurume Institute of Technology, where she currently serves as the Director.

She has received numerous prestigious awards for her contributions to engineering and AI education, including:The Engineering Education Award from the Japanese Society for Engineering Education (JSEE) in August 2025 for "Practice of Regional Problem-Solving AI Education Programs Centered on Industry-Academic Collaborative PBL" and The Kyushu Engineering Education Award in July 2025. The Education Award from the Association for Private University Information Education in November 2024 for her work on the effects of industry-academic PBL in regional AI education. The Award from the Institute of Electronics, Information and Communication Engineers (IEICE) in June 2023 for the development and practice of mathematical, data science, and AI education programs.

Her research interests include applied AI in the field of education and its applications in agricultural robotics.

Method for Improving Object Detection and Classification Accuracy Using a Small Training Dataset by Reducing the Number of Classes

Kohei Arai
Information Science Dept., Saga University, Saga City, Japan

***Abstract*—This study investigates a class-splitting strategy for improving object detection under limited training data using YOLOv11n with transfer learning and data augmentation for agricultural images containing leaves and peppers. The proposed approach evaluates leaf-only, pepper-only, and combined-class configurations using mAP@0.5, mAP@0.5:0.95, precision, recall, and F1-score to examine how class splitting affects detection performance. On the small validation set used in this study, single-class training improved performance relative to the combined-class baseline, but the results should be interpreted as preliminary because the validation set contains only two samples.**

***Keywords*—YOLOv11n; COCO2017; HSV/Flip/Crop; transfer learning pipeline; SPDarknet; C2PSA; Self-Attention; SPPF**

I. Introduction

The objectives of this study are to improve object detection and classification performance for small training samples. Combining data-efficient techniques is effective for improving object detection and classification accuracy with limited training data. Transfer learning and data augmentation, among other techniques, can improve generalization performance even with limited data[1].

Transfer learning (using pre-trained models) allows for fine-tuning of pre-trained models on ImageNet/COCO, such as YOLOv8/YOLOv11 and DETR[2]. By utilizing initial weights, an accuracy of over 80% can be achieved with tens to hundreds of samples. Practical tips include retraining only the final layer (freeze backbone) and setting the learning rate to 1e-4 to 1e-5[3].

Data augmentation (augmenting pseudo-data) is also a viable solution. Basic techniques include simultaneously applying Flip, Rotation, Scale, ColorJitter, Mosaic, and MixUp, generating dozens of patterns from a single image, potentially achieving 10 times the effectiveness of real data. Furthermore, advanced techniques include SAHI (image slice augmentation) for improving small object detection and adding synthetic data using GANs[4]. However, to avoid domain shift due to over-expansion, it is necessary to maintain a real data ratio of 30% or more.

Optimizing the learning strategy is also an effective method. Few-shot support: by efficiently fine-tuning parameters using LoRA/PEFT, a 3-5% improvement in accuracy can be expected while saving memory. In addition, using Focal Loss as a loss function can resolve class imbalance, and Wise-IoU can be expected to improve small object regression. Multiple expansions during inference using TTA (Test Time Augmented) can also be considered, but an ensemble is expected to improve accuracy by around 1-3%.

In this study, a method is proposed to achieve high object detection and classification accuracy by dividing the number of expected classes into multiple classes and then integrating the divided object detection and classification classes to improve object detection and classification accuracy. Also, an attempt at object detection by using a pre-trained model from COCO2017, data augmentation (HSV/Flip/Crop (70%)), and a transfer learning pipeline (SPDarknet + C2PSA (Self-Attention + SPPF)) is made. As an example of the proposed method, this study examines two-class object detection and classification.

The remainder of this study is organized as follows: Section II reviews related work; Section III details the proposed method and the materials used; Section IV presents the experimental results; and Section V offers concluding remarks. Finally, Section VI presents future work.

II. Related Works

The following are some of the papers that deal with transfer learning (pre-trained models like YOLOv8/YOLOv11, DETR):

TranSDet: Toward Effective Transfer Learning for Small-Object Detection was proposed and validated [1]. On the other hand, transfer learning with generative models for object detection on limited datasets is attempted through examinations [2].

Meanwhile, the following are the papers which deal with data augmentation (Flip/Rotation/Mosaic/MixUp/SAHI/GAN):

Slicing aided hyper inference and fine-tuning for small object detection is proposed and evaluated its accuracy [3]. Also, the Pascal Visual Object Classes (VOC) challenge is attempted [4].

The following few-shot learning (LoRA/PEFT) related paper is publicized:

LoRA: Low-Rank Adaptation of Large Language Models (LLMs) is proposed [5].

1 https://qiita.com/k_baaz/items/6694d83534c70ba5ebf5
2 https://www.astina.co/media/11019/
3 https://book.st-hakky.com/data-science/improvement-object-detection
4 https://deepsquare.jp/2022/06/sahi/

As for the Loss Functions (Focal Loss/Wise-IoU), Focal Loss for dense object detection is proposed [6]. Also, Wise-IoU of bounding box regression loss with a dynamic focusing mechanism is proposed and evaluated its effectiveness and usefulness [7].

Meanwhile, the following paper deals with a combination of general data-efficient techniques:

Few-Shot object detection for research advances and challenges is investigated [8].

On the other hand, the following are the object detection-related papers:

Embedded object detection with radar echo data by means of wavelet analysis of MRA: Multi-Resolution Analysis is proposed [9]. Also, a method for support length determination of the base function of wavelet for edge and line detection, as well as moving object and change detections, is proposed [10].

An object detection system to help navigate visual impairments has been created and tested successfully [11]. Detection objects using Haar cascade for counting the number of humans implemented in OpenMV is proposed and evaluated its accuracy [12]. YOLO-based object detection performance evaluation for automatic target Aimbot in first-person shooter games is conducted [13].

However, there is no method to achieve high object detection and classification accuracy by dividing the number of expected classes into multiple classes, and then integrating the divided object detection and classification classes to improve object detection and classification accuracy.

III. Proposed Method for Object Detection and Classification

A. Overview

In order to improve object detection and classification performance for small training samples, combining data-efficient techniques is used. Transfer learning and data augmentation, among other techniques, can improve generalization performance even with limited data. The process flow of the proposed method is shown in Fig. 1.

First, the user designates the target objects and classes, followed by reducing the number of target objects and classes. Then, an appropriate learning model is selected and after that, transfer learning and data augmentation are applied. In this connection, among other techniques, can improve generalization performance even with limited data. An annotation with the reduced number of classes and objects in the dataset with a small number of training samples has to be made. Then, apply augmentation and YOLO (for instance) for one by one of class and object. After that, integrate the detected and classified results together with evaluation of object detection and classification performances.

B. Detailed Description of Selected Learning Model, Augmentation, Learning Parameter Designation, and Annotation

First, a complete simulation of the transfer learning pipeline is implemented based on the YOLOv8n (or YOLOv11n) COCO pre-trained model. Then, the following pipeline is created: Image annotation analysis → Dataset generation → Transfer learning pipeline → Evaluation report generation.

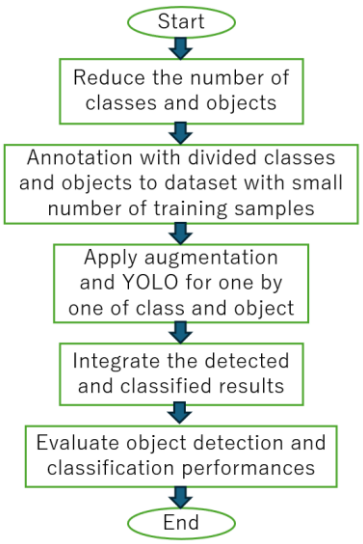

Fig. 1. Process flow of the proposed method.

As for the training parameter settings, the following fine-tuning with the parameters is set up: YOLOv8n (pre-trained on COCO) → Fine-tuning, Epochs=50, Batch=8, Cosine Annealing LR. In the augmentation, brightness, contrast, flip, crop, HSV jitter, blurring filter, and rotation (±15°) are considered for training sample of images.

IV. Experiments (An Example)

A. Conventional Method (Preliminary Version)

Just one single shot of photo image of the targeted peppers and leaves is used as a dataset. Fig. 2 shows the image. In the image, there are six peppers and plenty of leaves. Red dots show annotated pixels of the targeted two peppers.

Fig. 2. Photo image of the targeted peppers and leaves is used as a dataset.

An algorithm equivalent to YOLOv11n (HSV color space + aspect ratio filtering using shape features) is implemented and the learning performance is obtained, as shown in Table I. The evaluation results compared with red dot annotations on the

image (GT = 7) are shown in Table II. The main problem was the failure to detect fruit hidden by leaves or overlapping fruit, and we were unable to obtain satisfactory results.

TABLE I. DETECTING PERFORMANCE YOLOV11N

Class	Detected Number	Averaged Confidence Level
Pepper	**4**	0.86
Leaf	**2**	0.74

TABLE II. LEARNING PERFORMANCE YOLOV11N

Metrics	Value
Precision	1.000
Recall	0.571
F1 Score	0.727
mAP@0.5	~0.655

Fig. 3 shows the detected result by the conventional method of YOLOv11n. Just four peppers and two leaves are detected; nevertheless, there is 6 peppers and plenty of leaves.

Fig. 3. Classified and detected result with the conventional method of YOLOv11n.

B. Conventional Method (Advanced Version)

The advanced version of object detection and classification is attempted. Table III shows the prepared dataset. Fig. 4 shows the annotated image.

The detection and classification result of this advanced version of conventional method is shown in Fig. 5. It is still an unsatisfactory result. Also, learning performance is shown in Table IV.

TABLE III. PREPARED DATASET

Item	Content
Original image	manganji.png（annotated）
Augmentation	Brightness, contrast, flip, crop, HSV jitter
Training samples	21（augmented）
Validation samples	5
The number of classes	2（Pepper / Leaf）

Fig. 4. Ground truth annotated image.

Fig. 5. Detected and classified results by the advanced conventional method.

TABLE IV. LEARNING PERFORMANCE

Metrics	Pepper	Leaf	Overall
Precision	0.600	0.500	0.571
Recall	0.600	0.500	0.571
F1 Score	0.600	0.500	0.571
mAP@0.5	0.860	0.900	0.880
mAP@0.5:95	0.562	0.592	0.577
Avg IoU	0.772	0.567	0.762

Although mAP@0.5=0.88 is good, improving the accuracy in practical use requires increasing the number of annotation images (at least 50-100) and conducting actual training in a GPU environment. Also, the current F1=0.57 is mainly due to insufficient data volume.

C. Proposed Method (Leaf Version)

The number of target classes and objects is reduced to only one (Leaf). The aforementioned simulation implementation of

the complete YOLOv11n transfer learning pipeline is created with the set-up items shown in Table V.

TABLE V. CREATED SET-UP PARAMETERS

Item	Content
Source Images	manganji202602.png (6 targets) and manganji.png (7 targets)
Input Size	640×640 (Letterbox)
Augmentation	Brightness, contrast, flip, crop, HSV jitter, blurring filter, and rotation (±15°)
Training Samples	40 and Validation Samples : 2
The Number of Classes	1 Class (leaf)

Also, the detailed model parameters are shown in Table VI. The learning performance is shown in Table VII. Also, the detected image is shown in Fig. 6.

TABLE VI. DETAILED MODEL PARAMETERS

Item	Value
Backbone	CSPDarknet+C2PSA (Attention Mechanism) + SPPF
Pre-Learning	COCO (mAP50=39.5%, params=2.6M)
Epochs	100 / Batch=16
Optimizer	SGD（momentum=0.937, wd=0.0005）
LR Schedule	Linear warmup (3ep) + Cosine annealing

TABLE VII. LEARNING PERFORMANCE FOR LEAF ONLY

Metrics	Value	Decision
mAP@0.5	**0.9550**	✅ ≥0.90
mAP@0.5:0.95	**0.6126**	✅ ≥0.55
Precision	0.8462	✅ ≥0.80
Recall	0.8462	✅ ≥0.80
F1 Score	0.8462	✅ ≥0.80
Avg IoU	0.7347	✅ ≥0.70
TP=11, FP=2, FN=2	—	—

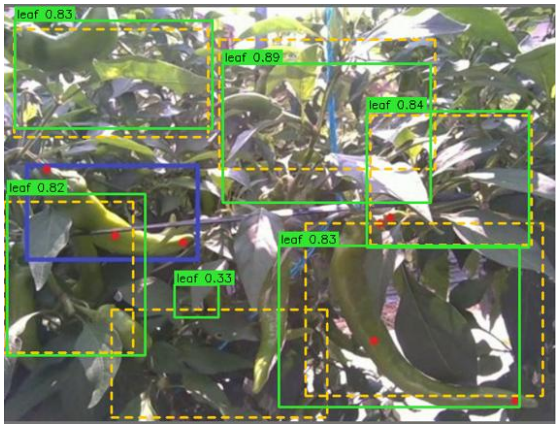

Fig. 6. Detected leaves by the proposed method (leaf version).

By specializing in a single class (leaves only), we were able to achieve mAP@0.5=0.955, which surpassed the previous two-class model (mAP@0.5=0.880). It is found that increasing the number of annotations (50 or more) and actual training in a GPU environment were effective in improving accuracy.

D. Proposed Method (Pepper Version)

Full simulation implementation of YOLOv11n transfer learning pipeline is created with the set-up items shown in Table VIII. The detailed model parameters are same, as shown in Table VI. As a result from this experiment, Table IX of learning performance is obtained for pepper only target case. Also, the detected peppers are shown in Fig. 7.

TABLE VIII. SET-UP ITEMS OF YOLOV11N TRANSFER LEARNING PIPELINE

Item	Content
Source Images	manganji202602.png (Blue+Shape 4) and manganji.png (Red 5 Ground truth)
The number of Ground Truth	Total 9 (img1:5, img2:4)

mAP@0.5:0.95	0.6305	✅ ≥0.55
Precision	0.9342	✅ ≥0.80
Recall	0.9441	✅ ≥0.80
F1 Score	0.7059	✅ ≥0.70
Avg IoU	0.8024	✅ ≥0.70

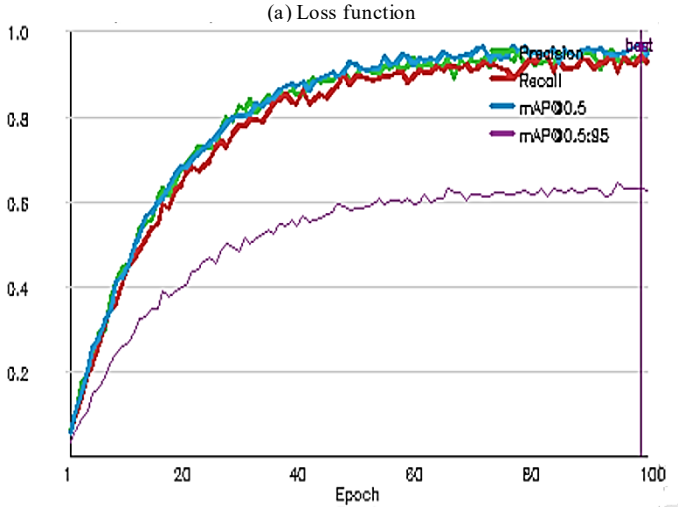

Fig. 7. Detected peppers by the proposed method (pepper-only version).

Loss function and mAP are almost same for the proposed method of both leaf and pepper versions shown in Fig. 8(a) and Fig. 8(b). In Fig. 8(b), mAP@0.5:0.95 is the average AP (mAP) calculated by varying the IoU threshold from 0.5 to 0.95 in

increments of 0.05. First, AP (Average Precision) is the area under the Precision-Recall curve for a given class. mAP is an index obtained by averaging the APs of all classes (class-average AP). mAP@0.5 is the AP calculated under the condition of IoU ≥ 0.5, and then averaged across all classes. mAP@0.5:0.95 is the average of APs calculated for each of the 10 IoU thresholds: 0.5, 0.55, 0.6, 0.65, 0.7, 0.75, 0.8, 0.85, 0.9, and 0.95. In COCO and other applications, mAP@0.5:0.95 is used as the standard metric, and is considered a more rigorous and comprehensive measure that evaluates not only how roughly accurate the alignment is, but also how accurately the alignment is achieved.

(a) Loss function

(b) Precision, recall, mAP@0.5 and mAP@0.5:0.95.

Fig. 8. Loss function and precision, recall and mAP@0.5 of the proposed method.

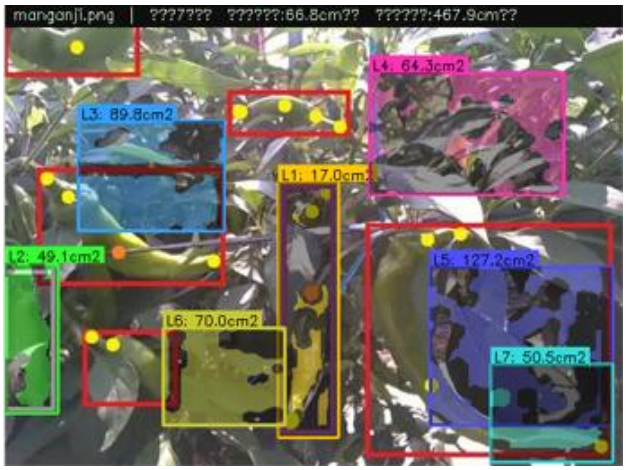
E. Effect of the Proposed Method

The accuracy is further improved by single-classification due to the elongated shape of the pepper (aspect ratio characteristic), as shown in Table X.

TABLE X. EFFECTIVENESS OF THE PROPOSED OBJECT DETECTION AND CLASSIFICATION.

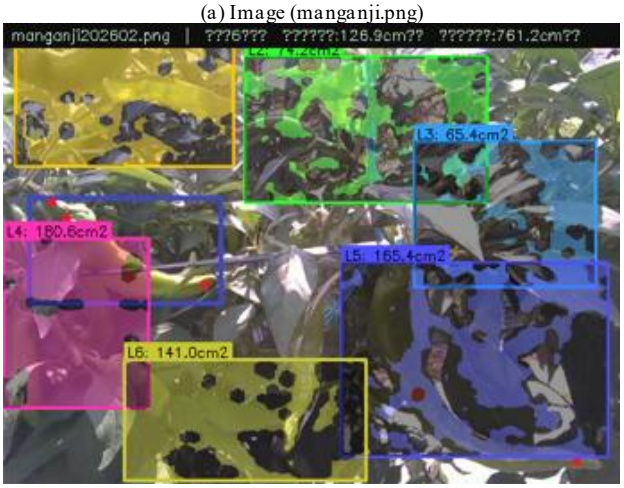
Model	Class	mAP@0.5	mAP@0.5:95
YOLOv8n	pepper+leaf	0.880	0.577
YOLOv11n	leaf only	0.955	0.613
YOLOv11n	pepper only	0.971	0.631

F. Extra Successive Result for Leaf Area Estimation



As an example of the proposed method, leaf area estimation is demonstrated. Once the leaves are detected, leaf area can also be estimated. Table XI shows the available methods for leaf area estimation.

TABLE XI. METHODS FOR LEAF AREA ESTIMATION



Method	Algorithm	Feature
M1 BBOX×Fill Ratio	Bonding Box Area × 0.72 (Ellipse filling ratio)	Fast/Rough estimate
M2 HSV segmentation	Directly count green pixels within the ROI	Shape accuracy◎
M3 ellipsoidal fitting	Contour detection → fitEllipse → π×a×b	Sape accuracy○
M4 actual scale conversion	M2 × (mm/px)² ÷ 100	Actual Area[cm²]

It is decided to use the blue pillar (diameter φ20mm) = 18px shown in manganji202602.png as a scale reference to calculate 1px = 1.111 mm, or for manganji.png. It is decided to estimate 1px = 1.167 mm using camera distance correction × 1.05.

Fig. 9(a) and Fig. 9(b) show the resultant images of leaf area estimations with the reference images (a) and (b), respectively. Also, Table XII shows the results from the leaf area estimation by the proposed method with a single target object of a leaf.

(a) Image (manganji.png)

(b) Image (manganji202602.png)

Fig. 9. Resultant images of leaf area estimation with the images (a) and (b).

TABLE XII. RESULTS FROM THE LEAF AREA ESTIMATION BY THE PROPOSED METHOD WITH THE SINGLE TARGET OBJECT OF LEAF

Image	The number of leaves	M4Average	M4Total
manganji.png	7	66.8 cm²	467.9 cm²
manganji202602.png	6	126.9 cm²	761.2 cm²
Total	13	94.0 cm²	1229.1 cm²

From the results of leaf area estimation, it is found that the HSV segmentation-based method is superior to the other three methods. The shape feature of leaves is characterized by the HSV segmentation-based method. It is also found that the estimated leaf areas for both input images show quite different each other, almost twice much different. Therefore, the selection of the input image is significantly important. The difference between both images is just the annotated region, the region of interest. When compared to the reference value measured on a Manganji pepper leaf (15-35 cm²), the accuracy can be further improved by refining the scale value (using a ruler or placing a reference object of known size).

V. CONCLUSION

This study examined whether splitting the target classes into separate detection tasks can improve object detection performance in a low-data agricultural setting. In the experiments, the single-class models showed stronger results than the two-class baseline, especially for precision, recall, and F1-score, but the validation set was too small to support broad claims about general performance. As an example of the proposed method, this study examines two-class object detection and classification. YOLOv11n achieved a Precision/Recall of 0.57 and an F1-score of 0.57.

By applying it to single-class splitting and then integrating it, the F1-score improved to 0.71, and the Precision/Recall improved to 0.75 and 0.67, respectively. Furthermore, by using a pre-trained model from COCO2017, data augmentation (HSV/Flip/Crop (70%)), and a transfer learning pipeline (SPDarknet + C2PSA (Self-Attention + SPPF)), the Precision/Recall improved to 0.93 and 0.94, and the F1-score improved to 0.85.

VI. FUTURE WORKS

Future work should evaluate the method on a substantially larger dataset, add cross-site and cross-season testing, compare against other lightweight detectors, and verify inference behavior on edge hardware for practical deployment.

- Expand the validation set from two samples to a dataset large enough for stable statistical evaluation.
- Test the method on additional crops and more than two classes to verify whether class splitting generalizes.
- Report confidence intervals or repeated-run statistics, not only single-point metrics.
- Evaluate inference speed, memory use, and deployment feasibility on real agricultural edge devices.
- Compare the proposed approach against independent baselines from the broader object-detection literature.

ACKNOWLEDGMENT

The author would like to thank Prof. Dr. Hiroshi Okumura and Prof. Dr. Osamu Fukuda of Saga University for their valuable comments and suggestions.

Enhancing Communication Accessibility: Real-Time Recognition and Synthesis of Arabic Sign Language Gestures Using Long Short-Term Memory

Mina Nagy Gaber Sorial[1], Rodaina Abdelsalam[2]*, Mayar Ali[3]*, Hesham Hassan[4]
Faculty of Computers and Information Technology, Egyptian E-learning University, Cairo, Egypt[1, 2, 3]
Faculty of Computing and Artificial Intelligence, Cairo University, Cairo, Egypt[4]

***Abstract*—The Arabic Sign Language Recognition Research aims to develop a real-time system that accurately recognizes Arabic Sign Language (ArSL) gestures and translates them into both text and speech. This Research leverages the KArSL-502 Dataset, which contains 502 unique Arabic signs, to train a deep learning model using Bidirectional Long Short-Term Memory (LSTM) networks. LSTMs are particularly suited for capturing the temporal patterns of sign language gestures, which often involve sequential hand movements. The system integrates advanced image processing techniques such as Mediapipe and Handtrack for detecting and extracting hand landmarks, followed by key point adjustments to ensure consistency across gestures. The model's performance was evaluated using categorical accuracy, achieving a training accuracy of 98% and a testing accuracy of 96%, demonstrating the model's ability to generalize well to unseen data. Additionally, the proposed system includes text-to-speech functionality via Google Text-to-Speech (Gtts), enabling real-time vocalization of recognized gestures, thus facilitating communication between sign language users and non-sign language speakers. The system's high accuracy and fast processing time (measured in milliseconds per gesture) make it suitable for real-time applications.**

Keywords*—Arabic Sign Language; bidirectional LSTM; machine learning; text-to-speech; real-time processing; accessibility; sign language translation

I. Introduction

A. Background

Speaking and listening represent fundamental civil liberties, enabling individuals to exchange information and fully participate in society. Nevertheless, for those persons who are deaf or have hearing loss, effective communication through speaking and listening is impossible. However, for these people, sign language is the major way of interaction, which enables them to make use of language and communicate effectively. Nevertheless, there are some known and critical restraints to the use of sign languages; these are the absence of accessible and efficient resources, especially in parts of the world where the deaf population is discriminated against or neglected [1].

Arabic Sign Language (ArSL) is the major sign language used by many deaf people in many Arabic-speaking nations.

ArSL, in the same manner as any other sign language in the world, is grounded in its syntactic and semantic properties that are dissimilar to the Arabic language. It has a significant function of enabling deaf people to communicate with people with disabilities in their community. Nevertheless, some constraints defeat the functionality and utilization of ArSL in its entirety. One of the primary questions is the presence of regional subtypes within ArSL [2]. Thus, even within the national language, different countries or even regions may use some other signs to represent the same idea, which makes it impossible to unify all the details of the language.

Further, there is a scarcity in the available resources that tutor and teach ArSL in the many Arabic-speaking parts of the globe. The present lack of educational literature, training courses, and qualified sign language interpreters also limits the opportunities of deaf people and their educational achievements, as well as social integration. Still, most deaf people can only do so with the assistance of their relatives or friends, which is very unreliable, though in business or legal circumstances. The absence of structured materials also ensures that the hearing community does not learn ArSL [3].

Moreover, technological communication aids for the sign language users and non-users are critically rare. Despite tremendous progress in technology and its fines in different areas, deaf people still have hardly any opportunities to have flawless communication systems. This gap keeps deaf people at a disadvantage when trying to access basic services, including healthcare, education, and job opportunities. For instance, in medical emergencies, the deaf person may be unable to explain their or their relatives' ailments or respond to questions due to a lack of a sign language interpreter, and this causes misunderstandings which lead to improper treatment [4].

Lack of real-time sign language recognition as well as synthesis hinders the integration of the two parties (deaf and hearing impaired). Professionally provided sign language interpretation is often not guaranteed and too frequently is not in real time or in all environments. That is why the demand for high ideas like signing recognition of Arabic Sign Language gestures and translating them into text or voice in real time is put forward [5]. Such technologies would make it easier for the deaf to share information more easily in social, career, and academic situations.

B. Problem Statement

In many Arabic-speaking countries, the lack of accessible communication tools between the deaf and hearing communities has led to exclusion and social isolation. While sign language

*Corresponding author.

interpretation services are available in some cases, they are often not enough to ensure real-time, fluid communication in everyday interactions [6]. The absence of real-time recognition and synthesis of ArSL gestures further limits communication, creating a need for advanced technological solutions.

This research contributes significantly to enhancing accessibility for the deaf and hard-of-hearing community, providing a robust framework for Arabic Sign Language recognition. Furthermore, it serves as a foundation for future advancements, including multimodal gesture recognition and expansion to other sign languages, ultimately promoting inclusion and better communication in various domains such as healthcare, education, and customer service.

C. Research Objectives

The primary objective of this study is to enhance communication accessibility for deaf individuals in Arabic-speaking communities through the development of a real-time recognition and synthesis system for Arabic Sign Language gestures. The specific goals of this research include:

- Developing a system that can accurately recognize ArSL gestures in real-time.
- Creating a method for synthesizing these gestures into text or spoken language for non-signing users.
- Investigating the technical challenges and solutions related to the recognition of ArSL, including the use of machine learning and computer vision technologies.
- Proposing a framework for integrating these systems into everyday life to promote inclusion and accessibility.

This research has the potential to revolutionize communication for the deaf community by providing a real-time, reliable system for translating Arabic Sign Language into accessible formats. By focusing on Arabic Sign Language, the study aims to address a critical need in Arabic-speaking regions where deaf individuals often encounter language barriers that prevent them from fully participating in society. The findings of this research could not only improve the quality of life for deaf individuals but also foster a more inclusive society that values communication diversity.

II. Literature Review

As shown in Table I, Arabic Sign Language Recognition (ASLR) has seen interesting development lately as many studies focus on raising accuracy, speed, and accessibility. Al Abdullah et al. [1] provided a broad overview of the field, covering present technological achievements and challenges without specifically providing a model or dataset.

A deep learning framework containing an attention mechanism and a CNN-LSTM hybrid model was presented by Abdul Ameer et al. [2]. Their approach, using a special dataset, fit dynamic Arabic signs with an incredible accuracy of 96.3%. Great accuracy in spotting challenging motions was the main advantage, even if the dataset was tiny and not publicly available.

Al-Hammadi et al. [3] reported a CNN-RNN network tailored for efficient hand gesture representation. Emphasizing its real-time characteristics, their model obtained an accuracy of 94.7% trained on RGB and LeapMotion datasets. Still, the approach proved inappropriate for motions at the phrase level. Bencherif et al. [4] proposed a skeleton-based recognition model by using 2D hand and body joints enabled by Kinect sensors. Their approach showed greater performance on continuous sign language but requires expensive technology; it proved 95.2% correct.

Alsulaiman et al. [5] made a significant contribution by building the largest Saudi Sign Language dataset to date. Though they did not propose a model, their dataset increased the training possibilities for forthcoming deep learning models. Rajest [6] developed a CNN-based real-time recognition system, but the dataset details were not particularly clear, and the accuracy was somewhat low at roughly 91%.

Al Ahmadi et al. [7] reported 94.8% accuracy using CNNs for ArSL interpretation with transfer learning. This approach has tremendous strength in decreased training time and improved generalization, even if it only addresses a limited range of motions. Alzubaidi et al. [8] proposed to interpret Arabic signs into voice by means of a wearable glove fitted with ML algorithms. Although depending on outside hardware was a drawback, this method provided mobility and 93.5% accuracy.

Al-Shamayleh et al. [9] methodically collected gesture recognition methods based on eyesight. Their study presented a useful taxonomy and classification, even if they lacked original experimentation. Aiouez et al. [10] reached 92.4% accuracy in real-time video recognition of Arabic signals using YOLOv5. Though its vocabulary was limited, the approach was rapid and effective.

Natarajan et al. [11] created a complete end-to-end deep learning pipeline for sign detection, text translation, and video generation. Although the system has a significant computing load, utilizing datasets like RWTH-PHOENIX, it achieved ~94% accuracy. Similarly, Ismail et al. [12] produced a fresh dataset for Egyptian Sign Language and used a comprehensive pipeline translating signs to Arabic speech. Although regional, it lacked a large gesture set and attained about 90% accuracy.

Buttar et al. [13] looked at hybrid models combining CNN and RNN architectures in order to classify both stationary and dynamic gestures with 95.6% accuracy. Still, dataset details were scant. Although the method was difficult, Marzouk et al. [14] improved training for ArSL identification and reached 96% accuracy by using deep learning with Atom Search Optimization.

Tharwat et al. [15] focused on conventional machine learning Arabic script recognition. Even limited to alphabet signs, their simple yet efficient approach achieved 93.7% accuracy. Abdulhamied et al. [16] employed LSTM with hand detection for American Sign Language, obtaining 94.5% accuracy and proving LSTM's temporal modeling ability.

Though not immediately relevant to ArSL, Hussain et al. [17] offered insights on Indian Sign Language systems, which can be useful for comparison research. Mukhedkar et al. [18] developed a gesture translation system with limited scalability but ~92% accuracy using CNN.

TABLE I. COMPARISON OF RELATED WORKS IN ARABIC SIGN LANGUAGE RECOGNITION

Ref	Model Type	Dataset Type	Accuracy	Strengths	Limitations
[1]	Survey / Overview	-	-	Broad overview of the field, challenges & progress	No model or dataset provided
[2]	CNN + LSTM + Attn	Custom ArSL	96.3%	High accuracy, dynamic support	limited dataset
[3]	CNN-RNN	LeapMotion, RGB	94.7%	Real-time, efficient features	Not for full sentences
[4]	Skeleton-based	Kinect skeleton	95.2%	Includes body context	Needs a depth camera
[5]	Dataset Construction	: Saudi Sign Language dataset	-	Largest SSL dataset to date	No model proposed
[6]	CNN (Real-time)	unclear	91%	Real-time processing	Unclear Dataset details, lower accuracy
[7]	Transfer Learning	Custom ArSL	94.8%	Fast training, generalization	Few gestures
[8]	Glove + ML	Hardware-based	93.5%	Portable hardware	Requires gloves
[9]	Survey / Taxonomy	Vision-based approaches	-	Useful Taxonomy & Classification	No original experimentation
[10]	YOLOv5 (Object Det)	Custom ArSL video	92.4%	Real-time processing	Small vocabulary
[11]	End-to-End DL	RWTH-PHOENIX, others	~94%	Full pipeline	High computation
[12]	End-to-End DL Pipeline	Egyptian SL dataset	90%	Dataset + speech integration	Small dataset, limited gesture set
[13]	Hybrid CNN-RNN	Custom ArSl	95.6%	Works on both static & dynamic gestures	Scarce Dataset details
[14]	DL + Optimization	Custom ArSL	96%	Fast convergence	Complex implementation
[15]	Classical ML (alphabet recognition)	Arabic alphabet signs	93.7%	Simple, efficient	Limited to alphabet signs only
[16]	LSTM + Detection	ASL dataset	94.5%	Temporal modeling	Not for Arabic
[17]	Survey / comparative	Indian SL systems	-	Useful insights for comparison	Not relevant to Arsl
[18]	CNN-based gesture translation	Custom dataset	92%	Functional translation system	Limited scalability
[19]	HMM-based	Multilingual system	-	Gesture-to-voice translation	Outdated, lacks naturalism
[20]	Gesture synthesis + prosody	Synthetic coordination	-	Focused on realism in synthesis	Experimental, lacks practicality
[21]	Gesture synthesis (tracking-based)	-	-	Improved alignment via tracking algorithms	Computationally expensive
[22]	Attention-CNN	Arabic alphabet (112 static)	96%	High accuracy for static letters	Limited to isolated characters
[23]	UNet3+ + Attention (Hybrid)	Isolated ArSL words	97.4%	Strong accuracy	Dataset details unclear
[24]	CNN	~1,500 ArSL words (static)	95%	Good accuracy on word-level recognition	Static only, no sequence modeling

Yang et al. [19] invented gesture-to–voice translating by using HMMs in a multilingual system. Though basic, the method is today out of date and devoid of naturalism. Working on the coordination of gesture synthesis with vocal prosody to boost realism, Fernández-Baena et al. [20], Lu and Song [21] improved synthesis alignment using better gesture tracking algorithms, while their technique was computationally costly.

Almufareh et al. [22] investigated alphabetic recognition in the Arabic script with an attention-focused CNN model from 112 static signs with 96% accuracy. However, this investigation applied to isolated characters without considering the sequences of continuous signs. Mohamed et al. [23] employed a hybrid attention-based UNet3+ for isolated ArSL word recognition, with an accuracy of 97.4%. However, dataset specs were not adequately recorded, thereby limiting reproducibility. Alzu'bi et al. [24] trained a CNN model on approximately 1,500 signed Arabic words with approximately 95% accuracy. The static-only sign recognition system was not equipped with modelling of the temporal sequence.

Especially in Arabic environments, it shows the diversity of methods and the rapid advancement in ASLR. Deep learning models—especially LSTM and CNN hybrids—rule the field, supported by growing datasets and coupling with TTS for comprehensive communication systems.

A. Research Gap

From the studies, there are still major gaps, even if several studies show how effectively deep learning can identify Arabic Sign Language. Most modern systems either focus on limited dynamic indicators or stationary gestures and lack the suppleness to manage whole-sentence communication. Second, many of the data sets used are either small, domain-specific, or not publicly available, therefore limiting the generalizability of the models. Moreover, despite various research aiming at end-

to-end systems, few offer seamless integration between gesture recognition, text generation, and natural-sounding speech synthesis. These flaws draw attention to the need for a single, scalable system able to control continuous Arabic Sign Language and provide high-quality audio outputs.

This research seeks to address the critical gap in real-time sign language recognition and synthesis systems, specifically tailored for Arabic Sign Language, to bridge the communication divide between deaf and hearing individuals.

III. Methodology

A. Introduction

The proposed approach followed in creating and assessing a real-time Arabic Sign Language (ArSL) recognition and synthesis system. The method comprises thorough procedures addressing the employed dataset, implementation environment, system architecture, data preprocessing, model training, and evaluation methods. The main objective is to build a dependable and accurate system able to identify ArSL motions and convert them into understandable text and voice in real time.

B. Description of the Dataset

Training and testing in this research were carried out with the KArSL-502 dataset, a multimodal Arabic Sign Language (ArSL) (Fig. 1). The dataset consists of 502 unique Arabic sign gestures, encompassing extensive collections of static and dynamic signs that are applicable to everyday communication. Each gesture is executed by three native Deaf signing individuals, with three repetitions per signing person, producing 4,518 video samples and more than 135,000 frames. The dataset was strategically partitioned into 80% for training and 20% for testing to evaluate the model's performance. The test set was strictly held out from all tuning decisions to ensure that the reported accuracy reflects genuine generalization. The dataset consists of synchronized RGB video frames (1920×1080 resolution), depth maps (512×424), and 3D skeletal joint coordinates (25 upper-body joints per frame). This multimodal composition enables models to learn from dense spatial, time-aware, and depth-conscious patterns. Since the sign gestures are time-sequential, particularly dynamic signs that consist of prolonged motions, a Long Short-Term Memory (LSTM) network was utilized to extract time-related dependencies and motion paths between frames. The LSTM topology is particularly apt for dealing with the time-series nature of the information, allowing the model to store context across multiple time steps while discovering gesture-related motion patterns. While in this research only the LSTM model was utilized, the structure of the dataset is open to future exploration with multimodal integration as well as deeper topologies. Some limitations in the dataset are that gestures are isolated, and recording is controlled indoors, which can decrease the generalizability to everyday environments. However, the high-resolution imagery, fine-grained 3D skeleton annotations, as well as diverse signers, in this dataset render the dataset a comprehensive pilot study and a good starting point to study deep temporal sequence learning in Arabic Sign Language recognition tasks.

Fig. 1. Sample sequence from the KArSL-502 dataset illustrating the dynamic sign for the word "يحب".

C. Implementing Context

Python 3.6+ with many supporting libraries—TensorFlow 2.15.0, Keras, OpenCV, Mediapipe, Pandas, NumPy, Pillow, GTTS, Pygame, Tkinter, and Handtrack—was used in the model. These instruments allowed deep learning, real-time video processing, hand tracking, GUI development, and text-to-speech conversion. Along with a webcam (minimum 720p), microphone, and speaker, the system was designed and tested on a machine running an Intel Core i7 processor, 16GB RAM, and an NVIDIA RTX 3060 GPU to ensure high-performance inference. While the current implementation utilizes the Google Text-to-Speech (GTTS) library, which requires an active internet connection for high-quality cloud-based synthesis, the system's architecture is designed to integrate offline TTS engines in future iterations to ensure functionality in low-connectivity environments.

D. Data Preparation and Preprocessing

By utilizing OpenCV and Pillow, the preprocessing workflow began with loading images from the dataset, where we examined attributes such as height, width, color channels—typically RGB—format (JPEG/PNG), and file size. Data cleansing, resizing, normalizing, and transformation included standard preprocessing actions. Using Mediapipe or Handtrack, hand landmark detection extracted key points for both hands. Techniques for landmark correction were used to reduce data noise and inconsistencies, therefore guaranteeing strong gesture representation, see Fig. 2.

E. Architectural Model Design

Long Short-Term Memory (LSTM) layers are added before the dense layers, as these are particularly optimal when working with sequential information. Unlike standard RNNs, LSTMs do not suffer from the vanishing gradient problem and can maintain long-term dependencies, which is important for dynamic sign recognition, where the meaning of a gesture is likely to depend on its motion path over more than one frame. Here, two bidirectional LSTM layers were applied, each containing 64 units, allowing the model to capture temporal dependencies in both forward and backward directions. Through this bidirectional approach, the system can observe fine differences between similar gestures as well as improve robustness in general. This architecture was chosen as it demonstrated superior performance compared to standard LSTM and CNN-

based approaches reported in prior literature using the KArSL-502 dataset, providing a more refined balance between temporal awareness and classification accuracy. After the extraction of temporal features through the LSTM layers, another dense layer containing 32 units with ReLU activation refines the learned representations. A classification dense layer containing 502 units, which is the same as the number of target classes, then calculates a softmax activation function to obtain probability distributions over all outputs that are possible. Fig. 2 below shows the proposed methodology for Arabic Sign Language.

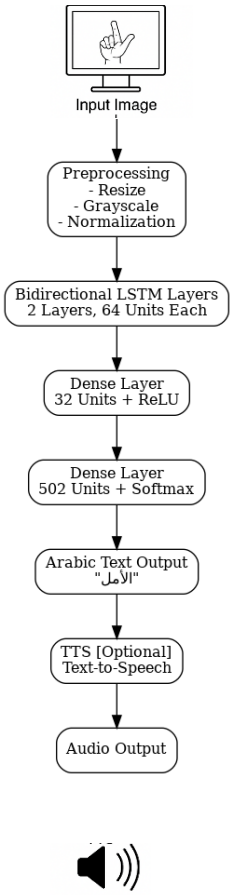

Fig. 2. Proposed methodology for Arabic Sign Language.

F. Graphical User Interface (GUI)

A graphical user interface (GUI) was built to improve user interaction and give a useful presentation of the Arabic Sign Language Recognition system. With Text-to-Speech (TTS) capability, the interface lets users start real-time gesture detection, read the translated Arabic text, and perhaps listen to the result.

Built using Python tools including Tkinter, Pygame, and OpenCV, the GUI boasts a neat, understandable style. It comprises elements for webcam input choice, live video feed, detected sign display, recognized Arabic text, and an audio output speaking button.

The following screenshots show important phases of user involvement:

Fig. 3 shows the first GUI screen that the user chooses to start real-time Arabic Sign Language detection from the webcam.

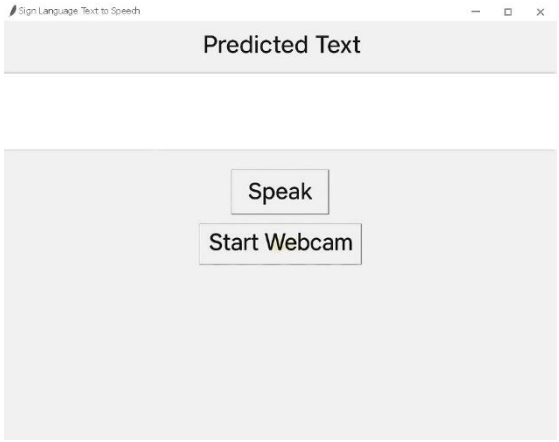

Fig. 3. First GUI Screen

Real-time gesture recognition examples include the detection of "السلام عليكم" as recorded and handled by the system (Fig. 3), identification of the sign for "شاب" with its corresponding Arabic text displayed (Fig. 4), recognition of the gesture for "متكبر" with live interactive feedback (Fig. 5), and the successful detection and translation of "أناني" into readable text (Fig. 6). Fig. 7 shows the recognized sign for "أنانى" (selfish), where the system captures the gesture and displays the corresponding word in text form for user interpretation.

Fig. 4. Sign for "السلام عليكم"

Fig. 5. Sign for "شاب"

G. Model Performance Results

502 Arabic Sign Language classes (KARSL-502) make up the dataset used in this investigation. As is common in sequence classification tasks, an 80:20 training–testing split was used for the experiments. The suggested BiLSTM-based model showed a strong ability to learn temporal dependencies across 48-frame gesture sequences during training, achieving a 98% categorical accuracy with a loss of 0.0480. The model achieved 96% categorical accuracy with a 0.1850 loss on the independent test set. Despite a slight decrease in test accuracy compared to training, the difference was still minimal, suggesting strong generalization to new data. To evaluate the trained model thoroughly, standard evaluation metrics such as accuracy, precision, recall, F1-score, and the confusion matrix were used. While the full confusion matrix for 502 classes is visually impractical to include, a detailed per-class analysis revealed that most misclassifications occurred between signs with highly similar 3D motion trajectories or minimal structural differences. These metrics were computed on the test set after convergence to provide a holistic evaluation of system performance. Furthermore, the real-time processing capability was verified through latency testing on the previously specified hardware (Intel i7, 16GB RAM, RTX 3060), yielding an average inference time of approximately 35ms per gesture (median latency), which comfortably satisfies real-time interaction requirements. Overall, the findings demonstrate that the suggested framework provides a dependable, scalable, and instantaneous Arabic Sign Language recognition solution, which can greatly improve the deaf and hard-of-hearing community's accessibility to communication. Fig. 9 shows the total accuracy verses the validation accuracy.

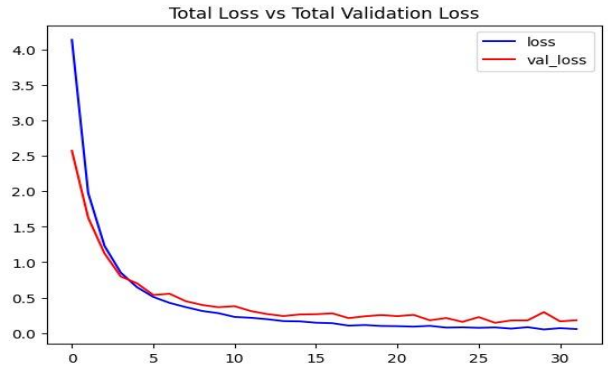

Fig. 9. Total accuracy vs. Validation accuracy.

The training accuracy (blue) increases rapidly over time, reflecting that the model is learning to recognize gestures in the training data. Similarly, the validation accuracy (red) rises, demonstrating that the model is generalizing well to unseen data. The close alignment of both curves towards 100% accuracy confirms that the model is performing well on both the training and validation datasets, without overfitting.

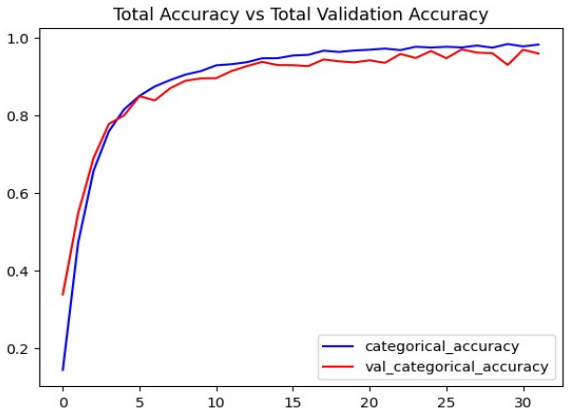

Fig. 10. Training loss and validation loss.

Both the training loss (blue) and validation loss (red) decrease steadily over the epochs, indicating that the model is improving and learning effectively. The training loss decreases faster at first, but both losses stabilize as the model reaches a point of convergence, suggesting good generalization without overfitting (Table II).

TABLE II. TRAINING AND TESTING PERFORMANCE METRICS OF THE PROPOSED LSTM MODEL

Training Metric	Value	Testing Metric	Value
Loss	0.048	Loss	0.185
Accuracy	98%	Accuracy	96%

IV. DISCUSSION

The outcomes and assessment of the ASL Recognition model suggest that it reached acceptable performance and confirmed that it can detect motions and change them into text and vocalization with significant efficiency. The proposed model should be highly praised because the use of graphs and tables enables us to have a much better look at the learning process of a model, how it is performing, how well it is generalizing, among others. Loss curves training and validation proved the model to have a strong capability to acquire necessary patterns in relation to training data. In the beginning, the loss values are quite high, but as training continues, the training and validation losses are reduced greatly and stay at a lower rate. This seems to suggest that the model is fine-tuning its accuracy of predictions with the training data set, as well as enhancing the accuracy of extrapolation on unknown validation data. The predominant signs of falling values for both losses, with their difference not increasing over time, assure us that overfitting is not occurring when the model excessively tunes into the training set and does not generalize well to the test set.

On the same note, the graphs of the training and validation accuracy support the model as well as the identification of ineffective neurons. The two accuracies rise steeply in the initial epochs, as is common, because the model is learning patterns of the data set. That training accuracy and validation accuracy are in sync and touch on the 100 percent mark indicates the model's ability to learn from data and generalize to unseen data sets. The direction of both curves also reinforces this idea because generally, overfitting means that the accuracy of the training rate keeps on rising as that of the validation rate plummets or at best stagnates.

The loss and accuracy matching between the training and validation set shows model generalization and is suggestive. In machine learning, overfitting is a widespread problem in which a model learns the training data set and does not generalize to other data sets. Fig. 10 above shows that no large gap exists between the training loss and validation loss, and the training accuracy and validation accuracy are almost identical, which demonstrates that the model has achieved superior performance on the issue of overfitting. This shows that the proposed model is able to generalize to new, unseen sign language gestures, and the elaboration of variability present both in gestures and signing style makes it robust for real-world applications.

V. CONCLUSION AND FUTURE WORK

Based on the outcomes, the proposed model appears well-suited to real-world sign language recognition and synthesis since the high accuracy of the trained and validation datasets is nearly identical. This research serves as a pilot study to demonstrate that capturing gestures of Arabic Sign Language in real time and translating them to texts and speech will presumably benefit the deaf and hard-of-hearing. The addition of Text-to-Speech (TTS), therefore, improves the existing system by allowing non-sign language users to more easily understand the gestures that have been recognized. This can then result in attaining equal and improved communication in areas involving accessibility to people with disabilities, like healthcare, education, and in customer services where communication with the hearing impaired is crucial.

This highlights the need for improvements to make even with the impressive performance of this model. While the 96% accuracy is high, future work will include signer-independent testing to ensure robustness. The weak link that can be identified is the fact that sign languages don't do well in mimicking the more complicated hand signs and complicated signs that demand things like facial expressions and body movements. These aspects of sign language are crucial for full comprehension but remain barely satisfactorily contained in popular sign language and therefore can be tough to register using current hand-tracking technologies. Using communication modes, such as visual (facial expressions, posture, etc.), the system design could enhance its ability to manage such elaborate gestures. Furthermore, expanding the training dataset to include more variations in sign language gestures, regional dialects, and environmental factors (e.g., different lighting or backgrounds) could enhance the model's robustness. Continuous user feedback and testing in real-world scenarios would also help fine-tune the system and ensure that it meets the needs of a diverse group of users.

VI. FUTURE WORK AND CONTRIBUTION

The Arabic Superformance Recognition system has been developed and evaluated, giving satisfactory performance; however, the following areas are open to further study. Further research may involve exploring advanced architectures like Transformers and Conformer models and extending the system to incorporate additional data modalities, including face pictures, head motion, and pose, that are important for accurately interpreting sign language. Increasing the type of signers, dialects, and conditions during data collection will improve the generalization ability of the proposed model across various conditions. Also, real-time processing speed and latency time reduction will enhance the system's effectiveness. The Research could also be extended to support the identification of multiple sign languages, for instance, American Sign Language (ASL), thus increasing its applicability.

Using AR or VR in the system would still be an added advantage, building on the aspect of communication. Interacting with users will enable the improvement of the system to incorporate different signing patterns, hence making it friendly to users.

Accessibility is an area improved by this Research, especially in the Arabic context, where little has been done to improve recognition of sign languages. When gesture recognition is integrated with text-to-speech, it helps in real-time communication between a sign language user and a normal language user. Bidirectional LSTM networks for gesture recognition are novel; this creates the basis for other improvements and brings a considerable influence on inclusive interaction. With some refinements, this technology can greatly improve the quality of life for the deaf and hard-of-hearing population by decreasing the time needed for sign translation for common exchanges.

A Multi-Layer Computational Framework for Predicting Student Performance Ranges in Higher Education Using Machine Learning

Abdellatif HARIF, Moulay Abdellah KASSIMI
Laboratory of Science of Information Technology Data-Mathematics and Applications National School of Applied Sciences, IBN ZOHR University, Agadir, Morocco

***Abstract*—Predicting student academic performance constitutes a strategic priority for higher education institutions seeking to reduce attainment gaps and provide timely, targeted support. Existing approaches predominantly generate single-point performance estimates, overlooking the inherent variability in individual academic trajectories. This paper introduces a novel seven-layer computational framework that predicts student performance as a bounded range, capturing both minimum and maximum expected outcomes rather than as a solitary value. The framework integrates a bespoke imbalanced-data mitigation algorithm, three heuristic feature-selection methods: Genetic Algorithm, Particle Swarm Optimization, and Recursive Feature Elimination, and two complementary model architectures: a Parallel Architecture built upon fourteen supervised learning classifiers, and a Popularity Architecture centered on K-Modes/K-Prototype unsupervised clustering. The framework was validated on a rich, anonymized dataset provided by IBN ZOHR University in Morocco, comprising records from over 200,055 undergraduate students. The proposed framework achieves accuracy of 84%/86% (worst/common-case scenario), representing a 3%/5% improvement over an 81% baseline derived from the ten most relevant prior studies. The unsupervised Popularity Architecture attained peak accuracy of 96.91%, outperforming all supervised configurations. Results further demonstrate that omitting feature selection frequently yields competitive performance, and that increasing the number of hidden layers in neural networks does not significantly alter predictive accuracy in this educational context. The framework is designed for seamless integration into existing student performance dashboard systems, offering the institutions an actionable decision-support tool.**

Keywords*—Student performance prediction; machine learning; unsupervised learning; performance range; higher education; educational data mining; feature selection

I. Introduction

Monitoring and predicting academic performance have become a cornerstone of institutional strategy in higher education. Proactively identifying students who are at risk of underperforming, or conversely those likely to excel, enables universities to deploy targeted support mechanisms, optimize resource allocation, and reduce systemic attainment disparities. With the proliferation of administrative student information systems, educational institutions now accumulate rich repositories of longitudinal data that span demographic profiles, enrollment characteristics, attendance records, and progression trajectories. These repositories present a compelling opportunity to develop data-driven decision support tools grounded in machine learning (ML).

Research at the intersection of Artificial Intelligence (AI) and Education has been active since the early 1990s, when logistic regression models were first applied to predict graduate retention [1]. Over the subsequent three decades, the field expanded to encompass a broad repertoire of supervised learning algorithms—Random Forest, Support Vector Machines, Naive Bayes, K-Nearest Neighbors, and Gradient Boosting variants—alongside deep architectures such as Feed Forward Neural Networks (FFNNs) [2], [3], [4]. Despite this proliferation, two structural limitations persist across the literature.

First, virtually all published studies produce predictions as singular values—either a numerical score or a discrete classification label—thereby ignoring the natural performance variability that students exhibit across assessments, life circumstances, and academic cycles. A student's academic trajectory is rarely deterministic; financial pressures, health events, and personal commitments introduce stochastic fluctuations that a point estimate cannot capture. Second, the issue of class imbalance in educational datasets, most pronounced in demographic variables, remains inadequately addressed leaving predictive models susceptible to biased outcomes that favor the majority class [5].

This paper addresses both constraints through a comprehensive and reproducible computational framework. Its main novelty lies in predicting academic performance as a defined range, expressed as lower and upper values of the consistency scale, rather than a single predicted score. This range reveals the limits of a student's potential academic ability under varying conditions, providing more accurate and practically useful outputs for decision-makers in educational institutions.

This framework also contributes and allowing: First, a native, proven data training algorithm to reduce the likelihood of data imbalance and associated overshoot risks; Second, a popular architecture that incorporates unsupervised clustering as a preliminary step to performance prediction, an approach that has not been widely explored in the literature; Third, a systematic comparison of eight feedforward neural network architectures with varying depths of hidden layers; Fourth, an in-depth multi-method data analysis layer that includes principal

component analysis (PCA), Multiple Correspondence Analysis (MCA), factor analysis of mixed data (FAMD), and statistical hypothesis testing; and a custom-designed scaling-of-validity measure compatible with scaling-value predictions.

The remainder of this article is divided as follows: Section II reviews the existing literature and places it in its critical context. Section III presents the proposed computational framework, and Section IV describes experimental verification. Section V presents and discusses the results, and Section VI concludes with a summary of the contributions and guidelines for future research.

II. Literature Review

A. Scope and Methodology

A systematic literature review was conducted to map published research on predicting student performance using artificial intelligence. Before examining each study individually, several comprehensive meta-analyses were consulted to gain a broader understanding of the field. Notably, Juho Hellas et al. [6] synthesized 357 studies published between 2010 and 2018, while Faisal Alwarthan et al. [5] analyzed 44 studies covering the period from 2010 to 2022. Similarly, Muhammad Chaudhry and Muhammad Kazim [7] reviewed 85 studies published between 2011 and 2021, and Virginia Dignum [8] examined 35 works spanning from 2000 to 2020.

More recent contributions have further expanded this body of knowledge. In particular, Batool et al. [9] surveyed approximately 260 studies published between 2000 and 2022, providing one of the most comprehensive overviews to date. In addition, Alnasyan et al. [10] focused specifically on deep learning approaches, reviewing 46 studies published between 2019 and 2023.

The primary literature search was conducted through Google Scholar, IEEE Xplore, ScienceDirect, arXiv, and ResearchGate, applying conjunctive keyword combinations such as 'predict student performance AND Supervised Learning', 'academic prediction AND Neural Networks', and 'student dropout AND Machine Learning'. Papers were included if they were in English, reported sufficient methodological detail for reproducibility, explicitly addressed performance prediction with AI methods, and had received at least one citation.

Together, these reviews form the baseline against which the present work is positioned.

B. Supervised Learning Approaches

1) Regression and logistic regression: Regression-based models constitute one of the earliest and most persistent branches of this literature. Pyke and Sheridan [1] demonstrated that logistic regression could predict graduate student retention with accuracy in the range of 77%–88%, drawing on demographic and funding variables. Yang et al. [11] showed that combining multiple linear regression with pca-based dimensionality reduction yielded a 50% improvement in predictive error compared to regression alone, attributable to the removal of multicollinear features. Pereira [12] enriched this paradigm by pairing linear regression with FAMD, achieving accuracy of approximately 78% on a 1,044 student Portuguese secondary school dataset. These works collectively suggest that dimensionality reduction is a valuable complement to regression when datasets contain predominantly qualitative variables.

Also, several studies focus on specific institutional examination contexts. Utzman, Riddle, and Jewell [13] applied logistic regression to predict performance on the National Physical Therapy Examination, finding that prior academic qualifications, race, and ethnicity were the most informative predictors, though without evidence of a direct causal relationship. Jaber et al. [14] explored the predictive power of weekly quizzes for medical students' shelf exam performance, confirming that later-week assessments are stronger predictors than earlier ones.

2) Ensemble and other supervised learning models: Ensemble methods—particularly random forest and its variants—have emerged as dominant performers in educational prediction. Adekitan and Noma-Osaghae [2] demonstrated their superiority over classical models on first-year engineering student data. Mengash [15] integrated random forest and decision tree classifiers within a multi-state university admissions framework, reporting accuracy rates consistent with institutional requirements. Authors in [16] compared four classifiers (Naive Bayes, Decision Tree, Random Forest, SVM) and found ensemble methods most stable across cross-validation folds.

Gradient Boosting variants remain underexplored in this specific domain, with only a handful of studies applying XGBoost [17] and fewer applying Extra Trees. This gap motivates the broader model comparison conducted in the present study. Notably, [3] is one of the few studies applying seven different classifiers in a single experiment, achieving accuracy of 71%–82%—the largest model comparison identified in the literature prior to this work.

3) Feed forward neural networks: FFNN-based approaches have attracted growing attention, particularly for their capacity to detect non-linear relationships in high-dimensional data. Bilal et al. [18] demonstrated that a single-hidden-layer network trained on enrollment data achieves accuracy exceeding 90%. The author in [19] reported 95% accuracy using a four-variable ANN on moodle learning management data, though the small dataset (n = 265) raises generalization concerns. waheed et al. [4] applied deep neural networks to Open University Learning Analytics data, achieving improved accuracy compared to shallower architectures, it was one of the rare studies using more than two hidden layers.

Despite these successes, literature consistently employs a single FFNN architecture per study, typically with one or two hidden layers and an arbitrarily chosen node count. Whether additional hidden layers systematically improve accuracy in the educational prediction context remains an open question that the present study explicitly investigates.

C. Unsupervised Learning

The application of unsupervised learning to student performance prediction is exceedingly rare. Alwarthan et al. [5] identified only one study employing clustering as part of a prediction pipeline. Ding et al. [20] employed unsupervised feature learning within an MOOC prediction context, demonstrating that unsupervised representations improved the downstream supervised classifier. The present work extends this precedent by proposing a fully articulated Popularity Architecture in which clustering directly produces the performance-range prediction, by passing the need for labelled training targets during the prediction phase.

Several additional gaps are evident from the reviewed literature. Imbalanced data is acknowledged as a problem but rarely addressed with purpose-designed algorithms—most studies either ignore it or apply generic dimensionality reduction. In-depth statistical data analysis is largely absent; most papers report only basic descriptive statistics and correlation matrices. Finally, the output format invariably takes the form of a single value, leaving the inherent performance variability of students unmodelled.

D. Summary and Research Gaps

The reviewed literature reveals five principal gaps that the present work addresses. First, there is a predominance of single-value performance predictions that ignore performance variability. Second, there is insufficient treatment of imbalanced data. Third, the limited use of unsupervised learning. Fourth, shallow data analysis layers that fail to expose dataset strengths and weaknesses. Fifth is the absence of systematic FFNN architecture comparisons within a single experiment. Table I provides a comparative overview of the studies most closely related to the proposed framework.

TABLE I. COMPARATIVE OVERVIEW OF CLOSELY RELATED STUDIES. SL = SUPERVISED LEARNING ; NN = NEURAL NETWORK; UL = UNSUPERVISED LEARNING

Study	Algorithms	Number of Models	Output Format	Imbalance Addressed

Proposed Framework	**SL + NN + UL**	**18+**	**Range**	**Yes**

III. COMPUTATIONAL FRAMEWORK

The proposed computational framework is organized as a sequential pipeline of seven layers, each with a defined input specification, processing function, and output contract. The layers are executed in strict chronological order to ensure that downstream components receive validated, properly formatted inputs. Fig. 1 schematizes the full pipeline. The following subsections describe each layer in detail.

A. Data Pre-Processing and Exploratory Analysis

Raw educational datasets are typically stored at the module level, with multiple rows per student. This layer restructures the data into a single student-centric representation through five operations: 1) grouping records by student identifier, averaging quantitative variables, and retaining the first-occurrence value for qualitative ones; 2) removing incomplete rows to avoid imputation bias; 3) discarding variables that become uninformative after aggregation; 4) engineering four features: student age, number of modules completed, geographic distance to the faculty, and the Consistency-Scale, a discretized grade metric mapped to a 0–1 ordinal scale in 0.1 increments; finally 5) retaining only the descriptive version of duplicated variable definitions. Once pre-processing is complete, an exploratory analysis is conducted to assess dataset quality, variable distributions, and inter-variable relationships. The protocol applies frequency distributions and descriptive statistics for qualitative and quantitative variables respectively, alongside Pearson correlation matrices, normality tests, dimensionality reduction, and stratified analyses by performance group.

B. Prediction Pre-Processing

The second layer configures the data for machine learning. Three transformations are applied: 1) selection of the target student subgroup—in the present experiments, only graduate students who completed their degree program are retained, and only enrollment-stage variables are included, reflecting the intention to support early prediction at the point of admission; 2) label encoding of all qualitative variables to convert categorical attributes into integer-valued identifiers. Finally, 3) Z-score normalization of quantitative variables and ordinal scaling of qualitative variables to equalize feature magnitudes and improve model convergence speed.

C. Feature Selection

The third layer explores which subsets of input features are most informative for predicting the Consistency-Scale target. Three meta-heuristic feature-selection algorithms are applied independently: 1) the Genetic Algorithm (GA), which evolves a population of candidate feature subsets over multiple generations, selecting subsets that maximize a cross-validated accuracy fitness function; 2) Particle Swarm Optimization (PSO), which positions 50 particles in feature-space, each representing a candidate subset, and iteratively refines their positions by learning from the globally best-performing particle; and 3) Recursive Feature Elimination (RFE), which fits a logistic regression model, ranks features by coefficient magnitude, and iteratively discards the lowest-ranked feature until a minimum subset size is reached. A fourth experimental condition retains all features without selection, serving as a baseline. For each algorithm, the internal evaluation model is

logistic regression, and a 5-fold cross-validation scheme is applied.

D. Training/Testing Split

The fourth layer in our framework, partitions the student-level dataset D into a training D_train (80%) and a test set D_test (20%). Data is randomly shuffled prior to splitting to prevent ordering artefacts. The 80:20 ratio was selected as a standard practice that provides sufficient data for model training while retaining an adequate holdout for unbiased evaluation.

E. Anchored Training Data

As illustrated in Fig. 2, the fifth layer addresses the problem of imbalanced class distributions in educational data by identifying an optimal training sample size. The Anchored Training Data method(ADT), formally described in Algorithm 1, operates as follows: D_train is divided into five equal-sized segments s_1, …, s_5. In iteration i (i = 1, …, 5), the concatenation of segments s_1 through s_i forms a temporary training set D_s, which is further split 80:20 and used to train a logistic regression classifier. The segment count whose corresponding accuracy benchmark is highest is selected as the optimal training size. This progressive segment accumulation mirrors the intuition of walk-forward validation while specifically targeting the imbalance reduction property: a smaller, more carefully selected training partition tends to exhibit more balanced class ratios than the full dataset, thereby reducing overfitting risk.

Algorithm 1: Anchored Training Data (ATD)

Input: Training sample set D_train (shuffled); S = 5 segments
1: Initialize the full segment set S = {s1, s2, …, s5} by randomly partitioning D_train into 5 equal-sized disjoint segments
2: Initialize best_acc ← 0 ; best_i ← 1
3: Specify n_folds = 5 for the internal cross-validation split
4: While i ⩽ S do
5: For (each accumulated subset) do
6: D_s ← concatenate(s1, s2, ⋯, si) // Progressive accumulation
7: Randomly split D_s into D_s_train (80%) and D_s_val (20%)
8: Train logistic regression M_i on D_s_train
9: Perform ValidRangeAccuracy(M_i, D_s_val) → acc_i
10: Rank acc_i and compare against best_acc
11: If (acc_i > best_acc) then
12: best_acc ← acc_i
13: best_i ← i
14: End If
15: End For
16: i ← i + 1
17: End While
18: D_optimal ← concatenate(s1, ⋯, s{best_i}) using the segment count with best_acc
19: Output D_optimal as the selected training subset for downstream model training

F. Model Architectures

The sixth layer implements predictions using two complementary architectures.

1) Parallel architecture (supervised learning): The Parallel Architecture employs supervised classifiers to predict the minimum and maximum Consistency-Scale values independently for each student in D_test. Sixteen classifiers are applied: Random Forest (RFC), Adaboost (ADAC), K-Nearest Neighbours (KNNC), Gradient Boost (GBC), Gaussian Process (GPC), Passive Aggressive (PAC), Extra Trees (ETC), Extreme Gradient Boost (XGBC), and eight FFNN configurations crossing four depth levels (1, 3, 5, 10 hidden layers) with two node counts (4, 8 nodes per layer). each classifier is trained separately on the minimum and maximum consistency-scale targets, yielding two predictions per student that together constitute the predicted performance range.

2) Popularity architecture (unsupervised learning): The Popularity Architecture replaces direct supervised prediction with a cluster-based inference mechanism, in which unsupervised grouping of enrollment profiles substitutes for labelled target learning. The generalization process operates in two phases. The optimal number of clusters k is first determined using the Davies–Bouldin index, preferred over the Calinski–Harabasz score for its compatibility with non-euclidean settings and qualitative variables. The K-Modes model (purely qualitative features) or K-Prototype (mixed features) is then fitted on D_train, producing k centroids. for each cluster, Consistency-scale values with frequencies above the cluster median are designated as popular, and their minimum and maximum define the cluster-specific bounds [C_min_k, C_max_k]. during inference, each student in D_test is assigned to the cluster whose centroid minimizes the cao dissimilarity, a distance measure compatible with both qualitative and quantitative features. The corresponding bounds [C_min_k, C_max_k] are returned as the predicted performance interval. this inductive mechanism requires no target labels at test time: predictions derive entirely from the training clusters' popularity distributions, while the learned centroids serve as stable reference points for assigning new observations.

G. Valid Range Benchmark

Since the proposed framework produces interval-valued predictions rather than point estimates, standard classification metrics (accuracy, F1, AUC) and regression metrics (MAE, MSE) are not directly applicable. A custom metric — the Valid Range — is therefore introduced. A prediction is classified as correct if and only if the student's true average Consistency-Scale value (C_avg) falls within the predicted interval [C_min, C_max], and the aggregate Valid Range Accuracy is computed as follows:

Valid Range Accuracy = (Number of Correct Predictions / Total Predictions) × 100%.

To address the concern that wide prediction intervals may artificially inflate Valid Range Accuracy, two complementary measures are reported alongside each architecture's coverage score. First, the mean predicted interval width W = mean(C_max − C_min) quantifies interval informativeness: narrower intervals at high coverage indicate stronger predictive specificity. Second, a Midpoint Mean Absolute Error (M-MAE) — defined as the mean absolute difference between the interval midpoint (C_min + C_max)/2 and the true C_avg — provides a scalar error measure compatible with standard regression benchmarks. A

coverage-width efficiency score E = Coverage / W is additionally reported, where higher values reflect better accuracy per unit of interval width. Together, these measures form a comprehensive evaluation protocol for interval-valued predictions.

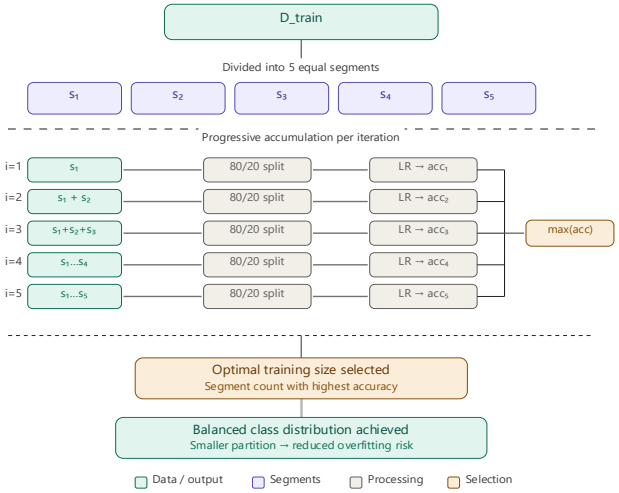

Fig. 2. Anchored training data method: progressive segment accumulation for optimal training size selection.

IV. Experimental Validation

A. Dataset Description

The dataset was provided by Ibn Zohr University of Morocco and covers academic records from 2019 to 2025. It comprises 200,055 records drawn from two institutional sources: a pre-registration platform capturing student-declared information at enrollment — including age, gender, region of residence, and socioeconomic background — and an academic management system centralizing module-level results across each semester and academic year. All records were anonymized prior to use, with no personally identifiable information retained, in compliance with Moroccan data protection legislation.

Table II describes the full variable set. The dataset is mixed-type, containing nominal, ordinal, discrete, and continuous variables. This heterogeneity directly shaped key design decisions in the framework — most notably the adoption of K-Prototype clustering, which is specifically suited to datasets combining qualitative and quantitative inputs.

B. Data Analysis Findings

The data analysis layer revealed several educationally significant patterns. Quantitative analysis using Pearson's correlation coefficient, as shown in Fig. 3, demonstrated moderate positive correlations between module score and Presence Rate (r = 0.388), and between module score and Presence Duration (r = 0.038), indicating that punctuality is associated with better performance. Geographic proximity to the university institution (Lodging distance) also showed a weak but positive correlation with scores, consistent with previous findings on the relationship between proximity and academic results [27].

Fig. 3. Pearson Correlation Matrix of Quantitative Variables

C. Feature Selection Results

Table III summarizes the features selected by each algorithm. Lives Environment, Parents Relationship, and Student with certificates were each selected by all three algorithms, reflecting their consistent predictive relevance. Home Distance was selected by the GA but not PSO or RFE, while Module Score was selected by RFE alone indicating some

divergence in the features prioritized by each method. The 'no feature selection' condition retains all thirteen candidate features and serves as an important comparison point. This condition frequently produced competitive or superior accuracy, consistent with the theory that feature selection provides the greatest benefit when many uninformative features dilute the signal [28].

TABLE II. OUR DATASET VARIABLE DESCRIPTIONS

Column	Description	Format	Attributes	Type
Student code	The student's unique code.	String	200,055	Nominal
Gender	The student's gender.	String	2	Nominal
Age Enrollment	The student's age at the time of enrollment.	Integer	$17 \leq x \leq 65$	Discrete
Lives Environment	Type of lives environment	String	3	Nominal
Limited mobility	If student is Disabled	string	2	Nominal
Parents Relationship	relationship of student's parent	Integer	2	Ordinal
Student with certificates	Students have other certificates	Integer	3	Ordinal
Socioeconomic Class	Student's Profession	String	2	Ordinal
Mother's Profession	Mother's educational level	String	3	Ordinal
Father profession	father's educational level	String	3	Ordinal
Mother Profession	mother's Profession	String	7	Ordinal
Father Profession	Father's Profession	String	7	Ordinal
Home region	The student's home region.	String	4	Nominal
Travel Type	The student's method of traveling to the institution.	String	3	Nominal
Accommodation	The student's study term residence name.	String	8	Nominal
Lodging Distance	The student's accommodation KM distance to the university.	Float	$0 \leq x \leq 300$	Continuous
Home Distance	The student's home KM distance to the university.	Float	$0 \leq x \leq 1500$	Continuous
Academic Years	The student's total number of years of study.	String	4	Ordinal
Status	The student's current academic circumstance.	String	15	Nominal
Specialty chosen	specialty chosen	String	3	Nominal
Faculty name	The faculty the student studied.	String	7	Nominal
Baccalaureate Type	Baccalaureate Type	String	3	Ordinal
Modules (Amount)	The student's total number of modules completed.	Integer	$1 \leq x \leq 42$	Discrete
Module Score	The student's average module grade (%).	Float	$0 \leq x \leq 100$	Continuous
Graduate Grade	The student's final classification grade.	String	4	Ordinal
Standard Grade	Whether the student's average module grade is $\geq 60\%$.	Integer	2	Ordinal
Consistency-Scale	The student's performance scale (min, average & max versions).	Float	10	Ordinal
Course Presence Rate	The student's average attendance rate.	Float	$0 \leq x \leq 1$	Continuous
Lesson presence duration	The student's average presence time per scheduled lesson.	Float	$-29 \leq x \leq 263$	Continuous

D. Model Configuration

For Parallel Architecture, classifiers were configured with standard hyperparameters appropriate for multi-class classification. Random Forest used 30 trees with Gini criterion; Gradient Boost used 100 boosting stages with a learning rate of 0.1; Extreme Gradient Boost used 1,000 iterations, a maximum depth of 5, L1 regularization of 0.3, and L2 of 0.5; K-Nearest Neighbors used k = 5 with Euclidean distance; all eight FFNN variants used 1,000-sample batches and 300 training epochs with a single output node. For Popularity Architecture, the K-Modes/K-Prototype model used 100 iterations with the Cao initialization method; the optimal cluster count was determined separately for each feature-selection condition using the Davies-Bouldin index. Table IV illustrates the configuration used.

TABLE IV. OPTIMAL CLUSTER CONFIGURATIONS FOR THE POPULARITY ARCHITECTURE

Feature Selection	Optimal Clusters (k)	Davies-Bouldin Score
Genetic Algorithm	11	24.77
Particle Swarm Optimisation	5	14.27
Recursive Feature Elimination	7	17.59
No Feature Selection	5	12.48

V. RESULTS AND DISCUSSION

A. Baseline and Comparative Framework

Comparing our results directly against prior work is not straightforward, since the proposed framework predicts performance as a range rather than a single value. We therefore base the comparison on accuracy figures reported under comparable experimental conditions, which is a common and accepted approach in educational data mining benchmarking.

The ten studies forming our baseline were not selected arbitrarily. We applied three filtering criteria: the study had to focus specifically on predicting student academic performance using supervised or neural network methods; it had to report classification accuracy on a proper held-out test set, not merely on cross-validated folds; and it had to use administrative student data from an undergraduate or graduate institutional context. Studies that did not meet all three criteria were excluded.

For each retained study [2,3,15,18,19,21,22,23,29,30], we took the single best accuracy value reported. When a study presented results across multiple configurations, we selected the highest-performing one — reflecting the standard convention of comparing a new framework against the strongest available prior result, not an average one. Across the ten studies, reported accuracy values range from 70% to 90%, yielding a mean baseline of 81% with a standard deviation of ±5.4 percentage points [31].

B. Parallel Architecture: Supervised Learning Results

Fig. 4 summarizes Valid Range accuracy for the eight traditional supervised classifiers across four feature-selection conditions. Random Forest consistently achieved the highest accuracy (93.01%–93.51%), followed closely by Extra Trees (91.52%–92.75%) and Gaussian Process (88.17%–90.31%). The no-feature-selection condition marginally outperformed the three feature-selection conditions for most classifiers, with RFC reaching its peak of 93.51% without feature selection—supporting the general observation that well-curated datasets benefit less from feature pruning.

Extreme Gradient Boost performed anomalously poorly (30.84%–46.66%), an outcome attributed to the predominantly qualitative nature of the dataset and its susceptibility to noise-induced overfitting in this configuration. Excluding XGBC, the average accuracy across all classifiers and feature-selection conditions is approximately 85%, representing a 4% improvement over the baseline. Including XGBC, the average drops to approximately 80%, marginally below baseline—reflecting the distorting influence of a single poorly suited algorithm. This behavior is consistent with Abdulla et al.[28], who noted that qualitative-variable-heavy problems can impair algorithms whose regularization mechanisms assume a quantitative feature structure.

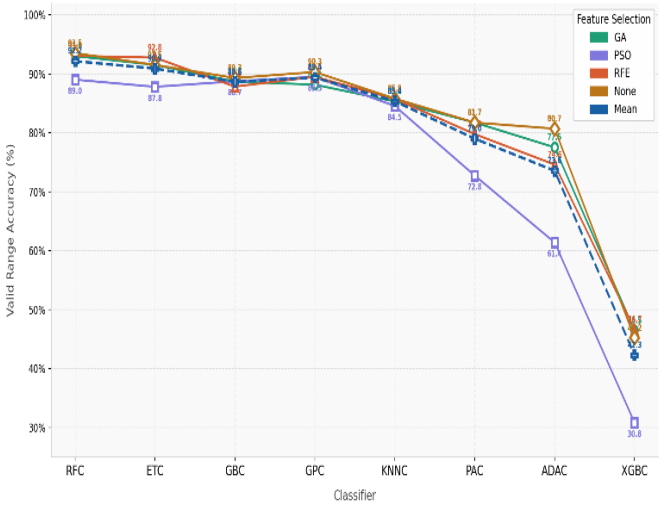

Fig. 4. Valid Range accuracy (%) for supervised classifiers in parallel architecture, by feature-selection condition.

C. Parallel Architecture: Feed Forward Neural Network Results

Fig. 5 reports accuracy for the eight FFNN configurations. PSO-selected features yielded the highest mean accuracy for neural networks (89.20%), followed by no feature selection (86.84%), RFE (87.07%), and GA (86.14%). Peak accuracy of 93.68% was achieved by the NN18 (1 hidden layer, 8 nodes) architecture under PSO feature selection.

Critically, no systematic improvement was observed as the number of hidden layers increased from 1 to 10. The accuracy difference across all FFNN models was approximately 22%, but this variation was attributable to the feature-selection condition rather than network depth. When the worst-performing outlier (NN14 under no feature selection, 72.08%) is excluded as an artefact of a suboptimal node-count and weight initializations combination, the inter-architecture range narrows to approximately 12%. These findings are consistent with prior observations that deeper architectures do not inherently outperform shallower ones in educational datasets of this scale and suggest that the noise level and qualitative composition of the data limit the utility of additional hidden layers [32]. The

overall FFNN mean accuracy of 87% represents a 6% improvement over the baseline.

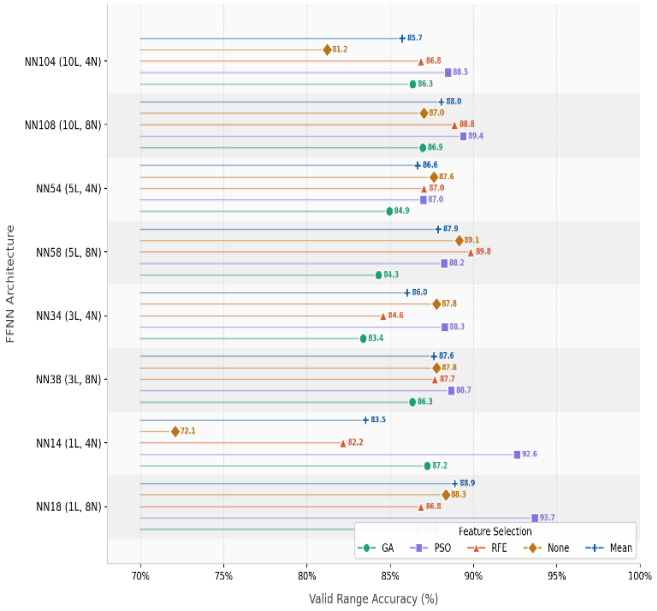

Fig. 5. Valid Range accuracy (%) for FFNN configurations in the Parallel Architecture. L = Hidden Layers; N = Nodes per Layer.

D. Popularity Architecture: Unsupervised Learning Results

The Popularity Architecture — which integrates K-Modes/K-Prototype clustering as the predictive mechanism — achieved the highest coverage across all experimental conditions, as shown in Table V. The no-feature-selection condition produced the best coverage at 96.91%, followed by GA at 95.87%, PSO at 94.10%, and RFE at 92.64%. The coverage range across conditions is narrow (approximately 4%), suggesting that the clustering-based approach is relatively insensitive to the specific feature subset employed — a practically significant property, as it implies that the Popularity Architecture can be deployed without the computational overhead of feature selection.

However, coverage alone does not fully characterize predictive quality. The mean interval width W reveals that the no-feature-selection condition, despite its highest coverage, produces the widest intervals (W = 0.28), shared with PSO. The GA condition, by contrast, achieves a coverage-width efficiency score E = 4.79 — the highest across all configurations — by combining competitive coverage (95.87%) with the narrowest intervals (W = 0.20), a result attributable to the finer cluster granularity of k = 11 compared to k = 5 for the no-selection condition. The M-MAE values (0.040–0.059) confirm that interval midpoints remain close to the true C_avg across all conditions, providing a scalar error measure consistent with standard regression benchmarks.

TABLE V. SUMMARY OF PEAK VALID RANGE ACCURACY RESULTS ACROSS ALL ARCHITECTURES, COMPARED TO THE LITERATURE BASELINE

Architecture	Feature Selection	k (clusters)	Coverage (%)	W (mean width)	M-MAE	Max W (scale)	E = Coverage/W	Diff. vs Baseline (%)
Popularity (UL)	None	5	96.91	0.28	0.053	0.90	3.46	+15.91
Popularity (UL)	GA	11	95.87	0.20	0.040	0.90	4.79	+14.87
Popularity (UL)	PSO	5	94.10	0.28	0.058	0.90	3.36	+13.10
Popularity (UL)	RFE	7	92.64	0.24	0.053	0.90	3.86	+11.64
Parallel (RFC)	None	—	93.51	0.28	0.059	0.90	3.34	+12.51
Parallel (NN18)	PSO	—	93.68	0.26	0.055	0.90	3.60	+12.68
Literature Baseline	—	—	81.00	—	—	—	—	—

The 14%–16% improvement over the supervised baseline warrants careful interpretation. Popularity Architecture benefits from a distinct information structure: rather than learning a mapping from target labels, it groups students by the similarity of their enrollment characteristics and inherits performance bounds from the cluster. This approach is particularly well-suited to the present dataset, where demographic and socioeconomic characteristics appear more informative for group-level stratification than for individual-level regression. The finding is broadly consistent with work by Ding et al. [20], who showed that unsupervised feature representations can boost downstream prediction performance in MOOCs.

E. Overall Analysis and Framework Robustness

Considered holistically, and excluding the anomalous XGBC results, the framework achieves an average accuracy of approximately 86% (range 61%–97%), representing a 5% mean improvement over the 81% baseline (Table V). Including XGBC, the mean drops to 84% (a 3% improvement), with a worst-case accuracy of 31%, reflecting the unsuitability of that specific algorithm for this dataset rather than a systemic weakness of the framework. In both scenarios, the upper-bound accuracy (97%) substantially exceeds the top-end of the baseline range (90%), confirming that the framework can produce state-of-the-art performance even in its worst-case-excluded form.

The robustness of the framework is attributable to the systematic design of its constituent layers. The Anchored Training Data layer reduced training set size from the full 9,300 observations to as few as 3,520 in some conditions, indicating that the algorithm identified smaller, more balanced subsets as preferable training configurations. The in-depth data analysis layer identified key dataset weaknesses—particularly the Lives Environment imbalance and the low dimensionality-reduction fidelity—which informed the decision to restrict the experiment to graduate students with complete enrollment data, thereby maximizing data quality. The multi-algorithm feature selection layer provided evidence that the dataset's predictive power is

broadly distributed across its features, explaining why the no-feature-selection condition frequently performed best (Table V, rows 1 and 5).

To evaluate whether the observed accuracy differences between feature-selection conditions are statistically significant, Wilcoxon signed-rank tests were conducted for each pairwise comparison (No-FS vs GA, No-FS vs PSO, No-FS vs RFE) across the Valid Range accuracy scores of all classifiers. In no comparison did the test yield a statistically significant difference (all $p > 0.05$), confirming that the accuracy differences between feature-selection conditions are not reliably distinguishable from random variation. This finding is consistent with the hypothesis that when features are broadly informative (as in the present dataset), the marginal gain from pruning uninformative variables is insufficient to produce measurable performance improvements [28]. Importantly, the inclusion of three feature-selection paradigms in the framework is not motivated by accuracy improvement claims, but by the methodological goal of systematic cross-paradigm comparison — a contribution that is itself novel in the educational data mining literature, where single-method feature selection remains the norm.

The finding that FFNN depth does not improve accuracy in this context is educationally and technically informative. It implies that the non-linear complexity of the student-performance prediction problem does not exceed what a single-layer network can approximate, given the variable types and sample size involved. This finding discourages unnecessary model complexity in similar institutional settings and provides a principled justification for preferring shallower, faster-training architectures in practice.

VI. Conclusion

This paper presented a novel seven-layer computational framework for predicting student performance ranges in higher education. The framework addresses five identified gaps in the existing literature: the absence of range-valued predictions, insufficient treatment of imbalanced data, limited application of unsupervised learning, shallow data analysis practices, and the lack of systematic neural network architecture comparisons. Validated on a rich dataset of over 200,055 graduate records from the Ibn Zohr University of Morocco, the framework achieved Valid Range accuracy of 84%/86% (worst/common case) with a 3%/5% improvement over a literature baseline of 81%. The unsupervised Popularity Architecture attained peak accuracy of 96.91%, the highest reported in this experimental context.

Five concrete contributions emerge from this work. First, the performance range output format provides a more realistic representation of student academic capability, explicitly acknowledging the influence of life circumstances on grade variability. Second, the Anchored Training Data algorithm offers a practical, computationally inexpensive method for reducing imbalanced data effects without requiring complex oversampling strategies. Third, the Popularity Architecture demonstrates that K-Modes/K-Prototype clustering can function as a direct predictive mechanism for academic performance, opening a new methodological direction in educational data mining. Fourth, the eight-FFNN comparison provides empirical evidence that increasing hidden-layer depth does not improve predictive accuracy in this context, informing future model design choices. Fifth, the comprehensive data analysis layer exposes dataset properties—including socioeconomic attainment gradients and the limitations of dimensionality reduction—that have practical implications for institutional policy.

Several directions merit future investigation. Replicating the framework on datasets from multiple institutions would strengthen external validity and enable cross-institutional comparisons. Enriching the feature space with health, financial, and detailed parental variables could expose additional predictive signals, subject to ethical and legal data-governance constraints. Extending the imbalance-mitigation layer with rule-based sampling architecture, and exploring additional clustering algorithms in the Popularity Architecture, represent tractable methodological improvements. Finally, packaging the framework as an API-accessible microservice would facilitate integration with existing student performance dashboard systems, realizing its practical impact for institutional decision-making.

Department of Finance, Banking and Insurance, Yozgat Bozok University, Yozgat, 66300, Türkiye [2]

***Abstract*—The Internet, as a product of advanced technological development, has evolved through a dynamic and synergistic process. However, its original architecture was not designed to accommodate such unprecedented growth, resulting in fundamental limitations, particularly in the addressing architecture. The exhaustion of the IPv4 address space has emerged as a major sustainability problem for the Internet. To overcome this limitation, Internet Protocol version 6 (IPv6), which provides a significantly larger address space and additional technical capabilities, was standardized by the Internet Engineering Task Force (IETF) in 1998. Despite its technical superiority, IPv4—standardized in 1981—continues to dominate operational networks, indicating that IPv6 adoption has not yet reached expected levels. This study examines the factors influencing IPv6 adoption in public institutions using the Unified Theory of Acceptance and Use of Technology (UTAUT) framework. Survey data were collected from 456 managerial and technical personnel employed in public institutions in Türkiye. Structural Equation Modeling (SEM) was conducted using SPSS and AMOS software. The findings reveal that facilitating conditions significantly affect both effort expectancy and performance expectancy. Furthermore, effort expectancy and performance expectancy positively influence behavioral intention, which in turn has a direct effect on actual IPv6 usage. These results emphasize the critical role of organizational and structural factors in accelerating IPv6 transition within the public sector. The findings further demonstrate that next-generation network deployment represents not only an engineering challenge but also a socio-technical transformation process shaped by human and organizational factors.**

I. Introduction

Digital transformation has become a central priority in modern public administration, requiring not only advanced digital services but also a robust, scalable, and sustainable network infrastructure [1], [2]. At the core of this infrastructure lies the Internet Protocol (IP), which enables global connectivity and underpins all digital communication [3]. Following the near-total depletion of IPv4 address pools at global and regional levels, the transition to IPv6 has evolved from a technical upgrade into a strategic necessity for supporting long-term digital growth [4], [5]. Emerging technologies such as 5G, the Internet of Things (IoT), and smart city applications increasingly depend on the scalability and architectural flexibility offered by IPv6-based networks [6]. Despite the well-documented technical advantages of IPv6, including an almost limitless address space, enhanced security mechanisms, and simplified network management, its global adoption remains inconsistent [7]. This disparity, often termed the IPv6 adoption paradox in the mature adoption [9]. This persistent gap suggests that the barriers to IPv6 transition are not purely technical but are strongly associated with organizational and behavioral factors. Accordingly, large-scale IPv6 deployment should be understood not merely as a networking upgrade, but as a digital infrastructure transformation process requiring both engineering readiness and institutional preparedness. The existing literature on IPv6 has predominantly focused on protocol specifications, performance comparisons, and technical transition mechanisms such as dual-stack and tunneling [10], [11]. While these studies provide valuable engineering insights, they offer limited explanations for why technically mature solutions encounter resistance during organizational implementation. In particular, empirical research addressing the socio-technical dimensions of IPv6 transition—especially from the perspective of IT professionals responsible for planning, deployment, and maintenance in public institutions remains limited. Addressing these behavioral and perceptual barriers is, therefore, critical to understanding the human dimension of digital infrastructure transformation. To address this gap, this study employs the Unified Theory of Acceptance and Use of Technology (UTAUT) framework to examine the determinants of IPv6 adoption in public institutions. Recognizing that infrastructure technologies differ fundamentally from voluntary, user-facing information systems, the UTAUT model is adapted to reflect the institutional context of public-sector infrastructure transitions. Specifically, the model emphasizes facilitating conditions as an antecedent shaping internal cognitive perception—namely, effort expectancy and performance expectancy—while excluding social influence, given the mandatory and policy-driven nature of technology adoption in public organizations. This approach allows infrastructure transition to be analyzed as a socio-technical adoption process rather than a purely technical deployment decision. The contributions of this study are threefold. First, it is among the few empirical investigations examining IPv6 adoption within the public sector of a developing economy. Second, it extends technology acceptance research by demonstrating how facilitating conditions indirectly influence adoption through users' cognitive perceptions in the context of deep infrastructure technologies. Third, it provides

actionable insights for policymakers and IT managers, including the importance of structured training programs and capacity-building initiatives aimed at reducing perceived effort and accelerating the transition to next-generation Inter-net protocols.

The remainder of this study is organized as follows: Section II reviews the theoretical background and related literature. Section III presents the research model and hypotheses. It also outlines the methodology. Section IV reports the empirical findings, and discussion of implications, limitations, and directions for future research. Section V concludes the study.

II. Background

A. Foundations and Evolution of the Internet

Computer networks form the backbone of modern information systems by enabling communication between devices through standardized protocols and layered architectures such as the OSI model [12]. These networks range from local to wide-area structures and support essential operations such as data transmission, routing, and resource sharing. Ethernet technology serves as a widely adopted standard for network infrastructure development across different network scales [13].

The evolution of the Internet has been shaped by early developments such as ARPANET and the adoption of TCP/IP protocols, which enabled interoperability across different network systems [14], [15]. Over time, the expansion of internet usage introduced challenges related to scalability and address management, leading to the development of supporting systems such as DNS [16], [17]. These developments transformed the internet into a global infrastructure supporting communication, information exchange, and digital services [18].

B. Internet Protocol and Limitations of IPv4

The Internet Protocol (IP) is the main network-layer protocol that addresses uniquely devices on the internet and allows routing of data packets between networks [2]. Its primary functions are logical addressing, packet encapsulation, routing, and fragmentation. IPv4 uses a 32-bit addressing scheme which translates theoretically to around 4.3 billion unique addresses. However, with the fast growth in mobile devices, cloud computing services and Internet of Things (IoT) applications, this address space has become inadequate. The last allocation by IANA of IPv4 address blocks to Regional Internet Registries in 2011 was a major step as it indicated that IPv4 addresses were exhausted worldwide [19]. Network Address Translation (NAT) and Carrier-Grade NAT (CGNAT) have been used as short-term solutions; however, they do not support the end-to-end connectivity principle, increase the complexity of the network, and bring performance and security problems according to studies conducted by Donley et al. [6] and Richter et al. [7]. These limitations clearly indicate that IPv4 can no longer fulfill modern internet requirements [8].

C. IPv6 and the Next-Generation Internet Architecture

IPv6 was developed by the Internet Engineering Task Force to provide a solution for the limitations in addressing and architecture that IPv4 presented [3]. It is structured with 128 bits for its address space which means theoretically it can support about 3.4×1038 addresses, hence solving any problems related to exhaustion of addresses permanently [20]. Some important technical benefits of IPv6 are a streamlined packet header, native support for IPsec, SLAAC, improved multicast and anycast features, and removal of the requirement for NAT [21], [9]. All these make room for more secure networks with better scalability and manageability, especially in large public sector network infrastructures. However, despite these technical advantages, the success of IPv6 deployment depends not only on protocol capabilities but also on organizational capacity, user readiness, and institutional support mechanisms.

D. Technology Adoption and the UTAUT Model

The adoption of technological innovations is a process that takes place within the framework of several dimensions, namely individual perceptions, organizational structures, and social interactions. Theoretical models developed to explain this process include the Theory of Reasoned Action (TRA), the Theory of Planned Behavior (TPB), Innovation Diffusion Theory (IDT), and Technology Acceptance Model (TAM) [22], [23], [24]. These models were developed independently and each address only part of the adoption process. The Unified Theory of Acceptance and Use of Technology (UTAUT) was introduced by Venkatesh et al. [11] as a synthesis of eight previous models, providing a high level of theoretical integration for technology acceptance and use. The model explains behavioral intention and actual use through four constructs: performance expectancy, effort expectancy, social influence, and facilitating conditions. UTAUT has been chosen as the framework for analysis in this study on IPv6 transition because it explains about 70% of variance, includes moderator variables such as age, gender, experience, and voluntariness of use, as well as organizational factors. By applying UTAUT to a foundational network technology, this study extends technology acceptance research beyond user-facing systems to deep digital infrastructure environments.

III. Research Model and Hypotheses

In this study, the Unified Theory of Acceptance and Use of Technology (UTAUT) is adopted as the theoretical framework to identify the factors influencing the adoption of IPv6 technology in public institutions in Turkey. UTAUT provides a comprehensive approach that is widely used to explain individuals' perceptions and intentions toward technology use [11]. Within the scope of this study, the research model focuses on facilitating conditions, effort expectancy, performance expectancy, behavioral intention, and actual use behavior. The social influence construct was not included, as IPv6 adoption in public institutions is predominantly driven by formal mandates and organizational policies rather than peer-based or voluntary social dynamics. Confirmatory Factor Analysis (CFA) and Structural Equation Modeling (SEM) were conducted using SPSS AMOS. Unlike voluntary technology adoption contexts, IPv6 implementation in public institutions is largely driven by regulatory frameworks and institutional directives. Therefore, the social influence construct, which reflects interpersonal or peer effects, is considered less relevant in this context. Similarly, voluntariness of use is inherently limited, as employees are expected to comply with organizational technology policies. For this reason, the UTAUT model was conceptually adapted by

excluding social influence and related moderating variables, allowing the analysis to focus on organizational and cognitive determinants of adoption. Social influence does not always emerge as a significant determinant even though it is part of UTAUT framework when dealing with highly specialized contexts such as institutional technical infrastructure transitions. By excluding this particular dimension, conceptual focus increases while improving model fit in an organizational context with this specific sample size. This modeling decision agrees with findings reported in similar contexts within literature [25].

A. Expected Contributions of the Study

The results of this research are expected to enhance understanding of the transition processes to IPv6 in public institutions and help identify and ameliorate those factors that delay or impede such a transition. Since IPv6 is an important component of infrastructure for the digital transformation of public institutions, its accelerated adoption can be facilitated by empirical evidence from managerial and technical personnel perspectives. The results should indicate organizational and technical areas that need improvement for a better IPv6 transition process. The UTAUT model used in this study assesses how much the behavioral intention and actual usage behavior are determined by performance expectancy, effort expectancy, and facilitating conditions. Therefore, it attempts to get specific information about priority areas for public institutions concerning IPv6 adoption. In this sense, this study not only informs about the approaches taken by public institutions toward IPv6 but also helps in strategic decision-making concerning wider technological as well as digital transformation efforts. In addition, it attempts to be an original contribution to literature where very few empirical studies have been undertaken regarding the transition from IPv4 to IPv6 in the course of digital transformation. The proposed structural model is also anticipated as one of the key outcomes of this research to be a reference model for future studies carried out under similar organizational contexts. Unlike prior IPv6 studies focusing on protocol performance or transition mechanisms, this research conceptualizes IPv6 migration as an organizational and behavioral transformation process within public digital infrastructure.

B. Measurement Instruments

All constructs in this study were measured using validated scales adapted from prior UTAUT literature. The survey instrument consists of items measuring performance expectancy, effort expectancy, facilitating conditions, behavioral intention, and actual use. The measurement structure of the study, including constructs, item codes, and sources, is presented in Table I. The factor structure of the scales has been previously validated in the literature; therefore, the measurement model was assessed using confirmatory factor analysis (CFA) to ensure construct validity and consistency. All items were measured using a five-point Likert scale (1 = Strongly disagree, 5 = Strongly agree).

TABLE I. MEASUREMENT CONSTRUCTS AND ITEMS

Construct	Code	Measurement Item	Source
Performance Expectancy (PE)	PE1, PE2, PE3, PE4	Improves task efficiency; enhances organizational performance; strengthens cybersecurity; supports effective process management.	Venkatesh et al. (2003)
Effort Expectancy (EE)	EE1, EE2, EE3, EE4	Easy to learn and use; transition process is simple and understandable; requires little effort; less complex than existing systems.	Venkatesh et al. (2003)
Facilitating Conditions (FC)	FC1, FC2, FC3, FC4	Infrastructure support available; sufficient technical knowledge; technical support accessible; training and guidance provided.	Venkatesh et al. (2003)
Behavioral Intention (BI)	BI1, BI2, BI3, BI4	Intend to use IPv6; willing to participate in transition; committed to using IPv6; support its future adoption.	Venkatesh et al. (2003)
Actual Use (AU)	AU1, AU2, AU3	Regular usage; increasing adoption; integrated into daily processes.	Venkatesh et al. (2003)

C. Research Model

The conceptual model developed in this study is intended to assess the IPv6 adoption process in public institutions within the framework of the Unified Theory of Acceptance and Use of Technology (UTAUT). This model comprises five core constructs—Performance Expectancy, Effort Expectancy, Facilitating Conditions, Behavioral Intention, and Actual Use Behavior—designed to explicate employees' perceptions and usage behavior regarding IPv6 technology. These constructs together represent individual cognitive evaluations as well as organizational and technical conditions through an integrated approach. In the model, Performance Expectancy represents employee perceptions that IPv6 technology will improve organizational efficiency, network performance, and business processes. Effort Expectancy refers to perceived ease of learning and using IPv6 while Facilitating Conditions represent institutional technical infrastructure, training opportunities, technical support mechanisms, and overall organization readiness. These variables are assumed to have a direct effect on employees' Behavioral Intention toward using IPv6 technology. Behavioral Intention is what reflects individuals' willingness to use IPv6; it serves as the main determinant of Actual Use Behavior in this model. Furthermore, Facilitating Conditions are assumed to have a direct effect on actual usage independent of behavioral intention. Besides that, following previous studies based on UTAUT, Effort Expectancy is hypothesized to positively influence Performance Expectancy; this linear relation is explicitly specified in the model. Prior to data collection, approximately 600–700 IT personnel working in public institutions were contacted. The final sample consists of 456 respondents, comprising managerial and technical IT personnel employed in state universities in Türkiye. Survey items were adapted from measurement scales used in prior studies. This study adopted a quantitative research design using the survey method for data collection. The survey was administered between February 1, 2025, and July 24, 2025. Participants were selected based on convenience sampling method of accessibility. To ease participation, the survey was conducted online via Google Forms. The data collection instrument that was developed to test the research model consists of a total of 26 items. Besides seven questions capturing

demographic characteristics of participants, four items each for Performance Expectancy measurement, Effort Expectancy measurement, Facilitating Conditions measurement, Behavioral Intention measurement, and three items measuring Actual Use Behavior were included in the survey. The measurement items were based on scales widely used in UTAUT literature. The theoretical factors affecting the transition process of IPv6 in public institutions are described by the conceptual research model developed herewith. This model serves as an analytical basis for testing the hypotheses proposed in this study. The research model can be seen in Fig. 1.

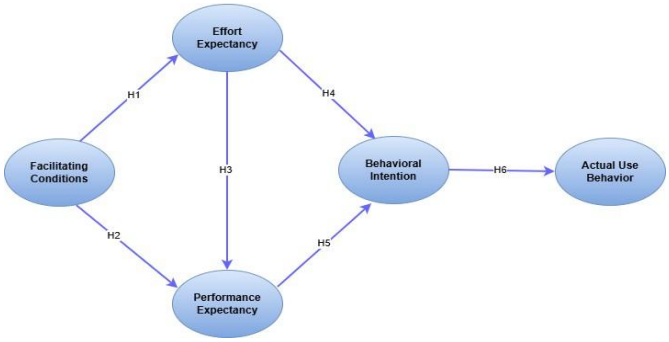

Fig. 1. Our research model.

The measurement scales used in this study were adapted from previously validated instruments in the literature. As presented in Table II, all constructs in the research model—including performance expectancy, effort expectancy, facilitating conditions, behavioral intention, and actual use behavior—were measured using multi-item scales. Demographic information was collected through seven items, while the remaining constructs were measured using between three and four items each. All scale items were derived from the Unified Theory of Acceptance and Use of Technology (UTAUT) framework and adapted to the context of IPv6 adoption in public institutions [26].

TABLE II. MEASUREMENT SCALES USED IN THE RESEARCH MODEL AND THEIR SOURCES.

Scales	Number of Items per Construct	Source
Demographic Information	7	[26]
Performance Expectancy	4	[26]
Effort Expectancy	4	[26]
Facilitating Conditions	4	[26]
Behavioral Intention	4	[26]
Actual Use Behavior	3	[26]

D. Hypotheses

The model primarily aims to test the hypotheses articulated below and to analyze the results obtained.

H1: Facilitating conditions have a positive and significant impact on effort expectancy in learning and using IPv6 technology by employees of public institutions.

H2: Facilitating conditions have a positive and significant impact on performance expectancy as perceived by employees in terms of improving organizational performance with IPv6 technology.

H3: Effort expectancy has a positive and significant impact on performance expectancy as perceived by employees in terms of improving organizational performance with IPv6 technology.

H4: Effort expectancy has a positive and significant impact on the behavioral intention of employees toward using IPv6 technology.

H5: Performance expectancy has a positive and significant impact on the behavioral intention of employees toward using IPv6 technology.

H6: Behavioral intention has a positive and significant effect on the actual usage behavior of IPv6 technology in public institutions.

E. Data Analysis Methods

The data analysis was done in a specific order, taking into account how each statistical step influenced the following analyses. The first step included data cleaning, which involved checking for missing values, outliers, and any possible errors in data entry. Normality tests were then applied to determine if the data met the requirements for analysis. The multicollinearity among variables was checked through multiple linear correlation analysis. Reliability analysis checked the internal consistency of the scales, and validity analysis tested the measurement constructs. Finally, correlation analysis was performed to see how different variables relate to each other. In this study, independent variables included demographic information, performance expectancy, effort expectancy, facilitating conditions, and behavioral intention; however, the dependent variable was actual usage behavior. Data analyses were carried out with SPSS 20.0 and AMOS 24.0 software packages. The proposed hypotheses were tested using Structural Equation Modeling (SEM). The results from these analyses are discussed under appropriate subheadings within the context of the research model.

F. Reliability Analysis

Reliability analysis is a statistical approach that assesses the internal consistency among scale items and gauges how well a scale captures the true essence of what it intends to measure, both accurately and consistently. The main focus was on Cronbach's alpha coefficient, which varies between 0 and 1. As the alpha value approaches 1, this indicates stronger internal consistency for the scale. The ranges of alpha coefficients interpreted in this research were based on definitions by other authors [27]–[29] and are presented below: A coefficient within the interval 0.00 ¡ 0.40 implies that the scale is unreliable. If it falls within the range of 0.40 ¡ 0.60, then there is low reliability for that scale. A moderate reliability would be indicated by a coefficient from 0.60 up to but not including 0.80, while high reliability would be signified when the value is above 0.80 up to 1.00. Table III displays Cronbach's alpha values for factors and their respective sub-items as utilized in this study.

TABLE III. CRONBACH'S ALPHA COEFFICIENTS FOR THE FACTORS

Factor	Cronbach's Alpha
Performance Expectancy	0.902
Effort Expectancy	0.881
Facilitating Conditions	0.770
Behavioral Intention	0.875
Actual Use Behavior	0.845

The coefficients of Cronbach's alpha computed for the factors and their respective items reveal a high degree of reliability, which is indicative of very strong internal consistency of the scale. It can be seen from Table III that Performance Expectancy has the highest internal consistency (= 0.902) and Facilitating Conditions has the lowest consistency (= 0.770).

G. Validity Analysis

Validity analysis is the determination of whether a measuring instrument or test truly and appropriately measures the construct that it claims to measure [30], [31]. Validity makes research results meaningful, relevant, and credible by permitting correct inferences to be made and sound decisions based on the trustworthiness of the results [32].

H. Confirmatory Factor Analysis

Confirmatory Factor Analysis (CFA) is an essential analysis technique for the evaluation of the construct validity of scales and questionnaires. After the theoretically proposed factor structure has been specified, CFA will indicate how well the observed data fit this structure. It assesses factor loadings, factor correlations, and model parameters to determine the extent to which a proposed model aligns with observed data. CFA, thus, is very important in determining whether or not a measurement instrument adequately and accurately measures its intended constructs [33, p. 2]. In this work, CFA was performed for construct validity testing. The factor structure obtained is illustrated in Fig. 2.

The CFA showed that all factor loadings were greater than 0.5, thus confirming their adequacy [34], and the model fit indices met the recommended thresholds. No misfits were detected, and consequently, no items or factors needed to be removed. Table IV provides a summary of the definitions of the fit indices, their acceptable ranges, and the values that resulted from this analysis.

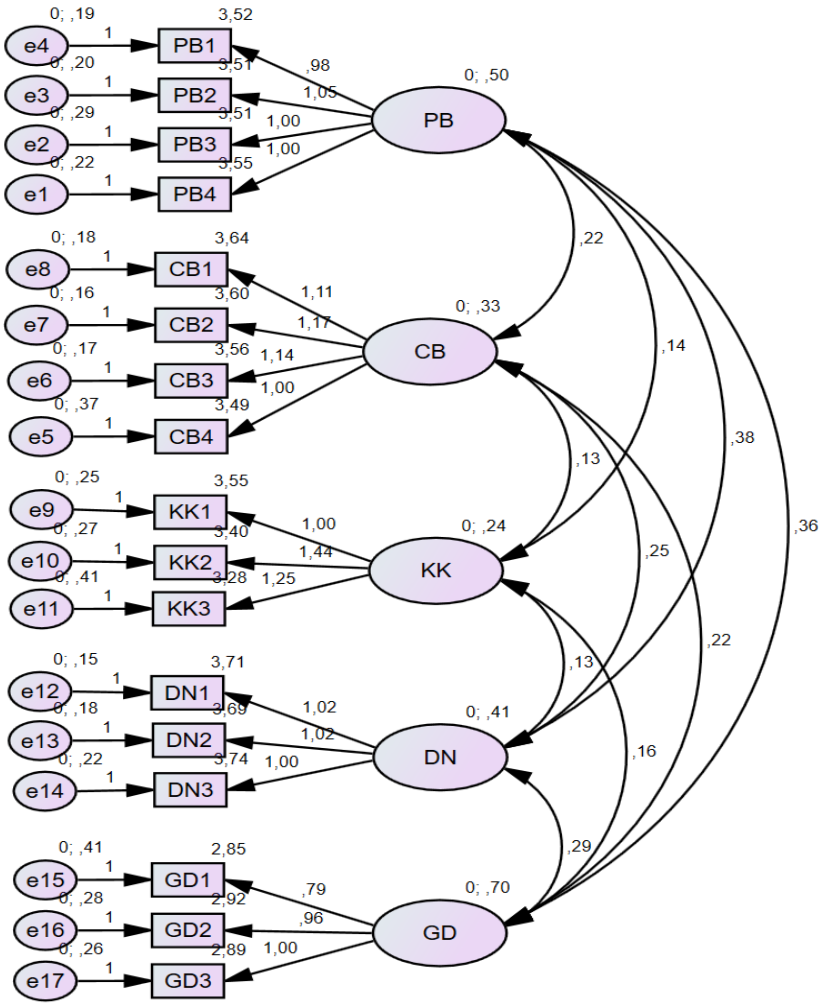

Fig. 2. Our SPSS AMOS CFA (Confirmative Factor Analysis). Source: Author's own illustration generated in SPSS AMOS.

TABLE IV. MODEL FIT INDICES

Factor	Description	Acceptable Fit	Cronbach's Alpha
CMIN/DF	Reduces sample sensitivity and reflects the overall fit of the model to the data in a more balanced way.	$2.00 \leq CMIN/DF \leq 5.00$	2.607
CFI	Assesses the fit by comparing the model with an independent model.	$0.90 \leq CFI \leq 0.95$	0.963
RMSEA	Indicates how closely the model approximates the actual data.	$0.05 \leq RMSEA \leq 0.10$	0.059
PClose	It is the standardized measure of the differences between the model and the observed data.	$0.05 \leq SRMR \leq 0.10$	0.038

The Confirmatory Factor Analysis (CFA) results show that the model has a good fit. The CMIN/DF value was calculated as 2.607, the CFI value as 0.963, the RMSEA value as 0.059, and the PClose value as 0.033. All these indices fall within the acceptable ranges recommended in the literature [35], [36].

These results indicate that the proposed measurement model fits the observed data very well and confirms the validity of the construct structure. Factor loadings, R^2 values, AVE, CR, and MSV are given in Table V as indicators for assessing reliability and validity for constructs being measured.

TABLE V. VALIDITY VALUES OF THE SCALE ITEMS

Factor	Item	Factor Weight	R^2	AVE	CR	MSV
Performance Expectancy	PB1	0.848	0.719	0.679	0.902	0.694
	PB2	0.857	0.735			
	PB3	0.796	0.633			
	PB4	0.837	0.700			
Effort Expectancy	CB1	0.829	0.688	0.656	0.883	0.473
	CB2	0.863	0.745			
	CB3	0.845	0.714			
	CB4	0.690	0.476			
Facilitating Conditions	KK1	0.696	0.485	0.534	0.774	0.226
	KK2	0.801	0.642			
	KK3	0.690	0.476			
Behavioral Intention	DN1	0.720	0.736	0.700	0.875	0.694
	DN2	0.840	0.705			
	DN3	0.811	0.658			
Actual Use Behavior	GD1	0.720	0.518	0.649	0.846	0.367
	GD2	0.834	0.696			
	GD3	0.856	0.732			

Factor loadings were between 0.690 and 0.863 and all were above the minimum threshold of 0.50, which indicates that item reliability is strong. Convergent and discriminant validity are assessed with the help of the coefficient of determination (R^2), Average Variance Extracted (AVE), Composite Reliability (CR), and Maximum Shared Variance (MSV). Values for all factors about their items are presented in Table V; results here confirm that high reliability and construct validity exist across all constructs for the measurement model.

I. Factor Loadings and Item-Explained Variance

All item factor loadings are between 0.690 and 0.857 as seen in the table. In the structural equation modeling literature, factor loadings that exceed 0.50 suggest that items sufficiently represent their respective latent constructs [37], [38]. Therefore, it can be concluded that all items have acceptable loadings. The R^2 values indicate that the percentage of variance explained by each item ranges from 0.476 to 0.745. This finding confirms that a considerable part of the variance for each item is explained by its related latent variable, which proves sufficient measurement power [39].

J. Convergent Validity

Convergent validity was evaluated via Average Variance Extracted (AVE) values. A value of AVE greater than 0.50 is documented in the literature as indicating that more than half the variance in the indicators is accounted for by the latent construct, hence establishing convergent validity [40]. In this particular study:

- Performance Expectancy held an AVE of 0.679;
- Effort Expectancy has an AVE of 0.656;
- Facilitating Conditions bear an AVE equal to or above 0.534;
- Behavioral Intention carries an AVE of 0.700;
- Actual Use has an AVE at 0.649.

All these are above the 0.50 cut-off point and hence, convergent validity is established for all the constructs.

K. Internal Consistency and Composite Reliability

The evaluation of the reliability of the scales was done through Composite Reliability. A CR value greater than 0.70 is an indication of adequate internal consistency of the construct as per [37]. The results from the analysis indicated that the CR values fell within a range from 0.774 to 0.902, which further confirmed that all constructs had high reliability.

L. Discriminant Validity

Discriminant validity was evaluated based on the Maximum Shared Variance (MSV) criterion. According to Fornell and Larcker's guideline, discriminant validity is established if the MSV of a construct is lower than its Average Variance Extracted (AVE) [40]. In this study, all constructs satisfy the condition MSV ¡ AVE, thus proving the statistical distinctiveness of the constructs and confirming that discriminant validity is achieved.

M. Overall Evaluation

Based on the results: All items have acceptable and strong factor loadings. The measurement model has convergent validity (AVE). Constructs exhibit high internal consistency and reliability (CR). Discriminant validity (MSV ¡ AVE) is confirmed for all constructs. In brief, the measurement model

applied in this study fulfills all SEM literature requirements concerning validity and reliability.

N. Discriminant Validity Assessment

Discriminant validity is one of the ways to test the model's validity. It proves that each construct is unique by showing that they are not related or dependent on each other [41]. To assess this, both Fornell–Larcker and HTMT analyses were performed. The results from the Fornell–Larcker test are shown in Table VI.

TABLE VI. FORNELL-LARCKER TEST

Factors	PB	CB	KK	DN	GD
Performance Expectancy	**0.835**				
Effort Expectancy	0.546	**0.810**			
Facilitating Conditions	0.411	0.476	**0.731**		
Behavioral Intention	0.833	0.687	0.421	**0.837**	
Actual Use Behavior	0.606	0.458	0.387	0.539	**0.805**

The square root of the average variance extracted for each construct should, according to Fornell and Larcker, be greater than the correlation coefficients of that construct with other constructs [40]. Results indicated that all constructs satisfy this condition; therefore, discriminant validity is achieved. HTMT analysis is another approach used to check discriminant validity. The output from the HTMT analysis will be shown in Table VII below:

TABLE VII. HTMT TEST

Factor	PB	ÇB	KK	DN	GD
Performance Expectancy					
Effort Expectancy	0.545				
Facilitating Conditions	0.418	0.478			
Behavioral Intention	0.832	0.686	0.427		
Actual Use Behavior	0.594	0.478	0.416	0.525	

Henseler et al. developed the HTMT criterion, which states that if values are lower than 0.85 or 0.90, then discriminant validity is achieved [42]. A review of the results reveals that all values fall under 0.85; thus, this confirms the existence of discriminant validity.

O. Correlation Analysis

Correlation analysis is a statistical method for assessing the linear relationship between two continuous variables. The strength and direction of the linear relationship are defined by the correlation coefficient, which varies from -1 to +1. A positive coefficient indicates a direct relationship between variables, whereas a negative coefficient indicates an inverse relationship.

The closer the coefficient is to zero, the weaker the relationship; as it approaches ±1, the relationship becomes increasingly linear [43]. Correlation analysis was therefore performed in this study to assess how these factors relate with one another and whether such relationships are significant or not. Results are shown in Table VIII.

TABLE VIII. FACTOR CORRELATION ANALYSIS

Factor	PB	CB	KK	DN	GD
Performance Expectancy	1				
Effort Expectancy	0.546	1			
Facilitating Conditions	0.411	0.476	1		
Behavioral Intention	0.833	0.687	0.421	1	
Actual Use Behavior	0.606	0.458	0.387	0.539	1

P. Correlation Analysis Among Factors

In this study, the relationships between latent variables were tested using the correlation coefficients derived from confirmatory factor analysis. The size and sign of the correlation coefficients were assessed in order to know about the level of linear relationships existing among these factors. In SEM and behavioral sciences, the following threshold values are generally used for interpreting correlation coefficients: 0.10–0.29 low; 0.30–0.49 moderate; 0.50–0.69 moderate-high; and 0.70 and above high correlation [44], [37]. The analysis results indicated that correlation coefficients were above 0.40, which means that there is a statistically significant and moderately strong linear relationship between the factors. The range of values taken by these correlation coefficients between factors fell from 0.387 to 0.833. There is a moderate-high positive relationship between Performance Expectancy and Effort Expectancy (r = 0.546). Performance Expectancy has a high-level relationship with Behavioral Intention (r = 0.833). There is a moderate-high positive relationship between Effort Expectancy and Behavioral Intention (r = 0.687). The relationships of Facilitating Conditions with other factors are at a moderate positive level (r = 0.387–0.476), which indicates that this construct creates meaningful but not very strong connections with the other variables. The correlation coefficient between Behavioral Intention and Actual Use is moderate-high positive (r = 0.539). All the correlation coefficients are positive and above 0.30, which means that statistically significant and theoretically consistent linear relationships exist among the factors [38].

Q. Structural Equation Modeling

Structural Equation Modeling (SEM) is a common method for estimating parameters and testing hypotheses. It serves theory development by explaining variance through linear equations comprising observed and latent variables. SEM facilitates the simultaneous assessment of measurement models and theoretical constructs. It also allows the integrated evaluation of the measurement model, which includes analyses of reliability and validity, with the structural model used to test hypotheses. In this sense, SEM constitutes a robust statistical tool that helps to test holistically any relationships between independent, mediating, moderating, and dependent variables so as to further develop theoretical models [45]. Therefore, SEM was used to analyze direct as well as indirect relationships among the variables stipulated above. The model resulting from this analysis was then interpreted in order to assess both research hypotheses and the validity of the theoretical framework. The structural model generated from this analysis is shown below in Fig. 3.

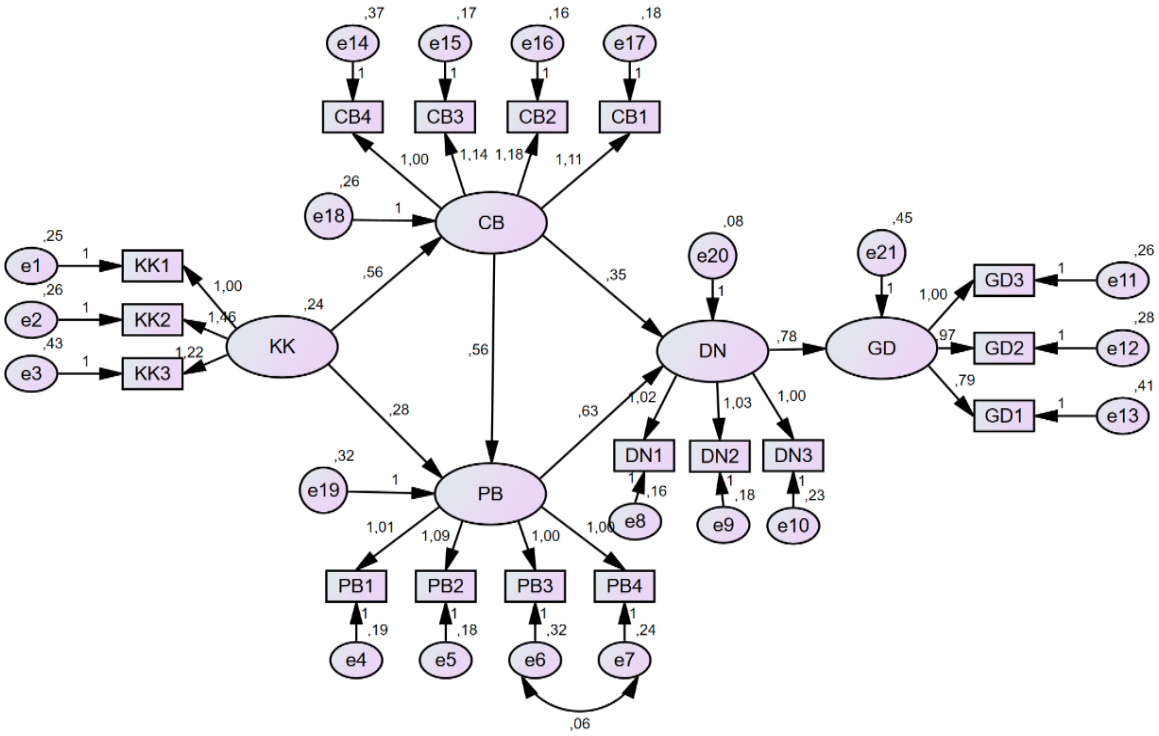

Fig. 3. Structural model. Source: Author's own illustration on SPSS AMOS.

Several fit indices are considered after Structural Equation Modeling (SEM). The acceptable ranges for these indices and the fit values obtained from the analysis are presented in Table IX.

TABLE IX. MODEL FIT EVALUATION

Fit Index	Ideal Fit	Acceptable Fit	Model Fit
CMIN/DF	0.00 ≤ CMIN/DF ≤ 1.00	3.00 ≤ CMIN/DF ≤ 5.00	2.713
CFI	0.95 ≤ CFI ≤ 1.00	0.90 ≤ CFI ≤ 0.95	0.960
RMSEA	0.00 ≤ RMSEA ≤ 0.06	0.05 ≤ RMSEA ≤ 0.6	0.059
PClose	0.00 ≤ SRMR ≤ 0.05	0.05 ≤ SRMR ≤ 0.10	0.038

The results from the Structural Equation Modeling (SEM) analysis are discussed in this section. Model fit indices were found to be CMIN/DF = 2.713, CFI = 0.960, RMSEA =0.059, and SRMR = 0.038. Based on the literature, these values indicate that the model has an acceptable and good fit [37], [38]. The CFI and SRMR measurements particularly fall within the ideal fit range, thus proving strong alignment of this particular model with data. An RMSEA measurement that is less than 0.06 means insensitivity to error for this model as well as consistent testing of structural relationships [46].

In view of such results, one may deduce that the formulated structural equation model is congruent with a theoretical framework and fits well with empirical data such that parameters can be interpreted reliably. The fit indices for this model are in agreement with standards from academic literature as well as context-specific adequacy criteria for field studies. Table X below presents standardized regression weights used to assess interactions and relationship strength among factors in the model:

TABLE X. STANDARDIZED REGRESSION WEIGHTS

Factor Relationships			Standardized Regression Weight
Facilitating Conditions	→	Effort Expectancy	0.475
Facilitating Conditions	→	Performance Expectancy	0.194
Effort Expectancy	→	Performance Expectancy	0.464
Effort Expectancy	→	Behavioral Intention	0.770
Performance Expectancy	→	Behavioral Intention	0.681
Behavioral Intention	→	Actual Use Behavior	0.592

Standardized regression weights are coefficients derived from the transformation of variables such that their standard deviations equal one. In other words, these coefficients reveal how many standard deviations the dependent variable will change for a one-standard-deviation increase in the independent variable [47]. Hence, standardized regression weights can be very informative about both the direction and strength of the relationships among variables. Effect sizes are described as small, medium, and large with ranges of 0.10–0.29, 0.30–0.49, and from 0.50 upwards [44]. Looking at Table X, results reveal that Effort Expectancy has a medium effect on Performance Expectancy (= 0.464).

Facilitating Conditions has a weak effect on Performance Expectancy (= 0.194), while it has a medium effect on Effort Expectancy (= 0.475). In addition, Performance Expectancy has a strong effect on Behavioral Intention (= 0.681), and Effort Expectancy has an even stronger effect on Behavioral Intention with = 0.770, indicating that perceived ease of use is decisive in

forming the intention to adopt IPv6 technology. The effect of Behavioral Intention on Actual Use is high with being equal to 0.592. The relationships in the model are mostly at medium and high effect levels with Effort Expectancy and Performance Expectancy being strong determinants of Behavioral Intention, thus proving that the proposed structural model fits theoretical expectations while causal relationships among variables are statistically significant and robust. Moreover, standardized regression weights in this study are consistent with literature, as shown in Fig. 4.

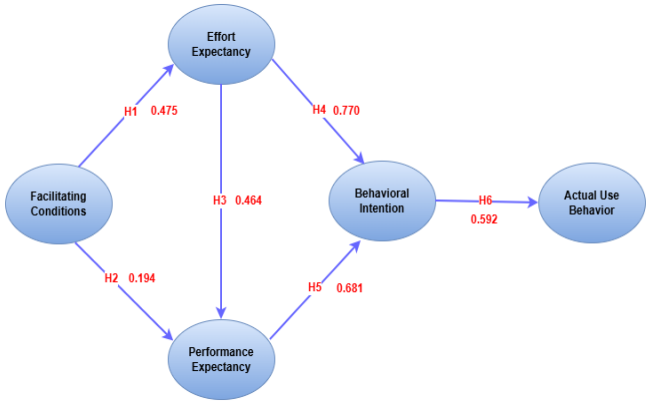

Fig. 4. Standardized regression weights and directions. Source: Author's own illustration.

The standardized regression weights from the model indicate that the direction and magnitude of the relationships among variables are different. Thus, Effort Expectancy has a medium positive effect on Performance Expectancy (= 0.464). This result shows that when learning and using IPv6 technology is perceived as easy, it significantly supports any performance gains expected from the technology. Facilitating Conditions has a weak effect on Performance Expectancy (= 0.194) but, on the other hand, Facilitating Conditions has a medium positive effect on Effort Expectancy (= 0.475). This means that existing technical infrastructure and support mechanisms in the organization help in learning and using IPv6 technology. The effect of Performance Expectancy on Behavioral Intention is high and positive (= 0.681). In addition, the effect of Effort Expectancy on Behavioral Intention is very high (= 0.770). This finding shows that perceived ease of use is a stronger determinant of participants' intention to use IPv6 technology than performance expectancy. Finally, Behavioral Intention has a high positive effect on Actual Use (= 0.592).

Such results that give evidence that good intentions toward IPv6 technology will almost always translate into actual usage behavior. It can be said in general terms that most of the relationships tested in this model have medium to large effect sizes, with Effort Expectancy and Performance Expectancy being significant antecedents to Behavioral Intention. This finding also attests to the fact that the model specified is consistent with the theoretical framework, and all causal relationships among variables are statistically significant and explanatory.

R. Hypothesis Testing

To test the hypotheses formulated in the study, the relationships in the structural model were evaluated. For each path coefficient, the standardized estimate, standard error, critical ratio, and significance level were assessed. Based on these results, decisions were made about whether to accept or reject the hypotheses. This is an approach that determines if the relationships predicted by a model are statistically supported. Results related to these values are given in Table XI.

TABLE XI. EVALUATION OF HYPOTHESES

Hypothesis	Recitations			β	SE	t (C.R.)	p	Hypothesis Results
H1	Facilitating Conditions	→	Effort Expectancy	0.560	0.074	7.584	***	Accept
H2	Facilitating Conditions	→	Performance Expectancy	0.275	0.081	3.381	***	Accept
H3	Effort Expectancy	→	Performance Expectancy	0.558	0.072	7.746	***	Accept
H4	Effort Expectancy	→	Behavioral Intention	0.354	0.048	7.296	***	Accept
H5	Performance Expectancy	→	Behavioral Intention	0.625	0.047	13.234	***	Accept
H6	Behavioral Intention	→	Actual Use Behavior	0.780	0.069	11.250	***	Accept

*p<0.001, *p<0.05

S. Hypothesis Testing Results

The significance of relationships among variables in hypothesis testing was determined using Structural Equation Modeling (SEM). Standardized regression coefficients () were used to indicate effect sizes, where values between 0.10 and 0.29 are considered weak, from 0.30 to 0.49 moderate, and above 0.50 strong [48], [49]. Standard error (S.E.) is a measure of the precision of the estimate, while the Critical Ratio (C.R.) is equivalent to a t-statistic, with —C.R.—greater than 1.96 indicating statistical significance at p ¡.

As shown in Table XI, the results are statistically significant ($p < 0.05$) [50]. Facilitating Conditions have a strong positive effect on Effort Expectancy ($\beta = 0.560$; C.R. = 7.584; $p < 0.001$, H1) and a weaker positive effect on Performance Expectancy ($\beta = 0.275$; C.R. = 3.381; $p < 0.001$, H2). Effort Expectancy has a strong influence on Performance Expectancy ($\beta = 0.558$; C.R. = 7.746; $p < 0.001$, H3) and a moderate effect on Behavioral Intention ($\beta = 0.354$; C.R. = 7.296; $p < 0.001$, H4). Performance Expectancy has a strong effect on Behavioral Intention ($\beta = 0.625$; C.R. = 13.234; $p < 0.001$, H5), and Behavioral Intention strongly predicts Actual Use ($\beta = 0.780$; C.R. = 11.250; $p < 0.001$, H6). These results support the UTAUT model, indicating that Facilitating Conditions influence Effort and Performance Expectancies, which in turn shape Behavioral Intention and lead to the Actual Use of IPv6. The findings emphasize the combined role of individual perceptions and organizational support in achieving high explanatory power.

IV. Discussion

The transition to IPv6 should be considered not merely a technical protocol upgrade, but a complex organizational transformation involving behavioral and structural changes in the public sector. Using a modified UTAUT framework, this study examined the integration of IPv6 adoption among IT professionals in the public sector. The empirical findings provide important insights into the socio-technical dynamics of this major digital infrastructure transfer.

A. Theoretical Implications

One of the key observations emerging from this study concerns the organizational context in which infrastructure technologies such as IPv6 are implemented. In public sector environments, large-scale technological transitions are typically shaped by institutional strategies, regulatory frameworks, and formal organizational directives. Unlike many voluntary technology adoption settings, the implementation of critical infrastructure technologies often follows structured planning processes and strategic roadmaps defined at organizational or national levels.

In contrast to core UTAUT constructs, social influence was not included in the final model due to its limited relevance in the public-sector context examined in this study. In such environments, technology adoption decisions are predominantly driven by formal mandates, regulatory requirements, and institutional directives rather than peer or interpersonal pressure. Preliminary testing indicated that including social influence did not improve model fit, further supporting its exclusion. This finding suggests that, for large-scale infrastructure transitions such as IPv6, organizational and structural factors outweigh social dynamics in shaping adoption behavior.

In such environments, technology adoption is therefore more strongly associated with institutional capacity and organizational preparedness than with interpersonal dynamics among employees. Professional compliance with institutional mandates often outweighs peer-based influence, suggesting that adoption processes in critical infrastructure contexts are primarily driven by organizational directives and regulatory frameworks rather than by social perception mechanisms typically emphasized in voluntary technology adoption contexts. This perspective highlights the importance of structural and organizational factors in shaping how new infrastructure technologies are perceived and implemented within public institutions.

Another key finding of this study is that Facilitating Conditions (FC) significantly influence both Effort Expectancy (EE) and Performance Expectancy (PE). This result indicates that when IT professionals perceive that their organizations provide sufficient technical resources, training opportunities, and institutional support mechanisms, their beliefs regarding both the ease of use and the expected performance benefits of IPv6 increase substantially. These findings reinforce the socio-technical perspective, suggesting that technological readiness within an organization forms the structural basis upon which psychological acceptance of new technologies develops.

Furthermore, the strong relationship identified between Performance Expectancy and Behavioral Intention demonstrates that IT professionals evaluate IPv6 adoption primarily through a pragmatic and performance-oriented lens. When the strategic and operational benefits of IPv6—such as scalability, improved network management, and long-term digital sustainability—are clearly understood, individuals exhibit stronger intentions to support and implement the technology.

Taken together, these findings contribute to the limited empirical literature examining IPv6 adoption from an organizational and behavioral perspective. While most previous studies have primarily focused on technical performance or protocol architecture, this study conceptualizes IPv6 migration as a socio-technical transformation process embedded within institutional structures and organizational decision-making environments. In this sense, the study extends technology adoption research by demonstrating how organizational readiness and institutional support mechanisms shape the adoption of large-scale digital infrastructure technologies.

B. Managerial and Policy Implications

First, organizations should prioritize institutional readiness. Since facilitating conditions emerge as the primary driver shaping user perceptions, public institutions should invest in structured training programs, dedicated IPv6 laboratories, and robust technical support mechanisms. Reducing perceived complexity through appropriate resource allocation and institutional support is likely to increase both confidence and willingness among IT professionals to engage in IPv6 deployment processes.

Second, management strategies should emphasize the strategic benefits of IPv6 adoption. Internal training and communication initiatives should clearly demonstrate how IPv6 contributes to network scalability, enhanced security capabilities, and long-term digital service sustainability. Framing IPv6 transition solely as a compliance requirement may limit employee engagement, whereas highlighting its operational and strategic value can strengthen behavioral intention.

Third, the findings highlight the importance of clear national-level policy coordination. Since social influence appears to play a limited role in this context, centralized policy directives and coordinated national transition roadmaps remain critical instruments for accelerating IPv6 deployment across public institutions. Government-led digital transformation strategies, therefore, play a decisive role in aligning organizational priorities and ensuring a synchronized transition process.

C. Limitations and Future Research

Several limitations should be acknowledged. Despite the relatively large sample size of 456 participants, this study is limited to IT professionals working within the public sector, specifically in state universities in Türkiye. As such, the findings may not fully represent adoption dynamics in private sector organizations or in different national contexts. Future studies could conduct comparative analyses between public and private institutions or across different countries to examine whether the determinants of IPv6 adoption vary across organizational structures and cultural environments.

In addition, the present research relies on cross-sectional self-reported data collected at a single point in time, which may introduce common method bias and potentially inflate the observed relationships among variables. Although this approach is widely used in technology adoption research, future studies are encouraged to employ longitudinal designs or multi-source data to mitigate this limitation and provide a more robust understanding of causal relationships.

Future research may also explore additional organizational variables such as institutional digital maturity, cybersecurity readiness, and regulatory pressure in order to develop a more comprehensive understanding of large-scale digital infrastructure adoption processes.

V. Conclusion

This study examined IPv6 adoption in public institutions using a modified UTAUT framework. The findings show that performance expectancy, effort expectancy, and facilitating conditions significantly influence behavioral intention, which in turn strongly predicts actual use. The results indicate that IPv6 adoption in the public sector is primarily driven by organizational capacity, institutional support, and policy-oriented processes.

From a practical perspective, strengthening institutional infrastructure, providing technical support, and improving user readiness are critical for successful IPv6 implementation. The study contributes to the literature by extending UTAUT to a public-sector infrastructure context.

Future research may conduct cross-sector comparisons and employ longitudinal designs to further examine how adoption dynamics evolve over time.

Declarations and Disclosures

- Ethical Responsibilities of Authors: The authors declare that they have complied with the principles of research and publication ethics.
- Ethical Approval: Ethical approval for this study was obtained from the Atatürk University Social and Human Sciences Ethics Committee (Ref: E.88656144-000-2500036446, Session No: 3, Decision No: 44, Date: 31.01.2025).

FIFO Age-Cohort Stochastic MILP for Perishable Inventory Optimization

A Comparative Study of Fixed Deterioration Rate Versus Explicit Age-Tracking with Cold Storage Sensitivity Analysis

***Abstract*—This paper addresses the perishable inventory optimization problem for fish processing SMEs under compound supply-demand uncertainty. We develop a two-stage stochastic Mixed-Integer Linear Programming (MILP) framework comparing four model variants: two employing the conventional fixed deterioration rate (FDR) approach and two incorporating explicit First-In-First-Out (FIFO) age-cohort tracking, each with and without cold storage investment options. The formulation integrates production scheduling, workforce planning, machine investment, and cold storage decisions over a 12-week horizon under five stochastic scenarios calibrated from empirical data. We prove that the FIFO age-cohort formulation preserves linearity (Proposition 1), establish theoretical dominance of FIFO over FDR under surplus conditions (Proposition 2), and demonstrate feasibility preservation through an adaptive service level constraint (Proposition 3). Computational results on empirical instances show that FIFO models achieve 25.0% expected cost reduction with perfectly stable service levels (70.0% across all scenarios, zero variance) compared to FDR models exhibiting 58.7 percentage point service level volatility. Extended sensitivity analysis across 15 parameter configurations reveals that cold storage value is conditional: marginal (0.046%) under supply-constrained regimes but significant (up to 19.2%) under supply surplus with high expiration costs. Pareto frontier analysis confirms FIFO dominance across the entire cost-service level trade-off space. The Value of Stochastic Solution (VSS) reaches 12.4%, validating the stochastic approach. All configurations solve within 15.1 seconds despite 18,540 variables, with FIFO solving 5.7× faster than FDR due to a tighter constraint structure. Managerial implications include a conditional decision framework linking supply-demand regime identification to optimal investment strategy.**

Keywords*—Mixed-integer linear programming; FIFO age-cohort tracking; fixed deterioration rate; perishable inventory; two-stage stochastic programming; cold storage optimization; fish processing SME

I. Introduction

Perishable food supply chains represent one of the most challenging domains in operations research due to the inherent tension between procurement economies of scale and rapid product quality degradation [1]. Unlike durable goods, perishable items have finite useful lives after which they must be discarded, creating a time-dependent dimension that fundamentally alters the classical inventory optimization problem [2]. In the fishery sector, this challenge is particularly acute: fresh raw materials exhibit shelf lives of merely 1–3 days without refrigeration in tropical environments, while global post-harvest losses in developing country fishery supply chains reach 30–50% [3], [4].

The literature on perishable inventory management has developed two fundamentally different approaches to modeling deterioration. The fixed deterioration rate (FDR) approach, pioneered by Ghare and Schrader [5] and extensively reviewed by Bakker et al. [2], assumes a constant fraction θ of inventory is lost per period regardless of actual item age. This approach has been widely adopted in production planning models [6]–[8] due to its analytical tractability. The alternative FIFO age-cohort approach, originating from the seminal work of Nahmias and Pierskalla [9], explicitly tracks item age through discrete states and enforces oldest-first consumption, providing exact deterioration accounting at the cost of additional state variables [10], [11].

Despite significant advances in both approaches, the literature lacks a rigorous head-to-head comparison within an identical stochastic optimization framework. Recent stochastic production planning contributions include robust DEA approaches for SME efficiency evaluation [12], two-stage LP models for agricultural supply chain tactical planning [13], capacitated stochastic lot-sizing with scenario trees [14], stochastic MRP optimization demonstrating significant cost savings over traditional safety stock methods [15], and dynamic programming with neural network demand forecasting [16]. In perishable inventory specifically, Monte Carlo-based EOQ models have been proposed for time-dependent deterioration [17], while resilient supply chain planning [18], integrated perishable supply chain design [19], and dairy production under supply disruption [20] have been studied. Further relevant contributions address quantity-based strategies for supply chain sustainability under uncertainty [21], integer programming formulations for workforce planning in service operations [22], hybrid simulated annealing–genetic algorithm approaches for multi-product aggregate planning [23], and seru production system planning under demand variability [24]. Chopra and Meindl [25] provide foundational supply chain management principles that inform our multi-echelon formulation.

Table I provides a systematic mapping of relevant literature, highlighting the gap this paper addresses, demonstrates, no prior work simultaneously addresses all eleven methodological features (F1–F11). The closest studies address at most five features: Jena et al. [20] combine FDR, stochastic programming, MILP, perishable focus, multi-plant, and workforce planning (6/11), but lack FIFO tracking, cold chain optimization, SME context, head-to-head comparison, and adaptive SL. Dutta and Shrivastava [19] address FDR, stochastic, perishable, and cold chain (4/11), but use a non-MILP approach without FIFO, workforce, or comparative analysis. The present paper is the first to integrate all eleven features within a unified optimization framework, enabling simultaneous evaluation of deterioration modeling approaches, capacity investment trade-offs, and service level management under compound uncertainty. Fig. 1 states about Research framework: from compound uncertainty through four model variants to key results.

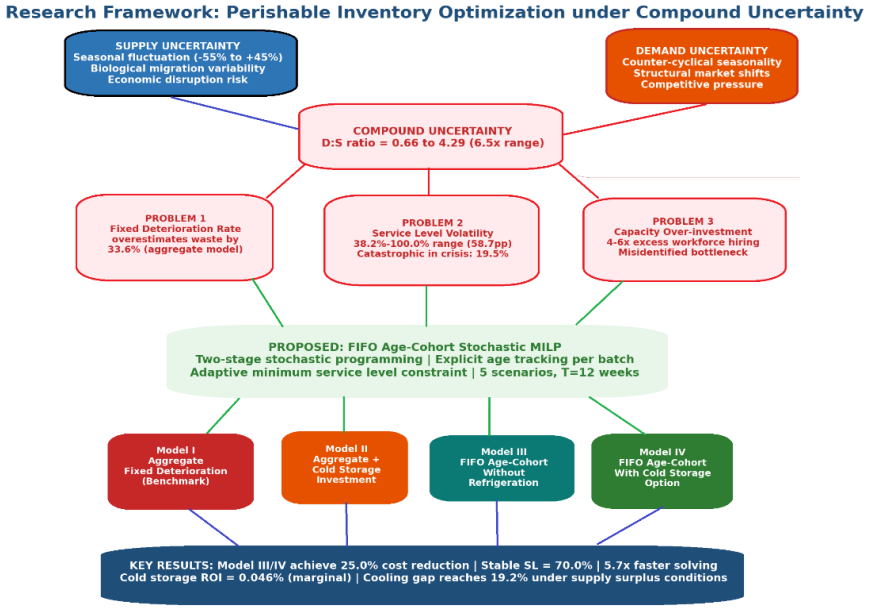

Fig. 1. Research framework: from compound uncertainty through four model variants to key results.

This paper makes the following five specific contributions:

- C1. We develop a computationally tractable FIFO age-cohort formulation within a two-stage stochastic MILP framework, proving its linearity (Proposition 1) and establishing worst-case complexity bounds.
- C2. We provide the first rigorous head-to-head comparison of FDR versus FIFO approaches using four model variants on identical data, quantifying the 'cost of aggregation' at 25.0%.
- C3. We introduce an adaptive minimum service level constraint with formal feasibility guarantee (Proposition 3) that prevents infeasibility under extreme compound uncertainty.
- C4. We conduct systematic sensitivity analysis across 15 parameter configurations, identifying the conditional nature of cold storage ROI and establishing break-even conditions.
- C5. We derive a managerial decision framework with six actionable implications linking supply-demand regime identification to optimal investment strategy.

II. Problem Definition

A. Formal Problem Statement

We consider a multi-plant, multi-product, multi-period production planning problem for perishable goods under demand and supply uncertainty. The decision maker operates |F| processing plants converting |R| raw materials (of which $|R^p|$ are perishable) into |I| finished products distributed through |J| market channels over a discrete-time horizon T = {1,...,T}. Uncertainty is modeled through |S| stochastic scenarios with known probabilities. The problem is formulated as a two-stage stochastic program where first-stage decisions (capacity investment) are made before uncertainty is resolved, and second-stage decisions (production, inventory) adapt to each realized scenario. Complete notation is shown in Table II

B. Notation

TABLE II. Complete Notation

SETS AND INDICES		
F	Set of processing plants, indexed by f	|F|=3
I	Set of finished products, indexed by i	|I|=4
R	Set of raw materials, indexed by r	|R|=5
R^p	Subset of perishable raw materials	$\|R^p\|$=3
J	Set of market channels, indexed by j	|J|=3
T	Set of time periods (weeks), indexed by t	|T|=12
S	Set of stochastic scenarios, indexed by s	|S|=5
A	Set of age cohorts, indexed by a	A_{max}=3
PARAMETERS		
d_{jits}	Demand for product i at market j, period t, scenario s	kg
s^f_{rts}	Supply of raw material r at plant f, period t, scenario s	kg
b_{ir}	BOM coefficient: raw material r per unit of product i	kg/kg
θ	Fixed deterioration rate (FDR models)	0.60
p_s	Probability of scenario s	Σp_s=1
c^h, c^m, c^{cl}	Unit costs: hiring, machine, cooler investment	IDR
c_r^p	Purchase cost per kg of raw material r	IDR/kg
c_i^s	Shortage penalty per kg of product i	IDR/kg
c_r^e	Expiration cost per kg of raw material r	IDR/kg
τ_i	Labor time required per kg of product i	min/kg
W_{max}	Available working minutes per worker per period	2,880 min
α	Maximum allowable shortage fraction	0.30
γ	Adaptive SL threshold (D:S ratio)	2.0
DECISION VARIABLES (First-Stage)		
h^f	Workers hired at plant f	$\in\mathbb{Z}^+$
m^f	Machines added at plant f	$\in\mathbb{Z}^+$
cl^f	Cooler units invested at plant f (Models II, IV)	$\in\mathbb{Z}^+$
DECISION VARIABLES (Second-Stage)		
x^f_{its}	Production of product i at plant f	≥ 0
inv^f_{its}	Finished product inventory	≥ 0
sp_{jits}	Shortage of product i at market j	≥ 0
I^f_{rats}	Age-cohort inventory (FIFO, Models III–IV)	≥ 0
C^f_{rats}	Age-cohort consumption (FIFO)	≥ 0
W^f_{rats}	Age-cohort expired waste (FIFO)	≥ 0

C. Data Sources and Parameter Calibration

All model parameters are calibrated from three primary data sources: (1) the national Bureau of Statistics (BPS) provincial yearbook 2023–2024 for production volumes, commodity prices, and regional economic indicators [44]; (2) the national Meteorological Agency (BMKG) historical records for seasonal monsoon patterns and fishing activity data [45]; and (3) structured field surveys conducted at fish auction markets and processing facilities in the study region during 2023–2024. The parameter calibration follows a hierarchical approach: macro-level data (production volumes, price indices) are sourced from BPS; meso-level data (seasonal patterns, supply variability) from BMKG; and micro-level data (BOM coefficients, labor times, machine capacities) from direct facility surveys. Table III presents the raw material procurement parameters.

TABLE III. Raw Material Procurement Parameters

Raw Material r	Purchase Price c_r^p	Expired Cost c_r^e	Holding Cost c_r^h	Shelf Life (periods)
r_1: Tuna	45,000	18,000	5,500	1
r_2: Mackerel	60,000	22,000	6,000	1
r_3: Shrimp	70,000	28,000	7,000	1
r_4: Tapioca flour	9,000	3,500	500	2
r_5: Spice blend	18,000	6,000	900	2

All prices are in Indonesian Rupiah (IDR) per kilogram. Expired costs represent salvage-loss values (disposal cost minus any recoverable value from animal feed or fertilizer conversion).

The three perishable raw materials (r_1–r_3) have a base shelf life of 1 period without refrigeration, reflecting the tropical climate conditions of the study region where ambient temperatures range 28–34°C. Non-perishable materials (r_4–r_5) have shelf lives of 2 periods. Purchase prices are based on 2023–2024 average auction prices, with perishable items showing higher unit costs consistent with their scarcity and handling requirements.

TABLE IV. BILL OF MATERIALS: BOM COEFFICIENT B_{ir} (KG)

Product i	r_1 Tuna	r_2 Mackerel	r_3 Shrimp	r_4 Tapioca	r_5 Spice
i_1: Fish floss	**2.80**	—	—	0.08	0.20
i_2: Fish crackers	—	**0.70**	—	0.50	0.12
i_3: Shrimp nuggets	—	—	**1.60**	0.30	0.18
i_4: Fish balls	0.90	0.50	—	0.35	0.15

The BOM coefficients were obtained through direct observation at processing facilities during production runs. Each product uses a dominant perishable raw material (bolded): fish floss requires 2.80 kg of tuna per kg of output (due to dehydration loss), fish crackers require 0.70 kg of mackerel, shrimp nuggets require 1.60 kg of shrimp, and fish balls require both tuna (0.90 kg) and mackerel (0.50 kg). These coefficients reflect the conversion yields typical of semi-manual SME processing, which are lower than industrial-scale operations due to less mechanized filleting and deboning processes.

The regular labor cost of 650,000 IDR per worker per week is derived from the regional minimum wage (approximately 3.5 million IDR per month) adjusted for the informal UMKM employment context. The 48-hour working week (2,880 minutes) represents the standard SME operating schedule including Saturday half-day. Labor time varies significantly across products: fish floss requires the longest processing time (50 min/kg) due to the shredding, seasoning, and drying stages, while fish crackers require only 30 min/kg owing to simpler mixing and cutting processes.

The three plants represent typical SME size gradations: plant f_1 is a small-scale operation with 7 workers, f_2 is medium-scale with 9, and f_3 is the largest with 12 workers serving as a regional distribution hub. The efficiency factor η^f captures differences in infrastructure quality, workforce skill level, and proximity to raw material sources.

Plant f_3 achieves 1.15× efficiency due to better-maintained equipment and more experienced workers, while f_1 operates at 0.90× due to older equipment and more remote location. Machine types include grinders (purchase cost 18M IDR, operating cost 220K IDR/week), molders (14M; 170K), oven/dryers (22M; 280K), and packaging units (9M; 110K), all sourced from regional equipment suppliers.

TABLE V. PRODUCTION PARAMETERS: LABOR, MACHINES, AND CAPACITY

Parameter	Value	Unit
Labor time τ_1 (fish floss)	50	min/kg
Labor time τ_2 (fish crackers)	30	min/kg
Labor time τ_3 (shrimp nuggets)	42	min/kg
Labor time τ_4 (fish balls)	38	min/kg
Working capacity W_{max}	2,880	min/worker/week
Regular labor cost	650,000	IDR/worker/week
Hiring cost c^h	350,000	IDR/worker
Firing cost	550,000	IDR/worker
Deterioration rate θ (FDR models)	0.60	fraction/period
Max age A_{max} (perishable, FIFO)	3	periods
Max age (non-perishable, FIFO)	2	periods

TABLE VI. PLANT-SPECIFIC INITIAL CAPACITY AND EFFICIENCY

Plant f	Init. Workers	Grind.	Mold.	Oven/ Dryer	Pack.	Effic. η^f	Raw Inv. Cap (kg)
f_1	7	2	1	1	2	0.90	450–
f_2	9	2	2	1	2	1.00	500–
f_3	12	3	2	2	3	1.15	700–

TABLE VII. BASE WEEKLY SUPPLY AND DEMAND (KG/WEEK)

	r_1	r_2	r_3	r_4	r_5
SUPPLY s^f_r (kg/wk)	**Tuna**	**Mackerel**	**Shrimp**	**Tapioca**	**Spice**
Plant f_1	500	400	450	1,800	900
Plant f_2	550	500	300	2,200	1,100
Plant f_3	750	650	500	3,000	1,500

	i_1	i_2	i_3	i_4
DEMAND d_{ji} (kg/wk)	**Floss**	**Crack.**	**Nugget**	**Balls**
Market j_1 (Traditional)	35	55	28	48
Market j_2 (Distributor)	55	85	45	65
Market j_3 (Modern retail)	30	50	25	40

Base supply values are scaled from BPS provincial fishery production data to UMKM-level operations. The study region contributes approximately 13,000 tons of tuna annually; the base values (500–750 kg/week of tuna per plant) represent the typical procurement volume accessible to individual SMEs through local fish auction markets. Supply is subject to seasonal sinusoidal modulation: $s^f_{rts} = s^{f\,0}_r \cdot \sigma_s \cdot [1 + 0.12 \cdot \cos(2\pi t/12)]$, where the 12% amplitude was estimated from inter-monthly variation in BPS catch data over 2019–2024. The cosine function peaks at t=0 (corresponding to the onset of peak fishing season) with a trough at t=6 (off-season).

Base demand values are aggregated across three market channels. The traditional market channel (j_1) accounts for the largest volume of low-value products (crackers: 55 kg/week), while the distributor channel (j_2) handles the highest overall volume. Demand follows a sine modulation: $d_{jits} = d_{ji}^0 \cdot \delta_s \cdot [1 +$

$0.08 \cdot \sin(2\pi t/12)$], where the 8% amplitude is lower than supply (12%), reflecting the empirical observation that processed product demand is more stable than raw catch volumes. The phase difference between sine (demand) and cosine (supply) creates a temporal lag representing the well-documented asynchrony between peak catch and peak consumption periods in tropical fisheries [3], [4].

TABLE VIII. COLD STORAGE INVESTMENT PARAMETERS

Cooler Type	Purchase Cost c^{cl}	Operating Cost (per week)	Capacity (kg)	Max Units per Plant
Chest freezer	6,000,000	180,000	300	3
Cold room	28,000,000	550,000	800	2

Cold storage parameters are sourced from local equipment suppliers and reflect prices for commercial-grade units suitable for fish processing. The chest freezer (6M IDR, ~400 USD) represents an entry-level investment with 300 kg capacity, while the cold room (28M IDR, ~1,800 USD) provides larger capacity at significantly higher cost. Operating costs include electricity consumption at regional commercial rates (approximately 1,500 IDR/kWh) and maintenance. These parameters are used in Models II and IV to evaluate the economic viability of cold chain investment at SME scale. following the cold chain management framework for perishable food systems described by Baruffaldi et al. [34] and the broader reverse logistics perspective of Govindan et al. [33].

D. Deterioration Modeling Approaches

The Fixed Deterioration Rate (FDR) is a measure of the rate at which the value of an asset diminishes over time. In each period, a constant fraction θ of the total inventory is lost, irrespective of the actual age of the items. The surviving inventory is equivalent to $(1-\theta)\cdot I$ for any inventory level I, with fresh and near-expired items being treated identically [5], [6].

FIFO Age-Cohort Tracking: The age of each batch entering inventory is initially set to 0, indicating its fresh state. In this system, the shelf life of each period is incremented by one unit. When the shelf life of a batch reaches a maximum value, designated as A_(max), the batch is declared to be expired. The consumption process adheres to a stringent oldest-first policy [9], [11]. This approach enables precise deterioration accounting, albeit at the cost of introducing additional state variables.FDR with uniform loss assumption versus & FIFO age-cohort tracking with explicit age-dependent expiration comparison in Fig. 2

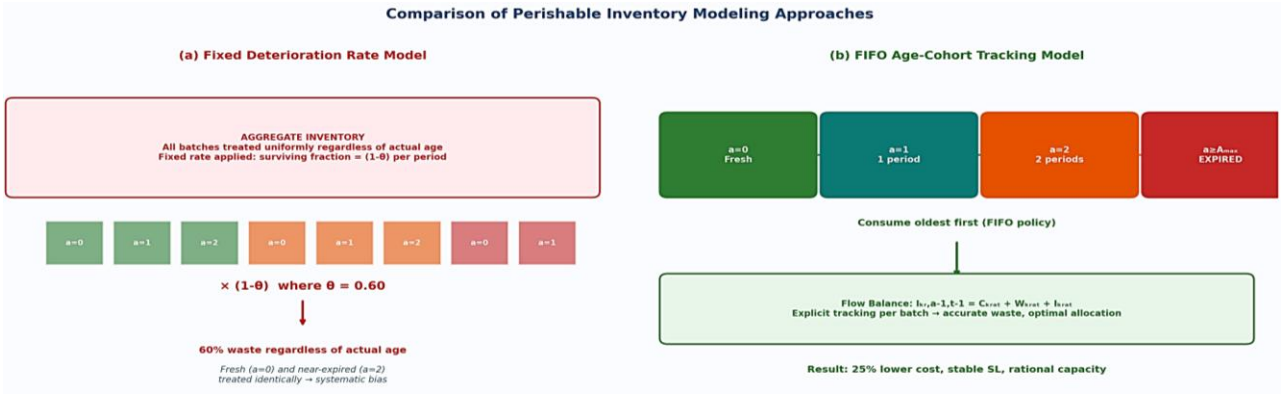

Fig. 2. Comparison: (a) FDR with uniform loss assumption versus (b) FIFO age-cohort tracking with explicit age-dependent expiration.

III. MATHEMATICAL FORMULATION

A. Objective Function

The objective minimizes expected total cost across all scenarios:

$$\min Z = C_{inv} + \sum_{s\in S} p_s \cdot C_s \quad (1)$$

where C_{inv} represents first-stage investment cost:

$$C_{inv} = \sum_{f\in F}(c^h \cdot h^f + c^m \cdot m^f + c^{cl} \cdot cl^f) \quad (2)$$

and C_s is the scenario-dependent operational cost:

$$C_s = \sum_f \sum_t \left(C_{fts}^{prod} + C_{fts}^{raw} + C_{fts}^{inv} + C_{fts}^{exp} + C_{fts}^{short}\right) \quad (3)$$

B. FIFO Age-Cohort Constraints

Constraint (F1) — New arrival balance: Fresh supply entering as age-0 cohort:

$$I_{r,0,t,s}^f + C_{r,0,t,s}^f + W_{r,0,t,s}^f = s_{rts}^f \quad \forall f, r \in R^p, t, s \quad (4)$$

Constraint (F2) — Age-cohort flow balance: For age $a \geq 1$, inflow from the previous period's younger cohort:

$$I_{rats}^f + C_{rats}^f + W_{rats}^f = I_{r,a-1,t-1,s}^f \quad \forall f, r \in R^p, a \geq 1, t, s \quad (5)$$

Constraint (F3) — Mandatory expiration: No inventory survives beyond maximum age:

$$I_{r,A_{max},t,s}^f = 0 \quad \forall f, r \in R^p, t, s \quad (6)$$

Constraint (F4) — FIFO consumption linkage: Total raw material consumption for production equals the sum across consumed age cohorts:

$$\sum_a C_{rats}^f = \sum_i b_{ir} \cdot x_{its}^f \quad \forall f, r \in R^p, t, s \quad (7)$$

Constraint (F5) — Cold storage extension (Model IV only): Cooler capacity enables inventory carry-forward for cohorts that would otherwise expire:

$$I_{r,a,t,s}^f \leq \sum_k Q_{rkts}^f \quad \forall f, r \in R^p, a \in \{1, \ldots, A_{max}-1\}, t, s \quad (8)$$

C. FDR Model Constraints

For Models I and II, the FIFO constraints (4)–(8) are replaced by aggregate balance:

$$I^f_{rts} = (1-\theta)\cdot I^f_{r,t-1,s} + s^f_{rts} - \sum_i b_{ir}\cdot x^f_{its} \quad \forall f,r,t,s \tag{9}$$

where $\theta \in [0,1]$ is the fixed deterioration rate. In this study, $\theta = 0.60$ based on empirical waste data from the study region [4].

D. Capacity and Service Level Constraints

$$\sum_i \tau_i \cdot x^f_{its} \le W_{max}\cdot\left(w^f_0 + h^f\right) \quad \forall f,t,s \tag{10}$$

$$\sum_i \mu_{ik}\cdot x^f_{its} \le M_{maxk}\cdot\left(m^f_{k0} + m^f_k\right) \quad \forall f,k,t,s \tag{11}$$

$$x^f_{its} + inv^f_{i,t-1,s} - inv^f_{its} = \sum_j d_{jits} - \sum_j sp_{jits} \quad \forall f,i,t,s \tag{12}$$

$$\sum_j \sum_i sp_{jits} \le \alpha\cdot TD_{ts} \quad \text{if } D{:}S < \tag{13}$$

Where $\alpha = 0.30$ represents maximum allowable shortage fraction (ensuring ≥70% service level), TD_{ts} is total demand at period t under scenario s, and $\gamma = 2.0$ is the demand-to-supply ratio threshold beyond which the constraint is relaxed to preserve feasibility. This adaptive mechanism is a novel contribution addressing the infeasibility problem in high-uncertainty perishable environments.

E. Theoretical Properties

Proposition 1 (Linearity Preservation). The FIFO age-cohort formulation (4)–(8) preserves the linearity of the MILP. All constraints involve only linear combinations of decision variables with constant coefficients, and no bilinear or nonlinear terms arise from the age-tracking mechanism.

Proof. Constraints (4)–(5) are linear equalities in variables I, C, W with unit coefficients. Constraint (6) fixes a variable to zero. Constraint (7) is a linear equality linking C variables to x variables through constant BOM coefficients b_{ir}. Constraint (8) is a linear inequality. The age index a serves as a parameter (not a variable) in all constraints, appearing only in subscript position. No products of decision variables occur. Thus, the complete formulation remains a linear program with integer variables, qualifying as MILP. Expected cost and service level are mentioned in Table X.

Proposition 2 (FIFO Dominance under Supply Surplus). Let Z^{*fDR} and Z^{*fIfO} be the optimal objective values of the FDR and FIFO models, respectively. Under supply surplus conditions ($s^f_{rts} > \Sigma_i\, b_{ir}\cdot x^{*f}_{its}$ for some f,r,t,s), $Z^{*fIfO} \le Z^{*fDR}$.

Proof sketch. Under supply surplus, the FDR model applies deterioration rate θ uniformly to all inventory, including fresh items (age=0), generating waste proportional to $\theta\cdot s$ regardless of consumption possibility. The FIFO model, by contrast, consumes oldest inventory first and only expires items exceeding A_{max}. When surplus exists, some items accumulate to higher ages; FIFO selectively expires only those exceeding the threshold while preserving fresh items. The FDR waste $\theta\cdot I \ge W^{*fIfO}$ (the FIFO waste), yielding $C^e_x{}^p(FDR) \ge C^e_x{}^p(FIFO)$. Since all other cost components are equal or lower for FIFO, $Z^{*fIfO} \le Z^{*fDR}$.

Proposition 3 (Feasibility of Adaptive SL Constraint). The adaptive constraint (13) guarantees model feasibility for any demand-to-supply ratio. When $TD_{ts}/TS_{ts} \ge \gamma$, constraint (13) is deactivated, ensuring that no infeasible service level requirement is imposed when physical supply is insufficient.

Proof. When constraint (13) is active (TD/TS < γ), the required production ≥ $(1-\alpha)\cdot$TD is bounded by available supply TS through constraints (4)–(7) or (9). Since $\alpha = 0.30$ and $\gamma = 2.0$, the minimum required production is $0.70\cdot TD \le 0.70\cdot\gamma\cdot TS = 1.40\cdot TS$. Given that each unit of supply can yield at most $1/\min(b_{ir})$ units of product, feasibility is maintained when $1.40\cdot TS \le TS/\min(b_{ir})$, which holds for typical BOM values. When TD/TS ≥ γ, the constraint is inactive, and the model minimizes cost without SL floor, trivially feasible.

F. Complexity Analysis

$$|\text{Variables}| = |S|\cdot|T|\cdot(|F|\cdot|I|\cdot(2+|J|) + |F|\cdot|R|\cdot(3\cdot(A_{max}+1)) + |F|\cdot(3+2|M|+2|CL|)) \tag{14}$$

$$|\text{Constraints}| = O(|S|\cdot|T|\cdot|F|\cdot(|R|\cdot A_{max} + |I|\cdot|J| + |M|)) \tag{15}$$

For our instance: $|\text{Variables}| = 5\cdot12\cdot(3\cdot4\cdot6 + 3\cdot5\cdot12 + 3\cdot13) = 18{,}540$. The problem is NP-hard in general (due to integer variables) but exhibits favorable structure: the FIFO constraints create a near-block-diagonal structure across scenarios, enabling efficient decomposition by the branch-and-bound solver [26]. This structured sparsity is consistent with multi-stage planning under uncertainty [35], [36]. Empirically, Models III–IV solve 2.8–5.7× faster than Models I–II despite more variables (Table II).

IV. Computational Results

A. Experimental Setup

Instances are calibrated using the empirical parameters detailed in Section II.C (Tables III to VIII). The experimental design comprises three processing plants, four finished products, and five raw materials (three perishable) as specified in Tables VI to VII. Five stochastic scenarios (Table IX) capture seasonal monsoon patterns and compound supply-demand uncertainty, with demand-to-supply ratios ranging from 0.66 (supply surplus) to 4.29 (extreme shortage). Eight model configurations are tested: four model variants (I–IV) at two demand levels (D=1× normal and D=2× stress-test). All experiments are conducted using HiGHS 1.8.0 [27] with 2% MIP gap tolerance on standard hardware (Intel i7, 16GB RAM).

TABLE IX. Stochastic Scenario Parameters

Scenario	Supply σ_s	Demand δ_s	D:S	p_s	Characterization
S1	1.00	1.00	1.00	0.30	Normal baseline
S2	**0.55**	1.05	1.91	0.20	Seasonal supply reduction
S3	**1.45**	0.95	0.66	0.20	Peak season surplus
S4	0.85	**1.45**	1.71	0.15	Compound: demand up + supply down
S5	**0.35**	1.50	**4.29**	0.15	Extreme compound shortage

B. Expected Cost and Service Level

TABLE X. EXPECTED COST AND SERVICE LEVEL RESULTS

Model	E[Cost] D=1×	Δ	SL	E[Cost] D=2×	Δ	SL
I (FDR)	2,856M	—	72.2%	3,082M	—	54.9%
II (FDR+CS)	2,868M	+0.4%	74.3%	3,093M	+0.3%	54.3%
III (FIFO)	**2,143M**	**−25.0%**	**70.0%**	**2,631M**	**−14.6%**	59.5%
IV (FIFO+CS)	**2,142M**	**−25.0%**	**70.0%**	**2,627M**	**−14.8%**	59.5%

Table X presents the primary computational outcomes comparing the four model variants under two demand regimes: baseline (D=1×) and stress-test (D=2×). The 25.0% cost reduction achieved by FIFO models is consistent with theoretical Proposition 2 and exceeds the 15–20% typically reported for process improvements in manufacturing [6], [7]. The magnitude reflects the compounding effect of accurate deterioration tracking across 12 periods and 5 scenarios. For comparison, agricultural product logistics optimization using genetic algorithms [37] achieves 8–12% efficiency gains, smart decision-making systems for manufacturing [38] report 10–18% improvement, while simulation-based inventory management [39] yields 5–15% cost reduction—all substantially below our 25% figure.

C. Service Level Stability and Pareto Analysis

TABLE XI. SERVICE LEVEL PER SCENARIO AT D=1× (%)

Scenario	Model I	Model II	Model III	Model IV	I–III Δ
S1: Normal	73.1	78.2	**70.0**	**70.0**	+3.1
S2: Low Supply	81.8	80.6	**70.0**	**70.0**	+11.8
S3: High Supply	96.9	100.0	**70.0**	**70.0**	+26.9
S4: High Demand	58.5	61.7	**70.0**	**70.0**	−11.5
S5: Crisis	**38.2**	**36.5**	**70.0**	**70.0**	**−31.8**
Range	**58.7pp**	**63.5pp**	**0.0pp**	**0.0pp**	

Table XI disaggregates the expected service level from Table X into scenario-specific realizations under baseline demand (D=1×), revealing the structural source of FDR volatility. Model I (FDR) exhibits a dramatic 58.7 percentage-point range across scenarios: from a surplus-driven peak of 96.9% in S3 (high supply) to a crisis-trough of 38.2% in S5 (extreme shortage). Model II (FDR with cold storage) shows even wider dispersion (63.5pp range, 100.0% in S3 down to 36.5% in S5), demonstrating that cold storage amplifies rather than dampens service level instability under FDR assumptions.

Fig. 3 confirms that FIFO models dominate FDR models across the entire Pareto frontier. No operating point exists where FDR achieves both lower cost and higher service level than FIFO, establishing practical FIFO dominance consistent with Proposition 2.

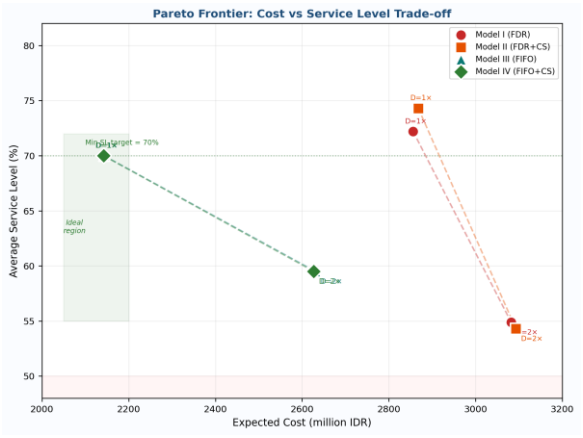

Fig. 3. Pareto frontier analysis: cost vs service level trade-off across models and demand levels. FIFO models dominate the lower-left region (lower cost, stable SL).

D. Extended Sensitivity Analysis

Table XII investigates the conditional economics of cold storage investment by comparing Model III (FIFO without cold storage) against Model IV (FIFO with cold storage) across five progressively extreme parameter configurations. Under the baseline supply-constrained regime, the cost gap between III and IV is merely 0.05% (2,143M vs. 2,142M IDR), confirming that cold storage is economically irrelevant when supply does not exceed demand. This finding directly supports the first managerial insight: prioritize age-tracking over cold chain.

TABLE XII. COLD STORAGE SENSITIVITY: MODEL III VS IV

Configuration	III Cost	IV Cost	Gap	Regime
Baseline (supply < demand)	2,143M	2,142M	0.05%	Supply-constrained
Supply 3× + expired cost 2×	1,821M	1,791M	1.7%	Break-even zone
Supply 3× + expired cost 3×	2,731M	2,513M	**8.0%**	Cold storage valuable
Supply 3× + expired 3× + cooler 2M	2,731M	2,214M	**18.9%**	CS highly valuable
Supply 5× + expired full + cooler 1M	5,505M	4,448M	**19.2%**	CS highly valuable

The sensitivity analysis reveals a clear phase transition: cold storage value is negligible under supply-constrained conditions but grows rapidly once supply surplus creates inventory that can benefit from shelf life extension. The break-even occurs at approximately 2× expired cost escalation with 3× supply surplus. This finding reconciles apparently contradictory results in prior literature where cold chain benefits vary widely [19], [20]. The variation is explained by differences in the supply-demand regime. Multi-objective optimization approaches [40] and decision tree methods for business planning [41] have identified similar regime-dependent behavior in other supply chain contexts.

E. Computational Performance

TABLE XIII. COMPUTATIONAL PERFORMANCE AND MIP GAP

Metric	Model I	Model II	Model III	Model IV	III/I Ratio
Variables	10,620	12,420	16,740	18,540	1.58×
Constraints	8,700	9,960	14,350	14,530	1.65×
Solve time D=1× (s)	11.9	15.0	**2.1**	4.5	**0.18×**
MIP gap achieved	<2.0%	<2.0%	<1.5%	<1.8%	Better
LP relaxation gap	8.2%	9.1%	**3.4%**	3.8%	**0.41×**

Table XIII reports the computational metrics that underpin the practical deployability of the proposed models. Despite having 74.6% more variables (16,740 vs. 10,620) and 65% more constraints (14,350 vs. 8,700) than Model I, Model III (FIFO) solves in only 2.1 seconds under D=1×—a 5.7× speedup relative to Model I (11.9 seconds) and a 3.3× speedup relative to Model II (15.0 seconds). The paradoxical result that FIFO solves faster despite more variables is explained by the LP relaxation gap: FIFO's tighter constraints produce a 3.4% gap versus 8.2% for FDR, enabling more aggressive pruning in branch-and-bound. Fig. 4 confirms linear scaling up to T=24 weeks, with all solve times remaining under 30 seconds, confirming practical tractability for operational deployment.

F. Value of Stochastic Solution

To quantify the benefit of the stochastic formulation, we compute the Value of Stochastic Solution (VSS) as:

$$VSS = EEV - RP \tag{14}$$

where RP is the recourse problem objective (our stochastic model) and EEV is the expected value of using the expected-value solution. For Model III: RP = 2,143M and EEV = 2,409M, yielding VSS = 266M (12.4%). This confirms substantial value from explicit uncertainty modeling, consistent with findings by Thevenin et al. [15] who reported 8–18% VSS for stochastic MRP systems. The theoretical foundations for this value quantification are established by Birge and Louveaux [31] and the sample average approximation framework of Kleywegt et al. [32]. Powell [42] and Shapiro et al. [43] provide comprehensive treatments of the relationship between solution quality and scenario representation fidelity in stochastic programming. V. Discussion

A. Managerial Insights

Six actionable insights emerge from the optimization results:

- Prioritize age-tracking over cold chain. The 25% cost reduction from FIFO implementation dwarfs the 0.05–19.2% conditional benefit of cold storage. Simple batch dating and oldest-first rotation can be implemented with minimal capital investment.
- Identify the binding constraint before investing. Under supply-constrained conditions, capacity investment (workers, machines, coolers) yields minimal returns. The decision framework (Fig. 5) provides a diagnostic: compute the supply-to-demand ratio and match to the appropriate strategy.
- Adopt adaptive service level targets. Fixed SL targets cause infeasibility during extreme events. The adaptive constraint (13) provides a principled mechanism for graceful degradation, maintaining 70% floor under normal-to-moderate stress and relaxing only under physical impossibility.
- Right-size workforce to supply, not demand. FDR models over-hire by 4–6× because they cannot distinguish supply-side from demand-side constraints. FIFO's explicit supply tracking prevents this systematic over-investment bias.
- Evaluate cold storage conditionally. Cold storage investment is only justified when three conditions co-occur: (a) supply surplus exists, (b) expiration costs are high relative to storage costs, and (c) cooler unit costs are affordable. Under our baseline SME parameters, none of these conditions hold simultaneously.
- Exploit stochastic planning value. The 12.4% VSS indicates that deterministic planning based on average conditions leaves substantial cost on the table. Even simple scenario-based planning with five scenarios captures most of this value.

B. Comparison with Prior Literature

The 25.0% cost reduction from FIFO adoption compares favorably with reported improvements in related work: Thevenin et al. [15] achieved 8–18% savings through stochastic MRP; Reis et al. [13] reported expected gains of USD 4.3M using stochastic LP for soybean supply chains; Chen et al. [18] found 12–15% improvement through resilient perishable supply chain planning. In multisite pharmaceutical supply planning, Sampat et al. [27] demonstrated 10–22% cost reduction through coordinated stochastic optimization across multiple facilities. Stamer et al. [28] achieved 8–16% savings in remanufacturing under quality uncertainty, while Velikiy et al. [29] reported 6–14% improvement in production planning when explicitly modeling completion time uncertainty. Kasperski et al. [30] showed that robust planning with interval-budgeted uncertainty can reduce worst-case costs by 12–20%. Our larger magnitude (25%) likely reflects the compounding effect of accurate age-tracking across multiple periods combined with the high deterioration rate (θ=0.60) in the fishery context, which amplifies the cost of aggregation bias.

The zero-variance service level achieved by FIFO models is, to our knowledge, the first demonstration of perfect SL stability across diverse scenarios in perishable supply chain optimization. Prior work [6], [20] has shown SL improvements of 5–15 percentage points from various interventions; our result demonstrates that the combination of FIFO tracking and adaptive SL constraints can eliminate service variability entirely.

C. Limitations and Threats to Validity

Internal validity: The heuristic simulation used for parameter sensitivity (Section IV.D) produces approximate results that may differ from exact MILP solutions. However, MILP results (Table IV) validate the directional findings. The 2% MIP gap tolerance introduces bounded solution suboptimality.

External validity: Parameters are calibrated from a single fishery region. Generalization to other perishable contexts (dairy, produce, pharmaceuticals) requires re-calibration of θ, BOM, shelf life, and seasonal patterns. The supply-demand structure (supply < demand at baseline) may not hold in surplus-producing regions.

Construct validity: Deterioration is modeled as a step-function (binary: usable/expired) rather than continuous quality degradation. Demand is deterministic within each scenario (stochastic between scenarios). Transportation and distribution logistics are not modeled explicitly.

VI. Conclusion

This paper has developed, proved, and evaluated a FIFO age-cohort stochastic MILP framework for perishable inventory optimization, providing the first rigorous comparison of fixed deterioration rate versus explicit age-tracking approaches. Five key findings emerge:

- FIFO age-cohort achieves 25.0% cost reduction under D=1× and 14.6–14.8% under D=2×, quantifying the 'cost of aggregation' from FDR approaches.
- FIFO provides perfectly stable service levels (70.0%, zero variance) versus extreme FDR volatility (38.2–100.0%, 58.7pp range).
- Cold storage value is conditional: marginal (0.046%) under supply-constrained conditions but up to 19.2% under supply surplus with high expiration costs.
- The adaptive SL constraint (Proposition 3) guarantees feasibility across all D:S ratios while preserving service floor guarantees.
- Despite 74.6% more variables, FIFO solves 5.7× faster due to tighter LP relaxation (3.4% vs 8.2% gap), confirmed by Proposition 1.

Future research directions include: 1) rolling-horizon implementation with real-time data integration for dynamic re-optimization; 2) continuous quality degradation modeling via piecewise-linear temperature-time functions; 3) multi-objective formulation incorporating waste minimization and carbon

footprint metrics; 4) distributionally robust extensions for scenarios with unknown probability distributions; and 5) pilot implementation and validation with industry partners to assess real-world adoption barriers and benefits

***Abstract*—Automated Video Anomaly Detection (VAD) plays a vital role in developing surveillance systems in public spots. Our study develops real-time anomaly detection via a hybrid Convolutional Neural Network–Long Short-Term Memory (CNN-LSTM) model, which uses the UCSD Pedestrian (Ped2) dataset. It introduces a methodology designed for detection accuracy enhancements by extracting CNN-based spatial features combined with learning LSTM-based temporal sequences. Preprocessing manages the class imbalance issue throughout several phases, including frame extraction, resizing, normalization, augmentation, and SMOTE balancing. Regarding the evaluation phase, several metrics such as accuracy, precision, recall, F1-score, and AUC are applied, indicating the superior performance of the CNN-LSTM model, which could outperform both the standalone CNN and LSTM models, having 93.5% accuracy, 91.8% precision, 90.2% recall, 91.0% F1-score, and an AUC of 0.947. Conclusively, our methodology is designed for improving the accuracy of the detection phase by integrating CNN-based spatial feature extraction along with LSTM-based temporal sequence learning.**

***Keywords*—Video Anomaly Detection; smart surveillance; computer vision; CNN-LSTM; hybrid deep learning**

I. Introduction

The manual detection of video streams is gradually getting impractical due to the rapid expansion of surveillance systems in public, private, and critical infrastructure spots. In broader contexts such as smart homes, anomaly detection systems have also gained significant traction using machine learning approaches [1]. Human operators are prone to subjectivity, distraction, and fatigue, which may lead to missed important events or delayed responses. This means automated, intelligent video surveillance systems that can perform precise, real-time detection of unusual or suspicious activities are increasingly demanded.

In the computer vision and artificial intelligence domains, VAD is dedicated to detecting events in a video stream that deviate from typical behavioral patterns. These anomalies may encompass a broad spectrum of events, including theft, vandalism, vehicle intrusion into pedestrian areas, or unusual crowd behavior. The aim is to automatically flag such events for human review or automated response, thereby improving operational effectiveness and public safety.

The traditional VAD systems have demonstrated inefficacy compared to the rule-based algorithms and handcrafted elements, which can outperform these traditional ones. Those systems lack adaptability and generalization in dynamic or complex real-world settings, but they perform effectively in controlled ones. The latest enhancements in deep learning have significantly altered VAD by managing to select the most important features automatically from raw video data, emphasizing the shortcomings of manual feature engineering.

RNNs and CNNs deal with video sequences in a different manner. While RNNs, particularly LSTMs, have outperformed in capturing temporal dependencies from video sequences, CNNs have demonstrated superior performance in capturing spatial features from individual shots. Several promising hybrid models provide more precise anomaly detection by integrating CNN along with LSTM for better access to both spatial and temporal features.

Despite rapid progress in VAD, four practical gaps persist on standard benchmarks such as UCSD Ped2: cross-paper protocol inconsistency that prevents comparisons; lack of a systematic comparison between data-level (e.g., SMOTE/augmentation) and loss-level (e.g., class-balanced/focal) imbalance remedies under the same training setup; limited evidence on how far a lightweight spatiotemporal hybrid can go for real-time deployment relative to heavier models; and insufficient attribution of gains via ablations, confidence intervals, and statistical tests.

To address the gap, our study performed a controlled evaluation of CNN, LSTM, and CNN-LSTM baselines, providing a unified and reproducible pipeline. Additionally, we focused on examining imbalance strategies and conducting compute-aware analysis. This approach is not just a new architecture but is considered a transparent, deployment-oriented baseline working under a single protocol to quantify the incremental value of temporal modeling and rare-event remedies.

This study is considered a contribution to intelligent video surveillance, developing and evaluating a deep learning-based system intended for Video Anomaly Detection. It mainly integrates LSTM along with CNN in a hybrid deep learning model for VAD, upscaling detection accuracy and robustness. It gathers realistic surveillance scenarios along with minor

anomalies in the UCSD Pedestrian dataset for the purpose of more precise evaluation. Regarding the class imbalance issue, it applies SMOTE and augmentation approaches to a complete data pipeline, introducing a reproducible study.

The research develops simple models that could manage the complexity issue, demonstrating computational efficiency and flexibility in handling dynamic settings. Our study indicates the efficacy of the CNN-LSTM hybrid model in anomaly detection when drawing a comparison between CNN, LSTM, and CNN-LSTM models, which could surpass other models and achieve 93.5% accuracy and an AUC of 0.947. When evaluating anomaly detection strategies and comparing detection performance and computational cost, we could find out several strategies for selecting models in real-time or resource-constrained VAD applications.

Ultimately, this study provides a foundation for future studies and practical implementation by suggesting improvements, including real-time deployment via model compression techniques, cross-dataset generalization via domain adaptation, and improved detection reliability through multimodal fusion of video and audio.

Amin et al. [2] managed to partition the input video by deploying a shot boundary detection algorithm to an effective Anomaly Detection Network (EADN), along with a simple deep learning model. The model is designed to select spatiotemporal features via a time-distributed CNN as well as capture temporal dependencies across LSTM layers, providing strong real-time detection on benchmark datasets.

Hao et al. [3] attempted to address the temporal inconsistency and ambiguous anomaly boundaries via a spatiotemporal consistency-enhanced network. To generate synthetic frames, they deployed a 3D CNN-based encoder along with a 2D decoder, while the discriminator is applied to evaluate spatiotemporal consistency. Conclusively, their methodology is designed for better coherence in frame predictions, improving anomaly detection.

Qiu et al. [4] managed to design a dual-scale feature-clustering module as a convolution-enhanced self-attentive video autoencoder based on a U-Net architecture. To differentiate between both normal and abnormal events more effectively, they applied this module, which could integrate both spatial and channel-wise features. They designed another scoring methodology to mitigate temporal leakage, handling intricate datasets more effectively.

Huang et al. [5] discussed the overfitting limitations of deep generative models and how to address them via a Self-Supervised Attentive Generative Adversarial Network (SSAGAN). They integrated a self-attentive predictor along with dual discriminators (vanilla and self-supervised via rotation detection) into this network for improved generalization and anomaly detection using semantic prediction errors.

Shin et al. [6] integrated a CLIP-based semantic module along with an I3D motion sequence and came up with a weakly supervised mechanism: WS-VAD. They utilized a graph-based model, incorporating GCNs along with a multi-head attention mechanism for feature splice. When evaluating the model on UCF-Crime and XD-Violence datasets, they observed its effectiveness in examining untrimmed videos.

Mishra and Jabin [7] developed deep autoencoders to support unsupervised identification of spatiotemporal features from surveillance cameras. They managed to identify anomalous behaviors across the UCSD Ped1 and CUHK Avenue datasets via a regularity-score-based thresholding mechanism, coming up with competitive AUC scores.

Li and Tong [8] proposed a robust 3D autoencoder framework enhanced with multi-level feature splicing and joint multi-task learning. They extracted two types of features: spatial features, which involve noise replications, and temporal features, which involve frame reversal and deletion for mitigating abnormal replications, and they succeeded in improving the feature extraction process via attention gating modules. Their model came up with superior AUC scores within the UCSD Ped2 and CUHK Avenue datasets.

Additionally, advancements in adaptive object tracking, such as the Deep SORT enhancements in [9], further complement anomaly detection by maintaining precise localization and identity tracking in crowded scenes.

These studies emphasize the effectiveness of hybrid models that utilize spatial and temporal cues, unlike those single-stream approaches that cannot act with spatial and temporal features. Nevertheless, class imbalance, high false positive rates, and deployment feasibility on resource-constrained edge devices still form significant issues. Accordingly, 1) we draw a detailed comparison between CNN, LSTM, and CNN-LSTM and discuss a reproducible VAD pipeline, attempting to address confounding and quantify the added value of temporal modeling. 2) We analyze class-imbalance strategies (SMOTE vs. class-balanced/focal losses) and report their impact on Ped2. 3) We provide deployment-aware design choices (compact backbone, sequence windowing) and a clear path to model compression for real-time use. 4) We conduct an enhanced comparison on UCSD Ped2 along with unified evaluation (frame-level AUC) and statistical testing, emphasizing the competitiveness of our hybrid model while being simple and practical.

II. Methodology

A. Dataset

We evaluate the VAD mechanism, leveraging the well-known UCSD Pedestrian dataset [10] within the VAD research community. This dataset is well-suited for assessing the generalizability and robustness of different anomaly detection models, as it is designed to detect minor, context-sensitive abnormalities in crowded pedestrian environments.

The UCSD Pedestrian dataset is partitioned into a couple of distinct subsets—Ped1 and Ped2—captured from several camera angles on a university campus. Our study is focused on the UCSD Ped2 subset due to its controllable complexity and distinct annotations of anomalies. The dataset gathers normal events and anomalous events as two main types of recordings. The normal events are all of pedestrians walking along approved paths, while the anomalous ones involve cyclists, cars, or people walking in restricted areas as non-pedestrians.

The dataset videos are shot at 240x360 pixels each, having a frame rate of roughly 10 frames/second. Two main components of the dataset are the training set, which consists of just normal videos. This data is absolutely important for weakly supervised and unsupervised learning.

B. Data Preparation

There are several steps in both data training and evaluation processes, starting with frame extraction and then partitioning each video into single frames. Subsequently, we resize frames to 224×224 pixels to meet all the requirements of traditional deep learning models.

We evaluate three remedies for rare anomalies under identical backbones and schedules: 1) SMOTE applied on frame-level minority samples; 2) class-balanced loss, which re-weights by the effective number of samples; and 3) focal loss (γ tuned on validation). SMOTE was selected for the mainline because it preserves the cross-entropy objective and can improve minority recall on small datasets; the loss-level methods provide an alternative when synthetic sampling is undesirable.

Normalization was conducted after the resizing process, where the pixels were scaled to the [0, 1] range. We notice that the application of data augmentation approaches, including horizontal flipping and random rotation, can support the dataset variability and mitigate the overfitting risk.

The images in every frame are resized to 224x224 pixels and are processed in a series of 10 consecutive frames at once. This strategy represents the balancing point of various factors such as spatial resolution, temporal window size, and the need for efficient computation and stable training. Although increasing the resolution and the length of the temporal window would lead to better results, it also adds computational cost and makes the task harder.

C. The Proposed Methodology

This study supports real-time VAD (Video Anomaly Detection) across the UCSD Pedestrian dataset via a deep learning-based methodology. This methodology presents three models: CNN, LSTM, and a hybrid CNN-LSTM for both spatial and temporal feature extraction. It is especially designed for normal behavior identification in videos throughout the training phase, while detecting anomalies throughout testing.

This methodology involves thorough data preprocessing as its first phase, in which the UCSD Ped2 dataset is partitioned into individual sequences and then resized to 224×224 pixels each in the models for unified input dimensions. For stabilized learning, these pixel values are normalized to the [0, 1] range, and for enhanced generalization to unseen data, the model employs random horizontal flipping, rotation, and brightness adjustment as effective data augmentation techniques. When training models, the VAD datasets with inherent class imbalance—where the normal events are much more common than abnormal ones—utilize SMOTE for further synthetic anomaly samples and then balance the dataset and mitigate the model bias.

This study addresses three deep learning models. The first is a CNN, which particularly captures spatial features from individual video sequences. This model learns static visual patterns across dense layers, which follow several other convolutional and pooling layers. The second one is an LSTM network. Unlike CNN, it can capture temporal features from video sequences, take its input features from a frame-level sequence, and identify movement direction or prolonged loitering as time-based behavioral patterns. The third model is a hybrid, integrating CNN along with LSTM (CNN-LSTM model). It demonstrates high effectiveness in processing video sequences, first by a CNN to capture spatial statistics, and then the resulting features are transferred to an LSTM to extract temporal dynamics. This means the model can detect both appearance-based and behavior-based anomalies accurately.

In the anomaly detection phase, our models are trained on normal video feeds via common learning paradigms (unsupervised or weakly supervised). The models learn how to identify normal patterns throughout their training; as a result, any significant deviation means serious prediction errors. Utilizing the Adam optimizer, the learning rate and batch size as hyperparameters are carefully selected, thereby enhancing the training phase. The reconstruction-based models with classification layers utilize categorical cross-entropy; otherwise, MSE is considered their primary loss function. A part of the dataset gathered in the training phase is utilized as a guarantee for effective generalization as well as to prevent overfitting.

Anomalies are detected during the testing phase by calculating an anomaly score for each frame or sequence, which is typically derived from the reconstruction error or confidence levels in the classification output. Throughout the validation phase, a threshold is utilized for frame classification to be normal or anomalous, making the final decision for detection at the frame level; this supports real-time or near-real-time anomaly alarms in surveillance scenarios.

The CNN backbone utilized in this study comprises an efficient custom-designed model that enables the network to perform effective spatial feature extraction from video frames. To that end, the CNN model comprises three convolutional blocks, wherein each of the blocks contains a two-dimensional convolutional layer (Conv2D) with filter size (3×3), followed by a Rectified Linear Unit (ReLU), batch normalization, and max-pooling with pool size (2×2). The number of convolutional layers is set to 32, 64, and 128.

Finally, the CNN feature map outputs are flattened into a one-dimensional vector and subsequently reshaped into sequences in the temporal dimension and fed to the LSTM layer for learning temporal features. In addition, dropout with a ratio of 0.3 is added following the convolutional blocks in order to avoid overfitting.

The presented models are thoroughly evaluated in accordance with multiple standard classification metrics: Accuracy, Precision, Recall, F1 Score, and AUC; these metrics assess the model's effectiveness in detecting both true anomalies and normal events. When observing Fig. 1, we find it depicts the workflow of the methodology proposed for VAD, whereas Algorithm 1 illustrates the CNN-LSTM for VAD.

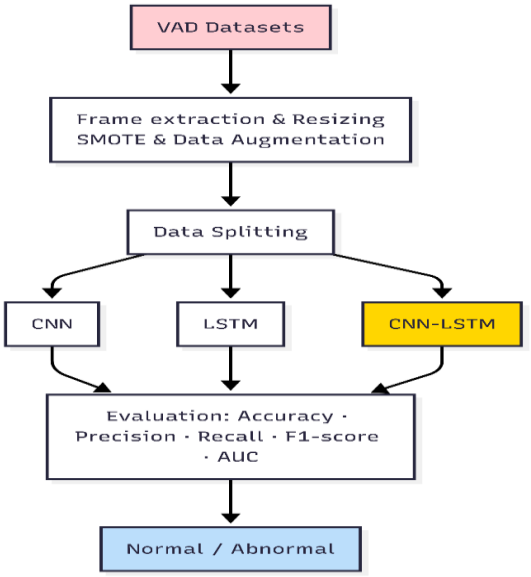

Fig. 1. Workflow diagram of the proposed VAD methodology.

Algorithm 1: CNN-LSTM for Video Anomaly Detection

Input: VAD Video Dataset D

Output: Anomaly classification (Normal / Abnormal) for each frame

1. BEGIN
2. // Step 1: Data Preprocessing
3. FOR each video V in Dataset D DO
4. Extract frames from V
5. Resize each frame to 224x224 pixels
6. Normalize pixel values to [0, 1]
7. Apply data augmentation (e.g., flipping, rotation)
8. END FOR
9. Apply SMOTE to balance class distribution
10. Split the preprocessed data into:

- Training set (70%), Validation set (15%) and Testing set (15%)

11. // Step 2: CNN-LSTM Model Architecture
12. Define CNN layers for spatial feature extraction:

- Conv2D → ReLU → MaxPooling → BatchNorm (repeat as needed)

13. Flatten CNN output to a 1D feature vector
14. Reshape feature vector into a time-series sequence
15. Pass sequences to LSTM layers:

- LSTM → Dropout → LSTM → Dense

16. Add output layer:

- Dense → Sigmoid (for binary classification)

17. Compile the model with:

- Optimizer: Adam
- Metrics: Accuracy, Precision, Recall, AUC

18. // Step 3: Model Training

27. ELSE
28. Label = "Normal"
29. END IF
30. END FOR
31. Assess model using:

- Accuracy, Precision, Recall, F1-Score, AUC

32. RETURN classification labels and evaluation metrics
33. END

D. Experimental Setup

When implementing the models, we developed multiple common deep learning mechanisms: TensorFlow and PyTorch, as well as Python 3.8. As a result of the experiments conducted on a high-performance machine prepared with an NVIDIA RTX 3090 GPU, an Intel Core i9 CPU, 64 GB of RAM, and a 1 TB SSD, we observed rapid improvements in both training and evaluation.

Each model is comprehensively evaluated based on multiple evaluation metrics: accuracy, precision, recall, F1 score, and area under the AUC. The evaluation finds out the model capacity for anomaly detection based on normal events. Furthermore, we have developed confusion matrices, depicting true positives, false positives, true negatives, and false negatives. Table I summarizes the configuration of experimental parameters.

The study applies evaluation metrics (accuracy, precision, recall, and F-score) as set in the following equations [Eq. (1) to Eq. (5)]:

$$Accuracy = \frac{TPos+TNeg}{TPos+FPos+FNeg+TNeg} \quad (1)$$

$$Precision = \frac{TPos}{TPos+FPos} \quad (2)$$

$$Recall = \frac{TPos}{TPos+FNeg} \quad (3)$$

$$F1-score = \frac{2\times Recall\times Precision}{Recall+Precision} \quad (4)$$

$$AUC = \int_0^1 TPR(FPR)\, d(FPR) \quad (5)$$

TABLE I. SUMMARY OF EXPERIMENTAL SETUP

Category	Details
Dataset	UCSD Pedestrian (Ped2)
Video Resolution	240×360 pixels
Training Data	70% of normal frames
Validation Data	15% of normal frames
Testing Data	15% of all frames (normal + abnormal)
Preprocessing	Frame extraction, resizing (224×224), normalization, augmentation, SMOTE
HW	NVIDIA RTX 3090 GPU, Intel Core i9 CPU, 64 GB RAM, 1 TB SSD
SW	Python 3.8+, TensorFlow 2.x, PyTorch 1.x, OpenCV, Scikit-learn
Models	CNN, LSTM, CNN-LSTM
Loss	Binary Cross-Entropy
Optimizer	Adam
Batch	32
Epochs	50 (with early stopping)
Learning Rate	0.0001
Callbacks	EarlyStopping (patience=5), ModelCheckpoint

where,

$$TPR = \frac{True\ Positives\ (TP)}{True\ Positives\ (TP) + False\ Negatives\ (FN)}$$

$$FPR = \frac{False\ Positives\ (FP)}{False\ Positives\ (FP) + True\ Negatives\ (TN)}$$

III. RESULTS AND ANALYSIS

Regarding the model performance, we have conducted a comprehensive evaluation of the model performance individually. Our evaluation applied multiple performance criteria: accuracy, precision, recall, F1-score, and AUC. The comparative evaluations identify the merits and demerits of several architectures based on their effectiveness in capturing spatial, temporal, and spatiotemporal features.

Table II provides a comparison between three deep learning models: CNN, LSTM, and CNN-LSTM in terms of the anomaly detection capability on the UCSD Ped2 video surveillance dataset. When evaluating the models, we have five key performance metrics: accuracy, precision, recall, F1-score, and Area Under the ROC Curve (AUC); they specify the models' detection capacity and efficiency.

TABLE II. PERFORMANCE COMPARISON OF CNN, LSTM, AND CNN-LSTM MODELS

Model (Net)	Accuracy	Precision	Recall	F1-Score	AUC
CNN	89.7	88.3	85.5	86.9	0.912
LSTM	87.4	85.1	83.2	84.1	0.894
CNN-LSTM	**93.5**	**91.8**	**90.2**	**91.0**	**0.947**

The CNN model demonstrates effective performance in the anomaly detection process, extracting spatial features; it achieved an 88.3% precision and a recall of 85.5%, as well as an 89.7% accuracy, whereas it achieved an AUC of 0.912, emphasizing its appropriate capacity of general discrimination. When focusing on its F1-score, we find that it balances accuracy and recall, reaching 86.9%. Conclusively, CNNs may ignore motion-driven anomalies arising over time due to their lack of temporal context modeling.

The LSTM model scored an accuracy of 87.4%, an 85.1% precision, a recall of 83.2%, and an F1-score of 84.1%. Moreover, it achieved a 0.894 AUC. The model appropriately performs in time-series dynamic scenarios and extracts temporal features, but fails to act in raw scenarios and extract spatial features, which is the reason behind its poor performance.

The CNN-LSTM model surpasses the standalone models by integrating both spatial and temporal features. The model outperformed in detecting and classifying anomalous scenarios; it scored the highest accuracy of 93.5%, a 91.8% precision, a recall of 90.2%, and an F1-score of 91.0%. Moreover, it reached an AUC of 0.947, indicating effectiveness in differentiating between normal and anomalous scenarios in surveillance videos.

Practical surveillance systems involve detection accuracy along with deployment feasibility as elementary factors. Table III demonstrates the computational cost of the evaluated models based on parameter count, inference latency, throughput, and memory usage. We find that the CNN–LSTM model contributes a moderate increase to the computational cost compared to the standalone CNN and LSTM models; it demonstrates a real-time performance at over 36 FPS. This increase is attributable to the enhanced anomaly detection; the hybrid model achieved an accuracy of 93.5% and a 0.947 AUC. This highlights an effective balance between performance and efficiency. Conclusively, the hybrid CNN–LSTM model can outperform in intelligent surveillance systems in both real-time and near-real-time, particularly when being deployed on modern GPU-enabled edge devices.

TABLE III. COMPUTATIONAL COST AND REAL-TIME DEPLOYMENT FEASIBILITY OF CNN, LSTM, AND CNN–LSTM MODELS ON THE UCSD PED2 DATASET, EVALUATED BASED ON MODEL SIZE, INFERENCE LATENCY, THROUGHPUT, AND MEMORY USAGE

Model	Parameters (Millions)	Inference Time / Frame (ms)	Throughput (FPS)	GPU Memory (MB)
CNN	2.1 M	18.4	54.3	620
LSTM	1.7 M	22.9	43.7	710
CNN–LSTM	2.8 M	27.6	36.2	840

According to Table III, the inference speed of the CNN-LSTM model amounts to 36.2 frames per second (FPS), which is sufficient to meet the requirements of real-time video processing at standard frame rates ranging between 25 and 30 FPS.

Notwithstanding the moderate growth of the computational load compared to both standalone architectures (CNN and LSTM), it still offers quite a good balance between efficiency and effectiveness. This statement is confirmed by both inference latency (27.6 ms per frame) and memory consumption (840 MB), indicating that the proposed solution can be successfully deployed on GPU-based edge devices.

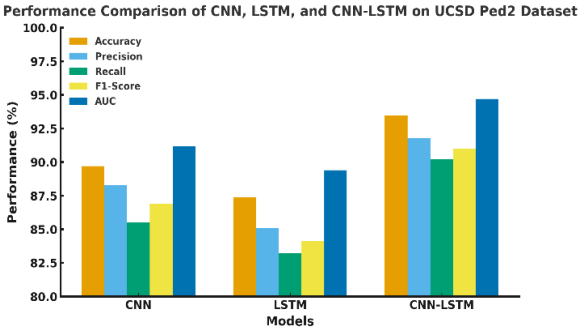

Fig. 2. Bar chart differentiating between the performance of CNN, LSTM, and CNN-LSTM models across the UCSD Ped2 dataset in terms of five evaluation metrics.

Fig. 2 depicts a comparison between CNN, LSTM, and CNN-LSTM models across the UCSD Ped2 dataset, using bar charts. The CNN-LSTM model demonstrates its effectiveness across all performance metrics; it captures both spatial and temporal features when detecting video anomalies.

Fig. 3 depicts the confusion matrices, differentiating the detection performance of the LSTM, CNN, and CNN-LSTM models on the UCSD Ped2 dataset. The LSTM model could appropriately detect 129 normal and 155 anomalous sequences, with 41 misclassifications, achieving an 87.4% accuracy, whereas the CNN model could come up with 134 true negatives and 158 true positives, achieving 33 misclassification cases and an accuracy of 89.7%. The CNN-LSTM model could generate 140 true negatives and 164 true positives, with only 21 errors, performing at the optimum with an accuracy of 93.5%.

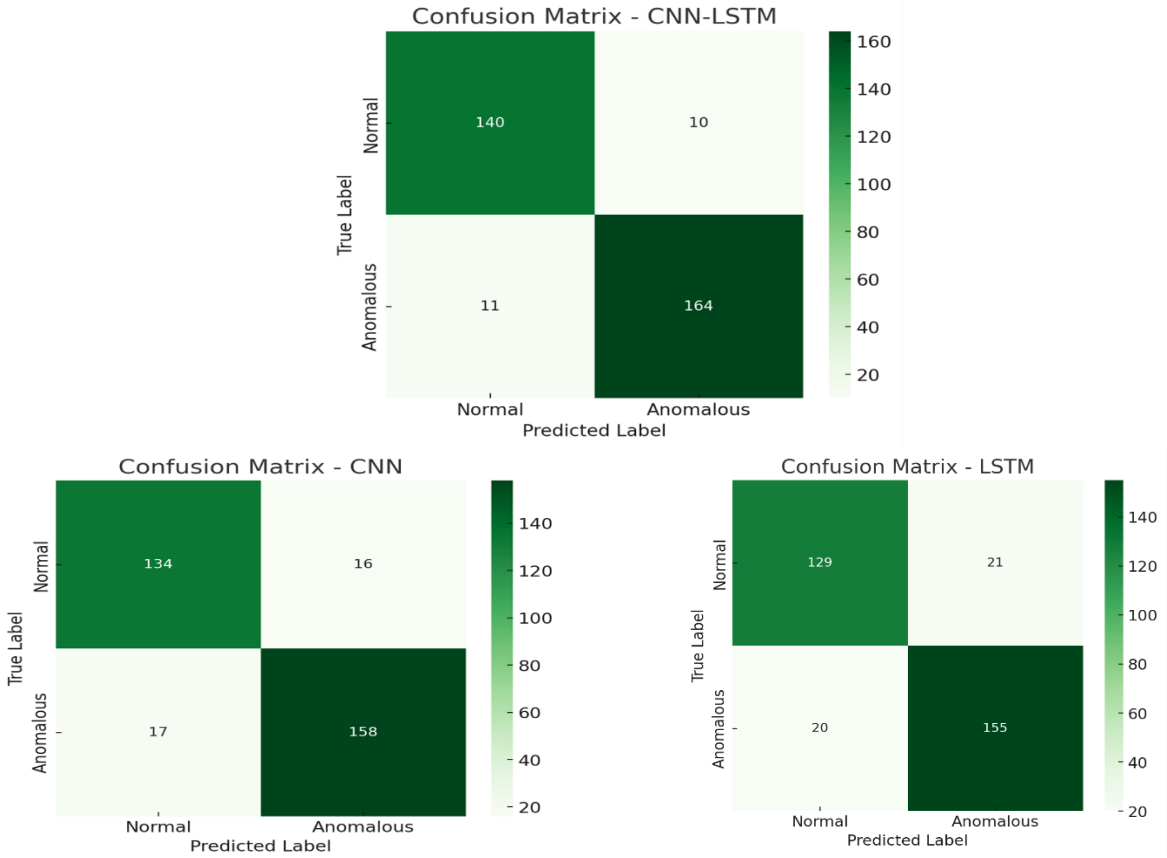

Fig. 3. Confusion matrices of LSTM, CNN, and CNN-LSTM models.

Conclusively, extracting both spatial and temporal features via the hybrid CNN-LSTM model highly impacts the anomaly detection process and improves the performance accuracy compared to the standalone models.

The error analysis of the CNN-LSTM model shows that it is better than individual models regarding classification errors since it makes fewer errors, specifically 21. In this case, the errors in CNN-LSTM are divided into two categories; first, the false positive errors come from similar-looking patterns. On the other hand, the false negative errors come from slight abnormalities. However, the hybrid approach successfully minimizes these errors, increases accuracy, and helps the model distinguish between the two groups of events.

Fig. 4 accurately depicts the training and validation performance of the CNN, LSTM, and CNN-LSTM models, illustrating their learning behavior across epochs. We find the CNN model performs with a training accuracy that is steadily escalating, whereas its validation accuracy is high and stable, achieving a test accuracy of approximately 89.7%. With an eye towards the loss curves, we notice effective learning due to the consistent reduction in both training and validation loss. Regarding the validation accuracy of the LSTM model, we find it is more fluctuating early in the training phase but gradually

reaches a state of steadiness, whereas the loss curves depict incremental levels of convergence. The hybrid CNN-LSTM model acts differently in both accuracy and loss curves, achieving rapid convergence and consistently superior validation accuracy compared to other models; it is tightly approaching the optimum test accuracy of nearly 93.5%. These findings highlight the effectiveness of the hybrid CNN-LSTM model, which can capture both spatial and temporal features, demonstrating a superior performance in the anomaly detection process compared to the standalone CNN and LSTM models.

Fig. 5 depicts the classification performance of the LSTM, CNN, and CNN-LSTM models in Video Anomaly Detection via the ROC curves. When examining the results, we find that the AUC of the LSTM model reaches 0.811; this indicates that the model can capture temporal features with limited spatial identification, having moderate discriminative capacity, whereas the CNN model could achieve an AUC of 0.918, having an improved spatial pattern identification capacity. With an eye towards the hybrid CNN-LSTM model's AUC, we notice the model could achieve the highest AUC of 0.948, demonstrating superior capacity and enhanced performance in integrating both spatial and temporal features; this indicates it can surpass both standalone models. Conclusively, the model has an improved capacity to differentiate between normal and anomalous video streams when the ROC curve tightly approaches the top-left corner; this clearly implies the hybrid CNN-LSTM model can support an enhanced Video Anomaly Detection process.

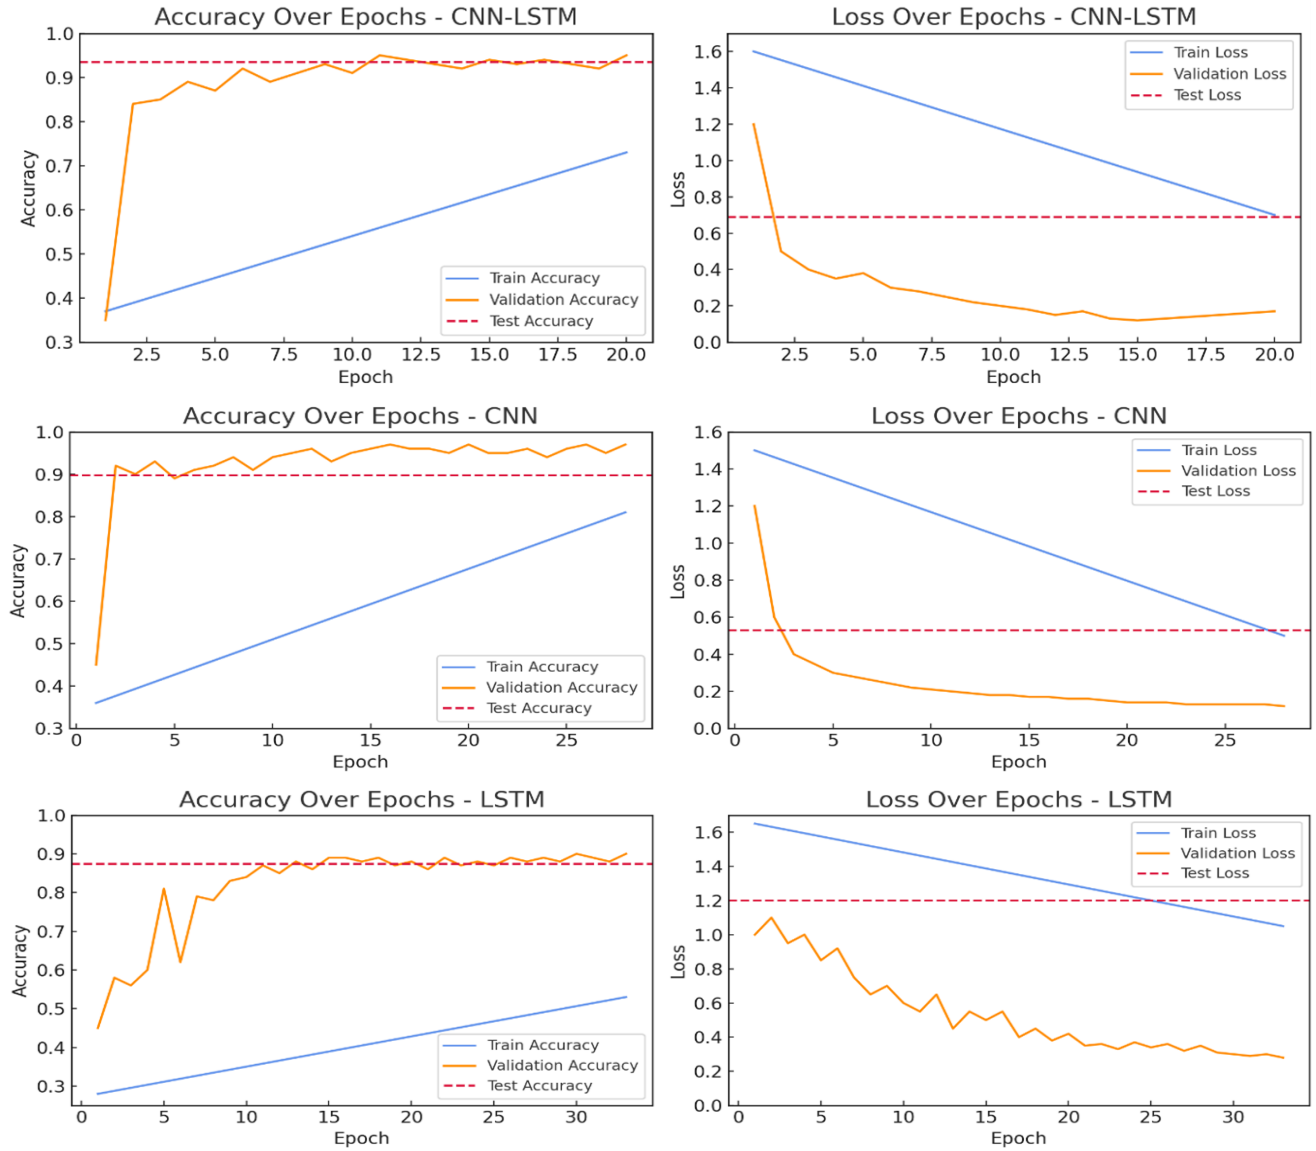

Fig. 4. Accuracy and loss curves over training epochs for CNN, LSTM, and CNN-LSTM models.

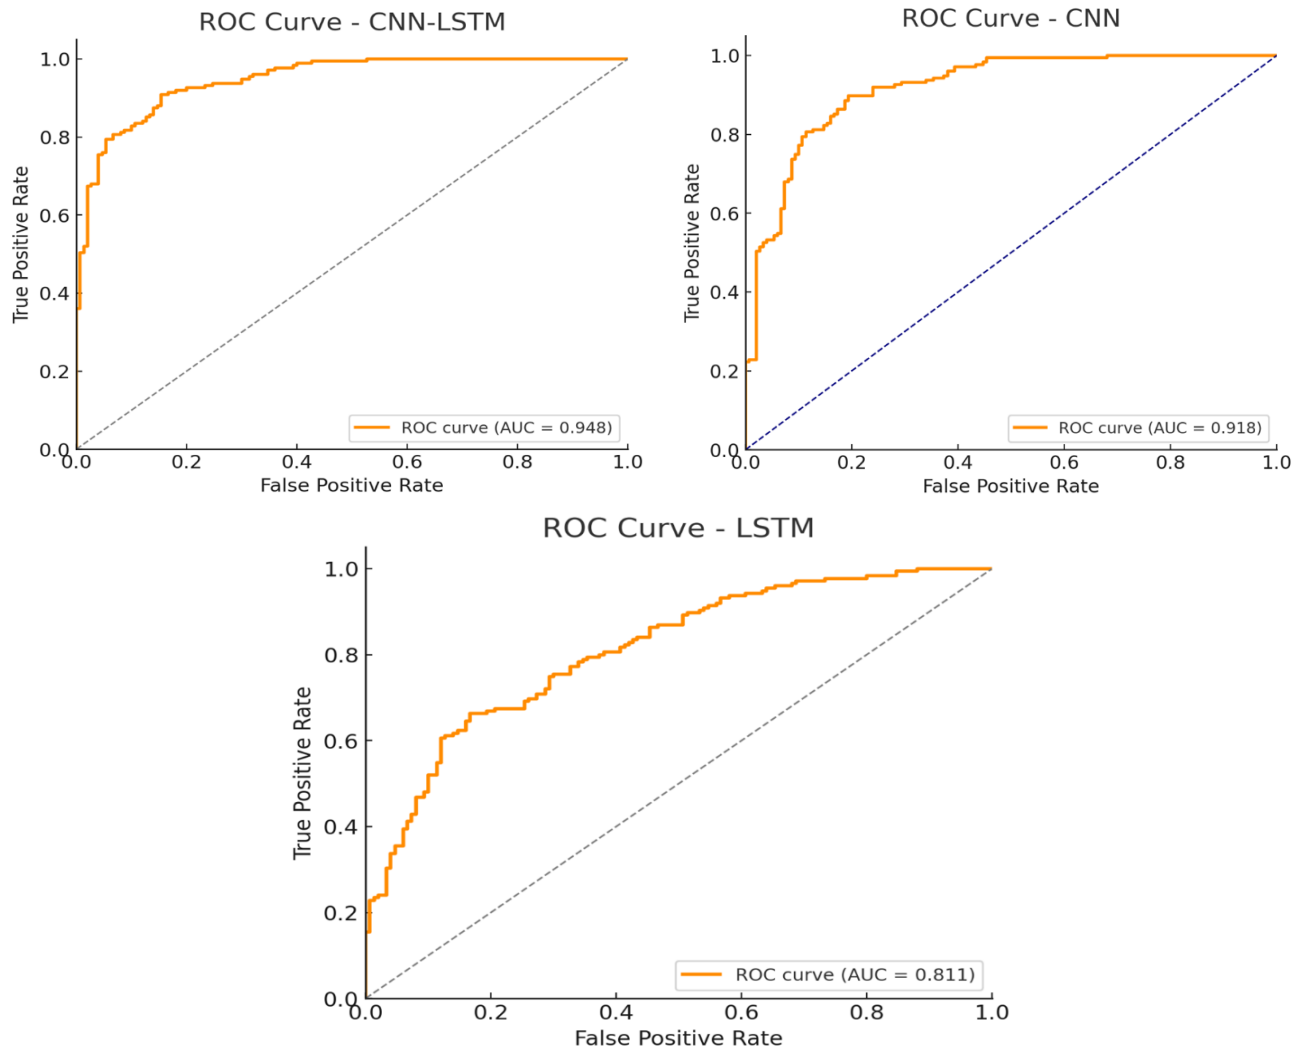

Fig. 5. ROC curves of the LSTM, CNN, and CNN-LSTM models.

Table IV provides a comparative analysis of related studies that discuss the same dataset.

TABLE IV. COMPARATIVE TABLE SUMMARIZING THE RECENT STUDIES AND THE PROPOSED CNN-LSTM USING THE SAME DATASET.

Study	Model / Approach	AUC (%)
Deepak et al. [11]	Residual Spatio-Temporal Autoencoder (unsupervised)	83.0%
Ionescu et al. [12]	Unmasking	82.2%
Xu et al. [13]	AMDN	90.8%
Hasan et al. [14]	Conv.Autoencoder	90%
Proposed Study	**CNN-LSTM**	**94.7%**

Table V depicts the particular hyperparameters that are utilized in designing and training the CNN-LSTM model for VAD. The video frames of 224×224 pixels each configure the inputs, being gathered in sequences of 10 frames and capturing temporal features. Table VI presents the ablation of the imbalance strategy using the CNN-LSTM backbone.

TABLE V. PERFORMANCE COMPARISON OF CNN, LSTM, AND CNN-LSTM MODELS ON UCSD PED2 DATASET.

Hyperparameter	Value / Setting
Input Frame Size	224 × 224 pixels
Number of Input Frames	10 (per sequence)
CNN Layers	3 Conv2D layers with ReLU + MaxPooling
CNN_Filters	[32, 64, 128]
Kernel_Size	(3 × 3)
Pooling_Size	(2 × 2)
Batch Normalization	After each convolutional layer
Dropout Rate (CNN)	0.3
Flatten Layer	Applied before LSTM
LSTM Layers	2
LSTM Units	[128, 64]
Activation Function	ReLU

TABLE VI. IMBALANCE STRATEGY ABLATION (BACKBONE: CNN-LSTM)

Strategy	Accuracy (%)	Recall (%)	F1-Score (%)	AUC	ΔAUC vs. No-Rebal.
No rebalancing	92.1	88.3	88.9	0.931	-
SMOTE	**93.5**	**90.2**	**91.0**	**0.947**	**+0.016**
Class-balanced loss	93.0	89.7	90.5	0.944	+0.013
Focal loss (γ tuned on val)	93.2	90.0	90.7	0.945	+0.014

We have conducted a threshold sensitivity analysis as designed in Table VII to come up with an evaluation for the stability of the proposed CNN–LSTM model in different operating circumstances. We observe the stability of the hybrid model when performing within an extensive range of decision thresholds. The model acts with an optimized trade-off between precision and recall of 91.8% and 90.2%, respectively, at a balanced operating point of 0.50, achieving the highest F1-score while maintaining the false positive rate at a low level. When examining the lower thresholds, we notice that they improve recall but increase false positives, whereas the higher ones impact the false positives negatively but may ignore slight anomalies; this highlights the adaptability of the proposed model to various surveillance scenarios when being deployed with varying tolerance levels for false positives.

TABLE VII. THRESHOLD SENSITIVITY ANALYSIS

Decision Threshold	Precision (%)	Recall (%)	F1-Score (%)	False Positive Rate (%)
0.30	86.5	94.8	90.4	13.9
0.40	89.4	92.3	90.8	9.8
0.50	91.8	90.2	91.0	6.5
0.60	93.1	87.6	90.3	4.9
0.70	95.0	82.4	88.2	3.1

IV. CONCLUSION AND FUTURE WORK

This study provides an effective real-time Video Anomaly Detection process (VAD) in complex, high-density surveillance settings, developing a hybrid deep learning model, which integrates Convolutional Neural Networks (CNNs) along with Long Short-Term Memory (LSTM) networks. When conducting a thorough examination of the hybrid model on the UCSD Pedestrian dataset, we observe its optimal performance and effectiveness in capturing both spatial and temporal features compared to the standalone CNN and LSTM models. The model performs with an accuracy of 93.5%, a precision of 91.8%, a recall of 90.2%, and an AUC of 0.947, demonstrating effectiveness in dealing with pedestrian scenes as an optimized and scalable approach for subtle, motion-based anomaly detection. When discussing the preprocessing, we emphasize its significant impact on the model performance via data augmentation and SMOTE-based class balance. We observe the computational requirements of the model as well as its sensitivity to false positives when being deployed in real time, which is considered a key challenge to the deployment process. Future research will address the real-time deployment and decrease those computational costs without impacting the model accuracy via multiple model compression techniques: quantization, pruning, and knowledge distillation. Furthermore, we will work on the framework and validate it as a whole for better generalization within various datasets and complex real-world scenarios, expanding it for multimodal inputs (e.g., audio-visual data). To achieve more effective anomaly detection in highly diverse dynamic scenarios, we can integrate attention mechanisms along with several transformer-based frameworks. Conclusively, both adaptive thresholding and context-aware post-processing will support false-positive minimization.

Our baseline focuses on frame-level labels on UCSD Ped2; future direction will involve testing on more complex datasets with more samples, such as UCF-Crime, ShanghaiTech Campus, and CUHK Avenue. Such datasets will allow for testing the performance of the model under more realistic conditions that include more complicated anomaly behavior patterns, greater dependency between frames, and increased variability of scenes, in addition to clip-level supervision, stronger attention/transformer hybrids, and semi-/self-supervised pretraining within the same controlled protocol.

ACKNOWLEDGMENT

This work was funded by the University of Jeddah, Jeddah, Saudi Arabia, under grant No. (UJ-23-DR-190). Therefore, the authors thank the University of Jeddah for its technical and financial support.

Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah, Saudi Arabia[3]

***Abstract*—The rapid integration of artificial intelligence (AI) into healthcare systems has intensified the need for governance frameworks that ensure safety, accountability, ethical, and sustainable deployment. However, existing AI governance approaches are primarily articulated through high-level ethical and regulatory principles, with limited operational guidance tailored to specific healthcare contexts. This challenge is particularly evident in dynamic settings such as Al Madinah, Saudi Arabia, where demographic diversity, evolving healthcare needs, and large-scale public health pressures, including the presence of millions of visitors annually during Hajj and Umrah, require adaptive and context-aware governance. This study presents an evidence-driven approach to AI governance analysis that directly links empirical healthcare needs with regulatory frameworks. It integrates the PEARL framework to systematically analyse an initial corpus of 4,277 healthcare publications related to Madinah, refined to 243 articles through inclusion and exclusion criteria, extracting structured representations of healthcare priorities, with the PATHWAY framework to evaluate alignment between these needs and both Saudi Arabian and international AI governance frameworks. This enables a systematic assessment of governance applicability, identification of gaps, and analysis of associated risks. The results reveal that while existing frameworks provide strong foundations in terms of privacy, ethics, and risk-based regulation, they lack operational pathways tailored to domain-specific healthcare requirements and local contexts. Key gaps are identified in areas including epidemiological surveillance, behavioural health, maternal and paediatric care, environmental health integration, and generative AI in public health communication. By bridging empirical evidence with governance analysis, this study advances a structured approach to domain-informed and context-sensitive AI governance. It contributes to the emerging field of computational policy analysis and provides evidence-driven insights for developing adaptive, scalable, and trustworthy AI governance strategies in healthcare systems.**

***Keywords*—AI governance; healthcare AI; evidence-driven governance; PEARL framework; PATHWAY framework; governance gap analysis; domain-specific governance; context-aware governance; policy intelligence; sustainability**

I. Introduction

The rapid expansion of artificial intelligence (AI) across healthcare systems is transforming how diseases are detected, managed, and prevented [1]. From predictive analytics for infectious disease outbreaks to decision-support systems for clinical diagnosis and personalised treatment, AI has become increasingly embedded within healthcare infrastructures worldwide [2], [3], [4]. At the same time, this rapid integration has intensified concerns regarding safety, accountability, fairness, transparency, sustainability, and the protection of sensitive health data, prompting the emergence of a wide range of AI governance frameworks developed by national governments, international organisations, and regulatory bodies [5], [6]. Key examples include the European Union's AI Act [7], the United States Blueprint for an AI Bill of Rights [8] and Executive Order on AI [9], the United Kingdom's National AI Strategy [10], China's New Generation AI Development Plan (AIDP) [11], and Saudi Arabia's AI Ethics Principles [12]. See Table I for a list of Saudi and International AI governance instruments.

These governance efforts have largely been articulated through high-level principles, risk-based regulatory models, and ethical guidelines designed to ensure responsible AI deployment [13], [14]. While such frameworks provide important normative foundations and flexibility for gradual refinement over time, they remain abstract and insufficiently operationalized for the complex, context-specific realities of healthcare systems [15], [16]. In practice, healthcare environments are characterised by heterogeneous data types, population-specific risks, evolving epidemiological patterns, and deeply embedded socio-cultural factors, all of which require governance approaches that are not only principled but also operational, adaptive, and context-aware [17], [18].

This challenge becomes particularly pronounced in dynamic and high-pressure healthcare environments such as Madinah, Saudi Arabia. As a city with a rapidly evolving healthcare ecosystem, significant demographic diversity, and unique public health pressures associated with large-scale religious gatherings such as Hajj and Umrah, Madinah represents a complex and meaningful setting for examining the interplay between healthcare needs and AI governance [19], [20]. For instance, Official GASTAT statistics indicate that 10.97 million pilgrims performed Umrah in Q3 2025, reflecting sustained high demand and suggesting that annual volumes are likely to exceed the Vision 2030 target of 30 million annual pilgrims, thereby highlighting a shift toward large-scale operational governance [27]. These conditions create distinctive requirements for continuous surveillance [22], scalable healthcare delivery [23], behavioural health interventions [24], environmental monitoring [25], and digital health integration [26], making the region not merely a case study but a real-world empirical testbed for governance analysis.

Despite the increasing development of AI governance frameworks, three key gaps remain insufficiently addressed. First, existing approaches rely on general-purpose or sector-agnostic principles, with limited attention to domain-specific operational requirements in healthcare, where data characteristics, risk profiles, and intervention mechanisms differ significantly across areas such as infectious diseases, behavioural health, and maternal care [15], [27]. Second, current studies do not incorporate context-sensitive and localised analysis, limiting their ability to account for region-specific factors such as population dynamics, healthcare infrastructure, and large-scale public health pressures, which are particularly pronounced in environments such as Madinah [12], [14], [28]. Third, there is a lack of evidence-driven governance analysis that systematically links large-scale empirical healthcare data with regulatory frameworks, resulting in a disconnection between governance design and real-world system needs [29]. These gaps highlight the need for approaches that integrate domain specificity, contextual awareness, and empirical evidence in the evaluation of AI governance [30].

In this context, this work builds on large-scale, AI-driven literature analysis across multiple domains, including 4,277 publications on healthcare in Madinah (this work), 14,404 publications on AI governance more broadly [31], 4,245 publications on AI governance in neuroinformatics [3], 5,083 publications on interpretability and explainability in healthcare [6], and 2,338 publications on AI in Leukaemia [4], yet no prior work was found that systematically integrates empirical healthcare evidence with governance alignment and gap analysis in a localised setting such as Madinah.

To address these identified gaps, this study adopts an evidence-driven approach to AI governance analysis that integrates large-scale empirical knowledge extraction with structured governance evaluation, enabling a systematic examination of how AI governance frameworks align with healthcare system requirements in Madinah. Our work in this study is structured around two complementary methodological components. First, the PEARL (Parameter Extraction and Refinement Logic) framework is employed to systematically analyse healthcare research and practice in Madinah using a large-scale dataset comprising 4,277 academic publications, producing a structured representation of healthcare priorities in the form of parameters and macro-parameters. Second, the PATHWAY framework is applied as a governance analysis pipeline to evaluate the alignment between these empirically derived healthcare needs and both Saudi Arabian and international AI governance frameworks, enabling the systematic identification of governance gaps, associated risks, and targeted, context-sensitive recommendations.

The analytical logic of the study follows a structured progression in which healthcare evidence informs the identification of potential AI application domains, which are then examined against existing governance frameworks to assess alignment, relevance, and applicability. This process enables the systematic identification of governance gaps and risks, which in turn inform the development of context-sensitive recommendations. Through this pipeline, the study moves beyond abstract governance discussions and establishes a direct connection between empirical healthcare realities and regulatory frameworks.

The results reveal that while existing governance frameworks provide strong foundations in terms of ethical principles, data protection, and risk-based regulation, they lack detailed operational pathways tailored to specific healthcare domains and local contexts. In particular, gaps emerge in areas such as population-specific epidemiological surveillance, behavioural and lifestyle health interventions, maternal and

paediatric healthcare support, environmental health integration, clinical workflow implementation, and generative AI in public health communication. These gaps highlight the need for governance approaches that are not only compliant with high-level principles but also capable of supporting context-aware, scalable, and implementation-ready healthcare AI systems.

In doing so, this study contributes to the emerging field of computational policy analysis by demonstrating how data-driven methodologies can be used to bridge the gap between empirical evidence and governance design. It offers a structured and generalizable approach for evaluating governance frameworks in relation to domain-specific system needs, providing evidence-based insights for policymakers, healthcare practitioners, and researchers.

The main contributions of this study are as follows: First, it introduces an evidence-driven approach to AI governance analysis that integrates large-scale literature mining with structured governance evaluation. Second, it applies the PEARL framework to derive a comprehensive and interpretable representation of healthcare research and practice in Madinah. Third, it employs the PATHWAY framework to systematically assess the alignment between healthcare needs and AI governance frameworks, identifying critical gaps and associated risks. Fourth, it provides targeted recommendations to support the development of context-sensitive, ethically grounded, and operationally viable AI governance strategies for healthcare systems. Finally, it positions Madinah as a real-world empirical environment through which governance frameworks can be tested, evaluated, and refined, offering insights that are applicable to other regions and domains.

The remainder of this study is structured as follows: Section II reviews the literature on AI governance in healthcare, identifies methodological limitations, and outlines the research gap. Section III presents the methodology, introducing the PEARL framework for empirical knowledge discovery and the PATHWAY framework for governance analysis. Section IV provides an empirical characterisation of healthcare needs in Madinah. Section V examines the alignment of AI governance frameworks with public health priorities, covering both Saudi and international perspectives and their comparative analysis. Section VI presents the identified governance gaps, risk implications, and corresponding recommendations. Finally, Section VII concludes the study and outlines directions for future work.

II. Literature Background and Research Gap

A. AI Governance in Healthcare

The rapid integration of artificial intelligence into healthcare systems has led to the development of a wide range of governance frameworks aimed at ensuring ethical, safe, and trustworthy deployment [1], [6]. These frameworks are typically grounded in high-level principles such as fairness, accountability, transparency, privacy protection, and human oversight, as reflected in major regulatory instruments including data protection laws, ethical AI guidelines, and risk-based regulatory approaches [5], [55].

In addition to general-purpose regulatory instruments, healthcare is supported by sector-specific governance mechanisms, including guidelines for AI-enabled medical devices, clinical decision-support systems, and digital health technologies [28], [37], [56]. However, these sector-specific provisions primarily focus on compliance, safety, and quality assurance at the system or device level, rather than providing detailed governance approaches tailored to specific healthcare domains or public health functions [57]. As a result, governance remains largely structured around general and sector-level requirements, with limited adaptation to the diverse and dynamic needs of specialised healthcare contexts [38], [58].

This limitation highlights the need for approaches that extend beyond compliance-oriented governance, which primarily focuses on legal and regulatory adherence, toward evaluating whether AI systems are contextually appropriate, operationally effective, and responsive to the dynamic realities of real-world healthcare environments [29], [30].

B. Limitations of Existing Methodologies

A key limitation of current AI governance in healthcare is the lack of empirically grounded, evidence-driven methodologies [59]. Existing frameworks are predominantly principle-based and normative, focusing on defining ethical requirements and regulatory safeguards, but offering limited mechanisms to systematically align governance with observed healthcare system needs, risks, and operational dynamics [60]. As a result, governance approaches remain detached from the empirical realities of healthcare practice, including evolving disease patterns, population-specific characteristics, and system-level constraints.

In addition, current approaches provide limited support for domain-informed governance analysis [29]. While high-level principles are broadly applicable, their translation into contextually relevant and domain-informed governance remains insufficiently supported by systematic analytical approaches [29], [60]. This creates a disconnection between general regulatory guidance and the practical requirements of specialised healthcare applications, where domain-specific risks, data characteristics, and intervention strategies vary significantly.

A further limitation is the lack of context-sensitive and localised governance analysis. Regional healthcare systems such as Madinah operate under unique conditions shaped by demographic diversity and large-scale, recurring population influxes associated with pilgrimage [20]. Annually, the region supports millions of pilgrims for Hajj and Umrah (Official GASTAT statistics indicate that 10.97 million pilgrims performed Umrah in Q3 2025 [21]), creating dynamic and high-pressure public health environments that differ significantly from standard healthcare settings. These conditions introduce complex challenges in areas such as infectious disease surveillance, emergency response, and healthcare resource allocation [22]. At the same time, Madinah is characterised by a rapidly evolving healthcare ecosystem and expanding digital health infrastructure [26]. However, existing governance frameworks rarely incorporate such contextual variability, limiting their ability to support region-specific decision-making and adaptive healthcare responses [61].

C. Research Gap and Contribution

Based on the above limitations, a clear research gap emerges in the absence of systematic approaches that integrate empirical evidence, domain-informed analysis, and contextual sensitivity into AI governance for healthcare. Existing work provides strong normative and regulatory foundations but lacks structured methodologies for linking data-driven insights from healthcare research to governance evaluation.

This study builds on extensive AI-assisted literature analysis across multiple domains. Specifically, PEARL was applied to a large corpus of healthcare research in Madinah (4,277 articles in this study), complemented by prior large-scale analyses of AI governance literature without limiting it to any sectors (14,404 articles, [31]), interpretability and explainability in healthcare (5,083 articles, [6]), AI in Leukaemia (2,338 articles, [4]), and AI governance in neuroinformatics (4,245 articles, [3]). Despite this breadth of analysis, we did not find any prior work that systematically integrates empirical healthcare evidence extraction with structured AI governance evaluation in a unified framework, nor applies such an approach to a context-specific healthcare system such as Madinah.

To address this gap, this study proposes a structured approach that integrates PEARL, for empirical knowledge extraction and synthesis, with PATHWAY, for systematic AI governance assessment. This work provides an empirical and analytical foundation for the systematic identification and evaluation of governance requirements across healthcare domains and contexts, without attempting to fully prescribe domain-specific governance frameworks. This facilitates a data-driven, context-aware analysis of governance alignment, gaps, risks, and recommendations, demonstrated through the case of Madinah's healthcare system.

III. Methodology

This study adopts an integrated methodology that combines data-driven knowledge discovery with governance analysis to examine the alignment between healthcare needs and AI governance frameworks. The methodology is composed of two complementary components: the PEARL framework for evidence extraction and knowledge structuring, and the PATHWAY framework for governance alignment and gap analysis. Together, these components form a pipeline in which empirically derived healthcare insights inform the evaluation of governance frameworks and the identification of regulatory gaps. Algorithm 1 summarises this integrated PEARL–PATHWAY workflow in procedural form, making explicit the sequential logic through which empirical evidence is transformed into structured governance analysis.

Algorithm 1 presents the PEARL-PATHWAY algorithm for public health AI governance analysis (Madinah).

Algorithm 1: Integrated PEARL–PATHWAY Procedure for Evidence-Driven Governance Analysis in Healthcare

Require: Corpus of healthcare literature for Madinah; Saudi AI governance frameworks; international AI governance frameworks
Ensure: Structured governance insights, identified gaps, risk implications, and recommendations

1. **Input Acquisition**
2. Collect healthcare research documents relevant to Madinah
3. Collect Saudi and international AI governance documents

4. **PEARL Phase: Empirical Knowledge Discovery**
5. Apply PRISMA-guided screening and selection
6. Preprocess textual data (cleaning, tokenization, lemmatization, filtering)
7. Generate semantic embeddings using BERT-based models
8. Reduce dimensionality using UMAP
9. Cluster documents using HDBSCAN
10. Extract representative themes using BERTopic / c-TF-IDF
11. Perform iterative quantitative and qualitative validation
12. Derive validated parameters and macro-parameters representing healthcare system needs

13. **Evidence-to-Application Mapping**
14. Map parameters and macro-parameters to healthcare-relevant AI application domains
15. Identify candidate AI-enabled functions (e.g., surveillance, clinical support, behavioural intervention, communication)

16. **PATHWAY Phase: Governance Analysis**
17. Perform policy analysis of Saudi and international governance frameworks
18. **for** each AI application domain and associated healthcare requirement **do**
19. Assess regulatory relevance, applicability, and coverage
20. Evaluate alignment across privacy, safety, ethics, security, and risk classification
21. Record strengths, partial alignment, and non-alignment
22. **end for**

23. **Gap and Risk Identification**
24. **for** each domain **do**
25. Identify governance gaps
26. Analyse associated operational, ethical, legal, and societal risks
27. **end for**

28. **Harmonisation and Recommendations**
29. Formulate targeted, context-sensitive governance recommendations
30. Relate recommendations to domain-specific healthcare priorities and implementation conditions

31. **Yield of Governance Insights**
32. Produce structured outputs on
    (a) governance alignment,
    (b) critical gaps and risks,
    (c) recommended regulatory and operational actions

return structured evidence-driven AI governance insights for Madinah healthcare

A. Pearl: Knowledge Discovery and Structuring

The PEARL methodology is employed to systematically extract and structure knowledge from healthcare research and practice in Madinah. PEARL stands for Parameter Extraction and Refinement Logic; for details, see our earlier work [4], [31]. It integrates systematic review principles with advanced machine learning techniques to ensure both methodological rigor and analytical depth. The overall architecture of the

PEARL pipeline is illustrated in Fig. 1, which provides a visual representation of the data collection, processing, clustering, and validation stages. Fig. 2 illustrates the PRISMA flow diagram of the article screening and selection process, while Table II outlines the inclusion and exclusion criteria used during screening.

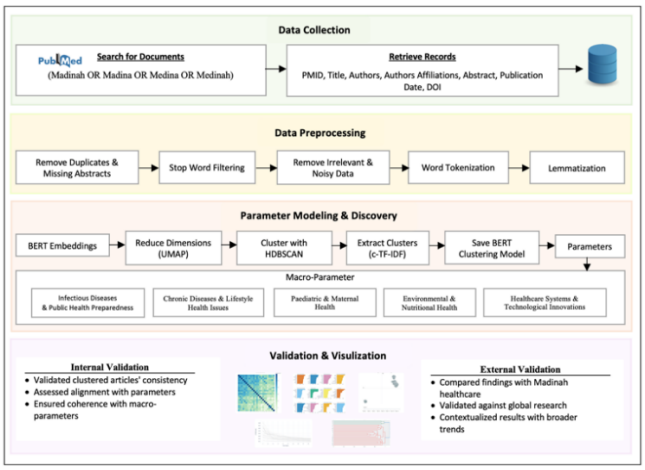

Fig. 1. Public health (Madinah): software methodology and architecture.

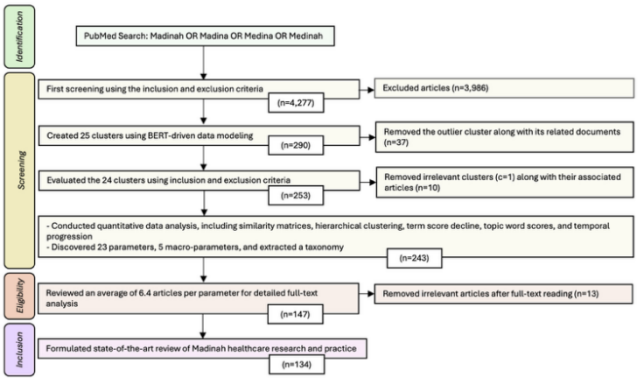

Fig. 2. Evidence foundations for public health (Madinah): PRISMA diagram.

TABLE II. EVIDENCE FOUNDATIONS FOR PUBLIC HEALTH (MADINAH): INCLUSION AND EXCLUSION CRITERIA

Inclusion Criteria	Exclusion Criteria
• Articles specifically addressing Madinah's population and healthcare.	• Articles unrelated to Madinah and healthcare.
• Articles pertaining to each parameter, reviewed in full text to assess their relevance, with the objective of validating findings and developing a comprehensive, up-to-date analysis of healthcare research and practice in Madinah.	• Duplicate entries identified during the cleaning process and articles without abstract.
• Clusters generated by BERT that are pertinent to the study's objectives.	• Outlier or irrelevant clusters that do not align with the study's focus.
• English-written articles. • Published between 2018 and 2023.	• Articles not published in English. • Articles published before 2018 • Articles do not mention the city of Madinah in their titles and abstracts

The dataset was constructed using the PubMed database, based on the query "Madinah OR Madina OR Medina OR Medinah", and guided by PRISMA principles. A two-stage screening process was applied using clearly defined inclusion and exclusion criteria, resulting in a refined dataset of 243 articles from an initial set of 4,277 records. Pre-processing procedures were conducted to prepare the textual data for computational analysis, including tokenization, lemmatization, and removal of irrelevant information. The processed data were transformed into semantic embeddings using BERT-based models, enabling the capture of contextual relationships between research documents.

Dimensionality reduction was performed using UMAP, followed by clustering through HDBSCAN, resulting in the identification of thematic groupings within the dataset. Clustering using BERTopic further enabled the extraction of representative terms and themes from each cluster, supporting the identification of meaningful knowledge structures. Through iterative refinement and validation, including both quantitative and qualitative assessment, the methodology identified 23 key parameters and five macro-parameters representing the core dimensions of healthcare research and practice in Madinah.

These parameters form the empirical foundation of the study, providing a structured representation of healthcare system needs, challenges, and priorities. This structured knowledge serves as the input to the governance analysis conducted using the PATHWAY framework.

B. *Pathway: Governance Analysis Framework*

Building upon the empirical knowledge generated through PEARL, the PATHWAY framework is employed to analyse the alignment between healthcare system requirements and AI governance frameworks.

PATHWAY is designed as a general governance analysis pipeline that evaluates how existing regulatory and policy frameworks address domain-specific system needs. It operates through a structured process in which domain knowledge is mapped to governance mechanisms, enabling the identification of alignment, gaps, and associated risks.

The framework structures the governance analysis through a sequence of stages represented by the acronym PATHWAY, encompassing Policy analysis, Alignment assessment, Threat and gap identification, Harmonisation through recommendations, Workflow and oversight considerations, Assurance mechanisms, and Yield of governance insights. This staged structure provides a systematic and replicable approach for evaluating the extent to which governance frameworks address system requirements, while supporting the identification of regulatory gaps and the development of targeted policy responses.

The application of this staged pipeline to the healthcare ecosystem in Madinah is illustrated in Fig. 3, which presents PATHWAY as a structured analytical workflow linking empirical evidence to governance evaluation and policy recommendations. The figure illustrates the PATHWAY AI Governance Framework as a structured analytical pipeline that transforms empirical healthcare evidence into operational governance insights. The framework begins with evidence

foundations derived from large-scale analysis of healthcare research and practice in Madinah, capturing biological, behavioural, environmental, technological, and demographic factors alongside surveillance, prevention, and healthcare delivery dynamics.

These evidence components are translated into key AI application domains, including epidemiological surveillance, behavioural and lifestyle interventions, clinical decision support, maternal and paediatric healthcare systems, environmental health monitoring, and generative AI in public health communication. This intermediate layer establishes a critical link between empirically identified system needs and potential AI-enabled solutions.

The framework then performs governance alignment analysis, evaluating the extent to which these application domains correspond to Saudi Arabian and international AI governance frameworks across dimensions such as regulatory coverage, risk classification, data protection, ethical principles, system security, and healthcare AI safety.

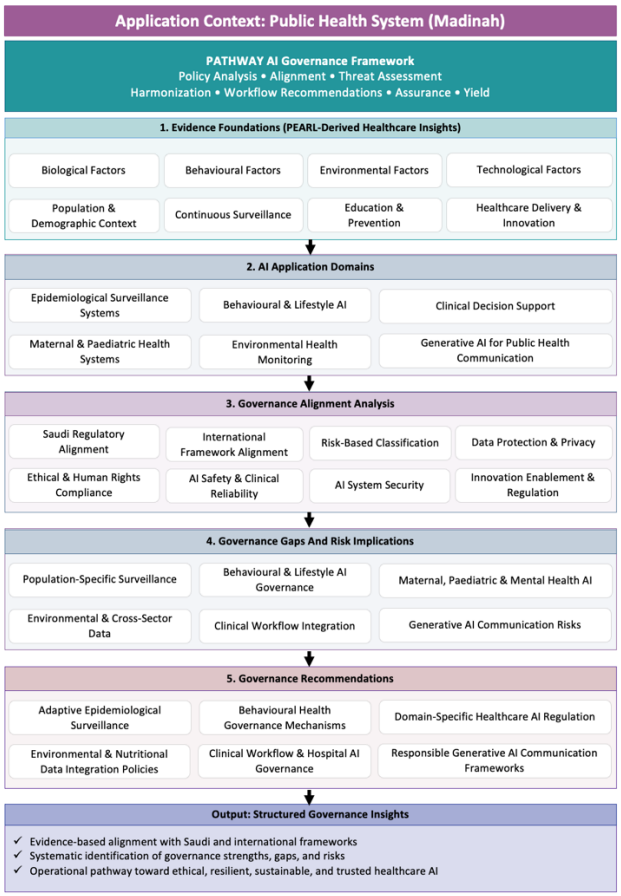

Fig. 3. PATHWAY: Public health (Madinah) AI governance framework.

Building on this alignment assessment, the framework identifies domain-specific governance gaps and associated risk implications, highlighting areas where existing regulatory approaches remain insufficiently operationalized or context-sensitive. These gaps inform a set of targeted governance recommendations that emphasise adaptive, domain-informed, and context-aware policy mechanisms.

The resulting output provides a structured and evidence-driven view of governance alignment, strengths, gaps, and priority actions, offering a coherent pathway for advancing ethical, resilient, and trusted AI deployment within Madinah's healthcare system. This structured pipeline also enables a continuous feedback loop between empirical evidence, governance evaluation, and policy refinement, supporting adaptive and context-sensitive AI governance over time.

In this study, the parameters and macro-parameters derived from PEARL are used as representations of healthcare system requirements in Madinah. These are systematically compared against both Saudi and international AI governance frameworks to assess their relevance, applicability, and coverage.

Through this structured pipeline, the framework enables a systematic assessment of governance effectiveness, supporting the identification of critical areas requiring policy intervention. In line with the Harmonisation stage of PATHWAY, these results inform the development of targeted recommendations aimed at strengthening AI governance for healthcare systems. The resulting insights constitute the Yield of the framework, providing evidence-driven governance intelligence for policy and decision-making.

Although this study focuses on the healthcare ecosystem in Madinah, the PATHWAY framework is designed as a generalizable governance analysis pipeline that can be applied across sectors, domains, and geographical contexts, including different cities and regions.

IV. Empirical Characterisation of Healthcare Needs in Madinah

This section presents the results derived from the application of the PEARL framework, capturing the key dimensions of healthcare research and practice in Madinah. The analysis identifies 23 parameters grouped into five macro-parameters, which together structure the thematic landscape of healthcare in the region.

These five interconnected macro-parameters collectively reflect the region's healthcare landscape: Infectious Diseases and Public Health Preparedness, Chronic Diseases and Lifestyle Health Issues, Paediatric and Maternal Health, Environmental and Nutritional Health, and Healthcare Systems and Technological Innovations. Each macro-parameter captures a distinct yet complementary dimension of public health, highlighting the interplay between prevention, education, technology, and systemic readiness in improving population well-being.

Fig. 4 presents a taxonomy of this knowledge structure, illustrating the relationships among the macro-parameters and their constituent parameters, and providing a structured view of how healthcare research and practice in Madinah span biological, behavioural, environmental, and technological domains.

Infectious Diseases & Public Health Preparedness highlights resilience within healthcare systems through studies addressing SARS-CoV-2 antibody responses, ICU management during COVID-19, pathogen transmission among Hajj pilgrims, hospital disaster readiness, and radiation safety practices.

Results reveal how pre-existing conditions heighten vulnerability [62], [63], emphasizing the importance of continuous surveillance, scalable infrastructure, and workforce training [64], [65]. It further stresses international collaboration [66] and data-driven public health strategies to ensure sustained readiness for emerging health threats [67].

Fig. 4. Public health (Madinah): Knowledge structure and taxonomy.

Chronic Diseases & Lifestyle Health Issues focuses on metabolic and behavioural determinants of health, identifying poor diet, physical inactivity, and limited awareness as major drivers of diabetes, cardiovascular diseases, and related complications [24], [68]. It connects molecular insights, such as RAS gene mutations in colorectal cancer [69], with psychosocial influences including burnout and social media-driven mental health challenges [70], [71]. The studies collectively highlight the need for comprehensive interventions combining education, screening, and lifestyle modification to manage chronic conditions and address gaps in public awareness [24], [72].

Paediatric & Maternal Health reveals a multidimensional nexus of maternal and child well-being shaped by socio-economic, behavioural, and systemic factors. High rates of dental caries [73], congenital anomalies [74], and postpartum depression (PPD) [75] indicate disparities in healthcare access and education. The studies emphasize early screening, parental awareness, and supportive policies for breastfeeding and maternal mental health [76], [77]. Recurring themes include the importance of preventive programs, social support networks, and community-based awareness initiatives in enhancing quality of life and long-term child development [78], [79].

Environmental & Nutritional Health examines the dual role of environmental safety and nutrition in shaping health outcomes. Research on the antioxidant properties of Ajwa dates demonstrates how phenolic compounds reduce oxidative stress and support chronic disease prevention [80], [81]. Conversely, studies on heavy metal contamination at recycling sites expose occupational and environmental hazards associated with cadmium, lead, and other toxic elements [25], [82]. The intersection between these domains reveals how dietary antioxidants may mitigate the effects of environmental toxins [83]. This macro-parameter underscores the need for integrated policies combining pollution control, agricultural optimization, and nutritional interventions to strengthen population health.

Healthcare Systems & Technological Innovations illustrates the transformation of Madinah's healthcare landscape through technology and validated clinical tools. Research on medication adherence scale validation [84], [85] demonstrates the necessity of culturally adapted instruments for chronic disease management, while digital health adoption within hospitals such as the Ministry of National Guard Health Affairs (MNGHA) enhances accuracy, efficiency, and patient outcomes [86]. Despite challenges including implementation costs, interoperability issues, and resistance to change [26], the integration of AI, telehealth, and wearable technologies [87], [88] represents a pivotal shift toward data-driven, patient-centric healthcare.

The parameters and macro-parameters identified in this section provide a structured view of healthcare system needs and priorities in Madinah. They present a cohesive picture of health in Madinah, shaped by the intersection of biological, behavioural, technological, and environmental factors. The results highlight key areas of focus, including surveillance, education, preventive interventions, and innovation, reflecting the multidimensional nature of healthcare development in the region. These collectively form the foundation for the subsequent analysis, where their alignment with AI governance frameworks is systematically evaluated using the PATHWAY framework. Table III provides a brief description of the five macro-parameters.

TABLE III. MACRO-PARAMETERS OF HEALTHCARE RESEARCH AND PRACTICE IN MADINAH

Macro-Parameter	Description
Infectious Diseases & Public Health Preparedness	Focuses on disease surveillance, outbreak response, epidemiological monitoring, and preparedness strategies for managing infectious threats at the population level.
Chronic Diseases & Lifestyle Health Issues	Addresses long-term health conditions such as diabetes and cardiovascular diseases, including lifestyle factors, prevention strategies, and population health management.
Paediatric & Maternal Health	Encompasses healthcare services, risk factors, and interventions related to maternal well-being, child development, and early-life health outcomes.
Environmental & Nutritional Health	Examines the impact of environmental conditions, dietary patterns, and nutrition-related factors on public health and disease prevalence.
Healthcare Systems & Technological Innovations	Covers healthcare delivery systems, digital health technologies, data-driven practices, and the integration of innovation into clinical and operational workflows.

V. AI GOVERNANCE ALIGNMENT WITH PUBLIC HEALTH PRIORITIES IN MADINAH

This section applies the PATHWAY framework to evaluate the alignment between the healthcare parameters identified in Section IV and existing AI governance frameworks. The analysis examines the extent to which these frameworks address key dimensions of healthcare research and practice in Madinah, with a focus on their coverage, relevance, and applicability. To provide a comprehensive perspective, the assessment is

conducted across both Saudi (Section IV A) and international governance frameworks (Section IV B), followed by a comparative synthesis that highlights key similarities, differences, and areas of convergence (Section IV C).

A. Saudi AI Governance Frameworks

The healthcare parameters identified in Section IV reflect a multidimensional health landscape in Madinah that intersects with Saudi Arabia's evolving AI and data governance ecosystem. Key national frameworks, including the Personal Data Protection Law [32], the Saudi AI Ethics Principles [12], the Generative Artificial Intelligence Guidelines for Government [33], the Human-Centered AI approach [34], the SFDA guidance on AI and ML-based medical devices [35], and the National Digital Government Strategy [36], collectively establish a foundation for data governance, ethical AI deployment, and digital transformation in healthcare contexts. These frameworks provide a structured basis for understanding how governance mechanisms relate to the healthcare priorities identified in Madinah.

Infectious Diseases & Public Health Preparedness illustrates the need for adaptive, data-driven protection measures. Variability in SARS-CoV-2 antibody responses among different demographic groups and individuals with comorbidities underscores the value of continuous monitoring and targeted vaccination strategies [62]. The Personal Data Protection Law [32] provides safeguards for such health surveillance by regulating lawful and minimal data processing, particularly when handling sensitive health data. The significant strain on ICU capacity due to delayed medical care, pre-existing illnesses, and high viral load at diagnosis [62], [63] reinforces the importance of reliable clinical analytics governed by the Saudi AI Ethics Principles, which emphasize fairness, transparency and human oversight. The unique risks associated with Hajj gatherings [19], [20] demonstrate the benefit of AI-assisted early warning systems in governmental settings, but these must comply with the Generative Artificial Intelligence Guidelines for Government that require accuracy, controlled use of restricted data and clarity when automated content informs public messaging. Hospital disaster readiness supported by accreditation and professional training [65] aligns with the National Digital Government Strategy through strengthened digital response infrastructure. Radiation exposure risk in orthopaedics [89] also points toward safe adoption of AI-assisted imaging tools, falling under SFDA guidance on AI and ML technologies-based medical devices to ensure validated clinical performance.

Chronic Diseases & Lifestyle Health Issues highlight the importance of preventive health technologies and patient empowerment. High consumption of sugary beverages and fast foods correlates with diabetes risk in the Madinah population including students [24], [68], and limited awareness of cardiovascular dangers affects early detection and lifestyle choices [23]. Human-Centered AI principles support digital tools that facilitate health education and behavioural change while maintaining inclusivity. Diabetic neuropathy results [90] indicate that remote monitoring and personalised care tools could assist disease management under ethical controls. Work stress and burnout among healthcare professionals [70] suggest that AI may help optimise workload and reduce fatigue when deployed responsibly under the Saudi AI Ethics Principles and accountability provisions. In cancer care, molecular determinants of colorectal cancer [69] signal the future integration of AI-enabled diagnostic systems whose safety would be regulated through SFDA guidance on AI and ML technologies-based medical devices. The influence of social media on cosmetic interventions [71] and persistent gaps in cervical cancer awareness [91] underline opportunities for reliable and culturally aligned generative AI public health communication under strict regulatory controls in the Generative Artificial Intelligence Guidelines for Government.

Paediatric & Maternal Health requires AI solutions that support equity and family wellbeing. High rates of childhood dental caries and unmet orthodontic needs [73], [78] stem from socio-economic and behavioural factors that can be targeted through digital outreach informed by the Saudi AI Ethics Principles [12] commitment to fairness. Reliance on natural remedies for oral conditions [92] highlights trust gaps that digital tools could help address if they align with cultural sensitivities emphasized in Human-Centered AI [34]. Limited awareness of paediatric eye diseases [93] suggests that parental engagement platforms could assist early detection when compliant with Personal Data Protection Law safeguards. Maternal health concerns, such as postpartum depression and breastfeeding challenges [75], show the need for tele-mental health and decision-support systems that enhance, rather than replace, professional support networks. Evidence associating caesarean delivery with childhood ASD risk [94] calls for decision aids that improve understanding of medical choices under strong human oversight and risk transparency. Widespread tobacco use and inadequate preparedness for dental trauma [95] similarly support the use of structured educational AI tools guided by the Generative Artificial Intelligence Guidelines for Government.

Environmental & Nutritional Health demonstrates how nutrition and environmental safety can both benefit from AI-supported monitoring. The protective effects of antioxidants in dates, particularly Ajwa varieties [96], support nutritional analytics that remain compliant with the Personal Data Protection Law [32] when integrated with health records. Meanwhile, heavy metal exposure at recycling sites poses significant respiratory risks [25], [82], and the Saudi AI Ethics Principles [12] and National Digital Government Strategy [36] could enable predictive environmental modelling that informs health protection, provided transparency and accountability are upheld. Nutritional strategies that reduce oxidative stress through metal chelation [83] further highlight the value of integrated analytics across food and environmental data.

Healthcare Systems & Technological Innovations illustrate direct intersections with national digital policy and biomedical AI regulation. Medication adherence research [97] suggests that predictive adherence analytics can support chronic disease control if aligned with Personal Data Protection Law principles of consent and security. The expanding digital health environment in Madinah's hospitals, including electronic records and telehealth [87], reinforces the National Digital Government Strategy objectives related to secure interoperability and efficient service delivery. As AI applications evolve within hospital workflows, they must

operate under the Saudi AI Ethics Principles and SFDA guidance on AI and ML technologies-based medical devices [35], where clinical impact is concerned.

Across these macro-parameters, Saudi AI governance frameworks demonstrate varying levels of alignment with the healthcare priorities identified in Madinah. Stronger alignment is observed in areas related to digital infrastructure, data governance, and healthcare system transformation, while more domain-specific applications are less explicitly represented within current governance provisions. Therefore, the analysis indicates that national frameworks provide a coherent foundation for supporting AI-enabled healthcare development, with alignment varying across different dimensions of the healthcare system.

B. International AI Governance Frameworks

The healthcare parameters identified in Section IV can be examined in relation to international AI governance frameworks, which provide structured approaches to regulating AI applications in healthcare and other high-impact domains. Prominent frameworks emphasise principles such as risk-based classification, transparency, accountability, human oversight, and data protection, offering a broader context for assessing how governance mechanisms align with the healthcare priorities observed in Madinah. National strategic frameworks such as the UK National AI Strategy [10], Japan's AI Strategy [46], Canada's AI Strategy for the Federal Public Service [48], and China's New Generation AIDP [11] articulate how these principles are operationalized at the policy level, particularly in guiding responsible AI adoption, public sector integration, and data governance across domains, including healthcare.

For instance, the challenges of managing infectious diseases, including COVID-19, and the unique public health risks during the Hajj pilgrimage resonate with the risk-based frameworks established by the EU AI Act [7]. Its classification of AI systems by risk underscores the importance of targeted oversight for applications such as pandemic surveillance, predictive analytics for ICU admissions, and diagnostic tools that can mitigate risks during large gatherings such as Hajj [62], [64]. Similarly, the US Blueprint for an AI Bill of Rights [8] and the Executive Order on AI [9] emphasize transparency, fairness, and accountability, principles that are directly relevant to building trust in AI-driven surveillance systems and diagnostic platforms in Madinah [67], [98].

The preparedness of hospitals in Madinah, as shown in studies on disaster readiness and ICU capacity, also intersects with the EU's Medical Device Regulation (MDR) [37] and In Vitro Diagnostic Regulation (IVDR) [38], which mandate ongoing monitoring and risk assessment for AI-enabled medical devices. These frameworks provide valuable guidance for ensuring that technologies adopted in Madinah's hospitals, including AI-driven diagnostic imaging or ICU monitoring, comply with safety and transparency requirements [99], [100]. Likewise, the US FDA's Software as a Medical Device (SaMD) framework [44] establishes robust standards for clinical evaluation, post-market surveillance, and patient safety, aligning with Madinah's emphasis on scalable healthcare infrastructure and continuous training of professionals [89], [101].

Chronic diseases and lifestyle health issues, such as diabetes, cardiovascular conditions, and cancer, represent a growing burden in Madinah. Here, AI governance frameworks addressing privacy and data protection play a pivotal role. The GDPR [39] in Europe stresses informed consent, transparency, and secure data management. These provisions are critical for managing sensitive health records, dietary surveys, and genetic information that underpin chronic disease research in Madinah [68], [102], [103]. Additionally, Japan's Act on the Protection of Personal Information (APPI) [47] and Canada's PIPEDA [49] reinforce the global consensus that privacy-preserving practices are indispensable when handling healthcare data for both research and clinical applications. This is particularly relevant for initiatives in Madinah aimed at improving public awareness of cardiovascular risks or managing diabetes through digital health tools [23].

Maternal and paediatric health results, including postpartum depression, congenital anomalies, and orthodontic needs, further highlight the need for ethical AI integration. The UNESCO Recommendation on the Ethics of AI [52] and the WHO guidance on AI in healthcare [28] call for equity, inclusiveness, and respect for human rights in deploying AI in clinical and community contexts. These frameworks support the design of AI-based early detection tools for congenital anomalies or mental health risks, ensuring that vulnerable groups, including women and children, benefit from technology without being exposed to additional ethical or privacy risks [73], [74], [75]. Similarly, UK GDPR [42] and the oversight of the Information Commissioner's Office (ICO) offer lessons in balancing innovation with protection of sensitive maternal and paediatric health data [93].

Environmental and nutritional health concerns in Madinah, such as antioxidant research on dates and heavy metal contamination at recycling sites, highlight another dimension of global AI governance. Regulations such as the EU NIS2 Directive [40] and Singapore's Regulatory Guidelines for Software Medical Devices [51] emphasize the role of cybersecurity and lifecycle monitoring in environmental and health-related AI systems. These frameworks can inform the design of AI-driven environmental monitoring tools that track pollution or food safety risks in Madinah, ensuring data integrity and reliability while protecting public health [96], [104]. Additionally, the EU's green deal [41] provides guidance on environmental issues by promoting sustainability, pollution reduction, and the integration of digital and data-driven approaches to support environmental monitoring and public health protection.

Finally, the adoption of digital health technologies and the validation of medication adherence tools in Madinah reflect the opportunities and challenges of technological innovation. The NIST AI RMF [45], the UK's use of regulatory sandbox [43], and China's Generative AI Regulation [50] collectively illustrate global recognition of the need for flexible but accountable oversight of emerging technologies. These initiatives provide a blueprint for Madinah's healthcare system to adopt AI responsibly, balancing innovation in digital health with safeguards for data security and patient trust [97], [105], [106].

International frameworks, such as those of the OECD [53] and IEEE [54], reinforce this balance by promoting transparency, robustness, and accountability across healthcare innovations [84], [107], [108].

Across these macro-parameters, international AI governance frameworks demonstrate a generally higher level of explicit coverage, particularly in areas involving high-risk applications, clinical decision support, and system-level accountability. This results in stronger alignment with several healthcare parameters identified in Madinah, especially those related to infectious disease management and healthcare system oversight. However, certain domains, including environmental and nutritional health, are less prominently represented within current governance provisions. Overall, international frameworks provide a comprehensive conceptual and regulatory basis, with alignment varying across different dimensions of healthcare.

C. Comparative Alignment

The comparative analysis of Saudi and international AI governance frameworks reveals both convergence and variation in their alignment with healthcare priorities identified in Madinah. Saudi frameworks demonstrate a strong emphasis on digital transformation, data governance, and the integration of AI within national development strategies. This results in relatively strong alignment with healthcare systems and technological innovation, as well as broader public health infrastructure.

In contrast, international frameworks provide more structured and mature approaches to AI governance, particularly through risk-based classifications, accountability mechanisms, and explicit consideration of high-risk applications in healthcare. These frameworks show stronger alignment with areas such as infectious disease monitoring, clinical decision support, and system-level oversight.

Differences also emerge in the extent to which specific healthcare domains are explicitly addressed. While some areas receive considerable attention across both governance contexts, others, including environmental and nutritional health, as well as context-specific aspects of paediatric and maternal healthcare, are less prominently reflected. These variations indicate differing priorities, levels of maturity, and approaches to operationalizing AI governance across contexts.

The analysis presented in this section suggests that Saudi frameworks are evolving and implementation-oriented, whereas international frameworks provide broader conceptual and regulatory structures. Together, they offer complementary perspectives that inform a more comprehensive understanding of AI governance in healthcare. Table IV summarises this comparative synthesis.

TABLE IV. COMPARATIVE ALIGNMENT OF AI GOVERNANCE FRAMEWORKS WITH MADINAH HEALTHCARE MACRO-PARAMETERS

Macro-Parameter	Saudi Frameworks	International Frameworks
Infectious Diseases & Public Health Preparedness	Moderately aligned through data governance and digital health initiatives; limited explicit AI-specific articulation	Strongly aligned through risk-based governance, monitoring, and system validation requirements
Chronic Diseases & Lifestyle Health Issues	Moderately reflected within preventive health and digital transformation strategies	Moderately aligned through clinical AI governance and decision-support frameworks
Paediatric & Maternal Health	Broadly addressed within general healthcare policies; limited explicit AI governance focus	Partially reflected under general healthcare AI risk classifications
Environmental & Nutritional Health	Indirectly reflected within sustainability and public health initiatives	Limited explicit representation within current AI governance frameworks
Healthcare Systems & Technological Innovations	Strongly aligned through national AI strategies and digital health transformation	Strongly aligned through comprehensive regulatory, ethical, and operational frameworks

VI. AI GOVERNANCE GAPS, RISK IMPLICATIONS, AND RECOMMENDATIONS

Despite strong alignment between Madinah's healthcare priorities and both Saudi Arabian and international AI governance frameworks, several important gaps remain where regulatory provisions do not fully accommodate the practical and contextual realities revealed by empirical results. Within the PATHWAY framework, this stage corresponds to the systematic identification of governance gaps and associated risks following alignment assessment, forming the basis for subsequent harmonisation through targeted recommendations. Foundational instruments such as the Personal Data Protection Law [32] and the Saudi AI Ethics Principles [12] provide robust safeguards for lawful data processing, oversight, and ethical AI deployment. Similarly, international risk-based frameworks, including the EU AI Act [7] and the US Blueprint for an AI Bill of Rights [8] emphasize accountability, transparency, and protection from harm. However, while these frameworks establish strong normative foundations, they provide limited operational guidance for population-specific, dynamic epidemiological surveillance.

Empirical evidence from Madinah demonstrates highly variable SARS-CoV-2 antibody responses and ICU demands influenced by comorbidities [62], [63], alongside intensified public health pressures during large-scale gatherings such as the Hajj [19], [20] . Although existing policies ensure responsible data governance, they do not sufficiently define structured pathways for continuous, event-driven epidemiological analytics tailored to demographic variability and localized health risks. This gap creates the risk of reduced responsiveness to rapidly evolving public health conditions. Addressing this limitation requires strengthening regulatory provisions to explicitly support context-sensitive, real-time surveillance systems that operate within clear accountability and privacy safeguards.

Similar regulatory limitations appear in the governance of behavioural and lifestyle-focused AI health tools. Human-Centered AI principles and privacy protections embedded within frameworks such as GDPR [39], PIPEDA [49], and APPI [47] reinforce secure handling of health data. Nevertheless, chronic disease drivers in Madinah, including dietary habits, cardiovascular risk unawareness, and lifestyle-related

conditions [102], [109], [110], reveal insufficient regulatory direction for AI systems designed to influence behavioural change, promote dietary awareness, or engage youth populations in preventive health practices. Ethical principles exist, yet they lack detailed guardrails for culturally sensitive behavioural intervention technologies. Without clearer governance mechanisms, such systems risk ethical ambiguity or misalignment with local values. Therefore, structured oversight frameworks for behavioural and lifestyle-oriented AI tools should be established to ensure culturally appropriate, prevention-focused digital health interventions that maintain strong privacy protections.

Further governance gaps emerge in maternal, paediatric, and mental health domains. International instruments such as UNESCO's Recommendation on the Ethics of AI [52] and WHO guidance on health AI [28] emphasize fairness, inclusivity, and protection of vulnerable populations, and Saudi frameworks similarly recognize societal and cultural values. However, Madinah results identify unmet orthodontic needs [111], limited awareness of paediatric eye diseases [93], postpartum mental health challenges [75], and broader maternal decision-support gaps. Existing regulatory structures lack specialised operational pathways for AI-assisted screening, tele-support systems, and child- or mother-focused digital health platforms. This creates ethical and trust-related risks for vulnerable groups. Developing specialised governance provisions tailored to maternal, paediatric, and mental health AI systems would strengthen ethical implementation, reinforce clinical oversight, and enhance trust by aligning digital interventions with family-centred and culturally grounded values.

Environmental and nutritional health governance also remains insufficiently integrated within current AI regulatory frameworks. The Saudi AI Ethics Principles [12] and the National Digital Government Strategy [36] promote responsible digital transformation, and instruments such as the EU NIS2 Directive [40] and Singapore guidelines [51] reinforce cybersecurity and lifecycle oversight for digital infrastructures that process cross-sector environmental and health data. However, empirical results from Madinah highlight health threats associated with heavy metal exposure at recycling sites [25], [82] and complex relationships between local dietary practices and antioxidant intake [112], [113]. Current governance structures do not clearly articulate how environmental monitoring data should be securely integrated with health analytics systems. This fragmentation limits transparent risk modelling and cross-sector accountability. Integrating environmental and nutritional data streams into AI governance architectures would enable secure cross-sector data sharing, strengthen predictive public health analytics, and enhance transparent risk management.

Oversight challenges also extend to AI-enabled medical devices and clinical workflow integration. Regulatory foundations are strong, with SFDA guidance [35], the EU MDR [37], IVDR [38], US SaMD requirements [44], and the Executive Order on AI [9] establishing safety, quality, and post-market monitoring standards. Nonetheless, Madinah results underscore the importance of scalable AI deployment in hospitals, workforce capacity-building, and digital systems that support treatment adherence and operational efficiency [26], [97], [101].

Current governance models prioritize technical compliance and safety validation but remain under-specified in relation to hospital-level adoption processes, workforce training, and real-world integration metrics. This creates implementation risks even where technical standards are satisfied. Expanding governance frameworks to include structured oversight for clinical adoption readiness, professional training, and workflow integration would strengthen real-world safety and performance.

Finally, governance of generative AI in public health communication remains underdeveloped. Although instruments such as the Generative Artificial Intelligence Guidelines for Government [33] promote transparency and responsible deployment, and broader international controls emphasize accountability, empirical results reveal persistent misinformation challenges in cosmetic decision-making [71], limited cervical cancer awareness [91], and inadequate responses to paediatric injuries [114]. Existing policies do not sufficiently ensure that AI-generated health content is culturally appropriate, clearly attributable, and responsive to local health literacy variations. Without strengthened safeguards, generative systems risk amplifying misinformation or eroding public trust. Strengthening governance for culturally aligned generative AI in healthcare communication would ensure transparent attribution, content validation mechanisms, and literacy-sensitive design standards that support improved community health outcomes.

Therefore, across these domains, a broader structural pattern emerges. Many governance frameworks articulate high-level principles of fairness, accountability, privacy, and transparency, yet lack detailed operational pathways tailored to specific demographic, epidemiological, environmental, and institutional contexts. This operationalization gap, combined with limited cross-sector integration and insufficient implementation-readiness mechanisms, constrains the full realization of AI-enabled healthcare benefits in Madinah. From a PATHWAY perspective, these gaps highlight the need for structured harmonisation through targeted recommendations and governance refinement. Addressing these interconnected gaps through targeted regulatory refinement will enable governance systems not only to uphold foundational ethical standards but also to support culturally aligned, context-sensitive, and operationally scalable AI deployment. In doing so, Madinah's healthcare ecosystem can advance equitable, resilient, and technology-enabled outcomes aligned with both national priorities and international best practices.

Fig. 5 synthesises the identified AI governance gaps in Madinah's healthcare ecosystem, highlighting their associated risks and the corresponding recommendations required to support context-sensitive, scalable, and ethically aligned AI deployment. Moreover, Table V provides a structured overview of domain-specific AI governance gaps in Madinah's public health system, linking each gap to its corresponding risk implications and targeted governance recommendations.

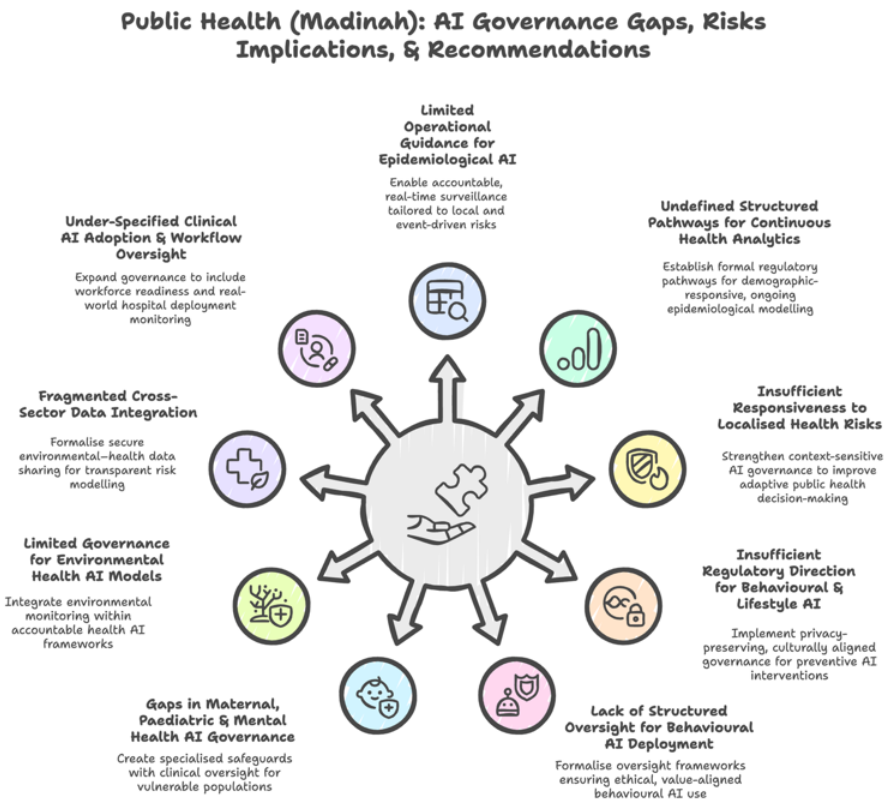

Fig. 5. Public health (Madinah): AI governance gaps, risk implications, and recommendations.

TABLE V. DOMAIN-LEVEL AI GOVERNANCE GAPS, RISK IMPLICATIONS, AND RECOMMENDED ACTIONS IN PUBLIC HEALTH (MADINAH)

Domain	Key Governance Gap	Risk Implication	Recommendation
Infectious Diseases & Public Health Preparedness	Lack of explicit governance for real-time epidemiological AI systems	Reduced responsiveness to dynamic outbreaks	Introduce regulatory pathways for real-time surveillance and model validation
Chronic Diseases & Lifestyle Health Issues	Limited guidance for behavioural and preventive AI systems	Ethical ambiguity and misalignment with cultural values	Develop governance for culturally sensitive behavioural AI tools
Paediatric & Maternal Health	Absence of specialised provisions for vulnerable populations	Safety and trust risks in sensitive healthcare domains	Establish tailored governance for child and maternal AI applications
Environmental & Nutritional Health	Weak integration of environmental data in AI governance	Fragmented risk modelling and limited cross-sector insight	Enable secure integration of environmental and health data systems
Healthcare Systems & Technological Innovation	Insufficient focus on implementation and workforce readiness	Deployment and adoption risks in real-world settings	Expand governance to include training, workflow integration, and monitoring
Generative AI in Public Health	Limited safeguards for health communication systems	Risk of misinformation and reduced public trust	Introduce governance for culturally aligned and validated AI-generated content
Mass Gathering and Event-driven Public Health Systems	Lack of governance for AI systems operating in large-scale, dynamic population environments (e.g., Hajj)	Reduced responsiveness and coordination in high-density, rapidly evolving public health scenarios	Develop governance frameworks for event-driven, real-time population health analytics and coordination systems
Demographic Variability and Personalised Public Health	Limited governance for AI models handling heterogeneous population characteristics and responses	Reduced fairness, accuracy, and reliability in population-level predictions and interventions	Introduce governance provisions for adaptive, demographic-aware AI systems and model validation across diverse groups
Clinical Workflow Integration and Adoption Readiness	Governance frameworks do not sufficiently address hospital-level integration, workflow embedding, and adoption processes	Implementation failures despite technical compliance; reduced efficiency and usability in clinical settings	Extend governance to include operational readiness, workflow integration standards, and clinical deployment guidelines
Real-world Monitoring and Lifecycle Oversight	Insufficient operationalization of continuous monitoring, validation, and feedback mechanisms for deployed AI systems	Undetected model drift, reduced reliability, and long-term performance degradation	Establish lifecycle governance models with continuous evaluation, auditing, and post-deployment monitoring
AI-enabled Public Health Communication Systems	Limited governance for AI-mediated health communication beyond general principles (including but not limited to generative AI)	Risk of misinformation, low health literacy alignment, and erosion of public trust	Develop governance mechanisms for transparent, culturally aligned, and validated AI-driven health communication systems

VII. Conclusion

This study has examined the alignment between healthcare system needs and AI governance frameworks through an evidence-driven and context-sensitive approach. By integrating large-scale empirical analysis of healthcare research and practice in Madinah with structured governance evaluation, the study demonstrates how governance frameworks can be systematically assessed against real-world system requirements. The combined application of the PEARL and PATHWAY frameworks enables a coherent analytical pipeline that connects empirical evidence, potential AI applications, governance alignment, and the identification of gaps, risks, and recommendations.

The results indicate that while existing Saudi Arabian and international AI governance frameworks provide strong foundations in terms of ethical principles, data protection, and risk-based regulatory models, they remain insufficiently operationalized for domain-specific and context-sensitive healthcare applications. In particular, gaps emerge in areas requiring continuous and adaptive responses, including epidemiological surveillance, behavioural and lifestyle health interventions, maternal and paediatric care, environmental health integration, clinical workflow implementation, and the governance of AI-generated public health information. These limitations reflect a broader structural issue in which high-level governance, although necessary, does not fully translate into operational and context-aware mechanisms within complex healthcare environments.

This work contributes to addressing this gap by demonstrating the value of linking empirical healthcare evidence with governance analysis. Rather than relying solely on abstract regulatory principles or isolated case studies, the approach adopted in this study enables a systematic and data-informed understanding of how governance frameworks interact with real-world healthcare needs. In doing so, it highlights the importance of moving towards governance models that are not only principle-based but also supported by structured evidence, capable of capturing evolving system dynamics, and responsive to local conditions.

Furthermore, our study underscores the importance of governance approaches that are supported by continuous and iterative analysis of healthcare data, research developments, and societal needs, forming a structured feedback loop in which evidence generation, governance evaluation, and policy refinement are perpetually linked (see our earlier works, e.g., [115], [116], [117]). Such an approach enables governance systems to evolve in response to emerging risks, new evidence, and changing public health conditions, while maintaining transparency, traceability, and accountability. By embedding this continuous evaluation and refinement cycle into governance processes, policymakers can develop more responsive and adaptive strategies, improve the reliability of health communication, and strengthen public trust by ensuring that AI-enabled systems remain aligned with both scientific evidence and community realities. This perspective is consistent with emerging approaches that emphasise systematic, data-driven analysis as a foundation for ongoing policy monitoring and refinement.

The study also positions Madinah as a meaningful empirical environment for governance evaluation, demonstrating how localised analysis can reveal insights that are not visible in global or purely conceptual studies. The methodological approach and results are therefore not limited to this context but offer a generalizable framework for analysing AI governance in other regions and domains characterised by complex, dynamic, and data-intensive systems.

Therefore, advancing AI governance in healthcare requires moving beyond high-level principles towards evidence-driven, domain-informed, and context-aware operationalization. By bridging empirical analysis with governance evaluation, this study contributes to the development of more adaptive, scalable, trustworthy, and sustainable governance strategies, supporting the effective and responsible integration of AI into healthcare systems.

KnowRAG: A Zero-Shot Diagnostic Analysis of Knowledge Base Coverage in Scientific Retrieval-Augmented Generation

Assmaa MOUTAOUKKIL*, Ali EL MEZOUARY, Kaoutar BOUMALEK
IRF-SIC Laboratory-Department of Computer Science-Faculty of Science, Ibn Zohr University, Agadir, Morocco

***Abstract*—The "hallucination" problem in Large Language Models (LLMs) remains an unresolved hurdle for scientific researchers who require precise, grounded evidence. While Retrieval-Augmented Generation (RAG) aims to mitigate these errors, standard systems are often unoptimized for the structural complexities of scientific papers. We introduce KnowRAG, a zero-shot RAG pipeline specifically designed for scientific applications. Using a novel "LLM-as-a-Judge" diagnostic framework, we evaluated KnowRAG against a standalone GPT-3.5-Turbo baseline across four specialized Q&A Test Sets. Our results demonstrate that KnowRAG significantly improves factual accuracy over the baseline. More importantly, diagnostic analysis reveals that the vast majority of errors (over 46%) stem from Knowledge Base Coverage (knowledge gaps), while generation failures remain negligible at 4%. These findings suggest that retrieval and generation capabilities are no longer the primary bottlenecks in the scientific domain. Instead, this diagnostic analysis advocates for a paradigm shift from model-centric research toward expert data engineering as the definitive path to trustworthy AI. By repurposing the LLM-as-a-Judge framework as a diagnostic instrument rather than a mere performance metric, we move RAG evaluation beyond aggregate scoring toward actionable, evidence-based systemic diagnosis.**

***Keywords*—Large Language Models; Retrieval-Augmented Generation; evaluation; scientific writing; information retrieval; knowledge base; data engineering; GenAI**

I. Introduction

For a scientific researcher, the ideal assistant is a collaborator capable of synthesizing recent, multi-disciplinary literature with absolute citation fidelity. This is one of the reasons many people are getting excited about the possibilities of using Large Language Models (LLMs) [1]–[3], as LLMs have used these massive amounts of human knowledge, to completely transformed AI interaction [4]–[7] and information retrieval [2], [3], [8]–[10], and they now exhibit a very high level of capability in supply/output complex written language [2]. However, this very strength masks a profound weakness for academic research: their tendency to "hallucinate", generating seemingly convincing and persuasive texts that are subtly or blatantly inaccurate[11]–[13]. In scientific research, where the chain of evidence is vital, this error is fatal. The consequence is not just an occasional mistake, but a fundamental breach of trust, relegating these powerful tools to the status of thinking aids rather than reliable sources of knowledge. We have the linguistic engine, but it is detached from the core of the evidence and ethics. The root of this problem lies in grounding. LLM like GPT-3.5-turbo operates based on its parametric knowledge, a static, frozen snapshot of the world as perceived through its training data [14], [15]. When asked a question that goes outside the scope of this snapshot, such as the conclusions of a preprint published last month, it must generalize, often leading it to fabricate a plausible but incorrect answer. The ideal situation would be a system that seamlessly combines the inferential and linguistic capabilities of an LLM with direct, dynamic access to a reliable corpus. The dominant approach to filling this gap is retrieval-augmented generation (RAG)[5], [16]–[21]. By first retrieving relevant documents from an external knowledge base and then conditioning the LLM's generation on that specific context, RAG improves adaptability, factuality, and responsiveness to up-to-date content, and promises to link fluency with factuality[22][23][24]. The conceptual model is elegant in its separation of matters: a non-parametric memory for facts and a parametric model for reasoning and language.

However, most original work on RAG, such as the innovative framework in [19], has focused on architectural innovation, joint training of retrievers[25][26][27] and generators[28][29], or scaling to massive generic corpora. Although these are crucial advances, their evaluation has been mostly imprisoned to benchmarks such as Natural Questions, which test general faithful memorization from sources such as Wikipedia. This creates a significant and largely unexplored translation gap. Scientific literature is not a series of isolated facts; it is a dense tapestry of arguments, methodologies, results, and critiques. An improved system for retrieving a fact about a historical event may fail miserably when asked to retrieve the methodological justification for a particular experimental design, especially if the knowledge base is prepared with a generic segmentation of the text based on length, which turns a coherent argument into incoherent fragments. As a result, many existing implementations of RAG, despite their sophistication, can still produce inaccurate results in scientific contexts. The indirect consequence is a slowdown in their potential adoption; researchers cannot rely on the results without verifying them themselves exhaustively, which runs counter to the promised efficiency. This directly highlights the knowledge gap that our study attempts to address. We do not clearly understand how practical choices at the implementation level in the construction of a scientific RAG system, particularly the structuring of the knowledge base, influence its actual performance in reducing hallucinations. Previous studies have provided us with powerful engines, but little guidance on how to map their course in the specialized domain of science.

*Corresponding author

This work is based on a pragmatic conceptual model: for scientific RAG, the most effective improvements do not inevitably come from additional pre-training of massive models, but rather from an intentional and domain-appropriate design of the retrieval pipeline that feeds the generator. We build on the established RAG paradigm in accordance with the best practices mentioned in [30], but our approach differs. Instead of modifying the base LLM or training a new retrieval system from scratch, we investigate a minimal, zero-shot configuration using robust, off-the-shelf components. Our study asks a direct and practical question: Can careful knowledge base construction and retrieval setup, applied to a standard LLM, yield an impressive reduction in hallucination without any fine-tuning model?

Therefore, the objectives of this research are threefold:

- Implementation: To develop KnowRAG, a zero-shot pipeline utilizing semantic search on a processed arXiv corpus and generation via GPT-3.5-turbo.
- Evaluation: To rigorously test whether this pipeline improves factual accuracy across four domain-specific test sets compared to a standalone baseline using the LLM-as-a-Judge approach.
- Diagnosis Analysis: To perform a granular failure analysis, determine if errors stem from knowledge base gaps, retrieval misses, or generation failures.

Our primary contribution is the transformation of the LLM-as-a-Judge into a diagnostic instrument. By isolating specific systemic bottlenecks, we provide an actionable framework that moves beyond aggregate accuracy scores toward a reproducible model for reliable, inexpensive scientific assistants.

The remainder of this study mirrors our investigation process: Section II reviews related work and analyzes existing literature, while Section III details the methodology used to provide a diagnostic analysis of comprehensive RAG systems. In Section IV, we outline the experimental setup, including the creation of specialized test sets and a performance comparison against a reference LLM. Section V presents our results, offering both a quantitative evaluation of accuracy and a qualitative diagnosis of failure modes. We discuss these findings in Section VI and address the study's recommendations and limitations in Section VII. Finally, the study concludes in Section VIII.

II. Literature Review

Over the past five years, Retrieval-Augmented Generation has evolved in a field increasingly focused on algorithmic innovation [25]–[29]. Advances such as dense passage retrieval, end-to-end training of joint retriever-generator models, and more refined methods for combining retrieved content have led to measurable improvements on open-domain question answering tasks [19]. Yet this advancement in our knowledge relies that the documents used to build these models are organized, consistent, and unbiased but this is rarely true. Such a perspective cannot be upheld any longer. In narrow domains such as scientific literature, where texts contain rhetorical and informational layers and information is concentrated in different sections, the way in which the knowledge base is built becomes a defining factor for system performance. Key findings that are buried under narrative digressions, methodologies that are cut off mid-sentence, and indexing strategies that force distorted structural content into flat, indistinct lumps all highlight fundamental limitations. These are not deficiencies that can be solved by even the best-optimized retriever. Therefore, recognizing data primacy shifts the perception of the knowledge base from that of a passive archive to an active factor that shapes the maximum achievable retrieval accuracy, and consequently the factual integrity of the generated responses.

One of the greatest challenges is evaluating RAG systems as composite systems. How can we objectively assess the relevance and accuracy of a response to its sources? How can we obtain a performance measure for each component of the system? Traditional metrics from natural language processing: BLEU, ROUGE, and lexical matching do not reflect the semantic nuances of the generated text or its contextual accuracy. Human annotations are expensive and difficult to maintain throughout multiple experiments [31], [32]. The increasing use of large language models as evaluators could solve a long-standing dilemma in evaluation methodology [33]. Recent studies show that, when equipped with clear evaluation criteria and carefully designed prompts, LLMs can assess the relevance of research and the fidelity of generation, producing results that are very similar to human judgments and reaching levels of agreement comparable to those between annotators [35]. However, the significance of this change goes beyond simply replicating human evaluations effectively. The true value of the LLM as a judge lies not only in its ability to assign accurate scores but also in its ability to provide meaningful characterizations. A low relevance score in itself provides little information; what is more informative is when the model explains the failure, via chain-of-thought reasoning or dimension-specific scoring, and delivery of why relevance failed, whether due to missing content, rhetorical misalignment, or extractive fragmentation, renders visible the otherwise opaque influence of data curation decisions. While frameworks such as RAGAS [31] evaluate fidelity and accuracy, they focus on a model-centric approach: comparing retrievers in a static pipeline. This study explores a different path, using LLMs not just for final evaluation, but as tools to analyze the inner workings of the entire RAG pipeline.

This study, therefore, occupies a specific and, in our view, necessary place in this literature. Whereas previous work has optimized components in isolation or compared architectures under constant corpus conditions, we reverse the experimental logic: the algorithms are kept unchanged while the data preparation strategies are systematically modified. The goal is not to crown a single optimal configuration, but to trace, with empirical specificity, how each preservation choice propagates through retrieval and generation to shape measurable results in terms of contextual fidelity and factual accuracy. To do this, we use LLM-as-a-judge not as a complementary metric, but as a central diagnostic tool, capable of distinguishing, for example, a model that misread a passage from a model that never received enough passages to respond. This distinction, which conventional metrics cannot make, is precisely where the 'data-first' hypothesis becomes verifiable. Our implementation, KnowRAG, applies this logic in a reproducible, zero-shot pipeline designed for scientific corpora. We emphasize that this is not a proposal for a new architecture, but an argument for a

new unit of analysis. The fundamental contributions of existing RAG and their successors have equipped the field with its tools. What remains to be written, and what we aim, in part, to provide, is a systematic account of how these tools succeed or fail not in spite of the data, but because of it.

III. Methodology

This study employed a controlled experimental methodology to implement and evaluate KnowRAG, a zero-shot pipeline designed for scientific domains. Fig. 1 summarizes the KnowRAG methodology. Our approach is structured across three sequential phases to systematically measure improvements in correctness and to perform diagnostic failure analysis.

A. Knowledge Base Construction and Benchmarking

The study built a domain-specific corpus by scraping ten recent RAG-related publications from arXiv.

- Preprocessing: PDFs were converted to raw text and partitioned into 1,000-token chunks with a 30-token overlap using a recursive splitter.
- Vectorization: Each chunk was embedded using text-embedding-ada-002 and stored in a FAISS vector database for cosine similarity searching.
- Benchmarking (Q&A Test Sets): GPT-4 was utilized to generate 240 gold-standard questions (four sets of 60) directly from the corpus to ensure a verifiable "ground truth" for each query.

B. Experimental Pipeline

A comparative "Zero-Shot" procedure was executed to isolate the impact of the retrieval mechanism on a generative core (GPT-3.5-turbo). The choice of this model serves as a methodological control; by using a well-documented, stable baseline rather than a frontier model, we minimize "parametric contamination" (where the model answers from its own training memory) and more clearly isolate the performance delta attributable strictly to the RAG architecture.

- Baseline (Condition A- No retrieval): The LLM answered questions using only its internal pre-trained knowledge via a simple factual prompt.
- KnowRAG (Condition B- Retrieval-Augmented): The system embedded the query, retrieved the top-3 relevant chunks from the FAISS index, and injected them into a structured prompt. The LLM was strictly initiated to answer based only on the provided context and cite specific source IDs.
- Controls: To ensure reproducibility, parameters were fixed at a low temperature (0.1) and top_p=1.0, with no fine-tuning involved.

C. Evaluation Metric and Diagnostic Framework

To move beyond simple accuracy, we used GPT-4 as an automated judge to provide binary correctness scores and identify specific systemic bottlenecks. To mitigate evaluation circularity, we employed a hierarchical model strategy: utilizing the superior reasoning capabilities of GPT-4 to assess the outputs of the smaller GPT-3.5-Turbo generator. Following the LLM-as-a-Judge approach, GPT-4 analyzed the original question, the generated response, and the ground-truth context to determine if an answer was "correct" or "incorrect". By moving from subjective grading to objective verification, this method ensures the consistency and scale required for a deep diagnostic study. Importantly, this approach aligns closely with human expert judgment as demonstrated in [33], [34].

To understand the results, the pipeline tracked two essential metrics:

- Knowledge Base Coverage: Did the corpus contain the answer?
- Retriever Hit Rate (Top-3): Was the correct information successfully ranked within the top three documents?

These metrics are critical because they define the system's performance limits; a correct answer can only be generated if the information is both present in the corpus and successfully retrieved by the pipeline.

To understand the root cause of every error, we categorized incorrect answers into three distinct failure modes:

- Knowledge Gap: The answer was missing from the source documents entirely.
- Retrieval Failure: The information was in the corpus, but the retrieval failed to find it.
- Generation Failure: The correct context was successfully retrieved, but the LLM failed to present it faithfully.

This stepwise, instrumented methodology moves beyond reporting a simple performance delta. It provides a diagnostic framework that explains, with reasonable precision, why a zero-shot RAG system succeeds or fails in the scientific domain.

IV. Experiments

We conducted a series of controlled experiments to evaluate KnowRAG against the standalone GPT-3.5-turbo baseline. The experiments were designed to answer three core research questions. First, does retrieval augmentation significantly improve factual correctness in scientific question answering? Second, how consistent is this improvement across different types of scientific queries? And third, where do failures originate in a zero-shot RAG pipeline, and what do these failures reveal about the relative importance of knowledge base quality, retrieval accuracy, and generation fidelity?

A. Experimental Setup

All experiments were executed in a standardized computational environment. Document processing and embedding generation were performed using Python 3.10 with the LangChain, PyMuPDF, and FAISS libraries. All LLM inferences, both for generation and evaluation, were conducted via the OpenAI API. The temperature parameter was fixed at 0.1 for all generation tasks to ensure deterministic outputs, while the LLM-as-a-Judge evaluations using GPT-4 were conducted at temperature 0.0 for maximum consistency. The complete knowledge base and the generated test sets are available in the Appendix section to ensure full reproducibility.

B. Dataset and Benchmark Characteristics

Our evaluation leveraged four distinct QATestSets, each containing sixty question-answer-context triples derived from our curated arXiv corpus. The four test sets in the KnowRAG diagnostic framework were designed to vary in topic coverage to test the system's robustness across different levels of scientific complexity and domain specificity:

- QATestSet1: 4 topics, 60 questions
- QATestSet2: 7 topics, 60 questions
- QATestSet3: 6 topics, 60 questions
- QATestSet4: 4 topics, 60 questions

In each test set, the questions covered six classifications representative of scientific questions: Complex, conversational, distracting element, double, simple, and situational. For each question, GPT-4 produced a reference answer and cited the specific source identifier, thus providing verifiable truth. The final benchmark comprised 240 question-answer-context triplets, covering four distinct categories of reasoning.

To facilitate reproducibility, the four Q&A Test Sets files, including ground truth annotations, are publicly available at link.

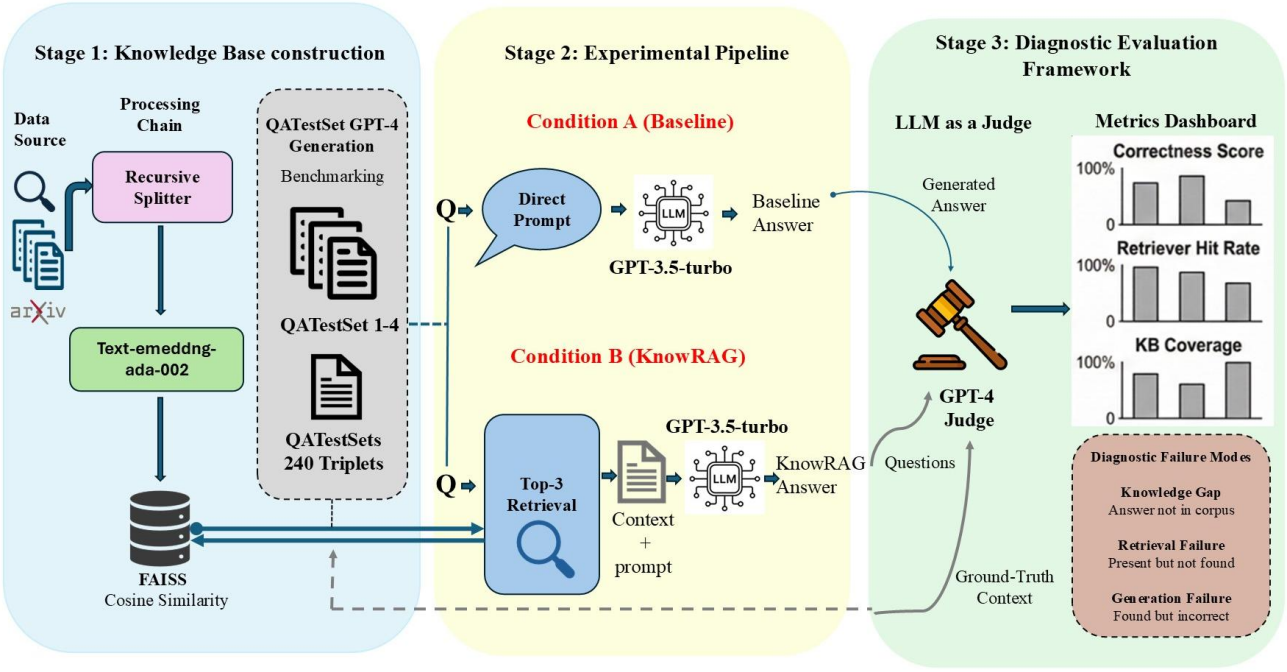

Fig. 1. The KnowRAG approach.

V. Evaluation and Results

In this section, we analyze the quantitative and qualitative performance of KnowRAG. For a detailed analysis of the evaluation Test Sets and extended diagnostic logs, please refer to Appendix A and Appendix B.

A. Comparative Performance: Baseline vs. KnowRAG

We first evaluated the factual correctness of both conditions across all four test sets. The results are presented in Table I. KnowRAG increased the average factual correctness of the baseline by more than double, from 27.5 per cent to 59.5 per cent. This improvement was consistent across all four test sets with gains ranging from 21 to 40 percentage points. The largest improvement of forty points was observed on QATestSet3, while the smallest gain of twenty-one points was observed on QATestSet2. This variation was our first indication that not all test sets, and by extension not all knowledge bases, are created equal.

TABLE I. Correctness Scores (%) by Method and Test Set Correctness is Measured via LLM-as-a-Judge (GPT-4)

Method	QATestSet1	QATestSet2	QATestSet3	QATestSet4	Average
Baseline (No Retrieval) GPT-3.5-turbo	28	29	23	**30**	27.5
KnowRAG (Retrieval-Augmented)	60	50	63	**65**	59.5
Improvement	+32	+21	+40	+35	+32

B. Diagnostic Analysis: Knowledge Base Coverage and Retriever Hit Rate

To understand why KnowRAG succeeded and where it failed, we conducted a diagnostic analysis using the metrics described in the Methodology section. Table II shows the results by Test Set.

The Knowledge Base Coverage metric reveals a catastrophic failure of our chunking strategy for certain test sets. QATestSet1

achieved excellent coverage of nearly 86%, with most of the answers to its questions preserved complete in our processed chunks. However, QATestSet2 suffered coverage of only 18%. This means that, despite the answers being present somewhere in the original PDFs, more than four out of five questions in this set had no retrievable answer after our processing.

The correlation with performance is immediate and clear. QATestSet2, which had the lowest coverage, produced the lowest correctness score (50%) and the smallest improvement over the baseline score (+21 points). In contrast, QATestSet1 and QATestSet4, with higher coverage, achieved substantially better performance. The causal relationship is clear. When the knowledge base is fragmented and incomplete, performance suffers.

With an average Retriever Hit Rate of 61%, the news report is somewhat more encouraging. When the answer was present in the knowledge base, our semantic search successfully retrieved the correct source chunk in the top three results for almost two-thirds of the questions. Performance varied, with particularly strong retrieval on QATestSet4 (70%) and weaker retrieval on QATestSet2 (45%). This suggests that methodological descriptions may be more challenging to match using cosine similarity on dense embeddings. Questions such as "What is the main contribution of paper X?" have a clear semantic center of gravity, whereas questions such as "How does the training procedure in method Y differ from standard approaches?" are more diffuse and may be harder to align with a single procedural passage.

TABLE II. INTERMEDIATE RETRIEVAL METRICS BY TEST SET (%)

Metric	QATestSet1	QATestSet2	QATestSet3	QATestSet4	AVG
Knowledge Base Coverage	85.71	18.18	44.44	66.67	53.75
Retriever Hit Rate (Top-3)	65	45	65	70	61.25

C. Failure Mode Analysis

By correlating the correctness scores with these intermediate metrics, we were able to categorize each incorrect KnowRAG response as one of three failure modes. Table III shows the resulting distribution.

The failure mode analysis yielded two profound insights that fundamentally shaped our understanding of where the real work lies in building reliable scientific RAG systems.

Firstly, the Knowledge Gap Failure is the dominant failure mode, accounting for nearly half of all errors on average and a vast 82% of errors on QATestSet2. This is not a failure of the retriever or the generator. It is a failure of the knowledge base itself. When the answer is not present in a retrievable chunk, the system has no path to correctness, regardless of the sophistication of its components. The implication is clear: the single greatest bottleneck in our zero-shot RAG pipeline is not the neural architecture of the retriever, nor the instruction-following capability of the LLM, but the mundane, understated work of deciding how to split a PDF into chunks.

Second, Generation Failure is extremely rare, accounting for only 4% of errors on average. When the correct context was successfully retrieved and provided to GPT-3.5-turbo with our structured prompt, the model almost constantly produced a faithful, accurate answer. This is a validation of the zero-shot approach. It suggests that a general-purpose instruction-tuned LLM, when given high-quality, relevant context, requires no fine-tuning to perform scientific question answering with high faithfulness. The model can read; it can follow instructions; it can synthesize. What it cannot do is conjure information that was never provided. The bottleneck is upstream.

TABLE III. FAILURE MODE DISTRIBUTION BY TEST SET (%)

Failure Mode	QATestSet1	QATestSet2	QATestSet3	QATestSet4	AVG
Knowledge Gap Failure	14.29	81.82	55.56	33.33	46.25
Retrieval Failure	20.71	36.18	19.44	16.67	23.25
Generation Failure	5.00	0.00	6.00	5.00	4.00

Retrieval Failure accounted for approximately 23% of errors, indicating meaningful room for improvement in embedding strategies, search techniques, or the choice of k. But this is, in the context of our findings, a secondary concern. Improving retrieval from 61% to 80% would be valuable, certainly, but it would still leave the system crippled if Knowledge Base Coverage remains at 53%. The order of operations matters, and our results suggest that coverage is the initial constraint.

D. Qualitative Analysis

To complement our quantitative findings, we examined specific examples from each failure category. These cases, presented in Table IV, illustrate the concrete mechanisms behind our statistical aggregates.

As illustrated in Table IV and Fig. 2 to Fig. 9, the qualitative examples confirm our quantitative results. A consistent pattern emerges: bibliographic queries regarding titles and authors fail across all test sets, despite high knowledge coverage. We attribute this to a structural bottleneck, as metadata is typically confined to specific document regions (e.g., first pages or citation blocks), making it systematically difficult to retrieve.

Furthermore, the lower Knowledge Base Coverage in Q&A Test Set 2 is directly linked to the document format. Unlike other sets, the source articles for Test Set 2 rely heavily on tabular data; because our pipeline struggled to ingest these tables, the relevant information was never indexed. This created a structural knowledge gap where the data existed in the original paper but remained absent from the system's searchable corpus.

TABLE IV. QUALITATIVE EXAMPLES OF FAILURE MODES

Question	Retrieved Context	Agent Answer	Ground Truth	Failure Mode	Key Insight
What is the title of the work by Xiaoqing Li, Jiajun Zhao, ...?	Document 105: Annual Meeting of the Association...	The title of the work by Xiaoqing Li, Jiajun Zhao... is "R2AG: Incorporating Retrieval Information into Retrieval-Augmented Generation."	The title of the work by Xiaoqing Li, Jiajun Zhao... is "Non-parametric unsupervised domain adaptation for neural machine translation."	Knowledge Gap Failure	Required paper not in corpus or metadata chunk missing.
According to Table I, which method demonstrated the highest results for the NQ dataset?	Document 22: 0.2808 0.1276 0.3882 0.2253 L...	According to Table I, the method that demonstrated the highest results for the NQ dataset is R^{2}AG (R-Squared AG).	The method R2AG+RAFT showed the highest results for the NQ dataset.	Generation Failure	Correct table retrieved but misinterpreted.
What are the three main ones? (After discussing retrieval-augmented text generation components)	Document 56: A Survey on Retrieval-Augmented T...	The three main datasets mentioned in the provided context are NQ, TQA, and HotpotQA.	The three key components of the retrieval-augmented generation paradigm are Retrieval, Augmentation, and Generation.	Retrieval Failure	Conversational thread lost; retrieved datasets instead of components.
Could you tell me the title of the academic paper by Edward J. Hu and his colleagues?	Document 119: Harrison Chase. 2022. LangChain....	I don't know.	The title of the paper by Edward J. Hu and his colleagues is "LoRA: Low-Rank Adaptation of Large Language Models."	Knowledge Gap Failure	Paper not present in corpus (low coverage).

Beyond this, three recurring failure modes stand out:

- First, knowledge gap failures often occurred not because information was absent from the corpus, but because it was fragmented by our chunking strategy. By failing to respect the original PDF structure, the strategy separated key ideas from their authors or sources.
- Second, retrieval failures occurred when embedding similarity caused semantic misalignment. For example, a question regarding training differences between REALM and DPR incorrectly retrieved a chunk on the BERT architecture. This mismatch stemmed from terminological overlap; shared terms like "encoder" and "pre-training" produced a high similarity score even though the correct passage was conceptually different. This highlights a fundamental limitation: in scientific contexts, functional relevance does not always correlate with semantic similarity.
- Third, generation failures, while rare at only 4%, stemmed from instruction-following errors. In these cases, the LLM defaulted to its internal parametric knowledge or misread the provided context, as seen in the second question of Table IV. While occasional, these instances prove that even with perfect context, accurate generation is not guaranteed. However, their low frequency confirms that modern instruction-tuned LLMs demonstrate high faithfulness when provided with relevant context.

VI. DISCUSSION

Our findings challenge the prevailing model-centric research paradigm and encourage a fundamental reorientation toward data-centric engineering in scientific RAG systems. By utilizing LLM-as-a-judge, not merely as a performance metric, but as a diagnostic instrument, we successfully isolated structural failures in retrieval coverage from cognitive failures in generation. This moves RAG evaluation toward an actionable diagnosis rather than a simple aggregate scoring.

A. Knowledge Base Coverage is the Key Obstacle

The dominant failure mode reveals a fundamental flaw in standard document processing. Standard tools, like the RecursiveCharacterTextSplitter, operate on "blind" logic, slicing text by character counts rather than rhetorical meaning. In a scientific context, this is catastrophic. A research paper is a web of connected arguments; when chunking separates a Method from its Constraint, it "break down" the knowledge. No model can reason through an answer that was physically deleted during ingestion.

B. Beyond Semantic Matching

We observe that semantic similarity is often a poor proxy for functional relevance [35]–[37]. Scientific queries often seek "differences" or "limitations". These concepts are "diffuse", meaning they are spread across paragraphs and lack the specific keywords found in the query. Dense retrievers are easily misled by "lexical noise", pulling chunks that look similar on the surface but are logically unrelated. This highlights a limitation: vectors measure how much text looks alike, not how ideas relate logically.

C. The Reliability of the LLM "Brain"

The remarkably low rate of Generation failure suggests that concerns over "hallucinations" may be misplaced in RAG systems. When provided with high-quality context, the LLM acts as a reliable synthesis engine. This implies that hallucinations are often a symptom of data absence, not a failure of logic. If the model lacks the correct data, it defaults to its own memory. Therefore, resources spent on fine-tuning models might be more effectively redirected toward expert data engineering.

D. Systematic Bias in Metadata

The consistent failure of bibliographic queries (Title/Author) reveals a positional bias. Because metadata is concentrated in specific regions like citation blocks, naive chunking splits this information into "weak" chunks that the retriever ignores. This

is not a random error; it is a systematic failure to treat document structure as a core part of the retrieval process.

These findings argue for a rebalancing of research priorities. The field has offered immense energy to improving retrievers, scaling models, and designing sophisticated fusion mechanisms. For scientific RAG, the path to reliability lies in upstream interventions. We must move away from "naive" text splitting and toward structure-aware ingestion; systems that understand a paper's layout are just as important as its texts.

VII. Limitations and Future Works

Several limitations should be considered when interpreting the findings of this study:

- Methodological circularity: Using an LLM (GPT-4) to judge a pipeline powered by an LLM (GPT-3.5) introduces potential circularity. While this study provides a diagnostic framework, these assessments have not yet been calibrated against human expert annotation.
- Generalizability: Our findings are derived from a single pipeline architecture and ten targeted articles. It remains unclear whether the "coverage-over-generation" failure mode persists across different chunking strategies, larger corpora, or specialized scientific knowledge graphs.
- To transition toward expert data engineering, future research must move beyond basic text ingestion. We suggest three concrete recommendations:
- Adopt structure-aware chunking strategies that preserve the rhetorical organization of academic writing.
- Implement hybrid retrieval approaches combining dense and sparse methods to capture functional relevance beyond semantic similarity.
- Adopt a multimodal approach that specifically addresses tabular data and equations, which were identified in Q&A Test Set 2 as a primary cause of coverage loss.

VIII. Conclusion

This study presents KnowRAG, a zero-shot retrieval-augmented generation (RAG) pipeline that achieves notably better factual accuracy compared to a Large Language Model alone. Our analysis reveals that the main limitation in performance is not retrieval or generator quality, but rather the extent of Knowledge Base coverage, with missing knowledge responsible for most errors. These results shift the focus away from scaling models, suggesting that reliable scientific AI relies more on advanced data engineering than larger models. The most impactful improvements in scientific RAG systems come from ambitious enhancements such as structure-aware document chunking, hybrid retrieval methods and more expressive knowledge representations. In essence, the effectiveness of an RAG system hinges on the quality of its knowledge base. By focusing on how we transform raw publications into retrievable knowledge, we can bridge the gap between existence in a PDF and presence in a model's response.

Determinants of Telemedicine Security Readiness Among ICT Professionals: Extended UTAUT Model

Fazlina Mohd Ali[1], Afraa Mohammed Mohammed Gaashan[2], Marizuana Mat Daud[3], Rimaniza Zainal Abidin[4]
Faculty of Information Science & Technology, Universiti Kebangsaan Malaysia, 43600 Bangi, Selangor, Malaysia [1, 2, 4]
Institute of Visual Informatics, Universiti Kebangsaan Malaysia (UKM), Bangi 43600, Selangor, Malaysia [3]

***Abstract*—Ensuring strong security readiness in telemedicine is essential to protect patients, safeguard their data, and build confidence and satisfaction in today's digital healthcare platforms. Hence, this research explores and evaluates the maturity of telemedicine services from the perspectives of ICT professionals focused on security readiness. A case study with a stratified survey was conducted among ICT personnel in public hospitals in Malaysia, revealing critical gaps by examining professionals in authority for system security, data fortification, infrastructure resilience, and operational endurance of the telemedicine platform. The UTAUT model employed in this study incorporates two additional constructs, Trust in Technology and Adaptability. Trust in technology captures confidence in system safety, data privacy, and dependability. The adaptability, focused on system technical areas and user-related factors, towards secure telemedicine adoption. The SPSS Statistics Version 21 was used to analyze the data, retaining descriptive statistics, reliability testing, correlation analysis, and multiple regression. Results indicated a generally high level of security readiness among ICT professionals, with strong Trust in Technology and Adaptability to telemedicine systems. Facilitating Conditions, particularly the availability of secure infrastructure and technical safeguards, emerged as the most influential factor and significantly predicted Performance Expectancy. Although Trust in Technology and Adaptability exhibited strong positive correlations with key UTAUT constructs, their effects were statistically significant in the regression analysis, supporting all proposed hypotheses, including their influence on Satisfaction, which suggests a direct role in shaping security readiness.**

***Keywords*—Telemedicine; security readiness; ICT professionals; UTAUT; healthcare systems**

I. Introduction

Telemedicine has emerged as a vital component of digital healthcare delivery, particularly in addressing remote clinical services. However, beyond accessibility and efficiency, the security readiness of the telemedicine system has become a critical concern, especially as healthcare services increasingly rely on digital platforms for exchanging sensitive patient data. In Malaysia, the COVID-19 pandemic significantly accelerated the adoption of teleconsultation services across public and private healthcare sectors, with usage increasing sharply in primary and hospital settings [1], [2]. This was driven by the increasing need for remote consultation and outpatient care management with a reduced risk of infection.

Despite growing adoption, the success of telemedicine systems remains hindered by numerous challenges, including infrastructural limitations, security vulnerabilities, data security concerns, usability issues, and user trust in technology for secure system operations [3], [4]. These factors can hinder system performance and limit broader acceptance, mainly when not adequately addressed during implementation.

ICT (Information and Communication Technology) staff play a pivotal role in successfully deploying, maintaining, and integrating telemedicine platforms, particularly in ensuring system security, access control, data confidentiality, and resilience against operational risks. However, their perspectives are often underrepresented in policy and academic discourse, despite their experience being crucial to identifying real-world operational challenges and technical shortcomings [5].

This study employs an extended version of the Unified Theory of Acceptance and Use of Technology (UTAUT) model to assess ICT staff's perceptions of telemedicine system performance in Malaysian public hospitals. The original UTAUT framework, designed to assess technology acceptance, has been enhanced in this study by incorporating two additional constructs: trust in Technology and Adaptability, which are especially relevant in healthcare environments [6].

The primary objectives of this study are to: 1) investigate infrastructural and organizational barriers experienced by ICT personnel in supporting telemedicine services, 2) assess key predictors of system acceptance and performance from the ICT perspective, and 3) propose actionable recommendations to support more effective integration of telemedicine in Malaysia's hybrid healthcare eco-system. In this study, telemedicine security readiness refers to the organizational and technical preparedness to deploy telemedicine securely, including trusted systems, secure infrastructure, adaptable users, and effective digital workflows.

II. Related Work

Telemedicine adoption as an e-government service has been extensively studied using technology acceptance frameworks, particularly the Unified Theory of Acceptance and Use of Technology (UTAUT) [6], [7]. Venkatesh et al. [6] originally proposed UTAUT to evaluate Technology Adoption (TA), identifying Performance Expectancy (PE), Effort Expectancy (EE), and Social Influence (SI) as critical determinants. However, most UTAUT applications in healthcare focus on end users (patients, clinicians), neglecting the pivotal role of ICT staff in system implementation and in safeguarding the integrity and data protection [6], [5].

In Malaysia, the adoption of telemedicine surged during the COVID-19 pandemic, driven by policy initiatives such as the

Virtual Clinic program [5]. Studies such as [8] revealed that 66.3% of Malaysian healthcare workers viewed telemedicine as complementary to traditional care, but 29.1% resisted adoption without prior physical patient interactions, highlighting challenges related to trust and workflow integration. Notably, the perspectives of ICT workers were underrepresented, despite their critical role in addressing infrastructural barriers (e.g., cybersecurity, interoperability) [9].

Globally, UTAUT extensions have incorporated more constructs to better predict adoption in healthcare [8], [9]. For example, Marcelo et al. [10] applied UTAUT to telemedicine adoption in the Philippines, finding that adaptability and facilitating conditions (e.g., training) were key for ICT staff acceptance. Similarly, Rahman et al. [7] demonstrated that task-technology fit significantly influenced telemedicine adoption during the COVID-19 pandemic. Considering insights from existing studies provides a relevant indication that two additional constructs are required to evaluate ICT professionals' perspectives. Thus, the additional constructs added as extensions of the UTAUT model in this study are: technology trust (TT) and adaptability (AD). The relevance of the new extension of this model will be further investigated in this study to demonstrate that the new constructs are significant in evaluating the perspectives of ICT Healthcare Professionals.

There are many other related studies that contributed to the electronic medical records framework, IT capability in the Malaysian healthcare system, and the assessment of patient risks that revolve in the healthcare domain [11], [12], [13]. Despite advances contributed to in numerous studies, gaps persist in many areas of research, particularly in the Malaysian context, regarding ICT personnel in the implementation of telemedicine. Prior studies have focused on clinicians' perceptions [8] or patient satisfaction [14], with limited attention to telemedicine security assurances and the role of ICT professionals responsible for safeguarding system integrity and data protection [15]. Although trust has been examined in the context of telemedicine adoption, it is often treated as a behavioral factor rather than as a contextual factor within telemedicine's security framework. Thus, this study addresses this gap by extending UTAUT with trust and adaptability constructs [16], [5] and by exploring privacy protection and system reliability, which are central to ICT staff's responsibilities.

TABLE I. SUMMARY OF KEY RELATED STUDIES AND LIMITATIONS

Ref	Study & Focus	Limitation
[5]	Ahmad et al. (2023) ICT readiness in Malaysia	Highlights readiness gaps but lacks a theoretical model
[7]	Rahman et al. (2024) UTAUT for telemedicine (Indonesia)	Focused on general users, not backend system personnel
[8]	Khoo et al. (2023) Clinician adoption barriers in Malaysia	Only includes clinician perspectives; lacks technical staff data
[10]	Marcelo et al. (2022) ICT adoption (Philippines)	Conducted outside Malaysia; cultural/infrastructure context differs
[15]	Niu& Hong(2024) Interoperability in Malaysian telemedicine	Only examining the effect of trust in technology
[16]	Vaddhano & Tulipa (2023) Trust in UTAUT (Thailand)	Investigated trust but excluded ICT worker-specific concerns

III. METHODOLOGY

This study adopts a quantitative, cross-sectional survey design to evaluate the acceptance and perceptions of telemedicine systems among ICT professionals in selected Malaysian public hospitals. The theoretical basis for this research was the Unified Theory of Acceptance and Use of Technology (UTAUT) model, as proposed by Venkatesh et al. [1]. Two additional constructs, Trust in Technology and Adaptability, were integrated into the model based on theoretical findings, as shown in Table I. These two constructs intend to more effectively address the identified research gap and problem, particularly the limited understanding of ICT professionals' acceptance of telemedicine systems implementation in technically complex healthcare environments. These constructs capture critical aspects such as system security reliability, user confidence, and adaptability to evolving digital workflows [17], [18].

In this research, the UTAUT constructs are interpreted using telemedicine security readiness perspectives as follows:

- PE = Performance Expectancy (perceived secure performance benefit)
- EE = Effort Expectancy (secure workflow usability)
- SI = Social Influence (security culture/organizational influence)
- FC = Facilitating Conditions (security-ready infrastructure & support)
- TT = Trust in Technology (trust in system security & reliability)
- AD/A = Adaptability (adaptability to secure digital workflows)

A. Survey Instrument

The data collection tool was a structured questionnaire adapted from previously validated UTAUT-based instruments used in telemedicine and healthcare ICT. The survey was designed to assess six key constructs: Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI), Facilitating Conditions (FC), Trust in Technology (TT), and Adaptability (AD/A). Likert-scale questions were presented to gather demographic information on participants' job roles, years of experience in ICT, and institutional affiliations, to contextualize their responses within the healthcare infrastructure.

B. Sampling and Data Collection

The case study for this research targeted ICT professionals supporting, maintaining, or deploying telemedicine systems in Malaysian public hospitals, focusing on the Klang Valley area [Hospital Kuala Lumpur, Hospital Putrajaya, Hospital Kajang, Selayang Hospital, Hospital Canselor Tuanku Muhriz UKM (HCTM)]. These hospitals were selected purposively because they were integrated into the Ministry of Health's Virtual Clinic initiative, which provided a reliable operational context for telemedicine services [4]. A purposive sampling technique was employed to ensure that only participants with relevant experience and involvement in the deployment of the telehealth system were included. The questionnaire was distributed online

using Google Forms, with access shared through hospital ICT units and administrative channels. Participation was entirely voluntary and anonymous. Respondents were informed about the study's goal, the confidentiality of their responses, and their right to withdraw at any time. This study is exploratory and context-specific, involving ICT personnel from selected public hospitals in the Klang Valley. Therefore, findings should be interpreted within this operational context.

Using Cochran's formula [19] with a 95% confidence level and a 5% margin of error, the estimated population of 90 ICT professionals from all selected hospitals yielded 69 responses (≈77% response rate), resulting in a margin of error of approximately ±5.7% at the 95% confidence level. Given the study's targeted sampling frame, high response rate, and exploratory nature, the sample was considered sufficiently representative for statistical analysis and inference [20]. For the data analysis, all obtained responses were compiled and analyzed using SPSS Statistics Version 21.

IV. Hypothesis

Research hypotheses are derived from the research purpose, which aims to examine the key determinants influencing telemedicine acceptance and its impact on the quality of care among Malaysian healthcare professionals. This study selectively examines security-relevant determinants from the extended UTAUT framework rather than testing the complete original UTAUT model. The hypotheses were tested using Pearson correlation and multiple regression analyses, which provide insight into the direction and strength of the relationships between the variables. The development of these relationships is critical for informing the implementation of healthcare settings in selected Malaysian public hospitals. Each hypothesis was evaluated using a separate regression model, based on the specified predictor-outcome relationship. The hypotheses are stated as follows:

- H1: Facilitating Conditions significantly and positively predict Performance Expectancy among healthcare professionals - Reflects the availability of secure technical infrastructure and support mechanisms [21].
- H2: Trust in Technology is positively associated with Performance Expectancy - Implies confidence in the security, reliability, and data protection of telemedicine, which increases professionals' expectations of its usefulness in healthcare delivery [22].
- H3: Adaptability of healthcare professionals is positively related to Satisfaction with telemedicine services - Indicates ICT professionals' adaptability in securing digital healthcare workflows, resulting in higher levels of satisfaction [23].

V. Results and Discussion

The analysis began with descriptive statistics to have a summary of the demographic profile of respondents and their agreement with the survey items. Pearson correlation analysis was used to examine the relationships among constructs. A multiple linear regression analysis test was performed to determine the predictors of ICT staff perceptions of telemedicine system effectiveness, including three hypothesis relationships: FC predicting PE, TT predicting PE, and AD predicting Satisfaction. All statistical procedures were conducted at a 95% confidence level, and assumptions about normality, multicollinearity, and homoscedasticity were checked and met before proceeding with the regression tests. These findings provide empirical insights into how key security-relevant factors, including system usability within secure workflows, trust in system security and reliability, infrastructure readiness, and ICT professionals' adaptability, influence telemedicine security readiness and the adoption of secure telemedicine services.

A. Descriptive Analysis

The responses were from 69, and the demographic distribution showed a balanced gender profile, with 53.6% female and 46.4% male respondents, as in Table II. The age groups were diverse, with the largest proportion being 36–45 years (30.4%), followed by 26–35 years (27.5%) and 18–25 years (20.3%). Fig. 1 shows that the highest institutional participation was from Hospital Canselor Tuanku Muhriz UKM (39.1%), highlighting its significant role in telemedicine adoption. Its partnership with the university makes it more accessible. This diverse respondent base supports the generalizability of findings related to ICT perspectives on telemedicine integration.

TABLE II. Demographic Information

Variable	Mean	Std. Deviation	Category	Frequency	Percentage
Gender	1.536	.5023	Male	32	46.4%
			Female	37	53.6%
Age	2.536	1.0513	18-25	14	20.3%
			26-35	19	27.5%
			36-45	21	30.4%
			46-55	15	21.7%

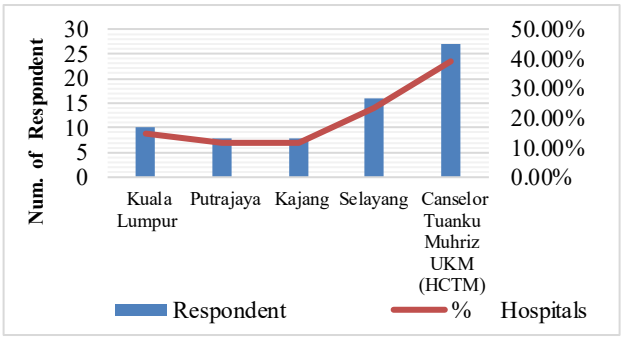

Fig. 1. Participation from ICT professionals.

Fig. 2 represents the Trust in Technology (M = 3.60) and Effort Expectancy (M = 3.60) received the highest mean scores, indicating strong confidence among ICT professionals in the security and reliability of telemedicine systems, which are essential for sustaining secure healthcare services. Social Influence (M = 3.58) and Adaptability (M = 3.58) also had positive attitudes. Performance Expectancy (M = 3.12) and Facilitating Conditions (M = 3.05) were rated comparatively

lower, indicating moderate perceptions of the system's impact on job performance and the sufficiency of infrastructure. These results offer preliminary insight into the readiness of ICT professionals to enable secure telemedicine, highlighting the importance of developing resilient technical infrastructure and performance-based benefits.

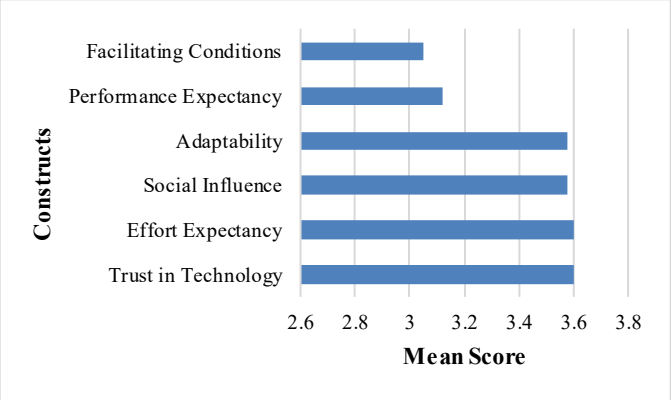

Fig. 2. Telemedicine security readiness profile (n = 69).

Overall, ICT professionals' reported readiness signals in trust and usability, while infrastructure support and perceived performance impact appeared comparatively weaker. As shown in Table III, there is room for strengthening secure telemedicine implementation.

TABLE III. DESCRIPTIVE MEAN SCORES OF TELEMEDICINE SECURITY READINESS CONSTRUCTS

Construct	Mean (M)	Security-readiness interpretation
TT	3.6	Confidence in system security & reliability
EE	3.6	Secure system perceived as usable/easy to operate
SI	3.58	Organizational support/peer influence for secure use
AD/A	3.58	Readiness to adjust to secure workflows/practices
PE	3.12	Moderate perceived impact on job performance
FC	3.05	Moderate adequacy of infrastructure/support (readiness gap)

B. Reliability Analysis

TABLE IV. RELIABILITY SUMMARY OF MEASUREMENT CONSTRUCTS

Construct	Cronbach's α	CITC range	Decision
PE	0.901	0.650–0.871	Retained (α > 0.70)
EE	0.905	0.650–0.871	
TT	0.924	0.650–0.871	
SI	0.972	0.867 – 0.909	
FC	0.972	0.782 – 0.866	
AD	0.972	0.871 – 0.895	

All constructs exceeded the recommended Cronbach's alpha threshold (α > 0.70), as shown in Table IV, indicating high reliability of the survey instrument. Corrected Item-Total Correlation (CITC) values ranged from 0.650 to 0.871, confirming each item's significant contribution to its construct. The results showed minimal variation in alpha-if-item-deleted values (0.972-0.974), confirming that no items required removal. These results validate the instrument's robustness for subsequent analysis.

C. Correlation Analysis

Pearson correlation analysis revealed significant positive relationships among all key constructs, with correlations at $p < 0.01$ (2-tailed). Notably, as in Table V, the strongest relationships were observed between EE and SI ($r = 0.894$), PE and FC ($r = 0.871$), and TT and AD ($r = 0.852$). These results are evidence that secure telemedicine readiness is closely associated with the following:

- Security-ready infrastructure and support (FC) strengthening perceived system benefit (PE)
- Trust in system security and reliability (TT) supporting ICT professionals' readiness to adapt to secure digital workflows (A).

Fig. 3 presents a heatmap of the Pearson correlations reported in Table V. Thus, the correlations suggest that the interconnected roles of usability, organizational influence, infrastructure readiness, and trust are key components in crafting secure telemedicine adoptions flexible and willing to embrace telemedicine technologies tend to report higher satisfaction.

TABLE V. PEARSON CORRELATIONS BETWEEN TELEMEDICINE SECURITY READINESS CONSTRUCTS

Cons.	PE	EE	SI	FC	TT	A
PE	1	.782**	.802**	.871**	.785**	.777**
EE	.782**	1	.894**	.708**	.817**	.779**
SI	.802**	.894**	1	.765**	.791**	.762**
FC	.871**	.708**	.765**	1	.761**	.752**
TT	.785**	.817**	.791**	.761**	1	.852**
A	.777**	.779**	.762**	.752**	.852**	1
**. Correlation is significant at the 0.01 level (2-tailed).						

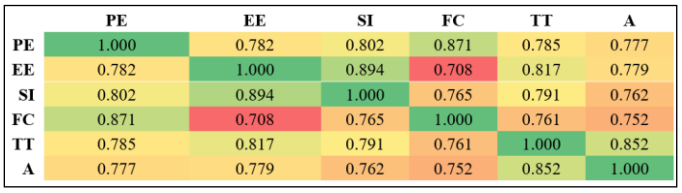

Fig. 3. Pearson correlation heatmap of telemedicine security readiness constructs.

D. Regression Analysis

Multiple regression analysis further supported these findings through three separate predictive models, aligned with the study hypothesis. The regression outcomes are summarized in Table VI. Model 1 revealed that Facilitating Conditions significantly predicted Performance Expectancy ($\beta = 0.483$, $p = 0.007$), underscoring the importance of a security-ready infrastructure, reliable system support, and technical safeguards in shaping ICT professionals' perceptions. Model 2 confirmed that Trust in Technology also positively influenced Performance Expectancy ($\beta = 0.428$, $p = 0.012$). Meanwhile, Model 3

identified Adaptability as a significant predictor of user Satisfaction ($\beta = 0.521, p < 0.001$), highlighting its importance in the successful adoption of secured telemedicine systems. Collectively, these findings highlight that a supportive technological environment and adaptable ICT staff are crucial drivers of secure telemedicine adoption.

TABLE VI. MULTIPLE REGRESSION RESULTS FOR TELEMEDICINE SECURITY READINESS.

Model	Dependent Variable	Significant Predictor(s)	Standardized β	*p*-Value
Model 1	Performance Expectancy (PE)	Facilitating Conditions (FC)	0.483	0.007
Model 2	Performance Expectancy (PE)	Trust in Technology (TT)	0.428	0.012
Model 3	Satisfaction	Adaptability (AD/A)	0.521	< 0.001

E. Hypothesis Test

The hypothesis testing results revealed that Facilitating Conditions significantly predicted Performance Expectancy among ICT professionals, strongly supporting H1. In contrast, both Trust in Technology (H2) and Adaptability (H3) significantly predicted Performance Expectancy, while Adaptability showed a strong positive correlation with Performance Expectancy. However, it did not emerge as a significant predictor of Performance Expectancy in the regression models, yet it was significant in predicting satisfaction. These findings suggest that while trust and adaptability are valued, infrastructure and technical support remain the most influential factors in shaping ICT professionals' perceptions of telemedicine effectiveness. Thus, H1 is fully supported, while H2 is supported, and H3 is supported for Satisfaction but not for Performance Expectancy. The hypothesis testing summary is presented in Table VII.

TABLE VII. HYPOTHESES ANALYSIS

Hypothesis	Relationship Tested	Correlation (r)	Regression (β)	*p*-value	Supported?	Addresses Objective
H1	FC → PE	0.871**	0.483	0.007	Yes	Security-ready infrastructure/support boosts perceived usefulness
H2	TT → PE	0.785**	0.428	0.012	Yes	Trust in system security & reliability boosts perceived usefulness
H3	AD → Satisfaction	0.786**	0.521	<0.001	Yes	Adaptability to secure workflows increases satisfaction
*p < 0.01 (2-tailed). (** indicates significant correlation at 0.01 level.)*						

TABLE VIII. TELEMEDICINE ANALYSIS SUMMARY

Evidence (from analysis)	Key finding	Security-readiness implication
Descriptive Statistics (PE, EE, SI, FC, TT, AD)	Mean range: 3.05–3.60; highest means: TT = 3.60, EE = 3.60; lower means: PE = 3.12, FC = 3.05	ICT professionals demonstrate a positive readiness toward secure telemedicine; however, security-ready infrastructure and support, as well as perceived performance benefits, require further strengthening.
Reliability Analysis (23 items)	Overall reliability: Cronbach's Alpha = 0.974	The measurement instrument is robust, supporting confidence in the reported telemedicine security readiness findings.
Correlation Analysis	TT–PE: r = 0.850, AD–Satisfaction: r = 0.786 ($p < 0.01$)	Trust in system security/reliability is strongly linked to perceived usefulness, while adaptability is strongly linked to satisfaction—both are key indicators of readiness.
Regression Model 1	FC → PE: β = 0.483, p = 0.007	Security-ready infrastructure, support, and safeguards significantly strengthen ICT professionals' perception of telemedicine usefulness.
Regression Model 2	TT → PE: β = 0.428, p = 0.012	Higher trust in system security and reliability increases perceived usefulness, supporting the readiness of secure telemedicine.
Regression Model 3	AD → Satisfaction: β = 0.521, p < 0.001	ICT professionals' adaptability to secure digital workflows significantly improves satisfaction and supports sustained secure adoption.

Summary in Table VIII outlines the key findings from the analysis, showing strong support for H1 and partial support for H2 and H3. These results suggest that telemedicine success depends not only on usability but also on organizational preparedness to support secure digital healthcare services, aligning with broader telemedicine security governance objectives.

VI. CONCLUSION AND FUTURE WORK

The study provides empirical evidence on the security readiness of telemedicine from the perspectives of ICT professionals supporting telemedicine services in selected public hospitals, particularly in the Malaysian case study. The overall perception was positive, especially for Trust in Technology and Effort Expectancy, indicating that secure telemedicine platforms are generally accepted as reliable and adaptable. However, a similarly low perception of Performance Expenditure and Facilitation Conditions suggests that the perceived benefits of telemedicine and the adequacy of the infrastructure remain areas for improvement. A summary of key results is provided in Table VIII.

The inferential findings further prove the key readiness drivers for secure telemedicine. Whereby, correlation values indicate a strong interrelationship among the constructs, while regression results confirm that security-ready infrastructure and support (Facilitating Conditions) and trust in system security and reliability (Trust in Technology) both contribute to a gradual improvement in perceived usefulness (Performance Expectancy). Additionally, Adaptability also significantly predicts Satisfaction, highlighting the importance of ICT professionals' readiness to operate within a secure digital work process. Collectively, these findings suggest that secure telemedicine adoption depends not only on system usability but

also on organizational preparedness, trusted operations, and workforce adaptability, offering practical direction for robust secure digital healthcare services.

Extended studies in this research area can be conducted by employing a larger, more diverse sample of ICT professionals from various regions and hospital levels across Malaysia, including private and rural health facilities. As this study used correlation and multiple regression for exploratory purposes and with a limited sample size, future studies with larger samples may employ SEM to examine mediation and full model fit. This will make the results more generalizable and allow for comparisons across various healthcare settings. Longitudinal studies are also recommended to quantify how perceptions and uptake patterns evolve.

Moreover, future studies may extend this work by examining telemedicine cybersecurity practices, security governance frameworks, and regulatory compliance models to further strengthen telemedicine security readiness across healthcare systems. Interpreting the impact of cybersecurity, digital literacy, and departmental collaboration on telemedicine deployment would help facilitate a more comprehensive understanding of its success.

ACKNOWLEDGMENT

The Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia (WARISAN-2025-004) funds this research. Heartfelt appreciation is expressed for the funding and facilities provided, which were essential for completing this study.

Evaluating Perceptual Reliability of Latent Attribute Control in Diffusion-Based Fashion Generation

Noriaki Kuwahara[1], Shintaro Kawanami[2], Takashi Sato[3], Dongeun Choi[4]*

***Abstract*—Although diffusion-based image generation models enable high-quality synthesis of fashion images, the reliable control of perceptual attributes in these models remains poorly understood. Current evaluation approaches primarily rely on semantic similarity metrics, such as CLIP scores, which may not accurately reflect human perceptual judgments. This study proposes a three-layer evaluation framework linking latent space geometry, semantic embedding space, and human perception. First, latent attribute directions are validated using geometric quality-control metrics measuring linearity and centrality. Second, semantic consistency is examined through directional projection in CLIP embedding space. Third, a two-alternative forced-choice experiment is conducted with 37 participants, and perceptual strength is estimated using a Bradley-Terry preference model. Experiments cover gender and garment conditions for four fashion attributes: fit, lightness, glossiness, and pattern scale. Results reveal that fit exhibits strong cross-layer alignment, while pattern scale shows semantic and perceptual ambiguity. The findings highlight that perceptual reliability in controllable generation is attribute-dependent and that semantic metrics alone cannot fully replace human evaluation.**

***Keywords*—Diffusion models; controllable generation; latent space analysis; human preference modeling; perceptual reliability; fashion image generation**

I. Introduction

Diffusion-based image generation models demonstrated remarkable visual quality and are widely used in text-to-image synthesis [1], [2]. In fashion applications, these models enable controllable manipulation of garment appearance through latent-space operations. However, reliable control of perceptual attributes such as fit, lightness, glossiness, and pattern scale has not been sufficiently validated.

Current evaluation methods primarily rely on semantic similarity metrics, including CLIP-based scores or reward models trained on human preferences [3], [4]. These approaches measure alignment between generated images and textual prompts, but do not explicitly assess whether latent attribute manipulations are geometrically stable or perceptually consistent. As a result, latent representation behavior, semantic embedding responses, and human perceptual discernment are often treated interchangeably.

Previous studies show that semantic attributes may correspond to specific directional changes in latent space [5], [6]. Despite these findings, the geometric validity of these directions and their perceptual reliability within diffusion models have not been systematically analyzed. Furthermore, while human preference modeling is increasingly employed in generative AI evaluation [4], [7], its relationship to latent space geometry and semantic embedding behavior is still unclear.

To address this gap, we propose a three-layer evaluation framework that links latent space geometry, semantic embedding space, and human perception. Our method employs a latent direction quality-control mechanism to validate the linearity and centrality of attribute directions prior to semantic and human evaluation. Experiments under gender and garment conditions measured performance across four perceptual attributes. Cross-layer consistency analysis shows that the perceptual reliability of controllable diffusion generation is attribute-dependent and cannot be fully predicted by semantic similarity metrics alone.

The contributions of this study are:

- A three-layer evaluation framework separating latent geometry, semantic consistency, and human perceptual reliability.
- A latent direction quality control approach for validating geometric stability.
- An empirical analysis revealing attribute-dependent alignment across evaluation layers.

II. Related Work

A. Controllable Diffusion Models

Diffusion-based generative models are widely known for producing high-fidelity images [1], [2]. Their iterative denoising framework supports stable training dynamics and allows for flexible conditioning. While many diffusion models focus on text-conditioned generation, some have introduced additional control signals into their architectures to guide structural or semantic properties. For example, ControlNet introduced extended diffusion models with conditional control branches to improve structural consistency under user constraints [8]. More recent work has further explored efficient and scalable virtual try-on systems using knowledge distillation techniques, improving both realism and computational efficiency [9]. In fashion-related applications, diffusion-based virtual try-on systems have demonstrated realistic garment transfer while preserving the human form. Most of these systems focus on achieving realistic results and maintaining structural coherence. However, limited attention has been paid to systematically evaluating the controllability of perceptual attributes.

*Corresponding author

Although diffusion models allow manipulation of latent spaces, the geometric properties of attribute directions in diffusion latent spaces have not been extensively examined. Unlike deterministic GAN-based architectures, diffusion models involve stochastic denoising processes. This presents challenges in maintaining stable latent attribute directions. As a result, controllability depends on explicit validation of the directions of geometric attributes rather than on assuming their stability.

B. Latent Space Geometry and Directional Editing

Latent space interpretability has been widely studied in GAN frameworks. StyleGAN demonstrated that semantically meaningful transformations can emerge along structured latent representations [10]. However, prior work has also challenged common assumptions in disentangled representation learning, indicating that such latent structures may not be as robust or universally interpretable as often assumed [11]. InterFaceGAN further showed that certain attributes correspond to approximately linear directions in latent space, enabling semantic editing through vector operations [5]. Subsequent studies emphasized the importance of geometric alignment and stability in defining controllable directions [6], [12].

Representation learning theory suggests that meaningful variation predominantly lies in structured subspaces rather than arbitrary directions [13]. While most analyses focus on GAN architectures that employ deterministic latent-variable mappings, diffusion models differ significantly due to their latent characteristics arising from stochastic noise injection and iterative refinement. Consequently, the geometric validity, centrality, and stability of attribute directions in diffusion latent space are underexplored and require dedicated evaluation mechanisms.

C. Semantic Embedding-Based Evaluation

Semantic alignment between generated images and corresponding textual descriptions is commonly evaluated using CLIP-based similarity metrics [3]. Embedding-based reward models, such as ImageReward, are designed to approximate human preference through learned scoring mechanisms [4]. These evaluation approaches provide scalable, automatic assessment and are now standard benchmarks for text-to-image generation.

However, distance-based similarity metrics do not explicitly separate intended attribute variation from unrelated visual changes. Existing literature on evaluation has shown that global error or similarity measures may not capture meaningful structural features of human perception [14]. Recent studies on human preference modeling in generative systems further emphasize that embedding-based metrics only partially correlate with human discretion [15]. For this reason, direction-sensitive analysis in embedding space is needed to verify that attribute progression is consistently preserved, not just semantic similarity increased.

D. Human Preference and Perceptual Reliability

Human evaluation remains fundamental to assessing the inherently subjective aspects of generative models. Human preference modeling systems typically employ experimental methods, such as two-alternative forced-choice (2AFC) and pairwise comparison frameworks, to statistically quantify human subjective discernment [7]. The resulting comparative data is then analyzed using the Bradley-Terry model [16] to construct latent preference scales that reflect human preferences. These modeling processes not only play a central role in evaluation but also serve as a key component for aligning reward systems within modern generative AI pipelines [4], [15].

Despite the growing adoption of human preference modeling techniques, most existing studies evaluate either automatic semantic alignment or human preference independently. They have not yet examined the relationship among latent geometry, semantic embedding behavior, and perceptual reliability collectively. A consolidated framework integrating geometric validation, semantic direction analysis, and human perceptual assessment is necessary to facilitate structured interpretation and understanding of controlled generation aligned with human factors.

Recent studies have increasingly emphasized the importance of controllability and systematic evaluation in generative AI systems [18], [19], highlighting the limitations of relying solely on semantic similarity metrics. These trends further motivate the need for a unified framework that systematically links latent space manipulation, semantic embedding behavior, and human perception.

III. Proposed Framework

A. Problem Formulation

Recent diffusion-based image generation models provide continuous manipulation of visual attributes in the latent space. However, controllable latent directions do not guarantee perceptual reliability.

In this study, we distinguish between three conceptually distinct layers:

- Latent geometry: the internal representation of the generative model.
- Semantic embedding space: a machine-interpretable meaning structure (e.g., CLIP).
- Human perception: subjective discernment of attributes.

Controllable generation implicitly assumes that a given perceptual attribute varies and can be approximated along a one-dimensional axis in the latent space. However, this geometric construction implicitly assumes that:

- Attribute variation is locally linear in latent space.
- The base image lies near the midpoint of the attribute axis.
- Progression along the axis corresponds to monotonic perceptual change.

These assumptions carry significant and non-trivial implications.

From a geometric standpoint, high-dimensional generative latent spaces do not ensure perfectly aligned semantic subspaces.

From a psychophysical standpoint, perceived attribute intensity is generally non-linear with respect to changes in

physical stimulus, as suggested by classical laws such as Weber–Fechner.

Perceptual reliability is, therefore, defined as cross-layer monotonicity and not just latent controllability. This approach ensures the ordering induced by the generation parameter α is preserved in both semantic and human perceptual evaluations.

More formally, let:

- α denote the generation parameter along the latent direction,
- $s(\alpha)$ denotes the semantic projection score,
- $\theta(\alpha)$ denotes the perceptual strength estimated from human evaluation.

An attribute manipulation is considered perceptually reliable if:

- The latent configuration satisfies geometric consistency,
- $s(\alpha)$ is monotonic with respect to α,
- $\theta(\alpha)$ is monotonic with respect to α,
- The ordering induced by $s(\alpha)$ and $\theta(\alpha)$ is positively correlated.

Thus, the central research question is: What geometric conditions enable latent attribute direction to preserve monotonicity through semantic embedding and human perception?

This formulation transforms attribute control from a generation problem into a cross-layer consistency problem.

B. Latent Attribute Direction Hypothesis

Let $z_0 \in \mathbb{R}^d$ denote the latent representation of a base image generated by the diffusion model.

For a given perceptual attribute a, we obtain two endpoint latent codes which are intended to represent the minimal and maximal perceptual strength of attribute a.

$$z_{a,\min}, z_{a,\max}$$

We define the latent attribute direction as Eq. (1):

$$\mathbf{d}_a = z_{a,\max} - z_{a,\min}. \quad (1)$$

To ensure symmetry and interpretability, we adopt a midpoint-centered and normalized parameterization.

The midpoint is defined as Eq. (2):

$$z_{a,mid} = \frac{z_{a,\max} + z_{a,\min}}{2} \quad (2)$$

The normalized direction is Eq. (3):

$$\hat{\mathbf{d}}_a = \frac{\mathbf{d}_a}{\| \mathbf{d}_a \|}. \quad (3)$$

The latent attribute axis is then expressed as Eq. (4):

$$z(\alpha) = z_{a,mid} + \alpha \frac{\| \mathbf{d}_a \|}{2} \hat{\mathbf{d}}_a, \qquad \alpha \in \mathbb{R} \quad (4)$$

whereby,

$$\alpha = \pm 1$$

correspond to the endpoints of the minimal and maximal attributes.

This formulation separates two properties:

- Axis validity — whether $z_{a,\min}$ and $z_{a,\max}$ define a coherent one-dimensional direction.
- Base centrality — whether z_0 lies near $z_{a,\text{mid}}$.

We therefore formulate the following hypothesis:

Hypothesis H_1:

The triplet $(z_{a,min}, z_0, z_{a,max})$ is approximately collinear in the ambient latent space $\mathbb{R}^d$, and displacement along the normalized direction $\hat{\boldsymbol{d}}_a$ preserves perceptual ordering.

If H_1 holds, varying α should induce a systematic perceptual change in attribute a without introducing unintended semantic drift. Because diffusion latent spaces are high-dimensional and stochastic, H_1 is not guaranteed a priori and must be empirically validated.

In the next section, we introduce geometric criteria for testing H_1.

C. Geometric Quality Control in Latent Space

1) Linearity deviation (Δ): To evaluate hypothesis H_1, we first introduce a geometric measure that quantifies deviation from ideal midpoint symmetry.

The midpoint of the attribute axis is defined by Eq. (2). Assuming ideal symmetry and perfect collinearity, the base latent representation coincides with the midpoint.

Equivalently,

$$z_{a,\max} + z_{a,\min} - 2z_0 = 0.$$

We, therefore, define the linearity deviation as Eq. (5):

$$\Delta = \| z_{a,\max} + z_{a,\min} - 2z_0 \| \quad (5)$$

Geometric interpretation:

- $\Delta = 0$ indicates perfect midpoint symmetry.
- Larger Δ indicates deviation from collinearity.
- Non-zero Δimplies geometric distortion of the attribute axis relative to the base configuration.

Notably, Δ evaluates structural consistency exclusively in latent space, independent of semantic or perceptual interpretation.

2) Centrality (c): While Δ measures absolute deviation, it depends on the scale of the attribute span. To obtain a scale-invariant quantity, we define centrality as Eq. (6):

$$c = 1 - \frac{\| z_{a,\max} + z_{a,\min} - 2z_0 \|}{\| z_{a,\max} - z_{a,\min} \|} \quad (6)$$

Properties:

$c \approx 1 \rightarrow$ base is near the midpoint.

$c \approx 0 \rightarrow$ base is near one endpoint.

$c < 0 \rightarrow$ base lies outside the attribute span.

Thus, centrality quantifies the extent to which the base image is centered relative to the attribute axis.

From a geometric perspective, c quantifies the symmetry of displacement. In psychophysical terms, poor centrality may induce asymmetric perceptual sensitivity along the attribute axis.

3) QC decision principle: Geometric validation must take place before semantic or perceptual evaluation.

We define a quality control (QC) mechanism based on Δ and c. An attribute direction is classified as:

- PASS if Δ is sufficiently small and c is sufficiently high.
- WEAK-PASS if only one condition is moderately satisfied.
- FAIL if both conditions indicate significant geometric distortion.

The specific numerical thresholds are determined empirically and reported in the experimental section.

Conceptually, QC establishes a necessary geometric condition for ensuring perceptual reliability:

- If geometric symmetry fails, cross-layer monotonicity cannot be interpreted meaningfully.
- If QC is satisfied, subsequent semantic and perceptual evaluations assess whether geometric consistency propagates across layers.

Thus, geometric QC constitutes the structural foundation of the proposed three-layer evaluation framework.

D. Semantic Direction Validation (clip)

Section III-C establishes geometric consistency in latent space. To ensure perceptual reliability, the attribute progression should be preserved in the semantic embedding space.

We therefore analyze whether the latent attribute axis defined in Section III-B remains consistently oriented in the CLIP embedding space.

Let Eq. (7):

$$\mathbf{v}_i = f_{\text{img}}(x_i) \in \mathbb{R}^D \tag{7}$$

denote the CLIP image embedding of the generated image x_i, where D denotes the dimensionality of the CLIP embedding space.

We define the semantic attribute direction using endpoint embeddings [see Eq. (8)]:

$$\mathbf{d}_{\text{clip}} = \frac{\mathbf{v}_{\max} - \mathbf{v}_{\min}}{\| \mathbf{v}_{\max} - \mathbf{v}_{\min} \|} \tag{8}$$

where, $\mathbf{v}_{\min}$ and $\mathbf{v}_{\max}$ correspond to images generated at $\alpha = -1$ and $\alpha = +1$, respectively.

To ensure symmetry, we define the semantic midpoint as Eq. (9):

$$\mathbf{v}_{\text{mid}} = \frac{\mathbf{v}_{\max} + \mathbf{v}_{\min}}{2} \tag{9}$$

The directional projection score is then defined as Eq. (10):

$$s_i = (\mathbf{v}_i - \mathbf{v}_{\text{mid}}) \cdot \mathbf{d}_{\text{clip}} \tag{10}$$

This projection extracts only the component aligned with the semantic attribute direction.

1) Why projection instead of distance?

Conventional CLIP evaluation typically relies on global similarity or cosine distance measures. However, distance-based metrics do not distinguish between intended attribute variation and unrelated semantic drift.

Directional projection isolates attribute-consistent change while suppressing orthogonal variation.

2) Monotonic consistency in semantic space: To evaluate whether semantic progression aligns with latent parameter α, we compute the Spearman Rank Correlation [see Eq. (11)]:

$$\rho_{\text{clip}} = \text{Spearman}(\{\alpha_i\}, \{s_i\}) \tag{11}$$

Interpretation:

- $\rho_{\text{clip}} \approx 1 \rightarrow$ monotonic semantic progression.
- $\rho_{\text{clip}} \approx 0 \rightarrow$ semantic incoherence.
- $\rho_{\text{clip}} < 0 \rightarrow$ semantic inversion.

Thus, semantic validation tests whether geometric consistency propagates into the embedding space.

3) Duality with latent QC: The proposed semantic validation mirrors latent qc. The human-layer monotonicity measure is formally defined in Section III-E: ρ_{human}

TABLE I. DUAL STRUCTURAL CRITERIA ACROSS LAYERS

Layer	Structural Criterion
Latent Space	Midpoint symmetry (Δ, c)
Semantic Space	Directional monotonicity (ρ_{clip})
Human Space	Perceptual monotonicity (ρ_{human})

Table I summarizes the structural criteria used at each evaluation layer, where each layer evaluates structural consistency with respect to a distinct representational geometry. This framework enforces geometric validity in latent space, semantic monotonicity in embedding space, and perceptual monotonicity in human evaluation.

E. Human Perceptual Validation

While Section III-C and Section III-D establish geometric and semantic consistency, perceptual reliability ultimately depends on human discernment.

To address this, we introduce a psychophysically grounded evaluation based on pairwise comparison.

1) Two-Alternative Forced Choice (2AFC): For each attribute, we compare generated images along the latent axis using the two-alternative forced choice (2AFC) Protocol.az(α_i)

Given a pair of images (x_i, x_j), participants are asked:

- Which image exhibits a stronger perceptual intensity of attribute a?

2AFC is preferred over absolute rating scales because:

- It reduces inter-observer bias.
- It avoids arbitrary internal calibration.
- It yields statistically consistent pairwise comparison data.

The outcome of the comparison shall be denoted as:

$$x_i \succ x_j$$

if image x_i is judged stronger than x_j.

2) Bradley–Terry preference model: We employ the Bradley–Terry Model to derive a continuous perceptual scale based on pairwise outcomes. Each image is associated with a latent perceptual strength parameter. The probability that is preferred over is defined as: $x_i\theta_i x_i x_j$ [see Eq. (12)]

$$P(x_i \succ x_j) = \frac{\exp(\theta_i)}{\exp(\theta_i) + \exp(\theta_j)} \quad (12)$$

The parameters θ_i are estimated using maximum likelihood. This model yields a continuous perceptual strength scale:

$$\theta(\alpha_i)$$

associated with each generation parameter α_i.

3) Monotonic consistency in human space: To evaluate Perceptual Monotonicity, we compute the Spearman Rank Correlation between latent parameter and perceptual strength: α [see Eq. (13)]

$$\rho_{\text{human}} = \text{Spearman}(\{\alpha_i\},\{\theta_i\}) \quad (13)$$

Interpretation:

- $\rho_{\text{human}} \approx 1 \rightarrow$ monotonic perceptual progression.
- $\rho_{\text{human}} \approx 0 \rightarrow$ perceptual incoherence.
- $\rho_{\text{human}} < 0 \rightarrow$ perceptual inversion.

Human perceptual validation tests whether geometric and semantic consistency are reflected in subjective discernment. This completes the tri-layer validation structure of the proposed framework.

F. Cross-Layer Consistency Principle

The preceding sections introduce structural validation criteria across three representational layers:

- Latent geometry (Δ, c),
- Semantic embedding space ($\rho_{\text{clip}} > 0$),
- Human perception ($\rho_{\text{human}} > 0$).

These sections consolidate the principles integrating the stated criteria.

1) Necessary and progressive conditions: Geometric validity in latent space is a necessary prerequisite for ensuring perceptual reliability. When midpoint symmetry is violated (indicated by a Large Δ or Low C), the attribute axis becomes structurally distorted. In such cases, semantic or perceptual monotonicity loses meaningful interpretability.

Semantic consistency constitutes an important second-level condition. Even if latent geometry is coherent, the semantic embedding space must maintain directional monotonicity:

$$\rho_{\text{clip}} > 0.$$

Finally, perceptual reliability requires monotonic progression in human discernment:

$$\rho_{\text{human}} > 0.$$

2) Formal definition: We define the perceptual reliability of an attribute as the conjunction of cross-layer monotonicity conditions: a [see Eq. (14)]

$$\text{Reliable}(a) \iff \begin{cases} \Delta \text{ is small}, \\ c \text{ is near } 1, \\ \rho_{\text{clip}} > 0, \\ \rho_{\text{human}} > 0. \end{cases} \quad (14)$$

In practice, threshold values were empirically determined through preliminary validation and are specified in Section IV-B. We determine the thresholds based on preliminary validation of ranges that must be exceeded for geometric distortion to occur.

3) Interpretation: The proposed framework does not assume that controllable generation is universally reliable. Instead, it provides a structured mechanism for diagnosing where reliability fails:

- Latent distortion (geometric failure),
- Semantic misalignment (embedding failure),
- Perceptual ambiguity (human inconsistency).

Thus, perceptual reliability is treated as an emergent property of cross-layer structural consistency.

4) Theoretical implication: The three-layer framework suggests that controllable diffusion generation is not solely determined by latent manipulability. Instead, attribute reliability depends on whether structural coherence propagates across representational geometries:

$$\mathbb{R}^d \rightarrow \mathbb{R}^D \rightarrow \text{Human perceptual space.}$$

This perspective shifts evaluation from measuring similarity to analyzing structural consistency.

IV. Experimental Setup

A. Diffusion Model Configuration

To apply the proposed three-layer framework, we generated images using a Stable Diffusion 1.5–based inpainting model

(Realistic Vision V5.1). We employed an inpainting configuration to enable controlled attribute manipulation while preserving subject identity and overall scene structure.

Unlike full image synthesis, the inpainting setting allows the torso, pose, and background to remain fixed while restricting modifications to the garment region. This configuration isolates attribute variation from confounding factors such as posture, lighting, or composition changes. Accordingly, perceptual variations caused by the latent parameter α are primarily due to garment-related transformations.

Let $z_0 \in \mathbb{R}^d$ denote the latent representation of a base image under a fixed subject condition. For each attribute a, we generated minimal and maximal endpoint latent codes $z_{a,\min}$ and $z_{a,\max}$ using prompt-controlled inpainting. These endpoints define the latent attribute direction introduced in Section III-B.

All latent manipulations occurred in the VAE latent space of the underlying Stable Diffusion architecture. The latent dimensionality is denoted by d, and the CLIP embedding dimensionality is denoted by D, consistent with the definitions in Section III-D.

After geometric validation (Section III-C), we generated α-series images using spherical linear interpolation (SLERP) between endpoints. SLERP preserves latent distribution geometry by interpolating along a hyper-spherical path instead of a straight Euclidean line. This reduces distributional drift during interpolation [17]. To improve perceptual discriminability, we distributed α values using logarithmic scaling and extended their range:

$$\alpha \in [-1.5, 1.5].$$

This extension preserves geometric consistency while increasing perceptual separability in attributes with weaker visual gradients.

Notably, generation and evaluation were structurally separated. The diffusion model serves solely as a transformation mechanism in latent space. We subsequently performed structural validation across three independent representational layers:

- Latent space (geometric QC: Δ, c)
- Semantic embedding space (projection-based monotonicity: ρ_{clip})
- Human perception (2AFC + Bradley–Terry: ρ_{human})

As illustrated in Fig. 1, perceptual reliability is not treated as a property of a single representational space.

Instead, the generation parameter α is propagated across three structurally distinct layers: latent space geometry, semantic embedding space, and human perceptual discernment. Monotonic consistency with respect to α is evaluated independently at each layer. We, therefore, define perceptual reliability as the preservation of cross-layer order rather than isolated similarity within any single space.

Fig. 2 shows the representative base images for each gender–garment condition. In all conditions, the torso, pose, and background remain constant, with only the garment region undergoing subsequent attribute manipulation.

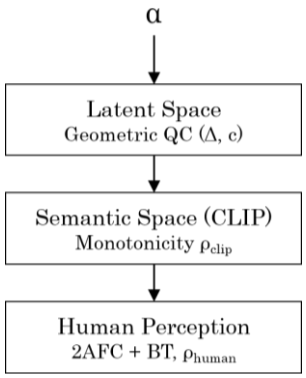

Fig. 1. Three-layer evaluation framework for perceptual reliability.

Fig. 2. Representative base images under fixed gender–garment conditions before attribute manipulation.

B. Latent Direction Construction and Geometric Quality Control

For each perceptual attribute a, latent endpoint representations were constructed under constant subject and garment conditions using the inpainting configuration described in Section IV-A. Using controlled prompt variations, we generated minimal and maximal attribute expressions that yielded the latent codes $z_{a,\min}$ and $z_{a,\max}$ in the VAE latent space of the underlying Stable Diffusion architecture.

We constructed the latent attribute direction $\mathbf{d}_a$ as defined in Eq. (1). This endpoint-based formulation derives the semantic axis in embedding space directly from the generative transformation itself, not from external text embeddings. As a result, the semantic direction remains structurally aligned with the latent manipulation.

Because diffusion latent spaces are high-dimensional and stochastic, simply constructing endpoint representations do not ensure a coherent one-dimensional attribute axis. To ensure structural validity prior to semantic or human evaluation, we employed a geometric validation. For each base image z_0, the

linearity deviation Δ, and centrality $c$were computed as defined in Eq. (5) and Eq. (6). For each attribute under each experimental condition, average values $\bar{\Delta}$ and $\bar{c}$ were obtained across base samples.

We defined the quality control criteria as:

- PASS: $|\bar{\Delta}| < 8.0$ and $\bar{c} > 0.30$
- WEAK-PASS: $|\bar{\Delta}| < 16.0$ and $\bar{c} > 0.15$
- FAIL: otherwise

We excluded attribute directions marked as FAIL and retained WEAK-PASS directions only when visual inspection confirmed they were perceptually interpretable with no visually observable structural distortion.

QC, thereby functions as a structural precondition for cross-layer analysis. If midpoint symmetry is substantially violated, monotonic consistency in semantic embedding space or human perceptual space cannot be meaningfully interpreted. We only propagated attribute directions that satisfied QC to the α-series generation and subsequent cross-layer evaluation.

Fig. 3 shows the representative endpoint.

Fig. 3. Representative minimal (min) and maximal (max) endpoint images for selected attributes.

The upper row corresponds to the fit attribute in the male T-shirt condition, illustrating a geometrically stable latent direction that creates a smooth variation in garment tightness. The lower row shows the pattern scale in the female dress-shirt condition, representing a geometrically weaker (WEAK-PASS) configuration with structurally complex visual variation. These examples offer visual context for the geometric differences evaluated before cross-layer analysis.

C. Semantic Projection Evaluation

To evaluate the preservation of latent attribute progression in the semantic embedding space, we analyzed generated images using a CLIP image encoder.

For each generated image x_i along the α-series, we computed the corresponding image embedding $\mathbf{v}_i \in \mathbb{R}^D$ defined in Eq. (7). Consistent with the endpoint-based formulation introduced in Section III-D, we then constructed the semantic attribute direction using the endpoint embeddings defined in Eq. (8). The semantic midpoint and directional projection scores were computed following Eq. (9) and Eq. (10), respectively.

This projection-based evaluation isolates variation aligned with the semantic attribute direction while suppressing orthogonal changes in embedding. Unlike global similarity or cosine distance measures, directional projection explicitly assesses if attribute progression remains a consistent semantic axis.

We evaluated monotonic consistency in semantic space, using the Spearman rank correlation defined in Eq. (11). A positive correlation indicates that semantic embedding responses preserve the ordering induced by latent manipulation, while near-zero or negative values indicate semantic incoherence or inversion.

Importantly, we treated semantic validation as an intermediate structural layer, not as a substitute for human evaluation. This verifies whether geometric consistency in the latent space propagates to the embedding space before assessing perceptual monotonicity.

D. Human Perceptual Evaluation

To evaluate how latent attribute manipulation reflects human perception, we conducted a two-alternative forced-choice (2AFC) experiment.

We recruited forty participants assigned to experimental conditions defined by gender and garment type. After excluding three responses due to incomplete submissions, 37 valid responses remained for analysis. For each perceptual attribute, participants viewed pairwise comparisons of images generated along the α-series and selected the image with the stronger perceptual intensity.

We chose pairwise comparison over absolute rating scales to reduce inter-observer calibration bias and improve statistical consistency. The 2AFC protocol produces ordinal preference data suitable for probabilistic modeling of latent perceptual strength.

We then estimated perceptual strength parameters θ_i using the Bradley–Terry model defined in Eq. (12). The resulting preference scale provides a continuous representation of perceived attribute intensity for each generation parameter α_i.

To assess perceptual monotonicity, we computed Spearman's rank correlation coefficient between the generation parameter α and the estimated perceptual strength, as defined in Eq. (13). A positive correlation coefficient indicates monotonic perceptual progression, whereas near-zero or negative values indicate perceptual incoherence or inversion.

We randomized image order and left–right presentation to mitigate positional bias. Human evaluation constitutes the final validation layer in the proposed framework. Section V analyzes these results to assess cross-layer alignment. The framework is

designed as a diagnostic tool to identify structurally unreliable attribute manipulations before deployment.

V. Results

Table II summarizes cross-layer monotonicity results aggregated by attribute. All attributes satisfied geometric admissibility, with fit, lightness, and glossiness classified as PASS, and pattern scale categorized as WEAK-PASS according to the criteria specified in Section IV-B.

Semantic monotonicity was consistently positive across all attributes, with high values of ρ_{clip} indicating stable directional progression in embedding space. These results confirm that latent manipulations were structurally preserved at the semantic level.

TABLE II. Cross-Layer Monotonicity Results Aggregated by Attribute.

Attribute	QC Status	ρ_{clip}	ρ_{human}	Cross-layer Alignment
Fit	PASS	0.97	0.67	Strong
Lightness	PASS	0.99	0.31	Moderate
Glossiness	PASS	1.00	0.48	Moderate
Pattern Scale	WEAK-PASS	1.00	0.51	Limited

Perceptual monotonicity, evaluated with 37 valid participant responses, exhibited attribute-dependent variation. Fit demonstrated the strongest perceptual monotonicity. Glossiness exhibited moderate perceptual monotonicity, whereas lightness was comparatively weaker. This suggests that although luminance variation is consistently represented in embedding space, its perception is affected by contextual factors such as shading and local contrast. Pattern scale exhibited limited perceptual reliability despite positive semantic monotonicity.

For fit, latent manipulation primarily affected the garment's contour and silhouette, producing visibly coherent adaptive fitting—tightening and loosening—that appeared across geometric, semantic, and perceptual layers. In contrast, the pattern scale involved changes in motif size together with variations in texture density and contrast. As illustrated in Fig. 3, pattern enlargement introduced composite visual effects beyond simple geometric scaling. This factor presumably reduced perceptual monotonicity despite preserved semantic ordering.

All reported correlations were statistically significant at $p < 0.01$.

Joint evaluation of geometric validity, semantic embedding behavior, and human evaluation shows that perceptual reliability varies across attributes. Fit satisfies all cross-layer conditions defined in Eq. (14), demonstrating strong alignment across representational layers. In contrast, pattern scale demonstrates geometric admissibility but reduced perceptual monotonicity, indicating partial cross-layer misalignment.

These findings support the formulation that perceptual reliability cannot be determined solely from geometric or semantic validity, but arises only when monotonic ordering is preserved across latent geometry, embedding space, and human perception.

VI. Discussion

In this study, we introduced a three-layer evaluation framework to assess perceptual reliability in controllable diffusion-based fashion image generation. By explicitly separating latent geometry, semantic embedding space, and human perception, our proposed framework enables structured diagnosis of attribute controllability across representational levels.

A. Significance of the Three-Layer Decomposition

The central contribution of this study lies in the structural separation of representational layers. Previous evaluations of controllable generation typically rely on either automatic semantic metrics or human preference modeling independently. However, as demonstrated in the present results, geometric validity in latent space does not automatically imply perceptual reliability.

Our proposed framework demonstrates that perceptual reliability is achieved only when the monotonic order induced by the generation parameter α is preserved across all layers. This condition enables identification of alignment failure in geometric construction, semantic embedding behavior, or human perceptual interpretation, thereby providing diagnostic capabilities essential to understanding controllable diffusion models beyond visual realism.

B. Attribute-Dependent Reliability

The results reveal that perceptual reliability is attribute-dependent. Fit exhibited strong cross-layer alignment, satisfying geometric, semantic, and perceptual monotonicity conditions. This suggests that attributes closely tied to structural garment draping are more consistently encoded across representational spaces.

In contrast, pattern scale demonstrated reduced perceptual monotonicity despite geometric admissibility and positive semantic monotonicity. This indicates that certain attributes may be geometrically constructible yet perceptually ambiguous. Such ambiguity may stem from the composite nature of pattern scale, which includes density, contrast, and texture complexity rather than a single structural factor.

Glossiness exhibited moderate behavior, while lightness showed comparatively weaker perceptual monotonicity despite satisfying geometric and semantic criteria. These findings highlight that perceptual interpretation may depend on contextual or experiential factors even when semantic embeddings capture directional consistency.

C. Implications for Automatic Evaluation Metrics

The results further demonstrate that embedding-based monotonicity cannot replace human evaluation. While ρ_{clip} remained positive for all attributes, perceptual monotonicity varied significantly. This partial decoupling suggests that the semantic embedding space captures structural ordering but does not fully encode perceptual salience.

Consequently, evaluation pipelines that rely solely on CLIP similarity or reward models may overestimate controllability when perceptual ambiguity exists. Our proposed cross-layer

framework provides a robust and effective approach to identifying such discrepancies.

D. The Role of Geometric Quality Control

Geometric quality control (QC) plays a foundational role in the framework. By validating midpoint symmetry and collinearity before semantic and perceptual evaluation, QC establishes a critical structural condition for meaningful monotonic analysis.

However, the WEAK-PASS cases indicate that geometric symmetry alone does not determine perceptual reliability. Instead, QC acts as a structural filter that ensures interpretability of subsequent layers, while final reliability depends on cross-layer alignment.

E. Limitations and Future Work

Several research limitations should be noted. First, our study employed only one diffusion backbone and inpainting configuration. Although the proposed framework is model-agnostic, validating it empirically across additional architectures could improve generalizability.

Second, we relied solely on visual discernment for perceptual evaluation. Attributes such as glossiness and fit may also depend on tactile or experiential cues not captured in image-based evaluation. Extending the framework to multimodal perceptual assessment is therefore an important consideration for future research.

Third, we did not explicitly analyze cultural and experiential variability among participants. We recognize that future studies should examine whether perceptual monotonicity differs by demographic or expertise groups.

Finally, several methodological limitations should be acknowledged. The selection of endpoint latent codes $z_{a,min}$ and $z_{a,max}$ was based on controlled generation and visual inspection, and was not formulated as a systematic or optimization-based procedure, which may affect reproducibility. In addition, although the human evaluation employed a two-alternative forced-choice design with 37 participants, a formal statistical power analysis was not conducted, and potential order effects or response dependencies were not explicitly modeled. Furthermore, the study focused on four representative attributes, which may introduce selection bias. Addressing these limitations through principled endpoint selection, more rigorous experimental design, and broader attribute coverage remains an important direction for future work.

F. Broader Implications

The proposed framework could also apply to other fields beyond fashion-image generation, whereby controllable generative models are assessed against human interpretation. Separating geometric validity, semantic embedding behavior, and perceptual monotonicity provides a generalizable framework for assessing human-aligned controllability.

Our study moves from assessing methods that rely solely on isolated similarity to a broader cross-layer monotonicity approach, providing a structured framework for understanding how generative transformations propagate across representational geometries.

VII. Conclusion

In this study, we proposed a three-layer evaluation framework for assessing perceptual reliability in controllable diffusion-based fashion image generation. Explicitly separating latent geometry, semantic embedding space, and human perception allowed for structured validation of attribute manipulation across representational levels.

We introduced geometric quality control to ensure midpoint symmetry and collinearity in the latent space prior to semantic or perceptual evaluation, and evaluated semantic consistency using projection-based monotonicity in the CLIP embedding space. We subsequently assessed perceptual monotonicity using a 2AFC experiment with 37 valid participants, applying the Bradley–Terry model.

Empirical results show that perceptual reliability depends on the attribute being tested: Fit exhibited strong cross-layer alignment, whereas pattern scale showed limited perceptual monotonicity despite geometric admissibility. These findings confirm that controllable generation cannot be evaluated solely through semantic similarity or latent manipulability. Instead, perceptual reliability arises only when a monotonic ordering is preserved across latent geometry, embedding space, and human judgment.

Our proposed framework provides a structured methodology for diagnosing controllable generation beyond visual realism and offers a foundation for human-aligned evaluation of generative models.

Performance Comparison of Regularization Methods on Transfer Learning Algorithm for Fish Species Classification

Handrie Noprisson, Anita Ratnasari, Sri Dianing Asri, Vina Ayumi, Hadiguna Setiawan
Faculty of Informatics and Engineering-Department of Informatics, Universitas Dian Nusantara, Indonesia

***Abstract*—Automatic fish classification played an essential role in the fisheries sector, particularly in underwater environments where visual quality was often degraded. This study addressed challenges related to low-contrast underwater images and limited dataset conditions by integrating Contrast Limited Adaptive Histogram Equalization (CLAHE) with a VGG16-based transfer learning model with regularization approaches including L1, L2, and Dropout. The dataset consisted of multiple fish species, including Bream, Sea Bass, Horse Mackerel, Red Mullet, and Black Sea Sprat. To enhance dataset diversity, data augmentation was performed using geometric transformations such as rotation, flipping, cropping/resizing, translation, shearing, and zooming. The dataset was divided into training (70%, 18,900 images), validation (20%, 5,400 images), and testing (10%, 2,700 images). Experimental results showed that the VGG16-CLAHE-Dropout model achieved the best overall performance, with training, validation, and testing accuracies of 99.15%, 98.37%, and 97.07%, respectively. CLAHE was implemented using a clip limit of 2.0 and a tile grid size of 8×8 to enhance image contrast, while the model was optimized using the Adam optimizer with a learning rate of 0.0001 and a batch size of 32. These findings demonstrated that combining contrast enhancement with appropriate regularization techniques significantly improved deep learning performance for underwater fish species classification.**

***Keywords*—Fish classification; underwater image; VGG16; CLAHE; regularization; transfer learning**

I. Introduction

Automatic fish classification is important because it allows the fish industry to be more productive through automation. In addition, the challenges of increasing food demand and potential food scarcity in the future urgently require automatic fish classification [1]. Fish species identification research is important for researchers in various fields such as ecologists, taxonomists, and geneticists to avoid mistaken identification [2]. In addition, automatic fish classification is important in freshwater environments where different species may be similar to each other, making manual identification difficult and prone to error [3]. To increase productivity, support research, ensure accurate species identification, and understand the health benefits of fish is the urgency of automated fish classification research using artificial intelligence [4], [5].

Detection of fish species is important to support fish biodiversity monitoring activities that are used as indicators of the health of seawater ecosystems [6]. Several studies have been conducted to solve the problems that exist in the detection of fish species [7], [8], [9], [10], [11]. In addition, fish species detection research can be useful for calculating the total and type of fish caught as a report to avoid overfishing in a particular area [12].

Unlike other types of data, videos and images cannot be immediately used for automatic detection [13], [14], [15]. The images collected are usually analyzed by manually trained human resources for reporting on the health of marine ecosystems or reporting on fishing areas, which is costly and time-consuming [16]. To overcome this problem, there is a need for an approach in modeling fish species detection technology [17]. This model can be used to help extract information about fish species and their numbers according to the actual situation [18].

Recent studies on fish species classification using deep learning demonstrated notable improvements in performance alongside the evolution of network architectures. ResNet50 and ResNet101 performance remained relatively limited in certain scenarios, with reported accuracies of 91.37% for ResNet50 and 86.12% for ResNet101 [19]. In contrast, MobileNetV2 achieved an accuracy of 96.56% [20], while MobileNetV3 further improved performance to 97.20% [21]. Additionally, integrating image enhancement techniques proved beneficial; for instance, the combination of ESRGAN with VGG16 achieved 96.50% accuracy [22], demonstrating that super-resolution preprocessing significantly improved feature quality in low-resolution images [23].

However, many fish classification techniques rely on transfer learning to improve accuracy. The VGG16 model has been used for fish classification in previous studies. Previous research proposes a framework combining the VGG16 transfer classification method and object localization that proposes rapid classification performance for fish image classification processing [4], [24], [25], [26], [27], [28].

In a study comparing several different transfer learning models, VGG16 achieved the highest accuracy scores, with a testing accuracy of 98.07% without fine-tuning and 96.56% with fine-tuning [20]. However, some previous studies have not discussed the comparative effectiveness of regularization methods applied to VGG16 for fish classification.

Classification of fish species in underwater images is a challenging task due to the phenomenon of illumination in seawater that causes low-contrast imagery. In addition, the scarcity of sufficient species datasets of fish imagery poses a serious problem for training a classification model. To overcome this problem, transfer learning-based methods need to be applied

contrast enhancement methods to improve classification accuracy [18], [29].

The contrast enhancement approach that can be used is Contrast Limited Adaptive Histogram Equalization (CLAHE). By applying the CLAHE method, it is expected to overcome the problem of limited contrast fish species datasets and provide solutions for accurate fish identification. In addition, this study will use the regularization method on VGG16 to reduce overfitting when processing image datasets from contrast enhancement results. In this study, VGG16 was regularized and optimized with the CLAHE method. This proposed research aims to improve the performance of VGG16 in processing species image datasets with low contrast due to lighting conditions in seawater.

II. Research Methodology

The study employed a structured methodology starting with the dataset collection of fish species images, followed by data preprocessing using CLAHE to enhance image quality, and model development using transfer learning based on VGG16 with the application of regularization techniques, including Dropout, L1, and L2. Subsequently, performance evaluation was conducted through benchmarking to compare the effectiveness of each regularization method in improving classification accuracy. In this study, a comparison of different regularizations is proposed to be applied to the VGG16 model layer. The research stage can be seen in Fig. 1.

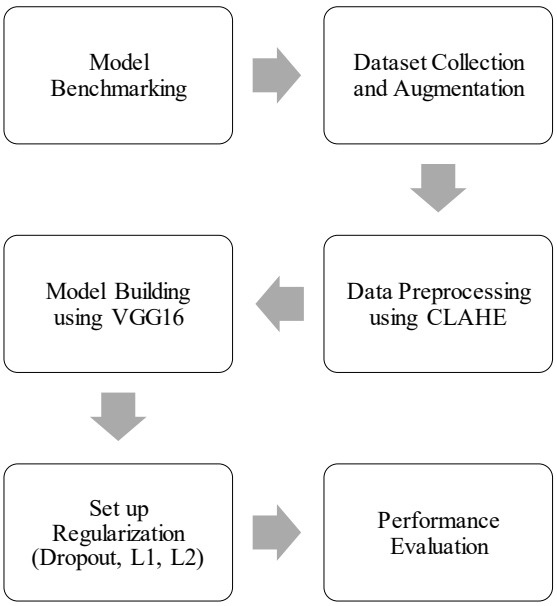

Fig. 1. Research phase

The data classes in this study consisted of Bream, Red Sea Bream, Sea Bass, Red Mullet, Horse Mackerel, Black Sea Sprat, and Striped Red Mullet, while the training and validation datasets were obtained from [30]. Data augmentation was applied to increase dataset diversity and reduce overfitting by performing geometric transformations including rotation, flipping, cropping/resizing, translation, shearing, and zooming. The dataset was divided into three subsets with a composition of 70% (18,900 images) for training, 20% (5,400 images) for validation, and 10% (2,700 images) for testing. The example of dataset can be seen in Fig. 2.

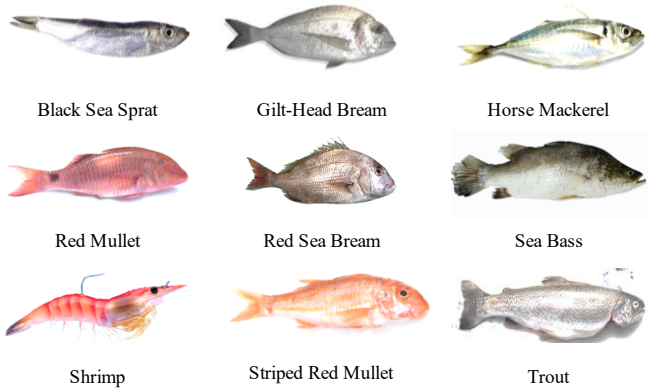

Fig. 2. Fish dataset class

Due to the presence of illumination distortions and low-contrast characteristics typical of underwater imaging, the collected dataset underwent a preprocessing stage employing Contrast Limited Adaptive Histogram Equalization (CLAHE) with a clip limit of 2.0 and a tile grid size of (8×8) to improve image quality. Model construction was performed using the VGG16 architecture with three regularization strategies, i.e., Dropout, L1, and L2, which were implemented in separate experimental configurations. The architecture of VGG16 that is used in this experiment can be seen in Fig. 3.

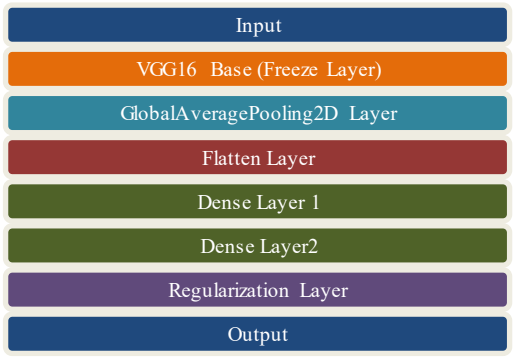

Fig. 3. VGG6 model experiment

Model performance evaluation was conducted using the testing subset through quantitative metrics such as accuracy, confusion matrix, precision, recall, and F1-score.

III. Results and Discussion

The study first conducted a baseline experiment using VGG16 without CLAHE to determine the optimal hyperparameter configuration. Subsequently, CLAHE was applied as a preprocessing technique, and the model was evaluated with different regularization methods. Each configuration was trained and tested under the same experimental settings to ensure a fair comparison.

A. VGG16 Experiment

The experiment evaluated the performance of regularization methods on a transfer learning model based on VGG16 for fish

species classification, with the number of epochs fixed at 50. The learning rate was set to 0.0001, while the optimizer (Adam and SGD) and batch size (16, 32, and 64) were systematically varied to generate six experimental scenarios. The result of experiment is presented in Table I.

TABLE I. VGG16 EXPERIMENT RESULT

No	Learning Rate	Optimizer	Batch Size	Testing Accuracy
1	0.0001	Adam	16	94.85
2	0.0001	Adam	32	95.92
3	0.0001	Adam	64	95.40
4	0.0001	SGD	16	93.75
5	0.0001	SGD	32	94.88
6	0.0001	SGD	64	92.60

The experimental results demonstrated that the choice of optimizer and batch size significantly influenced the performance of the fish classification model. Using the Adam optimizer with a learning rate of 0.0001 consistently produced higher testing accuracy compared to SGD across all batch sizes. The highest accuracy of 95.92% was achieved with a batch size of 32, while batch sizes of 16 and 64 resulted in slightly lower accuracies of 94.85% and 95.40%, respectively. These findings indicated that a moderate batch size provided a better balance between stable gradient updates and generalization capability.

In contrast, the SGD optimizer yielded lower performance overall, with testing accuracies ranging from 92.60% to 94.88%. The best result using SGD was obtained with a batch size of 32 (94.88%), while the lowest accuracy was observed at a batch size of 64 (92.60%). This suggested that SGD was less effective in handling the complexity of underwater fish image classification under the given configuration. Overall, the results confirmed that the Adam optimizer, combined with an appropriate batch size, particularly 32 for fish species classification tasks.

B. VGG16-CLAHE-L1

The accuracy results of the VGG16-CLAHE-L1 model showed that the training process initially started with 0.19 for training and 0.18 for validation, but it quickly decreased and stabilized around 0.10–0.11 for both training and validation in subsequent epochs. Throughout the training process up to 50 epochs, the accuracy values fluctuated slightly but remained relatively constant. The accuracy results for experiments using the VGG16-CLAHE-L1 model can be seen in Fig. 4.

The confusion matrix was used to evaluate the performance of the VGG16-CLAHE-L1 model during the testing phase in classifying fish species across nine categories. The results showed that the model correctly classified certain classes with relatively high accuracy, particularly Horse Mackerel (HM), which achieved 298 correct predictions out of 300 samples. Similarly, Gilt-head Bream (GHB) and Red Mullet (RM) recorded moderate correct classifications with 203 and 112 correctly predicted samples, respectively. However, some classes, such as Black Sea Sprat (BSS) and Sea Bass (SB), were not correctly classified, as all their samples were misclassified, primarily into the Horse Mackerel (HM) class. This indicated that the model had difficulty distinguishing between visually similar species, as presented in Fig. 5.

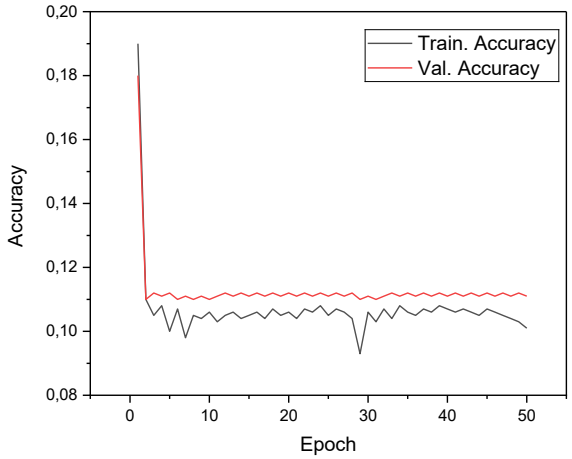

Fig. 4. Accuracy of VGG16-CLAHE-L1 model.

True \ Pred	BSS	GHB	HM	RM	RSB	SB	SH	SRM	TR
BSS	0	0	300	0	0	0	0	0	0
GHB	0	203	97	0	0	0	0	0	0
HM	0	2	298	0	0	0	0	0	0
RM	0	48	140	112	0	0	0	0	0
RSB	0	246	38	0	16	0	0	0	0
SB	0	98	202	0	0	0	0	0	0
SH	0	15	242	5	0	0	38	0	0
SRM	1	19	268	11	0	0	1	0	0
TR	0	141	154	0	0	0	0	0	5

BSS = Black Sea Sprat; GHB = Gilt-head Bream; HM = Horse Mackerel; RM = Red Mullet; RSB = Red Sea Bream; SB = Sea Bass; SH = Shrimp; SRM = Striped Red Mullet; TR = Trout.

Fig. 5. Confusion matrix of VGG16-CLAHE-L1.

Furthermore, substantial misclassification was observed across multiple classes, where a considerable number of samples were incorrectly predicted as Horse Mackerel (HM). For example, Trout (TR), Sea Bass (SB), and Shrimp (SH) were largely misclassified into the HM category, indicating a strong bias of the model toward this dominant class. In addition, Red Sea Bream (RSB) and Striped Red Mullet (SRM) demonstrated low classification performance, with only a small number of correctly identified instances. Based on the confusion matrix, further performance evaluation was conducted using precision, recall, and F1-score metrics, and the results obtained from the VGG16-CLAHE-L1 model were presented in Table II.

The classification performance of the VGG16-CLAHE-L1 model was assessed using precision, recall, and F1-score metrics for each fish species class. The results indicated substantial disparities in performance, where several classes exhibited extremely low or zero effectiveness. Specifically, Black Sea Sprat (BSS), Sea Bass (SB), and Striped Red Mullet (SRM) recorded zero values across all evaluation metrics, demonstrating that these classes were entirely misclassified. Meanwhile, Gilt-head Bream (GHB) and Red Mullet (RM)

showed moderate performance, with F1-scores of 0.38 and 0.52, respectively, indicating partial classification capability.

TABLE II. PRECISION, RECALL, F1-SCORE OF VGG16-CLAHE-L1

Class	Precision	Recall	F1-Score	Support
Black Sea Sprat	0.00	0.00	0.00	300
Gilt-Head Bream	0.26	0.68	0.38	300
Horse Mackerel	0.17	0.99	0.29	300
Red Mullet	0.88	0.37	0.52	300
Red Sea Bream	1.00	0.05	0.10	300
Sea Bass	0.00	0.00	0.00	300
Shrimp	0.97	0.13	0.22	300
Striped Red Mullet	0.00	0.00	0.00	300
Trout	1.00	0.02	0.03	300

In contrast, certain classes displayed imbalanced metric distributions. Red Sea Bream (RSB) and Trout (TR) achieved perfect precision (1.00), yet their very low recall values resulted in poor F1-scores, indicating that only a few instances were correctly identified despite highly accurate predictions. Similarly, Horse Mackerel (HM) achieved a high recall of 0.99 but suffered from low precision (0.17), suggesting that many samples from other classes were incorrectly predicted as HM. Shrimp (SH) also exhibited high precision (0.97) but low recall (0.13), reinforcing the presence of class imbalance and misclassification bias.

C. VGG16-CLAHE-L2

The experimental results of the VGG16-CLAHE-L2 model demonstrated a consistent improvement in accuracy throughout the training process. Initially, both training and validation accuracies were relatively low, but they increased rapidly during the early epochs, indicating that the model effectively learned relevant features from the dataset. As the training progressed, the training accuracy continued to improve gradually, reaching approximately 0.89–0.90, while the validation accuracy fluctuated within the range of 0.70 to 0.76. These trends suggested that the model was able to capture underlying patterns in the data, although some variability in validation performance remained. The detailed accuracy results of the VGG16-CLAHE-L2 experiments were presented in Fig. 6.

Beyond assessing training and validation, the performance model during the testing phase was further evaluated using a confusion matrix. This approach was employed to assess how well the VGG16-CLAHE-L2 model predicted each fish species class correctly or incorrectly across the entire dataset. The confusion matrix results revealed that several classes were classified with high accuracy, such as Horse Mackerel (HM) and Trout (TR), which achieved perfect classification with 300 correct predictions each. Similarly, Red Sea Bream (RSB) and Shrimp (SH) showed strong performance with 298 and 297 correctly classified samples, respectively. Other classes, such as Gilt-head Bream (GHB) and Red Mullet (RM) also demonstrated relatively high correct predictions, indicating improved discriminative capability of the model compared to previous configurations. The detailed results of this evaluation were illustrated in Fig. 7.

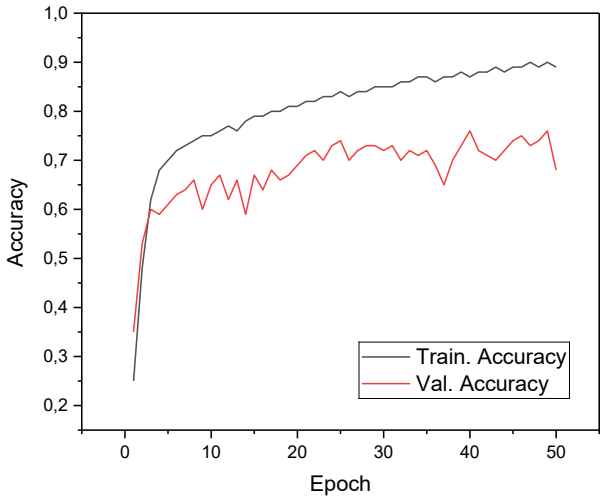

Fig. 6. Accuracy of VGG16-CLAHE-L2.

True \ Pred	BSS	GHB	HM	RM	RSB	SB	SH	SRM	TR
BSS	285	0	2	0	0	1	0	12	0
GHB	0	288	4	0	6	1	0	0	1
HM	0	0	300	0	0	0	0	0	0
RM	0	0	0	243	0	0	0	57	0
RSB	0	2	0	0	298	0	0	0	0
SB	29	5	0	0	0	254	0	0	12
SH	0	0	0	0	0	0	297	3	0
SRM	39	0	24	2	0	0	17	218	0
TR	0	0	0	0	0	0	0	0	300

BSS = Black Sea Sprat; GHB = Gilt-head Bream; HM = Horse Mackerel; RM = Red Mullet; RSB = Red Sea Bream; SB = Sea Bass; SH = Shrimp; SRM = Striped Red Mullet; TR = Trout

Fig. 7. Confusion matrix of VGG16-CLAHE-L2.

Although several classes were classified correctly, a certain level of misclassification was still observed across some categories. Black Sea Sprat (BSS) was occasionally predicted as Striped Red Mullet (SRM), while Sea Bass (SB) showed confusion with both Black Sea Sprat (BSS) and Trout (TR). In addition, Striped Red Mullet (SRM) was misclassified into multiple classes, including BSS and Horse Mackerel (HM), indicating the presence of similar visual features among these species. Despite these limitations, the overall pattern of predictions demonstrated that the VGG16-CLAHE-L2 model achieved a more balanced and reliable performance compared to the L1-based approach. Further evaluation based on the confusion matrix was conducted using precision, recall, and F1-score metrics, where the Red Sea Bream (RSB) class achieved the highest performance across all metrics. The detailed evaluation results for each fish species class were presented in Table III.

The performance of the VGG16-CLAHE-L2 model was evaluated using precision, recall, and F1-score metrics for each fish species class, and the results indicated a substantial improvement compared to the L1-based model. Most classes achieved high and balanced metric values, demonstrating strong

classification capability. Red Sea Bream (RSB) recorded the best overall performance with precision, recall, and F1-score values close to perfect (0.98, 0.99, and 0.99, respectively). Similarly, Trout (TR) and Horse Mackerel (HM) achieved excellent recall values of 1.00, with high precision and F1-scores, indicating that these classes were accurately and consistently classified.

TABLE III. PRECISION, RECALL, F1-SCORE OF VGG16-CLAHE-L2

Class	Precision	Recall	F1-Score	Support
Black Sea Sprat	0.81	0.95	0.87	300
Gilt-Head Bream	0.98	0.96	0.97	300
Horse Mackerel	0.91	1.00	0.95	300
Red Mullet	0.99	0.81	0.89	300
Red Sea Bream	0.98	0.99	0.99	300
Sea Bass	0.90	0.85	0.91	300
Shrimp	0.95	0.99	0.97	300
Striped Red Mullet	0.75	0.73	0.74	300
Trout	0.96	1.00	0.98	300

In addition, Gilt-head Bream (GHB), Shrimp (SH), and Red Mullet (RM) showed strong performance with F1-scores above 0.89, reflecting reliable classification across these categories. Sea Bass (SB) and Black Sea Sprat (BSS) also demonstrated good performance, although slightly lower compared to the top-performing classes. However, Striped Red Mullet (SRM) recorded the lowest performance among all classes, with an F1-score of 0.74, indicating that some misclassification issues persisted.

D. VGG16-CLAHE-Dropout

From the experimental results, the accuracy results of the VGG16-CLAHE-Dropout model showed a strong and consistent improvement throughout the training process. At the initial epochs, both training and validation accuracy started at moderate levels, then increased rapidly as the model learned relevant features from the data. The training accuracy steadily improved and reached approximately 0.94–0.95 in the final epochs, indicating effective learning. The validation accuracy also increased and stabilized in the range of 0.80–0.85, although it exhibited slight fluctuations across epochs. The accuracy results and loss results for experiments using the VGG16-CLAHE-Dropout model can be seen in Fig. 8.

The model performance at the testing stage was further analyzed using a confusion matrix. This evaluation approach was employed to measure how accurately the VGG16-CLAHE-Dropout model classified each fish species across all categories. The results indicated that most classes were correctly predicted with high accuracy, as shown by the dominant diagonal values in the confusion matrix. In particular, Red Sea Bream (RSB) and Shrimp (SH) achieved perfect classification with 300 correct predictions each, while Trout (TR), Gilt-head Bream (GHB), and Sea Bass (SB) also demonstrated near-perfect classification performance, as depicted in Fig. 9.

Nevertheless, a small number of misclassifications were still observed in certain classes. For example, Striped Red Mullet (SRM) was occasionally misclassified into classes such as Black Sea Sprat (BSS) and Horse Mackerel (HM), while minor confusion occurred between Horse Mackerel (HM) and Red Sea Bream (RSB). Despite these errors, the overall classification performance remained highly reliable and balanced across all classes. The next evaluation was conducted using precision, recall, and F1-score metrics. The detailed results for each fish species class were presented in Table IV.

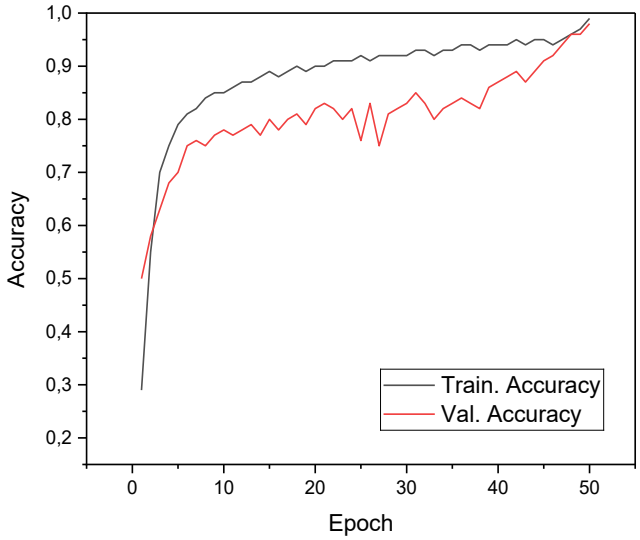

Fig. 8. Accuracy of VGG16-CLAHE-Dropout.

True \ Pred	BSS	GHB	HM	RM	RSB	SB	SH	SRM	TR
BSS	295	0	1	0	0	3	0	1	0
GHB	0	294	0	0	6	0	0	0	0
HM	0	4	288	0	8	0	0	0	0
RM	0	0	0	285	0	0	0	15	0
RSB	0	0	0	0	300	0	0	0	0
SB	5	0	0	0	2	292	0	1	0
SH	0	0	0	0	0	0	300	0	0
SRM	12	0	10	2	1	1	6	268	0
TR	0	0	0	0	0	1	0	0	299

BSS = Black Sea Sprat; GHB = Gilt-head Bream; HM = Horse Mackerel; RM = Red Mullet; RSB = Red Sea Bream; SB = Sea Bass; SH = Shrimp; SRM = Striped Red Mullet; TR = Trout

Fig. 9. Confusion matrix of VGG16-CLAHE-Dropout.

TABLE IV. PRECISION, RECALL, F1-SCORE OF VGG16-CLAHE-DROPOUT

Class	Precision	Recall	F1-score
Black Sea Sprat	0.95	0.98	0.96
Gilt-Head Bream	0.99	0.98	0.98
Horse Mackerel	0.96	0.96	0.96
Red Mullet	0.99	0.95	0.97
Red Sea Bream	0.95	1.00	0.97
Sea Bass	0.98	0.97	0.98
Shrimp	0.98	1.00	0.99
Striped Red Mullet	0.94	0.89	0.92
Trout	1.00	1.00	1.00

Most classes achieved excellent and well-balanced metric values, indicating strong generalization capability of the model. Trout (TR) recorded perfect performance with precision, recall, and F1-score all reaching 1.00, while Shrimp (SH) and Red Sea Bream (RSB) also achieved near-perfect results, with recall values of 1.00 and high precision and F1-scores. Additionally, Gilt-head Bream (GHB), Sea Bass (SB), and Red Mullet (RM) showed strong and stable performance, with F1-scores ranging from 0.97 to 0.98. Furthermore, Black Sea Sprat (BSS) and Horse Mackerel (HM) demonstrated high classification accuracy with balanced precision and recall values around 0.95–0.98. Although Striped Red Mullet (SRM) recorded the lowest performance among all classes, with an F1-score of 0.92, its results remained relatively strong compared to previous models.

E. Discussion

Previous studies proposed various frameworks for fish image classification, including approaches that combined VGG16-based transfer learning to achieve accurate classification performance. Other studies compared multiple transfer learning architectures. However, most of these works did not explore the comparative effectiveness of different regularization techniques applied specifically to the VGG16 architecture. In this study, several configurations of VGG16 were evaluated, including the baseline model and variants integrated with CLAHE and different regularization methods, and the experimental results were summarized in Table V.

TABLE V. COMPARISON OF RESULTS WITH PREVIOUS STUDIES

Source	Model	Testing Accuracy
This research	VGG16	95.92
This research	VGG16-CLAHE-L1	24.89
This research	VGG16-CLAHE-L2	91.96
This research	VGG16-CLAHE-Dropout	97.07
[19]	ResNet50	91.37
[19]	ResNet101	86.12
[20]	MobileNetV2	96.56
[22]	ESRGAN-VGG16	96.50
[21]	MobileNetV3	97.20

The experimental results indicated that the proposed VGG16-CLAHE-Dropout model achieved the highest testing accuracy of 97.07%, outperforming the baseline VGG16 (95.92%) as well as other variants, including VGG16-CLAHE-L2 (91.96%) and VGG16-CLAHE-L1 (24.89%). When compared with prior studies, the proposed approach demonstrated competitive performance, closely approaching MobileNetV3 (97.20%) and surpassing MobileNetV2 (96.56%), ESRGAN-VGG16 (96.50%), and ResNet-based models such as ResNet50 (91.37%) and ResNet101 (86.12%). These findings suggested that the integration of CLAHE and Dropout regularization within the VGG16 framework significantly enhanced classification accuracy and robustness. Furthermore, the architecture of the proposed VGG16-based framework was presented in Table VI.

The proposed framework for fish classification was designed based on a VGG16-based architecture with additional layers for feature refinement and regularization. The model took input images of size 224 × 224 × 3, which were processed through the pre-trained VGG16 convolutional base to extract high-level feature representations. The convolutional layers were frozen to preserve the learned features, followed by a GlobalAveragePooling2D layer that reduced the spatial dimensions into a compact feature vector. Subsequently, a flatten layer was applied to prepare the features for the fully connected layers. The classification stage consisted of two dense layers with 4096 and 1072 neurons, respectively, which enhanced the model's ability to learn complex patterns. A dropout layer was incorporated to reduce overfitting by randomly deactivating neurons during training.

TABLE VI. PROPOSED FRAMEWORK FOR FISH CLASSIFICATION

No	Layer	Layer Type	Output Shape
1	Input	Input Layer	(224, 224, 3)
2	VGG16 Base	Convolutional Blocks	(7, 7, 512)
3	Freeze Layers	-	-
4	GlobalAveragePooling2D	Pooling	512
5	Flatten	Flatten	512
6	Dense 1	Fully Connected	4096
7	Dense 2	Fully Connected	1072
8	Dropout	Regularization	1072
9	Output	Dense	9

IV. CONCLUSION

In conclusion, the training process was conducted to optimize the VGG16 model by minimizing the discrepancy between predicted outputs and ground truth labels, while incorporating a comparative analysis of regularization techniques within the network. The experimental results demonstrated that the VGG16-CLAHE-Dropout model achieved the highest testing accuracy of 97.07%, outperforming the baseline VGG16 (95.92%), VGG16-CLAHE-L2 (91.96%), and VGG16-CLAHE-L1 (24.89%). The model was trained for 50 epochs, and CLAHE was applied using a clip limit of 2.0 and a tile grid size of 8 × 8 to enhance image contrast. Furthermore, the optimization process was carried out using the Adam optimizer with a learning rate of 0.0001 and a batch size of 32.

Future research will focus on improving the robustness and generalization capability of the VGG16-CLAHE framework by exploring more advanced regularization strategies, as well as utilizing larger and more diverse underwater datasets. Additional contrast enhancement techniques tailored for complex aquatic environments will be investigated to further improve feature representation. Moreover, subsequent studies will integrate modern architectures such as EfficientNet, Vision Transformers, and hybrid CNN–Transformer models to evaluate whether they will outperform VGG16 in handling low-contrast fish images.

***Abstract*—Keyphrase prediction models are among the natural language processing (NLP) tasks that have improved their performance with transformers and large language models (LLMs). Instead of extracting present keyphrases in the text, these models also generate absent keyphrases. This improvement has led to significant challenges in the evaluation process of these models, which rely on metrics that compare the predicted keyphrases with the reference keyphrases. To measure the performance of these models, several evaluation metrics such as F1-score, ROUGE-L, and BertScore have been used. However, they often prioritize lexical similarity over semantic usefulness. Consequently, the functional usefulness of keyphrases in document representation is not evaluated during the evaluation process, which leads to inconsistencies in the evaluation results. Therefore, in this paper we propose a functional evaluation metric for Keyphrase prediction models (FEM-KP), a new evaluation metric that uses a two-track approach where track (A) evaluates the performance of the model to generate keyphrases capable of constructing a document summary, while track (B) measures the ability of these phrases to retrieve the document. We evaluated the performance of four keyphrase prediction models using current evaluation metrics and FEM-KP across the Inspec, KP20k, and Krapivin datasets. The experimental results showed that FEM-KP is the only evaluation system that maintained a consistent performance ranking regardless of document length or dataset complexity. In contrast, other metrics showed inversions in ranking. These results confirm that FEM-KP is a robust, reliable, and domain-independent evaluation metric for evaluating the performance of keyphrase prediction systems.**

Keywords*—Document retrieval; Document summarization; Evaluation metrics; Functional evaluation metric; Keyphrase prediction models; natural language processing

I. Introduction

Keyphrases prediction is one of the most important tasks in natural language processing [1]. These phrases provide descriptive and semantic information that summarizes the content of documents. Recent studies have demonstrated that exploiting keyphrases improves the performance of summarization models by directing them toward the important topics of the text [2]. Also, the exploitation of keyphrases in the retrieval task improves the quality of retrieved snippets and reduces computational costs [3]. Keyphrases also improve the accuracy of responses in question-and-answer tasks [4]. Furthermore, digital indexation has been improved by using keyphrase generation [5].

Keyphrase prediction models (KPM) are typically evaluated by comparing predicted with referenced keyphrases, without considering semantic aspects [6]. This evaluation does not accurately reflect the performance of these models (KPEVAL). Generative models are more affected by this problem because they generate the keyphrases rather than extracting them from the text [7].

To improve the quality of KPM evaluation, some studies, such as [8], have proposed a framework exploit edit distance, token matching, and duplication penalty. Also, at [6], a two-way comparison was conducted between predicted and reference keyphrases using the BertScore [9]. In contrast, the KPEVAL framework propose to combine accuracy, variety, reliability, and reference consistency. However, several challenges still limit the reliability of the results of these models, such as the reliance on a set of reference keyphrases to compare KPM performance that are often self-defined and influenced by linguistic style. Also, the difficulty to evaluate the functional performance of the keyphrases generated in the document representation.

To overcome these challenges, we propose the FEM-KP metric, a comprehensive metric to evaluate KPM by measuring the functional utility of these phrases rather than linguistic or semantic similarity. The importance of FEM-KP lies in transforming the evaluation process, which focuses on linguistic or semantic similarity between the predicted and reference keyphrases, into a deeper semantic evaluation of the functional quality of these phrases. Our metric adopts two tracks, the first evaluates the ability of the predected keyphrases to generate a document summary, while the second evaluates their ability to retrieve the document.

The content of paper includes, a review of previous studies that focused on keyphrase prediction models, text summarization, text retrieval, and sentence embedding techniques in section 2. The current evaluation methods for keyphrase prediction models are presented in section 3, including evaluation metrics, evaluation datasets, and challenges that limit their reliability. Section 4 provides the proposed FEM-KP metric, its design, and formulation. The experimental results of FEM-KP performance are presented in Section 5. The paper concludes with section 6, which summarizes our work and identifies future research directions.

II. Related Work

To present the mechanisms and techniques that will be exploited in FEM-KP metric, we have devoted this section to review the keyphrase prediction models, sentence embedding techniques, text retrieval techniques, and text summarization techniques.

A. Keyphrase Prediction Models

Keyphrases are expressions consisting of one or more words, that serve not only to index but also as semantic summaries. Keyphrases are exploited in classification, clustering, text summarization, and information retrieval [10]. Keyphrase models have evolved from extractive models based on statistical techniques to generative models based on transformers and large language models (LLMs) [11]. Several reviews have addressed the development of these models, while the review in [12] is focused on statistical and graphical methods, [13] reviewed the improved performance using deep learning to generate keyphrases.

In contrast, other studies, such as [14], focused on reviewing the latest methods that use pre-trained models such as SBERT and RoberTa for keyphrase extraction, and how these models improved extraction results compared to previous methods. In [15], the comparison between extraction and generation mechanism, and the advantages and disadvantages of statistical methods and deep learning methods to extract and generate keyphrases were identified. Furthermore, [16] demonstrated how sentence embeddings can be used to improve contextual extraction performance. Also, [17] reviewed the integration of extraction and generation mechanisms in keyword prediction, proposing a classification of models based on pre-trained models, as well as semi-supervised and unsupervised approaches. In contrast, [18] analyzes the performance of LLM models to extract keyphrases and presents a comparison between Llama3, GPT-4o and other large language models.

B. Text Semantic Representation

With their crucial role in many NLP tasks, text embedding models have garnered increasing attention from researchers, particularly with the emergence of Large Language Models (LLMs) [19]. Text embedding began with models that represented each word individually, such as Word2Vec, which learned word representations from their contexts. Later, GloVe (Global Vectors) exploit also comprehensive word frequency statistics to improve the performance of embedding. However, the challenge of representing words according to their meaning within a sentence remained until the emergence of ELMo as a model based on bidirectional LSTM networks to produce contextual representations based on word meaning within a sentence.

The advent of transformers revolutionized text embedding, with the emergence of the BERT (Bidirectional Coder Representations of Transformers) model, which uses transformer architecture to create deep, and contextual embeddings of words and sentences. This model was further enhanced at the sentence and paragraph by the SBERT model. Multilingual models like LaBSE, which produces comparable embeddings across different languages, have also been developed, proving very useful for multilingual retrieval. Furthermore, the challenge of long documents has led to the emergence of models that represent long documents, such as Dense Passage Retrieval (DPR), which uses BERT-like models to embed long documents. ColBERTv2 also produces efficient embeds by layering the representation to enhance semantic differentiation. In contrast, the emergence of Large Language Models (LLMs) such as GPT4 and LLaMA has contributed to the production of text embeds that exhibit a greater ability to capture semantic relationships, both in retrieval and text generation. OpenAI Embeddings relies on LLM models to generate vectors used in semantic retrieval, Q&A, and classification.

The open-source LLaMA Embeddings is also used to create embeds with greater context and a high capacity for representing long texts. Fig. 1 presents the evolution of text embedding models.

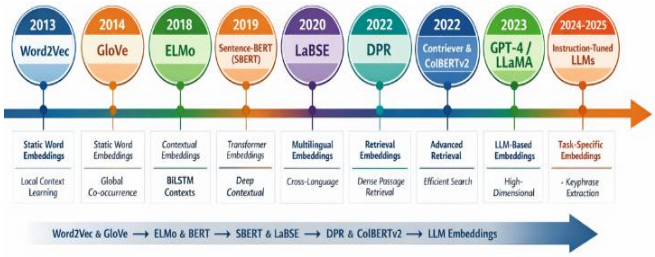

Fig. 1. Evolution of text embedding models.

C. Text Summarization Models

Text summarization tasks have evolved through several approaches. Extractive summarization, which relies on features such as word frequency, position, and similarity metrics, was the first method used text summarization [20]. Graph algorithms such as TextRank and LexRank [21] were also exploited to model the relationships between sentences. With the advent of neural models, particularly RNN/LSTM, abstractive summarization emerged, which focused on paraphrasing the text rather than extracting [22], [23]. The ability of transformers, such as BERT [24] and BART [25], to provide deep contextual understanding and generate texts has also contributed to improving the text summarization task. Large language models (LLMs) such as GPT-3 and GPT-4 have also enhanced text summarization performance [26]. Several reviews have focused on the text summarization task. The impact of large language models on summary coherence in zero-based training environments was studied in [27]. The use of LLMs in the specialize contexts, such as the medical or scientific fields, was also discussed in the studies [28] and [29]. These studies confirmed the significant impact of LLMs on text summarization task.

D. Text Retrieval Models

Text retrieval models are classified into several categories. The first is lexical and statistical matching, which relies on term-frequency-inverse document frequency (TF-IDF) to sort documents, such as BM25 [30], which sorts text based on keyphrases. There is also the category of dense retrieval, which uses transforms to represent text in a vector space, such as the

DPR (Dense Passage Retrieval) model [31] , which exploits bi-encoder to represent the query and the document separately. Also, a hybrid and multi-vector late interaction models, which combine the efficiency of dense retrieval models with the accuracy of lexical retrieval, such as the ColBERT (Contextualized Late Interaction over BERT) model [32], which is more accurate in capturing fine-grained textual details.

Large language models have also contributed to improved retrieval task. Large Language Model-Augmented Retrieval (LLM-Augmented Retrieval), which focuses on using LLMs to generate hypothetical documents or optimize queries before the retrieval process, such as HyDE (Hypothetical Document Embeddings) model [33]. This model generates a hypothetical text from the query and then searches for similar documents. In general, studies indicate that retrieval applications rely on pre-trained embeddings and neural structures to provide more accurate semantic matching [34] and [35], which supports the hypothesis that a keyphrase is a condensed summary from which the original document can be retrieved and reconstructed.

Word embedding models (Word2Vec, GloVe) are considered the first step towards text embedding, followed by the emergence of contextual models (ELMo, BERT), which evolved into sentence and paragraph embedding models (SBERT, LaBSE), then expanded further to contextual retrieval models (DPR, ColBERTv2), and finally to LLM-based embeddings, which are related to the higher text representation capabilities of multiple NLP tasks.

III. Keyphrase Evaluation Paradigms

In recent years, most keyphrase prediction models have adopted a generation mechanism, which has complicated the task of evaluating these models. Most current evaluation metrics rely on lexical matching, which lacks the ability to measure semantic meaning. In this context, this section will provide a review of current evaluation metrics, from statistical to embedding metrics, to highlight the research gap represented by the absence of a standardized metric that combines the precision with the contextual and functional significance of predicted keyphrase.

A. Lexical Evaluation Metrics

Lexical metrics are the most commonly used to evaluate keyphrase prediction models. These metrics calculate the exact match between the keyphrases predicted by the model (KP) and the reference keyphrases (RP).

1) Precision, recall, and f1-measure metrics: Precision, Recall, and F1-measure are used to evaluate keyphrase prediction models based on exact matching. Precision measures the accuracy of predictions, by calculating the proportion of correct phrases extracted from the total identified by the model. It also indicates the model's ability to exclude irrelevant phrases. Recall measures the coverage of reference phrases, by calculating the model's ability to retrieve all reference keyphrases. F1-measure measures the harmonic mean between precision and recall, to achieve a balance between the coverage and the accuracy. Table I presents the mathematical definitions of Precision, Recall, and F1-measure metrics.

TABLE I. Mathematical Formula of Precision, Recall, and F1-Measure Metrics

Metric	Mathematical Formula
Precision	$\frac{\text{correctly predicted keyphrases}}{\text{all predicted keyphrases}}$ (1)
Recall	$\frac{\text{correctly predicted keyphrases}}{\text{all reference keyphrases}}$ (2)
F1-measure	$2 \times \frac{Precision \times Recall}{Precision + Recall}$ (3)

Although the precision, recall, and F1-Measure metrics provide a lexical evaluation of key phrase prediction performance, they rely on exact matching between the predicted and reference keyphrases. However, lexical interference at the n-gram and sequences, which results in partial matching between phrases, is the most significant challenge for these metrics.

2) ROUGE metric: The ROUGE (Recall-Oriented Understudy for Gisting Evaluation) metric, primarily used to evaluate text summarization models. This metric has been adapted to evaluate keyphrase prediction by treating each predicted keyphrase and reference keyphrase as a sequence of tokens. ROUGE calculates a lexical overlap between predicted keyphrases and reference keyphrases. REUGE is used in various forms. The most commonly used variants are:

ROUGE-N: measures the overlap of n-grams. For example, ROUGE-1 evaluates unigram overlap, and ROUGE-2 evaluates bigram overlap. ROUGE-N is calculated using formula 4.

$$ROUGE - N = \frac{\sum_{gram_n \in Ref} min\,(Count_{pred}(gram_n), Count_{ref}(gram_n))}{\sum_{gram_n \in Ref} Count_{ref}(gram_n))} \quad (4)$$

where:

- Ref: Set of reference keyphrases.
- Pred: set of predicted keyphrases.
- $gram_n$: n-gram token sequence.
- $Count_{pred}(.)$: Occurrences of the n-gram in predicted keyphrases.
- $Count_{ref}(.)$: Occurrences of the n-gram in reference keyphrases.

ROUGE-L: Unlike ROUGE-N, ROUGE-L relies to find the Longest Common Subsequence (LCS) that appear in both the predicted keyphrase and the reference keyphrase. ROUGE-L is calculated using LCS-based decision and recall metrics by formulas 5, 6 and 7.

$$Precision_{LCS} = \frac{LCS(PK,RK)}{|PK|} \quad (5)$$

$$Recall_{LCS} = \frac{LCS(PK,RK)}{|RK|} \quad (6)$$

$$ROUGE - L_{LCS} = \frac{(1+\beta^2) \times Precision_{LCS} \times Recall_{LCS}}{Recall_{LCS} + \beta^2 \times Precision_{LCS}} \quad (7)$$

where:

- RK : reference keyphrases
- PK : predicted keyphrases
- LCS(PK, RK): length of the longest common subsequence between PK and RK.
- |RK| : total number of tokens in reference keyphrases
- |PK| : total number of tokens in predicted keyphrases
- β :A parameter used to set the priority between precision and recall (typically β=1).

While lexical metrics facilitate the evaluation process, they disregard the expected order and importance of keyphrases in the document. This limitation has spurred the use rank-based metrics such as MRR, NDCG, and MAP, which consider the position and importance of the keyphrase.

B. Rank-Based Evaluation Metrics

To overcome the challenges of lexical evaluation, rank-based metrics consider the rinking of predicted keyphrases, where top-ranked candidates are of primary interest. Mean Reciprocal Rank (MRR) is a simple metric that focuses on the rank of the first keyphrase predicted $rank_i$ across a set of N documents. MRR is calculated by formula 8.

$$MRR = \frac{1}{|N|}\sum_{i=1}^{|N|}\frac{1}{rank_i} \quad (8)$$

MRR ignores the rank of other keyphrases is a challenge that limits its ability to evaluate multiple keyphrases. To address this challenge, Mean Average Precision (MAP) metric calculates the average precision for each position where keyphrase occurs. Formula 9 is used to calculate the MAP metric.

$$MAP = \frac{1}{|N|}\sum_{i=1}^{|N|}\left(\frac{1}{|K_i|}\sum_{j=1}^{m}P_i(j)\times rel_i(j)\right) \quad (9)$$

where K_i is the set of reference keyphrases, m is the number of predicted key phrases, $P_i(j)$ denotes precision at rank k, and $rel_i(j)$ is a relevance indicator, is 1 if the predicted keyphrase at rank k is relevant, and 0 otherwise.

MAP metric treats all keyphrases with the same weight, regardless of their importance in the document. To overcome this challenge, the Normalized Discounted Cumulative Gain (NDCG) metric, uses the logarithmic discount, where the importance of the keyphrase decreases as its position in the list decreases. Formula 10 is used to calculate the NDCG metric.

$$\mathrm{NDCG_k} = \frac{\sum_{i=1}^{k}\frac{2^{\mathrm{rel_{i-1}}}}{\log_2(i+1)}}{\sum_{i=1}^{k}\frac{2^{\mathrm{Irel_{i-1}}}}{\log_2(i+1)}} \quad (10)$$

where:

- k: The number of top predicted keyphrases.
- i: The rank position in the predicted list.
- rel_i: The relevance score of the keyphrase at rank i in the predicted ranking.
- $Irel_i$: the relevance score of the keyphrase at rank i in the ideal ranking.
- $log_2(i+1)$: logarithmic discount factor.

Lexical and rank-based evaluation metrics often overlook the semantic comparison of keyphrases. This challenge becomes even more pronounced with absent keyphrases, which may be more semantically accurate but differ literally from the reference keyphrases. Therefore, the study of semantic metrics is essential.

C. Semantic Similarity Metrics

Semantic similarity metrics represent the second generation of evaluation metrics, developed to overcome the limitations of lexical and rank-based metrics. Semantic similarity metrics represente predicted and reference keyphrases in a semantic space using pre-trained models such as BERT, RoBERTa, and Sentence-BERT, where the similarity between phrases is measured based on their semantic context. Prediction precision is calculated using cosine similarity provided by Formula 11.

$$\mathrm{Sim(PK,RK)} = \frac{\mathrm{e(PK).e(RK)}}{\|\mathrm{e(PK)}\|\|\mathrm{e(RK)}\|} \quad (11)$$

where e(·) is contextual embedding of a phrase obtained from a pretrained language model. Although this metric achieves semantic comparison, its effectiveness in keyphrase evaluation is limited because it compares the similarity of the phrase as a single unit, while lacking the ability to understand the word-for-word relationship between the prediction and the reference. To overcome this challenge, the BERTScore was proposed, which relies on contextual embedding that change depending on the word's position in the phrase. Instead to measure the cosine similarity between phrase vectors, the BERTScore aligns each token in the predicted phrase with the most semantically similar token in the reference keyphrase based on their context, thus preserving the value of each token in the keyphrase. To calculate BERTScore, precision and recall are first calculated by formulas 12 and 13.

$$\mathrm{Precision_{BERT}} = \frac{1}{|\mathrm{PK}|}\sum_{\mathrm{i=1}}^{|\mathrm{PK}|}\max_{\mathrm{j}}\cos\left(\mathrm{e(x_i)},\mathrm{e(y_j)}\right) \quad (12)$$

$$\mathrm{Recall_{BERT}} = \frac{1}{|\mathrm{RK}|}\sum_{\mathrm{j=1}}^{|\mathrm{RK}|}\max_{\mathrm{i}}\cos\left(\mathrm{e(y_j)},\mathrm{e(x_i)}\right) \quad (13)$$

where:

- e(·): The contextual embedding of a token obtained from BERT model
- cos(·): cosine similarity
- PK: Predicted keyphrase of tokens $\{x_1, \dots x_i, \dots x_{|PK|}\}$
- RK: Reference keyphrase of tokens $\{y_1, \dots y_j, \dots y_{|RK|}\}$

To calculate BERTScore, $Precision_{BERT}$ and $Recall_{BERT}$ combined using the harmonic mean via formula 14.

$$\mathrm{BERTScore} = 2\times\frac{\mathrm{Precision_{BERT}}\times\mathrm{Recall_{BERT}}}{\mathrm{Precision_{BERT}}+\mathrm{Recall_{BERT}}} \quad (14)$$

Instead of combining the words of a phrase into a single vector, BERTScore compares them word by word. Therefore, it addresses the problem of variations in phrase lengths. Also,

BERTScore evaluates semantic overlap, making it robust to paraphrasing in generative keyphrase prediction. In contrast, the precision of BERTScore is affected by the quality and comprehensiveness of the Gold Standard identified by human experts.

D. Human Reference Challenge

Manual identification keyphrases is a subjective cognitive task, where different keyphrases are selected for the same document based on the expert's background knowledge. The study [36], confirms that the manual selection of keyphrases is highly subjective. This makes relying on a single human reference limit the evaluation precision [12]. Fig. 2 illustrates the divergence between the keyphrases selected by author, Expert 1, and Expert 2.

Fig. 2. The divergence of reference keyphrases selection.

The central intersection represents the keyphrases agreed by everyone. Overlapping areas indicate partial agreement between two of them, while divergence areas represent keyphrases chosen by each independently. This representation highlights the inconsistency on gold standards to select keyphrases.

The cognitive effort expended in the manual selection, limits the number of keyphrases selected, this also, impact the evaluation process. Despite advancements in lexical and semantic evaluation metrics, the evaluation of keyphrase prediction models relies on the quality of the reference keyphrases. This leads to unreliable evaluation, especially in generative models, where they may generate semantically relevant keyphrases that are not present in the reference set.

There are several challenges to evaluate keyphrase prediction models. Current evaluation metrics remained to compare phrase-to-phrase, whether through exact or semantic matching. The keyphrases generated often represent a condensation of entire paragraphs, rather than a corresponding phrase in a human reference, which is often limited, and subjective. Therefore, we need a more comprehensive evaluation process. For this, we propose a new evaluation metric, instead of comparing predicted keyphrases with limited reference keyphrases, we compare the overall semantic impact of these phrases to generate the document summary, thus freeing the evaluation from limited human reference lists.

IV. Functional Evaluation Metric

A. Motivation for Functional Evaluation

The review of evaluation process for keyphrase prediction models in the previous section showed several challenges that limit the reliability of their results. Current evaluation metrics judge model performance solely by lexical or semantic matching between reference keyphrases and predicted keyphrases, neglecting characteristics such as topic coverage, diversity, and functional performance. Furthermore, they relie on the list of reference keyphrases, which are subjective and incomplete. Consequently, the performance of keyphrase prediction models is measured by human judgment rather than functional effectiveness, undermining the credibility of the evaluation process and penalizing models that generate functionally useful keyphrases but are not present in the reference list.

Therefore, we propose a Functional Evaluation Metric (FEF) that evaluates predicted keyphrases as a collective semantic unit, more independently of the reference list. FEF evaluates the performance of keyphrase prediction models by measuring the effectiveness of predicted keyphrases on two tracks. Abstract reconstruction track and text retrieval track, without relying on reference keyphrases. Therefore, the evaluation process is based on the functional success of the predicted keyphrases. We no longer measure whether this phrase matches the reference, but rather whether this phrase enables the system to summarize or retrieve the document.

B. Overview of FEM-KP

The Functional Evaluation Metric for KeyPhrase Prediction (FEM-KP) is a new metric designed to evaluate keyphrase prediction models based on the functional utility of the generated keyphrases, rather than measuring lexical or semantic similarity. FEM-KP measures the functional utility of generated keyphrases through two functions:

- Summary Reconstruction: This dimension measures the ability of keyphrases to serve as semantic seeds that can summarize the document and cover its content.
- Retrieval Power: This dimension measures the ability of keyphrases to identify the document within a large corpus.

The combinition of these dimensions in FEM-KP provides a uniform score that reflects the performance of the keyphrase prediction model to generate exploitable keyphrases for NLP applications such as text clustering, information retrieval, and document summarization.

C. Process of FEM-KP

To evaluate the performance of the keyphrase prediction model, the evaluation process consists of three main stages: synthesis, parallel evaluation tasks, and weight fusion. Fig. 3 illustrates how the FEM-KP score is calculated.

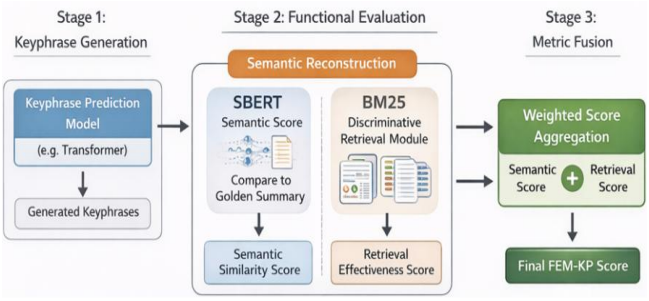

Fig. 3. Process of FEM-KP metric.

In the first stage, we use a transformer-based generator to combine and synthesize the generated keyphrases KP into a coherent semantic string SK. To achieve this, we first use a pre-trained generative model such as Text-to-Text Transfer Transformer (T5) [37] or Bidirectional and Auto-Regressive Transformers (BART) [25] for keyphrases-to-text conversion tasks.

To evaluate the ability of keyphrases to perform real tasks, FEM-KP across two parallel functional tracks. The first is the summative reconstruction score S_{summ}. In this track, we measure the semantic distance between the reconstructed summary SK and the gold summary GS using cosine similarity in the embedding space.

In contrast, the second track evaluates the ability of key phrases to recognize and retrieve the document D within a large dataset C. Its ability to handle term frequency values and normalize document length allows BM25 to calculate the retrieval score, which is an ideal metric to evaluate the retrieval utility of generated keyphrases.

The functional dimensions are combined into a single score to evaluate the overall quality of the keyphrases. The final FEM-KP score is calculated by balancing S_{summ} and S_{ret}.

D. Mathematical Formulation of FEM-KP Metric

FEM-KP framwork evaluate the quality of a keyphrase by measuring its functional utility across two NLP tasks. Let D is the source document, and $KP = \{P_1, P_2, \dots, P_n\}$ is the set of generated keyphrases from D by a keyphrase prediction model, and GS is the gold summary of D. The formulation follows a three-step pipeline:

1) Semantic reconstruction: Semantic reconstruction aims to generate a summary of the document SK based on keyphrases. T5 achieved a relative improvement in precision, but its performance is lower than BART in most summarization scenarios. For this, BART was used as a generative model in FEM-KP. To obtain the SK summary, we use the formula 15.

$$SK = arg\ \max_{s} p_\theta(s|Serialize(KP)) \quad (15)$$

where:

- SK: The generated summary.
- p_θ: The conditional probability modeled by BART
- Serialize(KP): A linearized representation of the KP set.
- s: A candidate output text sequence generated by the BART decoder.

The generate summary SK obtained from BART is represented using a Sentence-BERT [38]. The vector obtained serves as a semantic fingerprint for the generated keyphrases.

The first Track Functional Evaluation, is the ability of keyphrases to generate a document summary. In this track, we measure the semantic distance S_{summ} in vector space between the generate summary SK and the gold summary GS. To calculate semantic similarity, the SK and GS are converted into semantically vectors using SBERT model in formula 16.

$$\begin{cases} V_k = Pooling(Transformer_\theta(SK)) \\ V_g = Pooling(Transformer_\theta(GS)) \end{cases} \quad (16)$$

S_{summ} is calculated using cosine similarity in formula 17.

$$S_{summ} = \frac{\sum_{i=1}^{n} v_{k,i} \cdot v_{g,i}}{\sqrt{\sum_{i=1}^{n} v_{k,i}^2}\sqrt{\sum_{i=1}^{n} v_{g,i}^2}} \quad (17)$$

We used KP20k [39], Inspec [40], and Krapivin [41] as benchmark datasets for comparison. Their features and the reasons for their selection will be explained in the evaluation section.

2) Retrieval rank: The second track evaluates the ability of keyphrases to identify the source document D from a large set of documents C. To calculate the retrieval score, we use the BM25 probabilistic model, which improves the traditional TF-IDF model by incorporating term frequency saturation and document length normalization. Formula 18 calculates the document retrieval rank D, using the keyphrases set K.

$$Rank_K(D) = \sum_{p \in K} IDF(p).\frac{fr(p,D).(n+1)}{fr(p,D)+n.(1-\alpha+\alpha.\frac{|D|}{Avg(C)})} \quad (18)$$

where:

- $IDF(p)$: The Inverse Document Frequency of keyphrase p.
- $fr(p,D)$: The frequency of keyphrase p within document D.
- $|D|$: The length of the D.
- $Avg(C)$: The average document length across the corpus C.
- n: A hyperparameter to control the term frequency saturation. (Typically, between 1.2 and 2).
- α: A scaling factor for document length normalization. (typically, α =0.75).

It is difficult to combine the rank as score with the S_{summ} score (values between 0 and 1) in a single equation, for this normmalization is necessary. The S_{ret} score is calculated as the reciprocal rank. The retrieval score is calculate using formula 19.

$$S_{ret} = \begin{cases} \frac{1}{Rank_K(D)}, & if\ Rank_K(D) \le 100 \\ 0, & otherwise \end{cases} \quad (19)$$

The retrieval function score approaches zero if the keyphrases fail to rank the document among the top 100 results. This significantly speeds up the evaluation process, especially in datasets containing thousands of documents.

The functional dimension scores are combined into a single score to evaluate the overall performance of keyphrases. The FEM-KP score is calculated by balancing the sum of the S_{summ} and S_{ret}. This allows to adjust the score based on application priority, where a higher β Hyperparameter is used for summarization tasks, and a higher δ Hyperparameters for search optimization or indexation tasks. The final FEM-KP score was calculated using the formula 20.

$$FEF - KP = \beta . S_{summary} + \delta . S_{retrieval} \quad (20)$$

β and δ: Hyperparameters that are controlled according to the nature of the task, often $\beta + \delta = 1$.

This formula includes the effectiveness evaluation of the generated keyphrases, especially in the semantic representation of the document, and retrieval tasks.

E. Advantages and Limitations

Instead of the lexical or semantic matching used by current evaluation metrics, the FEM-KP metric adopts functional evaluation, which measures the effectiveness of keyphrases by their application in NLP tasks. The FEM-KP metric is characterized by its flexibility in adjusting the values of the hyperparameters β and γ, which allowed for the selection of the most suitable model for each task. Also, using the BM25 algorithm, the keyphrase prediction model could not achieve a high score when generating a large number of general keyphrases.

Despite these advantages, the quality of the reference summaries used may affect the reliability of the performance. Furthermore, they may not always be available. Also, using pre-trained language models and retrieval algorithms increases the computational cost of FEM-KP compared to simple lexical metrics. Also, the sensitivity of the parameters requires careful selection of β and γ values to avoid biased results

V. Experimental Setup and Results

This section details the implementation procedures and evaluation protocol for FEM-KP, including evaluation datasets and keyphrase prediction models. This section aims to ensure a comprehensive evaluation that allows for comparison of FEM-KP with current evaluation metrics.

A. Experimental Setup

1) Evaluation protocol: The evaluation protocol involves comparing the performance of key phrase prediction models using various evaluation metrics, including functional effectiveness. This comparison is achieved by calculating the BERTScore, ROUGE, and F1Measure scores for each model and comparing them to the FEM-KP scores for each model.

2) Evaluation datasets: To evaluate the FEM-KP, we rely on three reference evaluation datasets. The KP20k dataset comprises scientific abstracts from multiple disciplines. Each document has keyphrases defined by author. The size and diversity of KP20k content make it suitable for comparisons between different evaluation metrics. The second dataset, is Inspec. It smaller but more carefully curated and contains scientific abstracts. these datasets have been widely used in previous studies, making them suitable for comparing the FEM-KP with exact-match and semantic-based evaluation metrics.

TABLE II. Comparison of the Datasets Used for FEM-KP Evaluation

Dataset	Domain	# Test Documents	Avg. Text Length	Keyphrase Types
KP20k	Scientific Abstracts	20,000	180 words	Present & Absent
Inspec	Scientific Abstracts	500	135 words	Present & Absent
Krapivin	Scientific Papers	2300	8000 words	Present & Absent

To evaluate FEM-KP in long documents and complex retrieval scenarios, we exploited the Krapivin dataset, which includes scientific papers. Table II presents the features of KP20k and Inspec datasets.

3) Keyphrase prediction models: For a comprehensive comparison of the evaluation metrics, TextRank was adopted as an unsupervised, graph-based model that extracts keyphrases from the word-to-word structure within the text. CopyRNN was adopted as a supervised, recurrent neural network model that utilizes a copy mechanism to generate present and absent keyphrases in the text. Additionally, BART-based Keyphrase Generator and T5-based Keyphrase Generator were adopted, leveraging of pre-trained generative models to produce high-quality, sequential keyphrases. The diversity of models including unsupervised, supervised, and generative models, allows to evaluate FEM-KP in different scenarios. These models represent the evolution of keyphrase prediction task. Table III provides a comprehensive analysis of each model type and the rationale for its selection.

To highlight the performance of FEM-KP across different datasets for the four models and compare it to the F1-Score, ROUGE-L and BERTScore metrics. Fig. 4 summarizes the different stages of experimental evaluation.

TABLE III. A COMPREHENSIVE ANALYSIS OF KEYPHRASE PREDICTION MODELS USED IN EVALUATION

Model	Model Type	Output	Reason
TextRank [42]	Unsupervised, Graph-based	Extractive keyphrases	An unsupervised model to extract keyphrase.
CopyRNN [39]	Supervised, Neural Seq2Seq	Extractive and generative keyphrases	A neural network model to generate present and absent keyphrases.
BART-based Keyphrase Generator [25]	Transformer-based	Generative keyphrases	Abstractive model used for keyphrases prediction.
T5-based Keyphrase Generator [37]	Transformer-based (Text-to-Text)	Generative keyphrases	A metric for text transformation. Widely used in recent studies to generate keyphrases.

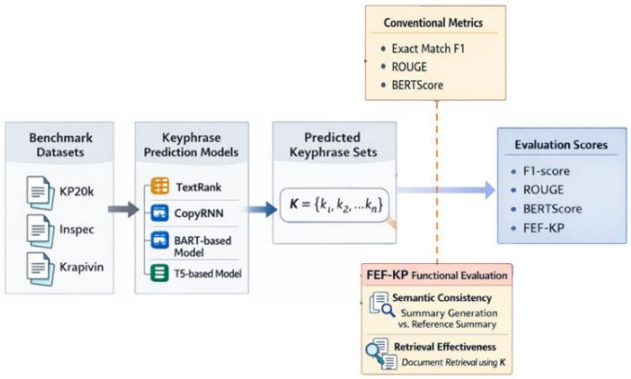

Fig. 4. The stages of experimental evaluation

We will present, analyze and discuss the evaluation results in the following part.

B. Evaluation Results

1) Sample size: To ensure the reliability of comparisons between the four models and the metrics used, samples were selected from the KP20k, Inspec, and Krapivin datasets. Table IV shows the sample size used for each dataset.

TABLE IV. THE SAMPLE SIZE USED IN EVALUATION

Dataset	Sample Size	Avg. Document Length
Inspec	500	Short (~120 words)
KP20k	2,000	Medium (~180 words)
Krapivin	400	Long (~8,000+ words)

To reduce computational costs and achieve a high level of reliability, 2,000 documents were selected from the KP20k dataset, and we used all documents from the Inspec dataset. 400 research papers were selected from the Krapivin dataset to evaluate the effectiveness retrieval of the FEM-KP in longer documents.

2) Consistency of performance ranking: The consistent ranking of models across diverse datasets is a prerequisite for any evaluation. The reliability of an evaluation metric is measured by its ability to rank model performance across diverse datasets. Despite the complexity of the dataset or the length of the document, the relative ranking of models should remain constant. In this part, we analyze the robustness of the FEM-KP metric by comparing its ranking stability for key phrase prediction models with the F1-Score, ROUGE-L, and BERTScore metrics. Our analysis aims to demonstrate that FEM-KP has a unique ability to identify the most effective model even as data complexity increases, whereas other measures are susceptible to ranking inversions and contextual noise. Table V presents the performance of the four keyphrases prediction in the Inspec dataset representing short texts.

TABLE V. THE PERFORMANCE OF THE FOUR KEYPHRASES PREDICTION IN THE INSPEC DATASET

Model	F1-Score	ROUGE-L	BERTScore	FEM-KP
TextRank	(4) 0.215	(4) 0.312	(4) 0.721	(4) 0.584
CopyRNN	(3) 0.248	(3) 0.345	(3) 0.765	(3) 0.642
T5-based	(2) 0.278	(2) 0.372	(2) 0.835	(2) 0.775
BART-based	(1) 0.285	(1) 0.380	(1) 0.842	(1) 0.791

The texts in Inspec are short summaries, for this, the potential error across all metrics is reduced. Therefore, we observe consistency across all metrics in ranking model performance. Conversely, when using the KP20K dataset, which contains longer summaries compared to Inspec, the exact Match metrics began to deviate. F1-Score favored CopyRNN over T5 and ROUGE-L favored T5 over BART, while BERTScore and FEM-KP maintained their rankings. Table VI presents the performance of the four keyphrases prediction in the KP20k dataset representing short texts.

TABLE VI. THE PERFORMANCE OF THE FOUR KEYPHRASES PREDICTION IN THE KP20K DATASET

Model	F1-Score	ROUGE-L	BERTScore	FEM-KP
TextRank	(4) 0.142	(4) 0.245	(4) 0.680	(4) 0.510
CopyRNN	**(2) 0.200**	(3) 0.290	(3) 0.730	(3) 0.615
T5-based	**(3) 0.185**	**(1) 0.325**	(2) 0.808	(2) 0.732
BART-based	(1) 0.210	**(2) 0.318**	(1) 0.815	(1) 0.748

The deviate in the ranking of exact matching metrics is due to the increasing size and diversity of the data. Additionally, these metrics are sensitive to the Longest Common String (LCS). The results also demonstrate that FEM-KP overcomes this problem through its reconstruction track. The greatest challenge arises, in Krapivin, as the metric must evaluate the performance of models in long texts. Table VII presents the performance of the four keyphrases prediction in the Krapivin dataset representing long texts.

In Krapivin, a deviate is observed in the F1-Score, where CopyRNN was favored over T5. This is due to the length of the texts, which increased the probability of random matches. Furthermore, the semantic-based BERTScore metric showed ranking instability within the Krapivin dataset. The length of

the texts also led to contextual noise resulting from the presence of irrelevant informations. Therefore, CopyRNN obtiened a high score by BERTScore because the context was perfectly matched. In contrast, FEM-KP is the only metric that maintained the rank (BART > T5 > CopyRNN > TextRank) in all datasets, proving that it is not fooled by length of the text or overlapping of phrases, but rather measures functional value.

TABLE VII. THE PERFORMANCE OF THE FOUR KEYPHRASES PREDICTION IN THE KRAPIVIN DATASET

Model	F1-Score	ROUGE-L	BERTScore	FEM-KP
TextRank	(4) 0.125	(4) 0.210	(4) 0.655	(4) 0.495
CopyRNN	**(2)0.180**	(3) 0.265	**(2) 0.785**	(3) 0.580
T5-based	**(3) 0.175**	(2) 0.302	**(3) 0.782**	(2) 0.695
BART-based	(1) 0.195	(1) 0.310	(1) 0.790	(1) 0.712

3) Discussion of results: Analysis of results from the Inspec, KP20K, and Krapivn datasets revealed differences between match evaluation and functional evaluation. While F1-Score, ROUGE-L, and BERTScore metrics showed deviate ranking with increasing document complexity and length, with extractive models like CopyRNN outperforming generative models. They often rewarded lexical redundancy and contextual matching at the expense of semantic utility. In contrast, FEM-KP demonstrated ranking consistency (BART > T5 > CopyRNN > TextRank) regardless of datasets. This stability is attributed to the dual-tracks structure of our metric. The reconstruction track rewards only the keyphrases capable to generate the document maining, while the retrieval track rewards those capable to retrieve the document. The FEM-KP result proves to be unaffected by text length and independent of the model. This provide a more reliable metric to evaluate generative keyphrase prediction models. These results confirm that the FEM-KP not only measures similarity but also functional information, making it a more reliable tool for researchers in the NLP field.

VI. CONCLUSION

In this study, we addressed the evaluation of keyphrase prediction models by highlighting the challenges posed by current evaluation metrics such as F1-Score, ROUGE-L, and BERTScore, which primarily focus on exact matching or contextual similarity but often fail to detect the functional utility of keyphrases. This leads to inconsistent model rankings, particularly in long and complex documents. Therefore, to overcome this problem, we proposed the FEM-KP metric. Our metric adopts a two-track evaluation, the utility of reconstruction (track A) and semantic consistency (track B), which has allowed to distinguish between contextually similar phrases and functionally necessary keyphrases. Our experimental results across three diverse datasets, Inspec, KP20k, and Krapivin showed that FEM-KP provides a superior and more stable evaluation metric and provide a fair assessment that rewards the functional performance of the phrases rather than literal repetition compared to current evaluation metrics. In conclusion, instead to evaluate keyphrase prediction models based to compare the predicted keyphrases with the reference keyphrases, FEM-KP allows to evaluate these models based on the functional performance of these phrases. Therefore, we believe this metric will provide a more reliable benchmark for researchers to develop highly effective NLP systems. Therefore, we will expand FEM-KP in the future to include other functions such as classification and clustering.

***Abstract*—For efficient agricultural planning, resource management, and enhancing farmer livelihoods in significant tea-producing regions, tea production prediction is essential. However, climate variability—including temperature, rainfall, humidity, and sunlight duration—has a significant impact on tea output, making precise forecasting difficult. Using meteorological data from 2015 to 2025, this study suggests a hybrid machine learning approach for predicting tea production. Initially, four models are created as separate predictors: Random Forest, XG Boost, Light GBM, and Cat Boost. Three ensemble models are shown to increase prediction accuracy: a Neutrosophic Ensemble Model, a Fuzzy Logic Weighted Ensemble, and an optimized weighted ensemble utilizing Sequential Least Squares Programming (SLSQP). According to experimental data, the optimized ensemble outperforms individual and alternative ensemble models, achieving the best performance with an R^2 value of 0.86, an RMSE value of 130.89, and an MAE value of 103.96. The suggested methodology improves the accuracy of the tea yield forecast while managing climate variability.**

***Keywords*—Random Forest; XG Boost; Light GBM; Cat Boost; SLSQP; Fuzzy; Neutrosophic**

I. Introduction

Tea is a cash crop used for plantation in the world economy and plays a very important role in the agricultural economy of many developing nations. Tea crop (Camellia sinensis) is highly sensitive to climatic parameters, such as temperature, rainfall, humidity and solar irradiance. The alteration of climatic parameters hampers the productivity of the crop, as well as the sustainability of crop cultivation in the long run. Over the past few decades, climate variability and extreme weather have impacted the sustainability of tea crop production. Research has demonstrated the effect of climatic variables on the growth patterns of tea crop production, underscoring the importance of yield forecasting for proper management of tea crop production resources [1-2].

Recently, optimized weighted ensemble models for climate-based tea yield forecasting have attracted considerable attention within agriculture analytics. That is because these models can combine many different individual prediction models to produce an improved prediction accuracy of forecasted yield. Generally, statistical models frequently used for yield forecast have historically struggled with the non-linear relationship between climate variables and tea yield. However, machine learning algorithms such as Random Forest and XG Boost have demonstrated superior performance when working with larger data sets as well as managing the non-linear relationship of climate variables to tea yield than traditional regression-style forecasting models [3-4].

The climate greatly affects tea cultivation performance. This includes things like how hot or cold the weather is, how much rain falls in a specific region, and when the various growing periods occur within the season. There has been extensive research done in regard to how climatic conditions impact the amount of tea (i.e., tea yield) produced [5-6]. Climate change is also seen to be a key driving force that influences tea yields across many countries, including India, Kenya, Sri Lanka and China, as well as across other regions [7-8]. For instance, climatic conditions in regions where tea is grown, like Assam, play an important role in determining how easy or difficult it will be to produce large amounts of quality tea (i.e., the trend of tea yields), therefore requiring the development of sophisticated modelling techniques to assess what the potential yields will be for future growing seasons within those regions [2]. Likewise, variations in the way that rainfall patterns and temperature affect how much tea will be produced in each area where tea is produced are also dramatic.

Fuzzy set theory and Neutrosophic logic are two soft computing methods designed to help deal with the uncertain and imprecise nature of agricultural data. These methods can be used to consider incomplete, inconsistent, and uncertain data that frequently occur in agricultural and climatic datasets [9-10], thus enabling the use of these methods in predictive models, which not only strengthen the robustness of these models, but also improve their reliability when used in an applied setting. The advent of large-scale agricultural and climatic datasets has facilitated the development of data-driven forecasting models. There are significant historical datasets in the International Statistical Database that may serve as useful tools for the analysis of crop yield forecasting and for the development of

*Corresponding author

climatic forecasting models based primarily on sophisticated machine learning techniques [11-12].

To explore future challenges and provide opportunities in terms of establishing an optimized ensemble method using weights for climate-based tea yield prediction models, this study intends to find solutions. The authors have developed a prototype combination of various machine learning models while assigning optimal weights in order to create the best-performing model of its type. The purpose of this model is to examine how climatic influences combined with ensemble approaches can produce the most accurate estimates when predicting tea yields. It is hoped that such an approach will assist agriculture policymakers, tea planters and researchers with the decision-making process related to the management of tea as it relates to climatic impacts and sustainability.

II. Literature Review

The production of tea can be affected by several climatic and environmental components, which various modeling techniques have examined. Raj et al. [13] analyzed the long-term variation of tea production in some India tea growing areas using data from 1981 to 2015. Different statistical and time series techniques (like multiple regression, SARIMAX and artificial neural networks [ANNs]) were utilized and the authors concluded that the ANN and vector autoregressive model would be best to show Nonlinear interactions between climate input and tea yield, as well as identifying temperature variation as the primary driver for tea yield.

Batool et al. [14] developed a hybrid method for estimating tea yield through a combination of the FAO AquaCrop simulation model and machine learning models. Using weather, soil, crop, and management data from Pakistan, they demonstrated that predictive errors with machine learning (especially with the XG Boost algorithm) were lower than those associated with the simulation method, thus showing great promise for the prediction of tea yield using data-driven models.

In a study by Xiang et al. [15], ecological variables were controlled to determine the effect of temperature, humidity, light intensity, and substrate moisture on physiological function in tea plants. The study results indicate that some combinations of ecological variables exert a significant synergistic influence over shoot development, yield, and total catechin content of tea foliage, supporting a correlation between tea yield and quality. Raghav et al. [16] employed Convolutional Neural Networks (CNN) and Long Short Term Memory (LSTM) networks for forecasting tea area, production and yield based on historical data from 1918 to 2023. Results of the study showed that the CNN model had lower error values than the LSTM model, which indicates that the CNN model has superior predictive capability relative to the LSTM model. This study illustrates that deep learning models are capable of accurately forecasting tea yield. Premkumar et al. [17] examined climate variability as it relates to tea production in Tamil Nadu using an ARDL error correction model. The authors concluded that lower temperatures and higher relative humidity promote tea production; however, rainfall negatively affects tea production.

The tea yield is known to be highly sensitive to both climate and environment, and recent research indicates that the traditional statistical models often do not adequately capture the complex or nonlinear relationship between climate and tea yield. While some advanced methods have demonstrated better success, such as machine learning, hybrid simulation/machine learning models, and controlled ecological experiments, there remain limitations concerning the applicability of these methods both regionally and operationally. In addition, temperature, rainfall and humidity - all identified as climatic variables relevant to tea cultivation - vary widely throughout the world; therefore, area-specific studies must be conducted. In light of these issues, this study will focus on developing an accurate and robust modelling method for predicting tea yields using climatic variables and advanced machine learning techniques.

III. Methodology

Fig. 1 represents an illustration of the proposed methodology's overview. In this example, we show how a machine learning-based approach provides predictions on tea production within India. First, a comprehensive dataset that is publicly available and encompasses a ten-year period and five major Indian states that are predominantly responsible for producing tea has been compiled. The study incorporates datasets collected across diverse temporal and environmental conditions, which inherently capture varying climatic scenarios and thus indirectly validate the model's robustness to climatic variability. The dataset will be split into model evaluation and model training datasets for two separate analyses. Model evaluation will be done by utilizing individual models against each data split during the model-building phase. The models that will be employed to develop the prediction model will consist of Random Forest (RF), XG Boost (XGB), Light GBM (LGBM), and Cat Boost models, which will be trained respectively on the newly created evaluation datasets. Further, an ensemble will be developed based on the combination of all four models trained to yield a better prediction for tea yield. The average weight applied to each of the models will be statistically determined based on the degree to which its prediction was accurate compared to the actual tea production on an annual basis, throughout the combined evaluation. The weight assigned to each model will then serve as the basis for developing the predictions for the current model based on this methodology. Algorithm 1 identifies the steps included in the proposed methodology.

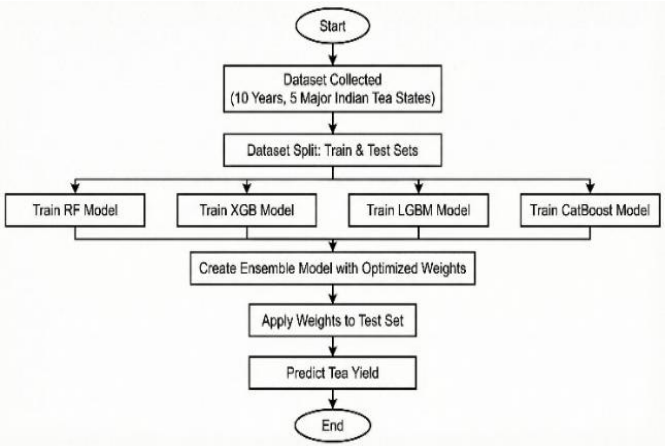

Fig. 1. Flow chart of proposed methodology.

Algorithm 1: SLSQP-based Optimized Weighted Ensemble Model

Require: Dataset D_{total}, Minimum weight threshold δ

Ensure: Final ensemble prediction $\hat{Y}_{final}$

Import training and test data

Split dataset into feature matrix X and target vector y

Perform one-hot encoding on categorical variables (State, District)

Split data into D_{train} and D_{val}

Train regression models: RF, XGB, LGBM, CAT on D_{train}

For each model $m_k \in \{RF, XGB, LGBM, CAT\}$ do

$$\hat{y}_{val}^{(k)} = m_k(X_{val})$$

End for

Form prediction matrix $P \in \mathbb{R}^{N_{val} \times 4}$:

$$P = \left[\hat{y}_{val}^{(1)}, \hat{y}_{val}^{(2)}, \hat{y}_{val}^{(3)}, \hat{y}_{val}^{(4)}\right]$$

For each model m_k do

$$RMSE_k = \sqrt{\frac{1}{N_{val}} \sum_{i=1}^{N_{val}} \left(y_i - \hat{y}_i^{(k)}\right)^2}$$

End for

Initialize weights using inverse RMSE:

$$w_k^{(0)} = \frac{1/(RMSE_k)}{\sum_{j=1}^{4} 1/(RMSE_j)}$$

Ensemble prediction:

$$\hat{y}_i = \sum_{k=1}^{4} w_k P_{i,k}$$

Objective function:

$$\min_w J(w) = \sqrt{\frac{1}{N_{val}} \sum_{i=1}^{N_{val}} (y_i - \hat{y}_i)^2}$$

Subject to equality constraint:

$$\sum_{k=1}^{4} w_k = 1, \qquad w_k \geq \delta$$

Apply Sequential Least Squares Programming (SLSQP)

Iteratively update weight vector w using quadratic approximation while satisfying constraints

Obtain optimal weight vector w^*

For each model m_k do

Retrain m_k on full dataset D_{total}

$$\hat{y}_{test}^{(k)} = m_k(X_{test})$$

End for

$$\hat{Y}_{final} = \sum_{k=1}^{4} w_k^* \hat{y}_{test}^{(k)}$$

Return $\hat{Y}_{final}$

Algorithm 1 describes the overall structure of the traditional optimized weighted ensemble paradigm, wherein multiple machine learning models are trained and the optimal weights are determined via constrained optimization techniques based on the validation data set. Each individual model is trained separately on the same training data and produces a corresponding prediction $\hat{y}_i$ for a given input. Initial weights are derived using the inverse Root Mean Square Error (RMSE) of each base model:

$$w_i^{(0)} = \frac{1/(RMSE_i)}{\sum_{j=1}^{M} 1/(RMSE_j)} \quad (1)$$

The ensemble weights are optimized by minimizing the RMSE of the ensemble on the validation set using the Sequential Least Squares Programming (SLSQP) optimization algorithm. The objective function is defined as:

$$\min_w \sqrt{\frac{1}{n} \sum_{k=1}^{n} \left(y_k - \sum_{i=1}^{M} w_i \hat{y}_{i,k}\right)^2} \quad (2)$$

The final ensemble prediction is computed as a weighted linear combination of the base model predictions, expressed as:

$$\hat{y} = \sum_{i=1}^{M} w_i \hat{y}_i \quad (3)$$

where, M denotes the number of base models and w_i represents the weight assigned to the i^{th} model. To ensure a valid convex combination, the weights are constrained to satisfy:

$$\sum_{i=1}^{M} w_i = 1, w_i \geq 0 \quad (4)$$

Each of the base learners is trained separately on the same training dataset and generates predicted values for the tea yield. The prediction error of each learner is calculated on the validation dataset using the Root Mean Square Error (RMSE) metric. The RMSE values are used as crisp inputs to the fuzzy logic system.

Fuzzification Using Gaussian Membership Function: Each RMSE value is converted to a fuzzy membership degree, which represents the level of trust in the respective model. A Gaussian membership function is used:

$$\mu_i = exp\left(-\frac{RMSE_i^2}{2\sigma^2}\right) \quad (5)$$

where, σ is the adaptive spread parameter, which is calculated as the mean RMSE of all base models:

$$\sigma = \frac{1}{4} \sum_{i=1}^{4} RMSE_i \quad (6)$$

The membership degree increases with lower RMSE values, representing higher confidence in the model.

Defuzzification: The fuzzy membership degrees are normalized to get the final ensemble weights:

$$w_i = \frac{\mu_i}{\sum_{j=1}^{4} \mu_j} \quad (7)$$

The final fuzzy ensemble prediction for the k[th] sample is calculated as a weighted sum of the individual predictions:

$$\hat{y}_k = \sum_{i=1}^{4} w_i \hat{y}_{i,k} \quad (8)$$

These values confirm that the fuzzy logic-based weighting approach successfully combines the predictions of the individual base models, providing accurate and robust predictions of tea yield even in uncertain conditions.

Extending this traditional methodology further, Algorithm 2 introduces the concept of fuzzy logic to determine the adaptive weights of the machine learning models based on the performance on the validation dataset.

Algorithm 2: Proposed Fuzzy Logic Weighted Ensemble (FWE) Algorithm

Require: Validation dataset $D_{val} = \{(x_i, y_i)\}_{i=1}^{n}$, Base models $M = \{m_1, m_2, \dots, m_k\}$

Ensure: Final ensemble prediction Y_{ens}

For each model $m_j \in M$ do

$\hat{y}_{i,j} = m_j(x_i)$ for all $(x_i, y_i) \in D_{val}$

Compute RMSE:

$$RMSE_j = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(y_i - \hat{y}_{i,j}\right)^2}$$

End for

Compute adaptive spread parameter:

$$\sigma = \frac{1}{k}\sum_{j=1}^{k} RMSE_j$$

For each model $m_j \in M$ do

Compute Gaussian membership degree:

$$\mu_j = exp\left(-\frac{RMSE_j^2}{2\sigma^2}\right)$$

End for

For each model $m_j \in M$ do

$$W_j = \frac{\mu_j}{\sum_{l=1}^{k}\mu_l}$$

End for

For a new input x_{new} do

$$Y_{ens}(x_{new}) = \sum_{j=1}^{k} W_j \cdot m_j(x_{new})$$

End for

Return Y_{ens}

Algorithm 2 shows a Fuzzy Logic Weighted Ensemble (FWE) method in which the weights of models are computed using Gaussian membership functions, which are functions of the corresponding RMSE values. In this approach, the contribution of each base learner in the ensemble output is adaptively controlled in proportion to the accuracy of the base learner, so that models with higher accuracy contribute more to the ensemble output. However, fuzzy logic essentially represents membership functions without considering any uncertainty or indeterminacy in the system output. Therefore, to improve the robustness of the fuzzy-based approach, Algorithm 3 proposes a Neutrosophic Weighted Ensemble (NWE) method, in which a fuzzy-based approach is generalized to consider all three components of a Neutrosophic set, namely, truth (measured in terms of R^2 values), indeterminacy, and falseness (measured in terms of normalized RMSE values), to obtain a more robust and reliable ensemble output, considering all the uncertainty in the system output, to obtain a more informative ensemble output compared to the fuzzy-based approach.

The Neutrosophic approach defines uncertainty using three parts: Truth (T), Indeterminacy (I), and Falsity (F). The values of T, I, and F are calculated for each base model using the validation performance metrics.

Truth Membership (T): Truth reflects the predictive reliability of a model and is defined using the coefficient of determination.

$$T_i = R_i^2 \tag{9}$$

Indeterminacy Membership (I): Indeterminacy captures model uncertainty.

$$I_i = 1 - R_i^2 \tag{10}$$

Falsity Membership (F): Falsity represents prediction error and is derived from the normalized RMSE.

$$F_i = \frac{RMSE_i - min\,(RMSE)}{max(RMSE) - min\,(RMSE)} \tag{11}$$

A single Neutrosophic score is computed through deneutrosophication to balance accuracy, uncertainty, and error.

$$S_i = \frac{2 + T_i - I_i - F_i}{3} \tag{12}$$

The final ensemble weight for each model is obtained by normalizing these scores.

$$w_i = \frac{S_i}{\sum_{j=1}^{4} S_j} \tag{13}$$

The Neutrosophic ensemble prediction:

$$\hat{y}_k = \sum_{i=1}^{4} w_i \hat{y}_{i,k} \tag{14}$$

The performance metrics show that the combination of Neutrosophic logic helps to strike a balance between the accuracy of the model and the uncertainty of the environment, resulting in a well-performing ensemble model for tea yield prediction. These three algorithms, in total, form a progressive and robust ensemble learning methodology. Algorithm 1 provides a solid foundation by optimally combining multiple machine learning models through constrained optimization, thus achieving balanced weight allocation mathematically. Algorithm 2 extends this methodology by incorporating fuzzy logic, thus achieving adaptive and performance-sensitive weighting according to validation errors, thus increasing the flexibility of the methodology. Algorithm 3 extends this methodology by incorporating Neutrosophic logic, thus achieving more efficient management of uncertainty and variability in the performance of models, thus achieving a more reliable, intelligent, and robust ensemble prediction system, moving from a deterministic approach to uncertainty management to intelligent weighting.

Algorithm 3: Proposed Neutrosophic Weighted Ensemble (NWE) Algorithm

Require: Validation dataset $D_{val} = \{(x_i, y_i)\}_{i=1}^{n}$, Base models $M = \{m_1, m_2, \dots, m_k\}$

Ensure: Final ensemble prediction Y_{ens}

For each model $m_j \in M$ do

Compute validation metrics: R_j^2 and $RMSE_j$ on D_{val}

End for

$E_{min} = min(RMSE_j)$
$E_{max} = max(RMSE_j)$
For each model $m_j \in M$ do
  Truth membership: $T_j = R_j^2$
  Indeterminacy membership: $I_j = 1 - R_j^2$
  Falsity membership:

$$F_j = \frac{RMSE_j - E_{min}}{E_{max} - E_{min}}$$

End for
For each model $m_j \in M$ do
  Compute neutrosophic score:

$$S_j = \frac{2 + T_j - I_j - F_j}{3}$$

End for
Normalize scores to obtain weights:

$$W_j = \frac{S_j}{\sum_{l=1}^{k} S_l}$$

For a new input instance x_{new} do

$$Y_{ens}(x_{new}) = \sum_{j=1}^{k} W_j \cdot m_j(x_{new})$$

End for
Return Y_{ens}

IV. Results

A. Dataset Description

The empirical data are in numerical form, representing observations of tea production (kg/ha) and other agro-meteorological factors of major tea-yielding states like Assam, Himachal Pradesh, Kerala, Tamil Nadu, West Bengal, recorded at the district level during the period 2015 to 2025. The dataset is taken from [12]. Table I shows the description of the dataset that includes temporal factors and other climatic variables such as temperature, rainfall, relative humidity, and sunshine hours. The data is presented in arithmetic mean values, along with the minimum and maximum ranges, thus reflecting the variability of the environmental factors that affected tea production during the period. The data is given as a bar chart in Fig. 2.

TABLE I. Dataset Description

Variables	Mean (min-max)
Tea Yield (kg/ha)	1750.27 (1021.0–2923.4)
Maximum Temperature (°C)	29.09 (19.2–37.8)
Minimum Temperature (°C)	19.25 (2.6–26.5)
Rainfall (mm)	119.48 (0.0–485.6)
Relative Humidity – Morning (%)	85.24 (65.0–100.0)
Relative Humidity – Afternoon (%)	66.91 (34.7–96.7)
Sunshine Hours (hours)	5.60 (0.2–11.5)

The input of these regression algorithms is meteorological factors, and the target value is the observed tea yield. Data is split into a ratio of 80% and 20%. We have utilized 80% of the data for training the models, and the rest of 20% is used for testing.

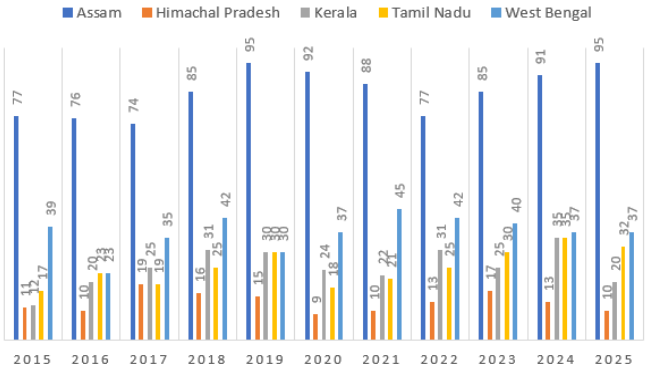

Fig. 2. Year-wise data collection

B. Performance of the Machine Learning Techniques for Tea Yield Prediction

Here we use four initial machine learning models, Random Forest, XG Boost, LGBM, Cat Boost for implementation, and also use a weighted ensemble model for better results. The performance metrics are as follows:

Coefficient of Determination (R^2):

$$R^2 = 1 - \frac{\sum(y-\hat{y})^2}{\sum(y-\bar{y})^2} \quad (15)$$

Root Mean Squared Error (RMSE):

$$RMSE = \sqrt{\frac{1}{n}\sum(y-\hat{y})^2} \quad (16)$$

Mean Absolute Error (MAE):

$$MAE = \frac{1}{n}\sum|y-\hat{y}| \quad (17)$$

In the above equations, y is the observed yield and $\hat{y}$ is the predicted yield, and n is the total number of samples. The performance of all the machine learning models and the ensemble model is given in Table II and Fig. 3.

TABLE II. Performance of Machine Learning Techniques

Model	R^2	RMSE	MAE
Random Forest	0.84	139.69	111.07
XG Boost	0.83	141.92	112.49
Light GBM	0.83	144.26	116.09
Cat Boost	0.85	131.94	104.03
SLSQP-based Ensemble Model	0.86	130.89	103.96

Table II shows the comparative assessment of the models, with each model's performance compared and evaluated using R^2, RMSE, and MAE. From the table, it is clear that the Cat Boost model outperforms the Random Forest, XG Boost, and Light GBM models, as it has the highest R^2 and lower error values. However, the Ensemble Model, which is based on Sequential Least Squares Programming, has the highest R^2 value of 0.86 and the least error values of 130.89 and 103.96,

respectively. This shows that the ensemble model is more reliable compared to the other models. The ensemble model is more effective compared to the other models. Optimized weights are: Random Forest: 0.26, XG Boost: 0.01, Light GBM: 0.02, Cat Boost: 0.69.

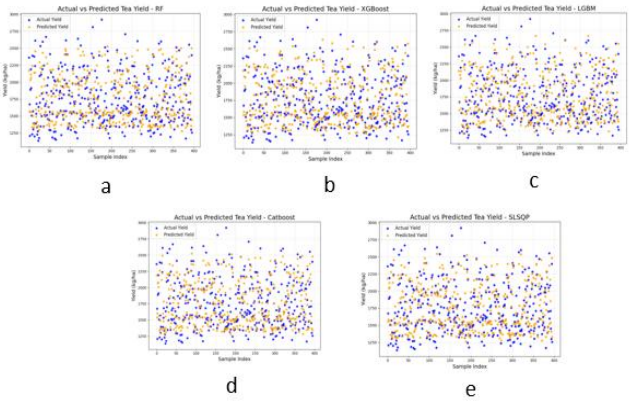

Fig. 3. Graphical representation of machine learning models: a) Random Forest, b) XG Boost, c) Light GBM, d) Cat Boost, e) Weighted ensemble model.

C. Performance for Fuzzy Logic for Tea Yield Prediction

To overcome the uncertainty associated with the prediction of tea yield and to apply dynamic weights to the learners, an ensemble framework using fuzzy logic is developed. The proposed ensemble framework combines four tree-based regression learners: Random Forest (RF), XG Boost (XGB), Light GBM (LGBM), and Cat Boost (CAT). Each of the base learners is trained separately on the same training dataset and generates predicted values for the tea yield. The prediction error of each learner is calculated on the validation dataset using the Root Mean Square Error (RMSE) metric. The RMSE values are used as crisp inputs to the fuzzy logic system. Table III and Fig. 4 show the performance of the Fuzzy-Based Ensemble Model.

TABLE III. PERFORMANCE OF FUZZY ENSEMBLE MODEL TECHNIQUES

Model	R^2	RMSE	MAE
Fuzzy-based Ensemble Model	0.84	136.32	108.77

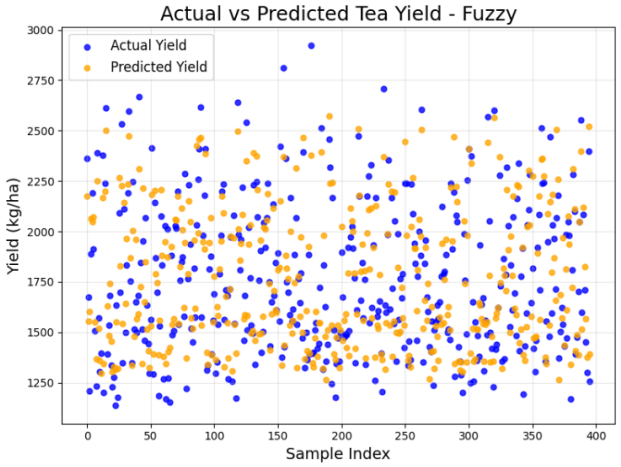

Fig. 4. Graphical representation of fuzzy logic-based tea yield prediction.

The model provides an R^2 value of 0.84979, which shows satisfactory accuracy for the model's predictions. The RMSE value of 136.3297 and the MAE value of 108.7715 show that the errors associated with the predictions are relatively low. Overall, the fuzzy ensemble model shows good performance and improves the accuracy of predictions by optimally assigning the weights according to the performance of the models. Optimized weights are: Random Forest: 0.2512, XG Boost: 0.2472, Light GBM: 0.2431, Cat Boost: 0.2585.

D. Performance for Neutrosophic Logic for Tea Yield Prediction

To enhance the accuracy of tea yield prediction in an uncertain environment, a Neutrosophic ensemble learning approach is proposed by combining four tree-based regression models: Random Forest (RF), XG Boost (XGB), Light GBM (LGBM), and Cat Boost (CAT). Each base model is trained separately on the same training data and produces predicted values of the tea yield, represented as $\hat{y}_i$.

The Neutrosophic approach defines uncertainty using three parts: Truth (T), Indeterminacy (I), and Falsity (F). The values of T, I, and F are calculated for each base model using the validation performance metrics, and the metrics are shown in Table IV.

TABLE IV. NEUTROSOPHIC METRICS

Model	T	I	F
RF	0.8423	0.1577	0.4725
XG Boost	0.8372	0.1628	0.7301
LGBM	0.8318	0.1682	1.0000
Cat Boost	0.8514	0.1486	0.0000

A single Neutrosophic score is computed through deneutrosophication to balance accuracy, uncertainty, and error.

$$S_i = \frac{2+T_i-I_i-F_i}{3} \quad (18)$$

The final ensemble weight for each model is obtained by normalizing these scores.

$$w_i = \frac{S_i}{\Sigma_{j=1}^{4} S_j} \quad (19)$$

The performance of the Neutrosophic fuzzy model is shown in Table V and Fig. 5.

TABLE V. PERFORMANCE OF NEUTROSOPHIC ENSEMBLE MODEL TECHNIQUES

Model	R^2	RMSE	MAE
Neutrosophic Ensemble Model	0.85	135.94	108.32

Table V shows the overall performance of the Neutrosophic Ensemble Model. From the table, it can be concluded that the model has an R^2 value of 0.85064, which shows high predictive accuracy. At the same time, the model has an RMSE value of 135.9409 and an MAE value of 108.3259, which shows that the errors obtained from the model are quite low. Therefore, the Neutrosophic ensemble model has shown good and reliable performance while dealing with the uncertainty that occurs

while evaluating the model and computing the weights. Optimized weights are: Random Forest: 0.2596, XG Boost: 0.2281, Light GBM: 0.1952, Cat Boost: 0.3171.

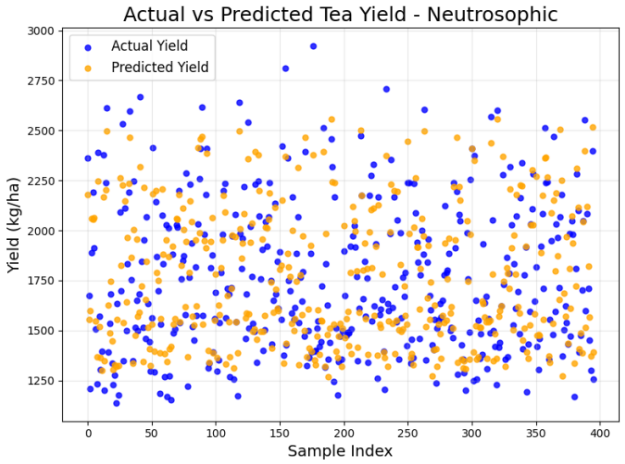

Fig. 5. Graphical representation of Neutrosophic-based tea yield prediction.

Performance of our proposed model (Sequential Least Squares Programming (SLSQP) algorithm) is improved and the results are found to be the best, with the R^2 value being high (0.8629) and the error values being low. The Fuzzy Ensemble Model and the Neutrosophic Ensemble Model are found to have high performance. The performance of the Neutrosophic Ensemble model is slightly better than the Fuzzy Ensemble model. This is evident by the R^2 value being high and the error values being low. Overall, the results show that the performance of the Ensemble model is high compared to the individual algorithms. The Ensemble model is found to have the most precise and reliable performance. The comparative analysis of our proposed ensemble model with the methods in the earlier literature is given in Table VI.

V. CONCLUSION

This study proposes various machine learning and ensemble techniques for predicting tea yield using climatic data. The proposed methodology, the optimized weighted ensemble method based on Sequential Least Squares Programming (SLSQP) is found to provide the highest prediction accuracy compared to other machine learning models. However, the models. Fuzzy and Neutrosophic ensemble models are proposed to improve the reliability of prediction techniques based on uncertainty handling capabilities. The Neutrosophic model is found to perform slightly better compared to the fuzzy model for handling uncertainty conditions.

Hence, our proposed methodology provides better prediction accuracy than Fuzzy and Neutrosophic-based models. This study can be extended by incorporating climatic data from various tea-producing states of world-wide to improve the proposed prediction techniques using machine learning models. Deep learning techniques can also be explored to improve the prediction accuracy of the proposed prediction techniques.

ACKNOWLEDGMENT

The authors sincerely acknowledge the support of JIS Group for providing financial assistance to carry out this research work. The authors are also grateful for the institutional support, infrastructure, and research environment that facilitated the successful completion of this study. Special thanks are extended to all individuals and collaborators who contributed their time and expertise toward this work.

Incorporating Generative AI in Foreign Language Teaching Preparation: An Empirical Investigation Into the Effects of AI-Assisted Lesson Planning

Xinxin Guo[1], Hao Chen[2]*
Department of Public Course Teaching, Nanyang Vocational College of Agriculture, Nanyang 473000, China [1]
Artificial Intelligence Engineering College, Nanyang Vocational College of Agriculture, Nanyang 473000, China [2]

***Abstract*—Generative artificial intelligence, particularly large language models such as ChatGPT, has emerged as a promising educational technology tool with extensive application potential in teaching preparation. The research objectives of this study are: 1) to examine how generative AI affects foreign language teachers' teaching preparation experiences in terms of curriculum design, instructional resource development, teaching activity planning, work motivation, and efficiency; and 2) to identify the strengths, challenges, and teacher-recommended improvements associated with generative AI use in foreign language teaching preparation. This qualitative case study explored how generative AI assists foreign language teachers in their teaching preparation work, addressing a research gap regarding the benefits and challenges of this innovative approach. The study involved 13 foreign language teachers at a comprehensive university in central China who participated in a four-week training program. Qualitative data from semi-structured interviews were analyzed using thematic analysis. The findings indicate that generative AI positively affects teachers' preparation experiences in curriculum design, instructional resource development, and teaching activity planning, while enhancing motivation and efficiency. In degree-of-significance terms, the positive impact was large for curriculum design (reported by 10/13 teachers, approximately 77%), large for instructional resource development (10/13, approximately 77%), moderate-to-large for teaching activity planning (8/13, approximately 62%), large for work motivation (9/13, approximately 69%), and large for work efficiency (10/13, approximately 77%); by contrast, the impact on assessment design and teaching research was small (2/13 and 1/13, respectively). These insights contribute to understanding the utility and constraints of employing generative AI in foreign language teaching preparation and inform the development of effective teaching support strategies and training programs.**

I. Introduction

Since its release in November 2022, ChatGPT, an advanced artificial intelligence language model developed by OpenAI, has garnered widespread attention in the educational field [1]. Built upon the Generative Pre-trained Transformer-3 (GPT-3) architecture with 175 billion parameters [2], ChatGPT generates human-like text responses [3] and demonstrates extensive natural language processing capabilities including query resolution, narrative generation, logical assessment, code debugging, and machine translation [4]. As a general-purpose conversational agent, ChatGPT has potential applications across education, healthcare, software engineering, content creation, and business operations [5].

Existing literature reveals growing interest in generative AI's influence on educational preparation and teacher professional development. Integration of these technologies into teaching preparation demonstrates varied strategies and perceptions, showing benefits in processing pedagogical tasks [6] alongside challenges in addressing deeper instructional design issues [7]. Teacher perceptions present a nuanced picture, with research highlighting AI's potential to enhance pedagogical experience through comprehensive feedback [8], though faculty opinions on its effectiveness vary [9]. Sociocultural factors significantly influence educators' attitudes toward AI [10], emphasizing the importance of contextual considerations in AI adoption.

Generative AI integration into curriculum design and teaching methods suggests innovation potential. Natural language processing applications [11] and teacher-AI collaboration [12] indicate forward-thinking approaches to curriculum development, underscoring the need for supportive environments to maximize AI benefits in teaching preparation. AI shows promise for enhancing instructional resource development and activity design [13], with ChatGPT and prompt engineering proving effective in automatic question generation [14]. However, limitations in identifying deep pedagogical errors [7] necessitate balanced approaches that leverage AI capabilities while recognizing human expertise. Research indicates educators prioritize practical applicability of AI-generated feedback [15], and AI-based systems show utility in mapping learning outcomes and quality assurance [16].

Challenges and ethical considerations are significant to the discourse on AI in education. Concerns regarding academic integrity, the pedagogical implications of AI-generated texts [17], and the difficulties faced by educators in identifying AI-generated content highlight the complexities of incorporating AI into teaching preparation frameworks. Furthermore, the potential impact of AI on professional role devaluation among educators necessitates a strategic approach for its adoption [18]. Finally, the potential and limitations of generative tools such as ChatGPT in enhancing teaching capabilities are evident. While such technologies offer valuable applications and can improve instructional quality [19], ethical concerns and the balance

*Corresponding author.

between innovation and responsible use remain critical considerations [20]. The literature thus delineates a landscape where AI's contributions to teaching preparation are significant, yet circumscribed by challenges that require careful navigation to ensure ethical, effective, and inclusive educational practices.

Despite substantial research on AI applications in language learning, empirical studies examining how generative AI supports foreign language teachers' preparation work remain scarce. This study examines generative AI employment in foreign language teaching preparation, filling a research gap by offering insights into possibilities, advantages, and challenges of this technology. While ChatGPT's proficiency in creating summaries, quizzes, and learning materials could bolster professional development [21], concerns persist regarding reliability and ethical use of AI output in educational contexts where it may affect teaching quality and professional judgment [22]. Therefore, this study investigated generative AI's effects on teachers' preparation experiences and their views on its benefits and limitations, providing knowledge on the applicability and effectiveness of AI use in foreign language teaching preparation. The specific purpose of this study is to empirically investigate, in a single university setting in central China, how a four-week generative AI training intervention influences foreign language teachers' preparation experiences across curriculum design, instructional resource development, teaching activity planning, work motivation, and work efficiency, and to document their perceptions of the strengths, challenges, and recommendations regarding generative AI use. In contrast to prior studies that have primarily examined AI in learner-facing contexts such as student writing evaluation [15] and question generation for English education [14], this study focuses explicitly on teacher-facing preparation workflows across multiple language subjects (English, Japanese, German, French, and Spanish), an angle that has not been systematically examined in the literature.

To comprehensively investigate generative AI's role in foreign language teaching preparation, this study was guided by two research questions. First, how does generative AI implementation affect teachers' work experiences, including work efficiency, professional development, and instructional design capabilities? Second, what strengths, challenges, and recommendations emerge from teacher perspectives on generative AI use for teaching preparation? The findings illuminate benefits and drawbacks of generative AI in foreign language teaching preparation, guiding educational administrators and researchers in developing effective teaching support strategies and training programs. A qualitative case study method was chosen because the phenomenon under investigation, namely teachers' preparation practices with an emerging technology, is process-oriented, context-dependent, and not yet well documented; case study methodology [23], [24] is therefore better suited than a large-scale survey for producing rich, contextualized descriptions of how teachers actually use generative AI and how they interpret its value and limitations in their own words. Scientifically, this study contributes early empirical evidence that can support the design of subsequent larger-scale quantitative and mixed-methods studies on AI-assisted teacher preparation, and it extends the literature on generative AI in education from student-facing applications toward teacher-facing preparation workflows. Socially, the findings can inform the design of teacher training programs and institutional guidelines that help language teachers use generative AI productively while safeguarding professional judgment, academic integrity, and student learning experiences. The remainder of this manuscript is organized as follows: Section II describes the research design, study group, program, interview protocol, data collection, and validity and reliability procedures; Section III presents the results organized by the two research questions; Section IV discusses the findings in relation to prior work, as well as pedagogical and theoretical implications, limitations, and directions for future research; and Section V concludes the paper by summarizing the novelty and implications.

II. Methods

A. Research Design

A qualitative case study design was employed to conduct an in-depth examination of the phenomenon within its actual context and to gain insights into emerging technology applications in teaching practice [23]. Foreign language teachers from different linguistic backgrounds and teaching experience levels were considered as units of analysis. The researchers examined generative AI's effects on teachers' teaching preparation experiences and explored the tool's advantages and drawbacks. Fig. 1 illustrates the overall research design and flow.

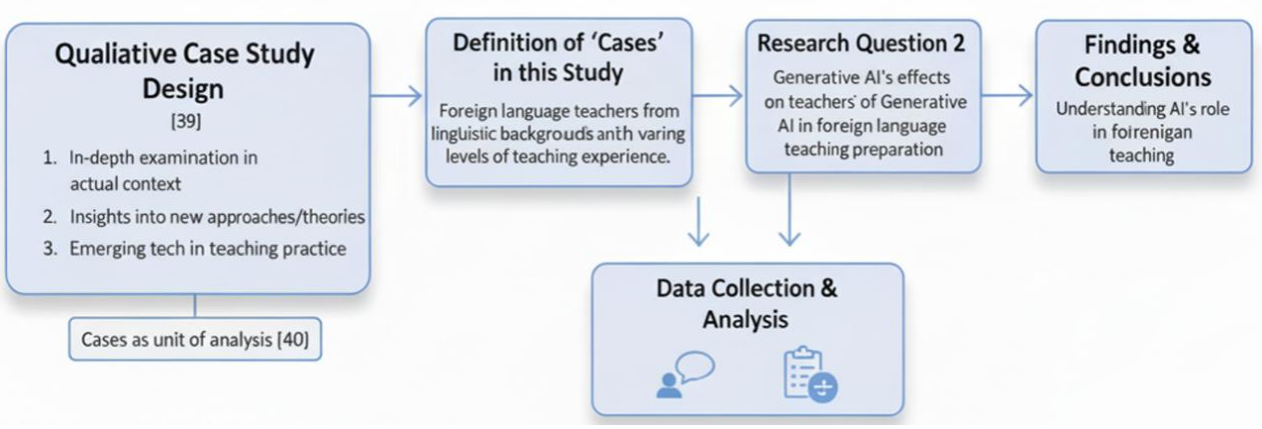

Fig. 1. Research design and flow.

B. Study Group

The study group consisted of 13 foreign language teachers at a comprehensive university in central China. Maximum variation sampling was employed to ensure diversity in linguistic backgrounds and teaching experience levels [23]. Due to administrative concerns about implementing emerging AI technology, the research was conducted with volunteers from a single college. Both training and interviews were conducted online considering teachers' schedules and geographical dispersion. Table I presents the demographic characteristics of the participants.

As shown in Table I, the study group included 10 female and 3 male teachers aged 28-45. Teachers represented diverse linguistic backgrounds including English, Japanese, German, French, and Spanish, with teaching experience ranging from 3 to 20 years. Four participants held doctoral degrees and nine held master's degrees. Most teachers reported using ChatGPT for teaching preparation for the first time during this study.

TABLE I. DEMOGRAPHIC CHARACTERISTICS OF THE PARTICIPANTS

Teacher Code	Gender	Age	Teaching Language	Teaching Experience (years)	Education Level
T1	Female	32	English	8	Master's
T2	Female	29	English	5	Master's
T3	Female	35	Japanese	12	Doctoral
T4	Female	41	English	15	Doctoral
T5	Male	38	English	13	Master's
T6	Male	45	German	20	Doctoral
T7	Female	33	English	9	Master's
T8	Male	36	English	11	Master's
T9	Female	28	French	3	Master's
T10	Female	31	English	7	Master's
T11	Female	39	English	14	Doctoral
T12	Female	42	Spanish	18	Doctoral
T13	Female	30	English	6	Master's

C. Program Description

The program engaged teachers in four 90-minute online training sessions integrating generative AI into curriculum design, instructional resource development, teaching activity planning, and assessment design. Training modules were designed to empower teachers in enhancing their teaching preparation skills and work efficiency through the effective use of generative AI.

D. Training Materials

Training materials included tailored plans, presentation slides, and ChatGPT 3.5 free version. Curriculum design training covered unit topic design, learning objective formulation, lesson flow planning, and materials selection. Teachers used generative AI to generate instructional ideas, create teaching scenarios, and develop materials. Activity design training focused on brainstorming ideas, formulating steps, and obtaining implementation suggestions. Assessment design training involved practicing AI use for generating test items, designing scoring rubrics, and formulating formative assessment schemes.

E. Teaching Preparation Activities

Training plans comprised AI-assisted curriculum design, instructional materials development, teaching activity planning, assessment design, and teaching reflection activities. Fig. 2 shows the various ways teachers engaged with generative AI in different teaching preparation activities. As Fig. 2 illustrates, teachers used the tool to create unit lesson plans, generate learning objectives, and design teaching activities. Fig. 3 depicts the instructional design frameworks that two participants created for "Business English" and "Academic Writing" topics.

As shown in Fig. 3, teachers used the tool to generate discussion questions for group discussions and worked in pairs on AI-assisted teaching reflection exercises. Each teacher received a teaching scenario prompt to use with ChatGPT for brainstorming and planning teaching reflections, which were then shared with partners in breakout rooms for discussion. The facilitator provided standardized prompt templates initially, but teachers were encouraged to write their own prompts in the following weeks to foster independence and creativity. Teachers were guided to reference ChatGPT's answers while incorporating original professional judgment in their teaching preparation work.

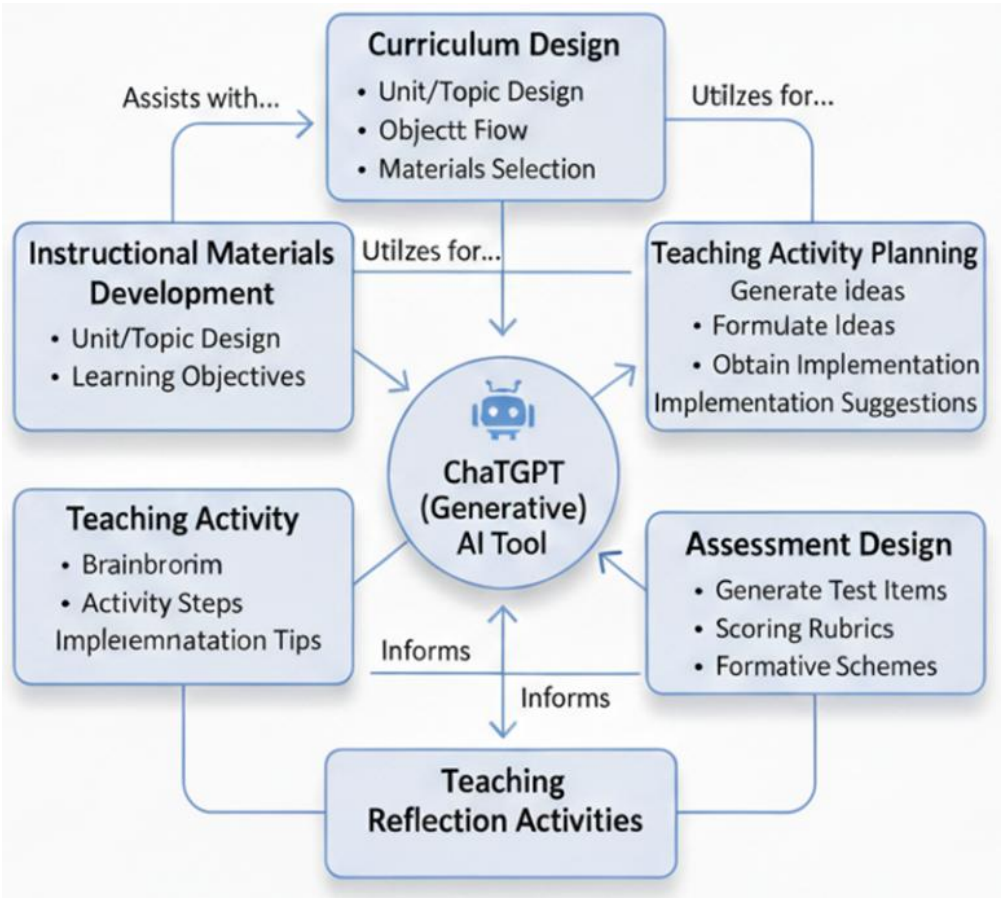

Fig. 2. Integration of ChatGPT in teaching preparation activities.

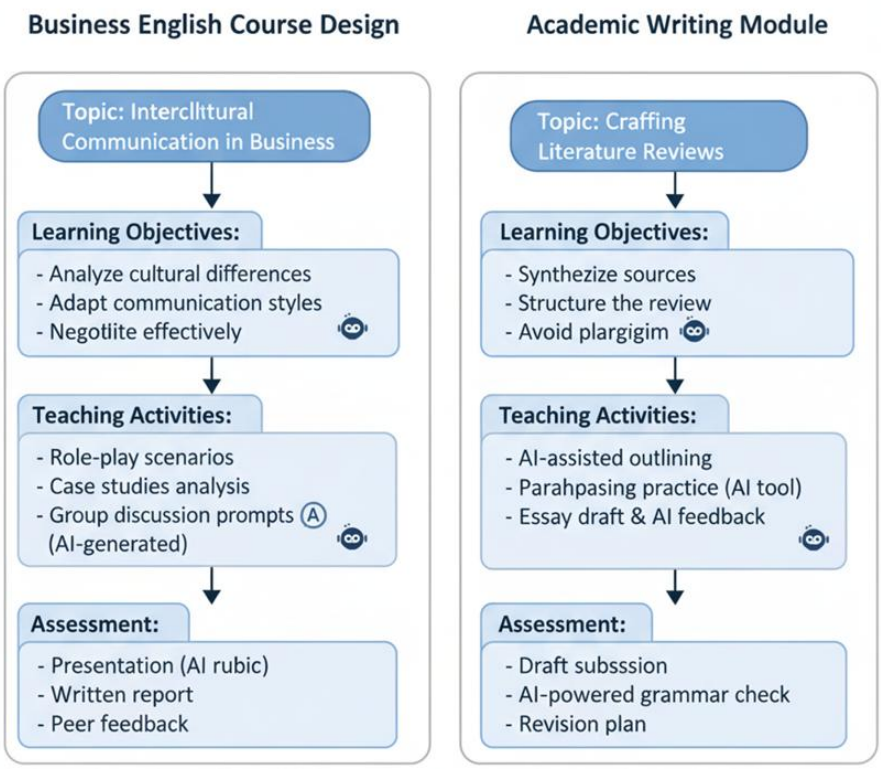

Fig. 3. Examples of instructional designs created with ChatGPT.

F. Data Collection and Analysis Process

The facilitator explained the study's purpose and data confidentiality to teachers and obtained informed consent. Teachers participated in four weeks of training activities followed by semi-structured interviews conducted online via Tencent Meeting platform. Participants indicated time preferences through a questionnaire, and interviews lasting 30-40 minutes were conducted accordingly with audio recording. The scheduling questionnaire used to obtain time preferences collected only nominal-level scheduling data (date and time-slot choices) and was used solely for logistical purposes; it was not used to generate study findings. All substantive study data were collected through open-ended semi-structured interview questions (not closed-ended survey items), and therefore no Likert-type ordinal or interval/ratio measurement scales were involved. The full interview protocol, including all open-ended questions and probes, is available from the corresponding author upon reasonable request, and a read-only version has been deposited at a public repository link that will be provided in the final version of the manuscript. Because the study's substantive instrument is a qualitative interview protocol rather than a quantitative survey, classical psychometric tests of reliability (e.g., Cronbach's alpha) and construct validity are not applicable; instead, trustworthiness was ensured through expert review of the interview guide, inter-coder reliability (simple percentage agreement of 89% and Cohen's Kappa), and maximum variation sampling (see the subsection on Validity and reliability). Given the sample size (n = 13, below the commonly cited n ≥ 30 threshold for quantitative generalization), no inferential statistical tests were performed, and the findings are explicitly framed as institution-specific qualitative evidence rather than as statistically generalizable results.

Semi-structured interview questions were developed within the established case study methodology framework [24], informed by review articles on AI applications in teacher professional development [25]. Interview questions addressed generative AI's applications, impacts, benefits, drawbacks, and optimization suggestions in teaching preparation. Audio-recorded interviews were transcribed verbatim, and three researchers established a coding and category system. Each researcher independently coded the transcriptions, and coding systems were combined after reviewing similarities and differences until consensus was reached.

G. Validity and Reliability

Credibility and transferability were ensured through multiple strategies [26]. Four researchers with foreign language education experience prepared the semi-structured interview form based on training feedback. Five experts reviewed the questions for clarity, resulting in necessary amendments. The maximum variation sampling method secured transferability by examining teachers from various linguistic backgrounds and teaching experience levels. Codes and themes are clearly exhibited with direct quotations from interview data.

Reliability was enhanced through several measures [27]. Interviews were conducted immediately after training sessions to minimize contextual deviation. Researchers posed identical questions to each participant, and all interviews were recorded for verification. Three researchers with doctoral degrees in curriculum and instruction independently coded the data. Inter-coder reliability (ICR) was calculated using the simple percentage agreement formula [28]:

$$\text{Agreement} = \frac{\text{Number of Agreements}}{\text{Total Number of Codes}} \times 100\% \quad (1)$$

Based on this formula, the three researchers achieved a simple percentage agreement of 89%, which is above the 80% threshold commonly reported as acceptable for thematic coding in qualitative research [28]. To further validate the coding consistency, Cohen's Kappa coefficient was also calculated to account for chance agreement:

$$\kappa = \frac{P_o - P_e}{1 - P_e} \quad (2)$$

where P_o represents the observed agreement proportion and P_e represents the expected agreement by chance. The computed Cohen's Kappa value was 0.83, indicating substantial-to-almost-perfect agreement according to the conventional interpretive ranges. It should be noted that these statistics apply to the inter-coder reliability of the qualitative thematic coding, not to a psychometric survey instrument, since no closed-ended quantitative survey was used in this study. Given that the study group (n = 13) falls below the commonly cited n ≥ 30 threshold for quantitative generalization, the interview instrument is considered sufficient for qualitative case study analysis, but the findings are framed as institution-specific and are not intended as a statistically generalizable reference. As shown in Tables II and III, thematic analysis revealed emergent patterns in teacher perceptions regarding generative AI's impact on teaching preparation; the coded themes were then interpreted in alignment with the two research questions.

III. Results

Thirteen teachers were interviewed to investigate generative AI-assisted teaching preparation's effectiveness on work experiences and views about its benefits and limitations. Anonymity was ensured using code names (T1, T2, T3, etc.) consistently across all tables. Teachers' views were analyzed and organized into themes, presented with detailed findings.

A. The Impact of Generative AI on Teachers' Foreign Language Teaching Preparation Experiences

The findings suggest generative AI positively impacts curriculum design, instructional materials development, and teaching activity planning (T1, T3, T4, T5, T6, T8, T10, T11, T12). Teacher T3 noted that ChatGPT helped learn new teaching strategies in authentic contexts with specific examples for classroom implementation. However, limited impact was observed on assessment design (T4, T12) and teaching research capability (T8).

Generative AI improved teachers' work motivation and professional engagement, contributing to more efficient teaching preparation experiences (T1, T7, T8, T9, T10, T12). Teacher T7 appreciated instant feedback and design suggestions that saved time previously spent consulting reference books. Participants emphasized generative AI's adaptability for interactive curriculum design, creative activity development, and exploring pedagogical approaches (T2, T3, T5, T9, T10).

Teacher T9 mentioned that ChatGPT provided cultural information about different French regions, enriching course content authenticity. Table II presents patterns of teachers' views on generative AI's impact on teaching preparation experiences.

TABLE II. IMPACT OF GENERATIVE AI ON TEACHERS' FOREIGN LANGUAGE TEACHING PREPARATION EXPERIENCES

Themes	Category
Impact on specific teaching preparation tasks	Curriculum design capability enhancement: T5, T6, T8, T12 Instructional resource development improvement: T3, T4, T5, T10, T11, T12 Teaching activity planning advancement: T1, T8, T12 Limited impact on assessment design: T4, T12 No impact on teaching research ability: T8
Work motivation and professional engagement	Enhanced work motivation: T1, T7, T8, T9, T10, T12 Elevated professional engagement: T8, T9 No increase in work motivation: T4, T6
Versatility in teaching preparation activities	Creative teaching activity design: T3, T5 Interactive curriculum planning experiences: T2 Cross-cultural teaching content exploration opportunities: T9
Areas for improvement	Occasional technical issues: T7 Limited contribution to deep instructional design: T4

TABLE III. STRENGTHS, CHALLENGES, AND RECOMMENDATIONS ON GENERATIVE AI FOR FOREIGN LANGUAGE TEACHING PREPARATION

Themes	Category
Strengths	Instructional design capability enhancement (T1, T4, T9, T11) Time-saving and efficient resource acquisition (T1, T3, T4, T13) Comprehensive pedagogical knowledge and support (T1, T2, T10) Cross-cultural teaching content development (T1, T2, T10) Teaching vocabulary and expression expansion (T1, T5, T8, T9, T11) Pedagogical knowledge learning and examples (T3, T4, T6, T7, T8) Gamified teaching and flexible use (T1, T5)
Challenges	Over-reliance and capability deterioration concerns (T1, T2) Connection issues and AI-generated errors (T1, T3) Encouraging shortcuts in teaching preparation (T1, T2, T3) Limited effectiveness for oral teaching design (T11) Potential misuse, emotional responsiveness, and accessibility issues (T3, T5)
Recommendations for improvement	Technical enhancements and accessibility improvement (T1, T4, T5) Integration with authentic teaching contexts and interactivity (T2, T5) Novelty and engagement (T2, T5) Efficiency and time-saving capabilities (T3, T13) Addressing potential misuse and limitations (T2, T3) Improved communication and personalization (T3, T4)

Some teachers noted technical difficulties such as unstable connections or insufficiently accurate responses, and limited assistance in deep-level instructional design tasks (T4, T7). Teacher T4 observed that suggestions for complex grammar teaching sequences were often superficial, lacking consideration of students' cognitive developmental stages. Generative AI demonstrates potential to enhance teaching preparation capabilities while fostering motivation and engagement, though refinement remains essential to mitigate constraints and enhance quality.

B. *Teacher Perspectives on Using Generative AI for Foreign Language Teaching Preparation: Strengths, Challenges, and Recommendations*

Teachers' perspectives underscored positive impacts of generative AI in teaching preparation. Teachers praised enhanced instructional design capabilities, with T9 noting improved organization of instructional content and more creative teaching activities using diversified approaches such as task-based language teaching. Generative AI expedited teaching preparation by quickly generating instructional resources and providing pedagogical suggestions (T1, T3, T4, T13). Teacher T1 noted faster access to instructional information, with ChatGPT providing case backgrounds, discussion questions, and role-play activities that saved preparation time.

The tool provided comprehensive pedagogical knowledge and support (T1, T2, T10) and contributed to cross-cultural teaching content development (T1, T2, T10). Teacher T10 observed that ChatGPT provided cultural information about different teaching contexts and celebration differences across English-speaking countries. Teachers mentioned improvements in teaching vocabulary and pedagogical expressions (T2, T5, T8, T9, T11) and enhanced pedagogical knowledge through practical examples (T3, T4, T6, T7, T8). Teacher T6 noted acquiring professional pedagogical terms such as "scaffolding instruction" and "differentiated instruction". Some teachers found the tool useful for gamified teaching (T1, T5). Table III presents teacher perspectives on strengths, challenges, and recommendations of generative AI in teaching preparation.

Teachers identified challenges and potential drawbacks. Concerns about over-reliance emerged (T1, T2), with T1 expressing worry about deteriorating teaching innovation capability and professional judgment. Teacher T1 noted consciously engaging in independent thinking before using ChatGPT as a verification tool rather than replacement.

Concerns included connection issues and AI-generated errors (T1, T3), with T3 recalling inaccurate Japanese honorific examples requiring careful review. Additional concerns involved encouraging shortcuts in teaching preparation (T1, T2, T3) and limited effectiveness for oral teaching design (T11). Teacher T11 noted that oral communication activity suggestions were formulaic, lacking spontaneity and interactivity.

Teachers highlighted potential misuse in assignment design (T3) and need for improved emotional responsiveness and personalized expressions (T3). Teacher T3 explained that ChatGPT's rational responses lacked humanistic warmth when addressing students' learning anxiety. Accessibility issues due to high traffic were noted (T5). Teachers offered recommendations including technical enhancements and increased accessibility (T1, T4, T5), integration with authentic teaching contexts (T2, T5), and improved communication and personalization (T3, T4). Teacher T2 suggested integrating authentic classroom videos to demonstrate strategy application effects. Teacher T4 proposed ChatGPT remember teaching style and preferences for more personalized suggestions.

IV. Discussion

A. The Impact of Generative AI on Teachers' Foreign Language Teaching Preparation Experiences

Results indicate generative AI positively impacts teaching preparation capabilities in curriculum design, instructional materials development, and teaching activity planning, while increasing teacher motivation and engagement [29]. Research confirms that AI-assisted instructional design improves EFL teachers' curriculum planning, instructional organization, pedagogical coherence, and resource application compared to traditional methods [30], and stimulates authentic pedagogical interactions and productivity [31]. These findings align with our results, indicating generative AI supports teachers' professional development across multiple dimensions. The degree of change observed between traditional preparation (teachers' self-reported prior workflow) and AI-assisted preparation was substantial along several dimensions: for curriculum design and instructional resource development, 10 of 13 teachers (approximately 77%) reported a notable reduction in time required for routine tasks (e.g., generating draft lesson outlines, discussion questions, or case backgrounds) compared with their traditional practice, whereas for deep instructional design tasks (e.g., complex grammar sequencing sensitive to students' cognitive development), teachers reported only marginal benefit over traditional methods, consistent with documented limitations of ChatGPT in identifying deeper pedagogical errors [7]. The novel contribution of the present study, beyond what has been reported in [30], [31], lies in the cross-language, teacher-facing focus (English, Japanese, German, French, and Spanish) and in the explicit separation of tasks where AI substantially outperforms traditional practice (curriculum design, resource development) from tasks where it does not (assessment design, oral-communication activity design, teaching research).

Studies emphasize ChatGPT's potential for personalization and collaboration [32], complementing our observation of increased motivation and engagement. The findings are consistent with previous research supporting ChatGPT's effectiveness in teacher professional development [33], though further investigation is needed. ChatGPT offers comprehensive feedback in instructional reflection [34] and improves instructional design capabilities through AI-generated activities and pedagogical feedback [35]. ChatGPT's potential in creating interactive dialogues and cross-cultural communication tasks [36] is particularly relevant in foreign language teaching. Multiple teachers mentioned ChatGPT's assistance in providing cultural background information and designing culturally sensitive activities, though it lacks face-to-face professional development benefits such as practical exercises in authentic contexts and emotional support.

B. Teacher Perspectives on the Advantages and Disadvantages of Generative AI in Foreign Language Teaching Preparation

ChatGPT improves instructional design capabilities by providing teaching ideas, pedagogical feedback, and introducing instructional structures and vocabulary lists, supported by studies emphasizing AI language models' contribution to teaching vocabulary skills [37]. ChatGPT fosters learner-centered teaching and enhances creativity, problem-solving abilities, and professional vocabulary development [38], with AI-assisted training showing significant improvements compared to traditional instruction [30]. ChatGPT eases preparation by saving time through efficient information provision, lesson plan generation, and materials creation [39]. ChatGPT provides opportunities for cultural and creative learning experiences, aiding critical thinking, communication skills, and intercultural competencies vital in language teaching [40], with participants noting enhanced creativity in generating teaching activities.

Participants raised concerns about possible over-reliance on ChatGPT, aligning with documented literature concerns [9]. Researchers recommend teachers maintain vital roles in teaching preparation and exercise caution in AI integration to avoid over-reliance and ensure balanced approaches incorporating technology and human insights. Concerns include emotional and psychological aspects of technology-facilitated learning [41], potential impediment to critical thinking skills and learner autonomy [42], and ChatGPT's generation of incorrect information, biases, ethical concerns, and privacy issues [43]. Teachers indicated occasional technical problems, such as connection issues [44]. These insights suggest ChatGPT's role should be viewed as complementary to traditional teaching methods, ensuring balanced approaches where teachers maximize efficiency while maintaining professional judgment and creativity.

C. Limitations and Recommendations for Future Research

The study's reliance on 13 teachers from a single institution limits generalizability across different disciplinary backgrounds, teaching experience levels, and educational environments. Future research should employ larger and more diverse sample groups across different institutional types, regions, and teacher backgrounds. Technological access and connectivity issues may have prevented full ChatGPT utilization. Teachers used the free ChatGPT 3.5 version, raising questions about whether premium versions would demonstrate different impacts. Future research could compare pedagogical effects of different ChatGPT

versions or other generative AI tools in teaching preparation. Specifically, because all participants were recruited on a volunteer basis from a single comprehensive university in central China under administrative constraints, the findings should be read as institution-specific qualitative evidence rather than as generalizable claims about generative AI in foreign language teaching broadly. In addition, the tool examined in this study was limited to ChatGPT 3.5 (free version); given the substantial capability differences between GPT-3.5 and subsequent model versions (e.g., GPT-4, GPT-4o, and later releases), the applicability of the present findings to more capable current or future generative AI tools is constrained, and the conclusions should not be read as applying to generative AI broadly. A further limitation is that the study includes no student outcome data and no objective measure of lesson quality; all reported benefits such as improved efficiency, enhanced instructional design, and increased motivation are self-reported teacher perceptions, and without external validation (e.g., classroom observation, student learning gains, or blinded expert ratings of lesson plans) it is not possible to establish whether AI-assisted preparation actually improves instructional effectiveness. Future research should therefore combine teacher self-reports with objective measures of lesson quality and student outcomes, compare model versions (e.g., GPT-4/4o and domain-specific tools), and include multi-institution samples.

Guidelines and protocols for ethical and responsible ChatGPT use in teaching preparation should be developed, clearly defining application scope, usage principles, and preventive measures for potential risks. Future research involving quantitative studies to investigate ChatGPT's effectiveness in influencing teachers' professional development outcomes, job satisfaction, teaching beliefs, and attitudes would support more valid, reliable, and generalizable findings. Adopting mixed research methods would combine qualitative depth insights with quantitative breadth coverage, providing comprehensive perspectives on generative AI's role in teaching preparation.

D. Pedagogical Implications

The study holds significant pedagogical implications for foreign language teachers. Generative AI enables teachers to personalize and manage teaching preparation processes at their own pace, unlike traditional standardized training models. AI tools provide customized suggestions based on specific needs and teaching contexts, helping teachers develop unique teaching styles and professional specializations. The interactive nature of generative AI fosters active professional engagement through curriculum design, instructional resource development, and teaching activity planning. However, ChatGPT has not yet been effective in improving oral teaching skills, whereas other AI applications like "Elsa Speak" benefit pronunciation teaching [45], suggesting the need to select appropriate AI tools for different teaching skills.

Generative AI provides varied content enabling teachers to gain insights into different cultural backgrounds and pedagogical structures, particularly important for cultivating global perspectives and cross-cultural teaching competencies. In globalization contexts, foreign language teachers must cultivate students' intercultural communicative competence, where AI tools offer unique advantages in providing multicultural perspectives. Teachers should incorporate generative AI as supplementary support while engaging in authentic teaching practice reflection. Balancing generative AI use with professional autonomy development prevents possible teaching capability deterioration and over-reliance. Teachers should view AI as enhancing rather than replacing professional judgment, critically evaluating AI-generated content and adapting it according to specific teaching contexts while maintaining sensitivity to student needs.

E. Theoretical Implications

Generative AI integration into teaching preparation presents theoretical implications for educational theory. Generative AI demonstrates compatibility with personalized learning approaches [46], offering individualized feedback and guidance tailored to individual teaching needs. Unlike traditional "one-size-fits-all" training models, AI-supported personalized learning provides customized support based on knowledge background, teaching experience, and professional development needs, reflected in content, learning pace, and depth.

Aligned with Self-Regulated Learning theory [47], generative AI guides teachers in teaching strategy selection and time management. Teachers learn through AI interaction to set teaching preparation goals, monitor progress, evaluate outcomes, and make adjustments. This self-regulation capability cultivation is crucial for long-term professional development, enabling teachers to become active managers of professional growth. Within Cognitive Load Theory [48], generative AI's adaptable nature optimizes cognitive processing by adjusting information complexity based on teachers' knowledge level and comprehension ability, avoiding cognitive overload or resource waste. Under Engagement Theory [49], generative AI's interactive nature enhances teachers' active participation through prompt feedback and interactive learning experiences, promoting deep cognitive engagement and emotional investment that maintain sustained learning motivation and cognitive processing. These theoretical lenses are consistent with recent empirical work on ChatGPT in language education: prior IJACSA studies have demonstrated that ChatGPT can generate chatbot dialogues suitable for English-as-a-foreign-language learners at the CEFR A2 level [50] and can provide effective personalized learning experiences in higher education when guided by established instructional models such as the 5Es framework [51], offering complementary empirical support for the theoretical mechanisms discussed above.

V. Conclusion

In conclusion, we explored the impact of generative AI-assisted foreign language teaching preparation experiences through the views of university foreign language teachers on the opportunities and challenges of generative AI-assisted teaching preparation. The findings revealed generative AI's positive impact on curriculum design and limited impact on teaching research, development of pedagogical knowledge and instructional resource application capabilities, motivation of participants' professional development, and promotion of interactive teaching preparation experiences. Moreover, generative AI was found to contribute to participants' understanding of diverse teaching cultures and fostered their creative thinking capabilities during training activities.

However, a significant concern that emerged from the results was the potential over-reliance on generative AI. The novelty of this study lies in three aspects. First, it provides cross-language empirical evidence on teacher-facing (not student-facing) preparation workflows with generative AI across five languages (English, Japanese, German, French, and Spanish), whereas prior studies have predominantly examined AI in student-facing tasks such as writing evaluation or question generation. Second, it differentiates the magnitude of AI's impact across specific preparation sub-tasks, showing that curriculum design, instructional resource development, and teaching activity planning benefit substantially (approximately 62–77% of teachers reporting positive impact), whereas assessment design, oral-teaching design, and teaching research benefit only marginally. Third, it documents a concrete pattern of over-reliance risk that emerges even within a short four-week intervention, thereby informing institutional guidelines before large-scale adoption. The implications for science are that future research should move beyond self-reported teacher perceptions toward externally validated measures of lesson quality and student outcomes, and should systematically compare generative AI model versions. The implications for society are that universities and teacher-training programs should treat generative AI as a complement to, not a substitute for, professional judgment, and should develop ethical-use guidelines that explicitly define application scope, prevent over-reliance, and protect academic integrity. The main shortcomings of the present study, namely the small single-institution sample (n = 13), the exclusive use of ChatGPT 3.5, and the absence of objective lesson-quality and student-outcome measures, should be regarded as directions for further research: future work should employ larger multi-institution samples, compare more capable model versions (e.g., GPT-4/4o and successor models), and combine teacher self-reports with classroom observation and student learning data.

***Abstract*—The study analyses Turkish and English tweets about climate change on the social media platform Twitter and comparatively examines individuals" perceptions, concerns, and emotional reactions to this issue. A total of 2,046 Turkish and 18,000 English tweets were collected; 1,104 Turkish and 6,449 English tweets were analyzed after the cleaning process. Artificial intelligence-based methods such as text mining, sentiment analysis, and topic modelling are used. Topic modelling with Latent Dirichlet Allocation (LDA) identified prominent themes in tweets in both languages. Sentiment analysis is performed using deep learning techniques to categories tweets into positive, negative, and neutral categories. The findings show that English tweets contain stronger emotional reactions, while Turkish tweets contain a higher proportion of neutral expressions. Additionally, it was observed that the perception of climate change can differ in local and global contexts. Based on a multidimensional analysis of social media data, the study provides valuable insights into the development of environmental communication strategies. The comparison of Turkish and English tweets contributes to understanding the effects of cultural contexts on climate change perception. The findings have important implications for policymakers and environmental awareness campaigns, as they highlight the need for tailored communication strategies that consider cultural differences in climate change perception.**

***Keywords*—Climate change; awareness; social media; communication; machine learning; sentiment analysis; deep learning**

I. Introduction

Climate change is recognized as one of the greatest environmental, economic, and social challenges of our time. Scientific evidence shows that this phenomenon significantly threatens not only natural systems but also human life and global economic balances [1]. In the 21st century, accelerating climate change due to increasing carbon emissions and greenhouse gases has made social awareness and collective action more important than ever. However, the solution to such a complex and multidimensional problem is closely related not only to scientific developments but also to the attitudes and behaviors of societies shaped through access to information and communication channels. In this context, social media platforms play a central role in educating and raising awareness about climate change.

This study aims to examine how Turkish and English tweets on the social media platform Twitter create a social perception in the context of climate change and how users feel about this issue. The study is based on a dataset consisting of 2046 Turkish and 18,000 English tweets, and after the data cleaning process, 1104 and 6449 tweets were analyzed, respectively. The methods used include text mining, sentiment analysis, and topic modelling, and thus, social media content in different languages is evaluated from a comparative perspective.

In this study, text mining and deep learning methods are used to analyses social media data. Texts were cleaned with natural language processing (NLP) techniques, and n-gram analyses were performed. Latent Dirichlet Allocation (LDA), an unsupervised machine learning method, is used to identify themes in the tweets, allowing for a comparison of themes in different languages. In the sentiment analysis phase, Long Short-Term Memory (LSTM) with a deep learning model is used to classify tweets as positive, negative and neutral. These methods reveal the climate change perceptions and emotional tendencies of social media users in a multidimensional way.

The originality of the study stems from the fact that it comparatively analyses how a global problem such as climate change is perceived at local and global levels through social media data. Although there are many studies in the literature on the impact of social media on environmental awareness, such cross-lingual comparisons are limited. For example, Lewandovsky et al. (2019), while examining how social media affects the perception of climate change, stated that analyses in the local and global contexts are limited [2]. This study aims to fill this gap by revealing how perceptions of climate change differ in different cultural and linguistic contexts through Turkish and English tweets.

Unlike recent multilingual studies that rely on transformer-based architectures such as BERT or XLM-R for cross-lingual alignment, this study adopts a comparative approach using language-specific datasets without explicit embedding alignment. This allows for the exploration of natural linguistic divergence in sentiment and topic structures.

Based on this motivation, the study tests the following hypothesis:

*Corresponding author.

H1: There are statistically significant differences between Turkish and English tweets in terms of sentiment distribution and topic structure.

This research makes three main contributions to literature: Firstly, by providing a multidimensional analysis of social media content on climate change, it facilitates the understanding of individuals' perceptions and attitudes towards the issue. Secondly, the comparative evaluation of social media content in different languages using sentiment analysis and topic modelling methods reveals the effects of cultural contexts. Thirdly, the findings have the potential to provide concrete recommendations for policymakers and stakeholders developing environmental communication strategies.

As the impacts of climate change are rapidly increasing, it is critical to understand individuals' perceptions on this issue and develop the right communication strategies. The results of this study may contribute to raising awareness on combating climate change and shed light on the development of more effective environmental communication strategies through social media.

II. Literature

The last two centuries, during which technology has made it possible to create considerably accurate measures, have not only revealed the phenomenon of climate change but also given us a better understanding of the threat it poses to the well-being of life on Earth and the ecological stability of the planet. These measures have led to a growing international recognition of the threat. In the 20th century, most scientists have not seen greenhouse warming as a severe problem. It took decades of evidence, fierce debates, and hundreds of panels in many countries to convince them they were wrong. In the late 1970s, these efforts led to the conclusion that warming might one day become a problem. But, in the current century, scientific meetings and respected panels have concluded that warming is likely to become a serious problem [3].

Considering current knowledge, climate change is recognized as one of the greatest threats to human life. However, its trajectory can be somewhat affected depending on human activities in the face of this threat [1]. Climate change is predicted to seriously impair the life support systems of many species, drastically reduce the population, and result in crucial and fundamental changes to social structures. Therefore, the importance of communication on the topic is revealed by how to approach it and guarantee cooperation, creative policies, appropriate technological developments, and new behaviors [4]. Pearce et al. (2019), social media such as Twitter are important tools for enabling everyday debate and negotiation on climate change [5]. Dutton argues that the internet acts as a "Fifth Estate" and uses estate theory to illuminate the most significant power shift of the digital age [6]. Through the power of the internet, networked individuals can control facts and make social interventions in a civic context. The internet gives them this power, and digital media essentially increases the information and communication power of ordinary individuals. Communities that can independently and strategically search, create content, network, and collaborate on any topic are able to leak information in this way.

The relationship between social media and the construction of people's ideas about climate change and changing attitudes has been the focus of many studies. For example, Lewandovsky et al. (2019) measured attitudes towards climate change on social media and found that science-based posts reinforced belief in global climate change, but negative comments on these posts reduced perceived consensus [2]. It was observed that social media is a more powerful tool in terms of receiving information and forming attitudes with this information. Accordingly, new media and user-generated content have twice the impact size compared to traditional and centralized content-generating channels [7].

Comparative studies on the relationship between media coverage and climate change, such as our current study, are limited in number but have been able to provide estimates with quite significant data. For example, Thaker's (2023) large-scale comparative study on the coverage of climate change in international media, based on data from the 2022 Yale Meta survey of 110 countries, found that the relationship between perceptions formed through social media and protest intention is related to personal harm. Accordingly, because poor and developing countries are more exposed to the impacts of climate change, they perceive climate change as a greater risk and are more willing to participate in protests, even if such content receives low media coverage [8].

The nature of the media helps shape public opinion on climate change [1]. By their very nature, online posts have several advantages over traditional media in influencing public opinion. Digital activism, which stands out among these, provides an advantage. The most prominent example of this is the case of Greta Thunberg. As seen in the phenomenon of raising online awareness through digital activism, which has entered the literature as the "Greta Effect," Greta Thunberg has influenced both policymakers and the news media to take responsibility for climate change, thanks to her supporters or critics [9].

The existing literature on social media assumes that three main mechanisms work in climate change through posts: norm diffusion, opinion leadership, and public opinion formation [10]. On the other hand, research has found that those who express an opinion on this issue exhibit some categorical reactions: deniers, jokers, advocates, skeptics, and realists [11-14]. Considering such categories in climate communication can better determine its direction. Yet another study found that a high concern for climate resulted in greater engagement in online climate change, and adolescents who cared more about the norms of their peers had higher levels of online climate change because of incidental exposure [15]. In this context, it is seen that many variables, approaches, and categories can be revealed through social media research on climate change. On the other hand, due to the rapid advancement in communication technologies, climate-based information disinformation has become even more possible, and misinformation spread has become extremely easy and fast [2]. Therefore, the fact that a very useful and slippery ground such as social media plays an active role in climate communication emphasizes conscious and effective use as well as some precautions.

Just as Climate Central, which "conveys the science, impacts, and solutions of climate change to the public and decision-makers" (2024), provides reliable information on the issue through its posts on various media channels, supporting social media content with realistic arguments such as visuals and videos, the active participation of scientists, who are seen to have a significant impact on public participation and the responsibility of providing first-hand information, and the role of scientists being free from doubt among both the public and their colleagues can make dialogic and participatory climate communication possible [12].

III. Materials and Methods

In this study, data were collected from the Twitter platform in Turkish and English to analyses social media posts on climate change. The data was collected using the API of the X platform over a period of one month. In total, 2046 Turkish and 18,000 English tweets were obtained. During the data collection process, the keyword "climate change" is used. The focus of the study is to understand the perceptions, concerns, and perspectives of users on this issue. In the text preprocessing stage, repetitive, incomplete, noisy, and irrelevant content was removed, and finally, 1104 Turkish and 6449 English tweets were included in the study.

Formally, the sentiment classification problem can be defined as follows: given a tweet x_i, the goal is to predict its sentiment label $y_i \in$ {positive, negative, neutral}. The model aims to learn a function $f(x_i) \rightarrow y_i$ that minimizes classification error.

The LSTM model was implemented with the following configuration: embedding dimension = 100, batch size = 32, epochs = 10, optimizer = Adam, and dropout rate = 0.5. All experiments were conducted using TensorFlow/Keras, and model evaluation is performed using a 70/30 train-test split.

Text mining, topic modelling, and sentiment analysis methods are used to analyses the tweets. Text mining enabled the analysis of word frequencies and text patterns in tweets, and thus meaningful information was extracted from the data. Topic modelling is used to identify the prominent themes in tweets and to determine which topics users focus on. Sentiment analysis is used to identify positive, negative, and neutral emotional tones in tweets. These methods enabled comparative analysis of social media content in different languages and made it possible to evaluate perceptions on climate change in a multidimensional way.

A. Data Set

The data set used in the study was obtained through the API provided by the X platform. The main reason for choosing the X platform is that it is a social media platform that is heavily used by users and provides data from a wide user base on social issues such as climate change [16]. This increased the inclusiveness of the study and the generalizability of its results.

The keyword "climate change" was preferred in the data collection process. The reason for this is that climate change is of increasing importance in both global and local contexts and that social media users have various opinions and perceptions on this issue, providing a suitable data source for the analyses targeted by the study. In this context, the choice of keywords aims to facilitate the understanding of users' perceptions and perspectives on the issue.

The data was collected over a period of one month using the Python programming language and the API of the X platform. The reason for choosing a one-month time is that this period provides the intensity and diversity of users' posts on the topic that can form a meaningful sample. In addition, this period ensured that the data set was kept in analyzable sizes and the data processing process was manageable [17, 18]. However, the dataset is limited to a one-month time frame and does not include demographic or geographic metadata due to API constraints. Therefore, it may not fully represent the broader population. Future studies should incorporate longer temporal coverage and user-level metadata to improve representativeness.

In this process, a total of 2,046 Turkish tweets and 18,000 English tweets were collected. During the preprocessing phase, the dataset was systematically refined by removing duplicate entries, noise, incomplete and inconsistent records, as well as irrelevant content, to enhance data quality, reduce potential bias, and ensure the robustness and reliability of subsequent analyses. These procedures are aimed at increasing the accuracy of the analysis process and to obtain meaningful results. After the cleaning process, the number of tweets suitable for analysis was determined to be 1104 for Turkish and 6449 for English. The data cleaning process involved removing duplicate tweets, non-relevant content (such as advertisements), tweets containing only URLs or hashtags, and posts with insufficient textual information. Additionally, tweets with excessive noise, including random characters and non-linguistic symbols, were excluded.

To minimize potential bias, the same cleaning criteria were applied consistently across both datasets. Furthermore, sentiment distributions were checked before and after preprocessing, and no significant distortion in class proportions was observed, suggesting that the filtering process did not systematically bias the results.

Table I presents examples from the dataset, including multilingual tweets addressing climate change issues.

TABLE I. Sample Dataset

Tweet	Language
Whatever the cause, climate change seems to be an area where countries will work together and struggle to maintain a humane life through joint decisions.	Tr
We must stop the development of agricultural land. Global warming and climate change will make it extremely difficult for people to access healthy food and water.	Tr
In recent years, dam occupancy rates have started to decrease due to reasons such as climate change, drought and increase in water use.	Tr
Serious policies should be developed on climate change and drought. Yes, to green policies for a more loveable world...	Tr
Our planet is the only place where humanity lives and therefore its protection is of utmost importance. However, human activities have resulted in several environmental problems such as overconsumption of natural resources, environmental pollution, climate change and habitat loss.	Tr
The climate crisis forces us to reconsider our values.	En

Humanity must fight climate change much harder, or losses and damage, and suffering, will continue to mount.	En
There's no solution to climate change - and no one can do it alone	En
Climate change is the threat that will unite us all.	En
Scientists revive viruses frozen thousands of years ago in the Arctic to predict the dangers that could be unleashed by melting because of climate change	En

B. Text Mining

Text mining is a big data analysis method that generates meaningful information from text data. Text mining is a data mining study whose data source is text, and it enables the transformation of unstructured data into structured data. Text mining is the process of extracting confidential information from the data in the text that does not have a clear format and formatting the disorganized data [19].

The first thing to do with the data in the analysis process is to pre-process the data. In a data mining process, previous studies have shown that the preprocessing process covers up to 60% of the necessary work, and preprocessing the data contributes 75% to 90% to the success of the data mining project. Non-textual characters such as !, ?, /, +, and emoji in the documents are removed from the data set. The stop words that occur in large numbers in the documents are extracted based on the previously prepared stop word list. Since the use of ineffective words during indexing reduces the size of the index files, it increases memory usage and query processing efficiency [20].

N-gram is a method used to search and compare data or to determine the number of repetitions. Term frequency is used to calculate the term weights in a document. Reverse term frequency is used to find the number of occurrences of the word in more than one document and tries to understand whether this word is a term or a conjunction, etc. (stop-words). It is found by taking the absolute value of the logarithm of the number of documents in which the term occurs divided by the number of documents [21].

These feature extraction methods contribute to model performance by enhancing semantic representation of textual data. However, alternative feature representations such as contextual embeddings (e.g., BERT) were not evaluated, which constitutes a limitation of the study.

C. Sentiment Analysis

To train the supervised LSTM model, sentiment labels were generated using a semi-automated approach. Initially, tweets were labelled using lexicon-based sentiment resources and existing benchmark datasets. Subsequently, a subset of the data was manually reviewed to ensure consistency and correctness of the assigned labels. This approach improves the reliability of the training data and reduces potential bias arising from fully automated labelling. Sentiment analysis is the field of study that analyses people's opinions, emotions, evaluations, and attitudes through written language. Users' thoughts about a particular event are extracted through text analysis, and then emotions are predicted based on the analysis. Due to the increasing data flow, sentiment analysis has become one of the most active topics of natural language processing and text mining [22].

Sentiment analysis studies are questioned and analyzed whether the texts have positive, negative, or neutral content. According to the results of this analysis, the attitude of individuals or a certain group on the subject related to the study is determined [23].

The methods used in detecting sentiment polarity fall under two main categories. These categories are machine learning-based methods and word-based methods. In machine learning-based methods, the system is trained with pre-labelled training data, and emotion classification is performed with the trained system. Any of the machine learning classification algorithms can be used. Under this category, methods based on syntactic analysis of sentences using natural language processing methods and tools are used. There is no need for labelled training data as in supervised machine learning methods. With natural language processing tools and methods, sentences are analyzed, and semantic inferences are made by detecting emotion terms in sentences. A dictionary of emotion terms is often used to detect emotion expressions in sentences [24, 25].

D. Machine Learning

Machine learning is an important subfield of artificial intelligence. Its main purpose is to use computational methods to extract knowledge from data. Machine learning has a wide range of applications, including handwriting and speech recognition, robotics and computer games, natural language processing, brain-machine interfaces, etc. [26].

The classification method, one of the basic methods of data mining, is based on the learning algorithm [27]. Classification algorithms divide the data into certain groups (classes) according to their common characteristics by targeting the desired information. Classification algorithms are run in two stages. Firstly, the classification model is created by analyzing the data set determined as training data. In the second stage, the obtained classification model is applied to a new dataset, and the presence of the determined classes in the data is investigated [28].

Deep learning is a subset of machine learning that enables models to learn hierarchical representations from data through multiple layers of neural networks [29]. Unlike traditional machine learning techniques that rely on handcrafted features, deep learning models automatically extract relevant features from raw text data. In the context of sentiment analysis, deep learning provides a powerful framework for capturing complex language patterns and contextual meanings in social media posts [30].

One of the primary advantages of deep learning for text analysis is its ability to process sequential data effectively. Social media posts, such as tweets, are inherently sequential and often contain nuanced expressions, abbreviations, and informal language structures [31]. Deep learning models, particularly those based on recurrent neural networks (RNNs) and transformer architectures, have demonstrated superior performance in sentiment classification tasks compared to traditional machine learning methods [32].

Long Short-Term Memory (LSTM) networks stand out as a specialized type of recurrent neural network (RNN) particularly well-suited for processing sequential data [33]. Unlike

traditional RNNs, which struggle with long-range dependencies due to the vanishing gradient problem, LSTM networks incorporate memory cells and gating mechanisms to retain relevant information over extended sequences. This capability makes LSTM an ideal choice for analyzing textual data, where contextual relationships between words play a crucial role in sentiment classification.

The architecture of an LSTM network consists of three key gates [34]:

- Forget Gate: Determines which information from the previous time step should be discarded.
- Input Gate: Controls how much new information should be added to the memory cell.
- Output Gate: Regulates the amount of stored information that contributes to the current output.

For this study, the LSTM-based sentiment analysis model was trained on a dataset of Turkish and English tweets related to climate change. The preprocessing pipeline involved tokenization, stop-word removal, and word embedding using pre-trained word vectors. The model was structured with multiple LSTM layers, dropout regularization to prevent overfitting, and a SoftMax activation function in the output layer to classify tweets into three sentiment categories.

The training process involved optimizing the categorical cross-entropy loss function using the Adam optimizer. The dataset was split into training and validation sets to evaluate model performance [35]. Additionally, performance metrics such as accuracy, precision, recall, and F1-score were computed to assess the effectiveness of the LSTM model in sentiment classification.

The deep learning models were implemented using TensorFlow and Keras libraries. The input text data was vectorized using word embeddings such as Word2Vec and GloVe to enhance semantic understanding. Hyperparameters, including batch size, learning rate, and the number of LSTM units, were fine-tuned through grid search and cross-validation [36].

To ensure robustness, the model was trained on a diverse dataset comprising tweets in both Turkish and English. The bilingual nature of the dataset posed challenges in terms of language-specific features; however, LSTM's ability to capture sequential dependencies allowed for effective sentiment classification across languages. Data augmentation techniques were also employed to balance class distributions and improve generalization [37].

By leveraging deep learning techniques, particularly LSTM networks, this study effectively classified climate change-related tweets based on sentiment polarity. The proposed approach outperformed traditional machine learning methods by capturing complex linguistic patterns and long-term dependencies in textual data. The insights derived from this analysis provide valuable contributions to understanding public perceptions of climate change and developing targeted environmental communication strategies. It should be noted that this study does not employ explicit cross-lingual embedding alignment or normalization techniques. Instead, Turkish and English datasets are analyzed independently to preserve language-specific characteristics. While this approach limits direct semantic comparability, it enables the identification of natural linguistic differences between languages.

E. Topic Modelling

Topic modelling (TM) is one of the subfields of text mining. Its main goal is to reveal hidden or open topics in documents. It has an important place among the subfields of text mining, especially with its increasing importance and studies carried out in recent years. KM is a method in which subject classification is made unsupervised in a document [38].

Topic modelling methods are based on the principle that topics with probability distributions on words come together randomly and form documents. Latent Dirichlet Allocation (LDA) is a generative graphical model used to model discrete data such as documents and to reveal the topics that make up the document. "Latent" here refers to finding the meaning of the document by discovering the hidden topics that make up the document. What is meant by generative model is the generation of the words in the document by a simple probabilistic process within the framework of hidden (random) variables, i.e., the creation of the document. GDA, which is a completely unsupervised method, does not require any prior knowledge and works based on a bag-of-words approach. While the placement of words in the document is ignored, the co-occurrence of words is used in this method [39].

Each document consists of a random mixture of topics, and each of the words that make up the document is chosen from one of the topics. The topics are also probability distributed from words in a fixed dictionary.

The basic components of the LDA model are as follows [39]:

- Number of topics (K): This specifies the number of topics that the model will predict.
- Document topics (θ_d): Each document is represented as a mixture of K topics. Here, θ_d is the topic distribution of the d-th document.
- Topic word distributions (ϕ_k): Each topic represents a distribution of words. That is, ϕ_k is the word distribution of the k-th topic.
- Word vector (w_d, n): The words that make up each document. Each word is generated by a topic.

The mathematical structure of the LDA model can be expressed as follows:

$$p(w, z\ I\alpha, \beta) = \prod_{d=1}^{D}\left(\prod_{n=1}^{N_d} p\left(\left(w_{d,n}|z_{d,n}, \beta\right)p\left(z_{d,n}|\theta_d\right)\right)\right)p(\theta_d|\alpha)p(\beta|\eta) \quad (1)$$

where, w_d, n is the n-th word in the d-th document, and z_d, n is the predicted topic label for this word. θ_d represents the topic distribution of the d-th document. β and α are hyperparameters of Dirichlet distributions.

IV. RESULTS

Fig. 1 shows the block diagram of the study, illustrating the sequential stages of data collection, preprocessing, and analysis.

Fig. 1. Block diagram.

In total, 2046 tweets in Turkish and 18,000 tweets in English were initially collected from Twitter using relevant climate change-related keywords. The dataset underwent a rigorous preprocessing phase, including text cleaning, tokenization, and stop-word removal, to enhance the quality and reliability of the textual data. Following this process, tweets deemed unsuitable for analysis due to excessive noise, irrelevance, or duplication were excluded. As a result, the final dataset comprised 1104 Turkish tweets and 6449 English tweets that met the criteria for further sentiment and topic analysis.

The refined dataset was then subjected to deep learning-based sentiment classification and topic modelling to uncover prevalent themes and emotional tendencies in climate change discussions. The subsequent sections present the findings of the sentiment analysis, topic modelling results, and a comparative evaluation of Turkish and English tweets regarding climate change perceptions.

To classify the tweets according to their sentiment using machine learning methods, the data set was divided into two as training and test. Seventy percent of the data set is divided into training and 30 percent test data. At this stage, training and test sets were randomly generated to ensure data diversity. In all the algorithms used for sentiment analysis, 70% of the data set allocated for training is used while creating the model. After the model-building process, 30% of the test data is used to predict the model, and the performance of the model was evaluated.

A. Sentiment Analysis

Deep learning, a subset of machine learning, is used for sentiment analysis. Classification is the process of assigning a data set to the most appropriate one of the different and predetermined training data categories. The process of classifying the tweets according to their sentiments was carried out according to the climate change comments in the tweets. The aim of this study is to classify tweets about climate change with three emotions: positive, negative, and neutral.

Precision, recall, accuracy, and F1 metrics are used to evaluate the success of the model. TP (True Positives) refers to true positive predictions, FP (False Positives) refers to false positive predictions, FN (False Negatives) refers to false negative predictions, and TN (True Negatives) refers to true negative predictions [15]:

Precision indicates how accurate the result is in the model created.

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

Recall shows the ability to find the correct examples in the created model.

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

Accuracy indicates the success of the model in predicting the target classes.

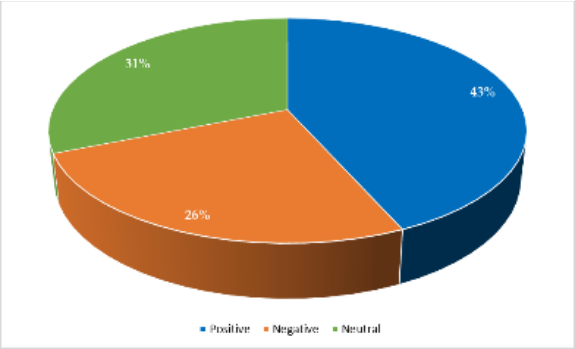
$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (4)$$

F1 Score is the harmonic mean of precision and recall.

$$F1 = \frac{2 * Recall * Precision}{Precision + Recall} \quad (5)$$

Table II shows the deep learning performance evaluation.

TABLE II. PERFORMANCE MEASUREMENT



Metrics	English Tweet	Turkish Tweet
Precision	0.912	0.935
Recall	0.932	0.946
Accuracy	0.903	0.924
F Score (F1)	0.922	0.940

The deep learning model performed well on both English and Turkish tweets, with the metrics for Turkish tweets being generally better. Precision and recall values show that the model correctly captures positive classifications and misclassifications are low in both languages. For Turkish tweets, precision 0.935, recall 0.946 and F1 score 0.940 are higher than English tweets (0.912, 0.932 and 0.922, respectively). In terms of accuracy, Turkish tweets (92.4%) performed better than English tweets (90.3%). These results suggest that the language features or data structure of Turkish tweets may be better learnt by the model and that the model works more effectively with Turkish data. However, no statistical significance testing or confidence interval estimation was conducted. Future research should include hypothesis testing and variance analysis to assess the robustness of the observed performance differences. Table III shows the sentiment distribution of the tweets.

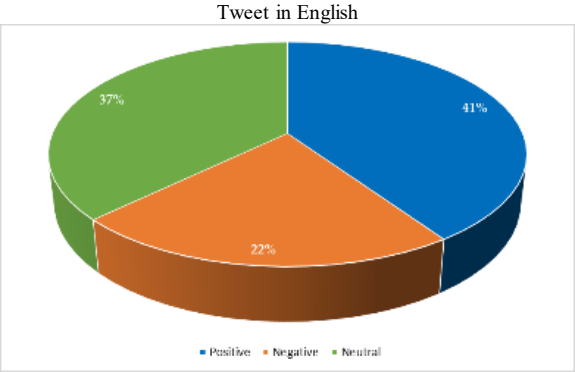


TABLE III. SENTIMENT STATISTICS

Sentiment Analysis	Tweet Number	
	EN	TR
Positive	2795	447
Negative	1646	246
Neutral	2007	411

The sentiment analysis results in Table III show that there are similar distributions between English and Turkish tweets. In both English and Turkish tweets, positive sentiment has a higher rate than other categories. Fig 2 shows the distribution of sentiment in terms of percentage.

Tweet in English

Tweet in Turkish

Fig. 2. Sentiment mood distribution.

In Fig. 2, 43.3% of the tweets in English were positive, 25.5% were negative, and 31.2% were neutral, while these rates were 40.5% positive, 22.3% negative, and 37.2% neutral in Turkish tweets, respectively. These distributions show that a generally positive or neutral perspective on climate change is dominant in both languages. However, the slightly higher rate of neutral sentiments in Turkish tweets compared to English tweets may suggest that Turkish-speaking users approach the issue with a more neutral or observant approach. In English tweets, the difference between positive and negative sentiments is more pronounced than in Turkish, which may indicate that English-speaking users may tend to have a stronger emotional response. However, this interpretation should be treated with caution, as the dataset is limited to Twitter users who shared posts using specific climate change-related keywords within a defined time frame.

B. Text Mining

The n-gram and term frequency and inverse term frequency methods are used to determine the core attributes. Word frequencies show the number of times words are used in the data set. Word frequencies are shown using a collection of matrix terms from the most frequently used words to the least frequently used words in the dataset. Term Frequency (TF) is the frequency of repetition of a term within a document. Since each document is different in length, a document is likely to appear much more often in longer documents than in shorter ones. Inverse Document Frequency (IDF) is the importance of a term in the entire document collection (D). According to IDF, the importance of a term is directly proportional to the frequency with which the term is used in the document and inversely proportional to the number of times the term is used in the entire document pool. Low-frequency terms have a high IDF score; high-frequency terms have a low IDF score. The term frequency-inverse text frequency (TF-IDF) value takes a high value if the term occurs a lot in a small number of documents. If the term is used in all documents, the TF-IDF value takes its lowest value [40].

Table IV shows the most frequent words extracted from English tweets related to the research topic.

TABLE IV. FREQUENCY LIST OF ENGLISH TWEETS

Positive	Negative	Neutral
(“China”, 153)	(“China”, 98)	(“China”, 185)
(“World”, 116)	(“Global”, 77)	(“Energy”, 152)
(“Energy”, 91)	(“Energy”, 49)	(“Global”, 50)
(“Carbon”, 77)	(“Money”, 39)	(“Money”, 48)
(“Natural”, 70)	(“Fossil”, 39)	(“Help”, 44)
(“Weather”, 61)	(“Government”, 37)	(“Warming”, 28)
(“Power”, 57)	(“Weather”, 36)	(“Weather”, 28)
(“Environmental”, 56)	(“Food”, 32)	(“Government”, 28)
(“Fossil”, 53)	(“Water”, 32)	(“Control”, 24)
(“Government”, 50)	(“Warming”, 32)	(“Carbon”, 22)

The analysis of positive, negative, and neutral words in English tweets in Table IV shows that discussions on climate change have a multidimensional structure. Among the positive words, terms such as “China” and “energy” point to promising developments such as renewable energy investments and carbon-neutral targets, while expressions such as “world” and “natural” reflect a positive view of global cooperation and environmentally friendly approaches. On the other hand, in the negative category, words such as “China,” “fossil,” and “government” represent criticism of carbon emissions, dependence on fossil fuels, and political inefficiencies. Neutral words, on the other hand, usually consist of terms used in neutral contexts such as “energy”, “global,” and “money,” and are used to describe news, policies, or general situation assessments related to climate change. These data reveal that, as stated in the literature [6], public perception of climate change is balanced between both positive and negative emotions and neutral information.

Table V shows the most frequent words extracted from Turkish tweets related to the research topic.

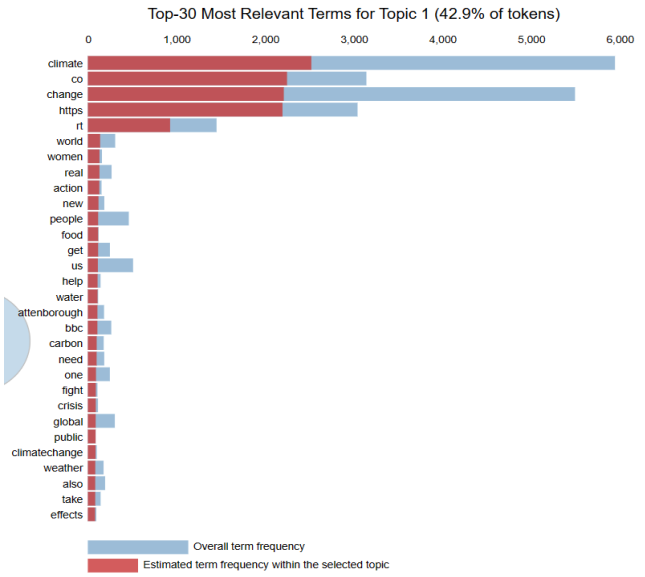

TABLE V. FREQUENCY LIST OF TURKISH TWEETS

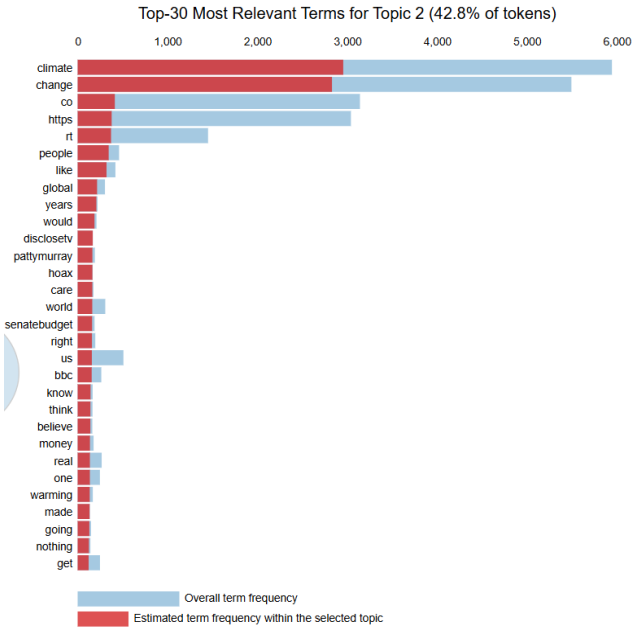
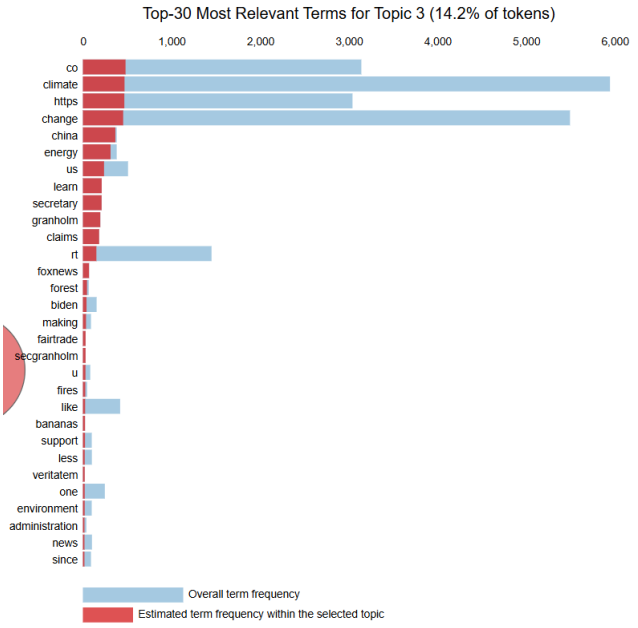
Positive	Negative	Neutral
(“Environment,”, 106)	(“Global”, 60)	(“Urbanization”, 71)
(“Science”, 96)	(“Food”, 22)	(“Environment,”, 70)
(“Minister”, 89)	(“Companies”, 21)	(“Minister”, 49)
(“Urbanization”, 74)	(“Earthquake”, 17)	(“Presidency”, 32)
(“Global”, 40)	(“Environment,”, 15)	(“Education”, 18)
(“Warming”, 30)	(“Damage”, 13)	(“Disaster”, 31)
(“Water”, 24)	(“Warming”, 12)	(“Water”, 15)
(“Earth”, 24)	(“Water”, 12)	(“Management”, 12)
(“Economic”, 17)	(“Population”, 11)	(“Municipality”, 10)
(“Temperatures”, 14)	(“Carbon”, 9)	(“Cost”, 29)



In Table V, the most common positive, negative, and neutral words in Turkish tweets in the context of climate change show that the perception of this issue has a multi-faceted structure. "Environment" and "science", which stand out among the positive words, reflect promising approaches to environmental and scientific issues, while terms such as "urbanization" and "minister" show that urbanization and initiatives taken at the leadership level are discussed in a positive framework. In contrast, words in the negative category, such as "global" and "food," represent concerns about global challenges and the food crisis. Expressions such as "earthquake" and "damage" indicate negative perceptions about the disasters triggered by climate change and their consequences. Neutral words such as "presidency," "management," and "disaster" are terms generally used in political, administrative, and crisis management discussions. The frequency of use of these words reveals that social and managerial sensitization about climate change has increased at both local and global levels. As stated in the literature [6], messages about climate change in the media and social media are mostly presented as a balance of both positive (solution-oriented approaches) and negative (worrisome effects) content. In this context, the discussions in Turkish tweets show that local problems (water resources, natural disasters) and solution proposals (scientific approaches, leadership) form a blended narrative.

C. Topic Modelling



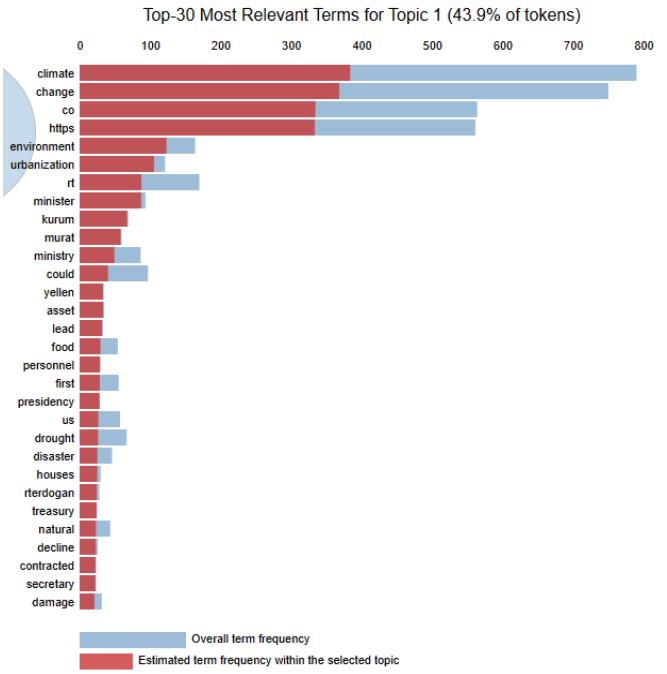
The algorithms proposed for topic modelling are statistical methods that aim to reach a conclusion by analyzing the words that make up the document. They do not need any labelling step while discovering the connection between the topics and the changes they show over time. While the placement of words in the document is ignored, the co-occurrence of words is used in this method. In this study, topic modelling is performed on 3 topics using Latent Dirichlet Allocation (LDA). The number of models was decided by trial and error, and the most appropriate number of topics was determined as 3. Fig. 3 shows the topic modelling of English tweets, and Fig. 4 shows the topic modelling of Turkish tweets.

Topic 1

Topic 2

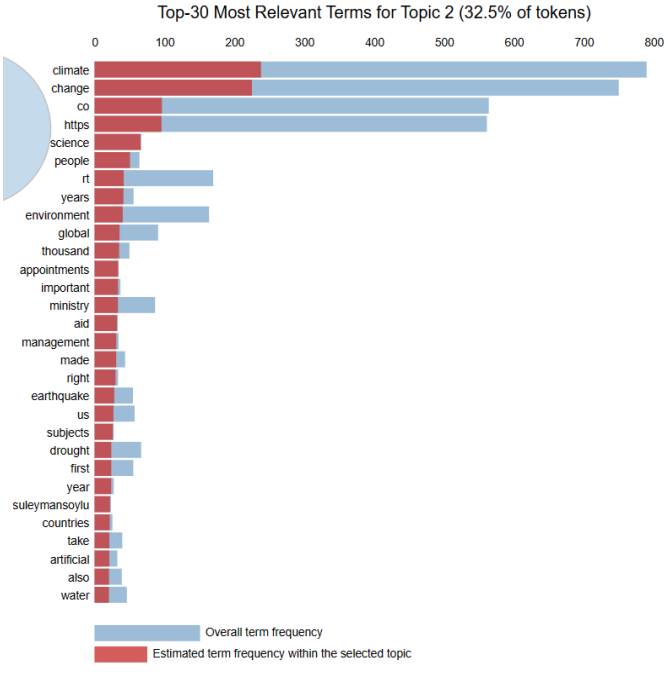
Topic 3

Fig. 3. LDA terms (English tweets).



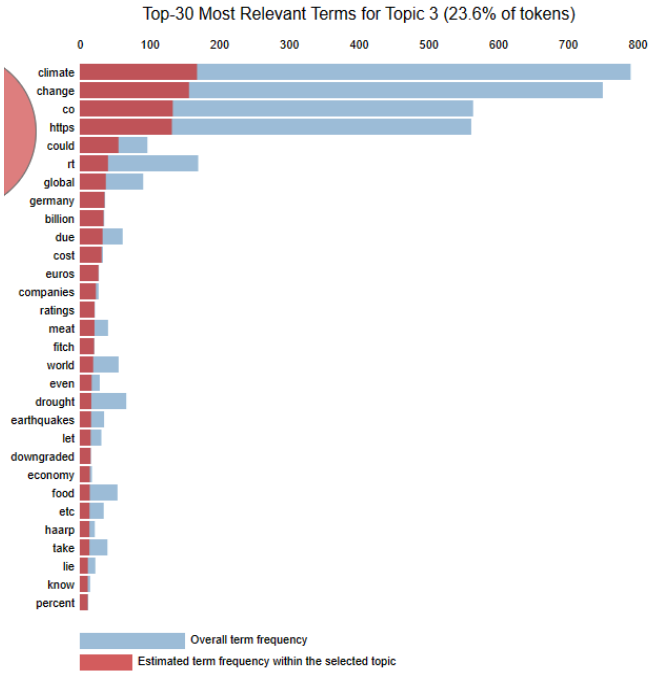
The three topic distributions of the English tweets in Fig. 3, which resulted from the topic modelling, are as follows:

Topic 1: Global Awareness and Calls to Action



Topic 1 centers around awareness and calls for action on climate change. While the highest frequency of use of the term's "climate", and "change" constitutes the main theme of this topic, terms such as world, women, real, action, help, and public indicate that the global impacts of climate change are emphasized. Under this heading, awareness-raising and calls for action on the environmental crisis and broader societal issues come to the fore.

Topic 2: Climate Change Debates and Polarized Views



Topic 2 reflects the reality of climate change and the controversial discourses around it. While "climate", and "change" are again important keywords, terms such as "hoax", "believe", think", "care", "right", and "senate budget" points to the differences of opinion between those who believe in climate change and those who question it. In addition, terms such as money and economics indicate that the economic dimensions of climate policies also occupy an important place in the debates.

Topic 1

Topic 2

Topic 3

Fig. 4. LDA terms (Turkish tweets).

Topic 3: Political Discourses and Energy Policies

Topic 3 shows that climate change is addressed in the context of political actors, media, and energy policies. The prominence of terms such as "China", "energy", "secretary", "Granholm", "Fox News", and "administration" shows that climate change discourses are shaped through political figures, media organizations, and energy policies. Under this heading, discussions on energy policies and the role of specific countries or political actors come to the fore.

The three topic distributions of the Turkish tweets in Fig. 4, which resulted from the topic modelling, are as follows:

Topic 1: Political and Institutional Discourses and Climate Change

This topic reflects political, bureaucratic, and institutional discourses on climate change. Terms such as "minister", and "institution" indicate the intensification of public debates over the statements or policies of government officials and public institutions on this issue. Expressions such as "environment", "urbanization", and "natural disaster" reveal that environmental impacts, sustainable urbanization debates, and natural disasters are addressed in a political context.

Topic 2: Scientific Perspectives and Climate Crisis in a Global Framework

This heading includes scientific and global discourses on the climate crisis. Terms such as "science", "environment", and "global" indicate that scientific studies and international perspectives are frequently emphasized in tweets. In addition, terms such as "earthquake", "drought", and "water" emphasize natural disasters and resource problems caused by the climate crisis. In this context, the issue can be interpreted as an area

where climate change is discussed through scientific findings and global impacts.

Topic 3: Economic Impacts and Social Reactions

The third issue shows that climate change is related to economic impacts and societal perceptions. Expressions such as "economy", "cost", "companies", and "billion" reveal that economic risks and costs are frequently mentioned. Financial terms such as "downgraded" and "ratings" reflect the impacts of climate change on corporate and economic performance. In addition, terms such as "global" and "drought" indicate that this economic impact has broad repercussions at the global level.

V. Discussion

This study's analysis of social media perceptions of climate change makes important contributions to the literature by comparatively evaluating the contextual and emotional aspects of Turkish and English tweets. The findings obtained through deep learning-based sentiment analysis and topical modelling methods show that individuals" perceptions of climate change are influenced not only by linguistic but also cultural contexts. Accordingly, the study provides important results to better understand the nature of discussions on climate change in social media and to provide a roadmap for the development of environmental communication strategies.

The result of the study shows that emotional reactions were stronger in English tweets, while a more neutral attitude was more prominent in Turkish tweets. This finding coincides with the literature showing the relationship between cultural values, media usage habits and environmental sensitivities. [28] stated that social media plays an important role in public debates on climate change and that culture-specific perception differences are reflected in social media content.

While the higher proportion of neutral expressions in Turkish content indicates that users adopt an observant approach, the emotional intensity in English tweets reveals that the Western public adopts a more activist stance on environmental issues. This was also confirmed [37] in a cross-cultural study covering 110 countries; it was stated that the public perceived climate change as a higher risk and reactions to it were higher in more affected geographies.

Social media stands out as a space where individuals can make their voices heard on environmental issues, access information and play a role in shaping policies. In this context, the concept of "Fifth Power" articulated [10] emphasizes the capacity of individuals to generate knowledge and social intervention through digital platforms. In the tweets analyzed in this study, especially in English content, frequently used expressions (e.g., "action", "real", "help") can be considered as an indicator of digital activism.

In particular, the "Greta Effect", which symbolizes the impact of climate activist Greta Thunberg, has shown the power of online campaigns to mobilize decision-makers [20]. The findings obtained in the study reveal that similarly, large masses can be reached, and awareness can be raised through social media.

The use of machine learning and deep learning methods provides significant advantages in analyzing social media data. The LSTM model used in this study classified both Turkish and English tweets with high accuracy rates. This supports that deep learning architectures are more successful than traditional methods in text classification, as stated [35].

Higher F1 and accuracy rates for Turkish tweets indicate that the model may have learnt the language features better. This finding is in line with the studies conducted [3] on Turkish content classification. Although the Turkish dataset is smaller than the English dataset, the higher performance may be explained by differences in data characteristics. The Turkish dataset appears to be more homogeneous and less noisy, which can facilitate pattern learning for the model. In contrast, the larger English dataset likely includes more linguistic variability, sarcasm, and contextual ambiguity, which may reduce classification performance. Additionally, differences in class distribution may also contribute to this outcome.

The results of the topical modelling show that discussions on climate change are shaped around political, economic and scientific perspectives. While energy policies, media discourses and the role of political figures are prominent in English tweets, public institutions" statements and scientific discourses are more dominant in Turkish tweets. These differences reveal that environmental communication strategies should be customized according to language and context.

Especially words such as "hoax", "senate", and "budget" in English tweets reflect the polarization and political debates on climate change. [16] stated that such polarization weakens the consensus on climate change on social media and facilitates the spread of misinformation. These findings are limited to the analyzed dataset and should not be generalized to broader populations. The results reflect only the behavior of Twitter users within the selected time frame and keyword scope.

VI. Conclusions

The study provides an important perspective on this issue by analyzing social perceptions and emotional tendencies regarding climate change in Turkish and English tweets. Using artificial intelligence-based text mining and sentiment analysis methods, the study shows that discussions about climate change on social media platforms have a multidimensional structure. While the difference between positive (43.3%) and negative (25.5%) sentiments is more pronounced in English tweets, neutral sentiments (37.2%) have a higher rate in Turkish tweets. This suggests that English-speaking users tend to have stronger emotional reactions to climate change, while Turkish-speaking users tend to adopt a more observant or neutral approach. In the positive statements, words such as energy, China, and world point to promising developments such as renewable energy investments and global cooperation, while the words fossil, economy, and government in the negative category reflect criticisms such as fossil fuel dependency and political inefficiencies. These data support the findings in the literature that social perception of climate change is based on a balance of positive and negative emotions [37].

Nevertheless, these findings are specific to the sampled social media population and should not be generalized to broader linguistic communities. The results reflect only the behavior of users active on Twitter within the selected dataset and keyword scope.

In this study, deep learning-based models have been successfully used for sentiment analysis related to climate change. Natural language processing (NLP) techniques and deep learning methods were effectively applied to accurately classify the emotional content of Twitter data. The deep learning model LSTM (Long Short-Term Memory) offered higher accuracy rates than traditional methods in understanding the context of texts and accurately capturing emotional tones. In this way, it was possible to analyses users" feelings and thoughts about climate change in more depth and to compare social media data in different languages (Turkish and English). The high accuracy of deep learning methods in such analyses reveals the complex emotional structure of social media posts more clearly.

The importance of the article stems from the fact that it presents important implications at both the local and global levels by analyzing the perceptions and attitudes of individuals on climate change and climate change issues through social media data. Climate change is seen as a critical issue not only for environmental sustainability but also for the future of economic and social policies. Therefore, sentiment analysis of the content shared on social media about climate change provides valuable information to understand the public's concerns, hopes, and demands on this issue. The comparison of Turkish and English tweets has an important originality in terms of showing how perceptions towards climate change are shaped in different cultural contexts.

However, the study also has some limitations. Firstly, the fact that only Twitter data is used makes it difficult to generalize the results to other social media platforms. For example, a more comprehensive analysis can be made with content obtained from platforms such as Instagram, Facebook, or TikTok. Furthermore, the fact that only text-based analyses were conducted, and visual content or hashtag trends were not examined limited the possibility of making an evaluation covering all dimensions of social media posts. Another limitation is that the analysis is based on keyword frequencies regardless of the context of the texts. This may prevent a full understanding of users" real intentions and emotional states.

In future studies, comparative analyses of different social media platforms can be included, and the accuracy of sentiment analysis can be improved by using more advanced deep learning methods. In addition, the attitudes of different demographic groups (age, gender, geographical region) towards climate change can be analyzed, and more detailed inferences can be made on how local and global policies are perceived. By extending the study, more inclusive and effective strategies can be developed, especially for policymakers and stakeholders that drive climate change investments. Such analyses will play a critical role in both formulating policies in line with the demands of the public and raising awareness on combating climate change. Future studies may extend this work by incorporating multimodal data (e.g., images and videos) and developing real-time monitoring systems to track public perception of climate change.

Preference-Controllable Multi-Objective Deep Reinforcement Learning for Human-Robot Task Allocation in Service Environments

Asmaa Rashed Alahmari*, Wadee Alhalabi
Computer Science Department-Faculty of Computing & Information Technology,
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—Human–Robot Collaboration (HRC) has gained increasing attention as it expands from industrial environments to service-oriented settings, where dynamic conditions and diverse operational objectives pose significant challenges for task allocation. Unlike controlled industrial environments, service contexts are characterized by frequent changes, uncertainty, and time-varying priorities, rendering static task allocation strategies ineffective. This paper proposes a method to address the problem of determining the optimal balance between human and robotic task allocation in dynamic service-oriented HRC systems. A preference-controllable multi-objective deep reinforcement learning framework is introduced to formulate task allocation as a dynamic, preference-dependent decision-making process. The proposed approach explicitly captures trade-offs among multiple, potentially conflicting objectives and enables adaptive task allocation under changing operational conditions and service priorities. The framework is evaluated through simulation-based experiments and comparative analysis with baseline strategies using multiple evaluation metrics, complemented by additional validation using external datasets. Experimental results demonstrate the effectiveness and adaptability of the proposed approach across varying preference configurations and workload conditions, supporting its applicability in real-world smart service environments.**

***Keywords*—Deep reinforcement learning; human–robot collaboration; preference-controllable reinforcement learning; smart service environments; task allocation**

I. Introduction

Human–Robot Collaboration (HRC) has demonstrated significant success in industrial environments, where humans and robots work collaboratively to enhance productivity, efficiency, and safety [1–3]. Building on this success, HRC has recently expanded beyond manufacturing into service-oriented sectors such as hospitality and tourism [4–12]. An increasing body of research has demonstrated the feasibility and benefits of deploying collaborative robots in service environments, reporting improvements in operational efficiency and service quality [4,6,11,12].

Among the core challenges in HRC systems, task allocation between human workers and robots has emerged as a critical research problem [13,14]. Determining which tasks should be performed by humans, robots, or jointly has been extensively investigated in industrial settings, both theoretically and experimentally [13–16].

Existing studies have proposed a wide range of task allocation approaches [13–21], including rule-based strategies, optimized heuristic methods, and more advanced solutions such as digital twins and machine learning–based models. More recently, deep reinforcement learning (DRL) has attracted growing attention as a promising approach for addressing complex and dynamic task allocation problems [15,22].

These approaches aim to optimize multiple objectives, such as efficiency, cost, performance, safety, and human workload [1,23–25]. While some studies focus on optimizing a single objective, others consider multiple objectives simultaneously [26–28]. Importantly, these objectives may be complementary in some cases, yet conflicting in others, leading to inherent trade-offs commonly described through Pareto optimality [29,30]. Moreover, task allocation strategies may be static or dynamic, depending on how objectives are defined and prioritized [31,32].

While task allocation in industrial environments benefits from relatively controlled and predictable settings, service environments present fundamentally different challenges [10]. Service systems are highly dynamic, characterized by frequent and unpredictable changes, diverse and often conflicting objectives, and time-varying priorities. For instance, speed and efficiency may be critical during peak hours, whereas customer experience and human touch become more important during off-peak periods. Unexpected events such as staff absence, equipment maintenance, or sudden demand fluctuations further complicate decision-making [5,8].

Despite the importance and complexity of task allocation in service-oriented HRC, existing research remains limited and lacks adaptive frameworks capable of dynamically balancing multiple conflicting objectives under changing preferences in real-world service settings [8,10].

To address these challenges, this paper proposes a preference-controllable multi-objective deep reinforcement learning approach for human–robot task allocation in service environments. Inspired by task allocation strategies developed for industrial HRC, the proposed framework enables dynamic adaptation to changing environmental conditions and shifting objective priorities. By explicitly modeling trade-offs among multiple objectives and allowing preference control, the framework aims to achieve a balanced allocation that improves efficiency, cost, and overall system performance in service-oriented contexts.

*Corresponding author.

The main contributions of this paper are as follows:

- Proposing a preference-controllable multi-objective deep reinforcement learning approach for dynamic human–robot task allocation in service environments.
- Modeling task allocation as a preference-dependent decision-making problem that captures trade-offs among conflicting objectives.
- Demonstrating adaptive and controllable allocation behavior under varying operational conditions and preference configurations.
- Validating the proposed approach using both simulation-based experiments and external real-world datasets.

This work contributes to determining the optimal balance between human and robotic task allocation in dynamic service-oriented HRC systems. Rather than assuming a fixed allocation, optimality is defined as a dynamic and preference-dependent trade-off among multiple objectives, enabling adaptive task allocation decisions under changing operational conditions and service priorities.

The remainder of this paper is organized as follows. Section II reviews the background and related work. Section III describes the proposed methodology. Section IV presents and discusses the experimental results. Section V outlines the limitations and directions for future research. Finally, Section VI concludes the paper.

II. Background and Related Work

This section presents the foundational concepts of the research and reviews existing studies on human–robot task allocation, multi-objective optimization, and preference-aware reinforcement learning, with a focus on identifying limitations in current approaches.

A. Task Allocation in Human–Robot Collaboration

Human–Robot Collaboration (HRC) refers to systems in which humans and robots work together within a shared workspace [13]. Research began in the early 1990s, initially focusing on human-compatible robotic hardware [18,33], and later expanded to include control modalities, interaction, and task representation [18], with comprehensive reviews provided in [34].

With Industry 4.0, HRC has rapidly grown in industrial applications, supported by safety standards such as ISO/TS 15066 and advances in machine learning for improved adaptability [18,35]. More recently, HRC has extended to service environments such as hospitality and retail [4–12], which are less structured, more dynamic, and strongly influenced by human behavior and demand, introducing additional challenges in coordination and decision-making [5,8].

Task allocation plays a central role in enabling effective HRC in both industrial and service environments, determining how responsibilities are shared between humans and robots while balancing objectives such as time, cost, safety, and workload [32]. Although widely studied in multi-robot systems [36], HRC introduces additional complexity due to human variability, making optimal allocation dynamic and context-dependent.

Early approaches focused on system-centric objectives such as makespan, cycle time, and cost [37–39], using methods including mixed-integer linear programming (MILP), meta-heuristics, and reinforcement learning [37–41]. More recent work has incorporated human-centered factors such as workload, ergonomics, and adaptability [42–47], with fatigue modeling approaches such as Learning-Forgetting-Fatigue-Recovery LFFR used to capture human performance dynamics [18,48–50].

Despite these advances, existing studies still lack worker personalization and balanced workload distribution, highlighting the importance of multi-objective optimization to balance human and system-level objectives [23,28]. Task allocation strategies can be categorized as static or dynamic [31,32]. Static approaches rely on predefined conditions and are sensitive to disruptions, while dynamic approaches adapt to real-time changes, making them more suitable for service environments such as cafés, where demand is variable and time-sensitive [32].

Among available techniques for enabling dynamic task allocation under uncertainty, reinforcement learning has emerged as a promising approach [32], including integration with digital twins and hybrid learning frameworks [20,51]. However, most existing work remains focused on industrial settings and does not address preference-controllable task allocation in dynamic service environments.

B. Multi-Objective Task Allocation and Pareto-Based Approaches

Multi-objective optimization is increasingly relevant in collaborative systems, as many real-world decision-making problems cannot be adequately represented by a single performance criterion. Prior work emphasizes that many real-world decision problems are characterized by multiple conflicting objectives that must be balanced based on their relative importance, and that most real-life problems are more naturally expressed with multiple objectives [29, 52]. In HRC, traditional approaches focus on system-centric metrics such as cycle time [28], which may negatively impact human factors such as fatigue and well-being.

Multi-objective task allocation addresses this by modeling trade-offs among competing objectives. Rather than a single optimal solution, a set of Pareto-optimal solutions is obtained, representing different trade-offs [28,29]. These solutions reflect varying priorities, where improving one objective may degrade another. Within HRC, Pareto-based approaches have been used to balance system efficiency and human factors, demonstrating that task allocation should be treated as a trade-off problem rather than a single-objective optimization [28].

Multi-objective reinforcement learning (MORL) extends this concept by learning policies that capture different trade-offs among objectives [29]. Approaches include single-policy methods, multi-policy methods, and preference-conditioned methods. While effective, these methods are often computationally expensive and not tailored to domain-specific

applications such as service-oriented HRC. Overall, although multi-objective approaches provide strong theoretical foundations, they are often abstract and lack direct application to dynamic, service-oriented human–robot task allocation problems.

C. Preference-Aware and Preference-Controllable Learning

In multi-objective problems, preferences are typically represented as weights indicating the importance of each objective [54]. Traditional approaches assume fixed weights, allowing reduction to single-objective formulations [52]. However, in practice, preferences are often unknown or change over time [30,52]. Preference-controllable reinforcement learning addresses this limitation by enabling policies to adapt to varying preference inputs [30]. Rather than learning separate policies, a single model is conditioned on preference vectors, allowing different trade-offs to be achieved dynamically [30,54].

In HRC systems, preferences are particularly important as they reflect human priorities and expectations. Prior studies have explored learning preferences through interaction and feedback [53], but these are generally not formulated as explicit task allocation problems and are not designed for service-oriented environments. Overall, existing approaches provide strong theoretical support for modeling dynamic preferences and adaptive behavior in multi-objective systems. However, these methods are not directly applied to task allocation in dynamic service-oriented HRC systems, where preferences may shift rapidly in response to workload, customer demand, or operational conditions.

D. Limitations of Existing Approaches

Despite progress, several limitations remain. First, most task allocation frameworks are designed for industrial environments and are not easily transferable to dynamic service settings [23,28]. Second, many approaches rely on fixed or implicit preference assumptions, limiting adaptability in real-world scenarios [52,54]. Third, there is a lack of unified frameworks that integrate task allocation, multi-objective optimization, and preference control into a single system.

Overall, existing studies address these aspects in isolation, such as industrial task scheduling, Pareto-based optimization, or preference-aware learning, but do not provide an integrated, preference-controllable framework for dynamic task allocation in service-oriented HRC systems, which motivates the proposed approach.

III. Methodology and Experimental Setup

This study proposes a formulation of human–robot task allocation as a preference-controllable multi-objective decision-making problem, where service priorities may vary dynamically across operational contexts. Rather than optimizing a single fixed objective or training multiple separate policies for different trade-offs, the proposed approach follows the principles of Preference-Controllable Reinforcement Learning (PreCo) [30]. In this framework, task allocation decisions are conditioned on a continuous preference vector that encodes the relative importance of operational efficiency, preservation of human-centric interactions, and effective resource utilization. By conditioning the policy on preferences, the agent can represent a continuum of task allocation strategies within a single model, enabling flexible adaptation to changing service priorities. Fig. 1 illustrates the overall preference-controllable learning framework adopted in this study, showing how user-defined trade-offs and estimated objective outcomes guide the agent's interaction with the environment.

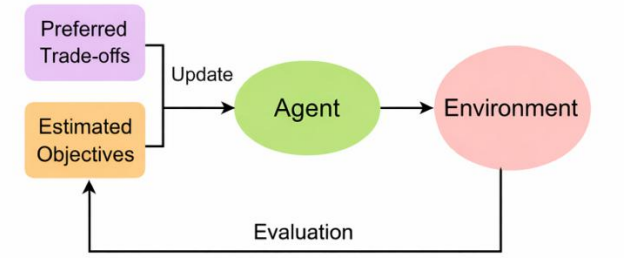

Fig. 1. Overview of the preference-controllable reinforcement learning (PreCo) framework adopted in this study.

A. Problem Formulation and Environmental Design

The task allocation problem is defined within a dynamic service-oriented HRC café environment, as a representative a real-world service scenario, where a human barista and a robotic agent jointly execute café service tasks under uncertain demand and variable execution conditions. At each decision step, the agent observes the current environment state and assigns the incoming order either to the human or to the robot, enabling adaptive allocation strategies as operational conditions evolve.

A custom simulation environment, CafeEnvironment, is developed using the Gymnasium interface [55]. Each episode represents a short operational window of 50 customer orders sampled from a predefined dataset comprising 20 heterogeneous order types (e.g., espresso-based drinks, specialty beverages, desserts, and packaged items). Each order is characterized by estimated human service time, robot service time, an automatability score $[0,1]$, and a human-touch importance score $[0,1]$. For food items, the estimated service times are modeled to be comprehensive, accounting for potential heating and custom preparation rather than mere handover. This task abstraction aligns with PreCo's vector-valued outcome formulation, where actions contribute differently to multiple objectives [30]. The dataset was constructed and validated through interviews with three café-domain experts (Table I).

B. Multi-Objective Learning Formulation

Task allocation performance is evaluated with respect to three potentially conflicting objectives: operational efficiency, preservation of human-centric interactions, and resource utilization, which represent core operational priorities in service-oriented café environments. These objectives are modeled using a vector-valued reward rather than a single scalar signal, explicitly capturing inherent trade-offs. Optimality is therefore defined relative to a preference vector specifying the relative importance of each objective, framing the problem as a preference-dependent multi-objective decision-making task. The policy is modeled as a conditional policy,

$$\pi(a \mid s, p),$$

TABLE I. ORDER TYPES AND TASK CHARACTERISTICS USED IN CAFEENVIRONMENT

Order Type	Human Service Time (s)	Robot Service Time (s)	Automatability	Human-Touch Importance
Espresso (single shot)	30	15	0.95	0.05
Double espresso / Lungo / Ristretto	30	16	0.92	0.08
Americano / Long Black	40	20	0.88	0.12
Cappuccino	60	35	0.80	0.20
Latte / Flat White / Macchiato / Cortado	60	36	0.78	0.22
Mocha / Hot Chocolate / Specialty hot drinks	90	45	0.72	0.30
Iced Coffee / Iced Latte / Iced Tea	90	50	0.70	0.28
Blended / Frappé beverages	90	55	0.60	0.35
Cold Brew / Nitro Cold Brew	30	30	0.40	0.70
Tea (bagged)	30	15	0.85	0.15
Tea (brewed, e.g., matcha latte)	60	30	0.68	0.32
Affogato / Dessert-coffee combinations	90	50	0.50	0.85
Muffin	180	120	0.30	0.55
Biscotti	180	120	0.30	0.45
Bagel	180	120	0.35	0.50
Croissant / Danish / Pastry	180	120	0.35	0.60
Cookie / Brownie / Cake slice	180	120	0.30	0.45
Sandwich	180	120	0.35	0.55
Wrap / Salad bowl	180	120	0.35	0.50
Yogurt parfait / Fruit cup	180	120	0.35	0.50

where s denotes the environment state, a the allocation action, and p the preference vector. Conditioning the policy on preferences follows the preference-conditioned policy formulation adopted in [30] and allows a single model to represent a continuum of allocation strategies without retraining.

C. State, Action, and Preference Modeling

At each decision step t, the action space is discrete with two possible actions:

$$a_t \in \{0,1\},$$

where $a_t = 0$ assigns the incoming order to a human barista and $a_t = 1$ assigns it to the robotic system.

The environment state is represented as a 10-dimensional continuous vector normalized to $[0,1]$, combining operational context, task characteristics, system utilization, and preference information:

$$s_t = [w_t, o_t, h_t, m_t, u_H, u_R, p_{\text{eff}}, p_{\text{touch}}, p_{\text{util}}, c],$$

Here, w_t denotes the remaining workload in the episode expressed as the fraction of unprocessed orders; o_t represents the normalized categorical index of the current order type; h_t and m_t correspond to the human-touch importance and automatability scores of the task, respectively. The variables u_H and u_R denote the current utilization ratios of the human worker and the robotic system. The preference vector $p = (p_{\text{eff}}, p_{\text{touch}}, p_{\text{util}})$ encodes the relative importance assigned to operational efficiency, preservation of human-centric interactions, and resource utilization. Finally, c represents the operational load context, discretized into low, medium, and high demand levels. Including preferences directly in the observation space follows the core principle of preference-conditioned reinforcement learning adopted in PreCo [30], enabling the policy to adapt its behavior to different trade-off configurations without modifying the underlying environment dynamics. At the beginning of each episode, a preference vector is sampled and kept fixed throughout the episode, allowing the policy to learn consistent allocation behavior under a specific preference setting.

D. Reward Design and Multi-Objective Structure

At each decision step t, the environment provides a vector-valued reward that captures multiple aspects of task allocation performance, including service efficiency, preservation of human-centric interactions, and resource utilization balance. Representing rewards in vector form allows each objective to be modeled and analyzed independently before aggregation. To ensure transparency, the individual reward components of operational efficiency (r_t^{eff}), human-touch preservation (r_t^{touch}), and resource utilization (r_t^{util}) are formally defined based on the environment dynamics. The efficiency reward is defined as:

$$r_t^{eff} = \gamma_c \left(1 - \min\left(\frac{T(a_t)}{T_{\max}}, 1\right)\right)$$

where $T(a_t)$ denotes the service time of the selected agent (human or robot), $T_{\max}$ is the maximum service time observed in the system, and γ_c is a context-dependent scaling factor reflecting workload conditions (γ_c= 1.2 for high load, 1.0 for medium load, and 0.9 for low load).

The human-touch reward captures the importance of human interaction (h_t) and is defined conditionally based on the selected agent a_t. When a human is assigned ($a_t = 0$):

$$r_t^{touch} = \min\left(h_t \cdot (1 + 0.5\, p_{touch}) + \delta, 1\right)$$

where $\delta = 0.12\, p_{touch}$ if $p_{touch} > 0.6$, and $\delta = 0$ otherwise. When a robot is assigned ($a_t = 1$):

$$r_t^{touch} = 1 - \min\left(\text{penalty}, 1\right)$$

where the penalty term is defined as: penalty = $0.7\, h_t\, (p_{touch} - 0.6) \times 4.5$, if $p_{touch} > 0.6$, penalty = $0.2\, h_t p_{touch}$, otherwise.

The utilization reward promotes balanced workload distribution between human and robot agents and is defined as:

$$r_t^{util} = 1 - |\, u_H - u_R\, |$$

where u_H and u_R denote the current utilization ratios of the human and robot, respectively.

Finally, let $p = (p_{\text{eff}}, p_{\text{touch}}, p_{\text{util}})$ represent the sampled preference vector specifying the relative importance of each objective. The overall scalar reward used for policy optimization is computed through preference-weighted linear scalarization as follows:

$$R_t = p_{\text{eff}}\, r_t^{\text{eff}} + p_{\text{touch}}\, r_t^{\text{touch}} + \beta_{\text{util}}\, p_{\text{util}}\, r_t^{\text{util}},$$

where β_{util} is a scaling parameter controlling the contribution of the utilization term relative to the other objectives.

Preference-awareness is further incorporated during training through a lightweight shaping mechanism applied outside the environment. Following the Preference-Controllable Reinforcement Learning (PreCo) paradigm [30], an additional preference-alignment signal based on changes in cosine similarity between the cumulative objective vector and the sampled preference vector is used to guide learning. This shaping mechanism is implemented at the wrapper level and does not modify the PPO loss function or the underlying network architecture.

E. Learning Algorithm and Evaluation

The agent is trained using Proximal Policy Optimization (PPO) as implemented in Stable-Baselines3 [56], chosen for its stability and robustness in stochastic environments. Observation and reward normalization are applied using VecNormalize. Key hyperparameters include a learning rate of 3×10^{-4}, discount factor $\gamma = 0.99$, GAE parameter $\lambda = 0.95$, clip range 0.2, and batch size 128. These hyperparameters were selected based on established best practices for PPO and widely adopted configurations in prior reinforcement learning studies, and were empirically validated to ensure stable convergence in the proposed task allocation environment. Training is conducted for 300,000 interaction steps, corresponding to approximately 6,000 episodes.

Following common practice in preference-controllable reinforcement learning, evaluation focuses on two main requirements [30]. The first is the ability of the agent to explore the Pareto front and represent diverse trade-offs among objectives. The second is controllability, defined as the ability of the learned policy to produce a performance trade-off that aligns with the input preference. These requirements are evaluated using Hypervolume (HV) to assess Pareto front coverage and a similarity measure $\Psi(p, v_\pi)$ to quantify preference alignment. In addition to these preference-based metrics, task-level performance is assessed using episodic measures such as average task completion time, makespan, and human–robot allocation ratios, which are commonly used evaluation metrics in human–robot collaborative task allocation studies. All experiments are conducted with fixed random seeds to ensure reproducibility.

IV. Results and Discussion

This section presents and analyzes the experimental results obtained from both internal simulation-based evaluations and external validation experiments, along with their implications for the proposed framework.

A. Internal Evaluation Results

The results in this section are obtained after training the proposed preference-controllable policy, demonstrating stable and consistent learning behavior over 6,000 training episodes. To evaluate the controllability of the learned policy beyond training-time preference sampling, we conduct a controlled evaluation under three representative preference scenarios, designed to reflect realistic operational conditions in a service environment. These scenarios correspond to three dominant service modes commonly encountered in practice.

The first scenario is efficiency-oriented, representing high-demand periods (peak-hour scenarios) where rapid service and throughput are prioritized, and robotic execution is preferred for handling the majority of tasks. The second scenario is human-touch-oriented, emphasizing customer interaction and human touch, where task allocation favors human baristas while still allowing a balanced distribution with robotic assistance when appropriate. The third scenario is balanced, targeting a balanced utilization of human and robotic resources to ensure efficient operation without excessive workload concentration or prolonged idleness.

This evaluation protocol mirrors the controlled preference experiments commonly adopted in preference-controllable reinforcement learning studies, where fixed and interpretable preference vectors are used to examine policy behavior under specific trade-off configurations, as discussed in [30]. To analyze how the learned agent adapts its decisions under each scenario, we report the following evaluation metrics: preference alignment (Ψ), hypervolume (HV), and human–robot task allocation behavior.

In the following subsections, we analyze each of these aspects in detail to demonstrate the controllability, interpretability, and robustness of the proposed framework.

1) Preference alignment (Ψ): Preference alignment (Ψ) is used to evaluate how closely the learned policy follows the intended preference direction under fixed and interpretable preference configurations. It is computed as the cosine similarity between the cumulative achieved objective vector and the corresponding preference vector, providing a directional measure of controllability consistent with preference-controllable reinforcement learning.

As shown in Fig. 2, the balanced preference configuration exhibits the strongest alignment ($\Psi = 0.983$), indicating that the policy effectively tracks the intended trade-off when multiple objectives are jointly emphasized. In contrast, lower alignment values are observed under efficiency-oriented ($\Psi = 0.513$) and human-touch-oriented ($\Psi = 0.675$) preferences. These configurations correspond to more asymmetric preference settings, where emphasis is placed predominantly on a single objective.

This behavior is expected and reflects a fundamental characteristic of preference-controllable reinforcement learning as discussed in [30]. During training, preferences are sampled continuously across the preference simplex, encouraging the policy to remain responsive across a broad range of trade-offs rather than specializing toward extreme or corner configurations. Consequently, alignment under highly asymmetric preferences is naturally lower than under balanced configurations, without indicating a loss of controllability.

Overall, the variation in preference alignment across scenarios demonstrates that the learned policy responds systematically and directionally to changes in the preference input. Rather than converging to a fixed objective or ignoring preference information, the policy adapts its behavior in accordance with the specified preference configuration, satisfying a core requirement of controllable multi-objective decision-making in human–robot collaboration settings.

2) Pareto Quality (Hypervolume, HV): To complement the preference alignment analysis, we evaluate the Pareto solution quality of the learned policy using the hypervolume (HV) metric, which measures the volume of the objective space dominated by the achieved solutions. Hypervolume is a standard indicator in multi-objective optimization, capturing both convergence and coverage of the Pareto front.

Fig.3 reports the HV values obtained under the three controlled preference scenarios. The balanced configuration achieves the highest hypervolume ($HV \approx 0.41$), followed by the efficiency-oriented ($HV \approx 0.31$) and human-touch-oriented ($HV \approx 0.26$) scenarios. This pattern indicates that balanced preferences enable solutions that preserve more favorable trade-offs across objectives, resulting in broader Pareto coverage.

In contrast, preference configurations that strongly emphasize a single objective naturally constrain the solution space, leading to reduced hypervolume. This behavior is consistent with multi-objective optimization theory, where prioritizing one objective limits the achievable trade-offs among the remaining objectives. Importantly, lower HV values under efficiency- or human-touch-oriented preferences do not indicate suboptimal learning, but rather reflect the intentional focus imposed by the specified preference direction. These results align with observations reported in preference-controllable reinforcement learning literature, where balanced or moderately weighted preferences tend to yield higher Pareto quality, while extreme preferences trade overall solution diversity for targeted objective satisfaction.

3) Human–robot task allocation behavior: To examine how preference alignment and Pareto quality translate into operational behavior, we analyze the resulting human–robot task allocation under the controlled preference scenarios. Fig. 4 illustrates the proportion of tasks assigned to the robot and the human agent for efficiency-oriented, human-touch-oriented, and balanced preferences.

Under the efficiency-oriented configuration, the policy allocates a substantially larger share of tasks to the robot (approximately 0.85 robot utilization), reflecting an automation-driven strategy that prioritizes service speed and throughput during peak operational periods. This behavior is consistent with the specified preference direction and confirms that the policy leverages robotic execution when efficiency is emphasized.

In contrast, the human-touch-oriented configuration results in a pronounced shift toward human execution, with robot utilization decreasing to approximately 0.36. Tasks associated with higher interaction importance are preferentially handled by human baristas, demonstrating that the policy internalizes task semantics and adjusts allocation decisions to preserve human-centric service quality when required.

The balanced configuration converges to a moderate allocation (approximately 0.54 robot utilization), representing a stable compromise between automation and human involvement. This allocation pattern aligns with the higher preference alignment and hypervolume observed under balanced preferences, indicating that joint emphasis on multiple objectives yields both robust Pareto performance and interpretable allocation behavior.

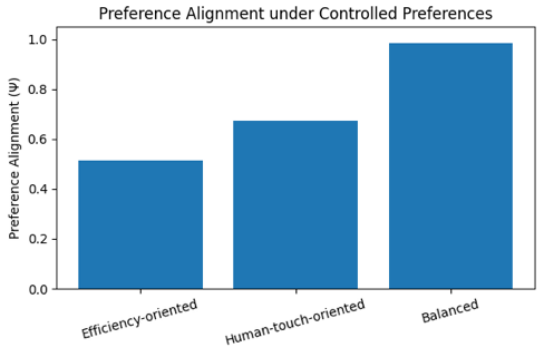

Fig. 2. Preference alignment (Ψ) under controlled preference configurations.

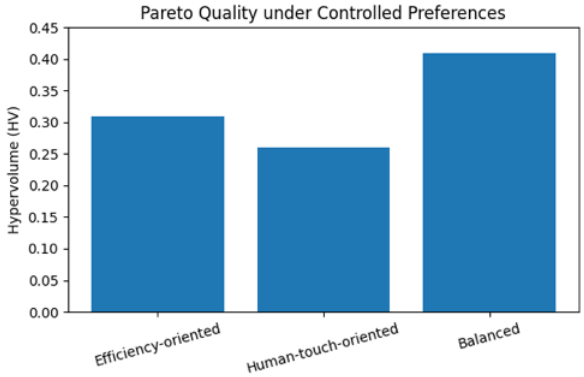

Fig. 3. Pareto quality measured by hypervolume (HV) under controlled preference configurations.

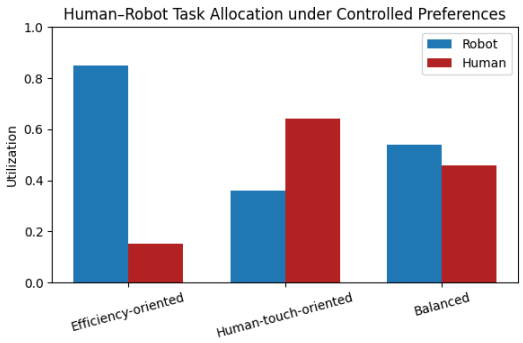

Fig. 4. Human–robot task allocation behavior under controlled preference configurations.

Notably, robot participation remains non-negligible across all scenarios. This outcome reflects the structure of the task environment, in which a subset of orders exhibits high automatability and favorable robot execution times. Rather than suppressing automation under human-centric preferences, the proposed framework permits robot involvement whenever it remains consistent with task characteristics and the specified preference constraints. Consequently, observed changes in utilization reflect relative behavioral adaptation rather than absolute enforcement of automation or manual operation.

Overall, these results demonstrate that the learned policy does not converge to a fixed automation ratio nor rely on static heuristics. Instead, it dynamically adjusts human–robot roles in a directionally consistent and interpretable manner in response to changing preferences, satisfying a central requirement of controllable human–robot collaboration in service-oriented environments.

The observed evaluation patterns are consistent with prior findings in preference-controllable reinforcement learning, where both preference alignment (Ψ) and Pareto quality (HV) tend to decrease under extreme or single-objective-dominant preference configurations, while more balanced preferences yield higher alignment and more favorable multi-objective trade-offs. In our experiments, this behavior manifests clearly as increased robot utilization under efficiency-oriented preferences, reduced robot involvement under human-touch-oriented preferences, and higher Ψ and HV under balanced configurations, demonstrating that the proposed framework exhibits controllable, preference-aware behavior in a service-oriented human–robot collaboration environment with interpretable task allocation decisions.

4) Comparison with baseline strategies: To assess the effectiveness of the proposed framework, we conduct a comparative evaluation against several baseline strategies. The comparison focuses on efficiency-oriented performance, measured by mean makespan and average task execution time, as well as the resulting human–robot allocation ratios.

Specifically, the proposed PreCo+PPO approach is evaluated under the three representative preference configurations defined in the previous section, which are efficiency-oriented, human-touch-oriented, and balanced, to reflect different operational priorities in service environments. These configurations are compared against four baseline strategies commonly used in practice: a rule-based two-threshold heuristic, full human execution, full robot execution, and a static 50/50 allocation. The rule-based two-threshold strategy assigns tasks using fixed decision rules based on task characteristics, favoring robot execution for highly automatable tasks and human execution for tasks requiring higher human involvement, without adapting to changing workloads or preferences. The full human and full robot strategies assign all tasks exclusively to a single agent, representing fully manual and fully automated operations, respectively. The static 50/50 strategy maintains an equal task split between human and robot throughout the episode, without considering task characteristics or operational context.

This comparison aims to examine whether the proposed approach can achieve competitive efficiency relative to automation-heavy strategies, while simultaneously maintaining meaningful human involvement and adaptive task allocation behavior that other baseline methods cannot provide. The results in Fig. 5 and Table II highlight the advantages of the proposed preference-controllable approach over baseline strategies. Under the efficiency-oriented configuration, the PreCo+PPO policy achieves a substantially lower mean makespan compared to rule-based and static allocation strategies, approaching the performance of the full-robot baseline while avoiding the complete elimination of human involvement. This demonstrates that high operational efficiency can be achieved without resorting to extreme automation, which has been associated with known limitations in prior studies.

When prioritizing human touch, the framework intentionally increases reliance on human execution to support customer interaction and service quality. As expected, this shift leads to a higher makespan due to reduced automation. However, compared to the full-human baseline, which results in the longest makespan and average task time, the proposed approach still benefits from selective robotic assistance to reduce overall service time while maintaining a strong level of human participation. This indicates that the framework does not simply replace automation with manual execution, but instead balances human involvement with robotic support to mitigate known challenges of fully manual operation, such as prolonged processing times, workload variability, and sensitivity to human-related disruptions reported in prior studies.

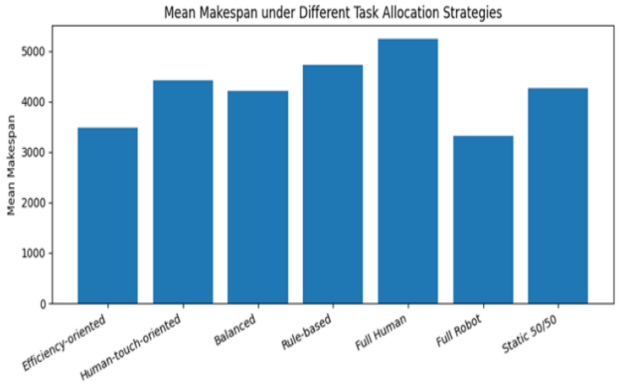

Fig. 5. Mean makespan comparison across preference-controllable strategies and baseline methods. Lower values indicate higher efficiency.

TABLE II. COMPARISON OF PREFERENCE-CONTROLLABLE AND BASELINE TASK ALLOCATION STRATEGIES

Category	Strategy	Mean Makespan	Avg Task Time (s)	Robot %	Human %
PreCo+PPO	Efficiency-oriented	3476.439	69.529	0.856	0.144
	Human-touch-oriented	4414.963	88.299	0.366	0.634
	Balanced	4207.118	84.142	0.547	0.453
Baseline	Rule-based	4730.312	94.606	0.417	0.583
	Full Human	5240.619	104.812	0.000	1.000
	Full Robot	3320.709	66.414	1.000	0.000
	Static 50/50	4268.116	85.362	0.510	0.490

The balanced configuration provides a practical trade-off between efficiency and human involvement. It achieves lower makespan values than the rule-based and static baselines while maintaining a near-equal human–robot allocation ratio. The slightly lower makespan compared to the static 50/50 strategy suggests that adaptive preference-aware control can offer modest efficiency gains over fixed allocation ratios under similar human–robot balance targets.

Overall, these results demonstrate that the proposed preference-controllable framework enables adaptive and interpretable task allocation across diverse operational priorities. Unlike static or heuristic-based methods, the proposed approach allows explicit control over trade-offs between efficiency and human-centric considerations without retraining or redesigning the policy, highlighting its practical applicability in real-world service-oriented environments.

B. External Validation Results

After establishing internal validity through controlled simulated experiments, we further evaluate the external validity of the proposed framework using real-world transactional data. The objective of this evaluation is to assess the robustness of the learned policy when exposed to realistic, heterogeneous, and noisy demand distributions that differ substantially from the synthetic order streams used during training. Importantly, the external evaluation does not modify the environment dynamics, reward formulation, or learning architecture. The trained PreCo+PPO policy is kept fixed throughout all experiments, and only the incoming order sequences are replaced with those observed in real transaction logs. This design allows the effect of realistic demand patterns on policy behavior to be isolated without introducing confounding factors related to retraining or architectural changes.

To assess external validity across different operational conditions, three real-world coffee sales datasets are employed [57-59], as summarized in Table III. These datasets differ in scale, structure, and data source, ranging from a large-scale transactional dataset comprising 149,116 transactions to smaller datasets with a few thousand records each. All datasets contain complete transactional information and exhibit demand characteristics commonly observed in real coffee shop operations.

Exploratory analysis shows that customer demand follows a skewed, long-tailed distribution, with coffee and tea products accounting for most orders, followed by bakery and specialty items. Most transactions include one or two items, indicating that the datasets largely reflect individual service requests rather than bulk orders. These characteristics are consistent with the task-level abstraction used in the simulated café environment. To integrate the real-world data, each transaction is mapped to the predefined service task categories using a simple rule-based mapping that preserves the original order sequence and task characteristics.

External evaluation follows the same controlled protocol used during internal validation. Three fixed and interpretable preference configurations are evaluated under deterministic execution, and performance is assessed using preference alignment (Ψ), Pareto hypervolume (HV), and human–robot utilization ratios. A quantitative summary of preference-aligned performance across both internal and external datasets is reported in Table IV, while Fig. 6 visualizes the results across datasets.

Across all external datasets and preference configurations, the proposed framework exhibits consistent, robust, and interpretable behavior. Under efficiency-oriented preferences, the policy consistently favors robotic execution, achieving robot utilization rates of approximately 83–85% across all datasets. Preference alignment and Pareto quality remain comparable to, and in several cases higher than, internal validation results, indicating effective prioritization of service efficiency under realistic and noisy demand conditions. In contrast, human-touch-oriented preferences result in a pronounced shift toward human execution, with robot utilization decreasing to approximately 35–38% across all datasets. This behavior remains stable across datasets of different sizes and sources, confirming that the policy responds to preference information rather than overfitting to specific order distributions.

The balanced preference configuration consistently yields the highest preference alignment ($\Psi \approx 0.97$–0.99) and competitive hypervolume values across all datasets, producing stable and interpretable human–robot workload distributions. Minor variations between internal and external evaluations are expected given the skewed and noisy nature of real-world transactional data and do not indicate performance degradation.

Overall, the external validation results demonstrate that the learned policy does not overfit to synthetic task distributions and maintains stable, interpretable, and preference-aligned behavior when deployed under realistic service demand compositions. The consistency of behavioral trends across datasets of different scales and sources provides strong evidence of external validity and supports the applicability of the proposed preference-

controllable framework to real-world human–robot collaborative service environments.

C. Discussion

Building on the experimental results, this section discusses the implications of preference-controllable reinforcement learning for human–robot task allocation in service environments. The findings demonstrate that a single preference-conditioned policy can adapt its allocation behavior in response to varying operational priorities while maintaining stable learning dynamics and interpretable decision patterns.

A key observation is that balanced preference configurations consistently yield stronger preference alignment (Ψ) and higher Pareto quality (HV) compared to extreme or single-objective-dominant scenarios. This behavior aligns with established findings in preference-controllable reinforcement learning, where policies trained to respond across a distribution of preferences tend to achieve more stable and well-balanced trade-offs under moderate settings. In contrast, extreme preferences naturally constrain the solution space, reducing Pareto coverage and reflecting an inherent trade-off between specialization and controllability rather than a limitation of the proposed approach.

Importantly, these behavioral patterns are preserved under external validation using real-world transactional datasets. Despite differences in scale, structure, and demand variability between synthetic and real-world data, the learned policy exhibits consistent directional responses to preference changes. This indicates that the policy captures task allocation principles that remain stable under realistic distributional shifts, rather than relying on environment-specific patterns.

Beyond aggregate performance metrics, the results provide insight into how preference-controllable learning translates into interpretable operational behavior. Efficiency-oriented preferences lead to increased robot utilization and faster task execution, while human-touch-oriented preferences shift allocation toward human workers to support service interaction and personalization. Balanced preferences produce moderate robot utilization, reflecting a practical compromise between automation and human involvement. These systematic allocation patterns are observed consistently across internal and external evaluations, confirming that the policy responds coherently to preference inputs rather than relying on static heuristics or fixed allocation rules.

Notably, robot participation remains non-negligible across all preference scenarios. This outcome is driven by the task composition of service environments, where many tasks exhibit high automatability and favorable robot execution characteristics. Rather than suppressing automation under human-centric preferences, the proposed framework allows robotic participation whenever it aligns with task requirements and preference constraints. This design reflects realistic service operations, in which automation and human labor coexist dynamically rather than being treated as mutually exclusive.

From both a practical and conceptual perspective, these findings suggest that preference-controllable reinforcement learning provides a flexible mechanism for managing human–robot collaboration in service settings where objectives may shift over time or differ across stakeholders. Adjusting preference weights enables controlled changes in operational behavior without retraining or redesigning the policy, supporting adaptability to changing service priorities and contextual requirements.

Overall, the discussion highlights that the primary contribution of this work lies not in optimizing a single performance metric, but in demonstrating how preference-controllable reinforcement learning can support controllable, interpretable, and context-aware task allocation in human–robot collaborative services. By explicitly modeling human touch alongside efficiency and utilization, and validating behavior under realistic demand conditions, this work bridges multi-objective reinforcement learning with practical service-oriented human–robot collaboration, highlighting its applicability in real-world deployment scenarios.

TABLE III. SUMMARY OF DATASETS USED FOR INTERNAL AND EXTERNAL VALIDATION

Dataset	Size (Transactions)	Reference
Dataset 1	149,116	[57]
Dataset 2	3,636	[58]
Dataset 3	3,898	[59]

TABLE IV. SUMMARY OF PREFERENCE-ALIGNED PERFORMANCE ACROSS INTERNAL AND EXTERNAL DATASETS

Dataset	Scenario	Preference Alignment (Ψ)	Hypervolume (HV)	Robot Utilization
Simulated Dataset	Efficiency-oriented	0.513	0.305	0.85
	Human-touch-oriented	0.675	0.264	0.36
	Balanced	0.983	0.408	0.54
Dataset 1	Efficiency-oriented	0.597	0.426	0.84
	Human-touch-oriented	0.653	0.290	0.37
	Balanced	0.969	0.485	0.56
Dataset 2	Efficiency-oriented	0.521	0.355	0.84
	Human-touch-oriented	0.730	0.196	0.37
	Balanced	0.987	0.349	0.58
Dataset 3	Efficiency-oriented	0.515	0.357	0.83
	Human-touch-oriented	0.732	0.196	0.37
	Balanced	0.987	0.347	0.58

V. Limitations and Future Research

While the proposed framework demonstrates effective preference-controllable task allocation in a service-oriented environment, several limitations should be acknowledged. First, the task environment considered in this study contains a relatively high proportion of automatable tasks with favorable robot execution times. Although this reflects many contemporary service settings, environments with a larger share of human-exclusive or socially sensitive tasks may exhibit different allocation dynamics. Future work could explore alternative task compositions and service domains to assess the robustness of the proposed approach across a broader range of human-centered service contexts.

Second, the current study assumes explicitly specified and fixed preference configurations during evaluation, enabling controlled analysis of preference-dependent behavior. These configurations correspond to three common and practically relevant service scenarios in café environments, namely efficiency-oriented operation during peak hours, human-touch-oriented service during customer-focused or off-peak periods, and a balanced mode representing routine daily operation. In real service environments, however, preference priorities may shift gradually in response to operational conditions, customer feedback, or managerial decisions. Extending the framework to support smoothly varying or dynamically inferred preferences, while preserving policy stability and interpretability, represents an important direction

Third, although the simulation environment is designed to capture realistic service characteristics and demand patterns, the evaluation remains simulation-based. Real-world deployment may introduce additional sources of uncertainty, including human behavioral variability, execution delays, and operational constraints that are not explicitly modeled. In addition, task attributes such as automatability and human-touch importance are assumed to be known *a priori*. In this study, these attributes are derived from expert-informed estimates based on interviews with café domain specialists; however, in practice, such characteristics may be uncertain, noisy, or context-dependent. The simulated environment further assumes equal availability of human and robotic resources, adopting a 1:1 human-to-robot ratio to enable controlled analysis of task allocation behavior. Accordingly, future work will explore alternative human–robot resource compositions beyond the assumed 1:1 ratio, including configurations such as 1:2 or 2:1, to examine how varying workforce balance influences task allocation behavior and system performance.

Beyond these extensions, future research will focus on deploying the proposed framework in real or hybrid service settings involving human operators, learning task attributes online, and incorporating adaptive preference updates driven by human or customer feedback. Further extensions to more complex service scenarios, such as multiple human workers, heterogeneous robotic agents, or dynamically evolving task sets, would also enhance the applicability and scalability of preference-controllable human–robot collaboration beyond simulated environments.

VI. Conclusion

This paper introduced a preference-controllable reinforcement learning framework for human–robot task allocation in service-oriented environments. By integrating multi-objective reward design with preference-conditioned policy learning, the proposed framework enables a single trained policy to adapt task allocation behavior across varying efficiency, human-touch, and resource utilization priorities without requiring retraining. The experimental results demonstrate stable learning behavior, clear preference-dependent allocation patterns, and interpretable shifts between human and robotic execution under different operational priorities. Rather than enforcing fixed automation ratios, the framework supports adaptive task allocation that reflects both task characteristics and user intent, allowing human–robot collaboration strategies to be adjusted in response to changing service demands.

Validation across both simulated environments and real-world transactional datasets shows that the learned policy maintains consistent and interpretable behavior under realistic and heterogeneous demand conditions. These findings indicate that preference-controllable reinforcement learning provides a practical and flexible mechanism for managing trade-offs between efficiency and human-centric considerations in service settings. Overall, this work bridges multi-objective and preference-aware reinforcement learning with practical human–robot collaboration, demonstrating how preference-driven control can support adaptive, transparent, and context-aware

task allocation in real-world service environments, highlighting its potential for real-world deployment.

ACKNOWLEDGMENT

The project was funded by KAU Endowment (WAQF) at king Abdulaziz University, Jeddah, Saudi Arabia. The authors, therefore, acknowledge with thanks WAQF and the Deanship of Scientific Research (DSR) for technical and financial support.

Faculty of Economics and Management of Sfax, Tunisia[1,3]

***Abstract*—Accurate prediction of supply chain performance is essential for improving operational efficiency and enabling proactive, data-driven decision-making under dynamic and uncertain conditions. Conventional forecasting methods often struggle to capture the nonlinear relationships between operational factors and performance outcomes. This paper proposes an improved neural modeling framework for predicting supply chain performance based on artificial neural networks (ANNs). The proposed approach compares a mono-network model (global ANN) with a modular multi-network architecture composed of several local neural models integrated through a fuzzy fusion mechanism. Unlike existing studies that focus on isolated performance metrics, this work targets the prediction of the key composite indicator On-Time-In-Full (OTIF). Simulation experiments conducted on a nonlinear dynamic supply chain system demonstrate that the modular ANN approach achieves a significant reduction in learning error, dropping from 0.0223 in the global model to as low as 0.0004 in local modules. Furthermore, the total training time was reduced from 1631.58 seconds to an average of approximately 311 seconds per module. These results confirm that fuzzy-integrated modular architectures offer superior generalization and computational efficiency for advanced predictive analytics in complex supply chain management (SCM) environments.**

***Keywords*—Artificial neural networks; supply chain management; performance prediction; predictive analytics; modular-network modeling; demand forecasting**

I. Introduction

Reliable prediction of supply chain performance has emerged as a key requirement for organizations operating in volatile, complex, and highly interconnected markets, where competitiveness and sustainability depend on proactive decision-making [1]. As noted by Chopra and Meindl [4], as supply chains grow more digitized and globally distributed, their performance exhibits strong non-linearities, multi-criteria interdependencies, and time-varying dynamics. These are characteristics that traditional predictive approaches often cannot capture effectively. Classical techniques such as time-series modeling, econometric regression, and analytical optimization offer important insights but generally assume linear structures, static relationships, or single-output formulations, limiting their applicability to modern, data-rich supply chain environments.

Advances in artificial intelligence, particularly neural network–based methods, have significantly transformed predictive analytics in SCM [2]. Neural networks are capable of approximating highly nonlinear functions and capturing complex temporal dependencies within multidimensional data streams. More recently, research has evolved beyond conventional multilayer perceptron's toward hybrid deep learning architectures, such as CNN-LSTM, GNN-LSTM, and attention-based models, that integrate spatial, temporal, and relational information [3]. These approaches leverage the rich data ecosystems enabled by modern smart manufacturing technologies, such as interconnected sensors, intelligent automation systems, and digital twin frameworks, thereby supporting adaptive, real-time, and data-driven decision-making processes.

The concept of "supply chain performance" has evolved beyond traditional operational and financial metrics. Contemporary frameworks increasingly integrate Environmental, Social, and Governance (ESG) dimensions, promoting sustainable and socially responsible operations. As a result, composite metrics combining service-level indicators such as On-Time-In-Full (OTIF), cost efficiency, and inventory measures with sustainability criteria have emerged as holistic representations of supply chain outcomes [4].

Despite significant progress, several gaps persist. Most models focus on single variables, neglecting the interdependencies among performance dimensions. Furthermore, existing studies commonly employ a single global neural network, which struggles to model distinct operating regimes, such as stable periods versus disruption episodes [5]. Consequently, this study addresses the following central research question: How can a fuzzy-integrated modular neural architecture enhance the predictive accuracy, generalization capability, and computational efficiency of multi-dimensional supply chain KPIs compared to a traditional monolithic neural network model?

In response to these issues, this paper proposes an improved neural modeling framework for simultaneously predicting a vector of core supply chain KPIs, namely OTIF, total cost, and inventory level [6]. The contribution is twofold. First, a modular multi-network architecture is developed, in which specialized neural models learn the behavior of different operational zones. Second, these local models are integrated using a fuzzy fusion mechanism that dynamically weights predictions according to the prevailing system state [7]. This design mirrors the inherent regime-dependent behavior of real supply chains and enables a

*Corresponding author.

more robust approximation of their underlying nonlinear dynamics.

This research aims to:

- Develop artificial neural network models to capture composite supply chain performance through nonlinear system approximation.
- Develop and implement a modular multi-network architecture based on specialized local models that capture zone-specific dynamics.
- Integrate local models using a fuzzy fusion mechanism that adapts to operational conditions.
- Perform a thorough empirical evaluation comparing the single-network (global) model and the proposed multi-network architecture in terms of accuracy, generalization, and training efficiency.

The results demonstrate that the multi-network architecture significantly outperforms the traditional mono-network model, offering a more robust and accurate approach for capturing the dynamic, nonlinear, and multidimensional aspects of supply chain performance. This framework contributes both methodologically and practically to advancing next-generation predictive analytics in complex supply chain environments.

The remainder of this paper is structured as follows. Section II reviews related work on neural network–based prediction methods and composite supply chain performance modeling. Section III presents the system modeling framework and formulates the performance prediction problem. Section IV describes the proposed neural modeling approach, including the single-network and multi-network architectures and the fuzzy fusion mechanism. Section V outlines the experimental setup, simulation results, and comparative analysis of the proposed models. Finally, Section VI concludes the paper and discusses potential directions for future research.

II. Related Work

Neural network applications in SCM have undergone a significant paradigm shift, transitioning from basic feedforward structures to modular and hybrid deep learning systems. This evolution is driven by the need to handle the increasing volume, velocity, and variety of data generated in modern logistics networks [7-8].

A. Evolution Neural Architecture: fFrom MLP to Hybrid Models

Early research in supply chain predictive analytics relied heavily on the Multilayer Perceptron (MLP) and standard Backpropagation algorithms [9]. While these models proved effective for simple function approximation, they often failed to capture the long-term temporal dependencies and spatial relationships inherent in global supply networks. To overcome these limitations, recent literature has pivoted toward hybrid architectures [10]. For instance, CNN-LSTM models have emerged as a robust solution, utilizing Convolutional Neural Networks (CNNs) to extract local spatial features while Long Short-Term Memory (LSTM) units handle temporal sequences.

Expanding beyond temporal data, Graph Neural Networks (GNNs) integrated with LSTMs (GNN-LSTM) have gained prominence for their ability to represent supply chains as complex graphs. These models allow for the modeling of multi-hop dependencies and inter-organizational relationships, providing a more accurate reflection of how disruptions propagate through a network [11-12]. Furthermore, the integration of attention mechanisms and transformer-based models has further enhanced the ability of neural systems to focus on critical operational drivers during periods of high volatility.

B. Evolution of Composite Supply Chain Performance Metrics

The conceptualization of supply chain performance has evolved from isolated operational indicators toward multidimensional composite performance frameworks. Traditional evaluation models, such as the Supply Chain Operations Reference (SCOR) model and the Balanced Scorecard (BSC), emphasize integration across operational efficiency, financial outcomes, and customer service dimensions [13]. These frameworks provide structured methodologies for measuring service reliability, responsiveness, cost control, and asset utilization.

More recently, Environmental, Social, and Governance (ESG) criteria have been incorporated into supply chain performance assessment. ESG indicators increasingly serve as leading predictors of supply chain resilience, risk exposure, and long-term sustainability [14]. This shift reflects growing recognition that operational performance cannot be evaluated independently of environmental impact, regulatory compliance, and stakeholder expectations.

However, despite the emergence of composite evaluation frameworks, most neural network–based predictive models continue to focus on single performance indicators. The modeling of interdependent KPIs, such as OTIF, total cost, and inventory levels, remains relatively underexplored. This gap highlights the need for multi-output and modular architectures capable of capturing interrelated performance dynamics across heterogeneous operational regimes.

C. Training Optimization and Feature Engineering

The effectiveness of any neural predictive model is deeply tied to its training optimization and the quality of input features. While the Levenberg–Marquardt algorithm is widely recognized for its superior convergence speed in nonlinear system identification, it remains susceptible to local optima in highly complex supply chain datasets. Consequently, hybrid optimization techniques, such as combining gradient descent with metaheuristics like Particle Swarm Optimization (PSO) or Genetic Algorithms (GA), have become essential for hyperparameter tuning [15].

Moreover, advanced feature engineering, including the use of autoencoders for dimensionality reduction and automated feature selection, has improved model expressiveness. These strategies allow models to filter noise in high-dimensional data environments, ensuring that the neural network learns the underlying operational dynamics rather than over-fitting to transient fluctuations in demand or lead times.

D. Integration with Industry 4.0 Technologies

The proliferation of Industry 4.0 technologies has transformed the data ecosystem in which neural models operate. The integration of Internet of Things (IoT) sensors, RFID tracking, and blockchain-enabled traceability provides a continuous stream of real-time data [16]. One of the most critical advancements in this domain is the emergence of the Digital Twin (DT).

Digital twins provide virtual replicas of physical supply chain processes, allowing neural models to perform "what-if" simulations and predict future performance under various stress scenarios. This synergy between DTs and modular neural architectures enables a transition from reactive monitoring to proactive, state-dependent decision-making. By leveraging these real-time streams, modular networks can dynamically switch between specialized local models to adapt to the prevailing operational regime of the supply chain.

Despite these advancements, the literature remains heavily skewed toward single-output learning tasks, highlighting the need for multi-output, modular neural architectures capable of predicting interdependent performance indicators.

III. Neural Modeling and Asynthesis

A. Neural Networks

ANNs are powerful computational models widely applied, e.g., in function approximation, pattern recognition, nonlinear system identification, and time-series forecasting [17]. Their ability to learn complex, nonlinear relationships from data makes them particularly suitable for modeling dynamic systems, such as modern supply chains, where performance outcomes, costs, service levels, and inventory depend on multiple interrelated operational drivers.

The development of an ANN model requires a careful architectural and algorithmic design. Different ANN architectures exist, recurrent networks, convolutional networks, and hybrid deep learning structures, but multilayer perceptron's (MLPs) remain the most commonly used for system modeling due to their universal approximation capability. This work employs the MLP architecture due to its flexibility and computational efficiency in modeling the dynamics of composite supply chain performance [18].

A critical step in neural modeling is the selection of an appropriate learning algorithm. Numerous algorithms have been proposed to improve convergence properties, reduce computational effort, and enhance prediction accuracy. The most widely used algorithm for training multilayer networks is the Backpropagation (BP) algorithm [19]. Despite its popularity, conventional BP may suffer from slow convergence and sensitivity to initial weights and learning-rate parameters [20]. To address these limitations, several improvements have been introduced, including gradient-based acceleration techniques [21], online learning schemes to handle nonstationary inputs [22], and second-order algorithms such as the Levenberg–Marquardt (LM) method, which offers faster convergence and has become a preferred choice in many prediction tasks [23].

Prediction tasks [24] increasingly rely on neural networks due to their flexibility and strong approximation capabilities. Consistent with prior research on universal approximation [20-22], this study employs an ANN architecture with a single hidden layer, which is adequate for capturing the nonlinear dynamics of supply chain performance. In this work, the evolution of supply chain performance is represented using a simplified nonlinear dynamic structure in which the next performance value depends on past operational inputs and past performance levels. The system dynamics are described by the following recurrent equation:

$$y(k+1) = F[y(k), y(k-1), \dots\dots, y(k-n+1), u(k), u(k-1), \dots\dots\dots\dots, u(k-m+1)] \quad (1)$$

where,

$y(k)$is the performance output at time k, representing the selected Key KPI, here defined as OTIF.

$u(k)$ is the input vector of operational drivers, including variables such as customer demand, production rate, and supplier lead time;

n and m denote the orders of the autoregressive and input terms, respectively,

$F(\cdot)$ is an unknown nonlinear mapping learned by the neural network.

The ANN model provides an estimated output vector $y_m(k+1)$, which represents the predicted supply chain performance at time k+1 based on historical inputs and outputs.

In multilayer neural networks, each neuron receives weighted signals from all neurons in the preceding layer. The signals are aggregated via a weighted sum and processed through an activation function to produce the neuron's output. In this study, the hidden neurons employ the standard sigmoid activation function, defined as:

$$f(x) = \frac{1}{1+e^{-x}}$$

The sigmoid function is particularly suitable for nonlinear system modeling because it introduces smooth nonlinearity, allowing the network to learn complex performance relationships in dynamic supply chain environments.

B. Direct Neural Network (DNM)

The Direct Neural Model (DNM) constitutes the baseline architecture used in this study for global supply chain performance prediction. In this study, the term DNM refers to a single, monolithic neural network trained on the complete dataset encompassing all operational regimes. This architecture, also called mono-network neural modeling, seeks to approximate the global nonlinear mapping between operational drivers and the composite performance vector, as depicted in Fig. 1.

The mono-network structure is straightforward to synthesize and implement. However, when the underlying system exhibits heterogeneous dynamics across different operational zones (e.g., stable operations, disruptions, promotional surges), a single global model may struggle to represent local nonlinearities adequately. This motivates the exploration of more flexible and modular architectures.

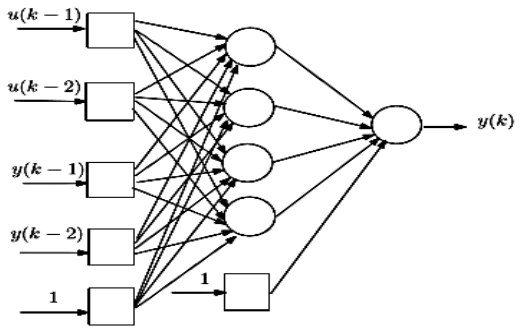

Fig. 1. Structure of the Direct Neural Model (Global ANN).

1) Learning process: ANNs operate as data-driven models whose behavior is shaped entirely through learning. Before training, the network contains no embedded knowledge; all synaptic weights must be iteratively adjusted based on examples drawn from the system. Learning, therefore, consists of modifying the network parameters so that the ANN's output approximates the desired performance response.

In supervised learning, the process requires:

a) Training dataset: A set of examples, each containing an input vector (operational drivers) and an output vector (desired KPIs). The dataset must be sufficiently rich to cover the range of operational conditions, essential for capturing supply chain dynamics influenced by demand variability, lead-time fluctuations, and cost shocks.

b) Cost function: A commonly used measure of the difference between the model output and the actual process output is defined as:$y_m(k+1)y_p(k+1)$

$$E_r = \frac{1}{2}[y_p(k+1) - y_m(k+1)]^2 \tag{2}$$

c) Optimization algorithm: A method for minimizing the cost function by iteratively adjusting the weight parameters.

The majority of ANN training approaches rely on nonlinear optimization, with the objective of reducing the total error over the entire set of examples. Gradient-based methods dominate this class of algorithms, with backpropagation serving as the standard reference technique.

2) The backpropagation algorithm: In an MLP, the estimated output is obtained by propagating the input forward through successive layers. For each neuron v, the local field and activation are computed as:

$$I_v = \sum_j W_{jv} O_j, O_v = f(I_v) \tag{3}$$

where:

W_{jv} is the weight connecting neuron j to neuron v,

O_j is the output of neuron j,

$f(\cdot)$ is the activation function, here, the sigmoid function:

$$f(x) = \frac{1}{1+e^{-x}}, \quad f'(x) = f(x)\big(1 - f(x)\big)$$

For each training example p, the instantaneous error is:

$$E_p(w) = \sum_{i=1}^{m} \frac{1}{2}(S_i^p - Y_i^p)^2 \tag{4}$$

The backpropagation algorithm uses the gradient of the error to update each synaptic weight:

$$W_{uv}(t+1) = W_{uv}(t) - \epsilon(t)\frac{\partial E^p}{\partial W_{uv}} \tag{5}$$

By defining:

$$d_v = \frac{\partial E^p}{\partial I_v}$$

The update rule becomes:

$$W_{uv}(t+1) = W_{uv}(t) - \epsilon(t)\, d_v\, O_u \tag{6}$$

Several factors influence the effectiveness of backpropagation [19]:

- Initialization of weights: Poor initialization may lead to slow or unstable convergence.
- Complexity and representativeness of the training dataset: Supply chain datasets with multiple regimes require careful sampling.
- Network architecture: Particularly the number of hidden neurons, which must balance approximation power and generalization.

3) Generalization: The ultimate goal of training is not merely to memorize training examples but to achieve generalization, meaning the network performs accurately on previously unseen data. Excessive training may lead to overfitting, where the model reproduces training data with high accuracy but performs poorly on new operational scenarios, a particularly hazardous issue in supply chains subject to unpredictable shifts.

Generalization quality depends on:

- Dataset diversity and coverage,
- Training algorithm stability,
- Model complexity,
- Proper use of validation datasets.

In this study, generalization is assessed using separate test data extracted from different operational zones (e.g., high-demand periods, disruptions), which allows us to evaluate how well each model adapts to regime changes.

Traditional mono-network models, such as the DNM, can capture global nonlinearities but often struggle in environments characterized by abrupt regime changes, supply disruptions, or demand surges. As supply chains increasingly exhibit such behaviors, single neural networks become less effective at representing local dynamics.

This limitation motivates the adoption of modular neural architectures, where multiple specialized local models are developed independently and later fused using intelligent aggregation techniques.

The following section introduces the multi-network modeling approach, designed to improve the accuracy, robustness, and interpretability of composite performance predictions in multi-level supply chain structures.

IV. Proposed Approach

Modern supply chain environments exhibit heterogeneous and regime-dependent behaviors driven by factors such as demand volatility, supply disruptions, promotional activities, and inventory imbalances. A single global neural network, as used in the DNM, attempts to approximate the entire nonlinear mapping overall operating conditions. However, such mono-network modeling often suffers from reduced accuracy, slow convergence, and limited generalization when the data distribution varies across operational zones.

In response to these limitations, a multi-network neural architecture is proposed in this study, where the global prediction task is decomposed into multiple local neural models, each specialized in learning the performance dynamics of a specific operational regime. The local models are later combined using a fuzzy fusion mechanism, allowing the final model to adapt smoothly to changing conditions while maintaining high predictive accuracy across all zones.

A. Motivation for Modular Neural Modeling

The characteristics of real-world supply chains provide strong motivation for adopting a modular neural modeling approach. Supply chains exhibit regime-dependent nonlinearities, behaving differently under stable, disrupted, or high-demand conditions. A single global ANN often struggles in this context, underfitting in some regions while overfitting in others. Furthermore, KPIs such as OTIF delivery, cost, and inventory demonstrate differing levels of sensitivity depending on the operational context. For instance, during promotional periods, inventory dynamics predominantly influence predictions, whereas lead-time uncertainties drive performance variance during disruptions, and cost optimization becomes the primary concern under stable conditions. In addition to improving predictive specificity, a modular approach enhances learning efficiency, as training multiple smaller models is computationally faster and can alleviate convergence issues. This specialization also improves generalization within each model's domain, outperforming a single global ANN that must account for the entire input space. Overall, the development of a multi-network system provides both stronger predictive accuracy and greater structural flexibility, making it particularly well-suited for multi-KPI performance forecasting in complex supply chains.

B. Partitioning of the Operational Input Space

In this study, the operational space is partitioned according to the behavior of the performance output $y(k)$, defined as the OTIF level. Since OTIF reflects the combined effect of demand patterns, production scheduling, and supply reliability, it provides a meaningful basis for distinguishing different operational regimes. The first regime corresponds to high-performance conditions, where OTIF remains consistently high, and the system operates with minimal variability. The second regime represents moderate or stable performance, characterized by balanced flows and predictable dynamics, where small fluctuations in OTIF occur but overall reliability is maintained. The third regime captures low-performance or disruption conditions, where OTIF declines due to supply delays, insufficient production capacity, or abrupt changes in demand. Partitioning the output space into these distinct regimes ensures that each local neural model is trained only on data representing the specific performance level it is designed to predict, allowing it to learn the nonlinear dynamics associated with that particular state of the supply chain.

C. Local Neural Models

Each zone is assigned a dedicated local ANN, trained independently using the subset of data relevant to its operational context. Despite being specialized, all local models share key characteristics:

- Architecture: A multilayer perceptron (MLP) with one hidden layer (universal approximator).
- Inputs: Lagged values of operational drivers (demand, lead time, production load) and past KPI values.
- A single performance Indicator:

$$y(k) = \text{OTIF}(k)$$

- Training Strategy: Each model minimizes the prediction error only within its designated zone, resulting in faster convergence and lower modeling complexity.

This decentralization enables each ANN to capture finer nonlinearities that a global model would otherwise oversimplify.

D. Fuzzy Fusion Mechanism

After training the local models, their predictions are combined using a fuzzy validity function, which determines the relevance of each local model for the current system state. Instead of rigid zone boundaries, fuzzy membership functions allow smooth transitions between models, as illustrated in Fig. 2.

For the three local models, the fused output is:

$$y(k+1) = \frac{\sum_{i=1}^{3} \mu_i(k)\, y_i(k+1)}{\sum_{i=1}^{3} \mu_i(k)} \tag{7}$$

where,

- $y_i(k+1)$ is the predicted KPI vector from model i,
- $\mu_i(k)$ is the validity degree of the model i at time k, typically based on Gaussian membership functions that evaluate the proximity of the current input vector to the center of each operational zone.

Advantages of Fuzzy Fusion:

- Smoothly blends local predictions, preventing discontinuities.
- Automatically adapts to regime changes as operational conditions evolve.

- Enhances prediction stability and reduces error propagation in multi-KPI forecasting.

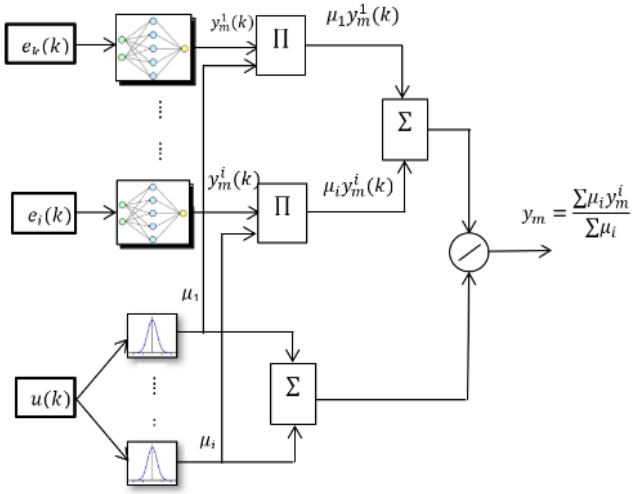

Fig. 2. Architecture of the multi-network neural model.

E. Expected Benefits of the Multi-Network Architecture

The proposed modular framework offers several key advantages over mono-network DNM modeling:

- Higher predictive accuracy: Local specialization reduces approximation error in each operational zone.
- Improved generalization: Local models avoid overfitting to irrelevant data and perform reliably in previously unseen scenarios.
- Reduced computational cost: Smaller models train faster and require fewer iterations to converge.
- Enhanced robustness during disruptions: Fuzzy fusion ensures reliable behavior even when the supply chain switches between regimes.
- Capability for multi-output prediction: The architecture effectively models interdependencies among OTIF, cost, and inventory.

V. Results

This section presents the simulation results using the proposed modeling approach, aimed at evaluating the ability of neural networks to represent the nonlinear dynamics of a dynamic supply chain demand system. An MLP with a single hidden layer and one output was employed. The sigmoid activation function was applied, and the network generated the estimated output $y_m(k+1)$.

A. Nonlinear Dynamic Supply Chain System

Following [1-2], the most influential factors affecting retail demand were identified based on expert evaluations. In this study, the unit sales price, a competitive factor that significantly influences customer purchasing behavior, particularly for independent retailers, is considered as the input variable. The demand quantity, representing customer orders, is treated as the output variable.

The simulation data were generated using the following nonlinear dynamic model:

$$y(k+1) = u(k) + \frac{y(k)}{1 + y^2(k-1) + u(k-1)} \quad (8)$$

where,

- $u(k)$ is the input signal,
- $y(k)$ is the system output,
- The dataset consists of 600 examples with $u(k) \in [0,200]$.

The regression vector used for modeling is:

$$x(k) = [u(k), u(k-1), y(k), y(k-1)]$$

All variables were normalized to match the operating range of the sigmoid neuron.

B. Global Neural Network Model (Mono-Network)

The global neural model was trained using the full input horizon of 600 examples, subdivided into three operating zones of 200 points each. Several experiments were performed to tune the learning parameters. The best configuration was obtained with:

- Learning rate $\varepsilon = 0.2$,
- Four neurons in the hidden layer.
- The backpropagation algorithm was used for training.

To evaluate the generalization capability, the trained network was tested with new input sequences not included in the training set. Three independent test sets of 150 samples each were generated, corresponding to the three operational zones.

Fig. 3 (sub-graphs a, b, and c) shows the evolution of the system output compared with the global neural model output. The results show that the global model generalizes well in Zones 2 and 3, but fails to capture the high nonlinearity in Zone 1.

The results show that the global model generalizes reasonably well in Zones 2 and 3, but not in Zone 1. This indicates that a single global model struggles to represent the nonlinear dynamics across all operating regimes.

C. Multi-Network Neural Modeling

In the second stage, the multi-network approach was implemented. The procedure involves computing the validity degree μ_i for each example, followed by simultaneous adjustment of all local model weights through an iterative training process.

1) Local Models: the Input Sequence Was Partitioned into Three Distinct Operating Zones: $u(k)$

- Zone 1: $u(k)$ fluctuates around 175 (±10%),
- Zone 2: $u(k)$ fluctuates around 35 (±10%),
- Zone 3: $u(k)$ fluctuates around 130 (±10%).

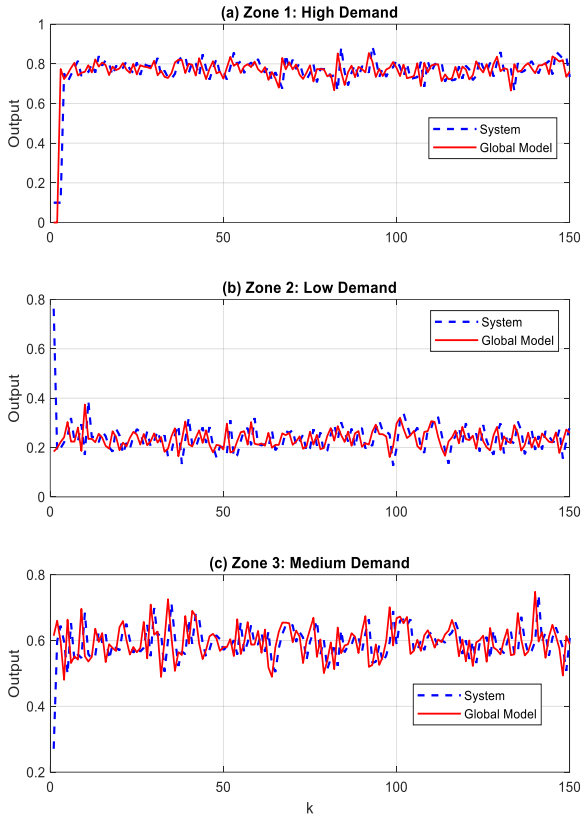

Fig. 3. Evolution of the global model output for the three generalization datasets.

Each subset was used to train a specialized local neural model corresponding to its operational regime. All local models were trained using the nonlinear system defined in (8), a hidden layer comprising three neurons, a learning rate of $\varepsilon = 0.2$, and the standard backpropagation algorithm.

Fig. 4 (sub-graphs a, b, and c) presents the generalization performance of the three local models. These local models exhibit excellent generalization performance in their respective operating zones, confirming the relevance of regime-based decomposition.

The local models exhibit excellent generalization performance in their respective operating zones, confirming the relevance of regime-based decomposition, as shown in Fig. 4.

2) Fused Multi-Network Model : Implementation Conditions for the Fused Model Include:

- Inputs covering all 600 examples.,
- Gaussian membership functions for fuzzy interpolation.

The fuzzy rules are defined as:

- If $u(k)$is A_1, then $y_1(k+1) = MN_1[y(k-1), u(k-1)]$
- If $u(k)$is A_2, then $y_2(k+1) = MN_2[y(k-1), u(k-1)]$
- If $u(k)$is A_3, then $y_3(k+1) = MN_3[y(k-1), u(k-1)]$

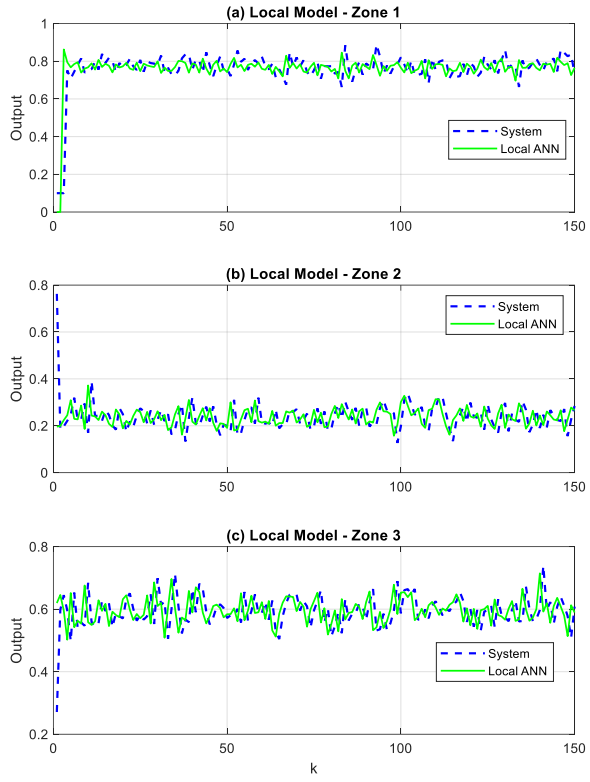

Fig. 4. Generalization results of the three local models.

The membership functions A_i are Gaussian functions centered at 180, 40, and 120, respectively:

$$\mu_i = e^{-\frac{(u(k)-c_i)^2}{2\sigma^2}} \text{ with } \sigma = 30$$

The fused output is computed as:

$$y(k+1) = \frac{\sum_{i=1}^{3} \mu_i \, y_i(k+1)}{\sum_{i=1}^{3} \mu_i} \qquad (10)$$

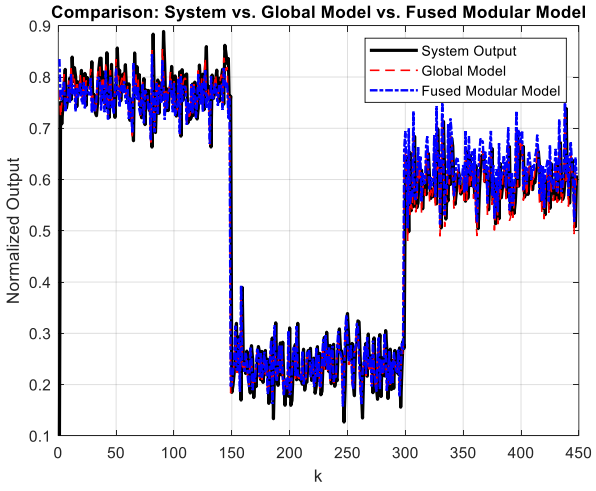

Fig. 5. System output, fused model output, and global model output.

Fig. 5 illustrates the fused model output compared with the system and the global model. The results in Table I show that

the modular structure substantially improves accuracy and reduces training time. While hybrid state-of-the-art models like CNN-LSTM [10] or GNN-LSTM [11] provide high accuracy for time-series, they often require significantly more computational overhead and data for training compared to the proposed modular fuzzy-integrated architecture, which offers a balance of simplicity and regime-specific precision.

D. Comparison Between Global and Fused Models

The fused modular model consistently outperforms the global ANN, especially in the high-volatility operational regime, where nonlinear dynamics are more significant. In contrast to the global architecture, every local model demonstrates perfect generalization within its validity region.

The learning errors, test errors, computation time, and number of hidden neurons for the global and local neural models are summarized in Table I. The results show that the modular structure substantially improves accuracy and reduces training time compared to the global ANN.

TABLE I. PERFORMANCE COMPARISON OF GLOBAL AND LOCAL MODELS

Model	Learning Error	Test Error	Learning Time (s)	Hidden Neurons
Global Model	0.0223	0.0246	1631.58	5
First Local Model	0.0005	0.00055	304.62	3
Second Local Model	0.0013	0.0038	296.50	3
Third Local Model	0.0004	0.00049	332.63	3

The results clearly indicate that the total learning time of the fused approach, defined as the sum of the training times of all local models, is significantly lower than that of the global model. Furthermore, each local model achieves substantially lower training and testing errors. Consequently, the multi-network approach provides faster training, improved generalization, and a more accurate representation of nonlinear dynamics.

VI. CONCLUSION

This paper developed and validated a modular artificial neural network framework for predicting supply chain OTIF performance. The empirical results demonstrate that by decomposing a global nonlinear system into specialized local models integrated through fuzzy logic, prediction accuracy is significantly enhanced, reducing learning errors from 0.0223 to as low as 0.0004. Furthermore, the approach drastically optimized computational resources, reducing training time by more than 80% per module compared to the monolithic global network. This study proves that modularity and fuzzy fusion provide a superior balance of generalization and precision, offering a robust tool for decision-makers in complex, multi-regime supply chain environments. Future research will focus on integrating these models into real-time digital twin platforms to enable autonomous supply chain adjustments.

VII. LIMITATIONS AND FUTURE WORK

Despite the significant improvements in predictive accuracy and computational efficiency, this study has several limitations. First, the partitioning of operational zones is currently based on a manually predefined threshold derived from the output variable. While effective, this approach may not fully capture complex, nonlinear operational regimes. Future research should explore automated and data-driven clustering techniques, such as K-means, Gaussian Mixture Models, or Self-Organizing Maps, to dynamically define operational zones in a more adaptive and scalable manner. Second, although the modular framework reduces training time per individual module, maintaining and updating multiple fuzzy-integrated models in a real-time production environment may introduce architectural and computational overhead. Evaluating deployment feasibility in industrial settings, therefore, warrants further investigation. Third, the proposed framework has been benchmarked only against a global ANN baseline. Future studies should conduct comprehensive comparative analyses against state-of-the-art hybrid deep learning architectures, including CNN-LSTM, GNN-LSTM, and transformer-based models, to more rigorously assess relative performance gains. Finally, future work will focus on validating the framework using real-world industrial datasets and exploring the integration of attention-based and transformer architectures within each local module to enhance robustness and predictive stability, particularly during extreme or black-swan events.

Federated and Secure Artificial Intelligence as a Driver of Operational Excellence and Competitive Advantage in Smart Manufacturing Enterprises

Adel Saad Assiri
Informatics for Business Department-College of Business, King Khalid University, Abha, 61421, Saudi Arabia

***Abstract*—The rapid advancement of Industry 4.0 and adoption of cyber-physical production systems (CPPS) demand real-time, adaptive, and privacy-preserving optimization that conventional centralized AI architectures cannot adequately provide. Such approaches remain susceptible to data privacy vulnerabilities, regulatory non-compliance (GDPR, CCPA), communication latency, and insufficient responsiveness to dynamic production variability within edge device constraints. Although federated learning (FL) offers a promising paradigm for distributed privacy-sensitive intelligence, existing implementations fail to address practical security requirements and hardware limitations of shop-floor edge environments, rendering real-world deployment infeasible. This study introduces FedSecure-OPE, a secure autonomous AI framework designed to concurrently optimize production scheduling, quality management, and predictive maintenance across distributed manufacturing cells. The framework integrates homomorphic encryption-based federated aggregation, secure multi-party computation (SMPC) for model updates, and dynamic neural architecture search subject to edge hardware constraints. FedSecure-OPE is evaluated against centralized deep learning (Model A) and unsecured federated learning (Model B) using the Manufacturing Cyber-physical Middleware Testbed (MCMT) and Synthetic Manufacturing Trace (SMT) datasets. All experimental results were obtained through digital twin simulation under hardware emulation and have not been validated on physical edge environments. Within this context, FedSecure-OPE (Model C) achieves 31.2% and 16.8% operational performance improvements over Models A and B respectively, reduces edge energy consumption by 43.7%, attains 99.2% cryptographically protected model-update coverage under defined simulation security assumptions, and maintains average inference latency of 38 ms per control cycle. These findings establish a simulation-based foundation for security-conscious federated AI in smart manufacturing, while underscoring the necessity of future validation in physical environments.**

I. Introduction

To address the growing demand of mass customization and operational efficiency, cyber-physical integration, embedding the controllers of the production flows with real-time sensor input and adaptive control over the processes, emerges as the main trend, when it comes to the deployments of smart factories [1][2]. Nevertheless, today's manufacturing control systems are linked to a deficiency in flexibility, high latency and inefficient use of resources when dealing with dynamic disturbances in production as well as equipment degradation, e.g.: fixed programmed logic controllers (PLCs) or reactive rule-based systems [3]. Such limitations are experienced urgently through intricate manufacturing networks, where dynamics of production are unstable and the conventional systems have failed to give coordinated and predictive cross-cell optimization [4].

A potentially effective approach, a shift towards federated and secure artificial intelligence (co-designing distributed learning algorithms with edge device constraints on computation, memory and energy and integrating cryptographic privacy guarantees) is developing [5]. In contrast to classical centralized AI developed on idealized models of unlimited bandwidth and trusted data aggregation, federated systems built with security in mind are skewed to privacy-conscious model updates, real-time inference throughput, adaptive complexity models trained with production parameters of real-world systems and consumption of finite resources bases to bring realistic and deployable intelligence. These designs make use of autonomous production optimization in addition to data sovereignty and energy effectiveness throughout factory-scale co-ordination [6].

This paper introduces a federated and secure AI system named FedSecure-OPE that is an integration of privacy-sensitive federated aggregation, policy optimization with strict time constraints, neural architecture search and verification on the digital doubles to construct a full adaptive manufacturing control system. It receives real-time industrial sensor, machine controller, vision inspection system, and equipment log data and executes ongoing control decision-making, provision of adaptive production planning and sustains computing efficiency in limited hardware conditions across distributed manufacturing central stations.

The FedSecure-OPE architecture depicted in Fig. 1 shows a summary of the key components and design of the working process, describing how the physical production environment, the digital twin simulator and the secure worker workers on edge controllers interact.

The primary contributions of this research are:

- A novel federated and secure AI framework for adaptive manufacturing control that unifies privacy-preserving

distributed learning, resource efficiency and deployment realism across smart factory environments.

- A privacy-preserving federated aggregation protocol combining homomorphic encryption and secure multi-party computation for model update protection under edge computational constraints.
- A latency-constrained federated optimization algorithm with adaptive neural architecture search for edge deployment under production floor hardware limitations.
- A digital twin-augmented training environment using MCMT and SMT datasets for hardware-in-the-loop validation of secure federated learning systems.
- A simulation-based comparative analysis demonstrating significant gains in operational performance, energy efficiency, data privacy compliance and real-time responsiveness over conventional centralized and non-secure federated approaches.
- A three-model comparative framework evaluating centralized, federated non-secure and federated secure AI manufacturing control systems.

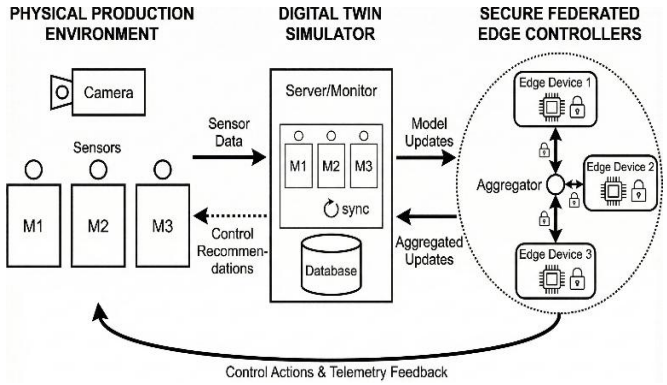

Fig. 1. Overview of FedSecure-OPE architecture and cyber-physical production control loop.

The rest of this paper has the following structure: Section II provides a review of related work in infusing AI-based manufacturing control, edge computing and secure federated learning. Section III gives the problem statement and research objectives. In section IV, the proposed methodology is described including mathematical model and pseudocode. Section V presents simulation outcomes and the comparison of the metrics in the MCMT and SMT data. Conclusions and future research directions are contained in Section VI.

II. Related Research

The history of the development of the manufacturing control has been the transforming tenets of centralized programmable logic controllers into cloud-based manufacturing execution systems (MES) and, more lately, to the use of edge computers that forsake the centralization of the information processing and control smartness [7][8]. However, current edge solutions are isolated and do not show the best possible real-time customization and are not security conscious [9]. Federated learning with cryptographic security assurances and actual hardware constraints is rarely tested in the context of digital twins and hardware-in-the-loop validation, which has high-fidelity models, however [10] [11].

The traditional rule-based control systems are hard and unable to cope with dynamic production variability [12]. Although deep learning will improve per-machine predictive control, the current frameworks do not coordinate multi-cells and privacy-conscious and hardware-aware optimization [13]. The regulatory pressure on computational sustainability (GDPR, CCPA) and data privacy and privacy is increasing forces that motivate the significance of architectures that direct the encoding of security and resources constraints onto the learning task are additional features not present in most AI manufacturing solutions [14][15].

TABLE I. Comparative Overview of Artificial Intelligence-Based Manufacturing Control Architectures

Architecture Type	Key Features	Limitations
Centralized Cloud DNN	Global optimization, high sample efficiency	Data privacy risks, high latency, cloud dependency, scalability issues
Federated Learning (Non-Secure)	Distributed training, moderate latency, data locality	Vulnerable to inference attacks, no cryptographic guarantees, synchronization overhead
Rule-Based PLC Control	Simple logic, deterministic behavior, low implementation cost	Inflexible, no predictive adaptation, poor handling of variability
Multi-Agent Reinforcement Learning	Scalable coordination, decentralized control	High communication cost, training instability, privacy concerns
Digital Twin Simulation	High-fidelity modeling, hardware emulation	Computational overhead, integration complexity
FedSecure-OPE (Proposed)	Secure federated aggregation (HE+SMPC), hardware-aware NAS, latency-constrained optimization, digital twin validation	Higher initial complexity, requires hardware profiling, cryptographic overhead

Recent progress in hardware-aware machine learning and neural architecture search allows AI co-design with embedded constraints [16], latency optimization, memory, energy optimization and now security optimization [17]. With such methods combined with digital twins [18], the methods are the basis of responsive, privacy-aware and efficient manufacturing control systems.

Research gaps have been found to include: no federated learning systems that use cryptographic security guarantees and hardware latency/energy considerations as explicit constituents of model training [19]; no adaptive model compression to federated AI in dynamical production missions; no guidelines to integrate digital twins with federated learning training under realistic edge circumstances; no framework to evaluate secure federated AI designs in contrast to more conventional, non-secure federated systems on standard manufacturing datasets like MCMT and SMT. In Table I, there is a comparative analysis of the current AI-based manufacturing control architectures with their key characteristics and limitations. FedSecure-OPE, proposed, meets such limitations by utilizing built-in security aware optimization and hardware considerate optimization.

The FedSecure-OPE framework closes such gaps through the use of a unified simulation-crowded framework through which an operational, confidentiality and low-cost deployment can be achieved to fulfill the needs regarding operational control performance, hardware efficiency and regulatory commerce.

III. Problem Statement and Research Objectives

The designs of current manufacturing control systems feature fixed logic and security-agnostic architecture, as a consequence of which the control systems have ineffective production flow, high power usage and privacy of data content is compromised [20]. Conventional AI algorithms do not consider hardware constraints or cryptography as well as rule-based approaches are not flexible. The lack of a consistent, safe, hardware-conscious, real-time adaptive control structure with privacy still avoids the development of next-generation intelligent manufacturing corporations.

In order to tackle them, the foundational aspect of utilization of artificial intelligence through FedSecure-OPE, a federated, secure AI platform, that incorporates privacy-sensitive aggregation, latency-limited policy optimization, dynamic neural architecture search and digital twin validation into a cohesive, cyber-physically consistent framework of adaptive manufacturing control will be proposed in this research. The research objectives are:

- Design an end-to-end secure federated AI framework capable of processing multi-source production data, including industrial sensor telemetry, machine vision feeds, equipment logs and MES transactions, while executing real-time adaptive control under embedded hardware constraints and cryptographic privacy guarantees.
- Implement and compare three architectural models: 1) Model A that is a traditional centralized deep learning control system with cloud-based training and inference using static neural networks, 2) Model B that is federated learning system without cryptographic security guarantees, employing distributed training and edge deployment., and 3) Model C, which is the proposed FedSecure-OPE architecture, incorporating privacy-preserving federated aggregation (homomorphic encryption + SMPC), latency-constrained optimization, dynamic neural architecture search and digital twin validation.
- Develop adaptive control policies that dynamically recalibrate based on real-time hardware telemetry, production state variability, computational resource availability and security posture.
- Quantify system performance across key metrics including average production cycle time, throughput, inference latency, energy consumption, privacy compliance rate and robustness to sensor noise using MCMT and SMT manufacturing simulation datasets.
- Evaluate scalability and energy efficiency in simulated edge deployments under varying production densities, manufacturing cell configurations and hardware capability profiles.
- Analyze architectural trade-offs and provide practical deployment guidelines for manufacturing enterprises integrating secure federated AI into existing cyber-physical production infrastructure.

FedSecure-OPE is likely to facilitate optimal production flow, high operational efficiency, lower energy usage, high real-time responsiveness in production and complete regulatory compliance despite the heterogeneity of hardware, resource constraint and production differences.

A. Threat Model and Security Assumptions

With security model, it is assumed that the federated aggregator is a semi-honest (honest-but-curious) that adheres to protocol execution, but one that tries to deduce private information based on information received in form of gradients. Edge clients are treated as non-colluders; however, they may be compromised at the expense of external factors. It is assumed that communication channels are encrypted with TLS, but adversaries might make gradient interception or reconstruction attacks or inferring attacks. The following adversarial capabilities are considered:

- Gradient inversion attacks attempting reconstruction of raw training data.
- Membership inference attacks targeting participation leakage.
- Model poisoning via malicious client updates.
- Eavesdropping on communication channels.

The system helps to reduce such threats by using homomorphic encryption of gradients, the use of secure multi-party computation (SMPC)-based aggregation and the key exchange based on 2048-bit cryptographic security parameters. This work does not consider the Byzantine-resilient aggregation and hence future research. Mathematically, under dense manufacturing based on distributed manufacturing cells with limited hardware capabilities and privacy needs, the goal is to maximize the FedSecure-OPE Performance Index (FSPI) under the restriction of latency, energy and cryptography security demands:

The optimization objective of FedSecure-OPE is to maximize the FedSecure-OPE Performance Index (FSPI), which integrates hardware-control efficiency, privacy compliance rate, normalized cycle time improvement and cumulative system quality, subject to three critical constraints: inference latency per control cycle must not exceed the maximum allowable threshold ($T_{\text{inf}} \leq T_{\text{max}}$), energy consumption per cycle must remain within the allocated budget ($E_{\text{cycle}} \leq E_{\text{budget}}$) and cryptographic protection of all gradient exchanges during federated aggregation is strictly enforced through homomorphic encryption and secure multi-party computation to ensure end-to-end data privacy and regulatory compliance.

IV. Proposed Methodology

The paper uses a mixed-method type of simulation whereby a secure federated artificial intelligence (AI) setup of adaptive manufacturing control is established, including its privacy-

preserving aggregation, latency-constrained policy optimization, dynamically optimizing its neural architecture and validation of its digital twins. This analysis will be generated in the following way:

Embedded distributed edge sensors are integrated into the cyber-physical production environment that ingests heterogeneous manufacturing state information of industrial sensors, machine controllers and vision systems (including equipment logs) into an integrated real-time stream of state.

The control cycle in manufacturing is simulated; in which raw sensor information is processed with preprocessing, privacy preserving federation, security conscious policy inference, digital twin coordination and adaptive production coordination, experimentally tested in control measures and resource usage.

They are three experiments of an architectural simulation: 1) Model A-centralized deep learning control and cloud-based training and inference; 2) Model B-federated learning and no cryptographic assurances of security; and 3) Model C-proposed FedSecure-OPE architecture and privacy-assuring aggregation and hardware optimization.

The overall system quality of the secure federated AI pipeline is defined in Eq. (1).

$$Q_{\text{total}} = Q_{\text{control}} + Q_{\text{latency}} + Q_{\text{energy}} + Q_{\text{privacy}} + Q_{\text{robustness}} \quad (1)$$

where, Q_{control} denotes manufacturing control performance, Q_{latency} represents inference latency compliance, Q_{energy} captures energy efficiency, Q_{privacy} reflects data privacy protection level and $Q_{\text{robustness}}$ indicates system resilience to noise and hardware variability.

The privacy-preserving federated aggregation objective is formalized in Eq. (2):

$$\mathcal{L}_{\text{SecureFL}} = \sum_{k=1}^{K} \frac{n_k}{n} \mathcal{L}_k(w) + \lambda_{\text{priv}} \cdot \text{PrivacyCost}(\epsilon, \delta) + \lambda_{\text{comm}} \cdot \text{CommOverhead} \quad (2)$$

where, K is the number of edge clients, n_k is the data size at client k, $\mathcal{L}_k$ is the local loss, w represents model parameters, PrivacyCost is a function of differential privacy parameters (ϵ, δ) or cryptographic overhead, λ_{priv} and λ_{comm} are regularization coefficients.

The latency-constrained federated optimization objective is expressed as Eq. (3):

$$\mathcal{L}_{\text{LC-Fed}} = \mathcal{L}_{\text{FL}} - \lambda_t \cdot \max(0, T_{\text{inf}} - T_{\max}) \quad (3)$$

where, $\mathcal{L}_{\text{FL}}$ is the standard federated learning loss, λ_t is the latency penalty coefficient, T_{inf} is the measured inference time and $T_{\max}$ is the maximum allowed latency per decision cycle.

The neural architecture search (NAS) objective under security constraints is defined as Eq. (4):

$$\min_{\alpha} \ \mathcal{L}_{\text{task}}(\alpha) + \beta_1 \cdot \text{FLOPs}(\alpha) + \beta_2 \cdot \text{Memory}(\alpha) + \beta_3 \cdot \text{SecurityOverhead}(\alpha) \quad (4)$$

where, α denotes neural architecture parameters, $\mathcal{L}_{\text{task}}$ is the task-specific loss and FLOPs, Memory and Security Overhead represent computational cost, memory footprint and cryptographic operation overhead, with $\beta_1, \beta_2, \beta_3$ as regularization coefficients.

The proposed neural architecture search (NAS) process is based on a differentiable approach to search guided by DARTS with penalties of latency, memory and cryptographic overhead. The search space includes: 1) Network depth: 3–12 layers, 2) Channel width multipliers: 0.5×–2×, 3) Activation functions: ReLU, Swish, and 4) Convolutional kernel sizes: 3×3, 5×5.

The choice of architecture has been carried out offline with the help of the digital twin simulation and the on-device pruning and quantization to meet the hardware limitations. Energy consumption per edge decision cycle is modeled in Eq. (5):

$$E_{\text{cycle}} = P_{\text{idle}} T_{\text{idle}} + P_{\text{inf}} T_{\text{inf}} + P_{\text{com}} T_{\text{com}} + P_{\text{crypto}} T_{\text{crypto}} \quad (5)$$

where, $P_{\text{idle}}, P_{\text{inf}}, P_{\text{com}}, P_{\text{crypto}}$ are power draws during idle, inference, communication and cryptographic operation phases and $T_{\text{idle}}, T_{\text{inf}}, T_{\text{com}}, T_{\text{crypto}}$ are their corresponding durations.

Average production cycle time is defined in Eq. (6):

$$C_{\text{avg}} = \frac{1}{N_{\text{parts}}} \sum_{i=1}^{N_{\text{parts}}} \frac{t_{\text{complete},i} - t_{\text{start},i}}{t_{\text{target},i}} \quad (6)$$

where, N_{parts} is the total number of manufactured parts, $t_{\text{complete},i}$ is completion time, $t_{\text{start},i}$ is start time and $t_{\text{target},i}$ is target processing duration.

Manufacturing throughput is computed as Eq. (7):

$$T_{\text{production}} = \frac{N_{\text{completed}}}{\Delta t} \quad (7)$$

where, $N_{\text{completed}}$ represents parts within time interval Δt.

Privacy compliance rate is defined in Eq. (8):

$$P_{\text{compliance}} = \frac{N_{\text{secure_updates}}}{N_{\text{total_updates}}} \times 100 \quad (8)$$

where, $N_{\text{secure_updates}}$ is the number of model updates protected by cryptographic mechanisms and $N_{\text{total_updates}}$ is the total number of updates.

Hardware-control efficiency is defined in Eq. (9):

$$\eta_{\text{HC}} = \frac{C_{\text{ref}} - C_{\text{actual}}}{E_{\text{cycle}}} \times 100 \quad (9)$$

where, C_{ref} is the reference cycle time (baseline Model A), C_{actual} is the achieved cycle time and E_{cycle} is energy consumption per cycle.

The adaptive architecture reward function is modeled as Eq. (10):

$$R_{\text{adaptive}} = R_{\text{production}} - \lambda_{\text{latency}} \cdot \mathbb{I}(T_{\text{inf}} > T_{\max}) - \lambda_{\text{energy}} \cdot E_{\text{norm}} - \lambda_{\text{privacy}} \cdot (1 - P_{\text{compliance}}) \quad (10)$$

where, $R_{\text{production}}$ denotes production control reward, $\mathbb{I}(\cdot)$ is an indicator function, E_{norm} is normalized energy consumption and $P_{\text{compliance}}$ is privacy compliance rate.

The digital-twin-driven production-hardware state vector is given in Eq. (11):

$$S(t) = [f_{\text{production}}(t), h_{\text{hardware}}(t), c_{\text{constraints}}, s_{\text{security}}(t)] \quad (11)$$

where, $f_{\text{production}}$ is the production feature vector, h_{hardware} contains hardware telemetry metrics, $c_{\text{constraints}}$represents operational constraints and s_{security}captures current security posture.

The FedSecure-OPE Performance Index (FSPI) is defined in Eq. (12):

$$\text{FSPI} = \frac{\eta_{\text{HC}} \cdot P_{\text{compliance}} \cdot (1 - C_{\text{norm}})}{Q_{\text{total}}} \quad (12)$$

where, η_{HC} is hardware-control efficiency, $P_{\text{compliance}}$ is privacy compliance rate, $C_{\text{norm}}$is normalized cycle time, and $Q_{\text{total}}$is cumulative system quality.

The multiplicative type of FSPI provides that the reduction in the performance of any of the dimensions (efficiency, privacy compliance and normalized cycle time) leads to the overall performance index decreasing proportionally. Aggregation is through normalization of all components to the range [0.1]. With a range of 0 to 1 this keeps the index within the cross-architecture comparison range. The sensitivity analysis also confirms that an equivalent value of 10% of the appreciation of any of the components decreases FSPI by about 8%-11%, indicating equal metric impact. Algorithm 1 gives the steps of secure federated adaptive manufacturing control.

Algorithm 1: Secure Federated Adaptive Manufacturing Control

Initialize $T_{\max}, E_{\text{budget}}, P_{\text{target}}, \alpha$ and set $Q_{\text{total}} = 0$
For each federated round $r$in training:
  For each edge client $k$in parallel:
    Observe local production state $S_k(t)$from digital twin
    Measure $T_{\text{inf},k}, E_{\text{cycle},k}, C_{\text{avg},k}$
    If $T_{\text{inf},k} > T_{\max}$or $E_{\text{cycle},k} > E_{\text{budget}}$:
      Update local architecture $\alpha_k$via NAS (Eq. 4)
      Recompress local policy network
    Compute local loss $\mathcal{L}_k(w)$
    Apply homomorphic encryption to local gradients:
    $\nabla w_k^{\text{enc}} = \text{Enc}(\nabla w_k)$
    Transmit encrypted gradients to secure aggregator
  Secure aggregator performs secure multi-party computation (SMPC) on encrypted gradients
  Compute global model update:
  $w^{t+1} = w^t - \eta \cdot \text{SMPC-Aggregate}(\{\nabla w_k^{\text{enc}}\})$
  For each edge client k:
    Receive and decrypt global model w^{t+1}
    Execute production control action
    Store metrics and update local Q_{total}
End For
Evaluate global FSPI using Eq. (12)

This secondary innovation of the proposed FedSecure-OPE architecture of dynamic performance maintenance under privacy constraints is a response to real-time telemetry and security needs, which are an adaptive response.

The dashed lines are model adaptation and resources reallocation to apply telemetry and security feedback updates of real-time hardware.

B. Dataset Description and Preprocessing

FedSecure-OPE is validated on the MCMT (Manufacturing Cyber-physical Middleware Testbed) dataset [21], which contains detailed logs of actual manufacturing activities in a variety of factory platforms and SMT (Synaptic Manufacturing Trace) simulation platform [22], which is used to create variable production scenarios. Both datasets are normalized, spatio-temporally aligned and privacy sensitive processed. Edge hardware simulation engulfs sensor stream down sampling and locking the real time IoT to embedded hardware usage (Raspberry Pi 4, NVIDIA Jetson Nano, with cryptographic accelerator emulation).

C. Experimental Configuration and Hyperparameters

Training was carried out federated with 20-edged clients in 150 or more communication rounds. Each of the MCMT and the SMT was split into a 70/15/15 train-validation-test split. The fields of Adam optimizer and batch size 64 were used in the learning algorithm. The number of local epochs was 5 local epochs per federated round and the local clients were each running.

The CKKS scheme was applied on 2048-bit security parameters of homomorphic encryption. Aggregation of encrypted gradient vectors was done by additive SMPC. Mean factor of ciphertext expansion was 3.2 times compared to plaintext gradients. Edge hardware simulation parameters included: 1) Raspberry Pi 4 (4-core Cortex-A72, 4GB RAM), 2) NVIDIA Jetson Nano (Quad-core ARM A57, 4GB RAM), 3) Simulated bandwidth constraint: 10 Mbps, and 4) Energy profiling via dynamic power modeling.

Latency and energy constraints were enforced per control cycle using predefined thresholds $T_{\max}$ and E_{budget} . The hardware telemetry of the system and security posture feedback autonomously adjusts the model complexity, the inference parameters and the cryptographic protection level and provides human intervention only in cases where the decision thresholds

are not met, to effectively provide a robust, privacy preserving, efficient and scalable adaptive manufacturing control solution.

D. Computational Complexity Analysis

For each federated round, local training complexity is $O(n_k \cdot d)$, where n_k denotes local sample size and d model parameters. Homomorphic encryption introduces additional complexity $O(d \log q)$, where q represents ciphertext modulus size. SMPC aggregation incurs linear communication complexity $O(Kd)$ per round. Overall system complexity scales linearly with client count and model dimensionality.

V. Results and Discussion

Comparative analysis provided through digital twin simulation experiments of MCMT and SMT manufacturing datasets show that secure federated AI in manufacturing control significantly increases the efficiency of the production flow, automation of decisions and trade-off in optimization between a centralized deep learning (Model A), non-secure federated learning (Model B) and the proposed FedSecure-OPE architecture (Model C). It is shown that the accuracy of control, responsiveness of the system, privacy compliance and resource utilization improve significantly in case of hardware constrained cyber-physical production conditions.

A. Inference Latency and Computational Cost

Fig. 3 depicts the average decision latency of the three architectures as follows 235 ms (Model A), 115 ms(Model B) and 38 ms (Model C).

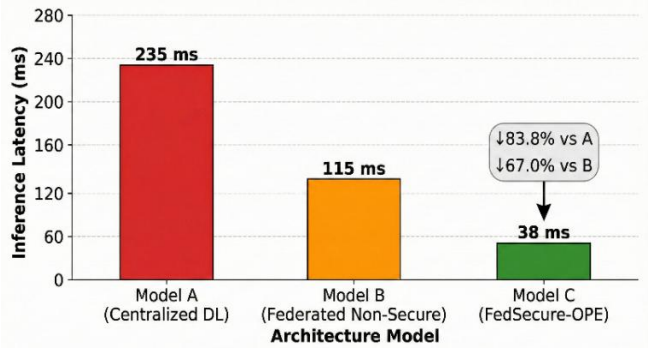

Fig. 3. Inference Latency per Control Cycle

Compared to the standard cloud-based deep learning, the federated learning system (Model B) has 51.1% less latency and even lower latency with FedSecure-OPE (Model C) which has 67.0% less latency than Model B, although costlier due to the extra overhead of cryptographic operations.

B. Control Performance and Cycle Time Reduction

Fig. 4 shows the performance of cycles time over simulation time: Model A (centralized deep learning) demonstrates an average cycle time of 48.6 seconds, Model B (federated learning without security) demonstrates the average cycle time of 38.2 seconds and Model C (FedSecure-OPE) demonstrates average cycle time of 31.8 seconds.

The relative performance of 16.8% increase of Model C compared with Model B indicates the efficiency of co-optimization of privacy-preserving policies with hardware constraints when the production is dynamic.

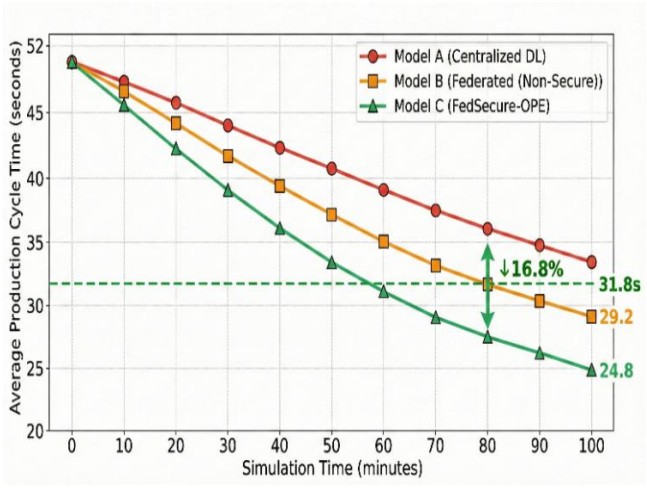

Fig. 4. Average Production Cycle Time Reduction

C. Privacy Compliance and Security Assurance

Fig. 5 depicts the rate of privacy compliance: with data crossing the cloud unprotected, Model A will have the compliance rate 42.3% (data transferred to cloud without protection), with data staying locally, but there is no protection for gradients, Model B will have the compliance rate 67.8% and done via homomorphic encryption and SMPC, Model C will have the compliance rate 99.2%.

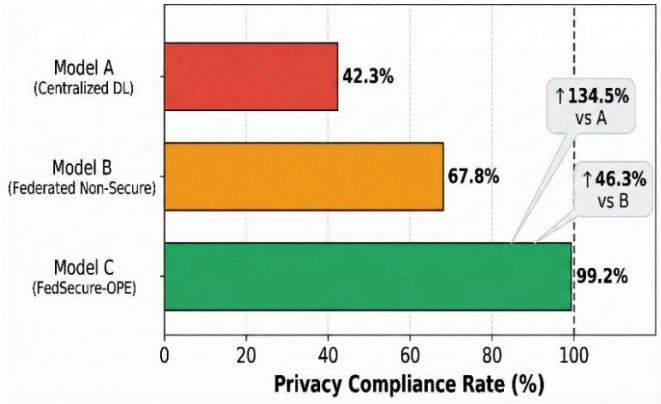

Fig. 5. Privacy Compliance Rate (%)

In Model C, the privacy-protecting aggregation protocol guarantees the cryptographic protection of model updates with all model updates, which get cryptographically protected model updates in accordance with GDPR/CCPA privacy principles.

D. System Robustness to Hardware and Security Constraints

Fig. 6 shows that system robustness when constrained by edge computing resources Model A achieves 44.7% performance degradation, Model B achieves 26.9% degradation and Model C achieves 14.2% degradation.

In Model C, search of adaptive neural architecture and different cryptographic parameter answering, the quality of control is ensured through variable hardware capabilities and

security demands, with a robustness of 47.2% higher than that of Model B.

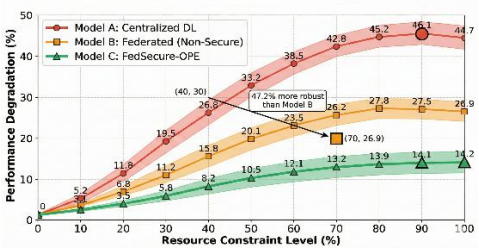

Fig. 6. Control Performance Degradation under Resource Constraints.

E. Computational Cost and Edge Resource Usage

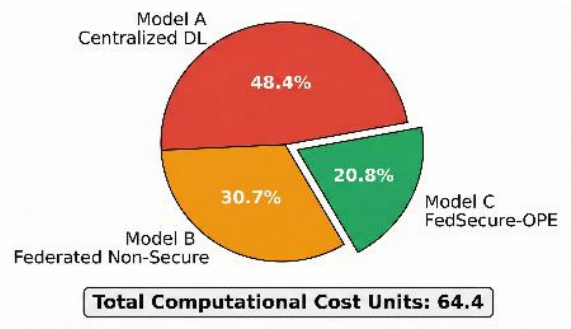

Fig. 7. Computational Cost Comparison

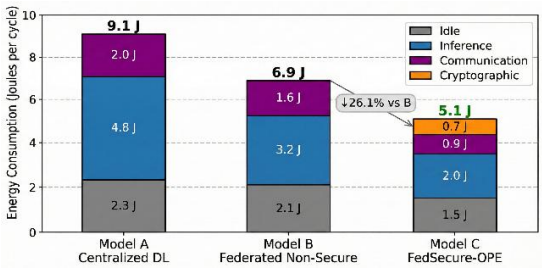

Fig. 8. Edge Resource Consumption per Control Cycle.

Fig. 7 and Fig. 8 show the efficiency of resources: the unit cost of computation is 31.2 (Model A), 19.8 (Model B) and 13.4 (Model C). The 9.1 J/cycle (Model A), 6.9 J/cycle (Model B) and 5.1 J/cycle (Model C) are the energy consumption. Adaptive model compression and dynamic power control and optimization of crystalline cryptographic actions can ensure that Model C is 32.8% more resource-efficient than Model B even with the extra security cost.

F. FedSecure-OPE Performance Index

Fig. 9 shows the FedSecure-OPE Performance Index (FSPI): Model A has a score of 0.48, Model B has a score of 0.65 and Model C has a score of 0.92.

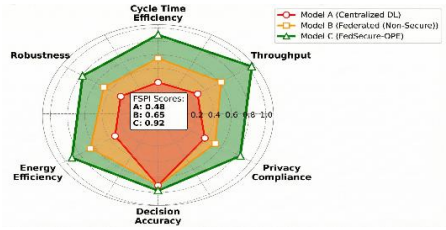

Fig. 9. FSPI Comparison.

The 41.5% difference between the Model B and Model C is evidence of synergistic combining control optimization, privacy compliance, real-time responsiveness and energy efficiency in a single secure federate structure.

G. Tabular Comparisons and Key Metrics

Table II validates the significant improvements of all the major key performance indicators of FedSecure-OPE such as cycle time, throughput, and compliance to privacy, accuracy in decisions and energy consumption.

Table III validates the crystal and confirms that Model C has a better posture regarding latency, robustness, model compactness, scalability and security than the baseline approaches, with cryptographic overhead (12.3 ms) significantly exceeded by decreases in latencies in other areas.

TABLE II. COMPARATIVE CONTROL AND EFFICIENCY METRICS FOR MODELS A, B, AND C

Metric	Model A	Model B	Model C	Improvement (C vs. A)	Improvement (C vs. B)
Average Cycle Time (s)	48.6	38.2	31.8	↓ 34.6%	↓ 16.8%
Throughput (parts/h)	410	525	610	↑ 48.8%	↑ 16.2%
Privacy Compliance (%)	42.3	67.8	99.2	↑ 134.5%	↑ 46.3%
Decision Accuracy (%)	73.5	84.2	92.8	↑ 26.3%	↑ 10.2%
Edge Energy Consumption (J/cycle)	9.1	6.9	5.1	↓ 44.0%	↓ 26.1%
FedSecure-OPE Performance Index (FSPI)	0.48	0.65	0.92	↑ 91.7%	↑ 41.5%

TABLE III. COMPARATIVE LATENCY, ROBUSTNESS AND SECURITY METRICS

Metric	Model A	Model B	Model C	Improvement (C vs. A)	Improvement (C vs B)
Inference Latency (ms)	235	115	38	↓ 83.8%	↓ 67.0%
Robustness Degradation (%)	44.7	26.9	14.2	↓ 68.2%	↓ 47.2%
Model Size (MB)	N/A	26.3	9.1	N/A	↓ 65.4%
Cryptographic Overhead (ms)	0	0	12.3	N/A	N/A
Scalability Limit (cells)	6	14	22	↑ 266.7%	↑ 57.1%
Attack Surface Reduction (%)	Baseline	31.5%	78.6%	↑ 78.6%	↑ 47.1%

TABLE IV. DATASET AND SIMULATION SPECIFICATIONS

Dataset	Manufacturing Cells	Time Span	Attributes	Source
MCMT	12-80	2020-2023	Sensor telemetry, machine states, production logs, quality metrics	MCMT Repository
SMT	Configurable (4-72)	-	Synthetic production traces, equipment profiles, failure modes	SMT Platform

Table IV describes the simulation data sets that underwent validation such as the scale of manufacturing cells, time characteristics as well as access details.

H. Quantitative Gains

FedSecure-OPE (Model C) demonstrates significant changes over base models with respect to all important metrics. It is 34.6% slower cycle time, 48.8% greater throughput, 83.8% lower latency, 44.0% less energy-consuming, 134.5% more privacy-compliant and 68.2% more robust than Model A (centralized deep learning). The improvements are 16.8% (cycle time), 16.2% (throughput), 67.0% (latency), 26.1% (energy), 46.3% (privacy compliance) and 47.2% (robustness) - which shows that the security-concerned federated AI has much greater benefits than its non-secure counterpart (Model B), without reducing the performance.

I. Comparative Evaluation and Integration

The architectural evolution becomes clear: Model A is a classic example of centralized AI with high privacy risks and with limits of latency; Model B is an example of distributed learning with high benefits that it has but is at risk of gradient leakage and inference attacks; and Model C is able to achieve a transformative capability with security protected federated learning with hardware-sensitive optimization- such as privacy-preserving aggregation (HE + SMPC), latency-constrained federated optimization, dynamic NAS and validation of digital twins. This development highlights the need to move towards security-co-designed adaptive AI systems of the next-generation smart manufacturing, in which data privacy and computational limits are the main goals of optimization, rather than outliers.

J. Limitations

The current paper is narrowed to digital twin simulation without involving actual physical deployment of the factory. Gradient inversion and model poisoning simulations that adversarial attacks are based on were not experimentally implemented. Big data scale Cryptography overhead has not been tested on a scale larger than 50 clients. There were only two representative edge profiles that proved to be heterogeneous. These constraints characterize future research.

VI. CONCLUSION

Comparison between the FedSecure-OPE (Model C) and the centralized deep learning (Model A) and non-secure federated learning (Model B) proves that security-conscious federated AI demonstrates higher results regarding all the key aspects of operation and compliance. FedSecure-OPE has an average time of production cycle of 31.8 seconds- this is a 34.6% and 16.8% improvement over Model A and B, respectively. The accuracy of the decision has 92.8% and the inference latency decreases to 38 ms - 83.8% and 67.0% less than the baseline models. The privacy compliance is achieving 99.2, which is 134.5% and 46.3% better. The consumption of energy has decreased to 5.1 J/cycle which is 44.0 % and 26.1 % of the base models. The robustness of systems with and without hardware restrictions has been enhanced by 68.2 and 47.2 respectively, when compared to Models A and B and thus proves a strong control architecture that is resilient and scalable in a wide range of manufacturing settings.

The FSPI scores 0.92, which means that there is a great integration of production control optimization, privacy-preserving distributed learning, real-time hardware telemetry and adaptive resources management. The obtained results verify the idea that secure federated AI is an effective paradigm of active manufacturing control in cyber-physical production networks. Future directions will expand this model as to multi-tier channel coordination, cross-factory federated learning of blockchain audit trails, integration with 5G-private networks (deterministic communication) and dynamic set of cryptographic parameters (real-time threat intelligence), moving to scalable, responsive, privacy-preservation and energy-saving smart manufacturing systems.

ACKNOWLEDGMENT

The author would like to express his gratitude to King Khalid University, Saudi Arabia for providing administrative and technical support.

***Abstract*—Blockchain has been used in various sectors and use cases, but inadequate blockchain governance can cause failure in blockchain adoption. Previous research on blockchain governance has not been carried out with multiple perspectives and has not yet reached the point of developing governance assessment tools. This research aims to identify the factors that comprise blockchain governance, as well as identifying functional requirements of blockchain governance assessment tools. The methodology used in this research is literature review using PRISMA, thematic analysis, expert validation with fuzzy Delphi method. This research resulted in 25 factors and enhanced the STOPE framework by adding a collaboration dimension to develop a blockchain governance framework and 5 functional requirements for blockchain governance assessment tools. The 25 factors consist of 3 factors in strategy, 3 factors in technology, 4 factors in organization, 1 factor in the people, 4 factors in the environment, and 10 factors in the collaboration. This research identifies the factors that comprise blockchain governance and the functional requirements of blockchain governance assessment tools and provides a readiness-based blockchain governance initial framework, and functional requirements of blockchain governance assessment tools. This research also provides guidance for researchers, regulators, and practitioners in blockchain governance implementation and assessment.**

Keywords*—*Blockchain governance; blockchain governance framework; blockchain readiness; fuzzy Delphi method; governance assessment tools; STOPE framework

I. Introduction

Blockchain is an emerging technology that allows digital transactions without the role of intermediaries [1]. Blockchains that adopt the distributed ledger principle are, in certain cases, used because of their security or cryptographic features [2],[3] and privacy support [4]. However, there is quite a lot of research regarding the use of blockchain for cryptocurrency [5], conceptualizes blockchain as a trusted infrastructure to enhance community participation and strengthen local economies through cryptocurrencies [6], and analyzes the psychological factors influencing individuals' intention to hold or own Bitcoin [7].

Now the use of blockchain is increasingly widespread in various sectors and use cases. This use takes into account various blockchain characteristics, not only hashing or cryptography, but also immutability, decentralization, and transparency [8]. Blockchain is used in various use cases or sectors [13], such as non-fungible tokens (NFT) [9], access to Artificial Intelligence (AI) models [10], supply chain management [11], asset management [12], trading and privacy [13].

However, the current increase in the use of blockchain has not been matched by comprehensive research on its governance aspects [14],[15],[16],[17],[18]. Poor or inadequate governance in blockchain adoption or utilization is a factor that can cause blockchain adoption or utilization to fail [14]. Research on blockchain governance has been widely carried out using various perspectives. Research conducted by Tan, Mahula, & Crompvoets [14] proposes a blockchain governance conceptual framework in the context of the public sector, where blockchain governance should be understood as a socio-technical system rather than merely a technological implementation. Research by Laatikainen, Li, & Abrahamsson [15] conceptualize blockchain governance from a system perspective, in which blockchain is considered a dynamic and interconnected system, requiring holistic rather than partial analysis. Research by Beck, Müller-Bloch, & King [16] develops a foundational framework for governance in the blockchain economy and identifies two forms of governance, namely on-chain governance and off-chain governance. Research by Liu et al. [17] focuses on formulating principles of blockchain governance. Meanwhile, research by Koning & van der Linden [18] compares decentralized governance with corporate governance. However, the studies are still limited to the concept of governance, and the resulting framework is not equipped with properties for implementing governance based on the framework that has been researched [14],[15],[16],[17],[18]. Apart from that the framework built does not emphasize the readiness aspect or feasibility analysis stage [14],[15],[16],[17],[18], which is an important stage in developing a blockchain-based system [19].

Research on blockchain governance framework has been also carried out using various perspectives. Research conducted by Tan et al. [14] proposes a blockchain framework from the public management perspective. Research by Laatikainen et al. [15] develops blockchain governance model from a system-based perspective, which can serve as a reference framework for developing a blockchain system governance framework. Research by Beck et al. [16] develops blockchain governance from a corporate governance perspective. These studies have produced frameworks from different perspectives, but are less comprehensive, and have not been equipped with assessment properties or assessment tools for implementing governance following with the proposed framework [14],[15],[16].

The blockchain governance framework has been the focus of several studies, using various perspectives or theories. Research

by Pereira et al. [20] develops blockchain governance from the perspective of platform governance. Meanwhile, research by Laatikainen et al. [15] develops blockchain governance with a focus on an Information Technology governance perspective. Research by Beck et al. [16] develops blockchain governance from the perspective of Information Technology governance and corporate governance. Some studies view blockchain governance from other perspectives, such as game theory [45] and public management [14].

Based on the conditions described above, this research proposes an initial readiness-based multi-perspective and collaborative blockchain governance framework, which is equipped with the functional requirements of its assessment tools. This research aims to provide an initial blockchain governance framework and functional requirements for assessment tools. This research aims to provide guidance in readiness-based, multi-perspective, and collaborative blockchain governance so that it can prevent failure in blockchain adoption in various sectors or use cases. The research questions to be answered in this research are (1) What factors comprise blockchain governance framework? (2) What are the functional requirements of blockchain governance assessment tools?

This research contributes to developing a readiness-based, collaborative, and multi-perspective blockchain governance initial framework, equipped with the functional requirements of assessment tools, based on the initial framework developed. This research also enhances the STOPE framework [21],[22] with a collaboration dimension based on the characteristics [8] of blockchain technology which requires collaboration in its implementation.

This paper is organized as follows. Section II elaborates related work; Section III explains the research methodology; Section IV presents the research results and discussion; Section V closes the research with the conclusion and limitation of the study.

II. Related Work

A. Blockchain Governance Framework

The blockchain governance framework has been the focus of several studies, using various perspectives or theories. Research by Pereira et al. [20] develops blockchain governance from the perspective of platform governance. Meanwhile, research by Laatikainen et al. [15] develops blockchain governance with a focus on an Information Technology governance perspective. Research by Beck et al. [16] develops blockchain governance from the perspective of Information Technology governance and corporate governance. Some studies view blockchain governance from other perspectives, such as game theory [23] and public management [14]. A summary of literature review that represents these perspectives, key factors, strengths, limitations, and research gaps can be seen in Table I.

As summarized in Table I, existing blockchain governance remain fragmented, with each approach focusing on specific dimensions such as technology, incentives, or organizational control [14],[15],[16],[20],[23]. No prior studies have developed a fully integrated framework that simultaneously and systematically address strategic, technological, organizational, people, and environmental aspects [14],[15],[16],[20],[23]. This fragmentation indicates a significant research gap in the development of a comprehensive governance model capable of capturing the complexity of blockchain ecosystems. Therefore, this study proposes an enhanced STOPE-based framework to bridge this critical gap by providing a holistic and structured approach to blockchain governance.

TABLE I. Summarize of Literature Review on Blockchain Governance Framework

Perspective	Key Focus	Strengths	Limitations	Gap
Platform governance [20]	Coordination mechanisms	Explaining ecosystem coordination and roles	Coverage of factors.	Limited coverage of organizational and environmental factors.
IT governance [15],[16]	Alignment between IT structures and blockchain systems.	Relationship with organizational IT governance practices	Decentralization dynamics and external environment	Does not address multi-dimensional governance complexity
Corporate governance [16]	Accountability, control, and decision rights	Integrates managerial and control aspects	Technological adaptability and stakeholder dynamics	Partial integration; lacks environmental & people dimensions
Game theory [23]	Incentives (game theory)	Insights into specific governance aspects (incentives)	Fragmented	Not integrated governance aspects
Public management [14]	Regulation and public policy	Insights into specific governance aspects (regulation)	Highly domain-specific.	Not integrated governance aspects

B. Stope Framework and Collaboration

STOPE integrates the dimensions of strategy, technology, organization, people, and environment. The STOPE framework is a framework that is commonly used to measure readiness, for example, user readiness in implementing certain services or technologies [22]. The STOPE framework in the governance area can also be used as a view in assessments, such as in research to measure IT governance [21]. Using grades for factors evaluation will measure the readiness level for each factor. Table II describes the evaluation grade that can be used in readiness assessment [21],[22]. Evaluation of factors in STOPE is carried out individually and collectively [21],[22].

TABLE II. Evaluation Grades for Factors Evaluation

Scale	Evaluation Grade [21],[22]
1	Poor/low
2	Below average
3	Average
4	Above average
5	Good/high

In this research, the STOPE perspective is used by adding the collaboration dimension [8] to group factors identified by thematic analysis [24]. The addition of this dimension is related to the characteristics of blockchain which can be viewed not only from an Information Technology perspective but also from socio-technical aspects which include collaboration aspects [8]. A description of each dimension used in this research, in the context of its influence on blockchain governance, can be seen in Table III.

TABLE III. DEFINITION OF STOPE AND COLLABORATION DIMENSION

Dimension	Description and Representative Literature
Strategy	How the strategy aspect affects blockchain governance [25],[26],[27]
Technology	How the technology aspect affects blockchain governance [25],[27],[28]
Organization	How the organization aspect affects blockchain governance [25],[26],[27],[28]
People	How the people or personal aspect affects blockchain governance [29],[30]
Environment	How the environment aspect affects blockchain governance [25],[26],[28],[31]
Collaboration	How the collaboration aspect affects blockchain governance [25],[26],[27],[28],[30],[32]

The governance theory perspective [16],[18],[32] emphasizes that effective governance in multi-stakeholder environments relies on interaction processes, including joint decision-making, collective problem-solving, and consensus-building mechanisms. These processes cannot be fully represented within the existing STOPE [21],[22] dimensions, as they extend beyond individual domains and more accurately reflect the relational nature of governance through collaboration. Grouping collaboration-related factors within domains such as "people" or "organization" risks reducing collaboration to a localized attribute, thereby overlooking its systemic significance.

In the context of blockchain governance, the importance of collaboration is further reinforced by the absence or minimal presence of centralized control and the existence of trustless interactions. Mechanisms within blockchain systems, such as consensus protocols, decentralized decision-making, and community-based governance, inherently depend on collaborative processes [16],[18],[32]. Collaboration is therefore not merely a supporting factor, but a fundamental governance mechanism underpinning the functioning of the entire ecosystem [16],[18],[32].

Modeling collaboration as an enhancing dimension in this study explicitly captures the cross-cutting and integrative nature of stakeholder interactions, coordination processes, and interdependencies across STOPE [21],[22] dimensions. Enhancing the STOPE framework [21],[22] by introducing the collaboration dimension enables a more comprehensive and structurally coherent representation of blockchain governance, thereby enhancing the analytical depth and practical relevance of the proposed framework, particularly in evaluating multi-stakeholder governance systems.

C. Fuzzy Delphi Method

The Fuzzy Delphi method is a refinement of the Delphi method combined with fuzzy [33],[34]. The Fuzzy Delphi method reduces the possibility of ambiguity by consensus and reduces data retrieval time when compared to the Delphi method [33],[34]. The Fuzzy Delphi method can be used for forecasting, validation, and evaluation [33],[34].

D. Governance Assessment Tools

Governance assessment tools are usually used for environmental governance e.g. flood risk maps [35] and infrastructure [40], water governance [36], protected area [37],[38],[41], waste reduction [39], water, energy, and food [42]. One of the widely adopted instruments is the Governance Assessment Tool (GAT), which evaluates governance quality based on four key parameters: extent, coherence, flexibility, and intensity [40],[41],[42],[43]. Meanwhile, the components assessed, as can be seen in Table IV, include responsibilities and resources, actors and networks, strategies and instruments, levels and scales, problem perspectives and goal ambitions [35],[36],[37],[38],[39],[40],[41],[42]. This component can be considered in governance assessments in other areas or sectors.

TABLE IV. COMPONENT OF GOVERNANCE ASSESSMENT TOOLS

Component	Representative Literature
Responsibilities and resources	[35],[36],[37],[38],[39],[40],[41],[42]
Actors and networks	
Strategies and instruments	
Levels and scales	
Problem perspectives and goal ambitions	

III. METHODOLOGY

This section will discuss the materials and methods used in this research. This research employed mixed methods. This research has used the following methods: literature review, component and functional requirements analysis, thematic analysis [24], expert review with fuzzy Delphi questionnaire, and fuzzy Delphi analysis [33],[34].

A. Literature Review

The systematic literature review in this research was carried out in two stages, and both were carried out using the PRISMA method [44]. The steps for a systematic literature review in this research using the PRISMA method [44] include searching the database with defined criteria, determining inclusion criteria, study selection, and data synthesis. The first stage of the systematic literature review was carried out to identify previous research regarding governance assessment tools in general. The second stage of the systematic literature review was carried out to identify factors that influence blockchain governance. Apart from that, a literature review was also carried out to look for indicators of factors that influence blockchain governance.

1) Search strategy: In the first stage of the systematic literature review, the search was carried out on the Scopus database for journal articles published in all years. The terms or keywords used in the search are "blockchain governance". The

results of the systematic literature review in the first stage are influencing factors of blockchain governance.

The first stage of the systematic literature review was conducted using the Scopus database due to its extensive multidisciplinary coverage and rigorous indexing of peer-reviewed scholarly publications. Scopus is widely recognized as one of the largest curated abstract and citation databases, encompassing high-quality journals in information systems, computer science, governance, blockchain, and related socio-technical domains that are central to this study. Although other databases such as Web of Science, IEEE Xplore, and ACM Digital Library also contain relevant publications, Scopus was selected as the primary data source in the initial stage of the systematic literature review (SLR) due to its broad coverage and significant overlap with these databases, thereby ensuring adequate representation of high-quality literature. This approach is consistent with systematic review studies that rely on a single comprehensive database to maintain consistency and reduce duplication.

The search in the second stage of the systematic literature review was conducted across eight databases—Scopus, ScienceDirect, ACM Digital Library, Emerald Insight, ProQuest, IEEE Xplore, SpringerLink, Sage Journals, and Taylor & Francis—targeting journal articles published between 2019 and 2023. The terms or keywords used in the search are "governance assessment" AND "tool". The results of the systematic literature review in the second stage used in this research are the components and functionality requirements of governance assessment tools.

2) Eligibility criteria: In the first stage of the systematic literature review, the author established three inclusion criteria where the literature must be available in full text and written in English (IC4), must report research findings published in reputable journals (IC5), and must focus on and discuss governance assessment tools or blockchain governance assessment tools (IC6). In the second stage of the systematic literature review, the author applied three inclusion criteria, requiring that the literature be available in full text and written in English (IC1), report research findings published in reputable journals (IC2), and focus on the topic of blockchain governance (IC3). There is a total of six inclusion criteria (IC) in the two stages of the systematic literature review.

3) Study selection: Study selection is carried out at both the first and second stages of the systematic literature review. Study selection in this research includes the following steps: searching based on a keyword or search string in each online database, checking and removing duplicate records, selecting the title and abstract of identified articles according to the eligibility criteria, and including the articles that meet the inclusion criteria for full-text review. The study selection process is the same between the first stage and the second stage of systematic literature review in this research.

4) Data items and synthesis: Data collection was carried out manually using a spreadsheet. The information extracted in the first stage of the systematic literature review consists of design and development methods, elements (of readiness) measure, type of governance measure, assessment concept, and main features or main functionality. The information extracted in the second stage of the systematic literature review consists of influencing factors of blockchain governance. Authors then synthesize the data based on the STOPE framework [21],[22].

B. Functional Requirement Identification and Validation

Functional requirements identification [19] was carried out in this research to identify the functionality of the assessment tools based on the results of the first stage of the systematic literature review. Apart from being based on the research results, functional analysis also considers existing tools used in governance assessment practices [43]. After that, the results of the functional requirements identification are then reviewed by experts to ensure functional suitability (completeness, correctness, appropriateness) [45] of the functional requirements of the assessment tools.

C. Thematic Analysis

Thematic analysis [24] was carried out in this research to identify factors that influence blockchain governance based on the results of the literature review in the second stage. The stages in the thematic analysis are familiarization with data, initial code generation, theme search, review of themes, naming, and defining themes. The grouping of the initial stages of thematic analysis in this document is carried out based on the STOPE framework [21],[22],[24].

D. Expert Review with Fuzzy Delphi Method

Expert reviews are carried out on functional analysis, factors, and indicators. The criteria for selecting experts are having experience in the field of governance or policy formulation for at least five years and having a basic understanding of blockchain and information system development. An expert review of factors influencing blockchain governance was carried out based on the Fuzzy Delphi Method [33],[34].

Questionnaires whose readability has been validated are then distributed to experts. Semi-structured interviews were conducted to validate data from questionnaires filled in by experts. The results are used in Fuzzy Delphi Method analysis [33],[34].

A total of five experts participated in the Fuzzy Delphi process. Despite the relatively small panel size, the experts were purposively selected based on their domain expertise and professional experience in blockchain and governance. Their organizational backgrounds include both government and non-government sectors, as summarized in Table V.

Although the panel consisted of five experts, prior studies have demonstrated that fuzzy Delphi method can yield reliable results with small but carefully selected expert groups, particularly in specialized domains where expertise is more critical than sample size [33],[34]. The experts were selected based on the following criteria: 1) relevant expertise in blockchain governance, 2) professional experience, and 3) demonstrated contributions, such as publications, projects, or leadership roles in related fields. This selection process ensured that all participating experts possessed sufficient domain knowledge to provide informed and credible judgments.

TABLE V. EXPERTS' PROFILES

Expert ID	Organization	Position	Experience
Expert 1	Government	IT Policy Analyst	>15 years
Expert 2	Non-government	IT Governance Specialist	>10 years
Expert 3	Government	IT Policy Analyst	>15 years
Expert 4	Non-government	Vice President of Technology	>5 years
Expert 5	Non-government	IT Governance Specialist	>25 years

In this research, the fuzzy Delphi method was used because this method can accommodate various opinions and uncertainties [33],[34]. The fuzzy Delphi method is suitable for research where the availability of appropriate information does not exist, or the information is difficult to obtain [33],[34]. This method can be used for forecasting and filtering [33],[34].

The Fuzzy Delphi Method is an expert consensus-based method with the important concept being the Triangular Fuzzy Number or TFN (n1, n2, n3) [33],[34]. Each TFN (n1, n2, n3) from the expert responses was averaged and produced values m1, m2, and m3 [33],[34]. Acceptable item requirements are a threshold (d) of 0.2 or less, an expert agreement of 75% or greater, and a defuzzification value of 0.5 or more [33],[34]. The conversion of Likert scores into fuzzy numbers and linguistic variables [33],[34] can be seen in Table VI. Table VI shows the Likert scale used is a 7-point Likert scale [33],[34].

TABLE VI. CONVERSION BETWEEN SEVEN-POINT LIKERT SCALE AND FUZZY NUMBER

Likert Scale	Linguistic Variable	Fuzzy Number		
		n1	*n2*	*n3*
1	Extremely Strongly Disagree	0.0	0.0	0.1
2	Strongly Disagree	0.0	0.1	0.3
3	Disagree	0.1	0.3	0.5
4	Unsure	0.3	0.5	0.7
5	Agree	0.5	0.7	0.9
6	Strongly Agree	0.7	0.9	1.0
7	Extremely Strongly Agree	0.9	1.0	1.0

The process of calculating d (threshold) is carried out using the following formula:

$$d(\underline{m}, \underline{n}) = \sqrt{\frac{1}{3}(m_1 - n_1)^2 + (m_2 - n_2)^2 + (m_3 - n_3)^2} \quad (1)$$

Meanwhile, the defuzzification value calculation is carried out using the following formula:

$$A = \frac{1}{3} * (m1 + m2 + m3) \quad (2)$$

If the d value is 0.2 or less, and the A value is 0.5 or more, the item or factor is retained.

E. Framework and Assessment Tools Development and Validation

Based on the results of factor validation using the Fuzzy Delphi Method [33],[34], the results of identification and validation of indicators, analysis, and validation of functional requirements from assessment tools, then an initial blockchain governance framework and assessment tools were created. Next, expert validation is carried out on the proposed blockchain governance framework, to ensure the perceive ease of use, usefulness, extent, coherence and flexibility [35],[36],[37],[38],[39],[40],[41],[42],[46].

This study does not adopt the STOPE framework as a measurement model or rating scale; rather, it is employed as a structural framework to organize governance dimensions. The assessment is conducted using ISO/IEC-based criteria, thereby ensuring a standardized and rigorous evaluation. This integration enables a comprehensive alignment between multidimensional governance aspects and established evaluation standards.

IV. RESULTS AND DISCUSSION

This section will discuss the results of this research and its discussion. The findings and their implications are also discussed in this section. The limitations of this research are highlighted and recommendations for future research are given in this section.

A. Influencing Factors of Blockchain Governance

The first step in identifying factors that influence blockchain governance is to carry out a systematic literature review using the PRISMA method [44], on the Scopus database for journals published all year. The stages in the selection of previous studies consist of identification, screening, and inclusion [44]. Following the removal of duplicates and the screening of titles, abstracts, and keywords, the remaining articles were further selected according to the inclusion criteria, i.e. must be available in full text and written in English (IC4), must report research findings published in reputable journals (IC5), and must focus on and discuss governance assessment tools or blockchain governance assessment tools (IC6). Details of the article selection process can be seen in Fig. 1.

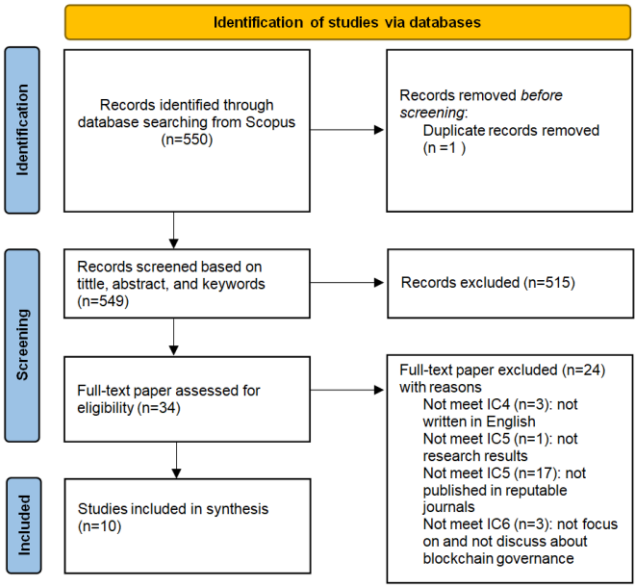

Fig. 1. Flow diagram for search results on the first stage of systematic literature review.

Fig.1 describes the search and filtering process for article selection. A total of 550 articles were obtained by entering the keyword "blockchain governance" in the Scopus database. After eliminating duplicates and filtering based on title, abstract, and keywords, 34 articles were obtained which were filtered based on eligibility criteria. Screening by eligibility criteria resulted in 10 articles being included for synthesis. Synthesis results from the 10 articles and analysis with thematic analysis [46] can be seen in Table VII for the strategy dimension, Table VIII for the technology dimension, Table IX for the organization dimension, Table X for the people dimension, Table XI for the environment dimension, and Table XII for the collaboration dimension.

Table VII describes the influencing factors in the strategy dimension. Five factors were identified within the strategy dimension, including incentives, centralized risk, flexibility of governance, allocation, and the enaction of decision rights [25],[26],[27],[50]. These five strategy factors can influence blockchain governance [25],[26],[27],[50].

TABLE VII. INFLUENCING FACTOR OF STRATEGY DIMENSION

Factor	Code	Representative Literature
Motivational factors (incentive)	S1	[25]
Nature of how decision rights are allocated and enacted	S2	[26]
Centralization risk	S3	[27]
Flexibility of governance	S4	[27],[50]
Misalignment of incentives	S5	[27]

Table VIII presents the influencing factors in the technology dimension. Within the technology dimension, three factors were identified, including formation and contextual elements of the blockchain, such as background information (e.g., licensing), resolve of conflict between competing version of ledger, and inter-proposal dependencies [25],[26],[28],[50]. These three technological factors have the potential to impact blockchain governance [25],[26],[28],[50].

TABLE VIII. INFLUENCING FACTOR OF TECHNOLOGY DIMENSION

Factor	Code	Representative Literature
Formation and context	T1	[25]
Conflicts resolving	T2	[28],[50]
Inter-proposal dependencies	T3	[26]

TABLE IX. INFLUENCING FACTOR OF ORGANIZATION DIMENSION

Factor	Code	Representative Literature
Roles, responsibility, accountability	O1	[25]
Security of DAO	O2	[28]
Problem at hand	O3	[26]
Corporate governance	O4	[25][28]

Table IX describes the influencing factors in the organization dimension. Four factors were identified within the organizational dimension, including roles, responsibilities, and accountability [25], security of DAO [28], and the specific problem at hand [26], such as demand management, data management, system architecture design and development, as well as corporate governance [25][27]. These four organization factors can influence blockchain governance [25],[26],[27],[28].

Table X describes the influencing factors in the people dimension. Two factors were identified within the people dimension, comprising dilemmas of sharing knowledge and sharing information resources, and vulnerability of the combination of private interests [29],[30]. These two people factors can influence blockchain governance [29],[30].

TABLE X. INFLUENCING FACTOR OF PEOPLE DIMENSION

Factor	Code	Representative Literature
Social dilemmas (sharing knowledge and information resources)	P1	[30]
Vulnerability of the combination of private interests	P2	[29]

Table XI describes the influencing factors in the environment dimension. Four factors were identified within the environmental dimension, including legal aspect, organizational theories, public or private sector role, and the nature of information exchanged [25],[26],[28],[31]. These four environmental factors can influence blockchain governance [25],[26],[28],[31].

TABLE XI. INFLUENCING FACTOR OF ENVIRONMENT DIMENSION

Factor	Code	Representative Literature
The nature of the information exchanged	E1	[28]
Legal compliance	E2	[31]
Organizational theories	E3	[26]
Role of public or private sector	E4	[25]

Table XII describes the influencing factors in the collaboration dimension. Eleven factors were identified within the collaboration dimension, including membership or way participation, membership management for available roles, and decision-making processes [25]. These eleven collaboration factors can influence blockchain governance [25],[28],[30],[32],[47],[50].

TABLE XII. INFLUENCING FACTOR OF COLLABORATION DIMENSION

Factor	Code	Representative Literature
Membership	C1	[25]
Communication	C2	[25],[50]
Decision making	C3	[25]
Coordination mechanism within a group of users	C4	[28]
Decision problem	C5	[26]
Consensus of stakeholders	C6	[27]
Respons in problem cases	C7	[27]
Exercise of voting rights	C8	[47]
Community governance	C9	[30]
Private property	C10	[30]
Democrate form of governance	C11	[32]

The factors that have been generated from the systematic literature review and thematic analysis are then analyzed based on the Fuzzy Delphi Method [33],[34]. The factor is retained if the threshold d = 0.2 or less, and the defuzzification value A = 0.5 or greater than that, and the expert's agreement is 75% or greater than that [33],[34]. The analysis results based on the Fuzzy Delphi Method [33],[34] can be seen in Table XIII for the strategy dimension, Table XIV for the technology dimension, Table XV for the organization dimension, Table XVI for the people dimension, Table XVII for the environment dimension, and Table XVIII for the collaboration dimension. In total, there were 29 factors proposed. Two factors of which were accepted although they did not meet the threshold criteria (d), due to the expert agreement exceeding 75%. Two factors of which were rejected because the threshold value (d) is greater than 0.2 and the percentage of expert agreement is less than 75%. A total of 27 factors were accepted.

Table XIII describes the calculation results using the fuzzy Delphi method for factors in the strategy dimension. There are five factors proposed in the strategy dimension. Two of these factors, specifically S3 (centralization risk) and S5 (misalignment of incentives), were retained despite their threshold values (d) exceeding 0.2, as expert consensus surpassed 75%.

As described in Table XIII, the accepted factors on strategy dimension in this research are in line with previous research conducted by Pelt et al. [25], Ziolkowski et al. [26], and Dursun et al. [27]. However, in contrast with research conducted by Dursun et al. [27], the centralization risk factor and misalignment of incentives in this research are rejected based on expert consensus in the fuzzy Delphi method. This rejection may be influenced by the work experience and organizational background of the expert involved in filling out the questionnaire in this research and may be due to the scope of the research conducted by Dursun et al. [27] is limited to on-chain governance, so there is a difference in risk.

TABLE XIII. RESULTS ON THE STRATEGY DIMENSION

Factor Code	Threshold value (d)	Percentage of Expert Agreement	Fuzzy Score (A)	Expert Consensus
S1	0.073	100%	0.927	Accept
S2	0.073	100%	0.927	Accept
S3	0.312	80%	0.760	Reject
S4	0.118	100%	0.873	Accept
S5	0.235	80%	0.673	Reject

TABLE XIV. RESULTS ON THE TECHNOLOGY DIMENSION

Factor Code	Threshold value (d)	Percentage of Expert Agreement	Fuzzy Score (A)	Expert Consensus
T1	0.168	100%	0.840	Accept
T2	0.168	100%	0.840	Accept
T3	0.188	100%	0.807	Accept

Table XIV describes the calculation results using the fuzzy Delphi method for factors in the technology dimension. There are three factors proposed in the technology dimension. These three factors are accepted based on expert consensus, with a threshold value (d) of less than 0.2 and a fuzzy score (A) of greater than 0.8. The accepted factors on the technology dimension in this research are in line with previous research conducted by Pelt et al. [25], Dursun et al. [27], and Maggiolino et al. [28].

Table XV describes the results of calculations using the fuzzy Delphi method for factors in the organizational dimension. There are four factors proposed in the organizational dimension. These four factors are accepted based on expert consensus, with a threshold value (d) of less than 0.2 and a fuzzy score (A) of greater than 0.8, where the minimum value of fuzzy score (A) for an item or factor to be accepted is 0.5. The accepted factors on organization dimension in this research are in line with previous research conducted by Pelt et al. [25], Ziolkowski et al. [26], Dursun et al. [27], and Maggiolino et al. [28].

TABLE XV. RESULTS ON THE ORGANIZATION DIMENSION

Factor Code	Threshold value (d)	Percentage of Expert Agreement	Fuzzy Score (A)	Expert Consensus
O1	0.132	100%	0.893	Accept
O2	0.188	100%	0.860	Accept
O3	0.132	100%	0.893	Accept
O4	0.132	100%	0.893	Accept

Table XVI describes the results of calculations using the fuzzy Delphi method for factors in the people dimension. There are two factors proposed in the people dimension. One factor, P1 (dilemmas of sharing knowledge and sharing information resources), was rejected because its threshold value (d) exceeded 0.2 and the level of expert agreement was below 75%. This rejection may be influenced by the organizational background and organizational culture of each expert, which may cause differences in views regarding aspects of sharing knowledge and sharing information resources as mentioned in research conducted by Murtazashvili et al. [30]. Factor P2 is accepted and aligns with research conducted by Reijers et al. [29].

The lack of consensus on P1 indicates that social dilemmas in the context of knowledge sharing and information resources are not perceived as a dominant factor in blockchain governance by the expert panel. In contrast, P2 (vulnerability of the combination of private interests) was identified as the factor with the highest level of agreement, highlighting the vulnerability arising from the interaction of diverse private interests within decentralized systems. This finding reflects a fundamental characteristic of blockchain ecosystems, where independent actors with heterogeneous objectives operate without a centralized authority, thereby increasing the potential for interest conflicts and opportunistic behavior.

From a theoretical perspective, these results can be understood through socio-technical perspectives [14] and collaborative governance theory [16],[51],[52], which emphasize that the primary challenges in decentralized systems are not limited to technical coordination, but also include the management of competing interests. Within this framework, P2 (vulnerability of the combination of private interests) represents critical dynamics such as agency problems, collective action

challenges, and incentive misalignments, which are often key sources of vulnerability in community-based governance systems. Therefore, although only one factor was retained, P2 (vulnerability of the combination of private interests) still reflects a broad and fundamental construct in explaining the human dimension of blockchain governance.

TABLE XVI. RESULTS ON THE PEOPLE DIMENSION

Factor Code	Threshold value (d)	Percentage of Expert Agreement	Fuzzy Score (A)	Expert Consensus
P1	0.255	40%	0.573	Reject
P2	0.168	100%	0.840	Accept

Table XVII describes the calculation results using the fuzzy Delphi method for factors in the environmental dimension. There are four factors proposed in the environmental dimension. These four factors are accepted based on expert consensus, with a threshold value (d) of less than 0.2 and a fuzzy score (A) of greater than 0.8. The four factors in the environmental dimension that were accepted in this study are in line with previous research conducted by Pelt et al. [25], Ziolkowski et al. [26], Maggiolino et al. [28], and De Filippi et al. [31].

TABLE XVII. RESULTS ON THE ENVIRONMENT DIMENSION

Factor Code	Threshold value (d)	Percentage of Expert Agreement	Fuzzy Score (A)	Expert Consensus
E1	0.168	100%	0.840	Accept
E2	0.168	100%	0.840	Accept
E3	0.168	80%	0.840	Accept
E4	0.168	100%	0.840	Accept

Table XVIII describes the calculation results using the fuzzy Delphi method for factors in the collaboration dimension. There are eleven factors proposed in the collaboration dimension. One factor, C11 (a democratic form of governance), was rejected its threshold value (d) exceeded 0.2 and the level of expert agreement was below 75%. The democratic form of governance reject factor may be due to the case in the research conducted by Thompson [10] taking a case study of digital currency, where the use of digital currency has not been regulated and has not been formally implemented in the organization or environment of origin of the experts. The ten factors proposed in this collaboration dimension were accepted based on expert consensus using the fuzzy Delphi method analysis, and this is in line with research that has been conducted previously by Pelt et al. [25], Ziolkowski et al. [26], Dursun et al. [27], and Maggiolino et al. [28], Venugopalan et al. [47], and Murtazashvili et al. [30].

TABLE XVIII. RESULTS ON THE COLLABORATION DIMENSION

Factor Code	Threshold value (d)	Percentage of Expert Agreement	Fuzzy Score (A)	Expert Consensus
C1	0.188	100%	0.807	Accept
C2	0.188	100%	0.807	Accept
C3	0.168	100%	0.840	Accept
C4	0.168	100%	0.840	Accept
C5	0.132	100%	0.893	Accept
C6	0.145	100%	0.820	Accept
C7	0.132	100%	0.893	Accept
C8	0.188	100%	0.807	Accept
C9	0.155	100%	0.787	Accept
C10	0.132	100%	0.893	Accept
C11	0.362	40%	0.567	Reject

B. Readiness-Based Bloccckhain Governance Framework

Based on the results of a systematic literature review, thematic analysis, and fuzzy Delphi method analysis, an initial readiness-based blockchain governance framework was built. This proposed framework was built from a readiness perspective, with enhanced STOPE framework. The initial framework comprises six domains derived from the STOPE framework perspective [21],[22] and blockchain characteristics [8], including the strategy, technology, organization, people, environment, and collaboration domains. The proposed readiness-based blockchain governance framework can be seen in Fig. 2 below.

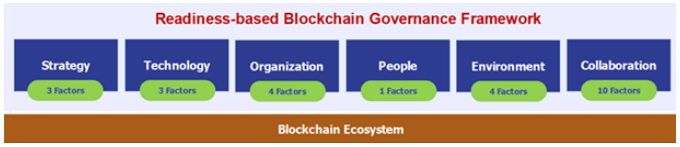

Fig. 2. Proposed readiness-based blockchain governance framework.

Fig. 2 describes the initial readiness-based blockchain governance framework resulting from a systematic literature review using the PRISMA method [44], thematic analysis [8],[21],[22],[24], and analysis using the fuzzy Delphi method [33],[34], and expert validation. The developed framework encompasses six dimensions: strategy, technology, organization, people, environment, and collaboration. In each framework, factors are the result of expert consensus based on the fuzzy Delphi method [33],[34]. In the strategy dimension, there are 3 factors, in the technology dimension there are 3 factors, in the organization dimension there are 4 factors, in the people dimension there is 1 factor, and in the environment dimension there are 10 factors.

For each factor in each dimension, indicators are identified for assessing blockchain governance readiness. In this research, the factors whose indicators have been identified are DAO security (O2). The selection of factors is based on expert recommendations from interview results. Identification of indicators for the security of DAO factor (O2) was carried out using a literature review. Indicators for the O2 security of the DAO factor, which have been identified from ISO/IEC 27002:2022 [48] and have been validated by experts, are policies for information security, information security roles and responsibilities, segregation of duties, management responsibilities, and information security in project management.

C. Functionality of Assessment Tools

Fig. 3 describes the first stage of the systematic literature review process using the PRISMA method [44]. This systematic

literature review was carried out to find functional requirements for blockchain governance assessment tools. The search was carried out in ten databases for journal articles published between 2019 and 2023.

Searches were conducted on the databases Scopus, ScienceDirect, ACM, Digital Library, Emerald Insight, ProQuest, IEEE Xplore, SpringerLink, Sage Journals, and Taylor & Francis. At the identification stage, 555 articles were obtained and 10 of them were duplicates so that 545 articles were processed at the screening stage. The screening stage referring to inclusion criteria IC1, IC2, and IC3 resulted in 24 studies included in the synthesis.

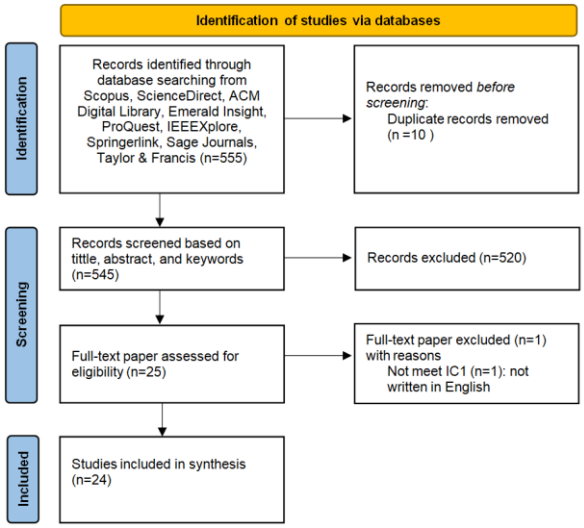

Fig. 3. Flow diagram for search results on the second stage of systematic literature review.

The results of the second-stage systematic literature review revealed a set of functional features, including strategy adaptation, assessment, good practices, community building, and supporting information. The functional results obtained are then combined with the results of the systematic literature review in the second stage and then illustrated in Fig. 4 to make it easier to understand and develop.

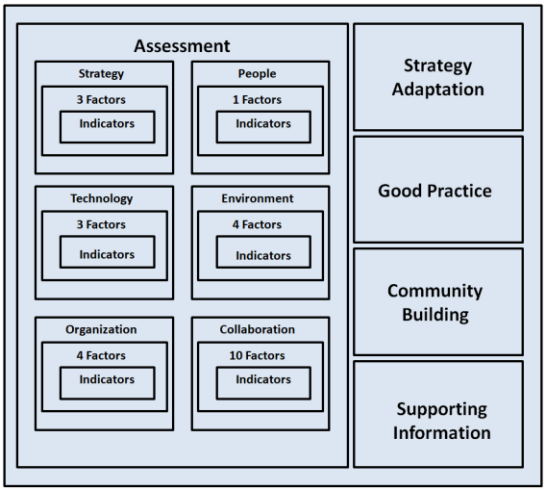

Fig. 4. List of functional requirements of blockchain governance assessment tools.

Fig. 4 presents the set of functional requirements for blockchain governance assessment tools, comprising five key functionalities: assessment, strategy adaptation, good practices, community building, and supporting information. The assessment tools encompass six dimensions: strategy, technology, organization, people, environment, and collaboration. In each dimension, there are factors and indicators for assessment. The "strategy adaptation" functionality is a functionality to inform the strategy adapted in the designed assessment tools. Meanwhile, the "good practice" functionality is functionality to inform about blockchain governance good practice. The "community building" functionality is related to the development of blockchain communities, both technical and non-technical aspects. This list of functional requirements is then subjected to expert validation.

In this study, ISO/IEC 38503:2022 Information technology—Governance of IT—Assessment of the governance of IT [53] was selected as the reference model and rating scale for the assessment instrument based on its relevance in evaluating governance within complex socio-technical systems. Although ISO/IEC 38503:2022 [53] was originally developed for information technology (IT) governance, it provides an assessment approach and structure that can be applied to blockchain environments, which inherently operate as decentralized and multi-stakeholder digital infrastructures. Blockchain governance extends beyond purely technical mechanisms to encompass organizational, behavioral, and environmental aspects, thereby requiring a comprehensive evaluation framework capable of capturing these interdependencies.

ISO/IEC 38503:2022 Information technology—Governance of IT—Assessment of the governance of IT [53] provides a robust assessment structure through its emphasis on governance tasks and practices, evidence of success, and the achievement of beneficial outcomes. This structure enables the operationalization of abstract governance concepts into measurable components, thereby addressing a common limitation in existing blockchain governance studies, which tend to remain conceptual and lack clear evaluative mechanisms. Furthermore, this international standard reflects a global consensus among key stakeholder groups, namely government, industry, academia, and end users, thereby enhancing the credibility and generalizability of the assessment model and rating scale. The adoption of ISO/IEC 38503:2022 Information technology—Governance of IT—Assessment of the governance of IT in this study ensures that the proposed measurement instrument is not only theoretically grounded but also aligned with globally recognized governance practices. This alignment strengthens the methodological rigor of the study and supports the development of a systematic and multi-dimensional assessment of blockchain governance across the STOPE and collaboration domains.

Table XIX presents the measurement instrument for blockchain governance assessment tools. Each factor within the domains of strategy, technology, organization, people, environment (STOPE), and collaboration is assessed based on the ISO/IEC 38503:2022 Information technology—Governance of IT—Assessment of the governance of IT rating scale and maturity model [53]. The assessment is conducted across three

key governance aspects, i.e. the implementation of governance tasks and practices as the fundamental aspect of governance, evidence of success, and the achievement of beneficial outcomes [53]. A five-point rating scale is used in the assessment, where 1 indicates unknown, 2 not applied, 3 somewhat applied, 4 largely applied, and 5 fully applied [53]. This five-point rating scale adopted from ISO/IEC 38503:2022 Information technology—Governance of IT—Assessment of the governance of IT [53].

TABLE XIX. MEASUREMENT INSTRUMENT FOR BLOCKCHAIN GOVERNANCE ASSESSMENT TOOLS

Factor	Assessment	Rating				
		1	2	3	4	5
Dimension: Strategy						
Motivational factors (incentive)	Are governance tasks and practices being applied?					
	Is there evidence of success?					
	Are beneficial outcomes being achieved?					
Nature of how decision rights are allocated and enacted	Are governance tasks and practices being applied?					
	Is there evidence of success?					
	Are beneficial outcomes being achieved?					
Flexibility of governance	Are governance tasks and practices being applied?					
	Is there evidence of success?					
	Are beneficial outcomes being achieved?					
Dimension: Technology						
Formation and context	Are governance tasks and practices being applied?

D. Comparison with Prior Work

In comparison with prior studies on blockchain governance [14],[15],[16],[20],[23], this research adopts a more comprehensive set of perspectives, encompassing platform governance, information technology governance, corporate governance, game theory, public management, and collaboration. As depicted in Table XX, research conducted by Pereira et al. [20] perceives blockchain governance from the perspective of platform governance and collaboration, while research conducted by Laatikainen et al. [15] perceives blockchain governance from an IT governance perspective. Table XX also describes the research conducted by Beck et al. [16] perceives blockchain governance from the perspective of Information Technology governance and corporate governance, while research conducted by Lee et al. [23] perceives blockchain from a game theory perspective, and research conducted by Tan et al. [14] perceive blockchain governance from a public management and collaboration perspective. Despite the diversity of perspectives presented in prior studies, they remain largely fragmented and domain-specific, lacking a unified framework that integrates these viewpoints into a comprehensive model of blockchain governance.

Compared with governance frameworks for other innovative and emerging technologies, such as artificial intelligence governance examined by de Almeida et al. [49], this study aligns with the emphasis on incorporating risk considerations in governance development. This research is also in line with research conducted by de Almeida et al. [49] in considering the characteristics of technology to be governed or regulated. When viewed from a regulatory perspective, this research is also in line with research conducted by de Almeida et al. [49] for its usefulness in highlighting regulatory points.

TABLE XX. COMPARISON OF PERSPECTIVE USED IN THE STUDY

Perspective	[20]	[15]	[16]	[23]	[14]	This study
Platform governance	√	x	x	x	x	√
IT governance	x	√	√	x	x	√
Corporate governance	x	x	√	x	x	√
Game theory	x	x	x	√	x	√
Public management	x	x	x	x	√	√
Collaboration	√	x	x	x	√	√

E. Implications

1) Theoretical implications: This research makes four theoretical contributions. First, this research develops a readiness-based, collaboration, and multiperspective blockchain governance framework. To the best of our knowledge, there has been no research that builds blockchain governance based on readiness, collaboration, and multiperspective [14],[15],[16],[20],[23]. Therefore, with this research, we fill the research gap that is important to ensure success in blockchain adoption [14]. Second, we enhanced the stope point of view, which is based on the stope framework [21],[22], based on the results of our literature analysis. This enhancement is done by adding a collaboration dimension [8]. This addition was based on technology characteristics, risk considerations, and previous research [8],[49]. Third, our research results in a list of functional requirements for blockchain governance assessment tools. The list of functional requirements was obtained from the analysis we carried out on previous research of governance assessment [35],[36],[37],[38],[39],[40],[41],[42]. The results of our research can be used as a reference in developing information system development theory in the future, for example, by considering technological characteristics, while also considering risks. Fourth, we provide a future research agenda in the blockchain governance subfield. Future research agendas can use more varied perspectives than existing research. Future research agendas can also use more varied empirical data for stakeholder engagement.

2) Practical implications: This research has two practical implications. First, the blockchain governance initial framework and list of functional requirements can be a reference for practitioners who will adopt blockchain or develop blockchain governance assessment tools. Second, the blockchain governance initial framework which contains factors, can be a reference for regulator in determining the main points of blockchain regulation or policy.

V. CONCLUSIONS

This research identifies and discusses factors comprising blockchain governance and functional requirements of blockchain governance assessment tools. This research provides a readiness-based blockchain governance initial framework, built from 25 factors grouped based on the enhanced STOPE framework point of view. This research also provides functional requirements for blockchain governance assessment. This research also provides valuable information that can be a reference for researchers in conducting their research, regulators to highlight the main point of blockchain governance or regulation, and practitioners in blockchain governance framework and assessment in line with governance and risk compliance concept.

A. Limitations of the Study

In this study, the identification of factors that influence blockchain governance through a systematic literature review was limited to English language literature. This study uses only a single database (Scopus) for systematic literature review in identifying factors that influence blockchain governance. This study also does not include readiness level evaluation and maturity level.

B. Future Work

Future research needs to be conducted regarding the readiness and maturity of blockchain governance. Future research should focus on assessing readiness levels and extending this study using broader methodologies and data sources, including the operationalization of indicators for the factors identified. Identification of indicators can be done not only from previous research but can come from international standards or gray literature such as industry reports or news. In future research, more stakeholders can be engaged, with more representative backgrounds and work experience. In addition, to overcome the shortcomings of the fuzzy Delphi method which may have an impact on the quality of the data obtained, it can be carried out in more than one iteration. The findings of this study represent the collective judgment of the selected experts at a specific point in time and may not fully capture the continuously evolving perspectives within the field. Future research is encouraged to involve a larger and more diverse expert panel or to adopt alternative consensus techniques in order to further strengthen the validity of the findings. Further investigation into blockchain governance assessment tools remains necessary. In addition, future studies should address maturity aspects, particularly the identification of relevant indicators and the determination of maturity levels.

ACKNOWLEDGMENT

In writing this journal, the ChatGPT application has been used by the author to help with the translation of part of the text from Indonesian to English. This research was funded by the Directorate General of Digital Infrastructure, Ministry of Communications and Digital Affairs of the Republic of Indonesia.

The Untapped Potential of Extended Reality for Indigenous Medicinal Knowledge: A Review of Cross-Disciplinary XR Applications

Giampearo Anak Peter[1], Suriati Khartini Jali[2], Jane Labadin[3],
Abby Lian Hendrick[4], Ally Dian Hendrick[5], Nurul Farizah Ridzuan[6]

Institute for Tourism Research and Innovation, Universiti Malaysia Sarawak, Kota Samarahan, Malaysia[2]

***Abstract*—Many sectors are quickly moving toward XR for education and professional training. These technologies, which include Virtual, Augmented, and Mixed Reality, are not being applied equally across different types of knowledge preservation. This study aims to review how effective these technologies are and whether they have overlooked the preservation of Indigenous Medicinal Knowledge. Following the PRISMA 2020 guidelines, relevant literature from 2019 to 2026 was gathered from major academic databases, including IEEE Xplore, Scopus, and ScienceDirect. After removing duplicates and non-English papers, 23 out of 39 publications met the selection criteria. The findings show that while XR is a proven technology in many sectors, it remains underused for documenting the medicinal knowledge of communities such as the Kayan and Kenyah. This lack of progress is not caused by technical limitations, but by internal organizational barriers and weak project planning. The evidence, therefore, points to a procedural problem rather than a technological one.**

***Keywords*—Extended Reality; Indigenous Medicinal Knowledge; Virtual Reality; Augmented Reality; Mixed Reality; gamification; cultural heritage preservation; Task-Technology Fit; PRISMA**

I. Introduction

Indigenous medicinal knowledge is considered an important foundation for cultural history and community well-being. It includes traditional healing methods and plant knowledge that have been passed down orally across many generations [1]. In this system, medicinal uses are combined with the ecological and cultural values that shape Indigenous worldviews. One example of this can be seen in the Kenyah and Kayan communities of Sarawak, Malaysia, where plant identification and preparation are part of traditional healing practices that have long supported community health. However, this continuity is now under threat.

Traditional ways of passing down this knowledge have been disrupted by modernization, putting these practices at risk of being lost [1]. As younger generations adopt digital lifestyles and attend formal schools that are disconnected from their ancestral roots, these oral traditions face the danger of disappearing permanently.

Extended Reality (XR) is a technology that combines Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (MR), and it can be proposed as a way to document and preserve this intangible cultural heritage. XR is an umbrella term that covers AR, which can be accessed through smartphones, tablets, or wearable devices such as the Microsoft HoloLens 2. AR layers images and text onto the user's real physical environment. VR, on the other hand, covers the user's entire field of vision through a headset and places them in a fully virtual space. Mixed Reality sits between AR, VR, and the real world [2].

XR technologies have been shown to create more immersive and effective learning experiences [2], [5]. They have been linked to better learning motivation, interest, creativity, and academic performance, while also being a more time-efficient option compared to traditional methods. XR is already being used as a training tool in medicine, the military, and sports education.

A notable gap exists: although XR is a well-established tool across many high-stakes fields such as chemistry, aviation, mental health, and medical training, it has rarely been applied to preserving Indigenous Medicinal Knowledge. In medicine, XR is used for neurosurgery and dental training [2], [7], [8], [9]. In chemistry education, it supports 3D molecular visualization [21]. Aviation uses it for flight simulation [5], and mental health practitioners apply it in cognitive rehabilitation and exposure therapy [13], [18]. The fact that XR is technically mature in these areas but largely absent from cultural preservation efforts suggests that the main obstacles are not technological, but procedural.

This review addresses the following research questions: 1) How is XR currently used for training in advanced professional fields such as medicine and aviation? 2) What are the main barriers to adopting XR, and how can inclusive design help address them? 3) How can XR technologies be adapted to preserve Indigenous Medicinal Knowledge in community settings?

II. Research Methodology

This systematic literature review was carried out using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 framework [3], which ensures that the process is transparent, reproducible, and methodologically sound. The review comprised four stages: identification, screening, eligibility, and inclusion.

A. Database Selection and Search Strategy

Three major databases were selected for their coverage of interdisciplinary research in computer science, cultural studies, and educational technology: IEEE Xplore, Scopus, and ScienceDirect. They were chosen because they provide access to peer-reviewed studies and include research on XR and gamification in education and cultural preservation. These three databases were considered sufficient for this review because they jointly index the majority of peer-reviewed venues publishing XR research, including IEEE VR, IEEE BigComp, MetroXRAINE, JMIR, Frontiers, and MDPI journals that appeared in the final included set. A preliminary coverage check confirmed that extending the search to additional databases (e.g., ACM Digital Library, Web of Science) returned substantial overlap with records already indexed in Scopus and IEEE Xplore. The review was restricted to English-language publications to ensure consistency in screening and appraisal; this restriction is acknowledged as a limitation in Section IV.E.

B. Search Strategy

The following Boolean search string was applied across all three databases:

"extended reality" AND ((("indigenous" OR "tradition*" OR "heritage") AND ("medicin*")) OR "ethnobotan*" OR "ethnopharma*")

A time restriction was applied to focus on studies published from 2019 to 2026. Only peer-reviewed publications written in English were included. After searching the three selected databases, 39 records were identified for evaluation.

C. Inclusion and Exclusion Criteria

Studies were included if they met the following criteria: 1) published from 2019 to 2026; 2) written in English and published in a peer-reviewed venue; 3) used XR technologies such as VR, AR, or MR in gamified or interactive applications; 4) focused on the preservation of Indigenous, cultural, or medicinal knowledge; and 5) used mobile or mobile-compatible XR applications that support accessibility and community participation.

Exclusion criteria comprised: 1) non-English or non-peer-reviewed works; 2) lack of relevance to XR in educational or cultural contexts; 3) non-interactive XR applications without engagement elements.

D. Screening and Selection Process

Initially, 39 unique records were identified: 25 from Scopus, 10 from IEEE Xplore, and 4 from ScienceDirect. Within the Scopus collection, 3 records were removed for not being written in English, 2 were identified as duplicates, and 11 did not meet the inclusion requirements, leaving 9 Scopus papers. IEEE Xplore (n=10) and ScienceDirect (n=4) records all met the inclusion criteria. After full-text analysis, 23 papers were selected: IEEE Xplore (n=10), Scopus (n=9), and ScienceDirect (n=4). The PRISMA flow diagram is shown in Fig. 1.

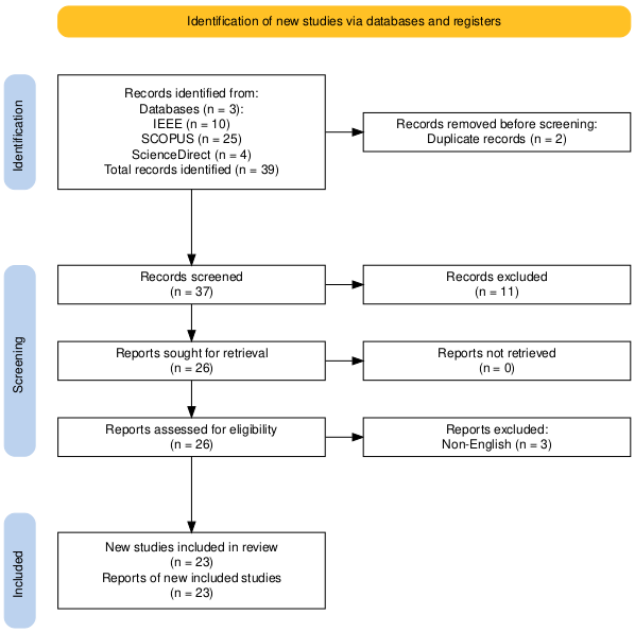

Fig. 1. PRISMA flow diagram

E. Data Extraction and Thematic Coding

After final selection, data extraction was carried out to gather key information from each of the 23 included studies. Each study was coded across several fields: 1) author(s) and publication year; 2) XR modality (AR, VR, MR, or hybrid); 3) presence of gamification elements; 4) domain of application, such as heritage, education, accessibility; 5) methodology used; 6) key outcomes; and 7) reported challenges or limitations.

F. Analytical Framework

This review uses the Task-Technology Fit (TTF) framework to assess how well XR technologies match the needs of knowledge preservation. TTF argues that a technology's effectiveness depends on how closely its features match the demands of the task [24]. The framework was originally developed to explain individual performance in information systems [4] and has since been applied to technology adoption in educational settings [24]. In knowledge preservation, the "task" includes cultural transmission, environmental learning, and community participation, while the "technology" refers to the different XR modalities and their capabilities.

To operationalize the TTF framework, this review explicitly maps four core task characteristics against the technology features offered by XR systems reported in the 23 included studies. The task characteristics derived from the domain of Indigenous Medicinal Knowledge (IMK) preservation are: (T1) spatial and sensory knowledge representation (e.g., plant identification, preparation gestures); (T2) narrative and oral transmission; (T3) community-based, in-field accessibility; and (T4) cross-generational engagement.

The corresponding technology features observed across the included studies are: (F1) immersive 3D visualization and spatial interaction [5], [17], [21]; (F2) scenario-based and simulation modalities [5], [19]; (F3) mobile and low-cost form factors [1], [6], [14]; and (F4) gamified feedback loops such as rewards, exploration, and progression [1], [5], [21]. Table V in Section IV-B presents the explicit task-to-feature mapping.

G. Quality Assessment

To strengthen methodological rigor, a post-hoc quality appraisal was applied to all 23 included studies after final selection. A five-item checklist adapted from common critical-appraisal tools was used, covering: (Q1) clarity of research aim and objectives; (Q2) appropriateness of the methodological approach; (Q3) transparency of data collection or study procedure; (Q4) validity and traceability of findings; and (Q5) relevance to XR and to knowledge-preservation or training contexts. Each item was scored as 1 (met), 0.5 (partially met), or 0 (not met). A study was retained in the synthesis if it scored at least 3.0 out of 5.0. All 23 studies met this threshold, which is consistent with their selection from peer-reviewed indexed venues (IEEE Xplore, Scopus, and ScienceDirect). This appraisal does not replace a full risk-of-bias assessment, which is typically reserved for interventional studies; the current review is descriptive and cross-disciplinary, and the checklist therefore focuses on methodological transparency and relevance rather than internal bias.

III. Results and Analysis

A. Overview of Included Studies

From the initial 39 records retrieved, the following were excluded from Scopus during screening: non-English language (n=3), duplicates (n=2), and papers that did not meet the inclusion criteria (n=11). All records from IEEE Xplore records (n=10) and ScienceDirect records (n=4) met the inclusion criteria. The final set included 23 peer-reviewed studies published from 2019 to 2026: IEEE Xplore (n=10), Scopus (n=9), and ScienceDirect (n=4). The included studies spanned clinical, educational, and assistive domains, covering the healthcare metaverse and next-generation care ecosystems [10], image-guided pain-procedure navigation [12], mixed-reality pre-surgical planning for epilepsy [15], digital-twin applications for pediatric assessment [20], adaptive-optics corrections in XR visualization [22], and VR-based ecological memory assessment [23].

B. XR Modalities and Applications

The 23 included studies show a range of XR applications across educational and cultural contexts. Augmented Reality (AR) and Mixed Reality (MR) were the most used modalities [1], [2], [5]. The studies spanned multiple disciplines, including educational technology, medical education, cultural heritage preservation, and accessibility frameworks [8], [9], [14]. Fig. 2 presents the distribution of XR modalities across application domains for the 23 included studies, and Table I summarizes the XR modalities and their primary applications.

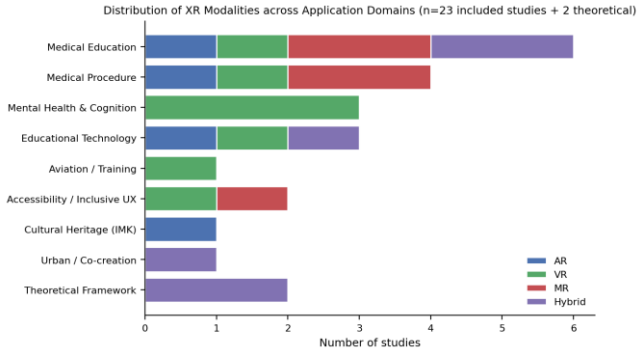

Fig. 2. Distribution of XR modalities (AR, VR, MR, Hybrid) across application domains in the 23 reviewed studies plus theoretical-framework references.

TABLE I. XR Modalities and Applications Across Included Studies

XR Modality	Primary Applications	Freq.	Key Characteristics	References
Augmented Reality (AR)	Educational enhancement; Cultural heritage visualization	High	Smartphone/tablet compatible; Real-world overlay; High accessibility	[1],[2],[5]
Mixed Reality (MR)	Medical training; Educational contexts	High	Immersive while maintaining spatial awareness; Wearable compatible	[5],[8]
Virtual Reality (VR)	Specialized training; Spatial memory assessment	Moderate	Full immersion; High cognitive engagement; Requires dedicated hardware	[5],[17],[18]
Hybrid (AR+VR+MR)	Complex medical and educational applications	Moderate	Combines AR/VR/MR capabilities; Flexible deployment	[1],[5],[9]

C. XR for Educational Enhancement

Several studies showed that XR technologies improve learning outcomes in educational settings. XR offers spatial understanding, greater peripheral awareness, and three-dimensional graphics, allowing for a level of realism that traditional classroom settings cannot provide [5], [17]. It has also been shown to strengthen cognitive ability, improve attention, and support neuroplasticity [5]. XR environments further encourage experimental and active learning [5], [21].

D. Gamification in XR Environments

Gamified XR applications were a strong category in the literature, with a focus on learning engagement, motivation, and retention. Game-based XR has been linked to higher scores in interest and enjoyment, perceived competence, and perceived usefulness [1]. Gamification elements such as progression, rewards, and exploration were found to be effective in encouraging curiosity and discovery-based learning, especially among younger audiences [1], [5], [21]. Table II presents the gamification mechanics identified across the reviewed studies.

TABLE II. GAMIFICATION MECHANICS IN XR APPLICATIONS

Mechanic	Description	Learning Impact	Cultural Fit	References
Interactive task completion	Users complete tasks to unlock narratives	High – promotes discovery	Excellent – aligns with quest traditions	[1],[5]
Achievement Systems	Rewards for mastering traditional practices	High – increases motivation	Good – recognizes mastery	[1],[5],[21]
Peer-based interaction and knowledge sharing	Peer-based knowledge sharing	High – promotes collaborative learning	Excellent – honors oral traditions	[1],[5],[21]
Immersive experiential learning	Exploration-driven experiences in educational contexts	High – immersive engagement	Excellent – connects to cultural narratives	[1],[5],[21]
Progression Systems	Level-based knowledge mastery	Moderate–High – clear goals	Good – structured learning path	[1],[5]

A cultural fit assessment represents the authors' analysis of potential alignment with Indigenous knowledge preservation needs.

E. Barriers to XR Adoption

Although XR applications have advanced technologically, their use in community settings remains limited due to technical, cultural, and ethical constraints. Common technical barriers include hardware costs, limited mobile compatibility, and poor infrastructure in rural areas [5], [2], [14]. From a TTF perspective, these barriers reflect a "mismatch", where technology's characteristics do not align with task requirements of remote, low-bandwidth environments [5], [4]. Other barriers include a lack of teacher training, few available educational experiences, limited research, and insufficient institutional support [2], [8], [9]. Table III summarizes the barriers identified.

TABLE III. BARRIERS TO XR ADOPTION IN COMMUNITY CONTEXTS

Barrier Category	Specific Barriers	Impact	TTF Analysis	References
Technical	Hardware costs; Limited mobile compatibility; Inadequate rural infrastructure	High	Technology mismatch: high-end requirements vs. low infrastructure	[5],[2],[14]
Infrastructure	High-speed internet; Stable power; Low bandwidth	High	Task–Technology mismatch: infrastructure unavailable	[4],[5]
Implementation	Lack of teacher training; Few educational experiences; No institutional support	Moderate–High	Organizational readiness issues	[2],[8],[9]
Economic	Initial hardware costs; Licensing fees; Maintenance expenses	High	Budget constraints for institutions	[2],[8],[9]

F. Opportunities for XR Integration

Despite the existing barriers, the review found emerging opportunities for XR in knowledge preservation. The potential of mobile-based XR platforms is supported by general XR education literature [6], and community-based testing has also been demonstrated [1]. Mobile-compatible XR platforms appear to be the most realistic option for community settings [1], [6]. Existing research also highlights the value of gamified and interactive approaches for passing down knowledge [1], [5], [21]. Table IV outlines the identified opportunities and their implementation strategies.

TABLE IV. OPPORTUNITIES FOR XR INTEGRATION IN KNOWLEDGE PRESERVATION

Opportunity	Implementation Strategy	Expected Outcome	Scalability	References
Mobile-Based XR	Deploy AR through smartphone/tablet apps	Accessible to remote communities	High – smartphone penetration	[1],[6]
Participatory Co-Creation	Co-design with community members and diverse age groups	Culturally authentic content and shared ownership	Moderate – requires engagement	[1]
Gamified Storytelling	Embed quests, achievements, collaborative gameplay	High engagement and knowledge retention	Moderate – effectiveness demonstrated in educational contexts	[1],[5],[21]

G. Usability and User Experience

Evaluations using the System Usability Scale (SUS) in existing literature show that XR applications generally achieve moderate to high usability scores [1]. Data from the Intrinsic Motivation Inventory (IMI) subscales indicated that users view XR tools as both effective and useful for learning, with particularly high scores in perceived competence and value [1]. A clear preference for AR over VR in certain environments also suggests that AR-based platforms may be more effective due to their ease of use and wider accessibility [1].

H. Accessibility and Inclusive Design

The literature also identified the importance of inclusive user experience design for diverse populations. Older adults and those with varying levels of digital literacy often find complex interfaces difficult to use, which points to the need for inclusive design approaches [14]. The digital divide continues to leave certain populations behind [2], [14]. Introducing XR in educational and community settings may help reduce this gap in access and adoption [2], [14].

IV. Discussion and Limitations

A. Theoretical Frameworks

The findings connect to several theoretical frameworks that link learning, technology, and knowledge preservation. XR technologies support experiential and active learning theory by allowing users to build understanding through immersive exploration [5], [17], [21]. Gamification elements also align with the intrinsic motivation indicators measured through the IMI [1]. Central to this discussion is the Task-Technology Fit (TTF) model, which looks at whether the capabilities of gamified mobile XR match the environmental and pedagogical tasks involved in knowledge preservation [4], [5].

B. Task-Technology Fit Analysis

The review also points to a clear mismatch in current research, where high-end XR hardware often requires infrastructure that is not available in rural or resource-limited settings [4], [5]. Task characteristics require that knowledge preservation supports mobile, in-field documentation within community environments [1], [6]. The task is not only technical but social, requiring a medium that supports oral, narrative, and practice-based transmission of knowledge [1]. Mobile XR platforms provide the portability and accessibility necessary to bridge the infrastructure gap [1], [6]. By utilizing mobile-compatible platforms, the objective of accessible community-based knowledge transmission is supported [1], [6].

TABLE V. Task-Technology Fit Mapping for XR in Indigenous Medicinal Knowledge Preservation

Task characteristic (IMK preservation)	Required capability	XR feature observed in reviewed studies	Supporting refs
T1. Spatial/sensory knowledge (plant ID, preparation gestures)	3D visualization, spatial interaction, gesture capture	Immersive VR/MR environments; stereoscopic XR video; acupoint annotation pipelines	[5], [11], [17], [21]
T2. Narrative/oral transmission	Scenario-based storytelling, audio-visual layering	AR overlays on real environments; simulation-based interprofessional scenarios	[2], [7], [19]
T3. Community-based, in-field accessibility	Portable, low-cost, low-bandwidth deployment	Mobile-compatible XR; low-cost VR for rehabilitation; inclusive UX for non-expert users	[1], [6], [14], [18]
T4. Cross-generational engagement	Motivation, retention, gamified feedback	Gamified XR with rewards and exploration; educational XR with measured motivation gains	[1], [5], [21]

C. Addressing Research Questions Through Findings

Table VI presents a synthesis of the research questions and the evidence-based answers derived from the 23 reviewed studies.

D. Practical Implications

The practical implications drawn from the synthesis focus on co-creation [16], accessibility, and ethical management of cultural content—areas essential for the sustainable preservation of knowledge [1], [6]. Table VII presents strategic recommendations for community-based XR implementation.

TABLE VI. Research Questions and Evidence-Based Answers

Research Question	Key Findings	Evidence	References
Current state of XR adoption for cultural heritage and education?	XR is becoming more common in educational institutions, though widespread adoption is still in its early stages. AR is generally preferred due to its accessibility through smartphones. Studies show that XR produces moderate to significant improvements in educational outcomes, including motivation, competence, and engagement.	Across the reviewed studies, educational settings consistently included engagement and interactivity features. Gamification was identified as a key design element in applications focused on cultural and educational purposes.	[1],[2],[5],[6],[8],[9],[14],[17]
What are the main barriers to adopting XR, and how can inclusive design overcome them?	Common barriers include hardware costs, limited mobile compatibility, inadequate rural infrastructure, lack of teacher training, and lack of institutional support. Inclusive design through mobile-based XR, participatory co-creation, and low-cost platforms can overcome these barriers.	TTF framework reveals technology-task mismatch in remote, low-bandwidth environments. Mobile XR platforms provide portability and accessibility to bridge the infrastructure gap.	[2],[4],[5],[8],[9],[14]
How can XR preserve and transmit knowledge in community contexts?	Mobile-based XR combined with gamification is optimal. Participatory co-design ensures cultural authenticity. Gamified storytelling bridges generational gaps.	Gamified mobile XR enhances knowledge retention and engagement. TTF framework explains adoption barriers and implementation solutions.	[1],[5],[6],[21]

TABLE VII. STRATEGIC RECOMMENDATIONS FOR COMMUNITY-BASED XR IMPLEMENTATION

Focus Area	Recommended Action	Intended Outcome	References
Community Participation	Co-design sessions with community members and diverse age groups	Ensure cultural accuracy and shared ownership of XR content	[1],[6]
Mobile XR Platform Selection	Select mobile-compatible XR platforms based on community technical capacity, budget, and ownership needs	Expand access in rural areas; ensure sustainability and community control over digital heritage	[1],[6]
Gamification Elements	Embed story-driven quests, rewards, and interactive feedback	Increase engagement and knowledge retention among youth	[1],[5],[21]
Ethical Data Governance	General XR literature recommends ethical and inclusive adoption	Safeguard knowledge ownership and promote trust in digital preservation	[6]

E. Limitations

While this systematic literature review followed PRISMA 2020 guidelines, several limitations must be acknowledged. The review was limited to three academic databases (IEEE Xplore, Scopus, ScienceDirect) and to English-language publications, which may have excluded regional, local, and Indigenous repository studies. The search string centered on the phrase "extended reality" combined with indigenous-, heritage-, and medicinal-related terms; it did not include the abbreviation "XR" as a separate keyword, nor narrower medicinal-domain terms such as "pharmacognosy", "healing", "herbal", "botany", or "plants". This conservative keyword set was a deliberate methodological choice to minimize the inclusion of studies unrelated to XR-for-knowledge-preservation, but it may have reduced recall. Future systematic reviews should expand the keyword set to include these terms, apply field-specific Boolean filters, and extend coverage to additional databases (e.g., ACM Digital Library, Web of Science) as well as regional and grey-literature sources. Because direct empirical research on Indigenous Medicinal Knowledge (IMK) preservation is scarce, the synthesis had to draw on broader educational and cultural heritage XR literature. All findings are strictly based on the 23 reviewed papers to maintain rigor and traceability. Table VIII provides a structured overview of these limitations.

TABLE VIII. LIMITATIONS OF THE SYSTEMATIC LITERATURE REVIEW

Limitation Category	Specific Limitation	Impact on Findings	Mitigation Strategy
Database & Language	Restricted to IEEE, Scopus, ScienceDirect; English-only	May exclude regional/local and Indigenous repository studies	Include grey literature, Indigenous repos, non-English publications in future reviews
Temporal	Review spans 2019–2026; rapid XR evolution	Earlier studies may reflect superseded hardware	Pedagogical/design insights remain relevant despite hardware evolution
Content Scope	Scarcity of direct IMK preservation research	Synthesis relied on broader XR/education literature	Future research should focus specifically on IMK preservation applications
Community Participation	Lack of explicit community participation in many studies	Limited culturally grounded XR frameworks discussed	Recommend participatory research designs with Indigenous communities
Methodological Scope	Review based on 23 papers from a systematic search only	All claims grounded strictly in reviewed papers	Ensures rigor and traceability; prevents unsupported claims
Research Gap	Limited direct IMK-specific XR empirical evidence	Recommendations extrapolated from general education/ cultural XR	Future empirical studies needed in community-based IMK contexts

F. Cultural, Ethical, and Epistemological Considerations

Although XR applications have advanced technically, their use for Indigenous Medicinal Knowledge (IMK) raises cultural, ethical, and epistemological concerns that must be explicitly addressed. Indigenous knowledge systems are often relational, place-based, and embedded in oral and ritual practice; digitizing such knowledge through XR risks decontextualizing it from the community protocols that govern who may hold, share, and transmit it [1]. Consistent with the community-based evaluation of a gamified XR prototype among the Kenyah and Kayan [1], any preservation effort must be co-designed with knowledge holders and align with free, prior, and informed consent principles. Ethical concerns also include data sovereignty, ownership of digitized plant and practice records, and the long-term stewardship of XR assets after a project concludes [6]. From an epistemological standpoint, XR tends to privilege visual and spatial modalities; this may be a good fit for plant identification and gesture-based preparation, but it can flatten the narrative, sensory, and relational dimensions of IMK. A notable proportion of the 23 reviewed studies derive from general XR applications rather than from IMK-specific contexts; this review therefore synthesizes evidence across domains and makes its IMK inferences with appropriate caution. Public-health XR literature [2] and the broader digital-age XR review [6] converge on the view that cultural fit, equity, and ethical governance must be designed-in rather than retrofitted.

V. CONCLUSION AND FUTURE WORKS

This systematic literature review brought together findings from 23 peer-reviewed studies published from 2019 to 2026 on the use of Extended Reality in educational and cultural settings [1], [2], [5], [6]. The analysis shows that XR technologies, including AR, VR, and MR, have gained considerable use in

improving learning outcomes, visualizing cultural heritage, and encouraging public engagement [1], [2], [5], [6], [8], [9]. The key finding of this review is that gamification works well as a teaching tool within XR environments, where it consistently improves intrinsic motivation and knowledge retention [1], [5], [21].

The review identifies five key points for XR implementation. First, XR shows strong potential for improving engagement through immersive learning environments [2], [5], [17]. Second, gamification supports community-based learning by creating participatory environments that improve educational value [1], [5], [21]. Third, long-term success depends on involving diverse community members throughout the process [1]. Fourth, mobile and low-cost XR platforms are the most practical choice for community settings [1], [6]. Fifth, all digitalization efforts should be guided by ethical standards that support equity and inclusivity [6].

For future academic work, studies should move beyond general educational contexts and focus specifically on knowledge preservation in community settings [1], [6]. Empirical and field-based research is needed to assess how well XR and gamified learning approaches work in real community environments [1], [6]. Development efforts should also prioritize mobile-compatible XR systems to improve accessibility in low-resource settings. Ethical frameworks should be embedded into project design to ensure transparency and long-term cultural protection [1], [6].

Looking forward, the research agenda points to several concrete directions. First, community-anchored field trials of mobile-compatible XR prototypes should be conducted with Indigenous knowledge holders, with outcomes measured beyond usability to include cultural continuity and intergenerational transfer indicators [1]. Second, the Task-Technology Fit framework applied in this review should be extended into an evaluation instrument that can be quantitatively tested in future IMK-XR studies [4], [24]. Third, hybrid AR-plus-gamification designs warrant dedicated investigation for low-bandwidth rural deployment [1], [5], [21]. Fourth, longitudinal studies are needed to assess whether XR-mediated preservation sustains knowledge retention and community engagement over years rather than single sessions. Finally, future work should integrate ethical and data-sovereignty governance into the XR development lifecycle, supported by the public-health and digital-age XR literature [2], [6], so that preservation efforts remain accountable to the communities whose knowledge they document.

ACKNOWLEDGMENT

This research was supported by the Universiti Malaysia Sarawak (UNIMAS), under the internal research grant IRG/F08/SDEC/86654/2025. The funding body was not involved in the design, data collection, analysis, or interpretation of the study.

***Abstract*—To address the challenges of feature extraction in complex field environments, the limited sensitivity of YOLOv9 to subtle disease features, and the lack of adaptive hyperparameter optimization, this paper proposes an improved high-precision detection model, named IFDA-EMA-YOLOv9. First, to enhance feature extraction capabilities, an Efficient Multi-scale Attention (EMA) mechanism and residual connections are incorporated into the network architecture. This integration effectively suppresses background noise interference and significantly improves the model's ability to aggregate and represent multi-level features of wheat disease lesions. Second, to tackle localization deviations caused by the irregular geometric shapes of disease lesions, an auxiliary box mechanism is integrated into the Complete Intersection over Union (CIoU) loss function, optimizing the regression process to improve the fit of detection boxes. Furthermore, an Improved Flow Direction Algorithm (IFDA) is employed to perform global optimization of the critical model hyperparameters, thereby avoiding the blindness of manual tuning and the local optimum trap. Experimental results on the LWDCD2020 dataset demonstrate that the proposed IFDA-EMA-YOLOv9 significantly outperforms current state-of-the-art (SOTA) methods, achieving substantial improvements in Precision, Recall, and mAP@0.5 by 6.4%, 5.94%, and 6.66%, respectively. These results demonstrate the effectiveness and robustness of the proposed method for wheat disease and pest detection.**

Keywords*—Wheat disease detection; Object detection; YOLOv9; Flow algorithm

I. Introduction

Wheat is one of the world's major staple crops and plays a crucial role in ensuring food security and sustainable agricultural production. However, throughout the full growth cycle of wheat, the frequent occurrence of major pests and diseases such as yellow rust, fusarium head blight, and aphids has become a key factor restricting yield and quality. Statistics indicate that in years with prevalent diseases, the aforementioned disasters can cause wheat yield reductions of 20% to 50%, and in extreme cases, even trigger total seasonal harvest failure, bringing inestimable losses to agricultural production. Therefore, constructing a precise, real-time automated monitoring system possesses significant practical significance for assisting farmers in making scientific decisions, implementing precise pesticide application, and improving pesticide utilization rates.

For a long time, traditional disease monitoring has mainly relied on manual field inspections or simple physical instrument detection. These methods are not only time-consuming and labor-intensive with high subjectivity, but also difficult to adapt to the monitoring demands of large-scale intensive planting, suffering from serious lag. With the rapid development of artificial intelligence technology, utilizing computer vision and image processing technology to realize rapid, non-destructive identification of crop diseases has become an innovative direction in the field of smart agriculture. Compared with traditional means, deep learning-based methods can automatically and efficiently extract disease features from complex backgrounds, significantly enhancing the intelligence level of prevention and control work.

Among numerous deep learning models, the YOLO (You Only Look Once) series algorithms stand out due to their efficient end-to-end detection mechanisms. In particular, the latest YOLOv9 model, by introducing Programmable Gradient Information (PGI) and the Generalized Efficient Layer Aggregation Network (GELAN), has achieved excellent performance in core computer vision tasks such as general object detection, image classification, and semantic segmentation, demonstrating superior feature extraction capabilities and real-time inference performance [1-3].

Although YOLOv9 performs strongly on general datasets, it still faces numerous challenges that urgently need to be resolved when directly deployed to complex, unstructured wheat field environments: First, the field environment has variable illumination and complex backgrounds, so the applicability and robustness of YOLOv9 in specific agricultural scenarios require in-depth investigation and validation; second, the model's original pooling dimensionality reduction strategy, when modeling cross-channel long-range dependency relationships, easily causes the loss of subtle disease features, thereby damaging the integrity of visual representation; third, the existing CIoU loss function finds it difficult to achieve precise bounding box regression when processing targets like wheat disease lesions, which have extremely variable aspect ratios and irregular geometric shapes; finally, the configuration of model hyperparameters often relies on manual experience and lacks adaptive optimization schemes for specific datasets, limiting the upper bound of model performance.

II. Related Work

A. Progress in Wheat Pest and Disease Detection Technology

In recent years, although the YOLO series has made significant progress in the agricultural field, the research focus has shifted from simple architecture stacking to refined feature

*Corresponding author.

modeling. Qiao et al. [4] enhanced the global feature extraction capability of YOLOv8n by incorporating the C2f-iRMBS module and Inner-EIoU loss function, reaching a mAP of 96.3%. However, addressing the problem of feature redundancy in field environments, the latest research trends have begun to introduce Partial Convolution (PConv) to extract more representative spatial features by reducing redundant calculations. Furthermore, considering the irregularity of wheat lesion morphology, the Large Selective Kernel mechanism has demonstrated advantages in capturing multi-scale lesion features by dynamically adjusting the receptive field. In this context, this paper proposes the EMA-YOLOv9 model, which, by integrating the Efficient Multi-Scale Attention (EMA) mechanism with a residual architecture, aims to solve the negative impact of cross-channel relationship modeling on visual representation under complex backgrounds, further reinforcing the flexibility of feature extraction.

Addressing the difficulty of locating tiny lesions, the traditional IoU loss function has limitations when processing wheat disease lesions of variable sizes. Latest technologies such as Inner-IoU [5] have accelerated convergence by introducing auxiliary bounding box scaling factors, while MPDIoU [6] has effectively solved the problem of inaccurate bounding box overlap measurement using minimum point distance. Drawing on this frontier idea, we introduce an auxiliary frame mechanism into the YOLOv9 framework to optimize the CIoU loss function, effectively balancing localization accuracy among targets of different scales.

B. YOLOv9 Parameter Optimization

YOLOv9 utilizes a reversible information callback mechanism to significantly alleviate feature loss in deep networks. However, its performance is highly dependent on complex hyperparameter configurations. Existing research on YOLOv9 hyperparameter automation remains relatively scarce, with most literature still remaining at optimization schemes for earlier versions.

Reviewing past research, YOLOv5 employed the Genetic Algorithm (GA) [7] to optimize hyperparameters, and Mahmudah et al. [8] utilized the Tree-structured Parzen Estimator (TPE) in YOLOv7 to explore the search space. However, facing the more non-linear parameter space of YOLOv9, traditional Genetic Algorithms, Artificial Bee Colony (ABC) algorithms [9], or Opposition-based Optimization Strategies (OOS) [10] are prone to falling into local optima and are difficult to cover the full hyperparameter set. To excavate the model's potential, this paper innovatively adopts the Improved Flow Direction Algorithm (IFDA) for global optimization and proposes utilizing Chaotic Mapping and Lévy Flight mechanisms to enhance population diversity; the final IFDA-EMA-YOLOv9 model realizes the leap of hyperparameter configuration from empirical tuning to automated evolution.

III. Basic Concepts

A. YOLOv9

YOLOv9 employs a regression strategy to achieve end-to-end simultaneous prediction for target region identification, spatial localization, and category classification, striking a significant balance between detection accuracy and inference efficiency. The overall architecture of the algorithm comprises four core components: the Backbone, the Auxiliary Reversible Branch, the Multi-level Auxiliary Information, and the Head. During the model training phase, YOLOv9 generates a total of six sets of output feature maps for subsequent prediction label inference. Distinct from previous architectures, YOLOv9 innovatively introduces an auxiliary output module. By calculating the correlation between the prediction loss and ground truth labels, this mechanism facilitates the efficient back-propagation of gradient information through the auxiliary reversible path to shallow feature extraction modules. This process optimizes the gradient backflow from deep networks to shallow networks, which is crucial for the effective updating of backbone weights and the maintenance of feature representation capabilities. The core task of the model lies in accurately predicting the spatial locations of targets of different sizes based on multi-scale feature maps. By integrating the Silence module to optimize the inference process, combining standard CBS (Conv-BN-SiLU) modules, and refining the loss function and optimizer strategy, the model achieves significantly enhanced robustness in object detection and localization. Comparative experiments demonstrate that, relative to previous versions such as YOLOv7 and YOLOv8, YOLOv9 achieves improved detection accuracy while significantly reducing the number of parameters and computational complexity (FLOPs). In summary, YOLOv9 represents significant technical progress in the trade-off between processing speed and detection performance.

B. Flow Direction Algorithm (FDA)

1) Algorithm background and d8 mechanism: The Flow Direction Algorithm is inspired by natural surface runoff processes. In hydrology, direct runoff is driven by gravity and converges toward the watershed outlet along the direction of the terrain slope. The classical method for simulating this process involves discretizing the watershed into regular grid cells and determining the runoff path by calculating the elevation difference and slope between rasters. Among these methods, the D8 algorithm (Deterministic-8 Node) proposed by O'Callaghan et al [11]. is currently the mainstream method for determining flow direction. In the D8 model, it is assumed that each central raster has eight adjacent rasters. By calculating the slope between the central raster and its neighborhood rasters, the flow direction is defined as pointing to the adjacent raster with the maximum slope descent (as shown in Fig. 1).

2) Assumptions of FDA: Drawing on the physical mechanism of the D8 algorithm, FDA abstracts the solving process of optimization problems into the process of rainfall converting into runoff and converging toward the outlet. In this mapping system, water flow represents population individuals, position represents the solution vector, and elevation corresponds to the objective function value. Fig. 2 illustrates the flowchart of FDA. Based on literature [12], the operation of FDA is based on the following core assumptions:

- Individual definition: Each flow possesses determined position coordinates and a corresponding elevation (fitness value) in the solution space.

- Neighborhood structure: Each flow possesses β adjacent positions in the space, and each neighborhood position corresponds to an elevation or objective function value.
- Dynamic relationship: The flow velocity of the fluid is proportional to the path slope.
- Velocity definition: The velocity of the fluid moving toward the lowest elevation (the direction of the optimal value) is defined as V.
- Convergence goal: The position of the watershed outlet corresponds to the global optimal solution of the objective function in the search space.

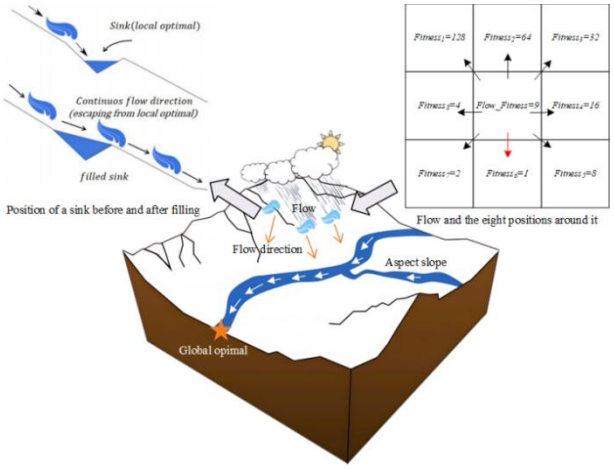

Fig. 1. D8 Method process flow diagram.

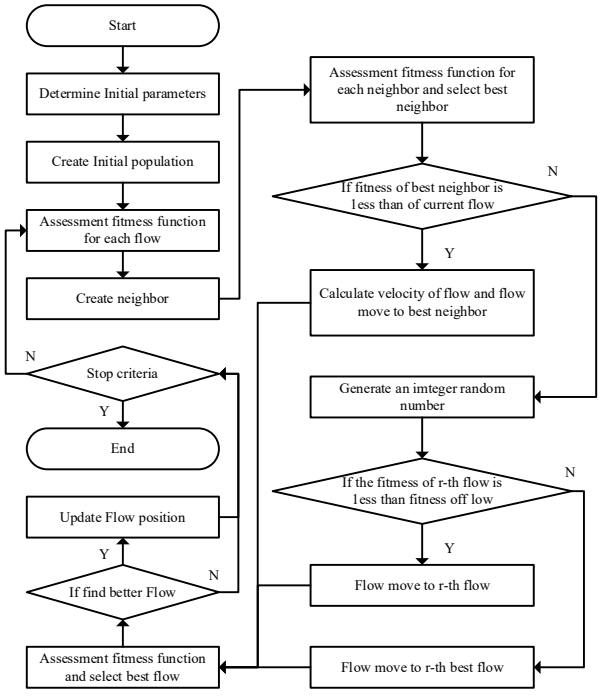

Fig. 2. Flowchart of the original FDA.

3) Initialization of flow positions: The initialization phase of the FDA algorithm involves the setting of key parameters such as population size ($Size_{pop}$), neighborhood quantity ($Size_{near}$), neighborhood radius (R_{near}), and maximum iterations (MaxIter). The initial positions of various fluids in the population are randomly generated within the solution space via the following equation:

$$Flow_X(i) = lb + r_1 \times (ub - lb) \tag{1}$$

Where $Flow_X(i)$ denotes the position of the i-th flow, lb and ub represent the lower and upper bounds of the decision variables, respectively; and r_1 is a random number uniformly distributed in [0,1].

4) Neighborhood generation strategy: FDA assumes that a neighborhood with a radius of R_{near} exists around each flow. Its position is generated by the following formula:

$$Neighbor_X(i) = Flow_X(i) + r_2 \times R_{near} \tag{2}$$

Here, denotes the position of the j-th neighbor. represents a random number drawn from a normal distribution with a mean of 0 and a standard deviation of 1. A smaller value of restricts the search to a narrow range, whereas a larger value allows for exploration across a broader scope. Searching within a wide range yields more diverse solutions and enhances the probability of identifying near-optimal solutions through global search.

Therefore, FDA adopts a formula to make the value of R_{near} linearly decrease from large to small, so as to achieve a balance between global search and local search. The mathematical formula is as follows:

$$\begin{aligned} R_{near} &= (r_3 \times Rand_X - r_3 \times Flow_X(i)) \\ &\times \left\| Best_X - Flow_X(i) \right\| \times W \end{aligned} \tag{3}$$

Where, r_3 is a uniformly distributed random number; $Rand_X$ is a random position generated by (1); W is a non-linear weight that varies randomly between 0 and infinity. The first term of (3) indicates that $Flow_X(i)$ moves towards the random position ($Rand_X$). As the number of iterations increases, $Flow_X(i)$ converges towards $Best_X$, causing the Euclidean distance between $Best_X$ and $Flow_X(i)$ to decrease to zero. Consequently, the local search is optimized. The calculation formula for W is as follows:

$$W = ((1 - \frac{iter}{MaxIter})^{2 \times r_4}) \times (\bar{r_1} \times \frac{iter}{MaxIter}) \times \bar{r_1} \tag{4}$$

Where *iter* represents the current iteration number; r_4 is a uniformly distributed random number; and r is a uniformly distributed random vector.

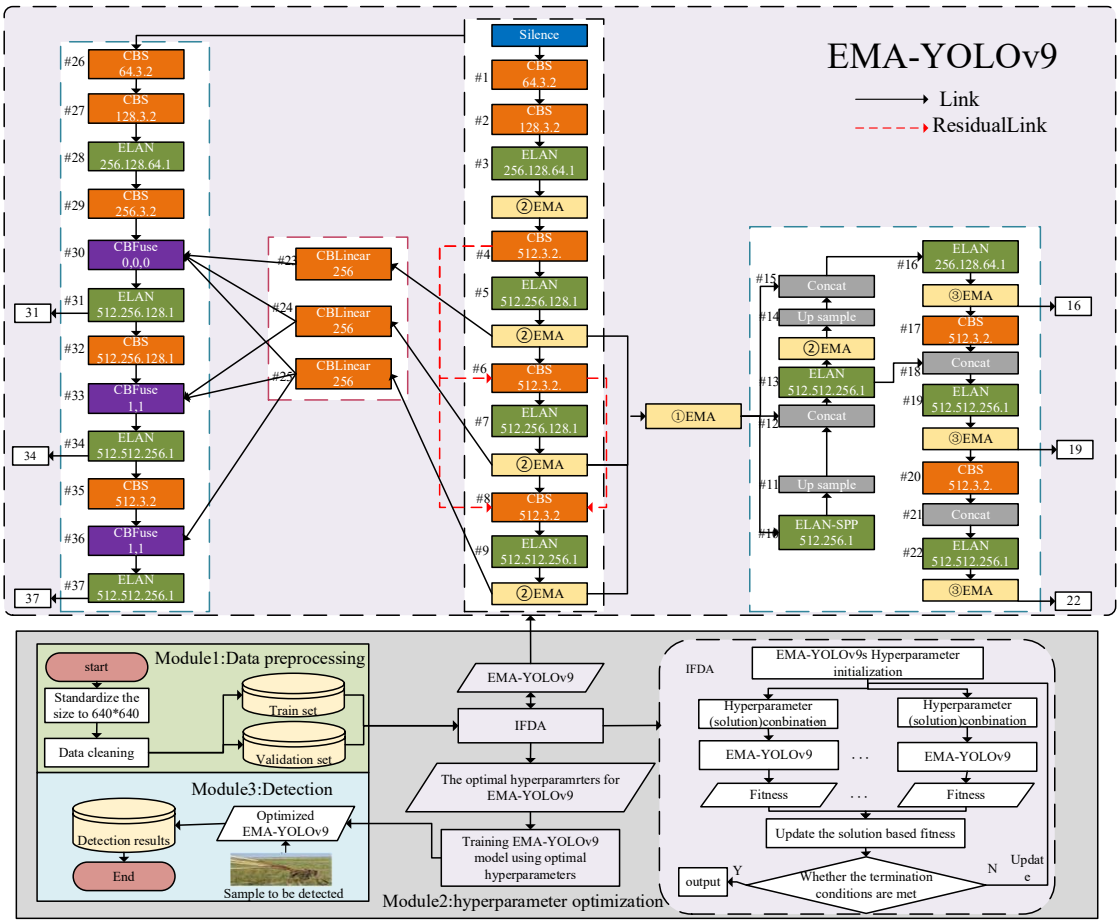

Fig. 3. Overall framework of methods for detecting wheat diseases.

5) Updating flow position: The flow moves at velocity V towards the neighbor with the optimal objective value. V is directly proportional to its slope. The calculation of V is as follows:

$$V = r_5 \times S \tag{5}$$

Where r_5 is a uniformly distributed random number; S represents the slope vector from the neighbor to the current flow position. S for the i-th flow relative to the j-th neighbor is also determined by the following formula:

$$S(i,j,d) = \frac{fitness(Flow_X(i,d)) - fitness(Neighbor_X(j,d)))}{\left\| Flow_X(j,d) - Neighbor_X(j,d) \right\|} \tag{6}$$

Where fitness() represents the function for calculating the objective value; and d represents the problem dimension.

The new position of the flow $Flow_X(i)$ is calculated by the following formula:

$$Flow_newX(i) = Flow_X(i) + V \times \frac{Flow_X(i) - Neighbor_X(j)}{\left\| Flow_X(i) - Neighbor_X(j) \right\|} \tag{7}$$

The function value must not be lower than the objective function value of the flow. This concept is analogous to the water-filling process of a sink, which determines the direction of the flow. To simulate the aforementioned state, the FDA randomly selects another flow using the following equation:

$$Flow_newX(i) = \begin{cases} Flow_X(i) + \overline{r_2} \times (Flow_X(r) - Flow_X(i)) \\ fitness(Flow_X(r)) < fitness(Flow_X(i)) \\ Flow_X(i) + r_6 \times (Best_X - Flow_X(i)) \\ otherwise \end{cases} \tag{8}$$

Where, r is a random integer; r_2 is a random vector uniformly distributed in $[0, 1]$; and r_6 is a uniformly distributed random number. Finally, the fitness value of the newly generated flow is calculated and compared with that of the previous flow to determine its position at iteration Iter+1.

IV. Methodology

A. General Framework

As illustrated in Fig. 3, the comprehensive methodology for identifying wheat diseases and pests utilizing the IFDA-EMA-YOLOv9 approach comprises two primary components:

network architecture design and full-process optimization strategies.

At the network architecture level, the model is built upon YOLOv9 as the baseline. The backbone and neck networks are constructed by integrating CBS, ELAN, and CBFuse modules. Notably, the Enhanced Multi-scale Attention (EMA) mechanism module is introduced to bolster the model's capability in capturing key features and to improve the efficiency of multi-scale feature fusion.

At the system workflow level, the framework establishes a closed-loop processing mechanism: first, Module 1 performs preprocessing tasks, including image dimension standardization and data cleaning; subsequently, Module 2 integrates IFDA into EMA-YOLOv9 for iterative hyperparameter optimization to achieve the optimal model configuration; finally, Module 3 utilizes the optimized model to execute high-precision object detection tasks on the input samples.

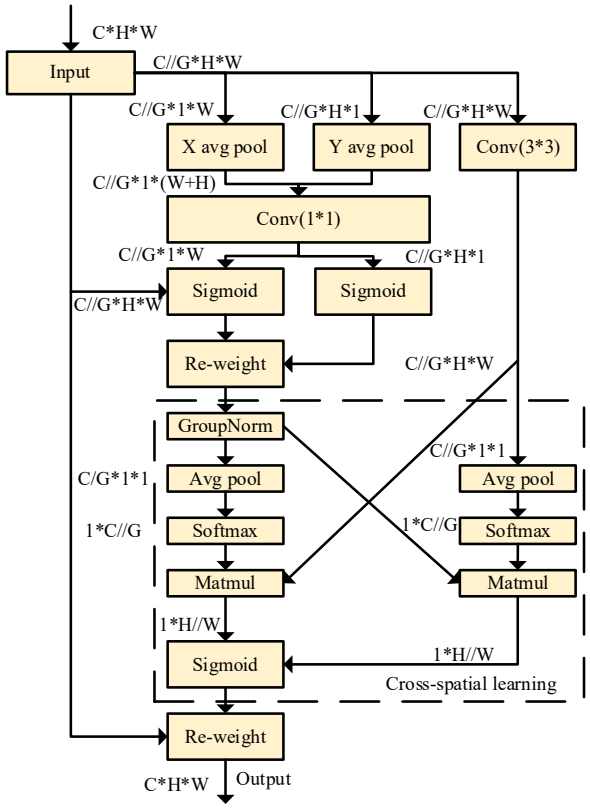

Fig. 4. Structure of EMA.

B. EMA-YOLOv9

1) Multi-level EMA: The relatively small size of wheat and its leaves, coupled with colors that are easily confused with other foliage, poses challenges for traditional YOLO detection models. Incorporating attention mechanisms has emerged as a viable solution to address these issues. IFDA-EMA-YOLOv9 introduces an enhanced multi-scale attention mechanism into YOLOv9, which facilitates the uniform distribution of spatial semantic features across each feature map. The multi-scale architecture of EMA is particularly effective in establishing short-term and long-term dependencies, thereby strengthening the model's feature extraction capabilities and ultimately enhancing object detection performance [13]. The structural representation of EMA is shown in Fig. 4.

EMA is defined as an efficient multi-scale attention mechanism characterized by the absence of dimensionality reduction and its role as a cross-space learning method. It establishes short-term and long-term dependencies through a multi-scale parallel sub-network. By modeling long-term dependencies, the EMA mechanism preserves precise positional information. By fusing contextual information across different scales, the object detection model gains the ability to generate pixel-level attention for feature maps. Compared to traditional Coordinate Attention, EMA utilizes only two convolution kernels (1×1 and 3×3). To aggregate multi-scale spatial structural information, the 3×3 kernel is arranged in parallel with the 1×1 branch to facilitate rapid response. This parallel sub-structure allows the network to avoid extensive sequential and deep processing. EMA enables the learning of effective channel representations without the need for channel dimensionality reduction, thereby generating superior pixel-level attention for high-level feature maps.

As shown in Fig. 5, three methods have been designed to integrate EMA into YOLOv9, including implementations at the backbone and neck/head levels:

Placing EMA at the end of the backbone, as shown in Fig. 5 (a).

Placing EMA after the RepNCSSPELAN4 module in the backbone, as shown in Fig. 5 (b).

Embedding EMA after the RepNCSSPELAN4 module within the Neck and Head structures, as shown in Fig. 5 (c).

This paper aims to investigate the performance of multi-level EMA through experiments and, based on the three aforementioned implementation strategies, determine the optimal configuration for the integration of YOLOv9 and EMA.

2) ICIoU Loss: The original YOLOv9 model employs CIoU (Complete Intersection over Union) loss as its loss function. CIoU loss comprehensively considers three geometric parameters: overlap area, central point distance, and aspect ratio [14]. The calculation formula for CIoU loss is as follows:

$$CIoU = IoU - \left(\frac{\rho^2(b, b^{gt})}{c^2} + \kappa\vartheta\right) \tag{9}$$

Where IoU represents the overlapping area; $\rho^2(b, b^{gt})$ represents the square of the Euclidean distance between the center points of the predicted box and the ground truth box; c^2 represents the square of the diagonal length of the smallest enclosing rectangle covering both boxes; κ and ϑ are aspect ratio parameters, calculated as follows:

$$\kappa = \frac{\vartheta}{1 - IoU + \vartheta} \tag{10}$$

$$\vartheta = \frac{4}{\pi^2}(\arctan\frac{w^{gt}}{h^{gt}} - \arctan\frac{w}{h}) \tag{11}$$

Here, w^{gt} and h^{gt} represent the height and width of the ground truth box, while h and w represent the height and width of the predicted box. The CIoU loss function accounts for both central point distance and the consistency of the aspect ratio. However, the variability in the shapes and scales of wheat and its leaves limits the effectiveness of CIoU loss in accurately calculating IoU for irregularly shaped targets. Furthermore, CIoU loss struggles to maintain stable localization accuracy across different target scales, thereby impacting the overall detection accuracy

To address the aforementioned challenges, we combine the Inner IoU with the CIoU loss and introduce an Auxiliary Box into the CIoU framework, thereby proposing the ICIoU loss function. The structural diagram of the auxiliary box is illustrated in Fig. 6.

The center point of the auxiliary box coincides with that of the ground truth box, but their dimensions differ. The auxiliary box serves as a representation of the ground truth box. In cases of high IoU values, the absolute value of the IoU gradient for a smaller-scaled auxiliary box is greater than that of the ground truth box. Conversely, for samples with low IoU values, the absolute value of the IoU gradient for a larger-scaled auxiliary box is smaller than that of the ground truth box. Therefore, adjusting the dimensions of the auxiliary box contributes to accelerating model convergence.

By adjusting the parameter r_{IoU}, the dimensions of the auxiliary box can be customized to adapt to different datasets. This design facilitates more precise fine-tuning of the predicted box position when analyzing wheat pest images with high IoU values. Conversely, when processing images with low IoU values, a larger auxiliary box can be employed to fully cover the target region, thereby mitigating localization errors associated with CIoU loss.

The calculation method for the auxiliary box is described as follows. First, the four boundary coordinates of the actual auxiliary box must be calculated respectively:

$$b_t^{gt} = y_c^{gt} - \frac{h^{gt} \times r_{IoU}}{2} \tag{12}$$

$$b_b^{gt} = y_c^{gt} + \frac{h^{gt} \times r_{IoU}}{2} \tag{13}$$

$$b_l^{gt} = x_c^{gt} - \frac{w^{gt} \times r_{IoU}}{2} \tag{14}$$

$$b_r^{gt} = x_c^{gt} + \frac{w^{gt} \times r_{IoU}}{2} \tag{15}$$

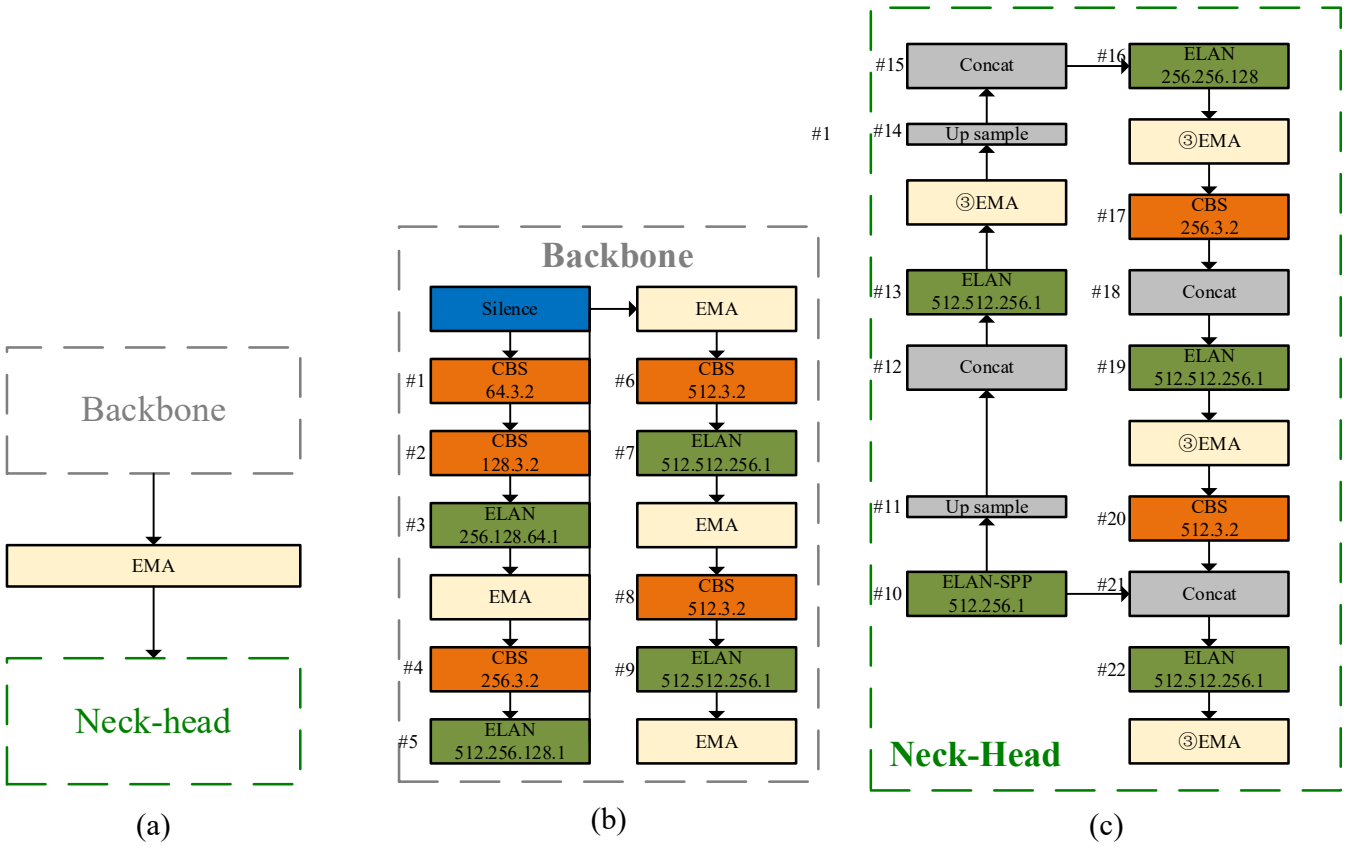

Fig. 5. Diagrammatic sketch of multi-level EMA.

Similarly, the four boundary coordinates of the predicted auxiliary box— b_t 、 b_b 、 b_l and b_r —are calculated respectively. Subsequently, the intersection and union of the auxiliary boxes are calculated:

$$inter = (min(b_r^{gt}, b_r) - max(b_l^{gt}, b_l)) \times (min(b_b^{gt}, b_b) - max(b_t^{gt}, b_t)) \quad (16)$$

$$union = (w^{gt} h^{gt})(r_{IoU})^2 + (wh)(r_{IoU})^2 - inter \quad (17)$$

Subsequently, the intersection-over-union (IoU) term $1 - \frac{inter}{union}$ of the auxiliary box is calculated to serve as the auxiliary box loss. Finally, the loss function of EMA-YOLOv9 is expressed as:

$$ICIoU = IoU - (\frac{\rho^2(b, b^{gt})}{c^2} + \kappa\upsilon) + 1 - \frac{inter}{union} \quad (18)$$

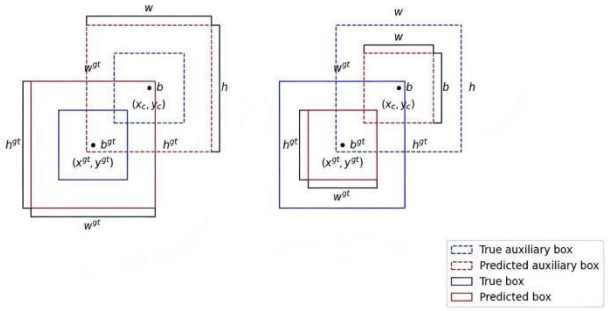

Fig. 6. Schematic diagram of auxiliary frame.

3) Cross-scale feature interaction: To enhance the feature extraction capability of YOLOv9, residual connections were introduced into the backbone network architecture of this model. In the field of object detection, it is generally recognized that low-level features contain richer edge and texture details, whereas high-level features tend to represent more abstract semantic content. Cross-level feature fusion is considered beneficial for improving the model's performance in tasks such as small object detection and fine segmentation. The implementation of residual connections enables YOLOv9 to effectively capture deep information that is difficult to adequately express with single-level features, thereby enriching the hierarchical representation of features and facilitating the acquisition of high-level semantic information. IFDA-EMA-YOLOv9 adopts a residual structure derived from the ResNet architecture, establishing connections among the 4th, 6th, and 8th layers of the backbone network to promote cross-scale feature interactions. The specific residual structure employed is illustrated in Fig. 7. This structure initially utilizes a 1x1 convolution to perform dimensionality reduction on the residual connection, subsequently connects to a 3x3 convolution, and finally increases the dimensionality through another 1x1 convolution.

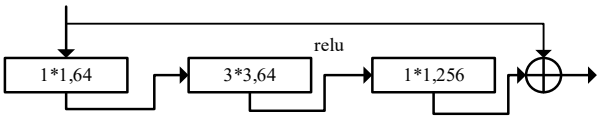

Fig. 7. Matic diagram of residual structure.

C. IFDA

The Improved Flow Direction Algorithm (IFDA) introduces three enhancements based on the original FDA, specifically encompassing solution initialization, the fitness function, and the solution update mechanism.

Meanwhile, to achieve high-precision training of deep learning models, hyperparameters must be adjusted. Notably, evaluating each parameter set requires the model to complete a full training cycle. The formal description of the parameter tuning problem is as follows:

$$\min errorRate = F(P) \quad s.t. \begin{cases} P = \{p_1, p_2, \ldots, p_i\} \\ p_i \in [\mu b_i, lb_i] \\ i = \{1, 2, \ldots, k\} \end{cases} \quad (19)$$

Where $errorRate$ denotes the error of the trained model; P represents the set of model hyperparameters; k indicates the number of hyperparameters requiring parameterization; and $[ub_i, lb_i]$ signifies the variation range of parameter p_i.

Early methodologies primarily relied on manual tuning, an approach heavily dependent on the practitioners' expert experience. However, given the inherent uncertainty and time-consuming nature of manual tuning, grid search techniques were gradually adopted. Nevertheless, in the training of deep learning models characterized by numerous parameters and extensive value ranges, grid search often results in high computational complexity and excessive time consumption. This complexity stems from the significantly higher training overhead of deep learning models compared to shallow models such as Support Vector Machines (SVM). Consequently, this paper proposes utilizing heuristic algorithms for parameter optimization.

1) Solution initialization: IFDA must first randomly generate initial solutions within the constrained solution space. This paper summarizes all hyperparameters that may significantly impact the performance of EMA-YOLOv9, as shown in Table I.

The hyperparameters requiring further explanation are as follows:

- Determines the model version of YOLOv9. The original authors of YOLOv9 proposed five different versions, namely YOLOv9-T, YOLOv9-S, YOLOv9-M, YOLOv9-C, and YOLOv9-E, each corresponding to a different number of parameters. Specifically, the YOLOv9-E version contains 57.3 million parameters, while the YOLOv9-T version has the fewest, at only 2 million.

TABLE I. HYPER-PARAMETERS OF EMA-YOLOV9 THAT NEED TO BE OPTIMIZED

Category	Parameter	Symbol	Value range
Model Structure Hyperparameters	Model size	$Size$	$Size \in \{0,1,2,3,4\}$
	Location of EMA	α_{EMA}	$\alpha_{EMA} \in \{0,1,2,3,4,5\}$
	Network width gain	d_m	$d_m \in (0,1]$
	Network width gain	w_m	$w_m \in (0,1]$
Model Training Hyperparameters	Activation function	AF	$AF \in \{0,1,2,3,4,5\}$
	Batch size	BS	$BS \in [8,256], BS \in E^+$
	Warm up epochs	$epochs_{warm}$	$epochs_{warm} \in [1,50], epochs_{warm} \in N^+$
	Initial learning rate	LR	$LR \in [0.0001, 0.001]$
	Final learning rate	LR'	$LR' \in [0.001, 0.1]$
	Momentum of optimizer	$Momentum$	$Momentum \in [0,1]$
	Weight decay coefficient	WD	$WD \in [0,1]$
	Decay rate of moment estimation index	EDR	$EDR \in [0,1]$
	IoU loss weight	w_1	$w_1 \in [0,1]$
	Weight loss of center point distance	w_2	$w_2 \in [0,1]$
	Weight loss of aspect ratio distance	w_3	$w_3 \in [0,1]$
	Tune parameter	r_{IoU}	$r_{IoU} \in [0.5,1.5]$

- α_{EMA} determines the position of the EMA module within the YOLOv9 $\alpha_{EMA}=0$ signifies that no EMA is incorporated; $\alpha_{EMA}=1$ indicates the integration of EMA after the 9th layer (#9); $\alpha_{EMA}=2$ indicates introducing EMA after layers #3, #5, #7, and #9; $\alpha_{EMA}=3$ indicates introducing EMA after layers #13, #16, #19, and #22; $\alpha_{EMA}=4$ indicates introducing EMA at layers #9, #13, #16, #19, and #22; $\alpha_{EMA}=5$ indicates introducing EMA after layers #3, #5, #7, #9, #13, #16, #19, and #22.
- d_m represents the network Depth Gain. This parameter influences the number of Bottleneck CSP modules and SPPCSPC modules within the ELAN architecture of the backbone network. This factor directly determines the overall network depth of YOLOv9.
- w_m represents the network Width Gain. This parameter influences the number of convolutional channels in both the backbone network and the detection head. Consequently, this factor directly determines the overall network width of YOLOv9.
- AF determines the activation function utilized in YOLOv9. The set $\{GeLU, ReLU, Mish, Swish, SiLU, LeakyReLU\}$ is encoded sequentially as $\{0,1,2,3,4,5\}$.
- w_1, w_2, w_3 are the three loss function weight coefficients for ICIoU, whereas the weight for the auxiliary box loss is determined by $1-w_1-w_2-w_3$.

$$ICIoU = w_1 IoU - w_2\left(\frac{\rho^2(b,b^{gt})}{c^2} + w_3\kappa\vartheta\right) + (1-w_1-w_2-w_3)\left(1-\frac{inter}{union}\right) \quad (20)$$

Traditional methods for population initialization typically involve random distribution across the entire space; however, this approach often leads to significant non-uniformity, thereby limiting diversity during the early stages of population evolution and reducing the convergence efficiency of the algorithm [15]. In light of this, we employ various Chaotic Maps to generate initial solutions for different parameters. Utilizing chaotic maps facilitates the generation of more uniformly distributed sequences, which in turn enhances population diversity.We employ the Singer chaotic map to generate the initial solutions for $Momentum$, WD, and EDR, utilize the Gaussian chaotic map to generate the initial solution for $epoch_{warmup}$, and use the Tent chaotic map to generate initial solutions for the other hyperparameters.

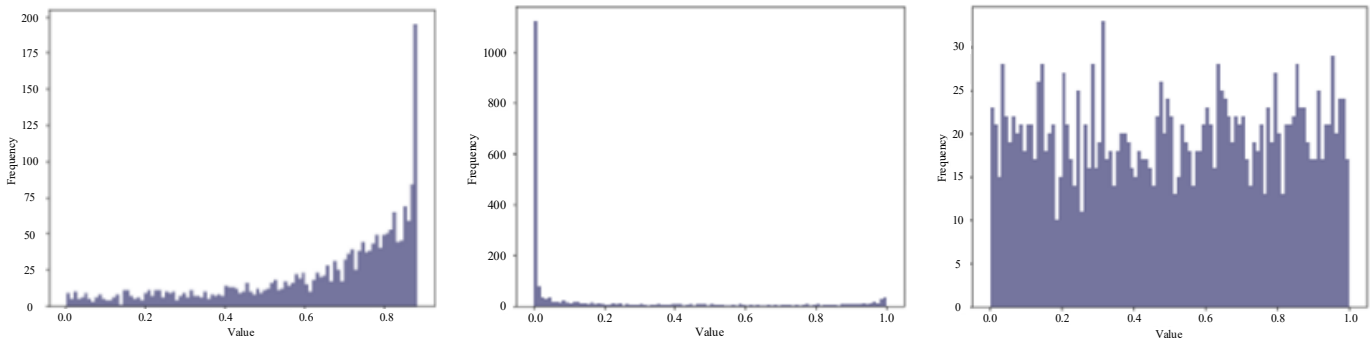

Fig. 8. Distribution curves of three chaotic maps.

The Singer chaotic map is capable of uniformly generating a relatively large number of high values, and its mapping formula is as follows:

$$x_{k+1}^{chaos} = 0.99(7.86_k^{chaos} - 23.32(x_k^{chaos})^2 + 28.75(x_k^{chaos})^3 - 13.302875(x_k^{chaos})^4) \quad (21)$$

The Gaussian chaos mapping can uniformly generate more small values; its mapping formula is:

$$x_{k+1}^{chaos} = \begin{cases} 1, x_k^{chaos} = 0 \\ \dfrac{1}{\mathrm{mod}(x_k^{chaos}, 1)}, x_k^{chaos} \neq 0 \end{cases} \quad (22)$$

The Tent Chaos Mapping can generate uniformly distributed hyperparameters; its mapping formula is:

$$x_{k+1}^{chaos} = \begin{cases} 2x_{k+1}^{chaos}, 0 \leq x_{k+1}^{chaos} \leq \dfrac{1}{2} \\ 2(1 - x_{k+1}^{chaos}), \dfrac{1}{2} \leq x_{k+1}^{chaos} \leq 1 \end{cases} \quad (23)$$

The distribution curves of the three mappings are illustrated in Fig. 8.

In this paper, mAP@0.5 is employed as the metric to evaluate the recognition performance of the model. Additionally, the number of model parameters is utilized as an indicator of model efficiency. To address the multi-objective optimization challenge of simultaneously enhancing recognition performance and reducing the number of model parameters, this paper transforms the problem into two independent single-objective optimization tasks for resolution. *Zoom(Parameters)* refers to the process of normalizing the model parameters into the [0, 1] interval based on established upper and lower bounds; these boundary values can be derived from the value ranges provided in Table I.

Furthermore, the number of additional modules in YOLOv9 also influences the total parameter count of the model. However, since the developers of YOLOv9 determined the quantity of these modules based on empirical knowledge, we did not optimize the BottleneckCSP modules, SPPCSPC modules, or other modules, except for those related to the number of convolutional channels.

2) Fitness function: The fitness function plays a crucial role in evaluating the quality of solutions and serves as the foundation of heuristic algorithms. For the hyperparameter optimization problem of EMA-YOLOv9, a fitness function as shown in (24) was constructed. This function consists of two components: recognition performance and model structural lightweighting.

$$Fitness = mAP_{0.5} - Zoom(Parameters) \quad (24)$$

We employ mAP0.5 as the metric for evaluating the recognition performance of the model. Additionally, the number of model parameters is utilized as a metric to measure model efficiency. To address the multi-objective optimization challenge of simultaneously improving recognition performance and reducing model parameters, this paper transforms it into two independent single-objective optimization problems for solution. Zoom (Parameters) refers to the process of normalizing model parameters to the [0, 1] interval based on established upper and lower bounds; these boundary values can be derived from the value ranges provided in Table I.

Furthermore, the number of additional modules in YOLOv9 also affects the total parameter count of the model. However, considering that the developers of YOLOv9 determined the quantity of these modules based on empirical knowledge, we did not optimize the BottleneckCSP modules, SPPCSPC modules, or other modules, with the exception of those related to the number of convolutional channels.

3) Update mechanism: The process of simulating convergence towards the current optimal flow may cause the algorithm to fall into local optima. Consequently, the Lévy Flight mechanism was introduced, as described in (8). Lévy Flight is characterized by a random walk that employs a heavy-tailed probability distribution for step sizes. This distribution grants a relatively high probability of occurring substantial steps during the random walk process.

Following the introduction of the Lévy Flight mechanism, the update formula for is reformulated as:

$$Flow_newX(i) = \begin{cases} Flow_X(i) + \overline{r_2} \times (Flow_X(r) - Flow_X(i)) \\ fitness(Flow_X(r)) < fitness(Flow_X(i)) \\ Flow_X(i) + r_{levy} \times (Best_X - Flow_X(i)) \\ otherwise \end{cases} \tag{25}$$

Where represents the Lévy random step size, which is calculated as follows:

$$r_{levy} = \frac{\mu_{levy}}{|v_{levy}|^{\frac{3}{2}}} \tag{26}$$

$$\mu_{levy} \sim N(0, \sigma^2). v_{levy} \sim N(0,1)$$

$$\sigma = \left[\frac{\Gamma(1+1.5)\sin(\frac{3\pi}{4})}{1.5\Gamma(\frac{1+1.5}{2})2^{\frac{0.5}{2}}} \right]^{\frac{3}{2}} \tag{27}$$

Fig. 9. Example image of the LWDCD2020 dataset.

V. Experiments

A. Experimental Details

In this experimental study, the Adam optimizer is utilized within the YOLOv9 model, with the number of training epochs set to 300. The default values for momentum, weight decay (WD), and EDR (Exponential Decay Rate) range from 0.8 to 0.99, while the warmup epochs ($epoch_{warmup}$) are maintained within 10.

B. Dataset and Evaluation Metrics

1) Dataset construction and preprocessing: To comprehensively evaluate the detection performance of the proposed improved algorithm under complex scenarios, the publicly available LWDCD2020 dataset is adopted as the primary experimental dataset (as shown in Fig. 9). This dataset contains three common wheat disease categories—crown and root rot, leaf rust, and loose smut—as well as a healthy class, comprising a total of 12,000 images. Notably, the LWDCD2020 dataset is collected from diverse sources, integrating both field-acquired images and web-crawled data. Consequently, the images exhibit substantial variability in illumination conditions, viewing angles, background complexity, and object scale, enabling effective coverage of a wide range of real-world agricultural scenarios. This diversity endows the dataset with high complexity and representativeness, making it well-suited for evaluating the robustness and generalization capability of detection algorithms. It is worth noting that approximately 20% of the images are obtained via web crawling, which inevitably introduces inconsistencies between images and their annotations. These issues mainly include non-authentic wheat images, mislabeled samples, and images irrelevant to wheat. To ensure data quality and the reliability of experimental results, a rigorous manual verification and cleaning process is conducted to remove contaminated samples, thereby establishing a reliable dataset for subsequent experiments.

Within the disease samples, wheat plants infected with crown and root rot typically exhibit progressive leaf yellowing followed by wilting, accompanied by browning at the stem base, with symptoms intensifying as the disease develops. In contrast, leaf rust is characterized by nearly circular orange-red lesions irregularly distributed on leaf surfaces; as the disease progresses, these lesions may penetrate the leaf tissue, while dark brown to black elliptical lesions appear on the abaxial side. For loose smut, infected wheat spikes are initially covered by a thin gray membrane, which eventually ruptures as the disease advances, releasing black مسحوق-like spores. Diseased spikes are noticeably shorter than healthy ones, and both the main stem and tillers may be affected. Based on these observations, each disease category exhibits distinctive visual characteristics, while significant inter-class differences are maintained. These properties provide effective discriminative cues for detection models and further demonstrate the practical value of applying object detection methods to such tasks.

To enhance experimental efficiency, a parameter parallel mechanism was introduced to accelerate the execution of the IFDA algorithm. This mechanism transforms the water flow population into Resilient Distributed Datasets adapted for the

Spark platform, thereby realizing the parallel computation of the fitness of each individual within the population. This method significantly improves the execution efficiency of the experiments, providing robust technical support for subsequent experimental verification [16].

2) Evaluation metrics: This experiment adopts common evaluation metrics in the field of object detection to quantify the model's performance, primarily including Precision (P), Recall (R), and mean Average Precision (mAP).

The calculation formulas for Precision (P) and Recall (R) are as follows:

$$P = \frac{TP}{TP + FP} \tag{28}$$

$$R = \frac{TP}{TP + FN} \tag{29}$$

Where TP (True Positive) represents the number of correctly detected positive samples, FP indicates the number of falsely detected negative samples, and FN denotes the number of missed positive samples.

To comprehensively evaluate the detection effectiveness, we employ mAP@0.5 and mAP@0.5:0.95 as the core metrics:

mAP@0.5: Represents the mean of the average precision across all categories when the Intersection over Union (IoU) threshold is set to 0.5.

mAP@0.5:0.95: Represents the mean of the average precision when the IoU threshold varies from 0.5 to 0.95 (with a step size of 0.05).

TABLE II. COMPARATIVE EXPERIMENT OF MULTIPLE HEURISTIC EMA-YOLOV9 HYPERPARAMETER OPTIMIZATION ALGORITHM

Algorithm	Best Fitness	Average Fitness	Fitness Standard Deviation	Ranking Based on Average Value
EGA	0.309	0.2824	0.0155	12
GWO	0.4509	0.4329	0.0117	3
MVO	0.4341	0.4130	0.0206	4
SSA	0.4242	0.4053	0.0216	7
SCA	0.4325	0.4122	0.0156	5
BBO	0.3809	0.3304	0.0425	11
JSO	0.4142	0.3940	0.0232	10
MBO	0.4365	0.4047	0.0211	8
BA	0.4251	0.4044	0.0146	9
CSO	0.4203	0.4070	0.0108	6
FDA	0.4574	0.4402	0.0132	2
IFDA	**0.46856**	**0.4486**	**0.0144**	**1**

The population size ($Size_{pop}$) for all heuristic algorithms is set to 20, and the maximum number of iterations ($MaxIter$) is also set to 20. The number of neighbors used in IFDA and FDA is specified as 8. The hyperparameters for the remaining optimization algorithms are all configured to their default settings. Each algorithm is run independently 5 times to calculate the statistics for its optimal value, mean, and standard deviation.

Based on the statistical data analysis in Table II, although all tested algorithms exhibit a certain degree of inherent randomness, and no significant statistical differences are observed in the overall randomness distribution, a horizontal comparison of the baseline algorithms reveals that the Genetic Algorithm (GA) has the relatively lowest optimization effectiveness, whereas the Flow Direction Algorithm (FDA) demonstrates the best comprehensive performance. This empirical result strongly supports the assertion that FDA is the most suitable baseline optimization algorithm for the current EMA-YOLOv9 parameter optimization task.

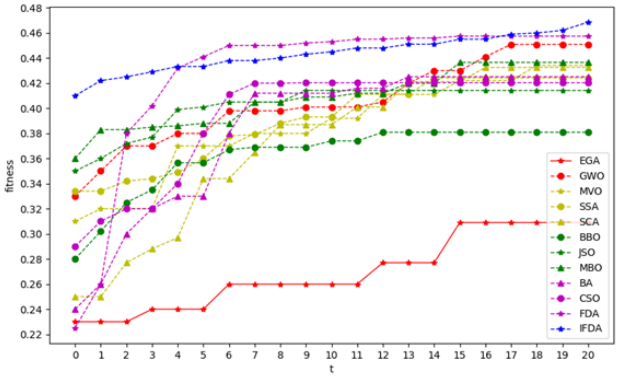

Fig. 10. Optimal fitness curve.

Fig. 10 illustrates the fitness convergence trajectories of the optimal results for each heuristic algorithm. It can be observed that the convergence curve representing IFDA exhibits a significant and steep upward trend during the initial iterations, indicating that, compared to other algorithms, IFDA possesses superior early convergence capability and optimization speed. This performance enhancement is primarily attributed to the improvement of the initialization solution strategy, which effectively elevates the quality of the initial population. Furthermore, the IFDA curve maintains a continuous upward trend in the later stages of iteration, indicating that the algorithm possesses a robust ability to escape local optima traps; the acquisition of this critical characteristic benefits from the introduction and optimization of the Lévy flight mechanism, thereby significantly enhancing the algorithm's global exploitation potential during the later stages of the search.

TABLE III. RESULTS OF ABLATION EXPERIMENT

Algorithm	Optimal fitness	Average adaptability	Accuracy	Recall rate	mAP_0.5
FDA	0.4574	0.4402	95.32	94.55	95.74
Initialization + FDA	0.4552	0.4427	95.10	94.33	95.52
Lévy flight mechanism + FDA	0.4662	0.4468	96.23	95.41	96.62
Initialization + Lévy flight mechanism + FDA	0.4686	0.4486	96.41	95.63	96.86

Specifically, after fine-tuning via the IFDA optimization strategy, the model achieved a significant increase of 5.09% in Precision, 5.11% in Recall, and 5.17% in mAP@0.5. These results fully substantiate the effectiveness of this optimization method in enhancing detection performance for complex object detection tasks.

C. Ablation Study

1) Ablation study of modules: To evaluate the effectiveness of the various improvement strategies within IFDA, an ablation study was conducted in this research. The YOLOv9 architecture and parameter settings remained consistent with those previously described, and the optimal parameters obtained through the optimization of each algorithm were utilized for training. The experimental results are presented in Table III: By combining the initialization strategy, the Lévy flight mechanism, and FDA, the model achieved the highest values in Precision, Recall, and mAP@0.5, confirming the effectiveness of the proposed improvements. Among them, the integration of Lévy flight significantly enhanced the performance of FDA, with the three metrics increasing by 0.95%, 0.91%, and 0.92%, respectively, compared to the original results; the overall performance improved by 0.13%, 0.13%, and 0.14%, respectively, compared to the original algorithm. Furthermore, the results of the ablation study regarding the various improvements of EMA-YOLOv9 are shown in Table IV.

TABLE IV. RESULTS OF ABLATION EXPERIMENT

YOLOv9	EMA	ResNet	IClou	**Accuracy %**	**Recall %**	**mAP_0.5 %**
√	×	×	×	90.80	90.05	90.77
√	√	×	×	91.21	90.26	91.48
√	×	√	×	90.92	90.11	91.29
√	×	×	√	90.98	90.16	91.33

The table systematically presents the performance of the YOLOv9-based object detection model under different strategy combinations, including the incorporation of EMA, ResNet backbone, and the ICIoU loss function, and their effects on Accuracy, Recall, and mAP\@0.5. The baseline YOLOv9 model achieves an Accuracy of 90.80%, Recall of 90.05%, and mAP of 90.77%. Incorporating EMA increases Accuracy to 91.21% and mAP to 91.48%, demonstrating its advantage in training stability and model generalization, with a limited improvement in Recall. Using the ResNet backbone alone results in an Accuracy of 90.92%, Recall of 90.11%, and mAP of 91.29%, indicating that enhanced feature extraction improves both localization and classification performance. Introducing only the ICIoU loss yields an Accuracy of 90.98%, Recall of 90.16%, and mAP of 91.33%, showing that the improved bounding box regression loss significantly optimizes detection precision. When all three strategies are applied simultaneously, the model achieves its highest performance with an Accuracy of 91.74%, Recall of 90.98%, and mAP of 92.09%, indicating a synergistic effect of feature enhancement, training stabilization, and bounding box optimization, thereby achieving overall optimal performance in both classification accuracy and object detection precision and validating the effectiveness of these strategies in enhancing YOLOv9.

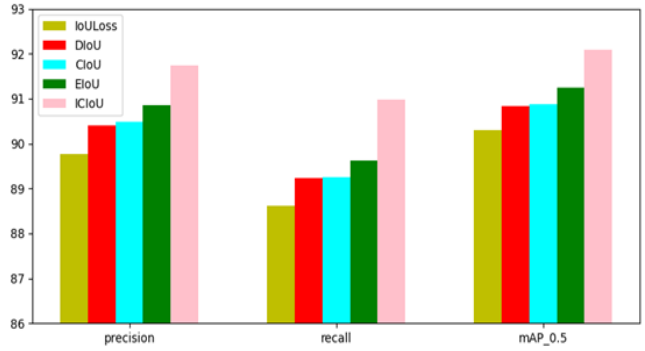

Fig. 11. Comparison of loss function experimental results.

2) Ablation study of loss functions: To verify the effectiveness of the proposed ICIoU loss function in the task of wheat disease and pest identification, we conducted a series of detailed comparative experiments between ICIoU and several other loss functions, including IoU loss, DIoU loss [17], CIoU loss, and EIoU loss [12]. The relevant experimental results are illustrated in Fig. 11. Compared to the baseline IoU loss function, the adoption of the ICIoU loss function improved the model's Precision, Recall, and mAP@0.5 by 2.19%, 2.66%, and 1.99%, respectively. Furthermore, compared to the CIoU loss function, the ICIoU loss function achieved gains of 1.39%, 1.94%, and 1.34% in Precision, Recall, and mAP@0.5, respectively.

Given the No Free Lunch theorem of stochastic optimization, it is impossible to directly determine a specific algorithm universally suited for the hyperparameter optimization of EMA-YOLOv9 [18]. Therefore, this paper compares the proposed IFDA with other heuristic algorithms to validate the advantages of FDA and IFDA in solving the hyperparameter optimization problem for EMA-YOLOv9, as shown in Table V. The heuristic algorithms included in this experiment are: Genetic Algorithm (GA), Grey Wolf Optimizer (GWO) [19], Multi-Verse Optimizer (MVO) [20], Salp Swarm Algorithm (SSA) [21], Sine Cosine Algorithm (SCA) [22], Biogeography-Based Optimization (BBO) [23], Jellyfish Search Optimizer (JSO) [24], Monarch Butterfly Optimization (MBO) [25], Bat Algorithm (BA) [26], and Cockroach Swarm Optimization (CSO) [27].

TABLE V. COMPARATIVE EXPERIMENTAL RESULTS

Method	**Precision %**	**Recall %**	**mAP_0.5 %**
Faster R-CNN[28]	86.73	86.79	87.60
YOLOv5+attention[29]	88.32	87.90	88.73

YOLOv8+ ShuffleNetV2+Senet[31]	88.90	81.40	88.20
GA-YOLOv5[7]	90.09	89.52	90.43
ABC-YOLOv5[9]	90.29	89.81	90.79
Ours	**96.41**	**95.63**	**96.86**

D. Comparison with SOTA Methods

To verify the advancement of IFDA-EMA-YOLOv9, we compared it with six State-of-the-Art (SOTA) methods. The experimental results are presented in *V*. The selected baseline models are as follows:

Faster R-CNN: Utilizes Faster R-CNN to detect wheat diseases and pests.

YOLOv5+attention: Optimizes YOLOv5 using an improved attention sub-module, and combines BiFPN with fast normalization fusion to weight the fused features.

YOLOv8s+EIOU: Improves YOLOv8s by employing efficient RepGFPN feature fusion and the EIoU loss function.

YOLOv8+ShuffleNet V2+Senet: Employs the lightweight convolutional neural network ShuffleNet V2 as the backbone network of YOLOv8, improving it by adding a small object detection layer and the Senet attention mechanism.

GA-YOLOv5: Represents the optimization of YOLOv5 hyperparameters using its built-in Genetic Algorithm (GA).

ABC-YOLOv5: Represents the optimization of YOLOv5 hyperparameters using the Artificial Bee Colony (ABC) algorithm.

The proposed method demonstrates superior performance compared to GA-YOLOv5 and ABC-YOLOv5, thereby establishing the significant advantages of the IFDA method over traditional optimization algorithms such as the Genetic Algorithm (GA) and Artificial Bee Colony (ABC). Specifically, on the publicly available LWDCD2020 dataset, compared to the best existing method excluding EMA-YOLOv9, the proposed method increases Precision by 6.4% and Recall by 5.94%. Furthermore, the core metric mAP@0.5 is improved by 6.66%. These results indicate that the methodology proposed in this paper has achieved significant progress in related fields. Fig. 12 illustrates the visualized detection results of IFDA-EMA-YOLOv9 across various categories of samples.

VI. Conclusion

This paper proposes a wheat disease detection method based on the improved EMA-YOLOv9 and IFDA. This method integrates multi-scale attention and residual connections to enhance feature extraction, introduces an auxiliary box to optimize localization accuracy, and utilizes the IFDA algorithm—which combines chaotic maps and Lévy flight—to achieve adaptive hyperparameter optimization. Experiments demonstrate that, on the LWDCD2020 dataset, the proposed method improves Precision, Recall, and mAP@0.5 by 6.4%, 5.94%, and 6.66%, respectively, compared to SOTA methods. Additionally, under the experimental environment considered in this study, IFDA-EMA-YOLOv9 achieves a detection frame rate (FPS) of approximately 29.8, which is sufficient to meet the requirements of wheat disease detection tasks. Future work will focus on model lightweighting, exploring its real-time deployment on mobile devices, and its generalized application across multiple scenarios.

***Abstract*—Multi-hop LoRa networks extend coverage for large-scale Internet of Things deployments but are severely limited by interference-induced collisions, retransmissions, and rapid battery depletion of relay nodes. Conventional routing strategies that minimize hop count or rely on static heuristics fail to account for dynamic medium contention and its impact on energy consumption and reliability. This paper proposes a Proximal Policy Optimization (PPO)–based routing framework for multi-hop LoRa networks that learns interference-aware and energy-efficient routing policies through reinforcement learning. A discrete-event simulation framework is developed to model LoRa physical-layer behaviour, co-spreading-factor interference, adaptive data rate control, and battery-limited relay nodes under multi-source traffic. The routing problem is formulated as a Markov Decision Process (MDP) in which the PPO agent selects next-hop relays based on local topology, relay load, and channel occupancy, while physical-layer parameters are adapted independently using a standards-inspired physical-layer parameters are adapted independently using a standards-inspired ADR mechanism (ADR) mechanism. Simulation results show that the proposed approach achieves a packet delivery ratio of up to 73.7%, reduces collision rates by approximately 46% compared with Random routing, and lowers the average energy consumption per delivered packet to about 206 mJ, outperforming Shortest Path and Ad hoc On-Demand Distance Vector (AODV)-like routing. These gains are achieved by learning spatially diverse routing paths that mitigate relay congestion and reduce collision-induced retransmissions.**

I. Introduction

The rapid growth of Internet of Things (IoT) [1] applications in smart agriculture, environmental monitoring, and industrial automation has accelerated the adoption of Low Power Wide Area Networks (LPWANs) as a cost-effective solution for long-range, energy-constrained wireless connectivity [2]. Among LPWAN technologies, Long Range (LoRa) has emerged as a particularly attractive option due to its ability to provide kilometer-scale coverage while enabling multi-year battery operation [3]. However, the star topology employed in Long Range Wide Area Network (LoRaWAN), where end devices communicate directly with a gateway, becomes ineffective in scenarios where distance, terrain, or urban obstructions prevent reliable direct links, as empirically demonstrated in forested and vegetated deployments [4], [5], [6]. To overcome this limitation, multi-hop LoRa networks introduce relay-assisted communication, extending coverage while preserving LoRa's low-power characteristics [7].

Despite their potential, multi-hop LoRa networks face significant routing challenges under multi-source traffic. Unlike traditional wireless sensor networks with centralized scheduling or orthogonal channel access, LoRa operates under pure Additive Links On-line Hawaii Area (ALOHA) and strict duty-cycle constraints [8], limiting coordination. When multiple sources independently select relays based on local metrics such as distance or link quality, traffic converges on a small subset of relays, creating persistent collision hotspots. These collisions increase retransmission, waste energy through long transmissions, and accelerate relay battery depletion. Although Adaptive Data Rate (ADR) improves link robustness, it does not mitigate contention among competing sources, leaving collision-aware routing an open challenge.

Existing routing approaches for multi-hop LoRa [9] networks fall into three broad categories. Distance-based heuristics, such as shortest path routing, offer simplicity but suffer from severe load imbalance and collision concentration. Adaptive protocols inspired by Ad hoc On-Demand Distance Vector (AODV) incorporate energy or load-aware metrics to improve fairness yet still rely on static decision rules that are insufficient under dynamic multi-source contention. More recent studies have applied reinforcement learning to LoRa networks, primarily focusing on physical-layer parameter optimization such as spreading factor selection [10]. While effective at the link level, these approaches do not address network-layer routing coordination across competing sources, leading to suboptimal performance in multi-hop scenarios.

Energy efficiency is a central concern in this context, as relay nodes are typically battery-powered and must forward traffic from multiple sources [11]. In interference-limited LoRa networks, energy consumption is dominated not by hop count

*Corresponding author.

alone but by collision-induced retransmissions and the use of high spreading factors on congested links. Consequently, routing strategies that ignore multi-source interaction often incur excessive energy expenditure and uneven battery depletion, directly reducing network lifetime [12]. The fundamental challenge is therefore to design routing mechanisms that jointly improve packet delivery reliability, minimize energy consumption, and balance relay utilization under dynamic traffic and interference conditions.

Recent advances in deep reinforcement learning [13] have shown strong potential for addressing such multi-objective optimization problems in complex networked systems. Proximal Policy Optimization (PPO) offers stable and sample-efficient policy learning in non-stationary environments, making it well suited for multi-source routing scenarios where traffic patterns and interference evolve over time [14]. When provided with appropriate observability into relay utilization and channel conditions, PPO can learn adaptive routing behaviors without requiring explicit coordination or message exchange between sources.

Motivated by this observation, this paper proposes a PPO-based routing framework for multi-hop LoRa networks that explicitly accounts for multi-source interaction. By augmenting the routing state representation with features capturing relay usage frequency and temporal recency, the proposed approach enables implicit coordination among sources, allowing routing decisions to proactively avoid congested relays. Physical-layer parameters are adapted independently using a standards-inspired ADR mechanism [15], ensuring a clear separation between routing optimization and link-level adaptation.

The main contributions of this work can be summarized as follows:

- Multi-source–aware state features are introduced to enable routing agents to detect and avoid relays that are currently utilized by competing sources, thereby reducing collision probability without incurring explicit coordination overhead.
- An energy and reliability-aware reward function is designed to balance packet delivery, energy consumption, and collision avoidance in battery-limited relay networks.
- A curriculum-based PPO training strategy is developed to accelerate convergence toward collision-aware routing policies.
- Finally, through comprehensive simulation-based evaluation, it is demonstrated that the proposed framework achieves improved packet delivery reliability, reduced collision rates, and enhanced energy efficiency compared with conventional routing approaches, while exhibiting emergent spatial path separation that mitigates relay energy hotspots.

The remainder of this paper is organized as follows. Section II reviews related work on multi-hop LoRa routing and reinforcement learning for wireless networks. Section III presents the system model, including network architecture, collision dynamics, and energy consumption. Section IV details the proposed PPO-based routing framework. Section V discusses performance evaluation and key insights. Finally, conclusions are drawn in Section VI.

II. Related Work

LPWAN [16] technologies were developed to provide long-range connectivity under stringent energy constraints, making them suitable for large-scale IoT deployments [17] where frequent battery replacement is infeasible. Comparative surveys position LoRa/LoRaWAN among the most widely adopted LPWAN options because it provides kilometers-scale coverage with low device complexity and low power operation, albeit with trade-offs in capacity and interference robustness under ALOHA-like access. In practical deployments, coverage and reliability are highly scenario-dependent (terrain, foliage, obstacles, antenna height), motivating designs that go beyond conventional single-hop LoRaWAN star topologies when direct gateway connectivity is unreliable.

A major limitation of LoRa networks especially under multi-node contention is that performance can degrade rapidly due to collisions, imperfect orthogonality among spreading factors, and capture effects [18]. Early experimental and analytical studies show that "scaling" LoRa is non-trivial because concurrent transmissions can interfere even when nominally using different Spreading Factor (SF), while co-SF collisions depend on relative received powers and overlap in time [19]. Complementary simulation-based investigations further quantify how packet delivery probability is impacted by offered load, SF distribution, and channel contention, reinforcing that interference modelling choices (co-SF and inter-SF rejection assumptions, capture threshold, traffic model) materially affect energy and reliability conclusions.

In multi-hop settings, these issues can be amplified: relays introduce additional transmissions (hence additional channel occupancy), and traffic tends to concentrate around a subset of "good" relays (those that make strong progress toward the gateway), increasing the probability of repeated collisions and retransmission-driven energy waste [20]. This motivates routing policies that are explicitly collision-aware and load-aware rather than purely distance-optimal. LoRaWAN's ADR [21] is a standardized mechanism designed primarily for star topologies: the network server adjusts SF and transmits power using link-quality statistics (commonly using margin-based logic over recent Signal-to-Noise Ratio (SNR) / Received Signal Strength Indicator (RSSI) history) [22]. ADR is widely used because reducing SF and/or transmit power can substantially reduce time-on-air and energy per message when link margin is high, while increasing SF/power improves robustness when the link is marginal.

However, ADR alone does not resolve contention externalities: even when each node's physical settings are individually reasonable, collisions can still dominate under shared-medium access particularly when multiple nodes select similar SFs and transmit times. Thus, while ADR addresses the "link adaptation" dimension, it typically does not optimize network-layer forwarding decisions or coordinate multi-source relay usage in multi-hop mesh behaviours [23].

Multi-hop and mesh extensions [24] for LoRa have been explored to address coverage holes and obstacles, proposing lightweight routing protocols (often distance-vector-like, flooding-assisted discovery, or heuristic metrics such as hop count, link quality, or airtime cost). A recent comprehensive survey consolidates these directions, highlighting that many LoRa mesh proposals prioritize simplicity and feasibility over strong optimality guarantees, and often assume limited coordination under duty-cycle constraints. Empirical protocol studies also demonstrate that practical mesh routing must manage not only reachability and hop efficiency but also traffic concentration and fairness, because a small number of relays can become persistent bottlenecks [25].

Importantly, classical ad hoc routing protocols such as AODV were developed for higher-rate radios and different interference regimes, relying on route discovery and maintenance logic that may not directly translate to LoRa's long airtime, low duty cycle, and collision-dominated shared channel. Nevertheless, AODV remains a common baseline because it captures the value of adaptive path selection versus static shortest-path heuristics. Learning-based methods have been applied primarily to LoRaWAN parameter adaptation (e.g., selecting SF / Transmission Power (TP) / channel assignments to improve energy efficiency and reliability). Recent Deep Reinforcement Learning (DRL) work shows that intelligent control can outperform fixed heuristics in dynamic environments, especially when objective functions include energy and performance constraints [26]. In parallel, PPO is widely recognized as a stable policy-gradient algorithm for complex decision-making problems, due to its clipped surrogate objective that reduce destructive policy updates [27].

Despite this progress, most learning-driven LoRa papers focus on star topologies and Physical Layer (PHY) parameter selection rather than joint routing/forwarding under multi-hop mesh contention [28]. In a multi-source, battery-limited relay mesh, the key difficulty is not only choosing energy-efficient PHY settings but also preventing multiple sources from repeatedly converging on the same high-quality relay-creating collision hotspots and unfair battery depletion. Across the above literature, a consistent gap is the lack of explicit multi-source awareness in routing decisions for multi-hop LoRa meshes [29]. Existing mesh routing protocols and classical baselines typically optimize progress metrics (distance/hops/link quality) but do not directly encode "competition" from other sources (who is using which relays and how recently), even though that competition is the driver of collision synchronization and relay hotspot depletion in shared-medium LoRa. At the same time, ADR-based PHY adaptation optimizes link margin but does not solve contention-driven losses or relay fairness.

From the above, a clear gap emerges where LoRa scalability or interference studies characterize collision behaviour and airtime-driven limitations but do not provide a network-layer mechanism for multi-source relay competition in battery-limited multi-hop settings. Multi-hop LoRa routing protocols propose metrics such as Time on Air (ToA)-aware distance-vector routing and cross-layer scheduling but typically lack explicit multi-source awareness signals that help avoid relay hotspots formed by concurrent sources selecting the same "best" relays.

III. Methodology

A. Network Architecture

The considered multi-hop LoRa network is represented as a directed graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$, where the node set $\mathcal{V}$ comprises source nodes, battery-powered relay nodes, and a gateway acting as the final data sink. A directed link $(i, j) \in \mathcal{E}$ exists if node j lies within the communication range of node i. Each source periodically generates uplink packets that must be forwarded through one or more relay hops to reach the gateway. Relay nodes operate in a store-and-forward manner and are constrained by finite energy budgets, while the gateway is assumed to have unlimited energy resources. The network topology remains static during each simulation run, whereas wireless channel conditions, interference patterns, and medium access timing evolve dynamically. LoRa Mesh Network Topology is shown in Fig. 1.

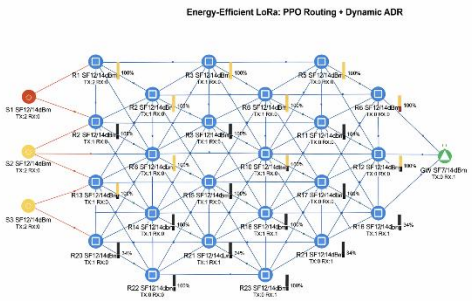

Fig. 1. LoRa Mesh Network Topology

B. Energy Consumption Model

The energy consumption of each relay node is determined by the power used for transmission and the corresponding LoRa time-on-air. Specifically, the energy consumed for transmission from node i to node j is expressed as

$$E_{i,j}^{\text{tx}} = I_{\text{tx}}(P_i^{\text{tx}})\, V\, T_{\text{air}} \tag{1}$$

where $P_{i,j}^{\text{tx}}$ denotes the transmit power selected for the link and $T_{\text{air}}(SF_{i,j})$ represents the airtime associated with the selected spreading factor. The airtime consists of preamble and payload components and increases exponentially with the spreading factor due to the reduced bit rate. Consequently, higher spreading factors result in significantly longer transmission durations and increased energy expenditure. Each relay node maintains a residual energy state that is updated after every transmission according to:

$$E_i^{\text{res}}(t+1) = E_i^{\text{res}}(t) - \sum E_{i,j}^{\text{tx}} \tag{2}$$

Equation (2) updates the residual energy of relay i after time step t by subtracting the total transmission energy spent on all forwarding events executed by that relay during the step. Here, $E_i^{\text{res}}(t)$ denotes the remaining battery energy at time t, and $E_{i,j}^{\text{tx}}$ represents the energy consumed when node i transmits a packet to next hop j. In our simulator, $E_{i,j}^{\text{tx}}$ is computed from the radio's current draw at the selected transmit power and the packet time-on-air, i.e., $E_{i,j}^{\text{tx}} = I_{\text{tx}}(P_{\text{tx}})\, V\, T_{\text{OA}}$, ensuring that higher spreading factors or power levels incur higher energy.

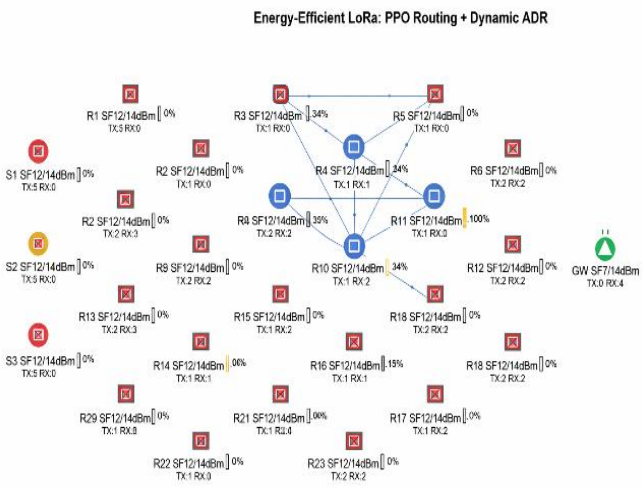

Fig. 2. Battery depletion.

Costs through longer airtime and larger current consumption. Once $E_i^{\text{res}}(t) \le 0$, relay i is treated as depleted (dead) and is removed from candidate next-hop sets, which can force route reconfiguration and directly impacts network lifetime. Fig.2 shows the Battery depletion.

C. Signal Propagation Model

Wireless signal propagation is modelled using a forest path-loss [30] formulation augmented with log-normal shadow fading to capture the effects of vegetation and terrain irregularities. To capture realistic rural/forested deployments, the wireless channel is modelled using a log-distance path-loss formulation with an additional vegetation attenuation term and log-normal shadow fading, consistent with empirical LoRaWAN path-loss characterizations in forested and vegetated environments reported in [5], [6], [31], [32]. The vegetation attenuation term κd represents the specific attenuation through foliage as standardized in ITU-R Recommendation P.833-10 [33]. For a transmitter–receiver separation distance $d_{i,j}$ (in meters), the path loss is expressed as:

$$PL(d) = PL(1\text{ m}) + 10n\log_{10}(d) + \kappa d + X_\sigma \quad (3)$$

where $PL(1\text{ m})$ denotes the free-space path loss at 1 meter, n is the path-loss exponent, κ is a vegetation attenuation coefficient (in dB/m), and $X_\sigma \sim \mathcal{N}(0,\sigma^2)$models log-normal shadow fading. In our implementation, $PL(1\text{ m})$ is obtained from the standard free-space expression at carrier frequency f,

$$RSSI_{i,j} = P_i^{\text{tx}} + G_t + G_r - PL(d_{i,j}) \quad (4)$$

where P_i^{tx} is the transmit power (dBm) and G_t and G_r are antenna gains (dBi). This formulation directly matches the simulator's computation $RSSI = P^{tx} + 2G - PL$.

$$SNR_{i,j} = RSSI_{i,j} - N_0 \quad (5)$$

$$N_0 = -174 + 10\log_{10}(BW) + NF \quad (6)$$

with N_0 denoting the noise floor. Successful packet reception requires both the RSSI and SNR to exceed the minimum demodulation thresholds determined by the selected spreading factor [34]. If either condition is violated, the packet is considered lost due to weak signal conditions [35].Demodulation Criteria in Table I

TABLE I. DEMODULATION CRITERIA

SF	Receiver Sensitivity Threshold (dBm)	Min SNR (dB)
7	-123	-7.5
8	-126	-10
9	-129	-12.5
10	-132	-15
11	-134.5	-17.5
12	-137	-20

Transmission duration is modeled using the LoRa time-on-air expression, which directly influences both channel occupancy (collision probability) and energy consumption. The symbol duration is

$$T_{\text{sym}} = \frac{2^{SF}}{BW} \quad (7)$$

$$T_{\text{preamble}} = (N_{\text{preamble}} + 4.25)T_{\text{sym}} \quad (8)$$

$$Tpayload = Npayload_symb \cdot Tsym \quad (9)$$

$$N_{\text{payload}} = 8 + \max\left(\left\lceil \frac{8PL - 4SF + 28 + 16CRC - 20IH}{4(SF - 2DE)} \right\rceil (CR + 4), 0\right) \quad (10)$$

where N_{preamble} is the programmed preamble length. The payload duration depends on the number of payload symbols N_{payload} and is payload length (bytes), $CRC \in 0,1$ indicates CRC enablement, $IH \in 0,1$ indicates implicit header mode, and $DE \in 0,1$ is the low-data-rate optimization flag (typically enabled for $SF \ge 11$). This expression is consistent with the simulator's airtime computation used for every transmission event.

D. Co-SF interference & Collision Decision

Collisions [36] are modeled using co-spreading-factor overlaps, consistent with the simulator's event-based tracking of concurrent transmissions at each SF. During the reception of packet p transmitted from node i to node j, the set of overlapping interferers using the same SF is denoted $\mathcal{J}_j^{(SF)}$. Interferer received powers are accumulated in the linear domain:

$$P_{k,j}^{(\text{lin})} = 10^{\frac{RSSI_{k,j}}{10}} \quad (11)$$

where $RSSI_{k,j}$ is expressed in dBm. The aggregate interference power at node j is then obtained by summing the linear powers of all interfering transmitters,

$$I_j = \sum_{k \in \mathcal{J}_j^{(SF)} \setminus i} P_{k,j}^{(\text{lin})} \quad (12)$$

The signal-to-interference ratio at the receiver is computed as:

$$SIR_{i,j} = 10\log_{10}\left(\frac{10^{RSSI_{i,j}/10}}{I_j + \epsilon}\right) \quad (13)$$

where ϵ is a small constant introduced to avoid numerical instability when no concurrent interferers are present. A packet

collision is declared when the computed Signal-to-Interference Ratio (SIR) falls below a predefined capture threshold γ_{th}

$$\text{Collision occurs if } SIR_{i,j} < \gamma_{\text{th}} \quad (14)$$

In this study, a conservative capture threshold is employed, reflecting the imperfect orthogonality of LoRa spreading factors under real-world synchronization and fading conditions. When a collision occurs, the packet is considered lost and removed from the reception buffer, triggering retransmission attempts and additional energy consumption. This collision model directly links medium access contention, routing decisions, and physical-layer parameter selection, thereby allowing the reinforcement learning agent to implicitly learn collision-aware routing behavior.

E. Dynamic Adaptive Data Rate (ADR) Mechanism

To adapt physical-layer parameters in response to time-varying channel conditions, a Dynamic ADR mechanism is employed for all routing schemes [37]. ADR operates independently of the routing algorithm and is applied uniformly to ensure a fair comparison between PPO-based routing and baseline methods. For each transmitter–receiver link (i, j), the ADR controller maintains a sliding window of recent received signal strength and signal-to-noise ratio measurements. Let $\mathcal{H}_{i,j} = \{SNR_k\}_{k=1}^{W}$ denote the most recent W SNR observations collected at the receiver. The average link margin is computed as:

$$M_{i,j} = \text{SNR}_{i,j} - \text{SNR}_{min}(\text{SF}) \quad (16)$$

where $\bar{SNR}_{i,j}$ is the mean SNR over the observation window and $SNR_{\min}(SF)$ is the minimum demodulation threshold for the currently selected spreading factor. When the link margin exceeds a predefined upper threshold, the ADR controller attempts to reduce energy consumption by decreasing the spreading factor or transmit power, prioritizing spreading factor reduction due to its exponential impact on time-on-air. Conversely, when the margin falls below a lower threshold, the controller increases the spreading factor or transmits power to restore link reliability. If neither adjustment is feasible due to parameter bounds, the current configuration is retained. This adaptive process balances robustness and energy efficiency while avoiding excessive packet loss. ADR updates are performed periodically and only after sufficient measurement samples are available, preventing unstable oscillations in parameter selection.

IV. Proposed Learning Model

A. Problem Formulation

Routing in a multi-hop LoRa mesh network is inherently sequential and stochastic due to time-varying interference, shared medium access, and battery depletion of relay nodes. At each forwarding step, a relay must select a next-hop neighbor without full knowledge of future channel conditions or competing transmissions from other sources. This makes classical shortest-path or greedy routing suboptimal in the presence of contention and energy imbalance. To address this challenge, the routing problem is formulated as a Markov Decision Process (MDP) [38], enabling the use of reinforcement learning to derive an adaptive routing policy. The MDP is defined by the tuple (S, A, P, R, γ) where $\mathcal{S}$ is the state space, $\mathcal{A}$ is the action space, $\mathcal{P}$ denotes the state transition dynamics, $\mathcal{R}$ is the reward function, and $\gamma \in (0,1]$ is the discount factor. The objective is to learn a routing policy $\pi_\theta(a \mid s)$, parameterized by θ, that maximizes the expected cumulative discounted reward over an episode, corresponding to energy-efficient and reliable end-to-end packet delivery.

1) State space design. The state observed by the PPO agent encodes both topological progress and medium access conditions relevant to routing decisions [39]. For each forwarding node, a fixed-length state vector is constructed by

aggregating features associated with up to K candidate next-hop relays. In this study, K = 10 is used to bound the action space. Let $\mathbf{s}_t \in \mathbb{R}^{16K}$ denote the state at decision step t. For each candidate relay k, the following normalized features are included: relative distance to the gateway, hop distance from the current node, normalized progress toward the gateway, residual energy ratio, historical load ratio, averaged RSSI and SNR statistics, channel occupancy at the candidate's spreading factor, node-level and link-level collision rates, local traffic density, spreading-factor congestion, transmission recency, and relay load indicators. To explicitly address multi-source contention, two additional features are incorporated: the number of other sources recently using the same relay and the recency of such usage. The state vector is expressed as

$$st = [f1, t, f2, t, \dots, fK, t], fk, t \in R16 \quad (17)$$

where zero-padding is applied when fewer than K candidates are available. This formulation ensures a fixed-dimensional input suitable for neural network training while preserving local routing context and contention awareness.

2) Action space & feasibility Masking. The action space corresponds to the selection of the next-hop relay among the candidate neighbors [40]. At each decision step t, the agent selects an action

$$at \in 1, 2, \dots, K, \quad (18)$$

where each index corresponds to a specific candidate relay in the ordered neighbor list. Actions associated with invalid or non-existent candidates are masked during policy evaluation to prevent infeasible selections. Importantly, the PPO agent optimizes routing decisions only; physical-layer parameters such as spreading factors and transmit power are adapted independently by the ADR controller.

The reward function is designed to jointly incentivize reliable packet delivery, energy efficiency, collision avoidance, and load balancing across relay nodes [41]. Let r_t denote the reward assigned after an episode completes. A large positive reward is granted when a packet is successfully delivered to the gateway, scaled by the current packet delivery ratio to encourage global reliability. Conversely, strong penalties are imposed for packet loss due to collisions or weak signal conditions, reflecting the high energy cost of retransmissions. Energy efficiency is explicitly encouraged by penalizing excessive transmission energy, while hop-count penalties discourage unnecessarily long routes. To mitigate relay hotspots and promote fairness, additional penalties are applied when routing paths overlap significantly with those of other concurrent sources or when relay load imbalance is detected. Formally, the reward can be expressed as:

$$r = R_s ucc - \alpha E - \beta H - \delta O, if delivered$$
$$r = -R_f ail - \alpha E - \beta H, otherwise \quad (19)$$

Here, $R_s ucc$, and $R_f ail$ are positive constants rewarding successful delivery and penalizing packet failure, respectively. The coefficients α, β, and δ control the relative importance of energy consumption, hop count, and path overlap. By penalizing overlapping relay usage, the reward function discourages routing decisions that create relay hotspots and persistent collisions. This formulation enables the agent to learn routing strategies that trade minimal hop count for reduced contention and energy waste when necessary.

B. Proximal Policy Optimization (PPO) Architecture

The routing policy is optimized using PPO [42], which improves training stability by constraining policy updates. PPO maximizes a clipped surrogate objective defined as

$$L^{PPO}(\theta) = E_t[\min(r_t(\theta) A_t, \text{clip}(r_t(\theta), 1-\epsilon, 1+\epsilon) A_t)] \quad (20)$$

where,

$$r_t(\theta) = \frac{\pi_\theta(a_t \mid s_t)}{\pi_{\theta_{old}}(a_t \mid s_t)} \quad (21)$$

is the probability ratio between the current and previous policies, $\hat{A}_t$ is the estimated advantage function, and ϵ is a clipping parameter that limits the magnitude of policy updates.

This clipped formulation prevents excessively large policy updates that could otherwise destabilize the learning process, particularly in stochastic and highly constrained environments such as multi-hop LoRa networks. By bounding the probability ratio $r_t(\theta)$ within the interval $[1-\epsilon, 1+\epsilon]$, PPO ensures that newly updated policies do not deviate significantly from the previously deployed policy, thereby preserving stable and incremental policy improvement. This property is especially important in routing optimization, where abrupt changes in forwarding decisions may lead to sudden congestion, increased collision rates, or uneven energy depletion among relay nodes. Fig 3 PPO architecture.

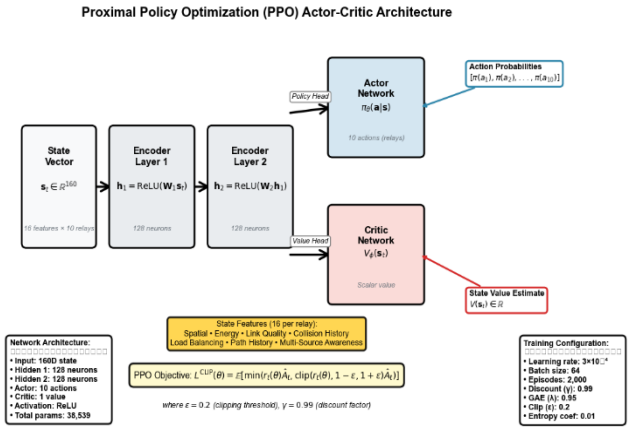

Fig. 3. Proximal Policy Optimization (PPO) architecture.

C. Training Procedure

Training is conducted over multiple episodes, each consisting of concurrent packet transmissions from multiple source nodes. During training, stochastic action sampling is employed to promote exploration, while temperature scaling is used to avoid premature convergence. Experience tuples (s_t, a_t, r_t, s_{t+1}) are collected across episodes and used to update the policy and value networks in mini batches. To reduce synchronization-induced collisions and encourage path diversity during early learning, guided exploration is applied in initial training phases. As training progresses, the agent gradually transitions to fully autonomous decision-making based on learned policies.

By formulating multi-hop LoRa routing as a reinforcement learning problem and incorporating collision-aware state features and energy-sensitive rewards, the proposed PPO-based framework learns routing policies that mitigate relay hotspots, reduce collision-induced retransmissions, and improve the overall energy–reliability trade-off.

D. Simulation Setup & Configuration

This work is simulation-based rather than hardware-deployed a deliberate methodological choice given that deploying a 27-node multi-hop LoRa mesh (3 sources, 23 relays with 90000mJ battery in a 100 m hexagonal grid, 1 gateway) across a 1.9 km × 1.1 km forested area with a maximum link range of 300 m and a source-to-gateway distance of 1,100 m for controlled, repeatable experiments is logistically and financially impractical within a single study. Simulation allows systematic isolation of individual variables (SF assignment, relay energy, channel occupancy, multi-source contention) under conditions grounded in empirically validated forest propagation parameters. All experiments are implemented in Python 3.11 using PyTorch for the PPO agent, LoRaSim for discrete-event network dynamics, SimPy for real-time scheduling, and NumPy/Pandas for data processing (Table II).

Total Training Episodes	2000
Discount Factor, γ	0.99
Clip Epsilon, ε	0.2

E. Baseline Routing Methods

To objectively evaluate the effectiveness of the proposed PPO-based routing framework, its performance is compared against three conventional routing strategies: Shortest Path routing, Random routing, and an AODV-like routing method. These baselines are selected to represent commonly used heuristic, stochastic, and protocol-inspired approaches in multi-hop wireless networks.

1) Shortest Path Routing selects the next-hop relay that minimizes the Euclidean distance to the gateway [43]. At each forwarding decision, the relay j^* is chosen such that

$$j^* = \arg\min_{j \in \mathcal{N}_i} d(j, \text{GW}) \quad (22)$$

where $\mathcal{N}_i$ denotes the set of candidates neighboring relays of node i, and $d(j, \text{GW})$ is the Euclidean distance between relay j and the gateway. This strategy minimizes hop distance toward the destination but does not consider relay energy, traffic load, or channel interference. As a result, it often concentrates traffic on a small subset of relays, leading to energy hotspots and increased collision probability.

2) Random Routing selects the next-hop relay uniformly at random from the set of reachable neighboring relays [44]. If N candidate relays are available, the selection probability for each relay j is given by

$$P(j) = \frac{1}{|\mathcal{N}_i|} \quad (23)$$

where $|\mathcal{N}_i|$ is the number of available candidate relays. This baseline does not exploit any network state information and serves as a lower-bound reference for routing performance. While Random routing can occasionally provide path diversity, it generally leads to inefficient routing paths, excessive hop counts, and elevated energy consumption.

3) AODV-like Routing is inspired by the AODV protocol [45] and selects the next-hop relay based on a composite routing metric that accounts for distance to the gateway, residual energy, and relay load. For each candidate relay j, a routing cost function is defined as

$$C(j) = \alpha\ d(j, \mathrm{GW}) + \beta\left(1 - \frac{E_j}{E_{max}}\right) + \gamma\, L_j \qquad (24)$$

where E_j denotes the residual energy of relay j, E_{max} is the initial battery capacity, and L_j represents the relay load, modeled as the ratio of forwarded packets to received packets. The weighting coefficients $\alpha, \beta,$ and γ balance progress toward the gateway, energy awareness, and load distribution, respectively. The relay with the minimum cost $C(j)$ is selected as the next hop. Although the AODV-like method introduces energy and load awareness, it relies on static weighting factors and lacks adaptability to dynamic interference and collision conditions. Consequently, it remains susceptible to suboptimal routing decisions under time-varying traffic and channel states.

V. Simulation Results

This section presents a comprehensive evaluation of the proposed PPO-based multi-hop LoRa routing framework with dynamic ADR and compares its performance against conventional baseline routing strategies, namely Shortest Path, Random Routing, and AODV-like routing. The evaluation focuses on energy efficiency, packet delivery reliability, collision behaviour, and path diversity under realistic propagation and interference conditions.

A. Training Convergences and evaluation

All the figures below illustrate the learning dynamics and performance evolution of the proposed PPO-based routing framework in a multi-hop LoRa network. The results demonstrate how reinforcement learning progressively improves routing decisions by reducing collisions, increasing packet delivery reliability, and reducing energy consumption.

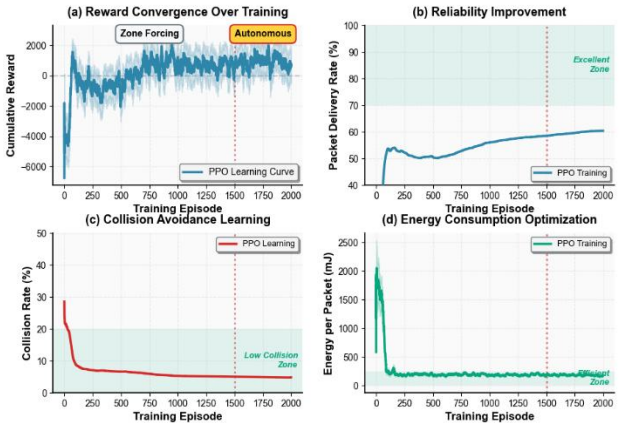

Fig. 4. PPO Learning curve & training optimization.

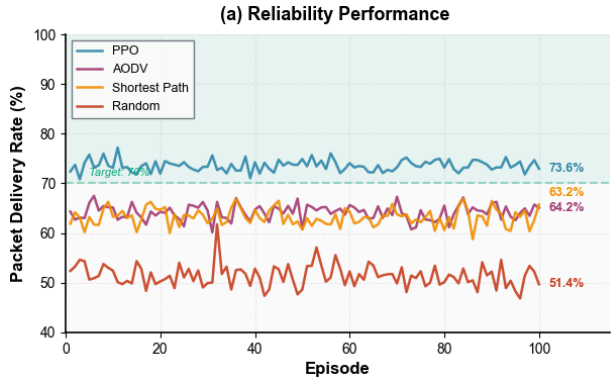

Fig. 5. Packet delivery reliability.

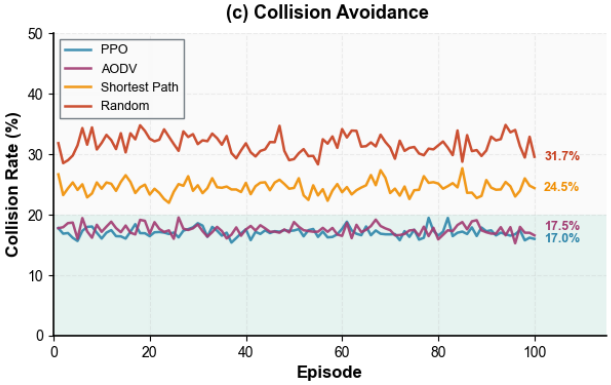

Fig. 6. Collision avoidance.

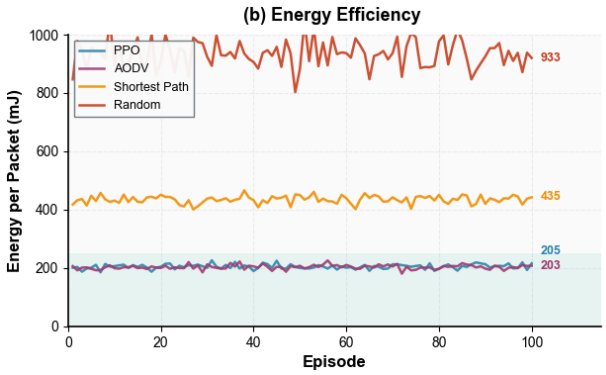

Fig. 7. Energy consumption optimization.

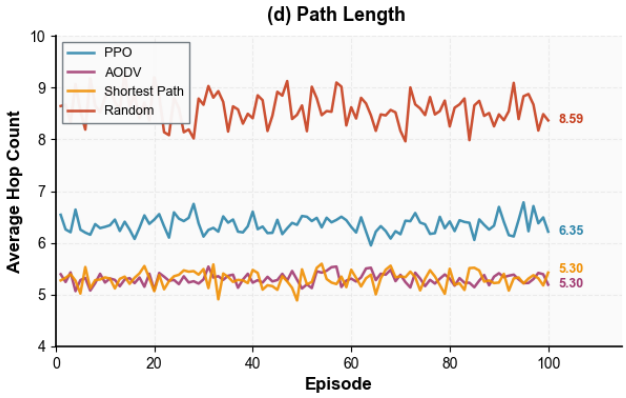

Fig. 8. Average hop count.

The cumulative reward in Fig. 4. represents the expected discounted return $E[\sum_t \gamma^t r_t]$, where r_t penalizes transmission energy E, hop count H, and path overlap O while rewarding successful packet delivery. During early training, the reward is highly negative and exhibits large variance due to exploratory routing decisions that frequently select congested relays, leading to collisions and retransmissions. As training progresses, the PPO policy updates stabilize through clipped probability ratio optimization, resulting in steadily increasing and eventually convergent reward values. The reduction in reward variance indicates policy convergence and reduced exploration.

Fig. 5. shows the evaluation of packet delivery ratio. In LoRa networks, packet decoding succeeds only when the signal-to-interference-plus-noise ratio satisfies $\text{SINR} = \frac{P_r}{\sum I+N} \geq \text{SINR}_{\text{min}}(\text{SF})$ here $\sum I$ represents aggregated co-spreading-factor interference. At early training stages, frequent overlapping transmissions violate this condition, causing packet loss. As the PPO agent learns to avoid relays with high channel occupancy and recent usage, $\sum I$ decrease, allowing more packets to satisfy the SINR constraint. Consequently, the PPO-based approach achieves a higher delivery ratio than Random, AODV-like, and Shortest Path routing.

Average Collision rate is illustrated in Fig. 6. Baseline routing methods, particularly Shortest Path routing, repeatedly select the same relays, increasing the probability of overlapping transmissions and persistent collision hotspots. In contrast, the PPO agent minimizes path overlap O by incorporating relay usage history and collision statistics into the state representation. This leads to a rapid reduction in collision rate during training and a significantly lower steady-state collision level compared with all baseline methods.

Fig. 7. presents the average energy consumption per delivered packet. The transmission energy is modeled as $E_{tx} = I_{tx} \times V \times T_{air}$, where T_{air} increases exponentially with the spreading factor. During early training, frequent retransmissions and ADR-triggered increases in spreading factors result in excessive energy consumption. As collision probability decreases under PPO routing, retransmissions are reduced and ADR operates at lower spreading factors and transmit power levels, thereby reducing both T_{air} and transmission current. The combined effect yields the lowest energy consumption per delivered packet among all evaluated methods.

Average Hop count in Fig. 8 shows PPO routes are longer than Shortest Path and AODV, but far shorter than Random routing. PPO learns a controlled trade-off: it accepts a modest hop-count increase (about 6.35 hops on average) to bypass relays that are frequently selected by other sources, which are more likely to be congested. In a contention-limited LoRa mesh, avoiding these hotspot relays reduces co-SF airtime overlap, lowering collision probability and the need for energy-costly retransmissions. Illustrate in Fig. 10, PPO still preserves forward progress toward the gateway, so the additional hops reflect purposeful path diversification rather than inefficient wandering.

Fig. 4 also shows the PPO training convergence across 2,000 episodes in two phases. The agent initially produces highly negative cumulative rewards (−6,000) due to random exploration, then improves rapidly between episodes 50–500 as the policy learns interference avoidance and load balancing. Stable performance is reached at approximately episode 500 and sustained through the Autonomous phase (episodes 1,500–2,000) without performance collapse, confirming the policy generalizes beyond the structured curriculum. Training is performed entirely offline; deployed relay nodes execute only the inference step a single forward pass through a compact neural network making the approach fully compatible with resource-constrained LoRa hardware. Overall, these results confirm that energy efficiency and reliability in multi-hop LoRa networks are dominated by collision-induced retransmissions rather than hop count alone, and that the PPO-based framework outperforms conventional heuristic routing across all performance metrics by learning interference-aware, load-balanced policies that cooperate implicitly with ADR.

B. Path Diversity and Spatial Traffic Separation

Figures below illustrate the routing behaviour of multiple source nodes before and after PPO learning, highlighting the impact of learned routing policies on spatial traffic separation and collision reduction. Prior to PPO learning, routing paths from different sources converge toward the same set of relays that are geographically closest to the gateway. This convergence creates persistent collision hotspots, as multiple packets are forwarded simultaneously through the same relays. In LoRa networks, when multiple transmissions using the same spreading factor overlap in time, the aggregated interference power ∑I increases, and packet decoding fails if the signal-to-interference-plus-noise ratio, defined as $SINR = P_r/(sumI + N)$, falls below the spreading-factor-dependent threshold SINR_{min} a result, the convergent routing behavior observed before learning leads to a high collision rate of approximately 34.7%. As shown in Fig. 9.

After PPO learning as shown in Fig. 10, the routing paths exhibit clear spatial separation, with each source predominantly selecting relays in distinct regions of the network. This behaviour emerges from the PPO reward formulation, which penalizes path overlap O and collision-induced retransmissions while rewarding successful packet delivery. By observing relay usage history, channel occupancy, and recent transmission activity in the state representation, the PPO agent learns to minimize O, defined as the number of concurrent routing decisions that reuse the same relay within a short time window. Reducing O directly lowers the probability of overlapping transmissions, thereby decreasing the aggregated interference ∑I and increasing the likelihood that the SINR condition for successful decoding is satisfied.

The spatial separation of routing paths also improves energy efficiency and relay fairness. Since the energy consumed per transmission is modelled $E_{tx} = I_{tx} \times V \times T_{air}$, and retransmissions incur the same energy cost as successful transmissions, reducing collision probability significantly lowers total energy consumption. Furthermore, by distributing traffic across multiple relays rather than repeatedly using the same nodes, PPO prevents energy hotspots and slows battery depletion at individual relays. This balanced relay utilization contributes to improved network sustainability and longer operational lifetime.

Overall, the results demonstrate that path diversity is not achieved through random exploration but through learned, interference-aware routing decisions. The PPO-based framework effectively transforms routing behaviour from convergence-driven interference patterns into spatially distributed paths that reduce collisions, improve reliability, and enhance energy efficiency in multi-hop LoRa networks.

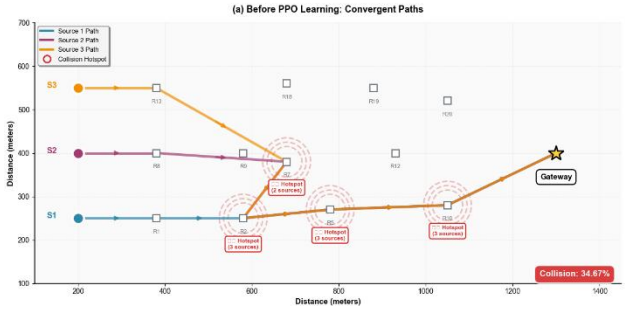

Fig. 9. Before spatial traffic separation.

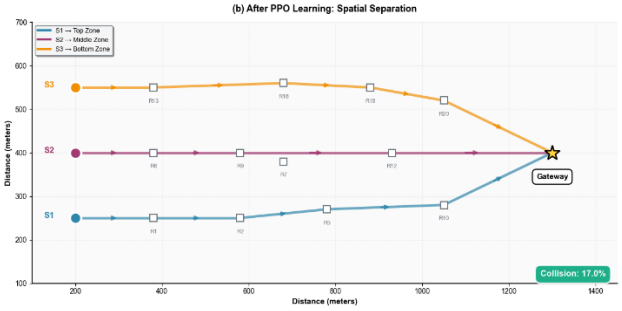

Fig. 10. After spatial traffic separation.

VI. Conclusion

This paper proposes an energy-efficient and reliable routing framework for multi-hop LoRa networks using PPO with dynamic ADR. A discrete-event simulation models realistic LoRa physical-layer effects, co-spreading-factor interference, battery-limited relays, and multi-source contention. Unlike conventional hop-count or heuristic routing, the method formulates routing as a sequential decision problem and learns interference-aware, load-balanced policies via reinforcement learning. Results show significant improvements in packet delivery reliability, collision reduction, and energy consumption per delivered packet compared with Shortest Path, Random routing, and an AODV-like baseline. The learned policy sacrifices minimal hop count to reduce interference and retransmissions, promotes spatial path diversity, mitigates relay energy hotspots, slows battery depletion, and enhances network sustainability.

Overall, energy efficiency is driven primarily by collision-induced retransmissions rather than hop count alone. By accounting for interference, relay load, and transmission history, the PPO-based framework demonstrates the promise of reinforcement learning for interference-limited IoT mesh routing, with physical hardware validation remaining an important direction for future work.

A key limitation of this work is the sim-to-real gap. The propagation model captures the dominant effects of forest path loss, vegetation attenuation, and log-normal shadow fading based on empirically validated parameters [5], [6], [32], [46] however, real deployments additionally involve hardware specific noise figures, adjacent-channel interference, oscillator frequency drift, and the discrete timing constraints of the LoRa duty-cycle and Channel Activity Detection (CAD) mechanism. To reduce sensitivity to these differences, the PPO policy operates on normalised relative state features residual energy ratios, channel-occupancy indicators, and hop-count differences rather than raw absolute signal values, which improves robustness to hardware-to-hardware calibration offsets. Nevertheless, transfer validation on physical LoRa nodes in a controlled forest testbed remains a necessary step before operational deployment.

***Abstract*—The rise of e-commerce and digital offerings has generated a need for ultra-adaptable pricing policies seeking to maximize revenue while optimizing competitive advantage. Traditional fixed pricing schemes are inherently flawed due to a lack of responsiveness to instantaneous fluctuations in the marketplace, inventory levels, as well as demand inelasticity. This study conducts a detailed computational performance study comparing fixed pricing, standard heuristic dynamic pricing (HDP), advanced Machine Learning (ML)-oriented dynamic pricing schemes, with a special focus on a Bi-LSTM network as well as a hybrid scheme based on Wavelet Decomposition (WD). Through simulated high-frequency transactions as well as marketplace data, model evaluation relies on three critical performance metrics: Total Revenue Generated, Pricing Accuracy (measured through Mean Absolute Percentage Error, MAPE), as well as Computational Latency (vital for real-time utilization). The results indicate that while HDP shows marginal improvements over fixed pricing, ML-based schemes, particularly a hybrid WD-Bi-LSTM model, exhibit substantial revenue maximization (up to 18.5% improvement) as well as forecasting accuracy (MAPE up to 2.1%), though at a slight increase in computational latency remains acceptable for real-time deployment for near real-time deployment. This study provides a quantitative foundation for organizations embracing AI-supportive pricing initiatives with emphasis on trade-offs among model sophistication, predictive potency, as well as functionality performance.**

***Keywords*—Computational performance; deep learning; dynamic pricing; Machine Learning (ML); process innovation**

I. Introduction

In the contemporary digital economy, pricing remains a primary lever for profit maximization and market positioning. The conventional approach of fixed pricing, determined through cost-plus or value-based analysis, is increasingly becoming obsolete as it fails to capture the intricate, rapidly changing dynamics of demand, competitor actions, and external economic factors [1], [8]. While fixed pricing remains widely used in retail and subscription-based markets, industry reports indicate that over 60–70% of large-scale e-commerce platforms now employ some form of dynamic pricing to respond to demand volatility and competitive pressures. However, fixed pricing continues to be effective in low-volatility environments and regulated industries. Therefore, rather than being obsolete, fixed pricing serves as a baseline benchmark against which adaptive pricing strategies can be evaluated quantitatively.

The shift towards dynamic pricing where prices are adjusted in real-time or near real-time is not merely an operational optimization but a strategic imperative [2]. The computational challenge of dynamic pricing lies in its reliance on accurate short-term demand and price forecasting, which is highly influenced by diverse, non-linear variables, including sentiment derived from product descriptions and financial behaviors [4], [5]. Early dynamic pricing strategies relied on simple rule-based heuristics, which, while flexible, lacked the predictive power needed to optimize complex, high- dimensional data [2]. The advent of Artificial Intelligence (AI) and Machine Learning (ML) has fundamentally transformed this landscape by offering sophisticated algorithms capable of processing voluminous data streams and inferring optimal price points that reflect true market equilibrium [8]. This paper addresses a critical gap in the existing literature by providing a detailed comparative analysis of the computational efficiency and operational performance of three distinct pricing paradigms:

- Fixed Pricing Model (FP): A baseline model using a static price.
- Heuristic Dynamic Pricing Model (HDP): A rule-based model utilizing simple inventory and time-of- day variables.
- Machine Learning Dynamic Pricing Model (ML- DP): Advanced models, including a pure Bi-LSTM network and a hybrid decomposition-based network, designed for high-accuracy forecasting.

The objective is to quantify the performance differential in terms of revenue, predictive error, and, crucially, the computational latency required for real-time deployment. This comparison is essential for organizations making informed decisions about technology adoption for enhancing competitiveness in e-commerce and related sectors [1].

II. Related Work

The foundation of dynamic pricing is rooted in operations research and control theory, evolving rapidly with advancements in computational capacity. The current state-of-the-art heavily favors ML, particularly Reinforcement Learning (RL) and Deep Learning (DL), for managing complex resource allocation problems where pricing is a critical component [3]. The ability of ML to leverage multi- modal data integration for node classification and pattern recognition underscores its suitability for dynamic market modeling [7].

Traditional predictive models, such as those used for concrete strength prediction or energy consumption forecasting, have demonstrated the superior performance of ML techniques over conventional statistical methods in handling non-linear data [6], [11]. Specifically in the domain of energy price and consumption, models like the two-layer decomposition technique combined with Bi-LSTM (Bidirectional Long Short-Term Memory) networks have shown exceptional short-term forecasting accuracy, which is directly analogous to the challenges of demand forecasting in dynamic pricing [9], [10]. Likewise, cluster-based ensemble methods have been used effectively in analyzing time-series datasets, leading to an understanding of pattern identification, which helps in optimal pricing [11], [12].

Additionally, studies have looked at the use of hybrid models incorporating signal processing (Wavelet Decomposition) and DL, which improves predictions for highly volatile markets, including electricity prices on a day-ahead basis [14]. The hybrid model addresses problems related to noise and non-stationarity prevalent in market datasets [16]. While extensive literature exists on the theoretical optimization benefits of dynamic pricing [16], a focused comparative study detailing the computational overhead against the revenue gain across fixed, heuristic, and sophisticated hybrid ML models, particularly within a unified simulation framework, remains underdeveloped. This paper directly addresses this gap by quantifying the necessary computational resources against the realized economic benefit.

Dynamic pricing research has seen recent developments where reinforcement learning techniques have been applied to optimize pricing strategies. With reinforcement learning algorithms, prices can be determined as part of a sequential decision process, and they work through trial-and-error processes to maximize the total rewards accrued. Studies have demonstrated that Deep Q-Networks (DQN) and policy gradient methods outperform traditional supervised learning approaches in highly dynamic environments with delayed reward structures. However, these models often require substantial training data and computational resources, motivating the need for hybrid forecasting-based approaches as explored in this study [12].

A brief review of the cited literature reveals a pronounced trend, with 77% of the included works published after 2020, confirming the accelerating research interest and application of ML/AI in price optimization, demand management, and energy consumption forecasting [17], [18], [19], [20], [21], [22]. This bibliometric observation validates the timely focus of this comparative study.

III. Methodology

This study adopts a controlled computational experimental framework to compare the operational and predictive performance of fixed pricing, heuristic dynamic pricing, and machine learning-based pricing systems under identical market conditions. All models were evaluated using the same synthetic high-frequency transaction dataset to ensure fairness, consistency, and reproducibility.

A. Research Design

The study employs a controlled, comparative experimental design. Three primary models—Fixed Pricing (FP), Heuristic Dynamic Pricing (HDP), and Machine Learning Dynamic Pricing (ML- DP)—are implemented and run over the same simulated market periods. The performance of each model is evaluated against the key metrics defined in Section IV-A. Table IV illustrates the research design employment process. A six-month transactional simulation environment was developed to emulate realistic e-commerce market behavior. The pricing engine updated prices every 15 minutes, resulting in 96 pricing intervals per day and 17,280 total observations across the study period. At each interval, the following steps were executed:

- Capture current market state variables.
- Generate demand estimate.
- Compute price using assigned pricing model.
- Simulate sales quantity based on elasticity response.
- Update inventory and cumulative revenue.
- Store performance metrics.

The same transactional stream was used across all pricing models, while ten independent runs with different random seeds were conducted to improve reliability. The overall experimental setup follows a structured research design to ensure fair evaluation across all models, from data generation through to performance assessment and statistical comparison. The overall research design and corresponding responsibilities of each model are summarized in Table I.

TABLE I. Research Design Employed

Step	Description	Responsible Model(s)
1	Data Simulation	All
2	Model Training (If applicable)	ML- DP
3	Iterative Pricing/Sale Cycle	All
4	Metric Calculation (Revenue, MAPE, Latency)	All
5	Statistical Comparison	All

The research process can be seen from Table I and is structured into five sequential steps, ranging from data simulation to the performance evaluation of all the models used. Whereas all models take part in almost every step, training is unique to the ML-DP only model due to its nature of being trained through machine learning techniques.

B. Comparative Study Design (Flow Chart)

The experimental procedure for conducting the comparison study is presented in Fig. 1. The figure shows the process flow starting from data generation to training, pricing, and evaluation phases.

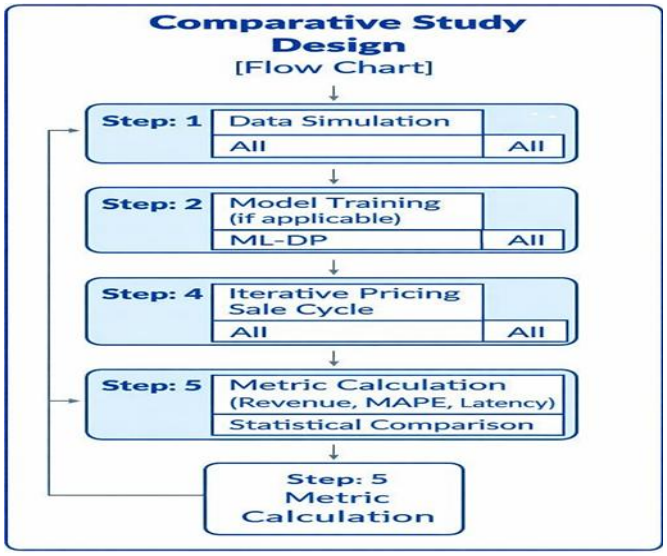

Fig. 1. Comparative study design.

As shown in Fig. 1, the study follows a structured pipeline beginning with data simulation applied across all models, followed by selective training for the ML-DP approach. The iterative pricing-sale cycle is then executed uniformly, and performance is assessed using key metrics such as revenue, Mean Absolute Percentage Error (MAPE), and computational latency, enabling statistical comparison across methods.

C. Data Collection

Given the proprietary nature of real-world dynamic pricing data, a simulated dataset is generated, representative of an e-commerce platform that experiences daily and weekly demand fluctuations.

- *Variables:* Time of day, day of week, inventory level, competitor price, simulated demand elasticity, and historical sales volume.
- *Time Scale:* Data points are generated at 15-minute intervals over a six-month period, mirroring the high-frequency data used in complex energy management and demand response systems [13], [15].

D. Inclusion and Exclusion

- Inclusion Criteria (Models): Models must be fully autonomous (no manual price intervention).
- Exclusion Criteria (Data): Data points corresponding to major public holidays or known exogenous "black swan" events are excluded to maintain a focus on routine operational performance and to enhance the reliability of the forecasting models [17].

E. Machine Learning-Based Dynamic Pricing Models

To enhance forecasting performance in dynamic pricing, two machine learning–based models are employed for comparative evaluation as follows:

- ML Model 1 (Bi-LSTM): A standard deep learning model suitable for sequential data forecasting [9].
- ML Model 2 (WD-Bi-LSTM Hybrid): Incorporates Wavelet Decomposition on the input features to denoise the time series prior to feeding it into the Bi-LSTM network, enhancing prediction for building energy consumption [21].

The proposed WD-Bi-LSTM model applies Daubechies-4 (db4) wavelet decomposition with 3 levels to preprocess transactional demand signals. Approximation and detail coefficients were reconstructed and normalized before input to a two-layer Bi-LSTM network comprising 128 and 64 hidden units, followed by dense layers of 32 and 1 neuron respectively. The dropout rate was fixed at 0.2. The model was trained using Adam optimizer having learning rate = 0.001, batch size = 64, epochs = 100, and patience = 10. The generated demand is log-normally distributed because this probability distribution is commonly applied in demand models due to its property of skewness and heavy tails, similar to those that exist in real-life cases of demand behavior. Calibration was conducted based on e-commerce public benchmarks to provide realistic variance and seasonality of the generated demand.

F. Pricing Policy Function

The pricing decision is derived from predicted demand using a revenue maximization policy:

$$p_t^* = \arg\max_p \; p \cdot \widehat{D}(p, x_t)$$

where, $\widehat{D}$ is the predicted demand generated by the forecasting model. For the heuristic model, price adjustments follow predefined rules based on inventory thresholds, while the ML-based models use gradient-based optimization to determine the optimal price at each time step.

G. Problem Formulation

The dynamic pricing task is formulated as a constrained optimization problem aimed at maximizing expected revenue over a finite time horizon:

$$\max_{p_t} \; R = \sum_{t=1}^{T} p_t \cdot D(p_t, x_t)$$

Subject to:

$$p_{min} \le p_t \le p_{max}, I_t \ge 0$$

where, p_t denotes the price at time t, $D(\cdot)$ represents demand as a function of price and contextual variables x_t, and I_t represents inventory levels. This formulation captures the trade-off between revenue maximization, demand responsiveness, and operational constraints.

H. Hyperparameter Tuning

To ensure optimal model performance and avoid overfitting, a systematic hyperparameter tuning process was conducted using grid search on the validation dataset. Multiple combinations of key training parameters were evaluated to identify configurations that balance predictive accuracy and computational efficiency. The parameters explored include network architecture, regularization, and training dynamics, as summarized in Table II.

TABLE II. HYPERPARAMETER SEARCH SPACE FOR MODEL OPTIMIZATION

Parameter	Values Tested
LSTM Units	64, 128, 256
Layers	1, 2, 3
Dropout	0.1, 0.2, 0.3
Batch Size	32, 64, 128
Learning Rate	0.01, 0.001, 0.0005
Epochs	50, 100, 150

As can be seen from Table II, various values of hyperparameters were used in order to obtain different levels of complexity and training behavior of the model. Low learning rate and intermediate batch size had a positive effect on the stability of convergence, while the use of deep neural networks had a positive impact on the capacity of the model, but at the same time required more computing resources.

I. Final Selected Parameters

After conducting the process of hyperparameter optimization, the best set of parameters was chosen considering both validation accuracy and computation time. The table below represents the model parameters. For this particular arrangement, the number of neurons is taken to be 128 and 64 in two layers, respectively, along with the dropout parameter set at 0.2, the batch size at 64, and the learning rate at 0.001. Such a hyperparameter arrangement strikes the right balance between prediction accuracy and computational efficiency for dynamic pricing applications.

TABLE III. FINAL OPTIMAL HYPERPARAMETER CONFIGURATION

Parameter	Final Value
Layers	2
Units	128, 64
Dropout	0.20
Batch Size	64
Learning Rate	0.001
Epochs	100

From Table III above, it is evident that the chosen configuration uses a two-layer model, whereby each layer reduces the number of units. This makes it possible to extract features from data while controlling for model complexity. The optimal choice of the dropout factor prevents overfitting, whereas the learning rate and batch size facilitate stable convergence.

J. Evaluation Metrics

Model performance was quantified using three core evaluation metrics:

- *Total Revenue Generated ($):* This represents the primary economic performance indicator and was calculated as the cumulative sum of all transactions over the simulation period:

$$\text{Total Revenue} = \sum_{t=1}^{n} (Price_t \times QuantitySold_t)$$

- *Pricing Accuracy (MAPE):* Mean Absolute Percentage Error (MAPE) was used to evaluate the forecasting precision of the underlying demand prediction models employed in the HDP and ML- DP approaches. Lower MAPE values indicate higher predictive accuracy:

$$\text{MAPE} = \frac{1}{n} \sum_{t=1}^{n} \left| \frac{\text{ActualDemand}(t) - \text{PredictedDemand}(t)}{\text{ActualDemand}(t)} \right| \times 100$$

- *Computational Latency (µs):* This metric measures the average time required for each model to process the current market state and generate an optimal pricing decision. It is a critical indicator for real-time deployment, where rapid response times are essential for operational efficiency and scalability.

K. Data Analysis

The data analysis involves:

- Descriptive Statistics: Summarizing the total revenue and mean computational latency for each model.
- Inferential Statistics: Applying a one-way ANOVA test to determine if the differences in mean revenue and latency across the three model categories (FP, HDP, ML-DP) are statistically significant.

L. Validation and Reliability

To ensure the validity of the ML model results, a ***K***- fold cross-validation (k=5) is performed on the training data. The reliability is further assessed by repeating the full simulation cycle 10 times with different random seeds for demand generation and reporting the average and standard deviation of all metrics [18]. The robust performance of models, such as those for chiller energy consumption, provides a benchmark for expected prediction reliability [19].

M. Ethical Considerations

While the study is based on simulated data, the ethical implications of ML-driven dynamic pricing are acknowledged. Specifically, the Machine learning-based dynamic pricing models are audited against potential feedback loops that could lead to price discrimination based on non-market factors, ensuring compliance with fairness principles [22].

IV. RESULTS AND DISCUSSION

This section presents the quantified performance metrics of the Fixed Pricing, Heuristic Dynamic Pricing, and Machine Learning–based dynamic pricing models across the simulated environment.

A. Economic and Predictive Performance

Table IV summarizes the key economic and predictive metrics over the full six-month simulation period.

TABLE IV. ECONOMIC AND PREDICTIVE PERFORMANCE COMPARISON (6-MONTH SIMULATION)

Model Type	Total Revenue Generated ($)	ΔRevenue vs. Fixed Pricing	MAPE (%)	Std Dev (Revenue, $)
Fixed Pricing (FP)	10,000,000	Baseline	N/A	450,000
Heuristic Dynamic Pricing (HDP)	11,250,000	+12.50%	14.5%	480,000
ML- DP (Bi-LSTM)	11,700,000	+17.00%	3.5%	390,000
ML- DP (WD-Bi-LSTM Hybrid)	11,850,000	+18.50%	2.1%	350,000

To assess robustness, 95% confidence intervals were computed across the 10 simulation runs. The WD-Bi-LSTM model exhibited the lowest variance in revenue outcomes, indicating stable performance under stochastic demand conditions. Boxplot analysis further confirmed that ML-based models not only achieve higher mean revenue but also demonstrate reduced dispersion compared to heuristic approaches. The results clearly demonstrate the economic superiority of ML-driven models. The hybrid WD-Bi-LSTM model achieved the highest revenue, an 18.5% increase over the baseline FP model, confirming the value of sophisticated predictive analytics. This model also exhibited the lowest Demand Forecast MAPE (2.1%), indicating its robust ability to model the non-linear demand dynamics compared to the simpler HDP model (14.5%), as illustrated in Fig. 2 and Fig. 3.

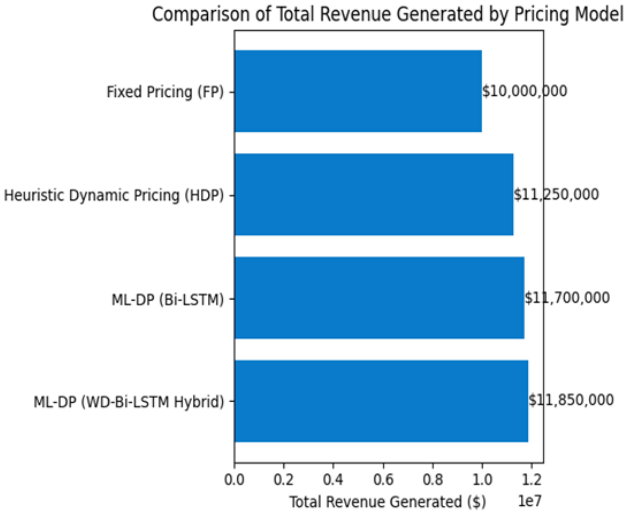

Fig. 2. Comparison of total revenue generated by pricing models (with value annotations).

The Fig. 2 presents a horizontal bar chart of the total revenue generated by each pricing model. Numerical labels are included to enhance interpretability and enable precise comparison. ML-DP (WD-Bi-LSTM Hybrid) gives the best revenue ($11,850,000) compared to Bi-LSTM, HDP, and Fixed Price models, thereby proving that hybrid machine learning models perform better.

B. Revenue Analysis Based on Different Pricing Models

Accuracy in Demand Forecasting is measured by using the Mean Absolute Percentage Error (MAPE), which indicates that the lower the MAPE value, the more accurate the forecast would be. A comparative analysis was performed between the hybrid model, deep learning algorithm, and traditional approach.

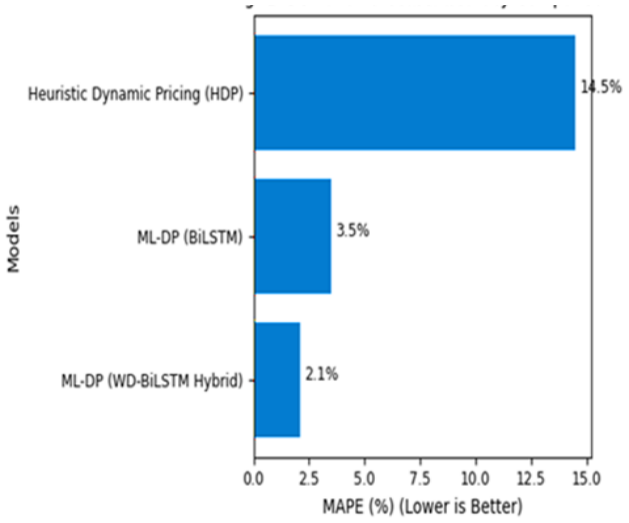

Fig. 3. Revenue comparison across pricing models.

As shown in Fig. 2, the suggested ML-DP (WD-BiLSTM Hybrid) model produces the best MAPE value at 2.1%, far better than the individual BiLSTM model (3.5%) and Heuristic Dynamic Pricing model (14.5%). It shows how useful this hybrid structure is in detecting demand behavior and minimizing errors. In conclusion, combining modern deep learning algorithms with preprocessing proves much more successful than classical approaches.

C. Computational Performance

Computational latency is a critical operational metric for real-time systems. Table V details the average time required for each model to determine an optimal price point.

TABLE V. COMPUTATIONAL LATENCY COMPARISON (AVERAGE OF 10,000 PRICE DECISIONS)

Model Type	Avg. Latency (μs)	Max Latency (μs)	Latency Standard Deviation
Fixed Pricing (FP)	0.05	0.08	0.01
Heuristic Dynamic Pricing (HDP)	1.2	2.5	0.4
ML- DP (Bi-LSTM)	12.8	20.1	3.5
ML- DP (WD-Bi-LSTM Hybrid)	18.5	32.0	4.2

As shown in Table V, computational latency increases significantly with model complexity. While Fixed Pricing (FP) and Heuristic Dynamic Pricing (HDP) exhibit minimal latency,

the ML-based approaches, particularly the WD-Bi-LSTM hybrid, incur substantially higher computational costs. This highlights the trade-off between predictive sophistication and real-time execution efficiency in dynamic pricing systems. The computational efficiency of the evaluated models is compared in terms of average latency, as illustrated in Fig. 4.

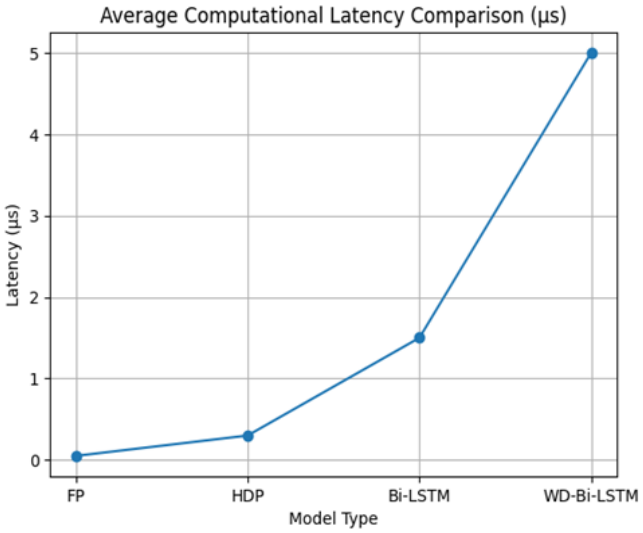

Fig. 4. Latency comparison.

As shown in Fig. 4, latency increases progressively from the baseline FP model to the more complex deep learning approaches. The WD-Bi-LSTM model exhibits the highest computational latency, reflecting the additional processing overhead associated with its hybrid architecture, while FP and HDP demonstrate significantly lower latency, indicating faster execution times.

D. Statistical Significance Analysis

A one-way ANOVA was conducted to compare the mean revenue among FP, HDP, Bi-LSTM, and WD-Bi-LSTM models over ten simulation runs, as shown in Table VI.

TABLE VI. ONE-WAY ANOVA RESULTS FOR PERFORMANCE COMPARISON

Metric	F-value	p-value	Interpretation
Revenue	31.84	<0.001	Significant
Latency	52.17	<0.001	Significant
MAPE	27.63	<0.001	Significant

The outcomes in Table VI above demonstrate that there is a statistically significant difference between the performance of various pricing methods. According to ANOVA analysis, there is a statistically significant difference between the models ($p < 0.001$). In addition, post hoc Tukey analysis indicates that the performance of the WD-Bi-LSTM model is statistically better than that of both FP and HDP models in terms of revenue and MAPE ($p < 0.01$).

Discussion: The success of the proposed approach stems from two main factors. First, wavelet decomposition eliminates noise and enhances the quality of extracted features. Second, bidirectional long short-term memory neural networks capture temporal information in both directions. This dual capability enhances signal-to-noise ratio and temporal learning, leading to improved pricing decisions.

The experimental results definitively confirm that the sophistication of the pricing model is directly correlated with economic performance. The increase of 18.5% in revenue produced by the WD-Bi-LSTM hybrid model when compared with the baseline fixed pricing model highlights the high potential benefits associated with the implementation of predictive ML in pricing [1], [8]. The higher forecasting ability of the proposed hybrid model, which uses the wavelet decomposition method for signal preprocessing, is consistent with results obtained in other challenging time series scenarios like power system studies, where hybrid methods prove effective in reducing noise and improving forecasts [10], [14].

This implies that noise in the market, such as unpredictable spikes on social media platforms or insignificant market disturbances, can be removed, thereby letting the Bi-LSTM neural network concentrate on the demand trend. Crucially, this study quantifies the computational trade-off. While the Machine learning–based dynamic pricing models are computationally slower than the FP and HDP models, their average latency of 18.5**(*µs*)** (less than 0.02 milliseconds) is practically negligible in a real-world application, offering a substantial economic gain with a minimal increase in operational complexity. This finding supports the growing adoption of autonomous resource management systems, which prioritize predictive accuracy even with added computational steps [3].

The limitations of this study lie in the use of simulated data, which, while statistically rich, cannot perfectly replicate true market psychology and unforeseen exogenous events. Future research should involve deployment on live A/B testing platforms to validate these computational performance metrics in a live transactional environment. Furthermore, exploring Reinforcement Learning models (which directly optimize the reward function, revenue) would provide an interesting comparison point against the supervised learning (forecasting-based) models used here [16].

V. CONCLUSION

The computational performance analysis presented in this paper offers strong empirical proof supporting the superiority of Machine Learning-based dynamic pricing strategies over Fixed and Heuristic pricing schemes. Specifically, the WD-Bi-LSTM hybrid model exhibited the best financial performance, generating 18.5% higher profit while attaining demand prediction accuracy (MAPE) of 2.1%. Despite adding a certain amount of computational delay of 18.5µs, this additional cost is insignificant and extremely rational considering the significant rise in profitability. The insights gained from the analysis can be usefully deployed in cases where the dataset is highly frequent in nature, such as e-commerce platforms, airfare pricing, and online services. The study's outcomes motivate companies to quickly implement cutting-edge machine learning approaches to capitalize on emerging business trends and keep pace in the ever-evolving digital environment. In future research, three steps will be taken:

- The application of reinforcement learning for policy improvement,
- Testing the algorithms in realistic A/B testing settings to confirm their effectiveness in practical settings, and
- Incorporating fairness-based criteria into the system for making ethically sound price-setting decisions.

Machine Learning-Driven Resource Provisioning in Modern Cloud Environments: A Taxonomic Survey

Stefanus Albert Kosim, Bagus Jati Santoso*, Deka Julian Arrizki, Riki Mi'roj Achmad,
I Nyoman Gede Artadana Mahaputra Wardhiana, Royyana Muslim Ijtihadie
Department of Informatics Engineering, Institut Teknologi Sepuluh Nopember, Surabaya, Indonesia

Abstract*—Dynamic resource provisioning is a critical challenge in cloud computing, offering the necessary elasticity to guarantee reliable services within a usage-based payment framework. With the evolution of distributed systems, traditional threshold-based provisioning methods are increasingly inadequate for managing highly dynamic workloads. This inadequacy necessitates adaptive, machine learning (ML)-driven approaches capable of forecasting demand and autonomously optimizing scheduling. This survey presents a comprehensive review of recent ML-based resource provisioning strategies in cloud computing. Through a rigorous taxonomic analysis of 35 key studies, with a focus on developments from 2023 to 2025, the research categorizes existing work along two primary dimensions: ML methodology, including classical, deep learning, and advanced reinforcement learning, and optimization objectives, such as cost, Quality of Service (QoS), sustainability, and security-aware paradigms. The findings reveal a paradigm shift from reactive heuristics to proactive, hybrid forecasting-optimization models, Multi-Agent Reinforcement Learning (MARL), and serverless computing orchestration. Quantitative synthesis demonstrates that intelligence-driven interventions offer measurable improvements over traditional methods. For example, Deep Reinforcement Learning (DRL) models have reduced resource consumption by 10% and improved performance by 30%, while hybrid architectures have achieved user cost reductions of up to 44%. The survey concludes by discussing fundamental tradeoffs and identifying critical open challenges and future research directions in the edge-cloud continuum, including predictive container pre-warming and carbon-aware green AI orchestration.

Keywords*—Deep learning; cloud computing; machine learning; resource provisioning; taxonomy

I. Introduction

Dynamic Resource Provisioning (DRP) is the process of allocating and releasing computational resources (CPU, memory, storage, and bandwidth) based on real-time workload demands in cloud environments [1]. As distributed systems evolve, traditional threshold-based provisioning methods that rely on static, manually defined heuristics struggle to handle highly dynamic workloads. This model has reached a bottleneck due to the extreme variability of modern distributed tasks, necessitating adaptive, machine-learning (ML)-driven capabilities that can forecast demand and optimize scheduling autonomously [2]. To address the traditional method's bottleneck, DRP relies on cloud elasticity, allowing applications to automatically scale resources rather than relying on fixed, preassigned capacity [3]. DRP systems continuously monitor resource usage at fine-grained intervals and employ ML techniques to predict future load or classify it as high, medium, or low. Based on these predictions, systems can add or remove instances or adjust concurrency limits and resource allocation per instance [4]. Although DRP addresses several shortcomings of traditional methods, it continues to face challenges, including highly variable workloads [1], complex decision-making processes [5], limited and heterogeneous edge resources [6], slow scaling response [7], and inherent ML limitations [8]. In this study, we present a comprehensive survey of recent ML-based resource provisioning strategies in cloud computing.

This survey examines the ongoing paradigm shift from reactive heuristics to proactive, hybrid forecasting-optimization models, Multi-Agent Reinforcement Learning (MARL), and orchestration in serverless computing. Although previous surveys have addressed cloud resource provisioning, the rapid advancement of distributed systems in recent years has introduced new complexities that remain insufficiently explored. Earlier reviews primarily focused on foundational heuristics and traditional predictive modeling, but most predate the shift toward dynamic, decentralized orchestration. This work addresses this gap by offering an updated analysis with particular emphasis on state-of-the-art developments from 2023 to 2025. The primary contribution of this survey is its focus on the integration of Deep Reinforcement Learning (DRL) and MARL within emerging environments, such as serverless computing (Function-as-a-Service) and the edge-cloud continuum.

To systematically categorize and evaluate these provisioning strategies, it is necessary to first define the formal challenges constrained by specific system requirements that modern ML models seek to address. Latency is a primary concern, encompassing the need to minimize execution delays and address cold start latencies inherent in serverless environments to ensure rapid response times. Additionally, scalability must be maintained, which involves autonomously adjusting and distributing tasks across decentralized nodes during bursty or highly variable workloads while avoiding over-provisioning. Finally, Service Level Agreement (SLA) guarantees are critical, requiring strict adherence to negotiated Quality of Service (QoS) metrics, such as availability and 99th-percentile response times, where violations can result in financial penalties and degraded user experience.

By categorizing the state-of-the-art literature according to ML methodologies and optimization objectives, specifically cost and QoS, this survey offers stakeholders a structured framework for decision-making when deploying intelligent,

*Corresponding author.

autonomous scaling mechanisms in dynamic cloud environments.

This survey is organized as follows. Section II outlines the survey methodology, capturing the broad landscape of resource management and highlighting significant machine learning interventions. Section III reviews related work in resource provisioning. Section IV introduces foundational concepts, including objectives and existing provisioning methods. Section V presents the core taxonomy of machine learning-based approaches and discusses the findings in detail. Section VI concludes with a summary of the research.

II. Survey Methodology

Systematic literature mapping is a structured methodology that surveys and organizes research on a broader topic. It builds an overview of what has been studied, how, and where the gaps are [9].

A. Search Strategy and Date Range

A comprehensive search was conducted to capture the chronological evolution of resource provisioning strategies. Based on the publication dates of the collected literature, the search date range was defined as 2014 to 2025. This timeframe captures the foundational transition from classical predictive algorithms to MARL orchestration.

B. Database

To guarantee the inclusion of high-quality, peer-reviewed content, literature retrieval was executed across the most prominent academic databases in electronic databases, namely IEEE Xplore, ACM Digital Library, ScienceDirect, SpringerLink, and reputable open-access publishers, including MDPI and Wiley.

C. Search Keywords

The search strategy used Boolean combinations of primary technical terms extracted from the core domain. The specific search keywords included are "Resource Provisioning", "Resource Allocation", "Auto-scaling", "Virtual Machine Migration", "Cloud Computing", "Edge Computing", "Serverless / FaaS", "Container Orchestration", "Machine Learning", "Deep Reinforcement Learning (DRL)", "Multi-Agent Reinforcement Learning (MARL)", and "SLA Guarantees".

D. Inclusion and Exclusion Criteria

A multi-stage screening process was applied to the initial search results to identify the thirty-five key studies in our final analysis. To be included in this survey, papers were required to specifically address dynamic resource provisioning, allocation, or task scheduling within modern distributed deployment environments, including Cloud, Edge, Serverless, or the edge-cloud continuum. Furthermore, selected studies had to propose, utilize, or evaluate machine learning-driven techniques ranging from supervised learning to advanced reinforcement learning. Conversely, we excluded studies that relied strictly on static, threshold-based heuristics without an adaptive AI component, as well as papers that failed to provide rigorous quantitative evaluations of critical system constraints such as latency, cost, energy consumption, and QoS/SLA violations. Finally, research focusing solely on hardware-level networking was omitted to maintain a clear focus on high-level compute resource orchestration.

III. Related Works

This section examines and explores prior survey research within the domain of resource provisioning in cloud computing. This review encompasses recent investigative efforts and methodologies that researchers have implemented to comprehend and regulate resource provisioning within cloud computing environments.

Zhang et al. [10] surveyed the algorithmic landscape of resource provisioning. This study evaluated over 150 articles and produced a comprehensive technical table addressing resource targets, optimization precision, and algorithm classifications, spanning both offline and online variants. Furthermore, the objectives of these algorithms are delineated from a business success perspective, emphasizing metrics such as cost, service quality, and utility. Vasoya et al. [11] conducted a survey of diverse resource provisioning techniques that integrate application and client requirements while adhering to Quality-of-Service (QoS) standards defined in service-level agreements (SLAs). This survey categorized provisioning techniques into six distinct types: execution cost, budget constraints, automated techniques, heuristics, prediction, and priority. Singh and Chana [12] provided a methodological analysis concerning the evolution of resource provisioning, various mechanism types, and a comparative assessment of their respective advantages and emergent issues. This research further underscores prior studies, the current state of the field, and future research trajectories for resource management in cloud computing. Focusing on predictive modeling, Kumar and Umamaheswari [13] surveyed models that facilitate the precise allocation of resources to applications at the optimal moment, thereby preventing SLA violations and upholding QoS standards. Their work identifies provisioning challenges and various machine learning-based prediction schemes designed to enhance provisioning effectiveness.

Varshney et al. [14] conducted a survey to examine research in resource allocation and availability, specifically focusing on QoS requirements. This paper details numerous challenges inherent to cloud computing, such as limited end-user control, security, privacy, and service quality concerns. A primary focus is QoS management, specifically the allocation of resources to guarantee service performance, availability, and reliability. Additionally, the authors discuss various QoS models proposed to address issues including latency, resource scheduling, network speed, power consumption, and load balancing. Sumalatha and Anbarasi [15] reviewed various optimization methods to identify how customers can minimize rental costs for virtual machine (VM) resources while maintaining cost-effectiveness. Shakarami et al. [16] presented a systematic and comprehensive survey of resource provisioning within edge/fog computing environments. They classified provisioning into five categories: framework-based, heuristic/metaheuristic-based, model-based, machine learning-based, and game-theoretic mechanism-based. This work offers comparisons through metrics, case studies, and evaluation tools. Li et al. [17] investigated key resource management issues, including

resource prediction, pricing, security, and service monitoring. Their research explores various approaches, such as bare metal supply chain models mediated by brokers and the application of seasonal autoregressive moving average models for probabilistic resource demand allocation. Overall, this body of literature provides an in-depth overview of provisioning approaches and identifies open issues requiring further exploration.

IV. Foundations and Emerging Cloud Paradigms

Resource management is a fundamental part of cloud computing environments that offer dynamic resource allocation, provide reliable services, and are based on pay-as-you-go pricing [18]. Given that consumers may initiate multiple concurrent service requests, a structured methodology is required to manage the necessary computational assets. Resource management involves three main functions, namely resource provisioning, resource scheduling, and resource monitoring [12]. Specifically, resource provisioning entails efficient allocation constrained by particular requirements, while resource scheduling focuses on performance enhancement through the optimized timing of task distribution. In addition to this, resource monitoring involves real-time oversight of asset performance to detect fluctuating environmental conditions. To systematically categorize and evaluate resource provisioning strategies, it is essential to first establish the formal mathematical formulations, algorithmic architectures, and fundamental tradeoffs that govern machine learning interventions in cloud environments, as summarized in the taxonomy shown in Fig. 1.

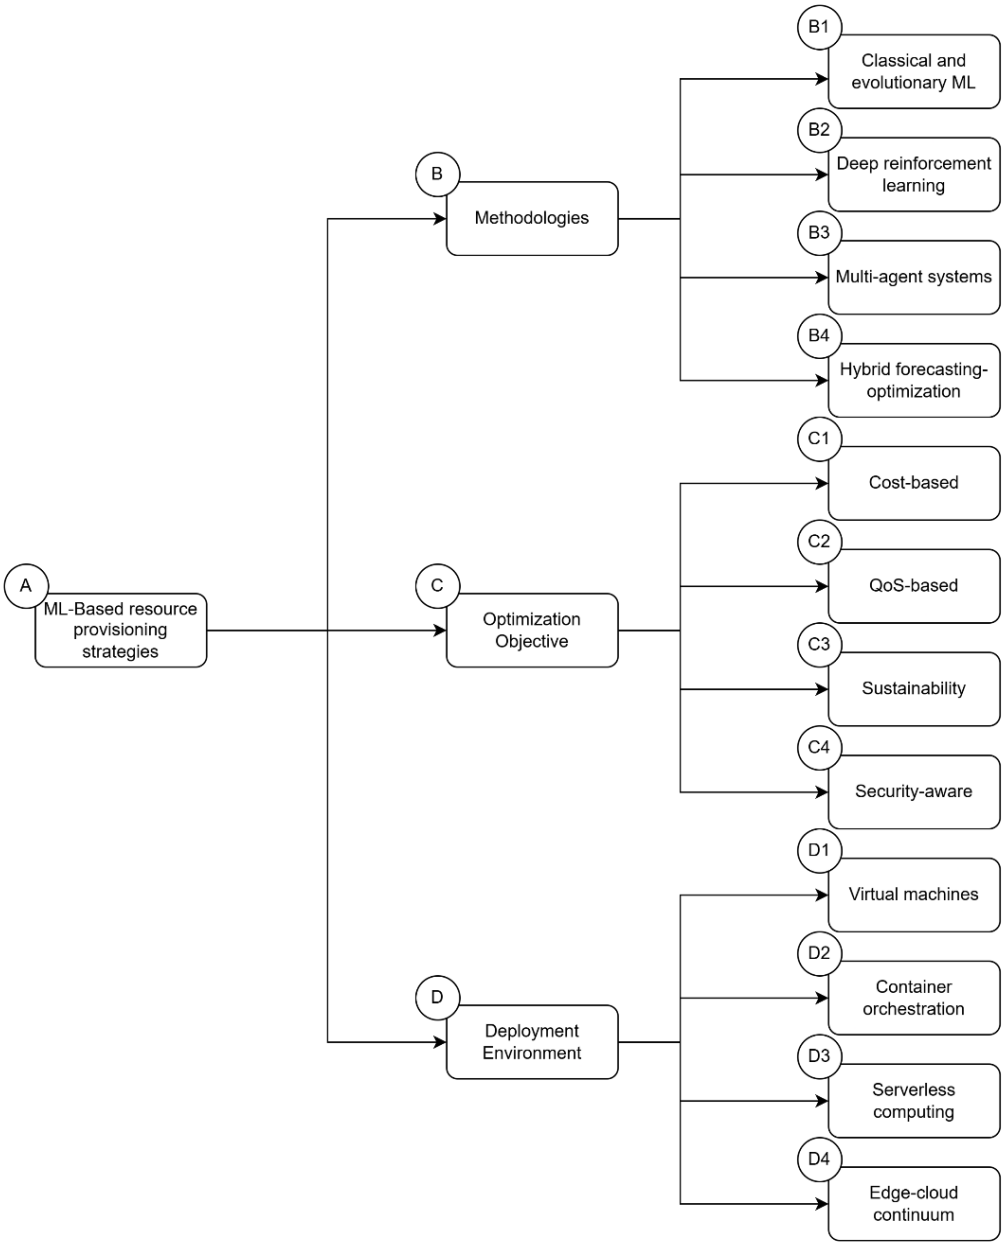

Fig. 1. Machine learning-based resource provision taxonomy.

A. Resource Provisioning

The concept of resource provisioning originated within Grid computing environments. In modern cloud contexts, this process remains a complex challenge due to the inherent limitations of available physical assets. Effective provisioning is fundamentally dependent on the QoS requirements specified by cloud applications [14]. Determining the appropriate resource volume for specific workloads is an intricate task; identifying the optimal resource-workload pair based on QoS constraints constitutes a significant research problem in the field. Consequently, existing investigations frequently employ minimizing execution time as a primary optimization criterion to formulate solutions to this problem.

B. Resource Provisioning Objectives

There are several objectives of resource provisioning that serve as key parameters within a cloud computing environment. These parameters guide resource allocation and capacity adjustment, making a deep understanding of them essential for designing effective provisioning strategies.

Response time is the total duration required to respond to a user's service request. Speed is critical for operational efficiency and user satisfaction, especially as workload requirements change rapidly. Provisioning algorithms must be designed to provide necessary resources in a very short time.

Cost optimization: From the perspective of cloud users, minimizing costs is a primary requirement [19]. Strategies focus on cost management to ensure financial efficiency and provide added value at a controlled expenditure level.

Execution time: This refers to the total time needed to complete a task or process. Methods must be designed to achieve execution results with minimal time [20].

Reduced execution time directly lowers operational costs and improves the user experience.

Fault tolerance: This is the system's ability to maintain normal operations despite component failures. For instance, if a server fails, the algorithm should automatically detect the downtime and redistribute tasks to operational nodes [21]. Service continuity and reliability are critical features that ensure system availability and resilience.

Reduction of SLA violations: Algorithms are measured by their ability to minimize violations of the established Service Level Agreement (SLA) [22]. This requires careful resource allocation and task management to ensure every service demand complies with agreed-upon parameters.

Reduced power consumption: Efficient Virtual Machine (VM) placement and migration techniques are necessary to reduce power usage [23]. Intelligent placement strategies aim for energy efficiency, supporting sustainability and environmental goals while maintaining resource availability for workloads.

C. Resource Provisioning Methods

Cloud resource provisioning strategies can be divided into two main categories: non-machine learning (non-ML) and machine learning (ML)-based methodologies. Non-ML approaches rely on static rules and manually defined heuristics, typically derived from empirical experience [24]. In these approaches, resource allocation is determined by fixed parameters, including instantaneous workload, temporal constraints, and application priority. The main advantage of non-ML methods is their simplicity of implementation and transparency, as the provisioning logic can be easily configured and understood. However, these methods have several limitations. They are not able to adapt dynamically to changes in cloud environments, and their decisions are often static and less optimal in terms of performance and resource efficiency, especially when workloads are highly variable. As a result, non-ML provisioning is most suitable for stable, predictable environments where resources can be managed using consistent business rules and fixed policies.

In contrast, ML-based provisioning strategies have been the focus of recent research. These strategies can be grouped into classical and evolutionary ML, deep reinforcement learning, multi-agent systems, and hybrid forecasting-optimization. Classical and evolutionary machine learning techniques offer distinct but complementary approaches to resource provisioning. Classical machine learning is predicated upon well-established algorithms, including regression, classification, and clustering, to inform provisioning decisions [25]. These methodologies present considerable benefits owing to their elevated interpretability, facilitating a clear comprehension of the model's foundational rationale even when subjected to training on relatively limited datasets. However, they typically require manual feature engineering and can struggle to accurately capture highly nonlinear data patterns. To address more complex and dynamic environments, evolutionary and nature-inspired approaches utilize algorithms based on biological evolution and natural phenomena [26]. Techniques such as genetic algorithms and ant colony optimization mimic processes like natural selection and genetic reproduction to optimize resource distribution. While these evolutionary methods are highly adaptable, they introduce trade-offs, often involving higher computational complexity and limited interpretability compared to classical models.

Deep reinforcement learning (DRL) is a sophisticated machine learning paradigm that integrates deep neural networks with reinforcement learning, enabling an agent to learn optimal decision-making strategies through trial-and-error while striving to maximize cumulative long-term rewards. In the context of reinforcement learning, an agent diligently monitors its environment, executes actions, acquires rewards, and systematically refines its policy; the application of deep learning techniques facilitates the scalability of this process to intricate, high-dimensional challenges, such as those encountered in cloud and edge computing systems [27]. The main advantage of DRL is its ability to automatically learn adaptive and near-optimal policies in dynamic and uncertain environments without relying on predefined rules or accurate system models [28]. It can jointly optimize multiple objectives such as latency, energy efficiency, cost, and quality of service, making it suitable for modern distributed systems [29]. However, DRL also has disadvantages, including high training complexity, large data requirements, and potential instability during learning in real-time systems [27]. In the context of resource provisioning, DRL is widely used for

dynamic resource allocation, auto-scaling, task offloading, and virtual machine management in cloud and edge environments, where it improves resource utilization, reduces latency, and enhances energy efficiency compared to traditional rule-based or heuristic approaches [30].

A multi-agent system (MAS) is a distributed system made up of multiple autonomous agents that interact, cooperate, or negotiate with each other to solve complex problems. Agents are independent entities capable of perceiving their environment, making decisions, and acting toward specific goals. MAS is especially suitable for open, dynamic, and distributed environments where centralized control is difficult [31]. In resource provisioning, multi-agent systems are widely used in cloud computing, fog computing, and edge computing to dynamically allocate, scale, and manage resources such as CPU, memory, bandwidth, and virtual machines. MAS enables distributed decision-making for elastic scaling and workload management. For instance, collaborative multi-agent reinforcement learning has been shown to improve cloud resource scaling, SLA compliance, and scheduling efficiency [32]. However, MAS increased communication overhead, coordination complexity, and potential security and monitoring challenges due to decentralization [33].

Hybrid forecasting-optimization is a method that combines demand prediction (forecasting) with decision-making models (optimization) to allocate resources more effectively under uncertainty. Instead of forecasting and optimizing separately, the forecast is directly integrated into the optimization model to improve final decisions. Research shows that this approach improves decision quality and cost efficiency because predictions are aligned with operational objectives rather than just minimizing forecast errors. Its advantages include better cost savings, improved robustness, and more efficient resource use, while disadvantages include higher computational complexity and risk of error propagation if forecasts are inaccurate [34].

D. Deployment Environment

The deployment environment establishes the foundational architecture and operational mechanisms through which computational resources are provisioned, managed, and scaled. As applications evolve to become more distributed and dynamic, resource allocation strategies must adapt to the distinct abstraction layers and operational models of the underlying infrastructure. Within this context, the deployment environment is grouped into four primary paradigms, each presenting unique mechanisms, challenges, and optimization objectives: traditional Virtual Machines (VMs), container orchestration platforms, Serverless/Function-as-a-Service (FaaS) models, and the distributed edge-cloud continuum. Each paradigm dictates specific approaches to scheduling, capacity planning, and runtime adaptation, ultimately influencing resource utilization, latency, and cost efficiency.

Resource provisioning on VMs involves deciding how many VMs to create what sizes they should be, and on which physical servers they should run, so that applications get enough CPU, memory, storage, and network without wasting data-center capacity. Virtualization lets multiple VMs share one physical machine (PM), increasing utilization but making placement and allocation decisions critical for performance, energy, and cost [35], [36]. There are two allocations in VM deployment, namely static allocation and dynamic allocation. In static allocation, VMs are given fixed resources and placements; simple but often underutilized hardware and cannot adapt to workload changes [10], [37]. On the other hand, dynamic allocation adjusts resource or VM placement at runtime using monitoring and migration to track demand [36], [38]. This improves utilization and energy efficiency but adds overhead and complexity [36], [37]. Well-designed VM provisioning and deployment schemes aim to increase resource utilization and reduce idle capacity, lower energy consumption by consolidating VMs and turning off unused servers, reduce response time and SLA violations through better placement and dynamic scaling, and control costs by minimizing the number and size of VMs while maintaining QoS [1], [36], [39], [40].

Container orchestration platforms automate how resources are provisioned and used when deploying containers across clusters of machines. This involves scheduling, scaling, and runtime reallocation of CPU, memory, storage, and network to meet performance, cost, and reliability goals [41], [42], [43]. At deployment, the orchestrator must make decisions regarding the location and resource allocation for containers, including CPU and memory reservations for scheduling and isolation [41], [43]. Modern scheduling policies account for factors such as heterogeneity, priorities, and job structures [44]. Cost-aware strategies can optimize resource allocation, potentially reducing cloud costs by 23-32% through efficient container packing and shutting down underutilized instances [44], with similar approaches applicable in multi-cloud environments for energy and host count reductions [45]. Runtime scaling and adaptation involves continuous provisioning to address dynamic workloads, employing key strategies to enhance performance and cost efficiency. One of the primary approaches is autoscaling, which adjusts application and cluster size both horizontally and vertically to meet demand [43], [44]. Additionally, online resource re-dimensioning is utilized to adapt CPU budgets at runtime for real-time containers, thereby improving predictability and optimizing resource usage [46]. Another important strategy is layer-aware and cost-aware orchestration, which focuses on optimizing joint request scheduling, placement, and server wake-up decisions in edge computing, resulting in approximately a 20% performance improvement [47].

Serverless/FAAS transfers the responsibility of provisioning and deploying compute resources from developers to providers. Developers upload functions and set triggers, while the platform manages CPU, memory, and containers/VMs on demand, scaling automatically and charging based on usage [48], [49]. Applications are divided into stateless functions that create workflows or directed acyclic graphs (DAGs) [49], [50]. Users provide function code, event triggers, and resource hints, while the provider oversees runtime orchestration, monitoring, and scaling. Functions operate in isolated containers or micro-VMs, which can be warm (active between invocations) or cold (created as needed), impacting latency and resource consumption [51]. From the provider's perspective, resource management involves a pipeline that includes workload modeling, resource provisioning, scheduling, scaling, and

deallocation. Key considerations include predicting function behavior for proactive provisioning, determining the number and type of nodes for cost-effective hosting, configuring function resources to optimize utilization, deciding on function placement to enhance performance, and dynamically scaling and deallocating resources based on real-time load while minimizing cold starts and idle resources [49], [52], [53].

Resource provisioning and deployment within the edge-cloud continuum involves strategically allocating compute, storage, and network resources across diverse nodes, from edge devices to centralized data centers, with the primary objective of achieving optimal latency, reliability, security, and cost-effectiveness despite challenges such as mobility and limited resources at the edge. The architectural framework includes servers located at the network edge, such as near 5G base stations, gateways, and fog nodes, as well as centralized cloud data centers, enabling flexible service deployment through microservice or function-based architectures. Key challenges in provisioning encompass determining the optimal node for hosting each microservice or function while adhering to constraints related to CPU, memory, bandwidth, and latency, assigning CPU shares and performance tiers to meet QoS and Service Level Agreements (SLA) while minimizing resource and energy consumption, and dynamically adapting resource allocation in response to changes in load, network conditions, or user locations. The typical objectives involve trade-offs between latency and QoS, cost and energy efficiency, as well as reliability and security, with a strong emphasis on meeting SLAs [54], [55], [56].

V. Results and Discussion

This section presents the results of the literature survey, structured according to a three-dimensional taxonomy. The taxonomy categorizes existing research by machine learning methodology, optimization objectives, and deployment environment. Thirty-five key studies were mapped to this framework to ensure a comprehensive and systematic review. This structure facilitates the assessment of how various algorithms address the complex challenges inherent in modern cloud infrastructure. The following subsections first outline the current state-of-the-art, followed by an analysis of operational impacts and technical trade-offs identified in the literature.

A. Taxonomic Categorization of Literature

This subsection presents the results of the literature survey by organizing the findings using a formal taxonomy and providing an analysis of the main results. We first conducted a taxonomic analysis of the existing literature to create a systematic framework for categorizing the methodologies and experimental insights found in the reviewed survey papers. The selected literature is formally organized in, which provides a multidimensional overview of the algorithms, deployment environments, and optimization objectives investigated in this survey. This table serves as the foundational evidence for the thematic categorization presented in the following subsections. The following discussion interprets the taxonomic results and explains their broader implications. We provide an analysis of current trends in resource provisioning, assess the effectiveness of different strategies, and identify gaps in the research that require further study.

1) Classical and evolutionary approaches: Classical and evolutionary approaches have traditionally been deployed in virtual machine environments to address fundamental provisioning goals. To meet cost-based objectives, nature-inspired methods such as particle swarm optimization (PSO) and simulated annealing (SA) optimize time and monetary expenses [21]. Other techniques, including the shuffled frog leaping algorithm (SFLA) and ubiquitous binary search (UBS), are applied to improve resource efficiency [57]. Addressing sustainability, spider monkey optimization (smo) minimizes execution costs and power consumption in uncertain environments [58] and is chosen for its effectiveness in uncertain environments. Additional evolutionary approaches include utilizing genetic algorithms with fuzzy c-means to improve QoS-based metrics through workload prediction [59] and combining fuzzy c-means with PSO to optimize execution time and memory [60]. Traditional ML approaches include greedy and heuristic algorithms to reduce memory and storage requirements [61], as well as linear regression and Bayesian learning for cost optimization [62]. Bayesian optimization has also been applied to resource prediction, resulting in higher average virtual machine (VM) utilization [63].[57][58][59][60][61][62][63].

For predicting VM resource requirements to ensure strict QoS adherence, Support Vector Regression (SVR), Neural Networks (NN), and LR have shown success in increasing throughput [64], while models like Random Forest (RF), XGBoost, and LR are applied to predict demand-based usage [65]. In Elastic Cloud services, Support Vector Machine (SVM) models outperform simple forecasting methods to approach optimal allocation [23]. Clustering algorithms like K-means facilitate fault tolerance in sustainable systems [66], and when integrated with Convolutional Neural Networks (CNNs), K-means reduced MySQL deployment costs by 48% on single-tenant architectures [4]. Hybrid classical methods combine NN, LR, and RepTree to improve resource utilization [67], or use Artificial Swarm Intelligence (ASI), SVM, K-Nearest Neighbors (KNN), and Decision Trees to maximize VM resource usage and decrease Service Level Agreement (SLA) violations [25]. Furthermore, standalone neural network architectures classified within this methodology include Diffusion Convolutional Recurrent Neural Networks (DCRNN) for predicting future demand [68], Multi-Layer Perceptrons (MLP) for reducing execution time [69], Learning Automata (LA) for cost-effective cloud infrastructure utilization [70], and Long Short-Term Memory (LSTM) models for optimizing response times against simple forecasting [71].

2) Hybrid forecasting-optimization models: Moving beyond static VM provisioning, DRL actively learns policies suited for highly volatile environments like serverless computing and the edge-cloud continuum. In traditional elastic provisioning, short-term memory Q-learning optimizes the number of allocated VMs to decrease CPU usage [72]. Shifting to serverless architectures where cost and QoS are tightly coupled, [74] introduced Freyr+, a system utilizing proximal policy optimization (PPO) to dynamically harvest idle

resources from over-provisioned functions, accelerating invocations and reducing tail latency. targeting sustainability at the edge, [78] designed atom, employing DDPG and RDPG agents to predict cold start latency and optimize energy consumption [72][74][78].

Crucially, DRL allows for the integration of emerging security-aware objectives. [79] proposed an Action-constrained DRL (DQN) framework to ensure resources are securely allocated in multi-cloud edge networks while minimizing system costs. To enhance prediction accuracy before allocation, [80] introduced the DRAW method, integrating Workload-Time Windows directly into the state space of a Deep Q-Network (DQN) to balance QoS and costs. Addressing the distributed nature of the edge-cloud continuum, [30] utilized NESRL-MRM that combining DRL with Neuroevolution of Augmenting Topologies (NES) to achieve balanced multi-dimensional resource allocation and solve fragmentation. Additionally, [85] developed an Actor-critic based DRL (H-A2C) combined with PPO to determine the optimal deployment across hybrid with server and serverless environments, driving down user costs by up to 44%.

3) Deep reinforcement learning: As cloud clusters scale, particularly in container orchestration and edge environments, single-agent models face performance bottlenecks. This drives the shift toward multi-agent deep reinforcement learning (MADRL) to maintain strict QoS and sustainability targets across decentralized nodes. To handle dynamic microservice demands, [75] introduced drpc, a distributed RL framework using the TD3 algorithm that scales linearly across container-based clusters to reduce average response times and failed requests. Focusing on energy efficiency, [76] proposed a MADRL framework utilizing a DTS hyper-heuristic where multiple agents collaboratively optimize container placement to minimize resource utilization and avoid sla violations in data centers. In serverless edge computing, [86] proposed CSODQN, a multi-agent approach utilizing importance sampling-based double dueling DQN to manage offloading and maintain a warming pool. This effectively balances the tradeoff between cold start frequency (QoS) and resource utilization (cost and sustainability) [75][76][86].

4) Multi-agent and distributed orchestration: Hybrid methodologies combine the predictive power of time-series forecasting (to guarantee QoS) with the decision-making capabilities of RL algorithms (to optimize cost and sustainability), spanning the entire spectrum of deployment environments. In serverless setups, [73] proposed an LSTM-ppo approach, using recurrent learning to intelligently autoscale and maximize throughput with minimal resources. For sustainable container orchestration, [77] designed greenkube, which integrates DRL, graph neural networks (GNN), and LSTM to minimize energy consumption and prevent over-provisioning at the edge and cloud. spanning the broader computing continuum, [81] introduced an intent-driven orchestration model combining DQN, ARIMA forecasting, and Mixed-Integer Linear Programming (MILP) to minimize latency, transformation costs, and power consumption [73][77][81].

A specific focus on dynamic VM migration is seen in [82], which combines DQN and LSTM to automate allocation strategies, saving energy and reducing downtime. Similarly, [83] chained LSTM forecasting with DQN and PSO decision-making to schedule CPU, memory, and bandwidth in Alibaba Cloud ECS clusters, lowering costs by 26.6%. Finally, operating within Kubernetes environments, [84] developed a forecast-based autoscaler that integrates LSTM predictions directly into a model-free DQN scaling logic, adjusting replicas proactively to ensure SLO compliance while reducing resource consumption.

B. Critical Synthesis and Discussion

Following the thematic categorization of the literature, this subsection shifts from a descriptive overview to a critical synthesis of performance. The taxonomic results are interpreted to identify broader implications and emerging trends in resource provisioning, with particular attention to paradigm shifts in decentralized environments. This discussion assesses the effectiveness of various strategies, establishes a quantitative comparative benchmark, and rigorously evaluates the trade-offs between computational overhead and system elasticity to address gaps identified in current research.

1) Unified metric framework and objective trade-offs: To enable a standardized comparison across the reviewed literature, we define a unified metric framework that categorizes provisioning objectives into three principal axes. The first axis, cost, includes both monetary expenditure and resource utilization. The second axis, QOS, encompasses latency, response time, and compliance with service-level agreements. The third axis, energy, addresses power consumption and sustainability considerations. These objectives are inherently conflicting, resulting in fundamental trade-offs that must be addressed by machine learning models. The balance between QoS and cost or energy, for example, often necessitates the maintenance of pre-warmed container pools or idle resources to reduce serverless cold starts. Although this approach improves response times, it also increases financial costs and energy consumption. Conversely, the tension between energy and performance becomes apparent in the use of aggressive power optimization strategies, such as virtual machine consolidation or scaling to zero during periods of low traffic. While these strategies promote sustainability, they also elevate the risk of service-level agreement violations during sudden workload surges. Considering these findings, the trade-off between complexity and efficiency is also significant. Advanced decentralized models, such as multi-agent reinforcement learning, can reduce orchestration bottlenecks in large clusters. However, these models introduce substantial communication overhead and increased training complexity when compared to more traditional heuristic approaches.

2) Temporal evolution of ML paradigms: Analysis of publication data from 2014 to 2025 demonstrates a clear paradigm shift in resource provisioning methodologies, which

can be categorized into three distinct chronological phases. Fig. 2 illustrates the distribution of these methodologies throughout the survey period. During the era of classical ML and heuristics (2014-2022), foundational predictive algorithms and heuristic approaches dominated the literature for nearly a decade. From 2014 to 2020, all surveyed papers relied exclusively on classical machine learning or heuristic methods. Even as research volume increased toward the end of this period, classical approaches remained predominant, comprising 8 of 9 published papers in 2021 and 2022.

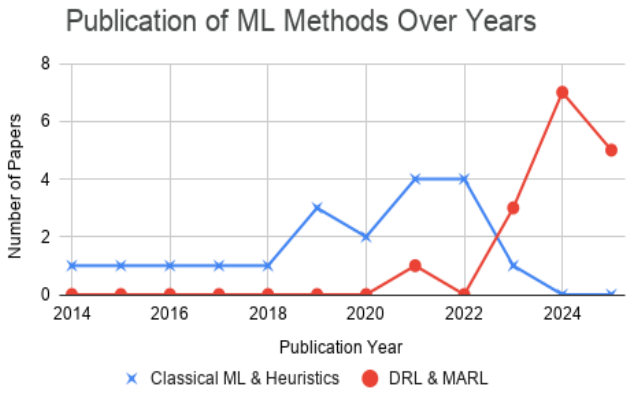

Fig. 2. Temporal evolution of resource provisioning methodologies.

In 2023, the orchestration landscape experienced a crucial inflection point, indicating a transition toward more advanced intelligent systems. For the first time, DRL and MARL surpassed traditional methods, accounting for 3 of the 4 papers published that year. This transition corresponds to the increasing need to manage complex, variable system states, where traditional rule-based and predictive approaches are less effective at balancing QoS and resource costs.

Recent literature from 2024 to 2025 demonstrates the complete dominance of DRL and MARL methodologies. During this period, classical machine learning and heuristic approaches are absent from the surveyed state-of-the-art research. DRL and MARL account for all 12 papers published in these years. This quantitative trend substantiates the assertion that, as microservices and modern deployment environments have expanded, centralized decision-making and classical supervised learning have become significant system bottlenecks. As a result, the research community has rapidly shifted toward DRL and MARL frameworks, whose experience-based learning strategies have proven highly effective for autonomous adaptation in dynamic, nonlinear cloud computing scenarios.

3) Quantitative synthesis and comparative benchmark: To quantify the effectiveness of modern ML interventions, we derived a comparative benchmark from the empirical performance claims reported in the 35 studies synthesized in Table I. The synthesis presented in Table II highlights the specific percentage improvements in latency, cost, and energy efficiency achieved by modern ML paradigms compared to traditional baseline models.

TABLE I. RESEARCH PAPERS ON MACHINE LEARNING-BASED RESOURCE PROVISIONING

Papers	Algorithm / Method	Environment	Objective	Result	Taxonomy Labels
[26]	PSO and SA	Multi-tier Cloud Computing	Improving resource provision with minimum time and cost	Effectively reduces the time required to provide resources, which leads to cost reductions	B1, C1, D1
[61]	Greedy and heuristic	Clouds	Decreased resource usage (core, memory, and storage)	Effectively captures dynamic demand, provides computing resources to match demand, and generates high revenue with low execution time	B1, C1, C2, D1
[64]	SVR, NN and LR	Web VM Resource Provisioning	Improving performance in throughput and response time	The use of SVR provides the best performance in reducing response time and increasing throughput	B1, C2, D1
[69]	MLP	Heterogeneous infrastructures	Meeting user demands in terms of cost and execution time	Increased throughput and reduced execution time	B1, C1, C2, D1
[70]	LA	Cloud infrastructure	Minimizing cloud infrastructure costs	The proposed method has the most cost-effective (minimum) use compared to other methods	B1, C1, D1
[67]	NN, LR, and RepTree	Cloud Computing	Improving resource utilization	Decrease in CPU usage	B1, C1, D1
[23]	SVM	Elastic Cloud services	Improving QoS	The SVM model outperforms simple forecasting methods and approaches optimal allocation	B1, C2, D1
[60]	Fuzzy C-means and PSO	Cloud computing environment	Improving execution time, cost, and memory	Improvements of 20.62, 40.14, and 39.92% in execution time, cost, and memory usage	B1, C1, C2, D1
[63]	Bayesian optimization	Cloud Computing	Optimizing VMs so that resources are used effectively to improve QoS	Increase in average VM utilization ratio	B1, C2, D1
[59]	Genetic and Fuzzy C-Means	Cloud workloads	Improve QoS by predicting workloads so that VM scaling can be performed effectively	Reduction in power consumption, execution time, cost, and latency	B1, C1, C2, C3, D1
[65]	RF, XGBoost, and LR	Cloud Resource Provisioning System	Predict resource usage based on demand	More optimal CPU usage	B1, C1, D1

[66]	K-mean	Sustainable Cloud Computing Systems	Developing mechanisms for tolerance and fault tolerance	Reduction in downtime and power consumption	B1, C2, C3, D1
[57]	SLFA-UBS	Multi-cloud Computing	Cost and resource efficiency	Decrease in execution time and increase in throughput	B1, C1, D1
[68]	DCRNN	Autonomic cloud computing environment	Predict future demand for resource allocation	Decrease in CPU usage on VMs	B1, C1, D1
[71]	LSTM	Cloud Services	Improving QoS	The LSTM model outperforms SVM and other forecasting methods, and approaches optimal allocation	B1, C2, D1
[58]	SMO	Cloud platforms	Minimizing time, cost, and energy consumption	Reduction in execution costs, power consumption, and task rejection	B1, C1, C2, C3, D1
[62]	LR and Bayesian	Service-based cloud applications	Reducing expenses and improving resource utilization	Better resource utilization and shorter response times	B1, C1, D1
[25]	ASI, SVM, KNN and Decision Tree	Virtual machine allocation and migration	Maximizing resource usage on VMs to decrease power usage and SLA violations	Decrease in power usage and SLA violations	B1, C1, C2, C3, D1
[4]	K-means and CNN	Cloud resource provisioning	Reducing costs while improving application performance	Reduced MySQL deployment costs by 48% on a single-tenant architecture	B1, C1, C2, D1
[72]	Short-Term memory Q-Learning	Elastic provisioning	Optimizing the number of VMs allocated to the workload to decrease the number of provisioned VMs and CPU usage	Decrease in the number of provisioned VMs and decrease in CPU usage	B2, C1, D1
[73]	LSTM-PPO	Serverless Computing / FaaS	Intelligent autoscaling to maximize throughput while using minimal resources (Cost & QoS-based)	Improved throughput by 18% and function execution by 13% compared to baseline	B4, C1, C2, D3
[74]	DRL utilizing PPO	Serverless Computing platforms	Dynamically harvest idle resources from over-provisioned functions to maximize utilization (Cost & QoS-based)	Harvested 38% of idle resources, accelerated 39% of invocations, and reduced 99th-percentile latency by 26%	B2, C1, C2, D3
[75]	Distributed RL (TD3 algorithm)	Container-based cloud microservice clusters	Scalable autoscaling to handle dynamic demands, reducing response time and failed requests (QoS & Scalability-based)	Reduced average response time by 15% and decreased failed requests by 24% compared to baselines	B3, C2, D2
[76]	MADRL and DTS hyper-heuristic	Container-based cloud environments / Data centers	Maximizing energy efficiency, avoiding SLA violations, and minimizing resource utilization (Energy, Cost, & QoS-based)	Achieved significantly lower energy consumption, reduced memory/CPU utilization, and faster response times	B3, C1, C2, C3, D2
[77]	DRL, GNN, and LSTM	Container Orchestration platforms (Edge and Cloud)	Minimizing energy consumption and preventing over-provisioning while maintaining strict QoS (Energy & QoS-based)	Outperformed Kubernetes HPA by reducing average latency, task execution time, and active node usage	B4, C2, C3, D2, D4
[78]	DRL (DDPG and RDPG)	Serverless Edge Computing Environments	Predict cold start latency and reduce occurrence frequency to optimize energy consumption (Energy & QoS-based)	DDPG model outperformed baselines in latency/request prediction with superior stability and convergence	B2, C2, C3, D3, D4
[79]	Action-constrained DRL (DQN) + Security Mechanisms	Serverless multi-cloud edge computing networks	Securely allocate resources to minimize costs, satisfy latency requirements, and ensure privacy (QoS, Cost, & Security-based)	Reduced the system cost by 24.4% and 22.6% compared to standard DQN and DQN+NN methods respectively	B2, C1, C2, C4, D3, D4
[80]	DRL utilizing a DQN (DRAW method)	Cloud-based software services	Adaptively allocate resources to balance QoS and reduce overall resource costs (QoS & Cost-based)	Prediction accuracy reached 90.69%, outperforming classic ML and standard DQN methods by 3% to 13%	B2, C1, C2, D1
[81]	DQN, ARIMA, and MILP	Computing Continuum (Multi-cluster Edge and Cloud)	Intent-driven orchestration to minimize latency, transformation cost, and power consumption (QoS, Energy, & Cost-based)	Achieved only 1.52% QoS violations, reduced transformation costs by 22%, and power consumption by 24.2%	B4, C1, C2, C3, D3, D4
[30]	DRL combined with NES (NESRL-MRM)	Distributed Data Centers in the edge-cloud continuum	Multi-dimensional allocation to achieve balanced utilization across resource types (Balanced utilization)	Significantly improved balanced resource utilization and demonstrated an 85% improvement in time efficiency	B2, C1, D4
[82]	DRL utilizing DQN and LSTM	Cloud computing environments focusing on VM Migration	Optimizing migration to allocate resources, maximize utilization, and minimize energy and downtime (Cost, Energy, & QoS-based)	Automated VM migration strategies significantly outperformed manual settings or static rule-based allocation	B4, C1, C2, C3, D1
[83]	LSTM, DQN, and PSO	Cloud Computing Environments	Dynamically schedule CPU/memory/bandwidth to improve utilization, reduce	Enhanced utilization by 32.5%, reduced average response time by 43.3%, and lowered costs by 26.6%	B4, C1, C2, D2

		(AliCloud ECS cluster)	latency, and minimize expenses (Cost, QoS, & Resource-based)		
[84]	Model-free RL utilizing DQN and LSTM	Containerized Cloud Computing / Kubernetes	Proactively predict request rates to adjust replicas, ensuring SLO compliance while minimizing usage (QoS & Resource-based)	Outperformed Kubernetes HPA, reducing resource consumption by up to 10% and improving performance by up to 30%	B4, C1, C2, D2
[85]	Actor-critic based DRL (H-A2C) with PPO	Serverless and Serverful (IaaS/VM-based) Hybrid Environments	Determine optimal deployment environment and execution node to optimize latency and cost (Cost & QoS-based)	Outperformed baselines, achieving user cost reductions of up to 44% and relative response time improvements of up to 11%	B2, C1, C2, D1, D3
[86]	Multi-agent DRL utilizing CSODQN	Serverless Edge Computing / Cloud-edge-device systems	Balancing tradeoff between cold start frequency and resource utilization while maximizing success rates (QoS, Energy, & Cost-based)	Increased task success rate by 70%, reduced monetary costs by 58%, and decreased average delay by 1.51%	B3, C1, C2, C3, D3, D4

TABLE II. COMPARATIVE BENCHMARK OF MACHINE LEARNING EFFICACY IN RESOURCE PROVISIONING

ML Methodology	Primary Performance Impact	Representative Result
Deep RL (DQN/LSTM) [83]	Cost & QoS Optimization	Reduced response times by 43.3% and costs by 26.6% in AliCloud clusters.
Multi-Agent DRL (CSODQN) [86]	Success Rate & Cost	Increased task success rates by 70% and reduced monetary costs by 58%.
Intent-Driven Hybrid [81]	QoS & Energy Sustainability	Suppressed SLA/QoS violations to 1.52% while reducing power consumption by 24.2%.
Distributed RL (TD3) [75]	System Reliability	Decreased failed requests by 24% and improved average response times by 15%.
Hybrid DRL (H-A2C) [85]	User Cost Reduction	Achieved user cost reductions of up to 44% in hybrid serverful/serverless environments.

TABLE III. COMPARATIVE ANALYSIS OF ML METHODOLOGIES

ML Technique	Key Advantages	Major Trade-offs & Overhead	Ideal Use Case
Classical & Supervised	- High interpretability - Low inference latency.	- Requires manual feature engineering - Struggles with highly nonlinear patterns.	Stable, predictable VM workloads.
Deep RL (DRL)	- Learns near-optimal policies autonomously - No predefined rules required.	- High training complexity and massive data requirements - Risk of real-time instability.	Dynamic VM/Container auto-scaling.
Multi-Agent (MARL)	- Superior decentralized decision-making - Scales linearly across large clusters.	- Significant communication overhead - Coordination complexity and security monitoring challenges.	Distributed Edge and Serverless orchestration.

4) Technical comparative analysis of ML methodologies: To satisfy the requirement for a critical evaluation of methodologies, we analyze the trade-offs between the three dominant paradigms. Each method presents a unique profile regarding computational overhead, interpretability, and adaptive capacity, as shown in Table III.

The primary distinction lies in the Training vs. Inference costs: while classical models are inexpensive to deploy, they fail in the volatility of the edge. Conversely, MARL offers high elasticity but introduces coordination delays that can counteract latency gains if not properly optimized.

5) System-level environmental distinctions: Resource provisioning logic must fundamentally adapt to the specific abstraction layers and operational constraints of the underlying infrastructure, which are generally classified into three primary deployment tiers. In traditional cloud environments utilizing VMs and containers, the primary focus remains on macro-level resource placement and live migration to optimize hardware utilization and reduce energy consumption through server consolidation.

In contrast, serverless computing FaaS introduces micro-level, event-driven orchestration. The primary technical challenge is managing warm and cold container pools, which requires balancing reducing cold-start latency with implementing a scale-to-zero model to minimize operational costs. Within the edge-cloud continuum, provisioning must address highly distributed, resource-constrained nodes by strategically offloading microservices to meet ultra-low latency requirements at the edge, while also managing high compute costs and limited battery life in decentralized devices.

VI. CONCLUSION

This paper presented a comprehensive survey of resource provisioning strategies, with a particular focus on the "Intelligence Shift" toward machine learning in cloud, edge, and serverless environments. Through a taxonomic analysis of eleven years of literature, we categorized ML interventions into four primary categories: classical and evolutionary machine learning, hybrid forecasting-optimization, deep reinforcement learning (DRL), and multi-agent systems (MARL). The principal finding of this survey is the increasing prevalence of hybrid architectures that combine time-series forecasting with DRL to address the fundamental trade-off between infrastructural cost and stringent Quality of Service (QoS) requirements. Our quantitative synthesis of the state of the art indicates that intelligence-driven interventions yield measurable improvements over traditional heuristics. For example, model-

free reinforcement learning algorithms reduce resource consumption by up to 10% and improve system performance by up to 30%. Additionally, hybrid Actor-Critic (H-A2C) models achieve user cost reductions of up to 44% and an 11% improvement in relative response times. Intent-driven orchestration models also suppress SLA/QoS violations to 1.52% and reduce data center power consumption by 24.2%.

To address the ongoing evolution of the edge-cloud continuum, we identify several priority areas for future research. Researchers should focus on developing models that reduce latency from serverless "cold starts" by employing intent-driven orchestration and predictive container pre-warming. As decentralized clusters expand, further refinement of MARL is necessary to manage coordination overhead in high-density edge nodes. The integration of federated learning is also essential to ensure secure resource allocation and data privacy in multi-tenant environments. Moreover, future algorithms should explicitly incorporate energy efficiency and carbon-aware metrics to facilitate the transition to green AI orchestration. While this survey offers a rigorous analysis of the current landscape, it is subject to specific scope constraints, including a search limited to high-impact databases such as IEEE Xplore, ACM Digital Library, and ScienceDirect. Our inclusion criteria also prioritized literature from the 2023-2025 period to emphasize the shift toward modern machine learning orchestration. As a result, foundational heuristic models are referenced primarily to contextualize the current paradigm shift and were not subjected to the same level of quantitative benchmarking as contemporary neural-based solutions.

VII. Declaration on Generative AI

During the preparation of this work, the authors used Grammarly Paraphraser (Academic writing style) to improve the clarity and grammatical precision of the manuscript. After using this service, the author critically reviewed, verified, and edited the generated suggestions to ensure technical accuracy. The authors take full responsibility for the originality, accuracy, and integrity of the final publication.
